<td>Similar to the <code>memcached_append()</code>, but has the option of an additional master key that can be used to identify an individual server.</td>
</tr>
<tr>
<td><code>memcached_cas_by_key(mmc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code></td>
<td>Similar to the <code>memcached_cas()</code>, but has the option of an additional master key that can be used to identify an individual server.</td>
</tr>
</tbody>
</table>
Developing a `memcached` Application

<table>
<thead>
<tr>
<th><code>libmemcached</code> Function</th>
<th>Equivalent Core Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>key_length, value, value_length,</td>
<td></td>
</tr>
<tr>
<td>expiration, flags)</td>
<td></td>
</tr>
</tbody>
</table>

The `by_key` methods add two further arguments that define the master key, to be used and applied during the hashing stage for selecting the servers. You can see this in the following definition:

```c
memcached_return
  memcached_set_by_key(memcached_st *ptr,
                       const char *master_key,
                       size_t master_key_length,
                       const char *key,
                       size_t key_length,
                       const char *value,
                       size_t value_length,
                       time_t expiration,
                       uint32_t flags);
```

All the functions return a value of type `memcached_return`, which you can compare against the `MEMCACHED_SUCCESS` constant.

### `libmemcached` Get Functions

The `libmemcached` functions provide both direct access to a single item, and a multiple-key request mechanism that provides much faster responses when fetching a large number of keys simultaneously.

The main get-style function, which is equivalent to the generic `get()` is `memcached_get()`. This function returns a string pointer, pointing to the value associated with the specified key.

```c
char *memcached_get (memcached_st *ptr,
                     const char *key, size_t key_length,
                     size_t *value_length,
                     uint32_t *flags,
                     memcached_return *error);
```

A multi-key get, `memcached_mget()`, is also available. Using a multiple key get operation is much quicker to do in one block than retrieving the key values with individual calls to `memcached_get()`. To start the multi-key get, call `memcached_mget()`:

```c
memcached_return
  memcached_mget (memcached_st *ptr,
                  char **keys, size_t *key_length,
                  unsigned int number_of_keys);
```

The return value is the success of the operation. The `keys` parameter should be an array of strings containing the keys, and `key_length` an array containing the length of each corresponding key. `number_of_keys` is the number of keys supplied in the array.

To fetch the individual values, use `memcached_fetch()` to get each corresponding value.

```c
char *memcached_fetch (memcached_st *ptr,
                       const char *key, size_t *key_length,
                       size_t *value_length,
                       uint32_t *flags,
                       memcached_return *error);
```

The function returns the key value, with the `key`, `key_length` and `value_length` parameters being populated with the corresponding key and length information. The function returns `NULL` when there are no more values to be returned. A full example, including the populating of the key data and the return of the information is provided here.
Developing a `memcached` Application

```c
#include <stdio.h>
#include <string.h>
#include <unistd.h>
#include <libmemcached/memcached.h>

int main(int argc, char *argv[]) {
  memcached_server_st *servers = NULL;
  memcached_st *memc;
  memcached_return rc;
  char *keys[] = {"huey", "dewey", "louie"};
  size_t key_length[3];
  char *values[] = {"red", "blue", "green"};
  size_t value_length[3];
  unsigned int x;
  uint32_t flags;
  char return_key[MEMCACHED_MAX_KEY];
  size_t return_key_length;
  char *return_value;
  size_t return_value_length;
  memc = memcached_create(NULL);
  servers = memcached_server_list_append(servers, "localhost", 11211, &rc);
  if (rc == MEMCACHED_SUCCESS)
    fprintf(stderr, "Added server successfully\n");
  else
    fprintf(stderr, "Couldn't add server: %s", memcached_strerror(memc, rc));

  for (x = 0; x < 3; x++) {
    key_length[x] = strlen(keys[x]);
    value_length[x] = strlen(values[x]);
    rc = memcached_set(memc, keys[x], key_length[x], values[x],
                        value_length[x], (time_t)0, (uint32_t)0);
    if (rc == MEMCACHED_SUCCESS)
      fprintf(stderr, "Key %s stored successfully\n", keys[x]);
    else
      fprintf(stderr, "Couldn't store key: %s", memcached_strerror(memc, rc));
  }

  rc = memcached_mget(memc, keys, key_length, 3);
  if (rc == MEMCACHED_SUCCESS) {
    while ((return_value = memcached_fetch(memc, return_key, &return_key_length,
                                            &return_value_length, &flags, &rc)) != NULL) {
      if (rc == MEMCACHED_SUCCESS)
        fprintf(stderr, "Key %s returned %s", return_key, return_value);
    }
  }

  return 0;
}
```

Running the above application produces the following output:

```
shell> memc_multi_fetch
Added server successfully
Key huey stored successfully
Key dewey stored successfully
Key louie stored successfully
Key huey returned red
```
Developing a memcached Application

Key dewey returned blue
Key louie returned green

Controlling libmemcached Behaviors

The behavior of libmemcached can be modified by setting one or more behavior flags. These can either be set globally, or they can be applied during the call to individual functions. Some behaviors also accept an additional setting, such as the hashing mechanism used when selecting servers.

To set global behaviors:

```c
memcached_return
memcached_behavior_set (memcached_st *ptr,
                     memcached_behavior flag,
                     uint64_t data);
```

To get the current behavior setting:

```c
uint64_t
memcached_behavior_get (memcached_st *ptr,
                     memcached_behavior flag);
```

The following table describes libmemcached behavior flags:

<table>
<thead>
<tr>
<th>Behavior</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MEMCACHED_BEHAVIOR_NO_BLOCK</td>
<td>Caused libmemcached to use asynchronous I/O.</td>
</tr>
<tr>
<td>MEMCACHED_BEHAVIOR_TCP_NODELAY</td>
<td>Turns on no-delay for network sockets.</td>
</tr>
<tr>
<td>MEMCACHED_BEHAVIOR_HASH</td>
<td>Without a value, sets the default hashing algorithm for keys to use MD5. Other valid values include MEMCACHED_HASH_DEFAULT, MEMCACHED_HASH_MD5, MEMCACHED_HASH_CRC, MEMCACHED_HASH_FNV1_64, MEMCACHED_HASH_FNV1A_64, MEMCACHED_HASH_FNV1_32, and MEMCACHED_HASH_FNV1A_32.</td>
</tr>
<tr>
<td>MEMCACHED_BEHAVIOR_DISTRIBUTION</td>
<td>Changes the method of selecting the server used to store a given value. The default method is MEMCACHED_DISTRIBUTION_MODULA. You can enable consistent hashing by setting MEMCACHED_DISTRIBUTION_CONSISTENT. MEMCACHED_DISTRIBUTION_CONSISTENT is an alias for the value MEMCACHED_DISTRIBUTION_CONSISTENT_KETAMA.</td>
</tr>
<tr>
<td>MEMCACHED_BEHAVIOR_CACHE_LOOKUPS</td>
<td>Cache the lookups made to the DNS service. This can improve the performance if you are using names instead of IP addresses for individual hosts.</td>
</tr>
<tr>
<td>MEMCACHED_BEHAVIOR_SUPPORT_CAS</td>
<td>Support CAS operations. By default, this is disabled because it imposes a performance penalty.</td>
</tr>
<tr>
<td>MEMCACHED_BEHAVIOR_KETAMA</td>
<td>Sets the default distribution to MEMCACHED_DISTRIBUTION_CONSISTENT_KETAMA and the hash to MEMCACHED_HASH_MD5.</td>
</tr>
<tr>
<td>MEMCACHED_BEHAVIOR_POLL_TIMEOUT</td>
<td>Modify the timeout value used by poll(). Supply a signed int pointer for the timeout value.</td>
</tr>
<tr>
<td>MEMCACHED_BEHAVIOR_BUFFER_REQUESTS</td>
<td>Buffers IO requests instead of them being sent. A get operation, or closing the connection causes the data to be flushed.</td>
</tr>
<tr>
<td>MEMCACHED_BEHAVIOR_VERIFY_KEY</td>
<td>Forces libmemcached to verify that a specified key is valid.</td>
</tr>
</tbody>
</table>
Developing a **memcached** Application

<table>
<thead>
<tr>
<th>Behavior</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MEMCACHED_BEHAVIOR_SORT_HOSTS</td>
<td>If set, hosts added to the list of configured hosts for a memcached_st structure are placed into the host list in sorted order. This breaks consistent hashing if that behavior has been enabled.</td>
</tr>
<tr>
<td>MEMCACHED_BEHAVIOR_CONNECT_TIMEOUT</td>
<td>In nonblocking mode this changes the value of the timeout during socket connection.</td>
</tr>
</tbody>
</table>

**libmemcached** Command-Line Utilities

In addition to the main C library interface, **libmemcached** also includes a number of command-line utilities that can be useful when working with and debugging **memcached** applications.

All of the command-line tools accept a number of arguments, the most critical of which is `servers`, which specifies the list of servers to connect to when returning information.

The main tools are:

- **memcat**: Display the value for each ID given on the command line:

  ```
  shell> memcat --servers=localhost hwkey
  Hello world
  ```

- **memcp**: Copy the contents of a file into the cache, using the file name as the key:

  ```
  shell> echo "Hello World" > hwkey
  shell> memcp --servers=localhost hwkey
  shell> memcat --servers=localhost hwkey
  Hello world
  ```

- **memrm**: Remove an item from the cache:

  ```
  shell> memcat --servers=localhost hwkey
  Hello world
  shell> memrm --servers=localhost hwkey
  shell> memcat --servers=localhost hwkey
  ```

- **memslap**: Test the load on one or more **memcached** servers, simulating get/set and multiple client operations. For example, you can simulate the load of 100 clients performing get operations:

  ```
  shell> memslap --servers=localhost --concurrency=100 --flush --test=get
  memslap --servers=localhost --concurrency=100 --flush --test=get Threads connecting to servers 100
  Took 13.571 seconds to read data
  ```

- **memflush**: Flush (empty) the contents of the **memcached** cache.

  ```
  shell> memflush --servers=localhost
  ```

**15.3.3.4 Using MySQL and **memcached** with Perl**

The **Cache::Memcached** module provides a native interface to the Memcache protocol, and provides support for the core functions offered by **memcached**. Install the module using your operating system’s package management system, or using **CPAN**:

```
root-shell> perl -MCPAN -e 'install Cache::Memcached'
```

To use **memcached** from Perl through the **Cache::Memcached** module, first create a new **Cache::Memcached** object that defines the list of servers and other parameters for the connection.
Developing a `memcached` Application

The only argument is a hash containing the options for the cache interface. For example, to create a new instance that uses three `memcached` servers:

```perl
use Cache::Memcached;
my $cache = new Cache::Memcached {
    'servers' => [
        '192.168.0.100:11211',
        '192.168.0.101:11211',
        '192.168.0.102:11211',
    ],
};
```

**Note**

When using the `Cache::Memcached` interface with multiple servers, the API automatically performs certain operations across all the servers in the group. For example, getting statistical information through `Cache::Memcached` returns a hash that contains data on a host-by-host basis, as well as generalized statistics for all the servers in the group.

You can set additional properties on the cache object instance when it is created by specifying the option as part of the option hash. Alternatively, you can use a corresponding method on the instance:

- `servers` or method `set_servers()`: Specifies the list of the servers to be used. The servers list should be a reference to an array of servers, with each element as the address and port number combination (separated by a colon). You can also specify a local connection through a Unix socket (for example `/tmp/sock/memcached`). To specify the server with a weight (indicating how much more frequently the server should be used during hashing), specify an array reference with the `memcached` server instance and a weight number. Higher numbers give higher priority.

- `compress_threshold` or method `set_compress_threshold()`: Specifies the threshold when values are compressed. Values larger than the specified number are automatically compressed (using `zlib`) during storage and retrieval.

- `no_rehash` or method `set_norehash()`: Disables finding a new server if the original choice is unavailable.

- `readonly` or method `set_readonly()`: Disables writes to the `memcached` servers.

Once the `Cache::Memcached` object instance has been configured, you can use the `set()` and `get()` methods to store and retrieve information from the `memcached` servers. Objects stored in the cache are automatically serialized and deserialized using the `Storable` module.

The `Cache::Memcached` interface supports the following methods for storing/retrieving data, and relate to the generic methods as shown in the table.

<table>
<thead>
<tr>
<th><code>Cache::Memcached</code> Function</th>
<th>Equivalent Generic Method</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>get()</code></td>
<td>Generic <code>get()</code></td>
</tr>
<tr>
<td><code>get_multi(keys)</code></td>
<td>Gets multiple <code>keys</code> from memcache using just one query. Returns a hash reference of key/value pairs.</td>
</tr>
<tr>
<td><code>set()</code></td>
<td>Generic <code>set()</code></td>
</tr>
<tr>
<td><code>add()</code></td>
<td>Generic <code>add()</code></td>
</tr>
<tr>
<td><code>replace()</code></td>
<td>Generic <code>replace()</code></td>
</tr>
<tr>
<td><code>delete()</code></td>
<td>Generic <code>delete()</code></td>
</tr>
<tr>
<td><code>incr()</code></td>
<td>Generic <code>incr()</code></td>
</tr>
</tbody>
</table>
Cache::Memcached Function | Equivalent Generic Method
--- | ---
decr() | Generic decr().

Below is a complete example for using memcached with Perl and the Cache::Memcached module:

```perl
#!/usr/bin/perl
use Cache::Memcached;
use DBI;
use Data::Dumper;

# Configure the memcached server
my $cache = new Cache::Memcached {
    'servers' => ['localhost:11211',
                 ],
};

# Get the film name from the command line
# memcached keys must not contain spaces, so create a key name by replacing spaces with underscores
my $filmname = shift or die "Must specify the film name\n";
my $filmkey = $filmname;
$filmkey =~ s//_/;

# Load the data from the cache
my $filmdata = $cache->get($filmkey);

# If the data wasn't in the cache, then we load it from the database
if (!defined($filmdata)) {
    $filmdata = load_filmdata($filmname);
    if (defined($filmdata)) {
        # Set the data into the cache, using the key
        if ($cache->set($filmkey, $filmdata)) {
            print STDERR "Film data loaded from database and cached\n";
        } else {
            print STDERR "Couldn't store to cache\n";
        }
    } else {
        die "Couldn't find $filmname\n";
    }
} else {
    print STDERR "Film data loaded from Memcached\n";
}

sub load_filmdata {
    my ($filmname) = @_;;
    my $dsn = "DBI:mysql:database=sakila;host=localhost;port=3306";
    $dbh = DBI->connect($dsn, 'sakila','password');
    my ($filmbase) = $dbh->selectrow_hashref(sprintf('select * from film where title = %s',
```
Developing a memcached Application

```perl
$dbh->quote($filmname));

if (!defined($filmname))
{
    return (undef);
}

$filmbase->{stars} =
$dbh->selectall_arrayref(sprintf('select concat(first_name," ",last_name) ' .
    'from film_actor left join (actor) ' .
    'on (film_actor.actor_id = actor.actor_id) ' .
    'where film_id=%s',
    $dbh->quote($filmbase->{film_id})));

return($filmbase);
```

The example uses the Sakila database, obtaining film data from the database and writing a composite record of the film and actors to memcached. When calling it for a film does not exist, you get this result:

```
shell> memcached-sakila.pl "ROCK INSTINCT"
Film data loaded from database and cached
```

When accessing a film that has already been added to the cache:

```
shell> memcached-sakila.pl "ROCK INSTINCT"
Film data loaded from Memcached
```

### 15.3.3.5 Using MySQL and memcached with Python

The Python memcache module interfaces to memcached servers, and is written in pure Python (that is, without using one of the C APIs). You can download and install a copy from Python Memcached.

To install, download the package and then run the Python installer:

```
python setup.py install
running install
running bdist_egg
running egg_info
creating python_memcached.egg-info
... removing 'build/bdist.linux-x86_64/egg' (and everything under it)
Processing python_memcached-1.43-py2.4.egg
creating /usr/lib64/python2.4/site-packages/python_memcached-1.43-py2.4.egg
Extracting python_memcached-1.43-py2.4.egg to /usr/lib64/python2.4/site-packages
Adding python-memcached 1.43 to easy-install.pth file
Installed /usr/lib64/python2.4/site-packages/python_memcached-1.43-py2.4.egg
Processing dependencies for python-memcached==1.43
Finished processing dependencies for python-memcached==1.43
```

Once installed, the memcache module provides a class-based interface to your memcached servers. When you store Python data structures as memcached items, they are automatically serialized (turned into string values) using the Python cPickle or pickle modules.

To create a new memcache interface, import the memcache module and create a new instance of the memcache.Client class. For example, if the memcached daemon is running on localhost using the default port:

```python
import memcache
memc = memcache.Client(['127.0.0.1:11211'])
```

The first argument is an array of strings containing the server and port number for each memcached instance to use. To enable debugging, set the optional debug parameter to 1.
By default, the hashing mechanism used to divide the items among multiple servers is \texttt{crc32}. To change the function used, set the value of \texttt{memcache.serverHashFunction} to the alternate function to use. For example:

```python
from zlib import adler32
memcache.serverHashFunction = adler32
```

Once you have defined the servers to use within the \texttt{memcache} instance, the core functions provide the same functionality as in the generic interface specification. The following table provides a summary of the supported functions:

<table>
<thead>
<tr>
<th>Python \texttt{memcache} Function</th>
<th>Equivalent Generic Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{get()}</td>
<td>Generic \texttt{get().}</td>
</tr>
<tr>
<td>\texttt{get_multi(keys)}</td>
<td>Gets multiple values from the supplied array of \texttt{keys}. Returns a hash reference of key/value pairs.</td>
</tr>
<tr>
<td>\texttt{set()}</td>
<td>Generic \texttt{set().}</td>
</tr>
<tr>
<td>\texttt{set_multi(dict [, expiry [, key_prefix]])}</td>
<td>Sets multiple key/value pairs from the supplied \texttt{dict}.</td>
</tr>
<tr>
<td>\texttt{add()}</td>
<td>Generic \texttt{add().}</td>
</tr>
<tr>
<td>\texttt{replace()}</td>
<td>Generic \texttt{replace().}</td>
</tr>
<tr>
<td>\texttt{prepend(key, value [, expiry])}</td>
<td>Prepends the supplied \texttt{value} to the value of the existing \texttt{key}.</td>
</tr>
<tr>
<td>\texttt{append(key, value [, expiry]}</td>
<td>Appends the supplied \texttt{value} to the value of the existing \texttt{key}.</td>
</tr>
<tr>
<td>\texttt{delete()}</td>
<td>Generic \texttt{delete().}</td>
</tr>
<tr>
<td>\texttt{delete_multi(keys [, expiry [, key_prefix]])}</td>
<td>Deletes all the keys from the hash matching each string in the array \texttt{keys}.</td>
</tr>
<tr>
<td>\texttt{incr()}</td>
<td>Generic \texttt{incr().}</td>
</tr>
<tr>
<td>\texttt{decr()}</td>
<td>Generic \texttt{decr().}</td>
</tr>
</tbody>
</table>

\textbf{Note}

Within the Python \texttt{memcache} module, all the \texttt{*_multi()} functions support an optional \texttt{key_prefix} parameter. If supplied, then the string is used as a prefix to all key lookups. For example, if you call:

```python
memc.get_multi(['a','b'], key_prefix='users:')
```

The function retrieves the keys \texttt{users:a} and \texttt{users:b} from the servers.

Here is an example showing the storage and retrieval of information to a \texttt{memcache} instance, loading the raw data from MySQL:

```python
import sys
import MySQLdb
import memcache

memc = memcache.Client(['127.0.0.1:11211'], debug=1);

try:
    conn = MySQLdb.connect (host = "localhost",
                           user = "sakila",
                           passwd = "password",
                           db = "sakila")
except MySQLdb.Error, e:
```
Developing a `memcached` Application

```python
print "Error %d: %s" % (e.args[0], e.args[1])
sys.exit (1)

popularfilms = memc.get('top5films')

if not popularfilms:
    cursor = conn.cursor()
    cursor.execute('select film_id,title from film order by rental_rate desc limit 5')
    rows = cursor.fetchall()
    memc.set('top5films',rows,60)
    print "Updated memcached with MySQL data"
else:
    print "Loaded data from memcached"
    for row in popularfilms:
        print "%s, %s" % (row[0], row[1])
```

When executed for the first time, the data is loaded from the MySQL database and stored to the `memcached` server.

```
shell> python memc_python.py
Updated memcached with MySQL data
```

Because the data is automatically serialized using `cPickle/pickle`, when you load the data back from `memcached`, you can use the object directly. In the example above, the information stored to `memcached` is in the form of rows from a Python DB cursor. When accessing the information (within the 60 second expiry time), the data is loaded from `memcached` and dumped:

```
shell> python memc_python.py
Loaded data from memcached
2, ACE GOLDFINGER
7, AIRPLANE SIERRA
8, AIRPORT POLLOCK
10, ALADDIN CALENDAR
13, ALI FOREVER
```

The serialization and deserialization happens automatically. Because serialization of Python data may be incompatible with other interfaces and languages, you can change the serialization module used during initialization. For example, you might use JSON format when you store complex data structures using a script written in one language, and access them in a script written in a different language.

### 15.3.3.6 Using MySQL and `memcached` with PHP

PHP provides support for the Memcache functions through a PECL extension. To enable the PHP `memcache` extensions, build PHP using the `--enable-memcache` option to `configure` when building from source.

If you are installing on a Red Hat-based server, you can install the `php-pecl-memcache` RPM:

```
root-shell> yum --install php-pecl-memcache
```

On Debian-based distributions, use the `php-memcache` package.

To set global runtime configuration options, specify the configuration option values within your `php.ini` file. The following table provides the name, default value, and a description for each global runtime configuration option.

<table>
<thead>
<tr>
<th>Configuration option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>memcache.allow_failover</code></td>
<td>1</td>
<td>Specifies whether another server in the list should be queried if the first server selected fails.</td>
</tr>
<tr>
<td><code>memcache.max_failover_attempts</code></td>
<td>20s</td>
<td>Specifies the number of servers to try before returning a failure.</td>
</tr>
</tbody>
</table>
Developing a **memcached** Application

<table>
<thead>
<tr>
<th>Configuration option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>memcache.chunk_size</code></td>
<td>8192</td>
<td>Defines the size of network chunks used to exchange data with the <strong>memcached</strong> server.</td>
</tr>
<tr>
<td><code>memcache.default_port</code></td>
<td>11211</td>
<td>Defines the default port to use when communicating with the <strong>memcached</strong> servers.</td>
</tr>
<tr>
<td><code>memcache.hash_strategy</code></td>
<td>standard</td>
<td>Specifies which hash strategy to use. Set to <code>consistent</code> to enable servers to be added or removed from the pool without causing the keys to be remapped to other servers. When set to <code>standard</code>, an older (modula) strategy is used that potentially uses different servers for storage.</td>
</tr>
<tr>
<td><code>memcache.hash_function</code></td>
<td>crc32</td>
<td>Specifies which function to use when mapping keys to servers. <code>crc32</code> uses the standard CRC32 hash. <code>fnv</code> uses the FNV-1a hashing algorithm.</td>
</tr>
</tbody>
</table>

To create a connection to a **memcached** server, create a new **Memcache** object and then specify the connection options. For example:

```php
<?php
    $cache = new Memcache;
    $cache->connect('localhost',11211);
?>
```

This opens an immediate connection to the specified server.

To use multiple **memcached** servers, you need to add servers to the memcache object using `addServer()`:

```php
bool Memcache::addServer ( string $host [, int $port [, bool $persistent [, int $weight [, int $timeout [, int $retry_interval [, bool $status [, callback $failure_callback ]]]]]]] ]
```

The server management mechanism within the **php-memcache** module is a critical part of the interface as it controls the main interface to the **memcached** instances and how the different instances are selected through the hashing mechanism.

To create a simple connection to two **memcached** instances:

```php
<?php
    $cache = new Memcache;
    $cache->addServer('192.168.0.100',11211);
    $cache->addServer('192.168.0.101',11211);
?>
```

In this scenario, the instance connection is not explicitly opened, but only opened when you try to store or retrieve a value. To enable persistent connections to **memcached** instances, set the `persistent` argument to true. This is the default setting, and causes the connections to remain open.

