MySQL Operator for Kubernetes
Abstract

MySQL Operator for Kubernetes manages MySQL InnoDB Cluster setups inside a Kubernetes Cluster. MySQL Operator for Kubernetes manages the full lifecycle with setup and maintenance including automating upgrades and backups.

This documentation is a work in progress; expect future changes to both content and structure.

For legal information, see the Legal Notices.

For help with using MySQL, please visit the MySQL Forums, where you can discuss your issues with other MySQL users.

Access to Oracle Support for Accessibility

Oracle customers that have purchased support have access to electronic support through My Oracle Support. For information, visit https://www.oracle.com/corporate/accessibility/learning-support.html#support-tab.
Chapter 1 Introduction

MySQL and Kubernetes share terminology. For example, a Node might be a Kubernetes Node or a MySQL Node, a Cluster might be a MySQL InnoDB Cluster or Kubernetes Cluster, and a ReplicaSet is a feature in both MySQL and Kubernetes. This documentation prefers the long names but these overloaded terms may still lead to confusion; context is important.

Kubernetes

The Kubernetes system uses Controllers to manage the life-cycle of containerized workloads by running them as Pods in the Kubernetes system. Controllers are general-purpose tools that provide capabilities for a broad range of services, but complex services require additional components and this includes operators. An Operator is software running inside the Kubernetes cluster, and the operator interacts with the Kubernetes API to observe resources and services to assist Kubernetes with the life-cycle management.

MySQL Operator for Kubernetes

The MySQL Operator for Kubernetes is an operator focused on managing one or more MySQL InnoDB Clusters consisting of a group of MySQL Servers and MySQL Routers. The MySQL Operator itself runs in a Kubernetes cluster and is controlled by a Kubernetes Deployment to ensure that the MySQL Operator remains available and running.

The MySQL Operator is deployed in the 'mysql-operator' Kubernetes namespace by default; and watches all InnoDB Clusters and related resources in the Kubernetes cluster. To perform these tasks, the operator subscribes to the Kubernetes API server to update events and connects to the managed MySQL Server instance as needed. On top of the Kubernetes controllers, the operator configures the MySQL servers, replication using MySQL Group Replication, and MySQL Router.

MySQL InnoDB Cluster

Once an InnoDB Cluster (InnoDBCluster) resource is deployed to the Kubernetes API Server, MySQL Operator for Kubernetes creates resources including:

- A Kubernetes StatefulSet for the MySQL Server instances.
  This manages the Pods and assigns the corresponding storage Volume. Each Pod managed by this StatefulSet runs multiple containers. Several provide a sequence of initialisation steps for preparing the MySQL Server configuration and data directory, and then two containers remain active for operational mode. One of those containers (named 'mysql') runs the MySQL Server itself, and the other (named 'sidecar') is a Kubernetes sidecar responsible for local management of the node in coordination with the operator itself.

- A Kubernetes Deployment for the MySQL Routers.
  MySQL Routers are stateless services routing the application to the current Primary or a Replica, depending on the application’s choice. The operator can scale the number of routers up or down as required by the Cluster’s workload.

A MySQL InnoDB Cluster deployment creates these Kubernetes Services:

- One service is the name of the InnoDB Cluster. It serves as primary entry point for an application and sends incoming connections to the MySQL Router. They provide stable name in the form '{clustername}.svc.cluster.local' and expose specific ports.

  See also Section 3.4, “MySQL InnoDB Cluster Service Explanation” and Chapter 4, Connecting to MySQL InnoDB Cluster.

- A second service named '{clustername}-instances' provides stable names to the individual servers. Typically these should not be directly used; instead use the main service to reliably reach the current
primary or secondary as needed. However, for maintenance or monitoring purposes, direct access to an instance might be needed. Each pod instance has MySQL Shell installed.

MySQL Operator for Kubernetes creates and manages additional resources that should not be manually modified, including:

- A Kubernetes ConfigMap named '{clusternamename-initconf}' that contains configuration information for the MySQL Servers.

  To modify the generated `my.cnf` configuration file, see Section 3.3, “Manifest Changes for InnoDBCluster”.

- A sequence of Kubernetes Secrets with credentials for different parts of the system; names include '{clusternamename.backup}', '{clusternamename.privsecrets}', and '{clusternamename.router}.'

  For a list of MySQL accounts (and associated Secrets) created by the operator, see Section 3.5, “MySQL Accounts Created by InnoDBCluster Deployment”.

**MySQL Operator for Kubernetes Architecture**

**Figure 1.1 MySQL Operator for Kubernetes Architecture Diagram**

![MySQL Operator for Kubernetes Architecture Diagram](image)
Chapter 2 Installing MySQL Operator for Kubernetes

Table of Contents

2.1 Install using Helm Charts ................................................................. 3
2.2 Install using Manifest Files ............................................................ 3

Two different installation methods are documented here; using either helm or manually applying manifests using kubectl. This documentation assumes that kubectl is available on a system configured with the desired Kubernetes context; and all examples use a Unix-like command line.

Note
MySQL Operator for Kubernetes requires these three container images to function: MySQL Operator for Kubernetes, MySQL Router, and MySQL Server.

2.1 Install using Helm Charts

Helm is an optional package manager for Kubernetes that helps manage Kubernetes applications; Helm uses charts to define, install, and upgrade Kubernetes Operators. For Helm specific usage information, see the Helm Quickstart and Installing Helm guides. Alternatively, see Section 2.2, “Install using Manifest Files”.

Add the Helm repository:

```
$> helm repo add mysql-operator https://mysql.github.io/mysql-operator/
$> helm repo update
```

Install MySQL Operator for Kubernetes, this example defines the release name as `my-mysql-operator` using a new namespace named `mysql-operator`:

```
$> helm install my-mysql-operator mysql-operator/mysql-operator --namespace mysql-operator --create-namespace
```

This latest MySQL Operator for Kubernetes can be downloaded from DockerHub and deployed. The operator deployment is customizable through other options that override built-in defaults. For example, useful when using a local (air-gapped) private container registry to use with the operator.

To use MySQL Operator for Kubernetes to create MySQL InnoDB Clusters, see Chapter 3, MySQL InnoDB Cluster.

2.2 Install using Manifest Files

This document assumes a familiarity with kubectl, and that you have it installed. Alternatively, see Section 2.1, “Install using Helm Charts”.

