MySQL NDB Cluster API Developer Guide

This is the MySQL NDB Cluster API Developer Guide, which provides information about developing applications using MySQL NDB Cluster as a data store. Application interfaces covered in this Guide include the low-level C++-language NDB API (see Chapter 2, The NDB API), the C-language MGM API for communicating with and controlling NDB Cluster management servers (see Chapter 3, The MGM API), and the MySQL NDB Cluster Connector for Java, which is a collection of Java APIs for writing applications against NDB Cluster, including JDBC, JPA, and ClusterJ (see Chapter 4, MySQL NDB Cluster Connector for Java).

MySQL NDB Cluster 8.0 (and later) also provides support for applications written using Node.js. See Chapter 5, MySQL NoSQL Connector for JavaScript, for more information.

This Guide includes concepts, terminology, class and function references, practical examples, common problems, and tips for using these APIs in applications.

For information about NDB internals that may be of interest to developers working with NDB, see MySQL NDB Cluster Internals Manual.

The information presented in this guide is current for recent releases of MySQL NDB Cluster 8.0 up to and including NDB Cluster 8.0.35, as well as the NDB Cluster 8.2 (8.2.0) Innovation release. Due to significant functional and other changes in NDB Cluster and its underlying APIs, you should not expect this information to apply to versions of the NDB Cluster software prior to NDB Cluster 7.5. Users of older NDB Cluster releases should upgrade to the latest available release of NDB Cluster 8.0, which is the most recent GA release series, or to the NDB Cluster 8.2 Innovation release.

For more information about NDB Cluster 8.0, see What is New in MySQL NDB Cluster 8.0. For information about NDB Cluster 8.2, see What is New in MySQL NDB Cluster 8.2.

For legal information, see the Legal Notices.

For help with using MySQL, please visit the MySQL Forums, where you can discuss your issues with other MySQL users.

Licensing information—NDB APIs. If you are using the NDB APIs with a Commercial release of MySQL NDB Cluster, see the MySQL NDB Cluster 8.0 Commercial Release License Information User Manual for licensing information, including licensing information relating to third-party software that may be included in this Commercial release. If you are using the NDB APIs with a Community release of MySQL NDB Cluster, see the MySQL NDB Cluster 8.0 Community Release License Information User Manual for licensing information, including licensing information relating to third-party software that may be included in this Community release.

Index .................................................................................................................................. 761
This is the MySQL NDB Cluster API Developer Guide, which provides information about developing applications using MySQL NDB Cluster as a data store. Application interfaces covered in this Guide include the low-level C++-language NDB API (see Chapter 2, The NDB API), the C-language MGM API for communicating with and controlling NDB Cluster management servers (see Chapter 3, The MGM API), and the MySQL NDB Cluster Connector for Java, which is a collection of Java APIs for writing applications against NDB Cluster, including JDBC, JPA, and ClusterJ (see Chapter 4, MySQL NDB Cluster Connector for Java).

MySQL NDB Cluster 8.0 also provides support for applications written using Node.js. See Chapter 5, MySQL NoSQL Connector for JavaScript, for more information.

This Guide includes concepts, terminology, class and function references, practical examples, common problems, and tips for using these APIs in applications.

For information about NDB internals that may be of interest to developers working with NDB, see MySQL NDB Cluster Internals Manual.

The information presented in this guide is current for recent releases of MySQL NDB Cluster 8.0 up to and including NDB Cluster 8.0.35, as well as the NDB Cluster 8.3 (8.3.0) Innovation release. Due to significant functional and other changes in NDB Cluster and its underlying APIs, you should not expect this information to apply to versions of the NDB Cluster software prior to NDB Cluster 7.5. Users of older NDB Cluster releases should upgrade to the latest available release of NDB Cluster 8.0, which is the most recent GA release series, or to the NDB Cluster 8.3 Innovation release.

For legal information, see the Legal Notices.

**Licensing information—MySQL NDB Cluster 8.0.** This product may include third-party software, used under license. If you are using a Commercial release of MySQL NDB Cluster 8.0, see the MySQL NDB Cluster 8.0 Commercial Release License Information User Manual for licensing information, including licensing information relating to third-party software that may be included in this Commercial release. If you are using a Community release of MySQL NDB Cluster 8.0, see the MySQL NDB Cluster 8.0 Community Release License Information User Manual for licensing information, including licensing information relating to third-party software that may be included in this Community release.

**Licensing information—MySQL NDB Cluster 8.3.** This product may include third-party software, used under license. If you are using a Commercial release of MySQL NDB Cluster 8.3, see the MySQL NDB Cluster 8.3 Commercial Release License Information User Manual for licensing information, including licensing information relating to third-party software that may be included in this Commercial release. If you are using a Community release of MySQL NDB Cluster 8.3, see the MySQL NDB Cluster 8.3 Community Release License Information User Manual for licensing information, including licensing information relating to third-party software that may be included in this Community release.

free. If you find any errors, please report them to us in writing.

Restricted Rights Notice

If this is software, software documentation, data (as defined in the Federal Acquisition Regulation), or
related documentation that is delivered to the U.S. Government or anyone licensing it on behalf of the
U.S. Government, then the following notice is applicable:

U.S. GOVERNMENT END USERS: Oracle programs (including any operating system, integrated
software, any programs embedded, installed, or activated on delivered hardware, and modifications
of such programs) and Oracle computer documentation or other Oracle data delivered to or accessed
by U.S. Government end users are "commercial computer software," "commercial computer software
documentation," or "limited rights data" pursuant to the applicable Federal Acquisition Regulation and
agency-specific supplemental regulations. As such, the use, reproduction, duplication, release, display,
disclosure, modification, preparation of derivative works, and/or adaptation of i) Oracle programs
(including any operating system, integrated software, any programs embedded, installed, or activated
on delivered hardware, and modifications of such programs), ii) Oracle computer documentation and/
or iii) other Oracle data, is subject to the rights and limitations specified in the license contained in
the applicable contract. The terms governing the U.S. Government's use of Oracle cloud services
are defined by the applicable contract for such services. No other rights are granted to the U.S.
Government.

Hazardous Applications Notice

This software or hardware is developed for general use in a variety of information management
applications. It is not developed or intended for use in any inherently dangerous applications, including
applications that may create a risk of personal injury. If you use this software or hardware in dangerous
applications, then you shall be responsible to take all appropriate fail-safe, backup, redundancy, and
other measures to ensure its safe use. Oracle Corporation and its affiliates disclaim any liability for any
damages caused by use of this software or hardware in dangerous applications.

Trademark Notice

1.5 Application-level partitioning ........................................................................... 15
1.6 Using NdbInterpretedCode .............................................................................. 15

This chapter provides a general overview of essential NDB Cluster, NDB API, and MGM API concepts, terminology, and programming constructs.

For an overview of Java APIs that can be used with NDB Cluster, see Section 4.1, “MySQL NDB Cluster Connector for Java: Overview”.

For information about writing JavaScript applications using Node.js with MySQL, see Chapter 5, MySQL NoSQL Connector for JavaScript.

1.1 NDB Cluster API Overview: Introduction

This section introduces the NDB Transaction and Scanning APIs as well as the NDB Management (MGM) API for use in building applications to run on NDB Cluster. It also discusses the general theory and principles involved in developing such applications.

1.1.1 NDB Cluster API Overview: The NDB API

The NDB API is an object-oriented application programming interface for NDB Cluster that implements indexes, scans, transactions, and event handling. NDB transactions are ACID-compliant in that they provide a means to group operations in such a way that they succeed (commit) or fail as a unit (rollback). It is also possible to perform operations in a “no-commit” or deferred mode, to be committed at a later time.

NDB scans are conceptually rather similar to the SQL cursors implemented in MySQL and other common enterprise-level database management systems. These provide high-speed row processing for record retrieval purposes. (NDB Cluster naturally supports set processing just as does MySQL in its non-Cluster distributions. This can be accomplished through the usual MySQL APIs discussed in the MySQL Manual and elsewhere.) The NDB API supports both table scans and row scans; the latter can be performed using either unique or ordered indexes. Event detection and handling is discussed in Section 2.3.16, “The NdbEventOperation Class”, as well as Section 2.5.9, “NDB API Event Handling Example”.

In addition, the NDB API provides object-oriented error-handling facilities in order to provide a means of recovering gracefully from failed operations and other problems. (See Section 2.5.4, “NDB API Example: Handling Errors and Retrying Transactions”, for a detailed example.)

The NDB API provides a number of classes implementing the functionality described above. The most important of these include the Ndb, Ndb_cluster_connection, NdbTransaction, and NdbOperation classes. These model (respectively) database connections, cluster connections,
transactions, and operations. These classes and their subclasses are listed in Section 2.3, “NDB API Classes, Interfaces, and Structures”. Error conditions in the NDB API are handled using NdbError.

Note

NDB API applications access the NDB Cluster’s data store directly, without requiring a MySQL Server as an intermediary. This means that such applications are not bound by the MySQL privilege system; any NDB API application has read and write access to any NDB table stored in the same NDB Cluster at any time without restriction.

1.1.2 NDB Cluster API Overview: The MGM API

The NDB Cluster Management API, also known as the MGM API, is a C-language programming interface intended to provide administrative services for the cluster. These include starting and stopping NDB Cluster nodes, handling NDB Cluster logging, backups, and restoration from backups, as well as various other management tasks. A conceptual overview of the MGM API and its uses can be found in Chapter 3, The MGM API.

The MGM API’s principal structures model the states of individual modes (ndb_mgm_node_state), the state of the NDB Cluster as a whole (ndb_mgm_cluster_state), and management server response messages (ndb_mgm_reply). See Section 3.4, “MGM API Data Structures”, for detailed descriptions of these.

1.2 NDB Cluster API Overview: Version Compatibility

The NDB API is now fairly mature, and has undergone few major changes in recent releases. Where they have occurred, such changes are indicated in the documentation of the affected objects and methods.

The API version of an NDB API application is determined by the version of libndbclient the application uses to provide NDB API functionality. Because it is necessary to support rolling upgrades, we perform basic testing across a number of versions (7.5 through 8.2) with regard to both older API versions connecting to data nodes of newer versions, and newer API versions connecting to data nodes of older versions. We no longer perform such testing with releases prior to NDB 7.5, since these are no longer maintained or supported in production.

In addition, in NDB 8.0, some compatibility has been dropped with API versions prior to 7.5, but is retained with versions 7.5 and 7.6.

When new a new feature is added to NDB, this is generally done in such a way that the new functionality includes checking that the data nodes which are currently connected are running versions which support the feature. This is done to guard against accidental use of the new feature during a rolling upgrade before the cluster is fully upgraded to the version adding support for it.

In the event that an application employing a newer version of the NDB API is run against an older cluster which does not support a newer feature used by the application, the application raises error code 4003 Function not implemented yet when trying to make use of the feature. Other errors are possible depending on the new functionality involved (see Section 2.4.2, “NDB Error Codes: by Type”).

When an application using an older version of libndbclient connects to a cluster running a newer version of NDB, the data nodes should support older API calls, but there other considerations as well. In particular, if the schema on the cluster makes use of newer features not supported by the older API version does not support, it is possible that operations may be less than optimal or give rise to errors. Some examples are listed here:

- There are tables in the cluster using the JSON data type, which is unknown to NDB prior to version 7.5
The cluster uses one or more fully replicated tables, which are not supported in NDB prior to version 7.5.

The cluster includes tables using generated columns, which are unsupported in NDB prior to version 7.5.

When upgrading a cluster online (that is, by using a rolling restart), existing table schemas are preserved, thus avoiding activation of new schema features too early. This is not the case when the upgrade recreates the schema and restores all data, when the new version may by default use new schema features. For this reason, it is best practice to test with specific schemas, operations, and versions prior upgrading a production system to catch any problems that may arise when connecting an older application or SQL node to a cluster running a newer version of NDB.

For information about general requirements for compiling NDB API and MGM API applications, see Section 2.1.1.1, “General Requirements”.

1.3 NDB Cluster API Overview: Terminology

This section provides a glossary of terms which are unique to the NDB and MGM APIs, or that have a specialized meaning when applied in the context of either or both of these APIs.

The terms in the following list are useful to an understanding of NDB Cluster, the NDB API, or have a specialized meaning when used in one of these:

- **Backup.** A complete copy of all NDB Cluster data, transactions and logs, saved to disk.
- **Restore.** Return the cluster to a previous state, as stored in a backup.
- **Checkpoint.** Generally speaking, when data is saved to disk, it is said that a checkpoint has been reached. When working with the NDB storage engine, there are two sorts of checkpoints which work together in order to ensure that a consistent view of the cluster's data is maintained. These two types, local checkpoints and global checkpoints, are described in the next few paragraphs:

  - **Local checkpoint (LCP).** This is a checkpoint that is specific to a single node; however, LCPs take place for all nodes in the cluster more or less concurrently. An LCP involves saving all of a node's data to disk, and so usually occurs every few minutes, depending upon the amount of data stored by the node.

  More detailed information about LCPs and their behavior can be found in the MySQL Manual; see in particular Defining NDB Cluster Data Nodes.

  - **Global checkpoint (GCP).** A GCP occurs every few seconds, when transactions for all nodes are synchronized and the REDO log is flushed to disk.

  A related term is GCI, which stands for “Global Checkpoint ID”. This marks the point in the REDO log where a GCP took place.

- **Node.** A component of NDB Cluster. 3 node types are supported:

  - A management (MGM) node is an instance of ndb_mgmd, the NDB Cluster management server daemon.

  - A data node an instance of ndbd, the NDB Cluster data storage daemon, and stores NDB Cluster data. This may also be an instance of ndbmt_d, a multithreaded version of ndbd.

  - An API node is an application that accesses NDB Cluster data. SQL node refers to a mysqld (MySQL Server) process that is connected to the NDB Cluster as an API node.

For more information about these node types, please refer to Section 1.4.3, “Review of NDB Cluster Concepts”, or to NDB Cluster Programs, in the MySQL Manual.
Node failure. An NDB Cluster is not solely dependent upon the functioning of any single node making up the cluster, which can continue to run even when one node fails.

Node restart. The process of restarting an NDB Cluster node which has stopped on its own or been stopped deliberately. This can be done for several different reasons, listed here:

- Restarting a node which has shut down on its own. (This is known as forced shutdown or node failure; the other cases discussed here involve manually shutting down the node and restarting it).
- To update the node's configuration.
- As part of a software or hardware upgrade.
- In order to defragment the node's DataMemory.

Initial node restart. The process of starting an NDB Cluster node with its file system having been removed. This is sometimes used in the course of software upgrades and in other special circumstances.

System crash (system failure). This can occur when so many data nodes have failed that the NDB Cluster's state can no longer be guaranteed.

System restart. The process of restarting an NDB Cluster and reinitializing its state from disk logs and checkpoints. This is required after any shutdown of the cluster, planned or unplanned.

Fragment. Contains a portion of a database table. In the NDB storage engine, a table is broken up into and stored as a number of subsets, usually referred to as fragments. A fragment is sometimes also called a partition.

Fragment replica. Under the NDB storage engine, each table fragment has number of fragment replications in order to provide redundancy.

Transporter. A protocol providing data transfer across a network. The NDB API supports three different types of transporter connections: TCP/IP (local), TCP/IP (remote), and SHM. TCP/IP is, of course, the familiar network protocol that underlies HTTP, FTP, and so forth, on the Internet. SHM stands for Unix-style shared memory segments.

NDB. This originally stood for “Network DataBase”. It now refers to the MySQL storage engine (named NDB or NDBCLUSTER) used to enable the NDB Cluster distributed database system.

ACC (Access Manager). An NDB kernel block that handles hash indexes of primary keys providing speedy access to the records. For more information, see The DBACC Block.

TUP (Tuple Manager). This NDB kernel block handles storage of tuples (records) and contains the filtering engine used to filter out records and attributes when performing reads or updates. See The DBTUP Block, for more information.

TC (Transaction Coordinator). Handles coordination of transactions and timeouts in the NDB kernel (see The DBTC Block). Provides interfaces to the NDB API for performing indexes and scan operations.

For more information, see NDB Kernel Blocks, elsewhere in this Guide.

See also NDB Cluster Overview, in the MySQL Manual.

1.4 The NDB Transaction and Scanning API

This section discusses the high-level architecture of the NDB API, and introduces the NDB classes which are of greatest use and interest to the developer. It also covers most important NDB API concepts, including a review of NDB Cluster Concepts.
1.4.1 Core NDB API Classes

The NDB API is an NDB Cluster application interface that implements transactions. It consists of the following fundamental classes:

- `Ndb_cluster_connection` represents a connection to a cluster.
- `Ndb` is the main class, and represents a connection to a database.
- `NdbDictionary` provides meta-information about tables and attributes.
- `NdbTransaction` represents a transaction.
- `NdbOperation` represents an operation using a primary key.
- `NdbScanOperation` represents an operation performing a full table scan.
- `NdbIndexOperation` represents an operation using a unique hash index.
- `NdbIndexScanOperation` represents an operation performing a scan using an ordered index.
- `NdbRecAttr` represents an attribute value.

In addition, the NDB API defines an `NdbError` structure, which contains the specification for an error.

It is also possible to receive events triggered when data in the database is changed. This is accomplished through the `NdbEventOperation` class.

The `NDB` event notification API is not supported prior to MySQL 5.1.

For more information about these classes as well as some additional auxiliary classes not listed here, see Section 2.3, “NDB API Classes, Interfaces, and Structures”.

1.4.2 Application Program Basics

The main structure of an application program is as follows:

1. Connect to a cluster using the `Ndb_cluster_connection` object.
2. Initiate a database connection by constructing and initialising one or more `Ndb` objects.
3. Identify the tables, columns, and indexes on which you wish to operate, using `NdbDictionary` and one or more of its subclasses.
4. Define and execute transactions using the `NdbTransaction` class.
5. Delete `Ndb` objects.
6. Terminate the connection to the cluster (terminate an instance of `Ndb_cluster_connection`).

1.4.2.1 Using Transactions

The procedure for using transactions is as follows:

1. Start a transaction (instantiate an `NdbTransaction` object).
2. Add and define operations associated with the transaction using instances of one or more of the `NdbOperation`, `NdbScanOperation`, `NdbIndexOperation`, and `NdbIndexScanOperation` classes.
3. Execute the transaction (call `NdbTransaction::execute()`).
The operation can be of two different types—Commit or NoCommit:

- If the operation is of type NoCommit, then the application program requests that the operation portion of a transaction be executed, but without actually committing the transaction. Following the execution of a NoCommit operation, the program can continue to define additional transaction operations for later execution.

  NoCommit operations can also be rolled back by the application.

- If the operation is of type Commit, then the transaction is immediately committed. The transaction must be closed after it has been committed (even if the commit fails), and no further operations can be added to or defined for this transaction.

See NdbTransaction::ExecType.

1.4.2.2 Synchronous Transactions

Synchronous transactions are defined and executed as follows:

1. Begin (create) the transaction, which is referenced by an NdbTransaction object typically created using Ndb::startTransaction(). At this point, the transaction is merely being defined; it is not yet sent to the NDB kernel.

2. Define operations and add them to the transaction, using one or more of the following, along with the appropriate methods of the respective NdbOperation class (or possibly one or more of its subclasses):

   - NdbTransaction::getNdbOperation()
   - NdbTransaction::getNdbScanOperation()
   - NdbTransaction::getNdbIndexOperation()
   - NdbTransaction::getNdbIndexScanOperation()

   At this point, the transaction has still not yet been sent to the NDB kernel.

3. Execute the transaction, using the NdbTransaction::execute() method.

4. Close the transaction by calling Ndb::closeTransaction().

For an example of this process, see Section 2.5.2, “NDB API Example Using Synchronous Transactions”.

To execute several synchronous transactions in parallel, you can either use multiple Ndb objects in several threads, or start multiple application programs.

1.4.2.3 Operations

An NdbTransaction consists of a list of operations, each of which is represented by an instance of NdbOperation, NdbScanOperation, NdbIndexOperation, or NdbIndexScanOperation (that is, of NdbOperation or one of its child classes).

See NDB Access Types, for general information about NDB Cluster access operation types.

NDB Access Types

The data node process has a number of simple constructs which are used to access the data in an NDB Cluster. We have created a very simple benchmark to check the performance of each of these.

There are four access methods:
• **Primary key access.** This is access of a record through its primary key. In the simplest case, only one record is accessed at a time, which means that the full cost of setting up a number of TCP/IP messages and a number of costs for context switching are borne by this single request. In the case where multiple primary key accesses are sent in one batch, those accesses share the cost of setting up the necessary TCP/IP messages and context switches. If the TCP/IP messages are for different destinations, additional TCP/IP messages need to be set up.

• **Unique key access.** Unique key accesses are similar to primary key accesses, except that a unique key access is executed as a read on an index table followed by a primary key access on the table. However, only one request is sent from the MySQL Server, and the read of the index table is handled by the data node. Such requests also benefit from batching.

• **Full table scan.** When no indexes exist for a lookup on a table, a full table scan is performed. This is sent as a single request to the ndbd process, which then divides the table scan into a set of parallel scans on all NDB data node processes.

• **Range scan using ordered index.** When an ordered index is used, it performs a scan in the same manner as the full table scan, except that it scans only those records which are in the range used by the query transmitted by the MySQL server (SQL node). All partitions are scanned in parallel when all bound index attributes include all attributes in the partitioning key.

**Single-row operations**

After the operation is created using NdbTransaction::getNdbOperation() or NdbTransaction::getNdbIndexOperation(), it is defined in the following three steps:

1. Specify the standard operation type using `NdbOperation::readTuple()`.
2. Specify search conditions using `NdbOperation::equal()`.
3. Specify attribute actions using `NdbOperation::getValue()`.

Here are two brief examples illustrating this process. For the sake of brevity, we omit error handling.

This first example uses an `NdbOperation`:

```cpp
// 1. Retrieve table object
myTable= myDict->getTable("MYTABLENAME");

// 2. Create an NdbOperation on this table
myOperation= myTransaction->getNdbOperation(myTable);

// 3. Define the operation's type and lock mode
myOperation->readTuple(NdbOperation::LM_Read);

// 4. Specify search conditions
myOperation->equal("ATTR1", i);

// 5. Perform attribute retrieval
myRecAttr= myOperation->getValue("ATTR2", NULL);
```

For additional examples of this sort, see Section 2.5.2, “NDB API Example Using Synchronous Transactions”.

The second example uses an `NdbIndexOperation`:

```cpp
// 1. Retrieve index object
myIndex= myDict->getIndex("MYINDEX", "MYTABLENAME");

// 2. Create
myOperation= myTransaction->getNdbIndexOperation(myIndex);

// 3. Define type of operation and lock mode
myOperation->readTuple(NdbOperation::LM_Read);
```
Another example of this second type can be found in Section 2.5.6, “NDB API Example: Using Secondary Indexes in Scans”.

We now discuss in somewhat greater detail each step involved in the creation and use of synchronous transactions.

1. **Define single row operation type.** The following operation types are supported:
   - `NdbOperation::insertTuple()` inserts a nonexisting tuple.
   - `NdbOperation::writeTuple()` updates a tuple if one exists, otherwise inserts a new tuple.
   - `NdbOperation::updateTuple()` updates an existing tuple.
   - `NdbOperation::deleteTuple()` deletes an existing tuple.
   - `NdbOperation::readTuple()` reads an existing tuple using the specified lock mode.

   All of these operations operate on the unique tuple key. When `NdbIndexOperation` is used, then each of these operations operates on a defined unique hash index.

   **Note**
   If you want to define multiple operations within the same transaction, then you need to call `NdbTransaction::getNdbOperation()` or `NdbTransaction::getNdbIndexOperation()` for each operation.

2. **Specify Search Conditions.** The search condition is used to select tuples. Search conditions are set using `NdbOperation::equal()`.

3. **Specify Attribute Actions.** Next, it is necessary to determine which attributes should be read or updated. It is important to remember that:
   - Deletes can neither read nor set values, but only delete them.
   - Reads can only read values.
   - Updates can only set values. Normally the attribute is identified by name, but it is also possible to use the attribute’s identity to determine the attribute.

   `NdbOperation::getValue()` returns an `NdbRecAttr` object containing the value as read. To obtain the actual value, one of two methods can be used; the application can either
   - Use its own memory (passed through a pointer `aValue`) to `NdbOperation::getValue()`, or
   - receive the attribute value in an `NdbRecAttr` object allocated by the NDB API.

   The `NdbRecAttr` object is released when `Ndb::closeTransaction()` is called. For this reason, the application cannot reference this object following any subsequent call to `Ndb::closeTransaction()`. Attempting to read data from an `NdbRecAttr` object before calling `NdbTransaction::execute()` yields an undefined result.

**Scan Operations**

Scans are roughly the equivalent of SQL cursors, providing a means to perform high-speed row processing. A scan can be performed on either a table (using an `NdbScanOperation`) or an ordered index (by means of an `NdbIndexScanOperation`).
Scan operations have the following characteristics:

- They can perform read operations which may be shared, exclusive, or dirty.
- They can potentially work with multiple rows.
- They can be used to update or delete multiple rows.
- They can operate on several nodes in parallel.

After the operation is created using `NdbTransaction::getNdbScanOperation()` or `NdbTransaction::getNdbIndexScanOperation()`, it is carried out as follows:

1. Define the standard operation type, using `NdbScanOperation::readTuples()`.

   **Note**

   See `NdbScanOperation::readTuples()`, for additional information about deadlocks which may occur when performing simultaneous, identical scans with exclusive locks.

2. Specify search conditions, using `NdbScanFilter`, `NdbIndexScanOperation::setBound()`, or both.

3. Specify attribute actions using `NdbOperation::getValue()`.

4. Execute the transaction using `NdbTransaction::execute()`.

5. Traverse the result set by means of successive calls to `NdbScanOperation::nextResult()`.

Here are two brief examples illustrating this process. Once again, in order to keep things relatively short and simple, we forego any error handling.

This first example performs a table scan using an `NdbScanOperation`:

```c++
// 1. Retrieve a table object
myTable= myDict->getTable("MYTABLENAME");

// 2. Create a scan operation (NdbScanOperation) on this table
myOperation= myTransaction->getNdbScanOperation(myTable);

// 3. Define the operation's type and lock mode
myOperation->readTuples(NdbOperation::LM_Read);

// 4. Specify search conditions
NdbScanFilter sf(myOperation);
sf.begin(NdbScanFilter::OR);
sf.eq(0, i);  // Return rows with column 0 equal to i or
sf.eq(1, i+1); // column 1 equal to (i+1)
sf.end();

// 5. Retrieve attributes
myRecAttr= myOperation->getValue("ATTR2", NULL);
```

The second example uses an `NdbIndexScanOperation` to perform an index scan:

```c++
// 1. Retrieve index object
myIndex= myDict->getIndex("MYORDEREDINDEX", "MYTABLENAME");

// 2. Create an operation (NdbIndexScanOperation object)
myOperation= myTransaction->getNdbIndexScanOperation(myIndex);

// 3. Define type of operation and lock mode
myOperation->readTuples(NdbOperation::LM_Read);

// 4. Specify search conditions
```
myOperation->setBound("ATTR1", NdbIndexScanOperation::BoundGE, i);
myOperation->setBound("ATTR1", NdbIndexScanOperation::BoundLE, i+1);

Some additional discussion of each step required to perform a scan follows:

1. **Define Scan Operation Type.** It is important to remember that only a single operation is supported for each scan operation (\texttt{NdbScanOperation::readTuples()}) or \texttt{NdbIndexScanOperation::readTuples()}).

   \begin{itemize}
     \item \textbf{Note}\hfill
     \begin{itemize}
       \item If you want to define multiple scan operations within the same transaction, then you need to call \texttt{NdbTransaction::getNdbScanOperation()} or \texttt{NdbTransaction::getNdbIndexScanOperation()} separately for each operation.
     \end{itemize}
   \end{itemize}

2. **Specify Search Conditions.** The search condition is used to select tuples. If no search condition is specified, the scan will return all rows in the table. The search condition can be an \texttt{NdbScanFilter} (which can be used on both \texttt{NdbScanOperation} and \texttt{NdbIndexScanOperation}) or bounds (which can be used only on index scans - see \texttt{NdbIndexScanOperation::setBound()}). An index scan can use both \texttt{NdbScanFilter} and bounds.

   \begin{itemize}
     \item \textbf{Note}\hfill
     \begin{itemize}
       \item When \texttt{NdbScanFilter} is used, each row is examined, whether or not it is actually returned. However, when using bounds, only rows within the bounds will be examined.
     \end{itemize}
   \end{itemize}

3. **Specify Attribute Actions.** Next, it is necessary to define which attributes should be read. As with transaction attributes, scan attributes are defined by name, but it is also possible to use the attributes' identities to define attributes as well. As discussed elsewhere in this document (see Section 1.4.2.2, "Synchronous Transactions"), the value read is returned by the \texttt{NdbOperation::getValue()} method as an \texttt{NdbRecAttr} object.

### Using Scans to Update or Delete Rows

Scanning can also be used to update or delete rows. This is performed as follows:

1. Scanning with exclusive locks using \texttt{NdbOperation::LM_Exclusive}.

2. (\textit{When iterating through the result set}) For each row, optionally calling either \texttt{NdbScanOperation::updateCurrentTuple()} or \texttt{NdbScanOperation::deleteCurrentTuple()}. 

3. (\textit{If performing \texttt{NdbScanOperation::updateCurrentTuple()}}:) Setting new values for records simply by using \texttt{NdbOperation::setValue()}. \texttt{NdbOperation::equal()} should not be called in such cases, as the primary key is retrieved from the scan.

   \begin{itemize}
     \item \textbf{Important}\hfill
     \begin{itemize}
       \item The update or delete is not actually performed until the next call to \texttt{NdbTransaction::execute()} is made, just as with single row operations. \texttt{NdbTransaction::execute()} also must be called before any locks are released; for more information, see \textbf{Lock Handling with Scans}.
     \end{itemize}
   \end{itemize}

### Features Specific to Index Scans.

When performing an index scan, it is possible to scan only a subset of a table using \texttt{NdbIndexScanOperation::setBound()}. In addition, result sets can be...
sorted in either ascending or descending order, using `NdbIndexScanOperation::readTuples()`.
Note that rows are returned unordered by default unless `sorted` is set to `true`.

It is also important to note that, when using `NdbIndexScanOperation::BoundEQ` (see `NdbIndexScanOperation::BoundType`) with a partition key, only fragments containing rows will actually be scanned. Finally, when performing a sorted scan, any value passed as the `NdbIndexScanOperation::readTuples()` method’s `parallel` argument will be ignored and maximum parallelism will be used instead. In other words, all fragments which it is possible to scan are scanned simultaneously and in parallel in such cases.

**Lock Handling with Scans**

Performing scans on either a table or an index has the potential to return a great many records; however, Ndb locks only a predetermined number of rows per fragment at a time. The number of rows locked per fragment is controlled by the batch parameter passed to `NdbScanOperation::readTuples()`.

In order to enable the application to handle how locks are released, `NdbScanOperation::nextResult()` has a Boolean parameter `fetchAllowed`. If `NdbScanOperation::nextResult()` is called with `fetchAllowed` equal to `false`, then no locks may be released as result of the function call. Otherwise the locks for the current batch may be released.

This next example shows a scan delete that handles locks in an efficient manner. For the sake of brevity, we omit error-handling.

```c
int check;

// Outer loop for each batch of rows
while((check = MyScanOperation->nextResult(true)) == 0)
{
    do
    {
        // Inner loop for each row within the batch
        MyScanOperation->deleteCurrentTuple();
    } while((check = MyScanOperation->nextResult(false)) == 0);

    // When there are no more rows in the batch, execute all defined deletes
    MyTransaction->execute(NoCommit);
}
```

For a more complete example of a scan, see Section 2.5.5, “NDB API Basic Scanning Example”.

**Error Handling**

Errors can occur either when operations making up a transaction are being defined, or when the transaction is actually being executed. Catching and handling either sort of error requires testing the value returned by `NdbTransaction::execute()`, and then, if an error is indicated (that is, if this value is equal to `-1`), using the following two methods in order to identify the error’s type and location:

- `NdbTransaction::getNdbErrorOperation()` returns a reference to the operation causing the most recent error.
- `NdbTransaction::getNdbErrorLine()` yields the method number of the erroneous method in the operation, starting with `1`.

This short example illustrates how to detect an error and to use these two methods to identify it:

```c
theTransaction = theNdb->startTransaction();
theOperation = theTransaction->getNdbOperation("TEST_TABLE");
if(theOperation == NULL)
    goto error;
```
theOperation->readTuple(NdbOperation::LM_Read);
theOperation->setValue("ATTR_1", at1);
theOperation->setValue("ATTR_2", at1);  //  Error occurs here
theOperation->setValue("ATTR_3", at1);
theOperation->setValue("ATTR_4", at1);

if(theTransaction->execute(Commit) == -1)
{
    errorLine = theTransaction->getNdbErrorLine();
    errorOperation = theTransaction->getNdbErrorOperation();
}

Here, errorLine is 3, as the error occurred in the third method called on the NdbOperation object (in this case, theOperation). If the result of NdbTransaction::getNdbErrorLine() is 0, then the error occurred when the operations were executed. In this example, errorOperation is a pointer to the object theOperation. The NdbTransaction::getNdbError() method returns an NdbError object providing information about the error.

### Note
Transactions are *not* automatically closed when an error occurs. You must call Ndb::closeTransaction() or NdbTransaction::close() to close the transaction.

See Ndb::closeTransaction(), and NdbTransaction::close().

One recommended way to handle a transaction failure (that is, when an error is reported) is as shown here:

1. Roll back the transaction by calling NdbTransaction::execute() with a special ExecType value for the type parameter.

   See NdbTransaction::execute() and NdbTransaction::ExecType, for more information about how this is done.

2. Close the transaction by calling NdbTransaction::close().

3. If the error was temporary, attempt to restart the transaction.

Several errors can occur when a transaction contains multiple operations which are simultaneously executed. In this case the application must go through all operations and query each of their NdbError objects to find out what really happened.

### Important
Errors can occur even when a commit is reported as successful. In order to handle such situations, the NDB API provides an additional NdbTransaction::commitStatus() method to check the transaction's commit status.

See NdbTransaction::commitStatus().

### 1.4.3 Review of NDB Cluster Concepts

This section covers the NDB Kernel, and discusses NDB Cluster transaction handling and transaction coordinators. It also describes NDB record structures and concurrency issues.

The *NDB Kernel* is the collection of data nodes belonging to an NDB Cluster. The application programmer can for most purposes view the set of all storage nodes as a single entity. Each data node is made up of three main components:

- **TC**: The transaction coordinator.
• **ACC**: The index storage component.
• **TUP**: The data storage component.

When an application executes a transaction, it connects to one transaction coordinator on one data node. Usually, the programmer does not need to specify which TC should be used, but in some cases where performance is important, the programmer can provide “hints” to use a certain TC. (If the node with the desired transaction coordinator is down, then another TC will automatically take its place.)

Each data node has an ACC and a TUP which store the indexes and data portions of the database table fragment. Even though a single TC is responsible for the transaction, several ACCs and TUPs on other data nodes might be involved in that transaction’s execution.

### 1.4.3.1 Selecting a Transaction Coordinator

The default method is to select the transaction coordinator (TC) determined to be the "nearest" data node, using a heuristic for proximity based on the type of transporter connection. In order of nearest to most distant, these are:

1. SHM
2. TCP/IP (localhost)
3. TCP/IP (remote host)

If there are several connections available with the same proximity, one is selected for each transaction in a round-robin fashion. Optionally, you may set the method for TC selection to round-robin mode, where each new set of transactions is placed on the next data node. The pool of connections from which this selection is made consists of all available connections.

As noted in Section 1.4.3, “Review of NDB Cluster Concepts”, the application programmer can provide hints to the NDB API as to which transaction coordinator should be used. This is done by providing a table and a partition key (usually the primary key). If the primary key is the partition key, then the transaction is placed on the node where the primary fragment replica of that record resides. Note that this is only a hint; the system can be reconfigured at any time, in which case the NDB API chooses a transaction coordinator without using the hint. For more information, see Column::getPartitionKey(), and Ndb::startTransaction().

The application programmer can specify the partition key from SQL by using the following construct:

```sql
CREATE TABLE ... ENGINE=NDDB PARTITION BY KEY (attribute_list);
```

For additional information, see Partitioning, and in particular KEY Partitioning, in the MySQL Manual.

### 1.4.3.2 NDB Record Structure

The **NDB** storage engine used by NDB Cluster is a relational database engine storing records in tables as with other relational database systems. Table rows represent records as tuples of relational data. When a new table is created, its attribute schema is specified for the table as a whole, and thus each table row has the same structure. Again, this is typical of relational databases, and **NDB** is no different in this regard.

**Primary Keys.** Each record has from 1 up to 32 attributes which belong to the primary key of the table.

**Transactions.** Transactions are committed first to main memory, and then to disk, after a global checkpoint (GCP) is issued. Since all data are (in most NDB Cluster configurations) synchronously replicated and stored on multiple data nodes, the system can handle processor failures without loss of data. However, in the case of a system-wide failure, all transactions (committed or not) occurring since the most recent GCP are lost.
Concurrent Control.

**NDB** uses *pessimistic concurrency control* based on locking. If a requested lock (implicit and depending on database operation) cannot be attained within a specified time, then a timeout error results.

Concurrent transactions as requested by parallel application programs and thread-based applications can sometimes deadlock when they try to access the same information simultaneously. Thus, applications need to be written in a manner such that timeout errors occurring due to such deadlocks are handled gracefully. This generally means that the transaction encountering a timeout should be rolled back and restarted.

**Hints and Performance.**

Placing the transaction coordinator in close proximity to the actual data used in the transaction can in many cases improve performance significantly. This is particularly true for systems using TCP/IP. For example, a Solaris system using a single 500 MHz processor has a cost model for TCP/IP communication which can be represented by the formula

\[
[30 \text{ microseconds}] + ([100 \text{ nanoseconds}] * [\text{number of bytes}])
\]

This means that if we can ensure that we use “popular” links we increase buffering and thus drastically reduce the costs of communication.

A simple example would be an application that uses many simple updates where a transaction needs to update one record. This record has a 32-bit primary key which also serves as the partitioning key. Then the **keyData** is used as the address of the integer of the primary key and **keyLen** is 4.

### 1.4.4 The Adaptive Send Algorithm

Discusses the mechanics of transaction handling and transmission in NDB Cluster and the NDB API, and the objects used to implement these.

When transactions are sent using `NdbTransaction::execute()`, they are not immediately transferred to the NDB Kernel. Instead, transactions are kept in a special send list (buffer) in the **Ndb** object to which they belong. The adaptive send algorithm decides when transactions should actually be transferred to the NDB kernel.

The NDB API is designed as a multithreaded interface, and so it is often desirable to transfer database operations from more than one thread at a time. The NDB API keeps track of which **Ndb** objects are active in transferring information to the NDB kernel and the expected number of threads to interact with the NDB kernel. Note that a given instance of **Ndb** should be used in at most one thread; different threads should not share the same **Ndb** object.

There are four conditions leading to the transfer of database operations from **Ndb** object buffers to the NDB kernel:

1. The NDB Transporter (TCP/IP or shared memory) decides that a buffer is full and sends it off. The buffer size is implementation-dependent and may change between NDB Cluster releases. When TCP/IP is the transporter, the buffer size is usually around 64 KB. Since each **Ndb** object provides a single buffer per data node, the notion of a “full” buffer is local to each data node.

2. The accumulation of statistical data on transferred information may force sending of buffers to all storage nodes (that is, when all the buffers become full).

3. Every 10 milliseconds, a special transmission thread checks whether or not any send activity has occurred. If not, then the thread will force transmission to all nodes. This means that 20 ms is the maximum amount of time that database operations are kept waiting before being dispatched. A 10-millisecond limit is likely in future releases of NDB Cluster; checks more frequent than this require additional support from the operating system.

4. For methods that are affected by the adaptive send algorithm (such as `NdbTransaction::execute()`), there is a **force** parameter that overrides its default behavior.
in this regard and forces immediate transmission to all nodes. See the individual NDB API class listings for more information.

The conditions listed above are subject to change in future releases of NDB Cluster.

### 1.5 Application-level partitioning

There is no restriction against instantiating multiple `Ndb_cluster_connection` objects representing connections to different management servers in a single application, nor against using these for creating multiple instances of the `Ndb` class. Such `Ndb_cluster_connection` objects (and the `Ndb` instances based on them) are not required even to connect to the same cluster.

For example, it is entirely possible to perform application-level partitioning of data in such a manner that data meeting one set of criteria are “handed off” to one cluster using an `Ndb` object that makes use of an `Ndb_cluster_connection` object representing a connection to that cluster, while data not meeting those criteria (or perhaps a different set of criteria) can be sent to a different cluster through a different instance of `Ndb` that makes use of an `Ndb_cluster_connection` “pointing” to the second cluster.

It is possible to extend this scenario to develop a single application that accesses an arbitrary number of clusters. However, in doing so, the following conditions and requirements must be kept in mind:

- A cluster management server (`ndb_mgmd`) can connect to one and only one cluster without being restarted and reconfigured, as it must read the data telling it which data nodes make up the cluster from a configuration file (`config.ini`).

- An `Ndb_cluster_connection` object “belongs” to a single management server whose host name or IP address is used in instantiating this object (passed as the `connection_string` argument to its constructor); once the object is created, it cannot be used to initiate a connection to a different management server.

  (See `Ndb_cluster_connection Class Constructor`.)

- An `Ndb` object making use of this connection (`Ndb_cluster_connection`) cannot be re-used to connect to a different cluster management server (and thus to a different collection of data nodes making up a cluster). Any given instance of `Ndb` is bound to a specific `Ndb_cluster_connection` when created, and that `Ndb_cluster_connection` is in turn bound to a single and unique management server when it is instantiated.

  (See `Ndb Class Constructor`.)

- The bindings previously described persist for the lifetimes of the `Ndb` and `Ndb_cluster_connection` objects in question.

Therefore, it is imperative in designing and implementing any application that accesses multiple clusters in a single session, that a separate set of `Ndb_cluster_connection` and `Ndb` objects be instantiated for connecting to each cluster management server, and that no confusion arises as to which of these is used to access which NDB Cluster.

It is also important to keep in mind that no direct “sharing” of data or data nodes between different clusters is possible. A data node can belong to one and only one cluster, and any movement of data between clusters must be accomplished on the application level.

For examples demonstrating how connections to two different clusters can be made and used in a single application, see Section 2.5.3, “NDB API Example Using Synchronous Transactions and Multiple Clusters”, and Section 3.6.2, “MGM API Event Handling with Multiple Clusters”.

### 1.6 Using NdbInterpretedCode

The next few sections provide information about performing different types of operations with `NdbInterpretedCode` methods, including resource usage.
NdbInterpretedCode Methods for Loading Values into Registers

The methods described in this section are used to load constant values into NdbInterpretedCode program registers. The space required by each of these methods is shown in the following table:

<table>
<thead>
<tr>
<th>Method</th>
<th>Buffer (words)</th>
<th>Request message (words)</th>
</tr>
</thead>
<tbody>
<tr>
<td>load_const_null()</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>load_const_u16()</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>load_const_u32()</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>load_const_u64()</td>
<td>3</td>
<td>3</td>
</tr>
</tbody>
</table>

NdbInterpretedCode Methods for Copying Values Between Registers and Table Columns

NdbInterpretedCode provides two methods for copying values between a column in the current table row and a program register. The read_attr() method is used to copy a table column value into a program register; write_attr() is used to copy a value from a program register into a table column. Both of these methods require that the table being operated on was specified when creating the NdbInterpretedCode object for which they are called.

The space required by each of these methods is shown in the following table:

<table>
<thead>
<tr>
<th>Method</th>
<th>Buffer (words)</th>
<th>Request message (words)</th>
</tr>
</thead>
<tbody>
<tr>
<td>read_attr()</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>write_attr()</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>
NdbInterpretedCode Register Arithmetic Methods

NdbInterpretedCode provides two methods for performing arithmetic operations on registers. Using `add_reg()`, you can load the sum of two registers into another register; `sub_reg()` lets you load the difference of two registers into another register.

The space required by each of these methods is shown in the following table:

Table 1.3 NdbInterpretedCode methods used to perform arithmetic operations on registers, with required buffer and request message space.

<table>
<thead>
<tr>
<th>Method</th>
<th>Buffer (words)</th>
<th>Request message (words)</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>add_reg()</code></td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td><code>sub_reg()</code></td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

For more information, see NdbInterpretedCode::add_reg(), and NdbInterpretedCode::sub_reg().

NdbInterpretedCode: Labels and Branching

The NdbInterpretedCode class lets you define labels within interpreted programs and provides a number of methods for performing jumps to these labels based on any of the following types of conditions:

- Comparison between two register values
- Comparison between a column value and a given constant
- Whether or not a column value matches a given pattern

To define a label, use the `def_label()` method.

To perform an unconditional jump to a label, use the `branch_label()` method.

To perform a jump to a given label based on a comparison of register values, use one of the `branch_*()` methods (`branch_ge()`, `branch_gt()`, `branch_le()`, `branch_lt()`, `branch_eq()`, `branch_ne()`, `branch_ne_null()`, or `branch_eq_null()`). See Register-Based NdbInterpretedCode Branch Operations.

To perform a jump to a given label based on a comparison of table column values, use one of the `branch_col_*()` methods (`branch_col_ge()`, `branch_col_gt()`, `branch_col_le()`, `branch_col_lt()`, `branch_col_eq()`, `branch_col_ne()`, `branch_col_ne_null()`, or `branch_col_eq_null()`). See Column-Based NdbInterpretedCode Branch Operations.

To perform a jump based on pattern-matching of a table column value, use one of the methods `branch_col_like()` or `branch_col_notlike()`. See Pattern-Based NdbInterpretedCode Branch Operations.

Register-Based NdbInterpretedCode Branch Operations

Most of these are used to branch based on the results of register-to-register comparisons. There are also two methods used to compare a register value with `NULL`. All of these methods require as a parameter a label defined using the `def_label()` method.

These methods can be thought of as performing the following logic:

```c
if(register_value1 condition register_value2)
```
The space required by each of these methods is shown in the following table:

### Table 1.4 Register-based NdbInterpretedCode branch methods, with required buffer and request message space.

<table>
<thead>
<tr>
<th>Method</th>
<th>Buffer (words)</th>
<th>Request message (words)</th>
</tr>
</thead>
<tbody>
<tr>
<td>branch_ge()</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>branch_gt()</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>branch_le()</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>branch_lt()</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>branch_eq()</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>branch_ne()</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>branch_ne_null()</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>branch_eq_null()</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

Column-Based NdbInterpretedCode Branch Operations

The methods described in this section are used to perform branching based on a comparison between a table column value and a given constant value. Each of these methods expects the attribute ID of the column whose value is to be tested rather than a reference to a `Column` object.

These methods, with the exception of `branch_col_eq_null()` and `branch_col_ne_null()`, can be thought of as performing the following logic:

```
if(constant_value condition column_value) goto Label
```

In each case (once again excepting `branch_col_eq_null()` and `branch_col_ne_null()`), the arbitrary constant is the first parameter passed to the method.

The space requirements for each of these methods is shown in the following table, where \( L \) represents the length of the constant value:

### Table 1.5 Column-based NdbInterpretedCode branch methods, with required buffer and request message space.

<table>
<thead>
<tr>
<th>Method</th>
<th>Buffer (words)</th>
<th>Request message (words)</th>
</tr>
</thead>
<tbody>
<tr>
<td>branch_col_eq_null()</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>branch_col_ne_null()</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>branch_col_eq()</td>
<td>2</td>
<td>2 + CEIL(L / 8)</td>
</tr>
<tr>
<td>branch_col_ne()</td>
<td>2</td>
<td>2 + CEIL(L / 8)</td>
</tr>
<tr>
<td>branch_col_lt()</td>
<td>2</td>
<td>2 + CEIL(L / 8)</td>
</tr>
<tr>
<td>branch_col_le()</td>
<td>2</td>
<td>2 + CEIL(L / 8)</td>
</tr>
<tr>
<td>branch_col_gt()</td>
<td>2</td>
<td>2 + CEIL(L / 8)</td>
</tr>
<tr>
<td>branch_col_ge()</td>
<td>2</td>
<td>2 + CEIL(L / 8)</td>
</tr>
</tbody>
</table>

Note

The expression `CEIL(L / 8)` is the number of whole 8-byte words required to hold the constant value to be compared.
Pattern-Based NdbInterpretedCode Branch Operations

The NdbInterpretedCode class provides two methods which can be used to branch based on a comparison between a column containing character data (that is, a CHAR, VARCHAR, BINARY, or VARBINARY column) and a regular expression pattern.

The pattern syntax supported by the regular expression is the same as that supported by the MySQL Server's LIKE and NOT LIKE operators, including the _ and % metacharacters. For more information about these, see String Comparison Functions and Operators.

Note

This is the same regular expression pattern syntax that is supported by NdbScanFilter; see NdbScanFilter::cmp(), for more information.

The table being operated upon must be supplied when the NdbInterpretedCode object is instantiated. The regular expression pattern should be in plain CHAR format, even if the column is actually a VARCHAR (in other words, there should be no leading length bytes).

These functions behave as shown here:

```c
if (column_value [NOT] LIKE pattern)
goto Label;
```

The space requirements for these methods are shown in the following table, where \( L \) represents the length of the constant value:

<table>
<thead>
<tr>
<th>Method</th>
<th>Buffer (words)</th>
<th>Request message (words)</th>
</tr>
</thead>
<tbody>
<tr>
<td>branch_col_like()</td>
<td>2</td>
<td>( 2 + \text{CEIL}(L/8) )</td>
</tr>
<tr>
<td>branch_col_notlike()</td>
<td>2</td>
<td>( 2 + \text{CEIL}(L/8) )</td>
</tr>
</tbody>
</table>

Note

The expression \( \text{CEIL}(L/8) \) is the number of whole 8-byte words required to hold the constant value to be compared.

NdbInterpretedCode Bitwise Comparison Operations

These instructions are used to branch based on the result of a logical AND comparison between a BIT column value and a bitmask pattern.

Use of these methods requires that the table being operated upon was supplied when the NdbInterpretedCode object was constructed. The mask value should be the same size as the bit column being compared. BIT values are passed into and out of the NDB API as 32-bit words with bits set in order from the least significant bit to the most significant bit. The endianness of the platform on which the instructions are executed controls which byte contains the least significant bits. On x86, this is the first byte (byte 0); on SPARC and PPC, it is the last byte.

The buffer length and the request length for each of the methods listed here each requires an amount of space equal to 2 words plus the column width rounded (up) to the nearest whole word:

- branch_col_and_mask_eq_mask()
- branch_col_and_mask_ne_mask()
- branch_col_and_mask_eq_zero()
NdbInterpretedCode Result Handling Methods

The methods described in this section are used to tell the interpreter that processing of the current row is complete, and—in the case of scans—whether or not to include this row in the results of the scan.

The space requirements for these methods are shown in the following table, where $L$ represents the length of the constant value:

Table 1.7 NdbInterpretedCode result handling methods, with required buffer and request message space.

<table>
<thead>
<tr>
<th>Method</th>
<th>Buffer (words)</th>
<th>Request message (words)</th>
</tr>
</thead>
<tbody>
<tr>
<td>interpret_exit_ok()</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>interpret_exit_nok()</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>interpret_exit_last_row()</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

NdbInterpretedCode Convenience Methods

The methods described in this section can be used to insert multiple instructions (using specific registers) into an interpreted program.

Important

In addition to updating the table column, these methods use interpreter registers 6 and 7, replacing any existing contents of register 6 with the original column value and any existing contents of register 7 with the modified column value. The table itself must be previously defined when instantiating the NdbInterpretedCode object for which the method is invoked.

The space requirements for these methods are shown in the following table, where $L$ represents the length of the constant value:

Table 1.8 NdbInterpretedCode convenience methods, with required buffer and request message space.

<table>
<thead>
<tr>
<th>Method</th>
<th>Buffer (words)</th>
<th>Request message (words)</th>
</tr>
</thead>
<tbody>
<tr>
<td>add_val()</td>
<td>4</td>
<td>1; if the supplied value $\geq 2^{16} : 2$; if $\geq 2^{32} : 3$</td>
</tr>
<tr>
<td>sub_val()</td>
<td>4</td>
<td>1; if the supplied value $\geq 2^{16} : 2$; if $\geq 2^{32} : 3$</td>
</tr>
</tbody>
</table>

Using Subroutines with NdbInterpretedCode

NdbInterpretedCode supports subroutines which can be invoked from within interpreted programs, with each subroutine being identified by a unique number. Subroutines can be defined only following all main program instructions.

Important

Numbers used to identify subroutines must be contiguous; however, they do not have to be in any particular order.

• The beginning of a subroutine is indicated by invoking the def_sub() method;
NdbInterpretedCode Utility Methods

- `ret_sub()` terminates the subroutine; all instructions following the call to `def_sub()` belong to the subroutine until it is terminated using this method.

- A subroutine is called using the `call_sub()` method.

Once the subroutine has completed, the program resumes execution with the instruction immediately following the one which invoked the subroutine. Subroutines can also be invoked from other subroutines; currently, the maximum subroutine stack depth is 32.

NdbInterpretedCode Utility Methods

Some additional utility methods supplied by `NdbInterpretedCode` are listed here:

- `copy()`: Copies an existing interpreted program by performing a deep copy on the associated `NdbInterpretedCode` object.

- `finalise()`: Prepares an interpreted program by resolving all branching instructions and subroutine calls.

- `getTable()`: Get a reference to the table for which the `NdbInterpretedCode` object was defined.

- `getNdbError()`: Get the most recent error associated with this `NdbInterpretedCode` object.

- `getWordsUsed()`: Obtain the number of words used from the buffer.

2.1 Getting Started with the NDB API

This section discusses preparations necessary for writing and compiling an NDB API application.

2.1.1 Compiling and Linking NDB API Programs

This section provides information on compiling and linking NDB API applications, including requirements and compiler and linker options.

2.1.1.1 General Requirements

To use the NDB API with MySQL, you must have the libndbclient client library and its associated header files installed alongside the regular MySQL client libraries and headers under install_dir/lib. These are automatically installed when you build MySQL using -DWITH_NDBCLUSTER=ON or use a MySQL binary package that supports the NDB storage engine.

This Guide is targeted for use with MySQL NDB Cluster 7.5 and later.

C and C++ language support. The following table provides information about minimum C and C++ language requirements for compiling MGM API applications, NDB API applications, and the libndbclient library against supported versions of NDB Cluster.

<table>
<thead>
<tr>
<th>NDB Cluster Version</th>
<th>MGM API</th>
<th>NDB API</th>
<th>header files</th>
<th>libndbclient</th>
</tr>
</thead>
<tbody>
<tr>
<td>7.5, 7.6</td>
<td>C99 a</td>
<td>C++98 b</td>
<td>C99 or C++98</td>
<td>C++03 c</td>
</tr>
<tr>
<td>8.0, 8.1 d, 8.2</td>
<td>C++11 e</td>
<td>C++11</td>
<td>C++11</td>
<td>C++03 f</td>
</tr>
<tr>
<td>8.3 and later</td>
<td>C99</td>
<td>C++11</td>
<td>C99 or C++11</td>
<td>C++17 f</td>
</tr>
</tbody>
</table>

a GCC 4.5; Clang (any version)
b GCC 4.8.1; Clang 3.3
c GCC 4.3; Clang (any version)
d NDB Cluster 8.1 was a MySQL NDB Cluster Innovation release which is no longer available; it was superseded by the NDB Cluster 8.2 Innovation release.
e GCC 4.8.1; Clang 3.3
f In these versions, this is the same as the level of C++ language support required to compile the MySQL server.
g GCC 8; Clang 5

For information about building MySQL and NDB Cluster from source, see Installing MySQL from Source. For information about building MySQL applications against the MySQL C API, see Building C API Client Programs.

2.1.1.2 Compiler Options

Header Files. In order to compile source files that use the NDB API, you must ensure that the necessary header files can be found. Header files specific to the NDB and MGM APIs are installed in the following subdirectories of the MySQL include directory, respectively:

- include/mysql/storage/ndb/ndbapi
- include/mysql/storage/ndb/mgapi
Compiling and Linking NDB API Programs

**Compiling and Linking NDB API Programs**

Compiler Flags. The MySQL-specific compiler flags needed can be determined using the `mysql_config` utility that is part of the MySQL installation:

```bash
$> mysql_config --cflags
-1/usr/local/mysql/include/mysql -Wreturn-type -Wtrigraphs -W -Wformat
-Wsign-compare -Wunused -mcput=pentium4 -march=pentium4
```

This sets the include path for the MySQL header files but not for those specific to the NDB API. The `--include` option to `mysql_config` returns the generic include path switch:

```bash
$> mysql_config --include
-1/usr/local/mysql/include/mysql
```

It is necessary to add the subdirectory paths explicitly, so that adding all the needed compile flags to the `CXXFLAGS` shell variable should look something like this:

CFLAGS="$CFLAGS "'mysql_config --cflags"
CFLAGS="$CFLAGS "'mysql_config --include'/storage/ndb
CFLAGS="$CFLAGS "'mysql_config --include'/storage/ndb/ndbapi
CFLAGS="$CFLAGS "'mysql_config --include'/storage/ndb/mgmapi

**Tip**

If you do not intend to use the NDB Cluster management functions, the last line in the previous example can be omitted. However, if you are interested in the management functions only, and do not want or need to access NDB Cluster data except from MySQL, then you can omit the line referencing the `ndbapi` directory.

2.1.1.3 Linker Options

NDB API applications must be linked against both the MySQL and NDB client libraries. The NDB client library also requires some functions from the `mystrings` library, so this must be linked in as well.

The necessary linker flags for the MySQL client library are returned by `mysql_config --libs`. For multithreaded applications you should use the `--libs_r` instead:

```bash
$> mysql_config --libs_r
-L/usr/local/mysql/lib/mysql -lmysqlclient_r -lz -lpthread -lcrypt
-llns -lIm -lpthread -L/usr/lib -lssl -lcrypto
```

It is now necessary only to add `-lndbclient` to `LD_FLAGS`, as shown here:

LDFLAGS="$LDFLAGS "'mysql_config --libs_r"
LDFLAGS="$LDFLAGS "'ldndbclient"

2.1.1.4 Using Autotools

It is often faster and simpler to use GNU autotools than to write your own makefiles. In this section, we provide an `autoconf` macro `WITH_MYSQL` that can be used to add a `--with-mysql` option to a configure file, and that automatically sets the correct compiler and linker flags for given MySQL installation.

All of the examples in this chapter include a common `mysql.m4` file defining `WITH_MYSQL`. A typical complete example consists of the actual source file and the following helper files:

- `acinclude`
- `configure.in`
- `Makefile.m4`

`automake` also requires that you provide `README`, `NEWS`, `AUTHORS`, and `ChangeLog` files; however, these can be left empty.
To create all necessary build files, run the following:

```
aclocal
autoconf
automake -a -c
configure --with-mysql=/mysql/prefix/path
```

Normally, this needs to be done only once, after which `make` will accommodate any file changes.

**Example 1-1: acinclude.m4.**

```
m4_include([../mysql.m4])
```

**Example 1-2: configure.in.**

```
AC_INIT(example, 1.0)
AM_INIT_AUTOMAKE(example, 1.0)
WITH_MYSQL()
AC_OUTPUT(Makefile)
```

**Example 1-3: Makefile.am.**

```
bin_PROGRAMS = example
eample_SOURCES = example.cc
```

**Example 1-4: WITH_MYSQL source for inclusion in acinclude.m4.**

```
dnl
dnl configure.in helper macros
dnl
AC_DEFUN([WITH_MYSQL], [  
  AC_MSG_CHECKING(for mysql_config executable)  
  AC_ARG_WITH(mysql, [  --with-mysql=PATH path to mysql_config binary or mysql prefix dir], [  
    if test -x $withval -a -f $withval  
    then  
      MYSQL_CONFIG=$withval  
    elif test -x $withval/bin/mysql_config -a -f $withval/bin/mysql_config  
    then  
      MYSQL_CONFIG=$withval/bin/mysql_config  
    fi  
  ], [  
    if test "x$MYSQL_CONFIG" = "x"  
    then  
      AC_MSG_RESULT(not found)  
      exit 3  
    else  
      AC_PROG_CC
      AC_PROG_CXX
      # add regular MySQL C flags
      ADDFLAGS="$MYSQL_CONFIG --cflags"  
      # add NDB API specific C flags
      IBASE="$MYSQL_CONFIG --include"
      ADDFLAGS="$ADDFLAGS $IBASE/storage/ndb"
      ADDFLAGS="$ADDFLAGS $IBASE/storage/ndb/ndbapi"
      ADDFLAGS="$ADDFLAGS $IBASE/storage/ndb/mgmapi"
      CFLAGS="$CFLAGS $ADDFLAGS"
      CXXFLAGS="$CXXFLAGS $ADDFLAGS"

```
2.1.2 Connecting to the Cluster

This section covers connecting an NDB API application to an NDB Cluster.

2.1.2.1 Include Files

NDB API applications require one or more of the following include files:

- Applications accessing NDB Cluster data using the NDB API must include the file `NdbApi.hpp`.
- Applications making use of the regular MySQL client API as well as the NDB API must also include `mysql.h` (in addition to `NdbApi.hpp`).
- Applications that use NDB Cluster management functions from the MGM API need the include file `mgmapi.h`.

2.1.2.2 API Initialization and Cleanup

Before using the NDB API, it must first be initialized by calling the `ndb_init()` function.

Once an NDB API application is complete, you can call `ndb_end(0)` to perform any necessary cleanup. Keep in mind that, before you invoke this function, all `Ndb_cluster_connection` objects created in your NDB API application must be cleaned up or destroyed; otherwise, threads created when an `Ndb_cluster_connection` object's `connect()` method is invoked do not exit properly, which causes errors on application termination. When an `Ndb_cluster_connection` is created statically, you must not call `ndb_end()` in the same scope as the connection object. When the connection object is created dynamically, you can destroy it using `delete()` before calling `ndb_end()`.

Each of the functions `ndb_init()` and `ndb_end()` is defined in the file `storage/ndb/include/ndb_init.h`.

Note

It should be possible to use `fork()` in NDB API applications, but you must do so prior to calling `ndb_init()` or `my_init()` to avoid sharing of resources such as files and connections between processes.

2.1.2.3 Establishing the Connection

To establish a connection to the server, you must create an instance of `Ndb_cluster_connection`, whose constructor takes as its argument a cluster connection string. If no connection string is given, `localhost` is assumed.

The cluster connection is not actually initiated until the `Ndb_cluster_connection::connect()` method is called. When invoked without any arguments, the connection attempt is retried indefinitely, once per second, until successful. No reporting is done until the connection has been made.

By default an API node connects to the “nearest” data node. This is usually a data node running on the same machine as the nearest, due to the fact that shared memory transport can be used instead of the slower TCP/IP. This may lead to poor load distribution in some cases, so it is possible to enforce a round-robin node connection scheme by calling the `set_optimized_node_selection()` method with 0 as its argument prior to calling `connect()`.
connect() initiates a connection to an NDB Cluster management node only. To enable connections with data nodes, use wait_until_ready() after calling connect(); wait_until_ready() waits up to a given number of seconds for a connection to a data node to be established.

In the following example, initialization and connection are handled in the two functions example_init() and example_end(), which are included in subsequent examples by means of including the file example_connection.h.

**Example 2-1: Connection example.**

```c
#include <stdio.h>
#include <stdlib.h>
#include <NdbApi.hpp>
#include <mysql.h>
#include <mgmapi.h>

Ndb_cluster_connection* connect_to_cluster();
void disconnect_from_cluster(Ndb_cluster_connection *c);

Ndb_cluster_connection* connect_to_cluster()
{
    Ndb_cluster_connection* c;
    if(ndb_init())
        exit(EXIT_FAILURE);
    c = new Ndb_cluster_connection();
    if(c->connect(4, 5, 1))
    {
        fprintf(stderr, "Unable to connect to cluster within 30 seconds.\n\n");
        exit(EXIT_FAILURE);
    }
    if(c->wait_until_ready(30, 0) < 0)
    {
        fprintf(stderr, "Cluster was not ready within 30 seconds.\n\n");
        exit(EXIT_FAILURE);
    }
    return c;
}

void disconnect_from_cluster(Ndb_cluster_connection *c)
{
    delete c;
    ndb_end(2);
}

int main(int argc, char* argv[])
{
    Ndb_cluster_connection *ndb_connection= connect_to_cluster();
    printf("Connection Established.\n\n");
    disconnect_from_cluster(ndb_connection);
    return EXIT_SUCCESS;
}
```

### 2.1.3 Mapping MySQL Database Object Names and Types to NDB

The next two sections discuss naming and other conventions followed by the NDB API with regard to MySQL database objects, as well as handling of MySQL data types in NDB API applications.

#### 2.1.3.1 MySQL Database Object Names in the NDB API

This section discusses mapping of MySQL database objects to the NDB API.
Databases and Schemas. Databases and schemas are not represented by objects as such in the NDB API. Instead, they are modelled as attributes of Table and Index objects. The value of the database attribute of one of these objects is always the same as the name of the MySQL database to which the table or index belongs. The value of the schema attribute of a Table or Index object is always 'def' (for “default”).

Tables. MySQL table names are directly mapped to NDB table names without modification. Table names starting with 'NDB$' are reserved for internal use, as is the SYSSTAB_0 table in the sys database.

Indexes. There are two different type of NDB indexes:

- *Hash indexes* are unique, but not ordered.
- *B-tree indexes* are ordered, but permit duplicate values.

Names of unique indexes and primary keys are handled as follows:

- For a MySQL UNIQUE index, both a B-tree and a hash index are created. The B-tree index uses the MySQL name for the index; the name for the hash index is generated by appending '$unique' to the index name.
- For a MySQL primary key only a B-tree index is created. This index is given the name PRIMARY. There is no extra hash; however, the uniqueness of the primary key is guaranteed by making the MySQL key the internal primary key of the NDB table.

Column Names and Values. NDB column names are the same as their MySQL names.

2.1.3.2 NDB API Handling of MySQL Data Types

This section provides information about the way in which MySQL data types are represented in NDBCLUSTER table columns and how these values can be accessed in NDB API applications.

Numeric data types. The MySQL TINYINT, SMALLINT, INT, and BIGINT data types map to NDB types having the same names and storage requirements as their MySQL counterparts.

The MySQL FLOAT and DOUBLE data types are mapped to NDB types having the same names and storage requirements.

Data types used for character data. The storage space required for a MySQL CHAR column is determined by the maximum number of characters and the column's character set. For most (but not all) character sets, each character takes one byte of storage. When using utf8, each character requires three bytes; utfmb4 uses up to four bytes per character. You can find the maximum number of bytes needed per character in a given character set by checking the Maxlen column in the output of SHOW CHARACTER SET.

An NDB VARCHAR column value maps to a MySQL VARCHAR, except that the first two bytes of the NDB VARCHAR are reserved for the length of the string. A utility function like that shown here can make a VARCHAR value ready for use in an NDB API application:

```c
void make_ndb_varchar(char *buffer, char *str)
{
    int len = strlen(str);
    int hlen = (len > 255) ? 2 : 1;
    buffer[0] = len & 0xff;
    if( len > 255 )
        buffer[1] = (len / 256);
    strcpy(buffer+hlen, str);
}
```

You can use this function as shown here:

```c
char myVal[128+1]; // Size of myVal (+1 for length)
```
make_ndb_varchar(myVal, "NDB is way cool!!");
myOperation->setValue("myVal", myVal);

See Section 2.5.12, “NDB API Simple Array Example”, for a complete example program that writes and reads VARCHAR and VARBINARY values to and from a table using the NDB API.

MySQL storage requirements for a VARCHAR or VARBINARY column depend on whether the column is stored in memory or on disk:

- For in-memory columns, the NDB storage engine supports variable-width columns with 4-byte alignment. This means that (for example) a the string 'abcde' stored in a VARCHAR(50) column using the latin1 character set requires 12 bytes—in this case, 2 bytes times 5 characters is 10, rounded up to the next even multiple of 4 yields 12.

- For Disk Data columns, VARCHAR and VARBINARY are stored as fixed-width columns. This means that each of these types requires the same amount of storage as a CHAR of the same size.

**Note**

We refer throughout this Guide to a column of any of MySQL's TEXT or BLOB types as a "blob column", and its type as "blob". NDB 7.5 and later also treats MySQL JSON columns as blob columns.

Each row in an NDB Cluster BLOB or TEXT column is made up of two separate parts. One of these is of fixed size (256 bytes), and is actually stored in the original table. The other consists of any data in excess of 256 bytes, which is stored in a hidden blobs table whose rows are always 2000 bytes long. This means that a record of size bytes in a TEXT or BLOB column requires

- 256 bytes, if $size \leq 256$
- $256 + 2000 \times \left( \left\lfloor \frac{size - 256}{2000} \right\rfloor + 1 \right)$ bytes otherwise

**Temporal data types.** Storage of temporal types in the NDB API depends on whether MySQL's "old" types without fractional seconds or "new" types with fractional second support are used. Support for fractional seconds was introduced in MySQL 5.6 as well as the NDB Cluster versions based on it—that is, NDB 7.3 and NDB 7.4. These and later versions of the MySQL Server and NDB Cluster use the new temporal types by default, can read and write data using the old temporal types, but cannot create tables that use the old types. See Fractional Seconds in Time Values, for more information.

Because support for the old temporal types is expected be removed in a future release, you are encouraged to migrate any tables using the old temporal types to the new versions of these types. You can do this by executing a copying ALTER TABLE operation on any table that uses the old temporals, or by backing up and restoring any such tables.

You can see whether a given table uses the old or new temporal types by checking the output of the ndb_desc utility supplied with the NDB Cluster distribution. Consider a table created in a database named test, using the following statement, on a mysqld started without the --create-old-temporals option:

```sql
CREATE TABLE t1 (
  c1 DATETIME,
  c2 DATE,
  c3 TIME,
  c4 TIMESTAMP,
  c5 YEAR) ENGINE=NDB;
```

The relevant portion (the Attributes block) of the output of ndb_desc looks like this:

```sql
$> ndb_desc -d test t1
...-- Attributes --
c1 Datetime2(0) NULL AT=FIXED ST=MEMORY
```
The names of the new MySQL temporal types are suffixed with 2 (for example, `Datetim2e2`) to set them apart from the old versions of these types. Assume that we restart `mysqld` with `--create-old-temporals=ON` and then create a table `t2`, also in the `test` database, using this statement:

```sql
CREATE TABLE t2 (  
  c1 DATETIME,  
  c2 DATE,  
  c3 TIME,  
  c4 TIMESTAMP,  
  c5 YEAR) ENGINE=NDB;
```

The output from executing `ndb_desc` on this table as shown includes the `Attributes` block shown here:

```
$> ndb_desc -d test t2
...
-- Attributes --
c1 Datetime NULL AT=FIXED ST=MEMORY
c2 Date NULL AT=FIXED ST=MEMORY
c3 Time NULL AT=FIXED ST=MEMORY
c4 Timestamp NOT NULL AT=FIXED ST=MEMORY DEFAULT 0
c5 Year NULL AT=FIXED ST=MEMORY
```

The affected MySQL types are `TIME`, `DATETIME`, and `TIMESTAMP`. The “new” versions of these types are reflected in the NDB API as `Time2`, `Datetim2e2`, and `Timestamp2`, respectively, each supporting fractional seconds with up to 6 digits of precision. The new variants use big-endian encoding of integer values which are then processed to determine the components of each temporal type.

For the fractional second part of each of these types, the precision affects the number of bytes needed, as shown in the following table:

### Table 2.2 Precision of NDB API new temporal types

<table>
<thead>
<tr>
<th>Precision</th>
<th>Bytes required</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>—</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>0-9</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>0-99</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
<td>0-999</td>
</tr>
<tr>
<td>4</td>
<td>2</td>
<td>0-9999</td>
</tr>
<tr>
<td>5</td>
<td>3</td>
<td>0-99999</td>
</tr>
<tr>
<td>6</td>
<td>3</td>
<td>0-999999</td>
</tr>
</tbody>
</table>

The fractional part for each of the new temporal types is stored in big-endian format—that is, with the highest order byte at the lowest address—using the necessary number of bytes.

The binary layouts of both the old and new versions of these types are described in the next few paragraphs.

**Time**: The “old” version of this type is stored as a 24-bit signed `int` value stored in little-endian format (lowest order byte in lowest order address). Byte 0 (bits 0-7) corresponds to hours, byte 2 (bits 8-15) to minutes, and byte 2 (bits 16-23) to seconds according to this formula:

```plaintext
value = 10000 * hour
       + 100 * minute
       + second
```

Bit 23 serves as the sign bit; if this bit is set, the time value is considered negative.
**Time2:** This is the “new” *TIME* type, and is stored as a 3-byte big-endian encoded value plus 0 to 3 bytes for the fractional part. The integer part is encoded as shown in the following table:

<table>
<thead>
<tr>
<th>Bits</th>
<th>Meaning</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>23</td>
<td>Sign bit</td>
<td>0-1</td>
</tr>
<tr>
<td>22</td>
<td>Interval</td>
<td>0-1</td>
</tr>
<tr>
<td>22-13</td>
<td>Hour</td>
<td>1-1023</td>
</tr>
<tr>
<td>12-7</td>
<td>Minute</td>
<td>0-63</td>
</tr>
<tr>
<td>6-0</td>
<td>Second</td>
<td>0-63</td>
</tr>
</tbody>
</table>

Any fractional bytes in addition to this are handled as described previously.

**Date:** The representation for the MySQL *DATE* type is unchanged across NDB versions, and uses a 3-byte unsigned integer stored in little-endian order. The encoding is as shown here:

<table>
<thead>
<tr>
<th>Bits</th>
<th>Meaning</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>23-9</td>
<td>Year</td>
<td>0-32767</td>
</tr>
<tr>
<td>8-5</td>
<td>Month</td>
<td>0-15</td>
</tr>
<tr>
<td>4-0</td>
<td>Day</td>
<td>0-31</td>
</tr>
</tbody>
</table>

**Datetime:** The “old” MySQL *DATETIME* type is represented by a 64-bit unsigned value stored in host byte order, encoded using the following formula:

\[
\text{value} = \text{second} + \text{minute} \times 10^2 + \text{hour} \times 10^4 + \text{day} \times 10^6 + \text{month} \times 10^8 + \text{year} \times 10^{10}
\]

**DateTime2:** The “new” *DATETIME* is encoded as a 5-byte big-endian with an optional fractional part of 0 to 3 bytes, the fractional portion being handled as described previously. The high 5 bytes are encoded as shown here:

<table>
<thead>
<tr>
<th>Bits</th>
<th>Meaning</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>23</td>
<td>Sign bit</td>
<td>0-1</td>
</tr>
<tr>
<td>22</td>
<td>Interval</td>
<td>0-1</td>
</tr>
<tr>
<td>22-13</td>
<td>Hour</td>
<td>1-1023</td>
</tr>
<tr>
<td>12-7</td>
<td>Minute</td>
<td>0-63</td>
</tr>
<tr>
<td>6-0</td>
<td>Second</td>
<td>0-63</td>
</tr>
</tbody>
</table>

The *YearMonth* bits are encoded as \( \text{Year} = \text{YearMonth} \div 13 \) and \( \text{Month} = \text{YearMonth} \mod 13 \).

**Timestamp:** The “old” version of this type uses a 32-bit unsigned value representing seconds elapsed since the Unix epoch, stored in host byte order.

**Timestamp2:** This is the “new” version of *TIMESTAMP*, and uses 4 bytes with big-endian encoding for the integer portion (unsigned). The optional 3-byte fractional portion is encoded as explained earlier in this section.

**Additional information.** More information about and examples using data types as expressed in the NDB API can be found in *ndb/src/common/util/NdbSqlUtil.cpp*. In addition, see
Section 2.5.14, “Timestamp2 Example”, which provides an example of a simple NDB API application that makes use of the Timestamp2 data type.

2.2 The NDB API Class Hierarachy

This section provides a hierarchical listing of all classes, interfaces, and structures exposed by the NDB API.

- Ndb
  - Key_part_ptr
  - PartitionSpec
- NdbBlob
- Ndb_cluster_connection
- NdbDictionary
  - AutoGrowSpecification
- Dictionary
  - List
    - Element
  - Column
  - Object
  - Datafile
  - Event
  - ForeignKey
  - HashMap
  - Index
  - LogfileGroup
  - Table
  - Tablespace
  - Undofile
  - RecordSpecification
- NdbError
- NdbEventOperation
- NdbInterpretedCode
- NdbOperation
  - NdbIndexOperation
  - NdbScanOperation
2.3 NDB API Classes, Interfaces, and Structures

This section provides a detailed listing of all classes, interfaces, and structures defined in the NDB API. Each listing includes the following information:

- Description and purpose of the class, interface, or structure.
- Pointers, where applicable, to parent and child classes.
- Detailed listings of all public members, including descriptions of all method parameters and type values.

Class, interface, and structure descriptions are provided in alphabetical order. For a hierarchical listing, see Section 2.2, “The NDB API Class Hierarchy”.

2.3.1 The Column Class

This section provides information about the Column class, which models a column in an NDBCLUSTER table.

- Column Class Overview
- Column::ArrayType
- Column Constructor
- Column::equal()
- Column::getArrayType()
- Column::getAutoIncrement()
- Column::getCharset()
- Column::getColumnNo()
- Column::getDefaultValue()
- Column::getInlineSize()
- Column::getLength()
The Column Class

- Column::getName()
- Column::getNullable()
- Column::getPartitionKey()
- Column::getPartSize()
- Column::getPrecision()
- Column::getPrimaryKey()
- Column::getScale()
- Column::getSize()
- Column::getSizeInBytesForRecord()
- Column::getStorageType()
- Column::getStripeSize()
- Column::getType()
- Column::setArrayType()
- Column::setAutoIncrement()
- Column::setAutoIncrementInitialValue()
- Column::setCharset()
- Column::setDefaultValue()
- Column::setInlineSize
- Column::setLength()
- Column::setName()
- Column::setNullable()
- Column::setPartitionKey()
- Column::setPartSize()
- Column::setPrecision()
- Column::setPrimaryKey()
- Column::setScale()
- Column::setStripeSize()
- Column::setStorageType()
- Column::setType()
- Column::StorageType
- Column::Type

Column Class Overview

<table>
<thead>
<tr>
<th>Parent class</th>
<th>NdbDictionary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Child classes</td>
<td>None</td>
</tr>
</tbody>
</table>
The Column Class

Description
Each instance of Column is characterized by its type, which is determined by a number of type specifiers:

- Built-in type
- Array length or maximum length
- Precision and scale (*currently not in use*)
- Character set (applicable only to columns using string data types)
- Inline and part sizes (applicable only to blob columns)

These types in general correspond to MySQL data types and their variants. The data formats are same as in MySQL. The NDB API provides no support for constructing such formats; however, they are checked by the NDB kernel.

Methods
The following table lists the public methods of this class and the purpose or use of each method:

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Column()</td>
<td>Class constructor; there is also a copy constructor</td>
</tr>
<tr>
<td>~Column()</td>
<td>Class destructor</td>
</tr>
<tr>
<td>equal()</td>
<td>Compares Column objects</td>
</tr>
<tr>
<td>getArrayType()</td>
<td>Gets the column's array type</td>
</tr>
<tr>
<td>getAutoIncrement()</td>
<td>Shows whether the column is auto-incrementing</td>
</tr>
<tr>
<td>getCharset()</td>
<td>Get the character set used by a string (text) column (not applicable to columns not storing character data)</td>
</tr>
<tr>
<td>getColumnNo()</td>
<td>Gets the column number</td>
</tr>
<tr>
<td>getDefaultValue()</td>
<td>Returns the column's default value</td>
</tr>
<tr>
<td>getInlineSize()</td>
<td>Gets the inline size of a blob column (not applicable to other column types)</td>
</tr>
<tr>
<td>getLength()</td>
<td>Gets the column's length</td>
</tr>
<tr>
<td>getName()</td>
<td>Gets the name of the column</td>
</tr>
<tr>
<td>getNullable()</td>
<td>Checks whether the column can be set to NULL</td>
</tr>
<tr>
<td>getPartitionKey()</td>
<td>Checks whether the column is part of the table’s partitioning key</td>
</tr>
<tr>
<td>getPartSize()</td>
<td>Gets the part size of a blob column (not applicable to other column types)</td>
</tr>
<tr>
<td>getPrecision()</td>
<td>Gets the column's precision (used for decimal types only)</td>
</tr>
<tr>
<td>getPrimaryKey()</td>
<td>Check whether the column is part of the table's primary key</td>
</tr>
<tr>
<td>getScale()</td>
<td>Gets the column's scale (used for decimal types only)</td>
</tr>
<tr>
<td>getSize()</td>
<td>Gets the size of an element</td>
</tr>
</tbody>
</table>
## The Column Class

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getSizeInBytesForRecord()</td>
<td>Gets the space required for a column by NdbRecord, according to the column's type (added in NDB 7.4.7)</td>
</tr>
<tr>
<td>getStripeSize()</td>
<td>Gets a BLOB column's stripe size (not applicable to other column types)</td>
</tr>
<tr>
<td>getType()</td>
<td>Gets the column's type (Type value)</td>
</tr>
<tr>
<td>getStorageType()</td>
<td>Gets the storage type used by this column</td>
</tr>
<tr>
<td>setArray()</td>
<td>Sets the column's ArrayType</td>
</tr>
<tr>
<td>setAutoIncrement()</td>
<td>Sets the column's auto-increment flag</td>
</tr>
<tr>
<td>setAutoIncrementInitialValue()</td>
<td>Sets an auto-incrementing column's starting value</td>
</tr>
<tr>
<td>setCharset()</td>
<td>Sets the character set used by a column containing character data (not applicable to nontextual columns)</td>
</tr>
<tr>
<td>setDefaultValue()</td>
<td>Sets the column's default value</td>
</tr>
<tr>
<td>setInlineSize()</td>
<td>Sets the inline size for a blob column (not applicable to columns not of blob types)</td>
</tr>
<tr>
<td>setLength()</td>
<td>Sets the column's length</td>
</tr>
<tr>
<td>setName()</td>
<td>Sets the column's name</td>
</tr>
<tr>
<td>setNullable()</td>
<td>Toggles the column's nullability</td>
</tr>
<tr>
<td>setPartitionKey()</td>
<td>Determines whether the column is part of the table's partitioning key</td>
</tr>
<tr>
<td>setPartSize()</td>
<td>Sets the part size for a blob column (not applicable to columns not of blob types)</td>
</tr>
<tr>
<td>setPrecision()</td>
<td>Sets the column's precision (used for decimal types only)</td>
</tr>
<tr>
<td>setPrimaryKey()</td>
<td>Determines whether the column is part of the primary key</td>
</tr>
<tr>
<td>setScale()</td>
<td>Sets the column's scale (used for decimal types only)</td>
</tr>
<tr>
<td>setStorageType()</td>
<td>Sets the storage type to be used by this column</td>
</tr>
<tr>
<td>setStripeSize()</td>
<td>Sets the stripe size for a blob column (not applicable to columns not of blob types)</td>
</tr>
<tr>
<td>setType()</td>
<td>Sets the column's Type</td>
</tr>
</tbody>
</table>

### Types

These are the public types of the `Column` class:

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ArrayType</td>
<td>Specifies the column's internal storage format</td>
</tr>
<tr>
<td>StorageType</td>
<td>Determines whether the column is stored in memory or on disk</td>
</tr>
<tr>
<td>Type</td>
<td>The column's data type. NDB columns have the same data types as found in MySQL</td>
</tr>
</tbody>
</table>

---

Table 2.7 Column class types and descriptionse.
The Column Class

The assignment (\(=\)) operator is overloaded for this class, so that it always performs a deep copy.

Important
Columns created using this class cannot be seen by the MySQL Server. This means that they cannot be accessed by MySQL clients, and that they cannot be replicated. For these reasons, it is often preferable to avoid working with them.

In the NDB API, column names are handled in case-sensitive fashion. (This differs from the MySQL C API.) To reduce the possibility for error, it is recommended that you name all columns consistently using uppercase or lowercase.

As with other database objects, Column object creation and attribute changes to existing columns done using the NDB API are not visible from MySQL. For example, if you change a column's data type using Column::setType(), MySQL will regard the type of column as being unchanged. The only exception to this rule with regard to columns is that you can change the name of an existing column using Column::setName().

Column::ArrayType

This section provides information about the ArrayType data type, which represents a column's internal attribute format.

**Description**
The attribute storage format can be either fixed or variable.

**Enumeration values**
Possible values are shown, along with descriptions, in the following table:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ArrayTypeFixed</td>
<td>stored as a fixed number of bytes</td>
</tr>
<tr>
<td>ArrayTypeShortVar</td>
<td>stored as a variable number of bytes; uses 1 byte overhead</td>
</tr>
<tr>
<td>ArrayTypeMediumVar</td>
<td>stored as a variable number of bytes; uses 2 bytes overhead</td>
</tr>
</tbody>
</table>

The fixed storage format is faster but also generally requires more space than the variable format. The default is ArrayTypeShortVar for Var* types and ArrayTypeFixed for others. The default is usually sufficient.

Column Constructor

**Description**
You can create a new Column or copy an existing one using the class constructor.

A Column created using the NDB API is not visible to a MySQL server.

The NDB API handles column names in case-sensitive fashion. For example, if you create a column named “myColumn”, you will not be able to access it later using “Mycolumn” for the name. You can reduce the possibility for error, by naming all columns consistently using only uppercase or only lowercase.

**Signature**
You can create either a new instance of the Column class, or by copying an existing Column object. Both of these are shown here:

- Constructor for a new Column:
The Column Class

```cpp
Column
{
    const char* name = ""
}
```

- **Copy constructor:**

```cpp
Column
{
    const Column& column
}
```

**Parameters**
When creating a new instance of `Column`, the constructor takes a single argument, which is the name of the new column to be created. The copy constructor also takes one parameter—in this case, a reference to the `Column` instance to be copied.

**Return value**
A `Column` object.

**Destructor**
The `Column` class destructor takes no arguments and returns nothing (`void`).

### `Column::equal()`

**Description**
This method is used to compare one `Column` with another to determine whether the two `Column` objects are the same.

**Signature**
```cpp
bool equal
(
    const Column& column
) const
```

**Parameters**
`equal()` takes a single parameter, a reference to an instance of `Column`.

**Return value**
`true` if the columns being compared are equal, otherwise `false`.

### `Column::getArrayType()`

**Description**
This method gets the column's array type.

**Signature**
```cpp
ArrayType getArrayType
(
    void
) const
```

**Parameters**
None.

**Return value**
An `ArrayType`; see `Column::ArrayType` for possible values.

### `Column::getAutoIncrement()`

**Description**
This method shows whether the column is an auto-increment column.

**Signature**
```cpp
bool getAutoIncrement
(
    void
) const
```

**Parameters**
None.

**Return value**
`TRUE` if the column is an auto-increment column, `FALSE` if it is not.

### `Column::getCharset()`

**Description**
This gets the character set used by a text column.
The Column Class

This method is applicable only to columns whose `Type` value is `Char`, `Varchar`, or `Text`.

The NDB API handles column names in case-sensitive fashion; “myColumn” and “Mycolumn” are not considered to refer to the same column. It is recommended that you minimize the possibility of errors from using the wrong lettercase for column names by naming all columns consistently using only uppercase or only lowercase.

### Signature

```cpp
CHARSET_INFO* getCharset()
{
    void
} const
```

### Parameters

None.

### Return value

A pointer to a `CHARSET_INFO` structure specifying both character set and collation. This is the same as a MySQL `MY_CHARSET_INFO` data structure; for more information, see `mysql_get_character_set_info()` in the MySQL Manual.

#### Column::getColumnNo()

**Description**

This method gets the sequence number of a column within its containing table or index. If the column is part of an index (such as when returned by `getColumn()`), it is mapped to its position within that index, and not within the table containing the index.

**Signature**

```cpp
int getColumnNo()
{
    void
} const
```

**Parameters**

None.

**Return value**

The column number as an integer.

#### Column::getDefaultValue()

**Description**

Gets a column’s default value data.

To determine whether a table has any columns with default values, use `Table::hasDefaultValues()`.

**Signature**

```cpp
const void* getDefaultValue(unsigned int* len = 0)
```

**Parameters**

`len` holds either the length of the default value data, or 0 in the event that the column is nullable or has no default value.

**Return value**

The default value data.

#### Column::getInlineSize()

**Description**

This method retrieves the inline size of a blob column—that is, the number of initial bytes to store in the table’s blob attribute. This part is normally in main memory and can be indexed.

This method is applicable only to blob columns.

Beginning with NDB 8.0.29, you can also obtain this information in the `mysql` client, by querying the `ndbinfo.blobs` table.
### Column Class

#### getInlineSize()

**Signature**

```cpp
int getInlineSize
(void)
const
```

**Parameters**

*None.*

**Return value**

The blob column’s inline size, as an integer.

#### getLength()

**Description**

This method gets the length of a column. This is either the array length for the column or—for a variable length array—the maximum length.

**Signature**

```cpp
int getLength
(void)
const
```

**Parameters**

*None.*

**Return value**

The (maximum) array length of the column, as an integer.

#### getName()

**Description**

This method returns the name of the column for which it is called.

The NDB API handles column names in case-sensitive fashion. For example, if you retrieve the name “myColumn” for a given column, attempting to access this column using “Mycolumn” for the name fails with an error such as *Column is NULL* or *Table definition has undefined column*. You can reduce the possibility for error, by naming all columns consistently using only uppercase or only lowercase.

**Signature**

```cpp
const char* getName
(void)
const
```

**Parameters**

*None.*

**Return value**

The name of the column.

#### getNullable()

**Description**

This method is used to determine whether the column can be set to NULL.

**Signature**

```cpp
bool getNullable
(void)
const
```

**Parameters**

*None.*

**Return value**

A Boolean value: `true` if the column can be set to NULL, otherwise `false`.

#### getPartitionKey()

**Description**

This method is used to check whether the column is part of the table’s partitioning key.
A partitioning key is a set of attributes used to distribute the tuples onto the data nodes. This key a hashing function specific to the NDB storage engine.

An example where this would be useful is an inventory tracking application involving multiple warehouses and regions, where it might be good to use the warehouse ID and district id as the partition key. This would place all data for a specific district and warehouse in the same storage node. Locally to each fragment the full primary key will still be used with the hashing algorithm in such a case.

For more information about partitioning, partitioning schemes, and partitioning keys in MySQL, see Partitioning, in the MySQL Manual.

The only type of user-defined partitioning that is supported for use with the NDB storage engine is key partitioning, including linear key partitioning.

```csharp
bool getPartitionKey()
{
    void
} const
```

Parameters

None.

Return value

true if the column is part of the partitioning key for the table, otherwise false.

Column::getPartSize()

Description

This method is used to get the blob part size of a BLOB column—that is, the number of bytes that are stored in each tuple of the blob table.

This method is applicable to BLOB columns only.

In NDB 8.0.29 and later, you can also obtain this information in the mysql client or other MySQL client, by querying the ndbinfo.blobs table.

```csharp
int getPartSize()
{
    void
} const
```

Parameters

None.

Return value

The column's part size, as an integer. In the case of a Tinyblob column, this value is 0 (that is, only inline bytes are stored).

Column::getPrecision()

Description

This method gets the precision of a column.

This method is applicable to decimal columns only.

```csharp
int getPrecision()
{
    void
} const
```

Parameters

None.
The Column Class

Return value
The column's precision, as an integer. The precision is defined as the number of significant digits; for more information, see the discussion of the **DECIMAL** data type in **Numeric Data Types**, in the MySQL Manual.

### Column::getPrimaryKey()

**Description**
This method is used to determine whether the column is part of the table's primary key.

**Signature**
```cpp
bool getPrimaryKey
(
    void
) const
```

**Parameters**
*None.*

**Return value**
A Boolean value: **true** if the column is part of the primary key of the table to which this column belongs, otherwise **false**.

### Column::getScale()

**Description**
This method gets the scale used for a decimal column value. This method is applicable to decimal columns only.

**Signature**
```cpp
int getScale
(
    void
) const
```

**Parameters**
*None.*

**Return value**
The decimal column's scale, as an integer. The scale of a decimal column represents the number of digits that can be stored following the decimal point. It is possible for this value to be **0**. For more information, see the discussion of the **DECIMAL** data type in **Numeric Data Types**, in the MySQL Manual.

### Column::getSize()

**Description**
This function is used to obtain the size of a column.

**Signature**
```cpp
int getSize
(
    void
) const
```

**Parameters**
*None.*

**Return value**
The column's size in bytes (an integer value).

### Column::getSizeInBytesForRecord()

**Description**
Gets the space required for a given column by an **NdbRecord**, depending on the column's type, as follows:

- For a BLOB column, this value is the same as `sizeof(NdbRecord*)`, which is 4 or 8 bytes (the size of a pointer; platform-dependent).
- For columns of all other types, it is the same as the value returned by `getSize()`.

This method was added in NDB NDB 7.4.7.
The Column Class

**Signature**

```cpp
int getSizeInBytesForRecord(
void
) const
```

**Parameters**

*None.*

**Return value**

An integer (see Description).

**Column::getStorageType()**

**Description**

This method obtains a column's storage type.

**Signature**

```cpp
StorageType getStorageType(
void
) const
```

**Parameters**

*None.*

**Return value**

A `StorageType` value; for more information about this type, see `Column::StorageType`.

**Column::getStripeSize()**

**Description**

This method gets the stripe size of a blob column—that is, the number of consecutive parts to store in each node group.

**Signature**

```cpp
int getStripeSize(
void
) const
```

**Parameters**

*None.*

**Return value**

The column's stripe size, as an integer.

**Column::getType()**

**Description**

This method gets the column's data type.

**Signature**

```cpp
Type getType(
void
) const
```

**Parameters**

*None.*

**Return value**

The `Type` (data type) of the column. For a list of possible values, see `Column::Type`.

**Column::setArrayType()**

**Description**

Sets the array type for the column.

**Signature**

```cpp
void setArrayType(
ArrayType type
)
```

**Parameters**

A `Column::ArrayType` value. See `Column::ArrayType`, for more information.

**Return value**

*None.*

**Column::setAutoIncrement()**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
<th>Signature</th>
</tr>
</thead>
<tbody>
<tr>
<td>setAutoIncrement()</td>
<td>Make the column auto-incrementing (or not).</td>
<td><code>void setAutoIncrement(bool flag)</code></td>
</tr>
<tr>
<td>setAutoIncrementInitialValue()</td>
<td>Set the initial value for an auto-incrementing column.</td>
<td><code>void setAutoIncrementInitialValue(Uint64 value)</code></td>
</tr>
<tr>
<td>setCharset()</td>
<td>This method can be used to set the character set and collation of a Char, Varchar, or Text column. This method is applicable to Char, Varchar, and Text columns only. Changes made to columns using this method are not visible to MySQL.</td>
<td><code>void setCharset(CHARSET_INFO* cs)</code></td>
</tr>
<tr>
<td>setDefaultValue()</td>
<td>This method sets a column value to its default, if it has one; otherwise it sets the column to NULL. To determine whether a table has any columns with default values, use Table::hasDefaultValues().</td>
<td><code>int setDefaultValue(const void* buf, unsigned int len)</code></td>
</tr>
</tbody>
</table>

**Parameters**
- `flag`: A boolean value: TRUE to make the column auto-incrementing; FALSE to remove this property of the column.
- `value`: The initial value for the column (a 64-bit integer).
- `cs`: This method takes one parameter. cs is a pointer to a CHARSET_INFO structure. For additional information, see Column::getCharset().
- `buf`: This method takes 2 arguments: a value pointer buf; and the length len of the data, as the number of significant bytes. For fixed size types, this is the type size. For variable length types, the leading 1 or 2 bytes pointed to by buffer also contain size information as normal for the type.
Return value
0 on success, 1 on failure.

**Column::setInlineSize**
Description
This method gets the inline size of a blob column—that is, the
number of initial bytes to store in the table's blob attribute. This
part is normally kept in main memory, and can be indexed and
interpreted.

This method is applicable to blob columns only.

Changes made to columns using this method are not visible
to MySQL. Beginning with NDB 8.0.30, you can change the
inline size of a blob column in the `mysql` client by setting
`BLOB_INLINE_SIZE` in a column comment as part of `CREATE
TABLE` or `ALTER TABLE`. See NDB_COLUMN Options, for more
information.

**Signature**
```c
void setInlineSize
  (int size)
```

**Parameters**
The integer `size` is the new inline size for the blob column.

**Return value**
None.

**Column::setLength()**
Description
This method sets the length of a column. For a variable-length array,
this is the maximum length; otherwise it is the array length.

Changes made to columns using this method are not visible to
MySQL.

**Signature**
```c
void setLength
  (int length)
```

**Parameters**
This method takes a single argument—the integer value `length` is
the new length for the column.

**Return value**
None.

**Column::setName()**
Description
This method is used to set the name of a column.

`setName()` is the only `Column` method whose result is visible from
a MySQL Server. MySQL cannot see any other changes made to
existing columns using the NDB API.

**Signature**
```c
void setName
  (const char* name)
```

**Parameters**
This method takes a single argument—the new name for the
column.

**Return value**
This method `None`.
### The Column Class

**Description**

This method toggles the nullability of a column.

Changes made to columns using this method are not visible to MySQL.

**Signature**

```cpp
void setNullable
    (bool nullable)
```

**Parameters**

A Boolean value. Using `true` makes it possible to insert `NULL` into the column; if `nullable` is `false`, then this method performs the equivalent of changing the column to `NOT NULL` in MySQL.

**Return value**

`None`.

---

**Column::setPartitionKey()**

**Description**

This method makes it possible to add a column to the partitioning key of the table to which it belongs, or to remove the column from the table's partitioning key.

Changes made to columns using this method are not visible to MySQL. For additional information, see `Column::getPartitionKey()`.

**Signature**

```cpp
void setPartitionKey
    (bool enable)
```

**Parameters**

The single parameter `enable` is a Boolean value. Passing `true` to this method makes the column part of the table's partitioning key; if `enable` is `false`, then the column is removed from the partitioning key.

**Return value**

`None`.

---

**Column::setPartSize()**

**Description**

This method sets the blob part size of a blob column—that is, the number of bytes to store in each tuple of the blob table.

This method is applicable to blob columns only.

Changes made to columns using this method are not visible to MySQL. You can increase the blob part size of a blob column to the maximum supported by NDB (13948) in `mysql` or another MySQL client by setting the `MAX_BLOB_PART_SIZE` option in a column comment as part of a `CREATE TABLE` or `ALTER TABLE` statement. See `NDB_COLUMN` Options.

**Signature**

```cpp
void setPartSize
    (int size)
```

**Parameters**

The integer `size` is the number of bytes to store in the blob table. Using zero for this value means only inline bytes can be stored, in effect making the column's type `TINYBLOB`.

**Return value**

`None`.
The Column Class

**Column::setPrecision()**

Description: This method can be used to set the precision of a decimal column. This method is applicable to decimal columns only.

Changes made to columns using this method are not visible to MySQL.

Signature:

```cpp
void setPrecision
{
    int precision
}
```

Parameters: This method takes a single parameter—precision is an integer, the value of the column's new precision. For additional information about decimal precision and scale, see `Column::getPrecision()` and `Column::setScale()`.

Return value: None.

**Column::setPrimaryKey()**

Description: This method is used to make a column part of the table's primary key, or to remove it from the primary key.

Changes made to columns using this method are not visible to MySQL.

Signature:

```cpp
void setPrimaryKey
{
    bool primary
}
```

Parameters: This method takes a single Boolean value. If it is `true`, then the column becomes part of the table's primary key; if `false`, then the column is removed from the primary key.

Return value: None.

**Column::setScale()**

Description: This method can be used to set the scale of a decimal column.

This method is applicable to decimal columns only.

Changes made to columns using this method are not visible to MySQL.

Signature:

```cpp
void setScale
{
    int scale
}
```

Parameters: This method takes a single parameter—the integer `scale` is the new scale for the decimal column. For additional information about decimal precision and scale, see `Column::getPrecision()`, and `Column::setScale()`.

Return value: None.

**Column::setStripeSize()**

Description: This method sets the stripe size of a blob column—that is, the number of consecutive parts to store in each node group.
This method is applicable to blob columns only.

Changes made to columns using this method are not visible to MySQL.

**Signature**

```java
void setStripeSize
    (int size)
```

**Parameters**

This method takes a single argument. The integer `size` is the new stripe size for the column.

**Return value**

`None`.

---

**Column::setStorageType()**

**Description**

Sets the storage type for the column.

**Signature**

```java
void setStorageType
    (StorageType type)
```

**Parameters**

A `Column::StorageType` value. See `Column::StorageType`, for more information.

**Return value**

`None`.

---

**Column::setType()**

**Description**

This method sets the `Type` (data type) of a column.

`setType()` resets all column attributes to their (type dependent) default values; it should be the first method that you call when changing the attributes of a given column.

Changes made to columns using this method are not visible to MySQL.

**Signature**

```java
void setType
    (Type type)
```

**Parameters**

This method takes a single parameter—the new `Column::Type` for the column. The default is `Unsigned`. For a listing of all permitted values, see `Column::Type`.

**Return value**

`None`.

---

**Column::StorageType**

This section provides information about the `StorageType` data type, which describes the storage type used by a `Column` object.

**Description**

The storage type used for a given column can be either in memory or on disk. Columns stored on disk mean that less RAM is required overall but such columns cannot be indexed, and are potentially much slower to access. The default is `StorageTypeMemory`.

**Enumeration values**

Possible values are shown, along with descriptions, in the following table:
Table 2.9 Column object StorageType data type values and descriptions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>StorageTypeMemory</td>
<td>Store the column in memory</td>
</tr>
<tr>
<td>StorageTypeDisk</td>
<td>Store the column on disk</td>
</tr>
</tbody>
</table>

**Column::Type**

This section provides information about the Type data type, which is used to describe a column's data type.

**Description**

Data types for Column objects are analogous to the data types used by MySQL. The types Tinyint, Tinyintunsigned, Smallint, Smallunsigned, Mediumint, Mediumunsigned, Int, Unsigned, Bigint, Bigunsigned, Float, and Double (that is, types Tinyint through Double in the order listed in the Enumeration Values table) can be used in arrays.

Do not confuse Column::Type with Object::Type.

