Chapter 1 Security

When thinking about security within a MySQL installation, you should consider a wide range of possible topics and how they affect the security of your MySQL server and related applications:

• General factors that affect security. These include choosing good passwords, not granting unnecessary privileges to users, ensuring application security by preventing SQL injections and data corruption, and others. See Chapter 2, *General Security Issues*.

• Security of the installation itself. The data files, log files, and all the application files of your installation should be protected to ensure that they are not readable or writable by unauthorized parties. For more information, see Chapter 3, *Postinstallation Setup and Testing*.

• Access control and security within the database system itself, including the users and databases granted with access to the databases, views and stored programs in use within the database. For more information, see Chapter 4, *Access Control and Account Management*.

• The features offered by security-related plugins. See Chapter 6, *Security Plugins*.

• Network security of MySQL and your system. The security is related to the grants for individual users, but you may also wish to restrict MySQL so that it is available only locally on the MySQL server host, or to a limited set of other hosts.

• Ensure that you have adequate and appropriate backups of your database files, configuration and log files. Also be sure that you have a recovery solution in place and test that you are able to successfully recover the information from your backups. See *Backup and Recovery*.

This section describes general security issues to be aware of and what you can do to make your MySQL installation more secure against attack or misuse. For information specifically about the access control system that MySQL uses for setting up user accounts and checking database access, see Chapter 3, Postinstallation Setup and Testing.

For answers to some questions that are often asked about MySQL Server security issues, see Appendix A, MySQL 5.6 FAQ: Security.

2.1 Security Guidelines

Anyone using MySQL on a computer connected to the Internet should read this section to avoid the most common security mistakes.

In discussing security, it is necessary to consider fully protecting the entire server host (not just the MySQL server) against all types of applicable attacks: eavesdropping, altering, playback, and denial of service. We do not cover all aspects of availability and fault tolerance here.

MySQL uses security based on Access Control Lists (ACLs) for all connections, queries, and other operations that users can attempt to perform. There is also support for SSL-encrypted connections between MySQL clients and servers. Many of the concepts discussed here are not specific to MySQL at all; the same general ideas apply to almost all applications.

When running MySQL, follow these guidelines:

- **Do not ever give anyone (except MySQL root accounts) access to the user table in the mysql system database!** This is critical.

- **Learn how the MySQL access privilege system works** (see Chapter 4, Access Control and Account Management). Use the `GRANT` and `REVOKE` statements to control access to MySQL. Do not grant more privileges than necessary. Never grant privileges to all hosts.

  **Checklist:**

  - Try `mysql -u root`. If you are able to connect successfully to the server without being asked for a password, anyone can connect to your MySQL server as the MySQL root user with full privileges! Review the MySQL installation instructions, paying particular attention to the information about setting a root password. See Section 3.4, “Securing the Initial MySQL Accounts”.

  - **Use the SHOW GRANTS statement to check which accounts have access to what. Then use the REVOKE statement to remove those privileges that are not necessary.**
• Do not store cleartext passwords in your database. If your computer becomes compromised, the intruder can take the full list of passwords and use them. Instead, use SHA2() or some other one-way hashing function and store the hash value.

To prevent password recovery using rainbow tables, do not use these functions on a plain password; instead, choose some string to be used as a salt, and use hash(hash(password)+salt) values.

• Do not choose passwords from dictionaries. Special programs exist to break passwords. Even passwords like “xfish98” are very bad. Much better is “duag98” which contains the same word “fish” but typed one key to the left on a standard QWERTY keyboard. Another method is to use a password that is taken from the first characters of each word in a sentence (for example, “Four score and seven years ago” results in a password of “Fsasya”). The password is easy to remember and type, but difficult to guess for someone who does not know the sentence. In this case, you can additionally substitute digits for the number words to obtain the phrase “4 score and 7 years ago”, yielding the password “4sa7ya” which is even more difficult to guess.

• Invest in a firewall. This protects you from at least 50% of all types of exploits in any software. Put MySQL behind the firewall or in a demilitarized zone (DMZ).

Checklist:

• Try to scan your ports from the Internet using a tool such as nmap. MySQL uses port 3306 by default. This port should not be accessible from untrusted hosts. As a simple way to check whether your MySQL port is open, try the following command from some remote machine, where server_host is the host name or IP address of the host on which your MySQL server runs:

  shell> telnet server_host 3306

  If telnet hangs or the connection is refused, the port is blocked, which is how you want it to be. If you get a connection and some garbage characters, the port is open, and should be closed on your firewall or router, unless you really have a good reason to keep it open.

• Applications that access MySQL should not trust any data entered by users, and should be written using proper defensive programming techniques. See Section 2.7, “Client Programming Security Guidelines”.

• Do not transmit plain (unencrypted) data over the Internet. This information is accessible to everyone who has the time and ability to intercept it and use it for their own purposes. Instead, use an encrypted protocol such as SSL or SSH. MySQL supports internal SSL connections. Another technique is to use SSH port-forwarding to create an encrypted (and compressed) tunnel for the communication.

• Learn to use the tcpdump and strings utilities. In most cases, you can check whether MySQL data streams are unencrypted by issuing a command like the following:

  shell> tcpdump -l -i eth0 -w - src or dst port 3306 | strings

  This works under Linux and should work with small modifications under other systems.

  Warning

  If you do not see cleartext data, this does not always mean that the information actually is encrypted. If you need high security, consult with a security expert.

2.2 Keeping Passwords Secure

Passwords occur in several contexts within MySQL. The following sections provide guidelines that enable end users and administrators to keep these passwords secure and avoid exposing them. There
End-User Guidelines for Password Security

is also a discussion of how MySQL uses password hashing internally and of a plugin that you can use to enforce stricter passwords.

### 2.2.1 End-User Guidelines for Password Security

MySQL users should use the following guidelines to keep passwords secure.

When you run a client program to connect to the MySQL server, it is inadvisable to specify your password in a way that exposes it to discovery by other users. The methods you can use to specify your password when you run client programs are listed here, along with an assessment of the risks of each method. In short, the safest methods are to have the client program prompt for the password or to specify the password in a properly protected option file.

- **Use the `mysql_config_editor` utility**, which enables you to store authentication credentials in an encrypted login path file named `.mylogin.cnf`. The file can be read later by MySQL client programs to obtain authentication credentials for connecting to MySQL Server. See `mysql_config_editor — MySQL Configuration Utility`.
- **Use a `--password=Password` or `-p password` option on the command line.** For example:

  ```shell
  shell> mysql -u francis -pfrank db_name
  ```

  **Warning**
  
  This is convenient but insecure. On some systems, your password becomes visible to system status programs such as `ps` that may be invoked by other users to display command lines. MySQL clients typically overwrite the command-line password argument with zeros during their initialization sequence. However, there is still a brief interval during which the value is visible. Also, on some systems this overwriting strategy is ineffective and the password remains visible to `ps` (SystemV Unix systems and perhaps others are subject to this problem.)

  If your operating environment is set up to display your current command in the title bar of your terminal window, the password remains visible as long as the command is running, even if the command has scrolled out of view in the window content area.

- **Use the `--password` or `-p` option on the command line with no password value specified.** In this case, the client program solicits the password interactively:

  ```shell
  shell> mysql -u francis -p db_name
  Enter password: ********
  ```

  The * characters indicate where you enter your password. The password is not displayed as you enter it.

  It is more secure to enter your password this way than to specify it on the command line because it is not visible to other users. However, this method of entering a password is suitable only for programs that you run interactively. If you want to invoke a client from a script that runs noninteractively, there is no opportunity to enter the password from the keyboard. On some systems, you may even find that the first line of your script is read and interpreted (incorrectly) as your password.

- **Store your password in an option file.** For example, on Unix, you can list your password in the `[client]` section of the `.my.cnf` file in your home directory:

  ```ini
  [client]
  password=Password
  ```

  To keep the password safe, the file should not be accessible to anyone but yourself. To ensure this, set the file access mode to 400 or 600. For example:
To name from the command line a specific option file containing the password, use the `--
defaults-file=file_name` option, where `file_name` is the full path name to the file. For example:

```
shell> mysql --defaults-file=/home/francis/mysql-opts
```

Using Option Files, discusses option files in more detail.

- Store your password in the `MYSQL_PWD` environment variable. See MySQL Environment Variables.

   This method of specifying your MySQL password must be considered extremely insecure and should not be used. Some versions of `ps` include an option to display the environment of running processes. On some systems, if you set `MYSQL_PWD`, your password is exposed to any other user who runs `ps`. Even on systems without such a version of `ps`, it is unwise to assume that there are no other methods by which users can examine process environments.

On Unix, the `mysql` client writes a record of executed statements to a history file (see mysql Client Logging). By default, this file is named `.mysql_history` and is created in your home directory. Passwords can be written as plain text in SQL statements such as `CREATE USER`, `GRANT`, and `SET PASSWORD`, so if you use these statements, they are logged in the history file. To keep this file safe, use a restrictive access mode, the same way as described earlier for the `.my.cnf` file.

If your command interpreter is configured to maintain a history, any file in which the commands are saved will contain MySQL passwords entered on the command line. For example, `bash` uses `~/.bash_history`. Any such file should have a restrictive access mode.

### 2.2.2 Administrator Guidelines for Password Security

Database administrators should use the following guidelines to keep passwords secure.

MySQL stores passwords for user accounts in the `mysql.user` system table. Access to this table should never be granted to any nonadministrative accounts.

Account passwords can be expired so that users must reset them. See Section 4.10, “Server Handling of Expired Passwords”.

The `validate_password` plugin can be used to enforce a policy on acceptable password. See Section 6.3, “The Password Validation Plugin”.

A user who has access to modify the plugin directory (the value of the `plugin_dir` system variable) or the `my.cnf` file that specifies the plugin directory location can replace plugins and modify the capabilities provided by plugins, including authentication plugins.

Files such as log files to which passwords might be written should be protected. See Section 2.2.3, “Passwords and Logging”.

### 2.2.3 Passwords and Logging

Passwords can be written as plain text in SQL statements such as `CREATE USER, GRANT, SET PASSWORD`, and statements that invoke the `PASSWORD()` function. If such statements are logged by the MySQL server as written, passwords in them become visible to anyone with access to the logs.

Statement logging avoids writing passwords as cleartext for the following statements:

```
CREATE USER ... IDENTIFIED BY ...
GRANT ... IDENTIFIED BY ...
SET PASSWORD ...
```
SLAVE START ...
CREATE SERVER ...
ALTER SERVER ...

Passwords in those statements are rewritten to not appear literally in statement text written to the general query log, slow query log, and binary log. Rewriting does not apply to other statements. In particular, `INSERT` or `UPDATE` statements for the `mysql.user` system table that refer to literal passwords are logged as is, so you should avoid such statements. (Direct modification of grant tables is discouraged, anyway.)

For the general query log, password rewriting can be suppressed by starting the server with the `--log-raw` option. For security reasons, this option is not recommended for production use. For diagnostic purposes, it may be useful to see the exact text of statements as received by the server.

Contents of the audit log file produced by the audit log plugin are not encrypted. For security reasons, this file should be written to a directory accessible only to the MySQL server and users with a legitimate reason to view the log. See Section 6.4.2, “MySQL Enterprise Audit Security Considerations”.

To guard log files against unwarranted exposure, locate them in a directory that restricts access to the server and the database administrator. If the server logs to tables in the `mysql` database, grant access to those tables only to the database administrator.

Replication slaves store the password for the replication master in the master info repository, which can be either a file or a table (see Replication Relay and Status Logs). Ensure that the repository can be accessed only by the database administrator. An alternative to storing the password in a file is to use the `START SLAVE` statement to specify credentials for connecting to the master.

Use a restricted access mode to protect database backups that include log tables or log files containing passwords.

### 2.2.4 Password Hashing in MySQL

> **Note**
>
> The information in this section applies only for accounts that use the `mysql_native_password` or `mysql_old_password` authentication plugins.

MySQL lists user accounts in the `user` table of the `mysql` database. Each MySQL account can be assigned a password, although the `user` table does not store the cleartext version of the password, but a hash value computed from it.

MySQL uses passwords in two phases of client/server communication:

- When a client attempts to connect to the server, there is an initial authentication step in which the client must present a password that has a hash value matching the hash value stored in the `user` table for the account the client wants to use.

- After the client connects, it can (if it has sufficient privileges) set or change the password hash for accounts listed in the `user` table. The client can do this by using the `PASSWORD()` function to generate a password hash, or by using a password-generating statement (`CREATE USER`, `GRANT`, or `SET PASSWORD`).

In other words, the server checks hash values during authentication when a client first attempts to connect. The server generates hash values if a connected client invokes the `PASSWORD()` function or uses a password-generating statement to set or change a password.

Password hashing methods in MySQL have the history described following. These changes are illustrated by changes in the result from the `PASSWORD()` function that computes password hash values and in the structure of the `user` table where passwords are stored.

#### The Original (Pre-4.1) Hashing Method

The original hashing method produced a 16-byte string. Such hashes look like this:
To store account passwords, the `Password` column of the `user` table was at this point 16 bytes long.

### The 4.1 Hashing Method

MySQL 4.1 introduced password hashing that provided better security and reduced the risk of passwords being intercepted. There were several aspects to this change:

- Different format of password values produced by the `PASSWORD()` function
- Widening of the `Password` column
- Control over the default hashing method
- Control over the permitted hashing methods for clients attempting to connect to the server

The changes in MySQL 4.1 took place in two stages:

- MySQL 4.1.0 used a preliminary version of the 4.1 hashing method. This method was short lived and the following discussion says nothing more about it.
- In MySQL 4.1.1, the hashing method was modified to produce a longer 41-byte hash value:

```
mysql> SELECT PASSWORD('mypass');
+-------------------+
| PASSWORD('mypass') |
| 6f8c14b58f2ce9e   |
+-------------------+
```

The longer password hash format has better cryptographic properties, and client authentication based on long hashes is more secure than that based on the older short hashes.

To accommodate longer password hashes, the `Password` column in the `user` table was changed at this point to be 41 bytes, its current length.

A widened `Password` column can store password hashes in both the pre-4.1 and 4.1 formats. The format of any given hash value can be determined two ways:

- The length: 4.1 and pre-4.1 hashes are 41 and 16 bytes, respectively.
- Password hashes in the 4.1 format always begin with a `*` character, whereas passwords in the pre-4.1 format never do.

To permit explicit generation of pre-4.1 password hashes, two additional changes were made:

- The `OLD_PASSWORD()` function was added, which returns hash values in the 16-byte format.
- For compatibility purposes, the `old_passwords` system variable was added, to enable DBAs and applications control over the hashing method. The default `old_passwords` value of 0 causes hashing to use the 4.1 method (41-byte hash values), but setting `old_passwords=1` causes hashing to use the pre-4.1 method. In this case, `PASSWORD()` produces 16-byte values and is equivalent to `OLD_PASSWORD()`.

To permit DBAs control over how clients are permitted to connect, the `secure_auth` system variable was added. Starting the server with this variable disabled or enabled permits or prohibits clients to connect using the older pre-4.1 password hashing method. Before MySQL 5.6.5,
secure_auth is disabled by default. As of 5.6.5, secure_auth is enabled by default to promote a more secure default configuration DBAs can disable it at their discretion, but this is not recommended, and pre-4.1 password hashes are deprecated and should be avoided. (For account upgrade instructions, see Section 6.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin”.)

In addition, the mysql client supports a --secure-auth option that is analogous to secure_auth, but from the client side. It can be used to prevent connections to less secure accounts that use pre-4.1 password hashing. This option is disabled by default before MySQL 5.6.7, enabled thereafter.

**Compatibility Issues Related to Hashing Methods**

The widening of the Password column in MySQL 4.1 from 16 bytes to 41 bytes affects installation or upgrade operations as follows:

- If you perform a new installation of MySQL, the Password column is made 41 bytes long automatically.
- Upgrades from MySQL 4.1 or later to current versions of MySQL should not give rise to any issues in regard to the Password column because both versions use the same column length and password hashing method.
- For upgrades from a pre-4.1 release to 4.1 or later, you must upgrade the system tables after upgrading. (See `mysql_upgrade — Check and Upgrade MySQL Tables`.)

The 4.1 hashing method is understood only by MySQL 4.1 (and higher) servers and clients, which can result in some compatibility problems. A 4.1 or higher client can connect to a pre-4.1 server, because the client understands both the pre-4.1 and 4.1 password hashing methods. However, a pre-4.1 client that attempts to connect to a 4.1 or higher server may run into difficulties. For example, a 4.0 mysql client may fail with the following error message:

```
shell> mysql -h localhost -u root
Client does not support authentication protocol requested by server; consider upgrading MySQL client
```

This phenomenon also occurs for attempts to use the older PHP mysql extension after upgrading to MySQL 4.1 or higher. (See Common Problems with MySQL and PHP.)

The following discussion describes the differences between the pre-4.1 and 4.1 hashing methods, and what you should do if you upgrade your server but need to maintain backward compatibility with pre-4.1 clients. (However, permitting connections by old clients is not recommended and should be avoided if possible.) Additional information can be found in Client does not support authentication protocol. This information is of particular importance to PHP programmers migrating MySQL databases from versions older than 4.1 to 4.1 or higher.

The differences between short and long password hashes are relevant both for how the server uses passwords during authentication and for how it generates password hashes for connected clients that perform password-changing operations.

The way in which the server uses password hashes during authentication is affected by the width of the Password column:

- If the column is short, only short-hash authentication is used.
- If the column is long, it can hold either short or long hashes, and the server can use either format:
  - Pre-4.1 clients can connect, but because they know only about the pre-4.1 hashing method, they can authenticate only using accounts that have short hashes.
  - 4.1 and later clients can authenticate using accounts that have short or long hashes.
Even for short-hash accounts, the authentication process is actually a bit more secure for 4.1 and later clients than for older clients. In terms of security, the gradient from least to most secure is:

- Pre-4.1 client authenticating with short password hash
- 4.1 or later client authenticating with short password hash
- 4.1 or later client authenticating with long password hash

The way in which the server generates password hashes for connected clients is affected by the width of the `Password` column and by the `old_passwords` system variable. A 4.1 or later server generates long hashes only if certain conditions are met: The `Password` column must be wide enough to hold long values and `old_passwords` must not be set to 1.

Those conditions apply as follows:

- The `Password` column must be wide enough to hold long hashes (41 bytes). If the column has not been updated and still has the pre-4.1 width of 16 bytes, the server notices that long hashes cannot fit into it and generates only short hashes when a client performs password-changing operations using the `PASSWORD()` function or a password-generating statement. This is the behavior that occurs if you have upgraded from a version of MySQL older than 4.1 to 4.1 or later but have not yet run the `mysql_upgrade` program to widen the `Password` column.

- If the `Password` column is wide, it can store either short or long password hashes. In this case, the `PASSWORD()` function and password-generating statements generate long hashes unless the server was started with the `old_passwords` system variable set to 1 to force the server to generate short password hashes instead.

The purpose of the `old_passwords` system variable is to permit backward compatibility with pre-4.1 clients under circumstances where the server would otherwise generate long password hashes. The option does not affect authentication (4.1 and later clients can still use accounts that have long password hashes), but it does prevent creation of a long password hash in the `user` table as the result of a password-changing operation. Were that permitted to occur, the account could no longer be used by pre-4.1 clients. With `old_passwords` disabled, the following undesirable scenario is possible:

- An old pre-4.1 client connects to an account that has a short password hash.
- The client changes its own password. With `old_passwords` disabled, this results in the account having a long password hash.
- The next time the old client attempts to connect to the account, it cannot, because the account has a long password hash that requires the 4.1 hashing method during authentication. (Once an account has a long password hash in the user table, only 4.1 and later clients can authenticate for it because pre-4.1 clients do not understand long hashes.)

This scenario illustrates that, if you must support older pre-4.1 clients, it is problematic to run a 4.1 or higher server without `old_passwords` set to 1. By running the server with `old_passwords=1`, password-changing operations do not generate long password hashes and thus do not cause accounts to become inaccessible to older clients. (Those clients cannot inadvertently lock themselves out by changing their password and ending up with a long password hash.)

The downside of `old_passwords=1` is that any passwords created or changed use short hashes, even for 4.1 or later clients. Thus, you lose the additional security provided by long password hashes.

To create an account that has a long hash (for example, for use by 4.1 clients) or to change an existing account to use a long password hash, an administrator can set the session value of `old_passwords` set to 0 while leaving the global value set to 1:

```
mysql> SET @@SESSION.old_passwords = 0;
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT @@SESSION.old_passwords, @@GLOBAL.old_passwords;
+-------------------------+------------------------+
<table>
<thead>
<tr>
<th>@@SESSION.old_passwords</th>
<th>@@GLOBAL.old_passwords</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>
```
The following scenarios are possible in MySQL 4.1 or later. The factors are whether the `Password` column is short or long, and, if long, whether the server is started with `old_passwords` enabled or disabled.

**Scenario 1:** Short `Password` column in user table:

- Only short hashes can be stored in the `Password` column.
- The server uses only short hashes during client authentication.
- For connected clients, password hash-generating operations involving the `PASSWORD()` function or password-generating statements use short hashes exclusively. Any change to an account's password results in that account having a short password hash.
- The value of `old_passwords` is irrelevant because with a short `Password` column, the server generates only short password hashes anyway.

This scenario occurs when a pre-4.1 MySQL installation has been upgraded to 4.1 or later but `mysql_upgrade` has not been run to upgrade the system tables in the `mysql` database. (This is not a recommended configuration because it does not permit use of more secure 4.1 password hashing.)

**Scenario 2:** Long `Password` column; server started with `old_passwords=1`:

- Short or long hashes can be stored in the `Password` column.
- 4.1 and later clients can authenticate for accounts that have short or long hashes.
- Pre-4.1 clients can authenticate only for accounts that have short hashes.
- For connected clients, password hash-generating operations involving the `PASSWORD()` function or password-generating statements use short hashes exclusively. Any change to an account's password results in that account having a short password hash.

In this scenario, newly created accounts have short password hashes because `old_passwords=1` prevents generation of long hashes. Also, if you create an account with a long hash before setting `old_passwords` to 1, changing the account's password while `old_passwords=1` results in the account being given a short password, causing it to lose the security benefits of a longer hash.

To create a new account that has a long password hash, or to change the password of any existing account to use a long hash, first set the session value of `old_passwords` set to 0 while leaving the global value set to 1, as described previously.

In this scenario, the server has an up to date `Password` column, but is running with the default password hashing method set to generate pre-4.1 hash values. This is not a recommended configuration but may be useful during a transitional period in which pre-4.1 clients and passwords are upgraded to 4.1 or later. When that has been done, it is preferable to run the server with `old_passwords=0` and `secure_auth=1`.

**Scenario 3:** Long `Password` column; server started with `old_passwords=0`:

- Short or long hashes can be stored in the `Password` column.
- 4.1 and later clients can authenticate using accounts that have short or long hashes.
• Pre-4.1 clients can authenticate only using accounts that have short hashes.

• For connected clients, password hash-generating operations involving the `PASSWORD()` function or password-generating statements use long hashes exclusively. A change to an account's password results in that account having a long password hash.

As indicated earlier, a danger in this scenario is that it is possible for accounts that have a short password hash to become inaccessible to pre-4.1 clients. A change to such an account's password made using the `PASSWORD()` function or a password-generating statement results in the account being given a long password hash. From that point on, no pre-4.1 client can connect to the server using that account. The client must upgrade to 4.1 or later.

If this is a problem, you can change a password in a special way. For example, normally you use `SET PASSWORD` as follows to change an account password:

```
SET PASSWORD FOR 'some_user'@'some_host' = PASSWORD('password');
```

To change the password but create a short hash, use the `OLD_PASSWORD()` function instead:

```
SET PASSWORD FOR 'some_user'@'some_host' = OLD_PASSWORD('password');
```

`OLD_PASSWORD()` is useful for situations in which you explicitly want to generate a short hash.

The disadvantages for each of the preceding scenarios may be summarized as follows:

In scenario 1, you cannot take advantage of longer hashes that provide more secure authentication.

In scenario 2, `old_passwords=1` prevents accounts with short hashes from becoming inaccessible, but password-changing operations cause accounts with long hashes to revert to short hashes unless you take care to change the session value of `old_passwords` to 0 first.

In scenario 3, accounts with short hashes become inaccessible to pre-4.1 clients if you change their passwords without explicitly using `OLD_PASSWORD()`.

The best way to avoid compatibility problems related to short password hashes is to not use them:

• Upgrade all client programs to MySQL 4.1 or later.

• Run the server with `old_passwords=0`.

• Reset the password for any account with a short password hash to use a long password hash.

• For additional security, run the server with `secure_auth=1`.

2.2.5 Implications of Password Hashing Changes in MySQL 4.1 for Application Programs

An upgrade to MySQL version 4.1 or later can cause compatibility issues for applications that use `PASSWORD()` to generate passwords for their own purposes. Applications really should not do this, because `PASSWORD()` should be used only to manage passwords for MySQL accounts. But some applications use `PASSWORD()` for their own purposes anyway.

If you upgrade to 4.1 or later from a pre-4.1 version of MySQL and run the server under conditions where it generates long password hashes, an application using `PASSWORD()` for its own passwords breaks. The recommended course of action in such cases is to modify the application to use another function, such as `SHA2()`, `SHA1()`, or `MD5()`, to produce hashed values. If that is not possible, you can use the `OLD_PASSWORD()` function, which is provided for generate short hashes in the old format. However, you should note that `OLD_PASSWORD()` may one day no longer be supported.

If the server is running with `old_passwords=1`, it generates short hashes and `OLD_PASSWORD()` is equivalent to `PASSWORD()`.
2.3 Making MySQL Secure Against Attackers

When you connect to a MySQL server, you should use a password. The password is not transmitted as cleartext over the connection. Password handling during the client connection sequence was upgraded in MySQL 4.1.1 to be very secure. If you are still using pre-4.1.1-style passwords, the encryption algorithm is not as strong as the newer algorithm. With some effort, a clever attacker who can sniff the traffic between the client and the server can crack the password. (See Section 2.2.4, “Password Hashing in MySQL”, for a discussion of the different password handling methods.)

All other information is transferred as text, and can be read by anyone who is able to watch the connection. If the connection between the client and the server goes through an untrusted network, and you are concerned about this, you can use the compressed protocol to make traffic much more difficult to decipher. You can also use MySQL's internal SSL support to make the connection even more secure. See Chapter 5, Using Encrypted Connections. Alternatively, use SSH to get an encrypted TCP/IP connection between a MySQL server and a MySQL client. You can find an Open Source SSH client at http://www.openssh.org/, and a comparison of both Open Source and Commercial SSH clients at http://en.wikipedia.org/wiki/Comparison_of_SSH_clients.

To make a MySQL system secure, you should strongly consider the following suggestions:

• Require all MySQL accounts to have a password. A client program does not necessarily know the identity of the person running it. It is common for client/server applications that the user can specify any user name to the client program. For example, anyone can use the mysql program to connect as any other person simply by invoking it as mysql -u other_user db_name if other_user has no password. If all accounts have a password, connecting using another user's account becomes much more difficult.

For a discussion of methods for setting passwords, see Section 4.9, “Assigning Account Passwords”.

• Make sure that the only Unix user account with read or write privileges in the database directories is the account that is used for running mysqld.

• Never run the MySQL server as the Unix root user. This is extremely dangerous, because any user with the FILE privilege is able to cause the server to create files as root (for example, ~root/.bashrc). To prevent this, mysqld refuses to run as root unless that is specified explicitly using the --user=root option.

mysqld can (and should) be run as an ordinary, unprivileged user instead. You can create a separate Unix account named mysql to make everything even more secure. Use this account only for administering MySQL. To start mysqld as a different Unix user, add a user option that specifies the user name in the [mysqld] group of the my.cnf option file where you specify server options. For example:

```
[mysqld]
user=mysql
```

This causes the server to start as the designated user whether you start it manually or by using mysqld_safe or mysql.server. For more details, see Section 2.5, “How to Run MySQL as a Normal User”.

Running mysqld as a Unix user other than root does not mean that you need to change the root user name in the user table. User names for MySQL accounts have nothing to do with user names for Unix accounts.

• Do not grant the FILE privilege to nonadministrative users. Any user that has this privilege can write a file anywhere in the file system with the privileges of the mysqld daemon. This includes the server's data directory containing the files that implement the privilege tables. To make FILE-
privilege operations a bit safer, files generated with `SELECT ... INTO OUTFILE` do not overwrite existing files and are writable by everyone.

The `FILE` privilege may also be used to read any file that is world-readable or accessible to the Unix user that the server runs as. With this privilege, you can read any file into a database table. This could be abused, for example, by using `LOAD DATA` to load `/etc/passwd` into a table, which then can be displayed with `SELECT`.

To limit the location in which files can be read and written, set the `secure_file_priv` system to a specific directory. See Server System Variables.

- Do not grant the `PROCESS` or `SUPER` privilege to nonadministrative users. The output of `mysqladmin processlist` and `SHOW PROCESSLIST` shows the text of any statements currently being executed, so any user who is permitted to see the server process list might be able to see statements issued by other users such as `UPDATE user SET password=PASSWORD('not_secure')`.

mysql reserves an extra connection for users who have the `SUPER` privilege, so that a MySQL `root` user can log in and check server activity even if all normal connections are in use.

The `SUPER` privilege can be used to terminate client connections, change server operation by changing the value of system variables, and control replication servers.

- Do not permit the use of symlinks to tables. (This capability can be disabled with the `--skip-symbolic-links` option.) This is especially important if you run `mysql` as `root`, because anyone that has write access to the server’s data directory then could delete any file in the system! See Using Symbolic Links for MyISAM Tables on Unix.

- Stored programs and views should be written using the security guidelines discussed in Stored Object Access Control.

- If you do not trust your DNS, you should use IP addresses rather than host names in the grant tables. In any case, you should be very careful about creating grant table entries using host name values that contain wildcards.

- If you want to restrict the number of connections permitted to a single account, you can do so by setting the `max_user_connections` variable in `mysqld`. The `GRANT` statement also supports resource control options for limiting the extent of server use permitted to an account. See GRANT Syntax.

- If the plugin directory is writable by the server, it may be possible for a user to write executable code to a file in the directory using `SELECT ... INTO DUMPFILE`. This can be prevented by making `plugin_dir` read only to the server or by setting `secure_file_priv` to a directory where `SELECT` writes can be made safely.

### 2.4 Security-Related mysqld Options and Variables

The following table shows `mysqld` options and system variables that affect security. For descriptions of each of these, see Server Command Options, and Server System Variables.

#### Table 2.1 Security Option and Variable Summary

2.5 How to Run MySQL as a Normal User

On Windows, you can run the server as a Windows service using a normal user account.

On Linux, for installations performed using a MySQL repository, RPM packages, or Debian packages, the MySQL server `mysqld` should be started by the local `mysql` operating system user. Starting by another operating system user is not supported by the init scripts that are included as part of the installation.

On Unix (or Linux for installations performed using `tar` or `tar.gz` packages), the MySQL server `mysqld` can be started and run by any user. However, you should avoid running the server as the Unix `root` user for security reasons. To change `mysqld` to run as a normal unprivileged Unix user `user_name`, you must do the following:

1. Stop the server if it is running (use `mysqladmin shutdown`).

2. Change the database directories and files so that `user_name` has privileges to read and write files in them (you might need to do this as the Unix `root` user):

   ```shell
   chown -R user_name /path/to/mysql/datadir
   ```

   If you do not do this, the server will not be able to access databases or tables when it runs as `user_name`.

   If directories or files within the MySQL data directory are symbolic links, `chown -R` might not follow symbolic links for you. If it does not, you will also need to follow those links and change the directories and files they point to.

3. Start the server as user `user_name`. Another alternative is to start `mysqld` as the Unix `root` user and use the `--user=user_name` option. `mysqld` starts, then switches to run as the Unix user `user_name` before accepting any connections.

4. To start the server as the given user automatically at system startup time, specify the user name by adding a `user` option to the `[mysqld]` group of the `/etc/my.cnf` option file or the `my.cnf` option file in the server's data directory. For example:
If your Unix machine itself is not secured, you should assign passwords to the MySQL root accounts in the grant tables. Otherwise, any user with a login account on that machine can run the mysql client with a \(--\text{user}=-\text{root}\) option and perform any operation. (It is a good idea to assign passwords to MySQL accounts in any case, but especially so when other login accounts exist on the server host.) See Section 3.4, “Securing the Initial MySQL Accounts”.

### 2.6 Security Issues with LOAD DATA LOCAL

The `LOAD DATA` statement can load a file located on the server host, or, if the `LOCAL` keyword is specified, on the client host.

There are two potential security issues with the `LOCAL` version of `LOAD DATA`:

- The transfer of the file from the client host to the server host is initiated by the MySQL server. In theory, a patched server could be built that would tell the client program to transfer a file of the server’s choosing rather than the file named by the client in the `LOAD DATA` statement. Such a server could access any file on the client host to which the client user has read access. (A patched server could in fact reply with a file-transfer request to any statement, not just `LOAD DATA LOCAL`, so a more fundamental issue is that clients should not connect to untrusted servers.)

- In a Web environment where the clients are connecting from a Web server, a user could use `LOAD DATA LOCAL` to read any files that the Web server process has read access to (assuming that a user could run any statement against the SQL server). In this environment, the client with respect to the MySQL server actually is the Web server, not a remote program being run by users who connect to the Web server.

To avoid `LOAD DATA` issues, clients should avoid using `LOCAL`. To avoid connecting to untrusted servers, clients can establish a secure connection and verify the server identity by connecting using the `--ssl-verify-server-cert` option and the appropriate CA certificate.

To enable administrators and applications to manage the local data loading capability, `LOCAL` configuration works like this:

- **On the server side:**
  - The `local_infile` system variable controls server-side `LOCAL` capability. Depending on the `local_infile` setting, the server refuses or permits local data loading by clients that have `LOCAL` enabled on the client side. By default, `local_infile` is enabled.
  - To explicitly cause the server to refuse or permit `LOAD DATA LOCAL` statements (regardless of how client programs and libraries are configured at build time or runtime), start `mysqld` with `local_infile` disabled or enabled, respectively. `local_infile` can also be set at runtime.

- **On the client side:**
  - The `ENABLED_LOCAL_INFILE` CMake option controls the compiled-in default `LOCAL` capability for the MySQL client library. Clients that make no explicit arrangements therefore have `LOCAL` capability disabled or enabled according to the `ENABLED_LOCAL_INFILE` setting specified at MySQL build time.

    By default, the client library in MySQL binary distributions is compiled with `ENABLED_LOCAL_INFILE` enabled. If you compile MySQL from source, configure it with `ENABLED_LOCAL_INFILE` disabled or enabled based on whether clients that make no explicit arrangements should have `LOCAL` capability disabled or enabled, respectively.

  - Client programs that use the C API can control load data loading explicitly by invoking `mysql_options()` to disable or enable the `MYSQL_OPT_LOCAL_INFILE` option. See `mysql_options()`.
• For the `mysql` client, local data loading is disabled by default. To disable or enable it explicitly, use the `--local-infile=0` or `--local-infile=1` option.

• For the `mysqlimport` client, local data loading is disabled by default. To disable or enable it explicitly, use the `--local=0` or `--local=1` option.

• If you use `LOAD DATA LOCAL` in Perl scripts or other programs that read the `{client}` group from option files, you can add an `local-infile` option setting to that group. To prevent problems for programs that do not understand this option, specify it using the `loose-` prefix:

```
[client]
loose-local-infile=0
```

or:

```
[client]
loose-local-infile=1
```

• In all cases, successful use of a `LOCAL` load operation by a client also requires that the server permits it.

If `LOCAL` capability is disabled, on either the server or client side, a client that attempts to issue a `LOAD DATA LOCAL` statement receives the following error message:

```
ERROR 1148: The used command is not allowed with this MySQL version
```

### 2.7 Client Programming Security Guidelines

Applications that access MySQL should not trust any data entered by users, who can try to trick your code by entering special or escaped character sequences in Web forms, URLs, or whatever application you have built. Be sure that your application remains secure if a user enters something like `; DROP DATABASE mysql;`. This is an extreme example, but large security leaks and data loss might occur as a result of hackers using similar techniques, if you do not prepare for them.

A common mistake is to protect only string data values. Remember to check numeric data as well. If an application generates a query such as `SELECT * FROM table WHERE ID=234` when a user enters the value `234`, the user can enter the value `234 OR 1=1` to cause the application to generate the query `SELECT * FROM table WHERE ID=234 OR 1=1`. As a result, the server retrieves every row in the table. This exposes every row and causes excessive server load. The simplest way to protect from this type of attack is to use single quotation marks around the numeric constants: `SELECT * FROM table WHERE ID='234'`. If the user enters extra information, it all becomes part of the string. In a numeric context, MySQL automatically converts this string to a number and strips any trailing nonnumeric characters from it.

Sometimes people think that if a database contains only publicly available data, it need not be protected. This is incorrect. Even if it is permissible to display any row in the database, you should still protect against denial of service attacks (for example, those that are based on the technique in the preceding paragraph that causes the server to waste resources). Otherwise, your server becomes unresponsive to legitimate users.

**Checklist:**

• Enable strict SQL mode to tell the server to be more restrictive of what data values it accepts. See [Server SQL Modes](#).

• Try to enter single and double quotation marks (`'` and `"`) in all of your Web forms. If you get any kind of MySQL error, investigate the problem right away.
• Try to modify dynamic URLs by adding %22 ("), %23 (#), and %27 (') to them.

• Try to modify data types in dynamic URLs from numeric to character types using the characters shown in the previous examples. Your application should be safe against these and similar attacks.

• Try to enter characters, spaces, and special symbols rather than numbers in numeric fields. Your application should remove them before passing them to MySQL or else generate an error. Passing unchecked values to MySQL is very dangerous!

• Check the size of data before passing it to MySQL.

• Have your application connect to the database using a user name different from the one you use for administrative purposes. Do not give your applications any access privileges they do not need.

Many application programming interfaces provide a means of escaping special characters in data values. Properly used, this prevents application users from entering values that cause the application to generate statements that have a different effect than you intend:

• MySQL C API: Use the mysql_real_escape_string() API call.

• MySQL++: Use the escape and quote modifiers for query streams.

• PHP: Use either the mysqli or pdo_mysql extensions, and not the older ext/mysql extension. The preferred API's support the improved MySQL authentication protocol and passwords, as well as prepared statements with placeholders. See also Choosing an API.

  If the older ext/mysql extension must be used, then for escaping use the mysql_real_escape_string() function and not mysql_escape_string() or addslashes() because only mysql_real_escape_string() is character set-aware; the other functions can be “bypassed” when using (invalid) multibyte character sets.

• Perl DBI: Use placeholders or the quote() method.

• Ruby DBI: Use placeholders or the quote() method.

• Java JDBC: Use a PreparedStatement object and placeholders.

Other programming interfaces might have similar capabilities.

3.4 Securing the Initial MySQL Accounts .................................................. 27
3.5 Starting and Stopping MySQL Automatically ....................................... 31

This section discusses tasks that you should perform after installing MySQL:

• If necessary, initialize the data directory and create the MySQL grant tables. For some MySQL
  installation methods, data directory initialization may be done for you automatically:

  • Installation on Windows
  • Installation on Linux using a server RPM or Debian distribution from Oracle.
  • Installation using the native packaging system on many platforms, including Debian Linux, Ubuntu
    Linux, Gentoo Linux, and others.
  • Installation on OS X using a DMG distribution.

For other platforms and installation types, you must initialize the data directory manually. These
include installation from generic binary and source distributions on Unix and Unix-like system, and
installation from a ZIP Archive package on Windows. For instructions, see Section 3.1, “Initializing
the Data Directory”.

• For instructions, see Section 3.2, “Starting the Server”, and Section 3.3, “Testing the Server”.

• Assign passwords to any initial accounts in the grant tables, if that was not already done during
data directory initialization. Passwords prevent unauthorized access to the MySQL server. You may
also wish to restrict access to test databases. For instructions, see Section 3.4, “Securing the Initial
MySQL Accounts”.

• Optionally, arrange for the server to start and stop automatically when your system starts and stops.
For instructions, see Section 3.5, “Starting and Stopping MySQL Automatically”.

• Optionally, populate time zone tables to enable recognition of named time zones. For instructions,
see MySQL Server Time Zone Support.

When you are ready to create additional user accounts, you can find information on the MySQL access
control system and account management in Chapter 4, Access Control and Account Management.

3.1 Initializing the Data Directory

After MySQL is installed, the data directory must be initialized, including the tables in the mysql
system database:

• For some MySQL installation methods, data directory initialization is automatic, as described in
Chapter 3, Postinstallation Setup and Testing.

• For other installation methods, you must initialize the data directory manually. These include
installation from generic binary and source distributions on Unix and Unix-like systems, and
installation from a ZIP Archive package on Windows.
This section describes how to initialize the data directory manually for MySQL installation methods for which data directory initialization is not automatic. For some suggested commands that enable testing whether the server is accessible and working properly, see Section 3.3, “Testing the Server”.

In the examples shown here, the server is intended to run under the user ID of the mysql login account. This assumes that such an account exists. Either create the account if it does not exist (see Create a mysql User and Group), or substitute the name of a different existing login account that you plan to use for running the server.

1. Change location to the top-level directory of your MySQL installation, which is typically /usr/local/mysql (adjust the path name for your system as necessary):

   ```bash
cd /usr/local/mysql
   ```

   You will find several files and subdirectories inside the directory, including the bin and scripts subdirectories, which contain the server as well as client and utility programs.

2. Initialize the data directory, including the mysql database containing the initial MySQL grant tables that determine how users are permitted to connect to the server. For example:

   ```bash
   scripts/mysql_install_db --user=mysql
   ```

   Typically, data directory initialization need be done only after you first install MySQL. (For upgrades to an existing installation, perform the upgrade procedure instead; see Upgrading MySQL.) However, the command that initializes the data directory does not overwrite any existing privilege tables, so it is safe to run in any circumstances.

   It is important to make sure that the database directories and files are owned by the mysql login account so that the server has read and write access to them when you run it later. To ensure this if you run `mysql_install_db` as root, include the --user option as shown.

   The `mysql_install_db` command initializes the server's data directory. Under the data directory, it creates directories for the mysql database that holds the grant tables and the test database that you can use to test MySQL. The program also creates privilege table entries for the initial account or accounts. test_. For a complete listing and description of the grant tables, see Chapter 4, Access Control and Account Management.

   It might be necessary to specify other options such as --basedir or --datadir if `mysql_install_db` cannot identify the correct locations for the installation directory or data directory. For example (enter the command on a single line):

   ```bash
   scripts/mysql_install_db --user=mysql
   --basedir=/opt/mysql/mysql
   --datadir=/opt/mysql/mysql/data
   ```

   For a more secure installation, invoke `mysql_install_db` with the --random-passwords option. This causes it to assign a random password to the MySQL root accounts, set the “password expired” flag for those accounts, and remove the anonymous-user MySQL accounts. For additional details, see `mysql_install_db — Initialize MySQL Data Directory`. (Install operations using RPMs for Unbreakable Linux Network are unaffected because they do not use `mysql_install_db`.)

   If you do not want to have the test database, you can remove it after starting the server, using the instructions in Section 3.4, “Securing the Initial MySQL Accounts”.

   If you have trouble with `mysql_install_db` at this point, see Section 3.1.1, “Problems Running `mysql_install_db`”.

   ```
3. In the absence of any option files, the server starts with its default settings. (See Server Configuration Defaults.) To specify options that the MySQL server should use at startup, put them in an option file such as /etc/my.cnf or /etc/mysql/my.cnf. (See Using Option Files.) For example, you can use an option file to set the secure_file_priv system variable.

4. To arrange for MySQL to start without manual intervention at system boot time, see Section 3.5, “Starting and Stopping MySQL Automatically”.

5. Data directory initialization creates time zone tables in the mysql database but does not populate them. To do so, use the instructions in MySQL Server Time Zone Support.

### 3.1.1 Problems Running mysql_install_db

The purpose of the mysql_install_db program is to initialize the data directory, including the tables in the mysql system database. It does not overwrite existing MySQL privilege tables, and it does not affect any other data.

To re-create your privilege tables, first stop the mysqld server if it is running. Then rename the mysql directory under the data directory to save it, and run mysql_install_db. Suppose that your current directory is the MySQL installation directory and that mysql_install_db is located in the bin directory and the data directory is named data. To rename the mysql database and re-run mysql_install_db, use these commands.