MySQL Operator for Kubernetes can be installed using raw manifest files with kubectl; first install the Custom Resource Definition (CRD) used by MySQL Operator for Kubernetes:

```
$> kubectl apply -f https://raw.githubusercontent.com/mysql/mysql-operator/trunk/deploy/deploy-crds.yaml
```

// Output is similar to:

customresourcedefinition.apiextensions.k8s.io/innodbclusters.mysql.oracle.com created
customresourcedefinition.apiextensions.k8s.io/mysqlbackups.mysql.oracle.com created
customresourcedefinition.apiextensions.k8s.io/clusterkopfpeerings.zalando.org created
customresourcedefinition.apiextensions.k8s.io/kopfpeerings.zalando.org created

Next deploy MySQL Operator for Kubernetes, which also includes RBAC definitions as noted in the output:
Install using Manifest Files

$> kubectl apply -f https://raw.githubusercontent.com/mysql/mysql-operator/trunk/deploy/deploy-operator.yaml

// Output is similar to:
clusterrole.rbac.authorization.k8s.io/mysql-operator created
clusterrole.rbac.authorization.k8s.io/mysql-sidecar created
clusterrolebinding.rbac.authorization.k8s.io/mysql-operator-rolebinding created
clusterkopfpeering.zalando.org/mysql-operator created
namespace/mysql-operator created
serviceaccount/mysql-operator-sa created
deployment.apps/mysql-operator created

Verify that the operator is running by checking the deployment that’s managing the operator inside the mysql-operator namespace, a configurable namespace defined by deploy-operator.yaml:

$> kubectl get deployment mysql-operator --namespace mysql-operator

After MySQL Operator for Kubernetes is ready, the output should look similar to this:

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>UP-TO-DATE</th>
<th>AVAILABLE</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql-operator</td>
<td>1/1</td>
<td>1</td>
<td>1</td>
<td>37s</td>
</tr>
</tbody>
</table>

To use MySQL Operator for Kubernetes to create MySQL InnoDB Clusters, see Chapter 3, *MySQL InnoDB Cluster.*
Chapter 3 MySQL InnoDB Cluster

Table of Contents

3.1 Deploy using Helm ................................................................. 5
3.2 Deploy using kubectl ............................................................. 6
3.3 Manifest Changes for InnoDBCluster ........................................ 7
3.4 MySQL InnoDB Cluster Service Explanation ............................... 9
3.5 MySQL Accounts Created by InnoDBCluster Deployment ................ 10
3.6 Upgrading a pre-release InnoDB Cluster to 8.0.29-2.0.4 GA ................ 12

Examples and documentation assumes the current default namespace is used, which defaults to 'default' although it can be modified, for example:

$> kubectl create namespace newdefaultnamespace
$> kubectl config set-context --current --namespace=newdefaultnamespace

Examples typically use 'innodbcluster' as the resource name but may use plural and short names as defined in deploy-crds.yaml:

```yaml
names:
  kind: InnoDBCluster
  listKind: InnoDBClusterList
  singular: innodbcluster
  plural: innodbclusters
  shortNames:
    - ic
    - ics
```

3.1 Deploy using Helm

Potential values for creating a MySQL InnoDB Cluster are visible here:

$> helm show values mysql-operator/mysql-innodbcluster

Public Registry

The most common Helm repository is the public https://artifacthub.io/, which is used by these examples.

This example uses all default values in the default namespace with mycluster as the release name:

$> helm install mycluster mysql-operator/mysql-innodbcluster

The manifest for this simple installation looks similar to this:

```yaml
$> helm get manifest mycluster
---
# Source: mysql-innodbcluster/templates/service_account_cluster.yaml
apiVersion: v1
kind: ServiceAccount
metadata:
  name: mycluster-sa
  namespace: default
---
# Source: mysql-innodbcluster/templates/cluster_secret.yaml
apiVersion: v1
kind: Secret
metadata:
  name: mycluster-cluster-secret
  namespace: default
stringData:
  rootUser: root
  rootHost: "%"
  rootPassword: sakila
```
# Source: mysql-innodbcluster/templates/deployment_cluster.yaml
apiVersion: mysql.oracle.com/v2
kind: InnoDBCluster
metadata:
  name: mycluster
  namespace: default
spec:
  instances: 3
  router:
    instances: 1
  secretName: mycluster-cluster-secret
  imagePullPolicy: IfNotPresent
  baseServerId: 1000
  version: 8.0.29
  serviceAccountName: mycluster-sa
tls:
  useSelfSigned: false

Alternatively set options using command-line parameters:

```
$> helm install mycluster mysql-operator/mysql-innodbcluster \
  --set credentials.root.user='root' \
  --set credentials.root.password='sakila' \
  --set credentials.root.host='%' \
  --set serverInstances=3 \
  --set routerInstances=1 \
  --set tls.useSelfSigned=true
```

To view user-supplied values for an existing cluster:

```
$> helm get values mycluster
```

**USER-SUPPLIED VALUES:**

```
credentials:
  root:
    host: '%'
    password: sakila
    user: root
  routerInstances: 1
  serverInstances: 3
  tls:
    useSelfSigned: true
```

See also Chapter 4, *Connecting to MySQL InnoDB Cluster.*

## 3.2 Deploy using kubectl

To create an InnoDB Cluster with *kubectl*, first create a secret containing credentials for a new MySQL root user, a secret named 'mypwds' in this example:

```
$> kubectl create secret generic mypwds \
  --from-literal=rootUser=root \
  --from-literal=rootHost=% \
  --from-literal=rootPassword="sakila"
```

Use that newly created user to configure a new MySQL InnoDB Cluster. This example’s InnoDBCluster definition creates three MySQL server instances and one MySQL Router instance:

```
apiVersion: mysql.oracle.com/v2
kind: InnoDBCluster
metadata:
  name: mycluster
spec:
  secretName: mypwds
tlsUseSelfSigned: true
  instances: 3
  router:
    instances: 1
```

Assuming a file named *mycluster.yaml* contains this definition, install this simple cluster:
Manifest Changes for InnoDBCluster

$> kubectl apply -f mycluster.yaml

Optionally observe the process by watching the `innodbcluster` type for the default namespace:

$> kubectl get innodbcluster --watch

Output looks similar to this:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ONLINE</th>
<th>INSTANCES</th>
<th>ROUTERS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>mycluster</td>
<td>PENDING</td>
<td>0</td>
<td>3</td>
<td>1</td>
<td>10s</td>
</tr>
</tbody>
</table>

Until reaching ONLINE status:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ONLINE</th>
<th>INSTANCES</th>
<th>ROUTERS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>mycluster</td>
<td>ONLINE</td>
<td>3</td>
<td>3</td>
<td>1</td>
<td>2m6s</td>
</tr>
</tbody>
</table>

To demonstrate, this example connects with MySQL Shell to show the host name:

$> kubectl run --rm -it myshell --image=mysql/mysql-operator -- mysqlsh root@mycluster --sql

If you don’t see a command prompt, try pressing enter.

******

MySQL mycluster SQL> SELECT @@hostname

+-------------+
| @@hostname  |
+-------------+
| mycluster-0  |

This shows a successful connection that was routed to the mycluster-0 pod in the MySQL InnoDB Cluster. For additional information about connecting, see Chapter 4, *Connecting to MySQL InnoDB Cluster*.