**Enumeration values**

Possible values are shown, along with descriptions, in the following table:

Table 2.10 Column object Type data type values and descriptions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Undefined</td>
<td>Undefined</td>
</tr>
<tr>
<td>Tinyint</td>
<td>1-byte signed integer</td>
</tr>
<tr>
<td>Tinyunsigned</td>
<td>1-byte unsigned integer</td>
</tr>
<tr>
<td>Smallint</td>
<td>2-byte signed integer</td>
</tr>
<tr>
<td>Smallunsigned</td>
<td>2-byte unsigned integer</td>
</tr>
<tr>
<td>Mediumint</td>
<td>3-byte signed integer</td>
</tr>
<tr>
<td>Mediumunsigned</td>
<td>3-byte unsigned integer</td>
</tr>
<tr>
<td>Int</td>
<td>4-byte signed integer</td>
</tr>
<tr>
<td>Unsigned</td>
<td>4-byte unsigned integer</td>
</tr>
<tr>
<td>Bigint</td>
<td>8-byte signed integer</td>
</tr>
<tr>
<td>Bigunsigned</td>
<td>8-byte signed integer</td>
</tr>
<tr>
<td>Float</td>
<td>4-byte float</td>
</tr>
<tr>
<td>Double</td>
<td>8-byte float</td>
</tr>
<tr>
<td>Olddecimal</td>
<td>Signed decimal as used prior to MySQL 5.0 (OBSOLETE)</td>
</tr>
<tr>
<td>Olddecimalunsigned</td>
<td>Unsigned decimal as used prior to MySQL 5.0 (OBSOLETE)</td>
</tr>
<tr>
<td>Decimal</td>
<td>Signed decimal as used by MySQL 5.0 and later</td>
</tr>
<tr>
<td>Decimalunsigned</td>
<td>Unsigned decimal as used by MySQL 5.0 and later</td>
</tr>
<tr>
<td>Char</td>
<td>A fixed-length array of 1-byte characters; maximum length is 255 characters</td>
</tr>
</tbody>
</table>
### The Datafile Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Varchar</td>
<td>A variable-length array of 1-byte characters; maximum length is 255 characters</td>
</tr>
<tr>
<td>Binary</td>
<td>A fixed-length array of 1-byte binary characters; maximum length is 255 characters</td>
</tr>
<tr>
<td>Varbinary</td>
<td>A variable-length array of 1-byte binary characters; maximum length is 255 characters</td>
</tr>
<tr>
<td>Datetime</td>
<td>An 8-byte date and time value, with a precision of 1 second (DEPRECATED)</td>
</tr>
<tr>
<td>Datetime2</td>
<td>An 8-byte date and time value, with fractional seconds.</td>
</tr>
<tr>
<td>Date</td>
<td>A 4-byte date value, with a precision of 1 day</td>
</tr>
<tr>
<td>Blob</td>
<td>A binary large object; see Section 2.3.13, “The NdbBlob Class”</td>
</tr>
<tr>
<td>Text</td>
<td>A text blob</td>
</tr>
<tr>
<td>Bit</td>
<td>A bit value; the length specifies the number of bits</td>
</tr>
<tr>
<td>Longvarchar</td>
<td>A 2-byte Varchar</td>
</tr>
<tr>
<td>Longvarbinary</td>
<td>A 2-byte Varbinary</td>
</tr>
<tr>
<td>Time</td>
<td>Time without date (DEPRECATED)</td>
</tr>
<tr>
<td>Time2</td>
<td>Time without date, with fractional seconds.</td>
</tr>
<tr>
<td>Year</td>
<td>1-byte year value in the range 1901-2155 (same as MySQL)</td>
</tr>
<tr>
<td>Timestamp</td>
<td>Unix time (DEPRECATED)</td>
</tr>
<tr>
<td>Timestamp2</td>
<td>Unix time, with fractional seconds.</td>
</tr>
</tbody>
</table>

The NDB API provides access to time types with microseconds (TIME, DATETIME, and TIMESTAMP) as Time2, Datetime2, and Timestamp2. (Time, Datetime, and Timestamp are deprecated as of the same version.) Use setPrecision() to set up to 6 fractional digits (default 0). Data formats are as in MySQL and must use the correct byte length.

Since NDB can compare any of these values as binary strings, it does not perform any checks on the actual data.

### 2.3.2 The Datafile Class

This section provides information about the Datafile class, which models an NDB Cluster data file.

- Datafile Class Overview
- Datafile Class Constructor
- Datafile::getFileNo()
- Datafile::getFree()
- Datafile::getNode()
- Datafile::getObjectId()
- Datafile::getObjectStatus()
The Datafile Class

- `Datafile::getObjectVersion()`
- `Datafile::getPath()`
- `Datafile::getSize()`
- `Datafile::getTablescape()`
- `Datafile::getTablescapeId()`
- `Datafile::setNode()`
- `Datafile::setPath()`
- `Datafile::setSize()`
- `Datafile::setTablescape()`

**Datafile Class Overview**

Parent class: Object

Child classes: None

Description: The Datafile class models an NDB Cluster data file, which is used to store Disk Data table and column data. Only unindexed column data can be stored on disk. Indexes and indexed columns are stored in memory.

Methods:
The following table lists the public methods of this class and the purpose or use of each method:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Datafile()</code></td>
<td>Class constructor</td>
</tr>
<tr>
<td><code>~Datafile()</code></td>
<td>Destructor</td>
</tr>
<tr>
<td><code>getFileSize()</code></td>
<td>Removed in NDB 7.5.0 (Bug #47960, Bug #11756088)</td>
</tr>
<tr>
<td><code>getFree()</code></td>
<td>Gets the amount of free space in the data file</td>
</tr>
<tr>
<td><code>getNode()</code></td>
<td>Removed in NDB 7.5.0 (Bug #47960, Bug #11756088)</td>
</tr>
<tr>
<td><code>getObjectId()</code></td>
<td>Gets the data file's object ID</td>
</tr>
<tr>
<td><code>getObjectStatus()</code></td>
<td>Gets the data file's object status</td>
</tr>
<tr>
<td><code>getObjectVersion()</code></td>
<td>Gets the data file's object version</td>
</tr>
<tr>
<td><code>getPath()</code></td>
<td>Gets the file system path to the data file</td>
</tr>
<tr>
<td><code>getSize()</code></td>
<td>Gets the size of the data file</td>
</tr>
<tr>
<td><code>getTablescape()</code></td>
<td>Gets the name of the tablespace to which the data file belongs</td>
</tr>
<tr>
<td><code>getTablescapeId()</code></td>
<td>Gets the ID of the tablespace to which the data file belongs</td>
</tr>
<tr>
<td><code>setNode()</code></td>
<td>Removed in NDB 7.5.0 (Bug #47960, Bug #11756088)</td>
</tr>
<tr>
<td><code>setPath()</code></td>
<td>Sets the name and location of the data file on the file system</td>
</tr>
</tbody>
</table>
### The Datafile Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>setSize()</td>
<td>Sets the data file's size</td>
</tr>
<tr>
<td>setTablespace()</td>
<td>Sets the tablespace to which the data file belongs</td>
</tr>
</tbody>
</table>

#### Types

The `Datafile` class defines no public types.

### Datafile Class Constructor

**Description**

This method creates a new instance of `Datafile`, or a copy of an existing one.

**Signature**

To create a new instance:

```cpp
Datafile()
{
    void
}
```

To create a copy of an existing `Datafile` instance:

```cpp
Datafile(const Datafile& datafile)
{
    const Datafile datafile
}
```

**Parameters**

New instance: *None*. Copy constructor: a reference to the `Datafile` instance to be copied.

**Return value**

A `Datafile` object.

### Datafile::getFileNo()

**Description**

This method did not work as intended, and was removed in NDB 7.5.0 (Bug #47960, Bug #11756088).

**Signature**

```cpp
Uint32 getFileNo()
{
    void
} const
```

**Parameters**

*None.*

**Return value**

The file number, as an unsigned 32-bit integer.

### Datafile::getFree()

**Description**

This method gets the free space available in the data file.

**Signature**

```cpp
Uint64 getFree()
{
    void
} const
```

**Parameters**

*None.*

**Return value**

The number of bytes free in the data file, as an unsigned 64-bit integer.

### Datafile::getNode()

**Description**

This method did not work as intended, and was removed in NDB 7.5.0 (Bug #47960, Bug #11756088).

**Signature**

```cpp
Uint32 getNode()
{
```
The Datafile Class

```c++
void
) const
```

**Parameters**
None.

**Return value**
The node ID as an unsigned 32-bit integer.

**Datafile::getObjectId()**

**Description**
This method is used to obtain the object ID of the data file.

**Signature**
```c++
virtual int getObjectId
{
    void
) const
```

**Parameters**
None.

**Return value**
The datafile's object ID, as an integer.

**Datafile::getObjectStatus()**

**Description**
This method is used to obtain the data file's object status.

**Signature**
```c++
virtual Object::Status getObjectStatus
{
    void
) const
```

**Parameters**
None.

**Return value**
The data file's Status. See Object::Status.

**Datafile::getObjectVersion()**

**Description**
This method retrieves the data file's object version (see NDB Schema Object Versions).

**Signature**
```c++
virtual int getObjectVersion
{
    void
) const
```

**Parameters**
None.

**Return value**
The data file's object version, as an integer.

**Datafile::getPath()**

**Description**
This method returns the file system path to the data file.

**Signature**
```c++
const char* getPath
{
    void
) const
```

**Parameters**
None.

**Return value**
The path to the data file on the data node's file system, a string (character pointer).

**Datafile::getSize()**

**Description**
This method gets the size of the data file in bytes.

**Signature**
```c++
Uint64 getSize
{
    void
```

```
The Datafile Class

Datafile::getTablespace()

Description This method can be used to obtain the name of the tablespace to which the data file belongs.

You can also access the associated tablespace’s ID directly. See Datafile::getTablespaceId().

Signature

```cpp
const char* getTablespace()
{
    void
} const
```

Parameters None.

Return value The name of the associated tablespace (as a character pointer).

Datafile::getTablespaceId()

Description This method gets the ID of the tablespace to which the data file belongs.

You can also access the name of the associated tablespace directly. See Datafile::getTablespace().

Signature

```cpp
Uint32 getTablespaceId()
{
    void
} const
```

Parameters None.

Return value This method returns the tablespace ID as an unsigned 32-bit integer.

Datafile::setNode()

Description This method did not work as intended, and was removed in NDB 7.5.0 (Bug #47960, Bug #11756088).

Signature

```cpp
void setNode(Uint32 nodeId)
```

Parameters The `nodeId` of the node on which the data file is to be located (an unsigned 32-bit integer value).

Return value None.

Datafile::setPath()

Description This method sets the path to the data file on the data node’s file system.

Signature

```cpp
const char* setPath()
{
    void
} const
```

Parameters The path to the file, a string (as a character pointer).
The Dictionary Class

Return value

None.

**Datafile::setSize()**

Description

This method sets the size of the data file.

Signature

```cpp
void setSize
{
  Uint64 size
}
```

Parameters

This method takes a single parameter—the desired size in bytes for the data file, as an unsigned 64-bit integer.

Return value

None.

**Datafile::setTablespace()**

Description

This method is used to associate the data file with a tablespace.

Signatures

`setTablespace()` can be invoked in either of the two ways listed here:

1. Using the name of the tablespace, as shown here:

   ```cpp
   void setTablespace
   {
     const char* name
   }
   ```

2. Using a reference to a `Tablespace` object.

   ```cpp
   void setTablespace
   {
     const class Tablespace& tablespace
   }
   ```

Parameters

This method takes a single parameter, which can be either one of the following:

- The name of the tablespace (as a character pointer).
- A reference `tablespace` to the corresponding `Tablespace` object.

Return value

None.

### 2.3.3 The Dictionary Class

This section provides information about the `Dictionary` class.

- **Dictionary Class Overview**
- **Dictionary Class Constructor**
- **Dictionary::beginSchemaTrans()**
- **Dictionary::createDatafile()**
- **Dictionary::createEvent()**
- **Dictionary::createForeignKey()**
- **Dictionary::createHashMap()**
- **Dictionary::createIndex()**
- Dictionary::createLogfileGroup()
- Dictionary::createRecord()
- Dictionary::createTable()
- Dictionary::createTablesace()
- Dictionary::createUndofile()

Dictionary Class Overview

Parent class: NdbDictionary
Child classes: List
Description: This is used for defining and retrieving data object metadata. It also includes methods for creating and dropping database objects.

Methods: The following table lists the public methods of this class and the purpose or use of each method:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dictionary()</td>
<td>Class constructor method</td>
</tr>
<tr>
<td>~Dictionary()</td>
<td>Destructor method</td>
</tr>
<tr>
<td>beginSchemaTrans()</td>
<td>Begins a schema transaction</td>
</tr>
<tr>
<td>createDatafile()</td>
<td>Creates a data file</td>
</tr>
<tr>
<td>createEvent()</td>
<td>Creates an event</td>
</tr>
<tr>
<td>createForeignKey()</td>
<td>Creates a foreign key</td>
</tr>
<tr>
<td>createHashMap()</td>
<td>Creates a hash map</td>
</tr>
<tr>
<td>createIndex()</td>
<td>Creates an index</td>
</tr>
<tr>
<td>createLogfileGroup()</td>
<td>Creates a log file group</td>
</tr>
<tr>
<td>createRecord()</td>
<td>Creates an Ndbrecord object</td>
</tr>
<tr>
<td>createTable()</td>
<td>Creates a table</td>

</tr>
<tr>
<td><code>removeCachedTable()</code></td>
<td>Removes a table from the local cache</td>
</tr>
<tr>
<td><code>removeCachedIndex()</code></td>
<td>Removes an index from the local cache</td>
</tr>
</tbody>
</table>

Database objects such as tables and indexes created using the `Dictionary::create*()` methods cannot be seen by the MySQL Server. This means that they cannot be accessed by MySQL clients, and that they cannot be replicated. For these reasons, it is often preferable to avoid working with them.

The `Dictionary` class does not have any methods for working directly with columns. You must use `Column` class methods for this purpose—see Section 2.3.1, “The Column Class”, for details.

#### Types

See Section 2.3.10, “The List Class”, and Section 2.3.4, “The Element Structure”.

### Dictionary Class Constructor

#### Description

This method creates a new instance of the `Dictionary` class.

Both the constructor and destructor for this class are protected methods, rather than public.

#### Signature

```cpp
protected Dictionary
{
    Ndb& ndb
}
```

#### Parameters

- An `Ndb` object.

#### Return value

A `Dictionary` object.
Destructor

The destructor takes no parameters and returns nothing:

```cpp
protected ~Dictionary
{
    void
}
```

**Dictionary::beginSchemaTrans()**

**Description**

Starts a schema transaction. An error occurs if a transaction is already active, or if the kernel metadata is locked. You can determine whether a schema transaction already exists using the `hasSchemaTrans()` method.

A *metadata operation* occurs whenever data objects are created, altered, or dropped; such an operation can create additional suboperations in the NDB kernel.

The Ndb object and its associated Dictionary support one schema transaction at a time. By default, each metadata operation is executed separately; that is, for each operation, a schema transaction is started implicitly, the operation (including any suboperations) is executed, and the transaction is closed.

It is also possible to begin and end a schema transaction explicitly, and execute a set of user-defined operations atomically within its boundaries. In this case, all operations within the schema transaction either succeed, or are aborted and rolled back, as a unit. This is done by following the steps listed here:

1. To begin the schema transaction, call `beginSchemaTrans()`.
2. Execute the desired operations (such as `createTable()`).
3. End the schema transaction by calling `endSchemaTrans`.

Each operation is sent to the NDB kernel, which parses and saves it. A parse failure results in a rollback to the previous user operation before returning, at which point the user can either continue with or abort the entire transaction.

After all operations have been submitted, `endSchemaTrans()` processes and commits them. In the event of an error, the transaction is immediately aborted.

If the user exits before calling `endSchemaTrans()`, the NDB kernel aborts the transaction. If the user exits before the call to `endSchemaTrans()` returns, the kernel continues with the request, and its completion status is reported in the cluster log.

**Signature**

```cpp
int beginSchemaTrans
{
    void
}
```

**Parameters**

None.

**Return value**

Returns 0 on success, -1 on error.

**Dictionary::createDatafile()**

**Description**

This method creates a new data file, given a Datafile object.
The Dictionary Class

**Signature**

```cpp
int createDatafile
{
    const Datafile& dFile
}
```

**Parameters**

A single argument—a reference to an instance of `Datafile`—is required.

**Return value**

0 on success, -1 on failure.

**Dictionary::createEvent()**

**Description**

Creates an event, given a reference to an `Event` object.

You should keep in mind that the NDB API does not track allocated event objects, which means that the user must delete the `Event` that was obtained using `createEvent()`, after this object is no longer required.

**Signature**

```cpp
int createEvent
{
    const Event& event
}
```

**Parameters**

A reference `event` to an `Event` object.

**Return value**

0 on success, -1 on failure.

**Dictionary::createForeignKey()**

**Description**

Creates a `ForeignKey` object, given a reference to this object and an `ObjectId`.

**Signature**

```cpp
int createForeignKey
{
    const ForeignKey&,
    ObjectId* = 0,
    int flags = 0
}
```

**Parameters**

A reference to the `ForeignKey` object, and an `ObjectId`. An optional value `flags`, if used, allows the creation of the foreign key without performing any foreign key checks. If set, its value must be `CreateFK_NoVerify` (1).

**Return value**

0 on success.

**Dictionary::createHashMap()**

**Description**

Creates a `HashMap`.

**Signature**

```cpp
int createHashMap
{
    const HashMap& hashmap,
    ObjectId* id = 0
}
```

**Parameters**

A reference to the hash map, and, optionally, an ID to be assigned to it.

**Return value**

Returns 0 on success; on failure, returns -1 and sets an error.

**Dictionary::createIndex()**

**Description**

This method creates an index given an instance of `Index` and possibly an optional instance of `Table`.
The Dictionary Class

**Signature**
This method can be invoked with or without a reference to a table object:

```c
int createIndex
{
    const Index& index
}
```

```c
int createIndex
{
    const Index& index,
    const Table& table
}
```

**Parameters**

*Required:* A reference to an `Index` object.  
*Optional:* A reference to a `Table` object.

**Return value**

0 on success, -1 on failure.

---

**Dictionary::createLogfileGroup()**

**Description**
This method creates a new log file group, given an instance of `LogfileGroup`.

**Signature**

```c
int createLogfileGroup
{
    const LogfileGroup& lGroup
}
```

**Parameters**

A single argument, a reference to a `LogfileGroup` object, is required.

**Return value**

0 on success, -1 on failure.

---

**Dictionary::createRecord()**

**Description**
This method is used to create an `NdbRecord` object for use in table or index scanning operations.

**Signature**

The signature of this method depends on whether the resulting `NdbRecord` is to be used in table or index operations:

To create an `NdbRecord` for use in table operations, use the following:

```c
NdbRecord* createRecord
{
    const Table* table,
    const RecordSpecification* recSpec,
    Uint32 length,
    Uint32 elSize
}
```

To create an `NdbRecord` for use in index operations, you can use either of the following:

```c
NdbRecord* createRecord
{
    const Index* index,
    const Table* table,
    const RecordSpecification* recSpec,
    Uint32 length,
    Uint32 elSize
}
```

or

```c
NdbRecord* createRecord
```
The Dictionary Class

Parameters

Dictionary::createRecord() takes the following parameters:

- If this NdbRecord is to be used with an index, a pointer to the corresponding Index object. If the NdbRecord is to be used with a table, this parameter is omitted. (See Section 2.3.8, “The Index Class”.)
- A pointer to a Table object representing the table to be scanned. If the NdbRecord produced is to be used with an index, then this optionally specifies the table containing that index. (See Section 2.3.27, “The Table Class”.)
- A RecordSpecification used to describe a column.
- The length of the record.
- The size of the elements making up this record.

Return value

An NdbRecord for use in operations involving the given table or index.

Example

See Section 2.3.22, “The NdbRecord Interface”.

Dictionary::createTable()

Description

Creates a table given an instance of Table.

Tables created using this method cannot be seen by the MySQL Server, cannot be updated by MySQL clients, and cannot be replicated.

Signature

```c
int createTable
{   const Table& table
}
```

Parameters

An instance of Table. See Section 2.3.27, “The Table Class”, for more information.

Return value

0 on success, -1 on failure.

Dictionary::createTablespace()

Description

This method creates a new tablespace, given a Tablespace object.

Signature

```c
int createTablespace
{   const Tablespace& tSpace
}
```

Parameters

This method requires a single argument—a reference to an instance of Tablespace.

Return value

0 on success, -1 on failure.

Dictionary::createUndofile()
### Dictionary::createUndofile()

**Description**
This method creates a new undo file, given an `Undofile` object.

**Signature**
```c++
int createUndofile
   {
      const Undofile& uFile
   }
```

**Parameters**
This method requires one argument: a reference to an instance of `Undofile`.

**Return value**
0 on success, -1 on failure.

### Dictionary::dropDatafile()

**Description**
This method drops a data file, given a `Datafile` object.

**Signature**
```c++
int dropDatafile
   {
      const Datafile& dFile
   }
```

**Parameters**
A single argument—a reference to an instance of `Datafile`—is required.

**Return value**
0 on success, -1 on failure.

### Dictionary::dropEvent()

**Description**
This method drops an event, given a reference to an `Event` object.

**Signature**
```c++
int dropEvent
   {
      const char* name,
      int force = 0
   }
```

**Parameters**
This method takes two parameters:
- The `name` of the event to be dropped, as a string.
- By default, `dropEvent()` fails if the event specified does not exist. You can override this behavior by passing any nonzero value for the (optional) `force` argument; in this case no check is made as to whether there actually is such an event, and an error is returned only if the event exists but it was for whatever reason not possible to drop it.

**Return value**
0 on success, -1 on failure.

### Dictionary::dropForeignKey()

**Description**
This method drops a foreign key, given a reference to an `ForeignKey` object to be dropped.

**Signature**
```c++
int dropForeignKey
   {
      const ForeignKey&
   }
```

**Parameters**
A reference to the `ForeignKey` to be dropped.

**Return value**
0 on success.

### Dictionary::dropIndex()

**Description**
This method drops an index given an instance of `Index`, and possibly an optional instance of `Table`.

---

64
### Dictionary::dropIndex()

**Signature**

```cpp
int dropIndex
{
    const Index& index
}
```

**Parameters**

This method takes two parameters, one of which is optional:

- **Required**: A reference to an `Index` object.
- **required**: A reference to a `Table` object.

**Return value**

0 on success, -1 on failure.

### Dictionary::dropLogfileGroup()

**Description**

Given an instance of `LogfileGroup`, this method drops the corresponding log file group.

**Signature**

```cpp
int dropLogfileGroup
{
    const LogfileGroup& lGroup
}
```

**Parameters**

A single argument, a reference to a `LogfileGroup` object, is required.

**Return value**

0 on success, -1 on failure.

### Dictionary::dropTable()

**Description**

Drops a table given an instance of `Table`.

This method drops all foreign key constraints on the `table` that is being dropped, whether the dropped table acts as a parent table, child table, or both.

Prior to NDB 8.0, an `NDB` table dropped using this method persisted in the MySQL data dictionary but could not be dropped using `DROP TABLE` in the `mysql` client. In NDB 8.0, such “orphan” tables can be dropped using `DROP TABLE`. (Bug #29125206, Bug #93672)

**Signature**

```cpp
int dropTable
{
    const Table& table
}
```

**Parameters**

An instance of `Table`. See Section 2.3.27, “The Table Class”, for more information.

**Return value**

0 on success, -1 on failure.

### Dictionary::dropTables(vector<Table>)

**Description**

This method drops a tablespace, given a `Tablespace` object.

**Signature**

```cpp
int dropTablesTablespaceTable
{
    const Tablespace& tSpace
}
```

**Parameters**

**Return value**

0 on success, -1 on failure.
Parameters This method requires a single argument—a reference to an instance of `Tablespace`.

Return value 0 on success, -1 on failure.

**Dictionary::dropUndofile()**

Description This method drops an undo file, given an `Undofile` object.

Signature
```
class Dictionary {
public:
  int dropUndofile(const Undofile& uFile);
};
```

Parameters This method requires one argument: a reference to an instance of `Undofile`.

Return value 0 on success, -1 on failure.

**Dictionary::endSchemaTrans()**

Description Ends a schema transaction begun with `beginSchemaTrans()`: causes operations to be processed and either committed, or aborted and rolled back. This method combines transaction execution and closing; separate methods for these tasks are not required (or implemented). This method may be called successfully even if no schema transaction is currently active.

As with many other NDB API methods, it is entirely possible for `endSchemaTrans()` to overwrite any current error code. For this reason, you should first check for and save any error code that may have resulted from a previous, failed operation.

Signature
```
class Dictionary {
public:
  int endSchemaTrans(Uint32 flags = 0);
};
```

Parameters The flags determines how the completed transaction is handled. The default is 0, which causes the transaction to be committed.

**Dictionary::SchemaTransFlag.** You can also use with `endSchemaTrans()` either of the `SchemaTransFlag` values shown here:

- `SchemaTransAbort` (= 1): Causes the transaction to be aborted
- `SchemaTransBackground` (= 2): Causes the transaction to execute in the background; the result is written to the cluster log, while the application continues without waiting for a response.

Return value Returns 0 on success; in the event of an error, returns -1 and sets an `NdbError` error code.

**Dictionary::getDatafile()**

Description This method is used to retrieve a `Datafile` object, given the node ID of the data node where a data file is located and the path to the data file on that node’s file system.

Signature
```
class Dictionary {
public:
  Datafile getDatafile(Uint32 nodeId);
};
```
The Dictionary Class

Parameters

This method must be invoked using two arguments, as shown here:

- The 32-bit unsigned integer `nodeId` of the data node where the
data file is located
- The `path` to the data file on the node's file system (string as
character pointer)

Return value

A `Datafile` object—see Section 2.3.2, “The Datafile Class”, for
details.

Dictionary::getDefaultHashMap()

Description

Get a table's default hash map.

Signature

```cpp
int getDefaultHashMap
(
    HashMap& dst,
    Uint32 fragments
)
```

or

```cpp
int getDefaultHashMap
(
    HashMap& dst,
    Uint32 buckets,
    Uint32 fragments
)
```

Return value

Returns 0 on success; on failure, returns -1 and sets an error.

Dictionary::getEvent()

Description

This method is used to obtain a new `Event` object representing an
event, given the event's name.

`getEvent()` allocates memory each time it is successfully called.
You should keep in mind that successive invocations of this method
using the same event name return multiple, distinct objects.

The NDB API does not track allocated event objects, which
means that the user must clean up each `Event` created using
`getEvent()` with `delete`, after the object is no longer required.
Beginning with NDB 8.0.30, you can do this with `releaseEvent()`
instead.

Signature

```cpp
const Event* getEvent
(
    const char* eventName
)
```

Parameters

The `eventName`, a string (character pointer).

Return value

A pointer to an `Event` object. See Section 2.3.5, “The Event Class”,
for more information.

Dictionary::getForeignKey()

Description

This method is used to obtain a new `ForeignKey` object
representing an event, given a reference to the foreign key and its
name.
The Dictionary Class

**getForeignKey()**

**Signature**

```c
int getForeignKey
{
    ForeignKeys dst,
    const char* name
}
```

**Parameters**

A reference to the foreign key and its *name*, a string (character pointer).

**Return value**

A pointer to a `ForeignKey` object.

**getHashMap()**

**Description**

Gets a hash map by name or by table.

**Signatures**

```c
int getHashMap
{
    HashMap dst,
    const char* name
}
```

or

```c
int getHashMap
{
    HashMap dst,
    const Table* table
}
```

**Parameters**

A reference to the hash map and either a name or a `Table`.

**Return value**

Returns 0 on success; on failure, returns -1 and sets an error.

**getIndex()**

**Description**

This method retrieves a pointer to an index, given the name of the index and the name of the table to which the table belongs.

**Signature**

```c
const Index* getIndex
{
    const char* iName,
    const char* tName
} const
```

**Parameters**

Two parameters are required:

- The name of the index (*iName*)
- The name of the table to which the index belongs (*tName*)

Both of these are string values, represented by character pointers.

**Return value**

A pointer to an Index. See Section 2.3.8, "The Index Class", for information about this object.

**getLogfileGroup()**

**Description**

This method gets a LogfileGroup object, given the name of the log file group.

**Signature**

```c
LogfileGroup getLogfileGroup
{
    const char* name
}
```

**Parameters**

The *name* of the log file group.
### The Dictionary Class

**Return value**
An instance of `LogfileGroup`; see Section 2.3.9, “The LogfileGroup Class”, for more information.

**Dictionary::getNdbError()**

**Description**
This method retrieves the most recent NDB API error.

**Signature**
```
const struct NdbError& getNdbError
    (    
    ) const
```

**Parameters**
None.

**Return value**
A reference to an `NdbError` object.

**Dictionary::getTable()**

**Description**
This method can be used to access a `Table` whose name is already known.

**Signature**
```
const Table* getTable
    (    const char* name
    ) const
```

**Parameters**
The `name` of the table.

**Return value**
A pointer to the table, or `NULL` if there is no table with the `name` supplied.

**Dictionary::get Tablespace()**

**Description**
Given either the name or ID of a tablespace, this method returns the corresponding `Tablespace` object.

**Signatures**
This method can be invoked in either of the following two ways:

- Using the tablespace name:
  ```
  Tablespace getTablespace
    ( const char* name
    )
  ```

- Using the tablespace ID:
  ```
  Tablespace getTablespace
    ( Uint32 id
    )
  ```

**Parameters**
Either one of the following:

- The `name` of the tablespace, a string (as a character pointer)
- The unsigned 32-bit integer `id` of the tablespace

**Return value**
A `Tablespace` object, as discussed in Section 2.3.28, “The Tablespace Class”.

**Dictionary::getUndofile()**

**Description**
This method gets an `Undofile` object, given the ID of the node where an undo file is located and the file system path to the file.

**Signature**
```
Undofile getUndofile
```

---

69
The Dictionary Class

```cpp
{  
  Uint32 nodeId,  
  const char* path
}
```

Parameters

This method requires the following two arguments:

- The `nodeId` of the data node where the undo file is located; this value is passed as a 32-bit unsigned integer
- The `path` to the undo file on the node's file system (string as character pointer)

Return value

An instance of `Undofile`. For more information, see Section 2.3.29, "The Undofile Class".

Dictionary::hasSchemaTrans()

Description

Tells whether an NDB API schema transaction is ongoing.

Signature

```cpp
bool hasSchemaTrans
{
  void
} const
```

Parameters

`None.`

Return value

Returns boolean `TRUE` if a schema transaction is in progress, otherwise `FALSE`.

Dictionary::initDefaultHashMap()

Description

Initialize a default hash map for a table.

Signature

```cpp
int initDefaultHashMap
{
  HashMap& dst,  
  Uint32 fragments
}
```

or

```cpp
int initDefaultHashMap
{
  HashMap& dst,  
  Uint32 buckets,  
  Uint32 fragments
}
```

Parameters

A reference to the hash map and the number of fragments. Optionally the number of buckets.

Return value

Returns 0 on success; on failure, returns -1 and sets an error.

Dictionary::invalidateIndex()

Description

This method is used to invalidate a cached index object.

Signature

The index invalidated by this method can be referenced either as an `Index` object (using a pointer), or by index name and table name, as shown here:

```cpp
void invalidateIndex
{
  const char* indexName,  
  const char* tableName
}
```
The Dictionary Class

```cpp
void invalidateIndex
{
    const Index* index
}
```

**Parameters**
The names of the index to be removed from the cache and the table to which it belongs (indexName and tableName, respectively), or a pointer to the corresponding Index object.

**Return value**
None.

Dictionary::invalidateTable()

**Description**
This method is used to invalidate a cached table object.

**Signature**
```cpp
void invalidateTable
{
    const char* name
}
```

It is also possible to use a Table object rather than the name of the table, as shown here:

```cpp
void invalidateTable
{
    const Table* table
}
```

**Parameters**
The name of the table to be removed from the table cache, or a pointer to the corresponding Table object.

**Return value**
None.

Dictionary::listEvents()

**Description**
This method returns a list of all events defined within the dictionary.

**Signature**
```cpp
int listEvents
{
    List& list
}
```

**Parameters**
A reference to an empty List. In NDB 8.0.29 and later, use clear() to empty a previously used List for reuse.

**Return value**
0 on success; -1 on failure.

Dictionary::listIndexes()

**Description**
This method is used to obtain a List of all the indexes on a table, given the table's name.

**Signature**
```cpp
int listIndexes
{
    List& list,
    const char* table
} const
```

**Parameters**
listIndexes() takes two arguments, both of which are required:

- A reference to an empty List that, following the call to this method, contains the indexes. In NDB 8.0.29 and later, use clear() to empty a previously used List for reuse.
- The name of the table whose indexes are to be listed

**Return value**
0 on success, -1 on failure.
Dictionary::listObjects()

Description
This method is used to obtain a list of objects in the dictionary. It is possible to get all of the objects in the dictionary, or to restrict the list to objects of a single type.

Signature
This method has two signatures:

```cpp
int listObjects
{
    List& list,
    Object::Type type = Object::TypeUndefined
} const
```

and

```cpp
int listObjects
{
    List& list,
    Object::Type type,
    bool fullyQualified
} const
```

Parameters
A reference to an empty List object is required—this is the list that contains the dictionary's objects after listObjects() is called. (See Section 2.3.10, "The List Class"). An optional second argument type may be used to restrict the list to only those objects of the given type—that is, of the specified Object::Type. If type is not given, then the list contains all of the dictionary's objects.

You can also specify whether or not the object names in the list are fully qualified (that is, whether the object name includes the database, schema, and possibly the table name). If you specify fullyQualified, then you must also specify the type.

In NDB 8.0.29 and later, you can call clear() to empty a previously used List for reuse.

Note
Setting fullyQualified to false causes listObjects() to return objects that use fully qualified names.

Return value
0 on success, -1 on failure.

Dictionary::prepareHashMap()

Description
Creates or retrieves a hash map suitable for alteration. Requires a schema transaction to be in progress; see Dictionary::beginSchemaTrans(), for more information.

Signatures
Either of the following:

```cpp
• int prepareHashMap
  {
    const Tables oldTable,
    Tables newTable
  }
```

```cpp
• int prepareHashMap
  {
    const Tables oldTable,
    Tables newTable,
    Uint32 buckets
  }
```
The Dictionary Class

Parameters
References to the old and new tables. Optionally, a number of buckets.

Return value
Returns 0 on success; on failure, returns -1 and sets an error.

**Dictionary::releaseEvent()**

Description
This method is used to free an Event after it is no longer needed. Typically this is an event returned by getEvent().

Signature

```cpp
void releaseEvent(
    const Event* event
)
```

Parameters
The Event to be cleaned up.

Return value
None.

This method was added in NDB 8.0.30.

**Dictionary::releaseRecord()**

Description
This method is used to free an NdbRecord after it is no longer needed.

Signature

```cpp
void releaseRecord(
    NdbRecord* record
)
```

Parameters
The NdbRecord to be cleaned up.

Return value
None.

Example
See Section 2.3.22, “The NdbRecord Interface”.

**Dictionary::removeCachedTable()**

Description
This method removes the table, specified by name, from the local cache.

Signature

```cpp
void removeCachedTable(
    const char* table
)
```

Parameters
The name of the table to be removed from the cache.

Return value
None.

**Dictionary::removeCachedIndex()**

Description
This method removes the specified index from the local cache, given the name of the index and that of the table in which it is contained.

Signature

```cpp
void removeCachedIndex(
    const char* index,
    const char* table
)
```

Parameters
The removeCachedIndex() method requires two arguments:

- The name of the index to be removed from the cache
2.3.4 The Element Structure

This section provides information about the Element structure.

Parent class

List

Description

The Element structure models an element of a list; it is used to store an object in a List populated by the Dictionary methods listObjects(), listIndexes(), and listEvents().

Attributes

An Element has the attributes shown in the following table:

Table 2.13 Name, type, initial value, and description of Element structure attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Type</th>
<th>Initial Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>unsigned int</td>
<td>0</td>
<td>The object’s ID</td>
</tr>
<tr>
<td>type</td>
<td>Object::Type</td>
<td>Object::TypeUndefined</td>
<td>The object’s type—see Object::Type for possible values</td>
</tr>
<tr>
<td>state</td>
<td>Object::State</td>
<td>Object::StateUndefined</td>
<td>The object’s state—see Object::State for possible values</td>
</tr>
<tr>
<td>store</td>
<td>Object::Store</td>
<td>Object::StoreUndefined</td>
<td>How the object is stored—see Object::Store for possible values</td>
</tr>
<tr>
<td>database</td>
<td>char*</td>
<td>0</td>
<td>The database in which the object is found</td>
</tr>
<tr>
<td>schema</td>
<td>char*</td>
<td>0</td>
<td>The schema in which the object is found</td>
</tr>
<tr>
<td>name</td>
<td>char*</td>
<td>0</td>
<td>The object’s name</td>
</tr>
</tbody>
</table>

2.3.5 The Event Class

This section provides information about the Event class.

- Event Class Overview
- Event::addEventColumn()
- Event::addEventColumns()
- Event::addTableEvent()
- Event Constructor
- Event::EventDurability
- Event::EventReport
- Event::getDurability()
- Event::getEventColumn()
The Event Class

- Event::getName()
- Event::getNoOfEventColumns()
- Event::getObjectStatus()
- Event::getObjectVersion()
- Event::getObjectId()
- Event::getReport()
- Event::getTable()
- Event::getTableEvent()
- Event::getTableName()
- Event::mergeEvents()
- Event::setDurability()
- Event::setReport()
- Event::setName()
- Event::setTable()
- Event::TableEvent

Event Class Overview

<table>
<thead>
<tr>
<th>Parent class</th>
<th>NdbDictionary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Child classes</td>
<td>None</td>
</tr>
<tr>
<td>Description</td>
<td>This class represents a database event in an NDB Cluster.</td>
</tr>
</tbody>
</table>

Methods

The following table lists the public methods of the Event class and the purpose or use of each method:

**Table 2.14 Event class methods and descriptions**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Event()</td>
<td>Class constructor</td>
</tr>
<tr>
<td>~Event()</td>
<td>Destructor</td>
</tr>
<tr>
<td>addEventColumn()</td>
<td>Adds a column on which events should be detected</td>
</tr>
<tr>
<td>addEventColumns()</td>
<td>Adds multiple columns on which events should be detected</td>
</tr>
<tr>
<td>addTableEvent()</td>
<td>Adds the type of event that should be detected</td>
</tr>
<tr>
<td>getDurability()</td>
<td>Gets the event's durability</td>
</tr>
<tr>
<td>getEventColumn()</td>
<td>Gets a column for which an event is defined</td>
</tr>
<tr>
<td>getName()</td>
<td>Gets the event's name</td>
</tr>
<tr>
<td>getNoOfEventColumns</td>
<td>Gets the number of columns for which an event is defined</td>
</tr>
<tr>
<td>getObjectId()</td>
<td>Gets the event's object ID</td>
</tr>
<tr>
<td>setObjectStatus()</td>
<td>Gets the event's object status</td>
</tr>
</tbody>
</table>
### The Event Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getObjectVersion()</td>
<td>Gets the event’s object version</td>
</tr>
<tr>

<tr>
<td>setReport()</td>
<td>The event’s reporting options</td>
</tr>
<tr>
<td>setTable()</td>
<td>Sets the Table object on which the event is defined</td>
</tr>
</tbody>
</table>

**Improved Event API (NDB 7.4 and later).** NDB 7.4 introduces an epoch-driven Event API that supercedes the earlier GCI-based model. The new version of the API also simplifies error detection and handling. These changes are realized in the NDB API by implementing a number of new methods for Ndb and NdbEventOperation, deprecating several other methods of both classes, and adding new type values to TableEvent.

Some of the new methods directly replace or stand in for deprecated methods, but not all of the deprecated methods map to new ones, some of which are entirely new. Old (deprecated) methods are shown in the first column of the following table, and new methods in the second column; old methods corresponding to new methods are shown in the same row.

#### Table 2.15 Deprecated and new Event API methods in the NDB API, NDB 7.4

<table>
<thead>
<tr>
<th>Old Method</th>
<th>New Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>NdbEventOperation::getEventType()</td>
<td>NdbEventOperation::getEventType2()</td>
</tr>
<tr>
<td>NdbEventOperation::getGCI()</td>
<td>NdbEventOperation::getEpoch</td>
</tr>
<tr>
<td>NdbEventOperation::getHighestQueuedEpoch()</td>
<td>NdbEventOperation::getEventType2()</td>
</tr>
<tr>
<td>NdbEventOperation::isOverrun()</td>
<td>None; use NdbEventOperation::getEventType2()</td>
</tr>
<tr>
<td>NdbEventOperation::hasError()</td>
<td>None; use NdbEventOperation::getEventType2()</td>
</tr>
<tr>
<td>NdbEventOperation::clearError()</td>
<td>None</td>
</tr>
<tr>
<td>NdbEventOperation::isEmptyEpoch()</td>
<td>None</td>
</tr>
<tr>
<td>NdbEventOperation::isErrorEpoch()</td>
<td>None</td>
</tr>
<tr>
<td>Ndb::pollEvents()</td>
<td>Ndb::pollEvents2()</td>
</tr>
<tr>
<td>Ndb::nextEvent()</td>
<td>Ndb::nextEvent2()</td>
</tr>
<tr>
<td>Ndb::getLatestGCI()</td>
<td>Ndb::getHighestQueuedEpoch()</td>
</tr>
<tr>
<td>Ndb::getGCIEventOperation::NextEventOpInEpoch()</td>
<td>Ndb::getEventType2()</td>
</tr>
<tr>
<td>Ndb::isConsistent()</td>
<td>None</td>
</tr>
</tbody>
</table>
The Event Class

<table>
<thead>
<tr>
<th>Old Method</th>
<th>New Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ndb::isConsistentGCI</td>
<td>None</td>
</tr>
</tbody>
</table>

Error handling using the new API is accomplished by checking the value returned from `getEventType2()`, and is no longer handled using the methods `hasError()` and `clearError()`, which are now deprecated and subject to removal in a future release of NDB Cluster. In support of this change, the range of possible `TableEvent` types has been expanded by those listed here:

- **TE_EMPTY**: Empty epoch
- **TE_INCONSISTENT**: Inconsistent epoch; missing data or overflow
- **TE_OUT_OF_MEMORY**: Inconsistent data; event buffer out of memory or overflow

The result of these changes is that, in NDB 7.4 and later, you can check for errors while checking a table event’s type, as shown here:

```c
NdbDictionary::Event::TableEvent* error_type = 0;
NdbEventOperation* pOp = nextEvent2();
if (pOp->isErrorEpoch(error_type))
{
    switch (error_type)
    {
    case TE_INCONSISTENT :
        // Handle error/inconsistent epoch...
        break;
    case TE_OUT_OF_MEMORY :
        // Handle error/inconsistent data...
        break;
    // ...
    }
}
```

For more information, see the detailed descriptions for the `Ndb` and `NdbEventOperation` methods shown in the table previously, as well as `Event::TableEvent`.

### Types

These are the public types of the `Event` class:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TableEvent()</td>
<td>Represents the type of a table event</td>
</tr>
<tr>
<td>EventDurability()</td>
<td>Specifies an event’s scope, accessibility, and lifetime</td>
</tr>
<tr>
<td>EventReport()</td>
<td>Specifies the reporting option for a table event</td>
</tr>
</tbody>
</table>

**Event::addEventColumn()**

**Description**

This method is used to add a column on which events should be detected. The column may be indicated either by its ID or its name.

You must invoke `Dictionary::createEvent()` before any errors will be detected. See `Dictionary::createEvent()`. 
If you know several columns by name, you can enable event detection on all of them at one time by using \texttt{addEventColumns()}. See \texttt{Event::addEventColumns()}. 

**Signatures**

This method can be invoked in either of the following ways:

- Identifying the event using its column ID:

  ```c
  void addEventColumn
  {
      unsigned attrId
  }
  ```

- Identifying the column by name:

  ```c
  void addEventColumn
  {
      const char* columnName
  }
  ```

**Parameters**

This method takes a single argument, which may be either one of the following:

- The column ID (\texttt{attrId}), which should be an integer greater than or equal to 0, and less than the value returned by \texttt{getNoOfEventColumns()}. 

- The column's \texttt{name} (as a constant character pointer).

**Return value**

\textit{None.}

\textbf{Event::addEventColumns()}

**Description**

This method is used to enable event detection on several columns at the same time. You must use the names of the columns.

As with \texttt{addEventColumn()}, you must invoke \texttt{Dictionary::createEvent()} before any errors will be detected. See \texttt{Dictionary::createEvent()}. 

**Signature**

```c
void addEventColumns
{
    int n,
    const char** columnNames
}
``` 

**Parameters**

This method requires the two arguments listed here:

- The number of columns \texttt{n} (an integer).

- The names of the columns \texttt{columnNames}—this must be passed as a pointer to a character pointer.

**Return value**

\textit{None.}

\textbf{Event::addTableEvent()}

**Description**

This method is used to add types of events that should be detected.

**Signature**

```c
void addTableEvent
{
    const TableEvent te
}
```
The Event Class

Parameters
This method requires a `TableEvent` value.

Return value
`None`.

Event Constructor

Description
The `Event` constructor creates a new instance with a given name, and optionally associated with a table.

You should keep in mind that the NDB API does not track allocated event objects, which means that the user must explicitly delete the `Event` thus created after it is no longer in use.

Signatures
It is possible to invoke this method in either of two ways, the first of these being by name only, as shown here:

```cpp
Event
{
  const char* name
}
```

Alternatively, you can use the event name and an associated table, like this:

```cpp
Event
{
  const char* name,
  const NdbDictionary::Table& table
}
```

Parameters
At a minimum, a `name` (as a constant character pointer) for the event is required. Optionally, an event may also be associated with a table; this argument, when present, is a reference to a `Table` object (see Section 2.3.27, “The Table Class”).

Return value
A new instance of `Event`.

Destructor.
A destructor for this class is supplied as a virtual method which takes no arguments and whose return type is `void`.

Event::EventDurability

This section provides information about `EventDurability`, a type defined by the `Event` class.

Description
The values of this type are used to describe an event’s lifetime or persistence as well as its scope.

Enumeration values
Possible values are shown, along with descriptions, in the following table:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ED_UNDEFINED</code></td>
<td>The event is undefined or of an unsupported type.</td>
</tr>
<tr>
<td><code>ED_SESSION</code></td>
<td>This event persists only for the duration of the current session, and is available only to the current application. It is deleted after the application disconnects or following a cluster restart.</td>
</tr>
</tbody>
</table>
The Event Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ED_SESSION</td>
<td>The value \texttt{ED_SESSION} is reserved for future use and is not yet supported in any NDB Cluster release.</td>
</tr>
<tr>
<td>ED_TEMPORARY</td>
<td>Any application may use the event, but it is deleted following a cluster restart.</td>
</tr>
<tr>
<td>ED_PERMANENT</td>
<td>Any application may use the event, and it persists until deleted by an application—even following a cluster restart</td>
</tr>
</tbody>
</table>

**Event::EventReport**

This section provides information about \texttt{EventReport}, a type defined by the \texttt{Event} class.

**Description**

The values of this type are used to specify reporting options for table events.

**Enumeration values**

Possible values are shown, along with descriptions, in the following table:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{ER_UPDATED}</td>
<td>Reporting of update events</td>
</tr>
<tr>
<td>\texttt{ER_ALL}</td>
<td>Reporting of all events, except for those not resulting in any updates to the inline parts of blob columns</td>
</tr>
<tr>
<td>\texttt{ER_SUBSCRIBE}</td>
<td>Reporting of subscription events</td>
</tr>
<tr>
<td>\texttt{ER_DDL}</td>
<td>Reporting of DDL events (see \texttt{Event::setReport()}, for more information)</td>
</tr>
</tbody>
</table>
### Event::getDurability()

**Description**
This method gets the event's lifetime and scope (that is, its [EventDurability](#)).

**Signature**

```cpp
definition getDurability()
    EventDurability getDurability
    (
        void
    ) const
```

**Parameters**
*None.*

**Return value**
An EventDurability value.

### Event::getEventColumn()

**Description**
This method is used to obtain a specific column from among those on which an event is defined.

**Signature**

```cpp
definition getEventColumn(unsigned no) const
```

**Parameters**
The number (no) of the column, as obtained using getNoOfColumns() (see Event::getNoOfEventColumns()).

**Return value**
A pointer to the Column corresponding to no.

### Event::getName()

**Description**
This method obtains the name of the event.

**Signature**

```cpp
definition getName()
    const char* get*
    (
        void
    ) const
```

**Parameters**
*None.*

**Return value**
The name of the event, as a character pointer.

### Event::getNoOfEventColumns()

**Description**
This method obtains the number of columns on which an event is defined.

**Signature**

```cpp
definition getNoOfEventColumns()
    int getNoOfEventColumns
    (
        void
    ) const
```

**Parameters**
*None.*

**Return value**
The number of columns (as an integer), or -1 in the case of an error.

### Event::getObjectStatus()

**Description**
This method gets the object status of the event.

**Signature**

```cpp
definition virtual Object::Status get*
    (void)
```

---

81
The Event Class

Parameters

Return value

None.
The object status of the event. For possible values, see Object::Status.

Event::getObjectVersion()

Description

This method gets the event's object version (see NDB Schema Object Versions).

Signature

virtual int getObjectVersion
{
    void
} const

Parameters

None.

Return value

The object version of the event, as an integer.

Event::getObjectId()

Description

This method retrieves an event's object ID.

Signature

virtual int getObjectId
{
    void
} const

Parameters

None.

Return value

The object ID of the event, as an integer.

Event::getReport()

Description

This method is used to obtain the reporting option in force for this event.

Signature

EventReport getReport
{
    void
} const

Parameters

None.

Return value

One of the reporting options specified in Event::EventReport.

Event::getTable()

Description

This method is used to find the table with which an event is associated. It returns a reference to the corresponding Table object. You may also obtain the name of the table directly using getTableName().

Signature

const NdbDictionary::Table* getTable
{
    void
} const

Parameters

None.

Return value

The table with which the event is associated—if there is one—as a pointer to a Table object; otherwise, this method returns NULL. (See Section 2.3.27, “The Table Class”.)
The Event Class

Event::getTableEvent()

Description This method is used to check whether a given table event will be detected.

Signature

```cpp
bool getTableEvent
(const TableEvent te) const
```

Parameters This method takes a single parameter, the table event's type—that is, a `TableEvent` value.

Return value This method returns `true` if events of `TableEvent` type `te` will be detected. Otherwise, the return value is `false`.

Event::getTableName()

Description This method obtains the name of the table with which an event is associated, and can serve as a convenient alternative to `getTable()` (See `Event::getTable()`).

Signature

```cpp
const char* getTableName
(void) const
```

Parameters None.

Return value The name of the table associated with this event, as a character pointer.

Event::mergeEvents()

Description This method is used to set the `merge events` flag, which is `false` by default. Setting it to `true` implies that events are merged as follows:

- For a given `NdbEventOperation` associated with this event, events on the same primary key within the same global checkpoint index (GCI) are merged into a single event.

- A blob table event is created for each blob attribute, and blob events are handled as part of main table events.

- Blob post/pre data from blob part events can be read via `NdbBlob` methods as a single value.

This flag is not inherited by `NdbEventOperation`, and must be set on `NdbEventOperation` explicitly.

Signature

```cpp
void mergeEvents
(bool flag)
```

Parameters A Boolean `flag` value.

Return value None.

Event::setDurability()

Description This method sets an event's durability—that is, its lifetime and scope.
The Event Class

**Event::setDurability()**

**Description**
This method requires a single `EventDurability` value as a parameter.

**Return value**
`None`.

**Event::setReport()**

**Description**
This method is used to set a reporting option for an event. Possible option values may be found in `Event::EventReport`.

**Reporting of DDL events**
You must call `setReport()` using the `EventReport` value `ER_DDL` (added in the same NDB Cluster versions).

For example, to enable DDL event reporting on an `Event` object named `myEvent`, you must invoke this method as shown here:

```c
myEvent.setReport(NdbDictionary::Event::ER_DDL);
```

**Event::setName()**

**Description**
This method is used to set the name of an event. The name must be unique among all events visible from the current application (see `Event::getDurability()`).

You can also set the event's name when first creating it. See `Event Constructor`.

**Event::setTable()**

**Description**
This method defines a table on which events are to be detected.

By default, event detection takes place on all columns in the table. Use `addEventColumn()` to override this behavior. For details, see `Event::addEventColumn()`.

You can also use a pointer with this method, as shown here:

```c
void setTable
{
    const NdbDictionary::Table*; table
```
The ForeignKey Class

Parameters
This method requires a single parameter, a reference or a pointer to the table (see Section 2.3.27, “The Table Class”) on which events are to be detected.

Return value
-1 if a null table pointer is used, otherwise null.

Event::TableEvent

This section describes TableEvent, a type defined by the Event class.

Description
TableEvent is used to classify the types of events that may be associated with tables in the NDB API.

Enumeration values
Possible values are shown, along with descriptions, in the following table:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TE_INSERT</td>
<td>Insert event on a table</td>
</tr>
<tr>
<td>TE_DELETE</td>
<td>Delete event on a table</td>
</tr>
<tr>
<td>TE_UPDATE</td>
<td>Update event on a table</td>
</tr>
<tr>
<td>TE_DROP</td>
<td>Occurs when a table is dropped</td>
</tr>
<tr>
<td>TE_ALTER</td>
<td>Occurs when a table definition is changed</td>
</tr>
<tr>
<td>TE_CREATE</td>
<td>Occurs when a table is created</td>
</tr>
<tr>
<td>TE_GCP_COMPLETE</td>
<td>Occurs on the completion of a global checkpoint</td>
</tr>
<tr>
<td>TE_CLUSTER_FAILURE</td>
<td>Occurs on Cluster failures</td>
</tr>
<tr>
<td>TE_STOP</td>
<td>Occurs when an event operation is stopped</td>
</tr>
<tr>
<td>TE_NODE_FAILURE</td>
<td>Occurs when a Cluster node fails</td>
</tr>
<tr>
<td>TE_SUBSCRIBE</td>
<td>Occurs when a cluster node subscribes to an event</td>
</tr>
<tr>
<td>TE_UNSUBSCRIBE</td>
<td>Occurs when a cluster node unsubscribes from an event</td>
</tr>
<tr>
<td>TE_EMPTY</td>
<td>Empty epoch received from data nodes</td>
</tr>
<tr>
<td>TE_INCONSISTENT</td>
<td>Missing data or buffer overflow at data node</td>
</tr>
<tr>
<td>TE_OUT_OF_MEMORY</td>
<td>Overflow in event buffer</td>
</tr>
<tr>
<td>TE_ALL</td>
<td>Occurs when any event occurs on a table (not relevant when a specific event is received)</td>
</tr>
</tbody>
</table>

TE_EMPTY, TE_INCONSISTENT, and TE_OUT_OF_MEMORY were added in NDB 7.4.

2.3.6 The ForeignKey Class

This section provides information about the ForeignKey class, which models a foreign key on an NDB table.
• ForeignKey Class Overview

• ForeignKey()

• ForeignKey::FkAction

• ForeignKey::getName()

• ForeignKey::getParentTable()

• ForeignKey::getChildTable()

• ForeignKey::getParentColumnCount()

• ForeignKey::getChildColumnCount()

• ForeignKey::getParentIndex()

• ForeignKey::getChildIndex()

• ForeignKey::getParentColumnNo()

• ForeignKey::getChildColumnNo()

• ForeignKey::getOnUpdateAction()

• ForeignKey::getOnDeleteAction()

• ForeignKey::setName()

• ForeignKey::setParent()

• ForeignKey::setChild()

• ForeignKey::setOnUpdateAction()

• ForeignKey::setOnDeleteAction()

• ForeignKey::getObjectStatus()

• ForeignKey::getObjectId()

• ForeignKey::getObjectVersion()

ForeignKey Class Overview

Parent class

Object

Child classes

None.

Methods

The following table lists the public methods of the ForeignKey class and the purpose or use of each method:

Table 2.20 ForeignKey class methods and descriptions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ForeignKey()</td>

<td>Set the foreign key's delete action (FkAction)</td>
</tr>
<tr>
<td>getObjectStatus()</td>
<td>Get the object status</td>
</tr>
<tr>
<td>getObjectId()</td>
<td>Get the object ID</td>
</tr>
<tr>
<td>getObjectVersion()</td>
<td>Get the object version</td>
</tr>
</tbody>
</table>

#### Types

The ForeignKey class has one public type, the FkAction type.

**ForeignKey()**

**Description**

Create either an entirely new foreign key reference, or a copy of an existing one.

**Signature**

New instance:

```
ForeignKey()
{
    void
}
```

Copy constructor:

```
ForeignKey(
    const ForeignKeys
)
```

**Parameters**

For a new instance: None.

For the copy constructor: A reference to an existing instance of ForeignKey.

**Return value**

A new instance of ForeignKey.

**ForeignKey::FkAction**

This section provides information about FkAction, which is an enumeration modelling a reference action for a foreign key when an update or delete operation is performed on the parent table.
The ForeignKey Class

Enumeration values

Possible values are shown, along with the corresponding reference action, in the following table:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NoAction</td>
<td>NO ACTION: Deferred check.</td>
</tr>
<tr>
<td>Restrict</td>
<td>RESTRICT: Reject operation on parent table.</td>
</tr>
<tr>
<td>Cascade</td>
<td>CASCADE: Perform operation on row from parent table; perform same operation on matching rows in child table.</td>
</tr>
<tr>
<td>SetNull</td>
<td>SET NULL: Perform operation on row from parent table; set any matching foreign key columns in child table to NULL.</td>
</tr>
<tr>
<td>SetDefault</td>
<td>SET DEFAULT: Currently not supported in NDB Cluster.</td>
</tr>
</tbody>
</table>

See also FOREIGN KEY Constraints, in the MySQL Manual.

ForeignKey::getName()

Description
Retrieve the name of the ForeignKey instance for which the method is invoked.

Signature
```cpp
const char* getName()
```

Parameters
None.

Return value
The name of the ForeignKey.

ForeignKey::getParentTable()

Description
Retrieve the parent table of the ForeignKey instance for which the method is invoked.

Signature
```cpp
const char* getParentTable()
```

Parameters
None.

Return value
A pointer to the parent table of the ForeignKey.

ForeignKey::getChildTable()

Description
Retrieve the child table of the ForeignKey instance for which the method is invoked.

Signature
```cpp
const char* getChildTable()
```

Parameters
None.

Return value
A pointer to the child table of this ForeignKey.
The ForeignKey Class

ForeignKey::getParentColumnCount()

Description
Retrieve the number of columns in the parent table of this Foreignkey.

Signature
unsigned getParentColumnCount(
    void
) const

Parameters
None.

Return value
The number of columns in the parent table.

ForeignKey::getChildColumnCount()

Description
Retrieve the number of columns in the child table of this ForeignKey.

Signature
unsigned getChildColumnCount(
    void
) const

Parameters
None.

Return value
The number of columns in the child table.

ForeignKey::getParentIndex()

Description
Returns 0 if the child table refers to the parent table’s primary key.

Signature
const char* getParentIndex(
    void
) const

Parameters
None.

Return value
See description.

ForeignKey::getChildIndex()

Description
Return 0 if child references are resolved using the child table’s primary key.

Signature
const char* getChildIndex(
    void
) const

Parameters
None.

Return value
See description.

ForeignKey::getParentColumnNo()

Description
This method gets the sequence number of a foreign key column in the parent table for a given index. See the documentation for Column::getColumnNo(), for information about handling columns in the NDB API.

Signature
int getParentColumnNo(
    
)
The ForeignKey Class

ForeignKey::getChildColumnNo()

Description
This method gets the sequence number of a foreign key column in the child table for a given index. See the documentation for Column::getColumnNo() for information about handling columns in the NDB API.

Signature
```cpp
int getChildColumnNo
{
  unsigned no
) const
```

Parameters
None.

Return value
The sequence number of the column.

ForeignKey::getOnUpdateAction()

Description
Get the foreign key's ON UPDATE action. This is a ForeignKey::FkAction and has one of the values NoAction, Restrict, Cascade, or SetNull.

Signature
```cpp
FkAction getOnUpdateAction
{
  void
) const
```

Parameters
None.

Return value
The sequence number of the column.

ForeignKey::getOnDeleteAction()

Description
Get the foreign key's ON DELETE action. This is a ForeignKey::FkAction and has one of the values NoAction, Restrict, Cascade, or SetNull.

Signature
```cpp
FkAction getOnDeleteAction
{
  void
) const
```

Parameters
None.

Return value
The sequence number of the column.

ForeignKey::setName()

Description
Set the name of the ForeignKey instance for which the method is invoked.

Signature
```cpp
void setName
{
  const char
)
```

Parameters
The name of the ForeignKey.
The ForeignKey Class

Return value

ForeignKey::setParent()
Description
Set the parent table of a ForeignKey, given a reference to the table, and optionally, an index to use as the foreign key.

Signature
void setParent
{
    const Table*,
    const Index* index = 0,
    const Column* cols[] = 0
}

Parameters
A reference to a Table (required). Optionally, an index using the indicated column or columns.

Return value
None.

ForeignKey::setChild()
Description
Set the child table of a ForeignKey, given a reference to the table, and optionally, an index to use as the foreign key.

Signature
void setChild
{
    const Table*,
    const Index* index = 0,
    const Column* cols[] = 0
}

Parameters
A reference to a Table (required). Optionally, an index using the indicated column or columns.

Return value
None.

ForeignKey::setOnUpdateAction()
Description
Set the foreign key's ON UPDATE action.

Signature
void setOnUpdateAction
{
    FkAction
}

Parameters
The ON UPDATE action to be performed. This must be a ForeignKey::FkAction having one of the values NoAction, Restrict, Cascade, or SetNull.

Return value
None

ForeignKey::setOnDeleteAction()
Description
Set the foreign key's ON DELETE action.

Signature
void setOnUpdateAction
{
    FkAction
}

Parameters
The ON UPDATE action to be performed, of type ForeignKey::FkAction. Must be one of the values NoAction, Restrict, Cascade, or SetNull.

Return value
None
The HashMap Class

ForeignKey::getObjectStatus()

Description Get the object status (see Object::Status) for this ForeignKey object.

Signature

```c++
virtual Object::Status getObjectStatus
{
    void
} const
```

Parameters None.

Return value The ForeignKey object’s status, as a value of type Object::Status. See this type’s documentation for possible values and their interpretation.

ForeignKey::getObjectId()

Description Get the object ID (see Object::getObjectId()) for this ForeignKey object.

Signature

```c++
virtual int getObjectId
{
    void
} const
```

Parameters None.

Return value The ForeignKey object’s ID, as returned by Object::getObjectId().

ForeignKey::getObjectVersion()

Description Get the object version (see Object::getObjectVersion()) for this ForeignKey object.

Signature

```c++
virtual int getObjectVersion
{
    void
} const
```

Parameters None.

Return value The ForeignKey object’s version number (an integer), as returned by Object::getObjectVersion().

2.3.7 The HashMap Class

This section provides information about the HashMap class, which models a hash map in an NDB Cluster.

- HashMap Class Overview
- HashMap Constructor
- HashMap::setName()
- HashMap::getName()
- HashMap::setMap()
- HashMap::getMapLen()
- HashMap::getMapValues()
The HashMap Class

- HashMap::equal()
- HashMap::getObjectStatus()
- HashMap::getObjectVersion()
- HashMap::getObjectId()

HashMap Class Overview

Parent class
Object

Child classes
None.

Methods
The following table lists the public methods of the HashMap class and the purpose or use of each method:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HashMap()</td>
<td>Class constructor</td>
</tr>
<tr>
<td>~HashMap()</td>
<td>Class destructor</td>
</tr>
<tr>
<td>setName()</td>
<td>Set a name for the hashmap</td>
</tr>
<tr>
<td>getName()</td>
<td>Gets a hashmap's name</td>
</tr>
<tr>
<td>setMap()</td>
<td>Sets a hashmap's length and values</td>
</tr>
<tr>
<td>getMapLen()</td>
<td>Gets a hashmap's length</td>
</tr>
<tr>
<td>getMapValues()</td>
<td>Gets the values contained in the hashmap</td>
</tr>
<tr>
<td>equal()</td>
<td>Compares this hashmap's values with those of another hashmap</td>
</tr>
<tr>
<td>getObjectStatus()</td>
<td>Gets the hashmap's object status</td>
</tr>
<tr>
<td>getObjectVersion()</td>
<td>Gets the hashmap's schema object version</td>
</tr>
<tr>
<td>getId()</td>
<td>Gets the hashmap's ID</td>
</tr>
</tbody>
</table>

Types
The HashMap class defines no public types.

HashMap Constructor

Description
The HashMap class constructor normally requires no arguments. A copy constructor is also available.

See also Dictionary::createHashMap(), for more information.

Signature
Base constructor:

```cpp
HashMap HashMap()
{
    void
}
```

Copy constructor:

```cpp
HashMap HashMap(const HashMap& hashmap)
```

Destructor:

```cpp
virtual ~HashMap
```
The HashMap Class

```cpp
{  
    void
}
```

Parameters: None, or the address of an existing HashMap object to be copied.

Return value: A new instance of HashMap, possibly a copy of an existing one.

HashMap::setName()

Description: Sets the name of the hash map.

Signature:
```cpp
void setName
{
    const char* name
}
```

Parameters: The name to be assigned to the hashmap.

Return value: None.

HashMap::getName()

Description: Gets the name of the hash map.

Signature:
```cpp
const char* getName
{
    void
} const
```

Parameters: None.

Return value: The name of the hash map.

HashMap::setMap()

Description: Assigns a set of values to a has map.

Signature:
```cpp
void setMap
{
    const Uint32* values,
    Uint32 len
}
```

Parameters: A pointer to a set of values of length len.

Return value: None.

HashMap::getMapLen()

Description: Gets the hash map's length; that is, the number of values which it contains. You can obtain the values using getMapValues().

Signature:
```cpp
Uint32 getMapLen
{
    void
} const
```

Parameters: None.

Return value: The length of the hash map.

HashMap::getMapValues()

Description: Gets the values listed in the hash map.
**Signature**

```c++
int getMapValues
{
    Uint32* dst,
    Uint32 len
} const
```

**Parameters**
A pointer to a set of values (`dst`) and the number of values (`len`).

**Return value**
Returns 0 on success; on failure, returns -1 and sets error.

**HashMap::equal()**

**Description**
Compares (only) the values of this `HashMap` with those of another one.

**Signature**
```c++
bool equal
{
    const HashMap& hashmap
} const
```

**Parameters**
A reference to the hash map to be compared with this one.

**Return value**
`None`.

**HashMap::getObjectStatus()**

**Description**
This method retrieves the status of the `HashMap` for which it is invoked. The return value is of type `Object::Status`.

**Signature**
```c++
virtual Status getObjectStatus
{
    void
} const
```

**Parameters**
`None`.

**Return value**
Returns the current `Status` of the `HashMap`.

**HashMap::getObjectVersion()**

**Description**
The method gets the hash map's schema object version.

**Signature**
```c++
virtual int getObjectVersion
{
    void
} const
```

**Parameters**
`None`.

**Return value**
The object's version number, an integer.

**HashMap::getObjectId()**

**Description**
This method retrieves the hash map's ID.

**Signature**
```c++
virtual int getObjectId
{
    void
} const
```

**Parameters**
`None`.

**Return value**
The object ID, an integer.

## 2.3.8 The Index Class
The Index Class

This section provides information about the Index class.

- Index Class Overview
- Index Class Constructor
- Index::addColumn()
- Index::addColumnName()
- Index::addColumnNames()
- Index::getColumn()
- Index::getLogging()
- Index::setName()
- Index::getNoOfColumns()
- Index::getObjectStatus()
- Index::getObjectVersion()
- Index::getObjectId()
- Index::getTable()
- Index::getType()
- Index::setLogging
- Index::setName()
- Index::setTable()
- Index::setType()
- Index::Type

Index Class Overview

Parent class

NdbDictionary

Child classes

None

Description

This class represents an index on an NDB Cluster table column. It is a descendant of the NdbDictionary class, using the Object class.

If you create or change indexes using the NDB API, these modifications cannot be seen by MySQL. The only exception to this is using Index::setName() to rename the index.

Methods

The following table lists the public methods of Index and the purpose or use of each method:

Table 2.23 Index class methods and descriptions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Index()</td>
<td>Class constructor</td>
</tr>
<tr>
<td>~Index()</td>
<td>Destructor</td>
</tr>
<tr>
<td>addColumn()</td>
<td>Adds a Column object to the index</td>
</tr>
</tbody>
</table>
## The Index Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>addColumnName()</td>
<td>Adds a column by name to the index</td>
</tr>
<tr>
<td>addColumnNames()</td>
<td>Adds multiple columns by name to the index</td>
</tr>
<tr>
<td>getColumn()</td>
<td>Gets a column making up (part of) the index</td>
</tr>
<tr>
<td>getLogging()</td>
<td>Checks whether the index is logged to disk</td>
</tr>
<tr>
<td>getName()</td>
<td>Gets the name of the index</td>
</tr>
<tr>
<td>getNoOfColumns()</td>
<td>Gets the number of columns belonging to the index</td>
</tr>
<tr>
<td>getObjectStatus()</td>
<td>Gets the index object status</td>
</tr>
<tr>
<td>getObjectVersion()</td>
<td>Gets the index object status</td>
</tr>
<tr>
<td>getObjectID()</td>
<td>Gets the index object ID</td>
</tr>
<tr>
<td>getTable()</td>
<td>Gets the name of the table being indexed</td>
</tr>
<tr>
<td>getType()</td>
<td>Gets the index type</td>
</tr>
<tr>
<td>setLogging()</td>
<td>Enable/disable logging of the index to disk</td>
</tr>
<tr>
<td>setName()</td>
<td>Sets the name of the index</td>
</tr>
<tr>
<td>setTable()</td>
<td>Sets the name of the table to be indexed</td>
</tr>
<tr>
<td>setType()</td>
<td>Set the index type</td>
</tr>
</tbody>
</table>

### Types

[Index](#) defines one public type, the **Type** type.

### Index Class Constructor

**Description**

This is used to create an new instance of [Index](#).

Indexes created using the NDB API cannot be seen by the MySQL Server.

**Signature**

```cpp
Index
{
    const char* name = ""
}
```

**Parameters**

The name of the new index. It is possible to create an index without a name, and then assign a name to it later using `setName()`. See `Index::setName()`.

**Return value**

A new instance of [Index](#).

**Destructor**

The destructor (`~Index()`) is supplied as a virtual method.

### Index::addColumn()

**Description**

This method may be used to add a column to an index.

The order of the columns matches the order in which they are added to the index. However, this matters only with ordered indexes.

**Signature**

```cpp
void addColumn
(
    const Column& c
)
```

**Parameters**

A reference `c` to the column which is to be added to the index.
Index::addColumnName()

Description This method works in the same way asaddColumn(), except that it takes the name of the column as a parameter. See Index::getColumn().

Signature

```cpp
void addColumnName
(  
  const char* name
)
```

Parameters The name of the column to be added to the index, as a constant character pointer.

Return value None.

Index::addColumnNames()

Description This method is used to add several column names to an index definition at one time.

As with theaddColumn() and addColumnName() methods, the indexes are numbered in the order in which they were added. This normally matters only for ordered indexes.

Signature

```cpp
void addColumnNames
(  
  unsigned noOfNames,  
  const char** names
)
```

Parameters This method takes two parameters, listed here:

- The number of columns and names noOfNames to be added to the index.
- The names to be added (as a pointer to a pointer).

Return value None.

Index::getColumn()

Description This method retrieves the column at the specified position within the index.

Signature

```cpp
const Column* getColumn
(  
  unsigned no
) const
```

Parameters The ordinal position number no of the column, as an unsigned integer. Use thegetNoOfColumns() method to determine how many columns make up the index—see Index::getNoOfColumns(), for details.

Return value The column having position no in the index, as a pointer to an instance of Column. See Section 2.3.1, “The Column Class”.

Index::getLogging()

Description Use this method to determine whether logging to disk has been enabled for the index.
Indexes which are not logged are rebuilt when the cluster is started or restarted.

Ordered indexes currently do not support logging to disk; they are rebuilt each time the cluster is started. (This includes restarts.)

**Signature**

```cpp
bool getLogging
()
) const
```

**Parameters**  
None.

**Return value**  
A Boolean value:

- **true**: The index is being logged to disk.
- **false**: The index is not being logged.

---

**Index::getName()**

**Description**  
This method is used to obtain the name of an index.

**Signature**

```cpp
const char* getName
()
) const
```

**Parameters**  
None.

**Return value**  
The name of the index, as a constant character pointer.

---

**Index::getNoOfColumns()**

**Description**  
This method is used to obtain the number of columns making up the index.

**Signature**

```cpp
unsigned getNoOfColumns
()
) const
```

**Parameters**  
None.

**Return value**  
An unsigned integer representing the number of columns in the index.

---

**Index::getObjectStatus()**

**Description**  
This method gets the object status of the index.

**Signature**

```cpp
virtual Object::Status getObjectStatus
()
) const
```

**Parameters**  
None.

**Return value**  
A `Status` value; see `Object::Status`, for more information.

---

**Index::getObjectVersion()**

**Description**  
This method gets the object version of the index (see `NDB Schema Object Versions`).
The Index Class

**Signature**

```cpp
virtual int getObjectVersion( ) const
{
    void
} const
```

**Parameters**

*None.*

**Return value**

The object version for the index, as an integer.

**Index::getObjectId()**

**Description**

This method is used to obtain the object ID of the index.

**Signature**

```cpp
virtual int getObjectId( ) const
{
    void
} const
```

**Parameters**

*None.*

**Return value**

The object ID, as an integer.

**Index::getTable()**

**Description**

This method can be used to obtain the name of the table to which the index belongs.

**Signature**

```cpp
const char* getTable( ) const
{
    void
} const
```

**Parameters**

*None.*

**Return value**

The name of the table, as a constant character pointer.

**Index::getType()**

**Description**

This method can be used to find the type of index.

**Signature**

```cpp
Type getType( ) const
{
    void
} const
```

**Parameters**

*None.*

**Return value**

An index type. See `Index::Type`, for possible values.

**Index::setLogging**

**Description**

This method is used to enable or disable logging of the index to disk.

**Signature**

```cpp
void setLogging( bool enable)
{
}
```

**Parameters**

`setLogging()` takes a single Boolean parameter `enable`. If `enable` is `true`, then logging is enabled for the index; if false, then logging of this index is disabled.

**Return value**

*None.*
The Index Class

**Index::setName()**

Description

This method sets the name of the index.

This is the only `Index::set*()` method whose result is visible to a MySQL Server.

Signature

```cpp
void setName
{
    const char* name
}
```

Parameters

The desired `name` for the index, as a constant character pointer.

Return value

`None`.

**Index::setTable()**

Description

This method sets the table that is to be indexed. The table is referenced by name.

Signature

```cpp
void setTable
{
    const char* name
}
```

Parameters

The `name` of the table to be indexed, as a constant character pointer.

Return value

`None`.

**Index::setType()**

Description

This method is used to set the index type.

Signature

```cpp
void setType
{
    Type type
}
```

Parameters

The `type` of index. For possible values, see `Index::Type`.

Return value

`None`.

**Index::Type**

This section provides information about the `Index` type.

Description

This is an enumerated type which describes the sort of column index represented by a given instance of `Index`.

Do not confuse this enumerated type with `Object::Type`, or with `Column::Type`.

Enumeration values

Possible values are shown, along with descriptions, in the following table:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Undefined</td>
<td>Undefined object type (initial/default value)</td>
</tr>
<tr>
<td>UniqueHashIndex</td>
<td>Unique unordered hash index (only index type currently supported)</td>
</tr>
</tbody>
</table>
2.3.9 The LogfileGroup Class

This section provides information about the LogfileGroup class, which models an NDB Cluster Disk Data log file group.

-LogFileGroup Class Overview
-LogFileGroup Constructor
-LogFileGroup::getAutoGrowSpecification()
-LogFileGroup::getName()
-LogFileGroup::getObjectId()
-LogFileGroup::getObjectStatus()
-LogFileGroup::getObjectVersion()
-LogFileGroup::getUndoBufferSize()
-LogFileGroup::getUndoFreeWords()
-LogFileGroup::setAutoGrowSpecification()
-LogFileGroup::setName()
-LogFileGroup::setUndoBufferSize()

LogFileGroup Class Overview

Parent class: NdbDictionary
Child classes: None
Description: This class represents an NDB Cluster Disk Data log file group, which is used for storing Disk Data undo files. For general information about log file groups and undo files, see NDB Cluster Disk Data Tables, in the MySQL Manual.

Only unindexed column data can be stored on disk. Indexes and indexes columns are always stored in memory.

Methods: The following table lists the public methods of this class and the purpose or use of each method:

Table 2.25 LogfileGroup class methods and descriptions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LogfileGroup()</td>
<td>Class constructor</td>
</tr>
<tr>
<td>~LogFileGroup()</td>
<td>Virtual destructor</td>
</tr>
<tr>
<td>getAutoGrowSpecification()</td>
<td>Gets the log file group's AutoGrowSpecification values</td>
</tr>
<tr>
<td>getName()</td>
<td>Retrieves the log file group's name</td>
</tr>
<tr>
<td>getObjectId()</td>
<td>Get the object ID of the log file group</td>
</tr>
<tr>
<td>getObjectStatus()</td>
<td>Gets the log file group's object status value</td>
</tr>
</tbody>
</table>
The LogfileGroup Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getObjectVersion()</td>
<td>Retrieves the log file group's object version</td>
</tr>
<tr>
<td>getUndoBufferSize</td>
<td>Gets the size of the log file group's undo buffer</td>
</tr>
<tr>
<td>getUndoFreeWords</td>
<td>Retrieves the amount of free space in the undo buffer</td>
</tr>
<tr>
<td>setAutoGrowSpecification()</td>
<td>Sets <code>AutoGrowSpecification</code> values for the log file group</td>
</tr>
<tr>
<td>setName()</td>
<td>Sets the name of the log file group</td>
</tr>
<tr>
<td>setUndoBufferSize</td>
<td>Sets the size of the log file group's undo buffer</td>
</tr>
</tbody>
</table>

Types

While the LogfileGroup class does not itself define any public types, two of its methods make use of the `AutoGrowSpecification` data structure as a parameter or return value.

LogfileGroup Constructor

**Description**

The LogfileGroup class has two public constructors, one of which takes no arguments and creates a completely new instance. The other is a copy constructor.

The Dictionary class also supplies methods for creating and destroying LogfileGroup objects. See Section 2.3.3, "The Dictionary Class".

**Signatures**

- **New instance:**

  ```cpp
  LogfileGroup()
  {
    void
  }
  ```

- **Copy constructor:**

  ```cpp
  LogfileGroup(const LogfileGroup& logfileGroup)
  {
    const LogfileGroup& logfileGroup
  }
  ```

**Parameters**

When creating a new instance, the constructor takes no parameters. When copying an existing instance, the constructor is passed a reference to the LogfileGroup instance to be copied.

**Return value**

A LogfileGroup object.

**Destructor**

```cpp
virtual ~LogfileGroup()
{
  void
}
```
The LogfileGroup Class

**LogfileGroup::getName()**

Description: This method gets the name of the log file group.

Signature:
```cpp
const char* getName()
{
    void
} const
```

Parameters: None.

Return value: The logfile group's name, a string (as a character pointer).

**LogfileGroup::getObjectId()**

Description: This method is used to retrieve the object ID of the log file group.

Signature:
```cpp
virtual int getObjectId()
{
    void
} const
```

Parameters: None.

Return value: The log file group's object ID (an integer value).

**LogfileGroup::getObjectStatus()**

Description: This method is used to obtain the object status of the LogfileGroup.

Signature:
```cpp
virtual Object::Status getObjectStatus()
{
    void
} const
```

Parameters: None.

Return value: The logfile group's Status—see Object::Status for possible values.

**LogfileGroup::getObjectVersion()**

Description: This method gets the log file group's object version (see NDB Schema Object Versions).

Signature:
```cpp
virtual int getObjectVersion()
{
    void
} const
```

Parameters: None.

Return value: The object version of the log file group, as an integer.

**LogfileGroup::getUndoBufferSize()**

Description: This method retrieves the size of the log file group's undo buffer.

Signature:
```cpp
Uint32 getUndoBufferSize()
{
    void
```
The List Class

Parameters

Return value

None.
The size of the undo buffer, in bytes.

LogfileGroup::getUndoFreeWords()

Description
This method retrieves the number of bytes unused in the log file group's undo buffer.

Signature

Parameters

Return value

None.
The number of bytes free, as a 64-bit integer.

LogfileGroup::setAutoGrowSpecification()

Description
This method sets the AutoGrowSpecification data for the log file group.

Signature

Parameters
The data is passed as a single parameter, an AutoGrowSpecification data structure.

Return value
None.

LogfileGroup::setName()

Description
This method is used to set a name for the log file group.

Signature

Parameters
The name to be given to the logfile group (character pointer).

Return value
None.

LogfileGroup::setUndoBufferSize()

Description
This method can be used to set the size of the log file group's undo buffer.

Signature

Parameters
The size in bytes for the undo buffer (using a 32-bit unsigned integer value).

Return value
None.

2.3.10 The List Class
This section provides information about the **List** class.

**Parent class**  
Dictionary

**Child classes**  
Element (structure)

**Description**  
The **List** class is a **Dictionary** subclass that is used for representing lists populated by the methods **Dictionary::listObjects()**, **Dictionary::listIndexes()**, and **Dictionary::listEvents()**.

**Methods**  
Beginning with NDB 8.0.29, this class has three methods, listed here:

- a constructor (**List()**)
- a destructor (**~List()**)
- a **clear()** method

None of the methods just listed take any arguments.

Calling the constructor creates a new **List** whose **count** and **elements** attributes are both set equal to **0**.

The **clear()** method, introduced in NDB 8.0.29, removes all data from the list. You can use this to prepare an existing **List** for reuse with **listEvents()**, **listIndexes()**, or **listObjects()**.

The destructor (**~List()**) removes all elements and their properties. Beginning with NDB 8.0.29, it first invokes **clear()** before doing so.

The definition of this class can be found in `/storage/ndb/include/ndbapi/NdbDictionary.hpp`.

**Attributes**  
A **List** has the following two attributes:

- **count**, an unsigned integer, which stores the number of elements in the list.
- **elements**, a pointer to an array of **Element** data structures contained in the list. See Section 2.3.4, "The Element Structure".

**Types**  
The **List** class also defines the **Element** structure.

### 2.3.11 The Ndb Class

This section provides information about the **Ndb** class, which models the **NDB** kernel; it is the primary class of the NDB API.

- Ndb Class Overview
- Ndb Class Constructor
- Ndb::closeTransaction()
- Ndb::computeHash()
- Ndb::createEventOperation()
- Ndb::dropEventOperation()
- Ndb::EventBufferMemoryUsage
- Ndb::getDictionary()
- Ndb::getDatabaseName()
- Ndb::getDatabaseSchemaName()
- Ndb::getGCIEventOperations() (DEPRECATED)
- Ndb::get_eventbuf_max_alloc()
- Ndb::get_eventbuffer_free_percent()
- Ndb::get_event_buffer_memory_usage()
- Ndb::getHighestQueuedEpoch()
- Ndb::getLatestGCI() (DEPRECATED)
- Ndb::getNdbError()
- Ndb::getNdbErrorDetail()
- Ndb::getNdbObjectName()
- Ndb::getNextEventOpInEpoch2()
- Ndb::getNextEventOpInEpoch3()
- Ndb::getReference()
- Ndb::init()
- Ndb::isConsistent() (DEPRECATED)
- Ndb::isConsistentGCI() (DEPRECATED)
- Ndb::isExpectingHigherQueuedEpochs()
- Ndb::Key_part_ptr
- Ndb::nextEvent() (DEPRECATED)
- Ndb::nextEvent2()
- Ndb::PartitionSpec
- Ndb::pollEvents()
- Ndb::pollEvents2()
- Ndb::setDatabaseName()
- Ndb::setDatabaseSchemaName()
- Ndb::setEventBufferQueueEmptyEpoch()
- Ndb::set_eventbuf_max_alloc()
- Ndb::set_eventbuffer_free_percent()
- Ndb::setNdbObjectName()
The Ndb Class

- Ndb::startTransaction()

Ndb Class Overview

Parent class

None

Child classes

None

Description

Any nontrivial NDB API program makes use of at least one instance of Ndb. By using several Ndb objects, it is possible to implement a multithreaded application. You should remember that one Ndb object cannot be shared between threads; however, it is possible for a single thread to use multiple Ndb objects. A single application process can support a maximum of 4711 Ndb objects.

Methods

The following table lists the public methods of this class and the purpose or use of each method:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ndb()</td>
<td>Class constructor; represents a connection to an NDB Cluster.</td>
</tr>
<tr>
<td>~Ndb()</td>
<td>Class destructor; terminates a Cluster connection when it is no longer to be used</td>
</tr>
<tr>
<td>closeTransaction()</td>
<td>Closes a transaction.</td>
</tr>
<tr>
<td>computeHash()</td>
<td>Computes a distribution hash value.</td>
</tr>
<tr>
<td>createEventOperation()</td>
<td>Creates a subscription to a database event. (See Section 2.3.16, “The NdbEventOperation Class”.)</td>
</tr>
<tr>
<td>dropEventOperation()</td>
<td>Drops a subscription to a database event.</td>
</tr>
<tr>
<td>getDictionary()</td>
<td>Gets a dictionary, which is used for working with database schema information.</td>
</tr>
<tr>
<td>getDatabaseName()</td>
<td>Gets the name of the current database.</td>
</tr>
<tr>
<td>getDatabaseSchemaName()</td>
<td>Gets the name of the current database schema.</td>
</tr>
<tr>
<td>get_eventbuf_max_alloc()</td>
<td>Gets the current allocated maximum size of the event buffer.</td>
</tr>
<tr>
<td>get_eventbuffer_free_percent()</td>
<td>Gets the percentage of event buffer memory that should be available before buffering resumes, once the limit has been reached. Added in NDB 7.4.</td>
</tr>
<tr>
<td>get_event_buffer_memory_usage()</td>
<td>Provides event buffer memory usage information. Added in NDB 7.4.</td>
</tr>
<tr>
<td>getGCIEventOperations()</td>
<td>Gets the next event operation from a GCI. Deprecated in NDB 7.4.</td>
</tr>
<tr>
<td>getLatestQueuedEpoch()</td>
<td>Gets the latest epoch in the event queue. Deprecated in NDB 7.4.</td>
</tr>
<tr>
<td>getLatestGCI()</td>
<td>Gets the most recent GCI. Deprecated in NDB 7.4.</td>
</tr>
<tr>
<td>getNdbError()</td>
<td>Retrieves an error. (See Section 2.3.15, “The NdbError Structure”.)</td>
</tr>
<tr>
<td>getNdbErrorDetail()</td>
<td>Retrieves extra error details.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>getNdbObjectName()</td>
<td>Retrieves the Ndb object name if one was set.</td>
</tr>
<tr>
<td>getNextEventOpInEpoch2()</td>
<td>Gets the next event operation in this global checkpoint.</td>
</tr>
<tr>
<td>getNextEventOpInEpoch3()</td>
<td>Gets the next event operation in this global checkpoint, showing any received anyvalues. Added in NDB 7.4.18 and 7.5.9.</td>
</tr>
<tr>
<td>getReference()</td>
<td>Retrieves a reference or identifier for the Ndb object instance.</td>
</tr>
<tr>
<td>init()</td>
<td>Initializes an Ndb object and makes it ready for use.</td>
</tr>
<tr>
<td>isConsistent()</td>
<td>Whether all received events are consistent. Deprecated in NDB 7.4.</td>
</tr>
<tr>
<td>isConsistentGCI()</td>
<td>Whether all received events for a given global checkpoint are consistent.</td>
</tr>
<tr>
<td></td>
<td>Deprecated in NDB 7.4.</td>
</tr>
<tr>
<td>isExpectingHigherQueuedEpochs()</td>
<td>Check whether there are new queued epochs, or there was a cluster failure event. Added in NDB 7.4.7.</td>
</tr>
<tr>
<td>nextEvent()</td>
<td>Gets the next event from the queue.</td>
</tr>
<tr>
<td></td>
<td>Deprecated in NDB 7.4.</td>
</tr>
<tr>
<td>nextEvent2()</td>
<td>Gets the next event from the queue.</td>
</tr>
<tr>
<td></td>
<td>Added in NDB 7.4.</td>
</tr>
<tr>
<td>pollEvents()</td>
<td>Waits for an event to occur.</td>
</tr>
<tr>
<td></td>
<td>Deprecated in NDB 7.4.</td>
</tr>
<tr>
<td>pollEvents2()</td>
<td>Waits for an event to occur.</td>
</tr>
<tr>
<td></td>
<td>Added in NDB 7.4.</td>
</tr>
<tr>
<td>setDatabaseName()</td>
<td>Sets the name of the current database.</td>
</tr>
<tr>
<td>setDatabaseSchemaName()</td>
<td>Sets the name of the current database schema.</td>
</tr>
<tr>
<td>setEventBufferQueueEmptyEpoch()</td>
<td>Enables queuing of empty events. Added in NDB 7.4.11.</td>
</tr>
<tr>
<td>set_eventbuf_max_alloc()</td>
<td>Sets the current allocated maximum size of the event buffer.</td>
</tr>
<tr>
<td>set_eventbuffer_free_percent()</td>
<td>Sets the percentage of event buffer memory that should be available before buffering resumes, once the limit has been reached. Added in NDB 7.4.</td>
</tr>
<tr>
<td>setNdbObjectName()</td>
<td>For debugging purposes: sets an arbitrary name for this Ndb object.</td>
</tr>
<tr>
<td>startTransaction()</td>
<td>Begins a transaction. (See Section 2.3.25, &quot;The NdbTransaction Class&quot;.)</td>
</tr>
</tbody>
</table>
The Ndb Class

Types

The Ndb class does not define any public types but does define three data structures, which are listed here:

- EventBufferMemoryUsage
- Key_part_ptr
- PartitionSpec.

Resource consumption by Ndb objects. An Ndb object consumes memory in proportion to the size of the largest operation performed over the lifetime of the object. This is particularly noticeable in cases of large transactions, use of blob columns, or both. This memory is held for the lifetime of the object, and once used in this way by the Ndb object, the only way to free this memory is to destroy the object (and then to create a new instance if desired).

Note

The Ndb object is multithread safe in that each Ndb object can be handled by one thread at a time. If an Ndb object is handed over to another thread, then the application must ensure that a memory barrier is used to ensure that the new thread sees all updates performed by the previous thread.

Semaphores and mutexes are examples of easy ways to provide memory barriers without having to bother about the memory barrier concept.

It is also possible to use multiple Ndb objects to perform operations on different clusters in a single application. See Section 1.5, “Application-level partitioning”, for conditions and restrictions applying to such usage.

Ndb Class Constructor

Description

This creates an instance of Ndb, which represents a connection to the NDB Cluster. All NDB API applications should begin with the creation of at least one Ndb object. This requires the creation of at least one instance of Ndb_cluster_connection, which serves as a container for a cluster connection string.

Signature

Ndb

{    
    Ndb_cluster_connection* ndb_cluster_connection,    
    const char* catalogName = "",    
    const char* schemaName = "def"    
}

Parameters

The Ndb class constructor can take up to 3 parameters, of which only the first is required:

- ndb_cluster_connection is an instance of Ndb_cluster_connection, which represents a cluster connection string. (See Section 2.3.12, “The Ndb_cluster_connection Class”.)

- catalogName is an optional parameter providing a namespace for the tables and indexes created in any connection from the Ndb object.

This is equivalent to what mysqld considers “the database”.

The default value for this parameter is an empty string.

- The optional schemaName provides an additional namespace for the tables and indexes created in a given catalog.
The default value for this parameter is the string “def”.

Return value

An Ndb object.

Destructor

The destructor for the Ndb class should be called in order to terminate an instance of Ndb. It requires no arguments, nor any special handling.

**Ndb::closeTransaction()**

Description

This is one of two NDB API methods provided for closing a transaction (the other being NdbTransaction::close()). You must call one of these two methods to close the transaction once it has been completed, whether or not the transaction succeeded.

If the transaction has not yet been committed, it is aborted when this method is called. See Ndb::startTransaction().

Signature

```cpp
void closeTransaction
{
    NdbTransaction *transaction
}
```

Parameters

This method takes a single argument, a pointer to the NdbTransaction to be closed.

Return value

None (void).

**Ndb::computeHash()**

Description

This method can be used to compute a distribution hash value, given a table and its keys.

computeHash() can be used only for tables that use native NDB partitioning.

Signature

```cpp
static int computeHash
{
    Uint32* hashvalueptr,
    const NdbDictionary::Table* table,
    const struct Key_part_ptr* keyData,
    void* xfrmbuf = 0,
    Uint32 xfrmbuflen = 0
}
```

Parameters

This method takes the following parameters:

- If the method call is successful, hashvalueptr is set to the computed hash value.

- A pointer to a table (see Section 2.3.27, “The Table Class”).

- keyData is a null-terminated array of pointers to the key parts that are part of the table’s distribution key. The length of each key part is read from metadata and checked against the passed value (see Ndb::Key_part_ptr).

- xfrmbuf is a pointer to temporary buffer used to calculate the hash value.

- xfrmbuflen is the length of this buffer.
If `xfrmbuf` is NULL (the default), then a call to `malloc()` or `free()` is made automatically, as appropriate.

Prior to NDB 7.5.30, 7.6.26, 8.0.33: `computeHash()` fails if `xfrmbuf` is not NULL and `xfrmbuflen` is too small.

NDB 7.5.30 and later, 7.6.26 and later, 8.0.33 and later: If the buffer passed is not of sufficient size, a temporary buffer is allocated automatically. (Bug #103814, Bug #32959894)

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>When <code>malloc()</code> provides a buffer to this method, the buffer is explicitly aligned after it is allocated, and before it is actually used. (Bug #16484617)</td>
</tr>
</tbody>
</table>

Return value 0 on success, an error code on failure. If the method call succeeds, the computed hash value is made available through `hashvalueptr`.

**Ndb::createEventOperation()**

**Description**
This method creates a subscription to a database event.

NDB API event subscriptions do not persist after an NDB Cluster has been restored using `ndb_restore`; in such cases, all of the subscriptions must be recreated explicitly.

**Signature**
```cpp
NdbEventOperation* createEventOperation
{
  const char *eventName
}
```

**Parameters**
This method takes a single argument, the unique `eventName` identifying the event to which you wish to subscribe.

**Return value**
A pointer to an `NdbEventOperation` object (or NULL, in the event of failure). See [Section 2.3.16, “The NdbEventOperation Class”](#).

**Ndb::dropEventOperation()**

**Description**
This method drops a subscription to a database event represented by an `NdbEventOperation` object.

Memory used by an event operation which has been dropped is not freed until the event buffer has been completely read. This means you must continue to call `pollEvents()` and `nextEvent()` in such cases until these methods return 0 and NULL, respectively in order for this memory to be freed.

**Signature**
```cpp
int dropEventOperation
{
  NdbEventOperation *eventOp
}
```

**Parameters**
This method requires a single input parameter, a pointer to an instance of `NdbEventOperation`.

**Return value**
0 on success; any other result indicates failure.

**Ndb::EventBufferMemoryUsage**
This section describes the `EventBufferMemoryUsage` structure.

**Parent class**  
`Ndb`

**Description**  
This structure was added in NDB 7.4 for working with event buffer memory usage statistics. It is used as an argument to `Ndb::get_event_buffer_memory_usage()`.

**Attributes**  
`EventBufferMemoryUsage` has the attributes shown in the following table:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Initial Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>allocated_bytes</td>
<td>unsigned</td>
<td>none</td>
<td>The total event buffer memory allocated, in bytes</td>
</tr>
<tr>
<td>used_bytes</td>
<td>unsigned</td>
<td>none</td>
<td>The total memory used, in bytes</td>
</tr>
<tr>
<td>usage_percent</td>
<td>unsigned</td>
<td>none</td>
<td>Event buffer memory usage, as a percent (100 \times \frac{\text{used_bytes}}{\text{allocated_bytes}})</td>
</tr>
</tbody>
</table>

**Ndb::getDictionary()**

**Description**  
This method is used to obtain an object for retrieving or manipulating database schema information. This `Dictionary` object contains meta-information about all tables in the cluster.

The dictionary returned by this method operates independently of any transaction. See Section 2.3.3, "The Dictionary Class", for more information.

**Signature**  
```cpp
NdbDictionary::Dictionary* getDictionary()
{
    void
} const
```

**Parameters**  
None.

**Return value**  
An instance of the `Dictionary` class.

**Ndb::getDatabaseName()**

**Description**  
This method can be used to obtain the name of the current database.

**Signature**  
```cpp
const char* getDatabaseName()
{
    void
}
```

**Parameters**  
None.

**Return value**  
The name of the current database.

**Ndb::getDatabaseSchemaName()**

**Description**  
This method can be used to obtain the current database schema name.
The Ndb Class

**Signature**

```c
const char* getDatabaseSchemaName
{
    void
}
```

**Parameters**

None.

**Return value**

The name of the current database schema.

**Ndb::getGCIEventOperations() (DEPRECATED)**

**Description**

Iterates over distinct event operations which are part of the current GCI, becoming valid after calling `nextEvent()`. You can use this method to obtain summary information for the epoch (such as a list of all tables) before processing the event data.

This method is deprecated, and subject to removal in a future release. Where possible, use `getNextEventOpInEpoch2()` instead.

**Signature**

```c
const NdbEventOperation* getGCIEventOperations
{
    Uint32* iter,
    Uint32* event_types
}
```

**Parameters**

An iterator and a mask of event types. Set `*iter=0` to start.

**Return value**

The next event operation; returns `NULL` when there are no more event operations. If `event_types` is not `NULL`, then after calling the method it contains a bitmask of the event types received.

**Ndb::get_eventbuf_max_alloc()**

**Description**

Gets the maximum memory, in bytes, that can be used for the event buffer. This is the same as reading the value of the `ndb_eventbuffer_max_alloc` system variable in the MySQL Server.

**Signature**

```c
unsigned get_eventbuf_max_alloc
{
    void
}
```

**Parameters**

None.

**Return value**

The maximum memory available for the event buffer, in bytes.

**Ndb::get_eventbuffer_free_percent()**

**Description**

Gets `ndb_eventbuffer_free_percent`—that is, the percentage of event buffer memory that should be available before buffering resumes, once `ndb_eventbuffer_max_alloc` has been reached. This value is calculated as `used * 100 / ndb_eventbuffer_max_alloc`, where `used` is the amount of event buffer memory actually used, in bytes.

This method was added in NDB 7.4.

**Signature**

```c
unsigned get_eventbuffer_free_percent
{
    void
}
```
The Ndb Class

Parameters
The percentage (\textit{pct}) of event buffer memory that must be present. Valid range is 1 to 99 inclusive.

Return value
\textit{None}.

\textbf{Ndb::get\_event\_buffer\_memory\_usage()}

Description
Gets event buffer usage as a percentage of \textit{ndb\_eventbuffer\_max\_alloc}. Unlike \textit{get\_eventbuffer\_free\_percent()}, this method makes complete usage information available in the form of an \textit{EventBufferMemoryUsage} data structure.

This method was added in NDB 7.4.

Signature
\begin{verbatim}
void get_event_buffer_memory_usage
(    EventBufferMemoryUsage&
)
\end{verbatim}

Parameters
A reference to an \textit{EventBufferMemoryUsage} structure, which receives the usage data.

Return value
\textit{None}.

\textbf{Ndb::get\_highest\_queued\_epoch()}

Description
Added in NDB 7.4, this method supersedes \textit{getLatestGCI()}, which is now deprecated and subject to removal in a future NDB Cluster release.

Prior to NDB 7.4.7, this method returned the highest epoch number in the event queue. In NDB 7.4.7 and later, it returns the highest epoch number found after calling \textit{pollEvents2()} (Bug #20700220).

Signature
\begin{verbatim}
Uint64 getHighestQueuedEpoch
(    void
)
\end{verbatim}

Parameters
None.

Return value
The most recent epoch number, an integer.

\textbf{Ndb::get\_latest\_gci() (DEPRECATED)}

Description
Gets the index for the most recent global checkpoint.

This method is deprecated in NDB 7.4, and is subject to removal in a future release. In NDB 7.4 and later, you should use \textit{getHighestQueuedEpoch()} instead.

Signature
\begin{verbatim}
Uint64 getLatestGCI
(    void
)
\end{verbatim}

Parameters
\textit{None}.

Return value
The most recent GCI, an integer.
The Ndb Class

Ndb::getNdbError()

Description
This method provides you with two different ways to obtain an NdbError object representing an error condition. For more detailed information about error handling in the NDB API, see NDB Cluster API Errors.

Signature
The getNdbError() method actually has two variants.

The first of these simply gets the most recent error to have occurred:

```cpp
const NdbError& getNdbError()
{
  void
}
```

The second variant returns the error corresponding to a given error code:

```cpp
const NdbError& getNdbError(int errorCode)
{
  int errorCode
}
```

Regardless of which version of the method is used, the NdbError object returned persists until the next NDB API method is invoked.

Parameters
To obtain the most recent error, simply call getNdbError() without any parameters. To obtain the error matching a specific errorCode, invoke the method passing the code (an int) to it as a parameter. For a listing of NDB API error codes and corresponding error messages, see Section 2.4, “NDB API Errors and Error Handling”.

Return value
An NdbError object containing information about the error, including its type and, where applicable, contextual information as to how the error arose. See Section 2.3.15, “The NdbError Structure”, for details.

Ndb::getNdbErrorDetail()

Description
This method provides an easy and safe way to access any extra information about an error. Rather than reading these extra details from the NdbError object’s details property (now now deprecated in favor of getNdbErrorDetail()—see Bug #48851). This method enables storage of such details in a user-supplied buffer, returning a pointer to the beginning of this buffer. In the event that the string containing the details exceeds the length of the buffer, it is truncated to fit.

ggetErrorDetail() provides the source of an error in the form of a string. In the case of a unique constraint violation (error 893), this string supplies the fully qualified name of the index where the problem originated, in the format database-name/schema-name/table-name/index-name, (NdbError.details, on the other hand, supplies only an index ID, and it is often not readily apparent to which table this index belongs.) Regardless of the type of error and details concerning this error, the string retrieved by getErrorDetail() is always null-terminated.

Signature
The getNdbErrorDetail() method has the following signature:

```cpp
const char* getNdbErrorDetail()
```
The Ndb Class

const NdbError& error,
char* buffer,
Uint32 bufferLength
) const

Parameters
To obtain detailed information about an error, call
getNdbErrorDetail() with a reference to the corresponding
NdbError object, a buffer, and the length of this buffer
(expressed as an unsigned 32-bit integer).

Return value
When extra details about the error are available, this method
returns a pointer to the beginning of the buffer supplied. As
stated previously, if the string containing the details is longer than
bufferLength, the string is truncated to fit. In the event that no
addition details are available, getNdbErrorDetail() returns
NULL.

Ndb::getNdbObjectName()

Description
If a name was set for the Ndb object prior to its initialization, you can
retrieve it using this method. Used for debugging.

Signature
const char* getNdbObjectName
(
    void
) const

Parameters
None.

Return value
The Ndb object name, if one has been set using
setNdbObjectName(). Otherwise, this method returns 0.

Ndb::getNextEventOpInEpoch2()

Description
Iterates over individual event operations making up the current
global checkpoint. Use following nextEvent2() to obtain summary
information for the epoch, such as a listing of all tables, before
processing event data.

Exceptional epochs do not have any event operations associated
with them.

Signature
const NdbEventOperation* getNextEventOpInEpoch2
(
    Uint32* iter,
    Uint32* event_types
)

Parameters
Set iter to 0 initially; this is NULL when there are no more events
within this epoch. If event_types is not NULL, it holds a bitmask of
the event types received.

Return value
A pointer to the next NdbEventOperation, if there is one.

Ndb::getNextEventOpInEpoch3()

Description
Iterates over individual event operations making up the current
global checkpoint. Use following nextEvent2() to obtain summary
information for the epoch, such as a listing of all tables, before processing event data. Is the same as
getNextEventOpInEpoch3() but with the addition of a third
argument which holds the merger of all AnyValues received, showing which bits are set for all operations on a given table.

Exceptional epochs do not have any event operations associated with them.

This method was added in NDB 7.4.18 and 7.5.9. (Bug #26333981)

**Signature**

```cpp
const NdbEventOperation* getNextEventOpInEpoch2
(
  Uint32* iter,
  Uint32* event_types
  Uint32* cumulative_any_value
)
```

**Parameters**

Set `iter` to 0 initially; this is `NULL` when there are no more events within this epoch. If `event_types` is not `NULL`, it holds a bitmask of the event types received. If `cumulative_any_value` is not `NULL`, it holds the merger of all AnyValues received.

**Return value**

A pointer to the next `NdbEventOperation`, if there is one.

**Ndb::getReference()**

**Description**

This method can be used to obtain a reference to a given `Ndb` object. This is the same value that is returned for a given operation corresponding to this object in the output of `DUMP 2350`.

**Signature**

```cpp
Uint32 getReference
{
  void
}
```

**Parameters**

None.

**Return value**

A 32-bit unsigned integer.

**Ndb::init()**

**Description**

This method is used to initialize an `Ndb` object.

**Signature**

```cpp
int init
{
  int maxNoOfTransactions = 4
}
```

**Parameters**

The `init()` method takes a single parameter `maxNoOfTransactions` of type integer. This parameter specifies the maximum number of parallel `NdbTransaction` objects that can be handled by this instance of `Ndb`. The maximum permitted value for `maxNoOfTransactions` is 1024; if not specified, it defaults to 4.

Each scan or index operation uses an extra `NdbTransaction` object.

**Return value**

This method returns an `int`, which can be either of the following two values:

- 0: indicates that the `Ndb` object was initialized successfully.
- -1: indicates failure.

**Ndb::isConsistent() (DEPRECATED)**
### The Ndb Class

**Description**

Check if all events are consistent. If a node failure occurs when resources are exhausted, events may be lost and the delivered event data might thus be incomplete. This method makes it possible to determine if this is the case.

This method is deprecated in NDB 7.4, and is subject to removal in a future release. In NDB 7.4 and later, you should instead use `NdbEventOperation::getEventType2()` to determine the type of event—in this instance, whether the event is of type `TE_INCONSISTENT`. See `Event::TableEvent`.

**Signature**

```cpp
def isConsistent
{
    Uint64& gci
}
```

**Parameters**

A reference to a global checkpoint index. This is the first inconsistent GCI found, if any.

**Return value**

`true` if all events are consistent.

---

**Ndb::isConsistentGCI() (DEPRECATED)**

**Description**

If a node failure occurs when resources are exhausted, events may be lost and the delivered event data might thus be incomplete. This method makes it possible to determine if this is the case by checking whether all events in a given GCI are consistent.

This method is deprecated in NDB 7.4, and is subject to removal in a future release. In NDB 7.4 and later, you should instead use `NdbEventOperation::getEventType2()` to determine the type of event—in this instance, whether the event is of type `TE_INCONSISTENT`. See `Event::TableEvent`.

**Signature**

```cpp
def isConsistentGCI
{
    Uint64 gci
}
```

**Parameters**

A global checkpoint index.

**Return value**

`true` if this GCI is consistent; `false` indicates that the GCI may be possibly inconsistent.

---

**Ndb::isExpectingHigherQueuedEpochs()**

**Description**

Check whether higher queued epochs have been seen by the last invocation of `Ndb::pollEvents2()`, or whether a `TE.Cluster.Failure` event was found.

It is possible, after a cluster failure has been detected, for the highest queued epoch returned by `pollEvents2()` not to be increasing any longer. In this case, rather than poll for more events, you should instead consume events with `nextEvent()` until it detects a `TE.Cluster.Failure` is detected, then reconnect to the cluster when it becomes available again.

**Signature**

```cpp
def isExpectingHigherQueuedEpochs
{
    void
}
```

**Parameters**

`None.`
Return value True if queued epochs were seen by the last pollEvents2() call or, in the event of cluster failure.

**Ndb::Key_part_ptr**

This section describes the `Key_part_ptr` structure.

Parent class `Ndb`

Description `Key_part_ptr` provides a convenient way to define key-part data when starting transactions and computing hash values, by passing in pointers to distribution key values. When the distribution key has multiple parts, they should be passed as an array, with the last part's pointer set equal to `NULL`. See `Ndb::startTransaction()`, and `Ndb::computeHash()`, for more information about how this structure is used.

Attributes A `Key_part_ptr` has the attributes shown in the following table:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Type</th>
<th>Initial Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ptr</code></td>
<td><code>const void*</code></td>
<td><code>none</code></td>
<td>Pointer to one or more distribution key values</td>
</tr>
<tr>
<td><code>len</code></td>
<td><code>unsigned</code></td>
<td><code>none</code></td>
<td>The length of the pointer</td>
</tr>
</tbody>
</table>

**Ndb::nextEvent() (DEPRECATED)**

Description Returns the next event operation having data from a subscription queue.

This method clears inconsistent data events from the event queue when processing them. In order to able to clear all such events, applications must call this method even in cases when `pollEvents()` has already returned 0.

This method is deprecated in NDB 7.4, and is subject to removal in a future release. In NDB 7.4 and later, you should use `nextEvent2()` instead.

Signature

```
NdbEventOperation* nextEvent
{
    void
}
```

Parameters None.

Return value This method returns an `NdbEventOperation` object representing the next event in a subscription queue, if there is such an event. If there is no event in the queue, it returns `NULL` instead.

**Ndb::nextEvent2()**

Description Returns the event operation associated with the data dequeued from the event queue. This should be called repeatedly after `pollEvents2()` populates the queue, until the event queue is empty.
The Ndb Class

Added in NDB 7.4, this method supersedes `nextEvent()`, which is now deprecated and subject to removal in a future NDB Cluster release.

After calling this method, use `NdbEventOperation::getEpoch()` to determine the epoch, then check the type of the returned event data using `NdbEventOperation::getEventType2()`. Handling must be provided for all exceptional `TableEvent` types, including `TE_EMPTY`, `TE_INCONSISTENT`, and `TE_OUT_OF_MEMORY` (also introduced in NDB 7.4). No other `NdbEventOperation` methods than the two named here should be called for an exceptional epoch. Returning empty epochs (`TE_EMPTY`) may flood applications when data nodes are idle. If this is not desirable, applications should filter out any empty epochs.

**Signature**

```cpp
NdbEventOperation* nextEvent2()
{
    void
}
```

**Parameters**

None.

**Return value**

This method returns an `NdbEventOperation` object representing the next event in an event queue, if there is such an event. If there is no event in the queue, it returns `NULL` instead.

**Ndb::PartitionSpec**

This section provides information about the `PartitionSpec` structure.

**Parent class**

`Ndb`

**Description**

A `PartitionSpec` is used for describing a table partition using any one of the following criteria:

- A specific partition ID for a table with user-defined partitioning.
- An array made up of a table's distribution key values for a table with native partitioning.
- A row in `NdbRecord` format containing a natively partitioned table's distribution key values.

**Attributes**

A `PartitionSpec` has two attributes, a `SpecType` and a `Spec`, which is a data structure corresponding to that `SpecType`, as shown in the following table:

**Table 2.29 PartitionSpec attributes with the SpecType values, data structures, and descriptions for each attribute.**

<table>
<thead>
<tr>

</tbody>
</table>

**Definition from Ndb.hpp.** Because this is a fairly complex structure, we here provide the original source-code definition of `PartitionSpec`, as given in `storage/ndb/include/ndbapi/Ndb.hpp`:

```c
struct PartitionSpec
{
    /*
    Size of the PartitionSpec structure.
    */
    static inline Uint32 size()
    {
        return sizeof(PartitionSpec);
    }

    enum SpecType
    {
        PS_NONE                = 0,
        PS_USER_DEFINED        = 1,
        PS_DISTR_KEY_PART_PTR  = 2,
        PS_DISTR_KEY_RECORD    = 3
    };

    Uint32 type;

    union
    {
        struct {
            Uint32 partitionId;
        } UserDefined;

        struct {
            const Key_part_ptr* tableKeyParts;
            void* xfrmbuf;
            Uint32 xfrmbuflen;
        } KeyPartPtr;

        struct {
            const NdbRecord* keyRecord;
            const char* keyRow;
            void* xfrmbuf;
            Uint32 xfrmbuflen;
        } KeyRecord;
    };
};
```

**Ndb::pollEvents()**

**Description**

This method waits for a GCP to complete. It is used to determine whether any events are available in the subscription queue.

This method waits for the next *epoch*, rather than the next GCP. See Section 2.3.16, “The NdbEventOperation Class”, for more information.

This method is deprecated and subject to removal in a future NDB Cluster release; use `pollEvents2()` instead.

**Signature**

```c
int pollEvents
{
    int     maxTimeToWait,
    Uint64* latestGCI = 0
}
```
The Ndb Class

Parameters

This method takes the two parameters listed here:

- The maximum time to wait, in milliseconds, before “giving up” and reporting that no events were available (that is, before the method automatically returns 0).

  A negative value causes the wait to be indefinite and never time out. This is not recommended (and is not supported by the successor method `pollEvents2()`).

- The index of the most recent global checkpoint. Normally, this may safely be permitted to assume its default value, which is 0.

Return value

`pollEvents()` returns a value of type `int`, which may be interpreted as follows:

- > 0: There are events available in the queue.
- 0: There are no events available.
- In NDB 7.6.28, 8.0.35, 8.2.0, and later releases, a negative value indicates failure and `NDB_FAILURE_GCI` (~(Uint64)0) indicates cluster failure (Bug #35671818); 1 is returned when encountering an exceptional event, except when only `TE_EMPTY` events are found, as described later in this section.

When `pollEvents()` finds an exceptional event at the head of the event queue, the method returns 1 and otherwise behaves as follows:

- Empty events (`TE_EMPTY`) are removed from the event queue head until an event containing data is found. When this results in the entire queue being processed without encountering any data, the method returns 0 (no events available) rather than 1. This behavior makes this event type transparent to an application using `pollEvents()`.

- After encountering an event containing inconsistent data (`TE_INCONSISTENT`) due to data node buffer overflow, the next call to `nextEvent()` call removes the inconsistent data event data from the event queue, and returns `NULL`. You should check the inconsistency by calling `isConsistent()` immediately thereafter.

  Important: Although the inconsistent event data is removed from the event queue by calling `nextEvent()`, information about the inconsistency is removed only by another `nextEvent()` call following this, that actually finds an event containing data.

- When `pollEvents()` finds a data buffer overflow event (`TE_OUT_OF_MEMORY`), the event data is added to the event queue whenever event buffer usage exceeds `ndb_eventbuffer_max_alloc`. In this case, the next call to `nextEvent()` exits the process.

Ndb::pollEvents2()

Description

Waits for an event to occur. Returns as soon as any event data is available. This method also moves an epoch's complete event data to the event queue.
The Ndb Class

This method supersedes pollEvents(), which is now deprecated and subject to removal in a future NDB Cluster release.

**Signature**

```c
int pollEvents2
{
    int aMillisecondNumber,
    Uint64* highestQueuedEpoch = 0
}
```

**Parameters**

This method takes the two parameters listed here:

- The maximum time to wait, in milliseconds, before giving up and reporting that no events were available (that is, before the method automatically returns 0).
  
  Specifying a negative value for this argument causes pollEvents2() to return -1, indicating an error.

- The index of the highest queued epoch. Normally, this may safely be permitted to assume its default value, which is 0. If this value is not NULL and new event data is available in the event queue, it is set to the highest epoch found in the available event data.

**Return value**

pollEvents2() returns an integer whose value can be interpreted as follows:

- > 0: There are events available in the queue.
- 0: There are no events available.
- < 0: Indicates failure (possible error).

---

**Ndb::setDatabaseName()**

**Description**

This method is used to set the name of the current database.

**Signature**

```c
void setDatabaseName
{
    const char *databaseName
}
```

**Parameters**

setDatabaseName() takes a single, required parameter, the name of the new database to be set as the current database.

**Return value**

None.

**Ndb::setDatabaseSchemaName()**

**Description**

This method sets the name of the current database schema.

**Signature**

```c
void setDatabaseSchemaName
{
    const char *databaseSchemaName
}
```

**Parameters**

The name of the database schema.

**Return value**

None.

**Ndb::setEventBufferQueueEmptyEpoch()**

**Description**

Queuing of empty epochs is disabled by default. This method can be used to enable such queuing, in which case any new, empty
epochs entering the event buffer following the method call are queued.

When queuing of empty epochs is enabled, nextEvent() associates an empty epoch to one and only one of the subscriptions (event operations) connected to the subscribing Ndb object. This means that there can be no more than one empty epoch per subscription, even though the user may have many subscriptions associated with the same Ndb object.

setEventBufferQueueEmptyEpoch() has no associated getter method. This is intentional, and is due to the fact this setter applies to queuing new epochs, whereas the queue itself may still reflect the state of affairs that existed prior to invoking the setter. Thus, during a transition period, an empty epoch might be found in the queue even if queuing is turned off.

setEventBufferQueueEmptyEpoch() was added in NDB 7.4.11.

**Signature**

```cpp
void setEventBufferQueueEmptyEpoch
    (bool queue_empty_epoch)
```

**Parameters**

This method takes a single input parameter, a boolean. Invoking the method with true enables queuing of empty events; passing false to the method disables such queuing.

**Return value**

None.

### Ndb::set_eventbuf_max Alloc()

**Description**

Sets the maximum memory, in bytes, that can be used for the event buffer. This has the same effect as setting the value of the ndb_eventbuffer_max_alloc system variable in the MySQL Server.

**Signature**

```cpp
void set_eventbuf_max_alloc
    (unsigned size)
```

**Parameters**

The desired maximum size for the event buffer, in bytes.

**Return value**

None.

### Ndb::set_eventbuffer_free_percent()

**Description**

Sets ndb_eventbuffer_free_percent—that is, the percentage of event buffer memory that should be available before buffering resumes, once ndb_eventbuffer_max_alloc has been reached.

This method was added in NDB 7.4.

**Signature**

```cpp
int set_eventbuffer_free_percent
    (unsigned pct)
```

**Parameters**

The percentage (pct) of event buffer memory that must be present. Valid range is 1 to 99 inclusive.
The Ndb Class

Return value

The value that was set.

Ndb::setNdbObjectName()

Description

You can also set an arbitrary, human-readable name to identify an Ndb object for debugging purposes. This name can then be retrieved using getNdbObjectName(). This must be done prior to calling init() for this object; trying to set a name after initialization fails with an error.

You can set a name only once for a given Ndb object; subsequent attempts after the name has already been set fail with an error.

Signature

```cpp
int setNdbObjectName
    (const char* name)
```

Parameters

A name that is intended to be human-readable.

Return value

0 on success.

Ndb::startTransaction()

Description

This method is used to begin a new transaction. There are three variants, the simplest of these using a table and a partition key or partition ID to specify the transaction coordinator (TC). The third variant makes it possible for you to specify the TC by means of a pointer to the data of the key.

When the transaction is completed it must be closed using NdbTransaction::close() or Ndb::closeTransaction(). Failure to do so aborts the transaction. This must be done regardless of the transaction's final outcome, even if it fails due to an error.

See Ndb::closeTransaction(), and NdbTransaction::close(), for more information.

Signature

```cpp
NdbTransaction* startTransaction
    (const NdbDictionary::Table* table = 0,
     const char* keyData = 0,
     Uint32* keyLen = 0)
```

Parameters

This method takes the following three parameters:

- **table**: A pointer to a Table object. This is used to determine on which node the transaction coordinator should run.
- **keyData**: A pointer to a partition key corresponding to table.
- **keyLen**: The length of the partition key, expressed in bytes.

Distribution-aware forms of startTransaction().

It is also possible to employ distribution awareness with this method; that is, to suggest which node should act as the transaction coordinator.

Signature

```cpp
NdbTransaction* startTransaction
    (const NdbDictionary::Table* table,
     const struct Key_part_ptr* keyData,
     void* xfrmbuf = 0,
     Uint32 xfrmbufLen = 0)
```
The Ndb Class

When specifying the transaction coordinator, this method takes the four parameters listed here:

- A pointer to a `Table` object used for deciding which node should act as the transaction coordinator.

- A null-terminated array of pointers to the values of the distribution key columns. The length of the key part is read from metadata and checked against the passed value.

  An `Ndb::Key_part_ptr` is defined as shown in `Ndb::Key_part_ptr`.

- A pointer to a temporary buffer, used to calculate the hash value.

  If `xfrmbuf` is `NULL` (the default), then a call to `malloc()` or `free()` is made automatically, as appropriate.

  Prior to NDB 7.5.30, 7.6.26, 8.0.33: `startTransaction()` fails if `xfrmbuf` is not `NULL` and `xfrmbuflen` is too small.

  NDB 7.5.30 and later, 7.6.26 and later, 8.0.33 and later: If the buffer passed is not of sufficient size, a temporary buffer is allocated automatically. (Bug #103814, Bug #32959894, Bug #34917498)

- The length of the buffer.

Return value

On success, an `NdbTransaction` object. In the event of failure, `NULL` is returned.

Example

Suppose that the table’s partition key is a single `BIGINT` column. Then you would declare the distribution key array as shown here:

```
Key_part_ptr distkey[2];
```

The value of the distribution key would be defined as shown here:

```
unsigned long long distkeyValue= 23;
```

The pointer to the distribution key array would be set as follows:

```
distkey[0].ptr= (const void*) &distkeyValue;
```

The length of this pointer would be set accordingly:

```
distkey[0].len= sizeof(distkeyValue);
```

The distribution key array must terminate with a `NULL` element. This is necessary to avoid to having an additional parameter providing the number of columns in the distribution key:

```
distkey[1].ptr= NULL;
distkey[1].len= NULL;
```

Setting the buffer to `NULL` permits `startTransaction()` to allocate and free memory automatically:

```
xfrmbuf= NULL;
```
Now, when you start the transaction, you can access the node that contains the desired information directly.

Another distribution-aware version of this method makes it possible for you to specify a table and partition (using the partition ID) as a hint for selecting the transaction coordinator, and is defined as shown here:

```cpp
NdbTransaction* startTransaction
{
    const NdbDictionary::Table* table,
    Uint32 partitionId
}
```

In the event that the cluster has the same number of data nodes as it has fragment replicas, specifying the transaction coordinator gains no improvement in performance, since each data node contains the entire database. However, where the number of data nodes is greater than the number of fragment replicas (for example, where NoOfReplicas is set equal to 2 in a cluster with four data nodes), you should see a marked improvement in performance by using the distribution-aware version of this method.

It is still possible to use this method as before, without specifying the transaction coordinator. In either case, you must still explicitly close the transaction, whether or not the call to `startTransaction()` was successful.

### 2.3.12 The Ndb_cluster_connection Class

This section provides information about the `Ndb_cluster_connection` class, which models a connection by a management server (`ndb_mgmd`) to a set of data nodes.

- `Ndb_cluster_connection` Class Overview
- `Ndb_cluster_connection` Class Constructor
- `Ndb_cluster_connection::configure_tls()`
- `Ndb_cluster_connection::connect()`
- `Ndb_cluster_connection::get_auto_reconnect()`
- `Ndb_cluster_connection::get_latest_error()`
- `Ndb_cluster_connection::get_latest_error_msg()`
- `Ndb_cluster_connection::get_max_adaptive_send_time()`
- `Ndb_cluster_connection::get_next_ndb_object()`
- `Ndb_cluster_connection::get_num_recv_threads()`
- `Ndb_cluster_connection::get_recv_thread_activation_threshold()`
- `Ndb_cluster_connection::get_system_name()`
- `Ndb_cluster_connection::get_tls_certificate_path()`
- `ndb_cluster_connection::lock_ndb_objects()`
- `Ndb_cluster_connection::set_auto_reconnect()`
The Ndb_cluster_connection Class

- Ndb_cluster_connection::set_data_node_neighbour()
- Ndb_cluster_connection::set_max_adaptive_send_time()
- Ndb_cluster_connection::set_name()
- Ndb_cluster_connection::set_num_recv_threads()
- Ndb_cluster_connection::set_optimized_node_selection()
- Ndb_cluster_connection::set_recv_thread_activation_threshold()
- Ndb_cluster_connection::set_service_uri()
- Ndb_cluster_connection::set_recv_thread_cpu()
- Ndb_cluster_connection::set_timeout()
- Ndb_cluster_connection::unlock_ndb_objects()
- Ndb_cluster_connection::unset_recv_thread_cpu()
- Ndb_cluster_connection::wait_until_ready()

Ndb_cluster_connection Class Overview

Parent class None
Child classes None
Description An NDB application program should begin with the creation of a single Ndb_cluster_connection object, and typically makes use of a single Ndb_cluster_connection. The application connects to a cluster management server when this object’s connect() method is called. By using the wait_until_ready() method it is possible to wait for the connection to reach one or more data nodes.

An instance of Ndb_cluster_connection is used to create an Ndb object.

Methods

The following table lists the public methods of this class and the purpose or use of each method:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ndb_cluster_connection()</td>
<td>Constructor; creates a connection to a cluster of data nodes.</td>
</tr>
<tr>
<td>configure_tls()</td>
<td>Provides TLS configuration data.</td>
</tr>
<tr>
<td>connect()</td>
<td>Connects to a cluster management server.</td>
</tr>
<tr>
<td>get_auto_reconnect()</td>
<td>Gets the auto-reconnection setting for API nodes using this Ndb_cluster_connection.</td>
</tr>
<tr>
<td>get_latest_error()</td>
<td>Whether or not the most recent attempt to connect succeeded.</td>
</tr>
<tr>
<td>get_latest_error_msg()</td>
<td>If the most recent attempt to connect failed, provides the reason.</td>
</tr>
<tr>
<td>get_max_adaptive_send_time()</td>
<td>Get timeout before adaptive send forces the sending of all pending signals.</td>
</tr>
</tbody>
</table>
The Ndb_cluster_connection Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>get_num_recv_threads()</td>
<td>Get number of receive threads. Used to iterate through multiple Ndb objects.</td>
</tr>
<tr>
<td>get_next_ndb_object()</td>
<td>Get activation level for bound receive threads.</td>
</tr>
<tr>
<td>get_recv_thread_activation_threshold()</td>
<td>Get the path to the active TLS certificate.</td>
</tr>
<tr>
<td>get_system_name()</td>
<td>Get the cluster's system name.</td>
</tr>
<tr>
<td>get_tls_certificate_path()</td>
<td>Disables the creation of new Ndb objects.</td>
</tr>
<tr>
<td>get_url()</td>
<td>Enables or disables auto-reconnection of API nodes using this Ndb_cluster_connection.</td>
</tr>
<tr>
<td>lock_ndb_objects()</td>
<td>Sets a neighbor node for optimal transaction coordinator placement</td>
</tr>
<tr>
<td>set_auto_reconnect()</td>
<td>Set timeout to elapse before adaptive send forces the sending of all pending signals.</td>
</tr>
<tr>
<td>set_data_node_neighbour()</td>
<td>Provides a name for the connection</td>
</tr>
<tr>
<td>set_max_adaptive_send_time()</td>
<td>Set number of receive threads to be bound.</td>
</tr>
<tr>
<td>set_name()</td>
<td>Set one or more CPUs to bind receive threads to.</td>
</tr>
<tr>
<td>set_num_recv_threads()</td>
<td>Used to control node-selection behavior.</td>
</tr>

<tr>
<td>wait_until_ready()</td>
<td></td>
</tr>
</tbody>
</table>

Ndb_cluster_connection Class Constructor

Description

This method creates a connection to an NDB Cluster, that is, to a cluster of data nodes. The object returned by this method is required in order to instantiate an Ndb object. Thus, every NDB API application requires the use of an Ndb_cluster_connection.

Signatures

Ndb_cluster_connection has two constructors. The first of these is shown here:

```cpp
Ndb_cluster_connection
{
    const char* connection_string = 0
}
```

The second constructor takes a node ID in addition to the connection string argument. Its signature and parameters are shown here:

```cpp
Ndb_cluster_connection
{
    const char* connection_string,
    int force_api_nodeid
}
```
The Ndb_cluster_connection Class

Parameters

The first version of the constructor requires a single
`connection_string` parameter, pointing to the location of the
management server.

The second version of the constructor takes two arguments, a
`connection_string` and the node ID (`force_api_nodeid`) to
be used by this API node. This node ID overrides any node ID value
set in the `connection_string` argument.

Return value

An instance of `Ndb_cluster_connection`.

Ndb_cluster_connection::configure_tls()

Description

Provides configuration information needed for a TLS connection.

If the node finds active NDB TLS node keys and certificates
(created using `ndb_sign_keys` or another tool) in the search
path, it can connect securely to other nodes. If this method is not
called for a connection, the search path is the compiled-in default
(`WITH_NDB_TLS_SEARCH_PATH`), and the TLS level is 0 (relaxed).

See also TLS Link Encryption for NDB Cluster.

Signature

```c
void configure_tls
{
    const char *tls_search_path,
    int mgm_tls_level
}
```

Parameters

`tls_search_path` A colon-delimited list of
directories that may contain
TLS private key files or signed
gpublic key certificates. A directory
reference contained in the search
path may be absolute or relative.
Environment variables are
expanded.

`mgm_tls_level` This is 0 or 1 to specify the
TLS requirement for securing
the MGM protocol connection
between this node and the
NDB Management server. 0
means the requirement for TLS
is relaxed; the node attempts
to use TLS, but the connection
succeeds even if TLS does not
do so. 1 sets a strict requirement
for TLS; failure to establish
TLS is treated as an error
(and a connection cannot be
established).

Return value

`none`

Ndb_cluster_connection::connect()

Description

This method connects to a cluster management server.

Signature

```c
int connect
{
    int retries = 30,
```
The Ndb_cluster_connection Class

```cpp
int delay = 1,
int verbose = 0
```

Parameters

This method takes three parameters, all of which are optional:

- `retries` specifies the number of times to retry the connection in the event of failure. The default value is 30.

  0 means that no additional attempts to connect are made in the event of failure; using a negative value for `retries` results in the connection attempt being repeated indefinitely.

- The `delay` represents the number of seconds between reconnect attempts; the default is 1 second.

- `verbose` indicates whether the method should output a report of its progress, with 1 causing this reporting to be enabled; the default is 0 (reporting disabled).

Return value

This method returns an `int`, which can have one of the following 3 values:

- 0: The connection attempt was successful.
- 1: Indicates a recoverable error.
- -1: Indicates an unrecoverable error.

Ndb_cluster_connection::get_auto_reconnect()

Description

This method retrieves the current `AutoReconnect` setting for a given `Ndb_cluster_connection`. For more detailed information, see `Ndb_cluster_connection::set_auto_reconnect()`.

Signature

```cpp
int get_auto_reconnect
{
    void
}
```

Parameters

None.

Return value

An integer value 0 or 1, corresponding to the current `AutoReconnect` setting in effect for this connection. 0 forces API nodes to use new connections to the cluster, while 1 enables API nodes to re-use existing connections.

Ndb_cluster_connection::get_latest_error()

Description

This method can be used to determine whether or not the most recent `connect()` attempt made by this `Ndb_cluster_connection` succeeded. If the connection succeeded, `get_latest_error()` returns 0; otherwise, it returns 1. If the connection attempt failed, use `Ndb_cluster_connection::get_latest_error_msg()` to obtain an error message giving the reason for the failure.

Signature

```cpp
int get_latest_error
{
    void
} const
```

Parameters

None.
Return value

1 or 0. A return value of 1 indicates that the latest attempt to connect failed; if the attempt succeeded, a 0 is returned.

**Ndb_cluster_connection::get_latest_error_msg()**

**Description**

If the most recent connection attempt by this Ndb_cluster_connection failed (as determined by calling get_latest_error()), this method provides an error message supplying information about the reason for the failure.

**Signature**

```cpp
const char* get_latest_error_msg()
```

**Parameters**

None.

**Return value**

A string containing an error message describing a failure by Ndb_cluster_connection::connect(). If the most recent connection attempt succeeded, an empty string is returned.

**Ndb_cluster_connection::get_max_adaptive_send_time()**

**Description**

Get the minimum time in milliseconds that is permit to lapse before the adaptive send mechanism forces all pending signals to be sent.

**Signature**

```cpp
Uint32 get_max_adaptive_send_time()
```

**Parameters**

None.

**Return value**

Wait time as a number of milliseconds. This should always be a value between 0 and 10, inclusive.

**Ndb_cluster_connection::get_next_ndb_object()**

**Description**

This method is used to iterate over a set of Ndb objects, retrieving them one at a time.

**Signature**

```cpp
const Ndb* get_next_ndb_object(const Ndb* p)
```

**Parameters**

This method takes a single parameter, a pointer to the last Ndb object to have been retrieved or NULL.

**Return value**

Returns the next Ndb object, or NULL if no more Ndb objects are available.

**Iterating over Ndb objects.**

To retrieve all existing Ndb objects, perform the following three steps:

1. Invoke the lock_ndb_objects() method. This prevents the creation of any new instances of Ndb until the unlock_ndb_objects() method is called.

2. Retrieve the first available Ndb object by passing NULL to get_next_ndb_object(). You can retrieve the second Ndb object by passing the pointer retrieved by the first call to the next get_next_ndb_object() call, and so on. When a pointer to the last available Ndb instance is used, the method returns NULL.

3. After you have retrieved all desired Ndb objects, you should re-enable Ndb object creation by calling the unlock_ndb_objects() method.
The Ndb_cluster_connection Class

**Ndb_cluster_connection::get_num_recv_threads()**

Description: Get the number of receiver threads.

Signature:

```c
int get_num_recv_threads
    (void) const
```

Parameters: None.

Return value: The number of receiver threads.

**Ndb_cluster_connection::get_recv_thread_activation_threshold()**

Description: Get the level set for activating the receiver thread bound by `set_recv_thread_cpu()`.

Signature:

```c
int get_recv_thread_activation_threshold
    (void) const
```

Parameters: None.

Return value: An integer threshold value. See `Ndb_cluster_connection::set_recv_thread_activation_threshold()`, for information about interpreting this value.

**Ndb_cluster_connection::get_system_name()**

Description: Gets the system name from the cluster configuration. This is the value of the Name system configuration parameter set in the cluster’s `config.ini` configuration file.

Signature:

```c
const char* get_system_name
    (void) const
```

Parameters: None.

Return value: The cluster system name. If not set in the cluster configuration file, this is a generated value in the form `MC_timestamp` (for example, `MC_20170426182343`), using the time that the management server was started.

**Ndb_cluster_connection::get_tls_certificate_path()**

Description: Retrieve the pathname for the active TLS certificate file. Call after calling `connect()`.

Returns null if `connect()` has not yet been called, or no valid key and certificate can be found in the TLS search path (whether supplied to `configure_tls()` or the default).

This method was added in NDB 8.3.0.

Signature:

```c
const char* get_tls_certificate_path
    (void) const
```

Parameters: None.
The Ndb_cluster_connection Class

Return value
The absolute path to the TLS certificate file that is currently active.

ndb_cluster_connection::lock_ndb_objects()

Description
Calling this method prevents the creation of new instances of the Ndb class. This method must be called prior to iterating over multiple Ndb objects using get_next_ndb_object().

Signature
```cpp
void lock_ndb_objects
{
    void
} const
```

This method is const beginning with NDB 7.4.13 (Bug #23709232).

For more information, see Ndb_cluster_connection::get_next_ndb_object().

Parameters
None.

Return value
None.

Ndb_cluster_connection::set_auto_reconnect()

Description
An API node that is disconnected from the cluster is forced to use a new connection object to reconnect, unless this behavior is overridden by setting AutoReconnect = 1 in the config.ini file or calling this method with 1 as the input value. Calling the method with 0 for the value has the same effect as setting the AutoReconnect configuration parameter (also introduced in those NDB Cluster versions) to 0; that is, API nodes are forced to create new connections.

Important
When called, this method overrides any setting for AutoReconnect made in the config.ini file.

For more information, see Defining SQL and Other API Nodes in an NDB Cluster.

Signature
```cpp
void set_auto_reconnect
{
    int value
}
```

Parameters
A value of 0 or 1 which determines API node reconnection behavior. 0 forces API nodes to use new connections (Ndb_cluster_connection objects); 1 permits API nodes to re-use existing connections to the cluster.

Return value
None.

Ndb_cluster_connection::set_data_node_neighbour()

Description
Set data node neighbor of the connection, used for optimal placement of the transaction coordinator. This method is used after creating the Ndb_cluster_connection, but prior to starting any query threads. This is due to the fact that this method may change the internal state of the Ndb_cluster_connection shared by the threads using it. This state is not thread-safe; changing it can lead to non-optimal node selection at the time of the change.

You can use the ndb_data_node_neighbour server system variable to set a data node neighbor for an NDB Cluster SQL node.
The Ndb_cluster_connection Class

This method was added in NDB 7.5.

**Signature**

```cpp
def set_data_node_neighbour
  (Uint32 neighbour_node)
```

**Parameters**
The ID of the node to be used as the neighbor.

**Return value**
`None`

---

**Ndb_cluster_connection::set_max_adaptive_send_time()**

**Description**
Set the minimum time in milliseconds that is permit to lapse before the adaptive send mechanism forces all pending signals to be sent.

**Signature**

```cpp
def set_max_adaptive_send_time
  (Uint32 milliseconds)
```

**Parameters**
Wait time in milliseconds. The range is 0-10, with 10 being the default value.

**Return value**
`None`

---

**Ndb_cluster_connection::set_name()**

**Description**
Sets a name for the connection. If the name is specified, it is reported in the cluster log.

**Signature**

```cpp
def set_name
  (const char* name)
```

**Parameters**
The `name` to be used as an identifier for the connection.

**Return value**
`None`

---

**Ndb_cluster_connection::set_num_recv_threads()**

**Description**
Set the number of receiver threads bound to the CPU (or CPUs) determined using `set_recv_thread_cpu()` and with the threshold set by `set_recv_thread_activation_threshold()`.

This method should be invoked before trying to connect to any other nodes.

**Signature**

```cpp
def set_num_recv_threads
  (Uint32 num_recv_threads)
```

**Parameters**
The number of receive threads. The only supported value is 1.

**Return value**
-1 indicates an error; any other value indicates success.

---

**Ndb_cluster_connection::set_optimized_node_selection()**

**Description**
This method can be used to override the `connect()` method's default behavior as regards which node should be connected to first.
The Ndb_cluster_connection Class

**Signature**

```c
void set_optimized_node_selection(
    int value
)
```

**Parameters**

An integer `value`.

**Return value**

`None`.

**Ndb_cluster_connection::set_recv_thread_activation_threshold()**

**Description**

Set the level for activating the receiver thread bound by `set_recv_thread_cpu()`. Below this level, normal user threads are used to receive signals.

**Signature**

```c
int set_recv_thread_activation_threshold(
    Uint32 threshold
)
```

**Parameters**

An integer `threshold` value. 16 or higher means that receive threads are never used as receivers. 0 means that the receive thread is always active, and that retains poll rights for its own exclusive use, effectively blocking all user threads from becoming receivers. In such cases care should be taken to ensure that the receive thread does not compete with the user thread for CPU resources; it is preferable for it to be locked to a CPU for its own exclusive use. The default is 8.

**Return value**

`-1` indicates an error; any other value indicates success.

**Ndb_cluster_connection::set_service_uri()**

**Description**

Beginning with NDB 7.5.7, this method can be used to create a URI for publication in `service_URI` column of the application's row in the `ndbinfo.processes` table.

Provided that this method is called prior to invoking `connect()`, the service URI is published immediately upon connection; otherwise, it is published after a delay of up to `HeartbeatIntervalDbApi` milliseconds.

**Signature**

```c
int set_service_uri(
    const char* scheme,
    const char* host,
    int port,
    const char* path
)
```

**Parameters**

This method takes the parameters listed here:

- **scheme**: The URI scheme. This is restricted to lowercase letters, numbers, and the characters .,+,-,(period, plus sign, and dash). The maximum length is 16 characters; any characters over this limit are truncated.

- **host**: The URI network address or host name. The maximum length is 48 characters (sufficient for an IPv6 network address); any characters over this limit are truncated. If null, each data node reports the network address from its own connection to this node. **An Ndb_cluster_connection that uses multiple transporters or network addresses to connect to different data**
nodes is reflected in multiple rows in the `ndbinfo.processes` table.

- **port**: The URI port. This is not published if it is equal to 0.
- **path**: The URI path, possibly followed by a query string beginning with `?`. The maximum combined length of the path and query may not exceed 128 characters; if longer, it is truncated to this length.

The path may not begin with a double slash (`//`).

Return value

0 on success, 1 in the event of a syntax error.

**Ndb_cluster_connection::set_recv_thread_cpu()**

Description

Set the CPU or CPUs to which the receiver thread should be bound. Set the level for activating the receiver thread as a receiver by invoking `set_recv_thread_activation_threshold()`. Unset the binding for this receiver thread by invoking `unset_recv_thread_cpu()`.

Signature

```
int set_recv_thread_cpu
{
    Uint16* cpuid_array,
    Uint32 array_len,
    Uint32 recv_thread_id = 0
}
```

Parameters

This method takes three parameters, listed here:

- An array of one or more CPU IDs to which the receive thread should be bound
- The length of this array
- The thread ID of the receive thread to bind. The default value is 0.

Return value

-1 indicates an error; any other value indicates success.

**Ndb_cluster_connection::set_timeout()**

Description

Used to set a timeout for the connection, to limit the amount of time that we may block when connecting.

This method is actually a wrapper for the MGM API function `ndb_mgm_set_timeout()`.

Signature

```
int set_timeout
{
    int timeout_ms
}
```

Parameters

The length of the timeout, in milliseconds (`timeout_ms`). Currently, only multiples of 1000 are accepted.

Return value

0 on success; any other value indicates failure.

**Ndb_cluster_connection::unlock_ndb_objects()**

Description

This method undoes the effects of the `lock_ndb_objects()` method, making it possible to create new instances of `Ndb`. `unlock_ndb_objects()` should be called after you have finished retrieving `Ndb` objects using the `get_next_ndb_object()` method.
The NdbBlob Class

### Signature

```cpp
template<class T>
void unlock_ndb_objects(
    T*) const
```

This method is `const` beginning with NDB 7.4.13 (Bug #23709232).

For more information, see `Ndb_cluster_connection::get_next_ndb_object()`.

### Parameters
None.

### Return value
None.

---

#### Ndb_cluster_connection::unset_recv_thread_cpu()

**Description**

Unset the CPU or CPUs to which the receiver thread was bound using `set_recv_thread_cpu()`.

**Signature**

```cpp
int unset_recv_thread_cpu(
    Uint32 recv_thread_id)
```

**Parameters**

The thread ID of the receiver thread to be unbound.

**Return value**

-1 indicates an error; any other value indicates success.

---

#### Ndb_cluster_connection::wait_until_ready()

**Description**

This method is needed to establish connections with the data nodes. It waits until the requested connection with one or more data nodes is successful, or until a timeout condition is met.

**Signature**

```cpp
int wait_until_ready(
    int timeoutBefore,
    int timeoutAfter)
```

**Parameters**

This method takes two parameters:

- `timeoutBefore` determines the number of seconds to wait until the first “live” node is detected. If this amount of time is exceeded with no live nodes detected, then the method immediately returns a negative value.

- `timeoutAfter` determines the number of seconds to wait after the first “live” node is detected for all nodes to become active. If this amount of time is exceeded without all nodes becoming active, then the method immediately returns a value greater than zero.

**Return value**

`wait_until_ready()` returns an `int`, whose value is interpreted as follows:

- = 0: All nodes are “live”.
- > 0: At least one node is “live” (however, it is not known whether all nodes are “live”).
- < 0: An error occurred.

---

2.3.13 The NdbBlob Class
The NdbBlob Class

This section provides information about the NdbBlob class, which models a handle to a blob column and provides read and write access to blob column values. This object has a number of different states and provides several modes of access to blob data; these are also described in this section.

- NdbBlob Class Overview
- NdbBlob::ActiveHook
- NdbBlob::blobsFirstBlob()
- NdbBlob::blobsNextBlob()
- NdbBlob::close()
- NdbBlob::getBlobEventName()
- NdbBlob::getBlobTableName()
- NdbBlob::getColumn()
- NdbBlob::getLength()
- NdbBlob::getNull()
- NdbBlob::getNdbError()
- NdbBlob::getNdbOperation()
- NdbBlob::getPos()
- NdbBlob::getState()
- NdbBlob::getValue()
- NdbBlob::getVersion()
- NdbBlob::readData()
- NdbBlob::setActiveHook()
- NdbBlob::setNull()
- NdbBlob::setPos()
- NdbBlob::setValue()
- NdbBlob::State
- NdbBlob::truncate()
- NdbBlob::writeData()

NdbBlob Class Overview

<table>
<thead>
<tr>
<th>Parent class</th>
<th>None</th>
</tr>
</thead>
<tbody>
<tr>
<td>Child classes</td>
<td>None</td>
</tr>
<tr>
<td>Description</td>
<td>This class has no public constructor. An instance of NdbBlob is created using the NdbOperation::getBlobHandle() method during the operation preparation phase. (See Section 2.3.20, “The NdbOperation Class.”) This object acts as a handle on a blob column.</td>
</tr>
<tr>
<td>Methods</td>
<td>The following table lists the public methods of this class and the purpose or use of each method:</td>
</tr>
</tbody>
</table>
### Table 2.34 NdbBlob class methods and descriptions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>blobsFirstBlob()</td>
<td>Gets the first blob in a list.</td>
</tr>
<tr>
<td>blobsNextBlob()</td>
<td>Gets the next blob in a list.</td>
</tr>
<tr>
<td>close()</td>
<td>Release internal resources prior to commit or abort</td>
</tr>
<tr>
<td>getBlobEventName()</td>
<td>Gets a blob event name</td>
</tr>
<tr>
<td>getBlobTableName()</td>
<td>Gets a blob data segment's table name.</td>
</tr>
<tr>
<td>getColumn()</td>
<td>Gets a blob column.</td>
</tr>
<tr>
<td>getLength()</td>
<td>Gets the length of a blob, in bytes</td>
</tr>
<tr>
<td>getNdbError()</td>
<td>Gets an error (an <code>NdbError</code> object)</td>
</tr>
<tr>
<td>getNdbOperation()</td>
<td>Get a pointer to the operation (<code>NdbOperation</code> object) to which this <code>NdbBlob</code> object belonged when created.</td>
</tr>
<tr>
<td>getNull()</td>
<td>Checks whether a blob value is NULL</td>
</tr>
<tr>
<td>getPos()</td>
<td>Gets the current position for reading/writing</td>
</tr>
<tr>
<td>getState()</td>
<td>Gets the state of an <code>NdbBlob</code> object</td>
</tr>
<tr>
<td>getValue()</td>
<td>Prepares to read a blob value</td>
</tr>
<tr>
<td>getVersion()</td>
<td>Checks whether a blob is statement-based or event-based</td>
</tr>
<tr>
<td>readData()</td>
<td>Reads data from a blob</td>
</tr>
<tr>
<td>setActiveHook()</td>
<td>Defines a callback for blob handle activation</td>
</tr>
<tr>
<td>setNull()</td>
<td>Sets a blob to NULL</td>
</tr>
<tr>
<td>setPos()</td>
<td>Sets the position at which to begin reading/writing</td>
</tr>
<tr>
<td>setValue()</td>
<td>Prepares to insert or update a blob value</td>
</tr>
<tr>
<td>truncate()</td>
<td>Truncates a blob to a given length</td>
</tr>
<tr>
<td>writeData()</td>
<td>Writes blob data</td>
</tr>
</tbody>
</table>

getBlobTableName() and `getBlobEventName()` are static methods.

Most `NdbBlob` methods (nearly all of those whose return type is `int`) return 0 on success and -1 in the event of failure.

### Types

The public types defined by `NdbBlob` are shown here:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ActiveHook()</td>
<td>Callback for <code>NdbBlob::setActiveHook()</code></td>
</tr>
<tr>
<td>State()</td>
<td>Represents the states that may be assumed by the <code>NdbBlob</code>.</td>
</tr>
</tbody>
</table>

### Blob Data Storage.

Blob data is stored in 2 locations:

- The header and inline bytes are stored in the blob column.
The blob's data segments are stored in a separate table named `NDB$BLOB_tid_cid`, where `tid` is the table ID, and `cid` is the blob column ID.

The inline and data segment sizes can be set using the appropriate `Column` methods when the table is created. See Section 2.3.1, “The Column Class”, for more information about these methods.

**Data Access Types.** `NdbBlob` supports 3 types of data access: These data access types can be applied in combination, provided that they are used in the order given above.

- In the preparation phase, the `NdbBlob` methods `getValue()` and `setValue()` are used to prepare a read or write of a blob value of known size.
- Also in the preparation phase, `setActiveHook()` is used to define a routine which is invoked as soon as the handle becomes active.
- In the active phase, `readData()` and `writeData()` are used to read and write blob values having arbitrary sizes.

**Blob operations.** Blob operations take effect when the next transaction is executed. In some cases, `NdbBlob` is forced to perform implicit execution. To avoid this, you should always operate on complete blob data segments.

Use `NdbTransaction::executePendingBlobOps()` to flush reads and writes, which avoids any execution penalty if no operations are pending. This is not necessary following execution of operations, or after the next scan result.

`NdbBlob` also supports reading post- or pre-blob data from events. The handle can be read after the next event on the main table has been retrieved. The data becomes available immediately. (See Section 2.3.16, “The NdbEventOperation Class”, for more information.)

**Blobs and NdbOperations.** `NdbOperation` methods acting on `NdbBlob` objects have the following characteristics:

- `NdbOperation::insertTuple()` must use `NdbBlob::setValue()` if the blob attribute is nonnullable.
- `NdbOperation::readTuple()` used with any lock mode can read but not write blob values.
  
  When the `LM_CommittedRead` lock mode is used with `readTuple()`, the lock mode is automatically upgraded to `LM_Read` whenever blob attributes are accessed.

- `NdbOperation::updateTuple()` can either overwrite an existing value using `NdbBlob::setValue()`, or update it during the active phase.

- `NdbOperation::writeTuple()` always overwrites blob values, and must use `NdbBlob::setValue()` if the blob attribute is nonnullable.

- `NdbOperation::deleteTuple()` creates implicit, nonaccessible blob handles.

- A scan with any lock mode can use its blob handles to read blob values but not write them.
  
  A scan using the `LM_Exclusive` lock mode can update row and blob values using `updateCurrentTuple()`; the operation returned must explicitly create its own blob handle.

  A scan using the `LM_Exclusive` lock mode can delete row values (and therefore blob values) using `deleteCurrentTuple()`; this create implicit nonaccessible blob handles.

- An operation which is returned by `lockCurrentTuple()` cannot update blob values.

**Known Issues.** The following are known issues or limitations encountered when working with `NdbBlob` objects:

- Too many pending blob operations can overflow the I/O buffers.
• The table and its blob data segment tables are not created atomically.

**NdbBlob::ActiveHook**

ActiveHook is a data type defined for use as a callback for the `setActiveHook()` method. (See `NdbBlob::setActiveHook()`.)

**Definition.** `ActiveHook` is a custom data type defined as shown here:

```c
typedef int ActiveHook
{
    NdbBlob* me,
    void* arg
}
```

**Description.** This is a callback for `NdbBlob::setActiveHook()`, and is invoked immediately once the prepared operation has been executed (but not committed). Any calls to `getValue()` or `setValue()` are performed first. The blob handle is active so `readData()` or `writeData()` can be used to manipulate the blob value. A user-defined argument is passed along with the `NdbBlob`. `setActiveHook()` returns a nonzero value in the event of an error.

**NdbBlob::blobsFirstBlob()**

**Description**
This method initialises a list of blobs belonging to the current operation and returns the first blob in the list.

**Signature**

```c
NdbBlob* blobsFirstBlob
{
    void
}
```

**Parameters**
None.

**Return value**
A pointer to the desired blob.

**NdbBlob::blobsNextBlob()**

**Description**
Use the method to obtain the next in a list of blobs that was initialised using `blobsFirstBlob()`. See `NdbBlob::blobsFirstBlob()`.

**Signature**

```c
NdbBlob* blobsNextBlob
{
    void
}
```

**Parameters**
None.

**Return value**
A pointer to the desired blob.

**NdbBlob::close()**

**Description**
Closes the blob handle, releasing internal resources as it does so, prior to committing or aborting the transaction. In other words, this signals that an application has finished with reading from a given blob. This method can be called only when the blob’s **State** is **Active**.

**Signature**

```c
int close
{
    bool execPendingBlobOps = true
}
```
The NdbBlob Class

Parameters

This method has a single boolean parameter execPendingBlobOps. If the value of this parameter true (the default), any pending blob operations are flushed before the blob handle is closed. If execPendingBlobOps is false, then it is assumed that the blob handle has no pending read or write operations to flush.

Return value

0 on success.

Read operations and locking.

When a blob handle is created on a read operation using LM_Read or LM_Exclusive as the LockMode, the read operation can be unlocked only once all Blob handles created on this operation have been closed.

When a row containing blobs has been read with lock mode LM_CommittedRead, the mode is automatically upgraded to LM_Read to ensure consistency. In this case, when all the blob handles for the row have been closed, an unlock operation for the row is automatically performed by the call to the close() method, which adds a pending write operation to the blob. The upgraded lock is released following the call to execute().

NdbBlob::getBlobEventName()

Description

This method gets a blob event name. The blob event is created if the main event monitors the blob column. The name includes the main event name.

Signature

```c
static int getBlobEventName
{
    char* name,
    Ndb* ndb,
    const char* event,
    const char* column
}
```

Parameters

This method takes the four parameters listed here:

- `name`: The name of the blob event.
- `ndb`: The relevant Ndb object.
- `event`: The name of the main event.
- `column`: The blob column.

Return value

0 on success, -1 on failure.

NdbBlob::getBlobTableName()

Description

This method gets the blob data segment table name.

This method is generally of use only for testing and debugging purposes.

Signature

```c
static int getBlobTableName
{
    char* name,
    Ndb* ndb,
    const char* table,
    const char* column
}
```

Parameters

This method takes the four parameters listed here:

- `name`: The name of the blob data segment table.
- `ndb`: The relevant Ndb object.
The NdbBlob Class

- **table**: The name of the main table.
- **column**: The blob column.

**NdbBlob::getColumn()**

**Description**
Use this method to get the blob column to which the NdbBlob belongs.

**Signature**
const Column* getColumn
{
  void
}

**Parameters**
None.

**Return value**
A Column object.

**NdbBlob::getLength()**

**Description**
This method gets the blob's current length in bytes.

**Signature**
int getLength
{
  Uint64& length
}

**Parameters**
A reference to the length.

**Return value**
The blob's length in bytes. For a NULL blob, this method returns 0. To distinguish between a blob whose length is 0 blob and one which is NULL, use the getNull() method.

**NdbBlob::getNull()**

**Description**
This method checks whether the blob's value is NULL.

**Signature**
int getNull
{
  int& isNull
}

**Parameters**
A reference to an integer isNull. Following invocation, this parameter has one of the following values, interpreted as shown here:

- **-1**: The blob is undefined. If this is a nonevent blob, this result causes a state error.
- **0**: The blob has a nonnull value.
- **1**: The blob's value is NULL.

**Return value**
None.

**NdbBlob::getNdbError()**

**Description**
Use this method to obtain an error object. The error may be blob-specific or may be copied from a failed implicit operation. The error code is copied back to the operation unless the operation already has a nonzero error code.
The NdbBlob Class

Signature

```c
const NdbError& getNdbError
{
    void
} const
```

Parameters None.

Return value An NdbError object.

**NdbBlob::getNdbOperation()**

Description This method can be used to find the operation with which the handle for this NdbBlob is associated.

Signature

```c
const NdbOperation* getNdbOperation
{
    void
} const
```

Parameters None.

Return value A pointer to an operation.

The operation referenced by the pointer returned by this method may be represented by either an NdbOperation or NdbScanOperation object.

See Section 2.3.20, “The NdbOperation Class”, and Section 2.3.24, “The NdbScanOperation Class”, for more information.

**NdbBlob::getPos()**

Description This method gets the current read/write position in a blob.

Signature

```c
int getPos
{
    Uint64& pos
}
```

Parameters One parameter, a reference to the position.

Return value Returns 0 on success, or -1 on failure. (Following a successful invocation, pos will hold the current read/write position within the blob, as a number of bytes from the beginning.)

**NdbBlob::getState()**

Description This method gets the current state of the NdbBlob object for which it is invoked. Possible states are described in NdbBlob::State.

Signature

```c
State getState
{
    void
}
```

Parameters None.

Return value A value of type State.

**NdbBlob::getValue()**

Description Use this method to prepare to read a blob value; the value is available following invocation. Use getNull() to check for a NULL value; use getLength() to get the actual length of the blob, and to check for truncation. getValue() sets the current read/write position to the point following the end of the data which was read.
The NdbBlob Class

Signature

```c
int getValue(
   void* data,
   Uint32 bytes
)
```

Parameters

This method takes two parameters. The first of these is a pointer to the `data` to be read; the second is the number of `bytes` to be read.

Return value

0 on success, -1 on failure.

**NdbBlob::getVersion()**

Description

This method is used to distinguish whether a blob operation is statement-based or event-based.

Signature

```c
void getVersion(
   int& version
)
```

Parameters

This method takes a single parameter, an integer reference to the blob version (operation type).

Return value

One of the following three values:

- -1: This is a “normal” (statement-based) blob.
- 0: This is an event-operation based blob, following a change in its data.
- 1: This is an event-operation based blob, prior to any change in its data.

`getVersion()` is always successful, assuming that it is invoked as a method of a valid instance of NdbBlob.

**NdbBlob::readData()**

Description

This method is used to read data from a blob.

Signature

```c
int readData(
   void* data,
   Uint32& bytes
)
```

Parameters

`readData()` accepts a pointer to the `data` to be read, and a reference to the number of `bytes` read.

Return value

Returns 0 on success, -1 on failure. Following a successful invocation, `data` points to the data that was read, and `bytes` holds the number of bytes read.

**NdbBlob::setActiveHook()**

Description

This method defines a callback for blob handle activation. The queue of prepared operations will be executed in no-commit mode up to this point; then, the callback is invoked. For additional information, see NdbBlob::ActiveHook.

Signature

```c
int setActiveHook(
   ActiveHook* activeHook,
   void* arg
)
```
The NdbBlob Class

Parameters
This method requires the two parameters listed here:

- A pointer to an ActiveHook.
- A pointer to void, for any data to be passed to the callback.

Return value
0 on success, -1 on failure.

NdbBlob::setNull()

Description
This method sets the value of a blob to NULL.

Signature
```c
int setNull
(void)
```

Parameters
None.

Return value
0 on success; -1 on failure.

NdbBlob::setPos()

Description
This method sets the position within the blob at which to read or write data.

Signature
```c
int setPos
(Uint64 pos)
```

Parameters
The setPos() method takes a single parameter pos (an unsigned 64-bit integer), which is the position for reading or writing data. The value of pos must be between 0 and the blob's current length.

Important
“Sparse” blobs are not supported in the NDB API; in other words, there can be no unused data positions within a blob.

Return value
0 on success, -1 on failure.

NdbBlob::setValue()

Description
This method is used to prepare for inserting or updating a blob value. Any existing blob data that is longer than the new data is truncated. The data buffer must remain valid until the operation has been executed. setValue() sets the current read/write position to the point following the end of the data. You can set data to a null pointer (0) in order to create a NULL value.

Signature
```c
int setValue
(const void* data,
Uint32 bytes)
```

Parameters
This method takes the two parameters listed here:

- The data that is to be inserted or used to overwrite the blob value.
- The number of bytes—that is, the length—of the data.
The NdbBlob Class

Return value
0 on success, -1 on failure.

NdbBlob::State

This is an enumerated data type which represents the possible states of an NdbBlob instance.

Description
An NdbBlob may assume any one of these states

Enumeration values
Possible values are shown, along with descriptions, in the following table:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Idle</td>
<td>The NdbBlob has not yet been prepared for use with any operations.</td>
</tr>
<tr>
<td>Prepared</td>
<td>This is the state of the NdbBlob prior to operation execution.</td>
</tr>
<tr>
<td>Active</td>
<td>This is the blob handle's state following execution or the fetching of the next result, but before the transaction is committed.</td>
</tr>
<tr>
<td>Closed</td>
<td>This state occurs after the transaction has been committed.</td>
</tr>
<tr>
<td>Invalid</td>
<td>This follows a rollback or the close of a transaction.</td>
</tr>
</tbody>
</table>

NdbBlob::truncate()

Description
This method is used to truncate a blob to a given length.

Signature
```c
int truncate
{
    Uint64 length = 0
}
```

Parameters
truncate() takes a single parameter which specifies the new length to which the blob is to be truncated. This method has no effect if length is greater than the blob's current length (which you can check using getLength()).

Return value
0 on success, -1 on failure.

NdbBlob::writeData()

Description
This method is used to write data to an NdbBlob. After a successful invocation, the read/write position will be at the first byte following the data that was written to the blob.

A write past the current end of the blob data extends the blob automatically.

Signature
```c
int writeData
{
    const void* data,
    Uint32 bytes
}
```

Parameters
This method takes two parameters, a pointer to the data to be written, and the number of bytes to write.

Return value
0 on success, -1 on failure.
2.3.14 The NdbDictionary Class

This section provides information about the NdbDictionary class, which stores meta-information about NDB database objects, such as tables, columns, and indexes.

While the preferred method of database object creation and deletion is through the MySQL Server, NdbDictionary also permits the developer to perform these tasks through the NDB API.

- NdbDictionary Class Overview
- NdbDictionary::AutoGrowSpecification
- NdbDictionary::getEmptyBitmask()
- NdbDictionary::getFirstAttrId()
- NdbDictionary::getNextAttrId()
- NdbDictionary::getNullBitOffset()
- NdbDictionary::getOffset()
- NdbDictionary::getRecordIndexName()
- NdbDictionary::getRecordRowLength()
- NdbDictionary::getRecordTableName()
- NdbDictionary::getRecordType()
- NdbDictionary::getValuePtr()
- NdbDictionary::isNull()
- NdbDictionary::RecordSpecification
- NdbDictionary::setNull()

NdbDictionary Class Overview

Parent class

None

Child classes

Dictionary, Column, Object

For the numeric equivalents to enumerations of NdbDictionary subclasses, see the file /storage/ndb/include/ndbapi/NdbDictionary.hpp in the NDB Cluster source tree.

Description

This is a data dictionary class that supports enquiries about tables, columns, and indexes. It also provides ways to define these database objects and to remove them. Both sorts of functionality are supplied using inner classes that model these objects. These include the following inner classes:

- Table for working with tables
- Column for creating table columns
- Index for working with secondary indexes
- Dictionary for creating database objects and making schema enquiries
• **Event** for working with events in the cluster.

Additional **Object** subclasses model the tablespaces, log file groups, data files, and undo files required for working with NDB Cluster Disk Data table, as well as with foreign key constraints.

Tables and indexes created using **NdbDictionary** cannot be viewed from the MySQL Server.

Dropping indexes through the NDB API that were created originally from an NDB Cluster causes inconsistencies. It is possible that a table from which one or more indexes have been dropped using the NDB API will no longer be usable by MySQL following such operations. In this event, the table must be dropped, and then re-created using MySQL to make it accessible to MySQL once more.

**Methods**

**NdbDictionary** itself has no public instance methods, only static methods that are used for working with **NdbRecord** objects. Operations not using **NdbRecord** are accomplished by means of **NdbDictionary** subclass instance methods. The following table lists the public methods of **NdbDictionary** and the purpose or use of each method:

**Table 2.37 NdbDictionary class methods and descriptions**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getEmptyBitmask()</td>
<td>Returns an empty column presence bitmask which can be used with <strong>NdbRecord</strong></td>
</tr>
<tr>
<td>getFirstAttrId()</td>
<td>Get the first attribute ID specified by a given <strong>NdbRecord</strong> object</td>
</tr>
<tr>
<td>getRecordIndexName()</td>
<td>Gets the name of the index object referred to by an <strong>NdbRecord</strong></td>
</tr>
<tr>
<td>getRecordRowLength()</td>
<td>Get the number of bytes needed to store one row of data using a given <strong>NdbRecord</strong></td>
</tr>
<tr>
<td>getRecordTableName()</td>
<td>Gets the name of the table object referred to by an <strong>NdbRecord</strong></td>
</tr>
<tr>
<td>getRecordType()</td>
<td>Gets the RecordType of an <strong>NdbRecord</strong></td>
</tr>
<tr>
<td>getValuePtr()</td>
<td>Returns a pointer to the beginning of stored data specified by attribute ID, using <strong>NdbRecord</strong></td>
</tr>
<tr>
<td>isNull()</td>
<td>Show whether the null bit for a column is true or false</td>
</tr>
<tr>
<td>setNull()</td>
<td>Set a column's null bit</td>
</tr>
</tbody>
</table>

**Types**

**NdbDictionary** defines two data structures, listed here:

• **AutoGrowSpecification**

• **RecordSpecification**

**NdbDictionary::AutoGrowSpecification**

This section provides information about the **AutoGrowSpecification** data structure.

**Parent class**

**NdbDictionary**
The NdbDictionary Class

Description

The AutoGrowSpecification is a data structure defined in the NdbDictionary class, and is used as a parameter to or return value of some of the methods of the Tablespace and LogfileGroup classes.

Members

AutoGrowSpecification has the members shown in the following table:

Table 2.38 NdbDictionary::AutoGrowSpecification data structure member names and descriptions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>min_free</td>
<td>???</td>
</tr>
<tr>
<td>max_size</td>
<td>???</td>
</tr>
<tr>
<td>file_size</td>
<td>???</td>
</tr>
<tr>
<td>filename_pattern</td>
<td>???</td>
</tr>
</tbody>
</table>

NdbDictionary::getEmptyBitmask()

Description

Returns an empty column presence bitmask which can be used with any NdbRecord to specify that no NdbRecord columns are to be included in the operation.

Signature

static const unsigned char* getEmptyBitmask()
{
    void
}

Parameters

None.

Return value

An empty bitmask.

NdbDictionary::getFirstAttrId()

Description

Get the first attribute ID specified by an NdbRecord object. Returns false if no attribute ID is specified.

Signature

static bool getFirstAttrId
(
    const NdbRecord* record,
    Uint32& firstAttrId
)

Parameters

A pointer to an NdbRecord and a reference to the attribute (firstAttrId).

Return value

Boolean false, when no attribute ID can be obtained.

NdbDictionary::getNextAttrId()

Description

Get the next attribute ID specified by an NdbRecord object following the attribute ID passed in. Returns false when there are no more attribute IDs to be returned.

Signature

static bool getNextAttrId
(
    const NdbRecord* record,
    Uint32& attrId
)

Parameters

A pointer to an NdbRecord and a reference to an attribute ID.

Return value

Boolean false, when no attribute ID can be obtained.
The NdbDictionary Class

NdbDictionary::getNullBitOffset()

Description
Get the offset of the given attribute ID's null bit from the start of the NdbRecord row. Returns false if the attribute ID is not present.

Signature
static bool getNullBitOffset
{
    const NdbRecord* record,
    Uint32 attrId,
    Uint32& bytes,
    Uint32& bit
}

Parameters
An NdbRecord record in which to get the null bit offset of the given attribute ID (attrId). The offset is expressed as a number of bytes (bytes) plus a number of bits within the last byte (bit).

Return value
Boolean false, if the attribute with the given ID is not present.

NdbDictionary::getOffset()

Description
Get the offset of the given attribute ID's storage from the start of the NdbRecord row. Returns false if the attribute id is not present

Signature
static bool getOffset
{
    const NdbRecord* record,
    Uint32 attrId,
    Uint32& offset
}

Parameters
The offset of the given attribute ID's storage from the start of the NdbRecord row.

Return value
Boolean false, if no attribute ID can be found.

NdbDictionary::getRecordIndexName()

Description
Get the name of the Index object that the NdbRecord refers to.

Signature
static const char* getRecordIndexName
{
    const NdbRecord* record
}

Parameters
A pointer to the NdbRecord for which to get the name.

Return value
The name, if any. Otherwise, or if the NdbRecord object is not of the IndexAccess type, this method returns null.

NdbDictionary::getRecordRowLength()

Description
Get the number of bytes needed to store one row of data laid out as described by the NdbRecord structure passed in to this method.

Signature
static Uint32 getRecordRowLength
{
    const NdbRecord* record
}

Parameters
An NdbRecord object.

Return value
The number of bytes needed per row.

NdbDictionary::getRecordTableName()
### NdbDictionary::getRecordTableName()

**Description**
Return the name of the table object that the `NdbRecord` refers to. This method returns null if the record is not a `TableAccess`.

**Signature**
```cpp
static const char* getRecordTableName
(const NdbRecord* record)
```

**Parameters**
The `record` (`NdbRecord` object) for which to get the table name.

**Return value**
The name of the table, or null if the `NdbRecord` object' type is not `TableAccess`.

### NdbDictionary::getRecordType()

**Description**
Return the type of the `NdbRecord` object passed.

**Signature**
```cpp
static RecordType getRecordType
(const NdbRecord* record)
```

**Parameters**
An `NdbRecord` object.

**Return value**
The `RecordType` of the `NdbRecord` (`IndexAccess` or `TableAccess`).

### NdbDictionary::getValuePtr()

**Description**
Returns a pointer to the beginning of stored data specified by attribute ID, by looking up the offset of the column stored in the `NdbRecord` object and returning the sum of the row position and the offset.

**Signature**
```cpp
static const char* getValuePtr
(const NdbRecord* record, const char* row, Uint32 attrId)
static char* getValuePtr
(const NdbRecord* record, char* row, Uint32 attrId)
```

**Parameters**
A pointer to an `NdbRecord` object describing the row format, a pointer to the start of the row data (`const` in the const version of this method), and the attribute ID of the column.

**Return value**
A pointer to the start of the attribute in the row. This is null if the attribute is not part of the `NdbRecord` definition.

### NdbDictionary::isNull()

**Description**
Indicate whether the null bit for the given column is set to `true` or `false`. The location of the null bit in relation to the row pointer is obtained from the passed `NdbRecord` object. If the column is not nullable, or if the column is not part of the `NdbRecord` definition, the method returns `false`.

**Signature**
```cpp
static bool isNull
()
```
The NdbDictionary Class

```c
const NdbRecord* record,
const char* row,
Uint32 attrId
)
```

**Parameters**
A pointer to an `NdbRecord` object describing the row format, a pointer to the start of the row data, and the attribute ID of the column to check.

**Return value**
Boolean `true` if the attribute ID exists in this `NdbRecord`, is nullable, and this row's null bit is set; otherwise, Boolean `false`.

**NdbDictionary::RecordSpecification**

This section provides information about the `RecordSpecification` structure.

**Parent class**
`NdbDictionary`

**Description**
This structure is used to specify columns and range offsets when creating `NdbRecord` objects.

**Members**
The elements making up this structure are shown in the following table:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>column</td>
<td>Column</td>
<td>The column described by this entry (the column's maximum size defines the field size for the row). Even when creating an <code>NdbRecord</code> for an index, this must point to a column obtained from the underlying table, and not from the index itself.</td>
</tr>
<tr>
<td>offset</td>
<td>Uint32</td>
<td>The offset of data from the beginning of a row. For reading blobs, the blob handle (<code>NdbBlob</code>), rather than the actual blob data, is written into the row. This means that there must be at least <code>sizeof(NdbBlob*)</code> must be available in the row.</td>
</tr>
<tr>
<td>nullbit_byte_offset</td>
<td>Uint32</td>
<td>The offset from the beginning of the row of the byte containing the NULL bit.</td>
</tr>
<tr>
<td>nullbit_bit_in_byte</td>
<td>Uint32</td>
<td>NULL bit (0-7).</td>
</tr>
</tbody>
</table>
nullbit_byte_offset and nullbit_bit_in_byte are not used for non-nullable columns.

For more information, see Section 2.3.22, “The NdbRecord Interface”.

**NdbDictionary::setNull()**

**Description**
Set the null bit for the given column to the supplied value. The offset for the null bit is obtained from the passed NdbRecord object. If the attribute ID is not part of the NdbRecord, or if it is not nullable, this method returns an error (-1).

**Signature**
```cpp
static int setNull
(const NdbRecord* record,
 char* row,
 Uint32 attrId,
 bool value)
```

**Parameters**
A pointer to the record (NdbRecord object) describing the row format; a pointer to the start of the row data; the attribute ID of the column (attrId); and the value to set the null bit to (true or false).

**Return value**
Returns 0 on success; returns -1 if the attrId is not part of the record, or is not nullable.

### 2.3.15 The NdbError Structure

This section provides information about the NdbError data structure, which contains status and other information about errors, including error codes, classifications, and messages.

- NdbError Overview
- NdbError::Classification
- NdbError::Status

**NdbError Overview**

**Description**
An NdbError consists of six parts, listed here, of which one is deprecated:

1. **Error status**: This describes the impact of an error on the application, and reflects what the application should do when the error is encountered.

   The error status is described by a value of the Status type. See NdbError::Status, for possible Status values and how they should be interpreted.

2. **Error classification**: This represents a logical error type or grouping.

   The error classification is described by a value of the Classification type. See NdbError::Classification, for possible classifications and their interpretation. Additional information is provided in Section 2.4.4, "NDB Error Classifications".
3. **Error code**: This is an NDB API internal error code which uniquely identifies the error.

**Important**

It is *not* recommended to write application programs which are dependent on specific error codes. Instead, applications should check error status and classification. More information about errors can also be obtained by checking error messages and (when available) error detail messages. However—like error codes—these error messages and error detail messages are subject to change.

A listing of current error codes, broken down by classification, is provided in Section 2.4.2, “NDB Error Codes: by Type”. This listing is updated with new NDB Cluster releases. You can also check the file `storage/ndb/src/ndbapi/ndberror.c` in the NDB Cluster sources.

4. **MySQL Error code**: This is the corresponding MySQL Server error code. MySQL error codes are not discussed in this document; please see Server Error Message Reference, in the MySQL Manual, for information about these.

5. **Error message**: This is a generic, context-independent description of the error.

6. **Error details**: This can often provide additional information (not found in the error message) about an error, specific to the circumstances under which the error is encountered. However, it is not available in all cases.

Where not specified, the error detail message is `NULL`.

**Note**

This property is deprecated and scheduled for eventual removal. For obtaining error details, you should use the `Ndb::getNdbErrorDetail()` method instead.

Specific NDB API error codes, messages, and detail messages are subject to change without notice.
Definition

The `NdbError` structure contains the following members, whose types are as shown here:

- **Status status**: The error status.
- **Classification classification**: The error type (classification).
- **int code**: The NDB API error code.
- **int mysql_code**: The MySQL error code.
- **const char* message**: The error message.
- **char* details**: The error detail message.

`details` is deprecated and scheduled for eventual removal. You should use the `Ndb::getNdbErrorDetail()` method instead. (Bug #48851)

Types

`NdbError` defines the two data types listed here:

- **Classification**: The type of error or the logical grouping to which the error belongs.
- **Status**: The error status.

### NdbError::Classification

This section provides information about the `Classification` data type.

**Description**

This type describes the type of error, or the logical group to which it belongs.

**Enumeration values**

Possible values are shown, along with descriptions, in the following table:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NoError</td>
<td>Indicates success (no error occurred)</td>
</tr>
<tr>
<td>ApplicationError</td>
<td>An error occurred in an application program</td>
</tr>
<tr>
<td>NoDataFound</td>
<td>A read operation failed due to one or more missing records.</td>
</tr>
<tr>
<td>ConstraintViolation</td>
<td>A constraint violation occurred, such as attempting to insert a tuple having a primary key value already in use in the target table.</td>
</tr>
<tr>
<td>SchemaError</td>
<td>An error took place when trying to create or use a table.</td>
</tr>
<tr>
<td>InsufficientSpace</td>
<td>There was insufficient memory for data or indexes.</td>
</tr>
<tr>
<td>TemporaryResource</td>
<td>This type of error is typically encountered when there are too many active transactions.</td>
</tr>
</tbody>
</table>
### The NdbEventOperation Class

This section provides information about the `NdbEventOperation` class, which is used to monitor changes (events) in a database. It provides the core functionality used to implement NDB Cluster Replication.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NodeRecoveryError</td>
<td>This is a temporary failure which was likely caused by a node recovery in progress, some examples being when information sent between an application and NDB is lost, or when there is a distribution change.</td>
</tr>
<tr>
<td>OverloadError</td>
<td>This type of error is often caused when there is insufficient log file space.</td>
</tr>
<tr>
<td>TimeoutExpired</td>
<td>A timeout, often caused by a deadlock.</td>
</tr>
<tr>
<td>UnknownResultError</td>
<td>It is not known whether a transaction was committed.</td>
</tr>
<tr>
<td>InternalError</td>
<td>A serious error has occurred in NDB itself.</td>
</tr>
<tr>
<td>FunctionNotImplemented</td>
<td>The application attempted to use a function which is not yet implemented.</td>
</tr>
<tr>
<td>UnknownErrorCode</td>
<td>This is seen where the NDB error handler cannot determine the correct error code to report.</td>
</tr>
<tr>
<td>NodeShutdown</td>
<td>This is caused by a node shutdown.</td>
</tr>
<tr>
<td>SchemaObjectExists</td>
<td>The application attempted to create a schema object that already exists.</td>
</tr>
<tr>
<td>InternalTemporary</td>
<td>A request was sent to a node other than the master.</td>
</tr>
</tbody>
</table>

Related information specific to certain error conditions can be found in Section 2.4.2, “NDB Error Codes: by Type”, and in Section 2.4.4, “NDB Error Classifications”.

### NdbError::Status

This section provides information about the `Status` data type.

- **Description**: This type is used to describe an error’s status.
- **Enumeration values**: Possible values are shown, along with descriptions, in the following table:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Success</td>
<td>No error has occurred</td>
</tr>
<tr>
<td>TemporaryError</td>
<td>A temporary and usually recoverable error; the application should retry the operation giving rise to the error</td>
</tr>
<tr>
<td>PermanentError</td>
<td>Permanent error; not recoverable</td>
</tr>
<tr>
<td>UnknownResult</td>
<td>The operation’s result or status is unknown</td>
</tr>
</tbody>
</table>

Related information specific to certain error conditions can be found in Section 2.4.4, “NDB Error Classifications”.

### 2.3.16 The NdbEventOperation Class

This section provides information about the `NdbEventOperation` class, which is used to monitor changes (events) in a database. It provides the core functionality used to implement NDB Cluster Replication.
The NdbEventOperation Class

- NdbEventOperation Class Overview

- NdbEventOperation::clearError() (DEPRECATED)
- NdbEventOperation::execute()
- NdbEventOperation::getBlobHandle()
- NdbEventOperation::getEpoch()
- NdbEventOperation::getEventType() (DEPRECATED)
- NdbEventOperation::getEventType2()
- NdbEventOperation::getGCI() (DEPRECATED)
- NdbEventOperation::getLatestGCI() (DEPRECATED)
- NdbEventOperation::getNdbError()
- NdbEventOperation::getPreBlobHandle()
- NdbEventOperation::getPreValue()
- NdbEventOperation::getState()
- NdbEventOperation::getValue()
- NdbEventOperation::hasError() (DEPRECATED)
- NdbEventOperation::isConsistent() (DEPRECATED)
- NdbEventOperation::isEmptyEpoch()
- NdbEventOperation::isErrorEpoch()
- NdbEventOperation::isOverrun()
- NdbEventOperation::mergeEvents()
- NdbEventOperation::State
- NdbEventOperation::tableFragmentationChanged()
- NdbEventOperation::tableFrmChanged()
- NdbEventOperation::tableNameChanged()
- NdbEventOperation::tableRangeListChanged()

**NdbEventOperation Class Overview**

Parent class

None

Child classes

None

Description

NdbEventOperation represents a database event.

Methods

The following table lists the public methods of this class and the purpose or use of each method:

**Table 2.42 NdbEventOperation class methods and descriptions**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>clearError()</td>
<td>Clears the most recent error. Deprecated in NDB 7.4.</td>
</tr>
<tr>
<td>execute()</td>
<td>Activates the NdbEventOperation</td>
</tr>
</tbody>
</table>
The NdbEventOperation Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getBlobHandle()</td>
<td>Gets a handle for reading blob attributes</td>
</tr>
<tr>
<td>getEpoch()</td>
<td>Retrieves the epoch for the event data most recently retrieved. Added in NDB 7.4.</td>
</tr>
<tr>
<td>getEventType()</td>
<td>Gets the event type. Deprecated in NDB 7.4.</td>
</tr>
<tr>
<td>getEventType2()</td>
<td>Gets the event type. Added in NDB 7.4.</td>
</tr>
<tr>
<td>getGCI()</td>
<td>Retrieves the GCI of the most recently retrieved event. Deprecated in NDB 7.4.</td>
</tr>
<tr>
<td>getLatestGCI()</td>
<td>Retrieves the most recent GCI (whether or not the corresponding event has been retrieved). Deprecated in NDB 7.4.</td>
</tr>
<tr>
<td>getNdbError()</td>
<td>Gets the most recent error</td>
</tr>
<tr>
<td>getPreBlobHandle()</td>
<td>Gets a handle for reading the previous blob attribute</td>
</tr>
<tr>
<td>getPreValue()</td>
<td>Retrieves an attribute’s previous value</td>
</tr>
<tr>
<td>getState()</td>
<td>Gets the current state of the event operation</td>
</tr>
<tr>
<td>getValue()</td>
<td>Retrieves an attribute value</td>
</tr>
<tr>
<td>hasError()</td>
<td>Whether an error has occurred as part of this operation. Deprecated in NDB 7.4.</td>
</tr>
<tr>
<td>isConsistent()</td>
<td>Detects event loss caused by node failure. Deprecated in NDB 7.4.</td>
</tr>
<tr>
<td>isEmptyEpoch()</td>
<td>Detects an empty epoch. Added in NDB 7.4.</td>
</tr>
<tr>
<td>isErrorEpoch()</td>
<td>Detects an error epoch, and retrieves the error if there is one. Added in NDB 7.4.</td>
</tr>
<tr>
<td>isOverrun()</td>
<td>Whether event loss has taken place due to a buffer overrun. Deprecated in NDB 7.4.</td>
</tr>
<tr>
<td>mergeEvents()</td>
<td>Makes it possible for events to be merged</td>

</tr>
<tr>
<td>tableFrmChanged()</td>
<td>Checks to see whether a table .FRM file has changed</td>
</tr>
<tr>
<td>tableNameChanged()</td>
<td>Checks to see whether the name of a table has changed</td>
</tr>
<tr>
<td>tableRangeListChanged()</td>
<td>Checks to see whether a table range partition list name has changed</td>
</tr>
</tbody>
</table>

Types

NdbEventOperation defines one enumerated type, the State type.

Creating an Instance of NdbEventOperation. This class has no public constructor or destructor. Instead, instances of NdbEventOperation are created as the result of method calls on Ndb and NdbDictionary objects, subject to the following conditions:

1. There must exist an event which was created using Dictionary::createEvent(). This method returns an instance of the Event class.

2. An NdbEventOperation object is instantiated using Ndb::createEventOperation(), which acts on an instance of Event.
The NdbEventOperation Class

An instance of this class is removed by invoking `Ndb::dropEventOperation`.

**Tip**

A detailed example demonstrating creation and removal of event operations is provided in Section 2.5.9, “NDB API Event Handling Example”.

**Known Issues.**

The following issues may be encountered when working with event operations in the NDB API:

- The maximum number of active `NdbEventOperation` objects is currently fixed at compile time at $2 \times \text{MaxNoOfTables}$.

- Currently, all `INSERT`, `DELETE`, and `UPDATE` events—as well as all attribute changes—are sent to the API, even if only some attributes have been specified. However, these are hidden from the user and only relevant data is shown after calling `Ndb::nextEvent()`.

  Note that false exits from `Ndb::pollEvents()` may occur, and thus the following `nextEvent()` call returns zero, since there was no available data. In such cases, simply call `pollEvents()` again.

  See `Ndb::pollEvents()`, and `Ndb::nextEvent()` (DEPRECATED).

- Event code does *not* check the table schema version. When a table is dropped, make sure that you drop any associated events.

- If you have received a complete epoch, events from this epoch are not re-sent, even in the event of a node failure. However, if a node failure has occurred, subsequent epochs may contain duplicate events, which can be identified by duplicated primary keys.

  In the NDB Cluster replication code, duplicate primary keys on `INSERT` operations are normally handled by treating such inserts as `REPLACE` operations.

**Tip**

To view the contents of the system table containing created events, you can use the `ndb_select_all` utility as shown here:

```
ndb_select_all -d sys 'NDB$EVENTS_0'
```

### NdbEventOperation::clearError() (DEPRECATED)

**Description**

Clears the error most recently associated with this event operation.

This method is deprecated in NDB 7.4, and is subject to removal in a future release.

**Signature**

```cpp
void clearError()
{
  void
}
```

**Parameters**

None.

**Return value**

None.

### NdbEventOperation::execute()

**Description**

Activates the `NdbEventOperation`, so that it can begin receiving events. Changed attribute values may be retrieved after `Ndb::nextEvent()` has returned a value other than `NULL`.

One of `getValue()`, `getPreValue()`, `getBlobValue()`, or `getPreBlobValue()` must be called before invoking `execute()`.
The NdbEventOperation Class

Before attempting to use this method, you should have read the explanations provided in Ndb::nextEvent() (DEPRECATED), and NdbEventOperation::getValue(). Also see Section 2.3.16, “The NdbEventOperation Class”.

**Signature**

```c
int execute
{
    void
}
```

**Parameters**

*None.*

**Return value**

This method returns 0 on success and -1 on failure.

---

**NdbEventOperation::getBlobHandle()**

**Description**

This method is used in place of `getValue()` for blob attributes. The blob handle (NdbBlob) returned by this method supports read operations only.

To obtain the previous value for a blob attribute, use `getPreBlobHandle()`.

**Signature**

```c
NdbBlob* getBlobHandle
{
    const char* name
}
```

**Parameters**

The *name* of the blob attribute.

**Return value**

A pointer to an NdbBlob object.

---

**NdbEventOperation::getEpoch()**

**Description**

Gets the epoch for the latest event data retrieved.

Added in NDB 7.4, this method supersedes `getGCI()`, which is now deprecated and subject to removal in a future NDB Cluster release.

**Signature**

```c
Uint64 getEpoch
{
    void
} const
```

**Parameters**

*None.*

**Return value**

An epoch number (an integer).

---

**NdbEventOperation::getEventType()** (DEPRECATED)

**Description**

This method is used to obtain the event’s type (`TableEvent`).

This method is deprecated in NDB 7.4, and is subject to removal in a future release. In NDB 7.4 and later, use `getEventType2()` instead.

**Signature**

```c
NdbDictionary::Event::TableEvent getEventType
{
    void
} const
```

**Parameters**

*None.*
### NdbEventOperation::getEventType2()

**Description**
This method is used to obtain the event's type (`TableEvent`).

Added in NDB 7.4, this method supersedes `getEventType()`, which is now deprecated and subject to removal in a future NDB Cluster release.

**Signature**
```cpp
getEventType2()
(  
   void  
) const
```

**Parameters**
None.

**Return value**
A `TableEvent` value.

### NdbEventOperation::getGCI() (DEPRECATED)

**Description**
This method retrieves the GCI for the most recently retrieved event.

This method is deprecated in NDB 7.4, and is subject to removal in a future release. In NDB 7.4 and later, use `getEpoch()` instead.

**Signature**
```cpp
Uint64 getGCI
(  
   void  
) const
```

**Parameters**
None.

**Return value**
The global checkpoint index of the most recently retrieved event (an integer).

### NdbEventOperation::getLatestGCI() (DEPRECATED)

**Description**
This method retrieves the most recent GCI.

This method returns the latest epoch number.

The GCI obtained using this method is not necessarily associated with an event.

This method is deprecated in NDB 7.4, and is subject to removal in a future release. In NDB 7.4 and later, use `Ndb::getHighestQueuedEpoch()` instead.

**Signature**
```cpp
Uint64 getLatestGCI
(  
   void  
) const
```

**Parameters**
None.

**Return value**
The index of the latest global checkpoint, an integer.

### NdbEventOperation::getNdbError()

**Description**
This method retrieves the most recent error.

**Signature**
```cpp
const struct NdbError& getNdbError
(  
) const
```
The NdbEventOperation Class

```
void
) const
```

Parameters None.

Return value A reference to an NdbError structure.

**NdbEventOperation::getPreBlobHandle()**

Description This function is the same as getBlobHandle(), except that it is used to access the previous value of the blob attribute. See NdbEventOperation::getBlobHandle().

Signature
```
NdbBlob* getPreBlobHandle
{  
    const char* name
}
```

Parameters The name of the blob attribute.

Return value A pointer to an NdbBlob.

**NdbEventOperation::getPreValue()**

Description This method performs identically to getValue(), except that it is used to define a retrieval operation of an attribute's previous value rather than the current value.

Signature
```
NdbRecAttr* getPreValue
{  
    const char* name,  
    char*      value = 0
}
```

Parameters This method takes the two parameters listed here:

- The name of the attribute (as a constant character pointer).
- A pointer to a value, such that:
  - If the attribute value is not NULL, then the attribute value is returned in this parameter.
  - If the attribute value is NULL, then the attribute value is stored only in the NdbRecAttr object returned by this method.

See value Buffer Memory Allocation, for more information regarding this parameter.

Return value An NdbRecAttr object to hold the value of the attribute, or a NULL pointer indicating that an error has occurred.

**NdbEventOperation::getState()**

Description This method gets the event operation's current state.

Signature
```
State getState
{  
    void
}
```

Parameters None.

Return value A State value.
The NdbEventOperation Class

NdbEventOperation::getValue()

Description

This method defines the retrieval of an attribute value. The NDB API allocates memory for the NdbRecAttr object that is to hold the returned attribute value.

This method does not fetch the attribute value from the database, and the NdbRecAttr object returned by this method is not readable or printable before calling the execute() method and Ndb::nextEvent() has returned a non-NULL value.

If a specific attribute has not changed, the corresponding NdbRecAttr will be in the state UNDEFINED. This can be checked by using NdbRecAttr::isNull() which in such cases returns -1.

getValue() retrieves the current value. Use getPreValue() for retrieving the previous value.

Signature

NdbRecAttr* getValue
{
    const char* name,
    char* value = 0
}

Parameters

This method takes the two parameters listed here:

• The name of the attribute (as a constant character pointer).

• A pointer to a value, such that:
  • If the attribute value is not NULL, then the attribute value is returned in this parameter.
  • If the attribute value is NULL, then the attribute value is stored only in the NdbRecAttr object returned by this method.

See value Buffer Memory Allocation, for more information regarding this parameter.

Return value

An NdbRecAttr object to hold the value of the attribute, or a NULL pointer indicating that an error has occurred.

value Buffer Memory Allocation. It is the application’s responsibility to allocate sufficient memory for the value buffer (if not NULL), and this buffer must be aligned appropriately. The buffer is used directly (thus avoiding a copy penalty) only if it is aligned on a 4-byte boundary and the attribute size in bytes (calculated as NdbRecAttr::get_size_in_bytes()) is a multiple of 4.

NdbEventOperation::hasError() (DEPRECATED)

Description

This method is used to determine whether there is an error associated with this event operation.

This method is deprecated in NDB 7.4, and is subject to removal in a future release. In NDB 7.4 and later, use getEventType2() to determine the event type. See Event::TableEvent.

Signature

int hasError
{
    void
} const

Parameters

None.
Return value
If event loss has taken place, then this method returns 0; otherwise, it returns 1.

**NdbEventOperation::isConsistent() (DEPRECATED)**

**Description**
This method is used to determine whether event loss has taken place following the failure of a node.

This method is deprecated in NDB 7.4, and is subject to removal in a future release. In NDB 7.4 and later, use `getEventType2()` to determine whether the event is of type TE_INCONSISTENT. See Event::TableEvent.

**Signature**
```cpp
bool isConsistent
{
    void
} const
```

**Parameters**
*None.*

**Return value**
If event loss has taken place, then this method returns `false`; otherwise, it returns `true`.

**NdbEventOperation::isEmptyEpoch()**

**Description**
This method is used to determine whether consumed event data marks an empty epoch.

This method was added in NDB 7.4.

**Signature**
```cpp
bool isEmptyEpoch
{
    void
}
```

**Parameters**
*None.*

**Return value**
If this epoch is empty, the method returns `true`; otherwise, it returns `false`.

**NdbEventOperation::isErrorEpoch()**

**Description**
This method is used to determine whether consumed event data marks an empty epoch.

This method was added in NDB 7.4.

**Signature**
```cpp
bool isErrorEpoch
{
    NdbDictionary::Event::TableEvent* error_type = 0
}
```

**Parameters**
If this is an error epoch, `error_type` contains the TableEvent value corresponding to the error.

**Return value**
If this epoch is in error, the method returns `true`; otherwise, it returns `false`.

**NdbEventOperation::isOverrun()**

**Description**
This method is used to determine whether event loss has taken place due to a buffer overrun.

**Signature**
```cpp
bool isOverrun
```
The NdbEventOperation Class

NdbEventOperation::mergeEvents()

Description
This method is used to set the merge events flag. For information about event merging, see Event::mergeEvents().

Signature
```cpp
void mergeEvents
    (bool flag)
```

Parameters
A Boolean flag.

Return value
None.

NdbEventOperation::State

This section provides information about the State data type.

Description
This type describes the event operation's state.

A State value is returned by the getState() method.

Enumeration values
Possible values are shown, along with descriptions, in the following table:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EO_CREATED</td>
<td>The event operation has been created, but execute() has not yet been called.</td>
</tr>
<tr>
<td>EO_EXECUTING</td>
<td>The execute() method has been invoked for this event operation.</td>
</tr>
<tr>
<td>EO_DROPPED</td>
<td>The event operation is waiting to be deleted, and is no longer usable.</td>
</tr>
<tr>
<td>EO_ERROR</td>
<td>An error has occurred, and the event operation is unusable.</td>
</tr>
</tbody>
</table>

NdbEventOperation::tableFragmentationChanged()

Description
This method is used to test whether a table’s fragmentation has changed in connection with a TE_ALTER event. (See Event::TableEvent.)

Signature
```cpp
bool tableFragmentationChanged
    (void) const
```

Parameters
None.
### NdbIndexOperation Class Overview

- NdbIndexOperation Class Overview
- NdbIndexOperation::deleteTuple()
- NdbIndexOperation::getIndex()
- NdbIndexOperation::readTuple()
- NdbIndexOperation::updateTuple()
**NdbIndexOperation Class Overview**

**Parent class**  
*NdbOperation*

**Child classes**  
*None*

**Description**  
*NdbIndexOperation* represents an index operation for use in transactions. This class inherits from *NdbOperation*.

*NdbIndexOperation* can be used only with unique hash indexes; to work with ordered indexes, use *NdbIndexScanOperation*.

This class has no public constructor. To create an instance of *NdbIndexOperation*, it is necessary to use the *NdbTransaction::getNdbIndexOperation()* method.

**Methods**  
The following table lists the public methods of this class and the purpose or use of each method:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>deleteTuple()</td>
<td>Removes a tuple from a table</td>
</tr>
<tr>
<td>getIndex()</td>
<td>Gets the index used by the operation</td>
</tr>
<tr>
<td>readTuple()</td>
<td>Reads a tuple from a table</td>
</tr>
<tr>
<td>updateTuple()</td>
<td>Updates an existing tuple in a table</td>
</tr>
</tbody>
</table>

Index operations are not permitted to insert tuples.

**Types**  
The *NdbIndexOperation* class defines no public types of its own.

For more information about the use of *NdbIndexOperation*, see Single-row operations.

**NdbIndexOperation::deleteTuple()**

**Description**  
This method defines the *NdbIndexOperation* as a DELETE operation. When the *NdbTransaction::execute()* method is invoked, the operation deletes a tuple from the table.

**Signature**  
```
int deleteTuple(
    void
)
```

**Parameters**  
*None.*

**Return value**  
0 on success, -1 on failure.

**NdbIndexOperation::getIndex()**

**Description**  
 Gets the index, given an index operation.

**Signature**  
```
const NdbDictionary::Index* getIndex(
    void
) const
```

**Parameters**  
*None.*

**Return value**  
A pointer to an Index object.

**NdbIndexOperation::readTuple()**
The NdbIndexScanOperation Class

**Description**

This method defines the `NdbIndexOperation` as a READ operation. When the `NdbTransaction::execute()` method is invoked, the operation reads a tuple.

**Signature**

```cpp
int readTuple
    (LockMode mode)
```

**Parameters**

`mode` specifies the locking mode used by the read operation. See `NdbOperation::LockMode`, for possible values.

**Return value**

0 on success, -1 on failure.

**NdbIndexOperation::updateTuple()**

**Description**

This method defines the `NdbIndexOperation` as an UPDATE operation. When the `NdbTransaction::execute()` method is invoked, the operation updates a tuple found in the table.

**Signature**

```cpp
int updateTuple
    (void)
```

**Parameters**

`None`.

**Return value**

0 on success, -1 on failure.

### 2.3.18 The NdbIndexScanOperation Class

This section provides information about the `NdbIndexScanOperation` class.

- `NdbIndexScanOperation Class Overview`
- `NdbIndexScanOperation::BoundType`
- `NdbIndexScanOperation::end_of_bound()`
- `NdbIndexScanOperation::getDescending()`
- `NdbIndexScanOperation::get_range_no()`
- `NdbIndexScanOperation::getSorted()`
- `NdbIndexScanOperation::IndexBound`
- `NdbIndexScanOperation::readTuples()`
- `NdbIndexScanOperation::reset_bounds()`
- `NdbIndexScanOperation::setBound()`

**NdbIndexScanOperation Class Overview**

- **Parent class**: `NdbScanOperation`
- **Child classes**: `None`
- **Description**: The `NdbIndexScanOperation` class represents a scan operation using an ordered index. This class inherits from `NdbScanOperation` and `NdbOperation`. `NdbIndexScanOperation` is for use with ordered indexes only; to work with unique hash indexes, use `NdbIndexOperation`.
The `NdbIndexScanOperation` Class

For more information about the use of `NdbIndexScanOperation`, see Scan Operations, and Using Scans to Update or Delete Rows.

Methods

The following table lists the public methods of this class and the purpose or use of each method:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>end_of_bound()</code></td>
<td>Marks the end of a bound</td>
</tr>
<tr>
<td><code>get_range_no()</code></td>
<td>Gets the range number for the current row</td>
</tr>
<tr>
<td><code>getDescending()</code></td>
<td>Checks whether the current scan is sorted</td>
</tr>
<tr>
<td><code>getSorted()</code></td>
<td>Checks whether the current scan is sorted</td>
</tr>
<tr>
<td><code>readTuples()</code></td>
<td>Reads tuples using an ordered index</td>
</tr>
<tr>
<td><code>reset_bounds()</code></td>
<td>Resets bounds, puts the operation in the send queue</td>
</tr>
<tr>
<td><code>setBound()</code></td>
<td>Defines a bound on the index key for a range scan</td>
</tr>
</tbody>
</table>

Types

The `NdbIndexScanOperation` class defines one public type `BoundType`.

This class also defines an `IndexBound` data structure, for use with operations employing `NdbRecord`.

### `NdbIndexScanOperation::BoundType`

This section provides information about the `BoundType` data type.

**Description**

This type is used to describe an ordered key bound.

**Enumeration values**

Possible values are shown, along with descriptions, in the following table:

<table>
<thead>
<tr>
<th>Value</th>
<th>Numeric Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BoundLE</td>
<td>0</td>
<td>Lower bound</td>
</tr>
<tr>
<td>BoundLT</td>
<td>1</td>
<td>Strict lower bound</td>
</tr>
<tr>
<td>BoundGE</td>
<td>2</td>
<td>Upper bound</td>
</tr>
<tr>
<td>BoundGT</td>
<td>3</td>
<td>Strict upper bound</td>
</tr>
<tr>
<td>BoundEQ</td>
<td>4</td>
<td>Equality</td>
</tr>
</tbody>
</table>

The numeric values just shown are “safe”; that is, they are fixed in the API, and so can be calculated and used explicitly.

### `NdbIndexScanOperation::end_of_bound()`

**Description**

This method is used to mark the end of a bound; it is used when batching index reads (that is, when employing multiple ranges).

**Signature**

```c
int end_of_bound
  (Uint32 range_no
```
The NdbIndexScanOperation Class

Parameters
The number of the range on which the bound occurs.

Return value
0 indicates success; -1 indicates failure.

NdbIndexScanOperation::getDescending()

Description
This method is used to check whether the scan is descending.

Signature
```cpp
bool getDescending
{
    void
} const
```

Parameters
None.

Return value
This method returns true if the scan is sorted in descending order; otherwise, it returns false.

NdbIndexScanOperation::get_range_no()

Description
This method returns the range number for the current row.

Signature
```cpp
int get_range_no
{
    void
}
```

Parameters
None.

Return value
The range number (an integer).

NdbIndexScanOperation::getSorted()

Description
This method is used to check whether the scan is sorted.

Signature
```cpp
bool getSorted
{
    void
} const
```

Parameters
None.

Return value
true if the scan is sorted, otherwise false.

NdbIndexScanOperation::IndexBound

This section provides information about the IndexBound data structure.

Parent class
NdbIndexScanOperation

Description
IndexBound is a structure used to describe index scan bounds for NdbRecord scans.

Members
Member names, types, and descriptions are shown in the following table:

Table 2.47 IndexBound structure member names, types, and descriptions

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>low_key</td>
<td>const char*</td>
<td>Row containing lower bound for scan (or NULL for scan from the start).</td>
</tr>
</tbody>
</table>
The NdbIndexScanOperation Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>low_key_count</td>
<td>Uint32</td>
<td>Number of columns in lower bound (for bounding by partial prefix).</td>
</tr>
<tr>
<td>low_inclusive</td>
<td>bool</td>
<td>True for &lt;= relation, false for &lt;.</td>
</tr>
<tr>
<td>high_key</td>
<td>const char*</td>
<td>Row containing upper bound for scan (or NULL for scan to the end).</td>
</tr>
<tr>
<td>high_key_count</td>
<td>Uint32</td>
<td>Number of columns in upper bound (for bounding by partial prefix).</td>
</tr>
<tr>
<td>high_inclusive</td>
<td>bool</td>
<td>True for &gt;= relation, false for &gt;.</td>
</tr>
<tr>
<td>range_no</td>
<td>Uint32</td>
<td>Value to identify this bound; may be read using the get_range_no() method (see NdbIndexScanOperation::get_range_no()). This value must be less than 8192 (set to zero if it is not being used). For ordered scans, range_no must be strictly increasing for each range, or else the result set will not be sorted correctly.</td>
</tr>
</tbody>
</table>

For more information, see Section 2.3.22, “The NdbRecord Interface”.

NdbIndexScanOperation::readTuples()

Description
This method is used to read tuples, using an ordered index.

Signature
```cpp
virtual int readTuples
{
    LockMode mode = LM_Read,
    Uint32 flags = 0,
    Uint32 parallel = 0,
    Uint32 batch = 0
}
```

Parameters
The readTuples() method takes the three parameters listed here:

- The lock mode used for the scan. This is a LockMode value; see NdbOperation::LockMode for more information, including permitted values.
- One or more scan flags; multiple flags are OR’ed together as they are when used with NdbScanOperation::readTuples(). See NdbScanOperation::ScanFlag for possible values.
- The number of fragments to scan in parallel; use 0 to specify the maximum automatically.
• The `batch` parameter specifies how many records will be returned to the client from the server by the next `NdbScanOperation::nextResult(true)` method call. Use 0 to specify the maximum automatically.

**Note**
This parameter was ignored prior to MySQL 5.1.12, and the maximum was used. (Bug #20252)

**Return value**
An integer: 0 indicates success; -1 indicates failure.

**NdbIndexScanOperation::reset_bounds()**

**Description**
 Resets the bounds, and puts the operation into the list sent on the next call to `NdbTransaction::execute()`.

**Signature**
```c++
int reset_bounds
{
    bool forceSend = false
}
```

**Parameters**
Set `forceSend` to `true` in order to force the operation to be sent immediately.

**Return value**
Returns 0 on success, -1 on failure.

**NdbIndexScanOperation::setBound()**

**Description**
This method defines a bound on an index key used in a range scan, and sets bounds for index scans defined using NdbRecord.

As used with NdbRecord, this method is called to add a range to an index scan operation which has been defined with a call to `NdbTransaction::scanIndex()`. To add more than one range, the index scan operation must have been defined with the `SF_MultiRange` flag set. (See `NdbScanOperation::ScanFlag`.)

Where multiple numbered ranges are defined with multiple calls to `setBound()`, and the scan is ordered, the range number for each range must be larger than the range number for the previously defined range.

**Signature**
```c++
int setBound
{
    const NdbRecord* keyRecord,
    const IndexBound& bound
}
```

**Parameters**
As used with NdbRecord, this method takes 2 parameters, listed here:

• `keyRecord`: This is an NdbRecord structure corresponding to the key on which the index is defined.

• The `bound` to add (see `NdbIndexScanOperation::IndexBound`).

**Return value**
Returns 0 on success, -1 on failure.

An additional version of this method can be used when the application knows that rows in-range will be found only within a particular partition. This is the same as that shown previously, except for...
the addition of a `PartitionSpec`. Doing so limits the scan to a single partition, improving system efficiency.

### Signature (when specifying a partition)