To help control the distribution of keys to different instances, use the global `memcache.hash_strategy` setting. This sets the hashing mechanism used to select. You can also add another weight to each server, which effectively increases the number of times the instance entry appears in the instance list, therefore increasing the likelihood of the instance being chosen over other instances. To set the weight, set the value of the `$weight` argument to more than one.
The functions for setting and retrieving information are identical to the generic functional interface offered by memcached, as shown in this table:

<table>
<thead>
<tr>
<th>PECL memcache Function</th>
<th>Generic Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>get()</td>
<td>Generic get()</td>
</tr>
<tr>
<td>set()</td>
<td>Generic set()</td>
</tr>
<tr>
<td>add()</td>
<td>Generic add()</td>
</tr>
<tr>
<td>replace()</td>
<td>Generic replace()</td>
</tr>
<tr>
<td>delete()</td>
<td>Generic delete()</td>
</tr>
<tr>
<td>increment()</td>
<td>Generic incr()</td>
</tr>
<tr>
<td>decrement()</td>
<td>Generic decr()</td>
</tr>
</tbody>
</table>

A full example of the PECL memcache interface is provided below. The code loads film data from the Sakila database when the user provides a film name. The data stored into the memcached instance is recorded as a mysqli result row, and the API automatically serializes the information for you.

```php
<?php
$memc = new Memcache;
$memc->addServer('localhost','11211');

if(empty($_POST['film'])) {
    echo "Loading data...
"
    <html xmlns="http://www.w3.org/1999/xhtml" xml:lang="en" lang="en">
        <head>
            <meta http-equiv="Content-Type" content="text/html; charset=utf-8" />
            <title>Simple Memcache Lookup</title>
        </head>
        <body>
            <form method="post">
                <p><b>Film</b>: <input type="text" size="20" name="film"></p>
                <input type="submit">
            </form>
        </body>
    </html>
} else {
    echo "Loading data...
"
    $film   = htmlspecialchars($_POST['film'], ENT_QUOTES, 'UTF-8');
    $mfilms = $memc->get($film);
    if ($mfilms) {
        printf("Film data for %s loaded from memcache\n", $mfilms['title']);
        foreach (array_keys($mfilms) as $key) {
            printf("%s\n", $key, $mfilms[$key]);
        }
    } else {
        $mysqli = mysqli('localhost','sakila','password','sakila');
        if (mysqli_connect_error()) {
            sprintf("Database error: (%d) %s", mysqli_connect_errno(), mysqli_connect_error());
            exit;
        }
        $sql = sprintf('SELECT * FROM film WHERE title="%s"', $mysqli->real_escape_string($film));
        $result = $mysqli->query($sql);
    }
```
With PHP, the connections to the `memcached` instances are kept open as long as the PHP and associated Apache instance remain running. When adding or removing servers from the list in a running instance (for example, when starting another script that mentions additional servers), the connections are shared, but the script only selects among the instances explicitly configured within the script.

To ensure that changes to the server list within a script do not cause problems, make sure to use the consistent hashing mechanism.

### 15.3.3.7 Using MySQL and `memcached` with Ruby

There are a number of different modules for interfacing to `memcached` within Ruby. The Ruby-MemCache client library provides a native interface to `memcached` that does not require any external libraries, such as `libmemcached`. You can obtain the installer package from [http://www.deveiate.org/projects/RMemCache](http://www.deveiate.org/projects/RMemCache).

To install, extract the package and then run `install.rb`:

```
shell> install.rb
```

If you have RubyGems, you can install the Ruby-MemCache gem:

```
shell> gem install Ruby-MemCache
```

Bulk updating Gem source index for: http://gems.rubyforge.org
Install required dependency io-reactor? [Yn]  y
Successfully installed Ruby-MemCache-0.0.1
Successfully installed io-reactor-0.05
Installing ri documentation for io-reactor-0.05...
Installing RDoc documentation for io-reactor-0.05...

To use a `memcached` instance from within Ruby, create a new instance of the MemCache object:

```
require 'memcache'
memc = MemCache::new '192.168.0.100:11211'
```

You can add a weight to each server to increase the likelihood of the server being selected during hashing by appending the weight count to the server host name/port string:

```
require 'memcache'
memc = MemCache::new '192.168.0.100:11211:3'
```

To add servers to an existing list, you can append them directly to the MemCache object:

```
memc += ['192.168.0.101:11211']
```
To set data into the cache, you can just assign a value to a key within the new cache object, which works just like a standard Ruby hash object:

```ruby
memc["key"] = "value"
```

Or to retrieve the value:

```ruby
print memc["key"]
```

For more explicit actions, you can use the method interface, which mimics the main `memcached` API functions, as summarized in the following table:

<table>
<thead>
<tr>
<th>Ruby Method</th>
<th>MemCache Method</th>
<th>Equivalent <code>memcached</code> API Functions</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>get()</code></td>
<td><code>get(key)</code></td>
<td>Generic <code>get()</code>, returning the information as a hash of the keys and their values.</td>
</tr>
<tr>
<td><code>get_hash(keys)</code></td>
<td><code>get_hash(keys)</code></td>
<td>Get the values of multiple <code>keys</code>, returning the information as a hash of the keys and their values.</td>
</tr>
<tr>
<td><code>set()</code></td>
<td><code>set(key, value)</code></td>
<td>Generic <code>set()</code>.</td>
</tr>
<tr>
<td><code>set_many(pairs)</code></td>
<td><code>set_many(pairs)</code></td>
<td>Set the values of the keys and values in the hash <code>pairs</code>.</td>
</tr>
<tr>
<td><code>add()</code></td>
<td><code>add(key, value)</code></td>
<td>Generic <code>add()</code>.</td>
</tr>
<tr>

</tr>
<tr>
<td><code>delete()</code></td>
<td><code>delete(key)</code></td>
<td>Generic <code>delete()</code>.</td>
</tr>
<tr>
<td><code>incr()</code></td>
<td><code>incr(key)</code></td>
<td>Generic <code>incr()</code>.</td>
</tr>
<tr>
<td><code>decr()</code></td>
<td><code>decr(key)</code></td>
<td>Generic <code>decr()</code>.</td>
</tr>
</tbody>
</table>

### 15.3.3.8 Using MySQL and `memcached` with Java

The `com.danga.MemCached` class within Java provides a native interface to `memcached` instances. You can obtain the client from [https://github.com/gwhalin/Memcached-Java-Client/downloads](https://github.com/gwhalin/Memcached-Java-Client/downloads). The Java class uses hashes that are compatible with `libmemcached`, so you can mix and match Java and `libmemcached` applications accessing the same `memcached` instances. The serialization between Java and other interfaces are not compatible. If this is a problem, use JSON or a similar nonbinary serialization format.

On most systems, you can download the package and use the `jar` directly.

To use the `com.danga.MemCached` interface, you create a `MemCachedClient` instance and then configure the list of servers by configuring the `SockIOPool`. Through the pool specification you set up the server list, weighting, and the connection parameters to optimized the connections between your client and the `memcached` instances that you configure.

Generally, you can configure the `memcached` interface once within a single class, then use this interface throughout the rest of your application.

For example, to create a basic interface, first configure the `MemCachedClient` and base `SockIOPool` settings:

```java
public class MyClass {

    protected static MemCachedClient mcc = new MemCachedClient();

    static {
        String[] servers = {
            "localhost:11211",
        };
```
Developing a **memcached** Application

```
Integer[] weights = { 1 };  
SockIOPool pool = SockIOPool.getInstance();
  
pool.setServers( servers );
pool.setWeights( weights );
```

In the above sample, the list of servers is configured by creating an array of the **memcached** instances to use. You can then configure individual weights for each server.

The remainder of the properties for the connection are optional, but you can set the connection numbers (initial connections, minimum connections, maximum connections, and the idle timeout) by setting the pool parameters:

```
pool.setInitConn( 5 );
pool.setMinConn( 5 );
pool.setMaxConn( 250 );
pool.setMaxIdle( 1000 * 60 * 60 * 6
```

Once the parameters have been configured, initialize the connection pool:

```
pool.initialize();
```

The pool, and the connection to your **memcached** instances should now be ready to use.

To set the hashing algorithm used to select the server used when storing a given key, use `pool.setHashingAlg()`:

```
pool.setHashingAlg( SockIOPool.NEW_COMPAT_HASH );
```

Valid values are **NEW_COMPAT_HASH**, **OLD_COMPAT_HASH** and **NATIVE_HASH** are also basic modula hashing algorithms. For a consistent hashing algorithm, use **CONSISTENT_HASH**. These constants are equivalent to the corresponding hash settings within **libmemcached**.

The following table outlines the Java `com.danga.MemCached` methods and the equivalent generic methods in the **memcached** interface specification.

<table>
<thead>
<tr>
<th>Java <code>com.danga.MemCached</code> Method</th>
<th>Equivalent Generic Method</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>get()</code></td>
<td>Generic <code>get()</code>.</td>
</tr>
<tr>
<td><code>getMulti(keys)</code></td>
<td>Get the values of multiple keys, returning the information as Hash map using <code>java.lang.String</code> for the keys and <code>java.lang.Object</code> for the corresponding values.</td>
</tr>
<tr>
<td><code>set()</code></td>
<td>Generic <code>set()</code>.</td>
</tr>
<tr>
<td><code>add()</code></td>
<td>Generic <code>add()</code>.</td>
</tr>
<tr>
<td><code>replace()</code></td>
<td>Generic <code>replace()</code>.</td>
</tr>
<tr>
<td><code>delete()</code></td>

</tr>
<tr>
<td><code>incr()</code></td>
<td>Generic <code>incr()</code>.</td>
</tr>
<tr>
<td><code>decr()</code></td>
<td>Generic <code>decr()</code>.</td>
</tr>
</tbody>
</table>

### 15.3.3.9 Using the **memcached** TCP Text Protocol

Communicating with a **memcached** server can be achieved through either the TCP or UDP protocols. When using the TCP protocol, you can use a simple text based interface for the exchange of information.
When communicating with memcached, you can connect to the server using the port configured for the server. You can open a connection with the server without requiring authorization or login. As soon as you have connected, you can start to send commands to the server. When you have finished, you can terminate the connection without sending any specific disconnection command. Clients are encouraged to keep their connections open to decrease latency and improve performance.

Data is sent to the memcached server in two forms:

- **Text lines**, which are used to send commands to the server, and receive responses from the server.
- **Unstructured data**, which is used to receive or send the value information for a given key. Data is returned to the client in exactly the format it was provided.

Both text lines (commands and responses) and unstructured data are always terminated with the string `\r\n`. Because the data being stored may contain this sequence, the length of the data (returned by the client before the unstructured data is transmitted should be used to determine the end of the data.

Commands to the server are structured according to their operation:

- **Storage commands**: `set`, `add`, `replace`, `append`, `prepend`, `cas`

Storage commands to the server take the form:

```
command key [flags] [exptime] length [noreply]
```

Or when using compare and swap (cas):

```
cas key [flags] [exptime] length [casunique] [noreply]
```

Where:

- **command**: The command name.
  - **set**: Store value against key
  - **add**: Store this value against key if the key does not already exist
  - **replace**: Store this value against key if the key already exists
  - **append**: Append the supplied value to the end of the value for the specified key. The `flags` and `exptime` arguments should not be used.
  - **prepend**: Append value currently in the cache to the end of the supplied value for the specified key. The `flags` and `exptime` arguments should not be used.
  - **cas**: Set the specified key to the supplied value, only if the supplied `casunique` matches. This is effectively the equivalent of change the information if nobody has updated it since I last fetched it.
  - **key**: The key. All data is stored using a the specific key. The key cannot contain control characters or whitespace, and can be up to 250 characters in size.
  - **flags**: The flags for the operation (as an integer). Flags in memcached are transparent. The memcached server ignores the contents of the flags. They can be used by the client to indicate any type of information. In memcached 1.2.0 and lower the value is a 16-bit integer value. In memcached 1.2.1 and higher the value is a 32-bit integer.
  - **exptime**: The expiry time, or zero for no expiry.
  - **length**: The length of the supplied value block in bytes, excluding the terminating `\r\n` characters.
• **casunique**: A unique 64-bit value of an existing entry. This is used to compare against the existing value. Use the value returned by the `gets` command when issuing `cas` updates.

• **noreply**: Tells the server not to reply to the command.

For example, to store the value `abcdef` into the key `xyzkey`, you would use:

```
set xyzkey 0 0 6\r\nabcdef\r\n```

The return value from the server is one line, specifying the status or error information. For more information, see Table 15.3, "memcached Protocol Responses".

• **Retrieval commands**: `get`, `gets`

Retrieval commands take the form:

```
get key1 [key2 .... keyn]
gets key1 [key2 ... keyn]
```

You can supply multiple keys to the commands, with each requested key separated by whitespace.

The server responds with an information line of the form:

```
VALUE key flags bytes [casunique]
```

Where:

• **key**: The key name.

• **flags**: The value of the flag integer supplied to the `memcached` server when the value was stored.

• **bytes**: The size (excluding the terminating `\r\n` character sequence) of the stored value.

• **casunique**: The unique 64-bit integer that identifies the item.

The information line is immediately followed by the value data block. For example:

```
get xyzkey\r\nVALUE xyzkey 0 6\r\nabcdef\r\n```

If you have requested multiple keys, an information line and data block is returned for each key found. If a requested key does not exist in the cache, no information is returned.

• **Delete commands**: `delete`

Deletion commands take the form:

```
delete key [time] [noreply]
```

Where:

• **key**: The key name.

• **time**: The time in seconds (or a specific Unix time) for which the client wishes the server to refuse `add` or `replace` commands on this key. All `add`, `replace`, `get`, and `gets` commands fail during this period. `set` operations succeed. After this period, the key is deleted permanently and all commands are accepted.
If not supplied, the value is assumed to be zero (delete immediately).

- **noreply**: Tells the server not to reply to the command.

Responses to the command are either **DELETED** to indicate that the key was successfully removed, or **NOT_FOUND** to indicate that the specified key could not be found.

- **Increment/Decrement**: **incr**, **decr**

The increment and decrement commands change the value of a key within the server without performing a separate get/set sequence. The operations assume that the currently stored value is a 64-bit integer. If the stored value is not a 64-bit integer, then the value is assumed to be zero before the increment or decrement operation is applied.

Increment and decrement commands take the form:

```
incr key value [noreply]
decr key value [noreply]
```

Where:

- **key**: The key name.
- **value**: An integer to be used as the increment or decrement value.
- **noreply**: Tells the server not to reply to the command.

The response is:

- **NOT_FOUND**: The specified key could not be located.
- **value**: The new value associated with the specified key.

Values are assumed to be unsigned. For **decr** operations, the value is never decremented below 0. For **incr** operations, the value wraps around the 64-bit maximum.

- **Statistics commands**: **stats**

The **stats** command provides detailed statistical information about the current status of the **memcached** instance and the data it is storing.

Statistics commands take the form:

```
STAT [name] [value]
```

Where:

- **name**: The optional name of the statistics to return. If not specified, the general statistics are returned.
- **value**: A specific value to be used when performing certain statistics operations.

The return value is a list of statistics data, formatted as follows:

```
STAT name value
```

The statistics are terminated with a single line, **END**.

For more information, see Section 15.3.4, “Getting **memcached** Statistics”.

This documentation is for an older version. If you're using the most current version, select the documentation for that version with the version switch in the upper right corner of the online documentation, or by downloading a newer PDF or EPUB file.
For reference, a list of the different commands supported and their formats is provided below.

<table>
<thead>
<tr>
<th>Command</th>
<th>Command Formats</th>
</tr>
</thead>
<tbody>
<tr>
<td>set</td>
<td>set key flags exptime length, set key flags exptime length noreply</td>
</tr>
<tr>
<td>add</td>
<td>add key flags exptime length, add key flags exptime length noreply</td>
</tr>
<tr>
<td>replace</td>
<td>replace key flags exptime length, replace key flags exptime length noreply</td>
</tr>
<tr>
<td>append</td>
<td>append key length, append key length noreply</td>
</tr>
<tr>
<td>prepend</td>
<td>prepend key length, prepend key length noreply</td>
</tr>
<tr>
<td>cas</td>
<td>cas key flags exptime length casunique, cas key flags exptime length casunique noreply</td>
</tr>
<tr>
<td>get</td>
<td>get key1 [key2 ... keyn]</td>
</tr>
<tr>
<td>gets</td>
<td></td>
</tr>
<tr>
<td>delete</td>
<td>delete key, delete key noreply, delete key expiry, delete key expiry noreply</td>
</tr>
<tr>
<td>incr</td>
<td>incr key, incr key noreply, incr key value, incr key value noreply</td>
</tr>
<tr>
<td>decr</td>
<td>decr key, decr key noreply, decr key value, decr key value noreply</td>
</tr>
<tr>
<td>stat</td>
<td>stat, stat name, stat name value</td>
</tr>
</tbody>
</table>

When sending a command to the server, the response from the server is one of the settings in the following table. All response values from the server are terminated by \r\n:

<table>
<thead>
<tr>
<th>String</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>STORED</td>
<td>Value has successfully been stored.</td>
</tr>
<tr>
<td>NOT_STORED</td>
<td>The value was not stored, but not because of an error. For commands where you are adding a or updating a value if it exists (such as add and replace), or where the item has already been set to be deleted.</td>
</tr>
<tr>
<td>EXISTS</td>
<td>When using a cas command, the item you are trying to store already exists and has been modified since you last checked it.</td>
</tr>
<tr>
<td>NOT_FOUND</td>
<td>The item you are trying to store, update or delete does not exist or has already been deleted.</td>
</tr>
<tr>
<td>ERROR</td>
<td>You submitted a nonexistent command name.</td>
</tr>
<tr>
<td>CLIENT_ERROR</td>
<td>There was an error in the input line, the detail is contained in errorstring.</td>
</tr>
<tr>
<td>SERVER_ERROR</td>
<td>There was an error in the server that prevents it from returning the information. In extreme conditions, the server may disconnect the client after this error occurs.</td>
</tr>
<tr>
<td>VALUE keys flags length</td>
<td>The requested key has been found, and the stored key, flags and data block are returned, of the specified length.</td>
</tr>
<tr>
<td>DELETED</td>
<td>The requested key was deleted from the server.</td>
</tr>
<tr>
<td>STAT name value</td>
<td>A line of statistics data.</td>
</tr>
</tbody>
</table>
15.3.4 Getting **memcached** Statistics

The **memcached** system has a built-in statistics system that collects information about the data being stored into the cache, cache hit ratios, and detailed information on the memory usage and distribution of information through the slab allocation used to store individual items. Statistics are provided at both a basic level that provide the core statistics, and more specific statistics for specific areas of the **memcached** server.

This information can be useful to ensure that you are getting the correct level of cache and memory usage, and that your slab allocation and configuration properties are set at an optimal level.

The stats interface is available through the standard **memcached** protocol, so the reports can be accessed by using **telnet** to connect to the **memcached**. The supplied **memcached-tool** includes support for obtaining the Section 15.3.4.2, "**memcached** Slabs Statistics" and Section 15.3.4.1, "**memcached** General Statistics" information. For more information, see Section 15.3.4.6, "Using **memcached-tool**".

Alternatively, most of the language API interfaces provide a function for obtaining the statistics from the server.

For example, to get the basic stats using **telnet**:

```
shell> telnet localhost 11211
Trying ::1...
Connected to localhost.
Escape character is '^]'.
stats
STAT pid 23599
STAT uptime 675
STAT time 1211439587
STAT version 1.2.5
STAT pointer_size 32
STAT rusage_user 1.404992
STAT rusage_system 4.694685
STAT curr_items 32
STAT total_items 56361
STAT bytes 2642
STAT curr_connections 53
STAT total_connections 438
STAT connection_structures 55
STAT cmd_get 113482
STAT cmd_set 80519
STAT get_hits 78926
STAT get_misses 34556
STAT evictions 0
STAT bytes_read 6379783
STAT bytes_written 4860179
STAT limit_maxbytes 67108864
STAT threads 1
END
```

When using Perl and the **Cache::Memcached** module, the `stats()` function returns information about all the servers currently configured in the connection object, and total statistics for all the **memcached** servers as a whole.

For example, the following Perl script obtains the stats and dumps the hash reference that is returned:

```
use Cache::Memcached;
use Data::Dumper;

my $memc = new Cache::Memcached;
```

This documentation is for an older version. If you're looking for the most current information, please visit the official website or documentation of the latest version.
When executed on the same `memcached` as used in the Telnet example above we get a hash reference with the host by host and total statistics:

```perl
$VAR1 = {
    'hosts' => {
        'localhost:11211' => {
            'misc' => {
                'bytes' => '2421',
                'curr_connections' => '3',
                'connection_structures' => '56',
                'pointer_size' => '32',
                'time' => '1211440166',
                'total_items' => '410956',
                'cmd_set' => '588167',
                'bytes_written' => '35715151',
                'evictions' => '0',
                'curr_items' => '31',
                'pid' => '23599',
                'limit_maxbytes' => '67108864',
                'uptime' => '1254',
                'rusage_user' => '9.857805',
                'cmd_get' => '838451',
                'rusage_system' => '34.096988',
                'version' => '1.2.5',
                'get_hits' => '581511',
                'bytes_read' => '46665716',
                'threads' => '1',
                'total_connections' => '3104',
                'get_misses' => '256940'
            },
            'sizes' => {
                '128' => '16',
                '64' => '15'
            }
        }
    },
    'self' => {},
    'total' => {
        'cmd_get' => 838451,
        'bytes' => 2421,
        'get_hits' => 581511,
        'connection_structures' => 56,
        'bytes_read' => 46665716,
        'total_items' => 410956,
        'total_connections' => 3104,
        'cmd_set' => 588167,
        'bytes_written' => 35715151,
        'curr_items' => 31,
        'get_misses' => 256940
    }
};
```

The statistics are divided up into a number of distinct sections, and then can be requested by adding the type to the `stats` command. Each statistics output is covered in more detail in the following sections.

- General statistics, see Section 15.3.4.1, "memcached General Statistics".
- Slab statistics (slabs), see Section 15.3.4.2, "memcached Slabs Statistics".
- Item statistics (items), see Section 15.3.4.3, "memcached Item Statistics".
- Size statistics (sizes), see Section 15.3.4.4, "memcached Size Statistics".
- Detailed status (detail), see Section 15.3.4.5, "memcached Detail Statistics".
15.3.4.1 memcached General Statistics

The output of the general statistics provides an overview of the performance and use of the memcached instance. The statistics returned by the command and their meaning is shown in the following table.

The following terms are used to define the value type for each statistics value:

- **32u**: 32-bit unsigned integer
- **64u**: 64-bit unsigned integer
- **32u:32u**: Two 32-bit unsigned integers separated by a colon
- **String**: Character string

<table>
<thead>

</tbody>
</table>

The most useful statistics from those given here are the number of cache hits, misses, and evictions.

A large number of `get_misses` may just be an indication that the cache is still being populated with information. The number should, over time, decrease in comparison to the number of cache `get_hits`. If, however, you have a large number of cache misses compared to cache hits after an extended period of execution, it may be an indication that the size of the cache is too small and you either need to increase the total memory size, or increase the number of the `memcached` instances to improve the hit ratio.

A large number of `evictions` from the cache, particularly in comparison to the number of items stored is a sign that your cache is too small to hold the amount of information that you regularly want to keep cached. Instead of items being retained in the cache, items are being evicted to make way for new items keeping the turnover of items in the cache high, reducing the efficiency of the cache.

### 15.3.4.2 `memcached` Slabs Statistics

To get the `slabs` statistics, use the `stats slabs` command, or the API equivalent.

The slab statistics provide you with information about the slabs that have created and allocated for storing information within the cache. You get information both on each individual slab-class and total statistics for the whole slab.

```plaintext
STAT 1:chunk_size 104
STAT 1:chunks_per_page 10082
STAT 1:total_pages 1
STAT 1:total_chunks 10082
STAT 1:used_chunks 10081
STAT 1:free_chunks 1
STAT 1:free_chunks_end 10079
STAT 9:chunk_size 696
STAT 9:chunks_per_page 1506
STAT 9:total_pages 63
STAT 9:total_chunks 94878
STAT 9:used_chunks 94878
STAT 9:free_chunks 0
STAT 9:free_chunks_end 0
STAT active_slabs 2
```
STAT total_malloced 67083616
END

Individual stats for each slab class are prefixed with the slab ID. A unique ID is given to each allocated slab from the smallest size up to the largest. The prefix number indicates the slab class number in relation to the calculated chunk from the specified growth factor. Hence in the example, 1 is the first chunk size and 9 is the 9th chunk allocated size.

The parameters returned for each chunk size and a description of each parameter are provided in the following table.