### 3.3 Manifest Changes for InnoDBCluster

This section covers common options defined while setting up a MySQL InnoDB Cluster. For a full list of options, see Table 7.1, “Spec table for InnoDBCluster”.

Here’s a simple example that uses most defaults:

```yaml
apiVersion: mysql.oracle.com/v2
kind: InnoDBCluster
metadata:
  name: mycluster
spec:
  secretName: mypwds
tlsUseSelfSigned: true
```

Here’s an expanded version of that with optional changes:

```yaml
apiVersion: mysql.oracle.com/v2
kind: InnoDBCluster
metadata:
  name: mycluster
spec:
  secretName: mypwds
tlsUseSelfSigned: true
  instances: 3
  version: 8.0.29
  router:
    instances: 1
    version: 8.0.29
datadirVolumeClaimTemplate:
  accessModes:
  -ReadWriteOnce
resources:
```

---

7
Router and Server Versions and Instances

By default, MySQL Operator for Kubernetes installs MySQL Server with the same version as the Operator, and installs Router with the same version as MySQL Server. It also installs 3 MySQL instances and 1 Router instance by default. Optionally configure each:

```
spec:
  instances: 3
  version: 8.0.29
  router:
    instances: 1
    version: 8.0.29
```

Setting PersistentVolumeClaim Size

Set a MySQL instance's storage configuration. For storing the MySQL Server's Data Directory (datadir), a PersistentVolumeClaim (PVC) is used for each MySQL Server pod. Each PVC follows the naming scheme `datadir-{clusternam e}-[0-9]`. A `datadirVolumeClaimTemplate` template allows setting different options, including size and storage class. For example:

```
datadirVolumeClaimTemplate:
  accessModes:
    - ReadWriteOnce
  resources:
    requests:
      storage: 40Gi
```

For additional configuration information, see the official Storage: Persistent Volumes documentation. The `datadirVolumeClaimTemplate` object is set to `x-kubernetes-preserve-unknown-fields: true`.

Note
MySQL Operator for Kubernetes currently does not support storage resizing.

For a related MySQLBackup example that uses a PersistentVolumeClaim, see Section 6.1, “Handling MySQL Backups”.

The initDB Object

Optionally initialize an InnoDBCluster with a database using the `initDB` object; it’s only used when the InnoDBCluster is created. It accepts `clone` or `dump` definitions.

This simple `initDB `clone` example clones a remote MySQL instance from a cluster. The donor MySQL server’s credentials are stored in a Secret on the target server with a ‘rootPassword’ key for the ‘rootUser’.

```
initDB:
  clone:
    donorUrl: mycluster-0.mycluster-instances.another.svc.cluster.local:3306
    rootUser: root
    secretKeyRef:
      name: mypwds
mycnf: |
  [mysqld]
  max_connections=162
```

Below are explanations of each change made to initial the `InnoDBCluster` configuration.
Modify my.cnf Settings

MySQL Server restarts after populating with the clone operation, and a "1" is seen in the restart column of the associated pods. Cloning utilizes MySQL Server’s The Clone Plugin and behaves accordingly.

For a dump example (instead of clone), see Section 6.2, “Bootstrap a MySQL InnoDB Cluster from a Dump using Helm”.

Modify my.cnf Settings

Use the mycnf option to add custom configuration additions to the my.cnf for each MySQL instance. This example adds a [mysqld] section that sets max_connections to 162:

```bash
cnf: |
[mysqld]
max_connections=162
```

This is added to the generated my.cnf; the default my.cnf template is visible in the initconf container’s ConfigMap. An example to see this template: kubectl get cm ${CLUSTER_NAME}-initconf -o json | jq -r '.data["my.cnf.in"]'.

3.4 MySQL InnoDB Cluster Service Explanation

For connecting to the InnoDB Cluster, a Service is created inside the Kubernetes cluster. The exported ports represent read-write and read-only ports for both the MySQL Protocol and X Protocol.

```bash
$> kubectl describe service mycluster
```

Output looks similar to this:

```bash
Name:              mycluster  
Namespace:         default       
Labels:            mysql.oracle.com/cluster=mycluster
                    tier=mysql
Annotations:       <none>        
Selector:          component=mysqlrouter,mysql.oracle.com/cluster=mycluster,tier=mysql
Type:              ClusterIP     
IP Family Policy:  SingleStack  
IP Families:       IPv4          
IP:                10.106.33.215 
IPs:               10.106.33.215 
Port:              mysql  3306/TCP 
TargetPort:        6446/TCP      
Endpoints:         172.17.0.12:6446
Port:              mysqlx  33060/TCP 
TargetPort:        6448/TCP      
Endpoints:         172.17.0.12:6448
Port:              mysql-alternate  6446/TCP
TargetPort:        6446/TCP      
Endpoints:         172.17.0.12:6446
Port:              mysqlx-alternate  6448/TCP
TargetPort:        6448/TCP      
Endpoints:         172.17.0.12:6448
Port:              mysql-ro  6447/TCP 
TargetPort:        6447/TCP      
Endpoints:         172.17.0.12:6447
Port:              mysqlx-ro  6449/TCP 
TargetPort:        6449/TCP      
Endpoints:         172.17.0.12:6449
Session Affinity:  None         
Events:            <none>       
```

An alternative view showing services named mycluster and mycluster-instances:

```bash
$> kubectl get service
```

Output looks similar to this:
MySQL Accounts Created by InnoDBCluster Deployment

---

<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>TYPE</th>
<th>CLUSTER-IP</th>
<th>EXTERNAL-IP</th>
<th>PORT(S)</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>default</td>
<td>kubernetes</td>
<td>ClusterIP</td>
<td>10.96.0.1</td>
<td>&lt;none&gt;</td>
<td>443/TCP</td>
<td>2d1h</td>
</tr>
<tr>
<td>default</td>
<td>mycluster</td>
<td>ClusterIP</td>
<td>10.102.198.226</td>
<td>&lt;none&gt;</td>
<td>3306/TCP, 33060/TCP, 6446/TCP,</td>
<td>2d</td>
</tr>
<tr>
<td></td>
<td>mycluster-instances</td>
<td>ClusterIP</td>
<td>None</td>
<td>&lt;none&gt;</td>
<td>3306/TCP, 33060/TCP, 33061/TCP</td>
<td></td>
</tr>
</tbody>
</table>

The long host name used to connect to an InnoDB Cluster from within a Kubernetes cluster is `{innodbclustername}.{namespace}.svc.cluster.local`, which routes to the current primary/replica using MySQL Router, depending on the port. Acceptable host name forms:

- `{innodbclustername}.{namespace}.svc.cluster.local`  
- `{innodbclustername}.{namespace}.svc`  
- `{innodbclustername}.{namespace}`  
- `{innodbclustername}`

Using these names goes to the Kubernetes LoadBalancer (part of Kubernetes Service), which redirects to MySQL Router. MySQL Router then talks to the individual server based on the role, such as PRIMARY or SECONDARY.