```c
int setBound
{
    const NdbRecord* keyRecord,
    const IndexBound& bound,
    const Ndb::PartitionSpec* partInfo,
    Uint32 sizeOfPartInfo = 0
}
```

### Parameters (when specifying a partition)
This method can also be invoked with the following four parameters:

- `keyRecord`: This is an `NdbRecord` structure corresponding to the key on which the index is defined.

- The `bound` to be added to the scan (see `NdbIndexScanOperation::IndexBound`).

- `partInfo`: This is a pointer to a `PartitionSpec`, which provides extra information making it possible to scan a reduced set of partitions.

- `sizeOfPartInfo`: The length of the partition specification.

`keyRecord` and `bound` are defined and used in the same way as with the 2-parameter version of this method.

### Return value
Returns 0 on success, -1 on failure.

### “Old” API usage (prior to introduction of NdbRecord)
Each index key can have a lower bound, upper bound, or both. Setting the key equal to a value defines both upper and lower bounds. Bounds can be defined in any order. Conflicting definitions gives rise to an error.

Bounds must be set on initial sequences of index keys, and all but possibly the last bound must be nonstrict. This means, for example, that “a >= 2 AND b > 3” is permissible, but “a > 2 AND b >= 3” is not.

The scan may currently return tuples for which the bounds are not satisfied. For example, a <= 2 && b <= 3 not only scans the index up to (a=2, b=3), but also returns any (a=1, b=4) as well.

When setting bounds based on equality, it is better to use `BoundEQ` instead of the equivalent pair `BoundLE` and `BoundGE`. This is especially true when the table partition key is a prefix of the index key.

`NULL` is considered less than any non-`NULL` value and equal to another `NULL` value. To perform comparisons with `NULL`, use `setBound()` with a null pointer (0).

An index also stores all-`NULL` keys as well, and performing an index scan with an empty bound set returns all tuples from the table.

### Signature (“Old” API)
Using the “old” API, this method could be called in either of two ways. Both of these use the bound type and value; the first also uses the name of the bound, as shown here:

```c
int setBound
{
    const char* name,
```
The second way to invoke this method under the “old” API uses the bound’s ID rather than the name, as shown here:

```c
int setBound
{
    Uint32 id,
    int type,
    const void* value
}
```

### Parameters (“Old” API)

This method takes 3 parameters:

- Either the `name` or the `id` of the attribute on which the bound is to be set.
- The bound `type`—see `NdbIndexScanOperation::BoundType`.
- A pointer to the bound `value` (use `0` for `NULL`).

### Return value

Returns `0` on success, `-1` on failure.

---

### 2.3.19 The NdbInterpretedCode Class

This section provides information about the `NdbInterpretedCode` class, which can be used to prepare and execute an NDB API interpreted program.

- `NdbInterpretedCode` Class Overview
- `NdbInterpretedCode Constructor`
- `NdbInterpretedCode::add_reg()`
- `NdbInterpretedCode::add_val()`
- `NdbInterpretedCode::branch_col_and_mask_eq_mask()`
- `NdbInterpretedCode::branch_col_and_mask_eq_zero()`
- `NdbInterpretedCode::branch_col_and_mask_ne_mask()`
- `NdbInterpretedCode::branch_col_and_mask_ne_zero()`
- `NdbInterpretedCode::branch_col_eq()`
- `NdbInterpretedCode::branch_col_eq_null()`
- `NdbInterpretedCode::branch_col_eq_param()`
- `NdbInterpretedCode::branch_col_ge()`
- `NdbInterpretedCode::branch_col_ge_param()`
- `NdbInterpretedCode::branch_col_gt()`
- `NdbInterpretedCode::branch_col_gt_param()`
- `NdbInterpretedCode::branch_col_le()`
- `NdbInterpretedCode::branch_col_le_param()`
- `NdbInterpretedCode::branch_col_like()`
- `NdbInterpretedCode::branch_col_lt()`
The NdbInterpretedCode Class

- NdbInterpretedCode::branch_col_lt_param()
- NdbInterpretedCode::branch_col_ne()
- NdbInterpretedCode::branch_col_ne_null()
- NdbInterpretedCode::branch_col_ne_param()
- NdbInterpretedCode::branch_col_notlike()
- NdbInterpretedCode::branch_eq()
- NdbInterpretedCode::branch_eq_null()
- NdbInterpretedCode::branch_ge()
- NdbInterpretedCode::branch_gt()
- NdbInterpretedCode::branch_label()
- NdbInterpretedCode::branch_le()
- NdbInterpretedCode::branch_lt()
- NdbInterpretedCode::branch_ne()
- NdbInterpretedCode::branch_ne_null()
- NdbInterpretedCode::call_sub()
- NdbInterpretedCode::copy()
- NdbInterpretedCode::def_label()
- NdbInterpretedCode::def_sub()
- NdbInterpretedCode::finalise()
- NdbInterpretedCode::getNdbError()
- NdbInterpretedCode::getTable()
- NdbInterpretedCode::getWordsUsed()
- NdbInterpretedCode::interpret_exit_last_row()
- NdbInterpretedCode::interpret_exit_nok()
- NdbInterpretedCode::interpret_exit_ok()
- NdbInterpretedCode::load_const_null()
- NdbInterpretedCode::load_const_u16()
- NdbInterpretedCode::load_const_u32()
- NdbInterpretedCode::load_const_u64()
- NdbInterpretedCode::read_attr()
- NdbInterpretedCode::reset()
- NdbInterpretedCode::ret_sub()
- NdbInterpretedCode::sub_reg()
- NdbInterpretedCode::sub_val()
The NdbInterpretedCode Class

- NdbInterpretedCode::write_attr()

NdbInterpretedCode Class Overview

<table>
<thead>
<tr>
<th>Parent class</th>
<th>None.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Child classes</td>
<td>None.</td>
</tr>
<tr>
<td>Description</td>
<td>NdbInterpretedCode represents an interpreted program for use in operations created using NdbRecord, or with scans created using the old API. The NdbScanFilter class can also be used to generate an NDB interpreted program using this class. To create an NdbInterpretedCode object, invoke the constructor, optionally supplying a table for the program to operate on, and a buffer for program storage and finalization. If no table is supplied, then only instructions which do not access table attributes can be used. In NDB 8.0, an instance of Ndbrecord can be used for this purpose, in place of the Table. Each NDB API operation applies to one table, and so does any NdbInterpretedCode program attached to that operation. If no buffer is supplied, then an internal buffer is dynamically allocated and extended as necessary. Once the NdbInterpretedCode object is created, you can add instructions and labels to it by calling the appropriate methods as described later in this section. When the program has completed, finalize it by calling the finalise() method, which resolves any remaining internal branches and calls to label and subroutine offsets. A single finalized NdbInterpretedCode program can be used by more than one operation. It need not be re-prepared for successive operations. To use the program with NdbRecord operations and scans, pass it at operation definition time using the OperationOptions or ScanOptions parameter. When the program is no longer required, the NdbInterpretedCode object can be deleted, along with any user-supplied buffer. For additional information and examples, see Section 1.6, “Using NdbInterpretedCode”. This interface is still under development, and so is subject to change without notice. The NdbScanFilter API is a more stable API for defining scanning and filtering programs.</td>
</tr>
</tbody>
</table>

Methods

The following table lists the public methods of this class and the purpose or use of each method:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<td>Return a row as part of the result, and do not check any more rows in this fragment</td>
</tr>
<tr>
<td>interpret_exit_nok()</td>
<td>Do not return a row as part of the result</td>
</tr>
<tr>
<td>interpret_exit_ok()</td>
<td>Return a row as part of the result</td>
</tr>
<tr>
<td>load_const_null()</td>
<td>Load a NULL value into a register</td>
</tr>
<tr>
<td>load_const_u16()</td>
<td>Load a 16-bit numeric value into a register</td>
</tr>
<tr>
<td>load_const_u32()</td>
<td>Load a 32-bit numeric value into a register</td>
</tr>
<tr>
<td>load_const_u64()</td>
<td>Load a 64-bit numeric value into a register</td>
</tr>
<tr>
<td>read_attr()</td>
<td>Read a table column value into a register</td>
</tr>
<tr>
<td>reset()</td>
<td>Discard program</td>
</tr>
<tr>
<td>ret_sub()</td>
<td>Return from a subroutine</td>
</tr>
<tr>
<td>sub_reg()</td>
<td>Subtract two register values and store the result in a third register</td>
</tr>
<tr>
<td>sub_val()</td>
<td>Subtract a value from a table column value</td>
</tr>
<tr>
<td>write_attr()</td>
<td>Write a register value into a table column</td>
</tr>
</tbody>
</table>

For reasons of efficiency, methods of this class provide minimal error checking.

See also Section 1.6, “Using NdbInterpretedCode”.

**Types**

This class defines no public types.

**NdbInterpretedCode Constructor**

**Description**

This is the NdbInterpretedCode class constructor.

**Signature**

```cpp
NdbInterpretedCode
{
    const NdbDictionary::Table* table = 0,
```
The NdbInterpretedCode Class

Alternative constructor (NDB 8.0)

NdbInterpretedCode
{
    const NdbRecord&,
    Uint32* buffer = 0,
    Uint32 buffer_word_size = 0);

Parameters
The NdbInterpretedCode constructor takes three parameters, as described here:

- The table against which this program is to be run. Prior to NDB 8.0, this parameter must be supplied if the program is table-specific—that is, if it reads from or writes to columns in a table. In NDB 8.0, the constructor accepts an NdbRecord in place of the Table.
- A pointer to a buffer of 32-bit words used to store the program.
- buffer_word_size is the length of the buffer passed in. If the program exceeds this length then adding new instructions will fail with error 4518 Too many instructions in interpreted program.

Alternatively, if no buffer is passed, a buffer will be dynamically allocated internally and extended to cope as instructions are added.

Return value
An instance of NdbInterpretedCode.

NdbInterpretedCode::add_reg()

Description
This method sums the values stored in any two given registers and stores the result in a third register.

Signature
int add_reg
{
    Uint32 RegDest,
    Uint32 RegSource1,
    Uint32 RegSource2
}

Parameters
This method takes three parameters. The first of these is the register in which the result is to be stored (RegDest). The second and third parameters (RegSource1 and RegSource2) are the registers whose values are to be summed.

For storing the result, it is possible to re-use one of the registers whose values are summed; that is, RegDest can be the same as RegSource1 or RegSource2.

Return value
Returns 0 on success, -1 on failure.

NdbInterpretedCode::add_val()

Description
This method adds a specified value to the value of a given table column, and places the original and modified column values in registers 6 and 7. It is equivalent to the following series of NdbInterpretedCode method calls, where attrId is the table column’s attribute ID and aValue is the value to be added:

read_attr(6, attrId);
### The NdbInterpretedCode Class

```c
load_const_u32(7, aValue);
add_reg(7,6,7);
write_attr(attrId, 7);
```

**aValue** can be a 32-bit or 64-bit integer.

#### Signature

This method can be invoked in either of two ways, depending on whether **aValue** is 32-bit or 64-bit.

**32-bit aValue:**

```c
int add_val
{
    Uint32 attrId,
    Uint32 aValue
}
```

**64-bit aValue:**

```c
int add_val
{
    Uint32 attrId,
    Uint64 aValue
}
```

#### Parameters

A table column attribute ID and a 32-bit or 64-bit integer value to be added to this column value.

#### Return value

Returns **0** on success, **−1** on failure.

### NdbInterpretedCode::branch_col_and_mask_eq_mask()

**Description**

This method is used to compare a BIT column value with a bitmask; if the column value ANDed together with the bitmask is equal to the bitmask, then execution jumps to a specified label specified in the method call.

**Signature**

```c
int branch_col_and_mask_eq_mask
{
    const void* mask,
    Uint32 unused,
    Uint32 attrId,
    Uint32 label
}
```

#### Parameters

This method can accept four parameters, of which three are actually used. These are described in the following list:

- A pointer to a constant **mask** to compare the column value to
- A **Uint32** value which is currently **unused**.
- The **attrId** of the column to be compared.
- A program **label** to jump to if the condition is true.

Prior to NDB 8.0.30, this argument was not handled correctly for nonzero values. (Bug #33888962)

#### Return value

This method returns **0** on success and **−1** on failure.

### NdbInterpretedCode::branch_col_and_mask_eq_zero()

**Description**

This method is used to compare a BIT column value with a bitmask; if the column value ANDed together with the bitmask is equal to 0,
then execution jumps to a specified label specified in the method call.

**Signature**

```
int branch_col_and_mask_eq_zero
{
    const void* mask,
    Uint32 unused,
    Uint32 attrId,
    Uint32 label
}
```

**Parameters**

This method can accept the following four parameters, of which three are actually used:

- A pointer to a constant `mask` to compare the column value to.
- A `Uint32` value which is currently `unused`.
- The `attrId` of the column to be compared.
- A program `label` to jump to if the condition is true.

Prior to NDB 8.0.30, this argument was not handled correctly for nonzero values. (Bug #33888962)

**Return value**

This method returns `0` on success and `-1` on failure.

---

**NdbInterpretedCode::branch_col_and_mask_ne_mask()**

**Description**

This method is used to compare a `BIT` column value with a bitmask; if the column value ANDed together with the bitmask is not equal to the bitmask, then execution jumps to a specified label specified in the method call.

**Signature**

```
int branch_col_and_mask_ne_mask
{
    const void* mask,
    Uint32 unused,
    Uint32 attrId,
    Uint32 label
}
```

**Parameters**

This method accepts four parameters, of which three are actually used. These described in the following list:

- A pointer to a constant `mask` to compare the column value to.
- A `Uint32` value which is currently `unused`.
- The `attrId` of the column to be compared.
- A program `label` to jump to if the condition is true.

Prior to NDB 8.0.30, this argument was not handled correctly for nonzero values. (Bug #33888962)

**Return value**

This method returns `0` on success and `-1` on failure.

---

**NdbInterpretedCode::branch_col_and_mask_ne_zero()**

**Description**

This method is used to compare a `BIT` column value with a bitmask; if the column value ANDed together with the bitmask is not equal to `0`, then execution jumps to a specified label specified in the method call.
The NdbInterpretedCode Class

Signature

```c
int branch_col_and_mask_ne_zero
{
    const void* mask,
    Uint32 unused,
    Uint32 attrId,
    Uint32 label
}
```

Parameters

This method accepts the following four parameters, of which three are actually used:

- A pointer to a constant `mask` to compare the column value to.
- A `Uint32` value which is currently `unused`.  
- The `attrId` of the column to be compared.
- A program `label` to jump to if the condition is true.

Prior to NDB 8.0.30, this argument was not handled correctly for nonzero values. (Bug #33888962)

Return value

This method returns 0 on success and -1 on failure.

NdbInterpretedCode::branch_col_eq()

Description

This method compares a table column value with an arbitrary constant and jumps to the specified program label if the values are equal. In NDB 8.0, it can also be used to compare two columns for equality.

Signature

Compare a column with a value:

```c
int branch_col_eq
{
    const void* val,
    Uint32 len,
    Uint32 attrId,
    Uint32 label
}
```

Compare two columns:

```c
int branch_col_eq
{
    Uint32 attrId1,
    Uint32 attrId2,
    Uint32 label
}
```

Parameters

When comparing a column and a value, this method takes the following four parameters:

- A constant value (`val`)
- The length of the value (in bytes)
- The attribute ID of the table column whose value is to be compared with `val`
- A `Label` (previously defined using `def_label()`) to jump to if the compared values are equal

When comparing two table column values, the parameters required are shown here:
The NdbInterpretedCode Class

- **AttrId1**: The attribute ID of the first table column whose value is to be compared
- **AttrId2**: The attribute ID of the second table column
- **label**: Location to jump to if the compared columns are the same. Must already have been defined using `def_label()`

When using this method to compare two columns, the columns must be of exactly the same type.

**Return value**

Returns 0 on success, -1 on failure.

**NdbInterpretedCode::branch_col_eq_null()**

**Description**

This method tests the value of a table column and jumps to the indicated program label if the column value is **NULL**.

**Signature**

```c
int branch_col_eq_null
    (Uint32 attrId,
     Uint32 Label)
```

**Parameters**

This method requires the following two parameters:

- The attribute ID of the table column
- The program label to jump to if the column value is **NULL**

**Return value**

Returns 0 on success, -1 on failure.

**NdbInterpretedCode::branch_col_eq_param()**

**Description**

Compares a table attribute with a parameter, each specified by ID, and branches to the specified label if they are equal. Added in NDB 8.0.27.

The parameter can be **NULL**, and is compared according to the **NULL** handling mode in effect; the default is to treat **NULL** as less than any other value, and **NULL** as equal to **NULL**. You can override this behavior and force **NULL** handling that complies with the SQL standard instead, by invoking `setSqlCmpSemantics()`.

**Signature**

```c
int branch_col_eq_param
    (Uint32 attrId,
     Uint32 paramId,
     Uint32 label)
```

**Parameters**

- `attrId`: ID of a table attribute.
- `paramId`: Parameter ID.
- `label`: Label to jump to if arguments are equal.

**Return value**

0 on success.

**NdbInterpretedCode::branch_col_ge()**

**Description**

This method compares a table column value with an arbitrary constant and jumps to the specified program label if the constant
column value. In NDB 8.0, it can also be used to compare two columns, and to perform the jump if the value of the first column is greater than or equal to that of the second.

**Signature**

**Compare value with column:**

```c
int branch_col_ge(
    const void* val,
    Uint32 len,
    Uint32 attrId,
    Uint32 label
)
```

**Compare values of two columns:**

```c
int branch_col_ge(
    Uint32 attrId1,
    Uint32 attrId2,
    Uint32 label
)
```

**Parameters**

When used to compare a value with a column, this method takes the four parameters listed here:

- A constant value (`val`)
- The length of the value (in bytes)
- The attribute ID of the table column whose value is to be compared with `val`
- A `label` (previously defined using `def_label()`) to jump to if the constant value is greater than or equal to the column value

The method takes the parameters listed here when used to compare two columns:

- `AttrId1`: The attribute ID of the first table column whose value is to be compared
- `AttrId2`: The attribute ID of the second table column
- `label`: Jump to this if the first column value is greater than or equal to the second

When comparing two columns, the types of the columns must be exactly the same in all respects.

**Return value**

Returns 0 on success, -1 on failure.

**NdbInterpretedCode::branch_col_ge_param()**

**Description**

Compares a table attribute with a parameter, each specified by ID, and branches to the specified label if the attribute value is greater than or equal to that of the parameter. Added in NDB 8.0.27.

The parameter can be `NULL`, and is compared according to the `NULL` handling mode in effect; the default is to treat `NULL` as less than any other value, and `NULL` as equal to `NULL`. You can override this behavior and force `NULL` handling that complies with the SQL standard instead, by invoking `setSqlCmpSemantics()`.
The NdbInterpretedCode Class

**Signature**

```c
int branch_col_ge_param
{
    Uint32 attrId,
    Uint32 paramId,
    Uint32 label
}
```

**Parameters**

- `attrId`: ID of a table attribute.
- `paramId`: Parameter ID.
- `label`: Label to jump to if column value is not less than parameter value.

**Return value**

0 on success.

---

**NdbInterpretedCode::branch_col_gt()**

**Description**

This method compares a table column value with an arbitrary constant and jumps to the specified program label if the constant is greater than the column value. In NDB 8.0, this method is overloaded such that it can be used to compare two column values, and to make the jump if the first is greater than the second.

**Signature**

**Compare value with column:**

```c
int branch_col_ge
{
    const void* val,
    Uint32 len,
    Uint32 attrId,
    Uint32 label
}
```

**Compare values of two columns:**

```c
int branch_col_ge
{
    Uint32 attrId1,
    Uint32 attrId2,
    Uint32 label
}
```

**Parameters**

When used to compare a value with a table column, this method takes the following four parameters:

- A constant value (`val`)
- The length of the value (in bytes)
- The attribute ID of the table column whose value is to be compared with `val`
- A Label (previously defined using `def_label()`) to jump to if the constant value is greater than the column value

The method takes the three parameters listed here when used to compare two columns:

- `AttrId1`: The attribute ID of the first table column whose value is to be compared
- `AttrId2`: The attribute ID of the second table column
• label: Jump to this if the first column value is greater than or equal to the second

When comparing two columns, the types of the columns must be exactly the same in all respects.

Return value
Returns 0 on success, -1 on failure.

**NdbInterpretedCode::branch_col_gt_param()**

Description
Compares a table attribute with a parameter, each specified by ID, and branches to the specified label if the attribute value is greater than that of the parameter. Added in NDB 8.0.27.

The parameter can be NULL, and is compared according to the NULL handling mode in effect; the default is to treat NULL as less than any other value, and NULL as equal to NULL. You can override this behavior and force NULL handling that complies with the SQL standard instead, by invoking setSqlCmpSemantics().

Signature
```c
int branch_col_gt_param
{
    Uint32 attrId,
    Uint32 paramId,
    Uint32 label
}
```

Parameters
attrId
ID of a table attribute.

paramId
Parameter ID.

label
Label to jump to if column value is greater than parameter value.

Return value
0 on success.

**NdbInterpretedCode::branch_col_le()**

Description
This method compares a table column value with an arbitrary constant and jumps to the specified program label if the constant is less than or equal to the column value. In NDB 8.0, it can also be used to compare two table column values in this fashion.

Signature
```c
int branch_col_le
{
    const void* val,
    Uint32 len,
    Uint32 attrId,
    Uint32 label
}
```

Compare a table column value with a constant:
```c
int branch_col_ge
{
    Uint32 attrId1,
    Uint32 attrId2,
    Uint32 label
}
```

Parameters
When comparing a table column value with a constant, this method takes the four parameters listed here:
- A constant value (`val`)
- The length of the value (in bytes)
- The attribute ID of the table column whose value is to be compared with `val`
- A `Label` (previously defined using `def_label()`) to jump to if the constant value is less than or equal to the column value

The method takes the three parameters listed here when used to compare two table column values:

- `AttrId1`: The attribute ID of the first table column whose value is to be compared
- `AttrId2`: The attribute ID of the second table column
- `label`: Jump to this if the first column value is less than or equal to the second

When comparing two table column values, the types of the column values must be exactly the same in all respects.

Return value

Returns 0 on success, -1 on failure.

### NdbInterpretedCode::branch_col_le_param()

**Description**

Compares a table attribute with a parameter, each specified by ID, and branches to the specified label if the attribute value is less than or equal to that of the parameter. Added in NDB 8.0.27.

The parameter can be `NULL`, and is compared according to the `NULL` handling mode in effect; the default is to treat `NULL` as less than any other value, and `NULL` as equal to `NULL`. You can override this behavior and force `NULL` handling that complies with the SQL standard instead, by invoking `setSqlCmpSemantics()`.

**Signature**

```c
int branch_col_le_param
    (Uint32 attrId,
     Uint32 paramId,
     Uint32 label)
```

**Parameters**

- `attrId`: ID of a table attribute.
- `paramId`: Parameter ID.
- `label`: Label to jump to if column value is not greater than parameter value.

**Return value**

Returns 0 on success.

### NdbInterpretedCode::branch_col_like()

**Description**

This method tests a table column value against a regular expression pattern and jumps to the indicated program label if they match.

**Signature**

```c
int branch_col_like
    (const void* val,
    ...)
```
The NdbInterpretedCode Class

NdbInterpretedCode::branch_col_lt()

Description
This method compares a table column value with an arbitrary constant and jumps to the specified program label if the constant is less than the column value. In NDB 8.0, two table column values can be compared instead.

Parameters
When comparing a table column value with a constant, this method takes the following four parameters:

- A constant value \( \text{val} \)
- The length of the value (in bytes)
- The attribute ID of the table column whose value is to be compared with \( \text{val} \)
- A \text{Label} (previously defined using \text{def_label()}\) to jump to if the constant value is less than the column value

When used to compare two table column values, branch_col_lt() takes the following three parameters:

- \text{AttrId1}: The attribute ID of the first table column whose value is to be compared
- \text{AttrId2}: The attribute ID of the second table column

Signature
Compare a table column value with a constant:

```c
int branch_col_lt
{
    const void* val,
    Uint32 len,
    Uint32 attrId,
    Uint32 Label
}
```

Compare two table column values:

```c
int branch_col_lt
{
    Uint32 attrId1,
    Uint32 attrId2,
    Uint32 label
}
```
• **label**: Jump to this if the first column value is less than the second

When comparing two table column values, the types of the table column values must be exactly the same. This means that they must have the same length, precision, and scale.

**Return value**

0 on success, -1 on failure.

### NdbInterpretedCode::branch_col_lt_param()

**Description**

Compares a table attribute with a parameter, each specified by ID, and branches to the specified label if the attribute value is less than that of the parameter. Added in NDB 8.0.27.

The parameter can be **NULL**, and is compared according to the **NULL** handling mode in effect; the default is to treat **NULL** as less than any other value, and **NULL** as equal to **NULL**. You can override this behavior and force **NULL** handling that complies with the SQL standard instead, by invoking `setSqlCmpSemantics()`.

**Signature**

```c
int branch_col_lt_param
    (Uint32 attrId, Uint32 paramId, Uint32 label)
```

**Parameters**

- `attrId`: ID of a table attribute.
- `paramId`: Parameter ID.
- `label`: Label to jump to if column value is less than parameter value.

**Return value**

0 on success.

### NdbInterpretedCode::branch_col_ne()

**Description**

This method compares a table column value with an arbitrary constant and jumps to the specified program label if the two values are not equal. In NDB 8.0, it can also be used to compare a table column value with another table column value instead.

**Signature**

1. Compare a table column value with a constant:

```c
int branch_col_ne
    (const void* val, Uint32 len, Uint32 attrId, Uint32 label)
```

2. Compare two table column values:

```c
int branch_col_ne
    (Uint32 attrId1, Uint32 attrId2, Uint32 label)
```

**Parameters**

When comparing a table column value with a constant, this method takes the four parameters listed here:
The NdbInterpretedCode Class

- A constant value \( (val) \)
- The length of the value (in bytes)
- The attribute ID of the table column whose value is to be compared with \( val \)
- A Label (previously defined using def_label()) to jump to if the compared values are unequal

When comparing two table column values, the parameters required are shown here:

- \( AttrId1 \): The attribute ID of the first table column whose value is to be compared
- \( AttrId2 \): The attribute ID of the second table column
- \( label \): Location to jump to if the compared columns are not the same. Must already have been defined using def_label()

When using this method to compare two table column values, the columns must be of exactly the same type.

Return value

Returns \( 0 \) on success, \( -1 \) on failure.

**NdbInterpretedCode::branch_col_ne_null()**

**Description**
This method tests the value of a table column and jumps to the indicated program label if the column value is not NULL.

**Signature**

```c
int branch_col_ne_null
{
    Uint32 attrId,
    Uint32 Label
}
```

**Parameters**
This method requires the following two parameters:

- The attribute ID of the table column
- The program label to jump to if the column value is not NULL. The label must have been defined previously using def_label().

**Return value**
Returns \( 0 \) on success, \( -1 \) on failure.

**NdbInterpretedCode::branch_col_ne_param()**

**Description**
Compares a table attribute with a parameter, each specified by ID, and branches to the specified label if they are not equal.

The parameter can be NULL, and is compared according to the NULL handling mode in effect; the default is to treat NULL as less than any other value, and NULL as equal to NULL. You can override this behavior and force NULL handling that complies with the SQL standard instead, by invoking setSqlCmpSemantics().

**Signature**

```c
int branch_col_ne_param
{
    Uint32 attrId,
    Uint32 paramId,
    Uint32 label
}
```
The NdbInterpretedCode Class

Parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>attrId</th>
<th>ID of a table attribute.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>paramId</td>
<td>Parameter ID.</td>
</tr>
<tr>
<td></td>
<td>label</td>
<td>Label to jump to if arguments are not equal.</td>
</tr>
</tbody>
</table>

Return value

0 on success.

NdbInterpretedCode::branch_col_notlike()

Description

This method is similar to branch_col_like() in that it tests a table column value against a regular expression pattern; however it jumps to the indicated program label only if the pattern and the column value do not match.

Signature

```c
int branch_col_notlike
{
    const void* val,
    Uint32 len,
    Uint32 attrId,
    Uint32 Label
}
```

Parameters

This method takes the following four parameters:

- A regular expression pattern (`val`); see Pattern-Based NdbInterpretedCode Branch Operations, for the syntax supported
- Length of the pattern (in bytes)
- The attribute ID for the table column being tested
- The program label to jump to if the table column value does not match the pattern. The `Label` must have been defined previously using `def_label()`.

Return value

Returns 0 on success, -1 on failure.

NdbInterpretedCode::branch_eq()

Description

This method compares two register values; if they are equal, then the interpreted program jumps to the specified label.

Signature

```c
int branch_eq
{
    Uint32 RegLvalue,
    Uint32 RegRvalue,
    Uint32 Label
}
```

Parameters

This method takes three parameters, the registers whose values are to be compared—`RegLvalue` and `RegRvalue`—and the program `Label` to jump to if they are equal. `Label` must have been defined previously using `def_label()`.

Return value

0 on success, -1 on failure.

NdbInterpretedCode::branch_eq_null()

Description

This method compares a register value with `NULL`; if the register value is null, then the interpreted program jumps to the specified label.
The NdbInterpretedCode Class

**Signature**

```c
int branch_eq_null
{
    Uint32 RegLvalue,
    Uint32 Label
}
```

**Parameters**

This method takes two parameters, the register whose value is to be compared with `NULL` (`RegLvalue`) and the program `Label` to jump to if `RegLvalue` is null. `Label` must have been defined previously using `def_label()`.

**Return value**

0 on success, -1 on failure.

**NdbInterpretedCode::branch_ge()**

**Description**

This method compares two register values; if the first is greater than or equal to the second, the interpreted program jumps to the specified label.

**Signature**

```c
int branch_ge
{
    Uint32 RegLvalue,
    Uint32 RegRvalue,
    Uint32 Label
}
```

**Parameters**

This method takes three parameters, the registers whose values are to be compared—`RegLvalue` and `RegRvalue`—and the program `Label` to jump to if `RegLvalue` is greater than or equal to `RegRvalue`. `Label` must have been defined previously using `def_label()`.

**Return value**

0 on success, -1 on failure.

**NdbInterpretedCode::branch_gt()**

**Description**

This method compares two register values; if the first is greater than the second, the interpreted program jumps to the specified label.

**Signature**

```c
int branch_gt
{
    Uint32 RegLvalue,
    Uint32 RegRvalue,
    Uint32 Label
}
```

**Parameters**

This method takes three parameters, the registers whose values are to be compared—`RegLvalue` and `RegRvalue`—and the program `Label` to jump to if `RegLvalue` is greater than `RegRvalue`. `Label` must have been defined previously using `def_label()`.

**Return value**

0 on success, -1 on failure.

**NdbInterpretedCode::branch_label()**

**Description**

This method performs an unconditional jump to an interpreted program label (see `NdbInterpretedCode::def_label()`).

**Signature**

```c
int branch_label
{
    Uint32 Label
}
```

**Parameters**

This method takes a single parameter, an interpreted program `Label` defined using `def_label()`.
The NdbInterpretedCode Class

Return value
0 on success, -1 on failure.

**NdbInterpretedCode::branch_le()**

Description
This method compares two register values; if the first is less than or equal to the second, the interpreted program jumps to the specified label.

Signature
```c
int branch_le
{
    Uint32 RegLvalue,
    Uint32 RegRvalue,
    Uint32 Label
}
```

Parameters
This method takes three parameters, the registers whose values are to be compared—RegLvalue and RegRvalue—and the program Label to jump to if RegLvalue is less than or equal to RegRvalue. Label must have been defined previously using def_label().

Return value
0 on success, -1 on failure.

**NdbInterpretedCode::branch_lt()**

Description
This method compares two register values; if the first is less than the second, the interpreted program jumps to the specified label.

Signature
```c
int branch_lt
{
    Uint32 RegLvalue,
    Uint32 RegRvalue,
    Uint32 Label
}
```

Parameters
This method takes three parameters, the registers whose values are to be compared—RegLvalue and RegRvalue—and the program Label to jump to if RegLvalue is less than RegRvalue. Label must have been defined previously using def_label().

Return value
0 on success, -1 on failure.

**NdbInterpretedCode::branch_ne()**

Description
This method compares two register values; if they are not equal, then the interpreted program jumps to the specified label.

Signature
```c
int branch_ne
{
    Uint32 RegLvalue,
    Uint32 RegRvalue,
    Uint32 Label
}
```

Parameters
This method takes three parameters, the registers whose values are to be compared (RegLvalue and RegRvalue) and the program label to jump to if they are not equal. Label must have been defined previously using def_label().

Return value
0 on success, -1 on failure.

**NdbInterpretedCode::branch_ne_null()**

Description
This method compares a register value with NULL; if the value is not null, then the interpreted program jumps to the specified label.
### The NdbInterpretedCode Class

**Signature**

```cpp
int branch_ne_null
{
    Uint32 RegLvalue,
    Uint32 Label
}
```

**Parameters**

This method takes two parameters, the register whose value is to be compared with NULL (`RegLvalue`) and the program `Label` to jump to if `RegLvalue` is not null. `Label` must have been defined previously using `def_label()`.

**Return value**

0 on success, -1 on failure.

---

**NdbInterpretedCode::call_sub()**

**Description**

This method is used to call a subroutine.

**Signature**

```cpp
int call_sub
{
    Uint32 SubroutineNumber
}
```

**Parameters**

This method takes a single parameter, the number identifying the subroutine to be called.

**Return value**

Returns 0 on success, -1 on failure.

---

**NdbInterpretedCode::copy()**

**Description**

Makes a deep copy of an `NdbInterpretedCode` object.

**Signature**

```cpp
int copy
{
    const NdbInterpretedCode& src
}
```

**Parameters**

A reference to the copy.

**Return value**

0 on success, or an error code.

---

**NdbInterpretedCode::def_label()**

**Description**

This method defines a label to be used as the target of one or more jumps in an interpreted program. `def_label()` uses a 2-word buffer and requires no space for request messages.

**Signature**

```cpp
int def_label
{
    int LabelNum
}
```

**Parameters**

This method takes a single parameter `LabelNum`, an integer whose value must be unique among all values used for labels within the interpreted program.

**Return value**

0 on success; -1 on failure.

---

**NdbInterpretedCode::def_sub()**

**Description**

This method is used to mark the start of a subroutine. See Using Subroutines with NdbInterpretedCode, for more information.

**Signature**

```cpp
int def_sub
{
    Uint32 SubroutineNumber
}
```
### The NdbInterpretedCode Class

| Method                        | Description                                                                                                                                                                                                                   | Signature                                                                                           | Parameters | Return value                                                                                   |
|-------------------------------|----------------------------------------------------------------ianmeter, a number used to identify the subroutine.                                                                  |                                                                                                        | A single parameter, a number used to identify the subroutine.                                                                 | Returns 0 on success, -1 otherwise. |
| NdbInterpretedCode::finalise() |                                                                                                               |                                                                                                        | None.                                                               |                                                                                           |
| NdbInterpretedCode::getNdbError() |                                                                                                               |                                                                                                        | None.                                                               | A reference to an NdbError object.                                                        |
| NdbInterpretedCode::getTable() |                                                                                                               |                                                                                                        | None.                                                               | A pointer to a Table object. Returns NULL if no table object was supplied when the NdbInterpretedCode was instantiated. |
| NdbInterpretedCode::getWordsUsed() |                                                                                                               |                                                                                                        | None.                                                               |                                                                                           |
The NdbInterpretedCode Class

Return value  
The 32-bit number of words used from the buffer.

**NdbInterpretedCode::interpret_exit_last_row()**

**Description**  
For a scanning operation, invoking this method indicates that this row should be returned as part of the scan, and that no more rows in this fragment should be scanned. For other types of operations, the method causes the operation to be aborted.

**Signature**

```c
int interpret_exit_last_row
{
  void
}
```

**Parameters**  
None.

**Return value**  
Returns 0 if successful, -1 otherwise.

**NdbInterpretedCode::interpret_exit_nok()**

**Description**  
For scanning operations, this method is used to indicate that the current row should not be returned as part of the scan, and to cause the program should move on to the next row. It causes other types of operations to be aborted.

**Signature**

```c
int interpret_exit_nok
{
  Uint32 ErrorCode = 626 // HA_ERR_KEY_NOT_FOUND
}
```

**Parameters**  
This method takes a single (optional) parameter `ErrorCode`. (For a complete listing of NDB error codes, see Section 2.4.2, “NDB Error Codes: by Type”). If not supplied, this defaults to 626 (HA_ERR_KEY_NOT_FOUND, Tuple did not exist). Applications should use error code 626 or another code in the range 6000 to 6999 inclusive.

For any values other than those mentioned here, the behavior of this method is undefined, and is subject to change at any time without prior notice.

**Return value**  
Returns 0 on success, -1 on failure.

**NdbInterpretedCode::interpret_exit_ok()**

**Description**  
For a scanning operation, this method indicates that the current row should be returned as part of the results of the scan and that the program should move on to the next row. For other operations, calling this method causes the interpreted program to exit.

**Signature**

```c
int interpret_exit_ok
{
  void
}
```

**Parameters**  
None.

**Return value**  
Returns 0 on success, -1 on failure.

**NdbInterpretedCode::load_const_null()**

**Description**  
This method is used to load a NULL value into a register.

**Signature**

```c
int load_const_null
{
```
The NdbInterpretedCode Class

NdbInterpretedCode::load_const_u16()

Description: This method loads a 16-bit value into the specified interpreter register.

Signature:

```c
int load_const_u16
{
    Uint32 RegDest,
    Uint32 Constant
}
```

Parameters: This method takes the following two parameters:

- `RegDest`: The register into which the value should be loaded.
- `Constant`: A Constant value to be loaded

Return value: Returns 0 on success, -1 otherwise.

NdbInterpretedCode::load_const_u32()

Description: This method loads a 32-bit value into the specified interpreter register.

Signature:

```c
int load_const_u32
{
    Uint32 RegDest,
    Uint32 Constant
}
```

Parameters: This method takes the following two parameters:

- `RegDest`: The register into which the value should be loaded.
- `Constant`: A Constant value to be loaded

Return value: Returns 0 on success, -1 otherwise.

NdbInterpretedCode::load_const_u64()

Description: This method loads a 64-bit value into the specified interpreter register.

Signature:

```c
int load_const_u64
{
    Uint32 RegDest,
    Uint64 Constant
}
```

Parameters: This method takes the following two parameters:

- `RegDest`: The register into which the value should be loaded.
- `Constant`: A Constant value to be loaded

Return value: Returns 0 on success, -1 otherwise.

NdbInterpretedCode::read_attr()
### The NdbInterpretedCode Class

**Description**

The `read_attr()` method is used to read a table column value into a program register. The column may be specified either by using its attribute ID or as a pointer to a `Column` object.

**Signature**

This method can be called in either of two ways. The first of these is by referencing the column by its attribute ID, as shown here:

```c
int read_attr
{
  Uint32 RegDest,
  Uint32 attrId
}
```

Alternatively, you can reference the column as a `Column` object, as shown here:

```c
int read_attr
{
  Uint32 RegDest,
  const NdbDictionary::Column* column
}
```

**Parameters**

This method takes two parameters, as described here:

- The register to which the column value is to be copied (`RegDest`).
- Either of the following references to the table column whose value is to be copied:
  - The table column's attribute ID (`attrId`)
  - A pointer to a `column`—that is, a pointer to a `Column` object referencing the table column

**Return value**

Returns 0 on success, and -1 on failure.

### NdbInterpretedCode::reset()

**Description**

This method clears any existing program from the `NdbInterpretedCode` object, which can then be used for constructing a new program.

**Signature**

```c
int ret_sub
{
  void
}
```

**Parameters**

*None.*

**Return value**

*None.*

This method was added in NDB 8.0.

### NdbInterpretedCode::ret_sub()

**Description**

This method marks the end of the current subroutine.

**Signature**

```c
int ret_sub
{
  void
}
```

**Parameters**

*None.*

**Return value**

Returns 0 on success, -1 otherwise.
NdbInterpretedCode::sub_reg()

Description
This method gets the difference between the values stored in any two given registers and stores the result in a third register.

Signature
```c
int sub_reg
{
    Uint32 RegDest,
    Uint32 RegSource1,
    Uint32 RegSource2
}
```

Parameters
This method takes three parameters. The first of these is the register in which the result is to be stored (RegDest). The second and third parameters (RegSource1 and RegSource2) are the registers whose values are to be subtracted. In other words, the value of register RegDest is calculated as the value of the expression shown here:

\[(\text{value in register } \text{RegSource1}) - (\text{value in register } \text{RegSource2})\]

It is possible to re-use one of the registers whose values are subtracted for storing the result; that is, RegDest can be the same as RegSource1 or RegSource2.

Return value
0 on success; -1 on failure.

NdbInterpretedCode::sub_val()

Description
This method subtracts a specified value from the value of a given table column, and places the original and modified column values in registers 6 and 7. It is equivalent to the following series of NdbInterpretedCode method calls, where attrId is the table column's attribute ID and aValue is the value to be subtracted:

```c
read_attr(6, attrId);
load_const_u32(7, aValue);
sub_reg(7, 6, 7);
write_attr(attrId, 7);
```

aValue can be a 32-bit or 64-bit integer.

Signature
This method can be invoked in either of two ways, depending on whether aValue is 32-bit or 64-bit.

32-bit aValue:
```c
int sub_val
{
    Uint32 attrId,
    Uint32 aValue
}
```

64-bit aValue:
```c
int sub_val
{
    Uint32 attrId,
    Uint64 aValue
}
```

Parameters
A table column attribute ID and a 32-bit or 64-bit integer value to be subtracted from this column value.

Return value
Returns 0 on success, -1 on failure.
### NdbInterpretedCode::write_attr()

**Description**
This method is used to copy a register value to a table column. The column may be specified either by using its attribute ID or as a pointer to a `Column` object.

**Signature**
This method can be invoked in either of two ways. The first of these requires referencing the column by its attribute ID, as shown here:

```c
int read_attr
{
    Uint32 attrId,
    Uint32 RegSource
}
```

You can also reference the column as a `Column` object instead, like this:

```c
int read_attr
{
    const NdbDictionary::Column* column,
    Uint32 RegSource
}
```

**Parameters**
This method takes two parameters as follows:

- A reference to the table column to which the register value is to be copied. This can be either of the following:
  - The table column's attribute ID (`attrId`)
  - A pointer to a `column`—that is, a pointer to a `Column` object referencing the table column
  - The register whose value is to be copied (`RegSource`).

**Return value**
Returns 0 on success; -1 on failure.

### 2.3.20 The NdbOperation Class

This section provides information about the `NdbOperation` class.

Beginning with NDB 8.0.30, `NdbOperation` supports an interpreted code API similar to that implemented by `NdbInterpretedCode`. See `NdbOperation Interpreted Code API`, for more information.

NdbOperation Class Overview

Parent class

None

Child classes

NdbIndexOperation, NdbScanOperation

Description

NdbOperation represents a “generic” data operation. Its subclasses represent more specific types of operations. See NdbOperation::Type for a listing of operation types and their corresponding NdbOperation subclasses.

Methods

The following table lists the public methods of this class and the purpose or use of each method:

Table 2.49 NdbOperation class methods and descriptions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>add_reg()</td>
<td>Add and store contents of two registers</td>
</tr>
<tr>

<tr>
<td>read_attr()</td>
<td>Read given attribute into register</td>
</tr>
<tr>
<td>readTuple()</td>
<td>Reads a tuple from a table</td>
</tr>
<tr>
<td>ret_sub()</td>
<td>Return from interpreted program subroutine</td>
</tr>
<tr>
<td>setValue()</td>
<td>Defines an attribute to set or update</td>
</tr>
<tr>
<td>sub_reg()</td>
<td>Store difference of two register values</td>
</tr>
<tr>
<td>subValue()</td>
<td>Subtracts value from attribute</td>
</tr>
<tr>
<td>updateTuple()</td>
<td>Updates an existing tuple in a table</td>
</tr>
<tr>
<td>write_attr()</td>
<td>Write given attribute from register</td>
</tr>
<tr>
<td>writeTuple()</td>
<td>Inserts or updates a tuple</td>
</tr>
</tbody>
</table>

This class has no public constructor. To create an instance of \texttt{NdbOperation}, you must use \texttt{NdbTransaction::getNdbOperation()}. 
The NdbOperation Class

Types

The NdbOperation class defines three public types, shown in the following table:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AbortOption</td>
<td>Determines whether a failed operation causes failure of the transaction of which it is part</td>
</tr>
<tr>
<td>LockMode</td>
<td>The type of lock used when performing a read operation</td>
</tr>
<tr>
<td>Type</td>
<td>Operation access types</td>
</tr>
</tbody>
</table>

For more information about the use of NdbOperation, see Single-row operations.

NdbOperation Interpreted Code API

NdbOperation in NDB 8.0.30 and later supports an interpreted code API similar to that used with NdbInterpretedCode.

To start with, use one of updateTuple(), writeTuple(), or deleteTuple() to define the operation as an operation of a given type (update, write, or delete). This is the operation that is to be performed by an interpreted program; the interpreted program itself is assembled from various register, comparison, and branch instructions.

The interpreted program is not a separate NdbInterpretedCode object, although it behaves much like one. Instructions are assigned to the NdbOperation instance (for example, myNdbOp->branch_col_lt(colid, val1, col2id, val2)). To run the interpreted program, call NdbTransaction::execute().

Another difference between the NdbOperation interpreted code API implementation and that supported by NdbInterpretedCode is that the order of arguments for analogous methods is not necessarily the same. One such pair of methods is listed here:

- In NdbOperation::branch_col_lt(ColId, val, len, bool, Label), comparison happens like this, using the second and first arguments passed to the method, in that order:
  ```
  if(val < ColId_value)
  branch_to Label
  ```

- NdbInterpretedCode::branch_col_lt(*val, Uint32, attrId, Label), compares the first argument passed with the third, like this:
  ```
  if(val < attrId_value)
  branch_to Label
  ```

Branch column method comparisons. The branch column methods such as branch_col_le() compare a supplied value with the value of a column. These methods act on the first two arguments from right to left, so that, for example, branch_col_le(myColId, myValue, 8, true, myLabel) acts as shown by the following pseudocode:

  ```
  if(myValue <= value(myColId))
  goto myLabel;
  ```

Bitwise logical comparisons. These comparison types are supported only for the bitfield type, and can be used to test bitfield columns against bit patterns. The value passed in is a bitmask which is bitwise-ANDed with the column data. Bitfields are passed in and out of the NDB API as 32-bit words with bits set from least significant bit (LSB) to most significant bit (MSB). The platform's endianness controls which byte contains the LSB: for x86, this is the first (0th) byte; for SPARC and PPC platforms, it is the last (3rd) byte.

You can set bit \( n \) of a bitmask to 1 from a Uint32* mask like this:
The NdbOperation Class

mask[n >> 5] |= (1 << (n & 31))

Four different sorts of branching on bitwise comparison are supported by the methods listed here:

- `branch_col_and_mask_eq_mask()`: Branch if column value AND mask == mask (all masked bits set in value).
- `branch_col_and_mask_ne_mask()`: Branch if column value AND mask != mask (not all masked bits are set in value).
- `branch_col_and_mask_eq_zero()`: Branch if column value AND mask == 0 (no masked bits are set in value).
- `branch_col_and_mask_ne_zero()`: Branch if column value AND mask != 0 (some masked bits are set in value).

See the descriptions of the individual methods for more information.

NdbOperation::AbortOption

This section provides information about the `AbortOption` data type.

Description

This type is used to determine whether failed operations should force a transaction to be aborted. It is used as an argument to the `execute()` method—see `NdbTransaction::execute()`, for more information.

Enumeration values

Possible values are shown, along with descriptions, in the following table:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AbortOnError</td>
<td>A failed operation causes the transaction to abort.</td>
</tr>
<tr>
<td>AO_IgnoreOnError</td>
<td>Failed operations are ignored; the transaction continues to execute.</td>
</tr>
<tr>
<td>DefaultAbortOption</td>
<td>The <code>AbortOption</code> value is set according to the operation type:</td>
</tr>
<tr>
<td></td>
<td>• Read operations: <code>AO_IgnoreOnError</code></td>
</tr>
<tr>
<td></td>
<td>• Scan takeover or DML operations: <code>AbortOnError</code></td>
</tr>
</tbody>
</table>

See `NdbTransaction::execute()`, for more information.

NdbOperation::add_reg()

Description

Add contents of two registers; store result in a third register.

Signature

```c
int add_reg
{
    Uint32 RegSource1,
    Uint32 RegSource2,
    Uint32 RegDest
}
```

Parameters

- `RegSource1` Register containing first value to be added.
**The NdbOperation Class**

**RegSource2**
Register containing second value to be added.

**RegDest**
Register in which to store the result.

Return value
0 on success, otherwise -1.

**NdbOperation::branch_col_eq_null()**
Description Branch to a label in an interpreted program if the specified column is NULL.

Signature

```c
int branch_col_eq_null
{
  Uint32 ColId,
  Uint32 Label
}
```

Parameters

- **ColId**
  ID of the column to check.

- **Label**
  Label to jump to if the column is NULL.

Return value
0 on success, otherwise -1.

**NdbOperation::branch_col_ne_null()**
Description Branch to a label in an interpreted program if the specified column is not NULL.

Signature

```c
int branch_col_ne_null
{
  Uint32 ColId,
  Uint32 Label
}
```

Parameters

- **ColId**
  ID of the column to check.

- **Label**
  Label to jump to if the column is not NULL.

Return value
none

**NdbOperation::branch_col_eq()**
Description Branch to a label in an interpreted program if a given value is equal to the value of the specified column.

**Note**
Like the other NdbOperation::branch_col_*() methods, branch_col_eq() compares its second argument with the first, in that order.

Signature

```c
int branch_col_eq
{
  Uint32 ColId,
  const void* val,
  Uint32 len,
  bool,
}
```
The NdbOperation Class

### NdbOperation::branch_col_ne()

**Description**
Branch to a label in an interpreted program if a given value is not equal to the value of the specified column.

**Note**
Like the other `NdbOperation::branch_col_*()` methods, `branch_col_ne()` compares its second argument with the first, in that order.

**Signature**
```c
int branch_col_ne
(
  Uint32 ColId,
  const void* val,
  Uint32 len,
  bool,
  Uint32 Label
)
```

**Parameters**
- **ColId**
  ID of column to compare.
- **val**
  Value to be compared.
- **len**
  Length of `val`.
- **-**
  Boolean `true` or `false` required for legacy reasons, but no longer used.
- **Label**
  Label to jump to if `val` is equal to the column value.

**Return value**
0 on success, -1 otherwise.

### NdbOperation::branch_col_lt()

**Description**
Branch to a label in an interpreted program if a given value is less than a column value.

**Note**
Like the other `NdbOperation::branch_col_*()` methods, it compares its second argument with the first, in that order.

**Signature**
```c
int branch_col_lt
(
  Uint32 ColId,
  const void* val,
  Uint32 len,
  bool,
  Uint32 Label
)
```
methods, `branch_col_lt()` compares its second argument with the first, in that order.

**Signature**

```c
int branch_col_lt
{
    Uint32 ColId,
    const void* val,
    Uint32 len,
    bool,       // Boolean true or false required for legacy reasons, but no longer used.
    Uint32 Label
}
```

**Parameters**

- **ColId**: ID of column to compare.
- **val**: Value to be compared.
- **len**: Length of **val**.
- **Label**: Label to jump to if **val** is less than the column value.

**Return value**: 0 on success, otherwise -1.

**NdbOperation::branch_col_le()**

**Description**

Branch to a label in an interpreted program if a given value is less than or equal to a column value.

**Note**

Like the other `NdbOperation::branch_col_*()` methods, `branch_col_le()` compares its second argument with the first, in that order.

**Signature**

```c
int branch_col_le
{
    Uint32 ColId,
    const void* val,
    Uint32 len,
    bool,       // Boolean true or false required for legacy reasons, but no longer used.
    Uint32 Label
}
```

**Parameters**

- **ColId**: ID of column to compare.
- **val**: Value to be compared.
- **len**: Length of **val**.
- **Label**: Label to jump to if **val** is less than or equal to the column value.

**Return value**: On success, 0; otherwise, -1.
### The NdbOperation Class

#### Description
Branch to a label in an interpreted program if a given value is greater than a column value.

**Note**
Like the other `NdbOperation::branch_col_*()` methods, `branch_col_gt()` compares its second argument with the first, in that order.

<table>
<thead>
<tr>
<th>Signature</th>
</tr>
</thead>
</table>

```c
int branch_col_gt
{
    Uint32 ColId,
    const void* val,
    Uint32 len,
    bool,
    Uint32 Label
}
```

**Parameters**
- **ColId** ID of column to compare.
- **val** Value to be compared.
- **len** Length of `val`.
- **Label** Label to jump to if `val` is greater than the column value.

**Return value**
0 on success, -1 otherwise.

#### NdbOperation::branch_col_ge()

Branch to a label in an interpreted program if a given value is greater than or equal to a column value.

**Note**
Like the other `NdbOperation::branch_col_*()` methods, `branch_col_ge()` compares its second argument with the first, in that order.

<table>
<thead>
<tr>
<th>Signature</th>
</tr>
</thead>
</table>

```c
int branch_col_ge
{
    Uint32 ColId,
    const void* val,
    Uint32 len,
    bool,
    Uint32 Label
}
```

**Parameters**
- **ColId** ID of column to compare.
- **val** Value to be compared.
- **len** Length of `val`.
- **Label** Label to jump to if `val` is greater than or equal to the column value.

**Return value**
0 on success, -1 otherwise.
The NdbOperation Class

Label
Label to jump to if val is greater than or equal to the column value.

Return value
0 if successful, else -1.

NdbOperation::branch_col_like()

Description
Branch if the column value matches a wildcard pattern. This method and branch_col_notlike() each support the wildcards used by the MySQL LIKE operator: % for any string of 0 or more characters, and _ for any single character.

The column's type must be one of CHAR, VARCHAR, BINARY, or VARBINARY.

Signature
```c
int branch_col_like
{
    Uint32 ColId,
    const void* val,
    Uint32 len,
    bool,
    Uint32 Label
}
```

Parameters
- ColId: ID of column whose value is to be compared.
- val: Pattern to match.
- len: Length of pattern value.
- _: Boolean true or false required for legacy reasons, but no longer used.
- Label: Label to jump to if column value matches pattern.

Return value
0 on success, otherwise -1.

NdbOperation::branch_col_notlike()

Description
Branch if the column value does not match the given wildcard pattern. This method and branch_col_like() each support the same wildcards % (0 or more characters) and _ (any one character) as the MySQL LIKE operator.

The column's type must be one of CHAR, VARCHAR, BINARY, or VARBINARY.

Signature
```c
int branch_col_notlike
{
    Uint32 ColId,
    const void* val,
    Uint32 len,
    bool,
    Uint32 Label
}
```

Parameters
- ColId: ID of column whose value is to be compared.
- val: Pattern to match.
The NdbOperation Class

- **len**
  Length of pattern value.

- **Boolean**
  true or false required for legacy reasons, but no longer used.

- **Label**
  Label to jump to if column value does not match pattern.

Return value
0 on success, -1 otherwise.

**NdbOperation::branch_col_and_mask_eq_mask()**

Description
Branch if the value of a column in a logical bitwise AND with a bitmask is equal to the bitmask.

See also Bitwise logical comparisons.

Signature
```c
int branch_col_and_mask_eq_mask
{
    Uint32 ColId,
    const void* mask,
    Uint32 len,
    bool,
    Uint32 Label
}
```

Parameters
- **ColId**
  Use the value of the column having this ID.

- **mask**
  Bitmask to compare with column value.

- **len**
  Length of `mask`.

- **Boolean**
  true or false required for legacy reasons, but no longer used.

- **Label**
  Branch to jump to if the result of the AND operation is the same as the mask.

Return value
0 on success, -1 otherwise.

**NdbOperation::branch_col_and_mask_ne_mask()**

Description
Branch if the value of a column in a logical bitwise AND with a bitmask is not equal to the bitmask.

See also Bitwise logical comparisons.

Signature
```c
int branch_col_and_mask_ne_mask
{
    Uint32 ColId,
    const void* mask,
    Uint32 len,
    bool,
    Uint32 Label
}
```
### The `NdbOperation` Class

#### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ColId</code></td>
<td>Use the value of the column having this ID.</td>
</tr>
<tr>
<td><code>mask</code></td>
<td>Bitmask to compare with column value.</td>
</tr>
<tr>
<td><code>len</code></td>
<td>Length of <code>mask</code>.</td>
</tr>
<tr>
<td><code>-</code></td>
<td>Boolean <code>true</code> or <code>false</code> required for legacy reasons, but no longer used.</td>
</tr>
<tr>
<td><code>Label</code></td>
<td>Branch to jump to if the result of the <code>AND</code> operation is not equal to the mask.</td>
</tr>
</tbody>
</table>

#### Return value

On success 0, else -1.

### `NdbOperation::branch_col_and_mask_eq_zero()`

**Description**

Branch if the value of a column in a logical bitwise `AND` with a bitmask is equal to 0.

See also [Bitwise logical comparisons](#).

**Signature**

```c
int branch_col_and_mask_eq_zero
(  
  Uint32 ColId,  
  const void* mask,  
  Uint32 len,  
  bool,  
  Uint32 Label
)
```

#### Parameters

- `ColId`: Use the value of the column having this ID.
- `mask`: Bitmask to compare with column value.
- `len`: Length of `mask`.
- `-`: Boolean `true` or `false` required for legacy reasons, but no longer used.
- `Label`: Branch to jump to if the result of the `AND` operation is equal to 0.

#### Return value

0 on success, -1 otherwise.

### `NdbOperation::branch_col_and_mask_ne_zero()`

**Description**

Branch if the value of a column in a logical bitwise `AND` with a bitmask is not equal to 0.

See also [Bitwise logical comparisons](#).

**Signature**

```c
int branch_col_and_mask_ne_zero
(  
  Uint32 ColId,  
  const void* mask,  
  Uint32 len,  
  bool,  
  Uint32 Label
)
```
The `NdbOperation` Class

```cpp
Uint32 len,
bool,
Uint32 Label
)
```

## Parameters

- **ColId**
  - Use the value of the column having this ID.

- **mask**
  - Bitmask to compare with column value.

- **len**
  - Length of `mask`.

- **-**
  - Boolean `true` or `false` required for legacy reasons, but no longer used.

- **Label**
  - Branch to jump to if the result of the AND operation is not equal to 0.

## Return value

Returns 0 on success, -1 otherwise.

### NdbOperation::branch_ge()

#### Description

Define a search condition in an interpreted program. Compares the right-hand register value with the left; branch to a label if the RH value is greater than or equal to the LH value.

#### Note

This method, like the other `NdbOperation` branch on comparison methods, compares the two register values from right to left.

#### Signature

```cpp
int branch_ge
{
    Uint32 RegLvalue,
    Uint32 RegRvalue,
    Uint32 Label
}
```

#### Parameters

- **RegLvalue**
  - Register value compared with `RegRvalue`.

- **RegRvalue**
  - Compare value of this register with `RegLvalue`; branch to the label if this value is greater than or equal to `RegLvalue`.

- **Label**
  - Label to branch to if `RegRvalue` is greater than or equal to `RegLvalue`.

#### Return value

0 on success, -1 otherwise.

### NdbOperation::branch_gt()

#### Description

Define a search condition in an interpreted program. Compares the right-hand register value with the left; branch to a label if the RH value is greater than the LH value.
The NdbOperation Class

**Note**

This method, like the other NdbOperation branch on comparison methods, compares the two register values from right to left.

**Signature**

```c
int branch_gt
{
    Uint32 RegLvalue,
    Uint32 RegRvalue,
    Uint32 Label
}
```

**Parameters**

- **RegLvalue**: Register value compared with **RegRvalue**.
- **RegRvalue**: Compare value of this register with **RegLvalue**; branch to the label if this value is greater than **RegLvalue**.
- **Label**: Label to branch to if **RegRvalue** is greater than **RegLvalue**.

**Return value**

0 on success, -1 otherwise.

**NdbOperation::branch_le()**

**Description**

Define a search condition in an interpreted program. Compares the right-hand register value with the left; branch to a label if the RH value is less than the LH value.

**Note**

This method, like the other NdbOperation branch on comparison methods, compares the two register values from right to left.

**Signature**

```c
int branch_le
{
    Uint32 RegLvalue,
    Uint32 RegRvalue,
    Uint32 Label
}
```

**Parameters**

- **RegLvalue**: Register value compared with **RegRvalue**.
- **RegRvalue**: Compare value of this register with **RegLvalue**; branch to the label if this value is less than **RegLvalue**.
- **Label**: Label to branch to if **RegRvalue** is less than **RegLvalue**.

**Return value**

0 on success, -1 otherwise.

**NdbOperation::branch_lt()**

**Description**

Define a search condition in an interpreted program. Compares the right-hand register value with the left; branch to a label if the RH value is less than or equal to the LH value.
The NdbOperation Class

**Note**
This method, like the other NdbOperation branch on comparison methods, compares the two register values from right to left.

### Signature
```c
int branch_lt
{
    Uint32 RegLvalue,
    Uint32 RegRvalue,
    Uint32 Label
}
```

**Parameters**
- `RegLvalue`: Register value compared with `RegRvalue`.
- `RegRvalue`: Compare value of this register with `RegLvalue`; branch to the label if this value is less than or equal to `RegLvalue`.
- `Label`: Label to branch to if `RegRvalue` is less than or equal to `RegLvalue`.

**Return value**
0 on success, -1 otherwise.

### NdbOperation::branch_eq()
**Description**
Branch to a label in an interpreted program when two register values are equal.

**Signature**
```c
int branch_eq
{
    Uint32 RegLvalue,
    Uint32 RegRvalue,
    Uint32 Label
}
```

**Parameters**
- `RegLvalue`: One of two register values to be compared.
- `RegRvalue`: The other register value to be compared.
- `Label`: Branch to this label if the register values are equal.

**Return value**
0 on success, -1 otherwise.

### NdbOperation::branch_ne()
**Description**
Branch to a label in an interpreted program when two register values are not equal.

**Signature**
```c
int branch_eq
{
    Uint32 RegLvalue,
    Uint32 RegRvalue,
    Uint32 Label
}
```

**Parameters**
- `RegLvalue`: One of two register values to be compared.
The NdbOperation Class

**RegRvalue**
The other register value to be compared.

**Label**
Branch to this label if the register values are not equal.

Return value
0 on success, otherwise -1.

### NdbOperation::branch_ne_null()

**Description**
Branch to a label in an interpreted program if a register value is not NULL.

**Signature**
```
int branch_ne_null
{
  Uint32 RegLvalue,
  Uint32 Label
}
```

**Parameters**
- **RegLvalue**: Register to be tested.
- **Label**: Branch to this label if RegLvalue is not NULL.

**Return value**
On success, returns 0; otherwise, returns -1.

### NdbOperation::branch_eq_null()

**Description**
Branch to a label in an interpreted program if a register value is NULL.

**Signature**
```
int branch_ne_null
{
  Uint32 RegLvalue,
  Uint32 Label
}
```

**Parameters**
- **RegLvalue**: Register to be tested.
- **Label**: Branch to this label if RegLvalue is NULL.

**Return value**
On success, returns 0; otherwise, -1.

### NdbOperation::branch_label()

**Description**
Jump to a label in an interpreted program.

**Signature**
```
int branch_label
{
  Uint32 Label
}
```

**Parameters**
- **Label**: The label to branch to.

**Return value**
0 if successful; otherwise, -1.

### NdbOperation::call_sub()

**Description**
Call a subroutine in an interpreted program.

**Signature**
```
int call_sub
{
  Uint32 Subroutine
}
```
The NdbOperation Class

NdbOperation::def_label()

Description
Define a jump label in an interpreted operation. Labels are numbered automatically starting with 0.

Signature
```
int def_label
{
    int labelNumber
}
```

Parameters
`labelNumber` The label number. For easier debugging, this should match the automatic numbering performed by NDB.

Return value
`labelNumber` on success, -1 otherwise.

NdbOperation::def_subroutine()

Description
Define a subroutine in an interpreted program.

Signature
```
int def_subroutine
{
    int SubroutineNumber
}
```

Parameters
`SubroutineNumber` The subroutine number.

Return value
0 on success, -1 otherwise.

NdbOperation::deleteTuple()

Description
This method defines the NdbOperation as a DELETE operation. When the NdbTransaction::execute() method is invoked, the operation deletes a tuple from the table.

Signature
```
virtual int deleteTuple
{
    void
}
```

Parameters
None.

Return value
Returns 0 on success, -1 on failure.

NdbOperation::equal()

Description
This method defines a search condition with an equality. The condition is true if the attribute has the given value. To set search conditions on multiple attributes, use several calls to equal(); in such cases all of them must be satisfied for the tuple to be selected.

If the attribute is of a fixed size, its value must include all bytes. In particular a Char value must be native-space padded. If the attribute is of variable size, its value must start with 1 or 2 little-endian length bytes (2 if its type is Long*).

When using insertTuple(), you may also define the search key with setValue(). See NdbOperation::setValue().
There are 10 versions of `equal()`, each having slightly different parameters. All of these are shown here:

```c
int equal(  
    const char* name,  
    const char* value
)

int equal(  
    const char* name,  
    Int32      value
)

int equal(  
    const char* name,  
    Uint32     value
)

int equal(  
    const char* name,  
    Int64      value
)

int equal(  
    const char* name,  
    Uint64     value
)

int equal(  
    Uint32 id,  
    const char* value
)

int equal(  
    Uint32 id,  
    Int32      value
)

int equal(  
    Uint32 id,  
    Uint32     value
)

int equal(  
    Uint32 id,  
    Int64      value
)

int equal(  
    Uint32 id,  
    Uint64     value
)
```
The NdbOperation Class

Parameters

This method requires two parameters:

- The first parameter can be either of the following:
  1. The name of the attribute (a string)
  2. The id of the attribute (an unsigned 32-bit integer)

- The second parameter is the attribute value to be tested. This value can be any one of the following 5 types:
  - String
  - 32-bit integer
  - Unsigned 32-bit integer
  - 64-bit integer
  - Unsigned 64-bit integer

Return value

Returns -1 in the event of an error.

NdbOperation::getBlobHandle()

Description

This method is used in place of getValue() or setValue() for blob attributes. It creates a blob handle (NdbBlob object). A second call with the same argument returns the previously created handle. The handle is linked to the operation and is maintained automatically.

Signature

This method has two forms, depending on whether it is called with the name or the ID of the blob attribute:

```cpp
virtual NdbBlob* getBlobHandle
  (const char* name)
```

or

```cpp
virtual NdbBlob* getBlobHandle
  (Uint32 id)
```

Parameters

This method takes a single parameter, which can be either one of the following:

- The name of the attribute
- The id of the attribute

Return value

Regardless of parameter type used, this method return a pointer to an instance of NdbBlob.

NdbOperation::getLockHandle

Description

Returns a pointer to the current operation's lock handle. When used with NdbRecord, the lock handle must first be requested with the OO_LOCKHANDLE operation option. For other operations, this method can be used alone. In any case, the NdbLockHandle object returned by this method cannot be used until the operation has been executed.
The NdbOperation Class

**Signature**

```c
const NdbLockHandle* getLockHandle(
    void
) const
```

**Parameters**  
None.

**Return value**
Pointer to an NdbLockHandle that can be used by the NdbTransaction methods unlock() and releaseLockHandle().

**Using lock handle methods.** Shared or exclusive locks taken by read operations in a transaction are normally held until the transaction commits or aborts. Such locks can be released before a transaction commits or aborts by requesting a lock handle when defining the read operation. Once the read operation has been executed, an NdbLockHandle can be used to create a new unlock operation (with NdbTransaction::unlock()). When the unlock operation is executed, the row lock placed by the read operation is released.

The steps required to release these locks are listed here:

- Define the primary key read operation in the normal way with LockMode set to LM_Read or LM_Exclusive.
- Call NdbOperation::getLockHandle() during operation definition, or, for Ndbrecord, set the OO_LOCKHANDLE operation option when calling NdbTransaction::readTuple().
- Call NdbTransaction::execute(); the row is now locked from this point on, as normal.
- (Use data, possibly making calls to NdbTransaction::execute().)
- Call NdbTransaction::unlock(), passing in the const NdbLockHandle obtained previously to create an unlock operation.
- Call NdbTransaction::execute(); this unlocks the row.

**Notes:**

- As with other operation types, unlock operations can be batched.
- Each NdbLockHandle object refers to a lock placed on a row by a single primary key read operation. A single row in the database may have concurrent multiple lock holders (mode LM_Read) and may have multiple lock holders pending (LM_Exclusive), so releasing the claim of one lock holder may not result in a change to the observable lock status of the row.
- Lock handles are supported for scan lock takeover operations; the lock handle must be requested before the lock takeover is executed.
- Lock handles and unlock operations are not supported for unique index read operations.

**NdbOperation::getLockMode()**

**Description**
This method gets the operation's lock mode.

**Signature**

```c
LockMode getLockMode(
    void
)
```
The **NdbOperation Class**

### Parameters None.

### Return value
A **LockMode** value. See **NdbOperation::LockMode**.

#### **NdbOperation::getNdbError()**

**Description** This method gets the most recent error (an **NdbError** object).

**Signature**

```cpp
const NdbError& getNdbError()
{
    void
} const
```

**Parameters** None.

**Return value** An **NdbError** object.

#### **NdbOperation::getNdbErrorLine()**

**Description** This method retrieves the method number in which the latest error occurred.

**Signature**

```cpp
int getNdbErrorLine()
{
    void
} const
```

**Parameters** None.

**Return value** The method number (an integer).

#### **NdbOperation::getTable()**

**Description** This method is used to retrieve the table object associated with the operation.

**Signature**

```cpp
const NdbDictionary::Table* getTable()
{
    void
} const
```

**Parameters** None.

**Return value** A pointer to an instance of **Table**.

#### **NdbOperation::getTableName()**

**Description** This method retrieves the name of the table used for the operation.

**Signature**

```cpp
const char* getTableName()
{
    void
} const
```

**Parameters** None.

**Return value** The name of the table.

#### **NdbOperation::getNdbTransaction()**

**Description** Gets the **NdbTransaction** object for this operation.

**Signature**

```cpp
virtual NdbTransaction* getNdbTransaction
```
The NdbOperation Class

NdbOperation::getType()

Description
This method is used to retrieve the access type for this operation.

Signature
```cpp
type getType()
{
    void
} const
```

Parameters
None.

Return value
A pointer to an NdbTransaction object.

NdbOperation::getValue()

Description
This method prepares for the retrieval of an attribute value. The NDB API allocates memory for an NdbRecAttr object that is later used to obtain the attribute value. This can be done by using one of the many NdbRecAttr accessor methods, the exact method to be used depending on the attribute's data type. (This includes the generic NdbRecAttr::aRef() method, which retrieves the data as char*, regardless of its actual type. You should be aware that this is not type-safe, and requires an explicit cast from the user.)

This method does not fetch the attribute value from the database; the NdbRecAttr object returned by this method is not readable or printable before calling NdbTransaction::execute().

If a specific attribute has not changed, the corresponding NdbRecAttr has the state UNDEFINED. This can be checked by using NdbRecAttr::isNULL(), which in such cases returns -1.

See NdbTransaction::execute(), and NdbRecAttr::isNULL().

Signature
There are three versions of this method, each having different parameters:

```cpp
NdbRecAttr* getValue
{
    const char* name,
    char* value = 0
}
```

```cpp
NdbRecAttr* getValue
{
    Uint32 id,
    char* value = 0
}
```

```cpp
NdbRecAttr* getValue
{
    const NdbDictionary::Column* col,
    char* value = 0
}
```

Parameters
All three forms of this method have two parameters, the second parameter being optional (defaults to 0). They differ only with regard
to the type of the first parameter, which can be any one of the following:

- The attribute `name`
- The attribute `id`
- The table `column` on which the attribute is defined

In all three cases, the second parameter is a character buffer in which a non-NULL attribute value is returned. If the event that the attribute is NULL, is it stored only in the `NdbRecAttr` object returned by this method.

If no `value` is specified in the `getValue()` method call, or if 0 is passed as the value, then the `NdbRecAttr` object provides memory management for storing the received data. If the maximum size of the received data is above a small fixed size, `malloc()` is used to store it. For small sizes, a small, fixed internal buffer (32 bytes in extent) is provided. This storage is managed by the `NdbRecAttr` instance; it is freed when the operation is released, such as at transaction close time; any data written here that you wish to preserve should be copied elsewhere before this freeing of memory takes place.

If you pass a non-zero pointer for `value`, then it is assumed that this points to an portion of memory which is large enough to hold the maximum value of the column; any returned data is written to that location. The pointer should be at least 32-bit aligned.

Index columns cannot be used in place of table columns with this method. In cases where a table column is not available, you can use the attribute name, obtained with `getName()`, for this purpose instead.

Return value  A pointer to an `NdbRecAttr` object to hold the value of the attribute, or a NULL pointer, indicating an error.

Retrieving integers.  Integer values can be retrieved from both the value buffer passed as this method's second parameter, and from the `NdbRecAttr` object itself. On the other hand, character data is available from `NdbRecAttr` if no buffer has been passed in to `getValue()` (see `NdbRecAttr::aRef()`). However, character data is written to the buffer only if one is provided, in which case it cannot be retrieved from the `NdbRecAttr` object that was returned. In the latter case, `NdbRecAttr::aRef()` returns a buffer pointing to an empty string.

Accessing bit values.  The following example shows how to check a given bit from the `value` buffer. Here, `op` is an operation (`NdbOperation` object), `name` is the name of the column from which to get the bit value, and `trans` is an `NdbTransaction` object:

```c
Uint32 buf[];
op->getValue(name, buf); /* bit column */
trans->execute();
if(buf[X/32] & 1 << (X & 31)) /* check bit X */
{
    /* bit X set */
}
```

**NdbOperation::GetValueSpec**

This section provides information about the `GetValueSpec` data structure.
The NdbOperation Class

Parent class

NdbOperation

Description

This structure is used to specify an extra value to obtain as part of an NdbRecord operation.

Members

The elements making up this structure are shown in the following table:

Table 2.52 GetValueSpec structure member names, types, and descriptions

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>column</td>
<td>const Column*</td>
<td>To specify an extra value to read, the caller must provide this, as well as (optionally NULL) appStorage pointer.</td>
</tr>
<tr>
<td>appStorage</td>
<td>void*</td>
<td>If this pointer is null, then the received value is stored in memory managed by the NdbRecAttr object. Otherwise, the received value is stored at the location pointed to (and is still accessible using the NdbRecAttr object).</td>
</tr>
</tbody>
</table>

Important

It is the caller's responsibility to ensure that the following conditions are met:

1. appStorage points to sufficient space to store any returned data.
2. Memory pointed to by appStorage is not reused or freed until after the execute()
The NdbOperation Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>recAttr</td>
<td>NdbRecAttr*</td>
<td>After the operation is defined, recAttr contains a pointer to the NdbRecAttr object for receiving the data.</td>
</tr>
</tbody>
</table>

Blob reads cannot be specified using `GetValueSpec`.

For more information, see Section 2.3.22, “The NdbRecord Interface”.

**NdbOperation::incValue()**

**Description**
Interpreted program instruction which adds a value to an attribute. The attribute can be specified by name or by ID. Thus, there are four versions of this method having slightly different parameters, as shown under Signature.

This instruction uses registers 6 and 7, and overwrites these registers in the course of its operation.

For scans and NdbRecord operations, use the NdbInterpretedCode interface instead.

**Signature**

```c
int incValue
{
    const char* anAttrName,
    Uint32 aValue
}
```

```c
int incValue
{
    const char* anAttrName,
    Uint64 aValue
}
```

```c
int incValue
{
    Uint32 anAttrId,
    Uint32 aValue
}
```

```c
int incValue
{
    Uint32 anAttrId,
    Uint64 aValue
}
```

**Parameters**

- `anAttrName` Name of the attribute.
- `anAttrId` The attribute ID.
- `aValue` The value to be added; this can be a 32-bit or 64-bit integer.

**Return value**
0 on success, -1 otherwise.

**NdbOperation::insertTuple()**

**Description**
This method defines the NdbOperation to be an INSERT operation. When the `NdbTransaction::execute()` method is called, this operation adds a new tuple to the table.
The NdbOperation Class

---

### Signature

**virtual int insertTuple**

```cpp
void
```

**Parameters**

None.

**Return value**

Returns 0 on success, −1 on failure.

### NdbOperation::interpret_exit_last_row()

**Description**

Terminate the entire transaction.

**Signature**

```cpp
int interpret_exit_last_row
void
```

**Parameters**

none

**Return value**

Returns 0 on success; otherwise, returns -1.

### NdbOperation::interpret_exit_nok()

**Description**

Exit interpreted program with status **NOT OK** and an optional error code (see Section 2.4.2, “NDB Error Codes: by Type”).

**Signature**

```cpp
int interpret_exit_nok
Uint32 ErrorCode
void
```

**Parameters**

- **ErrorCode**
  
  Optional error code, defaults to error 899. Applications should use error code 626 or any code in the 6000-6999 range. Error code 899 is supported for backwards compatibility, but 626 is recommended instead. For other error codes, the behavior is undefined and may change at any time without prior notice.

**Return value**

0 on success, -1 otherwise.

### NdbOperation::interpret_exit_ok()

**Description**

Exit interpreted program with status **OK**.

**Signature**

```cpp
int interpret_exit_ok
```

**Parameters**

none

**Return value**

0 on success, -1 otherwise.

---

### NdbOperation::interpretedDeleteTuple()

---
### The NdbOperation Class

| Description | Delete a tuple using an interpreted program. |
| Signature  | ```cpp
def interpretedDeleteTuple()
    {
        return 0;
    }
``` |
| Parameters | `None`. |
| Return value | 0 on success, -1 otherwise. |

#### NdbOperation::interpretedUpdateTuple()

| Description | Update a tuple using an interpreted program. |
| Signature  | ```cpp
def interpretedUpdateTuple()
    {
        return 0;
    }
``` |
| Parameters | `None`. |
| Return value | 0 on success, -1 otherwise. |

#### NdbOperation::interpretedWriteTuple()

| Description | Write a tuple using an interpreted program. |
| Signature  | ```cpp
def interpretedWriteTuple()
    {
        return 0;
    }
``` |
| Parameters | `None`. |
| Return value | 0 on success, -1 otherwise. |

#### NdbOperation::load_const_u32()

| Description | Load a 32-bit constant value into a register. |
| Signature  | ```cpp
int load_const_u32
    {
        Uint32 Dest, Constant;
        return 0;
    }
``` |
| Parameters | `RegDest` Destination register. `Constant` Value to load into the register. |
| Return value | 0 on success, -1 otherwise. |

#### NdbOperation::load_const_u64()

| Description | Load a 64-bit constant value into a register. |
| Signature  | ```cpp
int load_const_u64
    {
        Uint64 Dest, Constant;
        return 0;
    }
``` |
| Parameters | `RegDest` Destination register. `Constant` Value to load into the register. |
| Return value | 0 on success, -1 otherwise. |
The NdbOperation Class

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RegDest</td>
<td>Destination register.</td>
</tr>
<tr>
<td>Constant</td>
<td>Value to load into the register.</td>
</tr>
</tbody>
</table>

Return value

0 on success, otherwise -1.

**NdbOperation::load_const_null()**

Description

Load NULL into a register.

Signature

```c
int load_const_null
    (Uint32 RegDest)
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RegDest</td>
<td>Destination register.</td>
</tr>
</tbody>
</table>

Return value

0 on success, -1 otherwise.

**NdbOperation::LockMode**

This section provides information about the LockMode data type.

Description

This type describes the lock mode used when performing a read operation.

Enumeration values

Possible values for this type are shown, along with descriptions, in the following table:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LM_Read</td>
<td>Read with shared lock</td>
</tr>
<tr>
<td>LM_Exclusive</td>
<td>Read with exclusive lock</td>
</tr>
<tr>
<td>LM_CommittedRead</td>
<td>Ignore locks; read last committed</td>
</tr>
<tr>
<td>LM_SimpleRead</td>
<td>Read with shared lock, but release lock directly</td>
</tr>
</tbody>
</table>

There is also support for dirty reads (LM_Dirty), but this is normally for internal purposes only, and should not be used for applications deployed in a production setting.

**NdbOperation::OperationOptions**

This section provides information about the OperationOptions data structure.

Parent class

NdbOperation

Description

These options are passed to the NdbRecord-based primary key and scan takeover operation methods defined in the NdbTransaction and NdbScanOperation classes.

Most NdbTransaction::*Tuple() methods (see Section 2.3.25, "The NdbTransaction Class") take a supplementary sizeOfOptions parameter. This is optional, and is intended to permit the interface implementation to remain backward compatible with older un-recompiled clients that may pass an older (smaller) version of the OperationOptions structure. This effect is achieved by passing sizeof(OperationOptions) into this parameter.
Each option type is marked as present by setting the corresponding bit in `optionsPresent`. (Only the option types marked in `optionsPresent` need have sensible data.) All data is copied out of the `OperationOptions` structure (and any subtended structures) at operation definition time. If no options are required, then `NULL` may be passed instead.

Members

The elements making up this structure are shown in the following table:

**Table 2.54 NdbOperation::OperationOptions structure member names, types, and description**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>optionsPresent</td>
<td>Uint64</td>
<td>Which flags are present.</td>
</tr>
<tr>
<td>[...]</td>
<td>Flags:</td>
<td>Type of flags.</td>
</tr>
</tbody>
</table>

The accepted names and values are shown in the following list:

- **OO_ABORTOPTION**: 0x01
- **OO_GETVALUE**: 0x02
- **OO_SETVALUE**: 0x04
- **OO_PARTITION_ID**: 0x08
- **OO_INTERPRETED**: 0x10
- **OO_ANYVALUE**: 0x20
- **OO_CUSTOMDATA**: 0x40
- **OO_LOCKHANDLE**: 0x80
- **OO_QUEUABLE**: 0x100
- **OO_NOT_QUEUABLE**: 0x200
- **OO_DEFERRED_CONSTAINTS**: 0x400
- **OO_DISABLE_FK**

For more information, see [Section 2.3.22, “The NdbRecord Interface”](#).

**NdbOperation::read_attr()**

**Description**

Read an attribute identified by name or ID into a register.

**Signature**

```c
int read_attr
  (  
    const char* anAttrName,  
    Uint32  RegDest  
  )
```

---

235
The NdbOperation Class

```c
int read_attr
{
    Uint32 anAttrId,
    Uint32 RegDest
}
```

Parameters

- **anAttrName** Attribute name. Use this or the attribute ID.
- **anAttrId** Attribute ID. Use this or the name of the attribute.
- **RegDest** Destination register.

Return value

On success, 0; otherwise, -1.

### NdbOperation::readTuple()

**Description**

This method defines the NdbOperation as a READ operation. When the NdbTransaction::execute() method is invoked, the operation reads a tuple.

**Signature**

```c
virtual int readTuple
{
    LockMode mode
}
```

Parameters

- **mode** specifies the locking mode used by the read operation. See NdbOperation::LockMode, for possible values.

Return value

Returns 0 on success, -1 on failure.

### NdbOperation::ret_sub()

**Description**

Return from an interpreted program subroutine.

**Signature**

```c
int ret_sub
{
    void
}
```

Parameters

- none.

Return value

0 on success, -1 otherwise.

### NdbOperation::setValue()

**Description**

This method defines an attribute to be set or updated.

There are a number of NdbOperation::setValue() methods that take a certain type as input (pass by value rather than passing a pointer). It is the responsibility of the application programmer to use the correct types.

The NDB API does check that the application sends a correct length to the interface as given in the length parameter. A char* value can contain any data type or any type of array. If the length is not provided, or if it is set to zero, then the API assumes that the pointer is correct, and does not check it.

To set a **NULL** value, use the following construct:

```c
setValue("ATTR_NAME", (char*)NULL);
```
The NdbOperation Class

When you use `insertTuple()`, the NDB API automatically detects that it is supposed to use `equal()` instead.

In addition, it is not necessary when using `insertTuple()` to use `setValue()` on key attributes before other attributes.

**Signature**

There are 14 versions of `NdbOperation::setValue()`, each with slightly different parameters, as listed here:

```c
int setValue
{   
    const char* name,
    const char* value
}

int setValue
{   
    const char* name,
    Int32 value
}

int setValue
{   
    const char* name,
    Uint32 value
}

int setValue
{   
    const char* name,
    Uint32 value
}

int setValue
{   
    const char* name,
    Int64 value
}

int setValue
{   
    const char* name,
    Uint64 value
}

int setValue
{   
    const char* name,
    float value
}

int setValue
{   
    const char* name,
    double value
}

int setValue
{   
    Uint32 id,
    const char* value
}

int setValue
{   
    Uint32 id,
    Int32 value
}

int setValue
{   
    Uint32 id,
    Uint32 value
}
```
The NdbOperation Class

```c
{  
  Uint32 id,
  Int64 value
}
```

```c
int setValue
{  
  Uint32 id,
  Uint64 value
}
```

```c
int setValue
{  
  Uint32 id,
  float value
}
```

```c
int setValue
{  
  Uint32 id,
  double value
}
```

### Parameters

This method requires the following two parameters:

- The first parameter identifies the attribute to be set, and may be either one of the following:
  1. The attribute `name` (a string)
  2. The attribute `id` (an unsigned 32-bit integer)

- The second parameter is the `value` to which the attribute is to be set; its type may be any one of the following 7 types:
  1. String (`const char*`)
  2. 32-bit integer
  3. Unsigned 32-bit integer
  4. 64-bit integer
  5. Unsigned 64-bit integer
  6. Double
  7. Float

See `NdbOperation::equal()`, for important information regarding the value's format and length.

### Return value

Returns `-1` in the event of failure.

### NdbOperation::SetValueSpec

This section provides information about the `SetValueSpec` data structure.

#### Parent class

`NdbOperation`

#### Description

This structure is used to specify an extra value to set as part of an `NdbRecord` operation.

#### Members

The elements making up this structure are shown in the following table:
The NdbOperation Class

Table 2.55 NdbOperation::SetValueSpec attributes, with types and descriptions

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>column</td>
<td>Column</td>
<td>To specify an extra value to read, the caller must provide this, as well as (optionally NULL) appStorage pointer.</td>
</tr>
<tr>
<td>value</td>
<td>void*</td>
<td>This must point to the value to be set, or to NULL if the attribute is to be set to NULL. The value pointed to is copied when the operation is defined, and need not remain in place until execution time.</td>
</tr>
</tbody>
</table>

Blob values cannot be set using SetValueSpec.

For more information, see Section 2.3.22, “The NdbRecord Interface”.

NdbOperation::sub_reg()

Description Store difference of two register values in a third register.

Signature

```c
int sub_reg
{
    Uint32 RegSource1,
    Uint32 RegSource2,
    Uint32 RegDest
}
```

Parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>param</td>
<td>param</td>
</tr>
</tbody>
</table>

 REGSource1

 REGSource2

 REGDest

Registers contain value to be subtracted from.

Registers contain value to be subtracted from.

Register in which to store the result.
Return value 0 on success, otherwise -1.

**NdbOperation::subValue()**

**Description**
Interpreted program instruction which subtracts a value from an attribute in an interpreted operation. The attribute can be specified by name or by ID. Thus, there are four versions of this method having slightly different parameters, as shown under **Signature**.

As with **incValue()**, this instruction uses registers 6 and 7, and overwrites these registers in the course of its operation.

For scans and **NdbRecord** operations, use the **NdbInterpretedCode** interface instead.

**Signature**

```c
int subValue
{
    const char* anAttrName,
    Uint32 aValue
}
int subValue
{
    const char* anAttrName,
    Uint64 aValue
}
int subValue
{
    Uint32 anAttrId,
    Uint32 aValue
}
int subValue
{
    Uint32 anAttrId,
    Uint64 aValue
}
```

**Parameters**

- **anAttrName** Name of the attribute
- **anAttrId** The attribute ID
- **aValue** The value to be subtracted; this can be a 32-bit or 64-bit integer.

Return value 0 on success, -1 otherwise.

**NdbOperation::Type**

This section provides information about the **Type** data type.

**Description**
**Type** is used to describe the operation access type. Each access type is supported by **NdbOperation** or one of its subclasses, as shown in the following table:

**Enumeration values** Possible values are shown, along with descriptions, in the following table:

**Table 2.56 NdbOperation::Type data type values and descriptions**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PrimaryKeyAccess</td>
<td>A read, insert, update, or delete operation using primary key</td>
</tr>
</tbody>
</table>

<td>An ordered index scan</td>
<td>NdbIndexScanOperation</td>
</tr>
</tbody>
</table>

### NdbOperation::updateTuple()

**Description**

This method defines the `NdbOperation` as an `UPDATE` operation. When the `NdbTransaction::execute()` method is invoked, the operation updates a tuple found in the table.

**Signature**

```cpp
virtual int updateTuple
{
    void
}
```

**Parameters**

- None.

**Return value**

Returns 0 on success, -1 on failure.

### NdbOperation::write_attr()

**Description**

Write an attribute value from a register. The attribute to be written can be specified by name or ID.

**Signature**

```cpp
int write_attr
{
    const char* anAttrName,
    Uint32 RegSource
}
```

**Parameters**

- `anAttrName` Attribute name. Use this or the attribute ID.
- `anAttrId` Attribute ID. Use this or the name of the attribute.
- `RegSource` Source register.

**Return value**

Returns 0 on success; otherwise, returns -1.

### NdbOperation::writeTuple()

**Description**

This method defines the `NdbOperation` as a `WRITE` operation. When the `NdbTransaction::execute()` method is invoked, the operation writes a tuple to the table. If the tuple already exists, it is updated; otherwise an insert takes place.

**Signature**

```cpp
virtual int writeTuple
{
    void
}
```

**Parameters**

- None.

**Return value**

Returns 0 on success, -1 on failure.
2.3.21 The NdbRecAttr Class

This section provides information about the NdbRecAttr class.

- NdbRecAttr Class Overview
- ~NdbRecAttr()
- NdbRecAttr::aRef()
- NdbRecAttr::char_value()
- NdbRecAttr::clone()
- NdbRecAttr::double_value()
- NdbRecAttr::float_value()
- NdbRecAttr::get_size_in_bytes()
- NdbRecAttr::getColumn()
- NdbRecAttr::getType()
- NdbRecAttr::int8_value()
- NdbRecAttr::int32_value()
- NdbRecAttr::int64_value()
- NdbRecAttr::isNULL()
- NdbRecAttr::medium_value()
- NdbRecAttr::short_value()
- NdbRecAttr::u_8_value()
- NdbRecAttr::u_32_value()
- NdbRecAttr::u_64_value()
- NdbRecAttr::u_char_value()
- NdbRecAttr::u_medium_value()
- NdbRecAttr::u_short_value()

**NdbRecAttr Class Overview**

Parent class: None
Child classes: None

Description: NdbRecAttr contains the value of an attribute. An NdbRecAttr object is used to store an attribute value after it has been retrieved using the NdbOperation::getValue() method. This object is allocated by the NDB API. A brief example is shown here:

```c
MyRecAttr = MyOperation->getValue("ATTR2", NULL);
if(MyRecAttr == NULL)
    goto error;
if(MyTransaction->execute(Commit) == -1)
    goto error;
ndbout << MyRecAttr->u_32_value();
```

The NdbRecAttr Class

For additional examples, see Section 2.5.2, “NDB API Example Using Synchronous Transactions”.

An `NdbRecAttr` object is instantiated with its value only when `NdbTransaction::execute()` is invoked. Prior to this, the value is undefined. (Use `NdbRecAttr::isNull()` to check whether the value is defined.) This means that an `NdbRecAttr` object has valid information only between the times that `NdbTransaction::execute()` and `Ndb::closeTransaction()` are called. The value of the NULL indicator is -1 until the `NdbTransaction::execute()` method is invoked.

**Methods**

`NdbRecAttr` has a number of methods for retrieving values of various simple types directly from an instance of this class.

It is also possible to obtain a reference to the value regardless of its actual type, by using `NdbRecAttr::aRef()`; however, you should be aware that this is not type-safe, and requires a cast from the user.

The following table lists all of the public methods of this class and the purpose or use of each method:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>~NdbRecAttr()</td>
<td>Destructor method</td>
</tr>
<tr>
<td>aRef()</td>
<td>Gets a pointer to the attribute value</td>
</tr>
<tr>
<td>char_value()</td>
<td>Retrieves a <code>Char</code> attribute value</td>
</tr>
<tr>
<td>clone()</td>
<td>Makes a deep copy of the <code>RecAttr</code> object</td>
</tr>
<tr>
<td>double_value()</td>
<td>Retrieves a <code>Double</code> attribute value, as a double (8 bytes)</td>
</tr>
<tr>
<td>float_value()</td>
<td>Retrieves a <code>Float</code> attribute value, as a float (4 bytes)</td>
</tr>
<tr>
<td>get_size_in_bytes()</td>
<td>Gets the size of the attribute, in bytes</td>
</tr>
<tr>
<td>getColumn()</td>
<td>Gets the column to which the attribute belongs</td>
</tr>
<tr>
<td>getType()</td>
<td>Gets the attribute's type (<code>Column::Type</code>)</td>
</tr>
<tr>
<td>isNULL()</td>
<td>Tests whether the attribute is NULL</td>
</tr>
<tr>
<td>int8_value()</td>
<td>Retrieves a <code>Tinyint</code> attribute value, as an 8-bit integer</td>
</tr>
<tr>
<td>int32_value()</td>
<td>Retrieves an <code>Int</code> attribute value, as a 32-bit integer</td>
</tr>
<tr>
<td>int64_value()</td>
<td>Retrieves a <code>Bigint</code> attribute value, as a 64-bit integer</td>
</tr>
<tr>
<td>medium_value()</td>
<td>Retrieves a <code>Mediumint</code> attribute value, as a 32-bit integer</td>
</tr>
<tr>
<td>short_value()</td>
<td>Retrieves a <code>Smallint</code> attribute value, as a 16-bit integer</td>
</tr>
<tr>
<td>u_8_value()</td>
<td>Retrieves a <code>Tinyunsigned</code> attribute value, as an unsigned 8-bit integer</td>
</tr>
</tbody>
</table>
The NdbRecAttr Class

<table>
<thead>

</tr>
</tbody>
</table>

The NdbRecAttr class has no public constructor; an instance of this object is created using NdbTransaction::execute(). For information about the destructor, which is public, see ~NdbRecAttr().

Types

The NdbRecAttr class defines no public types.

~NdbRecAttr()

Description

The NdbRecAttr class destructor method.

You should delete only copies of NdbRecAttr objects that were created in your application using the clone() method.

Signature

```cpp
~NdbRecAttr
{
  void
}
```

Parameters

None.

Return value

None.

NdbRecAttr::aRef()

Description

This method is used to obtain a reference to an attribute value, as a char pointer. This pointer is aligned appropriately for the data type. The memory is released by the NDB API when NdbTransaction::close() is executed on the transaction which read the value.

Signature

```cpp
char* aRef
{
  void
} const
```

Parameters

A pointer to the attribute value. Because this pointer is constant, this method can be called anytime after NdbOperation::getValue() has been called.

Return value

None.

NdbRecAttr::char_value()

Description

This method gets a Char value stored in an NdbRecAttr object, and returns it as a char.

Signature

```cpp
char char_value
```
The NdbRecAttr Class

```cpp
void
) const
```

Parameters

None.

Return value

A char value.

**NdbRecAttr::clone()**

Description

This method creates a deep copy of an NdbRecAttr object.

The copy created by this method should be deleted by the application when no longer needed.

Signature

```cpp
NdbRecAttr* clone
(  
  void
) const
```

Parameters

None.

Return value

An NdbRecAttr object. This is a complete copy of the original, including all data.

**NdbRecAttr::double_value()**

Description

This method gets a Double value stored in an NdbRecAttr object, and returns it as a double.

Signature

```cpp
double double_value
(  
  void
) const
```

Parameters

None.

Return value

A double (8 bytes).

**NdbRecAttr::float_value()**

Description

This method gets a Float value stored in an NdbRecAttr object, and returns it as a float.

Signature

```cpp
float float_value
(  
  void
) const
```

Parameters

None.

Return value

A float (4 bytes).

**NdbRecAttr::get_size_in_bytes()**

Description

You can use this method to obtain the size of an attribute (element).

Signature

```cpp
Uint32 get_size_in_bytes
(  
  void
) const
```

Parameters

None.

Return value

The attribute size in bytes, as an unsigned 32-bit integer.
The NdbRecAttr Class

**NdbRecAttr::getColumn()**

Description: This method is used to obtain the column to which the attribute belongs.

Signature:

```cpp
const NdbDictionary::Column* getColumn(
    void
) const
```

Parameters: None.

Return value: A pointer to a Column object.

**NdbRecAttr::getType()**

Description: This method is used to obtain the column's data type.

Signature:

```cpp
NdbDictionary::Column::Type getType(
    void
) const
```

Parameters: None.

Return value: A Column::Type value.

**NdbRecAttr::int8_value()**

Description: This method gets a Small value stored in an NdbRecAttr object, and returns it as an 8-bit signed integer.

Signature:

```cpp
Int8 int8_value(
    void
) const
```

Parameters: None.

Return value: An 8-bit signed integer.

**NdbRecAttr::int32_value()**

Description: This method gets an Int value stored in an NdbRecAttr object, and returns it as a 32-bit signed integer.

Signature:

```cpp
Int32 int32_value(
    void
) const
```

Parameters: None.

Return value: A 32-bit signed integer.

**NdbRecAttr::int64_value()**

Description: This method gets a Bigint value stored in an NdbRecAttr object, and returns it as a 64-bit signed integer.

Signature:

```cpp
Int64 int64_value(
    void
) const
```

Parameters: None.
The NdbRecAttr Class

Return value

A 64-bit signed integer.

NdbRecAttr::isNULL()

Description

This method checks whether a given attribute value is NULL.

Signature

```cpp
int isNULL
{
    void
} const
```

Parameters

None.

Return value

One of the following three values:

- `-1`: The attribute value is not defined due to an error.
- `0`: The attribute value is defined, but is not NULL.
- `1`: The attribute value is defined and is NULL.

In the event that NdbTransaction::execute() has not yet been called, the value returned by isNULL() is not determined.

NdbRecAttr::medium_value()

Description

Gets the value of a Mediumint value stored in an NdbRecAttr object, and returns it as a 32-bit signed integer.

Signature

```cpp
Int32 medium_value
{
    void
} const
```

Parameters

None.

Return value

A 32-bit signed integer.

NdbRecAttr::short_value()

Description

This method gets a Smallint value stored in an NdbRecAttr object, and returns it as a 16-bit signed integer (short).

Signature

```cpp
short short_value
{
    void
} const
```

Parameters

None.

Return value

A 16-bit signed integer.

NdbRecAttr::u_8_value()

Description

This method gets a Smallunsigned value stored in an NdbRecAttr object, and returns it as an 8-bit unsigned integer.

Signature

```cpp
Uint8 u_8_value
{
    void
} const
```

Parameters

None.

Return value

An 8-bit unsigned integer.
### NdbRecAttr::u_32_value()

**Description**
This method gets an *Unsigned* value stored in an *NdbRecAttr* object, and returns it as a 32-bit unsigned integer.

**Signature**

```
Uint32 u_32_value
{
    void
} const
```

**Parameters**
None.

**Return value**
A 32-bit unsigned integer.

### NdbRecAttr::u_64_value()

**Description**
This method gets a *Bigunsigned* value stored in an *NdbRecAttr* object, and returns it as a 64-bit unsigned integer.

**Signature**

```
Uint64 u_64_value
{
    void
} const
```

**Parameters**
None.

**Return value**
A 64-bit unsigned integer.

### NdbRecAttr::u_char_value()

**Description**
This method gets a *Char* value stored in an *NdbRecAttr* object, and returns it as an unsigned *char*.

**Signature**

```
Uint8 u_char_value
{
    void
} const
```

**Parameters**
None.

**Return value**
An 8-bit unsigned *char* value.

### NdbRecAttr::u_medium_value()

**Description**
This method gets an *Mediumunsigned* value stored in an *NdbRecAttr* object, and returns it as a 32-bit unsigned integer.

**Signature**

```
Uint32 u_medium_value
{
    void
} const
```

**Parameters**
None.

**Return value**
A 32-bit unsigned integer.

### NdbRecAttr::u_short_value()

**Description**
This method gets a *Smallunsigned* value stored in an *NdbRecAttr* object, and returns it as a 16-bit (short) unsigned integer.

**Signature**