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>chunk_size</td>
<td>Space allocated to each chunk within this slab class.</td>
<td>1.3.x</td>
</tr>
<tr>
<td>chunks_per_page</td>
<td>Number of chunks within a single page for this slab class.</td>
<td></td>
</tr>
<tr>
<td>total_pages</td>
<td>Number of pages allocated to this slab class.</td>
<td></td>
</tr>
<tr>
<td>total_chunks</td>
<td>Number of chunks allocated to the slab class.</td>
<td></td>
</tr>
<tr>
<td>used_chunks</td>
<td>Number of chunks allocated to an item...</td>
<td></td>
</tr>
<tr>
<td>free_chunks</td>
<td>Number of chunks not yet allocated to items.</td>
<td></td>
</tr>
<tr>
<td>free_chunks_end</td>
<td>Number of free chunks at the end of the last allocated page.</td>
<td></td>
</tr>
<tr>
<td>get_hits</td>
<td>Number of get hits to this chunk</td>
<td>1.3.x</td>
</tr>
<tr>
<td>cmd_set</td>
<td>Number of set commands on this chunk</td>
<td>1.3.x</td>
</tr>
<tr>
<td>delete_hits</td>
<td>Number of delete hits to this chunk</td>
<td>1.3.x</td>
</tr>
<tr>
<td>incr_hits</td>
<td>Number of increment hits to this chunk</td>
<td>1.3.x</td>
</tr>
<tr>
<td>decr_hits</td>
<td>Number of decrement hits to this chunk</td>
<td>1.3.x</td>
</tr>
<tr>
<td>cas_hits</td>
<td>Number of CAS hits to this chunk</td>
<td>1.3.x</td>
</tr>
<tr>
<td>cas_badval</td>
<td>Number of CAS hits on this chunk where the existing value did not match</td>
<td>1.3.x</td>
</tr>
<tr>
<td>mem_requested</td>
<td>The true amount of memory of memory requested within this chunk</td>
<td>1.4.1</td>
</tr>
</tbody>
</table>

The following additional statistics cover the information for the entire server, rather than on a chunk by chunk basis:

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>active_slabs</td>
<td>Total number of slab classes allocated.</td>
<td></td>
</tr>
<tr>
<td>total_malloced</td>
<td>Total amount of memory allocated to slab pages.</td>
<td></td>
</tr>
</tbody>
</table>

The key values in the slab statistics are the chunk_size, and the corresponding total_chunks and used_chunks parameters. These give an indication of the size usage of the chunks within the system. Remember that one key/value pair is placed into a chunk of a suitable size.

From these stats, you can get an idea of your size and chunk allocation and distribution. If you store many items with a number of largely different sizes, consider adjusting the chunk size growth factor to increase in larger steps to prevent chunk and memory wastage. A good indication of a bad growth factor is a high number of different slab classes, but with relatively few chunks actually in use within each slab. Increasing the growth factor creates fewer slab classes and therefore makes better use of the allocated pages.

### 15.3.4.3 memcached Item Statistics

To get the items statistics, use the stats items command, or the API equivalent.
The items statistics give information about the individual items allocated within a given slab class.

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>number</td>
<td>The number of items currently stored in this slab class.</td>
</tr>
<tr>
<td>age</td>
<td>The age of the oldest item within the slab class, in seconds.</td>
</tr>
<tr>
<td>evicted</td>
<td>The number of items evicted to make way for new entries.</td>
</tr>
<tr>
<td>evicted_time</td>
<td>The time of the last evicted entry</td>
</tr>
<tr>
<td>evicted_nonzero</td>
<td>The time of the last evicted non-zero entry</td>
</tr>
<tr>
<td>outofmemory</td>
<td>The number of items for this slab class that have triggered an out of memory error (only value when the \texttt{-M} command line option is in effect).</td>
</tr>
<tr>
<td>tailrepairs</td>
<td>Number of times the entries for a particular ID need repairing</td>
</tr>
</tbody>
</table>

Item level statistics can be used to determine how many items are stored within a given slab and their freshness and recycle rate. You can use this to help identify whether there are certain slab classes that are triggering a much larger number of evictions that others.

### 15.3.4.4 memcached Size Statistics

To get size statistics, use the \texttt{stats sizes} command, or the API equivalent.

The size statistics provide information about the sizes and number of items of each size within the cache. The information is returned as two columns, the first column is the size of the item (rounded up to the nearest 32 byte boundary), and the second column is the count of the number of items of that size within the cache:

<table>
<thead>
<tr>
<th>Size</th>
<th>Count</th>
</tr>
</thead>
<tbody>
<tr>
<td>96</td>
<td>35</td>
</tr>
<tr>
<td>128</td>
<td>38</td>
</tr>
<tr>
<td>160</td>
<td>807</td>
</tr>
<tr>
<td>192</td>
<td>804</td>
</tr>
<tr>
<td>224</td>
<td>410</td>
</tr>
<tr>
<td>256</td>
<td>222</td>
</tr>
<tr>
<td>288</td>
<td>83</td>
</tr>
<tr>
<td>320</td>
<td>39</td>
</tr>
<tr>
<td>352</td>
<td>53</td>
</tr>
<tr>
<td>384</td>
<td>33</td>
</tr>
<tr>
<td>416</td>
<td>64</td>
</tr>
<tr>
<td>448</td>
<td>51</td>
</tr>
</tbody>
</table>
Caution

Running this statistic locks up your cache as each item is read from the cache and its size calculated. On a large cache, this may take some time and prevent any set or get operations until the process completes.

The item size statistics are useful only to determine the sizes of the objects you are storing. Since the actual memory allocation is relevant only in terms of the chunk size and page size, the information is only useful during a careful debugging or diagnostic session.

15.3.4.5 memcached Detail Statistics

For memcached 1.3.x and higher, you can enable and obtain detailed statistics about the get, set, and del operations on the individual keys stored in the cache, and determine whether the attempts hit (found) a particular key. These operations are only recorded while the detailed stats analysis is turned on.

To enable detailed statistics, you must send the `stats detail on` command to the memcached server:

```
$ telnet localhost 11211
Trying 127.0.0.1...
Connected to tiger.
Escape character is '^]'.
stats detail on
OK
```

Individual statistics are recorded for every get, set and del operation on a key, including keys that are not currently stored in the server. For example, if an attempt is made to obtain the value of key abckey and it does not exist, the get operating on the specified key are recorded while detailed statistics are in effect, even if the key is not currently stored. The hits, that is, the number of get or del operations for a key that exists in the server are also counted.

To turn detailed statistics off, send the `stats detail off` command to the memcached server:

```
$ telnet localhost 11211
Trying 127.0.0.1...
Connected to tiger.
Escape character is '^]'.
stats detail on
OK
```

To obtain the detailed statistics recorded during the process, send the `stats detail dump` command to the memcached server:

```
stats detail dump
PREFIX hykkey get 0 hit 0 set 1 del 0
PREFIX xyzkey get 0 hit 0 set 1 del 0
PREFIX yukkey get 1 hit 0 set 0 del 0
PREFIX abckey get 3 hit 3 set 1 del 0
END
```

You can use the detailed statistics information to determine whether your memcached clients are using a large number of keys that do not exist in the server by comparing the hit and get or del counts. Because the information is recorded by key, you can also determine whether the failures or operations are clustered around specific keys.
15.3.4.6 Using **memcached-tool**

The **memcached-tool**, located within the `scripts` directory within the **memcached** source directory. The tool provides convenient access to some reports and statistics from any memcached instance.

The basic format of the command is:

```
shell> ./memcached-tool hostname:port [command]
```

The default output produces a list of the slab allocations and usage. For example:

```
shell> memcached-tool localhost:11211 display
  #  Item_Size  Max_age  Pages  Count  Full?  Evicted  Evict_Time  OOM
  1    80B    93s     1     20    no      0        0    0
  2   104B    93s     1     16    no      0        0    0
  3   136B   1335s    1     28    no      0        0    0
  4   176B   1335s    1     24    no      0        0    0
  5   224B   1335s    1     32    no      0        0    0
  6   280B   1335s    1     34    no      0        0    0
  7   352B   1335s    1     36    no      0        0    0
  8   440B   1335s    1     46    no      0        0    0
  9   552B   1335s    1     58    no      0        0    0
 10   696B   1335s    1     66    no      0        0    0
 11   872B   1335s    1     89    no      0        0    0
 12   1.1K  1335s     1   112    no      0        0    0
 13   1.3K  1335s     1   145    no      0        0    0
 14   1.7K  1335s     1   123    no      0        0    0
 15   2.1K  1335s     1   198    no      0        0    0
 16   2.6K  1335s     1   199    no      0        0    0
 17   3.3K  1335s     1   229    no      0        0    0
 18   4.1K  1335s     1   248    yes     36       2    0
 19   5.2K  1335s     2   328    no      0        0    0
 20   6.4K  1335s     2   316    yes     387      1   0
 21   8.1K  1335s     3   381    yes     492      1   0
 22  10.1K  1335s     3   303    yes     598      2   0
 23  12.6K  1335s     5   405    yes     605      1   0
 24  15.8K  1335s     6   384    yes     766      2   0
 25  19.7K  1335s     7   357    yes     908      170  0
 26  24.6K  1336s     7   287    yes     1012     1   0
 27  30.8K  1336s     7   231    yes     1193     169  0
 28  38.5K  1336s     4   104    yes     1323     169  0
 29  48.1K  1336s     1   21     yes     1287     1   0
 30  60.2K  1336s     1   17     yes     1093     169  0
 31  75.2K  1337s     1   13     yes     713      168  0
 32  94.0K  1337s     1   10     yes     278      168  0
 33 117.5K  1336s     1   3      no      0        0    0
```

This output is the same if you specify the **command** as `display`:

```
shell> memcached-tool localhost:11211 display
  #  Item_Size  Max_age  Pages  Count  Full?  Evicted  Evict_Time  OOM
  1    80B    93s     1     20    no      0        0    0
  2   104B    93s     1     16    no      0        0    0
  ...  
```

The output shows a summarized version of the output from the `slabs` statistics. The columns provided in the output are shown below:

- **#: The slab number**
- **Item_Size**: The size of the slab
- **Max_age**: The age of the oldest item in the slab
- **Pages**: The number of pages allocated to the slab
• **Count**: The number of items in this slab
• **Full?**: Whether the slab is fully populated
• **Evicted**: The number of objects evicted from this slab
• **Evict_Time**: The time (in seconds) since the last eviction
• **OOM**: The number of items that have triggered an out of memory error

You can also obtain a dump of the general statistics for the server using the `stats` command:

```sh
shell> memcached-tool localhost:11211 stats
#localhost:11211   Field       Value
accepting_conns           1
    bytes         162
    bytes_read     485
    bytes_written  6820
cas_badval            0
cas_hits            0
cas_misses          0
cmd_flush          0
cmd_get           4
cmd_set           2
con_yields          0
connection_structures  11
curr_connections       10
curr_items          2
decr_hits           0
decr_misses         1
delete_hits         0
delete_misses       0
evictions          0
    get_hits       4
    get_misses      0
    incr_hits      0
    incr_misses     2
limit_maxbytes      67108864
listen_disabled_num   0
    pid       12981
    pointer_size    32
    rusage_system 0.013911
    rusage_user   0.011876
    threads         4
    time  1255518565
total_connections    20
    total_items      2
    uptime         880
    version     1.4.2
```

### 15.3.5 **memcached** FAQ

- **15.3.5.1** Can memcached be run on a Windows environment? .................................................. 1452
- **15.3.5.2** What is the maximum size of an object you can store in memcached? Is that configurable? ................................................................................................................................. 1452
- **15.3.5.3** Is it true memcached will be much more effective with db-read-intensive applications than with db-write-intensive applications? ................................................................................................................................. 1452
- **15.3.5.4** Is there any overhead in not using persistent connections? If persistent is always recommended, what are the downsides (for example, locking up)? .................................................. 1452
- **15.3.5.5** How is an event such as a crash of one of the memcached servers handled by the memcached client? ................................................................................................................................. 1452
- **15.3.5.6** What is a recommended hardware configuration for a memcached server? .................. 1453
- **15.3.5.7** Is memcached more effective for video and audio as opposed to textual read/writes? ..... 1453
- **15.3.5.8** Can memcached work with ASPX? .................................................................................. 1453
- **15.3.5.9** How expensive is it to establish a memcache connection? Should those connections be pooled? ................................................................................................................................. 1453
15.3.5.10 How is the data handled when the memcached server is down? .......................... 1453
15.3.5.11 How are auto-increment columns in the MySQL database coordinated across multiple instances of memcached? ..................................................... 1453
15.3.5.12 Is compression available? ....................................................................................... 1453
15.3.5.13 Can we implement different types of memcached as different nodes in the same server, so can there be deterministic and non-deterministic in the same server? ..................... 1453
15.3.5.14 What are best practices for testing an implementation, to ensure that it improves performance, and to measure the impact of memcached configuration changes? And would you recommend keeping the configuration very simple to start? ........................................... 1454

15.3.5.15 Can memcached be run on a Windows environment?

No. Currently memcached is available only on the Unix/Linux platform. There is an unofficial port available, see http://www.codeplex.com/memcachedproviders.

15.3.5.2 What is the maximum size of an object you can store in memcached? Is that configurable?

The default maximum object size is 1MB. In memcached 1.4.2 and later, you can change the maximum size of an object using the `-I` command line option.

For versions before this, to increase this size, you have to re-compile memcached. You can modify the value of the `POWER_BLOCK` within the `slabs.c` file within the source.

In memcached 1.4.2 and higher, you can configure the maximum supported object size by using the `-I` command-line option. For example, to increase the maximum object size to 5MB:

```
$ memcached -I 5m
```

If an object is larger than the maximum object size, you must manually split it. memcached is very simple: you give it a key and some data, it tries to cache it in RAM. If you try to store more than the default maximum size, the value is just truncated for speed reasons.

15.3.5.3 Is it true memcached will be much more effective with db-read-intensive applications than with db-write-intensive applications?

Yes. memcached plays no role in database writes, it is a method of caching data already read from the database in RAM.

15.3.5.4 Is there any overhead in not using persistent connections? If persistent is always recommended, what are the downsides (for example, locking up)?

If you don’t use persistent connections when communicating with memcached, there will be a small increase in the latency of opening the connection each time. The effect is comparable to use nonpersistent connections with MySQL.

In general, the chance of locking or other issues with persistent connections is minimal, because there is very little locking within memcached. If there is a problem, eventually your request will time out and return no result, so your application will need to load from MySQL again.

15.3.5.5 How is an event such as a crash of one of the memcached servers handled by the memcached client?

There is no automatic handling of this. If your client fails to get a response from a server, code a fallback mechanism to load the data from the MySQL database.

The client APIs all provide the ability to add and remove memcached instances on the fly. If within your application you notice that memcached server is no longer responding, you can remove the server from the list of servers, and keys will automatically be redistributed to another memcached server in the list. If retaining the cache content on all your servers is important, make sure you use an API that supports a consistent hashing algorithm. For more information, see Section 15.3.2.4, “memcached Hashing/Distribution Types”.
15.3.5.1. What is a recommended hardware configuration for a memcached server?

*memcached* has a very low processing overhead. All that is required is spare physical RAM capacity. A *memcached* server does not require a dedicated machine. If you have web, application, or database servers that have spare RAM capacity, then use them with *memcached*.

To build and deploy a dedicated *memcached* server, use a relatively low-power CPU, lots of RAM, and one or more Gigabit Ethernet interfaces.

15.3.5.2. Is *memcached* more effective for video and audio as opposed to textual read/writes?

*memcached* works equally well for all kinds of data. To *memcached*, any value you store is just a stream of data. Remember, though, that the maximum size of an object you can store in *memcached* is 1MB, but can be configured to be larger by using the `-I` option in *memcached* 1.4.2 and later, or by modifying the source in versions before 1.4.2. If you plan on using *memcached* with audio and video content, you will probably want to increase the maximum object size. Also remember that *memcached* is a solution for caching information for reading. It shouldn't be used for writes, except when updating the information in the cache.

15.3.5.3. Can *memcached* work with ASPX?

There are ports and interfaces for many languages and environments. ASPX relies on an underlying language such as C# or VisualBasic, and if you are using ASP.NET then there is a C# *memcached* library. For more information, see [https://sourceforge.net/projects/memcacheddotnet/](https://sourceforge.net/projects/memcacheddotnet/).

15.3.5.4. How expensive is it to establish a memcache connection? Should those connections be pooled?

Opening the connection is relatively inexpensive, because there is no security, authentication or other handshake taking place before you can start sending requests and getting results. Most APIs support a persistent connection to a *memcached* instance to reduce the latency. Connection pooling would depend on the API you are using, but if you are communicating directly over TCP/IP, then connection pooling would provide some small performance benefit.

15.3.5.5. How is the data handled when the *memcached* server is down?

The behavior is entirely application dependent. Most applications fall back to loading the data from the database (just as if they were updating the *memcached* information). If you are using multiple *memcached* servers, you might also remove a downed server from the list to prevent it from affecting performance. Otherwise, the client will still attempt to communicate with the *memcached* server that corresponds to the key you are trying to load.

15.3.5.6. How are auto-increment columns in the MySQL database coordinated across multiple instances of *memcached*?

They aren't. There is no relationship between MySQL and *memcached* unless your application (or, if you are using the MySQL UDFs for *memcached*, your database definition) creates one.

If you are storing information based on an auto-increment key into multiple instances of *memcached*, the information is only stored on one of the *memcached* instances anyway. The client uses the key value to determine which *memcached* instance to store the information. It doesn't store the same information across all the instances, as that would be a waste of cache memory.

15.3.5.7. Compression available?

Yes. Most of the client APIs support some sort of compression, and some even allow you to specify the threshold at which a value is deemed appropriate for compression during storage.

15.3.5.8. Can we implement different types of *memcached* as different nodes in the same server, so can there be deterministic and non-deterministic in the same server?
Yes. You can run multiple instances of memcached on a single server, and in your client configuration you choose the list of servers you want to use.

15.3.5. What are best practices for testing an implementation, to ensure that it improves performance, and to measure the impact of memcached configuration changes? And would you recommend keeping the configuration very simple to start?

The best way to test the performance is to start up a memcached instance. First, modify your application so that it stores the data just before the data is about to be used or displayed into memcached. Since the APIs handle the serialization of the data, it should just be a one-line modification to your code. Then, modify the start of the process that would normally load that information from MySQL with the code that requests the data from memcached. If the data cannot be loaded from memcached, default to the MySQL process.

All of the changes required will probably amount to just a few lines of code. To get the best benefit, make sure you cache entire objects (for example, all the components of a web page, blog post, discussion thread, and so on), rather than using memcached as a simple cache of individual rows of MySQL tables.

Keeping the configuration simple at the start, or even over the long term, is easy with memcached. Once you have the basic structure up and running, often the only ongoing change is to add more servers into the list of servers used by your applications. You don't need to manage the memcached servers, and there is no complex configuration; just add more servers to the list and let the client API and the memcached servers make the decisions.

Replication enables data from one MySQL database server (the master) to be replicated to one or more MySQL database servers (the slaves). Replication is asynchronous - slaves need not be connected permanently to receive updates from the master. This means that updates can occur over long-distance connections and even over temporary or intermittent connections such as a dial-up service. Depending on the configuration, you can replicate all databases, selected databases, or even selected tables within a database.

For answers to some questions often asked by those who are new to MySQL Replication, see Section A.13, "MySQL 5.0 FAQ: Replication".

The target uses for replication in MySQL include:

- Scale-out solutions - spreading the load among multiple slaves to improve performance. In this environment, all writes and updates must take place on the master server. Reads, however, may take place on one or more slaves. This model can improve the performance of writes (since the master is dedicated to updates), while dramatically increasing read speed across an increasing number of slaves.

- Data security - because data is replicated to the slave, and the slave can pause the replication process, it is possible to run backup services on the slave without corrupting the corresponding master data.

- Analytics - live data can be created on the master, while the analysis of the information can take place on the slave without affecting the performance of the master.

- Long-distance data distribution - if a branch office would like to work with a copy of your main data, you can use replication to create a local copy of the data for their use without requiring permanent access to the master.
Replication in MySQL features support for one-way, asynchronous replication, in which one server acts as the master, while one or more other servers act as slaves. This is in contrast to the synchronous replication which is a characteristic of MySQL Cluster (see Chapter 17, MySQL Cluster).

There are a number of solutions available for setting up replication between two servers, but the best method to use depends on the presence of data and the engine types you are using. For more information on the available options, see Section 16.1.1, “How to Set Up Replication”.

Replication is controlled through a number of different options and variables. These control the core operation of the replication, timeouts, and the databases and filters that can be applied on databases and tables. For more information on the available options, see Section 16.1.2, “Replication and Binary Logging Options and Variables”.

You can use replication to solve a number of different problems, including problems with performance, supporting the backup of different databases, and as part of a larger solution to alleviate system failures. For information on how to address these issues, see Section 16.3, “Replication Solutions”.

For notes and tips on how different data types and statements are treated during replication, including details of replication features, version compatibility, upgrades, and problems and their resolution, including an FAQ, see Section 16.4, “Replication Notes and Tips”.

For detailed information on the implementation of replication, how replication works, the process and contents of the binary log, background threads and the rules used to decide how statements are recorded and replication, see Section 16.2, “Replication Implementation”.

16.1 Replication Configuration

Replication between servers in MySQL is based on the binary logging mechanism. The MySQL instance operating as the master (the source of the database changes) writes updates and changes as “events” to the binary log. The information in the binary log is stored in different logging formats according to the database changes being recorded. Slaves are configured to read the binary log from the master and to execute the events in the binary log on the slave's local database.

The master is “dumb” in this scenario. Once binary logging has been enabled, all statements are recorded in the binary log. Each slave receives a copy of the entire contents of the binary log. It is the responsibility of the slave to decide which statements in the binary log should be executed; you cannot configure the master to log only certain events. If you do not specify otherwise, all events in the master binary log are executed on the slave. If required, you can configure the slave to process only events that apply to particular databases or tables.

Each slave keeps a record of the binary log coordinates: The file name and position within the file that it has read and processed from the master. This means that multiple slaves can be connected to the master and executing different parts of the same binary log. Because the slaves control this process, individual slaves can be connected and disconnected from the server without affecting the master’s operation. Also, because each slave remembers the position within the binary log, it is possible for slaves to be disconnected, reconnect and then “catch up” by continuing from the recorded position.

Both the master and each slave must be configured with a unique ID (using the server-id option). In addition, each slave must be configured with information about the master host name, log file name, and position within that file. These details can be controlled from within a MySQL session using the CHANGE MASTER TO statement on the slave. The details are stored within the slave's master.info file.

This section describes the setup and configuration required for a replication environment, including step-by-step instructions for creating a new replication environment. The major components of this section are:

- For a guide to setting up two or more servers for replication, Section 16.1.1, “How to Set Up Replication”, deals with the configuration of the systems and provides methods for copying data between the master and slaves.
16.1.1 How to Set Up Replication

This section describes how to set up complete replication of a MySQL server. There are a number of different methods for setting up replication, and the exact method to use depends on how you are setting up replication, and whether you already have data within your master database.

There are some generic tasks that are common to all replication setups:

- On the master, you must enable binary logging and configure a unique server ID. This might require a server restart. See Section 16.1.1.1, “Setting the Replication Master Configuration”.

- On each slave that you want to connect to the master, you must configure a unique server ID. This might require a server restart. See Section 16.1.1.2, “Setting the Replication Slave Configuration”.

- You may want to create a separate user that will be used by your slaves to authenticate with the master to read the binary log for replication. The step is optional. See Section 16.1.1.3, “Creating a User for Replication”.

- Before creating a data snapshot or starting the replication process, you should record the position of the binary log on the master. You will need this information when configuring the slave so that the slave knows where within the binary log to start executing events. See Section 16.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”.

- If you already have data on your master and you want to use it to synchronize your slave, you will need to create a data snapshot. You can create a snapshot using mysqldump (see Section 16.1.1.5, “Creating a Data Snapshot Using mysqldump”) or by copying the data files directly (see Section 16.1.1.6, “Creating a Data Snapshot Using Raw Data Files”).

- You will need to configure the slave with settings for connecting to the master, such as the hostname, login credentials, and binary log file name and position. See Section 16.1.1.10, “Setting the Master Configuration on the Slave”.

Once you have configured the basic options, you will need to follow the instructions for your replication setup. A number of alternatives are provided:

- If you are establishing a new MySQL master and one or more slaves, you need only set up the configuration, as you have no data to exchange. For guidance on setting up replication in this situation, see Section 16.1.1.7, “Setting Up Replication with New Master and Slaves”.

- If you are already running a MySQL server, and therefore already have data that must be transferred to your slaves before replication starts, have not previously configured the binary log and are able to shut down your MySQL server for a short period during the process, see Section 16.1.1.8, “Setting Up Replication with Existing Data”.

- If you are adding slaves to an existing replication environment, you can set up the slaves without affecting the master. See Section 16.1.1.9, “Introducing Additional Slaves to an Existing Replication Environment”.

If you will be administering MySQL replication servers, we suggest that you read this entire chapter through and try all statements mentioned in Section 13.4.1, “SQL Statements for Controlling Master Servers”, and Section 13.4.2, “SQL Statements for Controlling Slave Servers”. You should also familiarize yourself with the replication startup options described in Section 16.1.2, “Replication and Binary Logging Options and Variables”.
16.1.1.1 Setting the Replication Master Configuration

On a replication master, you must enable binary logging and establish a unique server ID. If this has not already been done, this part of master setup requires a server restart.

Binary logging must be enabled on the master because the binary log is the basis for sending data changes from the master to its slaves. If binary logging is not enabled, replication will not be possible.