For example, assuming 'mycluster' as the InnoDB Cluster name in the 'default' namespace:

```
mycluster.default.svc.cluster.local
```

Using only `{innodbclustername}` as the host name assumes the session's context is either the default namespace or set accordingly. Alternatively you may use the clusterIP instead of a host name; here's an example that retrieves it:

```
$> kubectl get service/mycluster -o jsonpath='{.spec.clusterIP}'
```

See also Chapter 4, Connecting to MySQL InnoDB Cluster.

### 3.5 MySQL Accounts Created by InnoDBCluster Deployment

MySQL Operator for Kubernetes creates and/or utilizes several MySQL accounts as when creating an InnoDB Cluster. Internal accounts created and only used by MySQL Operator for Kubernetes may be used by users but they must not be changed (dropped, password changes, grant changes, and so on).

Typically the only account a system administrator uses is the 'root' user, whereas other MySQL users are considered internal to the MySQL InnoDB Cluster installation.

**Table 3.1 MySQL accounts created and/or used by MySQL Operator.**

<table>
<thead>
<tr>
<th>MySQL User</th>
<th>Purpose</th>
<th>Creator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>root</strong></td>
<td>General system administration by the user</td>
<td>MySQL Operator for Kubernetes as defined by the user</td>
<td>Defined when InnoDB Cluster is created using a user-supplied Kubernetes secret object as referenced by the <code>secretsName</code> configuration option. It's typically <code>root@</code>'%' but can be overridden using the <code>rootUser</code> and <code>rootHost</code> configuration options. You may want to create less-privileged MySQL accounts with this user.</td>
</tr>
<tr>

Related: Deploying MySQL Operator for Kubernetes creates a Kubernetes service account with a name defaulting to `mysql-operator-sa` in the bundled `deploy-operator.yaml` and Helm deployment template.

For a list of all ports used by MySQL services, see MySQL Port Reference.

### 3.6 Upgrading a pre-release InnoDB Cluster to 8.0.29-2.0.4 GA

The first MySQL Operator for Kubernetes General Availability (GA) release improved the security configuration and this complicates the upgrade process from pre-GA preview releases. A migration from a preview release (v8.0.28-2.0.3 and earlier) to a GA release without downtime is not possible.

**Important**

This guide does not apply to future upgrades, say from 8.0.29-2.0.4 to a future release.

**Important**

If you run multiple clusters then these operations must be done for all clusters in order. In other words, perform step #1 for all clusters, then step #2 for all clusters, and so on.

### Prerequisites

A successful migration assumes InnoDB Cluster is managed by MySQL Operator 8.0.28-2.0.3, and that you have credentials to an account (rootUser) with root-style privileges. The InnoDB Cluster must have a minimum of two running MySQL instances. Have a backup before proceeding.

The InnoDBCluster is named `mycluster` in this guide, and assumes it's in the default namespace.

### Summary of the Upgrade

The upgrade process described here terminates the old InnoDB Cluster, and removes all data directories except for one. The old MySQL Operator for Kubernetes is then shut down. Then, a temporary MySQL server is configured to use the remaining data directory, which then becomes the donor to initialize a new InnoDB Cluster with a single instance. After the data is cloned, the temporary (donor) server is shutdown, the old data directory is deleted, and the new InnoDB Cluster is scaled up to three instances.

### Perform the Upgrade

**Step #1:** Terminate the old InnoDB Cluster and remove all data directories except for one. This example uses kubectl and observes the termination process:

```
$> kubectl delete innodbcluster mycluster
$> kubectl get pods -w
```

Deleting an InnoDB Cluster does not remove its associated PersistentVolumeClaims, as seen with:

```
$> kubectl get pvc
```

Delete all but the one with the highest number. For example, with a three-node cluster keep the one with index 2:

```
$> kubectl delete pvc datadir-mycluster-0  datadir-mycluster-1
```

Be careful to keep one as otherwise the data can not be recovered; in this case, do not delete datadir-mycluster-2.
Perform the Upgrade

**Step #2:** Terminate the MySQL Operator for Kubernetes; do so by deleting the associated Deployment that controls it:

```bash
$> kubectl delete deployment -n mysql-operator mysql-operator
```

**Step #3:** Create a temporary MySQL Server using the datadir PersistentVolumeClaim, but first store the credentials in a Secret:

```bash
$> kubectl create secret generic myfixer \
--from-literal=rootUser="root" \
--from-literal=rootPassword="YOUR_PASSWORD"
```

This Secret is used to set up the temporary server, and also used to clone the data into the new InnoDB Cluster.

Save the following manifest to a file, say to `myfixer.yaml`, and then apply it. If datadir-mycluster-2 is not the datadir PVC you kept then modify the name accordingly.

```yaml
apiVersion: v1
kind: ConfigMap
metadata:
  name: mycnf
data:
  my.cnf: |
    [mysqld]  
    plugin_load_add=auth_socket.so  
    loose_auth_socket=FORCE_PLUS_PERMANENT  
    skip_log_error  
    log_error_verbosity=3  
    skip_log_bin  
    skip_slave_start=1
---
apiVersion: v1
kind: Pod
metadata:
  name: myfixer
spec:
  restartPolicy: Never
  containers:
    - image: mysql/mysql-server:8.0.29
      imagePullPolicy: IfNotPresent
      name: myfixer
      args: [ 'mysqld', '-- defaults-file=/mycnf/my.cnf' ]
      env:
        - name: MYSQL_ROOT_PASSWORD
          valueFrom:
            secretKeyRef:
              key: rootPassword
              name: myfixer
      volumeMounts:
        - name: datadir
          mountPath: /var/lib/mysql
        - name: mycnf
          mountPath: /mycnf
  volumes:
    - name: datadir
      persistentVolumeClaim:
        claimName: datadir-mycluster-2
    - name: mycnf
      configMap:
        name: mycnf
```

Apply it:

```bash
$> kubectl apply -f myfixer.yaml
```

Retrieve the IP of the Pod when it's ready:
Perform the Upgrade

```bash
$> kubectl get pod -o wide myfixer

The sixth column has the IP address, you can verify the server started correctly by using a shell session using the credentials you stored (enter rootUser's password when you see "If you don't see a command prompt, try pressing enter.