```
Uint16 u_short_value
{
    void
}
```
2.3.22 The NdbRecord Interface

This section provides information about the NdbRecord interface.

NdbRecord is an interface which provides a mapping to a full or a partial record stored in NDB. In the latter case, it can be used in conjunction with a bitmap to assist in access.

NdbRecord has no API methods of its own; rather, it acts as a handle that can be passed between various method calls for use in many different sorts of operations, including the following:

- Unique key reads and primary key reads
- Table scans and index scans
- DML operations involving unique keys or primary keys
- Operations involving index bounds

The same NdbRecord can be used simultaneously in multiple operations, transactions, and threads.

An NdbRecord can be created in NDB API programs by calling Dictionary::createRecord(). In addition, a number of NDB API methods have additional declarations that enable the programmer to leverage NdbRecord:

- NdbScanOperation::nextResult()
- NdbScanOperation::lockCurrentTuple()
- NdbScanOperation::updateCurrentTuple()
- NdbScanOperation::deleteCurrentTuple()
- Dictionary::createRecord()
- Dictionary::releaseRecord()
- NdbTransaction::readTuple()
- NdbTransaction::insertTuple()
- NdbTransaction::updateTuple()
- NdbTransaction::writeTuple()
- NdbTransaction::deleteTuple()
- NdbTransaction::scanTable()
- NdbTransaction::scanIndex()

The following members of NdbIndexScanOperation and NdbDictionary can also be used with NdbRecord scans:
• **IndexBound** is a structure used to describe index scan bounds.

• **RecordSpecification** is a structure used to specify columns and range offsets.

You can also use **NdbRecord** in conjunction with the **PartitionSpec** structure to perform scans that take advantage of partition pruning, using **NdbIndexScanOperation::setBound()**.

### 2.3.23 The NdbScanFilter Class

This section provides information about the **NdbScanFilter** class.

- **NdbScanFilter Class Overview**
- **NdbScanFilter::begin()**
- **NdbScanFilter::BinaryCondition**
- **NdbScanFilter::cmp()**
- **NdbScanFilter::cmp_param()**
- **NdbScanFilter Constructor**
- **NdbScanFilter::end()**
- **NdbScanFilter::eq()**
- **NdbScanFilter::isfalse()**
- **NdbScanFilter::isnotnull()**
- **NdbScanFilter::isnull()**
- **NdbScanFilter::istrue()**
- **NdbScanFilter::ge()**
- **NdbScanFilter::getNdbError()**
- **NdbScanFilter::getNdbOperation()**
- **NdbScanFilter::Group**
- **NdbScanFilter::gt()**
- **NdbScanFilter::le()**
- **NdbScanFilter::lt()**
- **NdbScanFilter::ne()**
- **NdbScanFilter::reset()**
- **NdbScanFilter::setSqlCmpSemantics()**

</table>

Types

The NdbScanFilter class defines two public types:

- **BinaryCondition**: The type of condition, such as lower bound or upper bound.
- **Group**: A logical grouping operator, such as AND or OR.

**NdbScanFilter Integer Comparison Methods.** NdbScanFilter provides several convenience methods which can be used in lieu of the cmp() method when the arbitrary value to be compared is an integer: eq(), ge(), gt(), le(), lt(), and ne().

Each of these methods is essentially a wrapper for cmp() that includes an appropriate value of BinaryCondition for that method's condition parameter; for example, NdbScanFilter::eq() is defined like this:

```cpp
int eq(int columnId, Uint32 value) {
```
The NdbScanFilter Class

```cpp
return cmp(BinaryCondition::COND_EQ, columnId, svalue, 4);
```

### NdbScanFilter::begin()

**Description**
This method is used to start a compound, and specifies the logical operator used to group the conditions making up the compound. The default is **AND**.

**Signature**
```cpp
int begin
{
    Group group = AND
}
```

**Parameters**
A `Group` value: one of **AND**, **OR**, **NAND**, or **NOR**. See `NdbScanFilter::Group`, for additional information.

**Return value**
0 on success, -1 on failure.

### NdbScanFilter::BinaryCondition

This section provides information about the `BinaryCondition` data type.

**Description**
This type represents a condition based on the comparison of a column value with some arbitrary value—that is, a bound condition. A value of this type is used as the first argument to the `cmp()` method.

When used in comparisons with `COND_EQ`, `COND_NE`, `COND_LT`, `COND_LE`, `COND_GT`, or `COND_GE`, fixed-length character and binary column values must be prefixed with the column size, and must be padded to length. This is not necessary for such values when used in `COND_LIKE`, `COND_NOTLIKE`, `COL_AND_MASK_EQ_MASK`, `COL_AND_MASK_NE_MASK`, `COL_AND_MASK_EQ_ZERO`, or `COL_AND_MASK_NE_ZERO` comparisons.

Strings compared using `COND_LIKE` and `COND_NOTLIKE` can use the pattern metacharacters % and _. See `NdbScanFilter::cmp()`, for more information.

The **BIT** comparison operators are `COL_AND_MASK_EQ_MASK`, `COL_AND_MASK_NE_MASK`, `COL_AND_MASK_EQ_ZERO`, and `COL_AND_MASK_NE_ZERO`. Corresponding methods are available for `NdbInterpretedCode` and `NdbOperation`; for more information about these methods, see `NdbInterpretedCode Bitwise Comparison Operations`.

**Enumeration values**
Possible values are shown, along with descriptions, in the following table:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Column type compared</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>COND_EQ</code></td>
<td>Equality (=)</td>
<td>any</td>
</tr>
<tr>
<td><code>COND_NE</code></td>
<td>Inequality (&lt;&gt; or !=)</td>
<td>any</td>
</tr>
<tr>
<td><code>COND_LE</code></td>
<td>Lower bound (&lt;=)</td>
<td>any</td>
</tr>
<tr>
<td><code>COND_LT</code></td>
<td>Strict lower bound (&lt;)</td>
<td>any</td>
</tr>
<tr>
<td><code>COND_GE</code></td>
<td>Upper bound (&gt;=)</td>
<td>any</td>
</tr>
</tbody>
</table>

<td>BIT</td>
</tr>
<tr>
<td>COL_AND_MASK_NE_ZERO</td>
<td>Column value ANDed with bitmask is not equal to zero</td>
<td>BIT</td>
</tr>
</tbody>
</table>

**NdbScanFilter::cmp()**

**Description**

This method is used to define a comparison between a given value and the value of a column. In NDB 8.0, it can also be used to compare two columns. (This method does not actually execute the comparison, which is done later when performing the scan for which this NdbScanFilter is defined.)

In many cases, where the value to be compared is an integer, you can instead use one of several convenience methods provided by NdbScanFilter for this purpose. See NdbScanFilter Integer Comparison Methods.

**Signature**

```cpp
int cmp(
    BinaryCondition condition,
    int columnId,
    const void* value,
    Uint32 length = 0
)
```

Additionally, in NDB 8.0:

```cpp
int cmp(
    BinaryCondition condition,
    int ColumnId1,
    int ColumnId2
)
```

**Parameters**

When used to compare a value with a column, this method takes the following parameters:

- `condition`: This represents the condition to be tested which compares the value of the column having the column ID `columnID` with some arbitrary value. The `condition` is a `BinaryCondition` value; for permitted values and the relations that they represent, see NdbScanFilter::BinaryCondition.

  The `condition` values `COND_LIKE` or `COND_NOTLIKE` are used to compare a column value with a string pattern.
The NdbScanFilter Class

- **columnId**: This is the column's identifier, which can be obtained using the `Column::getColumnNo()` method.

- **value**: The value to be compared, represented as a pointer to `void`.

When using a `COND_LIKE` or `COND_NOTLIKE` comparison condition, the `value` is treated as a string pattern. This string must not be padded or use a prefix. The string `value` can include the pattern metacharacters or "wildcard" characters `%` and `_`, which have the meanings shown here:

<table>
<thead>
<tr>
<th>Metacharacter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>%</code></td>
<td>Matches zero or more characters</td>
</tr>
<tr>
<td><code>_</code></td>
<td>Matches exactly one character</td>
</tr>
</tbody>
</table>

These are the same wildcard characters that are supported by the SQL `LIKE` and `NOT LIKE` operators, and are interpreted in the same way. See String Comparison Functions and Operators, for more information.

- **length**: The length of the value to be compared. The default value is 0. Using 0 for the `length` has the same effect as comparing to `NULL`, that is using the `isnull()` method.

When used to compare two columns, `cmp()` takes the following parameters:

- **condition**: The condition to be tested when comparing the columns. The condition may be any one of the `BinaryCondition` values `EQ`, `NE`, `LT`, `LE`, `GT`, or `GE`. Other values are not accepted.

- **columnID1**: ID of the first of the two columns to be compared.

- **columnID2**: ID of the second column.

Columns being compared using this method must be of exactly the same type. This includes length, precision, scale, and all other particulars.

**Return value**

This method returns an integer: 0 on success, and -1 on failure.

**NdbScanFilter::cmp_param()**

**Description**

This method is used to define a comparison between the value of a column and that of a parameter having the specified ID. The comparison is actually performed later when executing the scan for which this `NdbScanFilter` is defined.

This method was added in NDB 8.0.27.
The NdbScanFilter Class

**Signature**

```cpp
int cmp_param()
{
    BinaryCondition condition,
    int colId,
    int paramId
}
```

**Parameters**

When used to compare a value with a column, this method takes the following parameters:

- **condition**: This represents the condition to be tested which compares the value of the column having the column ID `columnID` with some arbitrary value. The `condition` is a `BinaryCondition` value; for permitted values and the relations that they represent, see `NdbScanFilter::BinaryCondition`.

  The `condition` values `COND_LIKE` or `COND_NOTLIKE` are used to compare a column value with a string pattern.

- **colId**: This is the column's identifier, which can be obtained using the `Column::getColumnNo()` method.

- **paramId**: The ID of the parameter whose value is to be compared.

Values being compared using this method must be of exactly the same type. This includes length, precision, scale, and all other particulars.

**Return value**

This method returns an integer: 0 on success, and -1 on failure.

---

**NdbScanFilter Constructor**

**Description**

This is the constructor method for `NdbScanFilter`, and creates a new instance of the class.

**Signature**

```cpp
NdbScanFilter(class NdbOperation* op)
```

**Parameters**

This method takes a single parameter, a pointer to the `NdbOperation` to which the filter applies.

**Return value**

A new instance of `NdbScanFilter`.

**Destructor**

The destructor takes no arguments and does not return a value. It should be called to remove the `NdbScanFilter` object when it is no longer needed.

---

**NdbScanFilter::end()**

**Description**

This method completes a compound, signalling that there are no more conditions to be added to it.

**Signature**

```cpp
int end
{
    void
}
```

**Parameters**

None.

**Return value**

Returns 0 on success, or -1 on failure.

---

**NdbScanFilter::eq()**
### The NdbScanFilter Class

**Description**
This method is used to perform an equality test on a column value and an integer.

**Signature**
```c
int eq
{
    int  ColId,
    Uint32  value
}
or

int eq
{
    int  ColId,
    Uint64  value
}
```

**Parameters**
This method takes two parameters, listed here:
- The ID (`ColId`) of the column whose value is to be tested
- An integer with which to compare the column value; this integer may be either 32-bit or 64-bit, and is unsigned in either case.

**Return value**
Returns `0` on success, or `-1` on failure.

#### NdbScanFilter::isfalse()

**Description**
Defines a term of the current group as `FALSE`.

**Signature**
```c
int isfalse
{
    void
}
```

**Parameters**
None.

**Return value**
`0` on success, or `-1` on failure.

#### NdbScanFilter::isnotnull()

**Description**
This method is used to check whether a column value is not `NULL`.

**Signature**
```c
int isnotnull
{
    int  ColId
}
```

**Parameters**
The ID of the column whose value is to be tested.

**Return value**
Returns `0`, if the column value is not `NULL`.

#### NdbScanFilter::isnull()

**Description**
This method is used to check whether a column value is `NULL`.

**Signature**
```c
int isnull
{
    int  ColId
}
```

**Parameters**
The ID of the column whose value is to be tested.

**Return value**
Returns `0`, if the column value is `NULL`.

#### NdbScanFilter::istrue()

**Description**
Defines a term of the current group as `TRUE`.
The NdbScanFilter Class

**Signature**

```cpp
int istrue
{
    void
}
```

**Parameters**

*None.*

**Return value**

Returns 0 on success, -1 on failure.

**NdbScanFilter::ge()**

**Description**

This method is used to perform a greater-than-or-equal test on a column value and an integer.

**Signature**

```cpp
int ge
{
    int    ColId,
    Uint32 value
}
```

```cpp
int ge
{
    int    ColId,
    Uint64 value
}
```

**Parameters**

Like `eq()`, `lt()`, `le()`, and the other `NdbScanFilter` methods of this type, this method takes two parameters:

- The ID (`ColId`) of the column whose value is to be tested
- An integer with which to compare the column value; this integer may be either 32-bit or 64-bit, and is unsigned in either case.

**Return value**

0 on success; -1 on failure.

**NdbScanFilter::getNdbError()**

**Description**

Because errors encountered when building an `NdbScanFilter` do not propagate to any involved `NdbOperation` object, it is necessary to use this method to access error information.

**Signature**

```cpp
const NdbError& getNdbError
{
    void
}
```

**Parameters**

*None.*

**Return value**

A reference to an `NdbError`.

**NdbScanFilter::getNdbOperation()**

**Description**

If the `NdbScanFilter` was constructed with an `NdbOperation`, this method can be used to obtain a pointer to that `NdbOperation` object.

**Signature**

```cpp
NdbOperation* getNdbOperation
{
    void
}
```

**Parameters**

*None.*
The NdbScanFilter Class

Return value
A pointer to the NdbOperation associated with this NdbScanFilter, if there is one. Otherwise, NULL.

NdbScanFilter::Group
This section provides information about the Group data type.

Description
This type is used to describe logical (grouping) operators, and is used with the begin() method. (See NdbScanFilter::begin().)

Enumeration values
Possible values are shown, along with descriptions, in the following table:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AND</td>
<td>Logical AND: A AND B AND C</td>
</tr>
<tr>
<td>OR</td>
<td>Logical OR: A OR B OR C</td>
</tr>
<tr>
<td>NAND</td>
<td>Logical NOT AND: NOT (A AND B AND C)</td>
</tr>
<tr>
<td>NOR</td>
<td>Logical NOT OR: NOT (A OR B OR C)</td>
</tr>
</tbody>
</table>

NdbScanFilter::gt()

Description
This method is used to perform a greater-than (strict upper bound) test on a column value and an integer.

Signature
This method accommodates both 32-bit and 64-bit values:

```cpp
int gt
{
    int ColId,
    Uint32 value
}
```

```cpp
int gt
{
    int ColId,
    Uint64 value
}
```

Parameters
Like the other NdbScanFilter methods of this type, this method takes two parameters:

- The ID (ColId) of the column whose value is to be tested
- An integer with which to compare the column value; this integer may be either 32-bit or 64-bit, and is unsigned in either case.

Return value
0 on success; -1 on failure.

NdbScanFilter::le()

Description
This method is used to perform a less-than-or-equal test on a column value and an integer.

Signature
This method has two variants, to accommodate 32-bit and 64-bit values:

```cpp
int le
{
```

```cpp
```
The NdbScanFilter Class

```c
int ColId,
   Uint32 value
)

int le
(   int ColId,
    Uint64 value
)
```

### Parameters

Like the other `NdbScanFilter` methods of this type, this method takes two parameters:

- The ID (`ColId`) of the column whose value is to be tested
- An integer with which to compare the column value; this integer may be either 32-bit or 64-bit, and is unsigned in either case.

### Return value

Returns 0 on success, or -1 on failure.

#### NdbScanFilter::lt()

#### Description

This method is used to perform a less-than (strict lower bound) test on a column value and an integer.

#### Signature

This method has 32-bit and 64-bit variants, as shown here:

```c
int lt
(   int ColId,
    Uint32 value
)

int lt
(   int ColId,
    Uint64 value
)
```

### Parameters

Like `eq()`, `ne()`, and the other `NdbScanFilter` methods of this type, this method takes two parameters, listed here:

- The ID (`ColId`) of the column whose value is to be tested
- An integer with which to compare the column value; this integer may be either 32-bit or 64-bit, and is unsigned in either case.

### Return value

Retruns 0 on success, or -1 on failure.

#### NdbScanFilter::ne()

#### Description

This method is used to perform an inequality test on a column value and an integer.

#### Signature

This method has 32-bit and 64-bit variants, as shown here:

```c
int ne
(   int ColId,
    Uint32 value
)

int ne
(   int ColId,
    Uint64 value
)
```
The NdbScanOperation Class

Parameters

Like `eq()` and the other `NdbScanFilter` methods of this type, this method takes two parameters:

- The ID (`ColId`) of the column whose value is to be tested
- An integer with which to compare the column value; this integer may be either 32-bit or 64-bit, and is unsigned in either case.

Return value

Returns 0 on success, or -1 on failure.

### NdbScanFilter::reset()

**Description**

This method resets the `NdbScanFilter` object, discarding any previous filter definition and error state.

**Signature**

```
void reset
{
    void
}
```

**Parameters**

None.

**Return value**

None.

reset() has no effect on the SQL-compliant NULL comparison mode set by `setSqlCmpSemantics()`.

This method was added in NDB 8.0.

### NdbScanFilter::setSqlCmpSemantics()

**Description**

Traditionally, when making comparisons involving NULL, `NdbScanFilter` treats NULL as equal to NULL (and thus considers NULL == NULL to be TRUE). This is not the same as specified by the SQL Standard, which requires that any comparison with NULL return NULL, including NULL == NULL.

Beginning with NDB 8.0.26, it is possible to override this behavior by calling this method, which takes no arguments. Doing so causes the next `NdbScanFilter` object to be created to employ SQL-compliant NULL comparison for all operations for its entire lifetime. This cannot be unset once `setSqlCmpSemantics()` is called; invoking `reset()` has no effect in this regard. The effect of this method extends only to the next instance of `NdbScanFilter` to be created; any subsequent instance uses the traditional comparison mode unless `setSqlCmpSemantics()` is invoked beforehand.

This method has no effect on NULL sorting; `NdbScanFilter` always considers NULL to be less than any other value.

**Signature**

```
void setSqlCmpSemantics
{
    void
}
```

**Parameters**

None

**Return value**

None

This method was added in NDB 8.0.26.

### 2.3.24 The NdbScanOperation Class

This section provides information about the `NdbScanOperation` class.
NdbScanOperation Class Overview

Parent class
NdbOperation

Child classes
NdbIndexScanOperation

Description
The NdbScanOperation class represents a scanning operation used in a transaction. This class inherits from NdbOperation.

Methods
The following table lists the public methods of this class and the purpose or use of each method:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>close()</td>
<td>Closes the scan</td>
</tr>
<tr>
<td>deleteCurrentTuple()</td>
<td>Deletes the current tuple</td>
</tr>
<tr>
<td>lockCurrentTuple()</td>
<td>Locks the current tuple</td>
</tr>
<tr>
<td>nextResult()</td>
<td>Gets the next tuple</td>
</tr>
<tr>
<td>getNdbTransaction()</td>
<td>Gets the NdbTransaction object for this scan</td>
</tr>
<tr>
<td>getPruned()</td>
<td>Used to find out whether this scan is pruned to a single partition</td>
</tr>
<tr>
<td>readTuples()</td>
<td>Reads tuples</td>
</tr>
<tr>
<td>restart()</td>
<td>Restarts the scan</td>
</tr>
<tr>
<td>updateCurrentTuple()</td>
<td>Updates the current tuple</td>
</tr>
</tbody>
</table>

This class has no public constructor. To create an instance of NdbScanOperation, it is necessary to use the NdbTransaction::getNdbScanOperation() method.

Types
This class defines two public types, which are listed here:

- ScanFlag
- ScanOptions.
For more information about the use of \texttt{NdbScanOperation}, see \textit{Scan Operations}, and \textit{Using Scans to Update or Delete Rows}.

\textbf{\texttt{NdbScanOperation::close()}}

\textbf{Description} \hspace{1cm} Calling this method closes a scan. Rows returned by this scan are no longer available after the scan has been closed using this method.

See \textit{Scans with exclusive locks}, for information about multiple threads attempting to perform the same scan with an exclusive lock and how this can affect closing the scans.

\textbf{Signature} \hspace{1cm} \begin{verbatim}
void close(  
    bool forceSend = false,  
    bool releaseOp = false  
)
\end{verbatim}

\textbf{Parameters} \hspace{1cm} This method takes the two parameters listed here:

\begin{itemize}
    \item \texttt{forceSend} defaults to \texttt{false}; call \texttt{close()} with this parameter set to \texttt{true} in order to force transactions to be sent.
    \item \texttt{releaseOp} also defaults to \texttt{false}; set this to \texttt{true} in order to release the operation.
\end{itemize}

The buffer allocated by an \texttt{NdbScanOperation} for receiving the scanned rows is released whenever the cursor navigating the result set is closed using the \texttt{close()} method, regardless of the value of the \texttt{releaseOp} argument.

\textbf{Return value} \hspace{1cm} \textit{None}.

\textbf{\texttt{NdbScanOperation::deleteCurrentTuple()}}

\textbf{Description} \hspace{1cm} This method is used to delete the current tuple.

\textbf{Signature} \hspace{1cm} \begin{verbatim}
const NdbOperation* deleteCurrentTuple(  
    NdbTransaction* takeOverTrans,  
    const NdbRecord* record,  
    char* row = 0,  
    const unsigned char* mask = 0,  
    const NdbOperation::OperationOptions* opts = 0,  
    Uint32 sizeOfOpts = 0  
)
\end{verbatim}

For more information, see \textit{Section 2.3.22, "The NdbRecord Interface"}.

\textbf{Parameters} \hspace{1cm} When used with the \texttt{NdbRecord} interface, this method takes the parameters listed here:

\begin{itemize}
    \item The transaction (\texttt{takeOverTrans}) that should perform the lock; when using \texttt{NdbRecord} with scans, this parameter is not optional.
    \item The \texttt{NdbRecord} referenced by the scan. This \texttt{record} value is required, even if no records are being read.
    \item The \texttt{row} from which to read. Set this to \texttt{NULL} if no read is to occur.
\end{itemize}
• The mask pointer is optional. If it is present, then only columns for which the corresponding bit in the mask is set are retrieved by the scan.

• OperationOptions (opts) can be used to provide more finely-grained control of operation definitions. An OperationOptions structure is passed with flags indicating which operation definition options are present. Not all operation types support all operation options; the options supported for each type of operation are shown in the following table:

Table 2.63 Operation types for the NdbRecord

<table>
<thead>
<tr>
<th>Operation type (Method)</th>
<th>OperationOptions Flags Supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>readTuple()</td>
<td>OO_ABORTOPTION, OO_GETVALUE, OO_PARTITION_ID, OO_INTERPRETED</td>
</tr>
<tr>
<td>insertTuple()</td>
<td>OO_ABORTOPTION, OO_SETVALUE, OO_PARTITION_ID, OO_ANYVALUE</td>
</tr>
<tr>
<td>updateTuple()</td>
<td>OO_ABORTOPTION, OO_SETVALUE, OO_PARTITION_ID, OO_INTERPRETED, OO_ANYVALUE</td>
</tr>
<tr>
<td>writeTuple()</td>
<td>OO_ABORTOPTION, OO_SETVALUE, OO_PARTITION_ID, OO_ANYVALUE</td>
</tr>
<tr>
<td>deleteTuple()</td>
<td>OO_ABORTOPTION, OO_GETVALUE, OO_PARTITION_ID, OO_INTERPRETED, OO_ANYVALUE</td>
</tr>
</tbody>
</table>

• The optional sizeOfOptions parameter is used to preserve backward compatibility of this interface with previous definitions of the OperationOptions structure. If an unusual size is detected by the interface implementation, it can use this to determine how to interpret the passed OperationOptions structure. To enable this functionality, the caller should pass sizeof(NdbOperation::OperationOptions) for the value of this argument.

• If options are specified, their length (sizeOfOpts) must be specified as well.

Return value Returns 0 on success, or -1 on failure.

NdbScanOperation::getNdbTransaction()

Description Gets the NdbTransaction object for this scan.

Signature

```cpp
NdbTransaction* getNdbTransaction
{
  void
} const
```

Parameters None.

Return value A pointer to an NdbTransaction object.

NdbScanOperation::getPruned()
The NdbScanOperation Class

<table>
<thead>
<tr>
<th>Description</th>
<th>This method is used to determine whether or not a given scan operation has been pruned to a single partition. For scans defined using NdbRecord, this method can be called before or after the scan is executed. For scans not defined using NdbRecord, getPruned() is valid only after the scan has been executed.</th>
</tr>
</thead>
</table>
| Signature   | bool getPruned  
|             | {  
|             |  void  
|             | } const |
| Parameters  | None.                                                                                           |
| Return value| Returns true, if the scan is pruned to a single table partition.                                |

### NdbScanOperation::lockCurrentTuple()

<table>
<thead>
<tr>
<th>Description</th>
<th>This method locks the current tuple.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Signature</td>
<td>This method can be called with an optional single parameter, in either of the two ways shown here:</td>
</tr>
</tbody>
</table>

```
NdbOperation* lockCurrentTuple  
{  
  void  
}  
```

The following signature is also supported for this method, when using NdbRecord:

```
NdbOperation *lockCurrentTuple  
{  
  NdbTransaction* lockTrans  
}  
```

This method also supports specifying one or more OperationOptions (also when using NdbRecord):

```
NdbOperation *lockCurrentTuple  
{  
  NdbTransaction* takeOverTrans,  
  const NdbRecord* record,  
  char* row = 0,  
  const unsigned char* mask = 0  
}  
```

Parameters (without NdbRecord) This method takes a single, optional parameter—the transaction that should perform the lock. If this is omitted, the transaction is the current one.

Parameters (using NdbRecord) When using the NdbRecord interface, this method takes these parameters, as described in the following list:

- The transaction (takeOverTrans) that should perform the lock; when using NdbRecord with scans, this parameter is not optional.
• The NdbRecord referenced by the scan. This is required, even if no records are being read.

• The row from which to read. Set this to NULL if no read is to occur.

• The mask pointer is optional. If it is present, then only columns for which the corresponding bit in the mask is set are retrieved by the scan.

• The opts argument can take on any of the following OperationOptions values: OO_ABORTOPTION, OO_GETVALUE, and OO_ANYVALUE.

• If options are specified, their length (sizeOfOptions) must be specified as well.

Calling an NdbRecord scan lock takeover on an NdbRecAttr-style scan is not valid, nor is calling an NdbRecAttr-style scan lock takeover on an NdbRecord-style scan.

Return value
This method returns a pointer to an NdbOperation object, or NULL.

NdbScanOperation::nextResult()

Description
This method is used to fetch the next tuple in a scan transaction. Following each call to nextResult(), the buffers and NdbRecAttr objects defined in NdbOperation::getValue() are updated with values from the scanned tuple.

When nextResult() is executed following end-of-file, NDB returns error code 4210 (Ndb sent more info than length specified) and the extra transaction object is freed by returning it to the idle list for the right TC node.

Signatures
This method can be invoked in one of two ways. The first of these is shown here:

```c
int nextResult
{
  bool fetchAllowed = true,
  bool forceSend = false
}
```

It is also possible to use this method as shown here:

```c
int nextResult
{
  const char*& outRow,
  bool fetchAllowed = true,
  bool forceSend = false
}
```

Parameters (2-parameter version)
This method takes the following two parameters:

• Normally, the NDB API contacts the NDB kernel for more tuples whenever it is necessary; setting fetchAllowed to false keeps this from happening.

Disabling fetchAllowed by setting it to false forces NDB to process any records it already has in its caches. When there
are no more cached records it returns 2. You must then call
nextResult() with fetchAllowed equal to true in order to
contact NDB for more records.

While nextResult(false) returns 0, you should
transfer the record to another transaction using
execute(NdbTransaction::NoCommit). When
nextResult(false) returns 2, you should normally execute
and commit the other transaction. This causes any locks to be
transferred to the other transaction, updates or deletes to be
made, and then, the locks to be released. Following this, you
can call nextResult(true) to have more records fetched and
cached in the NDB API.

Note
If you do not transfer the records to
another transaction, the locks on those
records will be released the next time
that the NDB Kernel is contacted for more
records.

Disabling fetchAllowed can be useful when you want to
update or delete all of the records obtained in a given transaction,
as doing so saves time and speeds up updates or deletes of
scanned records.

• forceSend defaults to false, and can normally be omitted.
However, setting this parameter to true means that transactions
are sent immediately. See Section 1.4.4, “The Adaptive Send
Algorithm”, for more information.

Parameters (3-parameter
version)
This method can also be called with the following three parameters:

• Calling nextResult() sets a pointer to the next row in
calloutRow (if returning 0). This pointer is valid (only) until the
next call to nextResult() when fetchAllowed is true. The
NdbRecord object defining the row format must be specified
beforehand using NdbTransaction::scanTable() (or
NdbTransaction::scanIndex()).

• When false, fetchAllowed forces NDB to process any records it
already has in its caches. See the description for this parameter in
the previous Parameters subsection for more details.

• Setting forceSend to true means that transactions are sent
immediately, as described in the previous Parameters subsection,
as well as in Section 1.4.4, “The Adaptive Send Algorithm”.

Return value
This method returns one of the following 4 integer values,
interpreted as shown in the following list:

• -1: Indicates that an error has occurred.

• 0: Another tuple has been received.

• 1: There are no more tuples to scan.

• 2: There are no more cached records (invoke
nextResult(true) to fetch more records).
The NdbScanOperation Class

Example
See Section 2.5.5, "NDB API Basic Scanning Example".

NdbScanOperation::readTuples()
Description
This method is used to perform a scan.

Signature
virtual int readTuples
{
    LockMode mode = LM_Read,
    Uint32 flags = 0,
    Uint32 parallel = 0,
    Uint32 batch = 0
}

Parameters
This method takes the four parameters listed here:

- The lock mode; this is a LockMode value.

  **Scans with exclusive locks.** When scanning with an exclusive lock, extra care must be taken due to the fact that, if two threads perform this scan simultaneously over the same range, then there is a significant probability of causing a deadlock. The likelihood of a deadlock is increased if the scan is also ordered (that is, using SF_OrderBy or SF_Descending).

  The NdbScanOperation::close() method is also affected by this deadlock, since all outstanding requests are serviced before the scan is actually closed.

- One or more ScanFlag values. Multiple values are OR'ed together

- The number of fragments to scan in parallel; use 0 to require that the maximum possible number be used.

- The batch parameter specifies how many records will be returned to the client from the server by the next NdbScanOperation::nextResult(true) method call. Use 0 to specify the maximum automatically.

Return value
Returns 0 on success, -1 on failure.

NdbScanOperation::restart()
Description
Use this method to restart a scan without changing any of its getValue() calls or search conditions.

Signature
int restart
{
    bool forceSend = false
}

Parameters
Call this method with forceSend set to true in order to force the transaction to be sent.

Return value
0 on success; -1 on failure.

NdbScanOperation::ScanFlag
This section provides information about the ScanFlag data type.

Description
Values of this type are the scan flags used with the readTuples() method. More than one may be used, in which case, they are
The NdbScanOperation Class

OR’ed together as the second argument to that method. See
NdbScanOperation::readTuples(), for more information.

Enumeration values

Possible values are shown, along with descriptions, in the following table:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SF_TupScan</td>
<td>Scan in TUP order (that is, in the order of the rows in memory). Applies to table scans only.</td>
</tr>
<tr>
<td>SF_DiskScan</td>
<td>Scan in disk order (order of rows on disk). Applies to table scans only.</td>
</tr>
<tr>
<td>SF_OrderBy</td>
<td>Ordered index scan (ascending); rows returned from an index scan are sorted, and ordered on the index key. Scans in either ascending or descending order are affected by this flag, which causes the API to perform a merge-sort among the ordered scans of each fragment to obtain a single sorted result set.</td>
</tr>
</tbody>
</table>

Notes:

- Ordered indexes are distributed, with one ordered index for each fragment of a table.
- Range scans are often parallel across all index fragments. Occasionally, they can be pruned to one index fragment.
- Each index fragment range scan can return results in either ascending or descending order. Ascending is the default; to choose descending order, set the SF_Descending flag.
- When multiple index fragments are scanned in parallel, the results are sent back to NDB where they can optionally be merge-sorted before being returned to the user. This merge sorting is controlled using the SF_OrderBy and SF_OrderByFull flags.
- If SF_OrderBy or SF_OrderByFull is not used, the results from each index fragment are in order (either ascending or descending), but results from different fragments may be interleaved.
- When using SF_OrderBy or SF_OrderByFull, some extra
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>constraints are imposed internally; these are listed here:</td>
</tr>
<tr>
<td></td>
<td>1. If the range scan is not pruned to one index fragment then all index fragments must be scanned in parallel. (Unordered scans can be executed with less than full parallelism.)</td>
</tr>
<tr>
<td></td>
<td>2. Results from every index fragment must be available before returning any rows, to ensure a correct merge sort. This serialises the “scrolling” of the scan, potentially resulting in lower row throughput.</td>
</tr>
<tr>
<td></td>
<td>3. Unordered scans can return rows to the API client before all index fragments have returned any batches, and can overlap next-batch requests with row processing.</td>
</tr>
<tr>
<td>SF_OrderByFull</td>
<td>This is the same as SF_OrderBy, except that all key columns are added automatically to the read bitmask.</td>
</tr>
<tr>
<td>SF_Descending</td>
<td>Causes an ordered index scan to be performed in descending order.</td>
</tr>
<tr>
<td>SF_ReadRangeNo</td>
<td>For index scans, when this flag is set, ( \text{NdbIndexScanOperation::get_range_no()} ) can be called to read back the range_no defined in ( \text{NdbIndexScanOperation::setBound()} ). In addition, when this flag is set, and SF_OrderBy or SF_OrderByFull is also set, results from ranges are returned in their entirety before any results are returned from subsequent ranges.</td>
</tr>
<tr>
<td>SF_MultiRange</td>
<td>Indicates that this scan is part of a multirange scan; each range is scanned separately.</td>
</tr>
<tr>
<td>SF_KeyInfo</td>
<td>Requests KeyInfo to be sent back to the caller. This enables the option to take over the row lock taken by the scan, using lockCurrentTuple(), by making sure that the kernel sends back the information needed to identify the row and the lock. This flag is enabled by default for scans using LM_Exclusive, but must be explicitly specified to enable the taking over of LM_Read locks. (See the LockMode documentation for more information.)</td>
</tr>
</tbody>
</table>

### NdbScanOperation::ScanOptions

This section provides information about the ScanOptions data structure.
The NdbScanOperation Class

Parent class: NdbScanOperation

Description: This data structure is used to pass options to the NdbRecord-based scanTable() and scanIndex() methods of the NdbTransaction class. Each option type is marked as present by setting the corresponding bit in the optionsPresent field. Only the option types marked in the optionsPresent field need have sensible data.

All data is copied out of the ScanOptions structure (and any subtended structures) at operation definition time. If no options are required, then NULL may be passed as the ScanOptions pointer.

Members: The elements making up this structure are shown in the following table:

Table 2.65 NdbScanOperation::ScanOptions attributes, with types and descriptions

For more information, see Section 2.3.22, “The NdbRecord Interface”.

**NdbScanOperation::updateCurrentTuple()**

**Description**
This method is used to update the current tuple.

**Signature**
Originally, this method could be called with a single, optional parameter, in either of the ways shown here:

```c
NdbOperation* updateCurrentTuple
{
    void
}
```

```c
NdbOperation* updateCurrentTuple
{
    NdbTransaction* updateTrans
}
```

It is also possible to employ this method, when using NdbRecord with scans, as shown here:

```c
NdbOperation* updateCurrentTuple
{
    NdbTransaction* takeoverTrans,
```
The NdbTransaction Class

const NdbRecord* record,
const char* row,
const unsigned char* mask = 0)

See Section 2.3.22, "The NdbRecord Interface", for more information.

Parameters (original) This method takes a single, optional parameter—the transaction that should perform the lock. If this is omitted, the transaction is the current one.

Parameters (using NdbRecord) When using the NdbRecord interface, this method takes the following parameters, as described in the following list:

- The takeover transaction (takeOverTrans).
- The record (NdbRecord object) referencing the column used for the scan.
- The row to read from. If no attributes are to be read, set this equal to NULL.
- The mask pointer is optional. If it is present, then only columns for which the corresponding bit in the mask is set are retrieved by the scan.

Return value This method returns an NdbOperation object or NULL.

2.3.25 The NdbTransaction Class

This section provides information about the NdbTransaction class.

- NdbTransaction Class Overview
- NdbTransaction::close()
- NdbTransaction::commitStatus()
- NdbTransaction::CommitStatusType
- NdbTransaction::deleteTuple()
- NdbTransaction::ExecType
- NdbTransaction::execute()
- NdbTransaction::executePendingBlobOps()
- NdbTransaction::getGCI()
- NdbTransaction::getMaxPendingBlobReadBytes()
- NdbTransaction::getMaxPendingBlobWriteBytes()
- NdbTransaction::getNdbError()
- NdbTransaction::getNdbErrorLine()
- NdbTransaction::getNdbErrorOperation()
- NdbTransaction::getNdbIndexOperation()
- NdbTransaction::getNdbIndexScanOperation()
The NdbTransaction Class

- NdbTransaction::getNdbOperation()
- NdbTransaction::getNdbScanOperation()
- NdbTransaction::getNextCompletedOperation()
- NdbTransaction::getTransactionId()
- NdbTransaction::insertTuple()
- NdbTransaction::readTuple()
- NdbTransaction::refresh()
- NdbTransaction::releaseLockHandle()
- NdbTransaction::scanIndex()
- NdbTransaction::scanTable()
- NdbTransaction::setMaxPendingBlobReadBytes()
- NdbTransaction::setMaxPendingBlobWriteBytes()
- NdbTransaction::setSchemaObjectOwnerChecks()
- NdbTransaction::unlock()
- NdbTransaction::updateTuple()
- NdbTransaction::writeTuple()

NdbTransaction Class Overview

Parent class: None
Child classes: None

Description:
A transaction is represented in the NDB API by an NdbTransaction object, which belongs to an Ndb object and is created using Ndb::startTransaction(). A transaction consists of a list of operations represented by the NdbOperation class, or by one of its subclasses—NdbScanOperation, NdbIndexOperation, or NdbIndexScanOperation. Each operation access exactly one table.

Methods:
The following table lists the public methods of this class and the purpose or use of each method:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>close()</td>
<td>Closes a transaction</td>
</tr>
<tr>
<td>commitStatus()</td>
<td>Gets the transaction's commit status</td>
</tr>
<tr>
<td>deleteTuple()</td>
<td>Delete a tuple using NdbRecord</td>
</tr>
<tr>
<td>execute()</td>
<td>Executes a transaction</td>
</tr>
<tr>
<td>executePendingBlobOps()</td>
<td>Executes a transaction in NoCommit mode if it includes any blob part operations of the specified types that are not yet executed.</td>
</tr>
<tr>
<td>getGCI()</td>
<td>Gets a transaction's global checkpoint ID (GCI)</td>
</tr>
</tbody>
</table>
The NdbTransaction Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getMaxPendingBlobReadBytes()</td>
<td>Get the current blob read batch size</td>
</tr>
<tr>
<td>getMaxPendingBlobWriteBytes()</td>
<td>Get the current blob write batch size</td>
</tr>
<tr>
<td>getNdbError()</td>
<td>Gets the most recent error</td>
</tr>
<tr>
<td>getNdbErrorLine()</td>
<td>Gets the line number where the most recent error occurred</td>
</tr>
<tr>
<td>getNdbErrorOperation()</td>
<td>Gets the most recent operation which caused an error</td>
</tr>
<tr>
<td>getNextCompletedOperation()</td>
<td>Gets operations that have been executed; used for finding errors</td>
</tr>
<tr>
<td>getNdbOperation()</td>
<td>Gets an NdbOperation</td>
</tr>
<tr>
<td>getNdbScanOperation()</td>
<td>Gets an NdbScanOperation</td>
</tr>
<tr>
<td>getNdbIndexOperation()</td>
<td>Gets an NdbIndexOperation</td>
</tr>
<tr>
<td>getNdbIndexScanOperation()</td>
<td>Gets an NdbIndexScanOperation</td>
</tr>
<tr>
<td>getTransactionId()</td>
<td>Gets the transaction ID</td>
</tr>
<tr>
<td>insertTuple()</td>
<td>Insert a tuple using NdbRecord</td>
</tr>
<tr>
<td>readTuple()</td>
<td>Read a tuple using NdbRecord</td>
</tr>
<tr>
<td>refresh()</td>
<td>Keeps a transaction from timing out</td>
</tr>
<tr>
<td>releaseLockHandle()</td>
<td>Release an NdbLockHandle object once it is no longer needed</td>
</tr>
<tr>
<td>scanIndex()</td>
<td>Perform an index scan using NdbRecord</td>
</tr>
<tr>
<td>scanTable()</td>
<td>Perform a table scan using NdbRecord</td>
</tr>
<tr>
<td>setMaxPendingBlobReadBytes()</td>
<td>Set the blob read batch size</td>
</tr>
<tr>
<td>setMaxPendingBlobWriteBytes()</td>
<td>Set the blob write batch size</td>
</tr>
<tr>
<td>setSchemaObjectOwnerChecks()</td>
<td>Enable or disable schema object ownership checks</td>
</tr>
<tr>
<td>unlock()</td>
<td>Create an unlock operation on the current transaction</td>
</tr>
<tr>
<td>updateTuple()</td>
<td>Update a tuple using NdbRecord</td>
</tr>
<tr>
<td>writeTuple()</td>
<td>Write a tuple using NdbRecord</td>
</tr>
</tbody>
</table>

The methods `readTuple()`, `insertTuple()`, `updateTuple()`, `writeTuple()`, `deleteTuple()`, `scanTable()`, and `scanIndex()` require the use of `NdbRecord`.

Types

NdbTransaction defines 2 public types as shown in the following table:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CommitStatusType()</td>
<td>Describes the transaction’s commit status</td>
</tr>
<tr>
<td>ExecType()</td>
<td>Determines whether the transaction should be committed or rolled back</td>
</tr>
</tbody>
</table>

Using Transactions. After obtaining an NdbTransaction object, it is employed as follows:

1. An operation is allocated to the transaction using any one of the following methods:
   - `getNdbOperation()`
• `getNdbScanOperation()`
• `getNdbIndexOperation()`
• `getNdbIndexScanOperation()`

Calling one of these methods defines the operation. Several operations can be defined on the same `NdbTransaction` object, in which case they are executed in parallel. When all operations are defined, the `execute()` method sends them to the NDB kernel for execution.

2. The `execute()` method returns when the NDB kernel has completed execution of all operations previously defined.

   All allocated operations should be properly defined before calling the `execute()` method.

3. `execute()` operates in one of the three modes listed here:
   - `NdbTransaction::NoCommit`: Executes operations without committing them.
   - `NdbTransaction::Commit`: Executes any remaining operation and then commits the complete transaction.
   - `NdbTransaction::Rollback`: Rolls back the entire transaction.

   `execute()` is also equipped with an extra error handling parameter, which provides the two alternatives listed here:
   - `NdbOperation::AbortOnError`: Any error causes the transaction to be aborted. This is the default behavior.
   - `NdbOperation::AO_IgnoreError`: The transaction continues to be executed even if one or more of the operations defined for that transaction fails.

### `NdbTransaction::close()`

**Description**
This method closes a transaction. It is equivalent to calling `Ndb::closeTransaction()`.

If the transaction has not yet been committed, it is aborted when this method is called. See `Ndb::startTransaction()`.

**Signature**
```cpp
void close
{
    void
}
```

**Parameters**
`None.`

**Return value**
`None.`

### `NdbTransaction::commitStatus()`

**Description**
This method gets the transaction's commit status.

**Signature**
```cpp
CommitStatusType commitStatus
{
    void
}
```

**Parameters**
`None.`

**Return value**
The commit status of the transaction, a value of type `CommitStatusType`. 
NdbTransaction::CommitStatusType

This section provides information about the 
CommitStatusType data type.

Description
This type is used to describe a transaction’s commit status.

Enumeration values
Possible values are shown, along with descriptions, in the following table:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NotStarted</td>
<td>The transaction has not yet been started.</td>
</tr>
<tr>
<td>Started</td>
<td>The transaction has started, but is not yet committed.</td>
</tr>
<tr>
<td>Committed</td>
<td>The transaction has completed, and has been committed.</td>
</tr>
<tr>
<td>Aborted</td>
<td>The transaction was aborted.</td>
</tr>
<tr>
<td>NeedAbort</td>
<td>The transaction has encountered an error, but has not yet been aborted.</td>
</tr>
</tbody>
</table>

A transaction’s commit status can be read using commitStatus().

NdbTransaction::deleteTuple()

Deletes a tuple using NdbRecord.

Description
This method takes the following parameters:

- key_rec is a pointer to an NdbRecord for either a table or an index. If on a table, then the delete operation uses a primary key; if on an index, then the operation uses a unique key. In either case, the key_rec must include all columns of the key.

- The key_row passed to this method defines the primary or unique key of the tuple to be deleted, and must remain valid until execute() is called.

- The result_rec is the NdbRecord to be used.

- The result_row can be NULL if no attributes are to be returned.

- The result_mask, if not NULL, defines a subset of attributes to be read and returned to the client. The mask is copied, and so does not need to remain valid after the call to this method returns.

- OperationOptions (opts) can be used to provide more finely-grained control of operation definitions.
structure is passed with flags indicating which operation definition options are present. Not all operation types support all operation options; for the options supported by each type of operation, see `NdbTransaction::readTuple`.

- The optional `sizeOfOptions` parameter provides backward compatibility of this interface with previous definitions of the `OperationOptions` structure. If an unusual size is detected by the interface implementation, it can use this to determine how to interpret the passed `OperationOptions` structure. To enable this functionality, the caller should pass `sizeof(NdbOperation::OperationOptions)` for the value of this argument.

**Return value**
A `const` pointer to the `NdbOperation` representing this write operation. The operation can be checked for errors if necessary.

### NdbTransaction::ExecType

This section provides information about the `ExecType` data type.

**Description**
This type sets the transaction's execution type; that is, whether it should execute, execute and commit, or abort. It is used as a parameter to the `execute()` method. (See `NdbTransaction::execute()`.)

**Enumeration values**
Possible values are shown, along with descriptions, in the following table:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NoCommit</td>
<td>The transaction should execute, but not commit.</td>
</tr>
<tr>
<td>Commit</td>
<td>The transaction should execute and be committed.</td>
</tr>
<tr>
<td>Rollback</td>
<td>The transaction should be rolled back.</td>
</tr>
</tbody>
</table>

### NdbTransaction::execute()

**Description**
This method is used to execute a transaction.

**Signature**
```
int execute
(int executeType,
 NdbOperation::AbortOption abortOption = NdbOperation::DefaultAbortOption,
 int force = 0)
```

**Parameters**
The `execute()` method takes the three parameters listed here:

- The execution type (`ExecType` value); see `NdbTransaction::ExecType`, for more information and possible values.
- An abort option (`NdbOperation::AbortOption` value).

Errors arising from this method are found with `NdbOperation::getNdbError()` rather than `NdbTransaction::getNdbError()`.
The NdbTransaction Class

- A `force` parameter, which determines when operations should be sent to the NDB Kernel. It takes ones of the values listed here:
  - 0: Nonforced; detected by the adaptive send algorithm.
  - 1: Forced; detected by the adaptive send algorithm.
  - 2: Nonforced; not detected by the adaptive send algorithm.

See Section 1.4.4, “The Adaptive Send Algorithm”, for more information.

Return value

Returns 0 on success, or -1 on failure. The fact that the transaction did not abort does not necessarily mean that each operation was successful; you must check each operation individually for errors.

This method reports a failure if and only if the transaction was aborted. The transaction’s error information is set in such cases to reflect the actual error code and category.

In the case where a NoDataFound error is a possibility, you must check for it explicitly, as shown in this example:

```cpp
Ndb_cluster_connection myConnection;
if( myConnection.connect(4, 5, 1) )
{
    cout << "Unable to connect to cluster within 30 secs." << endl;
    exit(-1);
}
Ndb myNdb(&myConnection, "test");
// define operations...
myTransaction = myNdb->startTransaction();
if(myTransaction->getNdbError().classification == NdbError::NoDataFound)
{
    cout << "No records found." << endl;
    // ...
}
myNdb->closeTransaction(myTransaction);
```

You should be aware that a successful `execute()` call guarantees only that the scan request has been assembled and sent to the transaction coordinator without any errors; it does not wait for any signals to be sent in reply from the data nodes before returning.

NdbTransaction::executePendingBlobOps()

This method executes the transaction with `ExecType` equal to `NoCommit` if there remain any blob part operations of the given types which have not yet been executed.

**Signature**

```cpp
int executePendingBlobOps
{
    Uint8 flags = 0xFF
}
```

**Parameters**

The `flags` argument is the result of a bitwise OR, equal to `1 << optype`, where `optype` is an `NdbOperation::Type`. The default corresponds to `NdbOperation::Type::PrimaryKeyAccess`. 
Return value

Returns 0 on success, or -1 on failure. The fact that the transaction did not abort does not necessarily mean that each operation was successful; you must check each operation individually for errors.

**NdbTransaction::getGCI()**

**Description**

This method retrieves the transaction's global checkpoint ID (GCI).

Each committed transaction belongs to a GCI. The log for the committed transaction is saved on disk when a global checkpoint occurs.

By comparing the GCI of a transaction with the value of the latest GCI restored in a restarted NDB Cluster, you can determine whether or not the transaction was restored.

Whether or not the global checkpoint with this GCI has been saved on disk cannot be determined by this method.

The GCI for a scan transaction is undefined, since no updates are performed in scan transactions.

No GCI is available until `execute()` has been called with `ExecType::Commit`.

**Signature**

```cpp
int getGCI()
{
    void
}
```

**Parameters**

None.

**Return value**

The transaction's GCI, or -1 if none is available.

**NdbTransaction::getMaxPendingBlobReadBytes()**

**Description**

Gets the current batch size in bytes for blob read operations. When the volume of blob data to be read within a given transaction exceeds this amount, all of the transaction's pending blob read operations are executed.

**Signature**

```cpp
Uint32 getMaxPendingBlobReadBytes()
{
    void
    const
```

**Parameters**

None.

**Return value**

The current blob read batch size, in bytes. See `NdbTransaction::setMaxPendingBlobReadBytes()`, for more information.

**NdbTransaction::getMaxPendingBlobWriteBytes()**

**Description**

Gets the current batch size in bytes for blob write operations. When the volume of blob data to be written within a given transaction exceeds this amount, all of the transaction's pending blob write operations are executed.

**Signature**

```cpp
Uint32 getMaxPendingBlobWriteBytes()
{
    void
    const
```
The NdbTransaction Class

Parameters
None.

Return value
The current blob write batch size, in bytes. See NdbTransaction::setMaxPendingBlobWriteBytes(), for more information.

NdbTransaction::getNdbError()

Description
This method is used to obtain the most recent error (NdbError).

Signature

\[
\text{const NdbError& getNdbError} \\
\text{(void) const}
\]

Parameters
None.

Return value
A reference to an NdbError object.

For additional information about handling errors in transactions, see Error Handling.

NdbTransaction::getNdbErrorLine()

Description
This method return the line number where the most recent error occurred.

Signature

\[
\text{int getNdbErrorLine} \\
\text{(void)}
\]

Parameters
None.

Return value
The line number of the most recent error.

For additional information about handling errors in transactions, see Error Handling.

NdbTransaction::getNdbErrorOperation()

Description
This method retrieves the operation that caused an error.

To obtain more information about the actual error, use the NdbOperation::getNdbError() method of the NdbOperation object returned by getNdbErrorOperation().

Signature

\[
\text{NdbOperation* getNdbErrorOperation} \\
\text{(void)}
\]

Parameters
None.

Return value
A pointer to an NdbOperation.

For additional information about handling errors in transactions, see Error Handling.

NdbTransaction::getNdbIndexOperation()

Description
This method is used to create an NdbIndexOperation associated with a given table.

All index operations within the same transaction must be initialised with this method. Operations must be defined before they are executed.
### The NdbTransaction Class

#### NdbTransaction::getNdbIndexOperation()

**Description**
This method is used to create an `NdbIndexOperation` associated with a given table.

All index scan operations within the same transaction must be initialised with this method. Operations must be defined before they are executed.

**Signature**
```
NdbIndexOperation* getNdbIndexOperation
{
    const NdbDictionary::Index* index
}
```

**Parameters**
The `Index` object on which the operation is to be performed.

**Return value**
A pointer to the new `NdbIndexOperation`.

#### NdbTransaction::getNdbIndexScanOperation()

**Description**
This method is used to create an `NdbIndexScanOperation` associated with a given table.

All index scan operations within the same transaction must be initialised with this method. Operations must be defined before they are executed.

**Signature**
```
NdbIndexScanOperation* getNdbIndexScanOperation
{
    const NdbDictionary::Index* index
}
```

**Parameters**
The `Index` object on which the operation is to be performed.

**Return value**
A pointer to the new `NdbIndexScanOperation`.

#### NdbTransaction::getNdbOperation()

**Description**
This method is used to create an `NdbOperation` associated with a given table.

All operations within the same transaction must be initialized with this method. Operations must be defined before they are executed.

**Signature**
```
NdbOperation* getNdbOperation
{
    const NdbDictionary::Table* table
}
```

**Parameters**
The `Table` object on which the operation is to be performed.

**Return value**
A pointer to the new `NdbOperation`.

#### NdbTransaction::getNdbScanOperation()

**Description**
This method is used to create an `NdbScanOperation` associated with a given table.

All scan operations within the same transaction must be initialized with this method. Operations must be defined before they are executed.

**Signature**
```
NdbScanOperation* getNdbScanOperation
{
    const NdbDictionary::Table* table
}
```

**Parameters**
The `Table` object on which the operation is to be performed.

**Return value**
A pointer to the new `NdbScanOperation`.

#### NdbTransaction::getNextCompletedOperation()

...
The NdbTransaction Class

Description
This method is used to retrieve a transaction’s completed operations. It is typically used to fetch all operations belonging to a given transaction to check for errors.

\[
\text{NdbTransaction::getNextCompletedOperation(NULL)} \quad \text{returns the transaction’s first NdbOperation object;}
\]
\[
\text{NdbTransaction::getNextCompletedOperation(myOp)} \quad \text{returns the NdbOperation object defined after NdbOperation myOp.}
\]

This method should only be used after the transaction has been executed, but before the transaction has been closed.

Signature
\[
\text{const NdbOperation* getNextCompletedOperation(}\quad \text{const NdbOperation* op) \quad \text{const}}
\]

Parameters
This method requires a single parameter \( op \), which is an operation (\( \text{NdbOperation} \) object), or NULL.

Return value
The operation following \( op \), or the first operation defined for the transaction if \( \text{getNextCompletedOperation()} \) was called using NULL.

\[\text{NdbTransaction::getTransactionId()}\]

Description
This method is used to obtain the transaction ID.

Signature
\[
\text{Uint64 getTransactionId(\quad void)}
\]

Parameters
None.

Return value
The transaction ID, as an unsigned 64-bit integer.

\[\text{NdbTransaction::insertTuple()}\]

Description
Inserts a tuple using \( \text{NdbRecord} \).

Signatures
\[
\text{const NdbOperation* insertTuple(}\quad \text{const NdbRecord* key_rec,}
\]
\[
\text{const char* key_row,}
\]
\[
\text{const NdbRecord* attr_rec,}
\]
\[
\text{const char* attr_row,}
\]
\[
\text{const unsigned char* mask = 0,}
\]
\[
\text{const NdbOperation::OperationOptions* opts = 0,}
\]
\[
\text{Uint32 sizeOfOptions = 0)}
\]
\[
\text{const NdbOperation* insertTuple(}\quad \text{const NdbRecord* combined_rec,}
\]
\[
\text{const char* combined_row,}
\]
\[
\text{const unsigned char* mask = 0,}
\]
\[
\text{const NdbOperation::OperationOptions* opts = 0,}
\]
\[
\text{Uint32 sizeOfOptions = 0)}
\]

Parameters
\( \text{insertTuple()} \) takes the following parameters:

- A pointer to an \( \text{NdbRecord} \) indicating the record (\( \text{key_rec} \)) to be inserted.
This method can also be called using a single `NdbRecord` pointer and single `char` pointer (`combined_rec, combined_row`) where the single `NdbRecord` represents record and attribute and data.

- A row (`key_row`) of data to be inserted.
- A pointer to an `NdbRecord` indicating an attribute (`attr_rec`) to be inserted.
- A row (`attr_row`) of data to be inserted as the attribute.
- A `mask` which can be used to filter the columns to be inserted.
- `OperationOptions (opts)` can be used to provide more finely-grained control of operation definitions. An `OperationOptions` structure is passed with flags indicating which operation definition options are present. Not all operation types support all operation options; for the options supported by each type of operation, see `NdbTransaction::readTuple()`.
- The optional `sizeOfOptions` parameter is used to preserve backward compatibility of this interface with previous definitions of the `OperationOptions` structure. If an unusual size is detected by the interface implementation, it can use this to determine how to interpret the passed `OperationOptions` structure. To enable this functionality, the caller should pass `sizeof(NdbOperation::OperationOptions)` for the value of this argument.

Return value

A `const` pointer to the `NdbOperation` representing this insert operation.

### NdbTransaction::readTuple()

**Description**

This method reads a tuple using `NdbRecord` objects.

**Signature**

```c
const NdbOperation* readTuple(
    const NdbRecord* key_rec,
    const char* key_row,
    const NdbRecord* result_rec,
    char* result_row,
    NdbOperation::LockMode lock_mode = NdbOperation::LM_Read,
    const unsigned char* result_mask = 0,
    const NdbOperation::OperationOptions* opts = 0,
    Uint32 sizeOfOptions = 0
)
```

**Parameters**

This method takes the following parameters:

- `key_rec` is a pointer to an `NdbRecord` for either a table or an index. If on a table, then the operation uses a primary key; if on an index, then the operation uses a unique key. In either case, the `key_rec` must include all columns of the key.

- The `key_row` passed to this method defines the primary or unique key of the affected tuple, and must remain valid until `execute()` is called.

  The mask, if not `NULL`, defines a subset of attributes to read, update, or insert. Only if

  ```c
  (mask[attrId >> 3] &
  ```
The `NdbTransaction` Class

(1<<(attrId & 7))) is set is the column affected. The mask is copied by the methods, so need not remain valid after the call returns.

- `result_rec` is a pointer to an `NdbRecord` used to hold the result
- `result_row` defines a buffer for the result data.
- `lock_mode` specifies the lock mode in effect for the operation. See `NdbOperation::LockMode`, for permitted values and other information.
- `result_mask` defines a subset of attributes to read. Only if
  mask[attrId >> 3] & (1<<(attrId & 7)) is set is the column affected. The mask is copied, and so need not remain valid after the method call returns.
- `OperationOptions (opts)` can be used to provide more finely-grained control of operation definitions. An `OperationOptions` structure is passed with flags indicating which operation definition options are present. Not all operation types support all operation options; the options supported for each type of operation are shown in the following table:

<table>
<thead>
<tr>
<th>Operation type (Method)</th>
<th>OperationOptions Flags Supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>readTuple()</td>
<td>OO_ABORTOPTION, OO_GETVALUE,</td>
</tr>
<tr>
<td></td>
<td>OO_PARTITION_ID, OO_INTERPRETED</td>
</tr>
<tr>
<td>insertTuple()</td>
<td>OO_ABORTOPTION, OO_SETVALUE,</td>
</tr>
<tr>
<td></td>
<td>OO_PARTITION_ID, OO_ANYVALUE</td>
</tr>
<tr>
<td>updateTuple()</td>
<td>OO_ABORTOPTION, OO_SETVALUE,</td>
</tr>
<tr>
<td></td>
<td>OO_PARTITION_ID, OO_INTERPRETED,</td>
</tr>
<tr>
<td></td>
<td>OO_ANYVALUE</td>
</tr>
<tr>
<td>writeTuple()</td>
<td>OO_ABORTOPTION, OO_SETVALUE,</td>
</tr>
<tr>
<td></td>
<td>OO_PARTITION_ID, OO_ANYVALUE</td>
</tr>
<tr>
<td>deleteTuple()</td>
<td>OO_ABORTOPTION, OO_GETVALUE,</td>
</tr>
<tr>
<td></td>
<td>OO_PARTITION_ID, OO_INTERPRETED,</td>
</tr>
<tr>
<td></td>
<td>OO_ANYVALUE</td>
</tr>
</tbody>
</table>

- The optional `sizeOfOptions` parameter is used to preserve backward compatibility of this interface with previous definitions of the `OperationOptions` structure. If an unusual size is detected by the interface implementation, it can use this to determine how to interpret the passed `OperationOptions` structure. To enable this functionality, the caller should pass `sizeof(NdbOperation::OperationOptions)` for the value of this argument.

Return value

A pointer to the `NdbOperation` representing this read operation (this can be used to check for errors).

`NdbTransaction::refresh()`
### The NdbTransaction Class

#### Description

This method updates the transaction's timeout counter, and thus avoids aborting due to transaction timeout.

It is not advisable to take a lock on a record and maintain it for an extended time since this can impact other transactions.

#### Signature

```c
int refresh
{
    void
}
```

#### Parameters

None.

#### Return value

Returns 0 on success, -1 on failure.

### NdbTransaction::releaseLockHandle()

#### Description

This method is used to release a lock handle (see `NdbOperation::getLockHandle`) when it is no longer required. For NdbRecord primary key read operations, this cannot be called until the associated read operation has been executed.

All lock handles associated with a given transaction are released when that transaction is closed.

#### Signature

```c
int releaseLockHandle
{
    const NdbLockHandle* lockHandle
}
```

#### Parameters

The NdbLockHandle object to be released.

#### Return value

0 on success.

### NdbTransaction::scanIndex()

#### Description

Perform an index range scan of a table, with optional ordering.

#### Signature

```c
NdbIndexScanOperation* scanIndex
{
    const NdbRecord* key_record,
    const NdbRecord* result_record,
    NdbOperation::LockMode lock_mode = NdbOperation::LM_Read,
    const unsigned char* result_mask = 0,
    const NdbIndexScanOperation::IndexBound* bound = 0,
    const NdbScanOperation::ScanOptions* options = 0,
    Uint32 sizeOfOptions = 0
}
```

#### Parameters

- The key_record describes the index to be scanned. It must be a key record for the index; that is, it must specify, at a minimum, all of the key columns of the index. The key_record must be created from the index to be scanned (and not from the underlying table).

- The result_record describes the rows to be returned from the scan. For an ordered index scan, result_record must be a key record for the index to be scanned; that is, it must include (at a minimum) all of the columns in the index (the full index key is needed by the NDB API for merge-sorting the ordered rows returned from each fragment).

  Like the key_record, the result_record must be created from the underlying table, and not from the index to be scanned.
Both the `key_record` and `result_record` `NdbRecord` structures must stay in place until the scan operation is closed.

- The `result_mask` pointer is optional. If it is present, only those columns for which the corresponding bits (by attribute ID order) in `result_mask` are set are actually retrieved in the scan. The `result_mask` is copied internally, so in contrast to `result_record` it need not be valid when `execute()` is invoked.

- A single `IndexBound` can be specified either in this call or in a separate call to `NdbIndexScanOperation::setBound()`. To perform a multi-range read, the `scan_flags` in the `ScanOptions` structure must include `SF_MULTIRANGE`. Additional bounds can be added using successive calls to `NdbIndexScanOperation::setBound()`.

To specify an equals bound, use the same row pointer for the `low_key` and `high_key` with the low and high inclusive bits set. For multi-range scans, the `low_key` and `high_key` pointers must be unique. In other words, it is not permissible to reuse the same row buffer for several different range bounds within a single scan. However, it is permissible to use the same row pointer as `low_key` and `high_key` in order to specify an equals bound; it is also permissible to reuse the rows after the `scanIndex()` method returns—that is, they need not remain valid until `execute()` time (unlike the `NdbRecord` pointers).

- To specify additional options, pass a `ScanOptions` structure.

- The `sizeOfOptions` exists to enable backward compatability for this interface. This parameter indicates the size of the `ScanOptions` structure at the time the client was compiled, and enables detection of the use of an old-style `ScanOptions` structure. If this functionality is not required, this argument can be left set to 0.

**Return value**
The current `NdbIndexScanOperation`, which can be used for error checking.

### `NdbTransaction::scanTable()`

**Description**
This method performs a table scan, using an `NdbRecord` object to read out column data.

**Signature**
```cpp
define scanTable
{
    const NdbRecord* result_record,
    NdbOperation::LockMode lock_mode = NdbOperation::LM_Read,
    const unsigned char* result_mask = 0,
    Uint32 scan_flags = 0,
    Uint32 parallel = 0,
    Uint32 batch = 0
}
```

**Parameters**
The `scanTable()` method takes the following parameters:

- A pointer to an `NdbRecord` for storing the result. This `result_record` must remain valid until after the `execute()` call has been made.
The `lock_mode` in effect for the operation. See `NdbOperation::LockMode`, for permitted values and other information.

- The `result_mask` pointer is optional. If it is present, only those columns for which the corresponding bits (by attribute ID order) in `result_mask` are set are actually retrieved in the scan. The `result_mask` is copied internally, so in contrast to `result_record` it need not be valid when `execute()` is invoked.

- `scan_flags` can be used to impose ordering and sorting conditions for scans. See `NdbScanOperation::ScanFlag`, for a list of permitted values.

- The `parallel` argument is the desired parallelism, or 0 for maximum parallelism (receiving rows from all fragments in parallel), which is the default.

- `batch` determines whether batching is employed. The default is 0 (off).

Return value A pointer to the `NdbScanOperation` representing this scan. The operation can be checked for errors if necessary.

### `NdbTransaction::setMaxPendingBlobReadBytes()`

**Description**
Sets the batch size in bytes for blob read operations. When the volume of blob data to be read within a given transaction exceeds this amount, all of the transaction's pending blob read operations are executed.

**Signature**
```c
void setMaxPendingBlobReadBytes(
    Uint32 bytes
)
```

**Parameters**
The batch size, as the number of `bytes`. Using 0 causes blob read batching to be disabled, which is the default behavior (for backward compatibility).

**Return value**
`None`.

**Note**
blob read batching can also be controlled in the `mysql` client and other MySQL client application using the MySQL Server's `--ndb-blob-read-batch-bytes` option and its associated MySQL Server system variables.

### `NdbTransaction::setMaxPendingBlobWriteBytes()`

**Description**
Sets the batch size in bytes for blob write operations. When the volume of blob data to be written within a given transaction exceeds this amount, all of the transaction's pending blob write operations are executed.

**Signature**
```c
void setMaxPendingBlobWriteBytes(
    Uint32 bytes
)
```
The NdbTransaction Class

Parameters

The batch size, as the number of bytes. Using 0 causes blob write batching to be disabled, which is the default behavior (for backward compatibility).

Return value

None.

Note

Blob write batching can also be controlled in the mysql client and other MySQL client applications in NDB 8.0.30 and later by setting the MySQL Server's `ndb_replica_blob_write_batch_bytes` server system variable to an appropriate value. You should be aware that, when `ndb_replica_blob_write_batch_bytes` is not set, the effective blob batch size (that is, the maximum number of pending bytes to write for blob columns) is determined by the maximum of the default value of `ndb_replica_blob_write_batch_bytes` and the value set for the `--ndb-blob-write-batch-bytes` MySQL server option. For this reason, you should use `ndb_replica_blob_write_batch_bytes` rather than `--ndb-blob-write-batch-bytes`.

Prior to NDB 8.0.30, you must use the `--ndb-blob-write-batch-bytes` option, or one of its associated MySQL Server system variables, to set the blob batch size from `mysql` or another MySQL client program.

NdbTransaction::setSchemaObjectOwnerChecks()

Description

Enables or disables a schema object ownership check when multiple `Ndb_cluster_connection` objects are in use. When this check is enabled, objects used by this transaction are checked to make sure that they belong to the `NdbDictionary` owned by this connection. This is done by acquiring the schema objects of the same names from the connection and comparing these with the schema objects passed to the transaction. If they do not match, an error is returned.

This method is available for debugging purposes. (Bug #19875977)

You should be aware that enabling this check carries a performance penalty and for this reason you should avoid doing so in a production setting.

Signature

```cpp
void setSchemaObjOwnerChecks(
    bool runChecks
)
```

Parameters

A single parameter `runChecks`. Use `true` to enable ownership checks, `false` to disable them.

Return value

None.

NdbTransaction::unlock()

Description

This method creates an unlock operation on the current transaction; when executed, the unlock operation removes the lock referenced by the `NdbLockHandle` (see `NdbOperation::getLockHandle`) passed to the method.

Signature

```cpp
const NdbOperation* unlock
{
    const NdbLockHandle* lockHandle,
    NdbOperation::AbortOption ao = NdbOperation::DefaultAbortOption
}
The NdbTransaction Class

Parameters
A pointer to a lock handle; in addition, optionally, an AbortOption value ao.

In the event that the unlock operation fails—for example, due to the row already being unlocked—the AbortOption specifies how this is handled, the default being that errors cause transactions to abort.

Return value
A pointer to an NdbOperation (the unlock operation created).

NdbTransaction::updateTuple()

Description
Updates a tuple using an NdbRecord object.

Signature
const NdbOperation* updateTuple
(const NdbRecord* key_rec,
 const char* key_row,
 const NdbRecord* attr_rec,
 const char* attr_row,
 const unsigned char* mask = 0,
 const NdbOperation::OperationOptions* opts = 0,
 Uint32 sizeOfOptions = 0)

Parameters
updateTuple() takes the following parameters:

- key_rec is a pointer to an NdbRecord for either a table or an index. If on a table, then the operation uses a primary key; if on an index, then the operation uses a unique key. In either case, the key_rec must include all columns of the key.

- The key_row passed to this method defines the primary or unique key of the affected tuple, and must remain valid until execute() is called.

- attr_rec is an NdbRecord referencing the attribute to be updated.

  Note
  For unique index operations, the attr_rec must refer to the underlying table of the index, not to the index itself.

- attr_row is a buffer containing the new data for the update.

- The mask, if not NULL, defines a subset of attributes to be updated. The mask is copied, and so does not need to remain valid after the call to this method returns.

- OperationOptions (opts) can be used to provide more finely-grained control of operation definitions. An OperationOptions structure is passed with flags indicating which operation definition options are present. Not all operation types support all operation options; for the options supported by each type of operation, see NdbTransaction::readTuple().

- The optional sizeOfOptions parameter is used to preserve backward compatibility of this interface with previous definitions of the OperationOptions structure. If an unusual size is detected by the interface implementation, it can use this to determine how to interpret the passed OperationOptions structure. To enable this functionality, the caller should pass
### NdbTransaction::writeTuple()

**Description**
This method is used with NdbRecord to write a tuple of data.

**Signature**
```cpp
cnst NdbOperation* writeTuple
{
    const NdbRecord* key_rec,
    const char* key_row,
    const NdbRecord* attr_rec,
    const char* attr_row,
    const unsigned char* mask = 0,
    const NdbOperation::OperationOptions* opts = 0,
    Uint32 sizeOfOptions = 0
}
```

**Parameters**
This method takes the following parameters:

- **key_rec** is a pointer to an NdbRecord for either a table or an index. If on a table, then the operation uses a primary key; if on an index, then the operation uses a unique key. In either case, the key_rec must include all columns of the key.

- The **key_row** passed to this method defines the primary or unique key of the tuple to be written, and must remain valid until `execute()` is called.

- **attr_rec** is an NdbRecord referencing the attribute to be written.

  For unique index operations, the attr_rec must refer to the underlying table of the index, not to the index itself.

- **attr_row** is a buffer containing the new data.

- The **mask**, if not NULL, defines a subset of attributes to be written. The mask is copied, and so does not need to remain valid after the call to this method returns.

- **OperationOptions (opts)** can be used to provide more finely-grained control of operation definitions. An OperationOptions structure is passed with flags indicating which operation definition options are present. Not all operation types support all operation options; for the options supported by each type of operation, see NdbTransaction::readTuple().

- The optional **sizeOfOptions** parameter is used to provide backward compatibility of this interface with previous definitions of the OperationOptions structure. If an unusual size is detected by the interface implementation, it can use this to determine how to interpret the passed OperationOptions structure. To enable this functionality, the caller should pass `sizeof(NdbOperation::OperationOptions)` for the value of this argument.

**Return value**
A `const` pointer to the NdbOperation representing this write operation. The operation can be checked for errors if and as necessary.
2.3.26 The Object Class

This section provides information about the Object class, which contains meta-information about database objects such as tables and indexes. Object subclasses model these and other database objects.

- Object Class Overview
- Object::FragmentType
- Object::getObjectStatus()
- Object::getObjectId()
- Object::getObjectVersion()
- Object::PartitionBalance
- Object::State
- Object::Status
- Object::Store
- Object::Type

Object Class Overview

Parent class  NdbDictionary
Child classes  Datafile, Event, Index, LogfileGroup, Table, Tablespace, Undofile, HashMap, ForeignKey
Methods  The following table lists the public methods of the Object class and the purpose or use of each method:

Table 2.71 Object class methods and descriptions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getId()</td>
<td>Gets an object's ID</td>
</tr>
<tr>
<td>getStatus()</td>
<td>Gets an object's status</td>
</tr>
<tr>
<td>getVersion()</td>
<td>Gets the version of an object</td>
</tr>
</tbody>
</table>

All 3 of these methods are pure virtual methods, and are reimplemented in the Table, Index, and Event subclasses where needed.

Types  These are the public types of the Object class:

Table 2.72 Object class types and descriptions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FragmentType</td>
<td>Fragmentation type used by the object (a table or index)</td>
</tr>
<tr>
<td>State</td>
<td>The object's state (whether it is usable)</td>
</tr>
<tr>
<td>Status</td>
<td>The object's state (whether it is available)</td>
</tr>
<tr>
<td>Store</td>
<td>Whether the object has been temporarily or permanently stored</td>
</tr>
</tbody>
</table>
### The Object Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
<td>The object's type (what sort of table, index, or other database object the Object represents)</td>
</tr>
</tbody>
</table>

#### Object::FragmentType

This section provides information about the `FragmentType` type, which describes the fragmentation type of an instance of `Object`.

**Description**

This parameter specifies how data in the table or index is distributed among the cluster's data nodes, that is, the number of fragments per node. The larger the table, the larger the number of fragments that should be used. Note that all fragment replicas count as a single fragment. For a table, the default is `FragAllMedium`. For a unique hash index, the default is taken from the underlying table and cannot currently be changed.

**Enumeration values**

Possible values for `FragmentType` are shown, along with descriptions, in the following table:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FragUndefined</td>
<td>The fragmentation type is undefined or the default</td>
</tr>
<tr>
<td>FragAllMedium</td>
<td>Two fragments per node</td>
</tr>
<tr>
<td>FragAllLarge</td>
<td>Four fragments per node</td>
</tr>
<tr>
<td>DistrKeyHash</td>
<td>Distributed hash key</td>
</tr>
<tr>
<td>DistrKeyLin</td>
<td>Distributed linear hash key</td>
</tr>
<tr>
<td>UserDefined</td>
<td>User defined</td>
</tr>
<tr>
<td>HashMapPartition</td>
<td>Hash map partition</td>
</tr>
</tbody>
</table>

#### Object::getObjectStatus()

**Description**

This method retrieves the status of the object for which it is invoked.

**Signature**

```cpp
virtual Status getObjectStatus()
{
  void
} const
```

**Parameters**

None.

**Return value**

Returns the current `Status` of the `Object`.

#### Object::getObjectId()

**Description**

This method retrieves the object's ID.

**Signature**

```cpp
virtual int getObjectId()
{
  void
} const
```

**Parameters**

None.

**Return value**

The object ID, an integer.
The Object Class

**Object::getObjectVersion()**

**Description**
The method gets the current version of the object.

**Signature**
```cpp
virtual int getObjectVersion
(
  void
) const
```

**Parameters**
None.

**Return value**
The object's version number, an integer.

**Object::PartitionBalance**

This section provides information about the `PartitionBalance` data type.

**Description**
This type enumerates partition balance settings (fragment count types) from which to choose when using `setPartitionBalance()`. This is also the type returned by `getPartitionBalance()`.

**Enumeration values**
Possible values for `PartitionBalance` are shown, along with descriptions, in the following table:

**Table 2.74 Object::PartitionBalance data type values and descriptions**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PartitionBalance</td>
<td>Use one fragment per LDM per node</td>
</tr>
<tr>
<td>PartitionBalance</td>
<td>Use one fragment per LDM per node group</td>
</tr>
<tr>
<td>PartitionBalance</td>
<td>Use one fragment per node</td>
</tr>
<tr>
<td>PartitionBalance</td>
<td>Use one fragment per node group</td>
</tr>
<tr>
<td>PartitionBalance</td>
<td>Use setting determined by <code>setPartitionBalance()</code></td>
</tr>
</tbody>
</table>

In NDB 7.4 and earlier, this was known as `FragmentCountType`, and could take one of the values `FragmentCount_OnePerLDMPerNode`, `FragmentCount_OnePerLDMPerNodeGroup`, `FragmentCount_OnePerNode`, `FragmentCount_OnePerNodeGroup`, or `FragmentCount_Specific`. These values correspond to those shown in the previous table, in the order shown.

**Object::State**

This section provides information about the `State` type, which models the state of the `Object`.

**Description**
This parameter provides us with the object's state. By `state`, we mean whether or not the object is defined and is in a usable condition. The numeric values are used in the `state` columns of the `dict_obj_info` and `hash_maps` tables in the `ndbinfo` information database.

**Enumeration values**
Possible values for `State` are shown, along with descriptions, in the following table:

**Table 2.75 Object State type values and descriptions**

<table>
<thead>
<tr>
<th>ID</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>StateUndefined</td>
<td>Undefined</td>
</tr>
</tbody>
</table>
### The Object Class

<table>
<thead>

<td>Offline, not useable</td>
</tr>
<tr>
<td>2</td>
<td>StateBuilding</td>
<td>Building (e.g. restore?), not useable(?)</td>
</tr>
<tr>
<td>3</td>
<td>StateDropping</td>
<td>Going offline or being dropped; not usable</td>
</tr>
<tr>
<td>4</td>
<td>StateOnline</td>
<td>Online, usable</td>
</tr>
<tr>
<td>5</td>
<td>StateBackup</td>
<td>Online, being backed up, usable</td>
</tr>
<tr>
<td>6</td>
<td>StateBroken</td>
<td>Broken; should be dropped and re-created</td>
</tr>
</tbody>
</table>

#### Object::Status

This section provides information about the **Status** type, which models the status of an **Object**.

**Description**

Reading an object’s **Status** tells whether or not it is available in the NDB kernel.

**Enumeration values**

Possible values for **Status** are shown, along with descriptions, in the following table:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>New</td>
<td>The object exists only in memory, and has not yet been created in the NDB kernel</td>
</tr>
<tr>
<td>Changed</td>
<td>The object has been modified in memory, and must be committed in the NDB Kernel for changes to take effect</td>
</tr>
<tr>
<td>Retrieved</td>
<td>The object exists, and has been read into main memory from the NDB Kernel</td>
</tr>
<tr>
<td>Invalid</td>
<td>The object has been invalidated, and should no longer be used</td>
</tr>
<tr>
<td>Altered</td>
<td>The table has been altered in the NDB kernel, but is still available for use</td>
</tr>
</tbody>
</table>

#### Object::Store

This section provides information about the **Store** type, which describes the persistence of an **Object**.

**Description**

Reading this value tells us is the object is temporary or permanent.

**Enumeration values**

Possible values for **Store** are shown, along with descriptions, in the following table:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>StoreUndefined</td>
<td>The object is undefined</td>
</tr>
<tr>
<td>StoreTemporary</td>
<td>Temporary storage; the object or data will be deleted on system restart</td>
</tr>
<tr>
<td>StorePermanent</td>
<td>The object or data is permanent; it has been logged to disk</td>
</tr>
</tbody>
</table>
The Table Class

This section provides information about the **Type** type.

**Description**

The **Type** of the object can be one of several different sorts of index, trigger, tablespace, and so on.

**Enumeration values**

Possible values for **Type** are shown, along with descriptions, in the following table:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TypeUndefined</td>
<td>Undefined</td>
</tr>
<tr>
<td>SystemTable</td>
<td>System table</td>
</tr>
<tr>
<td>UserTable</td>
<td>User table (may be temporary)</td>
</tr>
<tr>
<td>UniqueHashIndex</td>
<td>Unique (but unordered) hash index</td>
</tr>
<tr>
<td>OrderedIndex</td>
<td>Ordered (but not unique) index</td>
</tr>
<tr>
<td>HashIndexTrigger</td>
<td>Index maintenance <em>(internal)</em></td>
</tr>
<tr>
<td>IndexTrigger</td>
<td>Index maintenance <em>(internal)</em></td>
</tr>
<tr>
<td>SubscriptionTrigger</td>
<td>Backup or replication <em>(internal)</em></td>
</tr>
<tr>
<td>ReadOnlyConstraint</td>
<td>Trigger <em>(internal)</em></td>
</tr>
<tr>
<td>Tablespace</td>
<td>Tablespace</td>

<tr>
<td>LogfileGroup</td>
<td>Log file group</td>
</tr>
<tr>
<td>Datafile</td>
<td>Data file</td>
</tr>
<tr>
<td>Undofile</td>
<td>Undo file</td>
</tr>
<tr>
<td>ReorgTrigger</td>
<td>Trigger</td>
</tr>
<tr>
<td>HashMap</td>
<td>Hash map</td>
</tr>
<tr>
<td>ForeignKey</td>
<td>Foreign key</td>
</tr>
<tr>
<td>FKParentrTrigger</td>
<td>Trigger on a foreign key's parent table</td>
</tr>
<tr>
<td>FKChildTrigger</td>
<td>Trigger on a foreign key's child table</td>
</tr>
</tbody>
</table>

For more information about **ForeignKey**, **FKParentTrigger**, and **FKChildTrigger**, see Section 2.3.6, “The ForeignKey Class”.

### 2.3.27 The Table Class

This section provides information about the **Table** class, which models a database table in the NDB API.

- Table Class Overview
- Table::addColumn()
- Table::aggregate()
- Table Constructor
- Table::equal()
- Table::getColumn()
- Table::getExtraMetadata()
- Table::getForceVarPart()
The Table Class

- Table::getFragmentCount()
- Table::getFragmentData()
- Table::getFragmentDataLen()
- Table::getFragmentNodes()
- Table::getFragmentType()
- Table::getFrmData()

- Table::setRowGCIIndicator()
- Table::setSingleUserMode()
- Table::setStatusInvalid()
- Table::setTablespace()
- Table::setTablespaceData()
- Table::setTablespaceNames()
The Table Class

- **Table::validate()**

### Table Class Overview

<table>
<thead>
<tr>
<th>Parent class</th>
<th>NdbDictionary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Child classes</td>
<td>None</td>
</tr>
</tbody>
</table>

**Description**
The Table class represents a table in an NDB Cluster database. This class extends the Object class, which in turn is an inner class of the NdbDictionary class.

It is possible using the NDB API to create tables independently of the MySQL server. However, it is usually not advisable to do so, since tables created in this fashion cannot be seen by the MySQL server. Similarly, it is possible using Table methods to modify existing tables, but these changes (except for renaming tables) are not visible to MySQL.

**Methods**
The following table lists the public methods of this class and the purpose or use of each method:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table()</td>
<td>Class constructor</td>
</tr>
<tr>
<td>~Table()</td>
<td>Destructor</td>
</tr>
<tr>
<td>addColumn()</td>
<td>Adds a column to the table</td>
</tr>
<tr>
<td>aggregate()</td>
<td>Computes aggregate data for the table</td>
</tr>
<tr>
<td>equal()</td>
<td>Compares the table with another table</td>
</tr>
<tr>
<td>getColumn()</td>
<td>Gets a column (by name) from the table</td>
</tr>
<tr>
<td>getDefaultNoPartitionsFlag()</td>
<td>Checks whether the default number of partitions is being used</td>
</tr>
<tr>
<td>getFragmentCount()</td>
<td>Gets the number of fragments for this table</td>
</tr>
<tr>
<td>getExtraMetadata()</td>
<td>Gets extra metadata for this table</td>
</tr>
<tr>
<td>getForceVarPart()</td>
<td>Whether the table is forced to allocate a variable part</td>
</tr>
<tr>
<td>getFragmentData()</td>
<td>Gets table fragment data (ID, state, and node group)</td>
</tr>
<tr>
<td>getFragmentDataLen()</td>
<td>Gets the length of the table fragment data</td>
</tr>
<tr>
<td>getFragmentNodes()</td>
<td>Gets IDs of data nodes on which fragments are located</td>
</tr>
<tr>
<td>getFragmentType()</td>
<td>Gets the table’s FragmentType</td>
</tr>
<tr>
<td>getFrmData()</td>
<td>Gets the data from the table .FRM file; deprecated in NDB 8.0.27</td>
</tr>
<tr>
<td>getFrmLength()</td>
<td>Gets the length of the table’s .FRM file; deprecated in NDB 8.0.27</td>
</tr>
<tr>
<td>getHashMap()</td>
<td>Gets the table’s hash map.</td>
</tr>
</tbody>
</table>
## The Table Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getKValue()</td>
<td>Gets the table’s KValue</td>
</tr>
<tr>
<td>getLinearFlag()</td>
<td>Gets the current setting for the table’s linear hashing flag</td>
</tr>
<tr>
<td>getLogging()</td>
<td>Checks whether logging to disk is enabled for this table</td>
</tr>
<tr>
<td>getMaxLoadFactor()</td>
<td>Gets the table’s maximum load factor</td>
</tr>
<tr>
<td>getMaxRows()</td>
<td>Gets the maximum number of rows that this table may contain</td>
</tr>
<tr>
<td>getMinLoadFactor()</td>
<td>Gets the table’s minimum load factor</td>
</tr>
<tr>
<td>getMinRows()</td>
<td>Gets the minimum number of rows in the table (for calculating partitions)</td>
</tr>
<tr>
<td>getName()</td>
<td>Gets the table’s name</td>
</tr>
<tr>
<td>getNoOfAutoIncrementColumns()</td>
<td>Gets the number of auto-increment columns in the table</td>
</tr>
<tr>
<td>getNoOfColumns()</td>
<td>Gets the number of columns in the table</td>
</tr>
<tr>
<td>getNoOfPrimaryKeys()</td>
<td>Gets the number of columns in the table’s primary key</td>
</tr>
<tr>
<td>getObjectId()</td>
<td>Gets the table’s object ID</td>
</tr>
<tr>
<td>getObjectStatus()</td>
<td>Gets the table’s object status</td>
</tr>
<tr>
<td>getObjectType()</td>
<td>Removed in NDB 7.5.0 (Bug #47960, Bug #11756088)</td>
</tr>
<tr>
<td>getObjectVersion()</td>
<td>Gets the table’s object version</td>
</tr>
<tr>
<td>getPartitionBalance()</td>
<td>Gets partition balance (fragment count type) used for this table (NDB 7.5 and later)</td>
</tr>
<tr>
<td>getPartitionBalanceString()</td>
<td>Gets partition balance used for this table, as a string (NDB 7.5 and later)</td>
</tr>
<tr>
<td>getPartitionId()</td>
<td>Gets a partition ID from a hash value</td>
</tr>
<tr>
<td>getPrimaryKey()</td>
<td>Gets the name of the table’s primary key</td>
</tr>
<tr>
<td>getRangeListData()</td>
<td>Gets a RANGE or LIST array</td>
</tr>
<tr>
<td>getRangeListDataLen()</td>
<td>Gets the length of the table RANGE or LIST array</td>
</tr>
<tr>
<td>getRowChecksumIndicator()</td>
<td>Checks whether the row checksum indicator has been set</td>
</tr>
<tr>
<td>getRowGCIIndicator()</td>
<td>Checks whether the row GCI indicator has been set</td>
</tr>
<tr>
<td>getRowGCIIndicator()</td>
<td>Checks whether the row GCI indicator has been set</td>
</tr>
<tr>
<td>getRowSizeInBytes()</td>
<td>Gets the size of a row of this table, in bytes</td>
</tr>
<tr>
<td>getSingleUserMode()</td>
<td>Gets the SingleUserMode for this table</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>getTableId()</td>
<td>Gets the table's ID</td>
</tr>
<tr>
<td>getTablespace()</td>
<td>Gets the tablespace containing this table</td>
</tr>
<tr>
<td>getTablespaceData()</td>
<td>Gets the ID and version of the tablespace containing the table</td>
</tr>
<tr>
<td>getTablespaceDataLen()</td>
<td>Gets the length of the table's tablespace data</td>
</tr>
<tr>
<td>getTablespaceNames()</td>
<td>Gets the names of the tablespaces used in the table fragments</td>
</tr>
<tr>
<td>hasDefaultValues()</td>
<td>Determine whether table has any columns using default values</td>
</tr>
<tr>
<td>setDefaultNoPartitionsFlag()</td>
<td>Toggles whether the default number of partitions should be used for the table</td>
</tr>
<tr>
<td>setExtraMetadata()</td>
<td>Sets extra metadata for this table</td>
</tr>
<tr>
<td>setForceVarPart()</td>
<td>Forces the table to allocate a variable part</td>
</tr>
<tr>
<td>getFragmentCount()</td>
<td>Gets the number of fragments for this table</td>
</tr>
<tr>
<td>setFragmentData()</td>
<td>Sets the fragment ID, node group ID, and fragment state</td>
</tr>
<tr>
<td>setFragmentType()</td>
<td>Sets the table's FragmentType</td>
</tr>
<tr>
<td>setFrm()</td>
<td>Sets the .FRM file to be used for this table; deprecated in NDB 8.0.27</td>
</tr>
<tr>
<td>setHashMap()</td>
<td>Sets the table's hash map.</td>
</tr>
<tr>
<td>setKValue()</td>
<td>Set the KValue</td>
</tr>
<tr>
<td>setLinearFlag()</td>
<td>Sets the table's linear hashing flag</td>
</tr>
<tr>
<td>setLogging()</td>
<td>Toggle logging of the table to disk</td>
</tr>
<tr>
<td>setMaxLoadFactor()</td>
<td>Set the table's maximum load factor (MaxLoadFactor)</td>
</tr>
<tr>
<td>setMaxRows()</td>
<td>Sets the maximum number of rows in the table</td>
</tr>
<tr>
<td>setMinLoadFactor()</td>
<td>Set the table's minimum load factor (MinLoadFactor)</td>
</tr>
<tr>
<td>setPartitionBalance()</td>
<td>Sets the partition balance (fragment count type) for this table (NDB 7.5 and later)</td>
</tr>
<tr>
<td>setName()</td>
<td>Sets the table's name</td>
</tr>
<tr>
<td>setObjectType()</td>
<td>Removed in NDB 7.5.0 (Bug #47960, Bug #11756088)</td>
</tr>
<tr>
<td>setRangeListData()</td>
<td>Sets LIST and RANGE partition data</td>
</tr>
<tr>
<td>setRowChecksumIndicator()</td>
<td>Sets the row checksum indicator</td>
</tr>
<tr>
<td>setRowGCIIndicator()</td>
<td>Sets the row GCI indicator</td>
</tr>
<tr>
<td>setSingleUserMode()</td>
<td>Sets the SingleUserMode value for this table</td>
</tr>
<tr>
<td>setStatusInvalid()</td>
<td></td>
</tr>
</tbody>
</table>
### The Table Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>setTablespace()</code></td>
<td>Set the tablespace to use for this table</td>
</tr>
<tr>
<td><code>setTablespaceData()</code></td>
<td>Sets the tablespace ID and version</td>
</tr>
<tr>
<td><code>setTablespaceNames()</code></td>
<td>Sets the tablespace names for fragments</td>
</tr>
<tr>
<td><code>validate()</code></td>
<td>Validates the definition for a new table prior to creating it</td>
</tr>
</tbody>
</table>

#### Types

The **Table** class defines a single public type **SingleUserMode**.

The assignment `=` operator is overloaded for this class, so that it always performs a deep copy.

As with other database objects, **Table** object creation and attribute changes to existing tables done using the NDB API are not visible from MySQL. For example, if you add a new column to a table using `Table::addColumn()`, MySQL cannot see the new column. The only exception to this rule with regard to tables is that a change of name of an existing NDB table using `Table::setName()` is visible to MySQL.

**Calculating Table Sizes.** When calculating the data storage one should add the size of all attributes (each attribute consuming a minimum of 4 bytes) and well as 12 bytes overhead. Variable size attributes have a size of 12 bytes plus the actual data storage parts, with an additional overhead based on the size of the variable part. For example, consider a table with 5 attributes: one 64-bit attribute, one 32-bit attribute, two 16-bit attributes, and one array of 64 8-bit attributes. The amount of memory consumed per record by this table is the sum of the following:

- 8 bytes for the 64-bit attribute
- 4 bytes for the 32-bit attribute
- 8 bytes for the two 16-bit attributes, each of these taking up 4 bytes due to right-alignment
- 64 bytes for the array (64 * 1 byte per array element)
- 12 bytes overhead

This totals 96 bytes per record. In addition, you should assume an overhead of about 2% for the allocation of page headers and wasted space. Thus, 1 million records should consume 96 MB, and the additional page header and other overhead comes to approximately 2 MB. Rounding up yields 100 MB.

### Table::addColumn()

**Description**

Adds a column to a table.

**Signature**

```cpp
definition
void addColumn
{
    const Column& column
}
```

**Parameters**

A reference to the column which is to be added to the table.

**Return value**

This method's return type is `void`, but it does create a copy of the original `Column` object.

### Table::aggregate()

**Description**

This method computes aggregate data for the table. It is required in order for aggregate methods such as `getNoOfPrimaryKeys()` to work properly before the table has been created and retrieved via `getTableId()`.
### The Table Class

<table>
<thead>
<tr>
<th>Signature</th>
<th>int aggregate</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>{</td>
</tr>
<tr>
<td></td>
<td>struct NdbError&amp; error</td>
</tr>
<tr>
<td>Parameters</td>
<td>A reference to an NdbError object.</td>
</tr>
<tr>
<td>Return value</td>
<td>An integer, whose value is 0 on success, and -1 if the table is in an inconsistent state. In the latter case, the error is also set.</td>
</tr>
</tbody>
</table>

#### Table Constructor

**Description**

Creates a Table instance. There are two versions of the Table constructor, one for creating a new instance, and a copy constructor.

Tables created in the NDB API using this method are not accessible from MySQL.

**Signature**

- **New instance:**
  ```
  Table |
  {     |
  const char* name = "" |
  }
  ```

- **Copy constructor:**
  ```
  Table |
  {     |
  const Table& table |
  }
  ```

**Parameters**

- For a new instance, the name of the table to be created. For a copy, a reference to the table to be copied.

**Return value**

A Table object.

**Destructor**

```virtual ~Table()```

#### Table::equal()

**Description**

This method is used to compare one instance of Table with another.

**Signature**

```bool equal |
{           |
  const Table& table |
} const```

**Parameters**

A reference to the Table object with which the current instance is to be compared.

**Return value**

true if the two tables are the same, otherwise false.

#### Table::getColumn()

**Description**

This method is used to obtain a column definition, given either the index or the name of the column.

**Signature**

This method can be invoked using either the column ID or column name, as shown here:

```Column* getColumn```
The Table Class

```cpp
{  
  const int AttributeId
}

Column* getColumn  
{  
  const char* name
}
```

Parameters Either of: the column's index in the table (as it would be returned by the column's `getColumnNo()` method), or the name of the column.

Return value A pointer to the column with the specified index or name. If there is no such column, then this method returns `NULL`.

**Table::getDefaultNoPartitionsFlag()**

Description This method is used to find out whether the default number of partitions is used for the table.

Signature ```cpp
Uint32 getDefaultNoPartitionsFlag  
{  
  void
} const
```

Parameters None.

Return value A 32-bit unsigned integer.

**Table::getExtraMetadata()**

Description Get and unpack extra metadata for this table.

This method was added in NDB 8.0.

Signature ```cpp
int getExtraMetadata  
{  
  Uint32& version,  
  void** data,  
  Uint32* length
} const
```

Parameters This method takes the following three parameters:

- **version**: By convention, as used in NDB Cluster code, 1 means that the extra metadata contains a `.frm` file (blob data) as in NDB 7.6 and earlier; 2 indicates that it is serialized dictionary information as in NDB 8.0. The values are actually arbitrary, and application-specific.

- **data**: The stored data retrieved as metadata.

- **length**: The length of the stored data (metadata).

Return value Returns 0 on success, any other value on failure. A non-zero value should be interpreted as an error code for the type of error.

**Table::getForceVarPart()**

Description Whether the table is forced to allocate a variable-size part, regardless of whether the table actually has any variable sized columns. This is needed to allow subsequent adding of columns to the table online (see Online Operations with ALTER TABLE in NDB Cluster).
## The Table Class

### Signature

```cpp
def getForceVarPart()
    void
) const
```  

### Parameters

*None.*

### Return value

`true` when the table is forced to allocate a variable size part.

### Table::getFragmentCount()

**Description**

This method gets the number of fragments in the table.

**Signature**

```cpp
uint32 getFragmentCount()
    void
) const
```  

**Parameters**

*None.*

**Return value**

The number of table fragments, as a 32-bit unsigned integer.

### Table::getFragmentData()

**Description**

This method gets the table's fragment data (ID, state, and node group).

**Signature**

```cpp
const void* getFragmentData()
    void
) const
```  

**Parameters**

*None.*

**Return value**

A pointer to the data to be read.

### Table::getFragmentDataLen()

**Description**

Gets the length of the table fragment data to be read, in bytes.

**Signature**

```cpp
uint32 getFragmentDataLen()
    void
) const
```  

**Parameters**

*None.*

**Return value**

The number of bytes to be read, as an unsigned 32-bit integer.

### Table::getFragmentNodes()

**Description**

This method retrieves a list of nodes storing a given fragment.

**Signature**

```cpp
uint32 getFragmentNodes
    Uint32
    Uint32* nodeIdArrayPtr,
    Uint32
) const
```  

**Parameters**

This method takes the following three parameters:

- `fragmentId`: The ID of the desired fragment.
- `nodeIdArrayPtr`: Pointer to an array of node IDs of the nodes containing this fragment.
The Table Class

Note
Normally, the primary fragment is entry 0 in this array.

- **arraySize**: The size of the array containing the node IDs. If this is less than the number of fragments, then only the first `arraySize` entries are written to this array.

Return value
A return value of 0 indicates an error; otherwise, this is the number of table fragments, as a 32-bit unsigned integer.

**Table::getFragmentType()**

Description
This method gets the table's fragmentation type.

Signature
```cpp
FragmentType getFragmentType()
{
    void
} const
```

Parameters
None.

Return value
An `Object::FragmentType` value.

**Table::getFrmData()**

Note
This feature is deprecated and should be avoided. It is subject to removal in a future version of NDB Cluster.

Description
Gets the data from the .FRM file associated with the table.

MySQL 8.0 and NDB 8.0 no longer use .FRM files but rather the MySQL data dictionary to store table metadata; thus this method is deprecated as of NDB 8.0.27, and subject to removal in a future NDB release. For reading and writing table metadata, use `getExtraMetadata()` and `setExtraMetadata()` instead.

Signature
```cpp
const void* getFrmData()
{
    void
} const
```

Parameters
None.

Return value
A pointer to the .FRM data.

**Table::getFrmLength()**

Note
This feature is deprecated and should be avoided. It is subject to removal in a future version of NDB Cluster.

Description
Gets the length of the table's .FRM file data, in bytes.

MySQL 8.0 and NDB 8.0 no longer use .FRM files but rather the MySQL data dictionary to store table metadata; thus this method is deprecated as of NDB 8.0.27, and subject to removal in a future NDB release. For reading and writing table metadata, use `getExtraMetadata()` and `setExtraMetadata()` instead.
The Table Class

**Signature**

```cpp
Uint32 getFrmLength(
    void
) const
```

**Parameters**

None.

**Return value**

The length of the .FRM file data (an unsigned 32-bit integer).

### Table::getHashMap()

**Description**

Get the hash map used for this table.

**Signature**

```cpp
bool getHashMap(
    Uint32* id = 0,
    Uint32* version = 0
) const
```

**Parameters**

The table ID and version.

**Return value**

True if the table has a hash map, otherwise false.

### Table::getKValue()

**Description**

This method gets the KValue, a hashing parameter which is currently restricted to the value 6. In a future release, it may become feasible to set this parameter to other values.

**Signature**

```cpp
int getKValue(
    void
) const
```

**Parameters**

None.

**Return value**

An integer (currently always 6).

### Table::getLinearFlag()

**Description**

This method retrieves the value of the table's linear hashing flag.

**Signature**

```cpp
bool getLinearFlag(
    void
) const
```

**Parameters**

None.

**Return value**

true if the flag is set, and false if it is not.

### Table::getLogging()

**Description**

This class is used to check whether a table is logged to disk—that is, whether it is permanent or temporary.

**Signature**

```cpp
bool getLogging(
    void
) const
```

**Parameters**

None.

**Return value**

Returns a Boolean value. If this method returns true, then full checkpointing and logging are done on the table. If false, then the
The Table Class

A table is a temporary table and is not logged to disk; in the event of a system restart the table still exists and retains its definition, but it will be empty. The default logging value is `true`.

### Table::getMaxLoadFactor()

**Description**
This method returns the load factor (a hashing parameter) when splitting of the containers in the local hash tables begins.

**Signature**
```c++
int getMaxLoadFactor()
{
    void
} const
```

**Parameters**
None.

**Return value**
An integer whose maximum value is 100. When the maximum value is returned, this means that memory usage is optimised. Smaller values indicate that less data is stored in each container, which means that keys are found more quickly but more memory is consumed.

### Table::getMaxRows()

**Description**
This method gets the maximum number of rows that the table can hold. This is used for calculating the number of partitions.

**Signature**
```c++
Uint64 getMaxRows()
{
    void
} const
```

**Parameters**
None.

**Return value**
The maximum number of table rows, as a 64-bit unsigned integer.

### Table::getMinLoadFactor()

**Description**
This method gets the value of the load factor when reduction of the hash table begins. This should always be less than the value returned by `getMaxLoadFactor()`.

**Signature**
```c++
int getMinLoadFactor()
{
    void
} const
```

**Parameters**
None.

**Return value**
A percentage expressed as an integer; see `Table::getMaxLoadFactor()`.

### Table::getMinRows()

**Description**
This method gets the minimum number of rows that the table can hold, for use in calculating the number of partitions.

**Signature**
```c++
Uint64 getMinRows()
{
    void
} const
```

**Parameters**
None.
### The Table Class

<td><strong>Table::getNoOfAutoIncrementColumns()</strong></td>
<td>This method is used to obtain the number of auto-increment columns in a table.</td>
<td><code>int getNoOfAutoIncrementColumns(void) const</code></td>
<td>None</td>
<td>An integer representing the number of auto-increment columns in the table.</td>
</tr>
<tr>
<td><strong>Table::getNoOfColumns()</strong></td>
<td>This method is used to obtain the number of columns in a table.</td>
<td><code>int getNoOfColumns(void) const</code></td>
<td>None</td>
<td>An integer representing the number of columns in the table.</td>
</tr>
<tr>
<td><strong>Table::getNoOfPrimaryKeys()</strong></td>
<td>This method finds the number of primary key columns in the table.</td>
<td><code>int getNoOfPrimaryKeys(void) const</code></td>
<td>None</td>
<td>An integer representing the number of primary key columns in the table.</td>
</tr>
<tr>
<td><strong>Table::getObjectId()</strong></td>
<td>This method gets the table's object ID.</td>
<td><code>virtual int getObjectId(void) const</code></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### The Table Class

**Parameters**

None.

**Return value**

The object ID is returned as an integer.

#### Table::getObjectStatus()

**Description**

This method gets the table's status.

**Signature**

```cpp
virtual Object::Status getObjectStatus
(
    void
) const
```

**Parameters**

None.

**Return value**

An `Object::Status` value.

#### Table::getObjectType() (OBSOLETE)

**Description**

This method did not work as intended, and was removed in NDB 7.5.0 (Bug #47960, Bug #11756088).

**Signature**

```cpp
Object::Type getObjectType
(
    void
) const
```

**Parameters**

None.

**Return value**

Returns an `Object::Type` value.

#### Table::getObjectVersion()

**Description**

This method gets the table's object version (see **NDB Schema Object Versions**).

**Signature**

```cpp
virtual int getObjectVersion
(
    void
) const
```

**Parameters**

None.

**Return value**

The table's object version, as an integer.

#### Table::getPartitionBalance()

**Description**

This method gets the table's partition balance scheme (fragment count type).

Prior to NDB 7.5, this method was known as `getFragmentCountType()`.

**Signature**

```cpp
Object::PartitionBalance getPartitionBalance
(
    void
) const
```

**Parameters**

None.

**Return value**

The partition balancing scheme, as a value of type `Object::PartitionBalance`.

#### Table::getPartitionBalanceString()
The Table Class

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
<th>Signature</th>
<th>Parameters</th>
<th>Return value</th>
</tr>
</thead>
</table>
| Table::getPartitionBalanceString()          | This method gets the table's partition balance scheme (fragment count type), and returns it as a string. | ```cpp
const char* getPartitionBalanceString
{
  void
} const
``` | None.                                                                 | The partition balancing scheme, as a string value.                         |
| Table::getPartitionId()                     | Gets a table partition ID, given its hash value.                             | ```cpp
Uint32 getPartitionId
{
  Uint32 hashvalue
} const
``` | A hashvalue. Note that if the table has not actually been retrieved (using, for example, getTableId()), then the result is likely not to be accurate or useful. | The identifier of the partition corresponding to the hashvalue.               |
| Table::getPrimaryKey()                      | This method is used to obtain the name of the table's primary key.          | ```cpp
const char* getPrimaryKey
{
  int no
} const
``` | None.                                                                 | The name of the primary key, a string (character pointer).                  |
| Table::getRangeListData()                   | This method gets the range or list data associated with the table.          | ```cpp
const void* getRangeListData
{
  void
} const
``` | None.                                                                 | A pointer to the data.                                                     |
| Table::getRangeListDataLen()                | This method gets the size of the table's range or list array.               | ```cpp
Uint32 getRangeListDataLen
{
  void
} const
``` | None.                                                                 |                                                                             |

</tr>
</tbody>
</table>
### The Table Class

#### Table::getTablespace()

**Description**
This method is used in two ways: to obtain the name of the tablespace to which this table is assigned; to verify that a given tablespace is the one being used by this table.