```bash
mv data/mysql data/mysql.old
scripts/mysql_install_db --user=mysql
```

When you run mysql_install_db, you might encounter the following problems:

- **mysql_install_db fails to install the grant tables**
  
  You may find that mysql_install_db fails to install the grant tables and terminates after displaying the following messages:

  ```
  Starting mysqld daemon with databases from XXXXXX
  mysqld ended
  ```

  In this case, you should examine the error log file very carefully. The log should be located in the directory XXXXXX named by the error message and should indicate why mysqld did not start. If you do not understand what happened, include the log when you post a bug report. See How to Report Bugs or Problems.

- **There is a mysqld process running**
  
  This indicates that the server is running, in which case the grant tables have probably been created already. If so, there is no need to run mysql_install_db at all because it needs to be run only once, when you first install MySQL.

- **Installing a second mysqld server does not work when one server is running**
  
  This can happen when you have an existing MySQL installation, but want to put a new installation in a different location. For example, you might have a production installation, but you want to create a second installation for testing purposes. Generally the problem that occurs when you try to run a second server is that it tries to use a network interface that is in use by the first server. In this case, you should see one of the following error messages:

  ```
  Can't start server: Bind on TCP/IP port: Address already in use
  Can't start server: Bind on unix socket...
  ```

  For instructions on setting up multiple servers, see Running Multiple MySQL Instances on One Machine.
• **You do not have write access to the `/tmp` directory**

If you do not have write access to create temporary files or a Unix socket file in the default location (the `/tmp` directory) or the `TMPDIR` environment variable, if it has been set, an error occurs when you run `mysql_install_db` or the `mysqld` server.

You can specify different locations for the temporary directory and Unix socket file by executing these commands prior to starting `mysql_install_db` or `mysqld`, where `some_tmp_dir` is the full path name to some directory for which you have write permission:

```
TMPDIR=/some_tmp_dir/
MYSQL_UNIX_PORT=/some_tmp_dir/mysql.sock
export TMPDIR MYSQL_UNIX_PORT
```

Then you should be able to run `mysql_install_db` and start the server with these commands:

```
scripts/mysql_install_db --user=mysql
bin/mysqld_safe --user=mysql &
```

If `mysql_install_db` is located in the `scripts` directory, modify the first command to `scripts/mysql_install_db`.

See [How to Protect or Change the MySQL Unix Socket File](#) and [MySQL Environment Variables](#).

There are some alternatives to running the `mysql_install_db` program provided in the MySQL distribution:

• If you want the initial privileges to differ from the standard defaults, use account-management statements such as `CREATE USER`, `GRANT`, and `REVOKE` to change the privileges after the grant tables have been set up. In other words, run `mysql_install_db`, and then use `mysql -u root mysql` to connect to the server as the MySQL root user so that you can issue the necessary statements. (See [Account Management Statements](#).)

   To install MySQL on several machines with the same privileges, put the `CREATE USER`, `GRANT`, and `REVOKE` statements in a file and execute the file as a script using `mysql` after running `mysql_install_db`. For example:

   ```
   scripts/mysql_install_db --user=mysql
   bin/mysql -u root < your_script_file
   ```

   This enables you to avoid issuing the statements manually on each machine.

• It is possible to re-create the grant tables completely after they have previously been created. You might want to do this if you are just learning how to use `CREATE USER`, `GRANT`, and `REVOKE` and have made so many modifications after running `mysql_install_db` that you want to wipe out the tables and start over.

   To re-create the grant tables, stop the server if it is running and remove the `mysql` database directory. Then run `mysql_install_db` again.

### 3.2 Starting the Server

This section describes how start the server on Unix and Unix-like systems. (For Windows, see [Starting the Server for the First Time](#).) For some suggested commands that you can use to test whether the server is accessible and working properly, see [Section 3.3, “Testing the Server”](#).

Start the MySQL server like this:

```
shell> bin/mysqld_safe --user=mysql &
```
It is important that the MySQL server be run using an unprivileged (non-root) login account. To ensure this if you run `mysqld_safe` as `root`, include the `--user` option as shown. Otherwise, execute the program while logged in as `mysql`, in which case you can omit the `--user` option from the command.

For further instructions for running MySQL as an unprivileged user, see Section 2.5, “How to Run MySQL as a Normal User”.

If the command fails immediately and prints `mysqld ended`, look for information in the error log (which by default is the `host_name.err` file in the data directory).

If the server is unable to access the data directory it starts or read the grant tables in the `mysql` database, it writes a message to its error log. Such problems can occur if you neglected to create the grant tables by initializing the data directory before proceeding to this step, or if you ran the command that initializes the data directory without the `--user` option. Remove the `data` directory and run the command with the `--user` option.

If you have other problems starting the server, see Section 3.2.1, “Troubleshooting Problems Starting the MySQL Server”. For more information about `mysqld_safe`, see `mysqld_safe — MySQL Server Startup Script`.

### 3.2.1 Troubleshooting Problems Starting the MySQL Server

This section provides troubleshooting suggestions for problems starting the server. For additional suggestions for Windows systems, see Troubleshooting a Microsoft Windows MySQL Server Installation.

If you have problems starting the server, here are some things to try:

- Check the [error log](https://dev.mysql.com/doc/refman/5.6/en/error-log-files.html) to see why the server does not start. Log files are located in the data directory (typically `C:\Program Files\MySQL\MySQL Server 5.6\data` on Windows, `/usr/local/mysql/data` for a Unix/Linux binary distribution, and `/usr/local/var` for a Unix/Linux source distribution). Look in the data directory for files with names of the form `host_name.err` and `host_name.log`, where `host_name` is the name of your server host. Then examine the last few lines of these files. Use `tail` to display them:

  ```bash
  shell> tail host_name.err
  shell> tail host_name.log
  ```

- Specify any special options needed by the storage engines you are using. You can create a `my.cnf` file and specify startup options for the engines that you plan to use. If you are going to use storage engines that support transactional tables (InnoDB, NDB), be sure that you have them configured the way you want before starting the server. If you are using InnoDB tables, see InnoDB Configuration for guidelines and InnoDB Startup Options and System Variables for option syntax.

  Although storage engines use default values for options that you omit, Oracle recommends that you review the available options and specify explicit values for any options whose defaults are not appropriate for your installation.

- Make sure that the server knows where to find the [data directory](https://dev.mysql.com/doc/refman/5.6/en/innodb-data-dir.html). The `mysqld` server uses this directory as its current directory. This is where it expects to find databases and where it expects to write log files. The server also writes the pid (process ID) file in the data directory.

  The default data directory location is hardcoded when the server is compiled. To determine what the default path settings are, invoke `mysqld` with the `--verbose` and `--help` options. If the data directory is located somewhere else on your system, specify that location with the `--datadir` option to `mysqld` or `mysqld_safe`, on the command line or in an option file. Otherwise, the server will not work properly. As an alternative to the `--datadir` option, you can specify `mysqld` the location of the base directory under which MySQL is installed with the `--basedir`, and `mysqld` looks for the data directory there.
Troubleshooting Problems Starting the MySQL Server

To check the effect of specifying path options, invoke `mysqld` with those options followed by the `--verbose` and `--help` options. For example, if you change location to the directory where `mysqld` is installed and then run the following command, it shows the effect of starting the server with a base directory of `/usr/local`:

```
shell> ./mysqld --basedir=/usr/local --verbose --help
```

You can specify other options such as `--datadir` as well, but `--verbose` and `--help` must be the last options. Once you determine the path settings you want, start the server without `--verbose` and `--help`.

If `mysqld` is currently running, you can find out what path settings it is using by executing this command:

```
shell> mysqladmin variables
```

Or:

```
shell> mysqladmin -h host_name variables
```

`host_name` is the name of the MySQL server host.

- Make sure that the server can access the data directory. The ownership and permissions of the data directory and its contents must allow the server to read and modify them.

If you get `Errcode` 13 (which means `Permission denied`) when starting `mysqld`, this means that the privileges of the data directory or its contents do not permit server access. In this case, you change the permissions for the involved files and directories so that the server has the right to use them. You can also start the server as `root`, but this raises security issues and should be avoided.

Change location to the data directory and check the ownership of the data directory and its contents to make sure the server has access. For example, if the data directory is `/usr/local/mysql/var`, use this command:

```
shell> ls -la /usr/local/mysql/var
```

If the data directory or its files or subdirectories are not owned by the login account that you use for running the server, change their ownership to that account. If the account is named `mysql`, use these commands:

```
shell> chown -R mysql /usr/local/mysql/var
shell> chgrp -R mysql /usr/local/mysql/var
```

Even with correct ownership, MySQL might fail to start up if there is other security software running on your system that manages application access to various parts of the file system. In this case, reconfigure that software to enable `mysqld` to access the directories it uses during normal operation.

- Verify that the network interfaces the server wants to use are available.

If either of the following errors occur, it means that some other program (perhaps another `mysqld` server) is using the TCP/IP port or Unix socket file that `mysqld` is trying to use:

```
Can't start server: Bind on TCP/IP port: Address already in use
Can't start server: Bind on unix socket...
```

24
Use `ps` to determine whether you have another `mysqld` server running. If so, shut down the server before starting `mysqld` again. (If another server is running, and you really want to run multiple servers, you can find information about how to do so in Running Multiple MySQL Instances on One Machine.)

If no other server is running, execute the command `telnet your_host_name tcp_ip_port_number`. (The default MySQL port number is 3306.) Then press Enter a couple of times. If you do not get an error message like `telnet: Unable to connect to remote host: Connection refused`, some other program is using the TCP/IP port that `mysqld` is trying to use. Track down what program this is and disable it, or tell `mysqld` to listen to a different port with the `--port` option. In this case, specify the same non-default port number for client programs when connecting to the server using TCP/IP.

Another reason the port might be inaccessible is that you have a firewall running that blocks connections to it. If so, modify the firewall settings to permit access to the port.

If the server starts but you cannot connect to it, make sure that you have an entry in `/etc/hosts` that looks like this:

```
127.0.0.1 localhost
```

- If you cannot get `mysqld` to start, try to make a trace file to find the problem by using the `--debug` option. See The DBUG Package.

### 3.3 Testing the Server

After the data directory is initialized and you have started the server, perform some simple tests to make sure that it works satisfactorily. This section assumes that your current location is the MySQL installation directory and that it has a `bin` subdirectory containing the MySQL programs used here. If that is not true, adjust the command path names accordingly.

Alternatively, add the `bin` directory to your `PATH` environment variable setting. That enables your shell (command interpreter) to find MySQL programs properly, so that you can run a program by typing only its name, not its path name. See Setting Environment Variables.

Use `mysqladmin` to verify that the server is running. The following commands provide simple tests to check whether the server is up and responding to connections:

```
shell> bin/mysqladmin version
shell> bin/mysqladmin variables
```

If you cannot connect to the server, specify a `--u root` option to connect as `root`. If you have assigned a password for the `root` account already, you'll also need to specify `--p` on the command line and enter the password when prompted. For example:

```
shell> bin/mysqladmin --u root --p version
Enter password: (enter root password here)
```

The output from `mysqladmin version` varies slightly depending on your platform and version of MySQL, but should be similar to that shown here:

```
shell> bin/mysqladmin version
mysqladmin Ver 14.12 Distrib 5.6.47, for pc-linux-gnu on i686 ...
  Server version: 5.6.47
  Protocol version: 10
  Connection: Localhost via UNIX socket
  UNIX socket: /var/lib/mysql/mysql.sock
  Uptime: 14 days 5 hours 5 min 21 sec
```
Testing the Server

| Threads: 1 | Questions: 366 | Slow queries: 0 |
| Opens: 0 | Flush tables: 1 | Open tables: 19 |
| Queries per second avg: 0.000 |

To see what else you can do with `mysqladmin`, invoke it with the `--help` option.

Verify that you can shut down the server (include a `-p` option if the `root` account has a password already):

```shell
shell> bin/mysqladmin -u root shutdown
```

Verify that you can start the server again. Do this by using `mysqld_safe` or by invoking `mysqld` directly. For example:

```shell
shell> bin/mysqld_safe --user=mysql &
```

If `mysqld_safe` fails, see Section 3.2.1, “Troubleshooting Problems Starting the MySQL Server”.

Run some simple tests to verify that you can retrieve information from the server. The output should be similar to that shown here.

Use `mysqlshow` to verify that you can retrieve information from the server. The output should be similar to that shown here.

```shell
shell> bin/mysqlshow
```

The list of installed databases may vary, but always includes at least `mysql` and `information_schema`.

If you specify a database name, `mysqlshow` displays a list of the tables within the database:

```shell
shell> bin/mysqlshow mysql
```

```
<table>
<thead>
<tr>
<th>Tables</th>
</tr>
</thead>
<tbody>
<tr>
<td>columns_priv</td>
</tr>
<tr>
<td>db</td>
</tr>
<tr>
<td>event</td>
</tr>
<tr>
<td>func</td>
</tr>
<tr>
<td>general_log</td>
</tr>
<tr>
<td>help_category</td>
</tr>
<tr>
<td>help_keyword</td>
</tr>
<tr>
<td>help_relation</td>
</tr>
<tr>
<td>help_topic</td>
</tr>
<tr>
<td>innodb_index_stats</td>
</tr>
<tr>
<td>innodb_table_stats</td>
</tr>
<tr>
<td>ndb_binlog_index</td>
</tr>
<tr>
<td>plugin</td>
</tr>
<tr>
<td>proc</td>
</tr>
<tr>
<td>procs_priv</td>
</tr>
<tr>
<td>proxies_priv</td>
</tr>
<tr>
<td>servers</td>
</tr>
<tr>
<td>slave_master_info</td>
</tr>
<tr>
<td>slave_relay_log_info</td>
</tr>
<tr>
<td>slave_worker_info</td>
</tr>
<tr>
<td>slow_log</td>
</tr>
<tr>
<td>tables_priv</td>
</tr>
<tr>
<td>time_zone</td>
</tr>
</tbody>
</table>
```
Use the `mysql` program to select information from a table in the `mysql` database:

```
shell> bin/mysql -e "SELECT User, Host, plugin FROM mysql.user" mysql
```

+------+-----------+-----------------------+
<table>
<thead>
<tr>
<th>User</th>
<th>Host</th>
<th>plugin</th>
</tr>
</thead>
<tbody>
<tr>
<td>root</td>
<td>localhost</td>
<td>mysql_native_password</td>
</tr>
</tbody>
</table>
+------+-----------+-----------------------+

At this point, your server is running and you can access it. To tighten security if you have not yet assigned passwords to the initial account or accounts, follow the instructions in Section 3.4, “Securing the Initial MySQL Accounts”.

For more information about `mysql`, `mysqladmin`, and `mysqlshow`, see `mysql — The MySQL Command-Line Client`, `mysqladmin — Client for Administering a MySQL Server`, and `mysqlshow — Display Database, Table, and Column Information`.

### 3.4 Securing the Initial MySQL Accounts

The MySQL installation process involves initializing the data directory, including the grant tables in the `mysql` system database that define MySQL accounts. For details, see Section 3.1, “Initializing the Data Directory”.

This section describes how to assign passwords to the initial accounts created during the MySQL installation procedure, if you have not already done so.

The `mysql.user` grant table defines the initial MySQL user accounts and their access privileges:

- Some accounts have the user name `root`. These are superuser accounts that have all privileges and can do anything. If these `root` accounts have empty passwords, anyone can connect to the MySQL server as `root without a password` and be granted all privileges.

- On Windows, `root` accounts are created that permit connections from the local host only. Connections can be made by specifying the host name `localhost`, the IP address `127.0.0.1`, or the IPv6 address `::1`. If the user selects the `Enable root access from remote machines` option during installation, the Windows installer creates another `root` account that permits connections from any host.

- On Unix, each `root` account permits connections from the local host. Connections can be made by specifying the host name `localhost`, the IP address `127.0.0.1`, the IPv6 address `::1`, or the actual host name or IP address.

An attempt to connect to the host `127.0.0.1` normally resolves to the `localhost` account. However, this fails if the server is run with the `--skip-name-resolve` option, so the `127.0.0.1` account is useful in that case. The `::1` account is used for IPv6 connections.

- If accounts for anonymous users were created, these have an empty user name. The anonymous accounts have no password, so anyone can use them to connect to the MySQL server.

- On Windows, there is one anonymous account that permits connections from the local host. Connections can be made by specifying a host name of `localhost`.

- On Unix, each anonymous account permits connections from the local host. Connections can be made by specifying a host name of `localhost` for one of the accounts, or the actual host name or IP address for the other.
Securing the Initial MySQL Accounts

- The 'root'@'localhost' account also has a row in the mysql.proxies_priv table that enables granting the PROXY privilege for '', that is, for all users and all hosts. This enables root to set up proxy users, as well as to delegate to other accounts the authority to set up proxy users. See Section 4.12, “Proxy Users”.

To display which accounts exist in the mysql.user system table and check whether their passwords are empty, use the following statement:

```
mysql> SELECT User, Host, Password FROM mysql.user;
+------+--------------------+----------+
| User | Host               | Password |
+------+--------------------+----------+
| root | localhost          |          |
| root | myhost.example.com |          |
| root | 127.0.0.1          |          |
| root | ::1                |          |
|      | localhost          |          |
|      | myhost.example.com |          |
+------+--------------------+----------+
```

This output indicates that there are several root and anonymous-user accounts, none of which have passwords. The output might differ on your system, but the presence of accounts with empty passwords means that your MySQL installation is unprotected until you do something about it:

- Assign a password to each MySQL root account that does not have one.
- To prevent clients from connecting as anonymous users without a password, either assign a password to each anonymous account or remove the accounts.

In addition, the mysql.db table contains rows that permit all accounts to access the test database and other databases with names that start with test_. This is true even for accounts that otherwise have no special privileges such as the default anonymous accounts. This is convenient for testing but inadvisable on production servers. Administrators who want database access restricted only to accounts that have permissions granted explicitly for that purpose should remove these mysql.db table rows.

The following instructions describe how to set up passwords for the initial MySQL accounts, first for the root accounts, then for the anonymous accounts. The instructions also cover how to remove anonymous accounts, should you prefer not to permit anonymous access at all, and describe how to remove permissive access to test databases. Replace new_password in the examples with the password that you want to use. Replace host_name with the name of the server host. You can determine this name from the output of the preceding SELECT statement. For the output shown, host_name is myhost.example.com.

You need not remove anonymous entries in the mysql.proxies_priv table, which are used to support proxy users. See Section 4.12, “Proxy Users”.

Note

- For additional information about setting passwords, see Section 4.9, “Assigning Account Passwords”. If you forget your root password after setting it, see How to Reset the Root Password.
- To set up additional accounts, see Section 4.7, “Adding Accounts, Assigning Privileges, and Dropping Accounts”.

You might want to defer setting the passwords until later, to avoid the need to specify them while you perform additional setup or testing. However, be sure to set them before using your installation for production purposes.
Assigning root Account Passwords

A root account password can be set several ways. The following discussion demonstrates three methods:

- Use the `SET PASSWORD` statement
- Use the `UPDATE` statement
- Use the `mysqladmin` command-line client program

To assign passwords using `SET PASSWORD`, connect to the server as root and issue a `SET PASSWORD` statement for each root account listed in the `mysql.user` system table.

For Windows, do this:

```
shell> mysql -u root
mysql> SET PASSWORD FOR 'root'@'localhost' = PASSWORD('new_password');
mysql> SET PASSWORD FOR 'root'@'127.0.0.1' = PASSWORD('new_password');
mysql> SET PASSWORD FOR 'root'@'::1' = PASSWORD('new_password');
mysql> SET PASSWORD FOR 'root'@'%' = PASSWORD('new_password');
```

The last statement is unnecessary if the `mysql.user` table has no root account with a host value of %.

For Unix, do this:

```
shell> mysql -u root
mysql> SET PASSWORD FOR 'root'@'localhost' = PASSWORD('new_password');
mysql> SET PASSWORD FOR 'root'@'127.0.0.1' = PASSWORD('new_password');
mysql> SET PASSWORD FOR 'root'@'::1' = PASSWORD('new_password');
mysql> SET PASSWORD FOR 'root'@'host_name' = PASSWORD('new_password');
```

You can also use a single statement that assigns a password to all root accounts by using `UPDATE` to modify the `mysql.user` table directly. This method works on any platform:

```
shell> mysql -u root
mysql> UPDATE mysql.user SET Password = PASSWORD('new_password')
    WHERE User = 'root';
mysql> FLUSH PRIVILEGES;
```
The `FLUSH` statement causes the server to reread the grant tables. Without it, the password change remains unnoticed by the server until you restart it.

To assign passwords to the `root` accounts using `mysqladmin`, execute the following commands:

```shell
shell> mysqladmin -u root password "new_password"
shell> mysqladmin -u root -h host_name password "new_password"
```

Those commands apply both to Windows and to Unix. The double quotation marks around the password are not always necessary, but you should use them if the password contains spaces or other characters that are special to your command interpreter.

The `mysqladmin` method of setting the `root` account passwords does not work for the `'root'@'127.0.0.1'` or `'root'@'::1'` account. Use the `SET PASSWORD` method shown earlier.

After the `root` passwords have been set, you must supply the appropriate password whenever you connect as `root` to the server. For example, to shut down the server with `mysqladmin`, use this command:

```shell
shell> mysqladmin -u root -p shutdown
Enter password: (enter root password here)
```

The `mysql` commands in the following instructions include a `-p` option based on the assumption that you have assigned the `root` account passwords using the preceding instructions and must specify that password when connecting to the server.

### Assigning Anonymous Account Passwords

To assign passwords to the anonymous accounts, connect to the server as `root`, then use either `SET PASSWORD` or `UPDATE`.

To use `SET PASSWORD` on Windows, do this:

```shell
shell> mysql -u root -p
Enter password: (enter root password here)
mysql> SET PASSWORD FOR ''@'localhost' = PASSWORD('new_password');
```

To use `SET PASSWORD` on Unix, do this:

```shell
shell> mysql -u root -p
Enter password: (enter root password here)
mysql> SET PASSWORD FOR ''@'localhost' = PASSWORD('new_password');
mysql> SET PASSWORD FOR ''@'host_name' = PASSWORD('new_password');
```

To set the anonymous-user account passwords with a single `UPDATE` statement, do this (on any platform):

```shell
shell> mysql -u root -p
Enter password: (enter root password here)
mysql> UPDATE mysql.user SET Password = PASSWORD('new_password') WHERE User = ''
mysql> FLUSH PRIVILEGES;
```

The `FLUSH` statement causes the server to reread the grant tables. Without it, the password change remains unnoticed by the server until you restart it.

### Removing Anonymous Accounts

If you prefer to remove any anonymous accounts rather than assigning them passwords, do so as follows on Windows:

```shell
shell> mysql -u root -p
```
Securing Test Databases

By default, the `mysql.db` table contains rows that permit access by any user to the `test` database and other databases with names that start with `test_`. These rows have an empty `User` column value, which for access-checking purposes matches any user name. This means that such databases can be used even by accounts that otherwise possess no privileges. If you want to remove any-user access to test databases, do so as follows:

```
shell> mysql -u root -p
Enter password: (enter root password here)
mysql>
DROP USER ''@'localhost';
```

On Unix, remove the anonymous accounts like this:

```
shell> mysql -u root -p
Enter password: (enter root password here)
mysql>
DROP USER ''@'localhost';
mysql>
DROP USER ''@'host_name';
```

Securing Test Databases

```
shell> mysql -u root -p
Enter password: (enter root password here)
mysql>
DELETE FROM mysql.db WHERE Db LIKE 'test%';
mysql>
FLUSH PRIVILEGES;
```

The `FLUSH` statement causes the server to reread the grant tables. Without it, the privilege change remains unnoticed by the server until you restart it.

With the preceding change, only users who have global database privileges or privileges granted explicitly for the `test` database can use it. However, if you prefer that the database not exist at all, drop it:

```
mysql> DROP DATABASE test;
```

3.5 Starting and Stopping MySQL Automatically

This section discusses methods for starting and stopping the MySQL server.

Generally, you start the `mysqld` server in one of these ways:

- Invoke `mysqld` directly. This works on any platform.
- On Windows, you can set up a MySQL service that runs automatically when Windows starts. See Start MySQL as a Windows Service.
- On Unix and Unix-like systems, you can invoke `mysqld_safe`, which tries to determine the proper options for `mysqld` and then runs it with those options. See mysqld_safe — MySQL Server Startup Script.
- On systems that use System V-style run directories (that is, `/etc/init.d` and run-level specific directories), invoke `mysql.server`. This script is used primarily at system startup and shutdown. It usually is installed under the name `mysql`. The `mysql.server` script starts the server by invoking `mysqld_safe`. See mysql.server — MySQL Server Startup Script.
- On OS X, install a launchd daemon to enable automatic MySQL startup at system startup. The daemon starts the server by invoking `mysqld_safe`. For details, see Installing a MySQL Launch Daemon. A MySQL Preference Pane also provides control for starting and stopping MySQL through the System Preferences. See Installing and Using the MySQL Preference Pane.
- On Solaris, use the service management framework (SMF) system to initiate and control MySQL startup.
The `mysqld_safe` and `mysql.server` scripts, Solaris SMF, and the OS X Startup Item (or MySQL Preference Pane) can be used to start the server manually, or automatically at system startup time. `mysql.server` and the Startup Item also can be used to stop the server.

The following table shows which option groups the server and startup scripts read from option files.

Table 3.1 MySQL Startup Scripts and Supported Server Option Groups

<table>
<thead>
<tr>
<th>Script</th>
<th>Option Groups</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>mysqld</code></td>
<td><code>[mysqld]</code>, <code>[server]</code>, <code>[mysqld-major_version]</code></td>
</tr>
<tr>
<td><code>mysqld_safe</code></td>
<td><code>[mysqld]</code>, <code>[server]</code>, <code>[mysqld_safe]</code></td>
</tr>
<tr>
<td><code>mysql.server</code></td>
<td><code>[mysqld]</code>, <code>[mysql.server]</code>, <code>[server]</code></td>
</tr>
</tbody>
</table>

`[mysqld-major_version]` means that groups with names like `[mysqld-5.5]` and `[mysqld-5.6]` are read by servers having versions 5.5.x, 5.6.x, and so forth. This feature can be used to specify options that can be read only by servers within a given release series.

For backward compatibility, `mysql.server` also reads the `[mysql_server]` group and `mysqld_safe` also reads the `[safe_mysqld]` group. However, you should update your option files to use the `[mysql.server]` and `[mysqld_safe]` groups instead.

For more information on MySQL configuration files and their structure and contents, see Using Option Files.

MySQL enables the creation of accounts that permit client users to connect to the server and access data managed by the server. The primary function of the MySQL privilege system is to authenticate a user who connects from a given host and to associate that user with privileges on a database such as SELECT, INSERT, UPDATE, and DELETE. Additional functionality includes the ability to grant privileges for administrative operations.

To control which users can connect, each account can be assigned authentication credentials such as a password. The user interface to MySQL accounts consists of SQL statements such as CREATE USER, GRANT, and REVOKE. See Account Management Statements.

The MySQL privilege system ensures that all users may perform only the operations permitted to them. As a user, when you connect to a MySQL server, your identity is determined by the host from which you connect and the user name you specify. When you issue requests after connecting, the system grants privileges according to your identity and what you want to do.

MySQL considers both your host name and user name in identifying you because there is no reason to assume that a given user name belongs to the same person on all hosts. For example, the user joe who connects from office.example.com need not be the same person as the user joe who connects from home.example.com. MySQL handles this by enabling you to distinguish users on different hosts that happen to have the same name: You can grant one set of privileges for connections by joe from office.example.com, and a different set of privileges for connections by joe from home.example.com. To see what privileges a given account has, use the SHOW GRANTS statement. For example:

```
SHOW GRANTS FOR 'joe'@'office.example.com';
SHOW GRANTS FOR 'joe'@'home.example.com';
```

Internally, the server stores privilege information in the grant tables of the mysql system database. The MySQL server reads the contents of these tables into memory when it starts and bases access-control decisions on the in-memory copies of the grant tables.

MySQL access control involves two stages when you run a client program that connects to the server:

**Stage 1**: The server accepts or rejects the connection based on your identity and whether you can verify your identity by supplying the correct password.

**Stage 2**: Assuming that you can connect, the server checks each statement you issue to determine whether you have sufficient privileges to perform it. For example, if you try to select rows from a table
in a database or drop a table from the database, the server verifies that you have the `SELECT` privilege for the table or the `DROP` privilege for the database.

For a more detailed description of what happens during each stage, see Section 4.5, “Access Control, Stage 1: Connection Verification”, and Section 4.6, “Access Control, Stage 2: Request Verification”. For help in diagnosing privilege-related problems, see Section 4.14, “Troubleshooting Problems Connecting to MySQL”.

If your privileges are changed (either by yourself or someone else) while you are connected, those changes do not necessarily take effect immediately for the next statement that you issue. For details about the conditions under which the server reloads the grant tables, see Section 4.8, “When Privilege Changes Take Effect”.

There are some things that you cannot do with the MySQL privilege system:

• You cannot explicitly specify that a given user should be denied access. That is, you cannot explicitly match a user and then refuse the connection.

• You cannot specify that a user has privileges to create or drop tables in a database but not to create or drop the database itself.

• A password applies globally to an account. You cannot associate a password with a specific object such as a database, table, or routine.

### 4.1 Account User Names and Passwords

MySQL stores accounts in the `user` table of the `mysql` system database. An account is defined in terms of a user name and the client host or hosts from which the user can connect to the server. For information about account representation in the `user` table, see Section 4.3, “Grant Tables”.

An account may also have authentication credentials such as a password. The credentials are handled by the account authentication plugin. MySQL supports multiple authentication plugins. Some of them use built-in authentication methods, whereas others enable authentication using external authentication methods. See Section 4.11, “Pluggable Authentication”.

There are several distinctions between the way user names and passwords are used by MySQL and your operating system:

• User names, as used by MySQL for authentication purposes, have nothing to do with user names (login names) as used by Windows or Unix. On Unix, most MySQL clients by default try to log in using the current Unix user name as the MySQL user name, but that is for convenience only. The default can be overridden easily, because client programs permit any user name to be specified with a `--user` option. This means that anyone can attempt to connect to the server using any user name, so you cannot make a database secure in any way unless all MySQL accounts have passwords. Anyone who specifies a user name for an account that has no password can connect successfully to the server.

• MySQL user names are up to 16 characters long. Operating system user names may have a different maximum length.

**Warning**

The MySQL user name length limit is hardcoded in MySQL servers and clients, and trying to circumvent it by modifying the definitions of the tables in the `mysql` database does not work.

You should never alter the structure of tables in the `mysql` database in any manner whatsoever except by means of the procedure that is described in *Upgrading MySQL*. Attempting to redefine MySQL’s system tables in any other fashion results in undefined and unsupported behavior. The server is free to ignore rows that become malformed as a result of such modifications.
Account User Names and Passwords

- To authenticate client connections for accounts that use built-in authentication methods, the server uses passwords stored in the `user` table. These passwords are distinct from passwords for logging in to your operating system. There is no necessary connection between the “external” password you use to log in to a Windows or Unix machine and the password you use to access the MySQL server on that machine.

  If the server authenticates a client using some other plugin, the authentication method that the plugin implements may or may not use a password stored in the `user` table. In this case, it is possible that an external password is also used to authenticate to the MySQL server.

- Passwords stored in the `user` table are encrypted using plugin-specific algorithms. For information about MySQL native password hashing, see Section 2.2.4, “Password Hashing in MySQL”.

- If the user name and password contain only ASCII characters, it is possible to connect to the server regardless of character set settings. To enable connections when the user name or password contain non-ASCII characters, client applications should call the `mysql_options()` C API function with the `MYSQL_SET_CHARSET_NAME` option and appropriate character set name as arguments. This causes authentication to take place using the specified character set. Otherwise, authentication fails unless the server default character set is the same as the encoding in the authentication defaults.

  Standard MySQL client programs support a `--default-character-set` option that causes `mysql_options()` to be called as just described. In addition, character set autodetection is supported as described in Connection Character Sets and Collations. For programs that use a connector that is not based on the C API, the connector may provide an equivalent to `mysql_options()` that can be used instead. Check the connector documentation.

  The preceding notes do not apply for `ucs2`, `utf16`, and `utf32`, which are not permitted as client character sets.

The MySQL installation process populates the grant tables with an initial account or accounts. The names and access privileges for these accounts are described in Section 3.4, “Securing the Initial MySQL Accounts”, which also discusses how to assign passwords to them. Thereafter, you normally set up, modify, and remove MySQL accounts using statements such as `CREATE USER`, `DROP USER`, `GRANT`, and `REVOKE`. See Section 4.7, “Adding Accounts, Assigning Privileges, and Dropping Accounts”, and Account Management Statements.

To connect to a MySQL server with a command-line client, specify user name and password options as necessary for the account that you want to use:

```shell
shell> mysql --user=finley --password db_name
```

If you prefer short options, the command looks like this:

```shell
shell> mysql -u finley -p db_name
```

If you omit the password value following the `--password` or `-p` option on the command line (as just shown), the client prompts for one. Alternatively, the password can be specified on the command line:

```shell
shell> mysql --user=finley --password=password db_name
shell> mysql -u finley -password db_name
```

If you use the `-p` option, there must be no space between `-p` and the following password value.

Specifying a password on the command line should be considered insecure. See Section 2.2.1, “End-User Guidelines for Password Security”. To avoid giving the password on the command line, use an option file or a login path file. See Using Option Files, and `mysql_config_editor` — MySQL Configuration Utility.
4.2 Privileges Provided by MySQL

The privileges granted to a MySQL account determine which operations the account can perform. MySQL privileges differ in the contexts in which they apply and at different levels of operation:

- Administrative privileges enable users to manage operation of the MySQL server. These privileges are global because they are not specific to a particular database.

- Database privileges apply to a database and to all objects within it. These privileges can be granted for specific databases, or globally so that they apply to all databases.

- Privileges for database objects such as tables, indexes, views, and stored routines can be granted for specific objects within a database, for all objects of a given type within a database (for example, all tables in a database), or globally for all objects of a given type in all databases.

Information about account privileges is stored in the grant tables in the `mysql` system database. For a description of the structure and contents of these tables, see Section 4.3, “Grant Tables”. The MySQL server reads the contents of the grant tables into memory when it starts, and reloads them under the circumstances indicated in Section 4.8, “When Privilege Changes Take Effect”. The server bases access-control decisions on the in-memory copies of the grant tables.

**Important**

Some MySQL releases introduce changes to the grant tables to add new privileges or features. To make sure that you can take advantage of any new capabilities, update your grant tables to the current structure whenever you upgrade MySQL. See Upgrading MySQL.

The following sections summarize the available privileges, provide more detailed descriptions of each privilege, and offer usage guidelines.

- **Summary of Available Privileges**
- **Privilege Descriptions**
- **Privilege-Granting Guidelines**

### Summary of Available Privileges

The following table shows the privilege names used in `GRANT` and `REVOKE` statements, along with the column name associated with each privilege in the grant tables and the context in which the privilege applies.

**Table 4.1 Permissible Privileges for GRANT and REVOKE**

<table>
<thead>
<tr>
<th>Privilege</th>

</tbody>
</table>
Privilege Descriptions

The following list provides general descriptions of each privilege available in MySQL. Particular SQL statements might have more specific privilege requirements than indicated here. If so, the description for the statement in question provides the details.

- **ALL, ALL PRIVILEGES**
  
  These privilege specifiers are shorthand for "all privileges available at a given privilege level" (except **GRANT OPTION**). For example, granting **ALL** at the global or table level grants all global privileges or all table-level privileges, respectively.

- **ALTER**
  
  Enables use of the **ALTER TABLE** statement to change the structure of tables. **ALTER TABLE** also requires the **CREATE** and **INSERT** privileges. Renaming a table requires **ALTER** and **DROP** on the old table, **CREATE**, and **INSERT** on the new table.

- **ALTER ROUTINE**
  
  Enables use of statements that alter or drop stored routines (stored procedures and functions).

- **CREATE**
  
  Enables use of statements that create new databases and tables.

<table>
<thead>
<tr>
<th>Privilege</th>

</tbody>
</table>
Privilege Descriptions

- **CREATE ROUTINE**
  Enables use of statements that create stored routines (stored procedures and functions).

- **CREATE TABLESPACE**
  Enables use of statements that create, alter, or drop tablespaces and log file groups.

- **CREATE TEMPORARY TABLES**
  Enables the creation of temporary tables using the `CREATE TEMPORARY TABLE` statement.
  After a session has created a temporary table, the server performs no further privilege checks on the table. The creating session can perform any operation on the table, such as `DROP TABLE`, `INSERT`, `UPDATE`, or `SELECT`. For more information, see [CREATE TEMPORARY TABLE Syntax](#).

- **CREATE USER**
  Enables use of the `ALTER USER`, `CREATE USER`, `DROP USER`, `RENAME USER`, and `REVOKE ALL PRIVILEGES` statements.

- **CREATE VIEW**
  Enables use of the `CREATE VIEW` statement.

- **DELETE**
  Enables rows to be deleted from tables in a database.

- **DROP**
  Enables use of statements that drop (remove) existing databases, tables, and views. The `DROP` privilege is required to use the `ALTER TABLE ... DROP PARTITION` statement on a partitioned table. The `DROP` privilege is also required for `TRUNCATE TABLE`.

- **EVENT**
  Enables use of statements that create, alter, drop, or display events for the Event Scheduler.

- **EXECUTE**
  Enables use of statements that execute stored routines (stored procedures and functions).

- **FILE**
  Affects the following operations and server behaviors:

  - Enables reading and writing files on the server host using the `LOAD DATA` and `SELECT ... INTO OUTFILE` statements and the `LOAD_FILE()` function. A user who has the `FILE` privilege can read any file on the server host that is either world-readable or readable by the MySQL server. (This implies the user can read any file in any database directory, because the server can access any of those files.)

  - Enables creating new files in any directory where the MySQL server has write access. This includes the server’s data directory containing the files that implement the privilege tables.

  - As of MySQL 5.6.35, enables use of the `DATA DIRECTORY` or `INDEX DIRECTORY` table option for the `CREATE TABLE` statement.

As a security measure, the server does not overwrite existing files.

To limit the location in which files can be read and written, set the `secure_file_priv` system variable to a specific directory. See [Server System Variables](#).
• **GRANT OPTION**

Enables you to grant to or revoke from other users those privileges that you yourself possess.

• **INDEX**

Enables use of statements that create or drop (remove) indexes. `INDEX` applies to existing tables. If you have the `CREATE` privilege for a table, you can include index definitions in the `CREATE TABLE` statement.

• **INSERT**

Enables rows to be inserted into tables in a database. `INSERT` is also required for the `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` table-maintenance statements.

• **LOCK TABLES**

Enables use of explicit `LOCK TABLES` statements to lock tables for which you have the `SELECT` privilege. This includes use of write locks, which prevents other sessions from reading the locked table.

• **PROCESS**

Enables display of information about the threads executing within the server (that is, information about the statements being executed by sessions). The privilege enables use of `SHOW PROCESSLIST` or `mysqladmin processlist` to see threads belonging to other accounts; you can always see your own threads. The `PROCESS` privilege also enables use of `SHOW ENGINE`.

• **PROXY**

Enables one user to impersonate or become known as another user. See Section 4.12, “Proxy Users”.

• **REFERENCES**

This privilege is unused before MySQL 5.6.22. As of 5.6.22, creation of a foreign key constraint requires at least one of the `SELECT`, `INSERT`, `UPDATE`, `DELETE`, or `REFERENCES` privileges for the parent table.

• **RELOAD**

Enables use of the `FLUSH` statement. It also enables `mysqladmin` commands that are equivalent to `FLUSH` operations: `flush-hosts`, `flush-logs`, `flush-privileges`, `flush-status`, `flush-tables`, `flush-threads`, `refresh`, and `reload`.

The `reload` command tells the server to reload the grant tables into memory. `flush-privileges` is a synonym for `reload`. The `refresh` command closes and reopens the log files and flushes all tables. The other `flush-xxx` commands perform functions similar to `refresh`, but are more specific and may be preferable in some instances. For example, if you want to flush just the log files, `flush-logs` is a better choice than `refresh`.

• **REPLICATION CLIENT**

Enables use of the `SHOW MASTER STATUS`, `SHOW SLAVE STATUS`, and `SHOW BINARY LOGS` statements. Grant this privilege to accounts that are used by slave servers to connect to the current server as their master.

• **REPLICATION SLAVE**

Enables the account to request updates that have been made to databases on the master server, using the `SHOW SLAVE HOSTS`, `SHOW RELAYLOG EVENTS`, and `SHOW BINLOG EVENTS` statements. This privilege is also required to use the `mysqlbinlog` options `--read-from-`
remote-server (-R) and --read-from-remote-master. Grant this privilege to accounts that are used by slave servers to connect to the current server as their master.

- **SELECT**

Enables rows to be selected from tables in a database. SELECT statements require the SELECT privilege only if they actually access tables. Some SELECT statements do not access tables and can be executed without permission for any database. For example, you can use SELECT as a simple calculator to evaluate expressions that make no reference to tables:

```sql
SELECT 1+1;
SELECT PI() * 2;
```

The SELECT privilege is also needed for other statements that read column values. For example, SELECT is needed for columns referenced on the right hand side of `col_name=expr` assignment in UPDATE statements or for columns named in the WHERE clause of DELETE or UPDATE statements.

The SELECT privilege is needed for tables or views used with EXPLAIN, including any underlying tables in view definitions.

- **SHOW DATABASES**

Enables the account to see database names by issuing the SHOW DATABASE statement. Accounts that do not have this privilege see only databases for which they have some privileges, and cannot use the statement at all if the server was started with the --skip-show-database option.

**Caution**

Because a global privilege is considered a privilege for all databases, any global privilege enables a user to see all database names with SHOW DATABASES or by examining the INFORMATION_SCHEMA SCHEMATA table.

- **SHOW VIEW**

Enables use of the SHOW CREATE VIEW statement. This privilege is also needed for views used with EXPLAIN.

- **SHUTDOWN**

Enables use of the mysqladmin shutdown command and the mysql_shutdown() C API function. There is no corresponding SQL statement.

- **SUPER**

Affects the following operations and server behaviors:

- Enables server configuration changes by modifying global system variables. For some system variables, setting the session value also requires the SUPER privilege. If a system variable is restricted and requires a special privilege to set the session value, the variable description indicates that restriction. Examples include `binlog_format`, `sql_log_bin`, and `sql_log_off`. See also System Variable Privileges.

- Enables changes to global transaction characteristics (see SET TRANSACTION Syntax).

- Enables the account to start and stop replication.

- Enables use of the CHANGE MASTER TO statement.

- Enables binary log control by means of the PURGE BINARY LOGS and BINLOG statements.

- Enables setting the effective authorization ID when executing a view or stored program. A user with this privilege can specify any account in the DEFINER attribute of a view or stored program.
Privilege-Granting Guidelines

• Enables use of the \texttt{CREATE\ SERVER}, \texttt{ALTER\ SERVER}, and \texttt{DROP\ SERVER} statements.

• Enables use of the \texttt{mysqladmin\ debug} command.

• Enables reading the DES key file by the \texttt{DES\_ENCRYPT()} function.

• Enables control over client connections not permitted to non-\texttt{SUPER} accounts:
  - Enables use of the \texttt{KILL} statement or \texttt{mysqladmin\ kill} command to kill threads belonging to other accounts. (An account can always kill its own threads.)

  • The server does not execute \texttt{init\_connect} system variable content when \texttt{SUPER} clients connect.

  • The server accepts one connection from a \texttt{SUPER} client even if the connection limit configured by the \texttt{max\_connections} system variable is reached.

  • Updates can be performed even when the \texttt{read\_only} system variable is enabled. This applies to explicit table updates, and to use of account-management statements such as \texttt{GRANT} and \texttt{REVOKE} that update tables implicitly.

You may also need the \texttt{SUPER} privilege to create or alter stored functions if binary logging is enabled, as described in \textit{Stored Program Binary Logging}.

• \texttt{TRIGGER}

  Enables trigger operations. You must have this privilege for a table to create, drop, execute, or display triggers for that table.

  When a trigger is activated (by a user who has privileges to execute \texttt{INSERT}, \texttt{UPDATE}, or \texttt{DELETE} statements for the table associated with the trigger), trigger execution requires that the user who defined the trigger still have the \texttt{TRIGGER} privilege for the table.

• \texttt{UPDATE}

  Enables rows to be updated in tables in a database.

• \texttt{USAGE}

  This privilege specifier stands for “no privileges.” It is used at the global level with \texttt{GRANT} to modify account attributes such as resource limits or SSL characteristics without naming specific account privileges in the privilege list. \texttt{SHOW\ GRANTS} displays \texttt{USAGE} to indicate that an account has no privileges at a privilege level.

Privilege-Granting Guidelines

It is a good idea to grant to an account only those privileges that it needs. You should exercise particular caution in granting the \texttt{FILE} and administrative privileges:

• \texttt{FILE} can be abused to read into a database table any files that the MySQL server can read on the server host. This includes all world-readable files and files in the server’s data directory. The table can then be accessed using \texttt{SELECT} to transfer its contents to the client host.

• \texttt{GRANT\ OPTION} enables users to give their privileges to other users. Two users that have different privileges and with the \texttt{GRANT\ OPTION} privilege are able to combine privileges.

• \texttt{ALTER} may be used to subvert the privilege system by renaming tables.

• \texttt{SHUTDOWN} can be abused to deny service to other users entirely by terminating the server.

• \texttt{PROCESS} can be used to view the plain text of currently executing statements, including statements that set or change passwords.
Grant Tables

- **SUPER** can be used to terminate other sessions or change how the server operates.

- Privileges granted for the `mysql` system database itself can be used to change passwords and other access privilege information:
  - Passwords are stored encrypted, so a malicious user cannot simply read them to know the plain text password. However, a user with write access to the `mysql.user` system table `Password` column can change an account's password, and then connect to the MySQL server using that account.
  - **INSERT** or **UPDATE** granted for the `mysql` system database enable a user to add privileges or modify existing privileges, respectively.
  - **DROP** for the `mysql` system database enables a user to remote privilege tables, or even the database itself.

4.3 Grant Tables

The `mysql` system database includes several grant tables that contain information about user accounts and the privileges held by them. This section describes those tables. For information about other tables in the system database, see The `mysql` System Database.

The discussion here describes the underlying structure of the grant tables and how the server uses their contents when interacting with clients. However, normally you do not modify the grant tables directly. Modifications occur indirectly when you use account-management statements such as **CREATE**, **GRANT**, and **REVOKE** to set up accounts and control the privileges available to each one. See Account Management Statements. When you use such statements to perform account manipulations, the server modifies the grant tables on your behalf.

**Note**

Direct modification of grant tables using statements such as **INSERT**, **UPDATE**, or **DELETE** is discouraged and done at your own risk. The server is free to ignore rows that become malformed as a result of such modifications.

As of MySQL 5.6.36, for any operation that modifies a grant table, the server checks whether the table has the expected structure and produces an error if not. **mysql_upgrade** must be run to update the tables to the expected structure.

- Grant Table Overview
- The user and db Grant Tables
- The tables_priv and columns_priv Grant Tables
- The procs_priv Grant Table
- The proxies_priv Grant Table
- Grant Table Scope Column Properties
- Grant Table Privilege Column Properties

**Grant Table Overview**

These `mysql` database tables contain grant information:

- **user**: User accounts, global privileges, and other nonprivilege columns.
- **db**: Database-level privileges.
Grant Table Overview

- **tables_priv**: Table-level privileges.
- **columns_priv**: Column-level privileges.
- **procs_priv**: Stored procedure and function privileges.
- **proxies_priv**: Proxy-user privileges.

Each grant table contains scope columns and privilege columns:

- **Scope columns**: Determine the scope of each row in the tables; that is, the context in which the row applies. For example, a user table row with **Host** and **User** values of 'h1.example.net' and 'bob' applies to authenticating connections made to the server from the host h1.example.net by a client that specifies a user name of bob. Similarly, a db table row with **Host**, **User**, and **Db** column values of 'h1.example.net', 'bob' and 'reports' applies when bob connects from the host h1.example.net to access the reports database. The tables_priv and columns_priv tables contain scope columns indicating tables or table/column combinations to which each row applies. The procs_priv scope columns indicate the stored routine to which each row applies.

- **Privilege columns**: Indicate which privileges a table row grants; that is, which operations it permits to be performed. The server combines the information in the various grant tables to form a complete description of a user's privileges. Section 4.6, “Access Control, Stage 2: Request Verification”, describes the rules for this.

In addition, a grant table may contain columns used for purposes other than scope or privilege assessment.

The server uses the grant tables in the following manner:

- **The user table scope columns** determine whether to reject or permit incoming connections. For permitted connections, any privileges granted in the user table indicate the user's global privileges. Any privileges granted in this table apply to all databases on the server.

  **Caution**

  Because a global privilege is considered a privilege for all databases, any global privilege enables a user to see all database names with **SHOW DATABASES** or by examining the INFORMATION_SCHEMA SCHEMATA table.

- **The db table scope columns** determine which users can access which databases from which hosts. The privilege columns determine the permitted operations. A privilege granted at the database level applies to the database and to all objects in the database, such as tables and stored programs.

- **The tables_priv and columns_priv tables** are similar to the db table, but are more fine-grained: They apply at the table and column levels rather than at the database level. A privilege granted at the table level applies to the table and to all its columns. A privilege granted at the column level applies only to a specific column.

- **The procs_priv table** applies to stored routines (stored procedures and functions). A privilege granted at the routine level applies only to a single procedure or function.

- **The proxies_priv table** indicates which users can act as proxies for other users and whether a user can grant the PROXY privilege to other users.

The server reads the contents of the grant tables into memory when it starts. You can tell it to reload the tables by issuing a **FLUSH PRIVILEGES** statement or executing a **mysqladmin flush-privileges** or **mysqladmin reload** command. Changes to the grant tables take effect as indicated in Section 4.8, "When Privilege Changes Take Effect".

When you modify an account, it is a good idea to verify that your changes have the intended effect. To check the privileges for a given account, use the **SHOW GRANTS** statement. For example, to
determine the privileges that are granted to an account with user name and host name values of bob and pc84.example.com, use this statement:

```
SHOW GRANTS FOR 'bob'@'pc84.example.com';
```

### The user and db Grant Tables

The server uses the `user` and `db` tables in the `mysql` database at both the first and second stages of access control (see Chapter 4, *Access Control and Account Management*). The columns in the `user` and `db` tables are shown here.

**Table 4.2 user and db Table Columns**

<td></td>
</tr>
</tbody>
</table>

The **user** table **plugin**, **Password**, and **authentication_string** columns store authentication plugin and credential information.

If an account row names a plugin in the **plugin** column, the server uses it to authenticate connection attempts for the account. It is up to the plugin whether it uses the **Password** and **authentication_string** column values.

If the **plugin** column for an account row is empty, the server authenticates the account using the mysql_native_password or mysql_old_password plugin implicitly, depending on the format of the password hash in the **Password** column. If the **Password** value is empty or a 4.1 password hash (41 characters), the server uses mysql_native_password. If the password value is a pre-4.1 password hash (16 characters), the server uses mysql_old_password. (For additional information about these hash formats, see Section 2.2.4, "Password Hashing in MySQL"). Clients must match the password in the **Password** column of the account row.

The **password_expired** column permits DBAs to expire account passwords and require users to reset their password. The default **password_expired** value is 'N', but can be set to 'Y' with the **ALTER USER** statement. After an account's password has been expired, all operations performed by the account in subsequent connections to the server result in an error until the user issues a **SET PASSWORD** statement to establish a new account password.

**Note**

Although it is possible to "reset" an expired password by setting it to its current value, it is preferable, as a matter of good policy, to choose a different password.

The tables_priv and columns_priv Grant Tables

During the second stage of access control, the server performs request verification to ensure that each client has sufficient privileges for each request that it issues. In addition to the **user** and **db** grant tables, the server may also consult the **tables_priv** and **columns_priv** tables for requests that involve tables. The latter tables provide finer privilege control at the table and column levels. They have the columns shown in the following table.

Table 4.3 tables_priv and columns_priv Table Columns

<table>
<thead>
<tr>
<th>Table Name</th>
<th>tables_priv</th>
<th>columns_priv</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope columns</td>
<td>Host</td>
<td>Host</td>
</tr>
<tr>
<td></td>
<td>Db</td>
<td>Db</td>
</tr>
<tr>
<td></td>
<td>User</td>
<td>User</td>
</tr>
</tbody>
</table>
The procs_priv Grant Table

For verification of requests that involve stored routines, the server may consult the `procs_priv` table, which has the columns shown in the following table.

Table 4.4 procs_priv Table Columns

<table>
<thead>
<tr>
<th>Table Name</th>
<th>procs_priv</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope columns</td>
<td>Host, Db, User, Routine_name, Routine_type</td>
</tr>
<tr>
<td>Privilege columns</td>
<td>Proc_priv</td>
</tr>
<tr>
<td>Other columns</td>
<td>Timestamp</td>
</tr>
</tbody>
</table>

The `Routine_type` column is an ENUM column with values of 'FUNCTION' or 'PROCEDURE' to indicate the type of routine the row refers to. This column enables privileges to be granted separately for a function and a procedure with the same name.

The `Timestamp` and `Grantor` columns are unused.

The proxies_priv Grant Table

The `proxies_priv` table records information about proxy accounts. It has these columns:

- `Host`, `User`: The proxy account; that is, the account that has the PROXY privilege for the proxied account.
- `Proxied_host`, `Proxied_user`: The proxied account.
- `Grantor`, `Timestamp`: Unused.
- `With_grant`: Whether the proxy account can grant the PROXY privilege to other accounts.

For an account to be able to grant the PROXY privilege to other accounts, it must have a row in the `proxies_priv` table with `With_grant` set to 1 and `Proxied_host` and `Proxied_user` set to indicate the account or accounts for which the privilege can be granted. For example, the 'root'@'localhost' account created during MySQL installation has a row in the `proxies_priv` table that enables granting the PROXY privilege for '%', that is, for all users and all hosts. This enables root to set up proxy users, as well as to delegate to other accounts the authority to set up proxy users. See Section 4.12, "Proxy Users".
Grant Table Scope Column Properties

Scope columns in the grant tables contain strings. The default value for each is the empty string. The following table shows the number of characters permitted in each column.

Table 4.5 Grant Table Scope Column Lengths

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Maximum Permitted Characters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host, Proxied_host</td>
<td>60</td>
</tr>
<tr>
<td>User, Proxied_user</td>
<td>16</td>
</tr>
<tr>
<td>Password</td>
<td>41</td>
</tr>
<tr>
<td>Db</td>
<td>64</td>
</tr>
<tr>
<td>Table_name</td>
<td>64</td>
</tr>
<tr>
<td>Column_name</td>
<td>64</td>
</tr>
<tr>
<td>Routine_name</td>
<td>64</td>
</tr>
</tbody>
</table>

Host and Proxied_host values are converted to lowercase before being stored in the grant tables.

For access-checking purposes, comparisons of User, Proxied_user, Password, Db, and Table_name values are case-sensitive. Comparisons of Host, Proxied_host, Column_name, and Routine_name values are not case-sensitive.

Grant Table Privilege Column Properties

The user and db tables list each privilege in a separate column that is declared as ENUM('N', 'Y') DEFAULT 'N'. In other words, each privilege can be disabled or enabled, with the default being disabled.

The tables_priv, columns_priv, and procs_priv tables declare the privilege columns as SET columns. Values in these columns can contain any combination of the privileges controlled by the table. Only those privileges listed in the column value are enabled.

Table 4.6 Set-Type Privilege Column Values

<table>
<thead>
<tr>
<th>Table Name</th>
<th>Column Name</th>
<th>Possible Set Elements</th>
</tr>
</thead>
<tbody>
<tr>
<td>tables_priv</td>
<td>Table_priv</td>
<td>'Select', 'Insert', 'Update', 'Delete', 'Create', 'Drop', 'Grant', 'References', 'Index', 'Alter', 'Create View', 'Show view', 'Trigger'</td>
</tr>
<tr>
<td>tables_priv</td>
<td>Column_priv</td>
<td>'Select', 'Insert', 'Update', 'References'</td>
</tr>
<tr>
<td>columns_priv</td>
<td>Column_priv</td>
<td>'Select', 'Insert', 'Update', 'References'</td>
</tr>
<tr>
<td>procs_priv</td>
<td>Proc_priv</td>
<td>'Execute', 'Alter Routine', 'Grant'</td>
</tr>
</tbody>
</table>

Only the user table specifies administrative privileges, such as RELOAD and SHUTDOWN. Administrative operations are operations on the server itself and are not database-specific, so there is no reason to list these privileges in the other grant tables. Consequently, the server need consult only the user table to determine whether a user can perform an administrative operation.

The FILE privilege also is specified only in the user table. It is not an administrative privilege as such, but a user's ability to read or write files on the server host is independent of the database being accessed.
4.4 Specifying Account Names

MySQL account names consist of a user name and a host name, which enables creation of distinct accounts for users with the same user name who can connect from different hosts. This section describes how to write account names, including special values and wildcard rules.

In SQL statements such as `CREATE USER`, `GRANT`, and `SET PASSWORD`, account names follow these rules:

- Account name syntax is `'user_name'@'host_name'`.
- An account name consisting only of a user name is equivalent to `'user_name'@'%'`. For example, `'me'` is equivalent to `'me'@'%'`.
- The user name and host name need not be quoted if they are legal as unquoted identifiers. Quotes are necessary to specify a `user_name` string containing special characters (such as space or `-`), or a `host_name` string containing special characters or wildcard characters (such as `. ` or `%`). For example, in the account name `'test-user'@'%.com'`, both the user name and host name parts require quotes.
- Quote user names and host names as identifiers or as strings, using either backticks (`), single quotation marks ('), or double quotation marks ("). For string-quoting and identifier-quoting guidelines, see String Literals, and Schema Object Names.
- The user name and host name parts, if quoted, must be quoted separately. That is, write `'me'@'localhost'`, not `'me@localhost'`. The latter is actually equivalent to `'me@localhost'@'%'`.
- A reference to the `CURRENT_USER` or `CURRENT_USER()` function is equivalent to specifying the current client’s user name and host name literally.

MySQL stores account names in grant tables in the `mysql` system database using separate columns for the user name and host name parts:

- The `user` table contains one row for each account. The `User` and `Host` columns store the user name and host name. This table also indicates which global privileges the account has.
- Other grant tables indicate privileges an account has for databases and objects within databases. These tables have `User` and `Host` columns to store the account name. Each row in these tables associates with the account in the `user` table that has the same `User` and `Host` values.
- For access-checking purposes, comparisons of User values are case-sensitive. Comparisons of Host values are not case sensitive.

For additional detail about the properties of user names and host names as stored in the grant tables, such as maximum length, see Grant Table Scope Column Properties.

User names and host names have certain special values or wildcard conventions, as described following.

The user name part of an account name is either a nonblank value that literally matches the user name for incoming connection attempts, or a blank value (empty string) that matches any user name. An account with a blank user name is an anonymous user. To specify an anonymous user in SQL statements, use a quoted empty user name part, such as `'@'localhost'`.

The host name part of an account name can take many forms, and wildcards are permitted:

- A host value can be a host name or an IP address (IPv4 or IPv6). The name `'localhost'` indicates the local host. The IP address `'127.0.0.1'` indicates the IPv4 loopback interface. The IP address `'::1'` indicates the IPv6 loopback interface.
- The `%` and `_` wildcard characters are permitted in host name or IP address values. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator. For example, a
Access Control, Stage 1: Connection Verification

The host value of '%' matches any host name, whereas a value of '%.mysql.com' matches any host in the mysql.com domain. '198.51.100.%' matches any host in the 198.51.100 class C network.

Because IP wildcard values are permitted in host values (for example, '198.51.100.%' to match every host on a subnet), someone could try to exploit this capability by naming a host 198.51.100.somewhere.com. To foil such attempts, MySQL does not perform matching on host names that start with digits and a dot. For example, if a host is named 1.2.example.com, its name never matches the host part of account names. An IP wildcard value can match only IP addresses, not host names.

- For a host value specified as an IPv4 address, a netmask can be given to indicate how many address bits to use for the network number. Netmask notation cannot be used for IPv6 addresses.

The syntax is `host_ip/netmask`. For example:

```
CREATE USER 'david'@'198.51.100.0/255.255.255.0';
```

This enables `david` to connect from any client host having an IP address `client_ip` for which the following condition is true:

```
client_ip & netmask = host_ip
```

That is, for the `CREATE USER` statement just shown:

```
client_ip & 255.255.255.0 = 198.51.100.0
```

IP addresses that satisfy this condition range from 198.51.100.0 to 198.51.100.255.

A netmask typically begins with bits set to 1, followed by bits set to 0. Examples:

- `198.0.0.0/255.0.0.0`: Any host on the 198 class A network
- `198.51.100.0/255.255.0.0`: Any host on the 198.51 class B network
- `198.51.100.0/255.255.255.0`: Any host on the 198.51.100 class C network
- `198.51.100.1`: Only the host with this specific IP address

The server performs matching of host values in account names against the client host using the value returned by the system DNS resolver for the client host name or IP address. Except in the case that the account host value is specified using netmask notation, the server performs this comparison as a string match, even for an account host value given as an IP address. This means that you should specify account host values in the same format used by DNS. Here are examples of problems to watch out for:

- Suppose that a host on the local network has a fully qualified name of `host1.example.com`. If DNS returns name lookups for this host as `host1.example.com`, use that name in account host values. If DNS returns just `host1`, use `host1` instead.

- If DNS returns the IP address for a given host as `198.51.100.2`, that will match an account host value of `198.51.100.2` but not `198.051.100.2`. Similarly, it will match an account host pattern like `198.51.100.%` but not `198.051.100.%`.

To avoid problems like these, it is advisable to check the format in which your DNS returns host names and addresses. Use values in the same format in MySQL account names.

4.5 Access Control, Stage 1: Connection Verification

When you attempt to connect to a MySQL server, the server accepts or rejects the connection based on your identity and whether you can verify your identity by supplying the correct password. If not, the
server denies access to you completely. Otherwise, the server accepts the connection, and then enters Stage 2 and waits for requests.

Credential checking is performed using the three user table scope columns (Host, User, and Password). The server accepts the connection only if the Host and User columns in some user table row match the client host name and user name and the client supplies the password specified in that row. The rules for permissible Host and User values are given in Section 4.4, “Specifying Account Names”.

Your identity is based on two pieces of information:

- The client host from which you connect
- Your MySQL user name

If the User column value is nonblank, the user name in an incoming connection must match exactly. If the User value is blank, it matches any user name. If the user table row that matches an incoming connection has a blank user name, the user is considered to be an anonymous user with no name, not a user with the name that the client actually specified. This means that a blank user name is used for all further access checking for the duration of the connection (that is, during Stage 2).

The Password column can be blank. This is not a wildcard and does not mean that any password matches. It means that the user must connect without specifying a password. If the server authenticates a client using a plugin, the authentication method that the plugin implements may or may not use the password in the Password column. In this case, it is possible that an external password is also used to authenticate to the MySQL server.

Nonblank Password values in the user table represent encrypted passwords. MySQL does not store passwords as cleartext for anyone to see. Rather, the password supplied by a user who is attempting to connect is encrypted (using the PASSWORD() function). The encrypted password then is used during the connection process when checking whether the password is correct. This is done without the encrypted password ever traveling over the connection. See Section 4.1, “Account User Names and Passwords”.

From MySQL's point of view, the encrypted password is the real password, so you should never give anyone access to it. In particular, do not give nonadministrative users read access to tables in the mysql system database.

The following table shows how various combinations of User and Host values in the user table apply to incoming connections.

<table>
<thead>
<tr>
<th>User Value</th>
<th>Host Value</th>
<th>Permissible Connections</th>
</tr>
</thead>
<tbody>
<tr>
<td>'fred'</td>
<td>'h1.example.net'</td>
<td>fred, connecting from h1.example.net</td>
</tr>
<tr>
<td>''</td>
<td>'h1.example.net'</td>
<td>Any user, connecting from h1.example.net</td>
</tr>
<tr>
<td>'fred'</td>
<td>'%'</td>
<td>fred, connecting from any host</td>
</tr>
<tr>
<td>''</td>
<td>'%'</td>
<td>Any user, connecting from any host</td>
</tr>
<tr>
<td>'fred'</td>
<td>'%.example.net'</td>
<td>fred, connecting from any host in the example.net domain</td>
</tr>
<tr>
<td>'fred'</td>
<td>'x.example.%'</td>
<td>fred, connecting from x.example.net, x.example.com, x.example.edu, and so on; this is probably not useful</td>
</tr>
<tr>
<td>'fred'</td>
<td>'198.51.100.177'</td>
<td>fred, connecting from the host with IP address 198.51.100.177</td>
</tr>
<tr>
<td>'fred'</td>
<td>'198.51.100.%'</td>
<td>fred, connecting from any host in the 198.51.100 class C subnet</td>
</tr>
<tr>
<td>'fred'</td>
<td>'198.51.100.0/255.255.255.0'</td>
<td>Same as previous example</td>
</tr>
</tbody>
</table>
It is possible for the client host name and user name of an incoming connection to match more than one row in the `user` table. The preceding set of examples demonstrates this: Several of the entries shown match a connection from `h1.example.net` by `fred`.

When multiple matches are possible, the server must determine which of them to use. It resolves this issue as follows:

- Whenever the server reads the `user` table into memory, it sorts the rows.
- When a client attempts to connect, the server looks through the rows in sorted order.
- The server uses the first row that matches the client host name and user name.

The server uses sorting rules that order rows with the most-specific `Host` values first. Literal host names and IP addresses are the most specific. (The specificity of a literal IP address is not affected by whether it has a netmask, so `198.51.100.13` and `198.51.100.0/255.255.255.0` are considered equally specific.) The pattern `'*'` means "any host" and is least specific. The empty string `''` also means "any host" but sorts after `'*'`. Rows with the same `Host` value are ordered with the most-specific `User` values first (a blank `User` value means "any user" and is least specific). For rows with equally-specific `Host` and `User` values, the order is nondeterministic.

To see how this works, suppose that the `user` table looks like this:

```
<table>
<thead>
<tr>
<th>Host</th>
<th>User</th>
<th>...</th>
</tr>
</thead>
<tbody>
<tr>
<td>%</td>
<td>root</td>
<td>...</td>
</tr>
<tr>
<td>%</td>
<td>jeffrey</td>
<td>...</td>
</tr>
<tr>
<td>localhost</td>
<td>root</td>
<td>...</td>
</tr>
<tr>
<td>localhost</td>
<td></td>
<td>...</td>
</tr>
</tbody>
</table>
```

When the server reads the table into memory, it sorts the rows using the rules just described. The result after sorting looks like this:

```
<table>
<thead>
<tr>
<th>Host</th>
<th>User</th>
<th>...</th>
</tr>
</thead>
<tbody>
<tr>
<td>localhost</td>
<td>root</td>
<td>...</td>
</tr>
<tr>
<td>localhost</td>
<td></td>
<td>...</td>
</tr>
<tr>
<td>%</td>
<td>jeffrey</td>
<td>...</td>
</tr>
<tr>
<td>%</td>
<td>root</td>
<td>...</td>
</tr>
</tbody>
</table>
```

When a client attempts to connect, the server looks through the sorted rows and uses the first match found. For a connection from `localhost` by `jeffrey`, two of the rows from the table match: the one with `Host` and `User` values of `'localhost'` and `''`, and the one with values of `'%'` and `'jeffrey'`. The `'localhost'` row appears first in sorted order, so that is the one the server uses.

Here is another example. Suppose that the `user` table looks like this:

```
<table>
<thead>
<tr>
<th>Host</th>
<th>User</th>
<th>...</th>
</tr>
</thead>
<tbody>
<tr>
<td>%</td>
<td>jeffrey</td>
<td>...</td>
</tr>
<tr>
<td>h1.example.net</td>
<td></td>
<td>...</td>
</tr>
</tbody>
</table>
```

The sorted table looks like this:

```
<table>
<thead>
<tr>
<th>Host</th>
<th>User</th>
<th>...</th>
</tr>
</thead>
</table>
```

51
A connection by `jeffrey` from `h1.example.net` is matched by the first row, whereas a connection by `jeffrey` from any host is matched by the second.

**Note**

It is a common misconception to think that, for a given user name, all rows that explicitly name that user are used first when the server attempts to find a match for the connection. This is not true. The preceding example illustrates this, where a connection from `h1.example.net` by `jeffrey` is first matched not by the row containing `'jeffrey'` as the `User` column value, but by the row with no user name. As a result, `jeffrey` is authenticated as an anonymous user, even though he specified a user name when connecting.

If you are able to connect to the server, but your privileges are not what you expect, you probably are being authenticated as some other account. To find out what account the server used to authenticate you, use the `CURRENT_USER()` function. (See Information Functions.) It returns a value in `user_name@host_name` format that indicates the `User` and `Host` values from the matching `user` table row. Suppose that `jeffrey` connects and issues the following query:

```sql
mysql> SELECT CURRENT_USER();
+----------------+
| CURRENT_USER() |
+----------------+
| @localhost     |
```

The result shown here indicates that the matching `user` table row had a blank `User` column value. In other words, the server is treating `jeffrey` as an anonymous user.

Another way to diagnose authentication problems is to print out the `user` table and sort it by hand to see where the first match is being made.

### 4.6 Access Control, Stage 2: Request Verification

After you establish a connection, the server enters Stage 2 of access control. For each request that you issue through that connection, the server determines what operation you want to perform, then checks whether you have sufficient privileges to do so. This is where the privilege columns in the grant tables come into play. These privileges can come from any of the `user`, `db`, `tables_priv`, `columns_priv`, or `procs_priv` tables. (You may find it helpful to refer to Section 4.3, “Grant Tables”, which lists the columns present in each grant table.)

The `user` table grants global privileges. The `user` table row for an account indicates the account privileges that apply on a global basis no matter what the default database is. For example, if the `user` table grants you the `DELETE` privilege, you can delete rows from any table in any database on the server host. It is wise to grant privileges in the `user` table only to people who need them, such as database administrators. For other users, leave all privileges in the `user` table set to `'N'` and grant privileges at more specific levels only (for particular databases, tables, columns, or routines).

The `db` table grants database-specific privileges. Values in the scope columns of this table can take the following forms:

- A blank `User` value matches the anonymous user. A nonblank value matches literally; there are no wildcards in user names.
- The wildcard characters `%` and `_` can be used in the `Host` and `Db` columns. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator. If you want to use either character literally when granting privileges, you must escape it with a backslash. For example,
to include the underscore character (\_) as part of a database name, specify it as \_ in the GRANT statement.

- A '%\%' or blank Host value means “any host.”
- A '%\%' or blank Db value means “any database.”

The server reads the db table into memory and sorts it at the same time that it reads the user table. The server sorts the db table based on the Host, Db, and User scope columns. As with the user table, sorting puts the most-specific values first and least-specific values last, and when the server looks for matching rows, it uses the first match that it finds.

The tables_priv, columnsPriv, and procs_priv tables grant table-specific, column-specific, and routine-specific privileges. Values in the scope columns of these tables can take the following forms:

- The wildcard characters % and _ can be used in the Host column. These have the same meaning as for pattern-matching operations performed with the LIKE operator.
- A '%\%' or blank Host value means “any host.”
- The Db, Table_name, Column_name, and Routine_name columns cannot contain wildcards or be blank.

The server sorts the tables_priv, columnsPriv, and procs_priv tables based on the Host, Db, and User columns. This is similar to db table sorting, but simpler because only the Host column can contain wildcards.

The server uses the sorted tables to verify each request that it receives. For requests that require administrative privileges such as SHUTDOWN or RELOAD, the server checks only the user table row because that is the only table that specifies administrative privileges. The server grants access if the row permits the requested operation and denies access otherwise. For example, if you want to execute mysqladmin shutdown but your user table row does not grant the SHUTDOWN privilege to you, the server denies access without even checking the db table. (The latter table contains no Shutdown_priv column, so there is no need to check it.)

For database-related requests (INSERT, UPDATE, and so on), the server first checks the user's global privileges in the user table row. If the row permits the requested operation, access is granted. If the global privileges in the user table are insufficient, the server determines the user's database-specific privileges from the db table:

The server looks in the db table for a match on the Host, Db, and User columns. The Host and User columns are matched to the connecting user's host name and MySQL user name. The Db column is matched to the database that the user wants to access. If there is no row for the Host and User, access is denied.

After determining the database-specific privileges granted by the db table rows, the server adds them to the global privileges granted by the user table. If the result permits the requested operation, access is granted. Otherwise, the server successively checks the user's table and column privileges in the tables_priv and columns_priv tables, adds those to the user's privileges, and permits or denies access based on the result. For stored-routine operations, the server uses the procs_priv table rather than tables_priv and columns_priv.

Expressed in boolean terms, the preceding description of how a user's privileges are calculated may be summarized like this:

```
global privileges
OR (database privileges AND host privileges)
OR table privileges
OR column privileges
OR routine privileges
```
Adding Accounts, Assigning Privileges, and Dropping Accounts

It may not be apparent why, if the global privileges are initially found to be insufficient for the requested operation, the server adds those privileges to the database, table, and column privileges later. The reason is that a request might require more than one type of privilege. For example, if you execute an `INSERT INTO ... SELECT` statement, you need both the `INSERT` and the `SELECT` privileges. Your privileges might be such that the `user` table row grants one privilege global and the `db` table row grants the other specifically for the relevant database. In this case, you have the necessary privileges to perform the request, but the server cannot tell that from either your global or database privileges alone. It must make an access-control decision based on the combined privileges.

4.7 Adding Accounts, Assigning Privileges, and Dropping Accounts

To manage MySQL accounts, use the SQL statements intended for that purpose:

- `CREATE USER` and `DROP USER` create and remove accounts.
- `GRANT` and `REVOKE` assign privileges to and revoke privileges from accounts.
- `SHOW GRANTS` displays account privilege assignments.

Account-management statements cause the server to make appropriate modifications to the underlying grant tables, which are discussed in Section 4.3, “Grant Tables”.

**Note**

Direct modification of grant tables using statements such as `INSERT`, `UPDATE`, or `DELETE` is discouraged and done at your own risk. The server is free to ignore rows that become malformed as a result of such modifications.

As of MySQL 5.6.36, for any operation that modifies a grant table, the server checks whether the table has the expected structure and produces an error if not. `mysql_upgrade` must be run to update the tables to the expected structure.

Another option for creating accounts is to use the GUI tool MySQL Workbench. Also, several third-party programs offer capabilities for MySQL account administration. `phpMyAdmin` is one such program.

This section discusses the following topics:

- Creating Accounts and Granting Privileges
- Checking Account Privileges
- Revoking Account Privileges
- Dropping Accounts

For additional information about the statements discussed here, see Account Management Statements.

Creating Accounts and Granting Privileges

The following examples show how to use the `mysql` client program to set up new accounts. These examples assume that the MySQL `root` account has the `CREATE USER` privilege and all privileges that it grants to other accounts.

At the command line, connect to the server as the MySQL `root` user, supplying the appropriate password at the password prompt:

```
shell> mysql -u root -p
Enter password: (enter root password here)
```
After connecting to the server, you can add new accounts. The following example uses `CREATE USER` and `GRANT` statements to set up four accounts (where you see 'password', substitute an appropriate password):

```
CREATE USER 'finley'@'localhost'
    IDENTIFIED BY 'password';
GRANT ALL
    ON *.*
    TO 'finley'@'localhost'
    WITH GRANT OPTION;
CREATE USER 'finley'@'%.example.com'
    IDENTIFIED BY 'password';
GRANT ALL
    ON *.*
    TO 'finley'@'%.example.com'
    WITH GRANT OPTION;
CREATE USER 'admin'@'localhost'
    IDENTIFIED BY 'password';
GRANT RELOAD,PROCESS
    ON *.*
    TO 'admin'@'localhost';
CREATE USER 'dummy'@'localhost';
```

The accounts created by those statements have the following properties:

- Two accounts have a user name of `finley`. Both are superuser accounts with full global privileges to do anything. The `finley'@'localhost'` account can be used only when connecting from the local host. The `finley'@'%.example.com` account uses the '%' wildcard in the host part, so it can be used to connect from any host in the `example.com` domain.

- The `finley'@'localhost'` account is necessary if there is an anonymous-user account for `localhost`. Without the `finley'@'localhost'` account, that anonymous-user account takes precedence when `finley` connects from the local host and `finley` is treated as an anonymous user. The reason for this is that the anonymous-user account has a more specific Host column value than the `finley'@'%'` account and thus comes earlier in the user table sort order. (For information about user table sorting, see Section 4.5, 'Access Control, Stage 1: Connection Verification'.)

- The `admin'@'localhost'` account can be used only by `admin` to connect from the local host. It is granted the global `RELOAD` and `PROCESS` administrative privileges. These privileges enable the `admin` user to execute the `mysqladmin reload`, `mysqladmin refresh`, and `mysqladmin flush-xxx` commands, as well as `mysqladmin processlist`. No privileges are granted for accessing any databases. You could add such privileges using `GRANT` statements.

- The `dummy'@'localhost'` account has no password (which is insecure and not recommended). This account can be used only to connect from the local host. No privileges are granted. It is assumed that you will grant specific privileges to the account using `GRANT` statements.

The previous example grants privileges at the global level. The next example creates three accounts and grants them access at lower levels; that is, to specific databases or objects within databases. Each account has a user name of `custom`, but the host name parts differ:

```
CREATE USER 'custom'@'localhost'
    IDENTIFIED BY 'password';
GRANT ALL
    ON bankaccount.*
    TO 'custom'@'localhost';
CREATE USER 'custom'@'host47.example.com'
    IDENTIFIED BY 'password';
GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP
    ON expenses.*
    TO 'custom'@'host47.example.com';
CREATE USER 'custom'@'%.example.com'
    IDENTIFIED BY 'password';
```
Checking Account Privileges

The three accounts can be used as follows:

- The 'custom'@'localhost' account has all database-level privileges to access the bankaccount database. The account can be used to connect to the server only from the local host.
- The 'custom'@'host47.example.com' account has specific database-level privileges to access the expenses database. The account can be used to connect to the server only from the host host47.example.com.
- The 'custom'@'%.example.com' account has specific table-level privileges to access the addresses table in the customer database, from any host in the example.com domain. The account can be used to connect to the server from all machines in the domain due to use of the % wildcard character in the host part of the account name.

Checking Account Privileges

To see the privileges for an account, use SHOW GRANTS:

```
mysql> SHOW GRANTS FOR 'admin'@'localhost';
+-----------------------------------------------------+
| Grants for admin@localhost                          |
| GRANT RELOAD, PROCESS ON *.* TO 'admin'@'localhost' |
+-----------------------------------------------------+
```

Revoking Account Privileges

To revoke account privileges, use the REVOKE statement. Privileges can be revoked at different levels, just as they can be granted at different levels.

Revoke global privileges:

```
REVOKE ALL
ON *.*
FROM 'finley'@'%.example.com';
REVOKE RELOAD
ON *.*
FROM 'admin'@'localhost';
```

Revoke database-level privileges:

```
REVOKE CREATE,DROP
ON expenses.*
FROM 'custom'@'host47.example.com';
```

Revoke table-level privileges:

```
REVOKE INSERT,UPDATE,DELETE
ON customer.addresses
FROM 'custom'@'%.example.com';
```

To check the effect of privilege revocation, use SHOW GRANTS:

```
mysql> SHOW GRANTS FOR 'admin'@'localhost';
+---------------------------------------------+
| Grants for admin@localhost                  |
| GRANT PROCESS ON *.* TO 'admin'@'localhost' |
+---------------------------------------------+
```
### Dropping Accounts

To remove an account, use the `DROP USER` statement. For example, to drop some of the accounts created previously:

```
DROP USER 'finley'@'localhost';
DROP USER 'finley'@'%.example.com';
DROP USER 'admin'@'localhost';
DROP USER 'dummy'@'localhost';
```

### 4.8 When Privilege Changes Take Effect

If the `mysqld` server is started without the `--skip-grant-tables` option, it reads all grant table contents into memory during its startup sequence. The in-memory tables become effective for access control at that point.

If you modify the grant tables indirectly using an account-management statement, the server notices these changes and loads the grant tables into memory again immediately. Account-management statements are described in Account Management Statements. Examples include `GRANT`, `REVOKE`, `SET PASSWORD`, and `RENAME USER`.

If you modify the grant tables directly using statements such as `INSERT`, `UPDATE`, or `DELETE` (which is not recommended), the changes have no effect on privilege checking until you either tell the server to reload the tables or restart it. Thus, if you change the grant tables directly but forget to reload them, the changes have no effect until you restart the server. This may leave you wondering why your changes seem to make no difference!

To tell the server to reload the grant tables, perform a flush-privileges operation. This can be done by issuing a `FLUSH PRIVILEGES` statement or by executing a `mysqladmin flush-privileges` or `mysqladmin reload` command.

A grant table reload affects privileges for each existing client session as follows:

- Table and column privilege changes take effect with the client's next request.
- Database privilege changes take effect the next time the client executes a `USE db_name` statement.

**Note**

Client applications may cache the database name; thus, this effect may not be visible to them without actually changing to a different database.

- Global privileges and passwords are unaffected for a connected client. These changes take effect only in sessions for subsequent connections.

If the server is started with the `--skip-grant-tables` option, it does not read the grant tables or implement any access control. Any user can connect and perform any operation, which is insecure. To cause a server thus started to read the tables and enable access checking, flush the privileges.

### 4.9 Assigning Account Passwords

Required credentials for clients that connect to the MySQL server can include a password. This section describes how to assign passwords for MySQL accounts.

MySQL stores credentials in the `user` table in the `mysql` system database. Operations that assign or modify passwords are permitted only to users with the `CREATE USER` privilege, or, alternatively, privileges for the `mysql` database (`INSERT` privilege to create new accounts, `UPDATE` privilege to modify existing accounts). If the `read_only` system variable is enabled, use of account-modification statements such as `CREATE USER` or `SET PASSWORD` additionally requires the `SUPER` privilege.
Assigning Account Passwords

The discussion here summarizes syntax only for the most common password-assignment statements. For complete details on other possibilities, see CREATE USER Syntax, GRANT Syntax, and SET PASSWORD Syntax.

MySQL uses plugins to perform client authentication; see Section 4.11, “Pluggable Authentication”. In password-assigning statements, the authentication plugin associated with an account performs any hashing required of a cleartext password specified. This enables MySQL to obfuscate passwords prior to storing them in the mysql.user system table. For most statements described here, MySQL automatically hashes the password specified. An exception is SET PASSWORD ... = PASSWORD('auth_string'), for which you use the PASSWORD() function explicitly to hash the password. There is also syntax for CREATE USER, GRANT, and SET PASSWORD that permits hashed values to be specified literally. For details, see the descriptions of those statements.

To assign a password when you create a new account, use CREATE USER and include an IDENTIFIED BY clause:

```sql
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';
```

CREATE USER also supports syntax for specifying the account authentication plugin. See CREATE USER Syntax.

To assign or change a password for an existing account, use SET PASSWORD with the PASSWORD() function:

```sql
SET PASSWORD FOR 'jeffrey'@'localhost' = PASSWORD('password');
```

If you are not connected as an anonymous user, you can change your own password by omitting the FOR clause:

```sql
SET PASSWORD = PASSWORD('password');
```

The PASSWORD() function hashes the password using the hashing method determined by the value of the old_passwords system variable value. If SET PASSWORD rejects the hashed password value returned by PASSWORD() as not being in the correct format, it may be necessary to change old_passwords to change the hashing method. See SET PASSWORD Syntax.

Use a GRANT USAGE statement at the global level (ON *.*) to change an account password without affecting the account's current privileges:

```sql
GRANT USAGE ON *.* TO 'jeffrey'@'localhost' IDENTIFIED BY 'password';
```

To change an account password from the command line, use the mysqladmin command:

```
mysqladmin -u user_name -h host_name password "password"
```

The account for which this command sets the password is the one with a row in the mysql.user system table that matches user_name in the User column and the client host from which you connect in the Host column.

**Warning**

Setting a password using mysqladmin should be considered insecure. On some systems, your password becomes visible to system status programs such as ps that may be invoked by other users to display command lines. MySQL clients typically overwrite the command-line password argument with zeros during their initialization sequence. However, there is still a brief interval during which the value is visible. Also, on some systems this overwriting strategy is
ineffective and the password remains visible to `ps`. (SystemV Unix systems and perhaps others are subject to this problem.)

If you are using MySQL Replication, be aware that, currently, a password used by a replication slave as part of a `CHANGE MASTER TO` statement is effectively limited to 32 characters in length; if the password is longer, any excess characters are truncated. This is not due to any limit imposed by the MySQL Server generally, but rather is an issue specific to MySQL Replication. (For more information, see Bug #43439.)

4.10 Server Handling of Expired Passwords

MySQL 5.6 introduces password-expiration capability, which enables database administrators to require that users reset their password. The immediately following discussion describes how password expiration works currently. Later, the development of this capability is detailed as it occurred over several versions, as background to help you understand what features are available when. However, to ensure that you can take advantage of all features, use the most recent available version of MySQL if possible.

- How Password Expiration Works
- Development of Password-Expiration Capability

How Password Expiration Works

The `ALTER USER` statement enables account password expiration. For example:

```
ALTER USER 'myuser'@'localhost' PASSWORD EXPIRE;
```

For each connection that uses an account with an expired password, the server either disconnects the client or restricts the client to “sandbox mode,” in which the server permits the client to perform only those operations necessary to reset the expired password. Which action is taken by the server depends on both client and server settings, as discussed later.

If the server disconnects the client, it returns an `ER_MUST_CHANGE_PASSWORD_LOGIN` error:

```
shell> mysql -u myuser -p
Password: ******
ERROR 1862 (HY000): Your password has expired. To log in you must change it using a client that supports expired passwords.
```

If the server restricts the client to sandbox mode, these operations are permitted within the client session:

- The client can reset the account password with `SET PASSWORD`. After that has been done, the server restores normal access for the session, as well as for subsequent connections that use the account.

  **Note**

  Although it is possible to “reset” an expired password by setting it to its current value, it is preferable, as a matter of good policy, to choose a different password.

- The client can use the `SET` statement. This might be necessary prior to using `SET PASSWORD` to reset the password if the account uses an authentication plugin for which the `old_passwords` system variable must first be set to a nondefault value to perform password hashing in a specific way.

For any operation not permitted within the session, the server returns an `ER_MUST_CHANGE_PASSWORD` error:
How Password Expiration Works

mysql> USE performance_schema;
ERROR 1820 (HY000): You must SET PASSWORD before executing this statement
mysql> SELECT 1;
ERROR 1820 (HY000): You must SET PASSWORD before executing this statement

That is what normally happens for interactive invocations of the `mysql` client because by default such invocations are put in sandbox mode. To resume normal functioning, select a new password.

For noninteractive invocations of the `mysql` client (for example, in batch mode), the server normally disconnects the client if the password is expired. To permit noninteractive `mysql` invocations to stay connected so that the password can be changed (using the statements permitted in sandbox mode), add the `--connect-expired-password` option to the `mysql` command.

As mentioned previously, whether the server disconnects an expired-password client or restricts it to sandbox mode depends on a combination of client and server settings. The following discussion describes the relevant settings and how they interact.

### Note

This discussion applies only for accounts with expired passwords. If a client connects using a nonexpired password, the server handles the client normally.

On the client side, a given client indicates whether it can handle sandbox mode for expired passwords. For clients that use the C client library, there are two ways to do this:

- **Pass the** `MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS` **flag to** `mysql_options()` **prior to connecting**:

```c
my_bool arg = 1;
mysql_options(mysql,
               MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS,
               &arg);
```

This is the technique used within the `mysql` client, which enables `MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS` if invoked interactively or with the `--connect-expired-password` option.

- **Pass the** `CLIENT_CAN_HANDLE_EXPIRED_PASSWORDS` **flag to** `mysql_real_connect()` **at connect time**:

```c
MYSQL mysql;
mypsql_init(&mysql);
if (!mysql_real_connect(&mysql,
                       host, user, password, db,
                       port, unix_socket,
                       CLIENT_CAN_HANDLE_EXPIRED_PASSWORDS))
{
    ... handle error ...
}
```

Other MySQL Connectors have their own conventions for indicating readiness to handle sandbox mode. See the documentation for the Connector in which you are interested.

On the server side, if a client indicates that it can handle expired passwords, the server puts it in sandbox mode.

If a client does not indicate that it can handle expired passwords (or uses an older version of the client library that cannot so indicate), the server action depends on the value of the `disconnect_on_expired_password` system variable:

- **If** `disconnect_on_expired_password` **is enabled** (the default), the server disconnects the client with an `ER_MUST_CHANGE_PASSWORD_LOGIN` error.
• If `disconnect_on_expired_password` is disabled, the server puts the client in sandbox mode.

**Development of Password-Expiration Capability**

The following timeline describes the versions in which various password-expiration features were added.

• MySQL 5.6.6: Initial implementation of password expiration.

  The `password_expired` column is introduced in the `mysql.user` system table to enable DBAs to expire account passwords. The column default value is 'N' (not expired).

  The `ALTER USER ... PASSWORD EXPIRE` statement is introduced as the SQL interface for setting the `password_expired` column to 'Y'.

  Connections that use an account with an expired password enter “sandbox mode” that permits only `SET PASSWORD` statements. For other statements, the server returns an `ER_MUST_CHANGE_PASSWORD` error. The intent is to force the client to reset the password before the server permits any other operations. `SET PASSWORD` resets the account password and sets `password_expired` to 'N'.

  A bug in the initial implementation is that `ALTER USER` sets the `Password` column in the `mysql.user` system table to the empty string. The implication is that users should wait until MySQL 5.6.7 to use this statement.

• MySQL 5.6.7: `ALTER USER` is fixed to not set the `Password` column to the empty string.

• MySQL 5.6.8: `ALTER USER` can be used as a prepared statement.

  `mysqladmin password` is made capable of resetting expired passwords for accounts that use the `mysql_native_password` or `mysql_old_password` authentication plugin.

  Sandbox mode is changed to permit clients to execute `SET` statements in addition to `SET PASSWORD` statements. For other statements, the server returns an `ER_MUST_CHANGE_PASSWORD` error. The intent is to force the client to reset the password before the server permits any other operations. `SET PASSWORD` resets the account password and sets `password_expired` to 'N'.

  It also broke some Connectors, which use `SET` extensively at connect time to initialize the session environment.

• MySQL 5.6.9: Sandbox mode is changed to permit `SET PASSWORD` only if the account named in the statement matches the account the client authenticated as.

• MySQL 5.6.10: Sandbox mode is changed to permit better control over how the server handles client connections for accounts with expired passwords, and to permit clients to signal whether they are capable of handling expired passwords:

  • The `disconnect_on_expired_password` system variable is added, which controls how the server treats expired-password accounts.

  • Two flags are added to the C API client library: `MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS` for `mysql_options()` and `CLIENT_CAN_HANDLE_EXPIRED_PASSWORDS` for `mysql_real_connect()`. Each flag enables a client program to indicate whether it can handle sandbox mode for accounts with expired passwords.

  `MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS` is enabled for `mysqltest` unconditionally, for `mysql` in interactive mode, and for `mysqladmin` if the first command is `password`.

  • The `ER_MUST_CHANGE_PASSWORD_LOGIN` error is added. The server returns this error when it disconnects a client that has an expired password.

• MySQL 5.6.12: The `--connect-expired-password` option is added to the `mysql` client to enable password-change statement execution in batch mode for accounts with an expired password.
Concurrent with these changes to sandbox mode in MySQL Server and the C API client library, work begins to modify Connectors for conformance to the changes.

4.11 Pluggable Authentication

When a client connects to the MySQL server, the server uses the user name provided by the client and the client host to select the appropriate account row from the `mysql.user` system table. The server then authenticates the client, determining from the account row which authentication plugin applies to the client:

• If the server cannot find the plugin, an error occurs and the connection attempt is rejected. Otherwise, if the account row specifies a plugin, the server invokes it to authenticate the user.

• If the account row specifies no plugin name, the server authenticates the account using either the `mysql_native_password` or `mysql_old_password` plugin, depending on whether the password hash value in the `Password` column used native hashing or the older pre-4.1 hashing method. Clients must match the password in the `Password` column of the account row.

The plugin returns a status to the server indicating whether the user provided the correct password and is permitted to connect.

Pluggable authentication enables these important capabilities:

• **Choice of authentication methods.** Pluggable authentication makes it easy for DBAs to choose and change the authentication method used for individual MySQL accounts.

• **External authentication.** Pluggable authentication makes it possible for clients to connect to the MySQL server with credentials appropriate for authentication methods that store credentials elsewhere than in the `mysql.user` system table. For example, plugins can be created to use external authentication methods such as PAM, Windows login IDs, LDAP, or Kerberos.

• **Proxy users:** If a user is permitted to connect, an authentication plugin can return to the server a user name different from the name of the connecting user, to indicate that the connecting user is a proxy for another user (the proxied user). While the connection lasts, the proxy user is treated, for purposes of access control, as having the privileges of the proxied user. In effect, one user impersonates another. For more information, see Section 4.12, “Proxy Users”.

Note

If you start the server with the `--skip-grant-tables` option, authentication plugins are not used even if loaded because the server performs no client authentication and permits any client to connect. Because this is insecure, you might want to use `--skip-grant-tables` in conjunction with `--skip-networking` to prevent remote clients from connecting.

• Available Authentication Plugins

• Authentication Plugin Usage

• Restrictions on Pluggable Authentication

Available Authentication Plugins

MySQL 5.6 provides these authentication plugins:

• Plugins that perform native authentication; that is, authentication based on the password hashing methods in use from before the introduction of pluggable authentication in MySQL. The `mysql_native_password` plugin implements authentication based on the native password hashing method. The `mysql_old_password` plugin implements native authentication based on the older (pre-4.1) password hashing method (and is now deprecated). See Section 6.1.1, “Native Pluggable Authentication”, and Section 6.1.2, “Old Native Pluggable Authentication”. Native
authentication using mysql_native_password is the default for new accounts, unless the --default-authentication-plugin option is set otherwise at server startup.

- A plugin that performs authentication using SHA-256 password hashing. This is stronger encryption than that available with native authentication. See Section 6.1.4, “SHA-256 Pluggable Authentication”.

- A client-side plugin that sends the password to the server without hashing or encryption. This plugin is used in conjunction with server-side plugins that require access to the password exactly as provided by the client user. See Section 6.1.5, “Client-Side Cleartext Pluggable Authentication”.

- A plugin that performs external authentication using PAM (Pluggable Authentication Modules), enabling MySQL Server to use PAM to authenticate MySQL users. This plugin supports proxy users as well. See Section 6.1.6, “PAM Pluggable Authentication”.

- A plugin that performs external authentication on Windows, enabling MySQL Server to use native Windows services to authenticate client connections. Users who have logged in to Windows can connect from MySQL client programs to the server based on the information in their environment without specifying an additional password. This plugin supports proxy users as well. See Section 6.1.7, “Windows Pluggable Authentication”.

- A plugin that authenticates clients that connect from the local host through the Unix socket file. See Section 6.1.8, “Socket Peer-Credential Pluggable Authentication”.

- A test plugin that checks account credentials and logs success or failure to the server error log. This plugin is intended for testing and development purposes, and as an example of how to write an authentication plugin. See Section 6.1.9, “Test Pluggable Authentication”.

Note
For information about current restrictions on the use of pluggable authentication, including which connectors support which plugins, see Restrictions on Pluggable Authentication.

Third-party connector developers should read that section to determine the extent to which a connector can take advantage of pluggable authentication capabilities and what steps to take to become more compliant.

If you are interested in writing your own authentication plugins, see Writing Authentication Plugins.

Authentication Plugin Usage

This section provides general instructions for installing and using authentication plugins. For instructions specific to a given plugin, see the section that describes that plugin under Section 6.1, “Authentication Plugins”.

In general, pluggable authentication uses a pair of corresponding plugins on the server and client sides, so you use a given authentication method like this:

- If necessary, install the plugin library or libraries containing the appropriate plugins. On the server host, install the library containing the server-side plugin, so that the server can use it to authenticate client connections. Similarly, on each client host, install the library containing the client-side plugin for use by client programs. Authentication plugins that are built in need not be installed.

- For each MySQL account that you create, specify the appropriate server-side plugin to use for authentication. If the account is to use the default authentication plugin, the account-creation statement need not specify the plugin explicitly. The --default-authentication-plugin option configures the default authentication plugin.

- When a client connects, the server-side plugin tells the client program which client-side plugin to use for authentication.
In the case that an account uses an authentication method that is the default for both the server and the client program, the server need not communicate to the client which client-side plugin to use, and a round trip in client/server negotiation can be avoided. This is true for accounts that use native MySQL authentication.

For standard MySQL clients such as mysql and mysqladmin, the `--default-auth=plugin_name` option can be specified on the command line as a hint about which client-side plugin the program can expect to use, although the server will override this if the server-side plugin associated with the user account requires a different client-side plugin.

If the client program does not find the client-side plugin library file, specify a `--plugin-dir=dir_name` option to indicate the plugin library directory location.

Restrictions on Pluggable Authentication

The first part of this section describes general restrictions on the applicability of the pluggable authentication framework described at Section 4.11, “Pluggable Authentication”. The second part describes how third-party connector developers can determine the extent to which a connector can take advantage of pluggable authentication capabilities and what steps to take to become more compliant.

The term “native authentication” used here refers to authentication against passwords stored in the Password column of the mysql.user system table. This is the same authentication method provided by older MySQL servers, before pluggable authentication was implemented. “Windows native authentication” refers to authentication using the credentials of a user who has already logged in to Windows, as implemented by the Windows Native Authentication plugin (“Windows plugin” for short).

- General Pluggable Authentication Restrictions
- Pluggable Authentication and Third-Party Connectors

General Pluggable Authentication Restrictions

- **Connector/C, Connector/C++:** Clients that use these connectors can connect to the server only through accounts that use native authentication.

  Exception: A connector supports pluggable authentication if it was built to link to `libmysqlclient` dynamically (rather than statically) and it loads the current version of `libmysqlclient` if that version is installed, or if the connector is recompiled from source to link against the current `libmysqlclient`.

- **Connector/NET:** Clients that use Connector/NET can connect to the server through accounts that use native authentication or Windows native authentication.

- **Connector/PHP:** Clients that use this connector can connect to the server only through accounts that use native authentication, when compiled using the MySQL native driver for PHP (`mysqlnd`).

- **Windows native authentication:** Connecting through an account that uses the Windows plugin requires Windows Domain setup. Without it, NTLM authentication is used and then only local connections are possible; that is, the client and server must run on the same computer.

- **Proxy users:** Proxy user support is available to the extent that clients can connect through accounts authenticated with plugins that implement proxy user capability (that is, plugins that can return a user name different from that of the connecting user). For example, the PAM and Windows plugins support proxy users. The native authentication plugins do not.

- **Replication:** Before MySQL 5.6.4, replication slaves can connect to the master server only through master accounts that use native authentication. As of 5.6.4, replication slaves can also connect through master accounts that use nonnative authentication if the required client-side plugin is available. If the plugin is built into `libmysqlclient`, it is available by default. Otherwise, the
plugin must be installed on the slave side in the directory named by the slave `plugin_dir` system variable.

- **FEDERATED tables:** A FEDERATED table can access the remote table only through accounts on the remote server that use native authentication.

### Pluggable Authentication and Third-Party Connectors

Third-party connector developers can use the following guidelines to determine readiness of a connector to take advantage of pluggable authentication capabilities and what steps to take to become more compliant:

- An existing connector to which no changes have been made uses native authentication and clients that use the connector can connect to the server only through accounts that use native authentication. However, you should test the connector against a recent version of the server to verify that such connections still work without problem.

Exception: A connector might work with pluggable authentication without any changes if it links to `libmysqlclient` dynamically (rather than statically) and it loads the current version of `libmysqlclient` if that version is installed.

- To take advantage of pluggable authentication capabilities, a connector that is `libmysqlclient`-based should be relinked against the current version of `libmysqlclient`. This enables the connector to support connections through accounts that require client-side plugins now built into `libmysqlclient` (such as the cleartext plugin needed for PAM authentication and the Windows plugin needed for Windows native authentication). Linking with a current `libmysqlclient` also enables the connector to access client-side plugins installed in the default MySQL plugin directory (typically the directory named by the default value of the local server's `plugin_dir` system variable).

If a connector links to `libmysqlclient` dynamically, it must be ensured that the newer version of `libmysqlclient` is installed on the client host and that the connector loads it at runtime.

- Another way for a connector to support a given authentication method is to implement it directly in the client/server protocol. Connector/NET uses this approach to provide support for Windows native authentication.

- If a connector should be able to load client-side plugins from a directory different from the default plugin directory, it must implement some means for client users to specify the directory. Possibilities for this include a command-line option or environment variable from which the connector can obtain the directory name. Standard MySQL client programs such as `mysql` and `mysqladmin` implement a `--plugin-dir` option. See also C API Client Plugin Functions.

- Proxy user support by a connector depends, as described earlier in this section, on whether the authentication methods that it supports permit proxy users.

### 4.12 Proxy Users

The MySQL server authenticates client connections using authentication plugins. The plugin that authenticates a given connection may request that the connecting (external) user be treated as a different user for privilege-checking purposes. This enables the external user to be a proxy for the second user; that is, to assume the privileges of the second user:

- The external user is a “proxy user” (a user who can impersonate or become known as another user).
- The second user is a “proxied user” (a user whose identity and privileges can be assumed by a proxy user).

This section describes how the proxy user capability works. For general information about authentication plugins, see Section 4.11, “Pluggable Authentication”. For information about specific
plugins, see Section 6.1, “Authentication Plugins”. For information about writing authentication plugins that support proxy users, see Implementing Proxy User Support in Authentication Plugins.

- Requirements for Proxy User Support
- Simple Proxy User Example
- Preventing Direct Login to Proxied Accounts
- Granting and Revoking the PROXY Privilege
- Default Proxy Users
- Default Proxy User and Anonymous User Conflicts
- Proxy User System Variables

**Requirements for Proxy User Support**

For proxying to occur for a given authentication plugin, these conditions must be satisfied:

- The plugin must support proxying.
- The account for the external proxy user must be set up to be authenticated by the plugin. Use the `CREATE USER` or `GRANT` statement to associate an account with an authentication plugin.
- The account for the proxied user must exist and be granted the privileges to be assumed by the proxy user. Use the `CREATE USER` and `GRANT` statements for this.
- Normally, the proxied user is configured so that it can be used only in proxying scenarios and not for direct logins.
- The proxy user account must have the `PROXY` privilege for the proxied account. Use the `GRANT` statement for this.
- For a client connecting to the proxy account to be treated as a proxy user, the authentication plugin must return a user name different from the client user name, to indicate the user name of the proxied account that defines the privileges to be assumed by the proxy user.

The proxy mechanism permits mapping only the external client user name to the proxied user name. There is no provision for mapping host names:

- When a client connects to the server, the server determines the proper account based on the user name passed by the client program and the host from which the client connects.
- If that account is a proxy account, the server attempts to determine the appropriate proxied account by finding a match for a proxied account using the user name returned by the authentication plugin and the host name of the proxy account. The host name in the proxied account is ignored.

**Simple Proxy User Example**

Consider the following account definitions:

```sql
-- create proxy account
CREATE USER 'employee_ext'@'localhost'
    IDENTIFIED WITH my_auth_plugin
    AS 'my_auth_string';
-- create proxied account and grant its privileges
CREATE USER 'employee'@'localhost'
    IDENTIFIED BY 'employee_password';
GRANT ALL
    ON employees.*
    TO 'employee'@'localhost';
```
When a client connects as `employee_ext` from the local host, MySQL uses the plugin named `my_auth_plugin` to perform authentication. Suppose that `my_auth_plugin` returns a user name of `employee` to the server, based on the content of `my_auth_string` and perhaps by consulting some external authentication system. The name `employee` differs from `employee_ext`, so returning `employee` serves as a request to the server to treat the `employee_ext` external user, for purposes of privilege checking, as the `employee` local user.

In this case, `employee_ext` is the proxy user and `employee` is the proxied user.

The server verifies that proxy authentication for `employee` is possible for the `employee_ext` user by checking whether `employee_ext` (the proxy user) has the `PROXY` privilege for `employee` (the proxied user). If this privilege has not been granted, an error occurs. Otherwise, `employee_ext` assumes the privileges of `employee`. The server checks statements executed during the client session by `employee_ext` against the privileges granted to `employee`. In this case, `employee_ext` can access tables in the `employees` database.

To ensure that the proxied account, `employee`, cannot be used directly, do not tell anyone else its password. If you do not let anyone know the password for the account, clients cannot use it to connect directly to the MySQL server.

When proxying occurs, the `USER()` and `CURRENT_USER()` functions can be used to see the difference between the connecting user (the proxy user) and the account whose privileges apply during the current session (the proxied user). For the example just described, those functions return these values:

```
mysql> SELECT USER(), CURRENT_USER();
+------------------------+--------------------+
| USER()                 | CURRENT_USER()     |
+------------------------+--------------------+
| employee_ext@localhost | employee@localhost |
+------------------------+--------------------+
```

In the `CREATE USER` statement that creates the proxy user account, the `IDENTIFIED WITH` clause that names the proxy-supporting authentication plugin is optionally followed by an `AS 'auth_string'` clause specifying a string that the server passes to the plugin when the user connects. If present, the string provides information that helps the plugin determine how to map the proxy (external) client user name to a proxied user name. It is up to each plugin whether it requires the `AS` clause. If so, the format of the authentication string depends on how the plugin intends to use it. Consult the documentation for a given plugin for information about the authentication string values it accepts.

## Preventing Direct Login to Proxied Accounts

Proxied accounts generally are intended to be used only by means of proxy accounts. That is, clients connect using a proxy account, then are mapped onto and assume the privileges of the appropriate proxied user.

To ensure that a proxied account cannot be used directly, create the account with a password but do not tell anyone else the password. If you do not let anyone know the password for the account, clients cannot use it to connect directly to the MySQL server.

## Granting and Revoking the PROXY Privilege

The `PROXY` privilege is needed to enable an external user to connect as and have the privileges of another user. To grant this privilege, use the `GRANT` statement. For example:

```
GRANT PROXY ON 'proxied_user' TO 'proxy_user';
```
The statement creates a row in the `mysql.proxies_priv` grant table.

At connect time, `proxy_user` must represent a valid externally authenticated MySQL user, and `proxied_user` must represent a valid locally authenticated user. Otherwise, the connection attempt fails.

The corresponding `REVOKE` syntax is:

```
REVOKE PROXY ON 'proxied_user' FROM 'proxy_user';
```

MySQL `GRANT` and `REVOKE` syntax extensions work as usual. Examples:

```
-- grant PROXY to multiple accounts
GRANT PROXY ON 'a' TO 'b', 'c', 'd';
-- revoke PROXY from multiple accounts
REVOKE PROXY ON 'a' FROM 'b', 'c', 'd';
-- grant PROXY to an account and enable the account to grant
-- PROXY to the proxied account
GRANT PROXY ON 'a' TO 'd' WITH GRANT OPTION;
-- grant PROXY to default proxy account
GRANT PROXY ON 'a' TO '>'; 
```

The `PROXY` privilege can be granted in these cases:

- By a user that has `GRANT PROXY ... WITH GRANT OPTION` for `proxied_user`.
- By `proxied_user` for itself: The value of `USER()` must exactly match `CURRENT_USER()` and `proxied_user`, for both the user name and host name parts of the account name.

The initial `root` account created during MySQL installation has the `PROXY ... WITH GRANT OPTION` privilege for `''@''`, that is, for all users and all hosts. This enables `root` to set up proxy users, as well as to delegate to other accounts the authority to set up proxy users. For example, `root` can do this:

```
CREATE USER 'admin'@'localhost'
    IDENTIFIED BY 'admin_password';
GRANT PROXY
    ON '>'; TO 'admin'@'localhost'
    WITH GRANT OPTION;
```

Those statements create an `admin` user that can manage all `GRANT PROXY` mappings. For example, `admin` can do this:

```
GRANT PROXY ON sally TO joe;
```

### Default Proxy Users

To specify that some or all users should connect using a given authentication plugin, create a “blank” MySQL account with an empty user name and host name (`''@'''`), associate it with that plugin, and let the plugin return the real authenticated user name (if different from the blank user). Suppose that there exists a plugin named `ldap_auth` that implements LDAP authentication and maps connecting users onto either a developer or manager account. To set up proxying of users onto these accounts, use the following statements:

```
-- create default proxy account
CREATE USER ''@'IDENTIFIED WITH ldap_auth
AS 'O=Oracle, OU=MySQL';
-- create proxied accounts
CREATE USER 'developer'@'localhost'
```
IDENTIFIED BY 'developer_password';
CREATE USER 'manager'@'localhost'
    IDENTIFIED BY 'manager_password';
-- grant to default proxy account the
-- PROXY privilege for proxied accounts
GRANT PROXY
    ON 'manager'@'localhost'
    TO ''@'';
GRANT PROXY
    ON 'developer'@'localhost'
    TO ''@'';

As with proxied accounts created in previous examples, the password should be kept secret so that
clients cannot use the accounts to log in directly to the MySQL server.

Now assume that a client connects as follows:

shell> mysql --user=myuser --password ...
Enter password: myuser_password

The server will not find myuser defined as a MySQL user. But because there is a blank user account
('''@''') that matches the client user name and host name, the server authenticates the client against
that account: The server invokes the ldap_auth authentication plugin and passes myuser and
myuser_password to it as the user name and password.

If the ldap_auth plugin finds in the LDAP directory that myuser_password is not the correct
password for myuser, authentication fails and the server rejects the connection.

If the password is correct and ldap_auth finds that myuser is a developer, it returns the user name
developer to the MySQL server, rather than myuser: Returning a user name different from the client
user name of myuser signals to the server that it should treat myuser as a proxy. The server verifies
that ''@'' can authenticate as developer (because ''@'' has the PROXY privilege to do so) and
accepts the connection. The session proceeds with myuser having the privileges of the developer
proxied user. (These privileges should be set up by the DBA using GRANT statements, not shown.) The
USER() and CURRENT_USER() functions return these values:

mysql> SELECT USER(), CURRENT_USER();
+------------------ +-------------------+
| USER()           | CURRENT_USER()    |
| myuser@localhost | developer@localhost|
+------------------ +-------------------+

If the plugin instead finds in the LDAP directory that myuser is a manager, it returns manager as the
user name and the session proceeds with myuser having the privileges of the manager proxied user.

mysql> SELECT USER(), CURRENT_USER();
+------------------ +-------------------+
| USER()           | CURRENT_USER()    |
| myuser@localhost | manager@localhost |
+------------------ +-------------------+

For simplicity, external authentication cannot be multilevel: Neither the credentials for developer nor
those for manager are taken into account in the preceding example. However, they are still used if a
client tries to connect and authenticate directly as the developer or manager account, which is why
those proxied accounts should be protected against direct login (see Preventing Direct Login to Proxied
Accounts).

Default Proxy User and Anonymous User Conflicts

If you intend to create a default proxy user, check for other existing “match any user” accounts that take
precedence over the default proxy user because they can prevent that user from working as intended.
In the preceding discussion, the default proxy user account has '' in the host part, which matches any host. If you set up a default proxy user, take care to also check whether nonproxy accounts exist with the same user part and '%' in the host part, because '%' also matches any host, but has precedence over '' by the rules that the server uses to sort account rows internally (see Section 4.5, “Access Control, Stage 1: Connection Verification”).

Suppose that a MySQL installation includes these two accounts:

```
-- create default proxy account
CREATE USER ''@''
    IDENTIFIED WITH some_plugin
    AS 'some_auth_string';
-- create anonymous account
CREATE USER ''@%'
    IDENTIFIED BY 'anon_user_password';
```

The first account ('''@''') is intended as the default proxy user, used to authenticate connections for users who do not otherwise match a more-specific account. The second account ('''@%''') is an anonymous-user account, which might have been created, for example, to enable users without their own account to connect anonymously.

Both accounts have the same user part (''), which matches any user. And each account has a host part that matches any host. Nevertheless, there is a priority in account matching for connection attempts because the matching rules sort a host of '%' ahead of ''. For accounts that do not match any more-specific account, the server attempts to authenticate them against ''@%' (the anonymous user) rather than ''@'' (the default proxy user). As a result, the default proxy account is never used.

To avoid this problem, use one of the following strategies:

- Remove the anonymous account so that it does not conflict with the default proxy user.
- Use a more-specific default proxy user that matches ahead of the anonymous user. For example, to permit only localhost proxy connections, use ''@localhost'':

```
CREATE USER ''@localhost'
    IDENTIFIED WITH some_plugin
    AS 'some_auth_string';
```

In addition, modify any GRANT PROXY statements to name ''@localhost' rather than ''@'' as the proxy user.

Be aware that this strategy prevents anonymous-user connections from localhost.

- Use a named default account rather than an anonymous default account. For an example of this technique, consult the instructions for using the authentication_windows plugin. See Section 6.1.7, “Windows Pluggable Authentication”.

- Create multiple proxy users, one for local connections and one for “everything else” (remote connections). This can be useful particularly when local users should have different privileges from remote users.

Create the proxy users:

```
-- create proxy user for local connections
CREATE USER ''@localhost'
    IDENTIFIED WITH some_plugin
    AS 'some_auth_string';
-- create proxy user for remote connections
CREATE USER ''@%'
    IDENTIFIED WITH some_plugin
    AS 'some_auth_string';
```

Create the proxied users:
Grant to each proxy account the `PROXY` privilege for the corresponding proxied account:

```sql
GRANT PROXY
    ON 'developer'@'localhost'
TO ''@'localhost';
GRANT PROXY
    ON 'developer'@'%
TO ''@'%';
```

Finally, grant appropriate privileges to the local and remote proxied users (not shown).

Assume that the `some_plugin/'some_auth_string'` combination causes `some_plugin` to map the client user name to `developer`. Local connections match the `''@'localhost'` proxy user, which maps to the `'developer'@'localhost'` proxied user. Remote connections match the `''@'%'` proxy user, which maps to the `'developer'@'%'` proxied user.

### Proxy User System Variables

Two system variables help trace the proxy login process:

- **proxy_user**: This value is `NULL` if proxying is not used. Otherwise, it indicates the proxy user account. For example, if a client authenticates through the `''@'%'` proxy account, this variable is set as follows:

  ```sql
  mysql> SELECT @@proxy_user;
  +--------------+
  | @@proxy_user |
  | ''@''        |
  +--------------+
  ```

- **external_user**: Sometimes the authentication plugin may use an external user to authenticate to the MySQL server. For example, when using Windows native authentication, a plugin that authenticates using the windows API does not need the login ID passed to it. However, it still uses a Windows user ID to authenticate. The plugin may return this external user ID (or the first 512 UTF-8 bytes of it) to the server using the `external_user` read-only session variable. If the plugin does not set this variable, its value is `NULL`.

### 4.13 Setting Account Resource Limits

One means of restricting client use of MySQL server resources is to set the global `max_user_connections` system variable to a nonzero value. This limits the number of simultaneous connections that can be made by any given account, but places no limits on what a client can do once connected. In addition, setting `max_user_connections` does not enable management of individual accounts. Both types of control are of interest to MySQL administrators.

To address such concerns, MySQL permits limits for individual accounts on use of these server resources:

- The number of queries an account can issue per hour
- The number of updates an account can issue per hour
- The number of times an account can connect to the server per hour
• The number of simultaneous connections to the server by an account

Any statement that a client can issue counts against the query limit, unless its results are served from the query cache. Only statements that modify databases or tables count against the update limit.

An “account” in this context corresponds to a row in the `mysql.user` system table. That is, a connection is assessed against the `User` and `Host` values in the `user` table row that applies to the connection. For example, an account `usera@%.example.com` corresponds to a row in the `user` table that has `user` and `Host` values of `usera` and `%.example.com`, to permit `usera` to connect from any host in the `example.com` domain. In this case, the server applies resource limits in this row collectively to all connections by `usera` from any host in the `example.com` domain because all such connections use the same account.

Before MySQL 5.0, an “account” was assessed against the actual host from which a user connects. This older method of accounting may be selected by starting the server with the `--old-style-user-limits` option. In this case, if `usera` connects simultaneously from `host1.example.com` and `host2.example.com`, the server applies the account resource limits separately to each connection. If `usera` connects again from `host1.example.com`, the server applies the limits for that connection together with the existing connection from that host.

To establish resource limits for an account, use the `GRANT` statement (see `GRANT Syntax`). Provide a `WITH` clause that names each resource to be limited. The default value for each limit is zero (no limit). For example, to create a new account that can access the `customer` database, but only in a limited fashion, issue these statements:

```
mysql> CREATE USER 'francis'@'localhost' IDENTIFIED BY 'frank';
mysql> GRANT ALL ON customer.* TO 'francis'@'localhost'
   -> WITH MAX_QUERIES_PER_HOUR 20
   -> MAX_UPDATES_PER_HOUR 10
   -> MAX_CONNECTIONS_PER_HOUR 5
   -> MAX_USER_CONNECTIONS 2;
```

The limit types need not all be named in the `WITH` clause, but those named can be present in any order. The value for each per-hour limit should be an integer representing a count per hour. For `MAX_USER_CONNECTIONS`, the limit is an integer representing the maximum number of simultaneous connections by the account. If this limit is set to zero, the global `max_user_connections` system variable value determines the number of simultaneous connections. If `max_user_connections` is also zero, there is no limit for the account.

To modify limits for an existing account, use a `GRANT USAGE` statement at the global level (`ON *.*`). The following statement changes the query limit for `francis` to 100:

```
mysql> GRANT USAGE ON *.* TO 'francis'@'localhost'
   -> WITH MAX_QUERIES_PER_HOUR 100;
```

The statement modifies only the limit value specified and leaves the account otherwise unchanged.

To remove a limit, set its value to zero. For example, to remove the limit on how many times per hour `francis` can connect, use this statement:

```
mysql> GRANT USAGE ON *.* TO 'francis'@'localhost'
   -> WITH MAX_CONNECTIONS_PER_HOUR 0;
```

As mentioned previously, the simultaneous-connection limit for an account is determined from the `MAX_USER_CONNECTIONS` limit and the `max_user_connections` system variable. Suppose that the global `max_user_connections` value is 10 and three accounts have individual resource limits specified as follows:

```
GRANT ... TO 'user1'@'localhost' WITH MAX_USER_CONNECTIONS 0;
GRANT ... TO 'user2'@'localhost' WITH MAX_USER_CONNECTIONS 5;
GRANT ... TO 'user3'@'localhost' WITH MAX_USER_CONNECTIONS 20;
```
user1 has a connection limit of 10 (the global max_user_connections value) because it has a MAX_USER_CONNECTIONS limit of zero. user2 and user3 have connection limits of 5 and 20, respectively, because they have nonzero MAX_USER_CONNECTIONS limits.

The server stores resource limits for an account in the user table row corresponding to the account. The max_questions, max_updates, and max_connections columns store the per-hour limits, and the max_user_connections column stores the MAX_USER_CONNECTIONS limit. (See Section 4.3, “Grant Tables”.)

Resource-use counting takes place when any account has a nonzero limit placed on its use of any of the resources.

As the server runs, it counts the number of times each account uses resources. If an account reaches its limit on number of connections within the last hour, the server rejects further connections for the account until that hour is up. Similarly, if the account reaches its limit on the number of queries or updates, the server rejects further queries or updates until the hour is up. In all such cases, the server issues appropriate error messages.

Resource counting occurs per account, not per client. For example, if your account has a query limit of 50, you cannot increase your limit to 100 by making two simultaneous client connections to the server. Queries issued on both connections are counted together.

The current per-hour resource-use counts can be reset globally for all accounts, or individually for a given account:

- To reset the current counts to zero for all accounts, issue a FLUSH USER_RESOURCES statement. The counts also can be reset by reloading the grant tables (for example, with a FLUSH PRIVILEGES statement or a mysqladmin reload command).
- The counts for an individual account can be reset to zero by setting any of its limits again. Specify a limit value equal to the value currently assigned to the account.

Per-hour counter resets do not affect the MAX_USER_CONNECTIONS limit.

All counts begin at zero when the server starts. Counts do not carry over through server restarts.

For the MAX_USER_CONNECTIONS limit, an edge case can occur if the account currently has open the maximum number of connections permitted to it: A disconnect followed quickly by a connect can result in an error (ER_TOO_MANY_USER_CONNECTIONS or ER_USER_LIMIT_REACHED) if the server has not fully processed the disconnect by the time the connect occurs. When the server finishes disconnect processing, another connection will once more be permitted.

4.14 Troubleshooting Problems Connecting to MySQL

If you encounter problems when you try to connect to the MySQL server, the following items describe some courses of action you can take to correct the problem.

- Make sure that the server is running. If it is not, clients cannot connect to it. For example, if an attempt to connect to the server fails with a message such as one of those following, one cause might be that the server is not running:

  ```
  shell> mysql
  ERROR 2003: Can't connect to MySQL server on 'host_name' (111)
  shell> mysql
  ERROR 2002: Can't connect to local MySQL server through socket '/tmp/mysql.sock' (111)
  ```

- It might be that the server is running, but you are trying to connect using a TCP/IP port, named pipe, or Unix socket file different from the one on which the server is listening. To correct this when you invoke a client program, specify a --port option to indicate the proper port number, or a --socket option to indicate the proper named pipe or Unix socket file. To find out where the socket file is, you can use this command:
Troubleshooting Problems Connecting to MySQL

shell> netstat -ln | grep mysql

• Make sure that the server has not been configured to ignore network connections or (if you are attempting to connect remotely) that it has not been configured to listen only locally on its network interfaces. If the server was started with `--skip-networking`, it will not accept TCP/IP connections at all. If the server was started with the `bind_address` system variable set to `127.0.0.1`, it will listen for TCP/IP connections only locally on the loopback interface and will not accept remote connections.

• Check to make sure that there is no firewall blocking access to MySQL. Your firewall may be configured on the basis of the application being executed, or the port number used by MySQL for communication (3306 by default). Under Linux or Unix, check your IP tables (or similar) configuration to ensure that the port has not been blocked. Under Windows, applications such as ZoneAlarm or Windows Firewall may need to be configured not to block the MySQL port.

• The grant tables must be properly set up so that the server can use them for access control. For some distribution types (such as binary distributions on Windows, or RPM distributions on Linux), the installation process initializes the MySQL data directory, including the `mysql` system database containing the grant tables. For distributions that do not do this, you must initialize the grant tables manually. For details, see Chapter 3, Postinstallation Setup and Testing.

To determine whether you need to initialize the grant tables, look for a `mysql` directory under the data directory. (The data directory normally is named `data` or `var` and is located under your MySQL installation directory.) Make sure that you have a file named `user.MYD` in the `mysql` database directory. If not, execute the `mysql_install_db` program. After running this program and starting the server, test the initial privileges by executing this command:

shell> mysql -u root

The server should let you connect without error.

• After a fresh installation, you should connect to the server and set up your users and their access permissions:

shell> mysql -u root mysql

The server should let you connect because the MySQL root user has no password initially. That is also a security risk, so setting the password for the root accounts is something you should do while you’re setting up your other MySQL accounts. For instructions on setting the initial passwords, see Section 3.4, “Securing the Initial MySQL Accounts”.

• If you have updated an existing MySQL installation to a newer version, did you perform the MySQL upgrade procedure? If not, do so. The structure of the grant tables changes occasionally when new capabilities are added, so after an upgrade you should always make sure that your tables have the current structure. For instructions, see Upgrading MySQL.

• If a client program receives the following error message when it tries to connect, it means that the server expects passwords in a newer format than the client is capable of generating:

```
shell> mysql
Client does not support authentication protocol requested by server; consider upgrading MySQL client
```

For information on how to deal with this, see Section 2.2.4, “Password Hashing in MySQL”, and Client does not support authentication protocol.

• Remember that client programs use connection parameters specified in option files or environment variables. If a client program seems to be sending incorrect default connection
parameters when you have not specified them on the command line, check any applicable option files and your environment. For example, if you get Access denied when you run a client without any options, make sure that you have not specified an old password in any of your option files!

You can suppress the use of option files by a client program by invoking it with the --no-defaults option. For example:

```
shell> mysqladmin --no-defaults -u root version
```

The option files that clients use are listed in Using Option Files. Environment variables are listed in MySQL Environment Variables.

- If you get the following error, it means that you are using an incorrect root password:

```
shell> mysqladmin -u root -pxxxx version
Access denied for user 'root'@'localhost' (using password: YES)
```

If the preceding error occurs even when you have not specified a password, it means that you have an incorrect password listed in some option file. Try the --no-defaults option as described in the previous item.

For information on changing passwords, see Section 4.9, “Assigning Account Passwords”.

If you have lost or forgotten the root password, see How to Reset the Root Password.

- If you change a password by using SET PASSWORD, INSERT, or UPDATE, you must encrypt the password using the PASSWORD() function. If you do not use PASSWORD() for these statements, the password will not work. For example, the following statement assigns a password, but fails to encrypt it, so the user is not able to connect afterward:

```
SET PASSWORD FOR 'abe'@'host_name' = 'eagle';
```

Instead, set the password like this:

```
SET PASSWORD FOR 'abe'@'host_name' = PASSWORD('eagle');
```

The PASSWORD() function is unnecessary when you specify a password using the CREATE USER or GRANT statements or the mysqladmin password command. Each of those automatically uses PASSWORD() to encrypt the password. See Section 4.9, “Assigning Account Passwords”, and CREATE USER Syntax.

- localhost is a synonym for your local host name, and is also the default host to which clients try to connect if you specify no host explicitly.

You can use a --host=127.0.0.1 option to name the server host explicitly. This will make a TCP/IP connection to the local mysqld server. You can also use TCP/IP by specifying a --host option that uses the actual host name of the local host. In this case, the host name must be specified in a user table row on the server host, even though you are running the client program on the same host as the server.

- The Access denied error message tells you who you are trying to log in as, the client host from which you are trying to connect, and whether you were using a password. Normally, you should have one row in the user table that exactly matches the host name and user name that were given in the error message. For example, if you get an error message that contains using password: NO, it means that you tried to log in without a password.

- If you get an Access denied error when trying to connect to the database with mysql -u user_name, you may have a problem with the user table. Check this by executing mysql -u root mysql and issuing this SQL statement:
Troubleshooting Problems Connecting to MySQL

```sql
SELECT * FROM user;
```

The result should include a row with the `Host` and `User` columns matching your client’s host name and your MySQL user name.

- If the following error occurs when you try to connect from a host other than the one on which the MySQL server is running, it means that there is no row in the `user` table with a `Host` value that matches the client host:

```
Host ... is not allowed to connect to this MySQL server
```

You can fix this by setting up an account for the combination of client host name and user name that you are using when trying to connect.

If you do not know the IP address or host name of the machine from which you are connecting, you should put a row with `'%'` as the `Host` column value in the `user` table. After trying to connect from the client machine, use a `SELECT USER()` query to see how you really did connect. Then change the `'%'` in the `user` table row to the actual host name that shows up in the log. Otherwise, your system is left insecure because it permits connections from any host for the given user name.

On Linux, another reason that this error might occur is that you are using a binary MySQL version that is compiled with a different version of the `glibc` library than the one you are using. In this case, you should either upgrade your operating system or `glibc`, or download a source distribution of MySQL version and compile it yourself. A source RPM is normally trivial to compile and install, so this is not a big problem.

- If you specify a host name when trying to connect, but get an error message where the host name is not shown or is an IP address, it means that the MySQL server got an error when trying to resolve the IP address of the client host to a name:

```
shell> mysqladmin -u root -p xxxx -h some_hostname ver
Access denied for user 'root'@'' (using password: YES)
```

If you try to connect as `root` and get the following error, it means that you do not have a row in the `user` table with a `User` column value of `'root'` and that `mysqld` cannot resolve the host name for your client:

```
Access denied for user ''@'unknown'
```

These errors indicate a DNS problem. To fix it, execute `mysqladmin flush-hosts` to reset the internal DNS host cache. See [DNS Lookup Optimization and the Host Cache](#).

Some permanent solutions are:
- Determine what is wrong with your DNS server and fix it.
- Specify IP addresses rather than host names in the MySQL grant tables.
- Put an entry for the client machine name in `/etc/hosts` on Unix or `\windows\hosts` on Windows.
- Start `mysqld` with the `--skip-name-resolve` option.
- Start `mysqld` with the `--skip-host-cache` option.
- On Unix, if you are running the server and the client on the same machine, connect to `localhost`. For connections to `localhost`, MySQL programs attempt to connect to the local server by using a Unix socket file, unless there are connection parameters specified to ensure that
the client makes a TCP/IP connection. For more information, see Connecting to the MySQL Server Using Command Options.

- On Windows, if you are running the server and the client on the same machine and the server supports named pipe connections, connect to the host name . (period). Connections to . use a named pipe rather than TCP/IP.

- If mysql -u root works but mysql -h your_hostname -u root results in Access denied (where your_hostname is the actual host name of the local host), you may not have the correct name for your host in the user table. A common problem here is that the Host value in the user table row specifies an unqualified host name, but your system's name resolution routines return a fully qualified domain name (or vice versa). For example, if you have a row with host 'pluto' in the user table, but your DNS tells MySQL that your host name is 'pluto.example.com', the row does not work. Try adding a row to the user table that contains the IP address of your host as the Host column value. (Alternatively, you could add a row to the user table with a Host value that contains a wildcard (for example, 'pluto.%'). However, use of Host values ending with % is insecure and is not recommended!)

- If mysql -u user_name works but mysql -u user_name some_db does not, you have not granted access to the given user for the database named some_db.

- If mysql -u user_name works when executed on the server host, but mysql -h host_name - u user_name does not work when executed on a remote client host, you have not enabled access to the server for the given user name from the remote host.

- If you cannot figure out why you get Access denied, remove from the user table all rows that have Host values containing wildcards (rows that contain '%' or '_' characters). A very common error is to insert a new row with Host='%' and User='some_user', thinking that this enables you to specify localhost to connect from the same machine. The reason that this does not work is that the default privileges include a row with Host=localhost and User=''. Because that row has a Host value 'localhost' that is more specific than '%', it is used in preference to the new row when connecting from localhost! The correct procedure is to insert a second row with Host=localhost and User='some_user', or to delete the row with Host=localhost and User='. After deleting the row, remember to issue a FLUSH PRIVILEGES statement to reload the grant tables. See also Section 4.5, “Access Control, Stage 1: Connection Verification”.

- If you are able to connect to the MySQL server, but get an Access denied message whenever you issue a SELECT ... INTO OUTFILE or LOAD DATA statement, your row in the user table does not have the FILE privilege enabled.

- If you change the grant tables directly (for example, by using INSERT, UPDATE, or DELETE statements) and your changes seem to be ignored, remember that you must execute a FLUSH PRIVILEGES statement or a mysqladmin flush-privileges command to cause the server to reload the privilege tables. Otherwise, your changes have no effect until the next time the server is restarted. Remember that after you change the root password with an UPDATE statement, you will not need to specify the new password until after you flush the privileges, because the server will not know you've changed the password yet!

- If your privileges seem to have changed in the middle of a session, it may be that a MySQL administrator has changed them. Reloading the grant tables affects new client connections, but it also affects existing connections as indicated in Section 4.8, “When Privilege Changes Take Effect”.

- If you have access problems with a Perl, PHP, Python, or ODBC program, try to connect to the server with mysql -u user_name db_name or mysql -u user_name -p password db_name. If you are able to connect using the mysql client, the problem lies with your program, not with the access privileges. (There is no space between -p and the password; you can also use the -ppassword syntax to specify the password. If you use the -p or -p option with no password value, MySQL prompts you for the password.)

- For testing purposes, start the mysqld server with the --skip-grant-tables option. Then you can change the MySQL grant tables and use the SHOW GRANTS statement to check whether
your modifications have the desired effect. When you are satisfied with your changes, execute `mysqladmin flush-privileges` to tell the mysqld server to reload the privileges. This enables you to begin using the new grant table contents without stopping and restarting the server.

- If everything else fails, start the mysqld server with a debugging option (for example, `--debug=d,general,query`). This prints host and user information about attempted connections, as well as information about each command issued. See The DBUG Package.

- If you have any other problems with the MySQL grant tables and ask on the MySQL Community Slack, always provide a dump of the MySQL grant tables. You can dump the tables with the `mysqldump mysql` command. To file a bug report, see the instructions at How to Report Bugs or Problems. In some cases, you may need to restart mysqld with `--skip-grant-tables` to run mysqldump.

### 4.15 SQL-Based Account Activity Auditing

Applications can use the following guidelines to perform SQL-based auditing that ties database activity to MySQL accounts.

MySQL accounts correspond to rows in the `mysql.user` system table. When a client connects successfully, the server authenticates the client to a particular row in this table. The User and Host column values in this row uniquely identify the account and correspond to the `user_name '@host_name'` format in which account names are written in SQL statements.

The account used to authenticate a client determines which privileges the client has. Normally, the `CURRENT_USER()` function can be invoked to determine which account this is for the client user. Its value is constructed from the User and Host columns of the user table row for the account.

However, there are circumstances under which the `CURRENT_USER()` value corresponds not to the client user but to a different account. This occurs in contexts when privilege checking is not based the client’s account:

- Stored routines (procedures and functions) defined with the `SQL SECURITY DEFINER` characteristic
- Views defined with the `SQL SECURITY DEFINER` characteristic
- Triggers and events

In those contexts, privilege checking is done against the DEFINER account and `CURRENT_USER()` refers to that account, not to the account for the client who invoked the stored routine or view or who caused the trigger to activate. To determine the invoking user, you can call the `USER()` function, which returns a value indicating the actual user name provided by the client and the host from which the client connected. However, this value does not necessarily correspond directly to an account in the user table, because the `USER()` value never contains wildcards, whereas account values (as returned by `CURRENT_USER()`) may contain user name and host name wildcards.

For example, a blank user name matches any user, so an account of `''@'localhost'` enables clients to connect as an anonymous user from the local host with any user name. In this case, if a client connects as `user1` from the local host, `USER()` and `CURRENT_USER()` return different values:

```sql
mysql> SELECT USER(), CURRENT_USER();
+-----------------+----------------+
| USER()          | CURRENT_USER() |
+-----------------+----------------+
| user1@localhost | @localhost     |
+-----------------+----------------+
```

The host name part of an account can contain wildcards, too. If the host name contains a `'%` or `'_` pattern character or uses netmask notation, the account can be used for clients connecting from multiple hosts and the `CURRENT_USER()` value will not indicate which one. For example, the account
'user2'@'%.example.com' can be used by user2 to connect from any host in the example.com domain. If user2 connects from remote.example.com, USER() and CURRENT_USER() return different values:

```
mysql> SELECT USER(), CURRENT_USER();
+--------------------------+---------------------+
| USER()                   | CURRENT_USER()      |
+--------------------------+---------------------+
| user2@remote.example.com | user2@%.example.com |
+--------------------------+---------------------+
```

If an application must invoke USER() for user auditing (for example, if it does auditing from within triggers) but must also be able to associate the USER() value with an account in the user table, it is necessary to avoid accounts that contain wildcards in the User or Host column. Specifically, do not permit User to be empty (which creates an anonymous-user account), and do not permit pattern characters or netmask notation in Host values. All accounts must have a nonempty User value and literal Host value.

With respect to the previous examples, the ''@'localhost' and 'user2'@'%.example.com' accounts should be changed not to use wildcards:

```
RENAME USER ''@'localhost' TO 'user1'@'localhost';
RENAME USER 'user2'@'%.example.com' TO 'user2'@'remote.example.com';
```

If user2 must be able to connect from several hosts in the example.com domain, there should be a separate account for each host.

To extract the user name or host name part from a CURRENT_USER() or USER() value, use the SUBSTRING_INDEX() function:

```
mysql> SELECT SUBSTRING_INDEX(CURRENT_USER(),'@',1);
+---------------------------------------+
| SUBSTRING_INDEX(CURRENT_USER(),'@',1) |
+---------------------------------------+
| user1                                 |
+---------------------------------------+

mysql> SELECT SUBSTRING_INDEX(CURRENT_USER(),'@',-1);
+----------------------------------------+
| SUBSTRING_INDEX(CURRENT_USER(),'@',-1) |
+----------------------------------------+
| localhost                              |
+----------------------------------------+
```

With an unencrypted connection between the MySQL client and the server, someone with access to
the network could watch all your traffic and inspect the data being sent or received between client and
server.

When you must move information over a network in a secure fashion, an unencrypted connection
is unacceptable. To make any kind of data unreadable, use encryption. Encryption algorithms must
include security elements to resist many kinds of known attacks such as changing the order of
encrypted messages or replaying data twice.

MySQL supports encrypted connections between clients and the server using the TLS (Transport
Layer Security) protocol. TLS is sometimes referred to as SSL (Secure Sockets Layer) but MySQL
does not actually use the SSL protocol for encrypted connections because its encryption is weak (see
Section 5.2, “Encrypted Connection TLS Protocols and Ciphers”).

TLS uses encryption algorithms to ensure that data received over a public network can be trusted. It
has mechanisms to detect data change, loss, or replay. TLS also incorporates algorithms that provide
identity verification using the X.509 standard.

X.509 makes it possible to identify someone on the Internet. In basic terms, there should be some
entity called a “Certificate Authority” (or CA) that assigns electronic certificates to anyone who needs
them. Certificates rely on asymmetric encryption algorithms that have two encryption keys (a public key
and a secret key). A certificate owner can present the certificate to another party as proof of identity. A
certificate consists of its owner’s public key. Any data encrypted using this public key can be decrypted
only using the corresponding secret key, which is held by the owner of the certificate.

MySQL can be compiled for encrypted-connection support using OpenSSL or yaSSL. For a
comparison of the two packages, see Section 5.4, “SSL Library-Dependent Capabilities” For
information about the encryption protocols and ciphers each package supports, see Section 5.2,
“Encrypted Connection TLS Protocols and Ciphers”.

Note
It is possible to compile MySQL using yaSSL as an alternative to OpenSSL only
prior to MySQL 5.6.46. As of MySQL 5.6.46, support for yaSSL is removed and
all MySQL builds use OpenSSL.

MySQL programs attempt to connect using encryption if the proper options are given and the
server supports encrypted connections. For information about options that affect use of encrypted
connections, see Section 5.1, “Configuring MySQL to Use Encrypted Connections” and Command
Options for Encrypted Connections.

MySQL performs encryption on a per-connection basis, and use of encryption for a given user can be
optional or mandatory. This enables you to choose an encrypted or unencrypted connection according
to the requirements of individual applications. For information on how to require users to use encrypted
connections, see the discussion of the REQUIRE clause of the GRANT statement in GRANT Syntax.
Encrypted connections are not used by default. For applications that require the security provided by encrypted connections, the extra computation to encrypt the data is worthwhile.

Encrypted connections can be used between master and slave replication servers. See Setting Up Replication to Use Encrypted Connections.

For information about using encrypted connections from the MySQL C API, see C API Encrypted Connection Support.

It is also possible to connect using encryption from within an SSH connection to the MySQL server host. For an example, see Section 5.5, “Connecting to MySQL Remotely from Windows with SSH”.

5.1 Configuring MySQL to Use Encrypted Connections

To enable encrypted connections, your MySQL distribution must be built with SSL support, as described in Configuring SSL Library Support. In addition, several options are available to indicate whether to use encrypted connections, and to specify the appropriate certificate and key files. This section provides general guidance about configuring the server and clients for encrypted connections:

• Server-Side Startup Configuration for Encrypted Connections

• Client-Side Configuration for Encrypted Connections

For a complete list of options related to establishment of encrypted connections, see Command Options for Encrypted Connections. Instructions for creating any required certificate and key files are available in Section 5.3, “Creating SSL and RSA Certificates and Keys”.

Encrypted connections also can be used in these contexts:

• Between master and slave replication servers. See Setting Up Replication to Use Encrypted Connections.

• By client programs that are based on the MySQL C API. See C API Encrypted Connection Support.

Note

If the server is compiled against OpenSSL, clients from MySQL 5.6 versions older than 5.6.17 are not able to connect to the server using encrypted connections if the client library is compiled using yaSSL. Either use a client and server compiled using the same SSL package, or upgrade to clients compiled against a client library version from MySQL 5.6.17 or higher.

Server-Side Startup Configuration for Encrypted Connections

These options on the server side specify the certificate and key files the server uses when permitting clients to establish encrypted connections:

• --ssl-ca: The path name of the Certificate Authority (CA) certificate file. (--ssl-capath is similar but specifies the path name of a directory of CA certificate files.)

• --ssl-cert: The path name of the server public key certificate file. This certificate can be sent to the client and authenticated against the CA certificate that it has.

• --ssl-key: The path name of the server private key file.

For example, to enable the server for encrypted connections, start it with these lines in the my.cnf file, changing the file names as necessary:

```
[mysqld]
ssl-ca=ca.pem
```
Client-Side Configuration for Encrypted Connections

Each certificate and key option names a file in PEM format. If you have a MySQL source distribution, you can test your setup using the demonstration certificate and key files in its `mysql-test/std_data` directory.

MySQL also provides these options for server-side SSL control:

- `--ssl-cipher`: The list of permissible ciphers for connection encryption.
- `--ssl-crl`: The path name of the file containing certificate revocation lists. (`--ssl-crlpath` is similar but specifies the path name of a directory of certificate revocation-list files.)

The values of the `--ssl-xxx` options set the values of the corresponding system variables (`ssl_ca`, `ssl_cert`, `ssl_key`, and so forth).

**Client-Side Configuration for Encrypted Connections**

These options on the client side identify the certificate and key files clients use when establishing encrypted connections to the server. They are similar to the options used on the server side, but `--ssl-cert` and `--ssl-key` identify the client public and private key:

- `--ssl-ca`: The path name of the Certificate Authority (CA) certificate file. This option, if used, must specify the same certificate used by the server. (`--ssl-capath` is similar but specifies the path name of a directory of CA certificate files.)
- `--ssl-cert`: The path name of the client public key certificate file.
- `--ssl-key`: The path name of the client private key file.

For additional security relative to that provided by the default encryption, clients can supply a CA certificate matching the one used by the server and enable host name identity verification. In this way, the server and client place their trust in the same CA certificate and the client verifies that the host to which it connected is the one intended:

- To specify the CA certificate, use `--ssl-ca` (or `--ssl-capath`).
- To enable host name identity verification as well, specify `--ssl-verify-server-cert`.
- To require an encrypted connection, specify `--ssl-mode=REQUIRED`.
- `--ssl-cipher`: The list of permissible ciphers for connection encryption.
- `--ssl-crl`: The path name of the file containing certificate revocation lists. (`--ssl-crlpath` is similar but specifies the path name of a directory of certificate revocation-list files.)

Depending on the encryption requirements of the MySQL account used by a client, the client may be required to specify certain options to connect using encryption to the MySQL server.

Suppose that you want to connect using an account that has no special encryption requirements or that was created using a `GRANT` statement that included the `REQUIRE SSL` clause. As a recommended set of encrypted-connection options, start the server with at least `--ssl-cert` and `--ssl-key`, and invoke the client with `--ssl-ca` (or `--ssl-capath`). A client can connect using encryption like this:

```
mysql --ssl-ca=ca.pem
```

To require that a client certificate also be specified, create the account using a `REQUIRE X509` clause. Then the client must also specify the proper client key and certificate files or the server will reject the connection:
Encrypted Connection TLS Protocols and Ciphers

For additional information about the REQUIRE clause, see GRANT Syntax.

To prevent use of encryption and override other --ssl-xxx options, invoke the client program with --ssl=0 or a synonym (--skip-ssl, --disable-ssl):

```
mysql --ssl=0
```

To determine whether the current connection with the server uses encryption, check the session value of the Ssl_cipher status variable. If the value is empty, the connection is not encrypted. Otherwise, the connection is encrypted and the value indicates the encryption cipher. For example:

```
mysql> SHOW SESSION STATUS LIKE 'Ssl_cipher';
+---------------+--------------------+
| Variable_name | Value              |
+---------------+--------------------+
| Ssl_cipher    | DHE-RSA-AES256-SHA |
+---------------+--------------------+
```

For the mysql client, an alternative is to use the STATUS or \s command and check the SSL line:

```
mysql> \s
...
SSL: Not in use
...
```

Or:

```
mysql> \s
...
SSL: Cipher in use is DHE-RSA-AES256-SHA
...
```

5.2 Encrypted Connection TLS Protocols and Ciphers

MySQL supports multiple TLS protocols and ciphers, and enables configuring which ciphers to permit for encrypted connections. It is also possible to determine which protocol and cipher the current session uses.

- Supported Connection TLS Protocols
- Connection TLS Protocol Configuration
- Connection Cipher Configuration
- Connection TLS Protocol Negotiation
- Monitoring Current Session TLS Protocol and Cipher

Supported Connection TLS Protocols

MySQL supports encrypted connections using the TLSv1 protocol and (as of MySQL 5.6.46) TLSv1.1 and TLSv1.2, listed in order from less secure to more secure.

As of MySQL 5.6.23, SSL 2.0 and SSL 3.0 are explicitly disabled because they provide weak encryption.
The set of protocols actually permitted for connections is subject to multiple factors:

- **MySQL configuration.** Permitted TLS protocols on the server side and client side must include at least one protocol in common or connection attempts cannot negotiate a protocol to use. For details, see Connection TLS Protocol Negotiation.

- **System-wide host configuration.** The host system may permit only certain TLS protocols, which means that MySQL connections cannot use nonpermitted protocols even if MySQL itself permits them:
  
  - Suppose that MySQL permits TLSv1, TLSv1.1, and TLSv1.2, but your host system configuration permits only connections that use TLSv1.2 or higher. In this case, you cannot establish MySQL connections that use TLSv1 or TLSv1.1, even though MySQL permits them, because the host system does not permit them.

  - If MySQL permits TLSv1, TLSv1.1, and TLSv1.2, but your host system configuration permits only connections that use TLSv1.3 or higher, you cannot establish MySQL connections at all, because no protocol permitted by MySQL is permitted by the host system.

Workarounds for this issue include:

- Change the system-wide host configuration to permit additional TLS protocols. Consult your operating system documentation for instructions. For example, your system may have an `/etc/ssl/openssl.cnf` file that contains these lines to restrict TLS protocols to TLSv1.2 or higher:

  ```
  [system_default_sect]
  MinProtocol = TLSv1.2
  ```

  Changing the value to a lower protocol version or `None` makes the system more permissive. However, this workaround has the disadvantage that permitting lower (less secure) protocols may have adverse security consequences.

- If you cannot or prefer not to change the host system TLS configuration, change MySQL applications to use higher (more secure) TLS protocols that are permitted by the host system. This may not be possible for older versions of MySQL that support only lower protocol versions. For example, TLSv1 is the only supported protocol prior to MySQL 5.6.46, so attempts to connect to a pre-5.6.46 server fail even if the client is from a newer MySQL version that supports higher protocol versions. In such cases, an upgrade to a version of MySQL that supports additional TLS versions may be required.

- The SSL library. If the SSL library does not support a particular protocol, neither does MySQL, and any parts of the following discussion that specify that protocol do not apply.

  - When compiled using OpenSSL 1.0.1 or higher, MySQL supports the TLSv1, TLSv1.1, and TLSv1.2 protocols as of MySQL 5.6.46, and TLSv1 prior to 5.6.46.

  - When compiled using yaSSL, MySQL supports the TLSv1 protocol.

Note

It is possible to compile MySQL using yaSSL as an alternative to OpenSSL only prior to MySQL 5.6.46. As of MySQL 5.6.46, support for yaSSL is removed and all MySQL builds use OpenSSL.

---

**Connection TLS Protocol Configuration**

MySQL supports encrypted connections using the TLSv1 protocol and (as of MySQL 5.6.46) TLSv1.1 and TLSv1.2. Protocol support is built in and cannot be configured as is possible in MySQL 5.7 and higher. The protocol chosen for a given connection depends on the negotiation process. See Connection TLS Protocol Negotiation.
Connection Cipher Configuration

A default set of ciphers applies to encrypted connections, which can be overridden by explicitly configuring the permitted ciphers. During connection establishment, both sides of a connection must permit some cipher in common or the connection fails. Of the permitted ciphers common to both sides, the SSL library chooses the one supported by the provided certificate that has the highest priority.

To specify a cipher or ciphers for encrypted connections, use the `--ssl-cipher` option, which is available for the server and for client programs.

For master/slave replication, the `MASTER_SSL_CIPHER` option for the `CHANGE MASTER TO` statement specifies which ciphers a slave server permits for connections to the master.

To determine which ciphers a given server supports, check the session value of the `Ssl_cipher_list` status variable:

```
SHOW SESSION STATUS LIKE 'Ssl_cipher_list';
```

The `Ssl_cipher_list` status variable lists the possible SSL ciphers (empty for non-SSL connections). The set of available ciphers depends on your MySQL version and whether MySQL was compiled using OpenSSL or yaSSL, and (for OpenSSL) the library version used to compile MySQL.

MySQL passes a default cipher list to the SSL library.

MySQL passes this default cipher list to OpenSSL:

- AES256-GCM-SHA384
- AES256-SHA
- AES256-SHA256
- CAMELLIA256-SHA
- DES-CBC3-SHA
- DHE-DSS-AES256-GCM-SHA384
- DHE-DSS-AES256-SHA
- DHE-DSS-AES256-SHA256
- DHE-DSS-CAMELLIA256-SHA
- DHE-RSA-AES256-GCM-SHA384
- DHE-RSA-AES256-SHA
- DHE-RSA-AES256-SHA256
- DHE-RSA-CAMELLIA256-SHA
- ECDH-ECDSA-AES256-GCM-SHA384
- ECDH-ECDSA-AES256-SHA
- ECDH-ECDSA-AES256-SHA384
- ECDH-ECDSA-DES-CBC3-SHA
- ECDH-RSA-AES256-GCM-SHA384
- ECDH-RSA-AES256-SHA
- ECDH-RSA-AES256-SHA256
- ECDH-RSA-CAMELLIA256-SHA
- ECDHE-ECDSA-AES128-GCM-SHA256
- ECDHE-ECDSA-AES128-SHA
- ECDHE-ECDSA-AES128-SHA256
- ECDHE-ECDSA-AES256-GCM-SHA384
- ECDHE-ECDSA-AES256-SHA
- ECDHE-ECDSA-AES256-SHA384
- ECDHE-ECDSA-DES-CBC3-SHA
- ECDHE-RSA-AES128-GCM-SHA256
- ECDHE-RSA-AES128-SHA
- ECDHE-RSA-AES128-SHA256
- ECDHE-RSA-CAMELLIA256-SHA
- EDH-DSS-DES-CBC3-SHA
- EDH-RSA-DES-CBC3-SHA
- PSK-3DES-EDE-CBC-SHA
- PSK-AES256-CBC-SHA
- SRP-DSS-3DES-EDE-CBC-SHA
SRP-DSS-AES-128-CBC-SHA
SRP-DSS-AES-256-CBC-SHA
SRP-RSA-3DES-EDC-CBC-SHA
SRP-RSA-AES-128-CBC-S
SRP-RSA-AES-256-CBC-SHA

MySQL passes this default cipher list to yaSSL:

AES128-RMD
AES128-SHA
AES256-RMD
AES256-SHA
DES-CBC-SHA
DES-CBC3-RMD
DES-CBC3-SHA
DHE-RSA-AES128-RMD
DHE-RSA-AES128-SHA
DHE-RSA-AES256-RMD
DHE-RSA-AES256-SHA
DHE-RSA-DES-CBC3-RMD
DHE-RSA-DES-CBC3-SHA
EDH-RSA-DES-CBC-SHA
EDH-RSA-DES-CBC3-SHA
RC4-MD5
RC4-SHA

Connection TLS Protocol Negotiation

Connection attempts in MySQL negotiate use of the highest TLS protocol version available on both sides for which a protocol-compatible encryption cipher is available on both sides. The negotiation process depends on factors such as the SSL library used to compile the server and client, the TLS protocol and encryption cipher configuration, and which key size is used:

• For a connection attempt to succeed, the server and client TLS protocol configuration must permit some protocol in common.

• Similarly, the server and client encryption cipher configuration must permit some cipher in common. A given cipher may work only with particular TLS protocols, so a protocol available to the negotiation process is not chosen unless there is also a compatible cipher.

• If the server and client are compiled using OpenSSL, TLSv1.2 is used if possible. If either or both the server and client are compiled using yaSSL, only TLSv1 is possible. (“Possible” means that server and client configuration both must permit the indicated protocol, and both must also permit some protocol-compatible encryption cipher.) Otherwise, MySQL continues through the list of available protocols, proceeding from more secure protocols to less secure.

• TLSv1.2 does not work with all ciphers that have a key size of 512 bits or less. To use this protocol with such a key, use `--ssl-cipher` to specify the cipher name explicitly:

AES128-SHA
AES128-SHA256
AES256-SHA
AES256-SHA256
CAMELLIA128-SHA
CAMELLIA256-SHA
DES-CBC3-SHA
DHE-RSA-AES256-SHA
RC4-MD5
RC4-SHA
SEED-SHA

• For better security, use a certificate with an RSA key size of at least 2048 bits.

If the server and client do not have a permitted protocol in common, and a protocol-compatible cipher in common, the server terminates the connection request. Examples:
Monitoring Current Session TLS Protocol and Cipher

- If the server is from MySQL 5.7 or higher and is configured with `tls_version=TLSv1.1,TLSv1.2`:

  - Connection attempts fail for pre-MySQL 5.6.46 clients that support only TLSv1.

  - Similarly, connection attempts fail for pre-MySQL 5.6.46 replication slaves that support only TLSv1.

- If the server is a pre-MySQL 5.6.46 server that supports only TLSv1:

  - Connection attempts fail for MySQL 5.7 or higher clients invoked with `--tls-version=TLSv1.1,TLSv1.2`.

  - Similarly, connection attempts fail for MySQL 5.7 or higher replication slaves configured with `MASTER_TLS_VERSION = 'TLSv1.1,TLSv1.2'`.

Monitoring Current Session TLS Protocol and Cipher

To determine which encryption TLS protocol and cipher the current session uses, check the session values of the `Ssl_version` and `Ssl_cipher` status variables:

```
mysql> SHOW SESSION STATUS LIKE 'Ssl_version';
+---------------+-------+
| Variable_name | Value |
+---------------+-------+
mysql> SHOW SESSION STATUS LIKE 'Ssl_cipher';
+---------------+--------------------+
| Variable_name | Value              |
+---------------+--------------------+
```

If the connection is not encrypted, both variables have an empty value.

5.3 Creating SSL and RSA Certificates and Keys

The following discussion describes how to create the files required for SSL and RSA support in MySQL. File creation is done by invoking the `openssl` command.

SSL certificate and key files enable MySQL to support encrypted connections using SSL. See Chapter 5, Using Encrypted Connections.

RSA key files enable MySQL to support secure password exchange over unencrypted connections for accounts authenticated by the `sha256_password` plugin. See Section 6.1.4, “SHA-256 Pluggable Authentication”.

5.3.1 Creating SSL Certificates and Keys Using openssl

This section describes how to use the `openssl` command to set up SSL certificate and key files for use by MySQL servers and clients. The first example shows a simplified procedure such as you might use from the command line. The second shows a script that contains more detail. The first two examples are intended for use on Unix and both use the `openssl` command that is part of OpenSSL. The third example describes how to set up SSL files on Windows.

**Important**

Whatever method you use to generate the certificate and key files, the Common Name value used for the server and client certificates/keys must each differ from the Common Name value used for the CA certificate. Otherwise, the
Certificate and key files will not work for servers compiled using OpenSSL. A typical error in this case is:

```
ERROR 2026 (HY000): SSL connection error:
error:00000001:lib(0):func(0):reason(1)
```

- **Example 1:** Creating SSL Files from the Command Line on Unix
- **Example 2:** Creating SSL Files Using a Script on Unix
- **Example 3:** Creating SSL Files on Windows

### Example 1: Creating SSL Files from the Command Line on Unix

The following example shows a set of commands to create MySQL server and client certificate and key files. You will need to respond to several prompts by the `openssl` commands. To generate test files, you can press Enter to all prompts. To generate files for production use, you should provide nonempty responses.

```
# Create clean environment
rm -rf newcerts
mkdir newcerts && cd newcerts

# Create CA certificate
openssl genrsa 2048 > ca-key.pem
openssl req -new -x509 -nodes -days 3600 -key ca-key.pem -out ca.pem

# Create server certificate, remove passphrase, and sign it
# server-cert.pem = public key, server-key.pem = private key
openssl req -newkey rsa:2048 -days 3600 -nodes -keyout server-key.pem -out server-req.pem
openssl rsa -in server-key.pem -out server-key.pem
openssl x509 -req -in server-req.pem -days 3600 -CA ca.pem -CAkey ca-key.pem -set_serial 01 -out server-cert.pem

# Create client certificate, remove passphrase, and sign it
# client-cert.pem = public key, client-key.pem = private key
openssl req -newkey rsa:2048 -days 3600 -nodes -keyout client-key.pem -out client-req.pem
openssl rsa -in client-key.pem -out client-key.pem
openssl x509 -req -in client-req.pem -days 3600 -CA ca.pem -CAkey ca-key.pem -set_serial 01 -out client-cert.pem
```

After generating the certificates, verify them:

```
oppenal verify -CAfile ca.pem server-cert.pem client-cert.pem
```

You should see a response like this:

```
server-cert.pem: OK
client-cert.pem: OK
```

Now you have a set of files that can be used as follows:

- **ca.pem:** Use this as the argument to `--ssl-ca` on the server and client sides. (The CA certificate, if used, must be the same on both sides.)

- **server-cert.pem, server-key.pem:** Use these as the arguments to `--ssl-cert` and `--ssl-key` on the server side.

- **client-cert.pem, client-key.pem:** Use these as the arguments to `--ssl-cert` and `--ssl-key` on the client side.

For additional usage instructions, see Section 5.1, “Configuring MySQL to Use Encrypted Connections”.

Example 2: Creating SSL Files Using a Script on Unix

Here is an example script that shows how to set up SSL certificate and key files for MySQL. After executing the script, use the files for SSL connections as described in Section 5.1, “Configuring MySQL to Use Encrypted Connections”.

```bash
DIR=`pwd`/openssl
PRIV=$DIR/private
mkdir $DIR $PRIV $DIR/newcerts
cp /usr/share/ssl/openssl.cnf $DIR
replace ./demoCA $DIR -- $DIR/openssl.cnf
# Create necessary files: $database, $serial and $new_cert_dir
touch $DIR/index.txt
echo "01" > $DIR/serial
# Generation of Certificate Authority(CA)
openssl req -new -x509 -keyout $PRIV/cakey.pem -out $DIR/ca.pem
   -days 3600 -config $DIR/openssl.cnf
# Sample output:
# Using configuration from /home/finley/openssl/openssl.cnf
# Generating a 1024 bit RSA private key
# ................++++++
# ...............++++++
# writing new private key to '/home/finley/openssl/private/cakey.pem'
# Enter PEM pass phrase:
# Verifying password - Enter PEM pass phrase:

Certificate is to be certified until Sep 13 16:45:17 2003 GMT
  (365 days)
Sign the certificate? [y/n]:y

1 out of 1 certificate requests certified, commit? [y/n]y
Write out database with 1 new entries
Data Base Updated

Create a my.cnf file that you can use to test the certificates

```bash
cat <<EOF > $DIR/my.cnf
[client]
ssl-ca=$DIR/ca.pem
ssl-cert=$DIR/client-cert.pem
ssl-key=$DIR/client-key.pem
[mysqld]
ssl-ca=$DIR/ca.pem
ssl-cert=$DIR/server-cert.pem
ssl-key=$DIR/server-key.pem
EOF
```

Example 3: Creating SSL Files on Windows

Download OpenSSL for Windows if it is not installed on your system. An overview of available packages can be seen here:

Choose the Win32 OpenSSL Light or Win64 OpenSSL Light package, depending on your architecture (32-bit or 64-bit). The default installation location will be `C:\OpenSSL-Win32` or `C:\OpenSSL-Win64`, depending on which package you downloaded. The following instructions assume a default location of `C:\OpenSSL-Win32`. Modify this as necessary if you are using the 64-bit package.

If a message occurs during setup indicating '...critical component is missing: Microsoft Visual C++ 2008 Redistributables', cancel the setup and download one of the following packages as well, again depending on your architecture (32-bit or 64-bit):

- Visual C++ 2008 Redistributables (x86), available at:

- Visual C++ 2008 Redistributables (x64), available at:

After installing the additional package, restart the OpenSSL setup procedure.

During installation, leave the default `C:\OpenSSL-Win32` as the install path, and also leave the default option 'Copy OpenSSL DLL files to the Windows system directory' selected.
When the installation has finished, add `C:\OpenSSL-Win32\bin` to the Windows System Path variable of your server (depending on your version of Windows, the following path-setting instructions might differ slightly):

1. On the Windows desktop, right-click the **My Computer** icon, and select **Properties**.
2. Select the **Advanced** tab from the **System Properties** menu that appears, and click the **Environment Variables** button.
3. Under **System Variables**, select **Path**, then click the **Edit** button. The **Edit System Variable** dialogue should appear.
4. Add `';C:\OpenSSL-Win32\bin'` to the end (notice the semicolon).
5. Press OK 3 times.
6. Check that OpenSSL was correctly integrated into the Path variable by opening a new command console (`Start>Run>cmd.exe`) and verifying that OpenSSL is available:

```
Microsoft Windows [Version ...]
Copyright (c) 2006 Microsoft Corporation. All rights reserved.
C:\Windows\system32>cd \C:\>openssl
openssl> exit <<< If you see the OpenSSL prompt, installation was successful.
C:\>
```

After OpenSSL has been installed, use instructions similar to those from Example 1 (shown earlier in this section), with the following changes:

- Change the following Unix commands:
  ```
  # Create clean environment
  rm -rf newcerts
  mkdir newcerts && cd newcerts
  ```

  On Windows, use these commands instead:
  ```
  # Create clean environment
  md c:\newcerts
  cd c:\newcerts
  ```

- When a `\` character is shown at the end of a command line, this `\` character must be removed and the command lines entered all on a single line.

After generating the certificate and key files, to use them for SSL connections, see Section 5.1, "Configuring MySQL to Use Encrypted Connections".

### 5.3.2 Creating RSA Keys Using openssl

This section describes how to use the `openssl` command to set up the RSA key files that enable MySQL to support secure password exchange over unencrypted connections for accounts authenticated by the `sha256_password` plugin.

To create the RSA private and public key-pair files, run these commands while logged into the system account used to run the MySQL server so the files will be owned by that account:

```
openssl genrsa -out private_key.pem 2048
openssl rsa -in private_key.pem -pubout -out public_key.pem
```

Those commands create 2,048-bit keys. To create stronger keys, use a larger value.
Then set the access modes for the key files. The private key should be readable only by the server, whereas the public key can be freely distributed to client users:

```bash
chmod 400 private_key.pem
chmod 444 public_key.pem
```

### 5.4 SSL Library-Dependent Capabilities

MySQL can be compiled using OpenSSL or yaSSL, both of which enable encrypted connections based on the OpenSSL API:

- MySQL Enterprise Edition binary distributions are compiled using OpenSSL. It is not possible to use yaSSL with MySQL Enterprise Edition.
- MySQL Community Edition binary distributions are compiled using yaSSL.
- MySQL Community Edition source distributions can be compiled using either OpenSSL or yaSSL (see Configuring SSL Library Support).

**Note**

It is possible to compile MySQL using yaSSL as an alternative to OpenSSL only prior to MySQL 5.6.46. As of MySQL 5.6.46, support for yaSSL is removed and all MySQL builds use OpenSSL.

OpenSSL and yaSSL offer the same basic functionality, but MySQL distributions compiled using OpenSSL have additional features:

- OpenSSL supports a more flexible syntax for specifying ciphers for the `--ssl-cipher` option, and supports a wider range of encryption ciphers from which to choose. See Command Options for Encrypted Connections, and Section 5.2, “Encrypted Connection TLS Protocols and Ciphers”.
- OpenSSL supports the `--ssl-capath` option. MySQL distributions compiled using yaSSL do not because yaSSL does not look in any directory and do not follow a chained certificate tree. yaSSL requires that all components of the CA certificate tree be contained within a single CA certificate tree and that each certificate in the file has a unique SubjectName value. To work around this limitation, concatenate the individual certificate files comprising the certificate tree into a new file and specify that file as the value of the `--ssl-ca` option.
- OpenSSL supports the `--ssl-crl` and `--ssl-crlpath` options. Distributions compiled using yaSSL do not because revocation lists do not work with yaSSL. (yaSSL accepts these options but silently ignores them.)
- Accounts that authenticate using the `sha256_password` plugin can use RSA key files for secure password exchange over unencrypted connections. See Section 6.1.4, “SHA-256 Pluggable Authentication”.
- OpenSSL supports more encryption modes for the `AES_ENCRYPT()` and `AES_DECRYPT()` functions. See Encryption and Compression Functions.

Certain OpenSSL-related system and status variables are present only if MySQL was compiled using OpenSSL:

- `sha256_password_private_key_path`
- `sha256_password_public_key_path`
- `Rsa_public_key`

To determine whether a server was compiled using OpenSSL, test the existence of any of those variables. For example, this statement returns a row if OpenSSL was used and an empty result if yaSSL was used:
SHOW STATUS LIKE 'Rsa_public_key';

Such tests assume that your server version is not older than the first appearance of the variable tested. For example, you cannot test for Rsa_public_key before MySQL 5.6.6, when that variable was added.

### 5.5 Connecting to MySQL Remotely from Windows with SSH

This section describes how to get an encrypted connection to a remote MySQL server with SSH. The original information was provided by David Carlson <dcarlson@mplcomm.com>.

2. Start your Windows SSH client. Set Host_Name = yourmysqlserver_URL_or_IP. Set userid=your_userid to log in to your server. This userid value might not be the same as the user name of your MySQL account.

3. Set up port forwarding. Either do a remote forward (Set local_port: 3306, remote_host: yourmysqlservername_or_ip, remote_port: 3306) or a local forward (Set port: 3306, host: localhost, remote_port: 3306).

4. Save everything, otherwise you will have to redo it the next time.

5. Log in to your server with the SSH session you just created.

6. On your Windows machine, start some ODBC application (such as Access).

7. Create a new file in Windows and link to MySQL using the ODBC driver the same way you normally do, except type in localhost for the MySQL host server, not yourmysqlservername.

At this point, you should have an ODBC connection to MySQL, encrypted using SSH.

  6.5.2 Installing or Uninstalling MySQL Enterprise Firewall ................ 167
  6.5.3 Using MySQL Enterprise Firewall ....................................... 169
  8.5.4 MySQL Enterprise Firewall Reference .................................. 173

MySQL includes several plugins that implement security features:

- Plugins for authenticating attempts by clients to connect to MySQL Server. Plugins are available for several authentication protocols. For general discussion of the authentication process, see Section 4.11, “Pluggable Authentication”. For characteristics of specific authentication plugins, see Section 6.1, “Authentication Plugins”.

- A password-validation plugin for implementing password strength policies and assessing the strength of potential passwords. See Section 6.3, “The Password Validation Plugin”.

- (MySQL Enterprise Edition only) MySQL Enterprise Audit, implemented using a server plugin, uses the open MySQL Audit API to enable standard, policy-based monitoring and logging of connection and query activity executed on specific MySQL servers. Designed to meet the Oracle audit specification, MySQL Enterprise Audit provides an out of box, easy to use auditing and compliance solution for applications that are governed by both internal and external regulatory guidelines. See Section 6.4, “MySQL Enterprise Audit”.

- (MySQL Enterprise Edition only) MySQL Enterprise Firewall, an application-level firewall that enables database administrators to permit or deny SQL statement execution based on matching against whitelists of accepted statement patterns. This helps harden MySQL Server against attacks such as SQL injection or attempts to exploit applications by using them outside of their legitimate query workload characteristics. See Section 6.5, “MySQL Enterprise Firewall”.

97
6.1 Authentication Plugins

The following sections describe pluggable authentication methods available in MySQL and the plugins that implement these methods. For general discussion of the authentication process, see Section 4.11, “Pluggable Authentication”.

The default plugin is **mysql_native_password** unless the **--default-authentication-plugin** option is set otherwise at server startup.

6.1.1 Native Pluggable Authentication

MySQL includes two plugins that implement native authentication; that is, authentication based on the password hashing methods in use from before the introduction of pluggable authentication. This section describes **mysql_native_password**, which implements authentication against the **mysql.user** system table using the native password hashing method. For information about **mysql_old_password**, which implements authentication using the older (pre-4.1) native password hashing method, see Section 6.1.2, “Old Native Pluggable Authentication”. For information about these password hashing methods, see Section 2.2.4, “Password Hashing in MySQL”.

The following table shows the plugin names on the server and client sides.

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin</td>
<td>mysql_native_password</td>
</tr>
<tr>
<td>Client-side plugin</td>
<td>mysql_native_password</td>
</tr>
<tr>
<td>Library file</td>
<td>None (plugins are built in)</td>
</tr>
</tbody>
</table>

The following sections provide installation and usage information specific to native pluggable authentication:

- **Installing Native Pluggable Authentication**
- **Using Native Pluggable Authentication**

For general information about pluggable authentication in MySQL, see Section 4.11, “Pluggable Authentication”.

Installing Native Pluggable Authentication

The **mysql_native_password** plugin exists in server and client forms:

- The server-side plugin is built into the server, need not be loaded explicitly, and cannot be disabled by unloading it.
- The client-side plugin is built into the **libmysqlclient** client library and is available to any program linked against **libmysqlclient**.

Using Native Pluggable Authentication

MySQL client programs use **mysql_native_password** by default. The **--default-auth** option can be used as a hint about which client-side plugin the program can expect to use:

```
shell> mysql --default-auth=mysql_native_password ...
```

If an account row specifies no plugin name, the server authenticates the account using either the **mysql_native_password** or **mysql_old_password** plugin, depending on whether the password
hash value in the Password column used native hashing or the older pre-4.1 hashing method. Clients must match the password in the Password column of the account row.

### 6.1.2 Old Native Pluggable Authentication

MySQL includes two plugins that implement native authentication; that is, authentication based on the password hashing methods in use from before the introduction of pluggable authentication. This section describes `mysql_old_password`, which implements authentication against the `mysql.user` system table using the older (pre-4.1) native password hashing method. For information about `mysql_native_password`, which implements authentication using the native password hashing method, see Section 6.1.1, “Native Pluggable Authentication”. For information about these password hashing methods, see Section 2.2.4, “Password Hashing in MySQL”.

**Note**

Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords are deprecated and support for them will be removed in a future MySQL release. For account upgrade instructions, see Section 6.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin”.

The following table shows the plugin names on the server and client sides.

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin</td>
<td><code>mysql_old_password</code></td>
</tr>
<tr>
<td>Client-side plugin</td>
<td><code>mysql_old_password</code></td>
</tr>
<tr>
<td>Library file</td>
<td>None (plugins are built in)</td>
</tr>
</tbody>
</table>

The following sections provide installation and usage information specific to old native pluggable authentication:

- **Installing Old Native Pluggable Authentication**
- **Using Old Native Pluggable Authentication**

For general information about pluggable authentication in MySQL, see Section 4.11, “Pluggable Authentication”.

#### Installing Old Native Pluggable Authentication

The `mysql_old_password` plugin exists in server and client forms:

- The server-side plugin is built into the server, need not be loaded explicitly, and cannot be disabled by unloading it.
- The client-side plugin is built into the `libmysqlclient` client library and is available to any program linked against `libmysqlclient`.

#### Using Old Native Pluggable Authentication

MySQL client programs can use the `--default-auth` option to specify the `mysql_old_password` plugin as a hint about which client-side plugin the program can expect to use:

```
shell> mysql --default-auth=mysql_old_password ...
```

If an account row specifies no plugin name, the server authenticates the account using either the `mysql_native_password` or `mysql_old_password` plugin, depending on whether the password
hash value in the `Password` column used native hashing or the older pre-4.1 hashing method. Clients must match the password in the `Password` column of the account row.

## 6.1.3 Migrating Away from Pre-4.1 Password Hashing and the `mysql_old_password` Plugin

The MySQL server authenticates connection attempts for each account listed in the `mysql.user` system table using the authentication plugin named in the `plugin` column. If the `plugin` column is empty, the server authenticates the account as follows:

- **Before MySQL 5.7**, the server uses the `mysql_native_password` or `mysql_old_password` plugin implicitly, depending on the format of the password hash in the `Password` column. If the `Password` value is empty or a 4.1 password hash (41 characters), the server uses `mysql_native_password`. If the password value is a pre-4.1 password hash (16 characters), the server uses `mysql_old_password`. (For additional information about these hash formats, see Section 2.2.4, "Password Hashing in MySQL".)

- **As of MySQL 5.7**, the server requires the `plugin` column to be nonempty and disables accounts that have an empty `plugin` value.

Pre-4.1 password hashes and the `mysql_old_password` plugin are deprecated in MySQL 5.6 and support for them is removed in MySQL 5.7. They provide a level of security inferior to that offered by 4.1 password hashing and the `mysql_native_password` plugin.

Given the requirement in MySQL 5.7 that the `plugin` column must be nonempty, coupled with removal of `mysql_old_password` support, DBAs are advised to upgrade accounts as follows:

- Upgrade accounts that use `mysql_native_password` implicitly to use it explicitly
- Upgrade accounts that use `mysql_old_password` (either implicitly or explicitly) to use `mysql_native_password` explicitly

The instructions in this section describe how to perform those upgrades. The result is that no account has an empty `plugin` value and no account uses pre-4.1 password hashing or the `mysql_old_password` plugin.

As a variant on these instructions, DBAs might offer users the choice to upgrade to the `sha256_password` plugin, which authenticates using SHA-256 password hashes. For information about this plugin, see Section 6.1.4, "SHA-256 Pluggable Authentication".

The following table lists the types of `mysql.user` accounts considered in this discussion.

<table>
<thead>
<tr>
<th><code>plugin</code> Column</th>
<th><code>Password</code> Column</th>
<th>Authentication Result</th>
<th>Upgrade Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Empty</td>
<td>Empty</td>
<td>Implicitly uses <code>mysql_native_password</code></td>
<td>Assign plugin</td>
</tr>
<tr>
<td>Empty</td>
<td>4.1 hash</td>
<td>Implicitly uses <code>mysql_native_password</code></td>
<td>Assign plugin</td>
</tr>
<tr>
<td>Empty</td>
<td>Pre-4.1 hash</td>
<td>Implicitly uses <code>mysql_old_password</code></td>
<td>Assign plugin, rehash password</td>
</tr>
<tr>
<td><code>mysql_native_password</code></td>
<td>Empty</td>
<td>Explicitly uses <code>mysql_old_password</code></td>
<td>None</td>
</tr>
<tr>
<td><code>mysql_native_password</code></td>
<td>4.1 hash</td>
<td>Explicitly uses <code>mysql_native_password</code></td>
<td>None</td>
</tr>
<tr>
<td><code>mysql_old_password</code></td>
<td>Empty</td>
<td>Explicitly uses <code>mysql_old_password</code></td>
<td>Upgrade plugin</td>
</tr>
</tbody>
</table>
Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin

<table>
<thead>
<tr>
<th>plugin Column</th>
<th>Password Column</th>
<th>Authentication Result</th>
<th>Upgrade Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql_old_password</td>
<td>Pre-4.1 hash</td>
<td>Explicitly uses mysql_old_password</td>
<td>Upgrade plugin, rehash password</td>
</tr>
</tbody>
</table>

Accounts corresponding to lines for the mysql_native_password plugin require no upgrade action (because no change of plugin or hash format is required). For accounts corresponding to lines for which the password is empty, consider asking the account owners to choose a password (or require it by using ALTER USER to expire empty account passwords).

### Upgrading Accounts from Implicit to Explicit mysql_native_password Use

Accounts that have an empty plugin and a 4.1 password hash use mysql_native_password implicitly. To upgrade these accounts to use mysql_native_password explicitly, execute these statements:

```
UPDATE mysql.user SET plugin = 'mysql_native_password'
WHERE plugin = '' AND (Password = '' OR LENGTH(Password) = 41);
FLUSH PRIVILEGES;
```

Before MySQL 5.7, you can execute those statements to upgrade accounts proactively. As of MySQL 5.7, you can run `mysql_upgrade`, which performs the same operation among its upgrade actions.

Notes:

- The upgrade operation just described is safe to execute at any time because it makes the mysql_native_password plugin explicit only for accounts that already use it implicitly.
- This operation requires no password changes, so it can be performed without affecting users or requiring their involvement in the upgrade process.

### Upgrading Accounts from mysql_old_password to mysql_native_password

Accounts that use mysql_old_password (either implicitly or explicitly) should be upgraded to use mysql_native_password explicitly. This requires changing the plugin and changing the password from pre-4.1 to 4.1 hash format.

For the accounts covered in this step that must be upgraded, one of these conditions is true:

- The account uses mysql_old_password implicitly because the plugin column is empty and the password has the pre-4.1 hash format (16 characters).
- The account uses mysql_old_password explicitly.

To identify such accounts, use this query:

```
SELECT User, Host, Password FROM mysql.user
WHERE (plugin = '' AND LENGTH(Password) = 16)
OR plugin = 'mysql_old_password';
```

The following discussion provides two methods for updating that set of accounts. They have differing characteristics, so read both and decide which is most suitable for a given MySQL installation.

#### Method 1.

Characteristics of this method:

- It requires that server and clients be run with secure_auth=0 until all users have been upgraded to mysql_native_password. (Otherwise, users cannot connect to the server using their old-format password hashes for the purpose of upgrading to a new-format hash.)
Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin

- It works for MySQL 5.5 and 5.6. In 5.7, it does not work because the server requires accounts to have a nonempty plugin and disables them otherwise. Therefore, if you have already upgraded to 5.7, choose Method 2, described later.

You should ensure that the server is running with `secure_auth=0`

For all accounts that use `mysql_old_password` explicitly, set them to the empty plugin:

```
UPDATE mysql.user SET plugin = ''
WHERE plugin = 'mysql_old_password';
FLUSH PRIVILEGES;
```

To also expire the password for affected accounts, use these statements instead:

```
UPDATE mysql.user SET plugin = '', password_expired = 'Y'
WHERE plugin = 'mysql_old_password';
FLUSH PRIVILEGES;
```

Now affected users can reset their password to use 4.1 hashing. Ask each user who now has an empty plugin to connect to the server and execute these statements:

```
SET old_passwords = 0;
SET PASSWORD = PASSWORD('user-chosen-password');
```

Note
The client-side `--secure-auth` option is enabled by default, so remind users to disable it or they will be unable to connect:

```
shell> mysql -u user_name -p --secure-auth=0
```

After an affected user has executed those statements, you can set the corresponding account plugin to `mysql_native_password` to make the plugin explicit. Or you can periodically run these statements to find and fix any accounts for which affected users have reset their password:

```
UPDATE mysql.user SET plugin = 'mysql_native_password'
WHERE plugin = '' AND (Password = '' OR LENGTH(Password) = 41);
FLUSH PRIVILEGES;
```

When there are no more accounts with an empty plugin, this query returns an empty result:

```
SELECT User, Host, Password FROM mysql.user
WHERE plugin = '' AND LENGTH(Password) = 16;
```

At that point, all accounts have been migrated away from pre-4.1 password hashing and the server no longer need be run with `secure_auth=0`.

Method 2.

Characteristics of this method:

- It assigns each affected account a new password, so you must tell each such user the new password and ask the user to choose a new one. Communication of passwords to users is outside the scope of MySQL, but should be done carefully.

- It does not require server or clients to be run with `secure_auth=0`.

- It works for any version of MySQL 5.5 or later (and for 5.7 has an easier variant).
With this method, you update each account separately due to the need to set passwords individually. Choose a different password for each account.

Suppose that 'user1@localhost' is one of the accounts to be upgraded. Modify it as follows:

- In MySQL 5.7, ALTER USER provides the capability of modifying both the account password and its authentication plugin, so you need not modify the mysql.user system table directly:

```
ALTER USER 'user1@localhost'
IDENTIFIED WITH mysql_native_password BY 'DBA-chosen-password';
```

To also expire the account password, use this statement instead:

```
ALTER USER 'user1@localhost'
IDENTIFIED WITH mysql_native_password BY 'DBA-chosen-password'
PASSWORD EXPIRE;
```

Then tell the user the new password and ask the user to connect to the server with that password and execute this statement to choose a new password:

```
ALTER USER USER() IDENTIFIED BY 'user-chosen-password';
```

- Before MySQL 5.7, you must modify the mysql.user system table directly using these statements:

```
SET old_passwords = 0;
UPDATE mysql.user SET plugin = 'mysql_native_password',
Password = PASSWORD('DBA-chosen-password')
WHERE (User, Host) = ('user1', 'localhost');
FLUSH PRIVILEGES;
```

To also expire the account password, use these statements instead:

```
SET old_passwords = 0;
UPDATE mysql.user SET plugin = 'mysql_native_password',
Password = PASSWORD('DBA-chosen-password'), password_expired = 'Y'
WHERE (User, Host) = ('user1', 'localhost');
FLUSH PRIVILEGES;
```

Then tell the user the new password and ask the user to connect to the server with that password and execute these statements to choose a new password:

```
SET old_passwords = 0;
SET PASSWORD = PASSWORD('user-chosen-password');
```

Repeat for each account to be upgraded.

### 6.1.4 SHA-256 Pluggable Authentication

MySQL provides an authentication plugin that implements SHA-256 hashing for user account passwords.

**Important**

To connect to the server using an account that authenticates with the sha256_password plugin, you must use either a TLS connection or an unencrypted connection that supports password exchange using an RSA key pair, as described later in this section. Either way, use of the sha256_password plugin requires that MySQL be built with SSL capabilities. See Chapter 5, Using Encrypted Connections.
The following table shows the plugin names on the server and client sides.

### Table 6.3 Plugin and Library Names for SHA-256 Authentication

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin</td>
<td>sha256_password</td>
</tr>
<tr>
<td>Client-side plugin</td>
<td>sha256_password</td>
</tr>
<tr>
<td>Library file</td>
<td>None (plugins are built in)</td>
</tr>
</tbody>
</table>

The following sections provide installation and usage information specific to SHA-256 pluggable authentication:

- **Installing SHA-256 Pluggable Authentication**
- **Using SHA-256 Pluggable Authentication**

For general information about pluggable authentication in MySQL, see Section 4.11, “Pluggable Authentication”.

### Installing SHA-256 Pluggable Authentication

The `sha256_password` plugin exists in server and client forms:

- The server-side plugin is built into the server, need not be loaded explicitly, and cannot be disabled by unloading it.
- The client-side plugin is built into the `libmysqlclient` client library and is available to any program linked against `libmysqlclient`.

### Using SHA-256 Pluggable Authentication

To set up an account that uses the `sha256_password` plugin for SHA-256 password hashing, use the following procedure.

1. Create the account and specify that it authenticates using the `sha256_password` plugin:

   ```sql
   CREATE USER 'sha256user'@'localhost' IDENTIFIED WITH sha256_password;
   ```

2. Set the `old_passwords` system variable to 2 to cause the `PASSWORD()` function to use SHA-256 hashing of password strings, then set the account password:

   ```sql
   SET old_passwords = 2;
   SET PASSWORD FOR 'sha256user'@'localhost' = PASSWORD('password');
   ```

   The server assigns the `sha256_password` plugin to the account and uses it to encrypt the password using SHA-256, storing those values in the `plugin` and `authentication_string` columns of the `mysql.user` system table.

   The preceding instructions do not assume that `sha256_password` is the default authentication plugin.

   If `sha256_password` is the default authentication plugin, a simpler `CREATE USER` syntax can be used.

   To start the server with the default authentication plugin set to `sha256_password`, put these lines in the server option file:

   ```ini
   [mysqld]
   default-authentication-plugin=sha256_password
   ```
SHA-256 Pluggable Authentication

That causes the `sha256_password` plugin to be used by default for new accounts. As a result, it is possible to create the account and set its password without naming the plugin explicitly:

```sql
CREATE USER 'sha256user'@'localhost' IDENTIFIED BY 'password';
```

Another consequence of setting `default-authentication-plugin` to `sha256_password` is that, to use some other plugin for account creation, you must specify that plugin explicitly in the `CREATE USER` statement, then set `old_passwords` appropriately for the plugin before using `SET PASSWORD` to set the account password. For example, to use the `mysql_native_password` plugin, do this:

```sql
CREATE USER 'nativeuser'@'localhost' IDENTIFIED WITH mysql_native_password;
SET old_passwords = 0;
SET PASSWORD FOR 'nativeuser'@'localhost' = PASSWORD('N@tivePa33');
```

To set or change the password for any account that authenticates using the `sha256_password` plugin, be sure that the value of `old_passwords` is 2 before using `SET PASSWORD`. If `old_passwords` has a value other than 2, an error occurs for attempts to set the password:

```sql
mysql> SET old_passwords = 0;
```

ERROR 1827 (HY000): The password hash doesn't have the expected format.
Check if the correct password algorithm is being used with the `PASSWORD()` function.

For more information about `old_passwords` and `PASSWORD()`, see Server System Variables, and Encryption and Compression Functions.

MySQL can be compiled using either OpenSSL or yaSSL (see Section 5.4, “SSL Library-Dependent Capabilities”). The `sha256_password` plugin works with distributions compiled using either package, but if MySQL is compiled using OpenSSL, `sha256_password` supports the use of RSA encryption. (To enable this capability, you must follow the RSA configuration procedure given later in this section.)

Note

It is possible to compile MySQL using yaSSL as an alternative to OpenSSL only prior to MySQL 5.6.46. As of MySQL 5.6.46, support for yaSSL is removed and all MySQL builds use OpenSSL.

RSA support has these characteristics:

- On the server side, two system variables name the RSA private and public key-pair files: `sha256_password_private_key_path` and `sha256_password_public_key_path`. The database administrator must set these variables at server startup if the key files to use have names that differ from the system variable default values.

- The `Rsa_public_key` status variable displays the RSA public key value used by the `sha256_password` authentication plugin.

- Clients that have the RSA public key can perform RSA key pair-based password exchange with the server during the connection process, as described later.

- For connections by accounts that authenticate with `sha256_password` and RSA public key pair-based password exchange, the server sends the RSA public key to the client as needed. However, if a copy of the public key is available on the client host, the client can use it to save a round trip in the client/server protocol:

  - For these command-line clients, use the `--server-public-key-path` option to specify the RSA public key file: `mysql`, `mysqltest`.

  - For programs that use the C API, call `mysql_options()` to specify the RSA public key file by passing the `MYSQL_SERVER_PUBLIC_KEY` option and the name of the file.
• For replication slaves, RSA key pair-based password exchange cannot be used to connect to master servers for accounts that authenticate with the `sha256_password` plugin. For such accounts, only secure connections can be used.

For clients that use the `sha256_password` plugin, passwords are never exposed as cleartext when connecting to the server. How password transmission occurs depends on whether a secure connection or RSA encryption is used:

• If the connection is secure, an RSA key pair is unnecessary and is not used. This applies to encrypted connections that use TLS. The password is sent as cleartext but cannot be snooped because the connection is secure.

• If the connection is not secure, and an RSA key pair is available, the connection remains unencrypted. This applies to unencrypted connections without TLS. RSA is used only for password exchange between client and server, to prevent password snooping. When the server receives the encrypted password, it decrypts it. A scramble is used in the encryption to prevent repeat attacks.

• If a secure connection is not used and RSA encryption is not available, the connection attempt fails because the password cannot be sent without being exposed as cleartext.

As mentioned previously, RSA password encryption is available only if MySQL was compiled using OpenSSL. The implication for MySQL distributions compiled using yaSSL is that, to use SHA-256 passwords, clients must use an encrypted connection to access the server. See Section 5.1, “Configuring MySQL to Use Encrypted Connections”.

### Note

To use RSA password encryption with `sha256_password`, the client and server both must be compiled using OpenSSL, not just one of them.

Assuming that MySQL has been compiled using OpenSSL, use the following procedure to enable use of an RSA key pair for password exchange during the client connection process:

1. Create the RSA private and public key-pair files using the instructions in Section 5.3, “Creating SSL and RSA Certificates and Keys”.

2. If the private and public key files are located in the data directory and are named `private_key.pem` and `public_key.pem` (the default values of the `sha256_password_private_key_path` and `sha256_password_public_key_path` system variables), the server uses them automatically at startup.

   Otherwise, to name the key files explicitly, set the system variables to the key file names in the server option file. If the files are located in the server data directory, you need not specify their full path names:

   ```
   [mysqld]
   sha256_password_private_key_path=myprivkey.pem
   sha256_password_public_key_path=mypubkey.pem
   ```

   If the key files are not located in the data directory, or to make their locations explicit in the system variable values, use full path names:

   ```
   [mysqld]
   sha256_password_private_key_path=/usr/local/mysql/myprivkey.pem
   sha256_password_public_key_path=/usr/local/mysql/mypubkey.pem
   ```

3. Restart the server, then connect to it and check the `Rsa_public_key` status variable value. The value will differ from that shown here, but should be nonempty:
If the value is empty, the server found some problem with the key files. Check the error log for diagnostic information.

After the server has been configured with the RSA key files, accounts that authenticate with the `sha256_password` plugin have the option of using those key files to connect to the server. As mentioned previously, such accounts can use either a secure connection (in which case RSA is not used) or an unencrypted connection that performs password exchange using RSA. Suppose that an unencrypted connection is used. For example:

```
shell> mysql --ssl-mode=DISABLED -u sha256user -p
Enter password: password
```

For this connection attempt by `sha256user`, the server determines that `sha256_password` is the appropriate authentication plugin and invokes it (because that was the plugin specified at `CREATE USER` time). The plugin finds that the connection is not encrypted and thus requires the password to be transmitted using RSA encryption. In this case, the plugin sends the RSA public key to the client, which uses it to encrypt the password and returns the result to the server. The plugin uses the RSA private key on the server side to decrypt the password and accepts or rejects the connection based on whether the password is correct.

The server sends the RSA public key to the client as needed. However, if the client has a file containing a local copy of the RSA public key required by the server, it can specify the file using the `--server-public-key-path` option:

```
shell> mysql --ssl-mode=DISABLED -u sha256user -p --server-public-key-path=file_name
Enter password: password
```

The public key value in the file named by the `--server-public-key-path` option should be the same as the key value in the server-side file named by the `sha256_password_public_key_path` system variable. If the key file contains a valid public key value but the value is incorrect, an access-denied error occurs. If the key file does not contain a valid public key, the client program cannot use it. In this case, the `sha256_password` plugin sends the public key to the client as if no `--server-public-key-path` option had been specified.

Client users can obtain the RSA public key two ways:

- The database administrator can provide a copy of the public key file.
- A client user who can connect to the server some other way can use a `SHOW STATUS LIKE 'Rsa_public_key'` statement and save the returned key value in a file.

### 6.1.5 Client-Side Cleartext Pluggable Authentication

A client-side authentication plugin is available that enables clients to send passwords to the server as cleartext, without hashing or encryption. This plugin is built into the MySQL client library.

The following table shows the plugin name.

<table>
<thead>
<tr>
<th>Table 6.4 Plugin and Library Names for Cleartext Authentication</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Plugin or File</strong></td>
</tr>
<tr>
<td>Server-side plugin</td>
</tr>
</tbody>
</table>
Many client-side authentication plugins perform hashing or encryption of a password before the client sends it to the server. This enables clients to avoid sending passwords as cleartext.

Hashing or encryption cannot be done for authentication schemes that require the server to receive the password as entered on the client side. In such cases, the client-side `mysql_clear_password` plugin is used to send the password to the server as cleartext. There is no corresponding server-side plugin. Rather, the client-side plugin can be used by any server-side plugin that needs a cleartext password. (The PAM authentication plugin is one such; see Section 6.1.6, “PAM Pluggable Authentication”.)

The following discussion provides usage information specific to cleartext pluggable authentication. For general information about pluggable authentication in MySQL, see Section 4.11, “Pluggable Authentication”.

### Note

Sending passwords as cleartext may be a security problem in some configurations. To avoid problems if there is any possibility that the password would be intercepted, clients should connect to MySQL Server using a method that protects the password. Possibilities include SSL (see Chapter 5, Using Encrypted Connections), IPsec, or a private network.

To make inadvertent use of the `mysql_clear_password` plugin less likely, MySQL clients must explicitly enable it. This can be done in several ways:

- Set the `LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN` environment variable to a value that begins with `1`, `Y`, or `y`. This enables the plugin for all client connections.
- The `mysql`, `mysqladmin`, and `mysqlslap` client programs (also `mysqlcheck`, `mysqldump`, and `mysqlshow` for MySQL 5.6.28 and later) support an `--enable-cleartext-plugin` option that enables the plugin on a per-invocation basis.
- The `mysql_options()` C API function supports a `MYSQL_ENABLE_CLEARTEXT_PLUGIN` option that enables the plugin on a per-connection basis. Also, any program that uses `libmysqlclient` and reads option files can enable the plugin by including an `enable-cleartext-plugin` option in an option group read by the client library.

### 6.1.6 PAM Pluggable Authentication

### Note

PAM pluggable authentication is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see [https://www.mysql.com/products/](https://www.mysql.com/products/).

MySQL Enterprise Edition supports an authentication method that enables MySQL Server to use PAM (Pluggable Authentication Modules) to authenticate MySQL users. PAM enables a system to use a standard interface to access various kinds of authentication methods, such as traditional Unix passwords or an LDAP directory.
PAM pluggable authentication provides these capabilities:

- **External authentication**: PAM authentication enables MySQL Server to accept connections from users defined outside the MySQL grant tables and that authenticate using methods supported by PAM.

- **Proxy user support**: PAM authentication can return to MySQL a user name different from the external user name passed by the client program, based on the PAM groups the external user is a member of and the authentication string provided. This means that the plugin can return the MySQL user that defines the privileges the external PAM-authenticated user should have. For example, an operating system user named `joe` can connect and have the privileges of a MySQL user named `developer`.

PAM pluggable authentication has been tested on Linux and macOS.

The following table shows the plugin and library file names. The file name suffix might differ on your system. The file must be located in the directory named by the `plugin_dir` system variable. For installation information, see Installing PAM Pluggable Authentication.

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin</td>
<td>authentication_pam</td>
</tr>
<tr>
<td>Client-side plugin</td>
<td>mysql_clear_password</td>
</tr>
<tr>
<td>Library file</td>
<td>authentication_pam.so</td>
</tr>
</tbody>
</table>

The client-side `mysql_clear_password` cleartext plugin that communicates with the server-side PAM plugin is built into the `libmysqlclient` client library and is included in all distributions, including community distributions. Inclusion of the client-side cleartext plugin in all MySQL distributions enables clients from any distribution to connect to a server that has the server-side PAM plugin loaded.

The following sections provide installation and usage information specific to PAM pluggable authentication:

- **How PAM Authentication of MySQL Users Works**
- **Installing PAM Pluggable Authentication**
- **Uninstalling PAM Pluggable Authentication**
- **Using PAM Pluggable Authentication**
- **PAM Unix Password Authentication without Proxy Users**
- **PAM LDAP Authentication without Proxy Users**
- **PAM Unix Password Authentication with Proxy Users and Group Mapping**
- **PAM Authentication Access to Unix Password Store**
- **PAM Authentication Debugging**

For general information about pluggable authentication in MySQL, see Section 4.11, “Pluggable Authentication”. For information about the `mysql_clear_password` plugin, see Section 6.1.5, “Client-Side Cleartext Pluggable Authentication”. For proxy user information, see Section 4.12, “Proxy Users”.