```bash
$> kubectl run testshell --restart=Never --rm --image=mysql/mysql-operator:8.0.29-2.0.4 -it -- mysqlsh -uroot -h{IP_HERE}
```

**Step #4:** Deploy a new MySQL Operator for Kubernetes, as described in the installation documentation. For example:

```bash
$> kubectl apply -f https://raw.githubusercontent.com/mysql/mysql-operator/trunk/deploy/deploy-crds.yaml
$> kubectl apply -f https://raw.githubusercontent.com/mysql/mysql-operator/trunk/deploy/deploy-operator.yaml
```

**Step #5:** Deploy your new InnoDB Cluster following the installation documentation, and by using the temporary server created earlier as the donor; but first create a secret for your administrative user as described in the manual. For example:

```bash
$> kubectl create secret generic mypwds
   --from-literal=rootUser="root"
   --from-literal=rootHost="%"
   --from-literal=rootPassword="YOUR_PASSWORD"
```

The following manifest shows the initDB definition, and this example assumes it to a file named `ic.yaml`

apiVersion: mysql.oracle.com/v2
kind: InnoDBCluster
metadata:
  name: mycluster
spec:
  tlsUseSelfSigned: true
  instances: 1
  # Important deploy a single instance only
  secretName: mypwds
  # Name of Secret for new InnoDBCluster
  version: 8.0.29
  # Important must equal the server used as temporary donor
  router:
    instances: 1
  initDB:
    clone:
      donorUrl: root@{IP_HERE}:3306
      # Use your myfixer user/ip here
      secretKeyRef:
        name: myfixer
        # Secret on the temporary server
        # Add custom options like configuration settings, storage configuration etc. as needed

Apply it:

```bash
$> kubectl apply -f ic.yaml
```

Now observe the status until the single MySQL instance cluster is ready. The time needed depends on the amount of data to clone.

```bash
$> kubectl get ic mycluster -w
```

**Step #6:** Remove the temporary server and scale up the InnoDB Cluster.

After confirming your new InnoDB Cluster is online and has your cloned data, remove the temporary server and its associated configuration, and also the old data directory’s PersistentVolumeClaim:

```bash
$> kubectl delete -f myfixer.yaml
$> kubectl delete secret myfixer
$> kubectl delete pvc datadir-mycluster-2
```

Scale up the InnoDB Cluster MySQL instances as desired, for example:

```bash
$> kubectl patch ic mycluster --type=merge -p '{"spec": {"instances": 3}}'
```
Chapter 4 Connecting to MySQL InnoDB Cluster

Table of Contents

4.1 Connect with MySQL Shell ................................................................. 15
4.2 Connect with Port Forwarding ......................................................... 16

This section utilizes the \{innodbclustername\}.\{namespace\}.svc.cluster.local form when connecting; and typically refers to the \{innodbclustername\} shorthand form that assumes the default namespace. See Section 3.4, “MySQL InnoDB Cluster Service Explanation” for additional information.

4.1 Connect with MySQL Shell

Create a new container with MySQL Shell to administer a MySQL InnoDB Cluster. This is the preferred method, although every MySQL Operator for Kubernetes and MySQL InnoDB Cluster container also has MySQL Shell installed if you need to troubleshoot a specific pod.

These examples assume the InnoDB Cluster is named 'mycluster' and using the 'default' namespace.

Create the new container with MySQL Shell; this example uses the MySQL Operator for Kubernetes image but other images work too, such as mysql/mysql-server:8.0.

This example creates a new container named "myshell" using the "mysql/mysql-operator" image, and immediately executes MySQL Shell:

$> kubectl run --rm -it myshell --image=mysql/mysql-operator -- mysqlsh
If you don't see a command prompt, try pressing enter.

MySQL JS >

Now connect to the InnoDB Cluster from within MySQL Shell's interface:

MySQL JS> \connect root@mycluster
Creating a session to 'root@mycluster'
Please provide the password for 'root@mycluster': *****

MySQL mycluster JS>

The root@mycluster shorthand works as it assumes port 3306 (MySQL Router redirects to 6446) and the default namespace.

Optionally pass in additional arguments to mysqlsh, for example:

$> kubectl run --rm -it myshell --image=mysql/mysql-operator -- mysqlsh root@mycluster --sql
If you don't see a command prompt, try pressing enter.

******

MySQL mycluster SQL>

The "*****" represents entering the MySQL user's password to MySQL Shell as MySQL Shell prompts for a password by default. The root@mycluster represents user root on host mycluster, and assumes the default namespace. Setting "--sql" initiates MySQL Shell into SQL mode.

Troubleshooting a Specific Container

Every MySQL Operator for Kubernetes and MySQL InnoDB Cluster container has MySQL Shell installed, so for troubleshooting you may need to connect to a specific pod in the cluster. For example, connecting to a pod named mycluster-0:

$> kubectl --namespace default exec -it mycluster-0 -- bash
4.2 Connect with Port Forwarding

Optionally use port forwarding to create a redirection from your local machine to easily use a MySQL client such as MySQL Workbench. We’ll use port 3306 for a read-write connection to the primary on port 6446:

```
$> kubectl port-forward service/mycluster 3306
Forwarding from 127.0.0.1:3306 -> 6446
Forwarding from [:1]:3306 -> 6446
```

To test, open a second terminal using the MySQL command line or MySQL Shell with the InnoDB Cluster user’s credentials:

```
$> mysql -h127.0.0.1 -uroot -p
```

To demonstrate the connection to a local MySQL instance:

```
mysql> select @@hostname;
+-------------+
| @@hostname  |
+-------------+
| mycluster-0 |
+-------------+
```

Not seeing a port-forward to 127.0.0.1:3306 in this example means a local MySQL installation is likely installed and active on the system.

Using port names instead of port numbers also works:

```
$> kubectl port-forward service/mycluster mysql
Forwarding from 127.0.0.1:3306 -> 6446
Forwarding from [:1]:3306 -> 6446
```

```
$> kubectl port-forward service/mycluster mysql-ro
Forwarding from 127.0.0.1:6447 -> 6447
Forwarding from [:1]:6447 -> 6447
```

A list of port names with their associated ports:

```
mysql:        3306
mysqlx:       33060
mysql-alternate: 6446
mysqlx-alternate: 6448
mysql-ro:     6446
mysql-rx:     6447
mysqlx-ro:    6448
mysqlx-rw:    6449
```

For a list of all ports used by MySQL services, see MySQL Port Reference. The ports used here are from MySQL Router.
Chapter 5 Private Registries

Table of Contents

5.1 Install MySQL Operator for Kubernetes from Private Registry using Helm ......................................................... 17
5.2 Install InnoDB Cluster from Private Registry using Helm ......................................................................................... 18
5.3 Copy Image to Private Registry using Docker ........................................................................................................ 18
5.4 Copy Image to Private Registry using Skopeo ............................................................................................................ 19

Tasks related to using private registries. This section is a work-in-progress.

5.1 Install MySQL Operator for Kubernetes from Private Registry using Helm

If the private registry is not authenticated, and after pushing the MySQL Operator for Kubernetes image to your private registry, execute the following on the host where helm is installed; and adjust the variable values as needed:

```bash
export REGISTRY="..."   # like 192.168.20.199:5000
export REPOSITORY="..." # like "mysql"
export NAMESPACE="mysql-operator"
helm install mysql-operator helm/mysql-operator \
  --namespace $NAMESPACE \n  --create-namespace \n  --set image.registry=$REGISTRY \n  --set image.repository=$REPOSITORY \n  --set envs.imagesDefaultRegistry=$REGISTRY \n  --set envs.imagesDefaultRepository=$REPOSITORY
```

Authenticated private registries need to create a namespace for MySQL Operator for Kubernetes, and also add a Kubernetes docker-registry secret in the namespace; then execute `helm install` with arguments that look similar to:

```bash
export REGISTRY="..."   # like 192.168.20.199:5000
export REPOSITORY="..." # like "mysql"
export NAMESPACE="mysql-operator"
export DOCKER_SECRET_NAME="priv-reg-secret"
kubectl create namespace $NAMESPACE

kubectl -n $NAMESPACE create secret docker-registry $DOCKER_SECRET_NAME \
  --docker-server="https://$REGISTRY/v2/" \n  --docker-username=user --docker-password=pass \n  --docker-email=user@example.com

helm install mysql-operator helm/mysql-operator \
  --namespace $NAMESPACE \n  --set image.registry=$REGISTRY \n  --set image.pullSecrets.enabled=true \n  --set image.pullSecrets.secretName=$DOCKER_SECRET_NAME \n  --set envs.imagesPullPolicy='IfNotPresent' \n  --set envs.imagesDefaultRegistry=$REGISTRY \n  --set envs.imagesDefaultRepository=$REPOSITORY
```

To confirm the installation, check the status with commands such as `helm list -n $NAMESPACE` and `kubectl -n $NAMESPACE get pods`. 

17
5.2 Install InnoDB Cluster from Private Registry using Helm

For example:

```
export REGISTRY="..." # like 192.168.20.199:5000
export REPOSITORY="..." # like "mysql"
export NAMESPACE="mynamespace"
export DOCKER_SECRET_NAME="priv-reg-secret"

$> kubectl create namespace $NAMESPACE

$> kubectl -n $NAMESPACE create secret docker-registry $DOCKER_SECRET_NAME \
--docker-server="https://$REGISTRY/v2/" \
--docker-username=user --docker-password=pass \
--docker-email=user@example.com

$> helm install mycluster mysql-operator/mysql-innodbcluster \
--namespace $NAMESPACE \
--set credentials.root.user='root' \
--set credentials.root.password='sakila' \
--set credentials.root.host='%' \
--set serverInstances=3 \
--set routerInstances=1 \
--set image.registry=$REGISTRY \
--set image.repository=$REPOSITORY \
--set image.pullSecrets.enabled=true \
--set image.pullSecrets.secretName=$DOCKER_SECRET_NAME
```

5.3 Copy Image to Private Registry using Docker

Using air-gapped or sanctioned images to avoid pulling images from the internet is another use case and described here.

```
Note
MySQL Operator for Kubernetes requires these three container images to function: MySQL Operator for Kubernetes, MySQL Router, and MySQL Server.

1. Choose the desired MySQL Operator for Kubernetes version. For example, latest is defined in helm/mysql-operator/Chart.yaml. For example, 8.0.29-2.0.4.
2. Execute `docker pull mysql/mysql-operator:VERSION` where VERSION is the desired MySQL Operator for Kubernetes version.
3. Execute `docker save mysql/mysql-operator:VERSION -o mysql-operator.tar` to export the container image where VERSION is the desired MySQL Operator for Kubernetes version.
4. Copy `mysql-operator.tar` to a host with access to the private registry.
5. Execute `docker load -i mysql-operator.yaml` to load the image into the local Docker cache on that host.
6. Execute `docker tag mysql/mysql-server:VERSION registry:port/repo/mysql-server:VERSION` to retag the image as preparation for pushing to the private registry; adjust VERSION accordingly.
7. Execute `docker push registry:port/repo/mysql-server:VERSION` to push the newly created tag to the private registry; adjust VERSION accordingly.
8. If you won't need the image from the importing host cache, then you can delete it with `docker rmi mysql/mysql-operator:VERSION registry:port/repo/mysql-server:VERSION`. This removes it from the host but the registry itself won't be affected. Adjust VERSION accordingly.
```
Alternatively, you can use the following commands to pull and push in one command. Execute it on a host with DockerHub access. If applicable, this host also needs access to the secure (bastion) host that
can access the private registry. Modify the variable values to fit your needs. The command does not consume local space for a tarball but will stream the container image over SSH.

```bash
export BASTION_USER='k8s'
export BASTION_HOST='k8'
export REGISTRY="..." # for example 192.168.20.199:5000
export REPOSITORY="..." # for example mysql
export OPERATOR_VERSION=$(grep appVersion helm/mysql-operator/Chart.yaml | cut -d '"' -f2)
docker pull mysql/mysql-operator:$OPERATOR_VERSION
docker save mysql/mysql-operator:$OPERATOR_VERSION | \\
    ssh $BASTION_USER@$BASTION_HOST "
    docker load && 
    docker tag mysql/mysql-operator:$OPERATOR_VERSION $REGISTRY/$REPOSITORY/mysql-operator:$OPERATOR_VERSION && 
    docker push $REGISTRY/$REPOSITORY/mysql-operator:$OPERATOR_VERSION && 
    docker rmi mysql/mysql-operator:$OPERATOR_VERSION $REGISTRY/$REPOSITORY/mysql-operator:$OPERATOR_VERSION"

docker rmi mysql/mysql-operator:$OPERATOR_VERSION
```

### 5.4 Copy Image to Private Registry using Skopeo

Similar to Section 5.3, “Copy Image to Private Registry using Docker”, but you might use Skopeo. **Skopeo** is a container utility that can also run as a container. The following example copies the operator image from DockerHub to a private registry. It needs to run on a host that has Docker or Podman, and also that has access to both DockerHub and your private registry. Change the variable names to fit your environment, and change docker to podman if using Podman. The `OPERATOR_VERSION` is the MySQL Operator for Kubernetes version, such as `8.0.29-2.0.4`.