**Signatures**
To obtain the name of the tablespace, invoke without any arguments:

```cpp
const char* getTablespace()
{
    void
} const
```

To determine whether the tablespace is the one indicated by the given ID and version, supply these as arguments, as shown here:

```cpp
bool getTablespace(Uint32* id = 0, Uint32* version = 0) const
```

**Parameters**
The number and types of parameters depend on how this method is being used:

A. When used to obtain the name of the tablespace in use by the table, it is called without any arguments.

B. When used to determine whether the given tablespace is the one being used by this table, then getTablespace() takes two parameters:

   - The tablespace `id`, given as a pointer to a 32-bit unsigned integer
   - The tablespace `version`, also given as a pointer to a 32-bit unsigned integer

The default value for both `id` and `version` is `0`.

**Return value**
The return type depends on how the method is called:

A. When `getTablespace()` is called without any arguments, it returns a `Tablespace` object instance.

B. When called with two arguments, it returns `true` if the tablespace is the same as the one having the ID and version indicated; otherwise, it returns `false`.

#### Table::getTablespaceData()

**Description**
This method gets the table's tablespace data (ID and version).

**Signature**

```cpp
const void* getTablespaceData()
{
    void
} const
```
The Table Class

```
) const

Parameters
Return value
None.
A pointer to the data.

Table::getTablespaceDataLen()

Description
This method is used to get the length of the table's tablespace data.

Signature
Uint32 getTablespaceDataLen
{
   void
} const

Parameters
None.

Return value
The length of the data, as a 32-bit unsigned integer.

Table::getTablespaceNames()

Description
This method gets a pointer to the names of the tablespaces used in the table fragments.

Signature
const void* getTablespaceNames
{
   void
}

Parameters
None.

Return value
Returns a pointer to the tablespace name data.

Table::getTablespaceNamesLen()

Description
This method gets the length of the tablespace name data returned by getTablespaceNames(). (See Table::getTablespaceNames().)

Signature
Uint32 getTablespaceNamesLen
{
   void
} const

Parameters
None.

Return value
Returns the length of the name data, in bytes, as a 32-bit unsigned integer.

Table::hasDefaultValues()

Description
Used to determine whether the table has any columns that are defined with default values other than NULL.

To read and write default column values, use Column::getDefaultValue() and Column::setDefaultValue().

Signature
bool hasDefaultValues
{
   void
} const

Parameters
None.
Table Class

Return value

Returns `true` if the table has any non-`NULL` columns with default values, otherwise `false`.

Table::setDefaultNoPartitionsFlag()

Description

This method sets an indicator that determines whether the default number of partitions is used for the table.

Signature

```c
void setDefaultNoPartitionsFlag
(   Uint32 indicator
) const
```

Parameters

This method takes a single argument `indicator`, a 32-bit unsigned integer.

Return value

`None`.

Table::setExtraMetadata()

Description

Store packed extra metadata for this table. The data is packed without any modification into the buffer of the given `Table` object.

Added in NDB 8.0.

Signature

```c
int setExtraMetadata
(   Uint32 version,
   const void* data,
   Uint32 length
)
```

Parameters

The three parameters used by this method are listed here:

- `version`: As used in NDB Cluster code, 1 means that the extra metadata contains a `.frm` file (blob data) as in NDB 7.6 and earlier; 2 indicates that it is serialized dictionary information as in NDB 8.0. You should be aware that this is merely a convention, and the values can be application-specific, as desired.
- `data`: The actual data to be stored as metadata.
- `length`: The length of the data to be stored.

Return value

`0` on success. Any other value indicates failure; in this case, the value is an error code indicating the type of error.

Table::setForceVarPart()

Description

Forces the table to allocate a variable sized part, to permit online operations on the table even when it has no variable sized columns. See Online Operations with ALTER TABLE in NDB Cluster, for more information about online operations in NDB Cluster.

Signature

```c
void setForceVarPart
(   bool force
)
```

Parameters

Use with `force` set to `true` to cause the table to have a variable size part.

Return value

`None`. 
### Table::setFragmentCount()

**Description**
Sets the number of table fragments.

**Signature**
```cpp
void setFragmentCount(
    Uint32 count
)
```

**Parameters**
- `count` is the number of fragments to be used for the table.

**Return value**
None.

### Table::setFragmentData()

**Description**
This method writes an array containing the following fragment information:
- Fragment ID
- Node group ID
- Fragment State

**Signature**
```cpp
void setFragmentData(
    const void* data,
    Uint32 len
)
```

**Parameters**
- A pointer to the fragment data to be written
- The length (`len`) of this data, in bytes, as a 32-bit unsigned integer

**Return value**
None.

### Table::setFragmentType()

**Description**
This method sets the table's fragmentation type.

**Signature**
```cpp
void setFragmentType(
    FragmentType fragmentType
)
```

**Parameters**
- This method takes one argument, an `Object::FragmentType` value.

**Return value**
None.

### Table::setFrm()

**Note**
This feature is deprecated and should be avoided. It is subject to removal in a future version of NDB Cluster.

**Description**
This method is used to write data to this table's `.FRM` file.

MySQL 8.0 and NDB 8.0 no longer use `.FRM` files but rather the MySQL data dictionary to store table metadata; thus this method
The Table Class

is deprecated as of NDB 8.0.27, and subject to removal in a future NDB release. For reading and writing table metadata, use `getExtraMetadata()` and `setExtraMetadata()` instead.

**Signature**

```cpp
void setFrm
{
    const void* data,
    Uint32 len
}
```

**Parameters**

This method takes the following two arguments:

- A pointer to the `data` to be written.
- The length (`len`) of the data.

**Return value**

`None`.

**Table::setHashMap()**

**Description**

Set a hash map for the table.

**Signature**

```cpp
int setHashMap
{
    const class HashMap &
}
```

**Parameters**

A reference to the hash map.

**Return value**

Returns 0 on success; on failure, returns -1 and sets error.

**Table::setKValue()**

**Description**

This sets the `KValue`, a hashing parameter.

**Signature**

```cpp
void setKValue
{
    int kValue
}
```

**Parameters**

`kValue` is an integer. Currently the only permitted value is 6. In a future version this may become a variable parameter.

**Return value**

`None`.

**Table::setLinearFlag()**

**Description**

Set the table’s linear hash flag. See `Table::getLinearFlag()`.

**Signature**

```cpp
void setLinearFlag
{
    Uint32 flag
}
```

**Parameters**

The `flag` is a 32-bit unsigned integer.

**Return value**

`None`.

**Table::setLogging()**

**Description**

Toggles the table’s logging state. See `Table::getLogging()`.

**Signature**

```cpp
void setLogging
{
    bool enable
}
```
The Table Class

<table>
<thead>
<tr>
<th>Parameters</th>
<th>If <code>enable</code> is <code>true</code>, then logging for this table is enabled; if it is <code>false</code>, then logging is disabled.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Return value</td>
<td>None.</td>
</tr>
</tbody>
</table>

**Table::setMaxLoadFactor()**

**Description**
This method sets the maximum load factor when splitting the containers in the local hash tables.

**Signature**
```cpp
void setMaxLoadFactor
{
    int max
}
```

**Parameters**
This method takes a single parameter `max`, an integer representation of a percentage (for example, 45 represents 45 percent). For more information, see `Table::getMaxLoadFactor()`.

**Return value**
None.

**Table::setMaxRows()**

**Description**
This method sets the maximum number of rows that can be held by the table.

**Signature**
```cpp
void setMaxRows
{
    Uint64 maxRows
}
```

**Parameters**
`maxRows` is a 64-bit unsigned integer that represents the maximum number of rows to be held in the table.

**Return value**
None.

**Table::setMinLoadFactor()**

**Description**
This method sets the minimum load factor when reduction of the hash table begins.

**Signature**
```cpp
void setMinLoadFactor
{
    int min
}
```

**Parameters**
This method takes a single parameter `min`, an integer representation of a percentage (for example, 45 represents 45 percent). For more information, see `Table::getMinLoadFactor()`.

**Return value**
None.

**Table::setName()**

**Description**
This method sets the name of the table.

This is the only `set *()` method of `Table` whose effects are visible to MySQL.

**Signature**
```cpp
void setName
{
    const char* name
}
```
The Table Class

Parameters

name is the (new) name of the table.

Return value

None.

Table::setObjectType() (OBSOLETE)

Description

This method did not work as intended, and was removed in NDB 7.5.0 (Bug #47960, Bug #11756088).

Signature

```c
void setObjectType
{
    Object::Type type
}
```

Parameters

The desired object type. This must be one of the Type values listed in Object::Type.

Return value

None.

Table::setPartitionBalance()

Description

Sets the table’s partition balancing scheme.

Prior to NDB 7.5, this method was known as setFragmentCountType().

Signature

```c
void setPartitionBalance
{
    Object::PartitionBalance scheme
}
```

Parameters

scheme is the partition balancing scheme to be used for the table. This is a value of type PartitionBalance.

Return value

None.

Table::setRangeListData()

Description

This method sets an array containing information that maps range values and list values to fragments. This is essentially a sorted map consisting of fragment-ID/value pairs. For range partitions there is one pair per fragment. For list partitions it could be any number of pairs, but at least as many pairs as there are fragments.

Signature

```c
void setRangeListData
{
    const void* data,
    Uint32 len
}
```

Parameters

This method requires the following two parameters:

- A pointer to the range or list data containing the ID/value pairs
- The length (len) of this data, as a 32-bit unsigned integer.

Return value

None.

Table::setRowChecksumIndicator()

Description

Set the row checksum indicator.

Signature

```c
void setRowChecksumIndicator
{
    bool value
}
```
### The Table Class

#### Table::setRowGCIIndicator()

**Description**
Sets the row GCI indicator.

**Signature**
```cpp
void setRowGCIIndicator(
    bool value
) const
```

**Parameters**
A `true` or `false` value.

**Return value**
None.

#### Table::setSingleUserMode()

**Description**
Sets a `SingleUserMode` for the table.

**Signature**
```cpp
void setSingleUserMode(
    enum SingleUserMode
)
```

**Parameters**
A `SingleUserMode` value.

**Return value**
None.

#### Table::setStatusInvalid()

**Description**
Forces the table's status to be invalidated.

**Signature**
```cpp
void setStatusInvalid(
    void
) const
```

**Parameters**
None.

**Return value**
None.

#### Table::setTablespace()

**Description**
This method sets the tablespace for the table.

See **Section 2.3.28, “The Tablespace Class”**.

**Signatures**
Using the name of the tablespace:
```cpp
void setTablespace(
    const char* name
)
```

Using a `Tablespace` object:
```cpp
void setTablespace(
    const class Tablespace& tablespace
)
```

**Parameters**
This method can be called with a single argument, which can be of either one of these two types:
The Table Class

- The name of the tablespace (a string).
- A reference to an existing Tablespace instance.

Return value

Table::setTablespaceData()

Description
This method sets the tablespace information for each fragment, and includes a tablespace ID and a tablespace version.

Signature
```cpp
void setTablespaceData
  (const void* data,
   Uint32 len)
```

Parameters
This method requires the following two parameters:

- A pointer to the data containing the tablespace ID and version
- The length (len) of this data, as a 32-bit unsigned integer.

Return value

Table::setTablespaceNames()

Description
Sets the names of the tablespaces used by the table fragments.

Signature
```cpp
void setTablespaceNames
  (const void* data
   Uint32 len)
```

Parameters
This method takes the following two parameters:

- A pointer to the tablespace names data
- The length (len) of the names data, as a 32-bit unsigned integer.

Return value

Table::SingleUserMode

This section provides information about the SingleUserMode data type.

Description
SingleUserMode specifies access rights to the table when single user mode is in effect.

Enumeration values
Possible values for SingleUserMode are shown, along with descriptions, in the following table:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SingleUserModeLocked</td>
<td>The table is locked (unavailable).</td>
</tr>
<tr>
<td>SingleUserModeReadOnly</td>
<td>The table is available in read-only mode.</td>
</tr>
<tr>
<td>SingleUserModeReadWrite</td>
<td>The table is available in read-write mode.</td>
</tr>
</tbody>
</table>

Table::validate()
### The Tablespace Class

**Description**
This method validates the definition for a new table prior to creating it, executes the `Table::aggregate()` method, and performs additional checks. `validate()` is called automatically when a table is created or retrieved. For this reason, it is usually not necessary to call `aggregate()` or `validate()` directly.

You should be aware that, even after the `validate()` method is called, there may still exist errors which can be detected only by the NDB kernel when the table is actually created.

**Signature**
```c
int validate
(struct NdbError& error)
```

**Parameters**
A reference to an `NdbError` object.

**Return value**
An integer, whose value is 0 on success, and -1 if the table is in an inconsistent state. In the latter case, the `error` is also set.

### 2.3.28 The Tablespace Class

This section provides information about the `Tablespace` class.

- Tablespace Class Overview
- Tablespace Constructor
- `Tablespace::getAutoGrowSpecification()`
- `Tablespace::getDefaultLogfileGroup()`
- `Tablespace::getDefaultLogfileGroupId()`
- `Tablespace::getExtentSize()`
- `Tablespace::getObjectId()`
- `Tablespace::getName()`
- `Tablespace::getObjectStatus()`
- `Tablespace::getObjectVersion()`
- `Tablespace::setAutoGrowSpecification()`
- `Tablespace::setDefaultLogfileGroup()`
- `Tablespace::setExtentSize()`
- `Tablespace::setName()`

#### Tablespace Class Overview

**Parent class**
`NdbDictionary`

**Child classes**
None

**Description**
The `Tablespace` class models an NDB Cluster Disk Data tablespace, which contains the data files used to store Cluster Disk Data. For an overview of Cluster Disk Data and data file characteristics, see [CREATE TABLESPACE Statement](#) in the MySQL Manual.
Only unindexed column data can be stored on disk. Indexes and indexes columns are always stored in memory.

The following table lists the public methods of this class and the purpose or use of each method:

### Table 2.81 Tablespace class methods and descriptions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tablespace()</td>
<td>Class constructor</td>
</tr>
<tr>
<td>~Tablespace()</td>
<td>Virtual destructor method</td>

<td>setExtentSize()</td>
<td>Sets the size of the extents used by the tablespace</td>
</tr>
<tr>
<td>setName()</td>
<td>Sets the name for the tablespace</td>
</tr>
</tbody>
</table>

#### Types

The Tablespace class defines no public types of its own; however, two of its methods make use of the AutoGrowSpecification data structure.

### Tablespace Constructor

#### Description

These methods are used to create a new instance of Tablespace, or to copy an existing one.

#### Note

The Dictionary class also supplies methods for creating and dropping tablespaces.

#### Signatures

New instance:

```
Tablespace()
    void
```
Copy constructor:

```cpp
class Tablespace
{
    const Tablespace& tablesce
}
```

Parameters

New instance: None. Copy constructor: a reference to an existing `Tablespace` instance.

Return value

A `Tablespace` object.

**Destructor.** The class defines a virtual destructor `~Tablespace()` which takes no arguments and returns no value.

### `Tablespace::getAutoGrowSpecification()`

**Description.**

**Signature**

```cpp
const AutoGrowSpecification& getAutoGrowSpecification()
{
    void
} const
```

Parameters

None.

Return value

A reference to the structure which describes the tablespace auto-grow characteristics; for details, see `NdbDictionary::AutoGrowSpecification`.

### `Tablespace::getDefaultLogfileGroup()`

**Description**

This method retrieves the name of the tablespace's default log file group.

Alternatively, you may wish to obtain the ID of the default log file group; see `Tablespace::getDefaultLogfileGroupId()`.

**Signature**

```cpp
const char* getDefaultLogfileGroup()
{
    void
} const
```

Parameters

None.

Return value

The name of the log file group (string value as character pointer).

### `Tablespace::getDefaultLogfileGroupId()`

**Description**

This method retrieves the ID of the tablespace's default log file group.

You can also obtain directly the name of the default log file group rather than its ID; see `Tablespace::getDefaultLogfileGroup()`.

**Signature**

```cpp
Uint32 getDefaultLogfileGroupId()
{
    void
} const
```

Parameters

None.

Return value

The ID of the log file group, as an unsigned 32-bit integer.
The Tablespace Class

**Tablespace::getExtentSize()**

**Description**
This method is used to retrieve the *extent size*—that is the size of the memory allocation units—used by the tablespace.

**Note**
The same extent size is used for all data files contained in a given tablespace.

**Signature**

```c
Uint32 getExtentSize
    (void) const
```

**Parameters**
None.

**Return value**
The tablespace's extent size in bytes, as an unsigned 32-bit integer.

**Tablespace::getObjectId()**

**Description**
This method retrieves the tablespace's object ID.

**Signature**

```c
virtual int getObjectId
    (void) const
```

**Parameters**
None.

**Return value**
The object ID, as an integer.

**Tablespace::getName()**

**Description**
This method retrieves the name of the tablespace.

**Signature**

```c
const char* getName
    (void) const
```

**Parameters**
None.

**Return value**
The name of the tablespace, a string value (as a character pointer).

**Tablespace::getObjectStatus()**

**Description**
This method is used to retrieve the object status of a tablespace.

**Signature**

```c
virtual Object::Status getObjectStatus
    (void) const
```

**Parameters**
None.

**Return value**
An `Object::Status` value.

**Tablespace::getObjectVersion()**

**Description**
This method gets the tablespace object version (see NDB Schema Object Versions).

**Signature**

```c
virtual int getObjectVersion
    (void)
```
The Tablespace Class

Parameters

None.

Return value

The object version, as an integer.

Tablespace::setAutoGrowSpecification()

Description

This method is used to set the auto-grow characteristics of the tablespace.

Signature

```cpp
void setAutoGrowSpecification
    (const AutoGrowSpecification& autoGrowSpec)
```

Parameters

This method takes a single parameter, an `AutoGrowSpecification` data structure.

Return value

None.

Tablespace::setDefaultLogFileGroup()

Description

This method is used to set a tablespace's default log file group.

Signature

This method can be called in two different ways. The first of these uses the name of the log file group, as shown here:

```cpp
void setDefaultLogFileGroup
    (const char* name)
```

This method can also be called by passing it a reference to a `LogFileGroup` object:

```cpp
void setDefaultLogFileGroup
    (const class LogfileGroup& lGroup)
```

The NDB API provides no method for setting a log file group as the default for a tablespace by referencing the log file group's ID.

Parameters

Either the `name` of the log file group to be assigned to the tablespace, or a reference `lGroup` to this log file group.

Return value

None.

Tablespace::setExtentSize()

Description

This method sets the tablespace's extent size.

Signature

```cpp
void setExtentSize
    (Uint32 size)
```

Parameters

The `size` to be used for this tablespace's extents, in bytes.

Return value

None.

Tablespace::setName()

Description

This method sets the name of the tablespace.
The Undofile Class

Signature

```cpp
void setName
  (const char* name) const
```

Parameters

The `name` of the tablespace, a string (character pointer).

Return value

None.

2.3.29 The Undofile Class

This section provides information about the `Undofile` class.

- Undofile Class Overview
- Undofile Constructor
- Undofile::getFileSize() (OBSOLETE)
- Undofile::getLogFileGroup()
- Undofile::getLogfileGroupId()
- Undofile::getNode() (OBSOLETE)
- Undofile::getObjectId()
- Undofile::getObjectStatus()
- Undofile::getObjectVersion()
- Undofile::getPath()
- Undofile::getSize()
- Undofile::setLogfileGroup()
- Undofile::setNode() (OBSOLETE)
- Undofile::setPath()
- Undofile::setSize()

Undofile Class Overview

<table>
<thead>
<tr>
<th>Parent class</th>
<th>NdbDictionary</th>
</tr>
</thead>
<tbody>
<tr>
<td>Child classes</td>
<td>None</td>
</tr>
</tbody>
</table>

Description

The `Undofile` class models an NDB Cluster Disk Data undo file, which stores data used for rolling back transactions.

Only unindexed column data can be stored on disk. Indexes and indexes columns are always stored in memory.

Methods

The following table lists the public methods of this class and the purpose or use of each method:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Undofile()</td>
<td>Class constructor</td>
</tr>
<tr>
<td>~Undofile()</td>
<td>Virtual destructor</td>
</tr>
</tbody>
</table>
The Undofile Class

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getFileNo()</code></td>
<td>Removed in NDB 7.5.0 (Bug #47960, Bug #11756088)</td>
</tr>
<tr>
<td><code>getLogfileGroup()</code></td>
<td>Gets the name of the log file group to which the undo file belongs</td>
</tr>
<tr>
<td><code>getLogfileGroupId()</code></td>
<td>Gets the ID of the log file group to which the undo file belongs</td>
</tr>
<tr>
<td><code>getNode()</code></td>
<td>Removed in NDB 7.5.0 (Bug #47960, Bug #11756088)</td>
</tr>
<tr>
<td><code>getObjectId()</code></td>
<td>Gets the undo file's object ID</td>
</tr>

<tr>
<td><code>setName()</code></td>
<td>Removed in NDB 7.5.0 (Bug #47960, Bug #11756088)</td>
</tr>
<tr>
<td><code>setPath()</code></td>
<td>Sets the file system path for the undo file</td>
</tr>
<tr>
<td><code>setSize()</code></td>
<td>Sets the undo file's size</td>
</tr>
</tbody>
</table>

Types

The Undofile class defines no public types.

Undofile Constructor

Description

The class constructor can be used to create a new Undofile instance, or to copy an existing one.

Signatures

Create a new instance:

```cpp
Undofile
{
    void
}
```

Copy constructor:

```cpp
Undofile
{
    const Undofile& undoFile
}
```

Parameters

New instance: None. The copy constructor takes a single argument—a reference to the Undofile object to be copied.

Return value

An Undofile object.

Destructor

void. The class defines a virtual destructor which takes no arguments and has the return type void.

Undofile::getFileNo() (OBSOLETE)

Description

This method did not work as intended, and was removed in NDB 7.5.0 (Bug #47960, Bug #11756088).

Signature

```cpp
Uint32 getFileNo
```
The Undofile Class

Parameters

Return value

The number of the undo file, as an unsigned 32-bit integer.

Undofile::getLogfileGroup()

Description

This method retrieves the name of the log file group to which the undo file belongs.

Signature

```
const char* getLogfileGroup()
{
    void
} const
```

Parameters

None.

Return value

The name of the log file group, a string value (as a character pointer).

Undofile::getLogfileGroupId()

Description

This method retrieves the ID of the log file group to which the undo file belongs.

It is also possible to obtain the name of the log file group directly. See Undofile::getLogfileGroup()

Signature

```
Uint32 getLogfileGroupId()
{
    void
} const
```

Parameters

None.

Return value

The ID of the log file group, as an unsigned 32-bit integer.

Undofile::getNode() (OBSOLETE)

Description

This method did not work as intended, and was removed in NDB 7.5.0 (Bug #47960, Bug #11756088).

Signature

```
Uint32 getNode()
{
    void
} const
```

Parameters

None.

Return value

The node ID, as an unsigned 32-bit integer.

Undofile::getObjectId()

Description

This method retrieves the undo file's object ID.

Signature

```
virtual int getObjectId()
{
    void
} const
```

Parameters

None.

Return value

The object ID, as an integer.
Undofile::getObjectStatus()

Description
This method is used to retrieve the object status of an undo file.

Signature
virtual Object::Status getObjectStatus
(  
   void  
 ) const

Parameters
None.

Return value
An Object::Status value.

Undofile::getObjectVersion()

Description
This method gets the undo file's object version (see NDB Schema Object Versions).

Signature
virtual int getObjectVersion
(  
   void  
 ) const

Parameters
None.

Return value
The object version, as an integer.

Undofile::getPath()

Description
This method retrieves the path matching the location of the undo file on the data node's file system.

Signature
const char* getPath
(  
   void  
 ) const

Parameters
None.

Return value
The file system path, a string (as a character pointer).

Undofile::getSize()

Description
This method gets the size of the undo file in bytes.

Signature
Uint64 getSize
(  
   void  
 ) const

Parameters
None.

Return value
The size in bytes of the undo file, as an unsigned 64-bit integer.

Undofile::setLogfileGroup()

Description
Given either a name or an object reference to a log file group, the setLogfileGroup() method assigns the undo file to that log file group.

Signature
void setLogfileGroup
(  
   const char* name  
 )
NDB API Errors and Error Handling

Using a reference to an instance of `LogfileGroup`:

```cpp
void setLogfileGroup
{
    const class LogfileGroup & logfileGroup
}
```

Parameters

The name of the log file group (a character pointer), or a reference to a `LogfileGroup` instance.

Return value

None.

**Undofile::setNode() (OBSOLETE)**

**Description**

This method did not work as intended, and was removed in NDB 7.5.0 (Bug #47960, Bug #11756088).

**Signature**

```cpp
void setNode
{
    Uint32 nodeId
}
```

Parameters

The `nodeId` of the data node where the undo file is to be placed; this is an unsigned 32-bit integer.

Return value

None.

**Undofile::setPath()**

**Description**

This method is used to set the file system path of the undo file on the data node where it resides.

**Signature**

```cpp
void setPath
{
    const char* path
}
```

Parameters

The desired `path` to the undo file.

Return value

None.

**Undofile::setSize()**

**Description**

Sets the size of the undo file in bytes.

**Signature**

```cpp
void setSize
{
    Uint64 size
}
```

Parameters

The intended `size` of the undo file in bytes, as an unsigned 64-bit integer.

Return value

None.

### 2.4 NDB API Errors and Error Handling

This section contains a discussion of error handling in NDB API applications as well as listing listings of the most common NDB error codes and messages, along with their classifications and likely causes for which they might be raised.

For information about the `NdbError` structure, which is used to convey error information to NDB API applications, see **Section 2.3.15, “The NdbError Structure”**.
Important
It is strongly recommended that you not depend on specific error codes in your NDB API applications, as they are subject to change over time. Instead, you should use the NdbError::Status and error classification in your source code, or consult the output of `perror --ndb error_code` to obtain information about a specific error code.

If you find a situation in which you need to use a specific error code in your application, please file a bug report at http://bugs.mysql.com/ so that we can update the corresponding status and classification.

2.4.1 Handling NDB API Errors
This section describes how NDB API errors can be detected and mapped onto particular operations.

NDB API errors can be generated in either of two ways:

- When an operation is defined
- When an operation is executed

**Errors raised during operation definition.** Errors generated during operation definition result in a failure return code from the method called. The actual error can be determined by examining the relevant NdbOperation object, or the operation's NdbTransaction object.

**Errors raised during operation execution.** Errors occurring during operation execution cause the transaction of which they are a part to be aborted unless the AO_IgnoreError abort option is set for the operation.

By default, read operations are run with AO_IgnoreError, and write operations are run with AbortOnError, but this can be overridden by the user. When an error during execution causes a transaction to be aborted, the execute() method returns a failure return code. If an error is ignored due to AO_IgnoreError being set on the operation, the execute() method returns a success code, and the user must examine all operations for failure using NdbOperation::getNdbError(). For this reason, the return value of getNdbError() should usually be checked, even if execute() returns success. If the client application does not keep track of NdbOperation objects during execution, then NdbTransaction::getNextCompletedOperation() can be used to iterate over them.

You should also be aware that use of NdbBlob can result in extra operations being added to the batches executed. This means that, when iterating over completed operations using getNextCompletedOperation(), you may encounter operations related to NdbBlob objects which were not defined by your application.

**Note**
A read whose LockMode is CommittedRead cannot be AbortOnError. In this case, it is always be IgnoreError.

In all cases where operation-specific errors arise, an execution error with an operation is marked against both the operation and the associated transaction object. Where there are multiple operation errors in a single NdbTransaction::execute() call, due to operation batching and the use of AO_IgnoreError, only the first is marked against the NdbTransaction object. The remaining errors are recorded against the corresponding NdbOperation objects only.

It is also possible for errors to occur during execution—such as a data node failure—which are marked against the transaction object, but not against the underlying operation objects. This is because these errors apply to the transaction as a whole, and not to individual operations within the transaction.

For this reason, applications should use NdbTransaction::getNdbError() as the first way to determine whether an NdbTransaction::execute() call failed. If the batch of operations being
executed included operations with the AO_IgnoreError abort option set, then it is possible that there were multiple failures, and the completed operations should be checked individually for errors using NdbOperation::getNdbError().

**Implicit NdbTransaction::execute() calls in scan and BLOB methods.** Scan operations are executed in the same way as other operations, and also have implicit execute() calls within the NdbScanOperation::nextResult() method. When NdbScanOperation::nextResult() indicates failure (that is, if the method returns -1), the transaction object should be checked for an error. The NdbScanOperation may also contain the error, but only if the error is not operation-specific.

Some blob manipulation methods also have implicit internal execute() calls, and so can experience operation execution failures at these points. The following NdbBlob methods can generate implicit execute() calls; this means that they also require checks of the NdbTransaction object for errors via NdbTransaction::getNdbError() if they return an error code:

- setNull()
- truncate()
- readData()
- writeData()

**Summary.** In general, it is possible for an error to occur during execution (resulting in a failure return code) when calling any of the following methods:

- NdbTransaction::execute()
- NdbBlob::setNull()
- NdbBlob::truncate()
- NdbBlob::readData()
- NdbBlob::writeData()
- NdbScanOperation::nextResult()

**Note**

This method does *not* perform an implicit execute() call. The NdbBlob methods can cause other defined operations to be executed when these methods are called; however, nextResult() calls do not do so.

If this happens, the NdbTransaction::getNdbError() method should be called to identify the first error that occurred. When operations are batched, and there are IgnoreError operations in the batch, there may be multiple operations with errors in the transaction. These can be found by using NdbTransaction::getNextCompletedOperation() to iterate over the set of completed operations, calling NdbOperation::getNdbError() for each operation.

When IgnoreError has been set on any operations in a batch of operations to be executed, the NdbTransaction::execute() method indicates success even where errors have actually occurred, as long as none of these errors caused a transaction to be aborted. To determine whether there were any ignored errors, the transaction error status should be checked using NdbTransaction::getNdbError(). Only if this indicates success can you be certain that no errors occurred. If an error code is returned by this method, and operations were batched, then you should iterate over all completed operations to find all the operations with ignored errors.

**Example (pseudocode).** We begin by executing a transaction which may have batched operations and a mix of AO_IgnoreError and AbortOnError abort options:
Handling NDB API Errors

```cpp
int execResult = NdbTransaction.execute(args);
```

**Note**

For the number and permitted values of `args`, see `NdbTransaction::execute()`.

Next, because errors on `AO_IgnoreError` operations do not affect `execResult`—that is, the value returned by `execute()`—we check for errors on the transaction:

```cpp
NdbError err = NdbTransaction.getNdbError();
if (err.code != 0)
{
    An nonzero value for the error code means that an error was raised on the transaction. This could be due to any of the following conditions:

    • A transaction-wide error, such as a data node failure, that caused the transaction to be aborted
    • A single operation-specific error, such as a constraint violation, that caused the transaction to be aborted
    • A single operation-specific ignored error, such as no data found, that did not cause the transaction to be aborted
    • The first of many operation-specific ignored errors, such as no data found when batching, that did not cause the transaction to be aborted
    • First of a number of operation-specific ignored errors such as no data found (when batching) before an aborting operation error (transaction aborted)

    if (execResult != 0)
    {
        The transaction has been aborted. The recommended strategy for handling the error in this case is to test the transaction error status and take appropriate action based on its value:

        ```cpp
        switch (err.status)
        {
            case value1:
                // statement block handling value1 ...
            case value2:
                // statement block handling value2 ...
                // (etc. . . .)
            case valueN:
                // statement block handling valueN ...
        }
        ```

        Since the transaction was aborted, it is generally necessary to iterate over the completed operations (if any) and find the errors raised by each only if you wish to do so for reporting purposes.

        } else
        {
            The transaction itself was not aborted, but there must be one or more ignored errors. In this case, you should iterate over the operations to determine what happened and handle the cause accordingly.
        }
```

To handle a `NdbScanOperation::nextResult()` which returns `−1`, indicating that the operation failed (omitting cases where the operation was successful):
int nextrc= NdbScanOperation.nextResult(args);

Note
For the number and permitted values of args, see NdbScanOperation::nextResult().

if (nextrc == -1)
{
First, you should check the NdbScanOperation object for any errors:

NdbError err= NdbScanOperation.getNdbError();
if (err.code == 0)
{
No error was found in the scan operation; the error must belong to the transaction as whole.
}
err= NdbTransaction.getNdbError();

Now you can handle the error based on the error status:

switch (err.status)
{
    case value1:
        // statement block handling value1 ...
    case value2:
        // statement block handling value2 ...
        // (etc. ...)  
    case valueN:
        // statement block handling valueN ...
}

For information about NDB API error classification and status codes, see Section 2.4.4, “NDB Error Classifications”. While you should not rely on a specific error code or message text in your NDB API applications—since error codes and messages are both subject to change over time—it can be useful to check error codes and messages to help determine why a particular failure occurred. For more information about these, see Section 2.4.2, “NDB Error Codes: by Type”. For more about NdbError and the types of information which can be obtained from NdbError objects, see Section 2.3.15, “The NdbError Structure”.

2.4.2 NDB Error Codes: by Type

This section contains a number of error code lists, one for each type of NDB API error. The error types include the following:

- No error
- Application error
- Scan application error
- Configuration or application error (currently unused)
- No data found
- Constraint violation
- Schema error
• User defined error
• Insufficient space
• Temporary Resource error
• Node Recovery error
• Overload error
• Timeout expired
• Node shutdown
• Internal temporary
• Unknown result error
• Unknown error code (currently unused)
• Internal error
• Function not implemented

The information in each list includes, for each error:

• The NDB error code
• The corresponding MySQL error code
• The NDB classification code
  
See Section 2.4.4, “NDB Error Classifications”, for the meanings of these classification codes.

• The text of the error message

Similar errors have been grouped together in each list. Each list is ordered alphabetically.

You can always obtain the latest error codes and information from the file storage/ndb/src/ndbapi/ndberror.cpp. (In previous releases of NDB Cluster, this file was named ndberror.c.)

These types are also shown in the error_status column of the ndbinfo.error_messages table.

2.4.2.1 No error

The following list enumerates all NDB errors of type NE (No error).

<table>
<thead>
<tr>
<th>NDB error code</th>
<th>MySQL error</th>
<th>Error message</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>No error</td>
</tr>
</tbody>
</table>

2.4.2.2 Application error

The following list enumerates all NDB errors of type AE (Application error).

<table>
<thead>
<tr>
<th>NDB error code</th>
<th>MySQL error</th>
<th>Error message</th>
</tr>
</thead>
<tbody>
<tr>
<td>1233</td>

</tbody>
</table>

2.4.3 NDB Error Codes: Single Listing

This section lists all NDB errors, ordered by NDB error code. Each listing also includes the error’s NDB error type, the corresponding MySQL Server error, and the text of the error message.

/* Scan trans timeout */
MySQL error. {237}
NDB error type. Error type not found
Error message. TO, Transaction had timed out when trying to commit it

// "Outer joined scans need FirstInner/Upper to be specified"
MySQL error.
NDB error type. Error type not found
Error message.

0
MySQL error. 0
NDB error type. No error
Error message. No error

</table>
NDB Error Codes: Single Listing

NDB error type.  Configuration or application error
Error message.  Encryption password is of zero length

1321
MySQL error.  DMEC
NDB error type.  User defined error
Error message.  Backup aborted by user request

1322
MySQL error.  DMEC
NDB error type.  Internal error
Error message.  Backup already completed

1323
MySQL error.  DMEC
NDB error type.  Internal error
Error message.  1323

1324
MySQL error.  DMEC
NDB error type.  Internal error
Error message.  Backup log buffer full

1325
MySQL error.  DMEC
NDB error type.  Internal error
Error message.  File or scan error

1326
MySQL error.  DMEC
NDB error type.  Internal error
Error message.  Backup aborted due to node failure

1327
MySQL error.  DMEC
NDB error type.  Internal error
Error message.  1327

1329
MySQL error.  DMEC
NDB error type.  Application error
Error message.  Backup during software upgrade not supported

1340
MySQL error.  DMEC
NDB error type.  Internal error
Error message.  Backup undefined error

1342
MySQL error.  DMEC
NDB error type.  Application error
NDB Error Codes: Single Listing

Error message.  Backup failed to allocate buffers (check configuration)

1343
MySQL error.  DMEC
NDB error type.  Application error

Error message.  Backup failed to setup fs buffers (check configuration)

1344
MySQL error.  DMEC
NDB error type.  Application error

Error message.  Backup failed to allocate tables (check configuration)

1345
MySQL error.  DMEC
NDB error type.  Application error

Error message.  Backup failed to insert file header (check configuration)

1346
MySQL error.  DMEC
NDB error type.  Application error

Error message.  Backup failed to insert table list (check configuration)

1347
MySQL error.  DMEC
NDB error type.  Application error

Error message.  Backup failed to allocate table memory (check configuration)

1348
MySQL error.  DMEC
NDB error type.  Application error

Error message.  Backup failed to allocate file record (check configuration)

1349
MySQL error.  DMEC
NDB error type.  Application error

Error message.  Backup failed to allocate attribute record (check configuration)

1350
MySQL error.  DMEC
NDB error type.  Temporary Resource error

Error message.  Backup failed: file already exists (use 'START BACKUP <backup id>')

1405
MySQL error.  DMEC
NDB error type.  Node Recovery error
NDB Error Codes: Single Listing

1407
MySQL error.  DMEC
NDB error type.  Schema error
Error message.  Subscriber manager busy with node recovery

1411
MySQL error.  DMEC
NDB error type.  Temporary Resource error
Error message.  Subscription not found in subscriber manager

1412
MySQL error.  DMEC
NDB error type.  Insufficient space
Error message.  Can't accept more subscribers, out of space in pool

1413
MySQL error.  DMEC
NDB error type.  Temporary Resource error
Error message.  Subscriber manager busy with adding the subscription

1414
MySQL error.  DMEC
NDB error type.  Temporary Resource error
Error message.  Subscriber manager has subscribers on this subscription

1415
MySQL error.  DMEC
NDB error type.  Schema error
Error message.  Subscription not unique in subscriber manager

1416
MySQL error.  DMEC
NDB error type.  Insufficient space
Error message.  Can't accept more subscriptions, out of space in pool

1417
MySQL error.  DMEC
NDB error type.  Schema error
Error message.  Table in subscription not defined, probably dropped

1418
MySQL error.  DMEC
NDB error type.  Schema error
Error message. Subscription dropped, no new subscribers allowed

1419 MySQL error. DMEC
NDB error type. Schema error
Error message. Subscription already dropped

1420 MySQL error. DMEC
NDB error type. Temporary Resource error
Error message. Subscriber manager busy with adding/removing a table

1421 MySQL error. DMEC
NDB error type. Schema error
Error message. Partially connected API in NdbOperation::execute()

1422 MySQL error. DMEC
NDB error type. Schema error
Error message. Out of subscription records

1423 MySQL error. DMEC
NDB error type. Schema error
Error message. Out of table records in SUMA

1424 MySQL error. DMEC
NDB error type. Schema error
Error message. Out of MaxNoOfConcurrentSubOperations

1425 MySQL error. DMEC
NDB error type. Schema error
Error message. Subscription being defined...while trying to stop subscriber

1426 MySQL error. DMEC
NDB error type. Schema error
Error message. No such subscriber

1427 MySQL error. DMEC
NDB error type. Node Recovery error
Error message. Api node died, when SUB_START_REQ reached node

1428 MySQL error. DMEC

NDB Error Codes: Single Listing

21028
MySQL error.  DMEC
NDB error type.  Schema error
Error message.  Create foreign key failed in NDB - invalid parent index version

21029
MySQL error.  DMEC
NDB error type.  Schema error
Error message.  Create foreign key failed in NDB - child index is not index

21030
MySQL error.  DMEC
NDB error type.  Internal error
Error message.  Create foreign key failed in NDB - object already exists in TC

21031
MySQL error.  DMEC
NDB error type.  Internal error
Error message.  Create foreign key failed in NDB - no more object records in TC

21032
MySQL error.  DMEC
NDB error type.  Internal error
Error message.  Create foreign key failed in NDB - invalid request to TC

21033
MySQL error.  HA_ERR_CANNOT_ADD_FOREIGN
NDB error type.  Application error
Error message.  Create foreign key failed in NDB - No parent row found

21034
MySQL error.  HA_ERR_CANNOT_ADD_FOREIGN
NDB error type.  Application error
Error message.  Create foreign key failed - child table has Blob or Text column and on-delete-cascade is not allowed

21040
MySQL error.  DMEC
NDB error type.  Application error
Error message.  Drop foreign key failed in NDB - foreign key not found

21041
MySQL error.  DMEC
NDB error type.  Schema error

</table>
269  MySQL error.  DMEC
NDB error type.  Application error
Error message.  No condition and attributes to read in scan

270  MySQL error.  DMEC
NDB error type.  Node shutdown
Error message.  Transaction aborted due to node shutdown

271  MySQL error.  DMEC
NDB error type.  Internal error
Error message.  Simple Read transaction without any attributes to read

272  MySQL error.  DMEC
NDB error type.  Internal error
Error message.  Update operation without any attributes to update

273  MySQL error.  DMEC
NDB error type.  Temporary Resource error
Error message.  Out of transaction markers databuffer in TC, increase SharedGlobalMemory

274  MySQL error.  HA_ERR_LOCK_WAIT_TIMEOUT
NDB error type.  Timeout expired
Error message.  {296, HA_ERR_LOCK_WAIT_TIMEOUT, TO, {297, HA_ERR_LOCK_WAIT_TIMEOUT, TO, Time-out in NDB, probably caused by deadlock

275  MySQL error.  DMEC
NDB error type.  Temporary Resource error
Error message.  Out of transaction records for complete phase (increase SharedGlobalMemory)

276  MySQL error.  DMEC
NDB error type.  Internal error
Error message.  276

277  MySQL error.  DMEC
NDB error type.  Internal error
Error message.  277

278  MySQL error.  DMEC

Error Message:
- Parameter error in API call
- Simple/dirty read failed due to node failure
- Scan already complete
- Cannot set name twice for an Ndb object
- Cannot set name after Ndb object is initialised
- Free percent out of range. Allowed range is 1-99
- Bad state handling unlock request
- Bad operation reference - double unlock

NDB Error Codes: Single Listing

Error message.  Unsupported multi node shutdown. Abort option required.

5062
MySQL error.  DMEC
NDB error type.  Application error
Error message.  The specified node is not an API node.

5063
MySQL error.  DMEC
NDB error type.  Application error
Error message.

623
MySQL error.  HA_ERR_RECORD_FILE_FULL
NDB error type.  Insufficient space
Error message.  623

624
MySQL error.  HA_ERR_RECORD_FILE_FULL
NDB error type.  Insufficient space
Error message.  624

625
MySQL error.  HA_ERR_INDEX_FILE_FULL
NDB error type.  Insufficient space
Error message.  Out of memory in Ndb Kernel, hash index part (increase DataMemory)

626
MySQL error.  HA_ERR_KEY_NOT_FOUND
NDB error type.  No data found
Error message.  Tuple did not exist

630
MySQL error.  HA_ERR_FOUND_DUPP_KEY
NDB error type.  Constraint violation
Error message.  Tuple already existed when attempting to insert

631
MySQL error.  DMEC
NDB error type.  Node Recovery error
Error message.  Scan take over error, restart scan transaction

632
MySQL error.  DMEC
NDB error type.  Internal error
Error message.  632

633
MySQL error.  HA_ERR_INDEX_FILE_FULL

In NDB 7.6 and later, you can also obtain the descriptions for the classification codes from the `error_classification` column of the `ndbinfo.error_messages` table.

### 2.5 NDB API Examples

This section provides code examples illustrating how to accomplish some basic tasks using the NDB API.

All of these examples can be compiled and run as provided, and produce sample output to demonstrate their effects.

**Note**

For an NDB API program to connect to the cluster, the cluster configuration file must have at least one `[api]` section that is not assigned to an SQL node and that can be accessed from the host where the NDB API application runs. You can also use an unassigned `[mysqld]` section for this purpose, although we recommend that you use `[mysqld]` sections for SQL nodes and `[api]` sections for NDB client programs. See NDB Cluster Configuration Files, and especially Defining SQL and Other API Nodes in an NDB Cluster, for more information.
2.5.1 Basic NDB API Examples

The next few sections contain the sources for a set of C++ programming examples demonstrating the basics of connecting to an NDB Cluster, inserting data into a table, reading data from a table, and deleting data from a table.

2.5.1.1 NDB API Basic Connection Example

This example, which can also be found in storage/ndb/ndbapi-examples/ndbapi_basic/ndbapi_basic_connect.cpp, demonstrates the use of Ndb_cluster_connection to connect to an NDB management server using a given connection string. On success, it obtains and prints out some information about the cluster. If it is unable to connect to the management or to the data nodes, it prints an appropriate error and exits.

```cpp
#include <iostream>
#include <cstdlib>
#include <NdbApi.hpp>

namespace
{
    inline void test_connection(const Ndb_cluster_connection &connection)
    {
        std::cout << "Connected to: " << connection.get_system_name()`
        << ",\n\ton port: " << connection.get_connected_port()
        << ",\n\taactive NDBDs: " << connection.get_active_ndb_objects()
        << std::endl;
    }
}

int main(int argc, char **argv)
{
    if (argc != 2)
    {
        std::cout << "Usage: ndb_ndbapi_basic_connect <connectstring>"`
        << std::endl;
        return EXIT_FAILURE;
    }

    const char *connectstring = argv[1];

    ndb_init();
    { Ndb_cluster_connection connection(connectstring);
        if (connection.connect() != 0)
        {
            std::cout << "Cannot connect to cluster management server" << std::endl;
            return EXIT_FAILURE;
        }

        if (connection.wait_until_ready(30, 0) != 0)
        {
            std::cout << "Cluster was not ready within 30 secs" << std::endl;
            return EXIT_FAILURE;
        }

        // Let's verify connection
        test_connection(connection);
    }

    ndb_end(0);
    return EXIT_SUCCESS;
}
```

2.5.1.2 NDB API Basic Insertion Example
Prior to running this example, start a mysql client session on an SQL node connected to the cluster and execute the following statements to create the database and table used by the example:

```sql
CREATE DATABASE ndbapi_examples;
USE ndbapi_examples;
CREATE TABLE basic (
   ATTR1 INT NOT NULL PRIMARY KEY,
   ATTR2 INT NOT NULL
) ENGINE=NDB;
```

After running the example, you can check the table using `SELECT * FROM basic` in the mysql client, or by running the example read program (see Section 2.5.1.3, "NDB API Basic Reading Example").

You can also find the source code for this example in the file `storage/ndb/ndbapi-examples/ndbapi_basic/ndbapi_basic_insert.cpp`.

```cpp
#include <iostream>
#include <cstdlib>
#include <string>
#include <NdbApi.hpp>

class BasicInsert
{
   public:
      BasicInsert(const char *connectstring)
         : m_connection(connectstring), m_ndb(&m_connection, "ndbapi_examples") {}
      bool init();
      bool do_insert(long long, long long);
   private:
      Ndb_cluster_connection m_connection;
      Ndb m_ndb;

      inline bool on_error(const struct NdbError &error,
         const std::string &explanation)
      {
         // prints error in format:
         // ERROR <NdbErrorCode>: <NdbError message>
         // explanation what went wrong on higher level (in the example code)
         std::cout << "ERROR " << error.code << " " << error.message << std::endl;
         std::cout << explanation << std::endl;
         return false;
      }
};

int main(int argc, char **argv)
{
   if (argc != 4)
   {
      std::cout << "Usage: 
      " << "<ndb_ndbapi_basic_insert <connectstring> <key: int> <value: int>" << std::endl;
      return EXIT_FAILURE;
   }

   const char *connectstring = argv[1];
   const long long key = std::strtoll(argv[2], nullptr, 10);
   const long long value = std::strtoll(argv[3], nullptr, 10);

   ndb_init();
   {
      BasicInsert example(connectstring);
      if (!example.init()) return EXIT_FAILURE;

      // Let's verify inserts
2.5.1.3 NDB API Basic Reading Example

This example illustrates basic retrieval of one or more rows from an NDB table using the NdbRecord interface and an NdbScanOperation. We assume that you have already created and populated the basic table, perhaps using the row insertion example shown previously (see Section 2.5.1.2, “NDB API Basic Insertion Example”).
#include <iostream>
#include <cstdlib>
#include <string>
#include <iterator>
#include <NdbApi.hpp>

class BasicRead
{
   public:
      BasicRead(const char *connectstring)
         : m_connection(connectstring), m_ndb(&m_connection, "ndbapi_examples") {}
      
      bool init();
      bool do_read();

   private:
      Ndb_cluster_connection m_connection;
      Ndb m_ndb;

      struct BasicRow
      {
         int attr1, attr2;
      };

      inline bool on_error(const struct NdbError &error,
                            const std::string &explanation)
      {
         // prints error in format:
         // ERROR <NdbErrorCode>: <NdbError message>
         //   explanation what went wrong on higher level (in the example code)
         std::cout << "ERROR " << error.code <<": " << error.message << std::endl;
         std::cout << explanation << std::endl;
         return false;
      }
};

int main(int argc, char **argv)
{
   if (argc != 2)
   {
      std::cout << "Usage: ndb_ndbapi_basic_read <connectstring>" << std::endl;
      return EXIT_FAILURE;
   }
   const char *connectstring = argv[1];
   ndb_init();
   {
      BasicRead example(connectstring);
      if (!example.init())
         return EXIT_FAILURE;
      
      // Let's verify reads
      if (!example.do_read()) return EXIT_FAILURE;
   }
   ndb_end(0);
   return EXIT_SUCCESS;
}

bool BasicRead::do_read()
{
   NdbDictionary::Dictionary *dict = m_ndb.getDictionary();
   const NdbDictionary::Table *table = dict->getTable("basic");
   if (table == nullptr)
      return on_error(dict->getNdbError(),
                      "Cannot access table 'ndbapi_examples.basic'");

   // Prepare record specification,
   // this will allow us later to access rows in the table
Basic NDB API Examples

```c
// using our structure BasicRow
NdbRecord* record;
NdbDictionary::RecordSpecification record_spec[] = {
    { table->getColumn("ATTR1"), offsetof(BasicRow, attr1), 0, 0, 0 },
    { table->getColumn("ATTR2"), offsetof(BasicRow, attr2), 0, 0, 0 }
};
record = dict->createRecord(table,
    record_spec,
    std::size(record_spec),
    sizeof(record_spec[0]));
if (record == nullptr)
    return on_error(dict->getNdbError(), "Failed to create record");

// All reads will be performed within single transaction
NdbTransaction *transaction = m_ndb.startTransaction(table);
if(transaction == nullptr)
    return on_error(m_ndb.getNdbError(), "Failed to start transaction");

// Note the usage of NdbScanOperation instead of regular NdbOperation
NdbScanOperation *operation = transaction->scanTable(record);
if(operation == nullptr)
    return on_error(transaction->getNdbError(), "Failed to start scanTable operation");

// Note the usage of NoCommit flag, as we are only reading the tuples
if (transaction->execute(NdbTransaction::NoCommit) != 0)
    return on_error(transaction->getNdbError(), "Failed to execute transaction");

const BasicRow *row_ptr;
int rc;
std::cout << "ATTR1" << "\t" << "ATTR2" << std::endl;
// Loop over all read results to print them
while ((rc = operation->nextResult(reinterpret_cast<const char **>(&row_ptr),
    true, false)) == 0)
    std::cout << row_ptr->attr1 << "\t" << row_ptr->attr2
    << std::endl;
if (rc == -1)
    return on_error(transaction->getNdbError(), "Failed to read tuple");

operation->close();
m_ndb.closeTransaction(transaction);
dict->releaseRecord(record);
return true;
}

bool BasicRead::init()
{
    if (m_connection.connect() != 0)
    {
        std::cout << "Cannot connect to cluster management server" << std::endl;
        return false;
    }

    if (m_connection.wait_until_ready(30, 0) != 0)
    {
        std::cout << "Cluster was not ready within 30 secs" << std::endl;
        return false;
    }

    if (m_ndb.init() != 0)
        return on_error(m_ndb.getNdbError(), "Failed to initialize ndb object");

    return true;
}
```
2.5.1.4 NDB API Basic Delete Example

This example shows deleting a row from a table already created and populated previously (see Section 2.5.1.2, "NDB API Basic Insertion Example"). It performs the deletion using a single NdbOperation within a transaction, and handles errors using NdbError.

You can verify afterwards that the row was deleted by running the read example (Section 2.5.1.3, "NDB API Basic Reading Example"), or by executing `SELECT * FROM basic` in the mysql client.

The source code for this example can also be found in the file `storage/ndb/ndbapi-examples/ndbapi_basic/ndbapi_basic_delete.cpp`.

```cpp
#include <iostream>
#include <cstdlib>
#include <string>
#include <NdbApi.hpp>

class BasicDelete
{
  public:
    BasicDelete(const char * connectstring)
      : m_connection(connectstring), m_ndb(&m_connection, "ndbapi_examples") {}

    bool init();
    bool do_delete(long long);

  private:
    Ndb_cluster_connection m_connection;
    Ndb m_ndb;

    inline bool on_error(const struct NdbError &error,
                          const std::string &explanation)
    {
      // prints error in format:
      // ERROR <NdbErrorCode>: <NdbError message>
      //   explanation what went wrong on higher level (in the example code)
      std::cout << "ERROR " << error.code << "": " << error.message << std::endl;
      std::cout << explanation << std::endl;
      return false;
    }
};

int main(int argc, char **argv)
{
  if (argc != 3)
  {
    std::cout << "Usage: ndb_ndbapi_basic_delete <connectstring> <key: int>" << std::endl;
    return EXIT_FAILURE;
  }

  const char *connectstring = argv[1];
  const long long key = std::strtoll(argv[2], nullptr, 10);

  ndb_init();
  {
    BasicDelete example(connectstring);
    if (!example.init()) return EXIT_FAILURE;

    // Let's verify delete
    if (example.do_delete(key))
      std::cout << "Done, check your database:\n" << "\tSELECT * FROM ndbapi_examples.basic;\n" << "\tor run the example: ndb_ndbapi_basic_read" << std::endl;
    else return EXIT_FAILURE;
  }
  ndb_end(0);
  return EXIT_SUCCESS;
}
```
bool BasicDelete::do_delete(long long key)
{
    const NdbDictionary::Dictionary *dict = m_ndb.getDictionary();
    const NdbDictionary::Table *table = dict->getTable("basic");
    if (table == nullptr)
        return on_error(dict->getNdbError(),
                        "Failed to access 'ndbapi_examples.basic'");

    // The delete operation will be performed within single transaction
    NdbTransaction *transaction = m_ndb.startTransaction(table);
    if(transaction == nullptr)
        return on_error(m_ndb.getNdbError(), "Failed to start transaction");

    NdbOperation *operation = transaction->getNdbOperation(table);
    if(operation == nullptr)
        return on_error(transaction->getNdbError(),
                        "Failed to start delete operation");

    operation->deleteTuple();
    operation->equal("ATTR1", key);
    if (transaction->execute(NdbTransaction::Commit) != 0)
        return on_error(transaction->getNdbError(),
                        "Failed to execute transaction");

    m_ndb.closeTransaction(transaction);
    return true;
}

bool BasicDelete::init()
{
    if (m_connection.connect() != 0)
    {
        std::cout << "Cannot connect to cluster management server" << std::endl;
        return false;
    }

    if (m_connection.wait_until_ready(30, 0) != 0)
    {
        std::cout << "Cluster was not ready within 30 secs" << std::endl;
        return false;
    }

    if (m_ndb.init() != 0)
        return on_error(m_ndb.getNdbError(), "Failed to initialize ndb object");

    return true;
}

2.5.2 NDB API Example Using Synchronous Transactions

This example illustrates the use of synchronous transactions in the NDB API. It first creates a database
ndb_examples and a table api_simple (if these objects do not already exist) using the MySQL C API with an SQL node, then performs a series of basic data operations (insert, update, read, and select) on this table using the NDB API.

The compiled program takes two arguments:

1. The path to a MySQL socket file (mysql --socket option)
2. An NDB Cluster connection string (see NDB Cluster Connection Strings)

The correct output from this program is as follows:

<table>
<thead>
<tr>
<th>ATTR1</th>
<th>ATTR2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>10</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>
The source code for this example can be found in storage/ndb/ndbapi-examples/ndbapi_simple/ndbapi_simple.cpp in the NDB Cluster source tree, and is reproduced here:

```c++
#include <mysql.h>
#include <mysqld_error.h>
#include <NdbApi.hpp>
// Used for cout
#include <stdio.h>
#include <iostream>

static void run_application(MYSQL &, Ndb_cluster_connection &);

#define PRINT_ERROR(code,msg) \
   std::cout << "Error in " << __FILE__ << ", line: " << __LINE__ \ 
   << ", code: " << code \ 
   << ", msg: " << msg << "," << std::endl
#define MYSQLERROR(mysql) { \
   PRINT_ERROR(mysql_errno(&mysql),mysql_error(&mysql)); \
   exit(-1); } \
#define APIERROR(error) { \
   PRINT_ERROR(error.code,error.message); \
   exit(-1); }

int main(int argc, char** argv)
{
    if (argc != 3)
    {
        std::cout << "Arguments are <socket mysqld> <connect_string cluster>.
* \n        exit(-1);
    }
    // ndb_init must be called first
    ndb_init();

    // connect to mysql server and cluster and run application
    {
        char * mysqld_sock = argv[1];
        const char *connection_string = argv[2];
        // Object representing the cluster
        Ndb_cluster_connection cluster_connection(connection_string);

        // Connect to cluster management server (ndb_mgmd)
        if (cluster_connection.connect(4 /* retries */,
           5 /* delay between retries */,
           1 /* verbose */))
        {
            run_application(mysql, cluster_connection);
        }
    }
}
```

The source code contains a definition of `run_application(MYSQL &, Ndb_cluster_connection &)`, which is not shown in the snippet. The main function connects to a MySQL server and a cluster, and then calls `run_application` with an MySQL connection object and a Ndb_cluster_connection. The main function also handles error cases by printing error messages and exiting the program.
NDB API Example Using Synchronous Transactions

```cpp
{  
  std::cout << "Cluster management server was not ready within 30 secs.\n";  
  exit(-1);  
}

// Optionally connect and wait for the storage nodes (ndbd's)  
if (cluster_connection.wait_until_ready(30,0) < 0)  
{  
  std::cout << "Cluster was not ready within 30 secs.\n";  
  exit(-1);  
}

// connect to mysql server  
MYSQL mysql;  
if ( !mysql_init(&mysql) ) {  
  std::cout << "mysql_init failed\n";  
  exit(-1);  
}  
if ( !mysql_real_connect(&mysql, "localhost", "root", ",", ",", ",", ",", mysqld_sock, 0) )  
  MYSQLERROR(mysql);

// run the application code  
  run_application(mysql, cluster_connection);  
  mysql_close(&mysql);
}
ndb_end(0);
return 0;
}

static void create_table(MYSQL &mysql);  
static void do_insert(Ndb &);  
static void do_update(Ndb &);  
static void do_delete(Ndb &);  
static void do_read(Ndb &);  

static void run_application(MYSQL &mysql,  
Ndb_cluster_connection &cluster_connection)  
{
  /* Connect to database via mysql-c */  
  mysql_query(&mysql, "CREATE DATABASE ndb_examples");  
  if (mysql_query(&mysql, "USE ndb_examples") != 0) MYSQLERROR(mysql);  
  create_table(mysql);
  /* Connect to database via NDB API */  
  Ndb myNdb( &cluster_connection, "ndb_examples" );  
  if (myNdb.init()) APIERROR(myNdb.getNdbError());  
  /* Do different operations on database */  
do_insert(myNdb);  
do_update(myNdb);  
do_delete(myNdb);  
do_read(myNdb);
}

/* Create a table named api_simple if it does not exist */  
static void create_table(MYSQL &mysql)  
{  
  while (mysql_query(mysql,  
"CREATE TABLE"  
  " api_simple")  
  return 0;
}
```

483
NDB API Example Using Synchronous Transactions

```c
/* (ATTR1 INT UNSIGNED NOT NULL PRIMARY KEY," 
  ATTR2 INT UNSIGNED NOT NULL) */
{
  if (mysql_errno(&mysql) == ER_TABLE_EXISTS_ERROR)
  {
    std::cout << "NDB Cluster already has example table: api_simple. " 
    << "Dropping it..." << std::endl;
    mysql_query(&mysql, "DROP TABLE api_simple");
  }
}

/************************************************************************

2.5.3 NDB API Example Using Synchronous Transactions and Multiple Clusters

This example demonstrates synchronous transactions and connecting to multiple clusters in a single NDB API application.

The source code for this program may be found in the NDB Cluster source tree, in the file `storage/ndb/ndbapi-examples/ndbapi_simple_dual/main.cpp`.

Note

The example file was formerly named `ndbapi_simple_dual.cpp`.

```c
/*
*  ndbapi_simple_dual: Using synchronous transactions in NDB API
*  Correct output from this program is:
*  ATTR1 ATTR2
*    0    10
*    1     1
*    2    12
*  Detected that deleted tuple doesn't exist!
*    4    14
*    5     5
*    6    16
*    7     7
*    8    18
*    9     9
*  ATTR1 ATTR2
*    0    10
*    1     1
*    2    12
*  Detected that deleted tuple doesn't exist!
*    4    14
*    5     5
*    6    16
*    7     7
*    8    18
*    9     9
*

Prior to NDB 8.0, this program could not be run more than once in succession during the same session (Bug #27009386).
2.5.4 NDB API Example: Handling Errors and Retrying Transactions

This program demonstrates handling errors and retrying failed transactions using the NDB API.

The source code for this example can be found in `storage/ndb/ndbapi-examples/ndbapi_retries/ndbapi_retries.cpp` in the NDB Cluster source tree.

There are many ways to program using the NDB API. In this example, we perform two inserts in the same transaction using `NdbTransaction::execute(NoCommit)`.

In NDB API applications, there are two types of failures to be taken into account:

1. **Transaction failures**: If nonpermanent, these can be handled by re-executing the transaction.
2. **Application errors**: These are indicated by `APIERROR`; they must be handled by the application programmer.

```cpp
#include <mysql.h>
#include <mysqld_error.h>
#include <NdbApi.hpp>

// Used for cout
#include <iostream>

// Used for sleep (use your own version of sleep)
#include <unistd.h>
#define TIME_TO_SLEEP_BETWEEN_TRANSACTION_RETRIES 1

#define PRINT_ERROR(code,msg) 
  std::cout << "Error in " << __FILE__ << 
  "", line: " << __LINE__ 
  "", code: " << code 
  "", msg: " << msg << 
  std::endl

#define MYSQLERROR(mysql) { 
  PRINT_ERROR(mysql_errno(&mysql),mysql_error(&mysql)); 
  exit(-1); }

#define APIERROR(error) 
  { std::cout << "API ERROR: " << error.code << " " << error.message 
    " " << std::endl; 
    " " << "Status: " << error.status 
    " " << "Classification: " << error.classification << std::endl
    " " << "File: " << __FILE__ 
    " " << "Line: " << __LINE__ << "" << std::endl; 
  }

#define TRANSERROR(ndbTransaction) 
  { NdbError error = ndbTransaction->getNdbError(); 
    std::cout << "TRANS ERROR: " << error.code << " " << error.message 
    " " << std::endl; 
    " " << "Status: " << error.status 
    " " << "Classification: " << error.classification << std::endl; 
  }
```
NDB API Example: Handling Errors and Retrying Transactions

<< "
" << "File: " << __FILE__ \
<< " (Line: " << __LINE__ << ")" << std::endl \
; \
printTransactionError(ndbTransaction); \
}
void printTransactionError(NdbTransaction *ndbTransaction) {
const NdbOperation *ndbOp = NULL;
int i=0;
/****************************************************************
* Print NdbError object of every operations in the transaction *
****************************************************************/
while ((ndbOp = ndbTransaction->getNextCompletedOperation(ndbOp)) != NULL) {
NdbError error = ndbOp->getNdbError();
std::cout << "
OPERATION " << i+1 << ": "
<< error.code << " " << error.message << std::endl
<< "
Status: " << error.status
<< ", Classification: " << error.classification << std::endl;
i++;
}
}

}

2.5.5 NDB API Basic Scanning Example

This example illustrates how to use the NDB scanning API. It shows how to perform a scan, how to scan for an update, and how to scan for a delete, making use of the NdbScanFilter and NdbScanOperation classes.

The source code for this example may found in the NDB Cluster source tree, in the file storage/ndb/ndbapi-examples/ndbapi_scan/ndbapi_scan.cpp.

This example makes use of the following classes and methods:

- Ndb_cluster_connection:
  - connect()
  - wait_until_ready()

- Ndb:
  - init()
  - getDictionary()
  - startTransaction()
  - closeTransaction()

- NdbTransaction:
  - getNdbScanOperation()
  - execute()

- NdbOperation:
  - insertTuple()
  - equal()
  - getValue()
  - setValue()

- NdbScanOperation:
  - readTuples()
  - nextResult()
  - deleteCurrentTuple()
  - updateCurrentTuple()

- NdbDictionary:
  - Dictionary::getTable()
NDB API Basic Scanning Example

- `Table::getColumn()`
- `Column::getLength()`
- `NdbScanFilter`:
  - `begin()`
  - `eq()`
  - `end()`

```c
/*

2.5.6 NDB API Example: Using Secondary Indexes in Scans

This program illustrates how to use secondary indexes in the NDB API.

The source code for this example may be found in the NDB Cluster source tree, in storage/ndb/ndbapi-examples/ndbapi_simple_index/main.cpp.

Note
This file was previously named ndbapi_simple_index.cpp.

The correct output from this program is shown here:

ATTR1 ATTR2
0   10
1   1
2   12
Detected that deleted tuple doesn't exist!
4   14
5   5
6   16
7   7
8   18
9   9

The listing for this program is shown here:

```cpp
#include <mysql.h>
#include <mysqld_error.h>
#include <NdbApi.hpp>
// Used for cout
#include <stdio.h>
#include <iostream>
#define PRINT_ERROR(code,msg) \
    std::cout << "Error in " << __FILE__ << ", line: " << __LINE__ \
    << ", code: " << code << " msg: " << msg << " " << std::endl
#define MYSQLERROR(mysql) { \

2.5.8 NDB API Example Comparing RecAttr and NdbRecord

This example illustrates the key differences between the old-style `NdbRecAttr` API and the newer approach using `NdbRecord` when performing some common tasks in an NDB API application.

The source code can be found can be found in the file `storage/ndb/ndbapi-examples/ndbapi_recattr_vs_record/main.cpp` in the NDB Cluster source tree.

```cpp
#include <mysql.h>
#include <NdbApi.hpp>
// Used for cout
#include <stdio.h>
#include <iostream>

// Do we use old-style (NdbRecAttr?) or new style (NdbRecord?)
enum ApiType {api_attr, api_record};

static void run_application(MYSQL &, Ndb_cluster_connection &, ApiType);

#define PRINT_ERROR(code,msg) \
    std::cout << "Error in " << __FILE__ \
             << ", line: " << __LINE__ \
             << ", code: " << code \
             << ", msg: " << msg << "." << std::endl
#define MYSQLERROR(mysql) { \
    PRINT_ERROR(mysql_errno(&mysql),mysql_error(&mysql)); \
    exit(-1); }
#define APIERROR(error) { \
    PRINT_ERROR(error.code,error.message); \
    exit(-1); }

int main(int argc, char** argv)
{
    if (argc != 4)
    {
        std::cout << "Arguments are <socket mysqld> " \
                 << "<connect_string cluster> <attr|record>.\n";
        exit(-1);
    }
    // ndb_init must be called first
    ndb_init();

    // connect to mysql server and cluster and run application
    {
        char * mysqld_sock = argv[1];
```

NDB API Example: Basic BLOB Handling

This example illustrates the manipulation of a blob column in the NDB API. It demonstrates how to perform insert, read, and update operations, using both inline value buffers as well as read and write methods.

The source code can be found in the file `storage/ndb/ndbapi-examples/ndbapi_blob/ndbapi_blob.cpp` in the NDB Cluster source tree.

Note

While the MySQL data type used in the example is actually TEXT, the same principles apply.

/*
   ndbapi_blob.cpp:
   Illustrates the manipulation of BLOB (actually TEXT in this example).
   Shows insert, read, and update, using both inline value buffer and read/write methods.
*/

/* Quote taken from Project Gutenberg. */
const char *text_quote=
"Just at this moment, somehow or other, they began to run.

  Alice never could quite make out, in thinking it over
afterwards, how it was that they began: all she remembers is,
that they were running hand in hand, and the Queen went so fast
that it was all she could do to keep up with her: and still the
Queen kept crying 'Faster! Faster!' but Alice felt she COULD NOT
'go faster, though she had not breath left to say so."

  The most curious part of the thing was, that the trees and the
other things round them never changed their places at all:
however fast they went, they never seemed to pass anything. 'I
wonder if all the things move along with us?' thought poor
puzzled Alice. And the Queen seemed to guess her thoughts, for
'she cried, 'Faster! Don't try to talk!'"

  Not that Alice had any idea of doing THAT. She felt as if she
would never be able to talk again, she was getting so much out of
breath: and still the Queen cried 'Faster! Faster!' and dragged
her along. 'Are we nearly there?' Alice managed to pant out at
'Last."

  'Nearly there!' the Queen repeated. 'Why, we passed it ten
minutes ago! Faster!' And they ran on for a time in silence,
with the wind whistling in Alice's ears, and almost blowing her
'hair off her head, she fancied."

  'Now! Now!' cried the Queen. 'Faster! Faster!' And they
'spent so fast that at last they seemed to skim through the air."
'hardly touching the ground with their feet, till suddenly, just
as Alice was getting quite exhausted, they stopped, and she found
'herself sitting on the ground, breathless and giddy."

  The Queen propped her up against a tree, and said kindly, 'You
'may rest a little now.'"

  Alice looked round her in great surprise. 'Why, I do believe
'we've been under this tree the whole time! Everything's just as"
 'it was!"

  'Of course it is,' said the Queen, 'what would you have it?'"

  'Well, in OUR country,' said Alice, still panting a little,"
you'd generally get to somewhere else--if you ran very fast"
'for a long time, as we've been doing.'"

  'A slow sort of country!' said the Queen. 'Now, HERE, you see,"
it takes all the running YOU can do, to keep in the same place."
'If you want to get somewhere else, you must run at least twice as"
'fast as that!'"

  'I'd rather not try, please!' said Alice. 'I'm quite content"
'to stay here--only I AM so hot and thirsty!'"

2.5.11 NDB API Example: Handling BLOB Columns and Values Using NdbRecord

This example illustrates the manipulation of a blob column in the NDB API using the NdbRecord interface. It demonstrates how to perform insert, read, and update operations, using both inline value buffers as well as read and write methods. It can be found in the file storage/ndb/ndbapi-examples/ndbapi_blob_ndbrecord/main.cpp in the NDB Cluster source trees.

Note

While the MySQL data type used in the example is actually TEXT, the same principles apply.

ndbapi_blob_ndbrecord

Illustrates the manipulation of BLOB (actually TEXT in this example). This example uses the NdbRecord style way of accessing tuples.
NDB API Example: Handling BLOB Columns and Values Using NdbRecord

Shows insert, read, and update, using both inline value buffer and read/write methods.

/* Quote taken from Project Gutenberg. */
const char *text_quote="Just at this moment, somehow or other, they began to run.

  Alice never could quite make out, in thinking it over afterwards, how it was that they began: all she remembers is, that they were running hand in hand, and the Queen went so fast that it was all she could do to keep up with her: and still the Queen kept crying 'Faster! Faster!' but Alice felt she COULD NOT go faster, though she had not breath left to say so.

  The most curious part of the thing was, that the trees and the other things round them never changed their places at all: however fast they went, they never seemed to pass anything. 'I wonder if all the things move along with us?' thought poor puzzled Alice. And the Queen seemed to guess her thoughts, for she cried, 'Faster! Don't try to talk!'

  Not that Alice had any idea of doing THAT. She felt as if she would never be able to talk again, she was getting so much out of breath: and still the Queen cried 'Faster! Faster!' and dragged her along. 'Are we nearly there?' Alice managed to pant out at last.

  'Nearly there!' the Queen repeated. 'Why, we passed it ten minutes ago! Faster!' And they ran on for a time in silence, with the wind whistling in Alice's ears, and almost blowing her hair off her head, she fancied.

  'Now! Now!' cried the Queen. 'Faster! Faster!' And they went so fast that at last they seemed to skim through the air, hardly touching the ground with their feet, till suddenly, just as Alice was getting quite exhausted, they stopped, and she found herself sitting on the ground, breathless and giddy.

  The Queen propped her up against a tree, and said kindly, 'You may rest a little now.' Alice looked round her in great surprise. 'Why, I do believe we've been under this tree the whole time! Everything's just as you said.'

2.5.12 NDB API Simple Array Example

This program inserts CHAR, VARCHAR, and BINARY column data into a table by constructing aRef objects using local functions. It then reads the columns back and extracts the data from them using local functions.

This example assumes you have a table named api_array_simple, created as follows:

```sql
CREATE TABLE api_array_simple (  
    ATTR1 INT UNSIGNED NOT NULL PRIMARY KEY,  
    ATTR2 CHAR(20) NOT NULL,  
    ATTR3 VARCHAR(20) NOT NULL,  
    ATTR4 VARCHAR(500) NOT NULL,  
    ATTR5 BINARY(20) NOT NULL,  
    ATTR6 VARBINARY(20) NOT NULL,  
    ATTR7 VARBINARY(500) NOT NULL  
) ENGINE NDB CHARSET latin1;
```

Note

This program uses a number of utilities which can be found in storage/ndb/ndbapi-examples/common/. See Section 2.5.15, “Common Files for NDB API Array Examples”, for listings of these.

The example file can be found as ndbapi_array_simple/ndbapi_array_simple.cpp in the NDB Cluster source distribution's storage/ndb/ndbapi-examples directory. (Bug #70550, Bug #17592990)

Prior to NDB 8.0, this program could not be run more than once in succession during the same session (Bug #27009386).

### 2.5.13 NDB API Simple Array Example Using Adapter

This program inserts *CHAR*, *VARCHAR*, and *BINARY* column data into a table by constructing aRef objects using array adapters of the type defined in *common/array_adapter.hpp* (see Section 2.5.15, “Common Files for NDB API Array Examples”). It then reads the columns back and extracts the data, again using array adapters.

The example uses the table shown here:

```sql
CREATE TABLE api_array_using_adapter (
    ATTR1 INT UNSIGNED NOT NULL PRIMARY KEY,
    ATTR2 CHAR(20) NOT NULL,
    ATTR3 VARCHAR(20) NOT NULL,
    ATTR4 VARCHAR(500) NOT NULL,
    ATTR5 BINARY(20) NOT NULL,
    ATTR6 VARBINARY(20) NOT NULL,
    ATTR7 VARBINARY(500) NOT NULL,
) ENGINE NDB CHARSET latin1;
```

The example file can be found as *ndbapi_array_using_adapter/ndbapi_array_using_adapter.cpp* in the NDB Cluster source distribution's *storage/ndb/ndbapi-examples* directory. (Bug #70550, Bug #17592990)

```cpp
#include "NdbApi.hpp"
#include <iostream>
```
#include <vector>
#include <cstdlib>
#include <cstring>
using namespace std;

/*
   See Section 2.5.15, "Common Files for NDB API Array Examples",
   for listings of these utilities.
*/
#include "../common/error_handling.hpp"
#include "../common/array_adapter.hpp"
#include "../common/ndb_util.hpp"
#include "../common/util.hpp"

2.5.15 Common Files for NDB API Array Examples

In the NDB Cluster source distribution, the storage/ndb/ndbapi-examples directory contains four header files with utilities for use in example NDB API programs. (Bug #70550, Bug #17592990) The names of these files are listed here:

- **array_adapter.hpp**: Contains utility classes for converting between C++ style strings or byte arrays and the format used by NDB internally for VARCHAR, CHAR, and VARBINARY types.
- **error_handling.hpp**: Contains error handling functions.
- **ndb_util.hpp**: Defines a column_type_to_string() function which handles NDB column types.
- **util.hpp**: Provides a method for generating strings of arbitrary length.

Following in this section are source listings for each of the header files.

**array_adapter.hpp**

```cpp
#ifndef ARRAY_ADAPTER_HPP
#define ARRAY_ADAPTER_HPP

#include <algorithm>
#include <assert.h>

/*
Utility classes to convert between C++ strings/byte arrays and the internal format used for [VAR]CHAR/BINARY types.

Base class that can be used for read operations. The column type is taken from the NdbRecAttr object, so only one object is needed to convert from different [VAR]CHAR/BINARY types. No additional memory is allocated.
*/

class ReadOnlyArrayAdapter {
public:
  ReadOnlyArrayAdapter() {}

  enum ErrorType {Success,
                 InvalidColumnType,
                 InvalidArrayType,
                 InvalidNullColumn,
                 InvalidNullAttribute,
                 InvalidNullRef,
                 BytesOutOfRange,
                 UnknownError};

  /*
  Return a C++ string from the aRef() value of attr. This value will use the column and column type from attr. The advantage is for reading; the same ArrayAdapter can be used for multiple columns. The disadvantage is; passing an attribute not of [VAR]CHAR/BINARY type will result in a traditional exit(-1)
  */
  std::string get_string(const NdbRecAttr* attr,
                        ErrorType& error) const;

This chapter discusses the NDB Cluster Management API, a C language API that is used for administrative tasks such as starting and stopping Cluster nodes, backups, and logging. It also covers MGM API concepts, programming constructs, and event types.

For information about general requirements for compiling MGM API applications, see Section 2.1.1.1, “General Requirements”.

3.1 MGM API Concepts

This section describes concepts basic to the NDB Cluster MGM API.

- NdbMgmHandle
- Working with Log Events
- Structured Log Events

**NdbMgmHandle**

Each MGM API function needs a management server handle of type NdbMgmHandle. This handle is created by calling the function ndb_mgm_create_handle() and freed by calling ndb_mgm_destroy_handle().

See ndb_mgm_create_handle(), and ndb_mgm_destroy_handle(), for more information about these two functions.

---

**Important**

You should not share an NdbMgmHandle between threads. While it is possible to do so (if you implement your own locks), this is not recommended; each thread should use its own management server handle.

A function can return any of the following:

- An integer value, with a value of -1 indicating an error.
• A nonconstant pointer value. A **NULL** value indicates an error; otherwise, the return value must be freed by the programmer.

• A constant pointer value, with a **NULL** value indicating an error. The returned value should not be freed.

Error conditions can be identified by using the appropriate error-reporting functions `ndb_mgm_get_latest_error()` and `ndb_mgm_error()`.

Here is an example using the MGM API (without error handling for brevity’s sake):

```c
NdbMgmHandle handle = ndb_mgm_create_handle();
ndb_mgm_connect(handle, 0, 0, 0);
struct ndb_mgm_cluster_state *state = ndb_mgm_get_status(handle);
for(int i=0; i < state->no_of_nodes; i++)
{
    struct ndb_mgm_node_state *node_state = &state->node_states[i];
    if(node_state->version != 0)
        printf("node with ID=%d connected\n", node_state->node_id);
    else
        printf("not connected\n");
}
free((void*)state);
ndb_mgm_destroy_handle(&handle);
```

Working with Log Events

Data nodes and management servers both regularly and on specific occasions report on various log events that occur in the cluster. These log events are written to the cluster log. Optionally an MGM API client may listen to these events using the method `ndb_mgm_listen_event()`. Each log event belongs to a category `ndb_mgm_event_category` and has a severity `ndb_mgm_event_severity` associated with it. Each log event also has a level (0-15) associated with it.

Which log events that come out is controlled with `ndb_mgm_listen_event()`, `ndb_mgm_set_clusterlog_loglevel()`, and `ndb_mgm_set_clusterlog_severity_filter()`.

This is an example showing how to listen to events related to backup:

```c
int filter[] = { 15, NDB_MGM_EVENT_CATEGORY_BACKUP, 0 };
int fd = ndb_mgm_listen_event(handle, filter);
```

Structured Log Events

Handling of structured log events in the MGM API involves the following steps:

1. Create an `NdbLogEventHandle` using `ndb_mgm_create_logevent_handle()`.

2. Wait for and store log events using `ndb_logevent_get_next()`.

3. The log event data is available in the structure `ndb_logevent`. The data which is specific to a particular event is stored in a union between structures; use `ndb_logevent::type` to decide which structure is valid.

The following sample code demonstrates listening to events related to backups:

```c
int filter[] = { 15, NDB_MGM_EVENT_CATEGORY_BACKUP, 0 };
NdbLogEventHandle le_handle = ndb_mgm_create_logevent_handle(handle, filter);
struct ndb_logevent le;
int r = ndb_logevent_get_next(le_handle, &le, 0);
if(r < 0)
    /* error */
else if(r == 0)
    /* no event */
```
switch(le.type)
{
    case NDB_LE_BackupStarted:
        ... le.BackupStarted.starting_node;
        ... le.BackupStarted.backup_id;
        break;
    case NDB_LE_BackupFailedToStart:
        ... le.BackupFailedToStart.error;
        break;
    case NDB_LE_BackupCompleted:
        ... le.BackupCompleted.stop_gci;
        break;
    case NDB_LE_BackupAborted:
        ... le.BackupStarted.backup_id;
        break;
    default:
        break;
}

For more information, see Section 3.2.1, "Log Event Functions".

Available log event types are listed in The Ndb_logevent_type Type, as well as in the file /storage/ndb/include/mgmapi/ndb_logevent.h in the NDB Cluster sources.

3.2 MGM API Function Listings

The next few sections provide information about the functions and data structures used by the MGM API. These listings are grouped by purpose or use.

3.2.1 Log Event Functions

This section provides information about MGM API functions used for listening to log events.

- ndb_mgm_listen_event()
- ndb_mgm_create_logevent_handle()
- ndb_mgm_destroy_logevent_handle()
- ndb_logevent_get_fd()
- ndb_logevent_get_next()
- ndb_logevent_get_next2()
- ndb_logevent_get_latest_error()
- ndb_logevent_get_latest_error_msg()

**ndb_mgm_listen_event()**

**Description**

This function is used to listen to log events, which are read from the return file descriptor. Events use a text-based format, the same as in the cluster log.

**Signature**

```c
int ndb_mgm_listen_event
    (NdbMgmHandle handle,
     const int filter[])
```

**Parameters**

This function takes two arguments:

**ndb_mgm_create_logevent_handle() does not support TLS. You can use ndb_mgm_create_logevent_handle(), which does.**
Log Event Functions

- An `NdbMgmHandle handle`.
- A `filter` which consists of a series of `{level, ndb_mgm_event_category}` pairs (in a single array) that are pushed to a file descriptor. Use 0 for the level to terminate the list.

Return value

The file descriptor from which events are to be read.

**ndb_mgm_create_logevent_handle()**

Description

This function is used to create a log event handle.

Signature

```c
NdbLogEventHandle ndb_mgm_create_logevent_handle
(NdbMgmHandle handle,
const int filter[])
```

Parameters

This function takes two arguments:

- An `NdbMgmHandle handle`.
- A `filter` which consists of a series of `{level, ndb_mgm_event_category}` pairs (in a single array) that are pushed to a file descriptor. Use 0 for the level to terminate the list.

Return value

A log event handle.

**ndb_mgm_destroy_logevent_handle()**

Description

Use this function to destroy a log event handle when there is no further need for it.

Signature

```c
void ndb_mgm_destroy_logevent_handle
(NdbLogEventHandle* handle)
```

Parameters

A pointer to a log event `handle`.

Return value

`None`.

**ndb_logevent_get_fd()**

Description

This function retrieves a file descriptor from an `NdbMgmLogEventHandle`; this descriptor can be used in (for example) an application `select()` call.

**Warning**

Do not attempt to read from the file descriptor returned by this function; this can cause the descriptor to become corrupted.

Signature

```c
int ndb_logevent_get_fd
(const NdbLogEventHandle handle)
```

Parameters

A `LogEventHandle`.

Return value

A file descriptor. In the event of failure, `-1` is returned.

**ndb_logevent_get_next()**
Log Event Functions

Description
This function is used to retrieve the next log event, using data from the event to fill in the supplied `ndb_logevent` structure.

Signature
```
int ndb_logevent_get_next
{
    const NdbLogEventHandle handle,
    struct ndb_logevent* logevent,
    unsigned timeout
}
```

Important
The log event's `ndb_mgm_event_category` is cast to an enum type. For an equivalent function that does not perform this cast, use `ndb_logevent_get_next2()` instead.

Parameters
Three parameters are expected by this function:

- An `NdbLogEventHandle`
- A pointer to an `ndb_logevent` data structure
- The number of milliseconds to wait for the event before timing out; passing 0 for this parameter causes the function to block until the next log event is received

Return value
The value returned by this function is interpreted as follows: If the return value is less than or equal to zero, then the `logevent` is not altered or affected in any way.

- > 0: The event exists, and it data was retrieved into the `logevent`
- 0: A timeout occurred while waiting for the event (more than `timeout` milliseconds elapsed)
- < 0: An error occurred.

ndb_logevent_get_next2()

Description
This function is used to retrieve the next log event, using data from the event to fill in the supplied `ndb_logevent` structure.

`ndb_logevent_get_next2()` corrects the `ndb_logevent_get_next()` function's handling of the structure's `ndb_mgm_event_category`, for applications which do not require backward compatibility. It is otherwise identical to `ndb_logevent_get_next()`.

Signature
```
int ndb_logevent_get_next2
{
    const NdbLogEventHandle handle,
    struct ndb_logevent* logevent,
    unsigned timeout
}
```

Parameters
Three parameters are expected by this function:

- An `NdbLogEventHandle`
- A pointer to an `ndb_logevent` data structure
- The number of milliseconds to wait for the event before timing out; passing 0 for this parameter causes the function to block until the next log event is received
Return value

The value returned by this function is interpreted as follows: If the return value is less than or equal to zero, then the \textit{logevent} is not altered or affected in any way.

- \( > 0 \): The event exists, and its data was retrieved into the \textit{logevent}.
- \( 0 \): A timeout occurred while waiting for the event (more than \textit{timeout} milliseconds elapsed).
- \( < 0 \): An error occurred.

\textbf{ndb\_logevent\_get\_latest\_error()}

\textbf{Description}

This function retrieves the error code from the most recent error.

\textbf{Note}

You may prefer to use \textit{ndb\_logevent\_get\_latest\_error\_msg()} instead. See \textit{ndb\_logevent\_get\_latest\_error\_msg()}.

\textbf{Signature}

\begin{verbatim}
int ndb\_logevent\_get\_latest\_error
(const NdbLogEventHandle handle)
\end{verbatim}

\textbf{Parameters}

A log event handle.

\textbf{Return value}

An error code.

\textbf{ndb\_logevent\_get\_latest\_error\_msg()}

\textbf{Description}

Retrieves the text of the most recent error obtained while trying to read log events.

\textbf{Signature}

\begin{verbatim}
const char* ndb\_logevent\_get\_latest\_error\_msg
(const NdbLogEventHandle handle)
\end{verbatim}

\textbf{Parameters}

A log event handle.

\textbf{Return value}

The text of the error message.

\subsection*{3.2.2 MGM API Error Handling Functions}

This section provides information about MGM API functions used for error handling.

Each MGM API error is characterised by an error code and an error message. There may also be an error description that provides additional information about the error. The MGM API includes functions to obtain this information in the event of an error.

- \textit{ndb\_mgm\_get\_latest\_error()}
- \textit{ndb\_mgm\_get\_latest\_error\_msg()}
- \textit{ndb\_mgm\_get\_latest\_error\_desc()}
- \textit{ndb\_mgm\_set\_error\_stream()}

\textbf{ndb\_mgm\_get\_latest\_error()}

\textbf{Description}

This function is used to get the latest error code associated with a given management server handle.
MGM API Error Handling Functions

Prior to NDB 7.4.8, this function was not safe for use with NULL. In later versions, `ndb_mgm_get_latest_error()` is null-safe but returns an arbitrary value. (Bug #78130, Bug #21651706)

**Signature**

```c
int ndb_mgm_get_latest_error(
    const NdbMgmHandle handle
)
```

**Parameters**

An `NdbMgmHandle`.

**Return value**

An error code corresponding to an `ndb_mgm_error` value. You can obtain the related error message using `ndb_mgm_get_latest_error_msg()`.

**ndb_mgm_get_latest_error_msg()**

**Description**

This function is used to obtain the latest general error message associated with an `NdbMgmHandle`.

Prior to NDB 7.4.8, this function was not safe for use with NULL. In later versions, `ndb_mgm_get_latest_error_msg()` is null-safe but returns an arbitrary value. (Bug #78130, Bug #21651706)

**Signature**

```c
const char* ndb_mgm_get_latest_error_msg(
    const NdbMgmHandle handle
)
```

**Parameters**

An `NdbMgmHandle`.

**Return value**

The error message text. More specific information can be obtained using `ndb_mgm_get_latest_error_desc()`.

**ndb_mgm_get_latest_error_desc()**

**Description**

Get the most recent error description associated with an `NdbMgmHandle`; this description provides additional information regarding the error message.

Prior to NDB 7.4.8, this function was not safe for use with NULL. In later versions, `ndb_mgm_get_latest_error_desc()` is null-safe but returns an arbitrary value. (Bug #78130, Bug #21651706)

**Signature**

```c
const char* ndb_mgm_get_latest_error_desc(
    const NdbMgmHandle handle
)
```

**Parameters**

An `NdbMgmHandle`.

**Return value**

The error description text.

**ndb_mgm_set_error_stream()**

**Description**

The function can be used to set the error output stream.

**Signature**

```c
void ndb_mgm_set_error_stream(
    NdbMgmHandle handle,
    FILE* file
)
```

**Parameters**

This function requires two parameters:
### 3.2.3 Management Server Handle Functions

This section provides information about MGM API functions used to create and destroy management server handles (see `NdbMgmHandle`).

- `ndb_mgm_create_handle()`
- `ndb_mgm_set_name()`
- `ndb_mgm_set_ignore_sigpipe()`
- `ndb_mgm_destroy_handle()`

**ndb_mgm_create_handle()**

*Description* This function is used to create a handle to a management server.

*Signature*

```c
NdbMgmHandle ndb_mgm_create_handle
{
    void
}
```

*Parameters* None.

*Return value* An `NdbMgmHandle`.

**ndb_mgm_set_name()**

*Description* This function can be used to set a name for the management server handle, which is then reported in the Cluster log.

*Signature*

```c
void ndb_mgm_set_name
{
    NdbMgmHandle handle,
    const char* name
}
```

*Parameters* This function takes two arguments:

- A management server `handle`.
- The desired `name` for the `handle`.

*Return value* None.

**ndb_mgm_set_ignore_sigpipe()**

*Description* The MGM API by default installs a signal handler that ignores all `SIGPIPE` signals that might occur when writing to a socket that has been closed or reset. An application that provides its own handler for `SIGPIPE` should call this function after creating the management server handle and before using the handle to connect to the management server. (In other words, call this function after using `ndb_mgm_create_handle()` but before calling `ndb_mgm_connect()`, which causes the MGM API's `SIGPIPE` handler to be installed unless overridden.)
### Management Server Connection Functions

**ndb_mgm_set_ignore_sigpipe**

**Signature**

```c
int ndb_mgm_set_ignore_sigpipe
{
    NdbMgmHandle handle,
    int ignore = 1
}
```

**Parameters**

This function takes two parameters:

- A management server handle
- An integer value which determines whether to *ignore* SIGPIPE errors. Set this to 1 (the default) to cause the MGM API to ignore SIGPIPE; set to zero if you wish for SIGPIPE to propagate to your MGM API application.

**Return value**

`None`.

**ndb_mgm_destroy_handle()**

**Description**

This function destroys a management server handle.

**Signature**

```c
void ndb_mgm_destroy_handle
{
    NdbMgmHandle* handle
}
```

**Parameters**

A pointer to the `NdbMgmHandle` to be destroyed.

**Return value**

`None`.

### 3.2.4 Management Server Connection Functions

This section provides information about MGM API functions that are used to initiate, configure, and terminate connections to an NDB management server.

- `ndb_mgm_get_connectstring()`
- `ndb_mgm_get_configuration_nodeid()`
- `ndb_mgm_get_connected_port()`
- `ndb_mgm_get_connected_host()`
- `ndb_mgm_get_version()`
- `ndb_mgm_is_connected()`
- `ndb_mgm_check_connection()`
- `ndb_mgm_number_of_mgmd_in_connect_string()`
- `ndb_mgm_set_bindaddress()`
- `ndb_mgm_set_connectstring()`
- `ndb_mgm_set_configuration_nodeid()`
- `ndb_mgm_set_timeout()`
- `ndb_mgm_connect()`
- `ndb_mgm_disconnect()`

**ndb_mgm_get_connectstring()**

**Description**

This function retrieves the connection string used for a connection.
**Management Server Connection Functions**

---

**Note**

This function returns the default connection string if no call to `ndb_mgm_set_connectstring()` has been performed. In addition, the returned connection string may be formatted slightly differently than the original in that it may contain specifiers not present in the original.

The connection string format is the same as that discussed for `ndb_mgm_set_connectstring()`.

**Signature**

```c
const char* ndb_mgm_get_connectstring
{
    NdbMgmHandle handle,
    char*   buffer,
    int     size
}
```

**Parameters**

This function takes three arguments:

- An `NdbMgmHandle`.
- A pointer to a `buffer` in which to place the result.
- The `size` of the buffer.

**Return value**

The connection string—this is the same value that is pushed to the `buffer`.

---

**ndb_mgm_get_configuration_nodeid()**

**Description**

This function gets the ID of the node to which the connection is being (or was) made.

**Signature**

```c
int ndb_mgm_get_configuration_nodeid
{
    NdbMgmHandle handle
}
```

**Parameters**

A management server handle.

**Return value**

A node ID.

---

**ndb_mgm_get_connected_port()**

**Description**

This function retrieves the number of the port used by the connection.

**Signature**

```c
int ndb_mgm_get_connected_port
{
    NdbMgmHandle handle
}
```

**Parameters**

An `NdbMgmHandle`.

**Return value**

A port number.

---

**ndb_mgm_get_connected_host()**

**Description**

This function is used to obtain the name of the host to which the connection is made.

**Signature**

```c
const char* ndb_mgm_get_connected_host
{
    NdbMgmHandle handle
}
```
Management Server Connection Functions

**ndb_mgm_get_version()**

**Description**
Given a management server handle, this function gets NDB engine and MySQL Server version information for the indicated management server.

**Signature**
```c
int ndb_mgm_get_version(
    NdbMgmHandle handle,
    int* major,
    int* minor,
    int* build,
    int length,
    char* string
)
```

**Parameters**
- An `NdbMgmHandle`, and pointers to the NDB engine `major`, `minor`, and `build` version values, as well as a pointer to the version `string` (along with the strength's `length`).

The version string uses the format `mysql-x.x.x ndb-y.y.y-status`, where `x.x.x` is the three-part MySQL Server version, and `y.y.y` is the three-part NDB storage engine version. The `status` string indicates the release level or status; usually this is one of `beta`, `rc`, or `ga`, but other values are sometimes possible.

**Return value**
`ndb_mgm_get_version()` returns an integer: 0 on success; any nonzero value indicates an error.

**ndb_mgm_is_connected()**

**Description**
Used to determine whether a connection has been established.

**Note**
This function does not determine whether or not there is a “live” management server at the other end of the connection. Use `ndb_mgm_check_connection()` to accomplish that task.

**Signature**
```c
int ndb_mgm_is_connected(
    NdbMgmHandle handle
)
```

**Parameters**
- A management server `handle`.

**Return value**
This function returns an integer, whose value is interpreted as follows:
- 0: Not connected to the management node.
- Any nonzero value: A connection has been established with the management node.

**ndb_mgm_check_connection()**

**Description**
This function can be used to determine whether a management server is running on a given connection from a management client.
Management Server Connection Functions

NdbMgmHandle handle

Parameters
An NdbMgmHandle (see Section 3.1, “MGM API Concepts”).

Return value
In NDB 7.5 and later, this function returns 0 on success, -1 when the handle is null, and -2 when not connected.

In NDB 7.4 and earlier, this function returned -1 in the event of an error; otherwise it returned 0, even when the management server handle was NULL, or when the connection check failed (Bug #53242, Bug #11760802).

ndb_mgm_number_of_mgmd_in_connect_string()

Description
This is a convenience function which provides an easy way to determine the number of management servers referenced in a connection string as set using ndb_mgm_set_connectstring().

Signature
int ndb_mgm_number_of_mgmd_in_connect_string
{
    NdbMgmHandle handle
}

Parameters
A management handle (NdbMgmHandle).

Return value
On success, a nonnegative integer; a negative integer indicates failure.

ndb_mgm_set_bindaddress()

Description
This function makes it possible to set a local bind address for the management server. If used, it must be called before connecting to the management server.

Signature
int ndb_mgm_set_bindaddress
{
    NdbMgmHandle handle,
    const char* address
}

Parameters
This function takes two parameters:

• A management handle (NdbMgmHandle).

• A string address of the form host[:port].

Return value
Returns an integer:

• 0 indicates success

• Any nonzero value indicates failure (the address was not valid)

Important
Errors caused by binding an otherwise valid local address are not reported until the connection to the management is actually attempted.

ndb_mgm_set_connectstring()

Description
This function is used to set the connection string for a management server connection to a node.
Management Server Connection Functions

**ndb_mgm_set_connectstring**

**Signature**

```c
int ndb_mgm_set_connectstring(
    NdbMgmHandle handle,
    const char* connection_string
)
```

**Parameters**

`ndb_mgm_set_connectstring()` takes two parameters:

- A management server `handle`.
- A `connection_string` whose format is shown here:

  ```
  connection_string :=
  [nodeid-specification,]host-specification[,host-specification]
  ```

  `ndb_mgm_get_connectstring()` also uses this format for connection strings.

  It is possible to establish connections with multiple management servers using a single connection string.