Each server within a replication group must be configured with a unique server ID. This ID is used to identify individual servers within the group, and must be a positive integer between 1 and \(2^{32} - 1\). How you organize and select the numbers is entirely up to you.

To configure the binary log and server ID options, you will need to shut down your MySQL server and edit the `my.cnf` or `my.ini` file. Add the following options to the configuration file within the `[mysqld]` section. If these options already exist, but are commented out, uncomment the options and alter them according to your needs. For example, to enable binary logging using a log file name prefix of `mysql-bin`, and configure a server ID of 1, use these lines:

```plaintext
[mysqld]
log-bin=mysql-bin
server-id=1
```

After making the changes, restart the server.

Note

If you omit `server-id` (or set it explicitly to its default value of 0), a master refuses connections from all slaves.

Note

For the greatest possible durability and consistency in a replication setup using InnoDB with transactions, you should use `innodb_flush_log_at_trx_commit=1` and `sync_binlog=1` in the master `my.cnf` file.

Note

Ensure that the `skip-networking` option is not enabled on your replication master. If networking has been disabled, your slave will not able to communicate with the master and replication will fail.

16.1.1.2 Setting the Replication Slave Configuration

On a replication slave, you must establish a unique server ID. If this has not already been done, this part of slave setup requires a server restart.

If the slave server ID is not already set, or the current value conflicts with the value that you have chosen for the master server, you should shut down your slave server and edit the configuration to specify a unique server ID. For example:

```plaintext
[mysqld]
server-id=2
```

After making the changes, restart the server.
If you are setting up multiple slaves, each one must have a unique server-id value that differs from that of the master and from each of the other slaves. Think of server-id values as something similar to IP addresses: These IDs uniquely identify each server instance in the community of replication partners.

**Note**

If you omit server-id (or set it explicitly to its default value of 0), a slave refuses to connect to a master.

You do not have to enable binary logging on the slave for replication to be enabled. However, if you enable binary logging on the slave, you can use the binary log for data backups and crash recovery on the slave, and also use the slave as part of a more complex replication topology (for example, where the slave acts as a master to other slaves).

### 16.1.1.3 Creating a User for Replication

Each slave must connect to the master using a MySQL user name and password, so there must be a user account on the master that the slave can use to connect. Any account can be used for this operation, providing it has been granted the REPLICATION SLAVE privilege. You may wish to create a different account for each slave, or connect to the master using the same account for each slave.

You need not create an account specifically for replication. However, you should be aware that the user name and password will be stored in plain text within the master.info file (see Section 16.2.2.2, "Slave Status Logs"). Therefore, you may want to create a separate account that has privileges only for the replication process, to minimize the possibility of compromise to other accounts.

To create a new account, use CREATE USER. To grant this account the privileges required for replication, use the GRANT statement. If you create an account solely for the purposes of replication, that account needs only the REPLICATION SLAVE privilege. For example, to set up a new user, repl, that can connect for replication from any host within the mydomain.com domain, issue these statements on the master:

```
mysql> CREATE USER 'repl'@'%.mydomain.com' IDENTIFIED BY 'slavepass';
mysql> GRANT REPLICATION SLAVE ON *.* TO 'repl'@'%.mydomain.com';
```

See Section 13.7.1, “Account Management Statements”, for more information on statements for manipulation of user accounts.

### 16.1.1.4 Obtaining the Replication Master Binary Log Coordinates

To configure replication on the slave you must determine the master's current coordinates within its binary log. You will need this information so that when the slave starts the replication process, it is able to start processing events from the binary log at the correct point.

If you have existing data on your master that you want to synchronize on your slaves before starting the replication process, you must stop processing statements on the master, and then obtain its current binary log coordinates and dump its data, before permitting the master to continue executing statements. If you do not stop the execution of statements, the data dump and the master status information that you use will not match and you will end up with inconsistent or corrupted databases on the slaves.

To obtain the master binary log coordinates, follow these steps:

1. Start a session on the master by connecting to it with the command-line client, and flush all tables and block write statements by executing the FLUSH TABLES WITH READ LOCK statement:

```
mysql> FLUSH TABLES WITH READ LOCK;
```

For InnoDB tables, note that FLUSH TABLES WITH READ LOCK also blocks COMMIT operations.
Warning
Leave the client from which you issued the `FLUSH TABLES` statement running so that the read lock remains in effect. If you exit the client, the lock is released.

2. In a different session on the master, use the `SHOW MASTER STATUS` statement to determine the current binary log file name and position:

```
mysql > SHOW MASTER STATUS;
+------------------+----------+--------------+------------------+
| File             | Position | Binlog_Do_DB | Binlog_Ignore_DB |
|------------------+----------+--------------+------------------+
| mysql-bin.000003 | 73       | test         | manual,mysql     |
+------------------+----------+--------------+------------------+
```

The `File` column shows the name of the log file and `Position` shows the position within the file. In this example, the binary log file is `mysql-bin.000003` and the position is 73. Record these values. You need them later when you are setting up the slave. They represent the replication coordinates at which the slave should begin processing new updates from the master.

If the master has been running previously without binary logging enabled, the log file name and position values displayed by `SHOW MASTER STATUS` or `mysqldump --master-data` will be empty. In that case, the values that you need to use later when specifying the slave's log file and position are the empty string (`''`) and `4`.

You now have the information you need to enable the slave to start reading from the binary log in the correct place to start replication.

If you have existing data that needs to be synchronized with the slave before you start replication, leave the client running so that the lock remains in place and then proceed to Section 16.1.1.5, “Creating a Data Snapshot Using `mysqldump`”, or Section 16.1.1.6, “Creating a Data Snapshot Using Raw Data Files”. The idea here is to prevent any further changes so that the data copied to the slaves is in synchrony with the master.

If you are setting up a brand new master and slave replication group, you can exit the first session to release the read lock.

### 16.1.1.5 Creating a Data Snapshot Using `mysqldump`

One way to create a snapshot of the data in an existing master database is to use the `mysqldump` tool to create a dump of all the databases you want to replicate. Once the data dump has been completed, you then import this data into the slave before starting the replication process.

The example shown here dumps all databases to a file named `dbdump.db`, and includes the `--master-data` option which automatically appends the `CHANGE MASTER TO` statement required on the slave to start the replication process:

```
shell> mysqldump --all-databases --master-data > dbdump.db
```

If you do not use `--master-data`, then it is necessary to lock all tables in a separate session manually (using `FLUSH TABLES WITH READ LOCK`) prior to running `mysqldump`, then exiting or running `UNLOCK TABLES` from the second session to release the locks. You must also obtain binary log position information matching the snapshot, using `SHOW MASTER STATUS`, and use this to issue the appropriate `CHANGE MASTER TO` statement when starting the slave.

When choosing databases to include in the dump, remember that you need to filter out databases on each slave that you do not want to include in the replication process.

To import the data, either copy the dump file to the slave, or access the file from the master when connecting remotely to the slave.
16.1.1.6 Creating a Data Snapshot Using Raw Data Files

If your database is particularly large, copying the raw data files may be more efficient than using `mysqldump` and importing the file on each slave.

However, using this method with tables in storage engines with complex caching or logging algorithms may not give you a perfect “in time” snapshot as cache information and logging updates may not have been applied, even if you have acquired a global read lock. How the storage engine responds to this depends on its crash recovery abilities.

In addition, this method does not work reliably if the master and slave have different values for `ft_stopword_file`, `ft_min_word_len`, or `ft_max_word_len` and you are copying tables having full-text indexes.

If you are using InnoDB tables, you can use the MySQL Enterprise Backup tool to obtain a consistent snapshot. This tool records the log name and offset corresponding to the snapshot to be later used on the slave. MySQL Enterprise Backup is a nonfree (commercial) tool that is not included in the standard MySQL distribution. See Section 22.2, “MySQL Enterprise Backup Overview” for detailed information.

Otherwise, you can obtain a reliable binary snapshot of InnoDB tables only after shutting down the MySQL Server.

To create a raw data snapshot of MyISAM tables you can use standard copy tools such as `cp` or `copy`, a remote copy tool such as `scp` or `rsync`, an archiving tool such as `zip` or `tar`, or a file system snapshot tool such as `dump`, providing that your MySQL data files exist on a single file system. If you are replicating only certain databases then make sure you copy only those files that related to those tables. (For InnoDB, all tables in all databases are stored in the shared tablespace files, unless you have the `innodb_file_per_table` option enabled.)

You may want to specifically exclude the following files from your archive:

- Files relating to the `mysql` database.
- The `master.info` file.
- The master's binary log files.
- Any relay log files.

To get the most consistent results with a raw data snapshot you should shut down the master server during the process, as follows:

1. Acquire a read lock and get the master's status. See Section 16.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”.

2. In a separate session, shut down the master server:

   ```
   shell> mysqladmin shutdown
   ```

3. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:

   ```
   shell> tar cf /tmp/db.tar ./data
   shell> zip -r /tmp/db.zip ./data
   shell> rsync --recursive ./data /tmp/dbdata
   ```

4. Restart the master server.

If you are not using InnoDB tables, you can get a snapshot of the system from a master without shutting down the server as described in the following steps:

1. Acquire a read lock and get the master's status. See Section 16.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”.
2. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:

```
shell> tar cf /tmp/db.tar ./data
shell> zip -r /tmp/db.zip ./data
shell> rsync --recursive ./data /tmp/dbdata
```

3. In the client where you acquired the read lock, release the lock:

```
mysql> UNLOCK TABLES;
```

Once you have created the archive or copy of the database, you will need to copy the files to each slave before starting the slave replication process.

### 16.1.1.7 Setting Up Replication with New Master and Slaves

The easiest and most straightforward method for setting up replication is to use new master and slave servers.

You can also use this method if you are setting up new servers but have an existing dump of the databases from a different server that you want to load into your replication configuration. By loading the data into a new master, the data will be automatically replicated to the slaves.

To set up replication between a new master and slave:

1. Configure the MySQL master with the necessary configuration properties. See Section 16.1.1.1, “Setting the Replication Master Configuration”.
2. Start up the MySQL master.
3. Set up a user. See Section 16.1.1.3, “Creating a User for Replication”.
4. Obtain the master status information. See Section 16.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”.
5. On the master, release the read lock:

```
mysql> UNLOCK TABLES;
```
6. On the slave, edit the MySQL configuration. See Section 16.1.1.2, “Setting the Replication Slave Configuration”.
7. Start up the MySQL slave.
8. Execute a `CHANGE MASTER TO` statement to set the master replication server configuration. See Section 16.1.1.10, “Setting the Master Configuration on the Slave”.

Perform the slave setup steps on each slave.

Because there is no data to load or exchange on a new server configuration you do not need to copy or import any information.

If you are setting up a new replication environment using the data from a different existing database server, you will now need to run the dump file generated from that server on the new master. The database updates will automatically be propagated to the slaves:

```
shell> mysql -h master < fulldb.dump
```

### 16.1.1.8 Setting Up Replication with Existing Data

When setting up replication with existing data, you will need to decide how best to get the data from the master to the slave before starting the replication service.
The basic process for setting up replication with existing data is as follows:

1. With the MySQL master running, create a user to be used by the slave when connecting to the master during replication. See Section 16.1.1.3, “Creating a User for Replication”.

2. If you have not already configured the `server-id` and enabled binary logging on the master server, you will need to shut it down to configure these options. See Section 16.1.1.1, “Setting the Replication Master Configuration”.

   If you have to shut down your master server, this is a good opportunity to take a snapshot of its databases. You should obtain the master status (see Section 16.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”) before taking down the master, updating the configuration and taking a snapshot. For information on how to create a snapshot using raw data files, see Section 16.1.1.6, “Creating a Data Snapshot Using Raw Data Files”.

3. If your master server is already correctly configured, obtain its status (see Section 16.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”) and then use `mysqldump` to take a snapshot (see Section 16.1.1.5, “Creating a Data Snapshot Using mysqldump”) or take a raw snapshot of the live server using the guide in Section 16.1.1.6, “Creating a Data Snapshot Using Raw Data Files”.

4. Update the configuration of the slave. See Section 16.1.1.2, “Setting the Replication Slave Configuration”.

5. The next step depends on how you created the snapshot of data on the master.

   If you used `mysqldump`:
   a. Start the slave, using the `--skip-slave-start` option so that replication does not start.
   b. Import the dump file:

   ```shell
   mysql < fulldb.dump
   ```

   If you created a snapshot using the raw data files:
   a. Extract the data files into your slave data directory. For example:

   ```shell
tar xvf dbdump.tar
   ```

   You may need to set permissions and ownership on the files so that the slave server can access and modify them.
   b. Start the slave, using the `--skip-slave-start` option so that replication does not start.

6. Configure the slave with the replication coordinates from the master. This tells the slave the binary log file and position within the file where replication needs to start. Also, configure the slave with the login credentials and host name of the master. For more information on the `CHANGE MASTER TO` statement required, see Section 16.1.1.10, “Setting the Master Configuration on the Slave”.

7. Start the slave threads:

   ```mysql
   START SLAVE;
   ```

   After you have performed this procedure, the slave should connect to the master and catch up on any updates that have occurred since the snapshot was taken.

   If you have forgotten to set the `server-id` option for the master, slaves cannot connect to it.

   If you have forgotten to set the `server-id` option for the slave, you get the following error in the slave's error log:
Warning: You should set server-id to a non-0 value if master_host is set; we will force server id to 2, but this MySQL server will not act as a slave.

You also find error messages in the slave's error log if it is not able to replicate for any other reason.

Once a slave is replicating, you can find in its data directory one file named `master.info` and another named `relay-log.info`. The slave uses these two files to keep track of how much of the master's binary log it has processed. Do not remove or edit these files unless you know exactly what you are doing and fully understand the implications. Even in that case, it is preferred that you use the `CHANGE MASTER TO` statement to change replication parameters. The slave will use the values specified in the statement to update the status files automatically.

### Note

The content of `master.info` overrides some of the server options specified on the command line or in `my.cnf`. See Section 16.1.2, “Replication and Binary Logging Options and Variables”, for more details.

A single snapshot of the master suffices for multiple slaves. To set up additional slaves, use the same master snapshot and follow the slave portion of the procedure just described.

#### 16.1.1.9 Introducing Additional Slaves to an Existing Replication Environment

To add another slave to an existing replication configuration, you can do so without stopping the master. Instead, set up the new slave by making a copy of an existing slave, except that you configure the new slave with a different `server-id` value.

To duplicate an existing slave:

1. Shut down the existing slave:

   ```
   shell> mysqladmin shutdown
   ```

2. Copy the data directory from the existing slave to the new slave. You can do this by creating an archive using `tar` or `WinZip`, or by performing a direct copy using a tool such as `cp` or `rsync`. Ensure that you also copy the log files and relay log files.

   A common problem that is encountered when adding new replication slaves is that the new slave fails with a series of warning and error messages like these:

   ```
   071118 16:44:10 [Warning] Neither --relay-log nor --relay-log-index were used; so replication may break when this MySQL server acts as a slave and has his hostname changed!! Please use '--relay-log={new_slave_hostname}-relay-bin' to avoid this problem.
   071118 16:44:10 [ERROR] Failed to open the relay log './old_slave_hostname-relay-bin.003525' (relay_log_pos 22940879)
   071118 16:44:10 [ERROR] Could not find target log during relay log initialization
   071118 16:44:10 [ERROR] Failed to initialize the master info structure
   ```

   This is due to the fact that, if the `--relay-log` option is not specified, the relay log files contain the host name as part of their file names. (This is also true of the relay log index file if the `--relay-log-index` option is not used. See Section 16.1.2, “Replication and Binary Logging Options and Variables”, for more information about these options.)

   To avoid this problem, use the same value for `--relay-log` on the new slave that was used on the existing slave. (If this option was not set explicitly on the existing slave, use `existing_slave_hostname-relay-bin`.) If this is not feasible, copy the existing slave's relay log index file to the new slave and set the `--relay-log-index` option on the new slave to match what was used on the existing slave. (If this option was not set explicitly on the existing slave, use `existing_slave_hostname-relay-bin.index`.) Alternatively—if you have already tried to
start the new slave (after following the remaining steps in this section) and have encountered errors like those described previously—then perform the following steps:

a. If you have not already done so, issue a `STOP SLAVE` on the new slave.
   
   If you have already started the existing slave again, issue a `STOP SLAVE` on the existing slave as well.
   
b. Copy the contents of the existing slave’s relay log index file into the new slave’s relay log index file, making sure to overwrite any content already in the file.
   
c. Proceed with the remaining steps in this section.

3. Copy the `master.info` and `relay-log.info` files from the existing slave to the new slave if they were not located in the data directory. These files hold the current log coordinates for the master’s binary log and the slave’s relay log.

4. Start the existing slave.

5. On the new slave, edit the configuration and give the new slave a unique `server-id` not used by the master or any of the existing slaves.

6. Start the new slave. The slave will use the information in its `master.info` file to start the replication process.

### 16.1.1.10 Setting the Master Configuration on the Slave

To set up the slave to communicate with the master for replication, you must tell the slave the necessary connection information. To do this, execute the following statement on the slave, replacing the option values with the actual values relevant to your system:

```mysql
mysql> CHANGE MASTER TO
->    MASTER_HOST='master_host_name',
->    MASTER_USER='replication_user_name',
->    MASTER_PASSWORD='replication_password',
->    MASTER_LOG_FILE='recorded_log_file_name',
->    MASTER_LOG_POS=recorded_log_position;
```

**Note**

Replication cannot use Unix socket files. You must be able to connect to the master MySQL server using TCP/IP.

The `CHANGE MASTER TO` statement has other options as well. For example, it is possible to set up secure replication using SSL. For a full list of options, and information about the maximum permissible length for the string-valued options, see Section 13.4.2.1, “CHANGE MASTER TO Syntax”.

### 16.1.2 Replication and Binary Logging Options and Variables

The next few sections contain information about `mysqld` options and server variables that are used in replication and for controlling the binary log. Options and variables for use on replication masters and replication slaves are covered separately, as are options and variables relating to binary logging. A set of quick-reference tables providing basic information about these options and variables is also included (in the next section following this one).

Of particular importance is the `--server-id` option.

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--server-id=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>server_id</code></td>
</tr>
<tr>
<td>Variable</td>
<td>Global</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
</tbody>
</table>
This option is common to both master and slave replication servers, and is used in replication to enable master and slave servers to identify themselves uniquely. For additional information, see Section 16.1.2.2, “Replication Master Options and Variables”, and Section 16.1.2.3, “Replication Slave Options and Variables”.

On the master and each slave, you must use the --server-id option to establish a unique replication ID in the range from 1 to $2^{32} - 1$. “Unique”, means that each ID must be different from every other ID in use by any other replication master or slave. Example: `server-id=3`.

If you omit --server-id, the default ID is 0, in which case the master refuses connections from all slaves, and slaves refuse to connect to the master. In MySQL 5.0, whether the server ID is set to 0 explicitly or the default is allowed to be used, the server sets the `server_id` system variable to 1; this is a known issue that is fixed in MySQL 5.7.

For more information, see Section 16.1.1.2, “Setting the Replication Slave Configuration”.

### 16.1.2.1 Replication and Binary Logging Option and Variable Reference

The following tables list basic information about the MySQL command-line options and system variables applicable to replication and the binary log.

<table>
<thead>
<tr>
<th>Option or Variable Name</th>
<th>Command Line</th>
<th>System Variable</th>
<th>Status Variable</th>
</tr>
</thead>
<tbody>
<tr>

Section 16.1.2.4, “Binary Log Options and Variables”, provides more detailed information about options and variables relating to binary logging. For additional general information about the binary log, see Section 5.4.3, “The Binary Log”.

For information about the `sql_log_bin` and `sql_log_off` variables, see Section 5.1.4, “Server System Variables”.

For a table showing all command-line options, system and status variables used with `mysqld`, see Section 5.1.1, “Server Option and Variable Reference”.

16.1.2.2 Replication Master Options and Variables

This section describes the server options and system variables that you can use on replication master servers. You can specify the options either on the command line or in an option file. You can specify system variable values using `SET`.

On the master and each slave, you must use the `server-id` option to establish a unique replication ID. For each server, you should pick a unique positive integer in the range from 1 to $2^{32} - 1$, and each ID must be different from every other ID in use by any other replication master or slave. Example: `server-id=3`.

For options used on the master for controlling binary logging, see Section 16.1.2.4, “Binary Log Options and Variables”.

System Variables Used on Replication Masters

The following system variables are used in controlling replication masters:

- `auto_increment_increment`

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.0.2</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name</td>
</tr>
<tr>
<td>Variable</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Scope</td>
<td></td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Variable</td>
<td></td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type</td>
</tr>
<tr>
<td>Default</td>
<td>1</td>
</tr>
</tbody>
</table>
auto_increment_increment and auto_increment_offset are intended for use with master-to-master replication, and can be used to control the operation of AUTO_INCREMENT columns. Both variables have global and session values, and each can assume an integer value between 1 and 65,535 inclusive. Setting the value of either of these two variables to 0 causes its value to be set to 1 instead. Attempting to set the value of either of these two variables to an integer greater than 65,535 or less than 0 causes its value to be set to 65,535 instead. Attempting to set the value of auto_increment_increment or auto_increment_offset to a noninteger value gives rise to an error, and the actual value of the variable remains unchanged.

These two variables affect AUTO_INCREMENT column behavior as follows:

• auto_increment_increment controls the interval between successive column values. For example:

```sql
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| auto_increment_increment | 1     |
| auto_increment_offset    | 1     |
+--------------------------+-------+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoinc1
    -> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
Query OK, 0 rows affected (0.04 sec)

mysql> SET @@auto_increment_increment=10;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| auto_increment_increment | 10    |
| auto_increment_offset    | 1     |
+--------------------------+-------+
2 rows in set (0.01 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
|   1 |
|  11 |
|  21 |
|  31 |
+-----+
4 rows in set (0.00 sec)
```

• auto_increment_offset determines the starting point for the AUTO_INCREMENT column value. Consider the following, assuming that these statements are executed during the same session as the example given in the description for auto_increment_increment:

```sql
mysql> SET @@auto_increment_offset=5;
Query OK, 0 rows affected (0.00 sec)
```
Replication and Binary Logging Options and Variables

```sql
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| auto_increment_increment | 10    |
| auto_increment_offset    | 5     |
+--------------------------+-------+
2 rows in set (0.00 sec)
```

```sql
mysql> CREATE TABLE autoinc2
  -> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
Query OK, 0 rows affected (0.06 sec)
```

```sql
mysql> INSERT INTO autoinc2 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0
```

```sql
mysql> SELECT col FROM autoinc2;
+-----+
| col |
+-----+
| 5   |
| 15  |
| 25  |
| 35  |
+-----+
4 rows in set (0.02 sec)
```

If the value of `auto_increment_offset` is greater than that of `auto_increment_increment`, the value of `auto_increment_offset` is ignored.

Should one or both of these variables be changed and then new rows inserted into a table containing an `AUTO_INCREMENT` column, the results may seem counterintuitive because the series of `AUTO_INCREMENT` values is calculated without regard to any values already present in the column, and the next value inserted is the least value in the series that is greater than the maximum existing value in the `AUTO_INCREMENT` column. In other words, the series is calculated like so:

\[ \text{auto_increment_offset} + N \times \text{auto_increment_increment} \]

where \( N \) is a positive integer value in the series \([1, 2, 3, \ldots]\). For example:

```sql
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| auto_increment_increment | 10    |
| auto_increment_offset    | 5     |
+--------------------------+-------+
2 rows in set (0.00 sec)
```

```sql
mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
| 1   |
| 11  |
| 21  |
| 31  |
+-----+
4 rows in set (0.00 sec)
```

```sql
mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0
```

```sql
mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
| 5   |
| 15  |
| 25  |
| 35  |
+-----+
4 rows in set (0.02 sec)
```
The values shown for auto_increment_increment and auto_increment_offset generate the series $5 + N \times 10$, that is, $[5, 15, 25, 35, 45, ...]$. The greatest value present in the col column prior to the INSERT is 31, and the next available value in the AUTO_INCREMENT series is 35, so the inserted values for col begin at that point and the results are as shown for the SELECT query.

It is not possible to confine the effects of these two variables to a single table, and thus they do not take the place of the sequences offered by some other database management systems; these variables control the behavior of all AUTO_INCREMENT columns in all tables on the MySQL server. If the global value of either variable is set, its effects persist until the global value is changed or overridden by setting the session value, or until mysqld is restarted. If the local value is set, the new value affects AUTO_INCREMENT columns for all tables into which new rows are inserted by the current user for the duration of the session, unless the values are changed during that session.

The auto_increment_increment variable was added in MySQL 5.0.2. Its default value is 1. See Section 16.4.1.1, “Replication and AUTO_INCREMENT”.

auto_increment_increment is supported for use with NDB tables beginning with MySQL 5.0.46. Previously, setting it when using MySQL Cluster tables produced unpredictable results.