```bash
export REGISTRY="..." # for example 192.168.20.199:5000
export REPOSITORY="..." # for example mysql
export OPERATOR_VERSION=$(grep appVersion helm/mysql-operator/Chart.yaml | cut -d '"' -f2)
```

For authenticated private registries, append `--dest-creds user:pass` to the skopeo command. Also append `--dest-tls-verify=false` if it does not use TLS.
Chapter 6 MySQL Operator Cookbook

Table of Contents

6.1 Handling MySQL Backups ................................................................. 21
6.2 Bootstrap a MySQL InnoDB Cluster from a Dump using Helm ....................... 24
6.3 Viewing Logs .................................................................................. 25

Tasks related to using MySQL Operator for Kubernetes.

6.1 Handling MySQL Backups

There are three main topics related to MySQL backups:

- **Backup profile**: describes the general backup structure that includes storage, schedule, and MySQL Shell dump related options. Defining profiles is optional, and profiles are separated by name.

- **Backup request**: requesting a backup initiates a new object that creates a new pod to perform the backup.

- **Backup schedule**: defined as a cron expression for regular backups, or with no schedule when performing one-off backups.

See also Chapter 7, MySQL Operator Custom Resource Properties for a list of all MySQLBackup resource options.

Backup Profiles with backupProfiles

Backup profiles are defined and reused for regular backups and one-off backups using the backupProfiles specification object. A profile is defined and called from within the InnoDB Cluster specification object, or values can be defined from within the individual backup requests without a profile.

How a Backup is Created

MySQL Operator for Kubernetes supports the dumpInstance() command using MySQL Shell by defining the associated dumpInstance specification object that contains the dumpOptions and storage specification objects:

- The optional dumpOptions value is a dictionary of key-value pairs passed directly to MySQL Shell's DumpInstance() function. See Instance Dump Utility, Schema Dump Utility, and Table Dump Utility for a list of relevant options.

MySQL Operator for Kubernetes adds definitions by default, such as defining threads based on what the system claims as its CPU count; but these values can be overridden.

- The storage configuration specification offers two options as of MySQL Operator for Kubernetes 8.0.29: persistentVolumeClaim or ociObjectStorage (OCI refers to Oracle Cloud Infrastructure).

Note

Limitations: Restore capability is not available for persistentVolumeClaim as of MySQL Operator for Kubernetes 8.0.29, and ociObjectStorage use is specific to the Oracle Cloud Infrastructure (OCI).

- The backupSchedules schedule utilizes the Kubernetes CronJob controller for regular backups.
A PersistentVolumeClaim Scheduled Backup Example

This example uses PersistentVolumeClaim (PVC), sets a daily backup schedule, and defines a backup profile named "myfancyprofile" in the backupProfiles object.

```
apiVersion: mysql.oracle.com/v2
kind: InnoDBCluster
metadata:
  name: mycluster
spec:
  instances: 3
  router:
    instances: 1
  secretName: mypwds
tlsUseSelfSigned: true
backupProfiles:
- name: myfancyprofile  # Embedded backup profile
dumpInstance:         # MySQL Shell Dump
dumpOptions:
  excludeTables: "[world.country]"  # Example to exclude one table
storage:
  persistentVolumeClaim:
    claimName: myexample-pvc # store to this pre-existing PVC
backupSchedules:
- name: mygreatschedule
  schedule: "0 0 * * *" # Daily, at midnight
  backupProfileName: myfancyprofile # reference the desired backupProfiles's name
  enabled: true # backup schedules can be temporarily disabled
```

This example requires a PersistentVolumeClaim definition named "myexample-pvc"; see the official Kubernetes Persistent Volumes documentation for PersistentVolumeClaim specifics. A simple example:

```
spec:
  storageClassName: manual
  capacity:
    storage: 2Gi
  accessModes:
  - ReadWriteOnce
  hostPath:
    path: /tmp
---
spec:
  storageClassName: manual
  accessModes:
  - ReadWriteOnce
  requests:
    storage: 2Gi
```

The example "mycluster" InnoDB Cluster definition uses a secret named "mypwds" for its root user, for example:
Using OciObjectStorage

```bash
$> kubectl create secret generic mypwds \
   --from-literal=rootUser=root \
   --from-literal=rootHost=% \
   --from-literal=rootPassword="sakila"
```

After creating the example InnoDB Cluster, you may want to execute a one-off backup using an existing profile, such as:

```yaml
apiVersion: mysql.oracle.com/v2
kind: MySQLBackup
metadata:
  name: a-cool-one-off-backup
spec:
  clusterName: mycluster
  backupProfileName: myfancyprofile
```

Executing this creates a pod with a name similar to `a-cool-one-off-backup-20220330-215635-t6thv` that executes the backup, and it remains in a Completed state after the backup operation.

Using OciObjectStorage

Using the same example but for Oracle Cloud Infrastructure (OCI) instead of a PVC, modify `dumpInstance.storage` from PrivateVolumeClaim to an ociObjectStorage object similar to:

```yaml
dumpInstance:
  storage:
    ociObjectStorage:
      prefix: someprefix  # a prefix (directory) used for ObjectStorage
      bucketName: bucket  # the ObjectStorage bucket
      credentials: backup-apikey  # a secret with credentials ...
```

The backup-apikey secret used in this OCI example looks similar to:

```yaml
apiVersion: v1
kind: Secret
type: Opaque
metadata:
  name: backup-apikey
stringData:
  passphrase: ....
  privatekey: |
    -----BEGIN RSA PRIVATE KEY-----
    MIIEogIBAAKCAQEAwmQ1JGOGUBNwyJuq4msGpBfK24toKrWaqAkb21S/XL0FLvEE
    ....
  region: us-ashburn-1..
  tenancy: ocid1.tenancy....
  user: ocid1.user.....
```

An example method to create the Secret; values are found in the configuration file downloaded from OCI, which is used with the OCI command-line tool.

```bash
$> kubectl create secret generic <secret_name> \
   --from-literal=user=<userid> \
   --from-literal=fingerprint=<fingerprint> \
   --from-literal=tenancy=<tenancy> \
   --from-literal=region=<region> \
   --from-literal=passphrase=<passphrase> \
   --from-file=privatekey=<path_to_api_key.pem>
```

Using profiles (`backupProfileName`) is optional, so instead it may look like the following with the same settings. This example restores to a new InnoDB Cluster from ociObjectStorage:

```yaml
apiVersion: mysql.oracle.com/v2
kind: InnoDBCluster
metadata:
  name: newcluster
spec:
```
Cloning

The secret (restore-apikey) could be the same as the backup example (backup-apikey) but may be a different user with different permissions, such as no write permissions to the OS.

Cloning

Data can be initialized using a backup or by cloning an existing and running MySQL instance using initDB and its donorURL option:

```yaml
apiVersion: mysql.oracle.com/v2
kind: InnoDBCluster
metadata:
  name: copycluster
spec:
  instances: 1
  secretName: pwds
tlsUseSelfSigned: true
initDB:
  clone:
    donorUrl: root@mycluster-0.mycluster-instances.testns.svc.cluster.local:3306
    secretKeyRef:
      name: donorpwds
```

The donorpwds secret contains a single field named rootPassword, so for example you could reuse the main secretName used when creating the original cluster (named mypwd in the example). This utilizes MySQL's cloning plugin, so standard limitations apply (such as requiring the same MySQL versions). Cloning can theoretically also be used for creating backups.

6.2 Bootstrap a MySQL InnoDB Cluster from a Dump using Helm

A MySQL InnoDB Cluster can be initialized with a database dump created by MySQL Shell or by MySQL Operator for Kubernetes. The backup could reside on a persistent volume accessible from the cluster, but our example uses an OCI Object Storage bucket.

Using an OCI Object Storage bucket

If you are bootstrapping from OCI OS, then the following must be known:

- The credentials of the user who has access to OCI OS
- The OCI OS Object Prefix (plays the role of a directory). The following Helm variables must be set:
  - `initDB.dump.name`: a name for the dump that follows the Kubernetes rules for naming an identifier, such as `dump-20210916-140352`
  - `initDB.dump.ociObjectStorage.prefix`: the prefix from list above
  - `initDB.dump.ociObjectStorage.bucketName`: the bucket name from the list above
  - `initDB.dump.ociObjectStorage.credentials`: name of the Kubernetes secret that holds the credentials for accessing the OCI OS bucket
Viewing Logs

For the credentials secret, the following information is needed: OCI OS User Name, Fingerprint, Tenancy Name, Region Name, Passphrase, and the Private Key of the user.

- The OCI OS Bucket Name

The OCI command-line tool provides this information in $HOME/config under the [DEFAULT] section. Once obtained, execute:

```bash
export NAMESPACE="mynamespace"
export OCI_CREDENTIALS_SECRET_NAME="oci-credentials"
export OCI_USER="..." # like ocid1.user.oc1....
export OCI_FINGERPRINT="..." # like 90:01:.......
export OCI_TENANCY="..." # like ocid1.tenancy.oc1...
export OCI_REGION="..." # like us-ashburn-1
export OCI_PASSPHRASE="..." # set to empty string if no passphrase
export OCI_PATH_TO_PRIVATE_KEY="..." # like $HOME/.oci/oci_api_key.pem

ekubectl -n $NAMESPACE create secret generic $OCI_CREDENTIALS_SECRET_NAME
--from-literal=user="$OCI_USER"
--from-literal=fingerprint="$OCI_FINGERPRINT"
--from-literal=tenancy="$OCI_TENANCY"
--from-literal=region="$OCI_REGION"
--from-literal=passphrase="$OCI_PASSPHRASE"
--from-file=privatekey="$OCI_PATH_TO_PRIVATE_KEY"
```

With the OCI secret created, now create the cluster that'll be initialized from the dump in OCI OS:

```bash
export NAMESPACE="mynamespace"
export OCI_DUMP_PREFIX="..." # like dump-20210916-140352
export OCI_BUCKET_NAME="..." # like idbcluster_backup
export OCI_CREDENTIALS_SECRET_NAME="oci-credentials"

helm install mycluster mysql-operator/mysql-innodbcluster
--namespace $NAMESPACE
--set credentials.root.user='root'
--set credentials.root.password='sakila'
--set serverInstances=3
--set routerInstances=1
--set initDB.dump.name="initdb-dump"
--set initDB.dump.ociObjectStorage.prefix="$OCI_DUMP_PREFIX"
--set initDB.dump.ociObjectStorage.bucketName="$OCI_BUCKET_NAME"
--set initDB.dump.ociObjectStorage.credentials="$OCI_CREDENTIALS_SECRET_NAME"
```

6.3 Viewing Logs

Information helpful for debugging and finding relevant log information.

Log locations include each InnoDBCluster Pod, which are divided into a set of containers. There are two operative containers (mysql and sidecar) and three initializer containers (initconf, initmysql, and fixdatadir) as described below here:

<table>
<thead>
<tr>
<th>Container Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sidecar</td>
<td>Initialization, including initial setup of data (initDB) and ongoing maintenance tasks for a specific instance, such as TLS certification updates</td>
</tr>
<tr>
<td>mysql</td>
<td>The MySQL Server itself</td>
</tr>
<tr>
<td>initconf</td>
<td>It prepares MySQL configuration files for a specific host. For example, to view its ConfigMap: kubectl get cm {cluster_name}-initconf -o json</td>
</tr>
<tr>
<td>initmysql</td>
<td>Initializes the MySQL Server, including its data directory.</td>
</tr>
</tbody>
</table>
There’s also the dynamic MySQL Operator for Kubernetes and MySQL Router pods.

Examples that assume a basic setup as per `samples/sample-cluster.yaml` which looks like:

```bash
$> kubectl get pods
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>mycluster-0</td>
<td>2/2</td>
<td>Running</td>
<td>0</td>
<td>99m</td>
</tr>
<tr>
<td>mycluster-1</td>
<td>2/2</td>
<td>Running</td>
<td>0</td>
<td>99m</td>
</tr>
<tr>
<td>mycluster-2</td>
<td>2/2</td>
<td>Running</td>
<td>0</td>
<td>99m</td>
</tr>
<tr>
<td>mycluster-router-6d49485474-ftw9r</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>97m</td>
</tr>
</tbody>
</table>

```bash
$> kubectl get pods --namespace mysql-operator
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql-operator-586f9f5d5b-7wtgl</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>3h48m</td>
</tr>
</tbody>
</table>

Viewing operational Pod logs for debugging active operations:

```bash
$> kubectl logs mycluster-0 -c sidecar
```

```plaintext
2022-04-21 19:15:08,571 sidecar [INFO    ] My pod is mycluster-0 in default
2022-04-21 19:15:08,571 sidecar [INFO    ] Bootstrapping
2022-04-21 19:15:10,600 sidecar [INFO    ] Configuring mysql pod default/mycluster-0, configured=None datadir=/var/lib/mysql
2022-04-21 19:15:10,626 sidecar [INFO    ] Creating root account root@
2022-04-21 19:15:10,670 sidecar [INFO    ] Creating account mysqladmin@
```

```bash
$> kubectl logs mycluster-router-6d49485474-ftw9r
```

```plaintext
# Bootstrapping MySQL Router instance at '/tmp/mysqlrouter'...
```

```bash
$> kubectl logs mysql-operator-586f9f5d5b-7wtgl -n mysql-operator
```

```plaintext
2022-04-21 17:06:13: Info: Credential store mechanism is going to be disabled.
2022-04-21 17:06:13: Info: Loading startup files...
2022-04-21 17:06:13: Info: Loading plugins...
```

Incremental state recovery is now in progress.
Viewing Logs

* Waiting for distributed recovery to finish...

online={<MySQLPod mycluster-0>, <MySQLPod mycluster-1>, <MySQLPod mycluster-2>}

Viewing Pods specific to the InnoDBCluster's initialization:

```bash
$> kubectl logs mycluster-0 -c initmysql
```

```
[Entrypoint] Initializing database
2022-04-21T19:14:40.315937Z 0 [Note] [MY-010949] [Server] Basedir set to /usr/.