**How PAM Authentication of MySQL Users Works**

This section provides a general overview of how MySQL and PAM work together to authenticate MySQL users. For examples showing how to set up MySQL accounts to use specific PAM services, see Using PAM Pluggable Authentication.
1. The client program and the server communicate, with the client sending to the server the client user name (the operating system user name by default) and password:
   - The client user name is the external user name.
   - For accounts that use the PAM server-side authentication plugin, the corresponding client-side plugin is `mysql_clear_password`. This client-side plugin performs no password hashing, with the result that the client sends the password to the server as cleartext.

2. The server finds a matching MySQL account based on the external user name and the host from which the client connects. The PAM plugin uses the information passed to it by MySQL Server (such as user name, host name, password, and authentication string). When you define a MySQL account that authenticates using PAM, the authentication string contains:
   - A PAM service name, which is a name that the system administrator can use to refer to an authentication method for a particular application. There can be multiple applications associated with a single database server instance, so the choice of service name is left to the SQL application developer.
   - Optionally, if proxying is to be used, a mapping from PAM groups to MySQL user names.

3. The plugin uses the PAM service named in the authentication string to check the user credentials and returns 'Authentication succeeded, Username is \texttt{user_name}' or 'Authentication failed'. The password must be appropriate for the password store used by the PAM service. Examples:
   - For traditional Unix passwords, the service looks up passwords stored in the `/etc/shadow` file.
   - For LDAP, the service looks up passwords stored in an LDAP directory.

   If the credentials check fails, the server refuses the connection.

4. Otherwise, the authentication string indicates whether proxying occurs. If the string contains no PAM group mapping, proxying does not occur. In this case, the MySQL user name is the same as the external user name.

5. Otherwise, proxying is indicated based on the PAM group mapping, with the MySQL user name determined based on the first matching group in the mapping list. The meaning of “PAM group” depends on the PAM service. Examples:
   - For traditional Unix passwords, groups are Unix groups defined in the `/etc/group` file, possibly supplemented with additional PAM information in a file such as `/etc/security/group.conf`.
   - For LDAP, groups are LDAP groups defined in an LDAP directory.

   If the proxy user (the external user) has the \texttt{PROXY} privilege for the proxied MySQL user name, proxying occurs, with the proxy user assuming the privileges of the proxied user.

### Installing PAM Pluggable Authentication

This section describes how to install the PAM authentication plugin. For general information about installing plugins, see Installing and Uninstalling Plugins.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base name is `authentication_pam`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To load the plugin at server startup, use the `--plugin-load-add` option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts.
For example, put these lines in the server `my.cnf` file (adjust the `.so` suffix for your platform as necessary):

```
[mysqld]
plugin-load-add=authentication_pam.so
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to load the plugin at runtime, use this statement (adjust the `.so` suffix for your platform as necessary):

```
INSTALL PLUGIN authentication_pam SONAME 'authentication_pam.so';
```

`INSTALL PLUGIN` loads the plugin immediately, and also registers it in the `mysql.plugins` system table to cause the server to load it for each subsequent normal startup without the need for `--plugin-load-add`.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see Obtaining Server Plugin Information). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
    FROM INFORMATION_SCHEMA.PLUGINS
    WHERE PLUGIN_NAME LIKE '%pam%';
+--------------------+---------------+
| PLUGIN_NAME        | PLUGIN_STATUS |
|--------------------|---------------+
| authentication_pam | ACTIVE        |
+--------------------+---------------+
```

If the plugin failed to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with the PAM plugin, see Using PAM Pluggable Authentication.

### Uninstalling PAM Pluggable Authentication

The method used to uninstall the PAM authentication plugin depends on how you installed it:

- If you installed the plugin at server startup using a `--plugin-load-add` option, restart the server without the option.

- If you installed the plugin at runtime using an `INSTALL PLUGIN` statement, it remains installed across server restarts. To uninstall it, use `UNINSTALL PLUGIN`:

```
UNINSTALL PLUGIN authentication_pam;
```

### Using PAM Pluggable Authentication

This section describes in general terms how to use the PAM authentication plugin to connect from MySQL client programs to the server. The following sections provide instructions for using PAM authentication in specific ways. It is assumed that the server is running with the server-side PAM plugin enabled, as described in Installing PAM Pluggable Authentication.

To refer to the PAM authentication plugin in the `IDENTIFIED WITH` clause of a `CREATE USER` or `GRANT` statement, use the name `authentication_pam`. For example:

```
CREATE USER user
    IDENTIFIED WITH authentication_pam
    AS 'auth_string';
```

The authentication string specifies the following types of information:
• The PAM service name (see How PAM Authentication of MySQL Users Works). Examples in the following discussion use a service name of mysql-unix for authentication using traditional Unix passwords, and mysql-ldap for authentication using LDAP.

• For proxy support, PAM provides a way for a PAM module to return to the server a MySQL user name other than the external user name passed by the client program when it connects to the server. Use the authentication string to control the mapping from external user names to MySQL user names. If you want to take advantage of proxy user capabilities, the authentication string must include this kind of mapping.

For example, if an account uses the mysql-unix PAM service name and should map operating system users in the root and users PAM groups to the developer and data_entry MySQL users, respectively, use a statement like this:

```
CREATE USER user
    IDENTIFIED WITH authentication_pam
    AS 'mysql-unix, root=developer, users=data_entry';
```

Authentication string syntax for the PAM authentication plugin follows these rules:

• The string consists of a PAM service name, optionally followed by a PAM group mapping list consisting of one or more keyword/value pairs each specifying a PAM group name and a MySQL user name:

```
pam_service_name[,...]
pam_group_name=mysql_user_name
```

The plugin parses the authentication string for each connection attempt that uses the account. To minimize overhead, keep the string as short as possible.

• Each `pam_group_name=mysql_user_name` pair must be preceded by a comma.

• Leading and trailing spaces not inside double quotation marks are ignored.

• Unquoted `pam_service_name`, `pam_group_name`, and `mysql_user_name` values can contain anything except equal sign, comma, or space.

• If a `pam_service_name`, `pam_group_name`, or `mysql_user_name` value is quoted with double quotation marks, everything between the quotation marks is part of the value. This is necessary, for example, if the value contains space characters. All characters are legal except double quotation mark and backslash (\). To include either character, escape it with a backslash.

If the plugin successfully authenticates the external user name (the name passed by the client), it looks for a PAM group mapping list in the authentication string and, if present, uses it to return a different MySQL user name to the MySQL server based on which PAM groups the external user is a member of:

• If the authentication string contains no PAM group mapping list, the plugin returns the external name.

• If the authentication string does contain a PAM group mapping list, the plugin examines each `pam_group_name=mysql_user_name` pair in the list from left to right and tries to find a match for the `pam_group_name` value in a non-MySQL directory of the groups assigned to the authenticated user and returns `mysql_user_name` for the first match it finds. If the plugin finds no match for any PAM group, it returns the external name. If the plugin is not capable of looking up a group in a directory, it ignores the PAM group mapping list and returns the external name.

The following sections describe how to set up several authentication scenarios that use the PAM authentication plugin:

• No proxy users. This uses PAM only to check login names and passwords. Every external user permitted to connect to MySQL Server should have a matching MySQL account that is defined to use PAM authentication. (For a MySQL account of `user_name@host_name` to match
the external user, user_name must be the external user name and host_name must match the
host from which the client connects.) Authentication can be performed by various PAM-supported
methods. Later discussion shows how to authenticate client credentials using traditional Unix
passwords, and passwords in LDAP.

PAM authentication, when not done through proxy users or PAM groups, requires the MySQL
user name to be same as the operating system user name. MySQL user names are limited to 16
characters (see Section 4.3, “Grant Tables”), which limits PAM nonproxy authentication to Unix
accounts with names of at most 16 characters.

• Proxy users only, with PAM group mapping. For this scenario, create one or more MySQL accounts
that define different sets of privileges. (Ideally, nobody should connect using those accounts directly.)
Then define a default user authenticating through PAM that uses some mapping scheme (usually
based on the external PAM groups the users are members of) to map all the external user names
to the few MySQL accounts holding the privilege sets. Any client who connects and specifies an
external user name as the client user name is mapped to one of the MySQL accounts and uses its
privileges. The discussion shows how to set this up using traditional Unix passwords, but other PAM
methods such as LDAP could be used instead.

Variations on these scenarios are possible:

• You can permit some users to log in directly (without proxying) but require others to connect through
proxy accounts.

• You can use one PAM authentication method for some users, and another method for other users,
by using differing PAM service names among your PAM-authenticated accounts. For example, you
can use the mysql-unix PAM service for some users, and mysql-ldap for others.

The examples make the following assumptions. You might need to make some adjustments if your
system is set up differently.

• The login name and password are antonio and antonio_password, respectively. Change these
to correspond to the user you want to authenticate.

• The PAM configuration directory is /etc/pam.d.

• The PAM service name corresponds to the authentication method (mysql-unix or mysql-ldap in
this discussion). To use a given PAM service, you must set up a PAM file with the same name in the
PAM configuration directory (creating the file if it does not exist). In addition, you must use the PAM
service name in the authentication string of CREATE USER or GRANT statements for any account that
authenticates using that service.

The PAM authentication plugin checks at initialization time whether the AUTHENTICATION_PAM_LOG
environment value is set in the server’s startup environment. If so, the plugin enables logging of
diagnostic messages to the standard output. Depending on how your server is started, the message
might appear on the console or in the error log. These messages can be helpful for debugging PAM-related
issues that occur when the plugin performs authentication. For more information, see PAM
Authentication Debugging.

**PAM Unix Password Authentication without Proxy Users**

This authentication scenario uses PAM to check external users defined in terms of operating system
user names and Unix passwords, without proxying. Every such external user permitted to connect to
MySQL Server should have a matching MySQL account that is defined to use PAM authentication
through traditional Unix password store.

---

**Note**

Traditional Unix passwords are checked using the /etc/shadow file. For information regarding possible issues related to this file, see PAM Authentication Access to Unix Password Store.
1. Verify that Unix authentication permits logins to the operating system with the user name \texttt{antonio} and password \texttt{antonio\_password}.

2. Set up PAM to authenticate MySQL connections using traditional Unix passwords by creating a \texttt{mysql-unix} PAM service file named \texttt{/etc/pam.d/mysql-unix}. The file contents are system dependent, so check existing login-related files in the \texttt{/etc/pam.d} directory to see what they look like. On Linux, the \texttt{mysql-unix} file might look like this:

```
# %PAM-1.0
auth      include      password-auth
account   include      password-auth
```

For macOS, use \texttt{login} rather than \texttt{password-auth}.

The PAM file format might differ on some systems. For example, on Ubuntu and other Debian-based systems, use these file contents instead:

```
@include common-auth
@include common-account
@include common-session-noninteractive
```

3. Create a MySQL account with the same user name as the operating system user name and define it to authenticate using the PAM plugin and the \texttt{mysql-unix} PAM service:

```
CREATE USER 'antonio'@'localhost'
  IDENTIFIED WITH authentication_pam
  AS 'mysql-unix';
GRANT ALL PRIVILEGES
  ON mydb.*
  TO 'antonio'@'localhost';
```

Here, the authentication string contains only the PAM service name, \texttt{mysql-unix}, which authenticates Unix passwords.

4. Use the \texttt{mysql} command-line client to connect to the MySQL server as \texttt{antonio}. For example:

```
shell> mysql --user=antonio --password --enable-cleartext-plugin
Enter password: antonio\_password
```

The server should permit the connection and the following query should return output as shown:

```
mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
+-------------------+-------------------+--------------+
| USER()            | CURRENT_USER()    | @@proxy_user |
|-------------------|-------------------|--------------+
| antonio@localhost | antonio@localhost | NULL         |
```

This demonstrates that the \texttt{antonio} operating system user is authenticated to have the privileges granted to the \texttt{antonio} MySQL user, and that no proxying has occurred.

\textbf{Note}

The client-side \texttt{mysql\_clear\_password} authentication plugin leaves the password untouched, so client programs send it to the MySQL server as cleartext. This enables the password to be passed as is to PAM. A cleartext password is necessary to use the server-side PAM library, but may be a security problem in some configurations. These measures minimize the risk:

- To make inadvertent use of the \texttt{mysql\_clear\_password} plugin less likely, MySQL clients must explicitly enable it (for example, with the \texttt{--enable-...}
PAM Pluggable Authentication

**cleartext-plugin option.** See Section 6.1.5, “Client-Side Cleartext Pluggable Authentication”.

- To avoid password exposure with the `mysql_clear_password` plugin enabled, MySQL clients should connect to the MySQL server using an encrypted connection. See Section 5.1, “Configuring MySQL to Use Encrypted Connections”.

### PAM LDAP Authentication without Proxy Users

This authentication scenario uses PAM to check external users defined in terms of operating system user names and LDAP passwords, without proxying. Every such external user permitted to connect to MySQL Server should have a matching MySQL account that is defined to use PAM authentication through LDAP.

To use PAM LDAP pluggable authentication for MySQL, these prerequisites must be satisfied:

- An LDAP server must be available for the PAM LDAP service to communicate with.
- LDAP users to be authenticated by MySQL must be present in the directory managed by the LDAP server.

Configure MySQL for PAM LDAP authentication as follows:

1. Verify that Unix authentication permits logins to the operating system with the user name `antonio` and password `antonio_password`.

2. Set up PAM to authenticate MySQL connections using LDAP by creating a `mysql-ldap` PAM service file named `/etc/pam.d/mysql-ldap`. The file contents are system dependent, so check existing login-related files in the `/etc/pam.d` directory to see what they look like. On Linux, the `mysql-ldap` file might look like this:

```ini
#%PAM-1.0
auth        required    pam_ldap.so
account     required    pam_ldap.so
```

If PAM object files have a suffix different from `.so` on your system, substitute the correct suffix.

The PAM file format might differ on some systems.

3. Create a MySQL account with the same user name as the operating system user name and define it to authenticate using the PAM plugin and the `mysql-ldap` PAM service:

```sql
CREATE USER 'antonio'@'localhost'
    IDENTIFIED WITH authentication_pam
    AS 'mysql-ldap';
GRANT ALL PRIVILEGES
    ON mydb.*
    TO 'antonio'@'localhost';
```

Here, the authentication string contains only the PAM service name, `mysql-ldap`, which authenticates using LDAP.

4. Connecting to the server is the same as described in PAM Unix Password Authentication without Proxy Users.

### PAM Unix Password Authentication with Proxy Users and Group Mapping

The authentication scheme described here uses proxying and PAM group mapping to map connecting MySQL users who authenticate using PAM onto other MySQL accounts that define different sets of privileges. Users do not connect directly through the accounts that define the privileges. Instead, they
connect through a default proxy account authenticated using PAM, such that all the external users are mapped to the MySQL accounts that hold the privileges. Any user who connects using the proxy account is mapped to one of those MySQL accounts, the privileges for which determine the database operations permitted to the external user.

The procedure shown here uses Unix password authentication. To use LDAP instead, see the early steps of PAM LDAP Authentication without Proxy Users.

**Note**

Traditional Unix passwords are checked using the `/etc/shadow` file. For information regarding possible issues related to this file, see PAM Authentication Access to Unix Password Store.

1. Verify that Unix authentication permits logins to the operating system with the user name `antonio` and password `antonio_password`.

2. Verify that `antonio` is a member of the `root` or `users` PAM group.

3. Set up PAM to authenticate the `mysql-unix` PAM service through operating system users by creating a file named `/etc/pam.d/mysql-unix`. The file contents are system dependent, so check existing login-related files in the `/etc/pam.d` directory to see what they look like. On Linux, the `mysql-unix` file might look like this:

   ```
   # %PAM-1.0
   auth        include         password-auth
   account     include         password-auth
   ```

   For macOS, use `login` rather than `password-auth`.

   The PAM file format might differ on some systems. For example, on Ubuntu and other Debian-based systems, use these file contents instead:

   ```
   @include common-auth
   @include common-account
   @include common-session-noninteractive
   ```

4. Create a default proxy user (`'@'`) that maps external PAM users to the proxied accounts:

   ```
   CREATE USER `'@'`
   IDENTIFIED WITH authentication_pam
   AS 'mysql-unix, root=developer, users=data_entry';
   ```

   Here, the authentication string contains the PAM service name, `mysql-unix`, which authenticates Unix passwords. The authentication string also maps external users in the `root` and `users` PAM groups to the `developer` and `data_entry` MySQL user names, respectively.

   The PAM group mapping list following the PAM service name is required when you set up proxy users. Otherwise, the plugin cannot tell how to perform mapping from external user names to the proper proxied MySQL user names.

   **Note**

   If your MySQL installation has anonymous users, they might conflict with the default proxy user. For more information about this issue, and ways of dealing with it, see Default Proxy User and Anonymous User Conflicts.

5. Create the proxied accounts and grant to them the privileges required for MySQL access:

   ```
   CREATE USER 'developer'@'localhost'
   ```
PAM Pluggable Authentication

```sql
CREATE USER 'data_entry'@'localhost'
IDENTIFIED BY 'very secret password';
GRANT ALL PRIVILEGES
ON mydevdb.*
TO 'developer'@'localhost';
GRANT ALL PRIVILEGES
ON mydb.*
TO 'data_entry'@'localhost';
```

If you do not let anyone know the passwords for these accounts, clients cannot use them to connect directly to the MySQL server. Instead, it is expected that users who authenticate using PAM will use the `developer` or `data_entry` account by proxy based on their PAM group.

6. Grant to the proxy account the PROXY privilege for each proxied account:

```sql
GRANT PROXY
ON 'developer'@'localhost'
TO ''@'';
GRANT PROXY
ON 'data_entry'@'localhost'
TO ''@'';
```

7. Use the `mysql` command-line client to connect to the MySQL server as `antonio`.

```
shell> mysql --user=antonio --password --enable-cleartext-plugin
Enter password: antonio_password
```

The server authenticates the connection using the default `'@'` proxy account. The resulting privileges for `antonio` depend on which PAM groups `antonio` is a member of. If `antonio` is a member of the `root` PAM group, the PAM plugin maps `root` to the `developer` MySQL user name and returns that name to the server. The server verifies that `'@'` has the PROXY privilege for `developer` and permits the connection. The following query should return output as shown:

```
mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
+-------------------+---------------------+--------------+
| USER()            | CURRENT_USER()      | @@proxy_user |
+-------------------+---------------------+--------------+
| antonio@localhost | developer@localhost | ''@''        |
+-------------------+---------------------+--------------+
```

This demonstrates that the `antonio` operating system user is authenticated to have the privileges granted to the `developer` MySQL user, and that proxying occurred through the default proxy account.

If `antonio` is not a member of the `root` PAM group but is a member of the `users` PAM group, a similar process occurs, but the plugin maps `user` PAM group membership to the `data_entry` MySQL user name and returns that name to the server:

```
mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
+-------------------+---------------------+--------------+
| USER()            | CURRENT_USER()       | @@proxy_user |
+-------------------+---------------------+--------------+
| antonio@localhost | data_entry@localhost | ''@''        |
+-------------------+---------------------+--------------+
```

This demonstrates that the `antonio` operating system user is authenticated to have the privileges of the `data_entry` MySQL user, and that proxying occurred through the default proxy account.

Note

The client-side `mysql_clear_password` authentication plugin leaves the password untouched, so client programs send it to the MySQL server as
cleartext. This enables the password to be passed as is to PAM. A cleartext password is necessary to use the server-side PAM library, but may be a security problem in some configurations. These measures minimize the risk:

- To make inadvertent use of the `mysql_clear_password` plugin less likely, MySQL clients must explicitly enable it (for example, with the `--enable-cleartext-plugin` option). See Section 6.1.5, “Client-Side Cleartext Pluggable Authentication”.

- To avoid password exposure with the `mysql_clear_password` plugin enabled, MySQL clients should connect to the MySQL server using an encrypted connection. See Section 5.1, “Configuring MySQL to Use Encrypted Connections”.

### PAM Authentication Access to Unix Password Store

On some systems, Unix authentication uses a password store such as `/etc/shadow`, a file that typically has restricted access permissions. This can cause MySQL PAM-based authentication to fail. Unfortunately, the PAM implementation does not permit distinguishing “password could not be checked” (due, for example, to inability to read `/etc/shadow`) from “password does not match.” If you are using Unix password store for PAM authentication, you may be able to enable access to it from MySQL using one of the following methods:

- Assuming that the MySQL server is run from the `mysql` operating system account, put that account in the `shadow` group that has `/etc/shadow` access:

  1. Create a `shadow` group in `/etc/group`.
  2. Add the `mysql` operating system user to the `shadow` group in `/etc/group`.
  3. Assign `/etc/group` to the `shadow` group and enable the group read permission:

     ```bash
     chgrp shadow /etc/shadow
     chmod g+r /etc/shadow
     ```
  4. Restart the MySQL server.

- If you are using the `pam_unix` module and the `unix_chkpwd` utility, enable password store access as follows:

  ```bash
  chmod u-s /usr/sbin/unix_chkpwd
  setcap cap_dac_read_search+ep /usr/sbin/unix_chkpwd
  ```

  Adjust the path to `unix_chkpwd` as necessary for your platform.

### PAM Authentication Debugging

The PAM authentication plugin checks at initialization time whether the `AUTHENTICATION_PAM_LOG` environment value is set (the value does not matter). If so, the plugin enables logging of diagnostic messages to the standard output. These messages may be helpful for debugging PAM-related issues that occur when the plugin performs authentication.

Some messages include reference to PAM plugin source files and line numbers, which enables plugin actions to be tied more closely to the location in the code where they occur.

Another technique for debugging connection failures and determining what is happening during connection attempts is to configure PAM authentication to permit all connections, then check the system log files. This technique should be used only on a temporary basis, and not on a production server.
Configure a PAM service file named `/etc/pam.d/mysql-any-password` with these contents (the format may differ on some systems):

```
# PAM-1.0
auth required pam_permit.so
account required pam_permit.so
```

Create an account that uses the PAM plugin and names the `mysql-any-password` PAM service:

```
CREATE USER 'testuser'@'localhost'
IDENTIFIED WITH authentication_pam
AS 'mysql-any-password';
```

The `mysql-any-password` service file causes any authentication attempt to return true, even for incorrect passwords. If an authentication attempt fails, that tells you the configuration problem is on the MySQL side. Otherwise, the problem is on the operating system/PAM side. To see what might be happening, check system log files such as `/var/log/secure`, `/var/log/audit.log`, `/var/log/syslog`, or `/var/log/messages`.

After determining what the problem is, remove the `mysql-any-password` PAM service file to disable any-password access.

### 6.1.7 Windows Pluggable Authentication

**Note**

Windows pluggable authentication is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see [https://www.mysql.com/products/](https://www.mysql.com/products/).

MySQL Enterprise Edition for Windows supports an authentication method that performs external authentication on Windows, enabling MySQL Server to use native Windows services to authenticate client connections. Users who have logged in to Windows can connect from MySQL client programs to the server based on the information in their environment without specifying an additional password.

The client and server exchange data packets in the authentication handshake. As a result of this exchange, the server creates a security context object that represents the identity of the client in the Windows OS. This identity includes the name of the client account. Windows pluggable authentication uses the identity of the client to check whether it is a given account or a member of a group. By default, negotiation uses Kerberos to authenticate, then NTLM if Kerberos is unavailable.

Windows pluggable authentication provides these capabilities:

- External authentication: Windows authentication enables MySQL Server to accept connections from users defined outside the MySQL grant tables who have logged in to Windows.
- Proxy user support: Windows authentication can return to MySQL a user name different from the external user name passed by the client program. This means that the plugin can return the MySQL user that defines the privileges the external Windows-authenticated user should have. For example, a Windows user named `joe` can connect and have the privileges of a MySQL user named `developer`.

The following table shows the plugin and library file names. The file must be located in the directory named by the `plugin_dir` system variable.

#### Table 6.6 Plugin and Library Names for Windows Authentication

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin</td>
<td>authentication_windows</td>
</tr>
<tr>
<td>Client-side plugin</td>
<td>authentication_windows_client</td>
</tr>
</tbody>
</table>
Windows Pluggable Authentication

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Library file</td>
<td>authentication_windows.dll</td>
</tr>
</tbody>
</table>

The library file includes only the server-side plugin. The client-side plugin is built into the libmysqlclient client library.

The server-side Windows authentication plugin is included only in MySQL Enterprise Edition. It is not included in MySQL community distributions. The client-side plugin is included in all distributions, including community distributions. This permits clients from any distribution to connect to a server that has the server-side plugin loaded.

The Windows authentication plugin is supported on any version of Windows supported by MySQL 5.6 (see https://www.mysql.com/support/supportedplatforms/database.html).

The following sections provide installation and usage information specific to Windows pluggable authentication:

- Installing Windows Pluggable Authentication
- Uninstalling Windows Pluggable Authentication
- Using Windows Pluggable Authentication

For general information about pluggable authentication in MySQL, see Section 4.11, “Pluggable Authentication”. For proxy user information, see Section 4.12, “Proxy Users”.

Installing Windows Pluggable Authentication

This section describes how to install the Windows authentication plugin. For general information about installing plugins, see Installing and Uninstalling Plugins.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the plugin_dir system variable). If necessary, configure the plugin directory location by setting the value of plugin_dir at server startup.

To load the plugin at server startup, use the --plugin-load-add option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server my.cnf file:

```
[mysqld]
plugin-load-add=authentication_windows.dll
```

After modifying my.cnf, restart the server to cause the new settings to take effect.

Alternatively, to load the plugin at runtime, use this statement:

```
INSTALL PLUGIN authentication_windows SONAME 'authentication_windows.dll';
```

INSTALL PLUGIN loads the plugin immediately, and also registers it in the mysql.plugins system table to cause the server to load it for each subsequent normal startup without the need for --plugin-load-add.

To verify plugin installation, examine the INFORMATION_SCHEMA.PLUGINS table or use the SHOW PLUGINS statement (see Obtaining Server Plugin Information). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
    FROM INFORMATION_SCHEMA.PLUGINS
    WHERE PLUGIN_NAME LIKE '%windows%';
```

+------------------------+---------------+
| PLUGIN_NAME            | PLUGIN_STATUS |
|------------------------+---------------+
Windows Pluggable Authentication

<table>
<thead>
<tr>
<th>authentication_windows</th>
<th>ACTIVE</th>
</tr>
</thead>
</table>

If the plugin failed to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with the Windows authentication plugin, see Using Windows Pluggable Authentication. Additional plugin control is provided by the `authentication_windows_use_principal_name` and `authentication_windows_log_level` system variables. See Server System Variables.

Uninstalling Windows Pluggable Authentication

The method used to uninstall the Windows authentication plugin depends on how you installed it:

- If you installed the plugin at server startup using a `--plugin-load-add` option, restart the server without the option.
- If you installed the plugin at runtime using an `INSTALL PLUGIN` statement, it remains installed across server restarts. To uninstall it, use `UNINSTALL PLUGIN`:

  ```sql
  UNINSTALL PLUGIN authentication_windows;
  ```

  In addition, remove any startup options that set Windows plugin-related system variables.

Using Windows Pluggable Authentication

The Windows authentication plugin supports the use of MySQL accounts such that users who have logged in to Windows can connect to the MySQL server without having to specify an additional password. It is assumed that the server is running with the server-side plugin enabled, as described in Installing Windows Pluggable Authentication. Once the DBA has enabled the server-side plugin and set up accounts to use it, clients can connect using those accounts with no other setup required on their part.

To refer to the Windows authentication plugin in the `IDENTIFIED WITH` clause of a `CREATE USER` or `GRANT` statement, use the name `authentication_windows`. Suppose that the Windows users Rafal and Tasha should be permitted to connect to MySQL, as well as any users in the `Administrators` or `Power Users` group. To set this up, create a MySQL account named `sql_admin` that uses the Windows plugin for authentication:

```sql
CREATE USER sql_admin
  IDENTIFIED WITH authentication_windows
  AS 'Rafal, Tasha, Administrators, "Power Users"';
```

The plugin name is `authentication_windows`. The string following the `AS` keyword is the authentication string. It specifies that the Windows users named Rafal or Tasha are permitted to authenticate to the server as the MySQL user `sql_admin`, as are any Windows users in the `Administrators` or `Power Users` group. The latter group name contains a space, so it must be quoted with double quote characters.

After you create the `sql_admin` account, a user who has logged in to Windows can attempt to connect to the server using that account:

```bash
C:\> mysql --user=sql_admin
```

No password is required here. The `authentication_windows` plugin uses the Windows security API to check which Windows user is connecting. If that user is named Rafal or Tasha, or is a member of the `Administrators` or `Power Users` group, the server grants access and the client is authenticated as `sql_admin` and has whatever privileges are granted to the `sql_admin` account. Otherwise, the server denies access.

Authentication string syntax for the Windows authentication plugin follows these rules:
The string consists of one or more user mappings separated by commas.

Each user mapping associates a Windows user or group name with a MySQL user name:

```
win_user_or_group_name=mysql_user_name
win_user_or_group_name
```

For the latter syntax, with no `mysql_user_name` value given, the implicit value is the MySQL user created by the `CREATE USER` statement. Thus, these statements are equivalent:

```
CREATE USER sql_admin
IDENTIFIED WITH authentication_windows
AS 'Rafal, Tasha, Administrators, "Power Users"';
CREATE USER sql_admin
IDENTIFIED WITH authentication_windows
AS 'Rafal=sql_admin, Tasha=sql_admin, Administrators=sql_admin,
"Power Users"=sql_admin';
```

Each backslash character (\) in a value must be doubled because backslash is the escape character in MySQL strings.

Leading and trailing spaces not inside double quotation marks are ignored.

Unquoted `win_user_or_group_name` and `mysql_user_name` values can contain anything except equal sign, comma, or space.

If a `win_user_or_group_name` and or `mysql_user_name` value is quoted with double quotation marks, everything between the quotation marks is part of the value. This is necessary, for example, if the name contains space characters. All characters within double quotes are legal except double quotation mark and backslash. To include either character, escape it with a backslash.

`win_user_or_group_name` values use conventional syntax for Windows principals, either local or in a domain. Examples (note the doubling of backslashes):

```
domain\user
.\user
domain\group
.\group
BUILTIN\WellKnownGroup
```

When invoked by the server to authenticate a client, the plugin scans the authentication string left to right for a user or group match to the Windows user. If there is a match, the plugin returns the corresponding `mysql_user_name` to the MySQL server. If there is no match, authentication fails.

A user name match takes preference over a group name match. Suppose that the Windows user named `win_user` is a member of `win_group` and the authentication string looks like this:

```
'win_group = sql_user1, win_user = sql_user2'
```

When `win_user` connects to the MySQL server, there is a match both to `win_group` and to `win_user`. The plugin authenticates the user as `sql_user2` because the more-specific user match takes precedence over the group match, even though the group is listed first in the authentication string.

Windows authentication always works for connections from the same computer on which the server is running. For cross-computer connections, both computers must be registered with Windows Active Directory. If they are in the same Windows domain, it is unnecessary to specify a domain name. It is also possible to permit connections from a different domain, as in this example:

```
CREATE USER sql_accounting
IDENTIFIED WITH authentication_windows
```
AS 'SomeDomain\Accounting';

Here `SomeDomain` is the name of the other domain. The backslash character is doubled because it is the MySQL escape character within strings.

MySQL supports the concept of proxy users whereby a client can connect and authenticate to the MySQL server using one account but while connected has the privileges of another account (see Section 4.12, “Proxy Users”). Suppose that you want Windows users to connect using a single user name but be mapped based on their Windows user and group names onto specific MySQL accounts as follows:

- The `local_user` and `MyDomain\domain_user` local and domain Windows users should map to the `local_wlad` MySQL account.
- Users in the `MyDomain\Developers` domain group should map to the `local_dev` MySQL account.
- Local machine administrators should map to the `local_admin` MySQL account.

To set this up, create a proxy account for Windows users to connect to, and configure this account so that users and groups map to the appropriate MySQL accounts (`local_wlad`, `local_dev`, `local_admin`). In addition, grant the MySQL accounts the privileges appropriate to the operations they need to perform. The following instructions use `win_proxy` as the proxy account, and `local_wlad`, `local_dev`, and `local_admin` as the proxied accounts.

1. Create the proxy MySQL account:

```sql
CREATE USER win_proxy
  IDENTIFIED WITH authentication_windows
AS 'local_user = local_wlad,
   MyDomain\domain_user = local_wlad,
   MyDomain\Developers = local_dev,
   BUILTIN\Administrators = local_admin';
```

2. For proxying to work, the proxied accounts must exist, so create them:

```sql
CREATE USER local_wlad IDENTIFIED BY 'secret_wlad_pass';
CREATE USER local_dev IDENTIFIED BY 'secret_dev_pass';
CREATE USER local_admin IDENTIFIED BY 'secret_admin_pass';
```

If you do not let anyone know the passwords for these accounts, clients cannot use them to connect directly to the MySQL server. Instead, it is expected that users who authenticate using Windows will use the `win_proxy` proxy account.

You should also execute `GRANT` statements (not shown) that grant each proxied account the privileges required for MySQL access.

3. Grant to the proxy account the `PROXY` privilege for each proxied account:

```sql
GRANT PROXY ON local_wlad TO win_proxy;
GRANT PROXY ON local_dev TO win_proxy;
GRANT PROXY ON local_admin TO win_proxy;
```

Now the Windows users `local_user` and `MyDomain\domain_user` can connect to the MySQL server as `win_proxy` and when authenticated have the privileges of the account given in the authentication string (in this case, `local_wlad`). A user in the `MyDomain\Developers` group who connects as `win_proxy` has the privileges of the `local_dev` account. A user in the `BUILTIN\Administrators` group has the privileges of the `local_admin` account.

To configure authentication so that all Windows users who do not have their own MySQL account go through a proxy account, substitute the default proxy account (``@``) for `win_proxy` in the preceding instructions. For information about default proxy accounts, see Section 4.12, “Proxy Users”.
6.1.8 Socket Peer-Credential Pluggable Authentication

The server-side `auth_socket` authentication plugin authenticates clients that connect from the local host through the Unix socket file. The plugin uses the `SO_PEERCRED` socket option to obtain information about the user running the client program. Thus, the plugin can be used only on systems that support the `SO_PEERCRED` option, such as Linux.

The source code for this plugin can be examined as a relatively simple example demonstrating how to write a loadable authentication plugin.

The following table shows the plugin and library file names. The file must be located in the directory named by the `plugin_dir` system variable.

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin</td>
<td><code>auth_socket</code></td>
</tr>
<tr>
<td>Client-side plugin</td>
<td>None, see discussion</td>
</tr>
<tr>
<td>Library file</td>
<td><code>auth_socket.so</code></td>
</tr>
</tbody>
</table>

The following sections provide installation and usage information specific to socket pluggable authentication:

- Installing Socket Pluggable Authentication
- Uninstalling Socket Pluggable Authentication
- Using Socket Pluggable Authentication

For general information about pluggable authentication in MySQL, see Section 4.11, “Pluggable Authentication”.

Installing Socket Pluggable Authentication

This section describes how to install the socket authentication plugin. For general information about installing plugins, see Installing and Uninstalling Plugins.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

To load the plugin at server startup, use the `--plugin-load-add` option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server `my.cnf` file:

```
[mysqld]
plugin-load-add=auth_socket.so
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to load the plugin at runtime, use this statement:
INSTALL PLUGIN auth_socket SONAME 'auth_socket.so';

INSTALL PLUGIN loads the plugin immediately, and also registers it in the mysql.plugins system table to cause the server to load it for each subsequent normal startup without the need for --plugin-load-add.

To verify plugin installation, examine the INFORMATION_SCHEMA.PLUGINS table or use the SHOW PLUGINS statement (see Obtaining Server Plugin Information). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE '%socket%';
+-------------+---------------+
<table>
<thead>
<tr>
<th>PLUGIN_NAME</th>
<th>PLUGIN_STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>auth_socket</td>
<td>ACTIVE</td>
</tr>
</tbody>
</table>
+-------------+---------------+
```

If the plugin failed to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with the socket plugin, see Using Socket Pluggable Authentication.

Uninstalling Socket Pluggable Authentication

The method used to uninstall the socket authentication plugin depends on how you installed it:

- If you installed the plugin at server startup using a --plugin-load-add option, restart the server without the option.

- If you installed the plugin at runtime using an INSTALL PLUGIN statement, it remains installed across server restarts. To uninstall it, use UNINSTALL PLUGIN:

```
UNINSTALL PLUGIN auth_socket;
```

Using Socket Pluggable Authentication

The socket plugin checks whether the socket user name (the operating system user name) matches the MySQL user name specified by the client program to the server, and permits the connection only if the names match.

Suppose that a MySQL account is created for an operating system user named valerie who is to be authenticated by the auth_socket plugin for connections from the local host through the socket file:

```
CREATE USER 'valerie'@'localhost' IDENTIFIED WITH auth_socket;
```

If a user on the local host with a login name of stefanie invokes mysql with the option --user=valerie to connect through the socket file, the server uses auth_socket to authenticate the client. The plugin determines that the --user option value (valerie) differs from the client user's name (stephanie) and refuses the connection. If a user named valerie tries the same thing, the plugin finds that the user name and the MySQL user name are both valerie and permits the connection. However, the plugin refuses the connection even for valerie if the connection is made using a different protocol, such as TCP/IP.

6.1.9 Test Pluggable Authentication

MySQL includes a test plugin that checks account credentials and logs success or failure to the server error log. This is a loadable plugin (not built in) and must be installed prior to use.

The test plugin source code is separate from the server source, unlike the built-in native plugin, so it can be examined as a relatively simple example demonstrating how to write a loadable authentication plugin.
Test Pluggable Authentication

Note
This plugin is intended for testing and development purposes, and is not for use in production environments or on servers that are exposed to public networks.

The following table shows the plugin and library file names. The file name suffix might differ on your system. The file must be located in the directory named by the plugin_dir system variable.

<table>
<thead>
<tr>
<th>Plugin or File</th>
<th>Plugin or File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server-side plugin</td>
<td>test_plugin_server</td>
</tr>
<tr>
<td>Client-side plugin</td>
<td>auth_test_plugin</td>
</tr>
<tr>
<td>Library file</td>
<td>auth_test_plugin.so</td>
</tr>
</tbody>
</table>

The following sections provide installation and usage information specific to test pluggable authentication:

- Installing Test Pluggable Authentication
- Uninstalling Test Pluggable Authentication
- Using Test Pluggable Authentication

For general information about pluggable authentication in MySQL, see Section 4.11, “Pluggable Authentication”.

Installing Test Pluggable Authentication

This section describes how to install the test authentication plugin. For general information about installing plugins, see Installing and Uninstalling Plugins.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the plugin_dir system variable). If necessary, configure the plugin directory location by setting the value of plugin_dir at server startup.

To load the plugin at server startup, use the --plugin-load-add option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server my.cnf file (adjust the .so suffix for your platform as necessary):

```
[mysqld]
plugin-load-add=auth_test_plugin.so
```

After modifying my.cnf, restart the server to cause the new settings to take effect.

Alternatively, to load the plugin at runtime, use this statement (adjust the .so suffix for your platform as necessary):

```
INSTALL PLUGIN test_plugin_server SONAME 'auth_test_plugin.so';
```

INSTALL PLUGIN loads the plugin immediately, and also registers it in the mysql.plugins system table to cause the server to load it for each subsequent normal startup without the need for --plugin-load-add.

To verify plugin installation, examine the INFORMATION_SCHEMA.PLUGINS table or use the SHOW PLUGINS statement (see Obtaining Server Plugin Information). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
        FROM INFORMATION_SCHEMA.PLUGINS
```
WHERE PLUGIN_NAME LIKE '%test_plugin%';

+--------------------+---------------+
| PLUGIN_NAME        | PLUGIN_STATUS |
|--------------------|---------------+
| test_plugin_server | ACTIVE        |

If the plugin failed to initialize, check the server error log for diagnostic messages.

To associate MySQL accounts with the test plugin, see Using Test Pluggable Authentication.

**Uninstalling Test Pluggable Authentication**

The method used to uninstall the test authentication plugin depends on how you installed it:

- If you installed the plugin at server startup using a `--plugin-load-add` option, restart the server without the option.

- If you installed the plugin at runtime using an `INSTALL PLUGIN` statement, it remains installed across server restarts. To uninstall it, use `UNINSTALL PLUGIN`:

  ```
  UNINSTALL PLUGIN test_plugin_server;
  ```

**Using Test Pluggable Authentication**

To use the test authentication plugin, create an account and name that plugin in the `IDENTIFIED WITH` clause:

```sql
CREATE USER 'testuser'@'localhost' IDENTIFIED WITH test_plugin_server;
SET PASSWORD FOR 'testuser'@'localhost' = PASSWORD('testpassword');
```

Then provide the `--user` and `--password` options for that account when you connect to the server. For example:

```shell
shell> mysql --user=testuser --password
```

You can look in the server error log for a message indicating whether authentication succeeded (notice that the password is reported as the "user"):

```
[Note] Plugin test_plugin_server reported:
'successfully authenticated user testpassword'
```

### 6.2 The Connection-Control Plugins

As of MySQL 5.6.35, MySQL Server includes a plugin library that enables administrators to introduce an increasing delay in server response to clients after a certain number of consecutive failed connection attempts. This capability provides a deterrent that slows down brute force attacks that attempt to access MySQL user accounts. The plugin library contains two plugins:

- `CONNECTION_CONTROL` checks incoming connections and adds a delay to server responses as necessary. This plugin also exposes system variables that enable its operation to be configured and a status variable that provides rudimentary monitoring information.

The `CONNECTION_CONTROL` plugin uses the audit plugin interface (see Writing Audit Plugins). To collect information, it subscribes to the `MYSQL_AUDIT_CONNECTION_CLASSMASK` event class, and processes `MYSQL_AUDIT_CONNECTION_CONNECT` and
**Connection-Control Plugin Installation**

*MYSQL_AUDIT_CONNECTION_CHANGE_USER* subevents to check whether the server should introduce a delay before responding to client connection attempts.

- *CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS* implements an *INFORMATION_SCHEMA* table that exposes more detailed monitoring information for failed connection attempts.

The following sections provide information about connection-control plugin installation and configuration. For information about the *CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS* table, see The *INFORMATION_SCHEMA* CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS Table.

### 6.2.1 Connection-Control Plugin Installation

This section describes how to install the connection-control plugins, *CONNECTION_CONTROL* and *CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS*. For general information about installing plugins, see Installing and Uninstalling Plugins.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the *plugin_dir* system variable). If necessary, configure the plugin directory location by setting the value of *plugin_dir* at server startup.

The plugin library file base name is *connection_control*. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To load the plugins at server startup, use the `--plugin-load-add` option to name the library file that contains them. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server *my.cnf* file (adjust the `.so` suffix for your platform as necessary):

```
[mysqld]
plugin-load-add=connection_control.so
```

After modifying *my.cnf*, restart the server to cause the new settings to take effect.

Alternatively, to load the plugins at runtime, use these statements (adjust the `.so` suffix for your platform as necessary):

```
INSTALL PLUGIN CONNECTION_CONTROL
SONAME 'connection_control.so';
INSTALL PLUGIN CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS
SONAME 'connection_control.so';
```

*INSTALL PLUGIN* loads the plugin immediately, and also registers it in the *mysql.plugins* system table to cause the server to load it for each subsequent normal startup without the need for `--plugin-load-add`.