- auto_increment_offset

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.0.2</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name</td>

<tr>
<td>Default</td>
<td>1</td>
</tr>
<tr>
<td>Min Value</td>
<td>1</td>
</tr>
<tr>
<td>Max Value</td>
<td>65535</td>
</tr>
</tbody>
</table>

This variable was introduced in MySQL 5.0.2. Its default value is 1. For particulars, see the description for auto_increment_increment.

auto_increment_offset is supported for use with NDB tables beginning with MySQL 5.0.46. Previously, setting it when using MySQL Cluster tables produced unpredictable results.

16.1.2.3 Replication Slave Options and Variables

Startup Options for Replication Slaves

System Variables Used on Replication Slaves
This section describes the server options and system variables that apply to slave replication servers. You can specify the options either on the command line or in an option file. Many of the options can be set while the server is running by using the `CHANGE MASTER TO` statement. You can specify system variable values using `SET`.

**Server ID.** On the master and each slave, you must use the `server-id` option to establish a unique replication ID in the range from 1 to $2^{32} - 1$. “Unique” means that each ID must be different from every other ID in use by any other replication master or slave. Example `my.cnf` file:

```
[mysqld]
server-id=3
```

Some slave server replication options are handled in a special way, in the sense that each is ignored if a `master.info` file exists when the slave starts and contains a value for the option. The following options are handled this way:

- `--master-host`
- `--master-user`
- `--master-password`
- `--master-port`
- `--master-connect-retry`
- `--master-ssl`
- `--master-ssl-ca`
- `--master-ssl-capath`
- `--master-ssl-cert`
- `--master-ssl-cipher`
- `--master-ssl-key`

The `master.info` file format in MySQL 5.0 includes as its first line the number of lines in the file. (See Section 16.2.2, “Replication Relay and Status Logs”.) If you upgrade an older server (before MySQL 4.1.1) to a newer version, the new server upgrades the `master.info` file to the new format automatically when it starts. However, if you downgrade a newer server to a version older than 4.1.1, you should manually remove the first line before starting the older server for the first time. Note that, in this case, the downgraded server can no longer use an SSL connection to communicate with the master.

If no `master.info` file exists when the slave server starts, it uses the values for those options that are specified in option files or on the command line. This occurs when you start the server as a replication slave for the very first time, or when you have run `RESET SLAVE` and then have shut down and restarted the slave.

If the `master.info` file exists when the slave server starts, the server uses its contents and ignores any startup options that correspond to the values listed in the file. Thus, if you start the slave server with different values of the startup options that correspond to values in the `master.info` file, the different values have no effect because the server continues to use the `master.info` file. To use different values, the preferred method is to use the `CHANGE MASTER TO` statement to reset the values while the slave is running. Alternatively, you can stop the server, remove the `master.info` file, and restart the server with different option values.

Suppose that you specify this option in your `my.cnf` file:

```
[mysqld]
master-host=some_host
```
The first time you start the server as a replication slave, it reads and uses that option from the `my.cnf` file. The server then records the value in the `master.info` file. The next time you start the server, it reads the master host value from the `master.info` file only and ignores the value in the option file. If you modify the `my.cnf` file to specify a different master host of `some_other_host`, the change still has no effect. You should use `CHANGE MASTER TO` instead.

Because the server gives an existing `master.info` file precedence over the startup options just described, you might prefer not to use startup options for these values at all, and instead specify them by using the `CHANGE MASTER TO` statement. See Section 13.4.2.1, “CHANGE MASTER TO Syntax”.

This example shows a more extensive use of startup options to configure a slave server:

```
[mysqld]
server-id=2
master-host=db-master.mycompany.com
master-port=3306
master-user=pertinax
master-password=freitag
master-connect-retry=60
report-host=db-slave.mycompany.com
```

### Startup Options for Replication Slaves

The following list describes startup options for controlling replication slave servers. Many of these options can be set while the server is running by using the `CHANGE MASTER TO` statement. Others, such as the `--replicate-*` options, can be set only when the slave server starts. Replication-related system variables are discussed later in this section.

* **`--abort-slave-event-count`**

  **Command-Line Format**
  
  `--abort-slave-event-count=##`

  **Permitted Values**
  
<table>
<thead>
<tr>
<th>Type</th>
<th>Default</th>
<th>Min Value</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>0</td>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

  When this option is set to some positive integer `value` other than 0 (the default) it affects replication behavior as follows: After the slave SQL thread has started, `value` log events are permitted to be executed; after that, the slave SQL thread does not receive any more events, just as if the network connection from the master were cut. The slave thread continues to run, and the output from `SHOW SLAVE STATUS` displays `Yes` in both the `Slave_IO_Running` and the `Slave_SQL_Running` columns, but no further events are read from the relay log.

  This option is used internally by the MySQL test suite for replication testing and debugging. It is not intended for use in a production setting.

* **`--disconnect-slave-event-count`**

  **Command-Line Format**
  
  `--disconnect-slave-event-count=##`

  **Permitted Values**
  
<table>
<thead>
<tr>
<th>Type</th>
<th>Default</th>
<th>Min Value</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>0</td>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

  This option is used internally by the MySQL test suite for replication testing and debugging.

* **`--log-slave-updates`**

  **Command-Line Format**
  
  `--log-slave-updates`

  **System Variable**
  
  Name `log_slave_updates`
 Normally, a slave does not log to its own binary log any updates that are received from a master server. This option tells the slave to log the updates performed by its SQL thread to its own binary log. For this option to have any effect, the slave must also be started with the \texttt{--log-bin} option to enable binary logging. \texttt{--log-slave-updates} is used when you want to chain replication servers. For example, you might want to set up replication servers using this arrangement:

\begin{verbatim}
A -> B -> C
\end{verbatim}

Here, \texttt{A} serves as the master for the slave \texttt{B}, and \texttt{B} serves as the master for the slave \texttt{C}. For this to work, \texttt{B} must be both a master and a slave. You must start both \texttt{A} and \texttt{B} with \texttt{--log-bin} to enable binary logging, and \texttt{B} with the \texttt{--log-slave-updates} option so that updates received from \texttt{A} are logged by \texttt{B} to its binary log.

- \texttt{--log-warnings[=level]}

This option causes a server to print more messages to the error log about what it is doing. With respect to replication, the server generates warnings that it succeeded in reconnecting after a network/connection failure, and informs you as to how each slave thread started. This option is enabled (1) by default; to disable it, use \texttt{--log-warnings=0}. Aborted connections are not logged to the error log unless the value is greater than 1.

Note that the effects of this option are not limited to replication. It produces warnings across a spectrum of server activities.

- \texttt{--master-connect-retry=seconds}

This option causes a server to print more messages to the error log about what it is doing. With respect to replication, the server generates warnings that it succeeded in reconnecting after a network/connection failure, and informs you as to how each slave thread started. This option is enabled (1) by default; to disable it, use \texttt{--log-warnings=0}. Aborted connections are not logged to the error log unless the value is greater than 1.

Note that the effects of this option are not limited to replication. It produces warnings across a spectrum of server activities.
Replication and Binary Logging Options and Variables

### Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>60</td>
</tr>
</tbody>
</table>

The number of seconds that the slave thread sleeps before trying to reconnect to the master in case the master goes down or the connection is lost. The value in the `master.info` file takes precedence if it can be read. If not set, the default is 60. Connection retries are not invoked until the slave times out reading data from the master according to the value of `--slave-net-timeout`. The number of reconnection attempts is limited by the `--master-retry-count` option.

- `--master-host=host_name`

#### Command-Line Format

```
--master-host=name
```

#### Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td></td>
</tr>
</tbody>
</table>

The host name or IP address of the master replication server. The value in `master.info` takes precedence if it can be read. If no master host is specified, the slave thread does not start.

- `--master-info-file=file_name`

#### Command-Line Format

```
--master-info-file=file_name
```

#### Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>file name</td>
<td>master.info</td>
</tr>
</tbody>
</table>

The name to use for the file in which the slave records information about the master. The default name is `master.info` in the data directory. For information about the format of this file, see Section 16.2.2.2, “Slave Status Logs”.

- `--master-password=password`

#### Command-Line Format

```
--master-password=name
```

#### Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td></td>
</tr>
</tbody>
</table>

The password of the account that the slave thread uses for authentication when it connects to the master. The value in the `master.info` file takes precedence if it can be read. If not set, an empty password is assumed.

- `--master-port=port_number`

#### Command-Line Format

```
--master-port=#
```

#### Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>3306</td>
</tr>
</tbody>
</table>

The TCP/IP port number that the master is listening on. The value in the `master.info` file takes precedence if it can be read. If not set, the compiled-in setting is assumed (normally 3306).

- `--master-retry-count=count`

#### Command-Line Format

```
--master-retry-count=#
```

#### Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
<th>Default</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>86400</td>
<td>0</td>
<td>4294967295</td>
</tr>
<tr>
<td>(32-bit platforms)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

This documentation is for an older version. If you're using the most current version, select the documentation for that version with the version switch in the upper right corner of the online documentation, or by downloading a newer PDF or EPUB file.
The number of times that the slave tries to connect to the master before giving up. Reconnects are attempted at intervals set by the `--master-connect-retry` option (or the `MASTER_CONNECT_RETRY` option of the `CHANGE MASTER TO` statement) and reconnects are triggered when data reads by the slave time out according to the `--slave-net-timeout` option. The default value is 86400. A value of 0 means "infinite"; the slave attempts to connect forever.

- `--master-ssl`, `--master-ssl-ca=file_name`, `--master-ssl-capath=directory_name`, `--master-ssl-cert=file_name`, `--master-ssl-cipher=cipher_list`, `--master-ssl-key=file_name`

These options are used for setting up a secure replication connection to the master server using SSL. Their meanings are the same as the corresponding `--ssl`, `--ssl-ca`, `--ssl-capath`, `--ssl-cert`, `--ssl-cipher`, `--ssl-key` options that are described in Section 6.3.6.5, "Command Options for Secure Connections". The values in the `master.info` file take precedence if they can be read.

- `--master-user=user_name`

The user name of the account that the slave thread uses for authentication when it connects to the master. This account must have the `REPLICATION SLAVE` privilege. The value in the `master.info` file takes precedence if it can be read. If the master user name is not set, the name `test` is assumed.

- `--max-relay-log-size=size`

The size at which the server rotates relay log files automatically. If this value is nonzero, the relay log is rotated automatically when its size exceeds this value. If this value is zero (the default), the size at which relay log rotation occurs is determined by the value of `max_binlog_size`. For more information, see Section 16.2.2.1, "The Slave Relay Log".
•  `--relay-log=file_name`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--relay-log=file_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name <em>relay_log</em></td>
</tr>
<tr>
<td></td>
<td>Variable Global</td>
</tr>
<tr>
<td></td>
<td>Scope</td>
</tr>
<tr>
<td></td>
<td>DynamicNo</td>
</tr>
<tr>
<td></td>
<td>Variable</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type <em>file_name</em></td>
</tr>
</tbody>
</table>

The base name for the relay log. The default base name is `host_name-relay-bin`. The server writes the file in the data directory unless the base name is given with a leading absolute path name to specify a different directory. The server creates relay log files in sequence by adding a numeric suffix to the base name.

Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; _the default base name is used only if the option is not actually specified_. If you use the `--relay-log` option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see Section 4.2.3, "Specifying Program Options".

If you specify this option, the value specified is also used as the base name for the relay log index file. You can override this behavior by specifying a different relay log index file base name using the `--relay-log-index` option.

You may find the `--relay-log` option useful in performing the following tasks:

• Creating relay logs whose names are independent of host names.

• If you need to put the relay logs in some area other than the data directory because your relay logs tend to be very large and you do not want to decrease `max_relay_log_size`.

• To increase speed by using load-balancing between disks.

•  `--relay-log-index=file_name`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--relay-log-index=file_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name <em>relay_log_index</em></td>
</tr>
<tr>
<td></td>
<td>Variable Global</td>
</tr>
<tr>
<td></td>
<td>Scope</td>
</tr>
<tr>
<td></td>
<td>DynamicNo</td>
</tr>
<tr>
<td></td>
<td>Variable</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type <em>file_name</em></td>
</tr>
</tbody>
</table>

The name to use for the relay log index file. The default name is `host_name-relay-bin.index` in the data directory, where `host_name` is the name of the slave server.

Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; _the default base name is used only if the option is not actually specified_. If you use the `--relay-log-index` option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see Section 4.2.3, "Specifying Program Options".
If you specify this option, the value specified is also used as the base name for the relay logs. You can override this behavior by specifying a different relay log file base name using the `--relay-log` option.

- `--relay-log-info-file=file_name`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--relay-log-info-file=file_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>Type</td>
</tr>
</tbody>
</table>

The name to use for the file in which the slave records information about the relay logs. The default name is `relay-log.info` in the data directory. For information about the format of this file, see Section 16.2.2.2, “Slave Status Logs”.

- `--relay-log-purge=(0|1)`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--relay_log_purge</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td><code>relay_log_purge</code></td>
</tr>
<tr>
<td>Variable</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type</td>
</tr>
</tbody>
</table>

Disable or enable automatic purging of relay logs as soon as they are no longer needed. The default value is 1 (enabled). This is a global variable that can be changed dynamically with `SET GLOBAL relay_log_purge = N`.

- `--relay-log-space-limit=size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--relay_log_space_limit=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name</td>
</tr>
<tr>
<td>Variable</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type</td>
</tr>
<tr>
<td></td>
<td>Min Value</td>
</tr>
<tr>
<td></td>
<td>Max Value</td>
</tr>
</tbody>
</table>

Permitted Values (32-bit platforms) Type integer

Permitted Values (64-bit platforms) Type integer

<table>
<thead>
<tr>
<th>Type</th>
<th>Default</th>
<th>Min Value</th>
<th>Max Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>0</td>
<td>0</td>
<td>18446744073709547520</td>
</tr>
</tbody>
</table>
This option places an upper limit on the total size in bytes of all relay logs on the slave. A value of 0 means "no limit." This is useful for a slave server host that has limited disk space. When the limit is reached, the I/O thread stops reading binary log events from the master server until the SQL thread has caught up and deleted some unused relay logs. Note that this limit is not absolute: There are cases where the SQL thread needs more events before it can delete relay logs. In that case, the I/O thread exceeds the limit until it becomes possible for the SQL thread to delete some relay logs because not doing so would cause a deadlock. You should not set --relay-log-space-limit to less than twice the value of --max-relay-log-size (or --max-binlog-size if --max-relay-log-size is 0). In that case, there is a chance that the I/O thread waits for free space because --relay-log-space-limit is exceeded, but the SQL thread has no relay log to purge and is unable to satisfy the I/O thread. This forces the I/O thread to ignore --relay-log-space-limit temporarily.

* --replicate-do-db=db_name

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--replicate-do-db=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>string</td>
</tr>
</tbody>
</table>

Tell the slave SQL thread to restrict replication to statements where the default database (that is, the one selected by USE) is db_name. To specify more than one database, use this option multiple times, once for each database. Note that this does not replicate cross-database statements such as UPDATE some_db.some_table SET foo='bar' while having selected a different database or no database.

**Warning**

To specify multiple databases you must use multiple instances of this option. Because database names can contain commas, if you supply a comma separated list then the list will be treated as the name of a single database.

An example of what does not work as you might expect: If the slave is started with --replicate-do-db=sales and you issue the following statements on the master, the UPDATE statement is not replicated:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this "check just the default database" behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table DELETE or multiple-table UPDATE statements that go across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

If you need cross-database updates to work, use --replicate-wild-do-table=db_name.% instead. See Section 16.2.3, "How Servers Evaluate Replication Filtering Rules".

Beginning with MySQL 5.0.84, this option has no effect on BEGIN, COMMIT, or ROLLBACK statements. (Bug #43263)

* --replicate-ignore-db=db_name

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--replicate-ignore-db=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>string</td>
</tr>
</tbody>
</table>

Tells the slave SQL thread not to replicate any statement where the default database (that is, the one selected by USE) is db_name. To specify more than one database to ignore, use this option multiple times, once for each database. You should not use this option if you are using cross-database
updates and you do not want these updates to be replicated. See Section 16.2.3, “How Servers Evaluate Replication Filtering Rules”.

An example of what does not work as you might expect: If the slave is started with `--replicate-ignore-db=sales` and you issue the following statements on the master, the UPDATE statement is replicated:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

Note
In the preceding example the statement is replicated because `--replicate-ignore-db` only applies to the default database (set through the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered.

If you need cross-database updates to work, use `--replicate-wild-ignore-table=db_name.%` instead. See Section 16.2.3, “How Servers Evaluate Replication Filtering Rules”.

Beginning with MySQL 5.0.84, this option has no effect on BEGIN, COMMIT, or ROLLBACK statements. (Bug #43263)

• `--replicate-do-table=db_name.tbl_name`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>Permitted Values</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--replicate-do-table=name</code></td>
<td>string</td>
<td></td>
</tr>
</tbody>
</table>

Tells the slave SQL thread to restrict replication to the specified table. To specify more than one table, use this option multiple times, once for each table. This works for both cross-database updates and default database updates, in contrast to `--replicate-do-db`. See Section 16.2.3, “How Servers Evaluate Replication Filtering Rules”.

This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the `--replicate-*-db` options.

• `--replicate-ignore-table=db_name.tbl_name`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>Permitted Values</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--replicate-ignore-table=name</code></td>
<td>string</td>
<td></td>
</tr>
</tbody>
</table>

Tells the slave SQL thread not to replicate any statement that updates the specified table, even if any other tables might be updated by the same statement. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates, in contrast to `--replicate-ignore-db`. See Section 16.2.3, “How Servers Evaluate Replication Filtering Rules”.

This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the `--replicate-*-db` options.

• `--replicate-rewrite-db=from_name->to_name`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>Permitted Values</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--replicate-rewrite-db=old_name-&gt;new_name</code></td>
<td>string</td>
<td></td>
</tr>
</tbody>
</table>
Tells the slave to translate the default database (that is, the one selected by `USE`) to `to_name` if it was `from_name` on the master. Only statements involving tables are affected (not statements such as `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`), and only if `from_name` is the default database on the master. To specify multiple rewrites, use this option multiple times. The server uses the first one with a `from_name` value that matches. The database name translation is done before the `--replicate-*` rules are tested.

Statements in which table names are qualified with database names when using this option do not work with table-level replication filtering options such as `--replicate-do-table`. Suppose we have a database named `a` on the master, one named `b` on the slave, each containing a table `t`, and have started the master with `--replicate-rewrite-db='a->b'`. At a later point in time, we execute `DELETE FROM a.t`. In this case, no relevant filtering rule works, for the reasons shown here:

1. `--replicate-do-table=a.t` does not work because the slave has table `t` in database `b`.
2. `--replicate-do-table=b.t` does not match the original statement and so is ignored.
3. `--replicate-do-table=*.t` is handled identically to `--replicate-do-table=a.t`, and thus does not work, either.

Similarly, the `--replication-rewrite-db` option does not work with cross-database updates.

If you use this option on the command line and the " -> " character is special to your command interpreter, quote the option value. For example:

```
shell> mysqld --replicate-rewrite-db="olddb->newdb"
```

---

**--replicate-same-server-id**

- **Introduced**: 5.0.1
- **Command-Line Format**: `--replicate-same-server-id`
- **Permitted Values**
  - **Type**: boolean
  - **Default**: FALSE

To be used on slave servers. Usually you should use the default setting of 0, to prevent infinite loops caused by circular replication. If set to 1, the slave does not skip events having its own server ID. Normally, this is useful only in rare configurations. Cannot be set to 1 if `--log-slave-updates` is used. By default, the slave I/O thread does not write binary log events to the relay log if they have the slave’s server ID (this optimization helps save disk usage). If you want to use `--replicate-same-server-id`, be sure to start the slave with this option before you make the slave read its own events that you want the slave SQL thread to execute.

---

**--replicate-wild-do-table=db_name.tbl_name**

- **Command-Line Format**: `--replicate-wild-do-table=name`
- **Permitted Values**
  - **Type**: string

Tells the slave thread to restrict replication to statements where any of the updated tables match the specified database and table name patterns. Patterns can contain the "%" and "_" wildcard characters, which have the same meaning as for the LIKE pattern-matching operator. To specify more than one table, use this option multiple times, once for each table. This works for cross-database updates. See Section 16.2.3, "How Servers Evaluate Replication Filtering Rules".

This option applies to tables, views, and triggers. It does not apply to stored procedures and functions. To filter statements operating on the latter objects, use one or more of the `--replicate-*-db` options.
Replication and Binary Logging Options and Variables

Example: `--replicate-wild-do-table=foo%.bar%` replicates only updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

If the table name pattern is `%`, it matches any table name and the option also applies to database-level statements (CREATE DATABASE, DROP DATABASE, and ALTER DATABASE). For example, if you use `--replicate-wild-do-table=foo%.%`, database-level statements are replicated if the database name matches the pattern `foo`.

To include literal wildcard characters in the database or table name patterns, escape them with a backslash. For example, to replicate all tables of a database that is named `my_own%db`, but not replicate tables from the `my1ownAABCdb` database, you should escape the `"_"` and `%` characters like this: `--replicate-wild-do-table=my\_own\%db`. If you use the option on the command line, you might need to double the backslashes or quote the option value, depending on your command interpreter. For example, with the `bash` shell, you would need to type `--replicate-wild-do-table=my\_own\%db`.

- `--replicate-wild-ignore-table=db_name.tbl_name`

  **Command-Line Format**
  
  `--replicate-wild-ignore-table=name`

  **Permitted Values**
  
  **Type** string

  Tells the slave thread not to replicate a statement where any table matches the given wildcard pattern. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates. See Section 16.2.3, “How Servers Evaluate Replication Filtering Rules”.

  Example: `--replicate-wild-ignore-table=foo%.bar%` does not replicate updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

  For information about how matching works, see the description of the `--replicate-wild-do-table` option. The rules for including literal wildcard characters in the option value are the same as for `--replicate-wild-ignore-table` as well.

- `--report-host=host_name`

  **Command-Line Format**
  
  `--report-host=host_name`

  **Permitted Values**
  
  **Type** string

  The host name or IP address of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server. Leave the value unset if you do not want the slave to register itself with the master. Note that it is not sufficient for the master to simply read the IP address of the slave from the TCP/IP socket after the slave connects. Due to NAT and other routing issues, that IP may not be valid for connecting to the slave from the master or other hosts.

- `--report-password=password`

  **Command-Line Format**
  
  `--report-password=name`

  **Permitted Values**
  
  **Type** string

  The account password of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the `--show-slave-auth-info` option is given.

  Although the name of this option might imply otherwise, `--report-password` is not connected to the MySQL user privilege system and so is not necessarily (or even likely to be) the same as the password for the MySQL replication user account.
### --report-port=slave_port_num

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--report-port=port_num</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td><strong>Type</strong> integer</td>
</tr>
<tr>
<td>Default</td>
<td>3306</td>
</tr>
<tr>
<td>Min Value</td>
<td>0</td>
</tr>
<tr>
<td>Max Value</td>
<td>65535</td>
</tr>
</tbody>
</table>

The TCP/IP port number for connecting to the slave, to be reported to the master during slave registration. Set this only if the slave is listening on a nondefault port or if you have a special tunnel from the master or other clients to the slave. If you are not sure, do not use this option.

### --report-user=user_name

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--report-user=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td><strong>Type</strong> string</td>
</tr>
</tbody>
</table>

The account user name of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the `--show-slave-auth-info` option is given.

Although the name of this option might imply otherwise, `--report-user` is not connected to the MySQL user privilege system and so is not necessarily (or even likely to be) the same as the name of the MySQL replication user account.

### --show-slave-auth-info

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--show-slave-auth-info</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td><strong>Type</strong> boolean</td>
</tr>
<tr>
<td>Default</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Display slave user names and passwords in the output of `SHOW SLAVE HOSTS` on the master server for slaves started with the `--report-user` and `--report-password` options.

### --skip-slave-start

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--skip-slave-start</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td><strong>Type</strong> boolean</td>
</tr>
<tr>
<td>Default</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Tells the slave server not to start the slave threads when the server starts. To start the threads later, use a `START SLAVE` statement.

### --slave_compressed_protocol={0|1}

| Command-Line Format          | --slave_compressed_protocol=0|1 |
|------------------------------|-----------------------------|
| System Variable              | slave_compressed_protocol   |
| Variable                     | Global                      |
| Scope                        |                            |
| DynamicYes                   |                            |
| Variable                     |                            |
| Permitted Values             | **Type** boolean            |
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Default</th>
<th>OFF</th>
</tr>
</thead>
</table>

If this option is set to 1, use compression for the slave/master protocol if both the slave and the master support it. The default is 0 (no compression).