  ```
  nodeid-specification := nodeid=id
  host-specification := host[:port]
  ```

  `id`, `port`, and `host` are defined as follows:

  - `id`: An integer greater than 0 identifying a node in `config.ini`.
  - `port`: An integer referring to a standard Unix port.
  - `host`: A string containing a valid network host address.

**Return value**

This function returns -1 in the event of failure.

**ndb_mgm_set_configuration_nodeid()**

**Description**

This function sets the connection node ID.

**Signature**

```c
int ndb_mgm_set_configuration_nodeid(
    NdbMgmHandle handle,
    int id
)
```

**Parameters**

This function requires two parameters:

- An `NdbMgmHandle`.
- The `id` of the node to connect to.

**Return value**

This function returns -1 in the event of failure.

**ndb_mgm_set_timeout()**

**Description**

Normally, network operations time out after 60 seconds. This function permits you to vary this time.

**Important**

The timeout set by this function applies not only to establishing network connections, but to every operation requiring communication using a network connection. This includes each network read or write performed by any MGM API function, NDB API method call, or `ndb_mgm` client command.
Cluster Status Functions

### ndb_mgm_set_timeout()

**Signature**

```c
int ndb_mgm_set_timeout
{
    NdbMgmHandle handle,
    unsigned int timeout
}
```

**Parameters**

This function takes two parameters:

- A management server handle (`NdbMgmHandle`).
- An amount of time to wait before timing out, expressed in milliseconds.

**Return value**

Returns 0 on success, with any other value representing failure.

### ndb_mgm_connect()(

**Description**

This function establishes a connection to a management server specified by the connection string set by `ndb_mgm_set_connectstring()`.

**Signature**

```c
int ndb_mgm_connect
{
    NdbMgmHandle handle,
    int retries,
    int delay,
    int verbose
}
```

**Parameters**

This function takes 4 arguments:

- A management server `handle`.
- The number of `retries` to make when attempting to connect. 0 for this value means that one connection attempt is made.
- The number of seconds to `delay` between connection attempts.
- If `verbose` is 1, then a message is printed for each connection attempt.

**Return value**

This function returns -1 in the event of failure.

### ndb_mgm_disconnect()

**Description**

This function terminates a management server connection.

**Signature**

```c
int ndb_mgm_disconnect
{
    NdbMgmHandle handle
}
```

**Parameters**

An `NdbMgmHandle`.

**Return value**

Returns -1 if unable to disconnect.

### 3.2.5 Cluster Status Functions

This section provides information about MGM API functions used to obtain status information from NDB Cluster nodes.

- `ndb_mgm_get_status()`
- `ndb_mgm_get_status2()`
Cluster Status Functions

- **ndb_mgm_get_status3()**
- **ndb_mgm_dump_state()**

**ndb_mgm_get_status()**

**Description**

This function is used to obtain the status of the nodes in an NDB Cluster.

**Note**

The caller must free the pointer returned by this function.

**Signature**

```c
struct ndb_mgm_cluster_state* ndb_mgm_get_status(NdbMgmHandle handle)
```

**Parameters**

This function takes a single parameter, a management server `handle`.

**Return value**

A pointer to an `ndb_mgm_cluster_state` data structure.

**ndb_mgm_get_status2()**

**Description**

This function is similar to `ndb_mgm_get_status()`, in that it is used to obtain the status of the nodes in an NDB Cluster. However, `ndb_mgm_get_status2()` allows one to specify the type or types of nodes (`ndb_mgm_node_type`) to be checked.

**Note**

The caller must free the pointer returned by this function.

**Signature**

```c
struct ndb_mgm_cluster_state* ndb_mgm_get_status2(NdbMgmHandle handle, const enum ndb_mgm_node_type types[])
```

**Parameters**

This function takes two parameters:

- A management server `handle`
- A pointer to array of the node types to be checked. These are `ndb_mgm_node_type` values. The array should be terminated by an element of type `NDB_MGM_NODE_TYPE_UNKNOWN`.

**Return value**

A pointer to an `ndb_mgm_cluster_state` data structure.

**ndb_mgm_get_status3()**

**Description**

This function is similar to `ndb_mgm_get_status2()`, and is used to obtain the status of the nodes in an NDB Cluster by specify the type or types of nodes (`ndb_mgm_node_type`) to be checked. Unlike that function (as well as `ndb_mgm_get_status()`), `ndb_mgm_get_status3()` works when the cluster uses IPv6 addressing.

**Note**

The caller must free the pointer returned by this function.
Cluster Status Functions

**Signature**

```c
struct ndb_mgm_cluster_state2 *ndb_mgm_get_status3
(NdbMgmHandle handle,
 const enum ndb_mgm_node_type types[]);
```

**Parameters**

This function takes two parameters:

- A management server `handle`
- A pointer to array of the node types to be checked. These are `ndb_mgm_node_type` values. The array should be terminated by an element of type `NDB_MGM_NODE_TYPE_UNKNOWN`.

**Return value**

A pointer to an `ndb_mgm_cluster_state2` data structure.

**ndb_mgm_dump_state()**

**Description**

This function can be used to dump debugging information to the cluster log. The NDB Cluster management client `DUMP` command is a wrapper for this function.

`ndb_mgm_dump_state()`, like the `DUMP` command, can cause a running NDB Cluster to malfunction or even to fail completely if it is used improperly. Be sure to consult the relevant documentation before using this function. For more information on the `DUMP` command, and for a listing of current `DUMP` codes and their effects, see NDB Cluster Management Client DUMP Commands.

**Signature**

```c
int ndb_mgm_dump_state
(NdbMgmHandle handle,
 int nodeId,
 const int* arguments,
 int numberOfArguments,
 struct ndb_mgm_reply* reply)
```

**Parameters**

This function takes the following parameters:

- A management server handle (`NdbMgmHandle`)
- The `nodeId` of a cluster data node.
- An array of `arguments`. The first of these is the `DUMP` code to be executed. Subsequent arguments can be passed in this array if needed by or desired for the corresponding `DUMP` command.
- The `numberOfArguments` to be passed.
- An `ndb_mgm_reply`, which contains a return code along with a response or error message.

**Return value**

`0` on success; otherwise, an error code.

**Example.**

The following example has the same result as running `2 DUMP 1000` in the management client:

```c
#include <mgmapi_debug.h>
// [...]  
// [...]  
struct ndb_mgm_reply reply;
int args[1];
int stat, arg_count, node_id;
```
Functions for Starting & Stopping Nodes

3.2.6 Functions for Starting & Stopping Nodes

The MGM API provides several functions which can be used to start, stop, and restart one or more Cluster data nodes. These functions are described in this section.

Starting, Stopping, and Restarting Nodes. You can start, stop, and restart Cluster nodes using the following functions, which are described in more detail in the next few sections.

- **Starting Nodes.** Use `ndb_mgm_start()`.
- **Stopping Nodes.** Use `ndb_mgm_stop()`, `ndb_mgm_stop2()`, `ndb_mgm_stop3()`, or `ndb_mgm_stop4()`.

  Normally, you cannot use any of these functions to stop a node while other nodes are starting. You can override this restriction using `ndb_mgm_stop4()` with the `force` parameter set to 1.

- **Restarting Nodes.** Use `ndb_mgm_restart()`, `ndb_mgm_restart2()`, `ndb_mgm_restart3()`, or `ndb_mgm_restart4()`.

  Normally, you cannot use any of these functions to restart a node while other nodes are starting. You can override this restriction using `ndb_mgm_restart4()` with the `force` parameter set to 1.

**ndb_mgm_start()**

Description This function can be used to start one or more Cluster nodes. The nodes to be started must have been started with the no-start option (`-n`), meaning that the data node binary was started and is waiting for a **START** management command which actually enables the node.

Signature

```c
int ndb_mgm_start
    (    
    NdbMgmHandle handle, 
    int number, 
    const int* list
    )
```

Parameters `ndb_mgm_start()` takes 3 parameters:

- An `NdbMgmHandle`. 

```c
args[0] = 1000; 
arg_count = 1; 
node_id = 2; 
stat = ndb_mgm_dump_state(h, node_id, args, arg_count, &reply); 
```
Functions for Starting & Stopping Nodes

- A **number** of nodes to be started. Use 0 to start all of the data nodes in the cluster.
- A **list** of the node IDs of the nodes to be started.

**Return value**

The number of nodes actually started; in the event of failure, -1 is returned.

**ndb_mgm_stop()**

**Description**

This function stops one or more data nodes.

**Signature**

```c
int ndb_mgm_stop
{
    NdbMgmHandle handle,
    int number,
    const int* list
}
```

**Parameters**

- A **NdbMgmHandle**.
- The **number** of nodes to be stopped. Use 0 to stop all of the data nodes in the cluster.
- A **list** of the node IDs of the nodes to be stopped.

**Return value**

The number of nodes actually stopped; in the event of failure, -1 is returned.

**ndb_mgm_stop2()**

**Description**

Like **ndb_mgm_stop()**, this function stops one or more data nodes. However, it offers the ability to specify whether or not the nodes shut down gracefully.

**Signature**

```c
int ndb_mgm_stop2
{
    NdbMgmHandle handle,
    int number,
    const int* list,
    int abort
}
```

**Parameters**

- A **NdbMgmHandle**.
- The **number** of nodes to be stopped. Use 0 to stop all of the data nodes in the cluster.
- A **list** of the node IDs of the nodes to be stopped.
- The value of **abort** determines how the nodes will be shut down. 1 indicates the nodes will shut down immediately; 0 indicates that the nodes will stop gracefully.

**Return value**

The number of nodes actually stopped; in the event of failure, -1 is returned.
Description

Like `ndb_mgm_stop()` and `ndb_mgm_stop2()`, this function stops one or more data nodes. Like `ndb_mgm_stop2()`, it offers the ability to specify whether the nodes should shut down gracefully. In addition, it provides for a way to check to see whether disconnection is required prior to stopping a node.

Signature

```c
int ndb_mgm_stop3
    (NdbMgmHandle handle,
     int number,
     const int* list,
     int abort,
     int* disconnect)
```

Parameters

`ndb_mgm_stop3()` takes 5 parameters:

- An `NdbMgmHandle`.
- The `number` of nodes to be stopped. Use 0 to stop all of the data nodes in the cluster.
- A `list` of the node IDs of the nodes to be stopped.
- The value of `abort` determines how the nodes will be shut down. 1 indicates the nodes will shut down immediately; 0 indicates that the nodes will stop gracefully.
- If `disconnect` returns 1 (`true`), this means you must disconnect before you can apply the command to stop. For example, disconnecting is required when stopping the management server to which the handle is connected.

Return value

The number of nodes actually stopped; in the event of failure, -1 is returned.

`ndb_mgm_stop4()`

Description

Like the other `ndb_mgm_stop*()` functions, this function stops one or more data nodes. Like `ndb_mgm_stop2()`, it offers the ability to specify whether the nodes should shut down gracefully; like `ndb_mgm_stop3()` it provides for a way to check to see whether disconnection is required prior to stopping a node. In addition, it is possible to force the node to shut down even if this would cause the cluster to become nonviable.

Signature

```c
int ndb_mgm_stop4
    (NdbMgmHandle handle,
     int number,
     const int* list,
     int abort,
     int force,
     int* disconnect)
```

Parameters

`ndb_mgm_stop4()` takes 6 parameters:

- An `NdbMgmHandle`.
- The `number` of nodes to be stopped. Use 0 to stop all of the data nodes in the cluster.
- A `list` of the node IDs of the nodes to be stopped.
Functions for Starting & Stopping Nodes

- The value of `abort` determines how the nodes will be shut down. `1` indicates the nodes will shut down immediately; `0` indicates that the nodes will stop gracefully.

- The value of `force` determines the action to be taken in the event that the shutdown of a given node would cause an incomplete cluster. `1` causes the node—and the entire cluster—to be shut down in such cases, `0` means the node will not be shut down.

Setting `force` equal to `1` also makes it possible to stop a node even while other nodes are starting. (Bug #58451)

- If `disconnect` returns `1` (true), this means the you must disconnect before you can apply the command to stop. For example, disconnecting is required when stopping the management server to which the handle is connected.

Return value

The number of nodes actually stopped; in the event of failure, `−1` is returned.

**ndb_mgm_restart()**

Description

This function can be used to restart one or more Cluster data nodes.

**Signature**

```c
int ndb_mgm_restart(NdbMgmHandle handle, int number, const int* list)
```

Parameters

- `ndb_mgm_restart()` takes 3 parameters:
  - An `NdbMgmHandle`.
  - The `number` of nodes to be stopped. Use `0` to stop all of the data nodes in the cluster.
  - A `list` of the node IDs of the nodes to be stopped.

Calling this function is equivalent to calling

```c
ndb_mgm_restart2(handle, number, list, 0, 0, 0);
```

See **ndb_mgm_restart2()**, for more information.

Return value

The number of nodes actually restarted; `−1` on failure.

**ndb_mgm_restart2()**

Description

Like `ndb_mgm_restart()`, this function can be used to restart one or more Cluster data nodes. However, `ndb_mgm_restart2()` provides additional restart options, including initial restart, waiting start, and immediate (forced) restart.

**Signature**

```c
int ndb_mgm_restart2(NdbMgmHandle handle, int number, const int* list, int initial, int nostart, int abort)
```
Functions for Starting & Stopping Nodes

Parameters

ndb_mgm_restart2() takes 6 parameters:

• An NdbMgmHandle.

• The number of nodes to be stopped. Use 0 to stop all of the data nodes in the cluster.

• A list of the node IDs of the nodes to be stopped.

• If initial is true (1), then each node undergoes an initial restart—that is, its file system is removed.

• If nostart is true, then the nodes are not actually started, but instead are left ready for a start command.

• If abort is true, then the nodes are restarted immediately, bypassing any graceful restart.

Return value

The number of nodes actually restarted; -1 on failure.

ndb_mgm_restart3()

Description

Like ndb_mgm_restart2(), this function can be used to cause an initial restart, waiting restart, and immediate (forced) restart on one or more Cluster data nodes. However, ndb_mgm_restart3() provides the additional options of checking whether disconnection is required prior to the restart.

Signature

```c
int ndb_mgm_restart3
(   
    NdbMgmHandle handle,
    int number,
    const int* list,
    int initial
    int nostart,
    int abort,
    int* disconnect
)
```

Parameters

ndb_mgm_restart3() takes 7 parameters:

• An NdbMgmHandle.

• The number of nodes to be stopped. Use 0 to stop all of the data nodes in the cluster.

• A list of the node IDs of the nodes to be stopped.

• If initial is true (1), then each node undergoes an initial restart—that is, its file system is removed.

• If nostart is true, then the nodes are not actually started, but instead are left ready for a start command.

• If abort is true, then the nodes are forced to restart immediately without performing a graceful restart.

• If disconnect returns 1 (true), this means the you must disconnect before you can apply the command to restart. For example, disconnecting is required when stopping the management server to which the handle is connected.

Return value

The number of nodes actually restarted; -1 on failure.
Cluster Log Functions

**ndb_mgm_restart4()**

**Description**
Like the other `ndb_mgm_restart*()` functions, this function restarts one or more data nodes. Like `ndb_mgm_restart2()` and `ndb_mgm_stop3()` it can be used to cause an initial restart, waiting restart, and immediate (forced) restart on one or more NDB Cluster data nodes; like `ndb_mgm_stop3()` it provides for a way to check to see whether disconnection is required prior to stopping a node. In addition, it is possible to force the node to restart even if this would cause a restart of the cluster.

**Signature**

```c
int ndb_mgm_restart4(
    NdbMgmHandle handle,
    int number,
    const int* list,
    int initial,
    int nostart,
    int abort,
    int force,
    int* disconnect
)
```

**Parameters**

- **ndb_mgm_restart4()** takes 7 parameters:
  - An `NdbMgmHandle`.
  - The `number` of nodes to be stopped. Use 0 to stop all of the data nodes in the cluster.
  - A `list` of the node IDs of the nodes to be stopped.
  - If `initial` is true (1), then each node undergoes an initial restart—that is, its file system is removed.
  - If `nostart` is true, then the nodes are not actually started, but instead are left ready for a start command.
  - If `abort` is true, then the nodes are forced to restart immediately without performing a graceful restart.
  - The value of `force` determines the action to be taken in the event that the loss of a given node due to restarting would cause an incomplete cluster. 1 causes the node—and the entire cluster—to be restarted in such cases, 0 means that the node will not be restarted.

  Setting `force` equal to 1 also makes it possible to restart a node even while other nodes are starting. (Bug #58451)

  - If `disconnect` returns 1 (true), this means the you must disconnect before you can apply the command to restart. For example, disconnecting is required when stopping the management server to which the handle is connected.

**Return value**

The number of nodes actually restarted; -1 on failure.

### 3.2.7 Cluster Log Functions

This section provides information about the functions available in the MGM API for controlling the output of the cluster log.
Cluster Log Functions

- `ndb_mgm_get_clusterlog_severity_filter()`
- `ndb_mgm_set_clusterlog_severity_filter()`
- `ndb_mgm_get_clusterlog_loglevel()`
- `ndb_mgm_set_clusterlog_loglevel()`

### `ndb_mgm_get_clusterlog_severity_filter()`

**Description**
This function is used to retrieve the cluster log severity filter currently in force.

**Signature**
```c
int ndb_mgm_get_clusterlog_severity_filter
(NdbMgmHandle handle,
 struct ndb_mgm_severity* severity,
 unsigned int size)
```

**Parameters**
- An `NdbMgmHandle`.
- A vector `severity` of seven `NDB_MGM_EVENT_SEVERITY_ALL` elements, each of which is an `ndb_mgm_severity` structure, where each element contains 1 if a severity indicator is enabled and 0 if not. A severity level is stored at position `ndb_mgm_clusterlog_level`; for example the error level is stored at position `NDB_MGM_EVENT_SEVERITY_ERROR`. The first element (position `NDB_MGM_EVENT_SEVERITY_ON`) in the vector signals whether the cluster log is disabled or enabled.
- The `size` of the vector (`NDB_MGM_EVENT_SEVERITY_ALL`).

**Return value**
The number of returned severities, or -1 in the event of an error.

### `ndb_mgm_set_clusterlog_severity_filter()`

**Description**
This function is used to set a cluster log severity filter.

**Signature**
```c
int ndb_mgm_set_clusterlog_severity_filter
(NdbMgmHandle handle,
 enum ndb_mgm_event_severity severity,
 int enable,
 struct ndb_mgm_reply* reply)
```

**Parameters**
- This function takes 4 parameters:
  - A management server `handle`.
  - A cluster log `severity` to filter.
  - A flag to `enable` or disable the filter; 1 enables and 0 disables the filter.
  - A pointer to an `ndb_mgm_reply` structure for a reply message.

**Return value**
The function returns -1 in the event of failure.

### `ndb_mgm_get_clusterlog_loglevel()`

**Description**
This function is used to obtain log category and level information, and is thread-safe.
Backup Functions

**Signature**

```c
int ndb_mgm_get_clusterlog_loglevel
{
    NdbMgmHandle handle,
    struct ndb_mgm_loglevel* loglevel,
    unsigned int size
}
```

**Parameters**

`ndb_mgm_get_clusterlog_loglevel()` takes the following parameters:

- A management `handle` (NdbMgmHandle).
- A `loglevel` (log level) vector consisting of twelve elements, each of which is an `ndb_mgm_loglevel` structure and which represents a log level of the corresponding category.
- The `size` of the vector (MGM_LOGLEVELS).

**Return value**

This function returns the number of returned loglevels or `-1` in the event of an error.

**ndb_mgm_set_clusterlog_loglevel()**

**Description**

This function is used to set the log category and levels for the cluster log.

**Signature**

```c
int ndb_mgm_set_clusterlog_loglevel
{
    NdbMgmHandle handle,
    int id,
    enum ndb_mgm_event_category category,
    int level,
    struct ndb_mgm_reply* reply
}
```

**Parameters**

This function takes 5 parameters:

- An `NdbMgmHandle`.
- The `id` of the node affected.
- An event `category` (this is one of the values listed in The `ndb_mgm_event_category` Type).
- A logging `level`.
- A pointer to an `ndb_mgm_reply` structure for the reply message.

**Return value**

In the event of an error, this function returns `-1`.

### 3.2.8 Backup Functions

This section provides information about the functions provided in the MGM API for starting and stopping NDB Cluster backups.

- `ndb_mgm_start_backup()`
- `ndb_mgm_start_backup2()`
- `ndb_mgm_start_backup3()`
- `ndb_mgm_start_backup4()`
- `ndb_mgm_abort_backup()`
Backup Functions

ndb_mgm_start_backup()

Description
This function is used to initiate a backup of an NDB Cluster.

Signature
```c
int ndb_mgm_start_backup
    (NdbMgmHandle handle,
     int wait,
     unsigned int* id,
     struct ndb_mgm_reply* reply)
```

Parameters
This function requires the four parameters listed here:

- A management server `handle` (an `NdbMgmHandle`).
- A `wait` flag, with the following possible values:
  - 0: Do not wait for confirmation of the backup.
  - 1: Wait for the backup to be started.
  - 2: Wait for the backup to be completed.
- Create the backup having backup ID `id`. (This is also the function's return value.)
  - No backup `id` is returned if `wait` is set equal to 0.
- A pointer `id` to an `ndb_mgm_reply` structure to accommodate a `reply`.

Return value
On success, the backup ID (`id`). In the event of failure, the function returns -1.

ndb_mgm_start_backup2()

Description
This function is used to initiate a backup of an NDB Cluster. It is the same as `ndb_mgm_start_backup()`, except that it additionally specifies a value to be used for the next backup taken.

Signature
```c
int ndb_mgm_start_backup2
    (NdbMgmHandle handle,
     int wait,
     unsigned int* id,
     struct ndb_mgm_reply* reply,
     unsigned int nextBackupId)
```

Parameters
This function requires the five parameters listed here:

- A management server `handle` (an `NdbMgmHandle`).
- A `wait` flag, with the following possible values:
  - 0: Do not wait for confirmation of the backup.
  - 1: Wait for the backup to be started.
  - 2: Wait for the backup to be completed.
- Create the backup having backup ID `id`. (This is also the function's return value.)
Backup Functions

No backup *id* is returned if *wait* is set equal to 0.

- A pointer to an *ndb_mgm_reply* structure to accommodate a *reply*.
- The ID of the next backup taken is set to the value of *nextBackupID + 1*.

**Return value**

On success, the backup ID passed as *id*. Otherwise, the function returns −1.

### ndb_mgm_start_backup3()

**Description**

This function is used to initiate a backup of an NDB Cluster. It is the same as *ndb_mgm_start_backup2()* , but adds an argument for specifying whether the state of the backup matches that of the cluster when the backup is started, or when it is completed.

**Signature**

```c
int ndb_mgm_start_backup(NdbMgmHandle handle, int wait, unsigned int* id, struct ndb_mgm_reply* reply, unsigned int nextBackupId, unsigned int backupPoint)
```

**Parameters**

This function requires the six parameters listed here:

- A management server *handle* (an *NdbMgmHandle*).
- A *wait* flag, with the following possible values:
  - 0: Do not wait for confirmation of the backup.
  - 1: Wait for the backup to be started.
  - 2: Wait for the backup to be completed.
- Create the backup having backup ID *id*. (This is also the function's return value.)
  - No backup *id* is returned if *wait* is set equal to 0.
- A pointer to an *ndb_mgm_reply* structure to accommodate a *reply*.
- The ID of the next backup taken is set to the value of *nextBackupID + 1*.
- *backupPoint* is 1 if the state of the backup should reflect that of the cluster the time when the backup is started, or 0 if its state should reflect that of the cluster when the backup is complete. Using 1 is equivalent to invoking the *ndb_mgm* client *START BACKUP* command with *SNAPSHOTSTART*; 0 is equivalent to invoking the command with *SNAPSHOTEND*.

**Return value**

On success, the backup ID passed as *id*. Otherwise, the function returns −1.

### ndb_mgm_start_backup4()

630
Backup Functions

Description

This function is used to initiate a backup of an NDB Cluster. It is the same as `ndb_mgm_start_backup3()`, except that it produces an encrypted backup using the password provided of the length specified.

This function was added in NDB 8.0.22.

Signature

```c
int ndb_mgm_start_backup
    (NdbMgmHandle handle,
    int wait,
    unsigned int* id,
    struct ndb_mgm_reply* reply,
    unsigned int nextBackupId,
    unsigned int backupPoint,
    const char* password,
    unsigned int password_length)
```

Parameters

This function requires the eight parameters listed here:

- A management server `handle` (an `NdbMgmHandle`).
- A `wait` flag, with the following possible values:
  - 0: Do not wait for confirmation of the backup.
  - 1: Wait for the backup to be started.
  - 2: Wait for the backup to be completed.
- Create the backup having backup ID `id`. (This is also the function's return value.) No backup `id` is returned if `wait` is set equal to 0.
- A pointer to an `ndb_mgm_reply` structure to accommodate a `reply`.
- The ID of the next backup taken is set to the value of `nextBackupID + 1`.
- `backupPoint` is 1 if the state of the backup should reflect that of the cluster the time when the backup is started, or 0 if its state should reflect that of the cluster when the backup is complete. Using 1 is equivalent to invoking the `ndb_mgm` client `START BACKUP` command with `SNAPSHOTSTART`; 0 is equivalent to invoking the command with `SNAPSHOTEND`.
- A password used to protect the encrypted backup. This is a string of up to 256 characters in length; any printable ASCII characters can be used in the password string with the exception of !, ', ", $, $, \, and ^.
- The length of the password.

It is possible to specify an empty password, but this is not recommended.

Return value

On success, the backup ID passed as `id`. Otherwise, the function returns -1.

`ndb_mgm_abort_backup()`
3.2.9 Single-User Mode Functions

The MGM API makes it possible for the programmer to put the cluster into single-user mode—and to return it to normal mode again—from within an application. This section covers the functions that are used for these operations.

- `ndb_mgm_enter_single_user()`  
- `ndb_mgm_exit_single_user()`

### `ndb_mgm_enter_single_user()`

**Description**  
This function is used to enter single-user mode on a given node.

**Signature**

```c
int ndb_mgm_enter_single_user(NdbMgmHandle handle, unsigned int id, struct ndb_mgm_reply* reply);
```

**Parameters**

This function takes 3 parameters:

- An `NdbMgmHandle`.
- The `id` of the node to be used in single-user mode.
- A pointer to an `ndb_mgm_reply` structure, used for a reply message.

**Return value**

Returns -1 in the event of failure.

### `ndb_mgm_exit_single_user()`

**Description**  
This function is used to exit single-user mode and to return to normal operation.

**Signature**

```c
int ndb_mgm_exit_single_user(NdbMgmHandle handle, struct ndb_mgm_reply* reply);
```

**Parameters**

This function requires 2 arguments:

- An `NdbMgmHandle`.
- A pointer to an `ndb_mgm_reply`.

---

### Single-User Mode Functions

**Description**

This function is used to stop an NDB Cluster backup.

**Signature**

```c
int ndb_mgm_abort_backup(NdbMgmHandle handle, unsigned int id, struct ndb_mgm_reply* reply);
```

**Parameters**

This function takes 3 parameters:

- An `NdbMgmHandle`.
- The `id` of the backup to be aborted.
- A pointer to an `ndb_mgm_reply` structure.

**Return value**

In case of an error, this function returns -1.
3.2.10 TLS Functions

The functions described in this section were added in NDB 8.3 to support Transport Layer Security for communications between nodes. Also included in this section is information about two data structures used by some of these functions.

For additional information about TLS support in NDB Cluster, see TLS Link Encryption for NDB Cluster.

- `ndb_mgm_cert_table_free()`
- `ndb_mgm_connect_tls()`
- `ndb_mgm_get_tls_stats()`
- `ndb_mgm_has_tls()`
- `ndb_mgm_list_certs()`
- `ndb_mgm_set_ssl_ctx()`
- `ndb_mgm_start_tls()`
- `ndb_mgm_cert_table`
- `ndb_mgm_tls_stats`

### `ndb_mgm_cert_table_free()`

**Description**
Frees a linked list of certificate descriptions.

**Signature**
```c
void ndb_mgm_cert_table_free
  (struct ndb_mgm_cert_table **list)
```

**Parameters**
- `list` A linked list of `ndb_mgm_cert_table` certificate descriptions

**Return value**
`none`

### `ndb_mgm_connect_tls()`

**Description**
Connects to a management server. This function wraps a call to `ndb_mgm_connect()`, followed by a call to `ndb_mgm_start_tls()`. The user must first have called `ndb_mgm_set_ssl_ctx()` before invoking this function.

Unlike the case with `ndb_mgm_connect()`, `ndb_mgm_connect_tls()` cannot be called on a handle which is already connected; such an attempt fails with error `NDB_MGM_ALREADY_CONNECTED`.

**Signature**
```c
int ndb_mgm_connect_tls
  (NdbMgmHandle handle,
   int no_retries,
   int retry_delay_in_seconds,
   int verbose,
   int tls_req_level)
```

**Parameters**
- `handle` Management server handle (`NdbMgmHandle`).
TLS Functions

no_retries

Number of times to make connection attempts (0 means connect once).

retry_delay_in_seconds

How long to wait before performing each retry for a connection.

verbose

Print out reports regarding connect retries.

tls_req_level

This parameter can take either of the following two values:

1. `CLIENT_TLS_RELAXED`:
   TLS authentication failures still result in errors, but a missing certificate or server refusal results in a successful cleartext connection.

2. `CLIENT_TLS STRICT`:
   Any failure to establish TLS is treated as an error, and the connection is closed.

Return value

`none`

__ndb_mgm_get_tls_stats()__

Get server TLS statistics

Signature

```c
int ndb_mgm_get_tls_stats
(
    NdbMgmHandle handle,
    struct ndb_mgm_tls_stats *result
)
```

Parameters

handle

Management server handle `NdbMgmHandle`.

result

Pointer to `ndb_mgm_tls_stats` structure holding result data

Return value

0 on success, -1 on error.

__ndb_mgm_has_tls()__

Checks whether a connected handle is using TLS.

Signature

```c
int ndb_mgm_has_tls
(
    NdbMgmHandle handle
)
```

Parameters

handle

Management server handle `NdbMgmHandle`.

Return value

One of the following integer values:

- 0: The handle is not using TLS.
- 12: The handle is using TLS version 1.2.
TLS Functions

- **13**: The handle is using TLS version 1.3.

### ndb_mgm_list_certs()

**Description**
Queries TLS certificates of connected MGM clients

**Signature**
```c
int ndb_mgm_list_certs
(    NdbMgmHandle handle,
    struct ndb_mgm_cert_table **list
)
```

**Parameters**
- `handle` Management server handle (`NdbMgmHandle`).
- `list` Address of a pointer to an `ndb_mgm_cert_table` structure.

**Return value**
One of the following values:
- > 0: The total number of linked descriptions.
- 0: Success, but with no TLS connections to report.
- -1: Error.

### ndb_mgm_set_ssl_ctx()

**Description**
Set an SSL context structure (CTX) for a handle.

**Signature**
```c
int ndb_mgm_set_ssl_ctx
(    NdbMgmHandle handle,
    struct ssl_ctx_st *ctx
)
```

**Parameters**
- `handle` Management server handle (`NdbMgmHandle`).
- `ctx` SSL_CTX to be used for TLS and HTTPS connections

**Return value**
0 on success, -1 if CTX has already been set

### ndb_mgm_start_tls()

**Description**
Start TLS by upgrading an open, unencrypted connection to a secure one.

**Signature**
```c
int ndb_mgm_start_tls
(    NdbMgmHandle handle
)
```

**Parameters**
- `handle` Management server handle (`NdbMgmHandle`).

**Return value**
0 on success

### ndb_mgm_cert_table

**Description**
`ndb_mgm_cert_table` is a linked structure describing a TLS client session.
### MGM API Data Types

#### Definition

```c
struct ndb_mgm_cert_table
{
    Uint64 session_id;
    char *peer_address;
    char *cert_serial;
    char *cert_name;
    char *cert_expires;
    struct ndb_mgm_cert_table *next;
}
```

<table>
<thead>
<tr>
<th>Members</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>session_id</td>
<td>TLS session ID</td>
</tr>
<tr>
<td>peer_address</td>
<td>Host making the connection</td>
</tr>
<tr>
<td>cert_serial</td>
<td>Certificate serial number</td>
</tr>
<tr>
<td>cert_name</td>
<td>Certificate name</td>
</tr>
<tr>
<td>cert_expires</td>
<td>Certificate expiration date</td>
</tr>
<tr>
<td>next</td>
<td>Pointer to the next <code>ndb_mgm_cert_table</code> in the list</td>
</tr>
</tbody>
</table>

#### ndb_mgm_tls_stats

**Description**

The `ndb_mgm_tls_stats` struct stores server statistics relating to TLS.

**Definition**

```c
struct ndb_mgm_tls_stats
{
    Uint32 accepted;
    Uint32 upgraded;
    Uint32 current;
    Uint32 tls;
    Uint32 authfail;
}
```

<table>
<thead>
<tr>
<th>Members</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>accepted</td>
<td>Total number of client connections accepted</td>
</tr>
<tr>
<td>upgraded</td>
<td>Number of client connections upgraded to TLS</td>
</tr>
<tr>
<td>current</td>
<td>Total number of current open client sessions</td>
</tr>
<tr>
<td>tls</td>
<td>Number of current open client sessions using TLS</td>
</tr>
<tr>
<td>authfail</td>
<td>Total number of authorization failures</td>
</tr>
</tbody>
</table>

### 3.3 MGM API Data Types

This section provides information about the data types defined by the MGM API.

The types described in this section are all defined in the file `/storage/ndb/include/mgmapi.mgmapi.h`, with the exception of `Ndb_logevent_type`, `ndb_mgm_event_severity`, `ndb_mgm_logevent_handle_error`, and `ndb_mgm_event_category`, which are defined in `/storage/ndb/include/mgmapi/ndb_logevent.h`.

- The `ndb_mgm_node_type` Type
- The `ndb_mgm_node_status` Type
The ndb_mgm_node_type Type

This is used to classify the different types of nodes in an NDB Cluster.

Possible values are shown, along with descriptions, in the following table:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB_MGM_NODE_TYPE_UNKNOWN</td>
<td>Unknown</td>
</tr>
<tr>
<td>NDB_MGM_NODE_TYPE_API</td>
<td>API Node (SQL node)</td>
</tr>
<tr>
<td>NDB_MGM_NODE_TYPE_NDB</td>
<td>Data node</td>
</tr>
<tr>
<td>NDB_MGM_NODE_TYPE_MGM</td>
<td>Management node</td>
</tr>
</tbody>
</table>

The ndb_mgm_node_status Type

This type describes a Cluster node's status.

Possible values are shown, along with descriptions, in the following table:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB_MGM_NODE_STATUS_UNKNOWN</td>
<td>The node's status is not known</td>
</tr>
<tr>
<td>NDB_MGM_NODE_STATUS_NO_CONTACT</td>
<td>The node cannot be contacted</td>
</tr>
<tr>
<td>NDB_MGM_NODE_STATUS_NOT_STARTED</td>
<td>The node has not yet executed the startup protocol</td>
</tr>
<tr>
<td>NDB_MGM_NODE_STATUS_STARTING</td>
<td>The node is executing the startup protocol</td>
</tr>
<tr>
<td>NDB_MGM_NODE_STATUS_STARTED</td>
<td>The node is running</td>
</tr>
<tr>
<td>NDB_MGM_NODE_STATUS_SHUTTING_DOWN</td>
<td>The node is shutting down</td>
</tr>
<tr>
<td>NDB_MGM_NODE_STATUS_RESTARTING</td>
<td>The node is restarting</td>
</tr>
<tr>
<td>NDB_MGM_NODE_STATUS_SINGLEUSER</td>
<td>The node is running in single-user (maintenance) mode</td>
</tr>
<tr>
<td>NDB_MGM_NODE_STATUS_RESUME</td>
<td>The node is in resume mode</td>
</tr>
<tr>
<td>NDB_MGM_NODE_STATUS_CONNECTED</td>
<td>The node is connected</td>
</tr>
</tbody>
</table>

The ndb_mgm_error Type

The values for this type are the error codes that may be generated by MGM API functions. These may be found in Section 3.5, "MGM API Errors".
The Ndb_logevent_type Type

Description
These are the types of log events available in the MGM API, grouped by event category. (See The ndb_mgm_event_category Type.)

Most of these log event types have one or more corresponding log event messages; these are listed in NDB Cluster Log Messages.

Enumeration values
Possible values are shown, along with descriptions, in the following table:

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
<th>Category</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB_LE_Connected</td>
<td>The node has connected</td>
<td>NDB_MGM_EVENT_CATEGORY_CONNECTION</td>
</tr>
<tr>
<td>NDB_LE_Disconnected</td>
<td>The node was disconnected</td>
<td>NDB_MGM_EVENT_CATEGORY_CONNECTION</td>
</tr>
<tr>
<td>NDB_LE_CommunicationClosed</td>
<td>Communication with the node has been closed</td>
<td>NDB_MGM_EVENT_CATEGORY_CONNECTION</td>
</tr>
<tr>
<td>NDB_LE_CommunicationOpened</td>
<td>Communication with the node has been started</td>
<td>NDB_MGM_EVENT_CATEGORY_CONNECTION</td>
</tr>
<tr>
<td>NDB_LE_ConnectedApiVersion</td>
<td>The API version used by an API node; in the case of a MySQL server (SQL node), this is the same as displayed by SELECT VERSION()</td>
<td>NDB_MGM_EVENT_CATEGORY_CONNECTION</td>
</tr>
<tr>
<td>NDB_LE_GlobalCheckpointStarted</td>
<td>A global checkpoint has been started</td>
<td>NDB_MGM_EVENT_CATEGORY_CHECKPOINT</td>
</tr>
<tr>
<td>NDB_LE_GlobalCheckpointCompleted</td>
<td>A global checkpoint has been completed</td>
<td>NDB_MGM_EVENT_CATEGORY_CHECKPOINT</td>
</tr>
<tr>
<td>NDB_LE_LocalCheckpointStarted</td>
<td>The node has begun a local checkpoint</td>
<td>NDB_MGM_EVENT_CATEGORY_CHECKPOINT</td>
</tr>
<tr>
<td>NDB_LE_LocalCheckpointCompleted</td>
<td>The node has completed a local checkpoint</td>
<td>NDB_MGM_EVENT_CATEGORY_CHECKPOINT</td>
</tr>
<tr>
<td>NDB_LE_LCPStoppedInCalcKeepGci</td>
<td>The local checkpoint was aborted, but the last global checkpoint was preserved</td>
<td>NDB_MGM_EVENT_CATEGORY_CHECKPOINT</td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
<td>Category</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-------------------------------</td>

</tbody>
</table>
The ndb_mgm_event_severity Type

These are the log event severities used to filter the cluster log by `ndb_mgm_set_clusterlog_severity_filter()`, and to filter listening to events by `ndb_mgm_listen_event()`.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB_MGM_ILLEGAL_EVENT_SEVERITY</td>
<td>Invalid event severity specified</td>
</tr>
</tbody>
</table>

Enumeration values

Possible values are shown, along with descriptions, in the following table:

Table 3.4 Type ndb_mgm_event_severity values and descriptions

</table>

`NDB_LEH_CONNECTION_ERROR` was added in NDB 7.4.13. (BUG #19474782)

The `ndb_mgm_event_category` Type

Description

These are the log event categories referenced in `The Ndb_logevent_type` Type. They are also used by the MGM API functions `ndb_mgm_set_clusterlog_loglevel()` and `ndb_mgm_listen_event()`.

Enumeration values

Possible values are shown, along with descriptions, in the following table:
### Table 3.6 Type ndb_mgm_event_category values and descriptions

</tr>
</tbody>
</table>

See `ndb_mgm_set_clusterlog_loglevel()`, and `ndb_mgm_listen_event()`, for more information.

### 3.4 MGM API Data Structures

This section provides information about the data structures defined by the MGM API.

- The `ndb_logevent` Structure
- The `ndb_mgm_node_state` Structure
- The `ndb_mgm_node_state2` Structure
- The `ndb_mgm_cluster_state` Structure
- The `ndb_mgm_cluster_state2` Structure
- The `ndb_mgm_reply` Structure

#### The `ndb_logevent` Structure

**Description**

This structure models a Cluster log event, and is used for storing and retrieving log event information.

**Definition.**

The `ndb_logevent` has 8 members, the first 7 of which are shown in the following list:

- `void* handle`: An NdbLogEventHandle, set by `ndb_logevent_get_next()`. This handle is used only for purposes of comparison.
The ndb_logevent Structure

- **type**: Tells which type of event (`Ndb_logevent_type`) this is.
- **unsigned time**: The time at which the log event was registered with the management server.
- **category**: The log event category (`ndb_mgm_event_category`).
- **severity**: The log event severity (`ndb_mgm_event_severity`).
- **unsigned level**: The log event level. This is a value in the range of 0 to 15, inclusive.
- **unsigned source_nodeid**: The node ID of the node that reported this event.

The 8th member of this structure contains data specific to the log event, and is dependent on its type. It is defined as the union of a number of data structures, each corresponding to a log event type. Which structure to use is determined by the value of `type`, and is shown in the following table:

<table>
<thead>
<tr>

The ndb_mgm_node_state Structure

**Description.** Provides information on the status of a Cluster node.

**Definition.** This structure contains the following members:

- **int node_id**: The cluster node's node ID.
- **enum ndb_mgm_node_type node_type**: The node type.
  
  See [The ndb_mgm_node_type Type](#), for permitted values.
- **enum ndb_mgm_node_status node_status**: The node's status.
  
  See [The ndb_mgm_node_status Type](#), for permitted values.
- **int start_phase**: The start phase.

  This is valid only if the `node_type` is `NDB_MGM_NODE_TYPE_NDB` and the `node_status` is `NDB_MGM_NODE_STATUS_STARTING`.
- **int dynamic_id**: The ID for heartbeats and master takeover.

  Valid only for data (ndbd) nodes.
- **int node_group**: The node group to which the node belongs.

  Valid only for data (ndbd) nodes.
- **int version**: Internal version number.
- **int connect_count**: The number of times this node has connected to or disconnected from the management server.
- **char connect_address[]**: The IP address of this node as seen by the other nodes in the cluster.
- **int mysql_version**: The MySQL version number, expressed as an integer (for example: 80200). Applies only to SQL nodes.
- **int is_single_user**: The node ID of the API or SQL node having exclusive access when the cluster is in single user mode. Does not otherwise apply. Added in NDB 8.0.

The ndb_mgm_node_state2 Structure

**Description.** Provides information on the status of a Cluster node.

**Definition.** This structure contains the following members:

- **int node_id**: The cluster node's node ID.
- **enum ndb_mgm_node_type node_type**: The node type.
  
  See [The ndb_mgm_node_type Type](#), for permitted values.
- **enum ndb_mgm_node_status node_status**: The node's status.
  
  See [The ndb_mgm_node_status Type](#), for permitted values.
The `ndb_mgm_cluster_state` Structure

- **int start_phase**: The start phase.
  
  This is valid only if the `node_type` is `NDB_MGM_NODE_TYPE_NDB` and the `node_status` is `NDB_MGM_NODE_STATUS_STARTING`.

- **int dynamic_id**: The ID for heartbeats and master takeover.
  
  Valid only for data (ndbd) nodes.

- **int node_group**: The node group to which the node belongs.
  
  Valid only for data (ndbd) nodes.

- **int version**: Internal version number.

- **int connect_count**: The number of times this node has connected to or disconnected from the management server.

- **int mysql_version**: The MySQL version number, expressed as an integer (for example: `80200`). Applies only to SQL nodes.

- **int is_single_user**: The node ID of the API or SQL node having exclusive access when the cluster is in single user mode. Does not otherwise apply.

- **char connect_address[]**: The IP address of this node as seen by the other nodes in the cluster.

The `ndb_mgm_cluster_state` Structure

Description

Provides information on the status of all Cluster nodes. This structure is returned by `ndb_mgm_get_status()`.

Definition.

This structure has the following two members:

- **int no_of_nodes**: The number of elements in the `node_states` array.
- **struct ndb_mgm_node_state node_states[]**: An array containing the states of the nodes.

  Each element of this array is an `ndb_mgm_node_state` structure.

See `ndb_mgm_get_status()`.

The `ndb_mgm_cluster_state2` Structure

Description

Provides information on the status of all Cluster nodes. This structure is returned by `ndb_mgm_get_status3()`, and was added in NDB 8.0.

Definition.

This structure has the following two members:

- **int no_of_nodes**: The number of elements in the `node_states` array.
- **struct ndb_mgm_node_state2 node_states[]**: An array containing the states of the nodes.

  Each element of this array is an `ndb_mgm_node_state2` structure.

See `ndb_mgm_get_status3()`.

The `ndb_mgm_reply` Structure

Description

Contains response information, consisting of a response code and a corresponding message, from the management server.

Definition.

This structure contains two members, as shown here:
**MGM API Errors**

- **int return_code**: For a successful operation, this value is 0; otherwise, it contains an error code. For error codes, see The ndb_mgm_error Type.

- **char message[256]**: contains the text of the response or error message. See **ndb_mgm_get_latest_error()**, and **ndb_mgm_get_latest_error_msg()**.

### 3.5 MGM API Errors

This section provides information about each of the six types MGM errors, with the listings that follow ordered by type.

- **Request Errors**
- **Node ID Allocation Errors**
- **Service Errors**
- **Backup Errors**
- **Single User Mode Errors**
- **Configuration Errors**
- **General Usage Errors**

#### Request Errors

These are errors generated by failures to connect to a management server.

**Table 3.8 Request errors generated by management server connection failures.**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB_MGM_ILLEGAL_CONNECT_STRING</td>
<td>Invalid connection string</td>
</tr>
<tr>
<td>NDB_MGM_ILLEGAL_SERVER_HANDLE</td>
<td>Invalid management server handle</td>
</tr>
<tr>
<td>NDB_MGM_ILLEGAL_SERVER_REPLY</td>
<td>Invalid response from management server</td>
</tr>
<tr>
<td>NDB_MGM_ILLEGAL_NUMBER_OF_NODES</td>
<td>Invalid number of nodes</td>
</tr>
<tr>
<td>NDB_MGM_ILLEGAL_NODE_STATUS</td>
<td>Invalid node status</td>
</tr>
<tr>
<td>NDB_MGM_OUT_OF_MEMORY</td>
<td>Memory allocation error</td>
</tr>
<tr>
<td>NDB_MGM_SERVER_NOT_CONNECTED</td>
<td>Management server not connected</td>
</tr>
<tr>
<td>NDB_MGM_COULD_NOT_CONNECT_TO_SOCKET</td>
<td>Not able to connect to socket</td>
</tr>
<tr>
<td>NDB_MGM_BIND_ADDRESS</td>
<td>Unable to bind local address...</td>
</tr>
<tr>
<td>NDB_MGM_ILLEGAL_BIND_ADDRESS</td>
<td>Illegal bind address</td>
</tr>
</tbody>
</table>

#### Node ID Allocation Errors

These errors result from a failure to assign a node ID to a cluster node.

**Table 3.9 Node ID allocation errors resulting from failure to assign a node ID**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB_MGM_ALLOCID_ERROR</td>
<td>Generic error; may be possible to retry and recover</td>
</tr>
<tr>
<td>NDB_MGM_ALLOCID_CONFIG_MISMATCH</td>
<td>Non-recoverable generic error</td>
</tr>
<tr>
<td>NDB_MGM_ALLOCID_CONFIG_RETRY</td>
<td>Mgm failed to match hostname, but AllowUnresolvedHostnames=true.</td>
</tr>
</tbody>
</table>
Service Errors

These errors result from the failure of a node or cluster to start, shut down, or restart.

Table 3.10 Service errors resulting from failure of a node or cluster to start, shut down, or restart.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB_MGM_START_FAILED</td>
<td>Startup failure</td>
</tr>
<tr>
<td>NDB_MGM_STOP_FAILED</td>
<td>Shutdown failure</td>
</tr>
<tr>
<td>NDB_MGM_RESTART_FAILED</td>
<td>Restart failure</td>
</tr>
</tbody>
</table>

Backup Errors

These are errors which result from problems with initiating or aborting backups.

Table 3.11 Backup errors resulting from problems initiating or aborting backups.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB_MGM_COULD_NOT_START_BACKUP</td>
<td>Unable to initiate backup</td>

3.6 MGM API Examples
This section provides MGM API coding examples.

3.6.1 Basic MGM API Event Logging Example

This example shows the basics of handling event logging using the MGM API.

The source code for this program may be found in the NDB Cluster source tree, in the file storage/ndb/ndbapi-examples/mgmapi_logevent/main.cpp.

```c
#include <mysql.h>
#include <ndbapi/NdbApi.hpp>
#include <mgmapi.h>
#include <stdio.h>
#include <stdlib.h>

#define MGMERROR(h)  
{  
fprintf(stderr, "code: %d msg: %s\n",  
    ndb_mgm_get_latest_error(h),  
    ndb_mgm_get_latest_error_msg(h));  
exit(-1);  
}

#define LOGEVENTERROR(h)  
{  
fprintf(stderr, "code: %d msg: %s\n",  
    ndb_logevent_get_latest_error(h),  
    ndb_logevent_get_latest_error_msg(h));  
exit(-1);  
}

#define make_uint64(a,b)  
{((Uint64)(a)) + (((Uint64)(b)) << 32)}

int main(int argc, char** argv)
{
    NdbMgmHandle h;
    NdbLogEventHandle le;
    int filter[] = { 15, NDB_MGM_EVENT_CATEGORY_BACKUP,  
                    15, NDB_MGM_EVENT_CATEGORY_CONNECTION,  
                    15, NDB_MGM_EVENT_CATEGORY_NODE_RESTART,  
                    15, NDB_MGM_EVENT_CATEGORY_STARTUP,  
                    15, NDB_MGM_EVENT_CATEGORY_ERROR,  
                    0,  
                };
    struct ndb_logevent event;
    if (argc < 2)
    {
        printf("Arguments are <connect_string cluster> [iterations]\n");
        exit(-1);
    }
    const char *connectstring = argv[1];
    int iterations = -1;
    if (argc > 2)
    {
        iterations = atoi(argv[2]);
    }
    ndb_init();
    h= ndb_mgm_create_handle();
    if ( h == 0)
    {
        printf("Unable to create handle\n");
        exit(-1);
    }
    if (ndb_mgm_set_connectstring(h, connectstring) == -1)
    {
        printf("Unable to set connection string\n");
        exit(-1);
    }
```
Basic MGM API Event Logging Example

```c
if (ndb_mgm_connect(h,0,0,0)) MGMERROR(h);

le= ndb_mgm_create_logevent_handle(h, filter);
if ( le == 0 )  MGMERROR(h);

while (iterations-- != 0)
{
    int timeout= 1000;
    int r= ndb_logevent_get_next(le,&event,timeout);
    if (r == 0)
        printf("No event within %d milliseconds\n", timeout);
    else if (r < 0)

This chapter discusses using NDB Cluster with MySQL NDB Cluster Connector for Java, also known as ClusterJ.

ClusterJ is a high level database API that is similar in style and concept to object-relational mapping persistence frameworks such as Hibernate and JPA. Because ClusterJ does not use the MySQL Server to access data in NDB Cluster, it can perform some operations much more quickly than can be done using JDBC. ClusterJ supports primary key and unique key operations and single-table queries; it does not support multi-table operations, including joins.

4.1 MySQL NDB Cluster Connector for Java: Overview

This section provides a conceptual and architectural overview of the APIs available using the MySQL NDB Cluster Connector for Java.

4.1.1 MySQL NDB Cluster Connector for Java Architecture

MySQL NDB Cluster Connector for Java, also known as ClusterJ, is a Java API for writing applications against NDB Cluster. It is one among different access paths and styles of access to NDB Cluster data. Section 4.1.2, “Java and NDB Cluster”, describes each of those APIs in more detail.

MySQL NDB Cluster Connector for Java is included with all NDB Cluster source and binary releases. Building MySQL NDB Cluster Connector for Java from source can be done as part of building NDB Cluster; however, it can also be built with Maven.

4.1.2 Java and NDB Cluster

A NDB Cluster is defined as one or more MySQL Servers providing access to an NDBCLUSTER storage engine—that is, to a set of NDB Cluster data nodes (ndbd processes). There are three main access paths from Java to NDBCLUSTER, listed here:

- JDBC and mysql. JDBC works by sending SQL statements to the MySQL Server and returning result sets. When using JDBC, you must write the SQL, manage the connection, and copy any data from the result set that you want to use in your program as objects. The JDBC implementation most often used with the MySQL Server is MySQL Connector/J.
• **Java Persistence API (JPA) and JDBC.** JPA uses JDBC to connect to the MySQL Server. Unlike JDBC, JPA provides an object view of the data in the database.

• **ClusterJ.** ClusterJ uses a JNI bridge to the NDB API for direct access to NDBCLUSTER. It employs a style of data access that is based on a domain object model, similar in many ways to that employed by JPA. ClusterJ does not depend on the MySQL Server for data access.

These paths are shown in the following API stack diagram:

**Figure 4.1 Java Access Paths To NDB**

![API Stack Diagram](image)

**JDBC and mysql.** Connector/J provides standard access through the MySQL JDBC driver. Using Connector/J, JDBC applications can be written to work with a MySQL server acting as an NDB Cluster SQL node in much the same way that other Connector/J applications work with any other MySQL Server instance.

For more information, see Section 4.2.3, “Using Connector/J with NDB Cluster”.

**ClusterJ.** ClusterJ is a native Java Connector for NDBCLUSTER (or NDB), the storage engine for NDB Cluster, in the style of Hibernate, JPA, and JDO. Like other persistence frameworks, ClusterJ uses the Data Mapper pattern, in which data is represented as domain objects, separate from business logic, mapping Java classes to database tables stored in the NDBCLUSTER storage engine.

**Note**

The NDBCLUSTER storage engine is often referred to (in MySQL documentation and elsewhere) simply as NDB. The terms NDB and NDBCLUSTER are synonymous, and you can use either ENGINE=NDB or ENGINE=NDBCLUSTER in a CREATE TABLE statement to create a clustered table.

ClusterJ does not need to connect to a mysql process, having direct access to NDBCLUSTER using a JNI bridge that is included in the dynamic library libnbdclient. However, unlike JDBC, ClusterJ does not support table creation and other data definition operations; these must be performed by some other means, such as JDBC or the mysql client. Also, ClusterJ is limited to queries on single tables, and does not support relations or inheritance; you should use another kind of access paths if you need support for those features in your applications.

**4.1.3 The ClusterJ API and Data Object Model**

This section discusses the ClusterJ API and the object model used to represent the data handled by the application.
The ClusterJ API and Data Object Model

**Application Programming Interface.** The ClusterJ API depends on 4 main interfaces: `Session`, `SessionFactory`, `Transaction`, and `QueryBuilder`.

**Session interface.** All access to NDB Cluster data is done in the context of a session. The `Session` interface represents a user's or application's individual connection to an NDB Cluster. It contains methods for the following operations:

- Finding persistent instances by primary key
- Creating, updating, and deleting persistent instances
- Getting a query builder (see `com.mysql.clusterj.query.QueryBuilder`)
- Getting the current transaction (see `com.mysql.clusterj.Transaction`).

**SessionFactory interface.** Sessions are obtained from a `SessionFactory`, of which there is typically a single instance for each NDB Cluster that you want to access from the Java VM. `SessionFactory` stores configuration information about the cluster, such as the hostname and port number of the NDB Cluster management server. It also stores parameters regarding how to connect to the cluster, including connection delays and timeouts. For more information about SessionFactory and its use in a ClusterJ application, see Getting the SessionFactory and getting a Session.

**Transaction interface.** Transactions are not managed by the `Session` interface; like other modern application frameworks, ClusterJ separates transaction management from other persistence methods. Transaction demarcation might be done automatically by a container or in a web server servlet filter. Removing transaction completion methods from `Session` facilitates this separation of concerns.

The `Transaction` interface supports the standard begin, commit, and rollback behaviors required by a transactional database. In addition, it enables the user to mark a transaction as being rollback-only, which makes it possible for a component that is not responsible for completing a transaction to indicate that—due to an application or database error—the transaction must not be permitted to complete normally.

**QueryBuilder interface.** The `QueryBuilder` interface makes it possible to construct criteria queries dynamically, using domain object model properties as query modeling elements. Comparisons between parameters and database column values can be specified, including equal, greater and less than, between, and in operations. These comparisons can be combined using methods corresponding to the Boolean operators AND, OR, and NOT. Comparison of values to `NULL` is also supported.

**Data model.** ClusterJ provides access to data in NDB Cluster using domain objects, similar in many ways to the way that JPA models data.

In ClusterJ, the domain object mapping has the following characteristics:

- All tables map to persistent interfaces. For every NDB table in the cluster, ClusterJ uses one or more interfaces. In many cases, a single interface is used; but for cases where different columns are needed by different parts of the application, multiple interfaces can be mapped to the same table.

  However, the classes themselves are not persistent.

- Users map a subset of columns to persistent properties in interfaces. Thus, all properties map to columns; however, not all columns necessarily map to properties.

  All ClusterJ property names default to column names. The interface provides getter and setter methods for each property, with predictable corresponding method names.

- Annotations on interfaces define mappings.

The user view of the application environment and domain objects is illustrated in the following diagram, which shows the logical relationships among the modeling elements of the ClusterJ interfaces:
The SessionFactory is configured by a properties object that might have been loaded from a file or constructed dynamically by the application using some other means (see Section 4.2.2.1, “Executing ClusterJ Applications and Sessions”).

The application obtains Session instances from the SessionFactory, with at most one thread working with a Session at a time. A thread can manage multiple Session instances if there is some application requirement for multiple connections to the database.

Each session has its own collection of domain objects, each of which represents the data from one row in the database. The domain objects can represent data in any of the following states:

• New; not yet stored in the database
• Retrieved from the database; available to the application
• Updated; to be stored back in the database
• To be deleted from the database

4.2 Using MySQL NDB Cluster Connector for Java

This section provides basic information about building and running Java applications using MySQL NDB Cluster Connector for Java (ClusterJ).

4.2.1 Getting, Installing, and Setting Up MySQL NDB Cluster Connector for Java

This section discusses how to obtain ClusterJ sources and binaries, and how to compile, install, and get started with ClusterJ.

Obtaining and Installing MySQL NDB Cluster Connector for Java. You can obtain the most recent NDB Cluster release, which includes ClusterJ, from downloads.mysql.com. The installation instructions given in NDB Cluster Installation also install ClusterJ.

Building and installing MySQL NDB Cluster Connector for Java from source. You can build and install ClusterJ as part of building and installing NDB Cluster, which always requires you to configure the build using the CMake option WITH_NDBCLUSTER_STORAGE_ENGINE (or its alias WITH_NDBCLUSTER).

A typical CMake command for configuring a build for NDB Cluster that supports ClusterJ might look like this:
Getting, Installing, and Setting Up MySQL NDB Cluster Connector for Java

```cmake
  .. -DWITH_NDBCLUSTER=ON
```

The `WITH_NDB_JAVA` option is enabled by default, which means ClusterJ is be built together with NDB Cluster by the above command. However, if CMake cannot find the location of Java on your system, the configuration process is going to fail; use the `WITH_CLASSPATH` option to provide the Java classpath if needed. For information about other CMake options that can be used, see `option_cmake_with_ndbcluster`.

After configuring the build with CMake, run `make` and `make install` as you normally would to compile and install the NDB Cluster software.

MySQL NDB Cluster Connector for Java jar files. Following the installation, these ClusterJ jar files can be found in the folder `share/java` under the MySQL installation directory (which is `/usr/local/mysql` by default for Linux platforms):

- `clusterj-api-version.jar`: This is the compile-time jar file, required for compiling ClusterJ application code.
- `clusterj-version.jar`: This is the runtime library required for executing ClusterJ applications.
- `clusterj-test-version.jar`: This is the ClusterJ test suite, required for testing your ClusterJ installation.

Building ClusterJ with Maven

The source files for ClusterJ are configured as Maven projects, allowing easy compilation and installation using Maven. Assuming you have obtained the NDB Cluster source and already compiled and installed NDB Cluster and ClusterJ following the instructions given above, these are the steps to take:

1. Add the file path for the folder that contains the NDB client library (`libndbclient.so`) as a property named `ndbclient.lib` to your local Maven `settings.xml` file (found in the local Maven repository, which is usually `/home/username/.m2` for Linux platforms). The client library is to be found under the `lib` folder in the NDB Cluster's installation folder. If `settings.xml` does not exist in your local Maven repository, create one. This is how a simple `settings.xml` file containing the `ndbclient.lib` property looks like:

   ```xml
   <settings xmlns="http://maven.apache.org/SETTINGS/1.0.0"
     xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
     xsi:schemaLocation="http://maven.apache.org/SETTINGS/1.0.0
     http://maven.apache.org/xsd/settings-1.0.0.xsd">
     <profiles>
       <profile>
         <id>jni-library</id>
         <activation>
           <activeByDefault>true</activeByDefault>
         </activation>
         <properties>
           <ndbclient.lib>/NDB_Cluster_installation_directory/lib/</ndbclient.lib>
         </properties>
       </profile>
     </profiles>
   </settings>
   ```

2. Go to the build directory you created when compiling NDB Cluster (which is `bld` in the sample steps in Build the Distribution), and then to the `storage/ndb/clusterj` folder under it. Run the `mvn_install_ndbjtie.sh` script in the folder:

   ```bash
   ./mvn_install_ndbjtie.sh
   ```

   It installs `ndbjtie.jar`, which provides the JNI layer for ClusterJ and is required for building ClusterJ.
3. Install ClusterJ with Maven by running `mvn install` in the `storage/ndb/clusterj` directory:

```
mvn install
```

This causes ClusterJ to be built, with the resulting `.jar` files installed in the local Maven repository.

**Note**

You can skip the tests that take place towards the end of the installation process by adding the option `skipTests` to the command:

```
mvn install -DskipTests
```

This prevents your installation from failing because you have not yet set up the testing environment.

**Building ClusterJ with Maven in IDEs**

Because the source files for ClusterJ are configured as Maven projects, you can easily import them into your favorite Maven-enabled IDEs, customize them, and rebuild them as needed by following these steps:

1. Make sure that your IDE’s support for Maven is enabled. You might need to install a Maven plugin for the purpose.

2. Follow step 1 and 2 in **Building ClusterJ with Maven**, which make the ClusterJ source ready to be used with Maven.

3. Import ClusterJ as a Maven project. This is how to do it in some popular IDEs:

   - **In NetBeans:**
     - In the main menu, choose **File > Open Project**. The **Open Project** dialogue box appears.
     - In the **Open Project** dialogue box, browse to the `storage/ndb` folder under the build directory (see step 2 in **Building ClusterJ with Maven**); select the `clusterj` folder, which has the Maven icon ( ), and click **Open Project**. The ClusterJ Aggregate project is imported, with **ClusterJ API**, **ClusterJ Core**, **ClusterJ Test Suite**, **ClusterJ Tie**, and **ClusterJ Unit Test Framework** imported as subprojects under **Modules**.
     - Work with the ClusterJ projects like you would with any other Maven projects in NetBeans. Any changes to the source code go into the source tree from which you compiled NDB Cluster to create the build directory.

   - **In Eclipse:**
     - In the main menu, choose **File > Import**. The **Import** dialogue box appears.
     - In the **Import** dialogue box, select **Maven > Existing Maven Projects** for import wizard and click **Next**. The **Import Maven Projects** dialogue box appears.
     - In the **Import Maven Projects** dialogue box, browse to the `storage/ndb` folder under the build directory (see step 2 in **Building ClusterJ with Maven**); select the `clusterj` folder and click **Select Folder**. The `clusterj-aggregate` project, as well as its subprojects `clusterj-api`, `clusterj-core`, `clusterj-test`, `clusterj-tie` and `clusterj-unit`, appear in the **Maven Projects** dialogue box. Click **Select All** and then **Finish**. All the ClusterJ projects are imported.
     - Work with the ClusterJ projects like you would with any other Maven projects in Eclipse.
4.2.2 Using ClusterJ

This section provides basic information for writing, compiling, and executing applications that use ClusterJ. For the API documentation for ClusterJ, see Section 4.3, "ClusterJ API Reference".

Requirements. ClusterJ requires Java 1.7 or 1.8. NDB Cluster must be compiled with ClusterJ support; NDB Cluster binaries supplied by Oracle include ClusterJ support. If you are building NDB Cluster from source, see Building and installing MySQL NDB Cluster Connector for Java from source, for information on configuring the build to enable ClusterJ support.

To compile applications that use ClusterJ, you either need to have the clusterj-api jar file in your classpath, or use a Maven dependency manager to install and configure the ClusterJ library in your project.

To run applications that use ClusterJ, you need the clusterj runtime jar file; in addition, libndbclient must be in the directory specified by java.library.path. Section 4.2.2.1, "Executing ClusterJ Applications and Sessions", provides more information about these requirements.

4.2.2.1 Executing ClusterJ Applications and Sessions

In this section, we discuss how to start ClusterJ applications and the ClusterJ application environment.

Executing a ClusterJ application. All of the ClusterJ jar files are normally found in share/mysql/java/ in the MySQL installation directory. When executing a ClusterJ application, you must set the classpath to point to these files. In addition, you must set java.library.path variable to point to the directory containing the Cluster ndbclient library, normally found in lib/mysql (also in the MySQL installation directory). Thus you might execute a ClusterJ program MyClusterJApp in a manner similar to what is shown here:

```
$ java -classpath /usr/local/mysql/share/mysql/java/clusterj.jar 
   -Djava.library.path=/usr/local/mysql/lib MyClusterJApp
```

Note
The precise locations of the ClusterJ jar files and of libndbclient depend on how the NDB Cluster software was installed. See Installation Layouts, for more information.

ClusterJ encourages you to use different jar files at compile time and runtime. This is to remove the ability of applications to access implementation artifacts accidentally. ClusterJ is intended to be independent of the NDB Cluster software version, whereas the ndbclient layer is version-specific. This makes it possible to maintain a stable API, so that applications written against it using a given NDB Cluster version continue to run following an upgrade of the cluster to a new version.

Getting the SessionFactory and getting a Session. SessionFactory is the source of all ClusterJ sessions that use a given NDB Cluster. Usually, there is only a single SessionFactory per NDB Cluster, per Java Virtual Machine.

SessionFactory can be configured by setting one or more properties. The preferred way to do this is by putting these in a properties file, like this:

```
com.mysql.clusterj.connectstring=localhost:1186
com.mysql.clusterj.database=mydb
```

The name of the properties file is arbitrary; however, by convention, such files are named with a .properties extension. For ClusterJ applications, it is customary to name the file clusterj.properties.

After editing and saving the file, you can load its contents into an instance of Properties, as shown here:
Using ClusterJ

```java
File propsFile = new File("clusterj.properties");
InputStream inStream = new FileInputStream(propsFile);
Properties props = new Properties();
props.load(inStream);
```

It is also possible to set these properties directly, without the use of a properties file:

```java
Properties props = new Properties();
props.put("com.mysql.clusterj.connectstring", "localhost:1186");
props.put("com.mysql.clusterj.database", "mydb");
```

Once the properties have been set and loaded (using either of the techniques just shown), you can obtain a `SessionFactory`, and then from that a `Session` instance. For this, you use the `SessionFactory`'s `getSession()` method, as shown here:

```java
SessionFactory factory = ClusterJHelper.getSessionFactory(props);
Session session = factory.getSession();
```

It is usually sufficient to set and load the `com.mysql.clusterj.connectstring` and `com.mysql.clusterj.database` properties (and these properties, along with `com.mysql.clusterj.max.transactions`, cannot be changed after starting the `SessionFactory`). For a complete list of available `SessionFactory` properties and usual values, see `com.mysql.clusterj.Constants`.

**Note**

Session instances must not be shared among threads. Each thread in your application should use its own instance of Session.

For `com.mysql.clusterj.connectstring`, we use the default NDB Cluster connection string `localhost:1186` (see NDB Cluster Connection Strings, for more information). For the value of `com.mysql.clusterj.database`, we use `mydb` in this example, but this value can be the name of any database containing NDB tables. For a listing of all `SessionFactory` properties that can be set in this manner, see `com.mysql.clusterj.Constants`.

**Error Handling and Reconnection.** Errors that occur while using ClusterJ should be handled by the application with a common error handler. The handler needs to be able to detect and distinguish among three types of errors, and handle them accordingly:

- **Normal errors**: These are errors at the application level (for example, those to deal with duplicate key, foreign key constraint, or timeout). They should be handled in application-specific ways, and, if resolved, the application can continue with the transaction.

- **Unexpected errors**: These are failures to work with the cluster that cannot be accounted for by the conditions of the application, but are nonfatal. The application should close the ClusterJ session and reopen a new one.

- **Connectivity errors**: These are errors like error 4009 and 4010, which indicate a network outage.

There are two possible scenarios, depending on whether the automatic reconnection feature (available for NDB Cluster 7.5.7 and later) has been enabled:

- **Automatic reconnection is enabled**: The feature is enabled when the connection property `com.mysql.clusterj.connection.reconnect.timeout` has been set to a positive number, which specifies a reconnection timeout in seconds.

When ClusterJ detects a disconnect with the NDB Cluster, it changes the State of the `SessionFactory` from OPEN to RECONNECTING; the `SessionFactory` then waits for the application to close all the sessions, and then attempts to reconnect the application to the NDB Cluster by closing all connections in the connection pool and recreating the pool using the original
pool properties. After reestablishing all the connections, the State of the SessionFactory becomes OPEN again, and the application can now obtain sessions.

The SessionFactory getState() method returns the State of the SessionFactory, which is one of OPEN, RECONNECTING, or CLOSED. Trying to obtain a session when the State is not OPEN results in a ClusterJUserException, with the message Session factory is not open.

If the application does not close all sessions by the end of the timeout period specified with com.mysql.clusterj.connection.reconnect.timeout, the SessionFactory closes any open sessions forcibly (which might result in loss of resources), and then attempts reconnection.

- **Automatic reconnection is not enabled:** This is when the connection property com.mysql.clusterj.connection.reconnect.timeout has not been set, or it has been set to zero (this is also the case for older NDB Cluster releases that do not support the automatic reconnection feature).

ClusterJ does not attempt to reconnect to the NDB Cluster once the connection is lost. The application should close all sessions and then restart the SessionFactory. The restarting of the SessionFactory can be an automatic application function or a manual intervention. In either case, the code should wait until all sessions have been closed (that is, the public method getConnectionPoolSessionCounts() in the SessionFactory interface returns zeros for all pooled connections). Then the SessionFactory can be closed and reopened, and the application can obtain sessions again.

Instead of enabling the feature and waiting for ClusterJ to detect a disconnection and attempt a reconnection, you can also have the application itself initiate the reconnection process upon the detection of a connection error by calling the SessionFactory.reconnect(int timeout) method: that triggers the reconnection process described above, but uses the timeout argument of the reconnect() method as the time limit for having all open sessions closed.

**Logging.** ClusterJ uses Java logging. Here are some default settings for the ClusterJ logging, which are specified in the logging.properties file and can be modified there:

- Logging level is set at INFO for all classes.
- Using java.util.logging.FileHandler as the handler.
- Default level for java.util.logging.FileHandler is set at FINEST
- Using java.util.logging.SimpleFormatter as the formatter for the handler.
- Log files are put inside the target directory under the current working directory, and file names are, generally, in the pattern of logNum, where Num is a unique number for resolving file name conflicts (see the Java documentation for java.util.logging.FileHandler for details).

The logging.properties file is located by default in the current working directory, but the location can be changed by specifying the system property java.util.logging.config.file when you start Java.

### 4.2.2.2 Creating tables

ClusterJ's main purpose is to read, write, and update row data in an existing database, rather than to perform DDL. You can create the employee table that matches this interface, using the following CREATE TABLE statement, in a MySQL client application such as mysql.

```sql
CREATE TABLE employee (
    id INT NOT NULL PRIMARY KEY,
    first VARCHAR(64) DEFAULT NULL,
    last VARCHAR(64) DEFAULT NULL,
    municipality VARCHAR(64) DEFAULT NULL,
```
Now that the table has been created in NDB Cluster, you can map a ClusterJ interface to it using annotations. We show you how to do this in the next section.

### 4.2.2.3 Annotations

In ClusterJ (as in JPA), annotations are used to describe how the interface is mapped to tables in a database. An annotated interface looks like this:

```java
@PersistenceCapable(table="employee")
@Index(name="idx_uhash")
public interface Employee {
    @PrimaryKey
    int getId();
    void setId(int id);

    String getFirst();
    void setFirst(String first);
    String getLast();
    void setLast(String last);

    @Column(name="municipality")
    @Index(name="idx_municipality")
    String getCity();
    void setCity(String city);

    Date getStarted();
    void setStarted(Date date);

    Date getEnded();
    void setEnded(Date date);

    Integer getDepartment();
    void setDepartment(Integer department);
}
```

This interface maps seven columns: `id`, `first`, `last`, `municipality`, `started`, `ended`, and `department`. The annotation `@PersistenceCapable(table="employee")` is used to let ClusterJ know which database table to map the `Employee` to (in this case, the `employee` table). The `@Column` annotation is used because the `city` property name implied by the `getCity()` and `setCity()` methods is different from the mapped column name `municipality`. The annotations `@PrimaryKey` and `@Index` inform ClusterJ about indexes in the database table.

The implementation of this interface is created dynamically by ClusterJ at runtime. When the `newInstance()` method is called, ClusterJ creates an implementation class for the `Employee` interface; this class stores the values in an internal object array.

ClusterJ does not require an annotation for every attribute. ClusterJ automatically detects the primary keys of tables; while there is an annotation in ClusterJ to permit the user to describe the primary keys of a table (see previous example), when specified, it is currently ignored. (The intended use of this annotation is for the generation of schemas from the domain object model interfaces, but this is not yet supported.)

The annotations themselves must be imported from the ClusterJ API. They can be found in package `com.mysql.clusterj.annotation`, and can be imported like this:

```java
import com.mysql.clusterj.annotation.Column;
import com.mysql.clusterj.annotation.Index;
import com.mysql.clusterj.annotation.PersistenceCapable;
import com.mysql.clusterj.annotation.PrimaryKey;
```
4.2.2.4 ClusterJ Basic Operations

In this section, we describe how to perform operations basic to ClusterJ applications, including the following:

- Creating new instances, setting their properties, and saving them to the database
- Performing primary key lookups (reads)
- Updating existing rows and saving the changes to the database
- Deleting rows from the database
- Constructing and executing queries to fetch a set of rows meeting certain criteria from the database

Creating new rows. To insert a new row into the table, first create a new instance of `Employee`. This can be accomplished by calling the `Session` method `newInstance()`, as shown here:

```java
Employee newEmployee = session.newInstance(Employee.class);
```

Set the `Employee` instance properties corresponding with the desired `employee` table columns. For example, the following sets the `id`, `firstName`, `lastName`, and `started` properties.

```java
emp.setId(988);
newEmployee.setFirstName("John");
newEmployee.setLastName("Jones");
newEmployee.setStarted(new Date());
```

Once you are satisfied with the changes, you can persist the `Employee` instance, causing a new row containing the desired values to be inserted into the `employee` table, like this:

```java
session.persist(newEmployee);
```

If autocommit is on, and a row with the same `id` as this instance of `Employee` already exists in the database, the `persist()` method fails. If autocommit is off and a row with the same `id` as this `Employee` instance already exists in the database, the `persist()` method succeeds but a subsequent `commit()` fails.

If you want the data to be saved even though the row already exists, use the `savePersistent()` method instead of the `persist()` method. The `savePersistent()` method updates an existing instance or creates a new instance as needed, without throwing an exception.

Values that you have not specified are stored with their Java default values (0 for integral types, 0.0 for numeric types, and `null` for reference types).

Primary key lookups. You can find an existing row in an `NDB` table using the `Session's find()` method, like this:

```java
Employee theEmployee = session.find(Employee.class, 988);
```

This is equivalent to the primary key lookup query `SELECT * FROM employee WHERE id = 988`.

ClusterJ also supports compound primary keys. The `find()` method can take an object array as a key, where the components of the object array are used to represent the primary key columns in the order they were declared. In addition, queries are optimized to detect whether columns of the primary key are specified as part of the query criteria, and if so, a primary key lookup or scan is executed as a strategy to implement the query.

Note

ClusterJ also supports multiple column ordered btree and unique hash indexes. As with primary keys, if a query specifies values for ordered or unique index fields, ClusterJ optimizes the query to use the index for scanning the table.
Using ClusterJ

NDB Cluster automatically spreads table data across multiple data nodes. For some operations—find, insert, delete, and update—it is more efficient to tell the cluster on which data node the data is physically located, and to have the transaction execute on that data node. ClusterJ automatically detects the partition key; if the operation can be optimized for a specific data node, ClusterJ automatically starts the transaction on that node.

**Update and save a row.** To update the value of a given column in the row that we just obtained as `theEmployee`, use the `set*()` method whose name corresponds to the name of that column. For example, to update the `started` date for this `Employee`, use the `Employee`'s `setStarted()` method, as shown here:

```java
theEmployee.setStarted(new Date(getMillisFor(2010, 01, 04)));
```

**Note**

For convenience, we use in this example a method `getMillisFor()`, which is defined as shown here, in the file `AbstractClusterJModelTest.java` (found in the `storage/ndb/clusterj/clusterj-test/src/main/java/testsuite/clusterj` directory of the NDB Cluster source tree):

```java
/** Convert year, month, day into milliseconds after the Epoch, UTC.  
 * Set hours, minutes, seconds, and milliseconds to zero.  
 * @param year the year  
 * @param month the month (0 for January)  
 * @param day the day of the month  
 * @return */
protected static long getMillisFor(int year, int month, int day) {
    Calendar calendar = Calendar.getInstance();
    calendar.clear();
    calendar.set(Calendar.YEAR, year);
    calendar.set(Calendar.MONTH, month);
    calendar.set(Calendar.DATE, day);
    calendar.set(Calendar.HOUR, 0);
    calendar.set(Calendar.MINUTE, 0);
    calendar.set(Calendar.SECOND, 0);
    calendar.set(Calendar.MILLISECOND, 0);
    long result = calendar.getTimeInMillis();
    return result;
}
```

See the indicated file for further information.

You can update additional columns by invoking other `Employee` setter methods, like this:

```java
theEmployee.setDepartment(3);
```

To save the changed row back to the NDB Cluster database, use the `Session`'s `updatePersistent()` method, like this:

```java
session.updatePersistent(theEmployee);
```

**Deleting rows.** You can delete a single row easily using the `deletePersistent()` method of `Session`. In this example, we find the employee whose ID is 13, then delete this row from the `employee` table:

```java
Employee exEmployee = session.find(Employee.class, 13);
session.deletePersistent(exEmployee);
System.out.println("Deleted employee named " + exEmployee.getFirst()  
                    + " " + exEmployee.getLast() + ",");
```
Using ClusterJ

There also exists a method for deleting multiple rows, which provides two options:

1. Delete all rows from a table.
2. Delete an arbitrary collection of rows.

Both kinds of multi-row delete can be performed using the `deletePersistentAll()` method. The first variant of this method acts on a `Class`. For example, the following statement deletes all rows from the `employee` table and returns the number of rows deleted, as shown here:

```java
int numberDeleted = session.deletePersistentAll(Employee);
System.out.println("There used to be " + numberDeleted + " employees, but now there are none.");
```

The call to `deletePersistentAll()` just shown is equivalent to issuing the SQL statement `DELETE FROM employee` in the `mysql` client.

`deletePersistentAll()` can also be used to delete a collection of rows, as shown in this example:

```java
// Assemble the collection of rows to be deleted...
List<Employee> redundancies = new ArrayList<Employee>();
for (int i = 1000; i < 2000; i += 100) {
    Employee redundant = session.newInstance(Employee.class);
    redundant.setId(i);
    redundancies.add(redundant);
}
numberDeleted = session.deletePersistentAll(redundancies);
System.out.println("Deleted " + numberDeleted + " rows.");
```

It is not necessary to find the instances in the database before deleting them.

**Writing queries.** The ClusterJ `QueryBuilder` interface is used to instantiate queries. The process begins with obtaining an instance of `QueryBuilder`, which is supplied by the current `Session`; we can then obtain a `QueryDefinition`, as shown here:

```java
QueryBuilder builder = session.getQueryBuilder();
QueryDomainType<Employee> domain = builder.createQueryDefinition(Employee.class);
```

This is then used to set a column for comparison by the query. Here, we show how to prepare a query that compares the value of the `employee` table’s `department` column with the constant value 8.

```java
domain.where( domain.get("department").equal(domain.param("department") ) );
Query<Employee> query = session.createQuery(domain);
query.setParameter("department", 8);
```

To obtain the results from the query, invoke the `Query`'s `getResultList()` method, as shown here:

```java
List<Employee> results = query.getResultList();
```

The return value is a `List` that you can iterate over to retrieve and process the rows in the usual manner.

**Transactions.** The `Transaction` interface can optionally be used to bound transactions, via the following methods:

- `begin()`: Begin a transaction.
- `commit()`: Commit a transaction.
• **rollback()**: Roll back a transaction.

It is also possible using `Transaction` to check whether the transaction is active (via the `isActive()` method, and to get and set a rollback-only flag (using `getRollbackOnly()` and `setRollbackOnly()`, respectively).

If you do not use the `Transaction` interface, methods in `Session` that affect the database—such as `persist()`, `deletePersistent()`, `updatePersistent()`, and so on—are automatically enclosed in a database transaction.

### 4.2.2.5 ClusterJ Mappings Between MySQL and Java Data Types

ClusterJ provides mappings for all of the common MySQL database types to Java types. Java object wrappers of primitive types should be mapped to nullable database columns.

#### Note
Since Java does not have native unsigned data types, **UNSIGNED** columns should be avoided in table schemas if possible.

**Compatibility with JDBC mappings.** ClusterJ is implemented so as to be bug-compatible with the JDBC driver in terms of mapping from Java types to the database. That is, if you use ClusterJ to store or retrieve data, you obtain the same value as if you used the JDBC driver directly or through JPA.

The following tables show the mappings used by ClusterJ between common Java data types and MySQL column types. Separate tables are provided for numeric, floating-point, and variable-width types.

#### Numeric types.
This table shows the ClusterJ mappings between Java numeric data types and MySQL column types:

<table>
<thead>
<tr>
<th>Java Data Type</th>
<th>MySQL Column Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>boolean, Boolean</code></td>
<td><code>BIT(1)</code></td>
</tr>
<tr>
<td><code>byte, Byte</code></td>
<td><code>BIT(1)</code> to <code>BIT(8), TINYINT</code></td>
</tr>
<tr>
<td><code>short, Short</code></td>
<td><code>BIT(1)</code> to <code>BIT(16), SMALLINT, YEAR</code></td>
</tr>
<tr>
<td><code>int, Integer</code></td>
<td><code>BIT(1)</code> to <code>BIT(32), INT</code></td>
</tr>
<tr>
<td><code>long, Long</code></td>
<td><code>BIT(1)</code> to <code>BIT(64), BIGINT, BIGINT UNSIGNED</code></td>
</tr>
<tr>
<td><code>float, Float</code></td>
<td><code>FLOAT</code></td>
</tr>
<tr>
<td><code>double, Double</code></td>
<td><code>DOUBLE</code></td>
</tr>
<tr>
<td><code>java.math.BigDecimal</code></td>

</tbody>
</table>

#### Date and time types.
The following table shows the ClusterJ mappings between Java date and time data types and MySQL column types:

<table>
<thead>
<tr>
<th>Java Data Type</th>
<th>MySQL Column Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Java.util.Date</code></td>
<td><code>DATETIME, TIMESTAMP, TIME, DATE</code></td>
</tr>
<tr>
<td><code>Java.sql.Date</code></td>
<td><code>DATE</code></td>
</tr>
<tr>
<td><code>Java.sql.Time</code></td>
<td><code>TIME</code></td>
</tr>
<tr>
<td><code>Java.sql.Timestamp</code></td>
<td><code>DATETIME, TIMESTAMP</code></td>
</tr>
</tbody>
</table>
Using Connector/J with NDB Cluster

Note
ClusterJ maps the MySQL \texttt{YEAR} type to a Java \texttt{short} (or \texttt{java.lang.Short}), as shown in the first table in this section.

\texttt{java.util.Date} represents date and time similar to the way in which Unix does so, but with more precision and a larger range. Where Unix represents a point in time as a 32-bit signed number of seconds since the Unix Epoch (01 January 1970), Java uses a 64-bit signed number of milliseconds since the Epoch.

Variable-width types. The following table shows the ClusterJ mappings between Java data types and MySQL variable-width column types:

Table 4.3 This table shows the ClusterJ mappings between Java data types and MySQL variable-width column types.

<table>
<thead>
<tr>
<th>Java Data Type</th>
<th>MySQL Column Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>\texttt{CHAR, VARCHAR, TEXT}</td>
</tr>
<tr>
<td>byte[]</td>
<td>\texttt{BINARY, VARBINARY, BLOB}</td>
</tr>
</tbody>
</table>

Note
No translation binary data is performed when mapping from MySQL \texttt{BINARY}, \texttt{VARBINARY}, or \texttt{BLOB} column values to Java byte arrays. Data is presented to the application exactly as it is stored.

4.2.3 Using Connector/J with NDB Cluster

JDBC clients of an NDB Cluster data source, and using Connector/J 5.0.6 (or later), accept \texttt{jdbc:mysql:loadbalance://} URLs (see Configuration Properties), with which you can take advantage of the ability to connect with multiple MySQL servers to achieve load balancing and failover.

However, while Connector/J does not depend on the MySQL client libraries, it does require a connection to a MySQL Server, which ClusterJ does not. JDBC also does not provide any object mappings for database objects, properties, or operations, or any way to persist objects.

See MySQL Connector/J Developer Guide, for general information about using Connector/J.

4.3 ClusterJ API Reference

The following sections contain specifications for ClusterJ packages, interfaces, classes, and methods.

4.3.1 \texttt{com.mysql.clusterj}

Provides classes and interfaces for using NDB Cluster directly from Java.

- A class for bootstrapping
- Interfaces for use in application programs
- Classes to define exceptions

This package contains three main groups of classes and interfaces:

4.3.1.1 Major Interfaces

ClusterJ provides these major interfaces for use by application programs:

and com.mysql.clusterj.Query. **Bootstrapping** The helper class com.mysql.clusterj.ClusterJHelper contains methods for creating the com.mysql.clusterj.SessionFactory. **Bootstrapping** is the process of identifying an NDB Cluster and obtaining the SessionFactory for use with the cluster. There is one SessionFactory per cluster per Java VM.

**SessionFactory**

The com.mysql.clusterj.SessionFactory is configured via properties, which identify the NDB Cluster that the application connects to:

- com.mysql.clusterj.connectstring identifies the ndb_mgmd host name and port
- com.mysql.clusterj.connect.retries is the number of retries when connecting
- com.mysql.clusterj.connect.delay is the delay in seconds between connection retries
- com.mysql.clusterj.connect.verbose tells whether to display a message to System.out while connecting
- com.mysql.clusterj.connect.timeout.before is the number of seconds to wait until the first node responds to a connect request
- com.mysql.clusterj.connect.timeout.after is the number of seconds to wait until the last node responds to a connect request
- com.mysql.clusterj.connect.database is the name of the database to use

```java
File propsFile = new File("clusterj.properties");
InputStream inStream = new FileInputStream(propsFile);
Properties props = new Properties();
props.load(inStream);
SessionFactory sessionFactory = ClusterJHelper.getSessionFactory(props);
```

**Session** The com.mysql.clusterj.Session represents the user's individual connection to the cluster. It contains methods for:

- finding persistent instances by primary key
- persistent instance factory (newInstance)
- persistent instance life cycle management (persist, remove)
- getting the QueryBuilder
- getting the Transaction (currentTransaction)

```java
Session session = sessionFactory.getSession();
Employee existing = session.find(Employee.class, 1);
if (existing != null) {
    session.remove(existing);
}
Employee newemp = session.newInstance(Employee.class);
newemp.initialize(2, "Craig", 15, 146000.00);
session.persist(newemp);
```

**Transaction** The com.mysql.clusterj.Transaction allows users to combine multiple operations into a single database transaction. It contains methods to:

- begin a unit of work
- commit changes from a unit of work
- roll back all changes made since the unit of work was begun
• mark a unit of work for rollback only
• get the rollback status of the current unit of work

```java
Transaction tx = session.currentTransaction();
    tx.begin();
    Employee existing = session.find(Employee.class, 1);
    Employee newemp = session.newInstance(Employee.class);
    newemp.initialize(2, "Craig", 146000.00);
    session.persist(newemp);
    tx.commit();
```

**QueryBuilder** The `com.mysql.clusterj.query.QueryBuilder` allows users to build queries. It contains methods to:

• define the Domain Object Model to query
• compare properties with parameters using:
  • equal
  • lessThan
  • greaterThan
  • lessEqual
  • greaterEqual
  • between
  • in
• combine comparisons using "and", "or", and "not" operators

```java
QueryBuilder builder = session.getQueryBuilder();
QueryDomainType<Employee> qemp = builder.createQueryDefinition(Employee.class);
Predicate service = qemp.get("yearsOfService").greaterThan(qemp.param("service"));
Predicate salary = qemp.get("salary").lessEqual(qemp.param("salaryCap"));
qemp.where(qemp.param("service")
          .lessEqual(qemp.param("salaryCap"));
query<Employee> query = session.createQuery(qemp);
query.setParameter("service", 10);
query.setParameter("salaryCap", 180000.00);
List<Employee> results = query.getResultList();
```

### 4.3.1.2 ClusterJDatastoreException

ClusterJUserException represents a database error. The underlying cause of the exception is contained in the "cause".

**Synopsis**

```java
public class ClusterJDatastoreException,
    extends  ClusterJException {
    // Public Constructors
    public ClusterJDatastoreException(  
        String message);
    public ClusterJDatastoreException(  
        String msg,  
        int code,  
        int mysqlCode,  
        int status,  
        int classification);
    public ClusterJDatastoreException(  
```
String message,
    Throwable t);

public ClusterJDatastoreException(
    Throwable t);
// Public Methods
public int getClassification();
public int getCode();
public int getMysqlCode();
public int getStatus();
}

Methods inherited from com.mysql.clusterj.ClusterJException: printStackTrace
Methods inherited from java.lang.Throwable: addSuppressed, fillInStackTrace, getCause
, getLocalizedMessage, getMessage, getStackTrace, getSuppressed, initCause,
setStackTrace, toString
Methods inherited from java.lang.Object: equals, getClass, hashCode, notify, notifyAll
, wait

glassification()

    public int getClassification();

Get the classification

getCode()

    public int getCode();

Get the code

    Since 7.3.15, 7.4.13, 7.5.4

getMysqlCode()

    public int getMysqlCode();

Get the mysql code

    Since 7.3.15, 7.4.13, 7.5.4

getStatus()

    public int getStatus();

Get the status

4.3.1.3 ClusterJDatastoreException.Classification

Helper class for getClassification(). import 
com.mysql.clusterj.ClusterJDatastoreException.Classification; Classification
   c = Classification.lookup(datastoreException.getClassification());
   System.out.println("exceptionClassification " + c + " with value " + c.value);

Synopsis

public static final class ClusterJDatastoreException.Classification,
extends Enum<Classification> {

// Public Static Fields

public static final Classification ApplicationError ;

public static final Classification ConstraintViolation ;

public static final Classification FunctionNotImplemented ;

public static final Classification InsufficientSpace ;

public static final Classification InternalError ;

public static final Classification InternalTemporary ;

public static final Classification NoDataFound ;

public static final Classification NoError ;

public static final Classification NodeRecoveryError ;

public static final Classification NodeShutdown ;

public static final Classification OverloadError ;

public static final Classification SchemaError ;

public static final Classification SchemaObjectExists ;

public static final Classification TemporaryResourceError ;

public static final Classification TimeoutExpired ;

public static final Classification UnknownErrorCode ;

public static final Classification UnknownResultError ;

public static final Classification UserDefinedError ;

// Public Static Methods

public static Classification lookup( int value);

public static Classification valueOf( String name);

public static Classification[] values();

}

Methods inherited from java.lang.Enum: compareTo, equals, getDeclaringClass, hashCode, name, ordinal, toString, valueOf
Methods inherited from java.lang.Object: getClass, notify, notifyAll, wait

Since 7.3.15, 7.4.13, 7.5.4

lookup(int)

```java
public static Classification lookup(
    int value);
```

Get the Classification enum for a value returned by ClusterJDatastoreException.getClassification().

Table 4.4 lookup(int)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>the classification returned by getClassification()</td>
</tr>
<tr>
<td>return</td>
<td>the Classification for the error</td>
</tr>
</tbody>
</table>

4.3.1.4 ClusterJException

ClusterJException is the base for all ClusterJ exceptions. Applications can catch ClusterJException to be notified of all ClusterJ reported issues.

- User exceptions are caused by user error, for example providing a connect string that refers to an unavailable host or port.
  - If a user exception is detected during bootstrapping (acquiring a SessionFactory), it is thrown as a fatal exception. com.mysql.clusterj.ClusterJFatalUserException
  - If an exception is detected during initialization of a persistent interface, for example annotating a column that doesn’t exist in the mapped table, it is reported as a user exception. com.mysql.clusterj.ClusterJUserException

- Datastore exceptions report conditions that result from datastore operations after bootstrapping. For example, duplicate keys on insert, or record does not exist on delete. com.mysql.clusterj.ClusterJDatastoreException

- Internal exceptions report conditions that are caused by errors in implementation. These exceptions should be reported as bugs. com.mysql.clusterj.ClusterJFatalInternalException

Exceptions are in three general categories: User exceptions, Datastore exceptions, and Internal exceptions.

Synopsis

```java
public class ClusterJException,
    extends RuntimeException {
    // Public Constructors
    public ClusterJException(
        String message);
    public ClusterJException(
        String message,
        Throwable t);
    public ClusterJException(
        Throwable t);
    // Public Methods
    public synchronized void printStackTrace(
        PrintStream s);
}
```

Methods inherited from java.lang.Throwable: addSuppressed, fillInStackTrace, getCause, getLocalizedMessage, getMessage, getStackTrace, getSuppressed, initCause, printStackTrace, setStackTrace, toString

Methods inherited from java.lang.Object: equals, getClass, hashCode, notify, notifyAll, wait

4.3.5 ClusterJFatalException

ClusterJFatalException represents an exception that is not recoverable.

Synopsis

```java
public class ClusterJFatalException, 
extends ClusterJException {
    // Public Constructors
    public ClusterJFatalException(
          String string);
    public ClusterJFatalException(
          String string,
          Throwable t);
    public ClusterJFatalException(
          Throwable t);
}
```

Methods inherited from com.mysql.clusterj.ClusterJException: printStackTrace

Methods inherited from java.lang.Throwable: addSuppressed, fillInStackTrace, getCause, getLocalizedMessage, getMessage, getStackTrace, getSuppressed, initCause, setStackTrace, toString

Methods inherited from java.lang.Object: equals, getClass, hashCode, notify, notifyAll, wait

4.3.6 ClusterJFatalInternalException

ClusterJFatalInternalException represents an implementation error that the user cannot recover from.

Synopsis

```java
public class ClusterJFatalInternalException, 
extends ClusterJFatalException {
    // Public Constructors
    public ClusterJFatalInternalException(
          String string);
    public ClusterJFatalInternalException(
          String string,
          Throwable t);
    public ClusterJFatalInternalException(
          Throwable t);
}
```
4.3.1.7 ClusterJFatalUserException

ClusterJFatalUserException represents a user error that is unrecoverable, such as programming errors in persistent classes or missing resources in the execution environment.

Synopsis

```
public class ClusterJFatalUserException,  
        extends ClusterJFatalException {  
    // Public Constructors

    public ClusterJFatalUserException(  
            String string);

    public ClusterJFatalUserException(  
            String string,  
            Throwable t);

    public ClusterJFatalUserException(  
            Throwable t);
}
```

4.3.1.8 ClusterJHelper

ClusterJHelper provides helper methods to bridge between the API and the implementation.

Synopsis

```
public class ClusterJHelper {  
    // Public Constructors

    public ClusterJHelper();

    // Public Static Methods

    public static boolean getBooleanProperty(  
            String propertyName,  
            String def);

    public static T getServiceInstance(  
            Class<T> cls);  

    public static T getServiceInstance(  
            Class<T> cls,  
            ClassLoader loader);  

    public static T getServiceInstance(  
```
Methods inherited from java.lang.Object: equals, getClass, hashCode, notify, notifyAll, toString, wait

**getBooleanProperty(String, String)**

```java
public static boolean getBooleanProperty(
    String propertyName,
    String def);
```

Get the named boolean property from either the environment or system properties. If the property is not 'true' then return false.

**Table 4.5 getBooleanProperty(String, String)**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>propertyName</td>
<td>the name of the property</td>
</tr>
<tr>
<td>def</td>
<td>the default if the property is not set</td>
</tr>
<tr>
<td>return</td>
<td>the system property if it is set via -D or the system environment</td>
</tr>
</tbody>
</table>

**getServiceInstance(Class<T>)**

```java
public static T getServiceInstance(
    Class<T> cls);
```

Locate a service implementation by services lookup of the context class loader.

**Table 4.6 getServiceInstance(Class<T>)**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cls</td>
<td>the class of the factory</td>
</tr>
<tr>
<td>return</td>
<td>the service instance</td>
</tr>
</tbody>
</table>

**getServiceInstance(Class<T>, ClassLoader)**

```java
public static T getServiceInstance(
    Class<T> cls,
    ClassLoader loader);
```

**getServiceInstances(Class<T>, ClassLoader, StringBuffer)**

```java
public static List<T> getServiceInstances(
    Class<T> cls,
    ClassLoader loader,
    StringBuffer errorMessages);
```

**getSessionFactory(Map)**

```java
public static SessionFactory getSessionFactory(
    Map props);
```

**getSessionFactory(Map, ClassLoader)**

```java
public static SessionFactory getSessionFactory(
    Map props,
    ClassLoader loader);
```

**getStringProperty(String, String)**

```java
public static String getStringProperty(
    String propertyName,
    String def);
```

**newDbug()**

```java
public static Dbug newDbug();
```
Locate a service implementation for a service by services lookup of a specific class loader. The first service instance found is returned.

Table 4.7 `getServiceInstance(Class<T>, ClassLoader)`

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cls</td>
<td>the class of the factory</td>
</tr>
<tr>
<td>loader</td>
<td>the class loader for the factory implementation</td>
</tr>
<tr>
<td>return</td>
<td>the service instance</td>
</tr>
</tbody>
</table>

`getServiceInstance(Class<T>, String)`

```java
public static T getServiceInstance(
Class<T> cls,
String implementationClassName);
```

Locate a service implementation for a service. If the implementation name is not null, use it instead of looking up. If the implementation class is not loadable or does not implement the interface, throw an exception. Use the ClusterJHelper class loader to find the service.

Table 4.8 `getServiceInstance(Class<T>, String)`

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cls</td>
<td>implementationClassName</td>
</tr>
<tr>
<td>implementationClassName</td>
<td></td>
</tr>
<tr>
<td>return</td>
<td>the implementation instance for a service</td>
</tr>
</tbody>
</table>

`getServiceInstance(Class<T>, String, ClassLoader)`

```java
public static T getServiceInstance(
Class<T> cls,
String implementationClassName,
ClassLoader loader);
```

Locate a service implementation for a service. If the implementation name is not null, use it instead of looking up. If the implementation class is not loadable or does not implement the interface, throw an exception.

Table 4.9 `getServiceInstance(Class<T>, String, ClassLoader)`

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cls</td>
<td>implementationClassName</td>
</tr>
<tr>
<td>loadingClassName</td>
<td>name of implementation class to load</td>
</tr>
<tr>
<td>loader</td>
<td>the ClassLoader to use to find the service</td>
</tr>
<tr>
<td>return</td>
<td>the implementation instance for a service</td>
</tr>
</tbody>
</table>

`getServiceInstances(Class<T>, ClassLoader, StringBuffer)`

```java
public static List<T> getServiceInstances(
Class<T> cls,
ClassLoader loader,
StringBuffer errorMessages);
```

Locate all service implementations by services lookup of a specific class loader. Implementations in the services file are instantiated and returned. Failed instantiations are remembered in the errorMessages buffer.
Table 4.10 `getServiceInstances(Class<T>, ClassLoader, StringBuffer)`

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cls</td>
<td>the class of the factory</td>
</tr>
<tr>
<td>loader</td>
<td>the class loader for the factory implementation</td>
</tr>
<tr>
<td>errorMessages</td>
<td>a buffer used to hold the error messages</td>
</tr>
<tr>
<td>return</td>
<td>the service instance</td>
</tr>
</tbody>
</table>

**getSessionFactory(Map)**

```java
public static SessionFactory getSessionFactory(
    Map props);
```

Locate a SessionFactory implementation by services lookup. The class loader used is the thread’s context class loader.

Table 4.11 `getSessionFactory(Map)`

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>props</td>
<td>properties of the session factory</td>
</tr>
<tr>
<td>return</td>
<td>the session factory</td>
</tr>
</tbody>
</table>

Exceptions

`ClusterFatalUserException` if the connection to the cluster cannot be made

**getSessionFactory(Map, ClassLoader)**

```java
public static SessionFactory getSessionFactory(
    Map props,
    ClassLoader loader);
```

Locate a SessionFactory implementation by services lookup of a specific class loader. The properties are a Map that might contain implementation-specific properties plus standard properties.

Table 4.12 `getSessionFactory(Map, ClassLoader)`

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>props</td>
<td>the properties for the factory</td>
</tr>
<tr>
<td>loader</td>
<td>the class loader for the factory implementation</td>
</tr>
<tr>
<td>return</td>
<td>the session factory</td>
</tr>
</tbody>
</table>

Exceptions

`ClusterFatalUserException` if the connection to the cluster cannot be made

**getStringProperty(String, String)**

```java
public static String getStringProperty(
    String propertyName,
    String def);
```

Get the named String property from either the environment or system properties.

Table 4.13 `getStringProperty(String, String)`

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>propertyName</td>
<td>the name of the property</td>
</tr>
<tr>
<td>def</td>
<td>the default if the property is not set</td>
</tr>
</tbody>
</table>
newDbug()

```java
public static Dbug newDbug();
```

Return a new Dbug instance.

**Table 4.14 newDbug()**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>a new Dbug instance</td>
</tr>
</tbody>
</table>

### 4.3.1.9 ClusterJUserException

ClusterJUserException represents a user programming error.

**Synopsis**

```java
public class ClusterJUserException, extends ClusterJException {
    // Public Constructors
    public ClusterJUserException(
        String message);
    public ClusterJUserException(
        String message,
        Throwable t);
    public ClusterJUserException(
        Throwable t);
}
```

**Methods inherited from com.mysql.clusterj.ClusterJException:** `printStackTrace`

**Methods inherited from java.lang.Throwable:** `addSuppressed, fillInStackTrace, getCause, getLocalizedMessage, getMessage, getStackTrace, getSuppressed, initCause, setStackTrace, toString`

**Methods inherited from java.lang.Object:** `equals, getClass, hashCode, notify, notifyAll, wait`

### 4.3.1.10 ColumnMetadata

```java
public interface ColumnMetadata {
    // Public Methods
    public abstract String charsetName();
    public abstract ColumnType columnType();
    public abstract boolean isPartitionKey();
    public abstract boolean isPrimaryKey();
    public abstract Class<?> javaType();
    public abstract int maximumLength();
    public abstract String name();
    public abstract boolean nullable();
    // Other methods...
}
```
public abstract int number();
public abstract int precision();
public abstract int scale();
}

charsetName()

public abstract String charsetName();

Return the charset name.