To verify plugin installation, examine the *INFORMATION_SCHEMA.PLUGINS* table or use the `SHOW PLUGINS` statement (see Obtaining Server Plugin Information). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
    FROM INFORMATION_SCHEMA.PLUGINS
    WHERE PLUGIN_NAME LIKE 'connection%';

+------------------------------------------+---------------+
| PLUGIN_NAME                              | PLUGIN_STATUS |
+------------------------------------------+---------------+
| CONNECTION_CONTROL                       | ACTIVE        |
| CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS | ACTIVE        |
+------------------------------------------+---------------+
```

If a plugin failed to initialize, check the server error log for diagnostic messages.

If the plugins have been previously registered with *INSTALL PLUGIN* or are loaded with `--plugin-load-add`, you can use the `--connection-control` and `--connection-control-failed-`
login-attempts options at server startup to control plugin activation. For example, to load the plugins at startup and prevent them from being removed at runtime, use these options:

```
[mysqld]
plugin-load-add=connection_control.so
connection-control=FORCE_PLUS_PERMANENT
connection-control-failed-login-attempts=FORCE_PLUS_PERMANENT
```

If it is desired to prevent the server from running without a given connection-control plugin, use an option value of FORCE or FORCE_PLUS_PERMANENT to force server startup to fail if the plugin does not initialize successfully.

---

**Note**

It is possible to install one plugin without the other, but both must be installed for full connection-control capability. In particular, installing only the CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS plugin is of little use because without the CONNECTION_CONTROL plugin to provide the data that populates the CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS table, retrievals from the table will always be empty.

- Connection Delay Configuration
- Connection Failure Assessment
- Connection Failure Monitoring

### Connection Delay Configuration

To enable you to configure its operation, the CONNECTION_CONTROL plugin exposes several system variables:

- **connection_control_failed_connections_threshold**: The number of consecutive failed connection attempts permitted to clients before the server adds a delay for subsequent connection attempts.

- **connection_control_min_connection_delay**: The amount of delay to add for each consecutive connection failure above the threshold.

- **connection_control_max_connection_delay**: The maximum delay to add.

To entirely disable checking for failed connection attempts, set `connection_control_failed_connections_threshold` to zero. If `connection_control_failed_connections_threshold` is nonzero, the amount of delay is zero up through that many consecutive failed connection attempts. Thereafter, the amount of delay is the number of failed attempts above the threshold, multiplied by `connection_control_min_connection_delay` milliseconds. For example, with the default `connection_control_failed_connections_threshold` and `connection_control_min_connection_delay` values of 3 and 1000, respectively, there is no delay for the first three consecutive failed connection attempts by a client, a delay of 1000 milliseconds for the fourth failed attempt, 2000 milliseconds for the fifth failed attempt, and so on, up to the maximum delay permitted by `connection_control_max_connection_delay`.

You can set the CONNECTION_CONTROL system variables at server startup or runtime. Suppose that you want to permit four consecutive failed connection attempts before the server starts delaying its responses, and to increase the delay by 1500 milliseconds for each additional failure after that. To set the relevant variables at server startup, put these lines in the server `my.cnf` file:

```
[mysqld]
plugin-load-add=connection_control.so
connection_control_failed_connections_threshold=4
```
To set the variables at runtime, use these statements:

```sql
SET GLOBAL connection_control_failed_connections_threshold = 4;
SET GLOBAL connection_control_min_connection_delay = 1500;
```

`SET GLOBAL` sets the value for the running MySQL instance. To make the change permanent, add a line in your `my.cnf` file, as shown previously.

The `connection_control_min_connection_delay` and `connection_control_max_connection_delay` system variables have fixed minimum and maximum values of 1000 and 2147483647, respectively. In addition, the permitted range of values of each variable also depends on the current value of the other:

- `connection_control_min_connection_delay` cannot be set greater than the current value of `connection_control_max_connection_delay`.
- `connection_control_max_connection_delay` cannot be set less than the current value of `connection_control_min_connection_delay`.

Thus, to make the changes required for some configurations, you might need to set the variables in a specific order. Suppose that the current minimum and maximum delays are 1000 and 2000, and that you want to set them to 3000 and 5000. You cannot first set `connection_control_min_connection_delay` to 3000 because that is greater than the current `connection_control_max_connection_delay` value of 2000. Instead, set `connection_control_max_connection_delay` to 5000, then set `connection_control_min_connection_delay` to 3000.

### Connection Failure Assessment

When the `CONNECTION_CONTROL` plugin is installed, it checks connection attempts and tracks whether they fail or succeed. For this purpose, a failed connection attempt is one for which the client user and host match a known MySQL account but the provided credentials are incorrect, or do not match any known account.

Failed-connection counting is based on the user/host combination for each connection attempt. Determination of the applicable user name and host name takes proxying into account and occurs as follows:

- If the client user proxies another user, the proxying user's information is used. For example, if `external_user@example.com` proxies `proxy_user@example.com`, connection counting uses the proxying user, `external_user@example.com`, rather than the proxied user, `proxy_user@example.com`. Both `external_user@example.com` and `proxy_user@example.com` must have valid entries in the `mysql.user` system table and a proxy relationship between them must be defined in the `mysql.proxies_priv` system table (see Section 4.12, “Proxy Users”).

- If the client user does not proxy another user, but does match a `mysql.user` entry, counting uses the `CURRENT_USER()` value corresponding to that entry. For example, if a user `user1` connecting from a host `host1.example.com` matches a `user1@host1.example.com` entry, counting uses `user1@host1.example.com`. If the user matches a `user1@%.example.com`, `user1%@.com`, or `user1%` entry instead, counting uses `user1@%.example.com`, `user1%@.com`, or `user1%`, respectively.

For the cases just described, the connection attempt matches some `mysql.user` entry, and whether the request succeeds or fails depends on whether the client provides the correct authentication credentials. For example, if the client presents an incorrect password, the connection attempt fails.

If the connection attempt matches no `mysql.user` entry, the attempt fails. In this case, no `CURRENT_USER()` value is available and connection-failure counting uses the user name provided
by the client and the client host as determined by the server. For example, if a client attempts to connect as user `user2` from host `host2.example.com`, the user name part is available in the client request and the server determines the host information. The user/host combination used for counting is `user2@host2.example.com`.

**Note**

The server maintains information about which client hosts can possibly connect to the server (essentially the union of host values for `mysql.user` entries). If a client attempts to connect from any other host, the server rejects the attempt at an early stage of connection setup:

```
ERROR 1130 (HY000): Host 'host_name' is not allowed to connect to this MySQL server
```

Because this type of rejection occurs so early, `CONNECTION_CONTROL` does not see it, and does not count it.

### Connection Failure Monitoring

To monitor failed connections, use these information sources:

- The `Connection_control_delay_generated` status variable indicates the number of times the server added a delay to its response to a failed connection attempt. This does not count attempts that occur before reaching the threshold defined by the `connection_control_failed_connections_threshold` system variable.

- The `INFORMATION_SCHEMA CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` table provides information about the current number of consecutive failed connection attempts per client user/host combination. This counts all failed attempts, regardless of whether they were delayed.

Assigning a value to `connection_control_failed_connections_threshold` at runtime resets all accumulated failed-connection counters to zero, which has these visible effects:

- The `Connection_control_delay_generated` status variable is reset to zero.

- The `CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` table becomes empty.

### 6.2.2 Connection-Control System and Status Variables

This section describes the system and status variables that the `CONNECTION_CONTROL` plugin provides to enable its operation to be configured and monitored.

- **Connection-Control System Variables**

- **Connection-Control Status Variables**

### Connection-Control System Variables

If the `CONNECTION_CONTROL` plugin is installed, it exposes these system variables:

- `connection_control_failed_connections_threshold`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--connection-control-failed-connections-threshold=##</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.35</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>connection_control_failed_connections_threshold</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
</tbody>
</table>
The number of consecutive failed connection attempts permitted to clients before the server adds a delay for subsequent connection attempts:

- If the variable has a nonzero value \( N \), the server adds a delay beginning with consecutive failed attempt \( N+1 \). If a client has reached the point where connection responses are delayed, the delay also occurs for the next subsequent successful connection.

- Setting this variable to zero disables failed-connection counting. In this case, the server never adds delays.

For information about how `connection_control_failed_connections_threshold` interacts with other connection-control system and status variables, see Section 6.2.1, “Connection-Control Plugin Installation”.

- `connection_control_max_connection_delay`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--connection-control-max-connection-delay=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.35</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>connection_control_max_connection_delay</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>2147483647</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1000</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2147483647</td>
</tr>
</tbody>
</table>

The maximum delay in milliseconds for server response to failed connection attempts, if `connection_control_failed_connections_threshold` is greater than zero.

For information about how `connection_control_max_connection_delay` interacts with other connection-control system and status variables, see Section 6.2.1, “Connection-Control Plugin Installation”.

- `connection_control_min_connection_delay`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--connection-control-min-connection-delay=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.35</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>connection_control_min_connection_delay</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1000</td>
</tr>
</tbody>
</table>
The Password Validation Plugin

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum Value</td>
<td>2147483647</td>
</tr>
</tbody>
</table>

The minimum delay in milliseconds for server response to failed connection attempts, if `connection_control_failed_connections_threshold` is greater than zero. This is also the amount by which the server increases the delay for additional successive failures once it begins delaying.

For information about how `connection_control_min_connection_delay` interacts with other connection-control system and status variables, see Section 6.2.1, “Connection-Control Plugin Installation”.

### Connection-Control Status Variables

If the `CONNECTION_CONTROL` plugin is installed, it exposes this status variable:

- **Connection_control_delay_generated**

  The number of times the server added a delay to its response to a failed connection attempt. This does not count attempts that occur before reaching the threshold defined by the `connection_control_failed_connections_threshold` system variable.

  This variable provides a simple counter. For more detailed connection-control monitoring information, examine the `INFORMATION_SCHEMA CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` table; see The `INFORMATION_SCHEMA CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` Table.

  Assigning a value to `connection_control_failed_connections_threshold` at runtime resets `Connection_control_delay_generated` to zero.

  This variable was added in MySQL 5.6.35.

### 6.3 The Password Validation Plugin

The `validate_password` plugin serves to improve security by requiring account passwords and enabling strength testing of potential passwords. This plugin exposes a set of system variables that enable you to configure password policy.

The `validate_password` plugin implements these capabilities:

- For SQL statements that assign a password supplied as a cleartext value, `validate_password` checks the password against the current password policy and rejects the password if it is weak (the statement returns an `ER_NOT_VALID_PASSWORD` error). This applies to the `CREATE USER`, `GRANT`, and `SET PASSWORD` statements, and passwords given as arguments to the `PASSWORD()` and `OLD_PASSWORD()` functions.

- For `CREATE USER` statements, `validate_password` requires that a password be given, and that it satisfies the password policy.

- `validate_password` implements a `VALIDATE_PASSWORD_STRENGTH()` SQL function that assesses the strength of potential passwords. This function takes a password argument and returns an integer from 0 (weak) to 100 (strong).

  **Note**

  For statements that assign, modify, or generate account passwords (`CREATE USER`, `GRANT`, and `SET PASSWORD`; statements that use `PASSWORD()` and `OLD_PASSWORD()`), the `validate_password` capabilities described here apply only to accounts that use an authentication plugin that stores credentials.
The Password Validation Plugin

internally in the `mysql.user` system table (`mysql_native_password` or `sha256_password`). For accounts that use plugins that perform authentication against an external credential system, password management must be handled externally against that system as well.

The preceding restriction does not apply to use of the `VALIDATE_PASSWORD_STRENGTH()` function because it does not affect accounts directly.

Examples:

- `validate_password` checks the cleartext password in the following statement. Under the default password policy, which requires passwords to be at least 8 characters long, the password is weak and the statement produces an error:

  ```sql
  mysql> SET PASSWORD = PASSWORD('abc');
  ERROR 1819 (HY000): Your password does not satisfy the current policy requirements
  ```

- Passwords specified as hashed values are not checked because the original password value is not available for checking:

  ```sql
  mysql> SET PASSWORD = '*0D3CED9BEC10A777AEC23CCC353A8C08A633045E';
  Query OK, 0 rows affected (0.01 sec)
  ```

- To check a password, use the `VALIDATE_PASSWORD_STRENGTH()` function:

  ```sql
  mysql> SELECT VALIDATE_PASSWORD_STRENGTH('weak');
  +------------------------------------+
  | VALIDATE_PASSWORD_STRENGTH('weak') |
  +------------------------------------+
  |                                 25 |
  +------------------------------------+
  mysql> SELECT VALIDATE_PASSWORD_STRENGTH('lessweak$_@123');
  +----------------------------------------------+
  | VALIDATE_PASSWORD_STRENGTH('lessweak$_@123') |
  +----------------------------------------------+
  |                                           50 |
  +----------------------------------------------+
  mysql> SELECT VALIDATE_PASSWORD_STRENGTH('NOTweak$_@123!');
  +----------------------------------------------+
  | VALIDATE_PASSWORD_STRENGTH('NOTweak$_@123!') |
  +----------------------------------------------+
  |                                          100 |
  +----------------------------------------------+
  ```

To configure password checking, modify the system variables having names of the form `validate_password_`xxx`; these are the parameters that control password policy. See Section 6.3.2, “Password Validation Plugin Options and Variables”.

If `validate_password` is not installed, the `validate_password_`xxx` system variables are not available, passwords in statements are not checked, and the `VALIDATE_PASSWORD_STRENGTH()` function always returns 0. For example, without the plugin installed, accounts can be assigned passwords shorter than 8 characters, or no password at all.

Assuming that `validate_password` is installed, it implements three levels of password checking: LOW, MEDIUM, and STRONG. The default is MEDIUM; to change this, modify the value of `validate_password_policy`. The policies implement increasingly strict password tests. The following descriptions refer to default parameter values, which can be modified by changing the appropriate system variables.

- LOW policy tests password length only. Passwords must be at least 8 characters long. To change this length, modify `validate_password_length`. 

• **MEDIUM** policy adds the conditions that passwords must contain at least 1 numeric character, 1 lowercase character, 1 uppercase character, and 1 special (nonalphanumeric) character. To change these values, modify `validate_password_number_count`, `validate_password_mixed_case_count`, and `validate_password_special_char_count`.

• **STRONG** policy adds the condition that password substrings of length 4 or longer must not match words in the dictionary file, if one has been specified. To specify the dictionary file, modify `validate_password_dictionary_file`.

### 6.3.1 Password Validation Plugin Installation

This section describes how to install the `validate_password` password-validation plugin. For general information about installing plugins, see Installing and Uninstalling Plugins.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, configure the plugin directory location by setting the value of `plugin_dir` at server startup.

The plugin library file base name is `validate_password`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To load the plugin at server startup, use the `--plugin-load-add` option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in the server `my.cnf` file (adjust the `.so` suffix for your platform as necessary):

```
[mysqld]
plugin-load-add=validate_password.so
```

After modifying `my.cnf`, restart the server to cause the new settings to take effect.

Alternatively, to load the plugin at runtime, use this statement (adjust the `.so` suffix for your platform as necessary):

```
INSTALL PLUGIN validate_password SONAME 'validate_password.so';
```

`INSTALL PLUGIN` loads the plugin, and also registers it in the `mysql.plugins` system table to cause the plugin to be loaded for each subsequent normal server startup without the need for `--plugin-load-add`.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see Obtaining Server Plugin Information). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
    -> FROM INFORMATION_SCHEMA.PLUGINS
    -> WHERE PLUGIN_NAME LIKE 'validate%';
```

```
+-------------------+---------------+
| PLUGIN_NAME       | PLUGIN_STATUS |
|-------------------|---------------+
| validate_password | ACTIVE        |
|-------------------|---------------+
```

If the plugin failed to initialize, check the server error log for diagnostic messages.

If the plugin has been previously registered with `INSTALL PLUGIN` or is loaded with `--plugin-load-add`, you can use the `--validate-password` option at server startup to control plugin activation. For example, to load the plugin at startup and prevent it from being removed at runtime, use these options:

```
my.cnf
```

```
[mysqld]
--validate-password
```

```
If it is desired to prevent the server from running without the password-validation plugin, use \texttt{--validate-password} with a value of \texttt{FORCE} or \texttt{FORCE_PLUS_PERMANENT} to force server startup to fail if the plugin does not initialize successfully.

### 6.3.2 Password Validation Plugin Options and Variables

This section describes the options, system variables, and status variables that \texttt{validate_password} provides to enable its operation to be configured and monitored.

- **Password Validation Plugin Options**
- **Password Validation Plugin System Variables**
- **Password Validation Plugin Status Variables**

#### Password Validation Plugin Options

To control activation of the \texttt{validate_password} plugin, use this option:

- \texttt{--validate-password\[=value\]}

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>\texttt{--validate-password[=value]}</td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.6</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
<tr>
<td>Valid Values</td>
<td>ON, OFF, FORCE, FORCE_PLUS_PERMANENT</td>
</tr>
</tbody>
</table>

This option controls how the server loads the \texttt{validate_password} plugin at startup. The value should be one of those available for plugin-loading options, as described in Installing and Uninstalling Plugins. For example, \texttt{--validate-password=FORCE_PLUS_PERMANENT} tells the server to load the plugin at startup and prevents it from being removed while the server is running.

This option is available only if the \texttt{validate_password} plugin has been previously registered with \texttt{INSTALL PLUGIN} or is loaded with \texttt{--plugin-load-add}. See Section 6.3.1, “Password Validation Plugin Installation”.

#### Password Validation Plugin System Variables

If the \texttt{validate_password} plugin is enabled, it exposes several system variables that enable configuration of password checking:

```
mysql> \texttt{SHOW VARIABLES LIKE 'validate_password\%';}
+-------------------------------+--------+
| Variable_name                 | Value  |
+-------------------------------+--------+
| validate_password_dictionary_file |        |
| validate_password_length      | 8      |
| validate_password_mixed_case_count | 1 |
| validate_password_number_count | 1      |
```
To change how passwords are checked, you can set these system variables at server startup or at runtime. The following list describes the meaning of each variable.

- **validate_password_dictionary_file**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--validate-password-dictionary-file=file_name</td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.6</td>
</tr>
<tr>
<td>System Variable</td>
<td>validate_password_dictionary_file</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic (&gt;= 5.6.26)</td>
<td>Yes</td>
</tr>
<tr>
<td>Dynamic (&lt;= 5.6.25)</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
</tbody>
</table>

The path name of the dictionary file that validate_password uses for checking passwords. This variable is unavailable unless validate_password is installed.

By default, this variable has an empty value and dictionary checks are not performed. For dictionary checks to occur, the variable value must be nonempty. If the file is named as a relative path, it is interpreted relative to the server data directory. File contents should be lowercase, one word per line. Contents are treated as having a character set of utf8. The maximum permitted file size is 1MB.

For the dictionary file to be used during password checking, the password policy must be set to 2 (STRONG); see the description of the validate_password_policy system variable. Assuming that is true, each substring of the password of length 4 up to 100 is compared to the words in the dictionary file. Any match causes the password to be rejected. Comparisons are not case sensitive.

For VALIDATE_PASSWORD_STRENGTH(), the password is checked against all policies, including STRONG, so the strength assessment includes the dictionary check regardless of the validate_password_policy value.

Before MySQL 5.6.26, changes to the dictionary file while the server is running require a restart for the server to recognize the changes. As of MySQL 5.6.26, validate_password_dictionary_file can be set at runtime and assigning a value causes the named file to be read without a server restart.

- **validate_password_length**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--validate-password-length=#</td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.6</td>
</tr>
<tr>
<td>System Variable</td>
<td>validate_password_length</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>8</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>

The minimum number of characters that validate_password requires passwords to have. This variable is unavailable unless validate_password is installed.
The `validate_password_length` minimum value is a function of several other related system variables. The value cannot be set less than the value of this expression:

\[
\text{validate_password_number_count} + \text{validate_password_special_char_count} + (2 \times \text{validate_password_mixed_case_count})
\]

If `validate_password` adjusts the value of `validate_password_length` due to the preceding constraint, it writes a message to the error log.

- **validate_password_mixed_case_count**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--validate-password-mixed-case-count=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.6</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>validate_password_mixed_case_count</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>

The minimum number of lowercase and uppercase characters that `validate_password` requires passwords to have if the password policy is `MEDIUM` or stronger. This variable is unavailable unless `validate_password` is installed.

For a given `validate_password_mixed_case_count` value, the password must have that many lowercase characters, and that many uppercase characters.

- **validate_password_number_count**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--validate-password-number-count=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.6</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>validate_password_number_count</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>

The minimum number of numeric (digit) characters that `validate_password` requires passwords to have if the password policy is `MEDIUM` or stronger. This variable is unavailable unless `validate_password` is installed.

- **validate_password_policy**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--validate-password-policy=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.6</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>validate_password_policy</code></td>
</tr>
</tbody>
</table>
Password Validation Plugin Options and Variables

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Valid Values</td>
<td>0, 1, 2</td>
</tr>
</tbody>
</table>

The password policy enforced by `validate_password`. This variable is unavailable unless `validate_password` is installed.

The `validate_password_policy` value can be specified using numeric values 0, 1, 2, or the corresponding symbolic values `LOW`, `MEDIUM`, `STRONG`. The following table describes the tests performed for each policy. For the length test, the required length is the value of the `validate_password_length` system variable. Similarly, the required values for the other tests are given by other `validate_password_xxx` variables.

<table>
<thead>
<tr>
<th>Policy</th>
<th>Tests Performed</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 or LOW</td>
<td>Length</td>
</tr>
<tr>
<td>1 or MEDIUM</td>
<td>Length; numeric, lowercase/uppercase, and special characters</td>
</tr>
<tr>
<td>2 or STRONG</td>
<td>Length; numeric, lowercase/uppercase, and special characters; dictionary file</td>
</tr>
</tbody>
</table>

- `validate_password_special_char_count`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--validate-password-special-char-count=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.6</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>validate_password_special_char_count</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>

The minimum number of nonalphanumeric characters that `validate_password` requires passwords to have if the password policy is `MEDIUM` or stronger. This variable is unavailable unless `validate_password` is installed.

Password Validation Plugin Status Variables

If the `validate_password` plugin is enabled, it exposes status variables that provide operational information:

```sql
mysql> SHOW STATUS LIKE 'validate_password%';
+-----------------------------------------------+---------------------+
| Variable_name                                 | Value               |
+-----------------------------------------------+---------------------+
| validate_password_dictionary_file_last_parsed | 2015-06-29 11:08:51  |
| validate_password_dictionary_file_words_count | 1902                |
```
The following list describes the meaning of each status variable.

- `validate_password_dictionary_file_last_parsed`

  When the dictionary file was last parsed.

  This variable was added in MySQL 5.6.26.

- `validate_password_dictionary_file_words_count`

  The number of words read from the dictionary file.

  This variable was added in MySQL 5.6.26.

### 6.4 MySQL Enterprise Audit

**Note**

MySQL Enterprise Audit is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see https://www.mysql.com/products/.

MySQL Enterprise Edition includes MySQL Enterprise Audit, implemented using a server plugin named `audit_log`. MySQL Enterprise Audit uses the open MySQL Audit API to enable standard, policy-based monitoring and logging of connection and query activity executed on specific MySQL servers. Designed to meet the Oracle audit specification, MySQL Enterprise Audit provides an out of box, easy to use auditing and compliance solution for applications that are governed by both internal and external regulatory guidelines.

When installed, the audit plugin enables MySQL Server to produce a log file containing an audit record of server activity. The log contents include when clients connect and disconnect, and what actions they perform while connected, such as which databases and tables they access.

After you install the audit plugin (see Section 6.4.1, “Installing MySQL Enterprise Audit”), it writes an audit log file. By default, the file is named `audit.log` in the server data directory. To change the name of the file, set the `audit_log_file` system variable at server startup.

Audit log file contents are not encrypted. See Section 6.4.2, “MySQL Enterprise Audit Security Considerations”.

The audit log file is written in XML, with auditable events encoded as `<AUDIT_RECORD>` elements. To select the file format, set the `audit_log_format` system variable at server startup. For details on file format and contents, see Section 6.4.3, “Audit Log File Formats”.

For more information about controlling how logging occurs, including audit log file naming and format selection, see Section 6.4.4, “Audit Log Logging Control”. To perform filtering of audited events, see Section 6.4.5, “Audit Log Filtering”. For descriptions of the parameters used to configure the audit log plugin, see Audit Log Options and System Variables.

If the audit log plugin is enabled, the Performance Schema (see MySQL Performance Schema) has instrumentation for it. To identify the relevant instruments, use this query:

```
SELECT NAME FROM performance_schema.setup_instruments 
WHERE NAME LIKE '%/alog/%';
```

### Changes from Older MySQL Enterprise Audit Versions

Several changes were made to the audit log plugin in MySQL 5.6.14 for better compatibility with Oracle Audit Vault.
A new audit log file format was implemented. It is possible to select either the old or new format using the `audit_log_format` system variable, which has permitted values of `OLD` and `NEW` (default `OLD`). The two formats differ as follows:

- Information within `<AUDIT_RECORD>` elements written in the old format using attributes is written in the new format using subelements.
- The new format includes more information in `<AUDIT_RECORD>` elements. Every element includes a `RECORD_ID` value providing a unique identifier. The `TIMESTAMP` value includes time zone information. Query records include `HOST`, `IP`, `OS_LOGIN`, and `USER` information, as well as `COMMAND_CLASS` and `STATUS_CODE` values.

Example of old `<AUDIT_RECORD>` format:

```
<AUDIT_RECORD
    TIMESTAMP="2013-09-15T15:27:27"
    NAME="Query"
    CONNECTION_ID="3"
    STATUS="0"
    SQLTEXT="SELECT 1"
/>```

Example of new `<AUDIT_RECORD>` format:

```
<AUDIT_RECORD>
    <TIMESTAMP>2013-09-15T15:27:27 UTC</TIMESTAMP>
    <RECORD_ID>3998_2013-09-15T15:27:27</RECORD_ID>
    <NAME>Query</NAME>
    <CONNECTION_ID>3</CONNECTION_ID>
    <STATUS>0</STATUS>
    <STATUS_CODE>0</STATUS_CODE>
    <USER>root[root] @ localhost [127.0.0.1]</USER>
    <OS_LOGIN></OS_LOGIN>
    <HOST>localhost</HOST>
    <IP>127.0.0.1</IP>
    <COMMAND_CLASS>select</COMMAND_CLASS>
    <SQLTEXT>SELECT 1</SQLTEXT>
</AUDIT_RECORD>```

When the audit log plugin rotates the audit log file, it uses a different file name format. For a log file named `audit.log`, the plugin previously renamed the file to `audit.log.TIMESTAMP`. The plugin now renames the file to `audit.log.TIMESTAMP.xml` to indicate that it is an XML file.

If you change the value of `audit_log_format`, use this procedure to avoid writing log entries in one format to an existing log file that contains entries in a different format:

1. Stop the server.
2. Rename the current audit log file manually.
3. Restart the server with the new value of `audit_log_format`. The audit log plugin creates a new log file, which will contain log entries in the selected format.

The API for writing audit plugins has also changed. The `mysql_event_general` structure has new members to represent client host name and IP address, command class, and external user. For more information, see Writing Audit Plugins.

### 6.4.1 Installing MySQL Enterprise Audit

This section describes how to install MySQL Enterprise Audit, which is implemented using the `audit_log` plugin. For general information about installing plugins, see Installing and Uninstalling Plugins.
Installing MySQL Enterprise Audit

Note

If installed, the audit_log plugin involves some minimal overhead even when disabled. To avoid this overhead, do not install MySQL Enterprise Audit unless you plan to use it.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the plugin_dir system variable). If necessary, configure the plugin directory location by setting the value of plugin_dir at server startup.

The plugin library file base name is audit_log. The file name suffix differs per platform (for example, .so for Unix and Unix-like systems, .dll for Windows).

To load the plugin at server startup, use the --plugin-load-add option to name the library file that contains it. With this plugin-loading method, the option must be given each time the server starts. For example, put the following lines in the server my.cnf file (adjust the .so suffix for your platform as necessary):

```
[mysqld]
plugin-load-add=audit_log.so
```

After modifying my.cnf, restart the server to cause the new settings to take effect.

Alternatively, to load the plugin at runtime, use this statement (adjust the .so suffix for your platform as necessary):

```
INSTALL PLUGIN audit_log SONAME 'audit_log.so';
```

INSTALL PLUGIN loads the plugin, and also registers it in the mysql.plugins system table to cause the plugin to be loaded for each subsequent normal server startup without the need for --plugin-load-add.

To verify plugin installation, examine the INFORMATION_SCHEMA.PLUGINS table or use the SHOW PLUGINS statement (see Obtaining Server Plugin Information). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
    FROM INFORMATION_SCHEMA.PLUGINS
    WHERE PLUGIN_NAME LIKE 'audit%';
```

```
<table>
<thead>
<tr>
<th>PLUGIN_NAME</th>
<th>PLUGIN_STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>audit_log</td>
<td>ACTIVE</td>
</tr>
</tbody>
</table>
```

If the plugin failed to initialize, check the server error log for diagnostic messages.

If the plugin has been previously registered with INSTALL PLUGIN or is loaded with --plugin-load-add, you can use the --audit-log option at server startup to control plugin activation. For example, to load the plugin at startup and prevent it from being removed at runtime, use these options:

```
[mysqld]
plugin-load-add=audit_log.so
audit-log=FORCE_PLUS_PERMANENT
```

If it is desired to prevent the server from running without the audit plugin, use --audit-log with a value of FORCE or FORCE_PLUS_PERMANENT to force server startup to fail if the plugin does not initialize successfully.

For additional information about the parameters used to configure operation of the audit_log plugin, see Audit Log Options and System Variables.

Audit log file contents are not encrypted. See Section 6.4.2, “MySQL Enterprise Audit Security Considerations”.
6.4.2 MySQL Enterprise Audit Security Considerations

Contents of audit log files produced by the audit log plugin are not encrypted and may contain sensitive information, such as the text of SQL statements. For security reasons, audit log files should be written to a directory accessible only to the MySQL server and to users with a legitimate reason to view the log. The default file name is `audit.log` in the data directory. This can be changed by setting the `audit_log_file` system variable at server startup. Other audit log files may exist due to log rotation.

6.4.3 Audit Log File Formats

The MySQL server calls the audit log plugin to write an audit record to its log file whenever an auditable event occurs. Typically the first audit record written after plugin startup contains the server description and startup options. Elements following that one represent events such as client connect and disconnect events, executed SQL statements, and so forth. Only top-level statements are logged, not statements within stored programs such as triggers or stored procedures. Contents of files referenced by statements such as `LOAD DATA` are not logged.

To select the log format that the audit log plugin uses to write its log file, set the `audit_log_format` system variable at server startup. These formats are available:

- New-style XML format (`audit_log_format=NEW`): An XML format that has better compatibility with Oracle Audit Vault than old-style XML format. MySQL 5.7 introduced this format, which was backported to MySQL 5.6 as of MySQL 5.6.14.

- Old-style XML format (`audit_log_format=OLD`): The original audit log format used by default in older MySQL series. MySQL 5.6 uses old-style XML format by default.

Note
Changing the value of `audit_log_format` can result in writing log entries in one format to an existing log file that contains entries in a different format. To avoid this issue, use the procedure described at Audit Log File Format.

Audit log file contents are not encrypted. See Section 6.4.2, “MySQL Enterprise Audit Security Considerations”.

The following sections describe the available audit logging formats:

- New-Style XML Audit Log File Format
- Old-Style XML Audit Log File Format

New-Style XML Audit Log File Format

Here is a sample log file in new-style XML format (`audit_log_format=NEW`), reformatted slightly for readability:

```xml
<?xml version="1.0" encoding="utf-8"?>
<AUDIT>
  <AUDIT_RECORD>
    <TIMESTAMP>2017-10-16T14:06:33 UTC</TIMESTAMP>
    <RECORD_ID>1_2017-10-16T14:06:33</RECORD_ID>
    <NAME>Audit</NAME>
    <SERVER_ID>1</SERVER_ID>
    <VERSION>1</VERSION>
    <STARTUP_OPTIONS>/usr/local/mysql/bin/mysqld
    --socket=/usr/local/mysql/mysql.sock
    --port=3306</STARTUP_OPTIONS>
    <OS_VERSION>i686-Linux</OS_VERSION>
    <MYSQL_VERSION>5.6.39-log</MYSQL_VERSION>
  </AUDIT_RECORD>
  <AUDIT_RECORD>
    <TIMESTAMP>2017-10-16T14:09:38 UTC</TIMESTAMP>
    <RECORD_ID>2_2017-10-16T14:06:33</RECORD_ID>
    <NAME>Connection</NAME>
    <SERVER_ID>1</SERVER_ID>
    <VERSION>1</VERSION>
    <STARTUP_OPTIONS>/usr/local/mysql/bin/mysqld
    --socket=/usr/local/mysql/mysql.sock
    --port=3306</STARTUP_OPTIONS>
    <OS_VERSION>i686-Linux</OS_VERSION>
    <MYSQL_VERSION>5.6.39-log</MYSQL_VERSION>
  </AUDIT_RECORD>
</AUDIT>
```
The audit log file is written as XML, using UTF-8 (up to 4 bytes per character). The root element is <AUDIT>. The root element contains <AUDIT_RECORD> elements, each of which provides information about an audited event. When the audit log plugin begins writing a new log file, it writes the XML declaration and opening <AUDIT> root element tag. When the plugin closes a log file, it writes the closing </AUDIT> root element tag. The closing tag is not present while the file is open.

Elements within <AUDIT_RECORD> elements have these characteristics:

- **Name**: The name of the event or action.
- **Connection ID**: Identification of the connection.
- **Status**: The status of the event.
- **Status Code**: The status code of the event.
- **User**: The user who performed the action.
- **OS Login**: Information about the operating system login.
- **Host**: The host from which the action was performed.
- **IP**: The IP address of the host.
- **Command Class**: The class of the command.
- **SQL Text**: The SQL text of the command.
• Some elements appear in every `<AUDIT_RECORD>` element. Others are optional and may appear depending on the audit record type.

• Order of elements within an `<AUDIT_RECORD>` element is not guaranteed.

• Element values are not fixed length. Long values may be truncated as indicated in the element descriptions given later.

• The `<`, `>`, `,`, and `&` characters are encoded as `<`, `>`, `,`, and `&`, respectively. NUL bytes (U+00) are encoded as the `?` character.

• Characters not valid as XML characters are encoded using numeric character references. Valid XML characters are:

```
#x9 | #xA | #xD | [#x20-#xD7FF] | [#xE000-#xFFFD] | [#x10000-#x1FFFF]
```

The following elements are mandatory in every `<AUDIT_RECORD>` element:

• `<NAME>`

A string representing the type of instruction that generated the audit event, such as a command that the server received from a client.

Example:

```
<NAME>Query</NAME>
```

Some common `<NAME>` values:

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Audit</td>
<td>When auditing starts, which may be server startup time</td>
</tr>
<tr>
<td>Connect</td>
<td>When a client connects, also known as logging in</td>
</tr>
<tr>
<td>Prepare</td>
<td>Preparation of an SQL statement; usually followed by Execute</td>
</tr>
<tr>
<td>Execute</td>
<td>Execution of an SQL statement; usually follows Prepare</td>
</tr>
<tr>
<td>Shutdown</td>
<td>Server shutdown</td>
</tr>
<tr>
<td>Quit</td>
<td>When a client disconnects</td>
</tr>
<tr>
<td>NoAudit</td>
<td>Auditing has been turned off</td>
</tr>
</tbody>
</table>

The possible values are Audit, Binlog Dump, Change user, Close stmt, Connect Out, Connect, Create DB, Daemon, Debug, Delayed insert, Drop DB, Execute, Fetch, Field List, Init DB, Kill, Long Data, NoAudit, Ping, Prepare, Processlist, Query, Quit, Refresh, Register Slave, Reset stmt, Set option, Shutdown, Sleep, Statistics, Table Dump, Time.

With the exception of Audit and NoAudit, these values correspond to the COM_xxx command values listed in the mysql_com.h header file. For example, Create DB and Change user correspond to COM_CREATE_DB and COM_CHANGE_USER, respectively.

• `<RECORD_ID>`

A unique identifier for the audit record. The value is composed from a sequence number and timestamp, in the format `<SEQ_TIMESTAMP>`. When the audit log plugin opens the audit log file, it initializes the sequence number to the size of the audit log file, then increments the sequence by 1 for each record logged. The timestamp is a UTC value in `YYYY-MM-DDThh:mm:ss` format indicating the date and time when the audit log plugin opened the file.

Example:

```
<RECORD_ID>12_2017-10-16T14:06:33</RECORD_ID>
```

• `<TIMESTAMP>`
A string representing a UTC value in `YYYY-MM-DDThh:mm:ss UTC` format indicating the date and time when the audit event was generated. For example, the event corresponding to execution of an SQL statement received from a client has a `<TIMESTAMP>` value occurring after the statement finishes, not when it was received.

Example:

```
<TIMESTAMP>2017-10-16T14:09:45 UTC</TIMESTAMP>
```

The following elements are optional in `<AUDIT_RECORD>` elements. Many of them occur only with specific `<NAME>` element values.

- `<COMMAND_CLASS>`
  A string that indicates the type of action performed.
  Example:

  ```
  <COMMAND_CLASS>drop_table</COMMAND_CLASS>
  ```

  The values correspond to the `Com_xxx` status variables that indicate command counts; for example `Com_drop_table` and `Com_select count DROP TABLE` and `SELECT` statements, respectively. The following statement displays the possible names:

  ```
  SELECT LOWER(REPLACE(VARIABLE_NAME, 'COM_', '')) AS name
  FROM INFORMATION_SCHEMA.GLOBAL_STATUS
  WHERE VARIABLE_NAME LIKE 'COM\'
  ORDER BY name;
  ```

- `<CONNECTION_ID>`
  An unsigned integer representing the client connection identifier. This is the same as the value returned by the `CONNECTION_ID()` function within the session.
  Example:

  ```
  <CONNECTION_ID>127</CONNECTION_ID>
  ```

- `<DB>`
  A string representing the default database name.
  Example:

  ```
  <DB>test</DB>
  ```

- `<HOST>`
  A string representing the client host name.
  Example:

  ```
  <HOST>localhost</HOST>
  ```

- `<IP>`
  A string representing the client IP address.
  Example:
Audit Log File Formats

- **<IP>127.0.0.1</IP>**

- **<MYSQL_VERSION>**
  A string representing the MySQL server version. This is the same as the value of the `VERSION()` function or `version` system variable.
  
  Example:
  
  `<MYSQL_VERSION>5.6.39-log</MYSQL_VERSION>`

- **<OS_LOGIN>**
  A string representing the external user name used during the authentication process, as set by the plugin used to authenticate the client. With native (built-in) MySQL authentication, or if the plugin does not set the value, this element is empty. The value is the same as that of the `external_user` system variable (see Section 4.12, “Proxy Users”).
  
  Example:
  
  `<OS_LOGIN>jeffrey</OS_LOGIN>`

- **<OS_VERSION>**
  A string representing the operating system on which the server was built or is running.
  
  Example:
  
  `<OS_VERSION>x86_64-Linux</OS_VERSION>`

- **<PRIV_USER>**
  A string representing the user that the server authenticated the client as. This is the user name that the server uses for privilege checking, and may differ from the `<USER>` value.
  
  Example:
  
  `<PRIV_USER>jeffrey</PRIV_USER>`

- **<PROXY_USER>**
  A string representing the proxy user (see Section 4.12, “Proxy Users”). The value is empty if user proxying is not in effect.
  
  Example:
  
  `<PROXY_USER>developer</PROXY_USER>`

- **<SERVER_ID>**
  An unsigned integer representing the server ID. This is the same as the value of the `server_id` system variable.
  
  Example:
  
  `<SERVER_ID>1</SERVER_ID>`
Audit Log File Formats

A string representing the text of an SQL statement. The value can be empty. Long values may be truncated. The string, like the audit log file itself, is written using UTF-8 (up to 4 bytes per character), so the value may be the result of conversion. For example, the original statement might have been received from the client as an SJIS string.

Example:

```xml
<SQLTEXT>DELETE FROM t1</SQLTEXT>
```

- `<STARTUP_OPTIONS>`

A string representing the options that were given on the command line or in option files when the MySQL server was started. The first option is the path to the server executable.

Example:

```xml
<STARTUP_OPTIONS>/usr/local/mysql/bin/mysqld --port=3306 --log_output=FILE</STARTUP_OPTIONS>
```

- `<STATUS>`

An unsigned integer representing the command status: 0 for success, nonzero if an error occurred. This is the same as the value of the `mysql_errno()` C API function. See the description for `<STATUS_CODE>` for information about how it differs from `<STATUS>`.

The audit log does not contain the SQLSTATE value or error message. To see the associations between error codes, SQLSTATE values, and messages, see Server Error Message Reference. Warnings are not logged.

Example:

```xml
<STATUS>1051</STATUS>
```

- `<STATUS_CODE>`

An unsigned integer representing the command status: 0 for success, 1 if an error occurred.

The `STATUS_CODE` value differs from the `STATUS` value: `STATUS_CODE` is 0 for success and 1 for error, which is compatible with the EZ_collector consumer for Audit Vault. `STATUS` is the value of the `mysql_errno()` C API function. This is 0 for success and nonzero for error, and thus is not necessarily 1 for error.

Example:

```xml
<STATUS_CODE>0</STATUS_CODE>
```

- `<USER>`

A string representing the user name sent by the client. This may differ from the `<PRIV_USER>` value.

Example:

```xml
<User>root[root] @ localhost [127.0.0.1]</USER>
```

- `<VERSION>`

An unsigned integer representing the version of the audit log file format.
Example:

```xml
<VERSION>1</VERSION>

Old-Style XML Audit Log File Format

Here is a sample log file in old-style XML format (audit_log_format=OLD), reformatted slightly for readability:

```xml
<?xml version="1.0" encoding="utf-8"?>
<AUDIT>
  <AUDIT_RECORD
    TIMESTAMP="2017-10-16T14:25:00 UTC"
    RECORD_ID="1_2017-10-16T14:25:00"
    NAME="Audit"
    SERVER_ID="1"
    VERSION="1"
    STARTUP_OPTIONS="--port=3306"
    OS_VERSION="i686-Linux"
    MYSQL_VERSION="5.6.39-log"/>
  <AUDIT_RECORD
    TIMESTAMP="2017-10-16T14:25:24 UTC"
    RECORD_ID="2_2017-10-16T14:25:00"
    NAME="Connect"
    CONNECTION_ID="4"
    STATUS="0"
    STATUS_CODE="0"
    USER="root"
    OS_LOGIN=""
    HOST="localhost"
    IP="127.0.0.1"
    COMMAND_CLASS="connect"
    PRIV_USER="root"
    PROXY_USER=""
    DB="test"/>
  ... 
  <AUDIT_RECORD
    TIMESTAMP="2017-10-16T14:25:24 UTC"
    RECORD_ID="6_2017-10-16T14:25:00"
    NAME="Query"
    CONNECTION_ID="4"
    STATUS="0"
    STATUS_CODE="0"
    USER="root[root] @ localhost [127.0.0.1]"
    OS_LOGIN=""
    HOST="localhost"
    IP="127.0.0.1"
    COMMAND_CLASS="drop_table"
    SQLTEXT="DROP TABLE IF EXISTS t"/>
  ... 
  <AUDIT_RECORD
    TIMESTAMP="2017-10-16T14:25:24 UTC"
    RECORD_ID="8_2017-10-16T14:25:00"
    NAME="Quit"
    CONNECTION_ID="4"
    STATUS="0"
    STATUS_CODE="0"
    USER="root"
    OS_LOGIN=""
    HOST="localhost"
    IP="127.0.0.1"
    COMMAND_CLASS="connect"
  <AUDIT_RECORD
    TIMESTAMP="2017-10-16T14:25:32 UTC"
    RECORD_ID="12_2017-10-16T14:25:00"
    NAME="NoAudit"
    SERVER_ID="1"/>
</AUDIT>
```
The audit log file is written as XML, using UTF-8 (up to 4 bytes per character). The root element is `<AUDIT>`. The root element contains `<AUDIT_RECORD>` elements, each of which provides information about an audited event. When the audit log plugin begins writing a new log file, it writes the XML declaration and opening `<AUDIT>` root element tag. When the plugin closes a log file, it writes the closing `</AUDIT>` root element tag. The closing tag is not present while the file is open.

**Attributes of `<AUDIT_RECORD>` elements have these characteristics:**

- Some attributes appear in every `<AUDIT_RECORD>` element. Others are optional and may appear depending on the audit record type.
- Order of attributes within an `<AUDIT_RECORD>` element is not guaranteed.
- Attribute values are not fixed length. Long values may be truncated as indicated in the attribute descriptions given later.
- The `<`, `>`, `,`, and `=` characters are encoded as `<`, `&gt;`, `&quot;`, and `&amp;`, respectively. NUL bytes (U+00) are encoded as the `?` character.
- Characters not valid as XML characters are encoded using numeric character references. Valid XML characters are:

  #x9 | #xA | #xD | [#x20-#xD7FF] | [#xE000-#xFFFD] | [#x10000-#x10FFFF]

The following attributes are mandatory in every `<AUDIT_RECORD>` element:

- **NAME**

  A string representing the type of instruction that generated the audit event, such as a command that the server received from a client.

  **Example:** `NAME="Query"

Some common **NAME** values:

<table>
<thead>
<tr>
<th>NAME</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Audit</td>
<td>When auditing starts, which may be server startup time</td>
</tr>
<tr>
<td>Connect</td>
<td>When a client connects, also known as logging in</td>
</tr>
<tr>
<td>Query</td>
<td>An SQL statement (executed directly)</td>
</tr>
<tr>
<td>Prepare</td>
<td>Preparation of an SQL statement; usually followed by Execute</td>
</tr>
<tr>
<td>Execute</td>
<td>Execution of an SQL statement; usually follows Prepare</td>
</tr>
<tr>
<td>Shutdown</td>
<td>Server shutdown</td>
</tr>
<tr>
<td>Quit</td>
<td>When a client disconnects</td>
</tr>
<tr>
<td>NoAudit</td>
<td>Auditing has been turned off</td>
</tr>
</tbody>
</table>

The possible values are Audit, Binlog Dump, Change user, Close stmt, Connect Out, Connect, Create DB, Daemon, Debug, Delayed insert, Drop DB, Execute, Fetch, Field List, Init DB, Kill, Long Data, NoAudit, Ping, Prepare, Processlist, Query, Quit, Refresh, Register Slave, Reset stmt, Set option, Shutdown, Sleep, Statistics, Table Dump, Time.

With the exception of "Audit" and "NoAudit", these values correspond to the COM_xxx command values listed in the `mysql_com.h` header file. For example, "Create DB" and "Change user" correspond to COM_CREATE_DB and COM_CHANGE_USER, respectively.

- **RECORD_ID**

  A unique identifier for the audit record. The value is composed from a sequence number and timestamp, in the format `SEQ_TIMESTAMP`. When the audit log plugin opens the audit log file, it initializes the sequence number to the size of the audit log file, then increments the sequence by 1 for each record logged. The timestamp is a UTC value in `YYYY-MM-DDThh:mm:ss` format indicating the date and time when the audit log plugin opened the file.
Audit Log File Formats

Example: \texttt{RECORD\_ID="12\_2017-10-16T14:25:00"}

- **TIMESTAMP**
  A string representing a UTC value in \texttt{YYYY-MM-DDThh:mm:ss UTC} format indicating the date and time when the audit event was generated. For example, the event corresponding to execution of an SQL statement received from a client has a **TIMESTAMP** value occurring after the statement finishes, not when it was received.

  Example: \texttt{TIMESTAMP="2017-10-16T14:25:32 UTC"}

The following attributes are optional in \texttt{<AUDIT\_RECORD>} elements. Many of them occur only for elements with specific values of the **NAME** attribute.

- **COMMAND\_CLASS**
  A string that indicates the type of action performed.

  Example: \texttt{COMMAND\_CLASS="drop\_table"}

  The values correspond to the Com\_xxx status variables that indicate command counts; for example, \texttt{Com\_drop\_table} and \texttt{Com\_select} count DROP TABLE and SELECT statements, respectively. The following statement displays the possible names:

  \begin{verbatim}
  SELECT LOWER(REPLACE(VARIABLE\_NAME, 'COM_', '')) AS name
  FROM INFORMATION\_SCHEMA.GLOBAL\_STATUS
  WHERE VARIABLE\_NAME LIKE 'COM%'
  ORDER BY name;
  \end{verbatim}

- **CONNECTION\_ID**
  An unsigned integer representing the client connection identifier. This is the same as the value returned by the \texttt{CONNECTION\_ID()} function within the session.

  Example: \texttt{CONNECTION\_ID="127"}

- **DB**
  A string representing the default database name.

  Example: \texttt{DB="test"}

- **HOST**
  A string representing the client host name.

  Example: \texttt{HOST="localhost"}

- **IP**
  A string representing the client IP address.

  Example: \texttt{IP="127.0.0.1"}

- **MYSQL\_VERSION**
  A string representing the MySQL server version. This is the same as the value of the \texttt{VERSION()} function or \texttt{version} system variable.

  Example: \texttt{MYSQL\_VERSION="5.6.39-log"}

- **OS\_LOGIN**
Audit Log File Formats

A string representing the external user name used during the authentication process, as set by the plugin used to authenticate the client. With native (built-in) MySQL authentication, or if the plugin does not set the value, this attribute is empty. The value is the same as that of the `external_user` system variable (see Section 4.12, “Proxy Users”).

Example: `OS_LOGIN="jeffrey"`

- **OS_VERSION**

A string representing the operating system on which the server was built or is running.

Example: `OS_VERSION="x86_64-Linux"`

- **PRIV_USER**

A string representing the user that the server authenticated the client as. This is the user name that the server uses for privilege checking, and it may differ from the `USER` value.

Example: `PRIV_USER="jeffrey"`

- **PROXY_USER**

A string representing the proxy user (see Section 4.12, “Proxy Users”). The value is empty if user proxying is not in effect.

Example: `PROXY_USER="developer"`

- **SERVER_ID**

An unsigned integer representing the server ID. This is the same as the value of the `server_id` system variable.

Example: `SERVER_ID="1"`

- **SQLTEXT**

A string representing the text of an SQL statement. The value can be empty. Long values may be truncated. The string, like the audit log file itself, is written using UTF-8 (up to 4 bytes per character), so the value may be the result of conversion. For example, the original statement might have been received from the client as an SJIS string.

Example: `SQLTEXT="DELETE FROM t1"`

- **STARTUP_OPTIONS**

A string representing the options that were given on the command line or in option files when the MySQL server was started.

Example: `STARTUP_OPTIONS="--port=3306 --log_output=FILE"`

- **STATUS**

An unsigned integer representing the command status: 0 for success, nonzero if an error occurred. This is the same as the value of the `mysql_errno()` C API function. See the description for `STATUS_CODE` for information about how it differs from `STATUS`.

The audit log does not contain the SQLSTATE value or error message. To see the associations between error codes, SQLSTATE values, and messages, see Server Error Message Reference.

Warnings are not logged.

Example: `STATUS="1051"`
• **STATUS_CODE**

An unsigned integer representing the command status: 0 for success, 1 if an error occurred.

The **STATUS_CODE** value differs from the **STATUS** value: **STATUS_CODE** is 0 for success and 1 for error, which is compatible with the EZ_collector consumer for Audit Vault. **STATUS** is the value of the `mysql_errno()` C API function. This is 0 for success and nonzero for error, and thus is not necessarily 1 for error.

Example: `STATUS_CODE="0"`

• **USER**

A string representing the user name sent by the client. This may differ from the **PRIV_USER** value.

• **VERSION**

An unsigned integer representing the version of the audit log file format.

Example: `VERSION="1"

### 6.4.4 Audit Log Logging Control

This section describes how to control general characteristics of audit logging, such as the file to which the audit log plugin writes events and the format of written events.

• Audit Log File Name

• Audit Log File Format

• Audit Logging Write Strategy

• Audit Log File Space Management and Name Rotation

For additional information about the system variables that affect audit logging, see [Audit Log Options and System Variables](#).

The audit log plugin can also control which audited events are written to the audit log file, based on the account from which events originate or event status. See [Section 6.4.5, “Audit Log Filtering”](#).

### Audit Log File Name

To control the audit log file name, set the `audit_log_file` system variable at server startup. By default, the name is `audit.log` in the server data directory. For security reasons, the audit log file should be written to a directory accessible only to the MySQL server and to users with a legitimate reason to view the log.

When the audit plugin initializes, it checks whether a file with the audit log file name already exists. If so, the plugin checks whether the file ends with an ```<AUDIT>``` tag and truncates the tag before writing any ```<AUDIT_RECORD>``` elements. If the log file exists but does not end with ```<AUDIT>``` or the ```</AUDIT>``` tag cannot be truncated, the plugin considers the file malformed and fails to initialize. This can occur if the server exits unexpectedly with the audit log plugin running. No logging occurs until the problem is rectified. Check the error log for diagnostic information:

```
[ERROR] Plugin 'audit_log' init function returned error.
```

To deal with this problem, either remove or rename the malformed log file and restart the server.

### Audit Log File Format

To control the audit log file format, set the `audit_log_format` system variable at server startup. By default, the format is **OLD** (old-style XML format). For information about available formats, see [Section 6.4.3, “Audit Log File Formats”](#).
Note
Changing the value of `audit_log_format` can result in writing log entries in one format to an existing log file that contains entries in a different format. To avoid this issue, use the following procedure:

1. Stop the server.
2. Either change the value of the `audit_log_file` system variable so the plugin writes to a different file, or rename the current audit log file manually.
3. Restart the server with the new value of `audit_log_format`. The audit log plugin creates a new log file and writes entries to it in the selected format.

Audit Logging Write Strategy

The audit log plugin can use any of several strategies for log writes. Regardless of strategy, logging occurs on a best-effort basis, with no guarantee of consistency.

To specify a write strategy, set the `audit_log_strategy` system variable at server startup. By default, the strategy value is `ASYNCHRONOUS` and the plugin logs asynchronously to a buffer, waiting if the buffer is full. It's possible to tell the plugin not to wait (`PERFORMANCE`) or to log synchronously, either using file system caching (`SEMISYNCHRONOUS`) or forcing output with a `sync()` call after each write request (`SYNCHRONOUS`).

For asynchronous write strategy, the `audit_log_buffer_size` system variable is the buffer size in bytes. Set this variable at server startup to change the buffer size. The plugin uses a single buffer, which it allocates when it initializes and removes when it terminates. The plugin does not allocate this buffer for nonasynchronous write strategies.

Asynchronous logging strategy has these characteristics:

- Minimal impact on server performance and scalability.
- Blocking of threads that generate audit events for the shortest possible time; that is, time to allocate the buffer plus time to copy the event to the buffer.
- Output goes to the buffer. A separate thread handles writes from the buffer to the log file.

With asynchronous logging, the integrity of the log file may be compromised if a problem occurs during a write to the file or if the plugin does not shut down cleanly (for example, in the event that the server host exits unexpectedly). To reduce this risk, set `audit_log_strategy` to use synchronous logging.

If the file system to which the audit log is being written fills up, a “disk full” error is written to the error log. Audit logging continues until the audit log buffer is full. If free disk space has not been made available by the time the buffer fills, client sessions will hang, and stopping the server at the time of client sessions hanging will result in audit log corruption. To avoid this if client sessions are hung, ensure that free space is available on the audit logging file system before stopping the server.

A disadvantage of `PERFORMANCE` strategy is that it drops events when the buffer is full. For a heavily loaded server, the audit log may have events missing.

Audit Log File Space Management and Name Rotation

The audit log file has the potential to grow very large and consume a lot of disk space. To enable management of the space used by its log files, the audit log plugin provides the `audit_log_rotate_on_size` and `audit_log_flush` system variables, which control audit log file rotation and flushing. Rotation can be done manually, or automatically based on file size.

**Manual audit log file rotation.** By default, `audit_log_rotate_on_size=0` and there is no log rotation except that which you perform manually. In this case, the audit log plugin closes and reopens the log file when the `audit_log_flush` value changes from disabled to enabled. Log file
renaming must be done externally to the server. Suppose that the log file name is `audit.log` and you want to maintain the three most recent log files, cycling through the names `audit.log.1` through `audit.log.3`. On Unix, perform rotation manually like this:

1. From the command line, rename the current log files:

   ```
   mv audit.log.2 audit.log.3
   mv audit.log.1 audit.log.2
   mv audit.log audit.log.1
   ```

   At this point, the plugin is still writing to the current log file, which has been renamed to `audit.log.1`.

2. Connect to the server and flush the log file so the plugin closes it and reopens a new `audit.log` file:

   ```
   SET GLOBAL audit_log_flush = ON;
   ```

**Automatic size-based audit log file rotation.** If `audit_log_rotate_on_size` is greater than 0, setting `audit_log_flush` has no effect. Instead, whenever a write to the log file causes its size to exceed the `audit_log_rotate_on_size` value, the audit log plugin closes the file, renames it, and opens a new log file.

The renamed file has a timestamp and `.xml` added to the end. For example, if the file name is `audit.log`, the plugin renames it to a value such as `audit.log.15081807937726520.xml`. The timestamp value is similar to a Unix timestamp, with the last 7 digits representing the fractional second part. By inserting a decimal point, the value can be interpreted using the `FROM_UNIXTIME()` function:

```
mysql> SELECT FROM_UNIXTIME(1508180793.7726520);
+--------------------------+
| FROM_UNIXTIME(1508180793.7726520) |
| 2017-10-16 14:06:33.772652 |
+--------------------------+
```

### Note

With size-based log file rotation, renamed log files do not rotate off the end of the name sequence. Instead, they have unique names and accumulate indefinitely. To avoid excessive space use, remove old files periodically, backing them up first as necessary.

### 6.4.5 Audit Log Filtering

The audit log plugin can filter audited events. This enables you to control whether audited events are written to the audit log file based on the account from which events originate or event status. Status filtering occurs separately for connection events and statement events.

#### Event Filtering by Account

As of MySQL 5.6.20, to filter audited events based on the originating account, set one of these system variables at server startup or runtime:

- **`audit_log_include_accounts`**: The accounts to include in audit logging. If this variable is set, only these accounts are audited.
- **`audit_log_exclude_accounts`**: The accounts to exclude from audit logging. If this variable is set, all but these accounts are audited.

The value for either variable can be `NULL` or a string containing one or more comma-separated account names, each in `user_name@host_name` format. By default, both variables are `NULL`, in which case, no account filtering is done and auditing occurs for all accounts.
Modifications to `audit_log_include_accounts` or `audit_log_exclude_accounts` affect only connections created subsequent to the modification, not existing connections.

Example: To enable audit logging only for the `user1` and `user2` local host account accounts, set the `audit_log_include_accounts` system variable like this:

```sql
SET GLOBAL audit_log_include_accounts = 'user1@localhost,user2@localhost';
```

Only one of `audit_log_include_accounts` or `audit_log_exclude_accounts` can be non-`NULL` at a time:

- If you set `audit_log_include_accounts`, the server sets `audit_log_exclude_accounts` to `NULL`.
- If you attempt to set `audit_log_exclude_accounts`, an error occurs unless `audit_log_include_accounts` is `NULL`. In this case, you must first clear `audit_log_include_accounts` by setting it to `NULL`.