- `--slave-load-tmpdir=dir_name`

**Command-Line Format**

```
--slave-load-tmpdir=dir_name
```

**System Variable**

- **Name**: `slave_load_tmpdir`
- **Variable**: Global
- **Scope**: Dynamic
- **Variable**: No

**Permitted Values**

- **Type**: directory name
- **Default**: `/tmp`

The name of the directory where the slave creates temporary files. This option is by default equal to the value of the `tmpdir` system variable. When the slave SQL thread replicates a `LOAD DATA INFILE` statement, it extracts the file to be loaded from the relay log into temporary files, and then loads these into the table. If the file loaded on the master is huge, the temporary files on the slave are huge, too. Therefore, it might be advisable to use this option to tell the slave to put temporary files in a directory located in some file system that has a lot of available space. In that case, the relay logs are huge as well, so you might also want to use the `--relay-log` option to place the relay logs in that file system.

The directory specified by this option should be located in a disk-based file system (not a memory-based file system) because the temporary files used to replicate `LOAD DATA INFILE` must survive machine restarts. The directory also should not be one that is cleared by the operating system during the system startup process.

- `--slave-net-timeout=seconds`

**Command-Line Format**

```
--slave-net-timeout=#
```

**System Variable**

- **Name**: `slave_net_timeout`
- **Variable**: Global
- **Scope**: Dynamic
- **Variable**: Yes

**Permitted Values**

- **Type**: integer
- **Default**: 3600
- **Min Value**: 1

The number of seconds to wait for more data from the master before the slave considers the connection broken, aborts the read, and tries to reconnect. The first retry occurs immediately after the timeout. The interval between retries is controlled by the `CHANGE MASTER TO` statement or `--master-connect-retry` option and the number of reconnection attempts is limited by the `--master-retry-count` option. The default is 3600 seconds (one hour).

- `--slave-skip-errors=[err_code1,err_code2,...]|all`

**Command-Line Format**

```
--slave-skip-errors=name
```

**System Variable**

- **Name**: `slave_skip_errors`
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Global Scope</th>
<th>Dynamic Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Global</td>
<td>Dynamic</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type string</td>
<td></td>
</tr>
<tr>
<td>Default</td>
<td>OFF</td>
<td></td>
</tr>
<tr>
<td>Valid Values</td>
<td>OFF</td>
<td></td>
</tr>
<tr>
<td></td>
<td>[list of error codes]</td>
<td></td>
</tr>
<tr>
<td></td>
<td>all</td>
<td></td>
</tr>
</tbody>
</table>

Normally, replication stops when an error occurs on the slave. This gives you the opportunity to resolve the inconsistency in the data manually. This option tells the slave SQL thread to continue replication when a statement returns any of the errors listed in the option value.

Do not use this option unless you fully understand why you are getting errors. If there are no bugs in your replication setup and client programs, and no bugs in MySQL itself, an error that stops replication should never occur. Indiscriminate use of this option results in slaves becoming hopelessly out of synchrony with the master, with you having no idea why this has occurred.

For error codes, you should use the numbers provided by the error message in your slave error log and in the output of `SHOW SLAVE STATUS`. Appendix B, Errors, Error Codes, and Common Problems, lists server error codes.

You can also (but should not) use the very nonrecommended value of all to cause the slave to ignore all error messages and keeps going regardless of what happens. Needless to say, if you use all, there are no guarantees regarding the integrity of your data. Please do not complain (or file bug reports) in this case if the slave’s data is not anywhere close to what it is on the master. You have been warned.

Examples:

```
--slave-skip-errors=1062,1053
--slave-skip-errors=all
```

System Variables Used on Replication Slaves

The following list describes system variables for controlling replication slave servers. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used with replication slaves are listed earlier in this section.

- **init_slave**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--init-slave=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name init_slave</td>
</tr>
<tr>
<td></td>
<td>Variable Global</td>
</tr>
<tr>
<td></td>
<td>Scope</td>
</tr>
<tr>
<td></td>
<td>Dynamic Yes</td>
</tr>
<tr>
<td></td>
<td>Variable</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type string</td>
</tr>
</tbody>
</table>

This variable is similar to `init_connect`, but is a string to be executed by a slave server each time the SQL thread starts. The format of the string is the same as for the `init_connect` variable.
Replication and Binary Logging Options and Variables

Note

The SQL thread sends an acknowledgment to the client before it executes `init_slave`. Therefore, it is not guaranteed that `init_slave` has been executed when `START SLAVE` returns. See Section 13.4.2.7, “START SLAVE Syntax”, for more information.

- `relay_log`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--relay-log=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name relay_log</td>
</tr>
<tr>
<td></td>
<td>Variable Global Scope</td>
</tr>
<tr>
<td></td>
<td>Dynamic No Variable</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type file name</td>
</tr>
</tbody>
</table>

  The name of the relay log file.

- `relay_log_index`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--relay-log-index</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name relay_log_index</td>
</tr>
<tr>
<td></td>
<td>Variable Global Scope</td>
</tr>
<tr>
<td></td>
<td>Dynamic No Variable</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type file name</td>
</tr>
<tr>
<td></td>
<td>Default <em>host_name</em>-relay-bin.index</td>
</tr>
</tbody>
</table>

  The name of the relay log index file. The default name is `host_name-relay-bin.index` in the data directory, where `host_name` is the name of the slave server.

- `relay_log_info_file`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--relay-log-info-file=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name relay_log_info_file</td>
</tr>
<tr>
<td></td>
<td>Variable Global Scope</td>
</tr>
<tr>
<td></td>
<td>Dynamic No Variable</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type file name</td>
</tr>
<tr>
<td></td>
<td>Default relay-log.info</td>
</tr>
</tbody>
</table>

  The name of the file in which the slave records information about the relay logs. The default name is `relay-log.info` in the data directory.

- `rpl_recovery_rank`

  This variable is unused, and is removed in MySQL 5.6.

- `slave_compressed_protocol`
### Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--slave_compressed_protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>System Variable</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Name</strong></td>
<td>slave_compressed_protocol</td>
</tr>
<tr>
<td><strong>Variable</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>Variable</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>boolean</td>
</tr>
<tr>
<td><strong>Default</strong></td>
<td>OFF</td>
</tr>
</tbody>
</table>

Whether to use compression of the slave/master protocol if both the slave and the master support it.

- **slave_load_tmpdir**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--slave-load-tmpdir=dir_name</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>System Variable</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Name</strong></td>
<td>slave_load_tmpdir</td>
</tr>
<tr>
<td><strong>Variable</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Variable</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>directory name</td>
</tr>
<tr>
<td><strong>Default</strong></td>
<td>/tmp</td>
</tr>
</tbody>
</table>

The name of the directory where the slave creates temporary files for replicating LOAD DATA INFILE statements.

- **slave_net_timeout**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--slave-net-timeout=#</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>System Variable</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Name</strong></td>
<td>slave_net_timeout</td>
</tr>
<tr>
<td><strong>Variable</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>Variable</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>integer</td>
</tr>
<tr>
<td><strong>Default</strong></td>
<td>3600</td>
</tr>
<tr>
<td><strong>Min Value</strong></td>
<td>1</td>
</tr>
</tbody>
</table>

The number of seconds to wait for more data from a master/slave connection before aborting the read. This timeout applies only to TCP/IP connections, not to connections made using Unix socket files, named pipes, or shared memory.

- **slave_skip_errors**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--slave-skip-errors=name</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>System Variable</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Name</strong></td>
<td>slave_skip_errors</td>
</tr>
<tr>
<td><strong>Variable</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Dynamic</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Variable</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td></td>
</tr>
</tbody>
</table>
Normally, replication stops when an error occurs on the slave. This gives you the opportunity to resolve the inconsistency in the data manually. This variable tells the slave SQL thread to continue replication when a statement returns any of the errors listed in the variable value.

- **slave_transaction_retries**

  **Introduced** 5.0.3

  **Command-Line Format** --slave_transaction_retries=#

  **System Variable**
  - **Name**: slave_transaction_retries
  - **Variable**: Global
  - **Scope**: Dynamic
  - **Variable**: Yes

  **Permitted Values** (32-bit platforms)
  - **Type**: integer
  - **Default**: 10
  - **Min Value**: 0
  - **Max Value**: 4294967295

  **Permitted Values** (64-bit platforms)
  - **Type**: integer
  - **Default**: 10
  - **Min Value**: 0
  - **Max Value**: 18446744073709547520

  If a replication slave SQL thread fails to execute a transaction because of an InnoDB deadlock or because the transaction’s execution time exceeded InnoDB’s innodb_lock_wait_timeout or NDBCLUSTER’s TransactionDeadlockDetectionTimeout or TransactionInactiveTimeout, it automatically retries slave_transaction_retries times before stopping with an error. Prior to MySQL 5.0.3, the default is 0, and you must explicitly set the value greater than 0 to enable the “retry” behavior. In MySQL 5.0.3 or newer, the default is 10.

- **sql_slave_skip_counter**

  **System Variable**
  - **Name**: sql_slave_skip_counter
  - **Variable**: Global
  - **Scope**: Dynamic
  - **Variable**: Yes

  **Permitted Values**
  - **Type**: integer

  The number of events from the master that a slave server should skip.
Important

If skipping the number of events specified by setting this variable would cause the slave to begin in the middle of an event group, the slave continues to skip until it finds the beginning of the next event group and begins from that point. For more information, see Section 13.4.2.6, “SET GLOBAL sql_slave_skip_counter Syntax”.

16.1.2.4 Binary Log Options and Variables

Startup Options Used with Binary Logging

System Variables Used with Binary Logging

You can use the `mysqld` options and system variables that are described in this section to affect the operation of the binary log as well as to control which statements are written to the binary log. For additional information about the binary log, see Section 5.4.3, “The Binary Log”. For additional information about using MySQL server options and system variables, see Section 5.1.3, “Server Command Options”, and Section 5.1.4, “Server System Variables”.

Startup Options Used with Binary Logging

The following list describes startup options for enabling and configuring the binary log. System variables used with binary logging are discussed later in this section.

- `--log-bin [=base_name]`

  **Command-Line Format**
  
  `--log-bin`

  **System Variable**
  
  Name `log_bin`
  
  **Variable**
  
  Global
  
  **Scope**
  
  Dynamic
  
  **Variable**
  
  Yes

  **Permitted Values**
  
  **Type**
  
  file name

  Enable binary logging. The server logs all statements that change data to the binary log, which is used for backup and replication. See Section 5.4.3, “The Binary Log”.

  The option value, if given, is the base name for the log sequence. The server creates binary log files in sequence by adding a numeric suffix to the base name. It is recommended that you specify a base name (see Section B.5.7, “Known Issues in MySQL”, for the reason). Otherwise, MySQL uses `host_name-bin` as the base name.

  Setting this option causes the `log_bin` system variable to be set to `ON` (or `1`), and not to the base name. This is a known issue; see Bug #19614 for more information.

- `--log-bin-index= [file_name]`

  **Command-Line Format**
  
  `--log-bin-index= file_name`

  **Permitted Values**
  
  **Type**
  
  file name

  The index file for binary log file names. See Section 5.4.3, “The Binary Log”. If you omit the file name, and if you did not specify one with `--log-bin`, MySQL uses `host_name-bin.index` as the file name.

- `--log-bin-trust-function-creators=[{0|1}]`

  **Introduced**
  
  5.0.16
Replication and Binary Logging Options and Variables

Command-Line Format

--log-bin-trust-function-creators

System Variable

Name log_bin_trust_function_creators
Variable Global
Scope Dynamic
Variable

Permitted Values

Type boolean
Default FALSE

This option sets the corresponding log_bin_trust_function_creators system variable. If no argument is given, the option sets the variable to 1. log_bin_trust_function_creators affects how MySQL enforces restrictions on stored function and trigger creation. See Section 18.6, "Binary Logging of Stored Programs".

This option was added in MySQL 5.0.16.

• --log-bin-trust-routine-creators[={0|1}]

Introduced 5.0.6
Deprecated 5.0.16
Command-Line Format --log-bin-trust-routine-creators

System Variable

Name log_bin_trust_routine_creators
Variable Global
Scope Dynamic
Variable

Permitted Values

Type boolean
Default FALSE

This is the old name for --log-bin-trust-function-creators. Before MySQL 5.0.16, it also applies to stored procedures, not just stored functions and sets the log_bin_trust_routine_creators system variable. As of 5.0.16, this option is deprecated. It is recognized for backward compatibility but its use results in a warning.

This option was added in MySQL 5.0.6.

Statement selection options. The options in the following list affect which statements are written to the binary log, and thus sent by a replication master server to its slaves. There are also options for slave servers that control which statements received from the master should be executed or ignored. For details, see Section 16.1.2.3, "Replication Slave Options and Variables".

• --binlog-do-db=db_name

Command-Line Format --binlog-do-db=name

Permitted Values

Type string

This option affects binary logging in a manner similar to the way that --replicate-do-db affects replication.

Tell the server to restrict binary logging to updates for which the default database is db_name (that is, the database selected by USE). All other databases that are not explicitly mentioned are ignored. If you use this option, you should ensure that you do updates only in the default database.
There is an exception to this for `CREATE DATABASE`, `ALTER DATABASE`, and `DROP DATABASE` statements. The server uses the database named in the statement (not the default database) to decide whether it should log the statement.

An example of what does not work as you might expect: If the server is started with `--binlog-do-db=sales` and you issue the following statements, the `UPDATE` statement is not logged:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this “just check the default database” behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` statements or multiple-table `UPDATE` statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

Another case which may not be self-evident occurs when a given database is replicated even though it was not specified when setting the option. If the server is started with `--binlog-do-db=sales`, the following `UPDATE` statement is logged even though `prices` was not included when setting `--binlog-do-db`:

```
USE sales;
UPDATE prices.discounts SET percentage = percentage + 10;
```

Because `sales` is the default database when the `UPDATE` statement is issued, the `UPDATE` is logged.

**Important**

To log multiple databases, use this option multiple times, specifying the option once for each database to be logged. Because database names can contain commas, the list will be treated as the name of a single database if you supply a comma-separated list.

- `--binlog-ignore-db=db_name`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--binlog-ignore-db=name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>Type</td>
</tr>
</tbody>
</table>

This option affects binary logging in a manner similar to the way that `--replicate-ignore-db` affects replication.

Tell the server to suppress binary logging of updates for which the default database is `db_name` (that is, the database selected by `USE`). If you use this option, you should ensure that you do updates only in the default database.

As with the `--binlog-do-db` option, there is an exception for the `CREATE DATABASE`, `ALTER DATABASE`, and `DROP DATABASE` statements. The server uses the database named in the statement (not the default database) to decide whether it should log the statement.

An example of what does not work as you might expect: If the server is started with `binlog-ignore-db=sales`, and you run `USE prices; UPDATE sales.january SET amount = amount + 1000;`, this statement is written into the binary log.

**Important**

To ignore multiple databases, use this option multiple times, specifying the option once for each database to be ignored. Because database names can
Testing and debugging options. The following binary log options are used in replication testing and debugging. They are not intended for use in normal operations.

- **--max-binlog-dump-events=N**

  **Command-Line Format**  
  --max-binlog-dump-events=\#  

  **Permitted Values**  
  Type integer  
  Default 0

  This option is used internally by the MySQL test suite for replication testing and debugging.

- **--sporadic-binlog-dump-fail**

  **Command-Line Format**  
  --sporadic-binlog-dump-fail  

  **Permitted Values**  
  Type boolean  
  Default FALSE

  This option is used internally by the MySQL test suite for replication testing and debugging.

System Variables Used with Binary Logging

The following list describes system variables for controlling binary logging. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used to control binary logging are listed earlier in this section. For information about the `sql_log_bin` and `sql_log_off` variables, see Section 5.1.4, “Server System Variables”.

- **log_bin**

  **System Variable**  
  Name  
  Variable log_bin  
  Scope Global  
  DynamicNo  
  Variable

  Whether the binary log is enabled. If the `--log-bin` option is used, then the value of this variable is ON; otherwise it is OFF. This variable reports only on the status of binary logging (enabled or disabled); it does not actually report the value to which `--log-bin` is set.

  See Section 5.4.3, “The Binary Log”.

- **log_slave_updates**

  **Command-Line Format**  
  --log-slave-updates  

  **Permitted Values**  
  Type boolean  
  Default FALSE
Whether updates received by a slave server from a master server should be logged to the slave's own binary log. Binary logging must be enabled on the slave for this variable to have any effect. See Section 16.1.2.3, “Replication Slave Options and Variables”.

- **max_binlog_cache_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max_binlog_cache_size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name max_binlog_cache_size</td>
</tr>
<tr>
<td></td>
<td>Variable Global</td>
</tr>
<tr>
<td></td>
<td>DynamicYes Variable</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type integer</td>
</tr>
<tr>
<td>(32-bit platforms)</td>
<td>Default 4294967295</td>
</tr>
<tr>
<td></td>
<td>Min Value 4096</td>
</tr>
<tr>
<td></td>
<td>Max Value 4294967295</td>
</tr>
<tr>
<td></td>
<td>Permitted Values (64-bit</td>
</tr>
<tr>
<td></td>
<td>platforms) Type integer</td>
</tr>
<tr>
<td></td>
<td>Default 18446744073709547520</td>
</tr>
<tr>
<td></td>
<td>Min Value  4096</td>
</tr>
<tr>
<td></td>
<td>Max Value 18446744073709547520</td>
</tr>
</tbody>
</table>

If a multiple-statement transaction requires more than this many bytes of memory, the server generates a Multi-statement transaction required more than 'max_binlog_cache_size' bytes of storage error. The minimum value is 4096. The maximum and default values are 4GB on 32-bit platforms and 16EB (exabytes) on 64-bit platforms. The maximum recommended value on 64-bit platforms is 4GB; this is due to the fact that MySQL currently cannot work with binary log positions greater than 4GB.

In MySQL 5.0, a change in max_binlog_cache_size takes immediate effect for all active sessions.

- **max_binlog_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max_binlog_size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name max_binlog_size</td>
</tr>
<tr>
<td></td>
<td>Variable Global</td>
</tr>
<tr>
<td></td>
<td>DynamicYes Variable</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type integer</td>
</tr>
<tr>
<td></td>
<td>Default 1073741824</td>
</tr>
<tr>
<td></td>
<td>Min Value 4096</td>
</tr>
<tr>
<td></td>
<td>Max Value 1073741824</td>
</tr>
</tbody>
</table>
If a write to the binary log causes the current log file size to exceed the value of this variable, the server rotates the binary logs (closes the current file and opens the next one). The minimum value is 4096 bytes. The maximum and default value is 1GB.

A transaction is written in one chunk to the binary log, so it is never split between several binary logs. Therefore, if you have big transactions, you might see binary log files larger than `max_binlog_size`.

If `max_relay_log_size` is 0, the value of `max_binlog_size` applies to relay logs as well.

- `sync_binlog`

| Introduced | 5.0.1 |
| Command-Line Format | `--sync-binlog=#` |
| System Variable | `sync_binlog` |
| Name | Global |
| Variable | Dynamic |
| Scope | Yes |
| | Type: integer |
| | Default: 0 |
| | Min Value: 0 |
| | Max Value: 4294967295 |

If the value of this variable is greater than 0, the MySQL server synchronizes its binary log to disk (using `fdatasync()`) after every `sync_binlog` writes to the binary log. There is one write to the binary log per statement if autocommit is enabled, and one write per transaction otherwise. The default value of `sync_binlog` is 0, which does no synchronizing to disk. A value of 1 is the safest choice because in the event of a crash you lose at most one statement or transaction from the binary log. However, it is also the slowest choice (unless the disk has a battery-backed cache, which makes synchronization very fast).

If the value of `sync_binlog` is 0 (the default), no extra flushing is done. The server relies on the operating system to flush the file contents occasionally as for any other file.

### 16.1.3 Common Replication Administration Tasks

Once replication has been started it should execute without requiring much regular administration. Depending on your replication environment, you will want to check the replication status of each slave periodically, daily, or even more frequently.

#### 16.1.3.1 Checking Replication Status

The most common task when managing a replication process is to ensure that replication is taking place and that there have been no errors between the slave and the master. The primary statement for this is `SHOW SLAVE STATUS`, which you must execute on each slave:
mysql> SHOW SLAVE STATUS\G
*************************** 1. row ***************************
Slave_IO_State: Waiting for master to send event
  Master_Host: master1
  Master_User: root
  Master_Port: 3306
  Connect_Retry: 60
  Master_Log_File: mysql-bin.000004
Read_Master_Log_Pos: 931
  Relay_Log_File: slave1-relay-bin.000056
  Relay_Log_Pos: 950
  Relay_Master_Log_File: mysql-bin.000004
Slave_IO_Running: Yes
Slave_SQL_Running: Yes
  Replicate_Do_DB: 
  Replicate_Ignore_DB: 
  Replicate_Do_Table: 
  Replicate_Ignore_Table: 
  Replicate_Wild_Do_Table: 
  Replicate_Wild_Ignore_Table: 
Last_Errno: 0
Last_Error: 
  Skip_Counter: 0
Exec_Master_Log_Pos: 931
  Relay_Log_Space: 1365
  Until_Condition: None
  Until_Log_File: 
  Until_Log_Pos: 0
  Master_SSL_Allowed: No
  Master_SSL_CA_File: 
  Master_SSL_CA_Path: 
  Master_SSL_Cert: 
  Master_SSL_Cipher: 
  Master_SSL_Key: 
Seconds_Behind_Master: 0

The key fields from the status report to examine are:

- **Slave_IO_State**: The current status of the slave. See Section 8.14.6, “Replication Slave I/O Thread States”, and Section 8.14.7, “Replication Slave SQL Thread States”, for more information.

- **Slave_IO_Running**: Whether the I/O thread for reading the master’s binary log is running. Normally, you want this to be Yes unless you have not yet started replication or have explicitly stopped it with STOP SLAVE.

- **Slave_SQL_Running**: Whether the SQL thread for executing events in the relay log is running. As with the I/O thread, this should normally be Yes.

- **Last_Error**: The last error registered when processing the relay log. Ideally this should be blank, indicating no error.

- **Seconds_Behind_Master**: The number of seconds that the slave SQL thread is behind processing the master binary log. A high number (or an increasing one) can indicate that the slave is unable to handle events from the master in a timely fashion.

A value of 0 for Seconds_Behind_Master can usually be interpreted as meaning that the slave has caught up with the master, but there are some cases where this is not strictly true. For example, this can occur if the network connection between master and slave is broken but the slave I/O thread has not yet noticed this—that is, slave_net_timeout has not yet elapsed.

It is also possible that transient values for Seconds_Behind_Master may not reflect the situation accurately. When the slave SQL thread has caught up on I/O, Seconds_Behind_Master displays 0; but when the slave I/O thread is still queuing up a new event, Seconds_Behind_Master may show a large value until the SQL thread finishes executing the new event. This is especially likely when the events have old timestamps; in such cases, if you execute SHOW SLAVE STATUS several
times in a relatively short period, you may see this value change back and forth repeatedly between 0 and a relatively large value.

Several pairs of fields provide information about the progress of the slave in reading events from the master binary log and processing them in the relay log:

- \( \text{Master(Log_file, Read_Master_Log_Pos)} \): Coordinates in the master binary log indicating how far the slave I/O thread has read events from that log.
- \( \text{Relay_Master_Log_File, Exec_Master_Log_Pos} \): Coordinates in the master binary log indicating how far the slave SQL thread has executed events received from that log.
- \( \text{Relay_Log_File, Relay_Log_Pos} \): Coordinates in the slave relay log indicating how far the slave SQL thread has executed the relay log. These correspond to the preceding coordinates, but are expressed in slave relay log coordinates rather than master binary log coordinates.

On the master, you can check the status of connected slaves using `SHOW PROCESSLIST` to examine the list of running processes. Slave connections have `Binlog Dump` in the `Command` field:

```sql
mysql> SHOW PROCESSLIST \G;
*************************** 4. row ***************************
    Id: 10
  User: root
     Host: slave1:58371
db: NULL  
Command: Binlog Dump
 Time: 777
   State: Has sent all binlog to slave; waiting for binlog to be updated
  Info: NULL
```

Because it is the slave that drives the replication process, very little information is available in this report.

For slaves that were started with the `--report-host` option and are connected to the master, the `SHOW SLAVE HOSTS` statement on the master shows basic information about the slaves. The output includes the ID of the slave server, the value of the `--report-host` option, the connecting port, and master ID:

```sql
mysql> SHOW SLAVE HOSTS;
+-----------+--------+-----+-------------------+-----------+
| Server_id | Host   | Port | Rpl_recovery_rank | Master_id |
|-----------+--------+-----+-------------------+-----------|
|          10 | slave1 | 3306 |                 0 |         1 |
+-----------+--------+-----+-------------------+-----------+
1 row in set (0.00 sec)
```

### 16.1.3.2 Pausing Replication on the Slave

You can stop and start the replication of statements on the slave using the `STOP SLAVE` and `START SLAVE` statements.