Table 4.15 charsetName()

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>the charset name</td>
</tr>
</tbody>
</table>

columnType()

public abstract ColumnType columnType();

Return the type of the column.

Table 4.16 columnType()

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>the type of the column</td>
</tr>
</tbody>
</table>

isPartitionKey()

public abstract boolean isPartitionKey();

Return whether this column is a partition key column.

Table 4.17 isPartitionKey()

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>true if this column is a partition key column</td>
</tr>
</tbody>
</table>

isPrimaryKey()

public abstract boolean isPrimaryKey();

Return whether this column is a primary key column.

Table 4.18 isPrimaryKey()

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>true if this column is a primary key column</td>
</tr>
</tbody>
</table>

javaType()

public abstract Class<?> javaType();

Return the java type of the column.

Table 4.19 javaType()

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>the java type of the column</td>
</tr>
</tbody>
</table>
maximumLength()  

```java
public abstract int maximumLength();
```

Return the maximum number of bytes that can be stored in the column after translating the characters using the character set.

**Table 4.20 maximumLength()**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>the maximum number of bytes that can be stored in the column</td>
</tr>
</tbody>
</table>

name()  

```java
public abstract String name();
```

Return the name of the column.

**Table 4.21 name()**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>the name of the column</td>
</tr>
</tbody>
</table>

nullable()  

```java
public abstract boolean nullable();
```

Return whether this column is nullable.

**Table 4.22 nullable()**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>whether this column is nullable</td>
</tr>
</tbody>
</table>

number()  

```java
public abstract int number();
```

Return the column number. This number is used as the first parameter in the get and set methods of DynamicColumn.

**Table 4.23 number()**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>the column number.</td>
</tr>
</tbody>
</table>

precision()  

```java
public abstract int precision();
```

Return the precision of the column.

**Table 4.24 precision()**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>the precision of the column</td>
</tr>
</tbody>
</table>

scale()  

```java
public abstract int scale();
```

Return the scale of the column.
Table 4.25 scale()

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>the scale of the column</td>
</tr>
</tbody>
</table>

4.3.1.11 ColumnType

This class enumerates the column types for columns in ndb.

Synopsis

```java
public final class ColumnType,
    extends Enum<ColumnType> {
    // Public Static Fields

    public static final ColumnType
        Bigint;
    public static final ColumnType
        Bigunsigned;
    public static final ColumnType
        Binary;
    public static final ColumnType
        Bit;
    public static final ColumnType
        Blob;
    public static final ColumnType
        Char;
    public static final ColumnType
        Date;
    public static final ColumnType
        Datetime;
    public static final ColumnType
        Datetime2;
    public static final ColumnType
        Decimal;
    public static final ColumnType
        Decimalunsigned;

4.3.1.12 Constants

Constants used in the ClusterJ project.

Synopsis

```java
public interface Constants {
    // Public Static Fields
    public static final String
```
DEFAULT_PROPERTY_CLUSTER_BYTE_BUFFER_POOL_SIZES = "256, 10240, 102400, 1048576";

public static final int DEFAULT_PROPERTY_CLUSTER_CONNECT_AUTO_INCREMENT_BATCH_SIZE = 10;

public static final long DEFAULT_PROPERTY_CLUSTER_CONNECT_AUTO_INCREMENT_START = 1L;

public static final long DEFAULT_PROPERTY_CLUSTER_CONNECT_AUTO_INCREMENT_STEP = 1L;

public static final int DEFAULT_PROPERTY_CLUSTER_CONNECT_DELAY = 5;

public static final int DEFAULT_PROPERTY_CLUSTER_CONNECT_RETRIES = 4;

public static final int DEFAULT_PROPERTY_CLUSTER_CONNECT_TIMEOUT_AFTER = 20;

public static final int DEFAULT_PROPERTY_CLUSTER_CONNECT_TIMEOUT_BEFORE = 30;

public static final int DEFAULT_PROPERTY_CLUSTER_CONNECT_TIMEOUT_MGM = 30000;

public static final int DEFAULT_PROPERTY_CLUSTER_CONNECT_VERBOSE = 0;

public static final String DEFAULT_PROPERTY_CLUSTER_DATABASE = "test";

public static final int DEFAULT_PROPERTY_CLUSTER_MAX_TRANSACTIONS = 4;

public static final int DEFAULT_PROPERTY_CONNECTION_POOL_RECV_THREAD_ACTIVATION_THRESHOLD = 8;

public static final int DEFAULT_PROPERTY_CONNECTION_POOL_SIZE = 1;

public static final int DEFAULT_PROPERTY_CONNECTION_RECONNECT_TIMEOUT = 0;

public static final String ENV_CLUSTERJ_LOGGER_FACTORY_NAME = "CLUSTERJ_LOGGER_FACTORY";

public static final String PROPERTY_CLUSTER_BYTE_BUFFER_POOL_SIZES = "com.mysql.clusterj.byte.buffer.pool.sizes";

public static final String
PROPERTY_CLUSTER_CONNECT_VERBOSE
    = "com.mysql.clusterj.connect.verbose";

public static final String
PROPERTY_CLUSTER_DATABASE
    = "com.mysql.clusterj.database";

public static final String
PROPERTY_CLUSTER_MAX_TRANSACTIONS
    = "com.mysql.clusterj.max.transactions";

public static final String
PROPERTY_CONNECTION_POOL_NODEIDS
    = "com.mysql.clusterj.connection.pool.nodeids";

public static final String
PROPERTY_CONNECTION_POOL_RECV_THREAD_ACTIVATION_THRESHOLD
    = "com.mysql.clusterj.connection.pool.recv.thread.activation.threshold";

public static final String
PROPERTY_CONNECTION_POOL_RECV_THREAD_CPUIDS
    = "com.mysql.clusterj.connection.pool.recv.thread.cpuids";

public static final String
PROPERTY_CONNECTION_POOL_SIZE
    = "com.mysql.clusterj.connection.pool.size";

public static final String
PROPERTY_CONNECTION_RECONNECT_TIMEOUT
    = "com.mysql.clusterj.connection.reconnect.timeout";

public static final String
PROPERTY_DEFER_CHANGES
    = "com.mysql.clusterj.defer.changes";

public static final String
```java
public static final String PROPERTY_JDBC_DRIVER_NAME = "com.mysql.clusterj.jdbc.driver";
public static final String PROPERTY_JDBC_PASSWORD = "com.mysql.clusterj.jdbc.password";
public static final String PROPERTY_JDBC_URL = "com.mysql.clusterj.jdbc.url";
public static final String PROPERTY_JDBC_USERNAME = "com.mysql.clusterj.jdbc.username";

public static final String SESSION_FACTORY_SERVICE_CLASS_NAME = "com.mysql.clusterj.SessionFactoryService";
public static final String SESSION_FACTORY_SERVICE_FILE_NAME = "META-INF/services/com.mysql.clusterj.SessionFactoryService";
```

**DEFAULT_PROPERTY_CLUSTER_BYTE_BUFFER_POOL_SIZES**

```java
public static final String DEFAULT_PROPERTY_CLUSTER_BYTE_BUFFER_POOL_SIZES = "256, 10240, 102400, 1048576";
```

The default value of the byte buffer pool sizes property: 256, 10K, 100K, 1M

**DEFAULT_PROPERTY_CLUSTER_CONNECT_AUTO_INCREMENT_BATCH_SIZE**

```java
public static final int DEFAULT_PROPERTY_CLUSTER_CONNECT_AUTO_INCREMENT_BATCH_SIZE = 10;
```

The default value of the connection autoincrement batch size property

**DEFAULT_PROPERTY_CLUSTER_CONNECT_AUTO_INCREMENT_START**

```java
public static final long DEFAULT_PROPERTY_CLUSTER_CONNECT_AUTO_INCREMENT_START = 1L;
```

The default value of the connection autoincrement start property

**DEFAULT_PROPERTY_CLUSTER_CONNECT_AUTO_INCREMENT_STEP**

```java
public static final long DEFAULT_PROPERTY_CLUSTER_CONNECT_AUTO_INCREMENT_STEP = 1L;
```

The default value of the connection autoincrement step property

**DEFAULT_PROPERTY_CLUSTER_CONNECT_DELAY**

```java
public static final int DEFAULT_PROPERTY_CLUSTER_CONNECT_DELAY = 5;
```

The default value of the connection delay property

**DEFAULT_PROPERTY_CLUSTER_CONNECT_RETRIES**
com.mysql.clusterj

```java
DEFAULT_PROPERTY_CLUSTER_CONNECT_RETRIES = 4;

The default value of the connection retries property

DEFAULT_PROPERTY_CLUSTER_CONNECT_TIMEOUT_AFTER

```public static final int
    DEFAULT_PROPERTY_CLUSTER_CONNECT_TIMEOUT_AFTER
        = 20;

The default value of the connection timeout after property

DEFAULT_PROPERTY_CLUSTER_CONNECT_TIMEOUT_BEFORE

```public static final int
    DEFAULT_PROPERTY_CLUSTER_CONNECT_TIMEOUT_BEFORE
        = 30;

The default value of the connection timeout before property

DEFAULT_PROPERTY_CLUSTER_CONNECT_TIMEOUT_MGM

```public static final int
    DEFAULT_PROPERTY_CLUSTER_CONNECT_TIMEOUT_MGM
        = 30000;

The default value of the connection timeout mgm property

DEFAULT_PROPERTY_CLUSTER_CONNECT_VERBOSE

```public static final int
    DEFAULT_PROPERTY_CLUSTER_CONNECT_VERBOSE
        = 0;

The default value of the connection verbose property

DEFAULT_PROPERTY_CLUSTER_DATABASE

```public static final String
    DEFAULT_PROPERTY_CLUSTER_DATABASE
        = "test";

The default value of the database property

DEFAULT_PROPERTY_CLUSTER_MAX_TRANSACTIONS

```public static final int
    DEFAULT_PROPERTY_CLUSTER_MAX_TRANSACTIONS
        = 4;

The default value of the maximum number of transactions property

DEFAULT_PROPERTY_CONNECTION_POOL_RECV_THREAD_ACTIVATION_THRESHOLD

```public static final int
    DEFAULT_PROPERTY_CONNECTION_POOL_RECV_THREAD_ACTIVATION_THRESHOLD
        = 8;

The default value of the receive thread activation threshold

DEFAULT_PROPERTY_CONNECTION_POOL_SIZE

```public static final int
    DEFAULT_PROPERTY_CONNECTION_POOL_SIZE
        = 1;
```
The default value of the connection pool size property

**DEFAULT_PROPERTY_CONNECTION_RECONNECT_TIMEOUT**

```java
public static final int DEFAULT_PROPERTY_CONNECTION_RECONNECT_TIMEOUT = 0;
```

**Since** 7.5.7

The default value of the connection reconnect timeout property. The default means that the automatic reconnection due to network failures is disabled.

**ENV_ClusterJ_LOGGER_FACTORY_NAME**

```java
public static final String ENV_CLUSTERJ_LOGGER_FACTORY_NAME = "CLUSTERJ_LOGGER_FACTORY";
```

The name of the environment variable to set the logger factory

**PROPERTY_CLUSTER_BYTE_BUFFER_POOL_SIZES**

```java
public static final String PROPERTY_CLUSTER_BYTE_BUFFER_POOL_SIZES = "com.mysql.clusterj.byte.buffer.pool.sizes";
```

The name of the byte buffer pool sizes property. To disable buffer pooling for blob objects, set the value of this property to "1". With this setting, buffers will be allocated and freed (and cleaned if possible) immediately after being used for blob data transfer.

**PROPERTY_CLUSTER_CONNECT_AUTO_INCREMENT_BATCH_SIZE**

```java
public static final String PROPERTY_CLUSTER_CONNECT_AUTO_INCREMENT_BATCH_SIZE = "com.mysql.clusterj.connect.autoincrement.batchsize";
```

The name of the connection autoincrement batch size property.

**PROPERTY_CLUSTER_CONNECT_AUTO_INCREMENT_START**

```java
public static final String PROPERTY_CLUSTER_CONNECT_AUTO_INCREMENT_START = "com.mysql.clusterj.connect.autoincrement.offset";
```

The name of the connection autoincrement start property.

**PROPERTY_CLUSTER_CONNECT_AUTO_INCREMENT_STEP**

```java
public static final String PROPERTY_CLUSTER_CONNECT_AUTO_INCREMENT_STEP = "com.mysql.clusterj.connect.autoincrement.increment";
```

The name of the connection autoincrement step property.

**PROPERTY_CLUSTER_CONNECT_DELAY**

```java
public static final String PROPERTY_CLUSTER_CONNECT_DELAY = "com.mysql.clusterj.connect.delay";
```

The name of the connection delay property. For details, see `Ndb_cluster_connection::connect()`

**PROPERTY_CLUSTER_CONNECT_RETRIES**

```java
public static final String
```

695
The name of the connection retries property. For details, see `Ndb_cluster_connection::connect()`.

```java
public static final String PROPERTY_CLUSTER_CONNECT_RETRIES
    = "com.mysql.clusterj.connect.retries";
```

The name of the connection timeout after property. For details, see `Ndb_cluster_connection::wait_until_ready()`.

```java
public static final String PROPERTY_CLUSTER_CONNECT_TIMEOUT_AFTER
    = "com.mysql.clusterj.connect.timeout.after";
```

The name of the connection timeout before property. For details, see `Ndb_cluster_connection::wait_until_ready()`.

```java
public static final String PROPERTY_CLUSTER_CONNECT_TIMEOUT_BEFORE
    = "com.mysql.clusterj.connect.timeout.before";
```

The name of the initial timeout for cluster connection to connect to MGM before connecting to data nodes `Ndb_cluster_connection::set_timeout()`.

```java
public static final String PROPERTY_CLUSTER_CONNECT_TIMEOUT_MGM
    = "com.mysql.clusterj.connect.timeout.mgm";
```

The name of the connection verbose property. For details, see `Ndb_cluster_connection::connect()`.

```java
public static final String PROPERTY_CLUSTER_CONNECT_VERBOSE
    = "com.mysql.clusterj.connect.verbose";
```

The name of the connection service property.

```java
public static final String PROPERTY_CLUSTER_CONNECTION_SERVICE
    = "com.mysql.clusterj.connection.service";
```

The name of the connection string property. For details, see `Ndb_cluster_connection constructor`.

```java
public static final String PROPERTY_CLUSTER_CONNECTSTRING
    = "com.mysql.clusterj.connectstring";
```

The name of the database property. For details, see the `catalogName` parameter in the `Ndb constructor`.

```java
public static final String PROPERTY_CLUSTER_DATABASE
    = "com.mysql.clusterj.database";
```

The name of the maximum transactions property.
The name of the maximum number of transactions property. For details, see \texttt{Ndb::init()}

\textbf{PROPERTY\_CONNECTION\_POOL\_NODEIDS}

The name of the connection pool node ids property. There is no default. This is the list of node ids to force the connections to be assigned to specific node ids. If this property is specified and connection pool size is not the default, the number of node ids of the list must match the connection pool size, or the number of node ids must be 1 and node ids will be assigned to connections starting with the specified node id.

\textbf{PROPERTY\_CONNECTION\_POOL\_RECV\_THREAD\_ACTIVATION\_THRESHOLD}

The receive thread activation threshold for all connections in the connection pool. The default is no activation threshold.

\textbf{PROPERTY\_CONNECTION\_POOL\_RECV\_THREAD\_CPUIDS}

The cpu binding of the receive threads for the connections in the connection pool. The default is no cpu binding for receive threads. If this property is specified, the number of cpu ids in the list must be equal to: a) the connection pool size if the connection pooling is not disabled (i.e. connection pool size > 0) (or) b) 1 if the connection pooling is disabled.

\textbf{PROPERTY\_CONNECTION\_POOL\_SIZE}

The name of the connection pool size property. This is the number of connections to create in the connection pool. The default is 1 (all sessions share the same connection; all requests for a SessionFactory with the same connect string and database will share a single SessionFactory). A setting of 0 disables pooling; each request for a SessionFactory will receive its own unique SessionFactory.

\textbf{PROPERTY\_CONNECTION\_RECONNECT\_TIMEOUT}

Since 7.5.7

The number of seconds to wait for all sessions to be closed when reconnecting a SessionFactory due to network failures. The default, 0, indicates that the automatic reconnection to the cluster due to network failures is disabled. Reconnection can be enabled by using the method \texttt{SessionFactory.reconnect(int timeout)} and specifying a new timeout value.

\textbf{PROPERTY\_DEFER\_CHANGES}
The flag for deferred inserts, deletes, and updates

public static final String PROPERTY_DEFER_CHANGES = "com.mysql.clusterj.defer.changes";

PROPERTY_JDBC_DRIVER_NAME

public static final String PROPERTY_JDBC_DRIVER_NAME = "com.mysql.clusterj.jdbc.driver";

The name of the jdbc driver

PROPERTY_JDBC_PASSWORD

public static final String PROPERTY_JDBC_PASSWORD = "com.mysql.clusterj.jdbc.password";

The jdbc password

PROPERTY_JDBC_URL

public static final String PROPERTY_JDBC_URL = "com.mysql.clusterj.jdbc.url";

The jdbc url

PROPERTY_JDBC_USERNAME

public static final String PROPERTY_JDBC_USERNAME = "com.mysql.clusterj.jdbc.username";

The jdbc username

SESSION_FACTORY_SERVICE_CLASS_NAME

public static final String SESSION_FACTORY_SERVICE_CLASS_NAME = "com.mysql.clusterjSessionFactoryService";

The name of the session factory service interface

SESSION_FACTORY_SERVICE_FILE_NAME

public static final String SESSION_FACTORY_SERVICE_FILE_NAME = "META-INF/services/com.mysql.clusterjSessionFactoryService";

The name of the files with names of implementation classes for session factory service

4.3.1.13 Dbug

Dbug allows clusterj applications to enable the DBUG functionality in cluster ndbapi library. The dbug state is a control string that consists of flags separated by colons. Flags are:

- \( d \) set the debug flag
- \( a[, \text{filename}] \) append debug output to the file
- \( A[, \text{filename}] \) like \( a[, \text{filename}] \) but flush the output after each operation
- \( d[, \text{keyword}[, \text{keyword}...]] \) enable output from macros with specified keywords
• D[,tenths] delay for specified tenths of a second after each operation
• f[,function[,function...]] limit output to the specified list of functions
• F mark each output with the file name of the source file
• i mark each output with the process id of the current process
• g[,function[,function...]] profile specified list of functions
• L mark each output with the line number of the source file
• n mark each output with the current function nesting depth
• N mark each output with a sequential number
• o[,filename] overwrite debug output to the file
• O[,filename] like o[,filename] but flush the output after each operation
• p[,pid[,pid...]] limit output to specified list of process ids
• P mark each output with the process name
• r reset the indentation level to zero
• t[,depth] limit function nesting to the specified depth
• T mark each output with the current timestamp

For example, the control string to trace calls and output debug information only for "jointx" and overwrite the contents of file "/tmp/dbug/jointx", use "t:d,jointx:o,/tmp/dbug/jointx". The above can be written as ClusterJHelper.newDbug().trace().debug("jointx").output("/tmp/dbug/jointx").set();

Synopsis

```java
public interface Dbug {
    // Public Methods
    public abstract Dbug append(
            String fileName);
    public abstract Dbug debug(
            String string);
    public abstract Dbug debug(
            String[] strings);
    public abstract Dbug flush();
    public abstract String get();
    public abstract Dbug output(
            String fileName);
    public abstract void pop();
    public abstract void print(
            String keyword,
            String message);
    public abstract void push();
    public abstract void push(
            String state);
    public abstract void set();
}
```
public abstract void set(String state);

public abstract Dbug trace();
}

append(String)

public abstract Dbug append(String fileName);

Specify the file name for debug output (append).

Table 4.26 append(String)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fileName</td>
<td>the name of the file</td>
</tr>
<tr>
<td>return</td>
<td>this</td>
</tr>
</tbody>
</table>

debug(String)

public abstract Dbug debug(String string);

Set the list of debug keywords.

Table 4.27 debug(String)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>the comma separated debug keywords</td>
</tr>
<tr>
<td>return</td>
<td>this</td>
</tr>
</tbody>
</table>

debug(String[])

public abstract Dbug debug(String[] strings);

Set the list of debug keywords.

Table 4.28 debug(String[])

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>strings</td>
<td>the debug keywords</td>
</tr>
<tr>
<td>return</td>
<td>this</td>
</tr>
</tbody>
</table>

flush()

public abstract Dbug flush();

Force flush after each output operation.

Table 4.29 flush()

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>this</td>
</tr>
</tbody>
</table>

get()

public abstract String get();

Return the current state.
Table 4.30 get()

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>the current state</td>
</tr>
</tbody>
</table>

output(String)

```java
public abstract Debug output(String fileName);
```

Specify the file name for debug output (overwrite).

Table 4.31 output(String)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fileName</td>
<td>the name of the file</td>
</tr>
<tr>
<td>return</td>
<td>this</td>
</tr>
</tbody>
</table>

pop()

```java
public abstract void pop();
```

Pop the current state. The new state will be the previously pushed state.

print(String, String)

```java
public abstract void print(String keyword, String message);
```

Print debug message.

push()

```java
public abstract void push();
```

Push the current state as defined by the methods.

push(String)

```java
public abstract void push(String state);
```

Push the current state and set the parameter as the new state.

Table 4.32 push(String)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>state</td>
<td>the new state</td>
</tr>
</tbody>
</table>

set()

```java
public abstract void set();
```

Set the current state as defined by the methods.

set(String)

```java
public abstract void set(String state);
```

Set the current state from the parameter.
Table 4.33 set(String)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>state</td>
<td>the new state</td>
</tr>
</tbody>
</table>

trace()

```java
public abstract Dbug trace();
```

Set the trace flag.

Table 4.34 trace()

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>this</td>
</tr>
</tbody>
</table>

4.3.1.14 DynamicObject

```java
public abstract class DynamicObject {
    // Public Constructors
    public DynamicObject();

    // Public Methods
    public final ColumnMetadata[] columnMetadata();
    public final DynamicObjectDelegate delegate();
    public final void delegate(    DynamicObjectDelegate delegate);
    public Boolean found();
    public final Object get(    int columnNumber);
    public final void set(    int columnNumber,    Object value);
    public String table();
}
```

Methods inherited from java.lang.Object: equals, getClass, hashCode, notify, notifyAll, toString, wait

4.3.1.15 DynamicObjectDelegate

```java
public interface DynamicObjectDelegate {
    // Public Methods
    public abstract ColumnMetadata[] columnMetadata();
    public abstract Boolean found();
    public abstract void found(    Boolean found);
    public abstract Object get(    int columnNumber);
    public abstract void release();
    public abstract void set(    int columnNumber,    Object value);
```
public abstract boolean wasReleased();
}

4.3.16 LockMode

Lock modes for read operations.

- **SHARED**: Set a shared lock on rows
- **EXCLUSIVE**: Set an exclusive lock on rows
- **READ_COMMITTED**: Set no locks but read the most recent committed values

Synopsis

```java
public final class LockMode,
    extends Enum<LockMode> {
    // Public Static Fields
    public static final LockMode
        EXCLUSIVE ;
    public static final LockMode
        READ_COMMITTED ;
    public static final LockMode
        SHARED ;
    // Public Static Methods
    public static LockMode valueOf( 
        String name);
    public static LockMode[] values();
}
```

Methods inherited from java.lang.Enum: compareTo, equals, getDeclaringClass, hashCode, name, ordinal, toString, valueOf

Methods inherited from java.lang.Object: getClass, notify, notifyAll, wait

4.3.17 Query

A Query instance represents a specific query with bound parameters. The instance is created by the method

com.mysql.clusterj.Session.<T>createQuery(com.mysql.clusterj.query.QueryDefinition<T>)

Synopsis

```java
public interface Query<E> {
    // Public Static Fields
    public static final String
        INDEX_USED = "IndexUsed";
    public static final String
        SCAN_TYPE = "ScanType";
    public static final String
        SCAN_TYPE_INDEX_SCAN = "INDEX_SCAN";
    public static final String
        SCAN_TYPE_PRIMARY_KEY
```
public static final String SCAN_TYPE_TABLE_SCAN = "TABLE_SCAN";

public static final String SCAN_TYPE_UNIQUE_KEY = "UNIQUE_KEY";

// Public Methods

public abstract int deletePersistentAll();

public abstract Results<E> execute(Object parameter);

public abstract Results<E> execute(Object[] parameters);

public abstract Results<E> execute(Map<String, ?> parameters);

public abstract Map<String, Object> explain();

public abstract List<E> getResultList();

public abstract void setLimits(long skip, long limit);

public abstract void setOrdering(Ordering ordering, String[] orderingFields);

public abstract void setParameter(String parameterName, Object value);

public static final String INDEX_USED = "IndexUsed";

The query explain index used key

public static final String SCAN_TYPE = "ScanType";

The query explain scan type key

public static final String SCAN_TYPE_INDEX_SCAN = "INDEX_SCAN";

The query explain scan type value for index scan

public static final String SCAN_TYPE_PRIMARY_KEY = "PRIMARY_KEY";
The query explain scan type value for primary key

**SCAN_TYPE_TABLE_SCAN**

```java
public static final String SCAN_TYPE_TABLE_SCAN = "TABLE_SCAN";
```

The query explain scan type value for table scan

**SCAN_TYPE_UNIQUE_KEY**

```java
public static final String SCAN_TYPE_UNIQUE_KEY = "UNIQUE_KEY";
```

The query explain scan type value for unique key

**deletePersistentAll()**

```java
public abstract int deletePersistentAll();
```

Delete the instances that satisfy the query criteria.

<table>
<thead>
<tr>
<th>Table 4.35 deletePersistentAll()</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Parameter</strong></td>
</tr>
<tr>
<td>return</td>
</tr>
</tbody>
</table>

**execute(Map<String, ?>)**

```java
public abstract Results<E> execute(
    Map<String, ?> parameters);
```

Execute the query with one or more named parameters. Parameters are resolved by name.

<table>
<thead>
<tr>
<th>Table 4.36 execute(Map&lt;String, ?&gt;)</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Parameter</strong></td>
</tr>
<tr>
<td>parameters</td>
</tr>
<tr>
<td>return</td>
</tr>
</tbody>
</table>

**execute(Object...)**

```java
public abstract Results<E> execute(
    Object[] parameters);
```

Execute the query with one or more parameters. Parameters are resolved in the order they were declared in the query.

<table>
<thead>
<tr>
<th>Table 4.37 execute(Object...)</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Parameter</strong></td>
</tr>
<tr>
<td>parameters</td>
</tr>
<tr>
<td>return</td>
</tr>
</tbody>
</table>

**execute(Object)**

```java
public abstract Results<E> execute(
    Object parameter);
```

Execute the query with exactly one parameter.
Table 4.38 execute(Object)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>parameter</td>
<td>the parameter</td>
</tr>
<tr>
<td>return</td>
<td>the result</td>
</tr>
</tbody>
</table>

explain()

```java
public abstract Map<String, Object> explain();
```

Explain how this query will be or was executed. If called before binding all parameters, throws ClusterJUserException. Return a map of key:value pairs that explain how the query will be or was executed. Details can be obtained by calling toString on the value. The following keys are returned:

- **ScanType**: the type of scan, with values:
  - PRIMARY_KEY: the query used key lookup with the primary key
  - UNIQUE_KEY: the query used key lookup with a unique key
  - INDEX_SCAN: the query used a range scan with a non-unique key
  - TABLE_SCAN: the query used a table scan
- **IndexUsed**: the name of the index used, if any

Table 4.39 explain()

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>the data about the execution of this query</td>
</tr>
</tbody>
</table>

Exceptions

- **ClusterJUserException**: if not all parameters are bound

getResultList()

```java
public abstract List<E> getResultList();
```

Get the results as a list.

Table 4.40 getResultList()

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>the result</td>
</tr>
</tbody>
</table>

Exceptions

- **ClusterJUserException**: if not all parameters are bound
- **ClusterJDatastoreException**: if an exception is reported by the datastore

setLimits(long, long)

```java
public abstract void setLimits(
    long skip,
    long limit);
```

Set limits on results to return. The execution of the query is modified to return only a subset of results. If the filter would normally return 100 instances, skip is set to 50, and limit is set to 40, then the first 50 results that would have been returned are skipped, the next 40 results are returned and the remaining 10 results are ignored.
Skip must be greater than or equal to 0. Limit must be greater than or equal to 0. Limits may not be used with deletePersistentAll.

Table 4.41 setLimits(long, long)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>skip</td>
<td>the number of results to skip</td>
</tr>
<tr>
<td>limit</td>
<td>the number of results to return after skipping; use Long.MAX_VALUE for no limit.</td>
</tr>
</tbody>
</table>

setOrdering(Query.Ordering, String...)

```java
class Query
{
    public abstract void setOrdering(
        Ordering ordering,
        String[] orderingFields);
}
```

Set ordering for the results of this query. The execution of the query is modified to use an index previously defined.

- There must be an index defined on the columns mapped to the ordering fields, in the order of the ordering fields.
- There must be no gaps in the ordering fields relative to the index.
- All ordering fields must be in the index, but not all fields in the index need be in the ordering fields.
- If an “in” predicate is used in the filter on a field in the ordering, it can only be used with the first field.
- If any of these conditions is violated, ClusterJUserException is thrown when the query is executed.

If an “in” predicate is used, each element in the parameter defines a separate range, and ordering is performed within that range. There may be a better (more efficient) index based on the filter, but specifying the ordering will force the query to use an index that contains the ordering fields.

Table 4.42 setOrdering(Query.Ordering, String...)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ordering</td>
<td>either Ordering.ASCENDING or Ordering.DESCENDING</td>
</tr>
<tr>
<td>orderingFields</td>
<td>the fields to order by</td>
</tr>
</tbody>
</table>

setParameter(String, Object)

```java
public abstract void setParameter(
    String parameterName,
    Object value);
```

Set the value of a parameter. If called multiple times for the same parameter, silently replace the value.

Table 4.43 setParameter(String, Object)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>parameterName</td>
<td>the name of the parameter</td>
</tr>
<tr>
<td>value</td>
<td>the value for the parameter</td>
</tr>
</tbody>
</table>

4.3.1.18 Query.Ordering

Ordering

Synopsis

```java
public static final class Query.Ordering{
}
```
```java
extends Enum<Ordering> {
    // Public Static Fields
    public static final Ordering ASCENDING;
    public static final Ordering DESCENDING;
    // Public Static Methods
    public static Ordering.valueOf(String name);
    public static Ordering[] values();
}
```

Methods inherited from java.lang.Enum: `compareTo`, `equals`, `getDeclaringClass`, `hashCode`, `name`, `ordinal`, `toString`, `valueOf`

Methods inherited from java.lang.Object: `getClass`, `notify`, `notifyAll`, `wait`

### 4.3.1.19 Results

Results of a query.

**Synopsis**

```java
public interface Results<E>,
    extends Iterable<E> {
    // Public Methods
    public abstract Iterator<E> iterator();
}
```

**iterator()**

```java
public abstract Iterator<E> iterator();
```

**Specified by:** Method `iterator` in interface `Iterable`

Get an iterator over the results of a query.

**Table 4.44 iterator()**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>the iterator</td>
</tr>
</tbody>
</table>

### 4.3.1.20 Session

Session is the primary user interface to the cluster. Session extends AutoCloseable so it can be used in the try-with-resources pattern. This pattern allows the application to create a session in the try declaration and regardless of the outcome of the try/catch/finally block, clusterj will clean up and close the session. If the try block exits with an open transaction, the transaction will be rolled back before the session is closed.

**Synopsis**

```java
public interface Session,
    extends AutoCloseable {
    // Public Methods
    public abstract void close();
    public abstract Query<T> createQuery();
```
QueryDefinition<T> qd;

public abstract Transaction currentTransaction();

public abstract void deletePersistent(
    Class<T> cls,
    Object key);

public abstract void deletePersistent(
    Object instance);

public abstract int deletePersistentAll(
    Class<T> cls);

public abstract void deletePersistentAll(
    Iterable<?> instances);

public abstract T find(
    Class<T> cls,
    Object key);

public abstract void flush();

public abstract Boolean found(
    Object instance);

public abstract QueryBuilder getQueryBuilder();

public abstract boolean isClosed();

public abstract T load(
    T instance);

public abstract T makePersistent(
    T instance);

public abstract Iterable<?> makePersistentAll(
    Iterable<?> instances);

public abstract void markModified(
    Object instance,
    String fieldName);

public abstract T newInstance(
    Class<T> cls);

public abstract T newInstance(
    Class<T> cls,
    Object key);

public abstract void persist(
    Object instance);

public abstract T release(
    T obj);

public abstract void remove(
    Object instance);

public abstract T savePersistent(
    T instance);

public abstract Iterable<?> savePersistentAll(
    Iterable<?> instances);

public abstract void setLockMode(
    LockMode lockmode);

public abstract void setPartitionKey(
    Class<?> cls,
    Object key);
public abstract String unloadSchema(Class<?> cls);

public abstract void updatePersistent(Object instance);

public abstract void updatePersistentAll(Iterable<?> instances);
}

public abstract void close();

Specified by: Method close in interface AutoCloseable

Close this session.

createQuery(QueryDefinition<T>)

public abstract Query<T> createQuery(QueryDefinition<T> qd);

Create a Query from a QueryDefinition.

Table 4.45 createQuery(QueryDefinition<T>)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>qd</td>
<td>the query definition</td>
</tr>
<tr>
<td>return</td>
<td>the query instance</td>
</tr>
</tbody>
</table>

currentTransaction()

public abstract Transaction currentTransaction();

Get the current com.mysql.clusterj.Transaction.

Table 4.46 currentTransaction()

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>the transaction</td>
</tr>
</tbody>
</table>

deletePersistent(Class<T>, Object)

public abstract void deletePersistent(Class<T> cls, Object key);

Delete an instance of a class from the database given its primary key. For single-column keys, the key parameter is a wrapper (e.g. Integer). For multi-column keys, the key parameter is an Object[] in which elements correspond to the primary keys in order as defined in the schema.

Table 4.47 deletePersistent(Class<T>, Object)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cls</td>
<td>the interface or dynamic class</td>
</tr>
<tr>
<td>key</td>
<td>the primary key</td>
</tr>
</tbody>
</table>

deletePersistent(Object)
Delete the instance from the database. Only the id field is used to determine which instance is to be deleted. If the instance does not exist in the database, an exception is thrown.

Table 4.48 deletePersistent(Object)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>instance</td>
<td>the instance to delete</td>
</tr>
</tbody>
</table>

deletePersistentAll(Class<T>)

```java
public abstract int deletePersistentAll(
    Class<T> cls);
```

Delete all instances of this class from the database. No exception is thrown even if there are no instances in the database.

Table 4.49 deletePersistentAll(Class<T>)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cls</td>
<td>the interface or dynamic class</td>
</tr>
<tr>
<td>return</td>
<td>the number of instances deleted</td>
</tr>
</tbody>
</table>

deletePersistentAll(Iterable<?>)

```java
public abstract void deletePersistentAll(
    Iterable<?> instances);
```

Delete all parameter instances from the database.

Table 4.50 deletePersistentAll(Iterable<?>)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>instances</td>
<td>the instances to delete</td>
</tr>
</tbody>
</table>

find(Class<T>, Object)

```java
public abstract T find(
    Class<T> cls,
    Object key);
```

Find a specific instance by its primary key. The key must be of the same type as the primary key defined by the table corresponding to the cls parameter. The key parameter is the wrapped version of the primitive type of the key, e.g. Integer for INT key types, Long for BIGINT key types, or String for char and varchar types. For multi-column primary keys, the key parameter is an Object[], each element of which is a component of the primary key. The elements must be in the order of declaration of the columns (not necessarily the order defined in the CONSTRAINT ... PRIMARY KEY clause) of the CREATE TABLE statement.

Table 4.51 find(Class<T>, Object)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cls</td>
<td>the interface or dynamic class to find an instance of</td>
</tr>
<tr>
<td>key</td>
<td>the key of the instance to find</td>
</tr>
<tr>
<td>return</td>
<td>the instance of the interface or dynamic class with the specified key</td>
</tr>
</tbody>
</table>

flush()

```java
public abstract void flush();
```
Flush deferred changes to the back end. Inserts, deletes, loads, and updates are sent to the back end.

**found(Object)**

```java
public abstract Boolean found(Object instance);
```

Was the row corresponding to this instance found in the database?

**Table 4.52 found(Object)**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>instance</td>
<td>the instance corresponding to the row in the database</td>
</tr>
</tbody>
</table>
| return    | • null if the instance is null or was created via newInstance and never loaded;  
|           | • true if the instance was returned from a find or query or created via newInstance and successfully loaded;  
|           | • false if the instance was created via newInstance and not found. |

**See Also**

load(T), newInstance(java.lang.Class<T>, java.lang.Object)

**getQueryBuilder()**

```java
public abstract QueryBuilder getQueryBuilder();
```

Get a QueryBuilder.

**Table 4.53 getQueryBuilder()**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>the query builder</td>
</tr>
</tbody>
</table>

**isClosed()**

```java
public abstract boolean isClosed();
```

Is this session closed?

**Table 4.54 isClosed()**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>true if the session is closed</td>
</tr>
</tbody>
</table>

**load(T)**

```java
public abstract T load(T instance);
```

Load the instance from the database into memory. Loading is asynchronous and will be executed when an operation requiring database access is executed: find, flush, or query. The instance must have been returned from find or query; or created via session.newInstance and its primary key initialized.

**Table 4.55 load(T)**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>instance</td>
<td>the instance to load</td>
</tr>
<tr>
<td>return</td>
<td>the instance</td>
</tr>
</tbody>
</table>

**See Also**

found(java.lang.Object)
makePersistent(T)

```java
public abstract T makePersistent(T instance);
```

Insert the instance into the database. If the instance already exists in the database, an exception is thrown.

**Table 4.56 makePersistent(T)**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>instance</td>
<td>the instance to insert</td>
</tr>
<tr>
<td>return</td>
<td>the instance</td>
</tr>
</tbody>
</table>

**See Also**

savePersistent(T)

makePersistenAll(Iterable<?>)

```java
public abstract Iterable<?> makePersistenAll(Iterable<?> instances);
```

Insert the instances into the database.

**Table 4.57 makePersistenAll(Iterable<?>)**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>instances</td>
<td>the instances to insert.</td>
</tr>
<tr>
<td>return</td>
<td>the instances</td>
</tr>
</tbody>
</table>

markModified(Object, String)

```java
public abstract void markModified(Object instance, String fieldName);
```

Mark the field in the object as modified so it is flushed.

**Table 4.58 markModified(Object, String)**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>instance</td>
<td>the persistent instance</td>
</tr>
<tr>
<td>fieldName</td>
<td>the field to mark as modified</td>
</tr>
</tbody>
</table>

newInstance(Class<T>)

```java
public abstract T newInstance(Class<T> cls);
```

Create an instance of an interface or dynamic class that maps to a table.

**Table 4.59 newInstance(Class<T>)**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cls</td>
<td>the interface for which to create an instance</td>
</tr>
<tr>
<td>return</td>
<td>an instance that implements the interface</td>
</tr>
</tbody>
</table>

newInstance(Class<T>, Object)

```java
public abstract T newInstance(Class<T> cls, Object key);
```
Create an instance of an interface or dynamic class that maps to a table and set the primary key of the new instance. The new instance can be used to create, delete, or update a record in the database.

**Table 4.60 newInstance(Class\<T\>, Object)**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cls</td>
<td>the interface for which to create an instance</td>
</tr>
<tr>
<td>return</td>
<td>an instance that implements the interface</td>
</tr>
</tbody>
</table>

**persist(Object)**

```java
public abstract void persist(
    Object instance);
```

Insert the instance into the database. This method has identical semantics to makePersistent.

**Table 4.61 persist(Object)**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>instance</td>
<td>the instance to insert</td>
</tr>
</tbody>
</table>

**release(T)**

```java
public abstract T release(
    T obj);
```

Release resources associated with an instance. The instance must be a domain object obtained via session.newInstance(T.class), find(T.class), or query; or Iterable, or array T[]. Resources released can include direct buffers used to hold instance data. Released resources may be returned to a pool.

**Table 4.62 release(T)**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>obj</td>
<td>a domain object of type T, an Iterable, or array T[]</td>
</tr>
<tr>
<td>return</td>
<td>the input parameter</td>
</tr>
</tbody>
</table>

**Exceptions**

*ClusterJUserException* if the instance is not a domain object T, Iterable, or array T[], or if the object is used after calling this method.

**remove(Object)**

```java
public abstract void remove(
    Object instance);
```

Delete the instance from the database. This method has identical semantics to deletePersistent.

**Table 4.63 remove(Object)**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>instance</td>
<td>the instance to delete</td>
</tr>
</tbody>
</table>

**savePersistent(T)**

```java
public abstract T savePersistent(
    T instance);
```

Save the instance in the database without checking for existence. The id field is used to determine which instance is to be saved. If the instance exists in the database it will be updated. If the instance does not exist, it will be created.
savePersistent(T)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>instance</td>
<td>the instance to update</td>
</tr>
</tbody>
</table>

savePersistentAll(Iterable<?>)

```
public abstract Iterable<?> savePersistentAll(Iterable<?> instances);
```

Update all parameter instances in the database.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>instances</td>
<td>the instances to update</td>
</tr>
</tbody>
</table>

setLockMode(LockMode)

```
public abstract void setLockMode(LockMode lockmode);
```

Set the lock mode for read operations. This will take effect immediately and will remain in effect until this session is closed or this method is called again.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lockmode</td>
<td>the LockMode</td>
</tr>
</tbody>
</table>

setPartitionKey(Class<?>, Object)

```
public abstract void setPartitionKey(Class<?> cls, Object key);
```

Set the partition key for the next transaction. The key must be of the same type as the primary key defined by the table corresponding to the cls parameter. The key parameter is the wrapped version of the primitive type of the key, e.g. Integer for INT key types, Long for BIGINT key types, or String for char and varchar types. For multi-column primary keys, the key parameter is an Object[], each element of which is a component of the primary key. The elements must be in the order of declaration of the columns (not necessarily the order defined in the CONSTRAINT ... PRIMARY KEY clause) of the CREATE TABLE statement.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>the primary key of the mapped table</td>
</tr>
</tbody>
</table>

Exceptions

- ClusterJUserException if a transaction is enlisted
- ClusterJUserException if a partition key is null
- ClusterJUserException if called twice in the same transaction
- ClusterJUserException if a partition key is the wrong type

unloadSchema(Class<?>)

```
public abstract String unloadSchema(Class<?> cls);
```
Unload the schema definition for a class. This must be done after the schema definition has changed in the database due to an alter table command. The next time the class is used the schema will be reloaded.

**Table 4.68 unloadSchema(Class<?>)**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cls</td>
<td>the class for which the schema is unloaded</td>
</tr>
<tr>
<td>return</td>
<td>the name of the schema that was unloaded</td>
</tr>
</tbody>
</table>

**updatePersistent(Object)**

```java
public abstract void updatePersistent(
    Object instance);
```

Update the instance in the database without necessarily retrieving it. The id field is used to determine which instance is to be updated. If the instance does not exist in the database, an exception is thrown. This method cannot be used to change the primary key.

**Table 4.69 updatePersistent(Object)**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>instance</td>
<td>the instance to update</td>
</tr>
</tbody>
</table>

**updatePersistentAll(Iterable<?>)**

```java
public abstract void updatePersistentAll(
    Iterable<?> instances);
```

Update all parameter instances in the database.

**Table 4.70 updatePersistentAll(Iterable<?>)**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>instances</td>
<td>the instances to update</td>
</tr>
</tbody>
</table>

### 4.3.1.21 SessionFactory

SessionFactory represents a cluster.

**Synopsis**

```java
public interface SessionFactory {
    // Public Methods
    public abstract void close();
    public abstract State currentState();
    public abstract List<Integer> getConnectionPoolSessionCounts();
    public abstract int getRecvThreadActivationThreshold();
    public abstract short[] getRecvThreadCPUids();
    public abstract Session getSession();
    public abstract Session getSession(
        Map properties);
    public abstract void reconnect();
    public abstract void reconnect(
        int timeout);
```
public abstract void setRecvThreadActivationThreshold(int threshold);

public abstract void setRecvThreadCPUids(short[] cpuids);
}

close()

public abstract void close();

Close this session factory. Release all resources. Set the current state to Closed. When closed, calls to
getSession will throw ClusterJUserException.

currentState()

public abstract State currentState();

Get the current state of this session factory.

Since 7.5.7

See Also com.mysql.clusterjSessionFactory.State

getConnectionPoolSessionCounts()

public abstract List<Integer> getConnectionPoolSessionCounts();

Get a list containing the number of open sessions for each connection in the connection pool.

Since 7.3.14, 7.4.12, 7.5.2

getRecvThreadActivationThreshold()

public abstract int getRecvThreadActivationThreshold();

Get the receive thread activation threshold for all connections in the connection pool. 16 or higher
means that receive threads are never used as receivers. 0 means that the receive thread is always
active, and that retains poll rights for its own exclusive use, effectively blocking all user threads from
becoming receivers. In such cases care should be taken to ensure that the receive thread does not
compete with the user thread for CPU resources; it is preferable for it to be locked to a CPU for its own
exclusive use. The default is 8.

Since 7.5.7

getRecvThreadCPUids()

public abstract short[] getRecvThreadCPUids();

Get receive thread bindings to cpus for all connections in the connection pool. If a receive thread is not
bound to a cpu, the corresponding value will be -1.

Since 7.5.7

ggetSession()

public abstract Session getSession();

Create a Session to use with the cluster, using all the properties of the SessionFactory.

Table 4.71 getSession()

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>the session</td>
</tr>
</tbody>
</table>
getSession(Map)

```java
public abstract Session getSession(
    Map properties);
```

Create a session to use with the cluster, overriding some properties. Properties
PROPERTY_CLUSTER_CONNECTSTRING, PROPERTY_CLUSTER_DATABASE, and
PROPERTY_CLUSTER_MAX_TRANSACTIONS may not be overridden.

Table 4.72 getSession(Map)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>properties</td>
<td>overriding some properties for this session</td>
</tr>
<tr>
<td>return</td>
<td>the session</td>
</tr>
</tbody>
</table>

reconnect()

```java
public abstract void reconnect();
```

Reconnect this session factory using the most recent timeout value specified. The timeout may have
been specified in the original session factory properties or may have been changed by an application
call to reconnect(int timeout).

See Also  reconnect(int)

Since 7.5.7

reconnect(int)

```java
public abstract void reconnect(
    int timeout);
```

Disconnect and reconnect this session factory using the specified timeout value and change the
saved timeout value. This is a heavyweight method and should be used rarely. It is intended for
cases where the process in which clusterj is running has lost connectivity to the cluster and is not
able to function normally. Reconnection is done in several phases. First, the session factory is set to
state Reconnecting and a reconnect thread is started to manage the reconnection procedure. In the
Reconnecting state, the getSession methods throw ClusterJUserException and the connection pool
is quiesced until all sessions have closed. If sessions fail to close normally after timeout seconds, the
sessions are forced to close. Next, all connections in the connection pool are closed, which frees their
connection slots in the cluster. Finally, the connection pool is recreated using the original connection
pool properties and the state is set to Open. The reconnection procedure is asynchronous. To observe
the progress of the procedure, use the methods currentState and getConnectionPoolSessionCounts. If
the timeout value is non-zero, automatic reconnection will be done by the clusterj implementation upon
recognizing that a network failure has occurred. If the timeout value is 0, automatic reconnection is
disabled. If the current state of this session factory is Reconnecting, this method silently does nothing.

Table 4.73 reconnect(int)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>timeout</td>
<td>the timeout value in seconds; 0 to disable automatic reconnection</td>
</tr>
</tbody>
</table>

Since 7.5.7

setRecvThreadActivationThreshold(int)

```java
public abstract void setRecvThreadActivationThreshold(
    int threshold);
```

Set the receive thread activation threshold for all connections in the connection pool. 16 or higher
means that receive threads are never used as receivers. 0 means that the receive thread is always
active, and that retains poll rights for its own exclusive use, effectively blocking all user threads from becoming receivers. In such cases care should be taken to ensure that the receive thread does not compete with the user thread for CPU resources; it is preferable for it to be locked to a CPU for its own exclusive use. The default is 8.

Exceptions
ClusterJUserException     if the value is negative
ClusterJFatalInternalException     if the method fails due to some internal reason.

Since    7.5.7

setRecvThreadCPUIds(short[])

public abstract void setRecvThreadCPUIds(short[] cpuids);

Bind receive threads to cpuids for all connections in the connection pool. Specify -1 to unset receive thread cpu binding for a connection. The cpuid must be between 0 and the number of cpus in the machine.

Exceptions
ClusterJUserException     if the cpuid is illegal or if the number of elements in cpuids is not equal to the number of connections in the connection pool.
ClusterJFatalInternalException     if the binding fails due to some internal reason.

Since    7.5.7

4.3.1.22 SessionFactory.State

State of this session factory

Synopsis

public static final class SessionFactory.State,
    extends Enum<State> {
    // Public Static Fields
    public static final State Closed;
    public static final State Open;
    public static final State Reconnecting;
    // Public Static Methods
    public static State valueOf(String name);
    public static State[] values();
}

Methods inherited from java.lang.Enum: compareTo, equals, getDeclaringClass, hashCode, name, ordinal, toString, valueOf

Methods inherited from java.lang.Object: getClass, notify, notifyAll, wait

Since    7.5.7

4.3.1.23 SessionFactoryService
This interface defines the service to create a SessionFactory from a Map<String, String> of properties.

**Synopsis**

```java
public interface SessionFactoryService {
    // Public Methods
    public abstract SessionFactory getSessionFactory(Map<String, String> props);
}
```

getSessionFactory(Map<String, String>)

```java
public abstract SessionFactory getSessionFactory(Map<String, String> props);
```

Create or get a session factory. If a session factory with the same value for PROPERTY_CLUSTER_CONNECTSTRING has already been created in the VM, the existing factory is returned, regardless of whether other properties of the factory are the same as specified in the Map.

**Table 4.74 getSessionFactory(Map<String, String>)**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>props</td>
<td>the properties for the session factory, in which the keys are defined in Constants and the values describe the environment</td>
</tr>
<tr>
<td>return</td>
<td>the session factory</td>
</tr>
</tbody>
</table>

See Also: com.mysql.clusterj.Constants

**4.3.1.24 Transaction**

Transaction represents a user transaction active in the cluster.

**Synopsis**

```java
public interface Transaction {
    // Public Methods
    public abstract void begin();
    public abstract void commit();
    public abstract boolean getRollbackOnly();
    public abstract boolean isActive();
    public abstract void rollback();
    public abstract void setRollbackOnly();
}
```

**begin()**

```java
public abstract void begin();
```

Begin a transaction.

**commit()**

```java
public abstract void commit();
```

Commit a transaction.
getRollbackOnly()

```java
public abstract boolean getRollbackOnly();
```

Has this transaction been marked for rollback only?

Table 4.75 getRollbackOnly()

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>true if the transaction has been marked for rollback only</td>
</tr>
</tbody>
</table>

isActive()

```java
public abstract boolean isActive();
```

Is there a transaction currently active?

Table 4.76 isActive()

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>true if a transaction is active</td>
</tr>
</tbody>
</table>

rollback()

```java
public abstract void rollback();
```

Roll back a transaction.

setRollbackOnly()

```java
public abstract void setRollbackOnly();
```

Mark this transaction as rollback only. After this method is called, commit() will roll back the transaction and throw an exception; rollback() will roll back the transaction and not throw an exception.

4.3.2 com.mysql.clusterj.annotation

This package provides annotations for domain object model interfaces mapped to database tables.

4.3.2.1 Column

Annotation for a column in the database.

Synopsis

```java
@Target(value={java.lang.annotation.ElementType.FIELD, java.lang.annotation.ElementType.METHOD}) @Retention(value=java.lang.annotation.RetentionPolicy.RUNTIME)
public @interface Column {
    public String name ;
    public String allowsNull ;
    public String defaultValue ;
}
```

allowsNull

Whether the column allows null values to be inserted. This overrides the database definition and requires that the application provide non-null values for the database column.
Table 4.77 allowsNull

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>whether the column allows null values to be inserted</td>
</tr>
</tbody>
</table>

defaultValue

Default value for this column.

Table 4.78 defaultValue

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>the default value for this column</td>
</tr>
</tbody>
</table>

name

Name of the column.

Table 4.79 name

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>the name of the column</td>
</tr>
</tbody>
</table>

4.3.2.2 Columns

Annotation for a group of columns. This annotation is used for multi-column structures such as indexes and keys.

Synopsis

```java
@Target(value={java.lang.annotation.ElementType.FIELD, java.lang.annotation.ElementType.METHOD, java.lang.annotation.ElementType.TYPE})
@Retention(value=java.lang.annotation.RetentionPolicy.RUNTIME)
public @interface Columns {
    Column[] value ;
}
```

value

The columns annotation information.

Table 4.80 value

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>the columns</td>
</tr>
</tbody>
</table>

4.3.2.3 Extension

Annotation for a non-standard extension.

Synopsis

```java
@Target(value={java.lang.annotation.ElementType.TYPE, java.lang.annotation.ElementType.FIELD, java.lang.annotation.ElementType.METHOD})
@Retention(value=java.lang.annotation.RetentionPolicy.RUNTIME)
public @interface Extension {
    public String vendorName ;
    public String key ;
    public String value ;
}
```
key

The key for the extension (required).

Table 4.81 key

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>the key</td>
</tr>
</tbody>
</table>

value

The value for the extension (required).

Table 4.82 value

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>the value</td>
</tr>
</tbody>
</table>

donorName

Vendor that the extension applies to (required to make the key unique).

Table 4.83 vendorName

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>the vendor</td>
</tr>
</tbody>
</table>

4.3.2.4 Extensions

Annotation for a group of extensions.

Synopsis

```java
@Target({java.lang.annotation.ElementType.TYPE, java.lang.annotation.ElementType.FIELD, java.lang.annotation.ElementType.METHOD})
@Retention(value=java.lang.annotation.RetentionPolicy.RUNTIME)
public @interface Extensions {
    Extension[] value ;
}
```

value

The extensions.

Table 4.84 value

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>the extensions</td>
</tr>
</tbody>
</table>

4.3.2.5 Index

Annotation for a database index.

Synopsis

```java
@Target({java.lang.annotation.ElementType.TYPE, java.lang.annotation.ElementType.FIELD, java.lang.annotation.ElementType.METHOD})
@Retention(value=java.lang.annotation.RetentionPolicy.RUNTIME)
public @interface Index {
    public String name ;
}
```
### com.mysql.clusterj.annotation

```java
public String
unique;
public Column[]
columns;
}
```

#### columns

Columns that compose this index.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>columns that compose this index</td>
</tr>
</tbody>
</table>

#### name

Name of the index

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>the name of the index</td>
</tr>
</tbody>
</table>

#### unique

Whether this index is unique

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>whether this index is unique</td>
</tr>
</tbody>
</table>

### 4.3.2.6 Indices

Annotation for a group of indices. This is used on a class where there are multiple indices defined.

#### Synopsis

```java
@Target(value=java.lang.annotation.ElementType.TYPE) @Retention(value=java.lang.annotation.RetentionPolicy.RUNTIME)
public @interface Indices {
public Index[]
value;
}
```

#### value

The indices.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>The indices</td>
</tr>
</tbody>
</table>

### 4.3.2.7 Lob

Annotation for a Large Object (lob). This annotation can be used with byte[] and InputStream types for binary columns; and with String and InputStream types for character columns.
Synopsis

4.3.2.8 NotPersistent

Annotation to specify that the member is not persistent. If used, this is the only annotation allowed on a member.

Synopsis

4.3.2.9 NullValue

Enumeration of the "null-value" behavior values. This behavior is specified in the @Persistent annotation.

Synopsis

public final class NullValue,
    extends Enum<NullValue> {
    // Public Static Fields
    public static final NullValue DEFAULT ;
    public static final NullValue EXCEPTION ;
    public static final NullValue NONE ;
    // Public Static Methods
    public static NullValue valueOf( String name);
    public static NullValue[] values();
}

Methods inherited from java.lang.Enum: compareTo, equals, getDeclaringClass, hashCode, name, ordinal, toString, valueOf

Methods inherited from java.lang.Object: getClass, notify, notifyAll, wait

4.3.2.10 PartitionKey

Annotation on a class or member to define the partition key. If annotating a class or interface, either a single column or multiple columns can be specified. If annotating a member, neither column nor columns should be specified.

Synopsis
column

Name of the column to use for the partition key

Table 4.89 column

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>the name of the column to use for the partition key</td>
</tr>
</tbody>
</table>

columns

The column(s) for the partition key

Table 4.90 columns

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>the column(s) for the partition key</td>
</tr>
</tbody>
</table>

4.3.2.11 PersistenceCapable

Annotation for whether the class or interface is persistence-capable.

Synopsis

```java
@Target(value=java.lang.annotation.ElementType.TYPE) @Retention(value=java.lang.annotation.RetentionPolicy.RUNTIME)
public @interface PersistenceCapable {
    public String table ;
    public String database ;
    public String schema ;
}
```

4.3.2.12 PersistenceModifier

Enumeration of the persistence-modifier values for a member.

Synopsis

```java
public final class PersistenceModifier,
    extends  Enum<PersistenceModifier> {
    // Public Static Fields
    public static final PersistenceModifier NONE ;
    public static final PersistenceModifier PERSISTENT ;
    public static final PersistenceModifier UNSPECIFIED ;
    // Public Static Methods
    public static PersistenceModifier valueOf(
        String name);
    public static PersistenceModifier[] values();
}
```

Methods inherited from java.lang.Enum: compareTo, equals, getDeclaringClass, hashCode, name, ordinal, toString, valueOf
4.3.2.13 Persistent

Annotation for defining the persistence of a member.

Synopsis

```java
@Target(value={java.lang.annotation.ElementType.FIELD, java.lang.annotation.ElementType.METHOD})
@Retention(value=java.lang.annotation.RetentionPolicy.RUNTIME)
public @interface Persistent {
    NullValue nullValue ;
    String primaryKey ;
    String column ;
    Extension[] extensions ;
}
```

**column**

Column name where the values are stored for this member.

**Table 4.91 column**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>the name of the column</td>
</tr>
</tbody>
</table>

**extensions**

Non-standard extensions for this member.

**Table 4.92 extensions**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>the non-standard extensions</td>
</tr>
</tbody>
</table>

**nullValue**

Behavior when this member contains a null value.

**Table 4.93 nullValue**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>the behavior when this member contains a null value</td>
</tr>
</tbody>
</table>

**primaryKey**

Whether this member is part of the primary key for the table. This is equivalent to specifying @PrimaryKey as a separate annotation on the member.

**Table 4.94 primaryKey**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>whether this member is part of the primary key</td>
</tr>
</tbody>
</table>

4.3.2.14 PrimaryKey
Annotation on a member to define it as a primary key member of a class or persistent interface.

**Synopsis**

```java
@Target(value={java.lang.annotation.ElementType.TYPE, java.lang.annotation.ElementType.FIELD, java.lang.annotation.ElementType.METHOD})
@Retention(value=java.lang.annotation.RetentionPolicy.RUNTIME)
public @interface PrimaryKey {
    String name;
    String column;
    Column[] columns;
}
```

column

Name of the column to use for the primary key

**Table 4.95 column**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>the name of the column to use for the primary key</td>
</tr>
</tbody>
</table>

columns

The column(s) for the primary key

**Table 4.96 columns**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>the column(s) for the primary key</td>
</tr>
</tbody>
</table>

name

Name of the primary key constraint

**Table 4.97 name**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>the name of the primary key constraint</td>
</tr>
</tbody>
</table>

### 4.3.2.15 Projection

Annotation on a type to define it as a projection of a table. Only the columns mapped to persistent fields/methods will be used when performing operations on the table.

**Synopsis**

```java
@Target(value=java.lang.annotation.ElementType.TYPE)
@Retention(value=java.lang.annotation.RetentionPolicy.RUNTIME)
public @interface Projection {
}
```

### 4.3.3 com.mysql.clusterj.query

Provides interfaces for building queries for ClusterJ.

#### 4.3.3.1 Predicate

Used to combine multiple predicates with boolean operations.
Synopsis

```java
public interface Predicate {
    // Public Methods
    public abstract Predicate and(Predicate predicate);
    public abstract Predicate not();
    public abstract Predicate or(Predicate predicate);
}
```

**and(Predicate)**

```java
public abstract Predicate and(Predicate predicate);
```

Combine this Predicate with another, using the "and" semantic.

**Table 4.98 and(Predicate)**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>predicate</td>
<td>the other predicate</td>
</tr>
<tr>
<td>return</td>
<td>a new Predicate combining both Predicates</td>
</tr>
</tbody>
</table>

**not()**

```java
public abstract Predicate not();
```

Negate this Predicate.

**Table 4.99 not()**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>this predicate</td>
</tr>
</tbody>
</table>

**or(Predicate)**

```java
public abstract Predicate or(Predicate predicate);
```

Combine this Predicate with another, using the "or" semantic.

**Table 4.100 or(Predicate)**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>predicate</td>
<td>the other predicate</td>
</tr>
<tr>
<td>return</td>
<td>a new Predicate combining both Predicates</td>
</tr>
</tbody>
</table>

### 4.3.3.2 PredicateOperand

PredicateOperand represents a column or parameter that can be compared to another

Synopsis

```java
public interface PredicateOperand {
    // Public Methods
    public abstract Predicate between();
}
```
between(PredicateOperand, PredicateOperand)

Return a Predicate representing comparing this to another using "between" semantics.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lower</td>
<td>another PredicateOperand</td>
</tr>
<tr>
<td>upper</td>
<td>another PredicateOperand</td>
</tr>
<tr>
<td>return</td>
<td>a new Predicate</td>
</tr>
</tbody>
</table>

equal(PredicateOperand)

Return a Predicate representing comparing this to another using "equal to" semantics.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>other</td>
<td>the other PredicateOperand</td>
</tr>
<tr>
<td>return</td>
<td>a new Predicate</td>
</tr>
</tbody>
</table>

greaterEqual(PredicateOperand)

Return a Predicate representing comparing this to another using "greater than or equal to" semantics.
### Table 4.103 `greaterEqual(PredicateOperand)`

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>other</td>
<td>the other PredicateOperand</td>
</tr>
<tr>
<td>return</td>
<td>a new Predicate</td>
</tr>
</tbody>
</table>

### `greaterThan(PredicateOperand)`

```java
public abstract Predicate greaterThan(
    PredicateOperand other);
```

Return a Predicate representing comparing this to another using "greater than" semantics.

### Table 4.104 `greaterThan(PredicateOperand)`

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>other</td>
<td>the other PredicateOperand</td>
</tr>
<tr>
<td>return</td>
<td>a new Predicate</td>
</tr>
</tbody>
</table>

### `in(PredicateOperand)`

```java
public abstract Predicate in(
    PredicateOperand other);
```

Return a Predicate representing comparing this to a collection of values using "in" semantics.

### Table 4.105 `in(PredicateOperand)`

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>other</td>
<td>another PredicateOperand</td>
</tr>
<tr>
<td>return</td>
<td>a new Predicate</td>
</tr>
</tbody>
</table>

### `isNotNull()`

```java
public abstract Predicate isNotNull();
```

Return a Predicate representing comparing this to not null.

### Table 4.106 `isNull()`

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>a new Predicate</td>
</tr>
</tbody>
</table>

### `isNull()`

```java
public abstract Predicate isNull();
```

Return a Predicate representing comparing this to null.

### Table 4.107 `isNull()`

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>a new Predicate</td>
</tr>
</tbody>
</table>

### `lessEqual(PredicateOperand)`

```java
public abstract Predicate lessEqual(
    PredicateOperand other);
```

Return a Predicate representing comparing this to another using "less than or equal to" semantics.
### lessEqual(PredicateOperand)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>other</td>
<td>the other PredicateOperand</td>
</tr>
<tr>
<td>return</td>
<td>a new Predicate</td>
</tr>
</tbody>
</table>

#### lessThan(PredicateOperand)

```java
public abstract Predicate lessThan(
    PredicateOperand other);
```

Return a Predicate representing comparing this to another using "less than" semantics.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>other</td>
<td>the other PredicateOperand</td>
</tr>
<tr>
<td>return</td>
<td>a new Predicate</td>
</tr>
</tbody>
</table>

#### like(PredicateOperand)

```java
public abstract Predicate like(
    PredicateOperand other);
```

Return a Predicate representing comparing this to another using "like" semantics.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>other</td>
<td>another PredicateOperand</td>
</tr>
<tr>
<td>return</td>
<td>a new Predicate</td>
</tr>
</tbody>
</table>

### 4.3.3.3 QueryBuilder

QueryBuilder represents a factory for queries.

#### Synopsis

```java
public interface QueryBuilder {
    // Public Methods

    public abstract QueryDomainType<T> createQueryDefinition(
        Class<T> cls);
}
```

#### See Also

- `getQueryBuilder()`

#### createQueryDefinition(Class<T>)

```java
public abstract QueryDomainType<T> createQueryDefinition(
    Class<T> cls);
```

Create a QueryDefinition to define queries.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cls</td>
<td>the class of the type to be queried</td>
</tr>
<tr>
<td>return</td>
<td>the QueryDomainType to define the query</td>
</tr>
</tbody>
</table>
4.3.3.4 QueryDefinition

QueryDefinition allows users to define queries.

Synopsis

```java
public interface QueryDefinition<E> {
    // Public Methods
    public abstract Predicate not(Predicate predicate);
    public abstract PredicateOperand param(String parameterName);
    public abstract QueryDefinition<E> where(Predicate predicate);
}
```

**not(Predicate)**

```java
public abstract Predicate not(Predicate predicate);
```

Convenience method to negate a predicate.

**Table 4.112 not(Predicate)**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>predicate</td>
<td>the predicate to negate</td>
</tr>
<tr>
<td>return</td>
<td>the inverted predicate</td>
</tr>
</tbody>
</table>

**param(String)**

```java
public abstract PredicateOperand param(String parameterName);
```

Specify a parameter for the query.

**Table 4.113 param(String)**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>parameterName</td>
<td>the name of the parameter</td>
</tr>
<tr>
<td>return</td>
<td>the PredicateOperand representing the parameter</td>
</tr>
</tbody>
</table>

**where(Predicate)**

```java
public abstract QueryDefinition<E> where(Predicate predicate);
```

Specify the predicate to satisfy the query.

**Table 4.114 where(Predicate)**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>predicate</td>
<td>the Predicate</td>
</tr>
<tr>
<td>return</td>
<td>this query definition</td>
</tr>
</tbody>
</table>

4.3.3.5 QueryDomainType

QueryDomainType represents the domain type of a query. The domain type validates property names that are used to filter results.
**Synopsis**

```java
public interface QueryDomainType<E>,
extends QueryDefinition<E> {
  // Public Methods
  public abstract PredicateOperand get(
      String propertyName);
  public abstract Class<E> getType();
}
```

**get(String)**

```java
public abstract PredicateOperand get(
    String propertyName);
```

Get a PredicateOperand representing a property of the domain type.

**Table 4.115 get(String)**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>propertyName</td>
<td>the name of the property</td>
</tr>
<tr>
<td>return</td>
<td>a representation the value of the property</td>
</tr>
</tbody>
</table>

**get(Type)**

```java
public abstract Class<E> getType();
```

Get the domain type of the query.

**Table 4.116 get(Type)**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>the domain type of the query</td>
</tr>
</tbody>
</table>

### 4.3.4 Constant field values

4.4 MySQL NDB Cluster Connector for Java: Limitations and Known Issues
This section discusses the limitations and known issues in the MySQL NDB Cluster Connector for Java APIs.

*Known issues in ClusterJ:*

- **Joins:** With ClusterJ, queries are limited to single tables. This is not a problem with JPA or JDBC, both of which support joins.

- **Database views:** Because MySQL database views do not use the NDB storage engine, ClusterJ applications cannot "see" views, and thus cannot access them. To work with views using Java, you should use JPA or JDBC.

- **Relations and inheritance:** ClusterJ does not support relations or inheritance. Tables are mapped one-to-one onto domain classes, and only single-table operations are supported. NDB tables support foreign keys, and foreign key constraints are enforced when using ClusterJ for inserts, updates, and deletes.

- **TIMESTAMP:** Currently, ClusterJ does not support the TIMESTAMP data type for a primary key field.

*Known issues in JDBC and Connector/J: For information about limitations and known issues with JDBC and Connector/J, see JDBC API Implementation Notes, and Troubleshooting Connector/J Applications.*

*Known issues in NDB Cluster: For information about limitations and other known issues with NDB Cluster, see Known Limitations of NDB Cluster.*

This section provides information about the MySQL NoSQL Connector for JavaScript, a set of Node.js adapters for NDB Cluster and MySQL Server, which make it possible to write JavaScript applications for Node.js using MySQL data.

⚠️ Important

Beginning with NDB 8.0.22, Node.js support is included only in NDB 8.0.

Node.js support was removed from previous versions of NDB Cluster as of the following releases:

- **NDB 7.5 series**: NDB 7.5.20
- **NDB 7.6 series**: NDB 7.6.16

5.1 MySQL NoSQL Connector for JavaScript Overview

This connector differs in a number of key respects from most other MySQL Connectors and APIs. The interface is asynchronous, following the built-in Node.js event model. In addition, it employs a domain object model for data storage. Applications retrieve data in the form of fully-instantiated objects, rather than as rows and columns.

The MySQL Node.js adapter includes 2 drivers. The **ndb** driver accesses the **NDB** storage engine directly, using the NDB API (see Chapter 2, *The NDB API*). No MySQL Server is required for the **ndb** driver. The **mysql** driver uses a MySQL Server for its data source, and depends on the node-mysql Node.js module from [https://github.com/felixge/node-mysql](https://github.com/felixge/node-mysql). Regardless of the driver in use, no SQL statements are required; when using the Connector for JavaScript, Node.js applications employ data objects for all requests made to the database.

5.2 Installing the JavaScript Connector

This section covers basic installation and setup of the MySQL JavaScript Connector and its prerequisites. The Connector requires both Node.js and NDB Cluster to be installed first; you can install these in either order. In addition, the mysql-js adapter requires the node-mysql driver.
the Connector also requires that your system have a working C++ compiler such as gcc or Microsoft Visual Studio.

To install all of the prerequisites for the JavaScript Connector, including node-mysql, you should perform the following steps:

1. **Node.js.** If you do not already have Node.js installed on your system, you can obtain it from http://nodejs.org/download/. In addition to source code, prebuilt binaries and installers are available for a number of platforms. Many Linux distributions also have Node.js in their repositories (you may need to add an alternative repository in your package manager).

   NDB uses node-gyp for compiling add-on Node.js modules; for more information about this tool, see https://npmjs.org/package/node-gyp.

   Beginning with NDB 8.0.22, **NDBCLUSTER** requires Node.js version 12.18.3 or later. Beginning with NDB 8.0.33, the minimum required Node.js version is 18.12.1.

   Regardless of the method by which you obtain Node.js, keep in mind that the architecture of the version you install must match that of the NDB Cluster binaries you intend to use; you cannot, for example, install the JavaScript Connector using 64-bit Node.js and 32-bit NDB Cluster. If you do not know the architecture of your existing Node.js installation, you can determine this by checking the value of global.process.arch.

2. **NDB Cluster.** If NDB Cluster, including all header and library files, is not already installed on the system, install it (see NDB Cluster Installation).

   As mentioned previously, you must make sure that the architecture (32-bit or 64-bit) is the same for both NDB Cluster and Node.js. You can check the architecture of an existing NDB Cluster installation in the output of ndb_mgm -V.

3. **node-mysql driver.** The mysql-js adapter also requires a working installation of the node-mysql driver from https://github.com/felixge/node-mysql/. You can install the driver using the Node.js npm install command; see the project website for the recommended version and package identifier.

Once the requirements just listed are met, you can find the files needed to install the MySQL Connector for JavaScript in share/nodejs in the NDB Cluster installation directory. (If you installed NDB Cluster as an RPM, this is /usr/share/mysql/nodejs.) To use the Node.js npm tool to perform a “best-guess” installation without any user intervention, change to the share/nodejs directory, then use npm as shown here:

```bash
$> npm install .
```

The final period (.) character is required. Note that you must run this command in share/node.js in the NDB Cluster installation directory.

You can test your installation using the supplied test program. This requires a running NDB Cluster, including a MySQL Server with a database named test. The mysql client executable must be in the path.

To run the test suite, change to the test directory, then execute command shown here:

```bash
$> node driver
```

By default, all servers are run on the local machine using default ports; this can be changed by editing the file test/test_connection.js, which is generated by running the test suite. If this file is not already present (see Bug #16967624), you can copy share/nodejs/test/lib/test_connection_js to the test directory for this purpose.

If you installed NDB Cluster to a nondefault location, you may need to export the LD_LIBRARY_PATH to enable the test suite. The test suite also requires that the test database be available on the MySQL server.
5.3 Connector for JavaScript API Documentation

This section contains prototype descriptions and other information for the MySQL Connector for JavaScript.

5.3.1 Batch

This class represents a batch of operations.

```javascript
Batch extends Context
execute(Function(Object error) callback);
```

Execute this batch. When a batch is executed, all operations are executed; the callback for each operation is called when that operation is executed (operations are not performed in any particular order). The `execute()` function's `callback` is also called.

A batch is executed in the context of the session's current state: this is autocommit if a transaction has not been started; this also includes the default lock mode and the partition key.

```javascript
clear();
```

Clear this batch without affecting the transaction state. After being cleared, the batch is still valid, but all operations previously defined are removed; this restores the batch to a clean state.

The callbacks for any operations that are defined for this batch are called with an error indicating that the batch has been cleared.

This function requires no arguments.

```javascript
getSession();
```

Get the session from which this batch was created.

This function requires no arguments.

5.3.2 Context

`Context` is the supertype of `Session` and `Batch`. It contains functions that are executed immediately if called from a session, or when the batch is executed.

The `Mynode` implementation does have any concept of a user and does not define any such property.

```javascript
find(Function constructor, Object keys, Function(Object error, Object instance[, ...]) callback[, ...]);
find(String tableName, Object keys, Function(Object error, Object instance[, ...]) callback[, ...]);
```

Find a specific instance based on a primary key or unique key value.

You can use either of two versions of this function. In the first version, the `constructor` parameter is the constructor function of a mapped domain object. Alternatively, you can use the `tableName` instead, in the second variant of the function.

For both versions of `find()`, the `keys` may be of any type. A key must uniquely identify a single row in the database. If `keys` is a simple type (number or string), then the parameter type must be the same type as or compatible with the primary key type of the mapped object. Otherwise, properties are taken from the parameter and matched against property names in the mapping. Primary key properties are used if all are present, and other properties ignored. If `keys` cannot be used identify the primary key, property names corresponding to unique key columns are used instead. If no complete primary
or unique key properties are found, an error is reported. The returned object is loaded based on the mapping and the current values in the database.

For multi-column primary or unique keys, all key fields must be set.

```javascript
load(Object instance, Function(Object error) callback);
```

Load a specific instance by matching its primary or unique key with a database row, without creating a new domain object. (This is unlike `find()`, which creates a new, mapped domain object.)

The `instance` must have its primary or unique key value or values set. The mapped values in the object are loaded based on the current values in the database. Unmapped properties in the object are not changed.

Primary key properties are used if all are present, and all other properties are ignored; otherwise, property names corresponding to unique key columns are used. If no complete primary or unique key properties can be found, an error is reported.

The `callback` function is called with the parameters provided when the operation has completed. The `error` is the Node.js `Error` object; see Section 5.3.4, “Errors”, for more information.

```javascript
persist(Object instance, Function(Object error) callback);
persist(Function constructor, Object values, Function(Object error) callback);
persist(String tableName, Object values, Function(Object error) callback);
```

Insert an instance into the database, unless the instance already exists in the database, in which case an exception is reported to a `callback` function. Autogenerated values are present in the instance when the `callback` is executed.

The role of an instance to be persisted can be fulfilled in any of three ways: by an instance object; by a constructor, with parameters, for a mapped domain object; or by table name and values to be inserted.

In all three cases, the `callback` function is called with the parameters provided, if any, when the operation has completed. The `error` is the Node.js `Error` object; see Section 5.3.4, “Errors”, for more information.

```javascript
remove(Object instance, Function(Object error) callback);
remove(Function constructor, Object keys, Function(Object error) callback);
remove(String tableName, Object keys, Function(Object error) callback);
```

Delete an instance of a class from the database by a primary or unique key.

There are three versions of `remove()`; these allow you to delete an instance by referring to the `instance` object, to a `constructor` function, or by name of the table. The `instance` object must contain key values that uniquely identify a single row in the database. Otherwise, if the `keys` supplied with the function constructor or table name is a simple type (Number or String), then the parameter type must be of either the same type as or a type compatible with the primary key type of the mapped object. If `keys` is not a simple type, properties are taken from the parameter and matched against property names in the mapping. Primary key properties are used if all are present, and other properties ignored. If `keys` does not identify the primary key, property names corresponding to unique key columns are used instead. If no complete primary or unique key properties are found, an error is reported to the `callback`.

All three versions of `remove()` call the `callback` function with the parameters provided, if any, when the operation is complete. The `error` object is a Node.js `Error`; see Section 5.3.4, “Errors”, for error codes.

```javascript
update(Object instance, Function(Object error) callback);
```
Update an instance in the database with the supplied values without retrieving it. The primary key is used to determine which instance is updated. If the instance does not exist in the database, an exception is reported in the callback.

As with the methods previously shown for persisting instances in and removing them from the database, update() exists in three variations, which allow you to use the instance as an object, an object constructor with keys, or by tableName and keys.

Unique key fields of the keys object determine which instance is to be updated. The values object provides values to be updated. If the keys object contains all fields corresponding to the primary key, the primary key identifies the instance. If not, unique keys are chosen in a nondeterministic manner.

Note
update() cannot be used to change the primary key.

Save an instance in the database without checking for its existence. If the instance already exists, it is updated (as if you had used update()); otherwise, it is created (as if persist() had been used). The instance id property is used to determine which instance should be saved. As with update(), persist(), and remove(), this method allows you to specify the instance using an object, object constructor, or table name.

All three versions of the save() method call the callback function with any parameters provided when the operation has been completed. The error is a Node.js Error object; see Section 5.3.4, “Errors”, for error codes and messages.

Boolean isBatch() Context also exposes an isBatch() instance method, which returns true if this Context is a Batch, and false if it is a Session. isBatch() takes no arguments.

5.3.3 Converter

Converter classes convert between JavaScript types and MySQL types. If the user supplies a JavaScript converter, it is used to read and write to the database.

Converters have several purposes, including the following:

- To convert between MySQL DECIMAL types and a user's preferred JavaScript fixed-precision utility library
- To convert between MySQL BIGINT types and a user's preferred JavaScript big number utility library
- To serialize arbitrary application objects into character or binary columns

The ndb back end also uses converters to support SET and ENUM columns. (The mysql back end does not use these.)

A Converter class has the interface defined here:

```javascript
function Converter() {};
```
Converter.prototype = {
    "toDB"    : function(obj) { },
    "fromDB"  : function(val) { }
};

The Converter must implement the following two functions:

1. toDB(obj): Convert an application object obj into a form that can be stored in the database.
2. fromDB(val): Convert a value val read from the database into application object format.

Each function returns the result of the conversion.

Converter invocations are chained in the following ways:

- When writing to the database, first the registered FieldConverter, if any, is invoked. Later, any registered TypeConverter is invoked.
- When reading from the database, first the registered TypeConverter, if any, is invoked. Later, any registered FieldConverter is invoked.

5.3.4 Errors

The Errors object contains the error codes and message exposed by the MySQL Node.js adapters.

```javascript
var Errors;

Errors = {
    /* Standard-defined classes, SQL-99 */
    "02000" : "No Data",
    "08000" : "Connection error",
    "08001" : "Unable to connect to server",
    "08004" : "Connection refused",

    /* data errors */
    "22000" : "Data error",
    "22001" : "String too long",
    "22003" : "Numeric value out of range",
    "22008" : "Invalid datetime",

    /* Constraint violations */
    "23000" : "Integrity Constraint Violation",

    /* misc. errors */
    "25000" : "Invalid Transaction State",
    "2C000" : "Invalid character set name",
    "42S02" : "Table not found",
    "IM001" : "Driver does not support this function",

    /* Implementation-defined classes (NDB) */
    "NDB00" : "Refer to ndb_error for details"
};
```

5.3.5 Mynode

This class is used to generate and obtain information about sessions (Session objects). To create an instance, use the Node.js require() function with the driver name, like this:

```javascript
var nosql = require("mysql-js");
```

ConnectionProperties can be used to retrieve or set the connection properties for a given session. You can obtain a complete set of of default connection properties for a given adapter using the
ConnectionProperties constructor, shown here, with the name of the adapter (a string) used as the value of `nameOrProperties`:

```
ConnectionProperties(nameOrProperties);
```

You can also create your own `ConnectionProperties` object by supplying a list of property names and values to a new `ConnectionProperties` object in place of the adapter name. Then you can use this object to set the connection properties for a new session, as shown here:

```
var NdbConnectionProperties = {
  "implementation" : "ndb",
  "ndb_connectstring" : "localhost:1186",
  "database" : "test",
  "mysql_user" : "root",
  "ndb_connect_retries" : 4,
  "ndb_connect_delay" : 5,
  "ndb_connect_verbose" : 0,
  "linger_on_close_msec": 500,
  "use_ndb_async_api" : false,
  "ndb_session_pool_min" : 4,
  "ndb_session_pool_max" : 100,
};
```

```
var sharePath = '/usr/local/mysql/share/nodejs';      // path to share/nodejs
var nosql = require(sharePath);
var dbProperties = nosql.ConnectionProperties(NdbConnectionProperties);
```

It is also possible to obtain an object with the adapter's default connection properties, after which you can update a selected number of these properties, then use the modified object to set connection properties for the session, as shown here:

```
var sharePath = '/usr/local/mysql/share/nodejs';      // path to share/nodejs
var spi   = require(sharePath + '/Adapter/impl/SPI'); // under share/nodejs
var serviceProvider         = spi.getDBServiceProvider('ndb');
var NdbConnectionProperties = serviceProvider.getDefaultConnectionProperties();
NdbConnectionProperties.mysql_user = 'nodejs_user';
NdbConnectionProperties.database   = 'my_nodejs_db';
var dbProperties = nosql.ConnectionProperties(NdbConnectionProperties);
```

The `ConnectionProperties` object includes the following properties:

- `implementation`: For Node.js applications using NDB Cluster, this is always “ndb”.
- `ndb_connectstring`: NDB Cluster connection string used to connect to the management server.
- `database`: Name of the MySQL database to use.
- `mysql_user`: MySQL user name.
- `ndb_connect_retries`: Number of times to retry a failed connection before timing out; use a number less than 0 for this to keep trying the connection without ever stopping.
- `ndb_connect_delay`: Interval in seconds between connection retries.
- `ndb_connect_verbose`: 1 or 0; 1 enables extra console output during connection.
- `linger_on_close_msec`: When a client closes a DBConnectionPool, the underlying connection is kept open for this many milliseconds in case another client tries to reuse it.
- `use_ndb_async_api`: If true, some operations are executed using asynchronous calls for improved concurrency. If false, the number of operations in transit is limited to one per worker thread.
• **ndb_session_pool_min**: Minimum number of DBSession objects per NdbConnectionPool.

• **ndb_session_pool_max**: Maximum number of DBSession objects per NdbConnectionPool.

Each NdbConnectionPool maintains a pool of DBSession objects, along with their underlying Ndb objects. This parameter, together with **ndb_session_pool_min**, sets guidelines for the size of that pool.

The **TableMapping** constructor is also visible as a top-level function. You can get the mapping either by name, or by using an existing mapping:

```javascript
TableMapping(tableName);
TableMapping(tableMapping);
```

```javascript
openSession(properties, mappings, Function(err, Session) callback);
```

Connect to the data source and get a Session in the callback function. This is equivalent to calling `connect()` (see later in this section), and then calling `getSession()` on the SessionFactory that is returned in the callback function.

**Note**

Executing this method could result in connections being made to many other nodes on the network, waiting for them to become ready, and making multiple requests to them. You should avoid opening new sessions unnecessarily for this reason.

The implementation member of the properties object determines the implementation of the Session.

If mappings is undefined, null, or an empty array, no mappings are loaded or validated. In this case, any required mappings are loaded and validated when needed during execution. If mappings contains a string or a constructor function, the metadata for the table (or mapped table) is loaded from the database and validated against the requirements of the mapping.

Multiple tables and constructors may be passed to `openSession()` as elements in an array.

```javascript
connect(properties, mappings, Function(err, SessionFactory) callback);
```

Connect to the data source to obtain a SessionFactory in the callback function. In order to obtain a Session, you must then call `getSession()` on this SessionFactory, whose implementation is determined by the implementation member of the properties object.

If mappings is undefined, null, or an empty array, no mappings are loaded or validated. In this case, any required mappings are loaded and validated when needed. If mappings contains a string or a constructor function, the metadata for the table (or mapped table) is loaded from the database and validated against the requirements of the mapping.

Multiple tables and constructors may be passed as elements in an array.

```javascript
Array getOpenSessionFactories()
```

Get an array of all the SessionFactory objects that have been created by this module.

**Note**

The following functions are part of the public API but are not intended for application use. They form part of the contract between Mynode and SessionFactory.
5.3.6 Session

A session is the main user access path to the database. The `Session` class models such a session.

```plaintext
Session extends Context

getMapping(Object parameter, Function(Object err, Object mapping) callback);
```

Get the mappings for a table or class. The `parameter` may be a table name, a mapped constructor function, or a domain object. This function returns a fully resolved `TableMapping` object.

```plaintext
Batch createBatch()
```

Creates a new, empty batch for collecting multiple operations to be executed together. In an application, you can invoke this function similarly to what is shown here:

```javascript
var nosql = require("mysql-js");
var myBatch = nosql.createBatch();
```

```plaintext
Array listBatches();
```

Return an array whose elements consist of all current batches belonging to this session.

```plaintext
Transaction currentTransaction();
```

Get the current `Transaction`.

```plaintext
void close(Function(Object error) callback);
```

Close this session. Must be called when the session is no longer needed.

```plaintext
boolean isClosed();
```

Returns true if this session is closed.

```plaintext
void setLockMode(String lockMode);
```

Set the lock mode for read operations. This takes effect immediately and remains in effect until the session is closed or this method is called again. `lockMode` must be one of 'EXCLUSIVE', 'SHARED', OR 'NONE'.

```plaintext
Array listTables(databaseName, callback);
```

List all tables in database `databaseName`.

```plaintext
TableMetadata getTableMetadata(String databaseName, String tableName, callback);
```

Fetch metadata for table `tableName` in database `databaseName`. 
5.3.7 SessionFactory

This class is used to generate and manage sessions. A Session provides a context for database transactions and operations. Each independent user should have its own session.

```javascript
openSession(Object mappings, Function(Object error, Session session) callback);
```

Open a database session object. Table mappings are validated at the beginning of the session. Resources required for sessions are allocated in advance; if those resources are not available, the method returns an error in the callback.

```javascript
Array getOpenSessions();
```

Get all open sessions that have been created by this SessionFactory.

```javascript
close(Function(Error err));
```

Close the connection to the database. This ensures proper disconnection. The function passed in is called when the close operation is complete.

5.3.8 TableMapping and FieldMapping

A TableMapping describes the mapping of a domain object in the application to a table stored in the database. A default table mapping is one which maps each column in a table to a field of the same name.

```javascript
TableMapping = {
    String table : "",
    String database : "",
    boolean mapAllColumns : true,
    Array fields : null
};
```

The table and data members are the names of the table and database, respectively. mapAllColumns, if true, creates a default FieldMapping for all columns not listed in fields, such that all columns not explicitly mapped are given a default mapping to a field of the same name. fields holds an array of FieldMapping objects; this can also be a single FieldMapping.

A FieldMapping describes a single field in a domain object. There is no public constructor for this object; you can create a FieldMapping using TableMapping.mapField(), or you can use FieldMapping literals can be used directly in the TableMapping constructor.

```javascript
FieldMapping = {
    String fieldName : "",
    String columnName : "",
    Boolean persistent : true,
    Converter converter : null
};
```

fieldName and columnName are the names of the field and the column where this field are stored, respectively, in the domain object. If persistent is true (the default), the field is stored in the database. converter specifies a Converter class, if any, to use with this field (defaults to null).}];

The TableMapping constructor can take either the name of a table (possibly qualified with the database name) or a TableMapping literal.

```javascript
TableMapping mapField(String fieldName, [String columnName], [Converter converter], [Boolean persistent])
```

Create a field mapping for a named field of a mapped object. The only mandatory parameter is fieldName, which provides the name a field in a JavaScript application object. The remaining parameters are optional, and may appear in any order. The current TableMapping object is returned.
TableMetadata

columnName specifies the name of the database column that maps to this object field. If omitted, columnName defaults to the same value as fieldName. A converter can be used to supply a Converter class that performs custom conversion between JavaScript and database data types. The default is null. persistent specifies whether the field is persisted to the database, and defaults to true.

Important
If persistent is false, then the columnName and converter parameters may not be used.

TableMapping applyToClass(Function constructor)

Attach a TableMapping to a constructor for mapped objects. After this is done, any object created from the constructor will qualify as a mapped instance, which several forms of the relevant Session and Batch methods can be used.

For example, an application can construct an instance that is only partly complete, then use Session.load() to populate it with all mapped fields from the database. After the application modifies the instance, Session.save() saves it back. Similarly, Session.find() can take the mapped constructor, retrieve an object based on keys, and then use the constructor to create a fully-fledged domain object.

5.3.9 TableMetadata

A TableMetadata object represents a table. This is the object returned in the getTable() callback. indexes[0] represents the table’s intrinsic primary key.

TableMetadata = {
  database : "" , // Database name
  name     : ""  , // Table Name
  columns  : {}    , // ordered array of ColumnMetadata objects
  indexes  : {}    , // array of IndexMetadata objects
  partitionKey : {} , // ordered array of column numbers in the partition key
}

ColumnMetadata object represents a table column.

ColumnMetadata = {
  /* Required Properties */
  name : ""           , // column name
  columnNumber : -1   , // position of column in table, and in columns array
  columnType : ""     , // a ColumnTypes value
  isIntegral : false  , // true if column is some variety of INTEGER type
  isNullable : false  , // true if NULLABLE
  isInPrimaryKey : false , // true if column is part of PK
  isInPartitionKey : false , // true if column is part of partition key
  columnSpace : 0     , // buffer space required for encoded stored value
  defaultValue : null  , // default value for column: null for default NULL;
                         // undefined for no default; or a type-appropriate
                         // value for column

  /* Optional Properties, depending on columnType */
  /* Group A: Numeric */
  isUnsigned : false , // true for UNSIGNED
  intSize : null    , // 1,2,3,4, or 8 if column type is INT
  scale : 0         , // DECIMAL scale
  precision : 0     , // DECIMAL precision
  isAutoincrement : false , // true for AUTO_INCREMENT columns

  /* Group B: Non-numeric */
  length : 0        , // CHAR or VARCHAR length in characters
  isBinary : false  , // true for BLOB/BINARY/VARBINARY
}
An `IndexMetadata` object represents a table index. The `indexes` array of `TableMetadata` contains one `IndexMetadata` object per table index.

**NDB** implements a primary key as both an ordered index and a unique index, and might be viewed through the NDB API adapter as two indexes, but through a MySQL adapter as a single index that is both unique and ordered. We tolerate this discrepancy and note that the implementation in `Adapter/api` must treat the two descriptions as equivalent.

```
IndexMetadata = {
  name : "" , // Index name; undefined for PK
  isPrimaryKey : true , // true for PK; otherwise undefined
  isUnique : true , // true or false
  isOrdered : true , // true or false; can scan if true
  columns : null , // an ordered array of column numbers
};
```

The `ColumnMetaData` object's `columnType` must be a valid `ColumnTypes` value, as shown in this object's definition here:

```
ColumnTypes = [
  "TINYINT",
  "SMALLINT",
  "MEDIUMINT",
  "INT",
  "BIGINT",
  "FLOAT",
  "DOUBLE",

### 5.3.10 Transaction

A transaction is always either automatic or explicit. If it is automatic, (autocommit), every operation is performed as part of a new transaction that is automatically committed.

**Beginning, committing, and rolling back a transaction**

```
begin();
```

Begin a transaction. No arguments are required. If a transaction is already active, an exception is thrown.

```
commit(Function(Object error) callback);
```

Commit a transaction.

This method takes as its sole argument a `callback` function that returns an error object.

```
rollback(Function(Object error) callback);
```
Roll back a transaction. Errors are reported in the `callback` function.

**Transaction information methods**

```javascript
Boolean isActive();
```

Determine whether or not a given transaction is currently active. Returns true if a transaction is active, and false otherwise.

`isActive()` requires no arguments.

```javascript
setRollbackOnly();
```

Mark the transaction as rollback-only. Once this is done, `commit()` rolls back the transaction and throws an exception; `rollback()` rolls the transaction back, but does not throw an exception. To mark a transaction as rollback-only, call the `setRollbackOnly()` method, as shown here.

This method is one-way; a transaction marked as rollback-only cannot be unmarked. Invoking `setRollbackOnly()` while in autocommit mode throws an exception. This method requires no arguments.

```javascript
boolean getRollbackOnly();
```

Determine whether a transaction has been marked as rollback-only. Returns true if the transaction has been so marked. `setRollbackOnly()` takes no arguments.

### 5.4 Using the MySQL JavaScript Connector: Examples

This section contains a number of examples performing basic database operations such as retrieving, inserting, or deleting rows from a table. The source for these files can also be found in `share/nodejs/samples`, under the NDB Cluster installation directory.

#### 5.4.1 Requirements for the Examples

The software requirements for running the examples found in the next few sections are as follows:

- A working Node.js installation
- Working installations of the `ndb` and `mysql-js` adapters
- The `mysql-js` adapter also requires a working installation of the `node-mysql` driver from [https://github.com/felixge/node-mysql/](https://github.com/felixge/node-mysql/)

Section 5.2, “Installing the JavaScript Connector”, describes the installation process for all three of these requirements.

**Sample database, table, and data.** All of the examples use a sample table named `tweet`, in the `test` database. This table is defined as in the following `CREATE TABLE` statement:

```sql
CREATE TABLE IF NOT EXISTS tweet  
     (id CHAR(36) NOT NULL PRIMARY KEY, 
      author VARCHAR(20), 
      message VARCHAR(140), 
      date_created TIMESTAMP, 
      KEY idx_btree_date_created (date_created), 
      KEY idx_btree_author(author) 
) ENGINE=NDB;
```

The `tweet` table can be created by running the included SQL script `create.sql` in the `mysql` client. You can do this by invoking `mysql` in your system shell, as shown here:
Requirements for the Examples

$> mysql < create.sql

All of the examples also make use of two modules defined in the file lib.js, whose contents are reproduced here:

```javascript
/* FILE: lib.js */

"use strict";

var udebug = unified_debug.getLogger("samples/lib.js");
var exec = require("child_process").exec;
var SQL = {};

/*@ Pseudo random UUID generator */
var randomUUID = function() {
    return 'xxxxxxxx-xxxx-4xxx-yxxx-xxxxxxxxxxxx'.replace(/[xy]/g, function(c) {
        var r = Math.random()*16|0, v = c == 'x' ? r : (r&0x3|0x8);
        return v.toString(16);
    });
};

/*@ Tweet domain object model */
var Tweet = function(author, message) {
    this.id = randomUUID();
    this.date_created = new Date();
    this.author = author;
    this.message = message;
};

/*@ SQL DDL Utilities */
var runSQL = function(sqlPath, source, callback) {
    function childProcess(error, stdout, stderr) {
        udebug.log('harness runSQL process completed.');
        udebug.log(source + ' stdout: ' + stdout);
        udebug.log(source + ' stderr: ' + stderr);
        if (error !== null) {
            console.log(source + 'exec error: ' + error);
        } else {
            udebug.log(source + ' exec OK');
        }
        if(callback) {
            callback(error);
        }
    }

    var p = mysql_conn_properties;
    var cmd = 'mysql';
    if(p) {
        if(p.mysql_socket) { cmd += " --socket=" + p.mysql_socket; }
        else if(p.mysql_port) { cmd += " --port=" + p.mysql_port; }
        if(p.mysql_host) { cmd += " -h " + p.mysql_host; }
        if(p.mysql_user) { cmd += " -u " + p.mysql_user; }
        if(p.mysql_password) { cmd += " --password=" + p.mysql_password; }
    }
    cmd += ' <' + sqlPath;
    udebug.log('harness runSQL forking process...');
    var child = exec(cmd, childProcess);
};

SQL.create =  function(suite, callback) {
    var sqlPath = path.join(suite.path, 'create.sql');
    udebug.log_detail("createSQL path: " + sqlPath);
    runSQL(sqlPath, 'createSQL', callback);
};

SQL.drop = function(suite, callback) {
    var sqlPath = path.join(suite.path, 'drop.sql');
    udebug.log_detail("dropSQL path: " + sqlPath);
};
```
Finally, a module used for random data generation is included in the file `ndb_loader/lib/RandomData.js`, shown here:

```javascript
# FILE: RandomData.js

var assert = require("assert");

function RandomIntGenerator(min, max) {
    assert(max > min);
    var range = max - min;
    this.next = function() {
        var x = Math.floor(Math.random() * range);
        return min + x;
    };
}

function SequentialIntGenerator(startSeq) {
    var seq = startSeq - 1;
    this.next = function() {
        seq += 1;
        return seq;
    };
}

function RandomFloatGenerator(min, max, prec, scale) {
    assert(max > min);
    this.next = function() {
        var x = Math.random();
        /* fixme! */
        return 100 * x;
    };
}

function RandomCharacterGenerator() {
    var intGenerator = new RandomIntGenerator(32, 126);
    this.next = function() {
        return String.fromCharCode(intGenerator.next());
    };
}

function RandomVarcharGenerator(length) {
    var lengthGenerator = new RandomIntGenerator(0, length),
        characterGenerator = new RandomCharacterGenerator();
    this.next = function() {
        var i = 0,
            str = ",",
            len = lengthGenerator.next();
        for(; i < len ; i++) str += characterGenerator.next();
        return str;
    };
}

function RandomCharGenerator(length) {
    var characterGenerator = new RandomCharacterGenerator();
    this.next = function() {
        var i = 0,
            str = "",
            for(; i < length ; i++) str += characterGenerator.next();
    }
```
Requirements for the Examples

```javascript
function RandomDateGenerator() {
    var generator = new RandomIntGenerator(0, Date.now());
    this.next = function() {
        return new Date(generator.next());
    }
}

function RandomGeneratorForColumn(column) {
    var g = {},
        min, max, bits;

    switch(column.columnType.toLocaleUpperCase()) {
    case "TINYINT":
    case "SMALLINT":
    case "MEDIUMINT":
    case "INT":
    case "BIGINT":
        if(column.isInPrimaryKey) {
            g = new SequentialIntGenerator(0);
        }
        else {
            bits = column.intSize * 8;
            max = column.isUnsigned ? Math.pow(2,bits)-1 : Math.pow(2, bits-1);
            min = column.isUnsigned ? 0 : 1 - max;
            g = new RandomIntGenerator(min, max);
        }
        break;
    case "FLOAT":
    case "DOUBLE":
    case "DECIMAL":
        g = new RandomFloatGenerator(0, 100000); // fixme
        break;
    case "CHAR":
        g = new RandomCharGenerator(column.length);
        break;
    case "VARCHAR":
        g = new RandomVarcharGenerator(column.length);
        break;
    case "TIMESTAMP":
        g = new RandomIntGenerator(0, Math.pow(2,32)-1);
        break;
    case "YEAR":
        g = new RandomIntGenerator(1900, 2155);
        break;
    case "DATE":
    case "TIME":
    case "DATETIME":
        g = new RandomDateGenerator();
        break;
    case "BLOB":
    case "TEXT":
    case "BIT":
    case "BINARY":
    case "VARBINARY":
        default:
            throw("UNSUPPORTED COLUMN TYPE " + column.columnType);
        break;
    }

    return g;
}

function RandomRowGenerator(table) {
    var i = 0,
        generators = [];
```
for(; i < table.columns.length ; i++) {
    generators[i] = RandomGeneratorForColumn(table.columns[i]);
}

this newRow = function() {
    var n, col, row = {}; 
    for(n = 0; n < table.columns.length ; n++) {
        col = table.columns[n];
        row[col.name] = generators[n].next();
    }
    return row;
}

exports.RandomRowGenerator = RandomRowGenerator;
exports.RandomGeneratorForColumn = RandomGeneratorForColumn;

5.4.2 Example: Finding Rows

# FILE: find.js
var nosql = require('..');
var lib = require('./lib.js');
var adapter = 'ndb';
global.mysql_conn_properties = {};
var user_args = [];

// *** program starts here ***

// analyze command line
var usageMessage =
    "Usage: node find key\n" +
    "  -h or --help: print this message\n" +
    "  --debug: set the debug flag\n" +
    "--adapter=<adapter>: run on the named adapter (e.g. ndb or mysql)\n";

// handle command line arguments
var i, exit, val, values;
for(i = 2; i < process.argv.length ; i++) {
    val = process.argv[i];
    switch (val) {
        case '--debug':
        case '-d':
            unified_debug.on();
            unified_debug.level_debug();
            break;
        case '--detail':
            unified_debug.on();
            unified_debug.level_detail();
            break;
        case '--help':
        case '-h':
            exit = true;
            break;
        default:
            values = val.split('=');
            if (values.length !== 2) {
                switch (values[0]) {
                    case '--adapter':

    }
};

// connect to the database
nosql.openSession(dbProperties, annotations, onSession);
Chapter 6 ndbmemcache—Memcache API for NDB Cluster
(NO LONGER SUPPORTED)

This feature was deprecated in NDB 8.0.22 and removed in NDB 8.0.23; it not supported by any subsequent version of NDB Cluster.