```
-- This sets audit_log_exclude_accounts to NULL
SET GLOBAL audit_log_include_accounts = value;
-- This fails because audit_log_include_accounts is not NULL
SET GLOBAL audit_log_exclude_accounts = value;
-- To set audit_log_exclude_accounts, first set audit_log_include_accounts to NULL
SET GLOBAL audit_log_include_accounts = NULL;
SET GLOBAL audit_log_exclude_accounts = value;
```

If you inspect the value of either variable, be aware that `SHOW VARIABLES` displays `NULL` as an empty string. To avoid this, use `SELECT` instead:

```
mysql> SHOW VARIABLES LIKE 'audit_log_include_accounts';
+-------------------------+-------+
| Variable_name           | Value |
+-------------------------+-------+
| audit_log_include_accounts |       |
+-------------------------+-------+
mysql>
```

```
mysql> SELECT @@audit_log_include_accounts;
+--------------------------+
| @@audit_log_include_accounts |
| NULL                      |
+--------------------------+
```

If a user name or host name requires quoting because it contains a comma, space, or other special character, quote it using single quotes. If the variable value itself is quoted with single quotes, double each inner single quote or escape it with a backslash. The following statements each enable audit logging for the local `root` account and are equivalent, even though the quoting styles differ:

```sql
SET GLOBAL audit_log_include_accounts = 'root@localhost';
SET GLOBAL audit_log_include_accounts = '''root'@'localhost''' ;
SET GLOBAL audit_log_include_accounts = '\'root'@\'localhost'\';
SET GLOBAL audit_log_include_accounts = '\\root'@'localhost\';
```

The last statement will not work if the `ANSI_QUOTES` SQL mode is enabled because in that mode double quotes signify identifier quoting, not string quoting.

### Event Filtering by Status

As of MySQL 5.6.20, to filter audited events based on status, set these system variables at server startup or runtime:

- `audit_log_connection_policy`: Logging policy for connection events
- `audit_log_statement_policy`: Logging policy for statement events
Each variable takes a value of **ALL** (log all associated events; this is the default), **ERRORS** (log only failed events), or **NONE** (do not log events). For example, to log all statement events but only failed connection events, use these settings:

```sql
SET GLOBAL audit_log_statement_policy = ALL;
SET GLOBAL audit_log_connection_policy = ERRORS;
```

Before MySQL 5.6.20, `audit_log_connection_policy` and `audit_log_statement_policy` are not available. Instead, use `audit_log_policy` at server startup or runtime. It takes a value of **ALL** (log all events; this is the default), **LOGINS** (log connection events), **QUERIES** (log statement events), or **NONE** (do not log events). For any of those values, the audit log plugin logs all selected events without distinction as to success or failure.

As of MySQL 5.6.20, `audit_log_policy` is still available but can be set only at server startup. At runtime, it is a read-only variable. Its use at startup works as follows:

- If you do not set `audit_log_policy` or set it to its default of **ALL**, any explicit settings for `audit_log_connection_policy` or `audit_log_statement_policy` apply as specified. If not specified, they default to **ALL**.

- If you set `audit_log_policy` to a non-**ALL** value, that value takes precedence over and is used to set `audit_log_connection_policy` and `audit_log_statement_policy`, as indicated in the following table. If you also set either of those variables to a value other than their default of **ALL**, the server writes a message to the error log to indicate that their values are being overridden.

<table>
<thead>
<tr>
<th>Startup <code>audit_log_policy</code> Value</th>
<th>Resulting <code>audit_log_connection_policy</code> Value</th>
<th>Resulting <code>audit_log_statement_policy</code> Value</th>
</tr>

### Audit Log Options and System Variables

This section describes the command options and system variables that control operation of MySQL Enterprise Audit. If values specified at startup time are incorrect, the audit log plugin may fail to initialize properly and the server does not load it. In this case, the server may also produce error messages for other audit log settings because it will not recognize them.

To control activation of the audit log plugin, use this option:

- `--audit-log[=value]`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--audit-log[=value]</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.10</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>ON</td>
</tr>
<tr>
<td>Valid Values</td>
<td>ON, OFF, FORCE, FORCE_PLUS_PERMANENT</td>
</tr>
</tbody>
</table>

This option controls how the server loads the `audit_log` plugin at startup. It is available only if the plugin has been previously registered with `INSTALL PLUGIN` or is loaded with `--plugin-load` or `--plugin-load-add`. See Section 6.4.1, "Installing MySQL Enterprise Audit".

The option value should be one of those available for plugin-loading options, as described in Installing and Uninstalling Plugins. For example, `--audit-log=FORCE_PLUS_PERMANENT` tells the server to load the plugin at startup and prevents it from being removed while the server is running.

If the audit log plugin is enabled, it exposes several system variables that permit control over logging:

```sql
mysql> SHOW VARIABLES LIKE 'audit_log%';
+------------------------------+-----------------+
| Variable_name                | Value           |
|------------------------------+-----------------|
| audit_log_connection_policy  | ALL             |
| audit_log_buffer_size        | 1048576         |
| audit_log_strategy           |                 |
| audit_log_write_waits        |                 |
| Audit_log_total_size         |                 |
| Audit_log_events_written     |                 |
| Audit_log_exclude_accounts   |                 |
| audit_log_file               |                 |
| audit_log_flush              |                 |
| audit_log_format             |                 |
| audit_log_include_accounts   |                 |
| audit_log_policy             |                 |
| audit_log_rotate_on_size     |                 |
| audit_log_statement_policy   |                 |
+------------------------------+-----------------+
```

---

158
You can set any of these variables at server startup, and some of them at runtime.

• **audit_log_buffer_size**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--audit-log-buffer-size=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.10</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>audit_log_buffer_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1048576</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>4096</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>18446744073709547520</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

When the audit log plugin writes events to the log asynchronously, it uses a buffer to store event contents prior to writing them. This variable controls the size of that buffer, in bytes. The server adjusts the value to a multiple of 4096. The plugin uses a single buffer, which it allocates when it initializes and removes when it terminates. The plugin allocates this buffer only if logging is asynchronous.

• **audit_log_connection_policy**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--audit-log-connection-policy=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.20</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>audit_log_connection_policy</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>ALL</td>
</tr>
<tr>
<td>Valid Values</td>
<td>ALL, ERRORS, NONE</td>
</tr>
</tbody>
</table>

The policy controlling how the audit log plugin writes connection events to its log file. The following table shows the permitted values.
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL</td>
<td>Log all connection events</td>
</tr>
<tr>
<td>ERRORS</td>
<td>Log only failed connection events</td>
</tr>
<tr>
<td>NONE</td>
<td>Do not log connection events</td>
</tr>
</tbody>
</table>

**Note**

At server startup, any explicit value given for `audit_log_connection_policy` may be overridden if `audit_log_policy` is also specified, as described in Section 6.4.4, “Audit Log Logging Control”.

- **audit_log_current_session**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.6.20</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>audit_log_current_session</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>depends on filtering policy</td>
</tr>
</tbody>
</table>

Whether audit logging is enabled for the current session. The session value of this variable is read only. It is set when the session begins based on the values of the `audit_log_include_accounts` and `audit_log_exclude_accounts` system variables. The audit log plugin uses the session value to determine whether to audit events for the session. (There is a global value, but the plugin does not use it.)

- **audit_log_exclude_accounts**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--audit-log-exclude-accounts=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.20</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>audit_log_exclude_accounts</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The accounts for which events should not be logged. The value should be `NULL` or a string containing a list of one or more comma-separated account names. For more information, see Section 6.4.5, “Audit Log Filtering”.

Modifications to `audit_log_exclude_accounts` affect only connections created subsequent to the modification, not existing connections.

- **audit_log_file**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--audit-log-file=file_name</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.10</td>
</tr>
</tbody>
</table>
### Audit Log Reference

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>audit_log_file</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>audit.log</td>
</tr>
</tbody>
</table>

The name of the file to which the audit log plugin writes events. The default value is `audit.log`. If the value of `audit_log_file` is a relative path name, the plugin interprets it relative to the data directory. If the value is a full path name, the plugin uses the value as is. A full path name may be useful if it is desirable to locate audit files on a separate file system or directory. For security reasons, the audit log file should be written to a directory accessible only to the MySQL server and to users with a legitimate reason to view the log. For more information, see Section 6.4.4, “Audit Log Logging Control”.

- **audit_log_flush**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.6.10</td>
</tr>
<tr>
<td>System Variable</td>
<td>audit_log_flush</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Boolean</td>
</tr>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

When this variable is set to enabled (1 or `ON`), the audit log plugin closes and reopens its log file to flush it. (The value remains `OFF` so that you need not disable it explicitly before enabling it again to perform another flush.) Enabling this variable has no effect unless `audit_log_rotate_on_size` is 0. For more information, see Section 6.4.4, “Audit Log Logging Control”.

- **audit_log_format**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--audit-log-format=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.14</td>
</tr>
<tr>
<td>System Variable</td>
<td>audit_log_format</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>OLD</td>
</tr>
<tr>
<td>Valid Values</td>
<td>OLD, NEW</td>
</tr>
</tbody>
</table>

The audit log file format. Permitted values are `OLD` and `NEW` (default `OLD`). For details about each format, see Section 6.4.3, “Audit Log File Formats”.
Note
Changing the value of `audit_log_format` can result in writing log entries in one format to an existing log file that contains entries in a different format. To avoid this issue, use the procedure described at Audit Log File Format.

- **audit_log_include_accounts**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--audit-log-include-accounts=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.20</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>audit_log_include_accounts</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The accounts for which events should be logged. The value should be `NULL` or a string containing a list of one or more comma-separated account names. For more information, see Section 6.4.5, “Audit Log Filtering”.

Modifications to `audit_log_include_accounts` affect only connections created subsequent to the modification, not existing connections.

- **audit_log_policy**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--audit-log-policy=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.10</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>audit_log_policy</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic (&gt;= 5.6.20)</td>
<td>No</td>
</tr>
<tr>
<td>Dynamic (&lt;= 5.6.19)</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>ALL</td>
</tr>
<tr>
<td>Valid Values</td>
<td>ALL</td>
</tr>
<tr>
<td></td>
<td>LOGINS</td>
</tr>
<tr>
<td></td>
<td>QUERIES</td>
</tr>
<tr>
<td></td>
<td>NONE</td>
</tr>
</tbody>
</table>

The policy controlling how the audit log plugin writes events to its log file. The following table shows the permitted values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL</td>
<td>Log all events</td>
</tr>
<tr>
<td>LOGINS</td>
<td>Log only login events</td>
</tr>
<tr>
<td>QUERIES</td>
<td>Log only query events</td>
</tr>
<tr>
<td>NONE</td>
<td>Log nothing (disable the audit stream)</td>
</tr>
</tbody>
</table>
As of MySQL 5.6.20, `audit_log_policy` can be set only at server startup. At runtime, it is a read-only variable. This is due to the introduction of two other system variables, `audit_log_connection_policy` and `audit_log_statement_policy`, that provide finer control over logging policy and that can be set either at startup or at runtime. If you continue to use `audit_log_policy` at startup instead of the other two variables, the server uses its value to set those variables. For more information about the policy variables and their interaction, see Section 6.4.4, “Audit Log Logging Control”.

Before MySQL 5.6.20, the `audit_log_connection_policy` and `audit_log_statement_policy` system variables do not exist. `audit_log_policy` is the only policy control variable and it can be set at server startup or runtime.

- `audit_log_rotate_on_size`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--audit-log-rotate-on-size=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.10</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>audit_log_rotate_on_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

If the `audit_log_rotate_on_size` value is 0, the audit log plugin does not perform automatic log file rotation. Instead, use `audit_log_flush` to close and reopen the log on demand. In this case, manually rename the file externally to the server before flushing it.

If the `audit_log_rotate_on_size` value is greater than 0, automatic size-based log file rotation occurs. Whenever a write to the log file causes its size to exceed the `audit_log_rotate_on_size` value, the audit log plugin closes the current log file, renames it, and opens a new log file.

For more information about audit log file rotation, see Audit Log File Space Management and Name Rotation.

If you set this variable to a value that is not a multiple of 4096, it is truncated to the nearest multiple. (Thus, setting it to a value less than 4096 has the effect of setting it to 0 and no rotation occurs, except manually.)

- `audit_log_statement_policy`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--audit-log-statement-policy=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.20</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>audit_log_statement_policy</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>ALL</td>
</tr>
<tr>
<td>Valid Values</td>
<td>ALL</td>
</tr>
</tbody>
</table>

ERRORS
The policy controlling how the audit log plugin writes statement events to its log file. The following table shows the permitted values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL</td>
<td>Log all statement events</td>
</tr>
<tr>
<td>ERRORS</td>
<td>Log only failed statement events</td>
</tr>
<tr>
<td>NONE</td>
<td>Do not log statement events</td>
</tr>
</tbody>
</table>

Note

At server startup, any explicit value given for `audit_log_statement_policy` may be overridden if `audit_log_policy` is also specified, as described in Section 6.4.4, “Audit Log Logging Control”.

- `audit_log_strategy`

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--audit-log-strategy=value</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.10</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>audit_log_strategy</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>ASYNCHRONOUS</td>
</tr>
<tr>
<td>Valid Values</td>
<td>ASYNCHRONOUS, PERFORMANCE, SEMISYNCHRONOUS, SYNCHRONOUS</td>
</tr>
</tbody>
</table>

The logging method used by the audit log plugin. These strategy values are permitted:

- **ASYNCHRONOUS**: Log asynchronously. Wait for space in the output buffer.
- **PERFORMANCE**: Log asynchronously. Drop requests for which there is insufficient space in the output buffer.
- **SEMISYNCHRONOUS**: Log synchronously. Permit caching by the operating system.
- **SYNCHRONOUS**: Log synchronously. Call `sync()` after each request.

**Audit Log Plugin Status Variables**

If the audit log plugin is enabled, it exposes several status variables that provide operational information.

- `Audit_log_current_size`
The size of the current audit log file. The value increases when an event is written to the log and is reset to 0 when the log is rotated.

• **Audit_log_event_max_drop_size**
  The size of the largest dropped event in performance logging mode. For a description of logging modes, see Section 6.4.4, “Audit Log Logging Control”.

• **Audit_log_events**
  The number of events handled by the audit log plugin, whether or not they were written to the log based on filtering policy (see Section 6.4.4, “Audit Log Logging Control”).

• **Audit_log_events_filtered**
  The number of events handled by the audit log plugin that were filtered (not written to the log) based on filtering policy (see Section 6.4.4, “Audit Log Logging Control”).

• **Audit_log_events_lost**
  The number of events lost in performance logging mode because an event was larger than the available audit log buffer space. This value may be useful for assessing how to set `audit_log_buffer_size` to size the buffer for performance mode. For a description of logging modes, see Section 6.4.4, “Audit Log Logging Control”.

• **Audit_log_events_written**
  The number of events written to the audit log.

• **Audit_log_total_size**
  The total size of events written to all audit log files. Unlike `Audit_log_current_size`, the value of `Audit_log_total_size` increases even when the log is rotated.

• **Audit_log_write_waits**
  The number of times an event had to wait for space in the audit log buffer in asynchronous logging mode. For a description of logging modes, see Section 6.4.4, “Audit Log Logging Control”.

### 6.4.7 Audit Log Restrictions

MySQL Enterprise Audit is subject to these general restrictions:

• Only SQL statements are logged. Changes made by no-SQL APIs, such as memcached, Node.JS, and the NDB API, are not logged.

• Only top-level statements are logged, not statements within stored programs such as triggers or stored procedures.

• Contents of files referenced by statements such as `LOAD DATA` are not logged.

**NDB Cluster.** It is possible to use MySQL Enterprise Audit with MySQL NDB Cluster, subject to the following conditions:

• All changes to be logged must be done using the SQL interface. Changes using no-SQL interfaces, such as those provided by the NDB API, memcached, or ClusterJ, are not logged.

• The plugin must be installed on each MySQL server that is used to execute SQL on the cluster.

• Audit plugin data must be aggregated amongst all MySQL servers used with the cluster. This aggregation is the responsibility of the application or user.
6.5 MySQL Enterprise Firewall

Note
MySQL Enterprise Firewall is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see https://www.mysql.com/products/.

As of MySQL 5.6.24, MySQL Enterprise Edition includes MySQL Enterprise Firewall, an application-level firewall that enables database administrators to permit or deny SQL statement execution based on matching against whitelists of accepted statement patterns. This helps harden MySQL Server against attacks such as SQL injection or attempts to exploit applications by using them outside of their legitimate query workload characteristics.

Each MySQL account registered with the firewall has its own statement whitelist, enabling protection to be tailored per account. For a given account, the firewall can operate in recording, protecting, or detecting mode, for training in the accepted statement patterns, active protection against unacceptable statements, or passive detection of unacceptable statements. The diagram illustrates how the firewall processes incoming statements in each mode.

![MySQL Enterprise Firewall Operation Diagram](image)

The following sections describe the components of MySQL Enterprise Firewall, discuss how to install and use it, and provide reference information for its components.

6.5.1 MySQL Enterprise Firewall Components

MySQL Enterprise Firewall is based on a plugin library that implements these components:

- A server-side plugin named `MYSQL_FIREWALL` examines SQL statements before they execute and, based on its in-memory cache, renders a decision whether to execute or reject each statement.

- Server-side plugins named `MYSQL_FIREWALL_USERS` and `MYSQL_FIREWALL_WHITELIST` implement `INFORMATION_SCHEMA` tables that provide views into the firewall data cache.
• System tables named `firewall_users` and `firewall_whitelist` in the `mysql` database provide persistent storage of firewall data.

• Stored procedures named `sp_set_firewall_mode()` and `sp_reload_firewall_rules()` perform tasks such as registering MySQL accounts with the firewall, establishing their operational mode, and managing transfer of firewall data between the cache and the underlying system tables.

• A set of user-defined functions provides an SQL-level API for lower-level tasks such as synchronizing the cache with the underlying system tables.

• System variables enable firewall configuration and status variables provide runtime operational information.

6.5.2 Installing or Uninstalling MySQL Enterprise Firewall

MySQL Enterprise Firewall installation is a one-time operation that installs the components described in Section 6.5.1, “MySQL Enterprise Firewall Components”. Installation can be performed using a graphical interface or manually:

• On Windows, MySQL Installer includes an option to enable MySQL Enterprise Firewall for you.

• MySQL Workbench 6.3.4 or higher can install MySQL Enterprise Firewall, enable or disable an installed firewall, or uninstall the firewall.

• Manual MySQL Enterprise Firewall installation involves running a script located in the `share` directory of your MySQL installation.

**Note**

If installed, MySQL Enterprise Firewall involves some minimal overhead even when disabled. To avoid this overhead, do not install the firewall unless you plan to use it.

**Note**

MySQL Enterprise Firewall does not work together with the query cache. If the query cache is enabled, disable it before installing the firewall (see Query Cache Configuration).

For usage instructions, see Section 6.5.3, “Using MySQL Enterprise Firewall”. For reference information, see Section 6.5.4, “MySQL Enterprise Firewall Reference”.

• Installing MySQL Enterprise Firewall

• Uninstalling MySQL Enterprise Firewall

### Installing MySQL Enterprise Firewall

If MySQL Enterprise Firewall is already installed from an older version of MySQL, uninstall it using the instructions given later in this section and then restart your server before installing the current version. In this case, it is also necessary to register your configuration again.

On Windows, you can use MySQL Installer to install MySQL Enterprise Firewall, as shown in Figure 6.2, “MySQL Enterprise Firewall Installation on Windows”. Check the Enable Enterprise Firewall checkbox. (Open Firewall port for network access has a different purpose. It refers to Windows Firewall and controls whether Windows blocks the TCP/IP port on which the MySQL server listens for client connections.)
To install MySQL Enterprise Firewall using MySQL Workbench 6.3.4 or higher, see MySQL Enterprise Firewall Interface.

To install MySQL Enterprise Firewall manually, look in the share directory of your MySQL installation and choose the script that is appropriate for your platform. The available scripts differ in the suffix used to refer to the plugin library file:

- `win_install_firewall.sql`: Choose this script for Windows systems that use `.dll` as the file name suffix.
- `linux_install_firewall.sql`: Choose this script for Linux and similar systems that use `.so` as the file name suffix.

The installation script creates stored procedures in the default database, so choose a database to use. Then run the script as follows, naming the chosen database on the command line. The example here uses the `mysql` database and the Linux installation script. Make the appropriate substitutions for your system.

```
shell> mysql -u root -p mysql < linux_install_firewall.sql
Enter password: (enter root password here)
```

Installing MySQL Enterprise Firewall either using a graphical interface or manually should enable the firewall. To verify that, connect to the server and execute this statement:

```
mysql> SHOW GLOBAL VARIABLES LIKE 'mysql_firewall_mode';
+--------------------+--------+
| Variable_name      | Value  |
+--------------------+--------+
```
Using MySQL Enterprise Firewall

<table>
<thead>
<tr>
<th>mysql_firewall_mode</th>
<th>ON</th>
</tr>
</thead>
</table>
| +---------------------+-------+

If the plugin failed to initialize, check the server error log for diagnostic messages.

## Uninstalling MySQL Enterprise Firewall

MySQL Enterprise Firewall can be uninstalled using MySQL Workbench or manually.

To uninstall MySQL Enterprise Firewall using MySQL Workbench 6.3.4 or higher, see MySQL Enterprise Firewall Interface.

To uninstall MySQL Enterprise Firewall manually, execute the following statements. It is assumed that the stored procedures were created in the `mysql` database. Adjust the `DROP PROCEDURE` statements appropriately if the procedures were created in a different database.

```
drop table mysql.firewall_whitelist;
drop table mysql.firewall_users;
uninstall plugin mysql_firewall;
uninstall plugin mysql_firewall_whitelist;
uninstall plugin mysql_firewall_users;
drop function set_firewall_mode;
drop function normalize_statement;
drop function read_firewall_whitelist;
drop function read_firewall_users;
drop function mysql_firewall_flush_status;  # MySQL 5.6.26 and up only
drop procedure mysql.sp_set_firewall_mode;
drop procedure mysql.sp_reload_firewall_rules;  # MySQL 5.6.26 and up only
```

### 6.5.3 Using MySQL Enterprise Firewall

Before using MySQL Enterprise Firewall, install it according to the instructions provided in Section 6.5.2, “Installing or Uninstalling MySQL Enterprise Firewall”. Also, MySQL Enterprise Firewall does not work together with the query cache; disable the query cache if it is enabled (see Query Cache Configuration).

This section describes how to configure MySQL Enterprise Firewall using SQL statements. Alternatively, MySQL Workbench 6.3.4 or higher provides a graphical interface for firewall control. See MySQL Enterprise Firewall Interface.

To enable or disable the firewall, set the `mysql_firewall_mode` system variable. By default, this variable is enabled when the firewall is installed. To control the initial firewall state explicitly, you can set the variable at server startup. For example, to enable the firewall in an option file, use these lines:

```
[mysqld]
mysql_firewall_mode=ON
```

It is also possible to disable or enable the firewall at runtime:

```
mysql> SET GLOBAL mysql_firewall_mode = OFF;
mysql> SET GLOBAL mysql_firewall_mode = ON;
```

In addition to the global on/off firewall mode, each account registered with the firewall has its own operational mode. For an account in recording mode, the firewall learns an application's "fingerprint," that is, the acceptable statement patterns that, taken together, form a whitelist. After training, switch the firewall to protecting mode to harden MySQL against access by statements that deviate from the fingerprint. For additional training, switch the firewall back to recording mode as necessary to update the whitelist with new statement patterns. As of MySQL 5.6.26, an intrusion-detection mode is available that writes suspicious statements to the error log but does not deny access.

The firewall maintains whitelist rules on a per-account basis, enabling implementation of protection strategies such as these:
For an application that has unique protection requirements, configure it to use an account that is not used for any other purpose.

For applications that are related and share protection requirements, configure them as a group to use the same account.

Firewall operation is based on conversion of SQL statements to normalized digest form. Firewall digests are like the statement digests used by the Performance Schema (see Performance Schema Statement Digests). However, unlike the Performance Schema, the relevant digest-related system variable is `max_digest_length`.

For a connection from a registered account, the firewall converts each incoming statement to normalized form and processes it according to the account mode:

- In recording mode, the firewall adds the normalized statement to the account whitelist rules.

- In protecting mode, the firewall compares the normalized statement to the account whitelist rules. If there is a match, the statement passes and the server continues to process it. Otherwise, the server rejects the statement and returns an error to the client. As of MySQL 5.6.25, the firewall also writes the rejected statement to the error log if the `mysql_firewall_trace` system variable is enabled.

- In detecting mode, the firewall matches statements as in protecting mode, but writes nonmatching statements to the error log without denying access.

Accounts that have a mode of `OFF` or are not registered with the firewall are ignored by it.

**Note**

Before MySQL 5.6.25, MySQL Enterprise Firewall records prepared statements as they are received by the server, not as normalized digests. Thus, spaces, tabs, and lettercase are significant for comparison of whitelist rules against incoming statements.

To protect an account using MySQL Enterprise Firewall, follow these steps:

1. Register the account and put it in recording mode.
2. Connect to the MySQL server using the registered account and execute statements to be learned. This establishes the account's whitelist of accepted statements.
3. Switch the registered account to protecting mode.

The following example shows how to register an account with the firewall, use the firewall to learn acceptable statements for that account, and protect the account against execution of unacceptable statements. The example account, `'fwuser'@'localhost'`, is for use by an application that accesses tables in the `sakila` database. (This database is available at https://dev.mysql.com/doc/index-other.html.)

**Note**

The user and host parts of the account name are quoted separately for statements such as `CREATE USER` and `GRANT`, whereas to specify an account for use with a firewall component, name it as a single quoted string `'fwuser@localhost'`.

The convention for naming accounts as a single quoted string for firewall components means that you cannot use accounts that have embedded `@` characters in the user name.

Perform the steps in the following procedure using an administrative MySQL account, except those designated for execution by the account registered with the firewall. The default database should be `sakila` for statements executed using the registered account.
1. If necessary, create the account to be protected (choose an appropriate password) and grant it privileges for the sakila database:

   mysql> CREATE USER 'fwuser'@'localhost' IDENTIFIED BY 'fWp@3sw0rd';
   mysql> GRANT ALL ON sakila.* TO 'fwuser'@'localhost';

2. Use the sp_set_firewall_mode() stored procedure to register the account with the firewall and place it in recording mode (if the procedure is located in a database other than mysql, adjust the statement accordingly):

   mysql> CALL mysql.sp_set_firewall_mode('fwuser@localhost', 'RECORDING');

   During the course of its execution, the stored procedure invokes firewall user-defined functions, which may produce output of their own.

3. Using the registered account, connect to the server, then execute some statements that are legitimate for it:

   mysql> SELECT first_name, last_name FROM customer WHERE customer_id = 1;
   mysql> UPDATE rental SET return_date = NOW() WHERE rental_id = 1;
   mysql> SELECT get_customer_balance(1, NOW());

   The firewall converts the statements to digest form and records them in the account whitelist.

   Note
   Until the account executes statements in recording mode, its whitelist is empty, which is equivalent to “deny all.” If switched to protecting mode, the account will be effectively prohibited from executing statements.

4. At this point, the user and whitelist information is cached and can be seen in the firewall INFORMATION_SCHEMA tables:

   mysql> SELECT MODE FROM INFORMATION_SCHEMA.MYSQL_FIREWALL_USERS
       WHERE USERHOST = 'fwuser@localhost';
   +-----------+
   | MODE      |
   +-----------+
   | RECORDING |
   +-----------+
   mysql> SELECT RULE FROM INFORMATION_SCHEMA.MYSQL_FIREWALL_WHITELIST
       WHERE USERHOST = 'fwuser@localhost';
   +----------------------------------------------------------------------------+
   | RULE                                                                       |
   +----------------------------------------------------------------------------+
   | SELECT `first_name` , `last_name` FROM `customer` WHERE `customer_id` = ?    |
   | SELECT `get_customer_balance` ( ? , NOW ( ) )                              |
   | UPDATE `rental` SET `return_date` = NOW ( ) WHERE `rental_id` = ?           |
   | SELECT @@version_comment LIMIT ?                                          |
   +----------------------------------------------------------------------------+

   Note
   The @@version_comment rule comes from a statement sent automatically by the mysql client when you connect to the server as the registered user.

   It is important to train the firewall under conditions matching application use. For example, a given MySQL connector might send statements to the server at the beginning of a connection to determine server characteristics and capabilities. If an application normally is used through that connector, train the firewall that way, too. That enables those initial statements to become part of the whitelist for the account associated with the application.
5. Use the stored procedure to switch the registered user to protecting mode:

```sql
CALL mysql.sp_set_firewall_mode('fwuser@localhost', 'PROTECTING');
```

**Important**

Switching the account out of RECORDING mode synchronizes its firewall cache data to the underlying mysql system database tables for persistent storage. If you do not switch the mode for a user who is being recorded, the cached whitelist data is not written to the system tables and will be lost when the server is restarted.

6. Using the registered account, execute some acceptable and unacceptable statements. The firewall matches each one against the account whitelist and accepts or rejects it.

This statement is not identical to a training statement but produces the same normalized statement as one of them, so the firewall accepts it:

```sql
mysql> SELECT first_name, last_name FROM customer WHERE customer_id = '48';
+------------+-----------+
| first_name | last_name |
|-----------+----------|
| ANN       | EVANS    |
+------------+-----------+
```

These statements do not match anything in the whitelist and each results in an error:

```sql
mysql> SELECT first_name, last_name FROM customer WHERE customer_id = 1 OR TRUE;
ERROR 1045 (28000): Statement was blocked by Firewall
mysql> SHOW TABLES LIKE 'customer%';
ERROR 1045 (28000): Statement was blocked by Firewall
mysql> TRUNCATE TABLE mysql.slow_log;
ERROR 1045 (28000): Statement was blocked by Firewall
```

As of MySQL 5.6.25, the firewall also writes the rejected statements to the error log if the `mysql_firewall_trace` system variable is enabled. For example:

```
[Note] Plugin MYSQL_FIREWALL reported:
'ACCESS DENIED for fwuser@localhost. Reason: No match in whitelist.
Statement: TRUNCATE TABLE `mysql` . `slow_log` '
```

You can use these log messages in your efforts to identify the source of attacks.

7. As of MySQL 5.6.26, you can log nonmatching statements as suspicious without denying access.

To do this, put the account in intrusion-detecting mode:

```sql
CALL mysql.sp_set_firewall_mode('fwuser@localhost', 'DETECTING');
```

8. Using the registered account, connect to the server, then execute a statement that does not match the whitelist:

```sql
mysql> SHOW TABLES LIKE 'customer%';
+-------------------------------+
| Tables_in_sakila (customer%) |
+-------------------------------|
| customer                     |
| customer_list                |
+-------------------------------+
```

In detecting mode, the firewall permits the nonmatching statement to execute but writes a message to the error log:
9. To assess firewall activity, examine its status variables:

```sql
table | value
------------------|-------
Firewall_access_denied | 3
Firewall_access_granted | 4
Firewall_access_suspicious | 1
Firewall_cached_entries | 4
```

The variables indicate the number of statements rejected, accepted, logged as suspicious, and added to the cache, respectively. The `Firewall_access_granted` count is 4 because of the @@version_comment statement sent by the `mysql` client each of the three times you used it to connect as the registered user, plus the `SHOW TABLES` statement that was not blocked in DETECTING mode.

Should additional training for an account be necessary, switch it to recording mode again, then back to protecting mode after executing statements to be added to the whitelist.

### 6.5.4 MySQL Enterprise Firewall Reference

The following discussion serves as a reference to MySQL Enterprise Firewall components:

- MySQL Enterprise Firewall Tables
- MySQL Enterprise Firewall Procedures and Functions
- MySQL Enterprise Firewall System Variables
- MySQL Enterprise Firewall Status Variables

#### MySQL Enterprise Firewall Tables

MySQL Enterprise Firewall maintains account and whitelist information. It uses INFORMATION_SCHEMA tables to provide views into cached data, and tables in the `mysql` system database to store this data in persistent form. When enabled, the firewall bases its operational decisions on the cached data.

The INFORMATION_SCHEMA tables are accessible by anyone. The `mysql` tables can be accessed only by users with privileges for that database.

The INFORMATION_SCHEMA.MYSQL_FIREWALL_USERS and `mysql.firewall_users` tables list registered firewall accounts and their operational modes. The tables have these columns:

- **USERHOST**
  
  An account registered with the firewall. Each account has the format `user_name@host_name` and represents actual user and host names as authenticated by the server. Patterns and netmasks should not be used when registering users.

- **MODE**
  
  The current firewall operational mode for the account. The permitted mode values are OFF, DETECTING (as of MySQL 5.6.26), PROTECTING, RECORDING, and RESET. For details about their meanings, see the description of `sp_set_firewall_mode()` in MySQL Enterprise Firewall Procedures and Functions.
The `INFORMATION_SCHEMA.MYSQL_FIREWALL_WHITELIST` and `mysql.firewall_whitelist` tables list registered firewall accounts and their whitelists. The tables have these columns:

- **USERHOST**
  An account registered with the firewall. The format is the same as for the user account tables.

- **RULE**
  A normalized statement indicating an acceptable statement pattern for the account. An account whitelist is the union of its rules.

MySQL Enterprise Firewall Procedures and Functions

MySQL Enterprise Firewall has stored procedures that perform tasks such as registering MySQL accounts with the firewall, establishing their operational mode, and managing transfer of firewall data between the cache and the underlying system tables. It also has a set of user-defined functions (UDFs) that provides an SQL-level API for lower-level tasks such as synchronizing the cache with the underlying system tables.

Under normal operation, the stored procedures implement the user interface. The UDFs are invoked by the stored procedures, not directly by users.

To invoke a stored procedure when the default database is not the database that contains the procedure, qualify the procedure name with the database name. For example:

```sql
CALL mysql.sp_set_firewall_mode('user', 'mode');
```

The following list describes each firewall stored procedure and UDF:

- **sp_reload_firewall_rules(user)**
  This stored procedure uses firewall UDFs to reset a registered account and reload the in-memory rules for it from the rules stored in the `mysql.firewall_whitelist` table. This procedure provides control over firewall operation for individual accounts.

  The `user` argument names the affected account, as a string in `user_name@host_name` format.

  Example:

  ```sql
  CALL mysql.sp_reload_firewall_rules('fwuser@localhost');
  ```

  **Warning**
  This procedure sets the account mode to **RESET**, which clears the account whitelist and sets its mode to **OFF**. If the account mode was not **OFF** prior to the `sp_reload_firewall_rules()` call, use `sp_set_firewall_mode()` to restore its previous mode after reloading the rules. For example, if the account was in **PROTECTING** mode, that is no longer true after calling `sp_reload_firewall_rules()` and you must set it to **PROTECTING** again explicitly.

- **sp_set_firewall_mode(user, mode)**
  This stored procedure registers a MySQL account with the firewall and establishes its operational mode. The procedure also invokes firewall UDFs as necessary to transfer firewall data between the cache and the underlying system tables. This procedure may be called even if the `mysql_firewall_mode` system variable is **OFF**, although setting the mode for an account has no operational effect while the firewall is disabled.

  The `user` argument names the affected account, as a string in `user_name@host_name` format.
The **mode** is the operational mode for the user, as a string. These mode values are permitted:

- **OFF**: Disable the firewall for the account.
- **DETECTING**: Intrusion-detection mode: Write suspicious (nonmatching) statements to the error log but do not deny access.
- **PROTECTING**: Protect the account by matching incoming statements against the account whitelist.
- **RECORDING**: Training mode: Record acceptable statements for the account. Incoming statements that do not immediately fail with a syntax error are recorded to become part of the account whitelist rules.
- **RESET**: Clear the account whitelist and set the account mode to **OFF**.

Switching the mode for an account to any mode but **RECORDING** synchronizes the firewall cache data to the underlying mysql system database tables for persistent storage. Switching the mode from **OFF** to **RECORDING** reloads the whitelist from the `mysql.firewall_whitelist` table into the cache.

If an account has an empty whitelist, setting its mode to **PROTECTING** produces an error message that is returned in a result set, but not an SQL error:

```sql
mysql> CALL mysql.sp_set_firewall_mode('a@b','PROTECTING');
+----------------------------------------------------------------------+
| set_firewall_mode(arg_userhost, arg_mode)                            |
| ERROR: PROTECTING mode requested for a@b but the whitelist is empty. |
+----------------------------------------------------------------------+
1 row in set (0.02 sec)
Query OK, 0 rows affected (0.02 sec)
```

- **mysql_firewall_flush_status()**

  This UDF resets several firewall status variables to 0:

  ```sql
  Firewall_access_denied
  Firewall_access_granted
  Firewall_access_suspicious
  ```

  Example:

  ```sql
  SELECT mysql_firewall_flush_status();
  ```

- **normalize_statement(stmt)**

  This UDF normalizes an SQL statement into the digest form used for whitelist rules.

  Example:

  ```sql
  SELECT normalize_statement('SELECT * FROM t1 WHERE c1 > 2');
  ```

- **read_firewall_users(user, mode)**

  This aggregate UDF updates the firewall user cache through a **SELECT** statement on the `mysql.firewall_users` table.

  Example:

  ```sql
  SELECT read_firewall_users('fwuser@localhost', 'RECORDING')
  ```
FROM mysql.firewall_users;

• `read_firewall_whitelist(user, rule)`

This aggregate UDF updates the recorded statement cache through a `SELECT` statement on the `mysql.firewall_whitelist` table.

Example:

```
SELECT read_firewall_whitelist('fwuser@localhost', 'RECORDING')
FROM mysql.firewall_whitelist;
```

• `set_firewall_mode(user, mode)`

This UDF manages the user cache and establishes the user operational mode.

Example:

```
SELECT set_firewall_mode('fwuser@localhost', 'RECORDING');
```

### MySQL Enterprise Firewall System Variables

MySQL Enterprise Firewall supports the following system variables. Use them to configure firewall operation. These variables are unavailable unless the firewall is installed (see Section 6.5.2, “Installing or Uninstalling MySQL Enterprise Firewall”).

- **mysql_firewall_max_query_size**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--mysql-firewall-max-query-size=#</code></td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.24</td>
</tr>
<tr>
<td>Removed</td>
<td>5.6.26</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>mysql_firewall_max_query_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>4096</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

The maximum size of a normalized statement that can be inserted in the MySQL Enterprise Firewall cache. Normalized statements longer than this size are truncated. Truncated statements are discarded if the firewall mode for the current user is `RECORDING` and rejected if the mode is `PROTECTING`.

`mysql_firewall_max_query_size` was removed in MySQL 5.6.26. `max_digest_length` should be set large enough to avoid statement truncation.

- **mysql_firewall_mode**

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--mysql-firewall-mode=[OFF</td>
</tr>
<tr>
<td>Introduced</td>
<td>5.6.24</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>mysql_firewall_mode</code></td>
</tr>
</tbody>
</table>
### MySQL Enterprise Firewall Status Variables

MySQL Enterprise Firewall supports the following status variables. Use them to obtain information about firewall operational status. These variables are unavailable unless the firewall is installed (see Section 6.5.2, “Installing or Uninstalling MySQL Enterprise Firewall”). Firewall status variables are set to 0 whenever the `MYSQL_FIREWALL` plugin is installed or the server is started. Many of them are reset to zero by the `mysql_firewall_flush_status()` UDF (see MySQL Enterprise Firewall Procedures and Functions).

- **Firewall_access_denied**
  The number of statements rejected by MySQL Enterprise Firewall.

- **Firewall_access_granted**
  The number of statements accepted by MySQL Enterprise Firewall.

- **Firewall_access_suspicious**
  The number of statements logged by MySQL Enterprise Firewall as suspicious for users who are in DETECTING mode.

- **Firewall_cached_entries**
  The number of statements recorded by MySQL Enterprise Firewall, including duplicates.
Appendix A MySQL 5.6 FAQ: Security

Questions

- **A.1**: Where can I find documentation that addresses security issues for MySQL?
- **A.2**: What is the default authentication plugin in MySQL 5.6?
- **A.3**: Does MySQL 5.6 have native support for SSL?
- **A.4**: Is SSL support built into MySQL binaries, or must I recompile the binary myself to enable it?
- **A.5**: Does MySQL 5.6 have built-in authentication against LDAP directories?
- **A.6**: Does MySQL 5.6 include support for Roles Based Access Control (RBAC)?

Questions and Answers

**A.1**: Where can I find documentation that addresses security issues for MySQL?

The best place to start is *Chapter 1, Security*.

Other portions of the MySQL Documentation which you may find useful with regard to specific security concerns include the following:

- *Section 2.1, “Security Guidelines”*.
- *Section 2.3, “Making MySQL Secure Against Attackers”*.
- *How to Reset the Root Password*.
- *Section 2.5, “How to Run MySQL as a Normal User”*.
- *UDF Security Precautions*.
- *Section 2.4, “Security-Related mysqld Options and Variables”*.
- *Section 2.6, “Security Issues with LOAD DATA LOCAL”*.
- *Chapter 3, Postinstallation Setup and Testing*.
- *Chapter 5, Using Encrypted Connections*.

**A.2**: What is the default authentication plugin in MySQL 5.6?

The default authentication plugin in MySQL 5.6 is `mysql_native_password`. For information about this plugin, see *Section 6.1.1, “Native Pluggable Authentication”*. For general information about pluggable authentication and other available authentication plugins, see *Section 4.11, “Pluggable Authentication”, and Section 6.1, “Authentication Plugins”*.

**A.3**: Does MySQL 5.6 have native support for SSL?

Most 5.6 binaries have support for SSL connections between the client and server. See *Chapter 5, Using Encrypted Connections*.

You can also tunnel a connection using SSH, if (for example) the client application does not support SSL connections. For an example, see *Section 5.5, “Connecting to MySQL Remotely from Windows with SSH”*.

**A.4**: Is SSL support built into MySQL binaries, or must I recompile the binary myself to enable it?
Most 5.6 binaries have SSL enabled for client/server connections that are secured, authenticated, or both. See Chapter 5, *Using Encrypted Connections*.

**A.5: Does MySQL 5.6 have built-in authentication against LDAP directories?**

**A.6: Does MySQL 5.6 include support for Roles Based Access Control (RBAC)?**

Not at this time.