To stop processing of the binary log from the master, use `STOP SLAVE`:

```sql
mysql> STOP SLAVE;
```

When replication is stopped, the slave I/O thread stops reading events from the master binary log and writing them to the relay log, and the SQL thread stops reading events from the relay log and executing them. You can pause the I/O or SQL thread individually by specifying the thread type:

```sql
mysql> STOP SLAVE IO_THREAD;
mysql> STOP SLAVE SQL_THREAD;
```
To start execution again, use the `START SLAVE` statement:

```sql
mysql> START SLAVE;
```

To start a particular thread, specify the thread type:

```sql
mysql> START SLAVE IO_THREAD;
mysql> START SLAVE SQL_THREAD;
```

For a slave that performs updates only by processing events from the master, stopping only the SQL thread can be useful if you want to perform a backup or other task. The I/O thread will continue to read events from the master but they are not executed. This makes it easier for the slave to catch up when you restart the SQL thread.

Stopping only the I/O thread enables the events in the relay log to be executed by the SQL thread up to the point where the relay log ends. This can be useful when you want to pause execution to catch up with events already received from the master, when you want to perform administration on the slave but also ensure that it has processed all updates to a specific point. This method can also be used to pause event receipt on the slave while you conduct administration on the master. Stopping the I/O thread but permitting the SQL thread to run helps ensure that there is not a massive backlog of events to be executed when replication is started again.

### 16.2 Replication Implementation

Replication is based on the master server keeping track of all changes to its databases (updates, deletes, and so on) in its binary log. The binary log serves as a written record of all events that modify database structure or content (data) from the moment the server was started. Typically, `SELECT` statements are not recorded because they modify neither database structure nor content.

Each slave that connects to the master requests a copy of the binary log. That is, it pulls the data from the master, rather than the master pushing the data to the slave. The slave also executes the events from the binary log that it receives. This has the effect of repeating the original changes just as they were made on the master. Tables are created or their structure modified, and data is inserted, deleted, and updated according to the changes that were originally made on the master.

Because each slave is independent, the replaying of the changes from the master's binary log occurs independently on each slave that is connected to the master. In addition, because each slave receives a copy of the binary log only by requesting it from the master, the slave is able to read and update the copy of the database at its own pace and can start and stop the replication process at will without affecting the ability to update to the latest database status on either the master or slave side.

For more information on the specifics of the replication implementation, see Section 16.2.1, “Replication Implementation Details”.

Masters and slaves report their status in respect of the replication process regularly so that you can monitor them. See Section 8.14, “Examining Thread Information”, for descriptions of all replicated-related states.

The master binary log is written to a local relay log on the slave before it is processed. The slave also records information about the current position with the master's binary log and the local relay log. See Section 16.2.2, “Replication Relay and Status Logs”.

Database changes are filtered on the slave according to a set of rules that are applied according to the various configuration options and variables that control event evaluation. For details on how these rules are applied, see Section 16.2.3, “How Servers Evaluate Replication Filtering Rules”.

### 16.2.1 Replication Implementation Details

MySQL replication capabilities are implemented using three threads, one on the master server and two on the slave:
• **Binlog dump thread.**  The master creates a thread to send the binary log contents to a slave when the slave connects. This thread can be identified in the output of `SHOW PROCESSLIST` on the master as the Binlog Dump thread.

The binary log dump thread acquires a lock on the master's binary log for reading each event that is to be sent to the slave. As soon as the event has been read, the lock is released, even before the event is sent to the slave.

• **Slave I/O thread.**  When a `START SLAVE` statement is issued on a slave server, the slave creates an I/O thread, which connects to the master and asks it to send the updates recorded in its binary logs.

The slave I/O thread reads the updates that the master's Binlog Dump thread sends (see previous item) and copies them to local files that comprise the slave's relay log.

The state of this thread is shown as Slave_IO_running in the output of `SHOW SLAVE STATUS` or as Slave_running in the output of `SHOW STATUS`.

• **Slave SQL thread.**  The slave creates an SQL thread to read the relay log that is written by the slave I/O thread and execute the events contained therein.

In the preceding description, there are three threads per master/slave connection. A master that has multiple slaves creates one binary log dump thread for each currently connected slave, and each slave has its own I/O and SQL threads.

A slave uses two threads to separate reading updates from the master and executing them into independent tasks. Thus, the task of reading statements is not slowed down if statement execution is slow. For example, if the slave server has not been running for a while, its I/O thread can quickly fetch all the binary log contents from the master when the slave starts, even if the SQL thread lags far behind. If the slave stops before the SQL thread has executed all the fetched statements, the I/O thread has at least fetched everything so that a safe copy of the statements is stored locally in the slave's relay logs, ready for execution the next time that the slave starts. This enables the master server to purge its binary logs sooner because it no longer needs to wait for the slave to fetch their contents.

The `SHOW PROCESSLIST` statement provides information that tells you what is happening on the master and on the slave regarding replication. For information on master states, see Section 8.14.5, “Replication Master Thread States”. For slave states, see Section 8.14.6, “Replication Slave I/O Thread States”, and Section 8.14.7, “Replication Slave SQL Thread States”.

The following example illustrates how the three threads show up in the output from `SHOW PROCESSLIST`.

On the master server, the output from `SHOW PROCESSLIST` looks like this:

```
mysql> SHOW PROCESSLIST\G
*************************** 1. row ***************************
    Id: 2
    User: root
    Host: localhost:32931
db: NULL
Command: Binlog Dump
    Time: 94
    State: Has sent all binlog to slave; waiting for binlog to be updated
    Info: NULL
```

Here, thread 2 is a Binlog Dump replication thread that services a connected slave. The State information indicates that all outstanding updates have been sent to the slave and that the master is waiting for more updates to occur. If you see no Binlog Dump threads on a master server, this means that replication is not running; that is, no slaves are currently connected.
On a slave server, the output from `SHOW PROCESSLIST` looks like this:

```sql
mysql> SHOW PROCESSLIST\G
*************************** 1. row ***************************
  Id: 10
  User: system user
  Host: 
  db: NULL
Command: Connect
  Time: 11
  State: Waiting for master to send event
  Info: NULL
*************************** 2. row ***************************
  Id: 11
  User: system user
  Host: 
  db: NULL
Command: Connect
  Time: 11
  State: Has read all relay log; waiting for the slave I/O thread to update it
  Info: NULL
```

The `State` information indicates that thread 10 is the I/O thread that is communicating with the master server, and thread 11 is the SQL thread that is processing the updates stored in the relay logs. At the time that `SHOW PROCESSLIST` was run, both threads were idle, waiting for further updates.

The value in the `Time` column can show how late the slave is compared to the master. See Section A.13, “MySQL 5.0 FAQ: Replication”. If sufficient time elapses on the master side without activity on the `Binlog Dump` thread, the master determines that the slave is no longer connected. As for any other client connection, the timeouts for this depend on the values of `net_write_timeout` and `net_retries_count`; for more information about these, see Section 5.1.4, “Server System Variables”.

The `SHOW SLAVE STATUS` statement provides additional information about replication processing on a slave server. See Section 16.1.3.1, “Checking Replication Status”.

### 16.2.2 Replication Relay and Status Logs

During replication, a slave server creates several logs that hold the binary log events relayed from the master to the slave, and to record information about the current status and location within the relay log. There are three types of logs used in the process, listed here:

- The **relay log** consists of the events read from the binary log of the master and written by the slave I/O thread. Events in the relay log are executed on the slave as part of the SQL thread.

- The **master info log** contains status and current configuration information for the slave’s connection to the master. This log holds information on the master host name, login credentials, and coordinates indicating how far the slave has read from the master’s binary log.

- The **relay log info log** holds status information about the execution point within the slave’s relay log.

#### 16.2.2.1 The Slave Relay Log

The relay log, like the binary log, consists of a set of numbered files containing events that describe database changes, and an index file that contains the names of all used relay log files.

The term “relay log file” generally denotes an individual numbered file containing database events. The term “relay log” collectively denotes the set of numbered relay log files plus the index file.

Relay log files have the same format as binary log files and can be read using `mysqlbinlog` (see Section 4.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”).

This documentation is for an older version. If you're looking for the latest version, please visit the official MySQL documentation site.
By default, relay log file names have the form `host_name-relay-bin.nnnnnn` in the data directory, where `host_name` is the name of the slave server host and `nnnnnn` is a sequence number. Successive relay log files are created using successive sequence numbers, beginning with `000001`. The slave uses an index file to track the relay log files currently in use. The default relay log index file name is `host_name-relay-bin.index` in the data directory.

The default relay log file and relay log index file names can be overridden with, respectively, the `--relay-log` and `--relay-log-index` server options (see Section 16.1.2, "Replication and Binary Logging Options and Variables").

If a slave uses the default host-based relay log file names, changing a slave’s host name after replication has been set up can cause replication to fail with the errors `Failed to open the relay log` and `Could not find target log during relay log initialization`. This is a known issue (see Bug #2122). If you anticipate that a slave’s host name might change in the future (for example, if networking is set up on the slave such that its host name can be modified using DHCP), you can avoid this issue entirely by using the `--relay-log` and `--relay-log-index` options to specify relay log file names explicitly when you initially set up the slave. This will make the names independent of server host name changes.

If you encounter the issue after replication has already begun, one way to work around it is to stop the slave server, prepend the contents of the old relay log index file to the new one, and then restart the slave. On a Unix system, this can be done as shown here:

```
shell> cat new_relay_log_name.index >> old_relay_log_name.index
shell> mv old_relay_log_name.index new_relay_log_name.index
```

A slave server creates a new relay log file under the following conditions:

- Each time the I/O thread starts.
- When the logs are flushed; for example, with `FLUSH LOGS` or `mysqladmin flush-logs`.
- When the size of the current relay log file becomes “too large,” determined as follows:
  - If the value of `max_relay_log_size` is greater than 0, that is the maximum relay log file size.
  - If the value of `max_relay_log_size` is 0, `max_binlog_size` determines the maximum relay log file size.

The SQL thread automatically deletes each relay log file as soon as it has executed all events in the file and no longer needs it. There is no explicit mechanism for deleting relay logs because the SQL thread takes care of doing so. However, `FLUSH LOGS` rotates relay logs, which influences when the SQL thread deletes them.

**16.2.2 Slave Status Logs**

A replication slave server creates two logs. By default, these logs are files named `master.info` and `relay-log.info` and created in the data directory. The names and locations of these files can be changed by using the `--master-info-file` and `--relay-log-info-file` options, respectively. See Section 16.1.2, “Replication and Binary Logging Options and Variables”.

The two status logs contain information like that shown in the output of the `SHOW SLAVE STATUS` statement, which is discussed in Section 13.4.2, “SQL Statements for Controlling Slave Servers”. Because the status logs are stored on disk, they survive a slave server’s shutdown. The next time the slave starts up, it reads the two logs to determine how far it has proceeded in reading binary logs from the master and in processing its own relay logs.

The master info log should be protected because it contains the password for connecting to the master. See Section 6.1.2.3, “Passwords and Logging”.

---

This documentation is for an older version. If you’re using the most current version, select the documentation for that version with the version switch in the upper right corner of the online documentation, or by downloading a newer PDF or EPUB file.
The slave I/O thread updates the master info log. The following table shows the correspondence between the lines in the `master.info` file and the columns displayed by `SHOW SLAVE STATUS`.

<table>
<thead>
<tr>
<th>Line in <code>master.info</code></th>

<td>The list of possible ciphers used in the handshake for the SSL connection</td>
</tr>
<tr>
<td>14</td>
<td><code>Master_SSL_Key</code></td>
<td>The name of the SSL key file</td>
</tr>
</tbody>
</table>

The slave SQL thread updates the relay log info log. The following table shows the correspondence between the lines in the `relay-log.info` file and the columns displayed by `SHOW SLAVE STATUS`.

<table>
<thead>
<tr>
<th>Line in <code>relay-log.info</code></th>
<th><code>SHOW SLAVE STATUS</code> Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td><code>Relay_Log_File</code></td>
<td>The name of the current relay log file</td>
</tr>
<tr>
<td>2</td>
<td><code>Relay_Log_Pos</code></td>
<td>The current position within the relay log file; events up to this position have been executed on the slave database</td>
</tr>
<tr>
<td>3</td>
<td><code>Relay_Master_Log_File</code></td>
<td>The name of the master binary log file from which the events in the relay log file were read</td>
</tr>
<tr>
<td>4</td>
<td><code>Exec_Master_Log_Pos</code></td>
<td>The equivalent position within the master’s binary log file of events that have already been executed</td>
</tr>
</tbody>
</table>

The contents of the `relay-log.info` file and the states shown by the `SHOW SLAVE STATUS` statement might not match if the `relay-log.info` file has not been flushed to disk. Ideally, you should only view `relay-log.info` on a slave that is offline (that is, `mysql` is not running). For a running system, `SHOW SLAVE STATUS` should be used.

When you back up the slave’s data, you should back up these two status logs, along with the relay log files. The status logs are needed to resume replication after you restore the data from the slave.
If you lose the relay logs but still have the relay log info log, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use CHANGE MASTER TO with the MASTER_LOG_FILE and MASTER_LOG_POS options to tell the slave to re-read the binary logs from that point. Of course, this requires that the binary logs still exist on the master.

### 16.2.3 How Servers Evaluate Replication Filtering Rules

If a master server does not write a statement to its binary log, the statement is not replicated. If the server does log the statement, the statement is sent to all slaves and each slave determines whether to execute it or ignore it.

On the master, you can control which databases to log changes for by using the `--binlog-do-db` and `--binlog-ignore-db` options to control binary logging. For a description of the rules that servers use in evaluating these options, see Section 16.2.3.1, “Evaluation of Database-Level Replication and Binary Logging Options”. You should not use these options to control which databases and tables are replicated. Instead, use filtering on the slave to control the events that are executed on the slave.

On the slave side, decisions about whether to execute or ignore statements received from the master are made according to the `--replicate-*` options that the slave was started with. (See Section 16.1.2, “Replication and Binary Logging Options and Variables”.)

In the simplest case, when there are no `--replicate-*` options, the slave executes all statements that it receives from the master. Otherwise, the result depends on the particular options given.

**Database-level options** (`--replicate-do-db, --replicate-ignore-db`) are checked first; see Section 16.2.3.1, “Evaluation of Database-Level Replication and Binary Logging Options”, for a description of this process. If no database-level options are used, option checking proceeds to any table-level options that may be in use (see Section 16.2.3.2, “Evaluation of Table-Level Replication Options”, for a discussion of these). If one or more database-level options are used but none are matched, the statement is not replicated.

To make it easier to determine what effect an option set will have, it is recommended that you avoid mixing “do” and “ignore” options, or wildcard and nonwildcard options. An example of the latter that may have unintended effects is the use of `--replicate-do-db` and `--replicate-wild-do-table` together, where `--replicate-wild-do-table` uses a pattern for the database name that matches the name given for `--replicate-do-db`. Suppose a replication slave is started with `--replicate-do-db=dbx --replicate-wild-do-table=db%.t1`. Then, suppose that on the master, you issue the statement `CREATE DATABASE dbx`. Although you might expect it, this statement is not replicated because it does not reference a table named `t1`.

If any `--replicate-rewrite-db` options were specified, they are applied before the `--replicate-*` filtering rules are tested.

**Note**

Database-level filtering options are case-sensitive on platforms supporting case sensitivity in filenames, whereas table-level filtering options are not (regardless of platform). This is true regardless of the value of the `lower_case_table_names` system variable.

### 16.2.3.1 Evaluation of Database-Level Replication and Binary Logging Options

When evaluating replication options, the slave begins by checking to see whether there are any `--replicate-do-db` or `--replicate-ignore-db` options that apply. When using `--binlog-do-db` or `--binlog-ignore-db`, the process is similar, but the options are checked on the master.

Checking of the database-level options proceeds as shown in the following diagram.
The steps involved are listed here:

1. **Are there any** `--replicate-do-db` **options?**
   - **Yes.** Do any of them match the database?
     - **Yes.** Execute the statement and exit.
     - **No.** Ignore the statement and exit.
   - **No.** Continue to step 2.

2. **Are there any** `--replicate-ignore-db` **options?**
   - **Yes.** Do any of them match the database?
     - **Yes.** Ignore the statement and exit.
     - **No.** Continue to step 3.
   - **No.** Continue to step 3.

3. Proceed to checking the table-level replication options, if there are any. For a description of how these options are checked, see Section 16.2.3.2, “Evaluation of Table-Level Replication Options”.

---

**Important**

A statement that is still permitted at this stage is not yet actually executed. The statement is not executed until all table-level options (if any) have also
been checked, and the outcome of that process permits execution of the statement.

For binary logging, the steps involved are listed here:

1. Are there any `--binlog-do-db` or `--binlog-ignore-db` options?
   - **Yes.** Continue to step 2.
   - **No.** Log the statement and exit.

2. Is there a default database (has any database been selected by `USE`)?
   - **Yes.** Continue to step 3.
   - **No.** Ignore the statement and exit.

3. There is a default database. Are there any `--binlog-do-db` options?
   - **Yes.** Do any of them match the database?
     - **Yes.** Log the statement and exit.
     - **No.** Ignore the statement and exit.
   - **No.** Continue to step 4.

4. Do any of the `--binlog-ignore-db` options match the database?
   - **Yes.** Ignore the statement and exit.
   - **No.** Log the statement and exit.

---

**Important**

An exception is made in the rules just given for the `CREATE_DATABASE`, `ALTER_DATABASE`, and `DROP_DATABASE` statements. In those cases, the database being `created`, `altered`, or `dropped` replaces the default database when determining whether to log or to ignore updates.

`--binlog-do-db` can sometimes mean "ignore other databases". For example, a server running with only `--binlog-do-db=sales` does not write to the binary log statements for which the default database differs from `sales`.

Relay log files have the same format as binary log files and can be read using `mysqlbinlog`.

---

### 16.2.3.2 Evaluation of Table-Level Replication Options

The slave checks for and evaluates table options only if either of the following two conditions is true:

- No matching database options were found.
- One or more database options were found, and were evaluated to arrive at an “execute” condition according to the rules described in the previous section (see Section 16.2.3.1, “Evaluation of Database-Level Replication and Binary Logging Options”).

First, as a preliminary condition, the slave checks whether the statement occurs within a stored function, in which case the slave executes the statement and exits.

Having reached this point, if there are no table options, the slave simply executes all statements. If there are any `--replicate-do-table` or `--replicate-wild-do-table` options, the statement
must match one of these if it is to be executed; otherwise, it is ignored. If there are any `--replicate-ignore-table` or `--replicate-wild-ignore-table` options, all statements are executed except those that match any of these options. This process is illustrated in the following diagram.

The `master.info` file should be protected because it contains the password for connecting to the master. See Section 6.1.2.3, “Passwords and Logging”.

The following steps describe this evaluation in more detail:
1. Are there any table options?
   - Yes. Continue to step 2.
   - No. Execute the statement and exit.

2. Are there any `--replicate-do-table` options?
   - Yes. Does the table match any of them?
     - Yes. Execute the statement and exit.
     - No. Continue to step 3.
   - No. Continue to step 3.

3. Are there any `--replicate-ignore-table` options?
   - Yes. Does the table match any of them?
     - Yes. Ignore the statement and exit.
     - No. Continue to step 4.
   - No. Continue to step 4.

4. Are there any `--replicate-wild-do-table` options?
   - Yes. Does the table match any of them?
     - Yes. Execute the statement and exit.
     - No. Continue to step 5.
   - No. Continue to step 5.

5. Are there any `--replicate-wild-ignore-table` options?
   - Yes. Does the table match any of them?
     - Yes. Ignore the statement and exit.
     - No. Continue to step 6.
   - No. Continue to step 6.

6. Are there any `--replicate-do-table` or `--replicate-wild-do-table` options?
   - Yes. Ignore the statement and exit.
   - No. Execute the statement and exit.

### 16.2.3.3 Replication Rule Application

This section provides additional explanation and examples of usage for different combinations of replication filtering options.

Some typical combinations of replication filter rule types are given in the following table:

<table>
<thead>
<tr>
<th>Condition (Types of Options)</th>
<th>Outcome</th>
</tr>
</thead>
<tbody>
<tr>
<td>No <code>--replicate-*</code> options at all:</td>
<td>The slave executes all events that it receives from the master.</td>
</tr>
</tbody>
</table>
Condition (Types of Options) | Outcome
--- | ---
--replicate-*-db options, but no table options: | The slave accepts or ignores statements using the database options. It executes all statements permitted by those options because there are no table restrictions.

--replicate-*-table options, but no database options: | All statements are accepted at the database-checking stage because there are no database conditions. The slave executes or ignores statements based solely on the table options.

A combination of database and table options: | The slave accepts or ignores statements using the database options. Then it evaluates all statements permitted by those options according to the table options. This can sometimes lead to results that seem counterintuitive; see the text for an example.

A more complex example follows.

Suppose that we have two tables `mytbl1` in database `db1` and `mytbl2` in database `db2` on the master, and the slave is running with the following options (and no other replication filtering options):

```plaintext
replicate-ignore-db = db1
replicate-do-table  = db2.tbl2
```

Now we execute the following statements on the master:

```plaintext
USE db1;
INSERT INTO db2.tbl2 VALUES (1);
```

The outcome may not match initial expectations, because the `USE` statement causes `db1` to be the default database. Thus the `--replicate-ignore-db` option matches, which causes the `INSERT` statement to be ignored. Because there was a match with a database-level option, the table options are not checked; processing immediately moves to the next statement executed on the master.

### 16.3 Replication Solutions

Replication can be used in many different environments for a range of purposes. This section provides general notes and advice on using replication for specific solution types.

For information on using replication in a backup environment, including notes on the setup, backup procedure, and files to back up, see Section 16.3.1, “Using Replication for Backups”.

For advice and tips on using different storage engines on the master and slaves, see Section 16.3.2, “Using Replication with Different Master and Slave Storage Engines”.

Using replication as a scale-out solution requires some changes in the logic and operation of applications that use the solution. See Section 16.3.3, “Using Replication for Scale-Out”.

For performance or data distribution reasons, you may want to replicate different databases to different replication slaves. See Section 16.3.4, “Replicating Different Databases to Different Slaves”.

As the number of replication slaves increases, the load on the master can increase and lead to reduced performance (because of the need to replicate the binary log to each slave). For tips on improving your replication performance, including using a single secondary server as a replication master, see Section 16.3.5, “Improving Replication Performance”.

For guidance on switching masters, or converting slaves into masters as part of an emergency failover solution, see Section 16.3.6, “Switching Masters During Failover”.
To secure your replication communication, you can encrypt the communication channel. For step-by-step instructions, see Section 16.3.7, "Setting Up Replication to Use Secure Connections".

### 16.3.1 Using Replication for Backups

To use replication as a backup solution, replicate data from the master to a slave, and then back up the data slave. The slave can be paused and shut down without affecting the running operation of the master, so you can produce an effective snapshot of "live" data that would otherwise require the master to be shut down.

How you back up a database depends on its size and whether you are backing up only the data, or the data and the replication slave state so that you can rebuild the slave in the event of failure. There are therefore two choices:

- If you are using replication as a solution to enable you to back up the data on the master, and the size of your database is not too large, the `mysql` tool may be suitable. See Section 16.3.1.1, "Backing Up a Slave Using mysqldump".

- For larger databases, where `mysql` would be impractical or inefficient, you can back up the raw data files instead. Using the raw data files option also means that you can back up the binary and relay logs that will enable you to recreate the slave in the event of a slave failure. For more information, see Section 16.3.1.2, "Backing Up Raw Data from a Slave".

#### 16.3.1.1 Backing Up a Slave Using mysqldump

Using `mysqldump` to create a copy of a database enables you to capture all of the data in the database in a format that enables the information to be imported into another instance of MySQL Server (see Section 4.5.4, "mysqldump — A Database Backup Program"). Because the format of the information is SQL statements, the file can easily be distributed and applied to running servers in the event that you need access to the data in an emergency. However, if the size of your data set is very large, `mysqldump` may be impractical.

When using `mysqldump`, you should stop replication on the slave before starting the dump process to ensure that the dump contains a consistent set of data:

1. Stop the slave from processing requests. You can stop replication completely on the slave using `mysqladmin`:

   ```shell>
   mysqladmin stop-slave
   ```

   Alternatively, you can stop only the slave SQL thread to pause event execution:

   ```shell>
   mysql -e 'STOP SLAVE SQL_THREAD;'
   ```

   This enables the slave to continue to receive data change events from the master's binary log and store them in the relay logs using the I/O thread, but prevents the slave from executing these events and changing its data. Within busy replication environments, permitting the I/O thread to run during backup may speed up the catch-up process when you restart the slave SQL thread.

2. Run `mysqldump` to dump your databases. You may either dump all databases or select databases to be dumped. For example, to dump all databases:

   ```shell>
   mysqldump --all-databases > fulldb.dump
   ```

3. Once the dump has completed, start slave operations again:

   ```shell>
   mysqladmin start-slave
   ```

   In the preceding example, you may want to add login credentials (user name, password) to the commands, and bundle the process up into a script that you can run automatically each day.

   If you use this approach, make sure you monitor the slave replication process to ensure that the time taken to run the backup does not affect the slave's ability to keep up with events from the master. See
Section 16.1.3.1, "Checking Replication Status". If the slave is unable to keep up, you may want to add another slave and distribute the backup process. For an example of how to configure this scenario, see Section 16.3.4, "Replicating Different Databases to Different Slaves".

16.3.1.2 Backing Up Raw Data from a Slave

To guarantee the integrity of the files that are copied, backing up the raw data files on your MySQL replication slave should take place while your slave server is shut down. If the MySQL server is still running, background tasks may still be updating the database files, particularly those involving storage engines with background processes such as InnoDB. With InnoDB, these problems should be resolved during crash recovery, but since the slave server can be shut down during the backup process without affecting the execution of the master it makes sense to take advantage of this capability.

To shut down the server and back up the files:

1. Shut down the slave MySQL server:

   ```
   shell> mysqladmin shutdown
   ```

2. Copy the data files. You can use any suitable copying or archive utility, including cp, tar or WinZip. For example, assuming that the data directory is located under the current directory, you can archive the entire directory as follows:

   ```
   shell> tar cf /tmp/dbbackup.tar ./data
   ```

3. Start the MySQL server again. Under Unix:

   ```
   shell> mysql_safe &
   ```

   Under Windows:

   ```
   C:\> "C:\Program Files\MySQL\MySQL Server 5.0\bin\mysqld"
   ```

Normally you should back up the entire data directory for the slave MySQL server. If you want to be able to restore the data and operate as a slave (for example, in the event of failure of the slave), then in addition to the slave’s data, you should also back up the slave status files, `master.info` and `relay-log.info`, along with the relay log files. These files are needed to resume replication after you restore the slave’s data.

If you lose the relay logs but still have the `relay-log.info` file, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use `CHANGE MASTER TO` with the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options to tell the slave to re-read the binary logs from that point. This requires that the binary logs still exist on the master server.

If your slave is replicating `LOAD DATA INFILE` statements, you should also back up any `SQL_LOAD-*` files that exist in the directory that the slave uses for this purpose. The slave needs these files to resume replication of any interrupted `LOAD DATA INFILE` operations. The location of this directory is the value of the `--slave-load-tmpdir` option. If the server was not started with that option, the directory location is the value of the `tmpdir` system variable.

16.3.2 Using Replication with Different Master and Slave Storage Engines

It does not matter for the replication process whether the source table on the master and the replicated table on the slave use different engine types. In fact, the system variables `storage_engine` and `table_type` are not replicated.

This provides a number of benefits in the replication process in that you can take advantage of different engine types for different replication scenarios. For example, in a typical scale-out scenario (see Section 16.3.3, "Using Replication for Scale-Out"), you want to use InnoDB tables on the master to take advantage of the transactional functionality, but use MyISAM on the slaves where transaction
support is not required because the data is only read. When using replication in a data-logging environment you may want to use the Archive storage engine on the slave.

Configuring different engines on the master and slave depends on how you set up the initial replication process:

- If you used `mysqldump` to create the database snapshot on your master, you could edit the dump file text to change the engine type used on each table.

  Another alternative for `mysqldump` is to disable engine types that you do not want to use on the slave before using the dump to build the data on the slave. For example, you can add the `--skip-innodb` option on your slave to disable the InnoDB engine. If a specific engine does not exist for a table to be created, MySQL will use the default engine type, usually MyISAM. (This requires that the `NO_ENGINE_SUBSTITUTION` SQL mode is not enabled.) If you want to disable additional engines in this way, you may want to consider building a special binary to be used on the slave that only supports the engines you want.

- If you are using raw data files (a binary backup) to set up the slave, you will be unable to change the initial table format. Instead, use `ALTER TABLE` to change the table types after the slave has been started.

- For new master/slave replication setups where there are currently no tables on the master, avoid specifying the engine type when creating new tables.

If you are already running a replication solution and want to convert your existing tables to another engine type, follow these steps:

1. Stop the slave from running replication updates:

   ```
   mysql> STOP SLAVE;
   ```

   This will enable you to change engine types without interruptions.

2. Execute an `ALTER TABLE ... ENGINE='engine_type'` for each table to be changed.

3. Start the slave replication process again:

   ```
   mysql> START SLAVE;
   ```

   Although the `storage_engine` and `table_type` variables are not replicated, be aware that `CREATE TABLE` and `ALTER TABLE` statements that include the engine specification will be correctly replicated to the slave. For example, if you have a CSV table and you execute:

   ```
   mysql> ALTER TABLE csvtable Engine='MyISAM';
   ```

   The above statement will be replicated to the slave and the engine type on the slave will be converted to MyISAM, even if you have previously changed the table type on the slave to an engine other than CSV. If you want to retain engine differences on the master and slave, you should be careful to use the `storage_engine` variable on the master when creating a new table. For example, instead of:

   ```
   mysql> CREATE TABLE tablea (columna int) Engine=MyISAM;
   ```

   Use this format:

   ```
   mysql> SET storage_engine=MyISAM;
   mysql> CREATE TABLE tablea (columna int);
   ```

   When replicated, the `storage_engine` variable will be ignored, and the `CREATE TABLE` statement will execute on the slave using the slave's default engine.
16.3.3 Using Replication for Scale-Out

You can use replication as a scale-out solution; that is, where you want to split up the load of database queries across multiple database servers, within some reasonable limitations.

Because replication works from the distribution of one master to one or more slaves, using replication for scale-out works best in an environment where you have a high number of reads and low number of writes/updates. Most Web sites fit into this category, where users are browsing the Web site, reading articles, posts, or viewing products. Updates only occur during session management, or when making a purchase or adding a comment/message to a forum.

Replication in this situation enables you to distribute the reads over the replication slaves, while still enabling your web servers to communicate with the replication master when a write is required. You can see a sample replication layout for this scenario in Figure 16.1, “Using Replication to Improve Performance During Scale-Out”.

Figure 16.1 Using Replication to Improve Performance During Scale-Out

If the part of your code that is responsible for database access has been properly abstracted/modularized, converting it to run with a replicated setup should be very smooth and easy. Change the implementation of your database access to send all writes to the master, and to send reads to either the master or a slave. If your code does not have this level of abstraction, setting up a replicated system gives you the opportunity and motivation to clean it up. Start by creating a wrapper library or module that implements the following functions:

- `safe_writer_connect()`
- `safe_reader_connect()`
- `safe_reader_statement()`
- `safe_writer_statement()`

`safe_` in each function name means that the function takes care of handling all error conditions. You can use different names for the functions. The important thing is to have a unified interface for connecting for reads, connecting for writes, doing a read, and doing a write.

Then convert your client code to use the wrapper library. This may be a painful and scary process at first, but it pays off in the long run. All applications that use the approach just described are able to take advantage of a master/slave configuration, even one involving multiple slaves. The code is much easier to maintain, and adding troubleshooting options is trivial. You need modify only one or two functions; for example, to log how long each statement took, or which statement among those issued gave you an error.
If you have written a lot of code, you may want to automate the conversion task by using the `replace` utility that comes with standard MySQL distributions, or write your own conversion script. Ideally, your code uses consistent programming style conventions. If not, then you are probably better off rewriting it anyway, or at least going through and manually regularizing it to use a consistent style.

### 16.3.4 Replicating Different Databases to Different Slaves

There may be situations where you have a single master and want to replicate different databases to different slaves. For example, you may want to distribute different sales data to different departments to help spread the load during data analysis. A sample of this layout is shown in Figure 16.2, “Using Replication to Replicate Databases to Separate Replication Slaves”.

Figure 16.2 Using Replication to Replicate Databases to Separate Replication Slaves

You can achieve this separation by configuring the master and slaves as normal, and then limiting the binary log statements that each slave processes by using the `--replicate-wild-do-table` configuration option on each slave.

**Important**

You should *not* use `--replicate-do-db` for this purpose, since its affects vary according to the database that is currently selected.

For example, to support the separation as shown in Figure 16.2, “Using Replication to Replicate Databases to Separate Replication Slaves”, you should configure each replication slave as follows, before executing `START SLAVE`:

- Replication slave 1 should use `--replicate-wild-do-table=databaseA.%`.
- Replication slave 2 should use `--replicate-wild-do-table=databaseB.%`.
- Replication slave 3 should use `--replicate-wild-do-table=databaseC.%`.

Each slave in this configuration receives the entire binary log from the master, but executes only those events from the binary log that apply to the databases and tables included by the `--replicate-wild-do-table` option in effect on that slave.

If you have data that must be synchronized to the slaves before replication starts, you have a number of choices:

- Synchronize all the data to each slave, and delete the databases, tables, or both that you do not want to keep.
- Use `mysqldump` to create a separate dump file for each database and load the appropriate dump file on each slave.
- Use a raw data file dump and include only the specific files and databases that you need for each slave.

**Note**

This does not work with InnoDB databases unless you use `innodb_file_per_table`. 
16.3.5 Improving Replication Performance

As the number of slaves connecting to a master increases, the load, although minimal, also increases, as each slave uses a client connection to the master. Also, as each slave must receive a full copy of the master binary log, the network load on the master may also increase and create a bottleneck.

If you are using a large number of slaves connected to one master, and that master is also busy processing requests (for example, as part of a scale-out solution), then you may want to improve the performance of the replication process.

One way to improve the performance of the replication process is to create a deeper replication structure that enables the master to replicate to only one slave, and for the remaining slaves to connect to this primary slave for their individual replication requirements. A sample of this structure is shown in Figure 16.3, “Using an Additional Replication Host to Improve Performance”.

Figure 16.3 Using an Additional Replication Host to Improve Performance

For this to work, you must configure the MySQL instances as follows:

- Master 1 is the primary master where all changes and updates are written to the database. Binary logging should be enabled on this machine.

- Master 2 is the slave to the Master 1 that provides the replication functionality to the remainder of the slaves in the replication structure. Master 2 is the only machine permitted to connect to Master 1. Master 2 also has binary logging enabled, and the \(--log-slave-updates\) option so that replication instructions from Master 1 are also written to Master 2’s binary log so that they can then be replicated to the true slaves.

- Slave 1, Slave 2, and Slave 3 act as slaves to Master 2, and replicate the information from Master 2, which actually consists of the upgrades logged on Master 1.

The above solution reduces the client load and the network interface load on the primary master, which should improve the overall performance of the primary master when used as a direct database solution.

If your slaves are having trouble keeping up with the replication process on the master, there are a number of options available:

- If possible, put the relay logs and the data files on different physical drives. To do this, use the \(--relay-log\) option to specify the location of the relay log.

- If the slaves are significantly slower than the master, you may want to divide up the responsibility for replicating different databases to different slaves. See Section 16.3.4, “Replicating Different Databases to Different Slaves”.

- If your master makes use of transactions and you are not concerned about transaction support on your slaves, use MyISAM or another nontransactional engine on the slaves. See Section 16.3.2, “Using Replication with Different Master and Slave Storage Engines”.

- If your slaves are not acting as masters, and you have a potential solution in place to ensure that you can bring up a master in the event of failure, then you can switch off \(--log-slave-updates\). This prevents “dumb” slaves from also logging events they have executed into their own binary log.
16.3.6 Switching Masters During Failover

There is in MySQL 5.0 no official solution for providing failover between master and slaves in the event of a failure. Instead, you must set up a master and one or more slaves; then, you need to write an application or script that monitors the master to check whether it is up, and instructs the slaves and applications to change master in case of failure. This section discusses some of the issues encountered when setting up failover in this fashion.

Note
The MySQL Utilities include a mysqlfailover tool that provides failover capability using GTIDs, support for which requires MySQL 5.6 or later. For more information, see mysqlfailover — Automatic replication health monitoring and failover, and Replication with Global Transaction Identifiers.

You can tell a slave to change to a new master using the CHANGE MASTER TO statement. The slave does not check whether the databases on the master are compatible with those on the slave; it simply begins reading and executing events from the specified coordinates in the new master's binary log. In a failover situation, all the servers in the group are typically executing the same events from the same binary log file, so changing the source of the events should not affect the structure or integrity of the database, provided that you exercise care in making the change.

Slaves should be run with the --log-bin option and without --log-slave-updates. In this way, the slave is ready to become a master without restarting the slave mysqld. Assume that you have the structure shown in Figure 16.4, “Redundancy Using Replication, Initial Structure”.

Figure 16.4 Redundancy Using Replication, Initial Structure

In this diagram, the MySQL Master holds the master database, the MySQL Slave hosts are replication slaves, and the Web Client machines are issuing database reads and writes. Web clients that issue only reads (and would normally be connected to the slaves) are not shown, as they do not need to switch to a new server in the event of failure. For a more detailed example of a read/write scale-out replication structure, see Section 16.3.3, “Using Replication for Scale-Out”.

Each MySQL Slave (Slave 1, Slave 2, and Slave 3) is a slave running with --log-bin and without --log-slave-updates. Because updates received by a slave from the master are not logged in the binary log unless --log-slave-updates is specified, the binary log on each slave is empty initially. If for some reason MySQL Master becomes unavailable, you can pick one of the slaves to become the new master. For example, if you pick Slave 1, all Web Clients should be redirected to Slave 1, which writes the updates to its binary log. Slave 2 and Slave 3 should then replicate from Slave 1.
The reason for running the slave without `--log-slave-updates` is to prevent slaves from receiving updates twice in case you cause one of the slaves to become the new master. If `Slave 1` has `--log-slave-updates` enabled, it writes any updates that it receives from `Master` in its own binary log. This means that, when `Slave 2` changes from `Master` to `Slave 1` as its master, it may receive updates from `Slave 1` that it has already received from `Master`.

Make sure that all slaves have processed any statements in their relay log. On each slave, issue `STOP SLAVE IO_THREAD`, then check the output of `SHOW PROCESSLIST` until you see `Has read all relay log`. When this is true for all slaves, they can be reconfigured to the new setup. On the slave `Slave 1` being promoted to become the master, issue `STOP SLAVE` and `RESET MASTER`.

On the other slaves `Slave 2` and `Slave 3`, use `STOP SLAVE` and `CHANGE MASTER TO MASTER_HOST='Slave1'` (where `Slave1` represents the real host name of `Slave 1`). To use `CHANGE MASTER TO`, add all information about how to connect to `Slave 1` from `Slave 2` or `Slave 3` (`user`, `password`, `port`). When issuing the `CHANGE MASTER TO` statement in this, there is no need to specify the name of the `Slave 1` binary log file or log position to read from, since the first binary log file and position 4, are the defaults. Finally, execute `START SLAVE` on `Slave 2` and `Slave 3`.

Once the new replication setup is in place, you need to tell each `Web Client` to direct its statements to `Slave 1`. From that point on, all updates statements sent by `Web Client` to `Slave 1` are written to the binary log of `Slave 1`, which then contains every update statement sent to `Slave 1` since `Master` died.

The resulting server structure is shown in Figure 16.5, “Redundancy Using Replication, After Master Failure”.

Figure 16.5 Redundancy Using Replication, After Master Failure

When `Master` becomes available again, you should make it a slave of `Slave 1`. To do this, issue on `Master` the same `CHANGE MASTER TO` statement as that issued on `Slave 2` and `Slave 3` previously. `Master` then becomes a slave of `Slave 1` and picks up the `Web Client` writes that it missed while it was offline.

To make `Master` a master again, use the preceding procedure as if `Slave 1` was unavailable and `Master` was to be the new master. During this procedure, do not forget to run `RESET MASTER` on `Master` before making `Slave 1`, `Slave 2`, and `Slave 3` slaves of `Master`. If you fail to do this, the slaves may pick up stale writes from the `Web Client` applications dating from before the point at which `Master` became unavailable.
16.3.7 Setting Up Replication to Use Secure Connections

To use a secure connection for encrypting the transfer of the binary log required during replication, both the master and the slave servers must support encrypted network connections. If either server does not support secure connections (because it has not been compiled or configured for them), replication through an encrypted connection is not possible.

Setting up secure connections for replication is similar to doing so for client/server connections. You must obtain (or create) a suitable security certificate that you can use on the master, and a similar certificate (from the same certificate authority) on each slave. You must also obtain suitable key files.

For more information on setting up a server and client for secure connections, see Section 6.3.6.4, “Configuring MySQL to Use Secure Connections”.

To enable secure connections on the master, you must create or obtain suitable certificate and key files, and then add the following configuration options to the master's configuration within the [mysqld] section of the master's my.cnf file, changing the file names as necessary:

```
[mysqld]
ssl-ca=cacert.pem
ssl-cert=server-cert.pem
ssl-key=server-key.pem
```

The options are as follows:

- `ssl-ca` identifies the Certificate Authority (CA) certificate.
- `ssl-cert` identifies the server public key certificate. This can be sent to the client and authenticated against the CA certificate that it has.
- `ssl-key` identifies the server private key.

On the slave, there are two ways to specify the information required for connecting securely to the master. You can either name the slave certificate and key files in the [client] section of the slave's my.cnf file, or you can explicitly specify that information using the CHANGE MASTER TO statement:

- To name the slave certificate and key files using an option file, add the following lines to the [client] section of the slave's my.cnf file, changing the file names as necessary:

```
[client]
ssl-ca=cacert.pem
ssl-cert=client-cert.pem
ssl-key=client-key.pem
```

Restart the slave server, using the `--skip-slave-start` option to prevent the slave from connecting to the master. Use CHANGE MASTER TO to specify the master configuration, using the MASTER_SSL option to connect securely:

```bash
mysql> CHANGE MASTER TO
```
To specify the certificate and key names using the `CHANGE MASTER TO` statement, append the appropriate `MASTER_SSL_` options:

```sql
mysql> CHANGE MASTER TO
      -> MASTER_HOST='master_hostname',
      -> MASTER_USER='replicate',
      -> MASTER_PASSWORD='password',
      -> MASTER_SSL=1,
      -> MASTER_SSL_CA = 'ca_file_name',
      -> MASTER_SSL_CAPATH = 'ca_directory_name',
      -> MASTER_SSL_CERT = 'cert_file_name',
      -> MASTER_SSL_KEY = 'key_file_name';
```

After the master information has been updated, start the slave replication process:

```sql
mysql> START SLAVE;
```

You can use the `SHOW SLAVE STATUS` statement to confirm that a secure connection was established successfully.

For more information on the `CHANGE MASTER TO` statement, see Section 13.4.2.1, “CHANGE MASTER TO Syntax”.

If you want to enforce the use of secure connections during replication, then create a user with the `REPLICATION SLAVE` privilege and use the `REQUIRE SSL` option for that user. For example:

```sql
mysql> CREATE USER 'repl'@'%.mydomain.com' IDENTIFIED BY 'slavepass';
mysql> GRANT REPLICATION SLAVE ON *.*
      -> TO 'repl'@'%.mydomain.com' REQUIRE SSL;
```

If the account already exists, you can add `REQUIRE SSL` to it with this statement:

```sql
mysql> GRANT USAGE ON *.*
      -> TO 'repl'@'%.mydomain.com' REQUIRE SSL;
```

### 16.4 Replication Notes and Tips

#### 16.4.1 Replication Features and Issues

The following sections provide information about what is supported and what is not in MySQL replication, and about specific issues and situations that may occur when replicating certain statements.

Statement-based replication depends on compatibility at the SQL level between the master and slave. In others, successful SBR requires that any SQL features used be supported by both the master and the slave servers. For example, if you use a feature on the master server that is available only in MySQL 5.0 (or later), you cannot replicate to a slave that uses MySQL 4.1 (or earlier).

Such incompatibilities also can occur within a release series when using pre-production releases of MySQL. For example, the `SLEEP()` function is available beginning with MySQL 5.0.12. If you use this function on the master, you cannot replicate to a slave that uses MySQL 4.1 (or earlier).

For this reason, use Generally Available (GA) releases of MySQL for statement-based replication in a production setting, since we do not introduce new SQL statements or change their behavior within a given release series once that series reaches GA release status.
If you are planning to use replication between MySQL 5.0 and a previous MySQL release series, it is also a good idea to consult the edition of the MySQL Reference Manual corresponding to the earlier release series for information regarding the replication characteristics of that series.

For additional information specific to replication and InnoDB, see Section 14.2.3.5, “InnoDB and MySQL Replication”.

16.4.1.1 Replication and AUTO_INCREMENT

Replication of AUTO_INCREMENT, LAST_INSERT_ID(), and TIMESTAMP values is done correctly, subject to the following exceptions.

• AUTO_INCREMENT columns in tables on the slave must match the same columns on the master; that is, AUTO_INCREMENT columns must be replicated to AUTO_INCREMENT columns.

This is a known issue which is fixed in MySQL 5.5. (Bug #12669186)

• INSERT DELAYED ... VALUES(LAST_INSERT_ID()) inserts a different value on the master and the slave. (Bug #20819) This is fixed in MySQL 5.1 when using row-based or mixed-format binary logging. For more information, see Replication Formats.

• Before MySQL 5.0.26, a stored procedure that uses LAST_INSERT_ID() does not replicate properly.

• When a statement uses a stored function that inserts into an AUTO_INCREMENT column, the generated AUTO_INCREMENT value is not written into the binary log, so a different value can in some cases be inserted on the slave. This is also true of a trigger that causes an INSERT into an AUTO_INCREMENT column.

• An insert into an AUTO_INCREMENT column caused by a stored routine or trigger running on a master that uses MySQL 5.0.60 or earlier does not replicate correctly to a slave running MySQL 5.1.12 through 5.1.23 (inclusive). (Bug #33029)

• An INSERT into a table that has a composite primary key that includes an AUTO_INCREMENT column that is not the first column of this composite key is not logged or replicated correctly. This issue does not affect tables using the InnoDB storage engine, since InnoDB does not allow the creation of a composite key that includes an AUTO_INCREMENT column that is not the first column in the key.

• Adding an AUTO_INCREMENT column to a table with ALTER TABLE might not produce the same ordering of the rows on the slave and the master. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the master and slave, the rows must be ordered before assigning an AUTO_INCREMENT number. Assuming that you want to add an AUTO_INCREMENT column to a table t1 that has columns col1 and col2, the following statements produce a new table t2 identical to t1 but with an AUTO_INCREMENT column:

```sql
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

Important

To guarantee the same ordering on both master and slave, the ORDER BY clause must name all columns of t1.

The instructions just given are subject to the limitations of CREATE TABLE ... LIKE: Foreign key definitions are ignored, as are the DATA DIRECTORY and INDEX DIRECTORY table options. If a table definition includes any of those characteristics, create t2 using a CREATE TABLE statement that is identical to the one used to create t1, but with the addition of the AUTO_INCREMENT column.
Regardless of the method used to create and populate the copy having the \texttt{AUTO_INCREMENT} column, the final step is to drop the original table and then rename the copy:

\begin{verbatim}
DROP t1;
ALTER TABLE t2 RENAME t1;
\end{verbatim}

See also Section B.5.6.1, "Problems with ALTER TABLE".

16.4.1.2 Replication and Character Sets

The following applies to replication between MySQL servers that use different character sets:

- If the master has databases with a character set different from the global \texttt{character_set_server} value, you should design your \texttt{CREATE TABLE} statements so that they do not implicitly rely on the database default character set. A good workaround is to state the character set and collation explicitly in \texttt{CREATE TABLE} statements.

16.4.1.3 Replication and CHECKSUM TABLE

\texttt{CHECKSUM TABLE} returns a checksum that is calculated row by row, using a method that depends on the table row storage format, which is not guaranteed to remain the same between MySQL release series. For example, the storage format for \texttt{VARCHAR} changed between MySQL 4.1 and 5.0, so if a 4.1 table is upgraded to MySQL 5.0, the checksum value may change.

16.4.1.4 Replication of CREATE TABLE ... SELECT Statements

This section discusses the rules that are applied when a \texttt{CREATE TABLE ... SELECT} statement is replicated.

\begin{table}[h]
\centering
\begin{tabular}{|c|}
\hline
\textbf{Statement succeeds.} & A successful \texttt{CREATE TABLE ... SELECT} is itself replicated. \\
\hline
\textbf{Statement fails.} & A failed \texttt{CREATE TABLE ... SELECT} replicates as follows: \\
\hline
\hspace{1cm} & \textbf{Statement does not use IF NOT EXISTS.} The statement has no effect. However, the implicit commit caused by the statement is logged. This is true regardless of the storage engine used and the reason for which the statement failed. \\
\hspace{1cm} & \textbf{Statement uses IF NOT EXISTS.} The \texttt{CREATE TABLE IF NOT EXISTS ... SELECT} is logged with an error.
\hline
\end{tabular}
\end{table}

16.4.1.5 Replication of DROP ... IF EXISTS Statements

The \texttt{DROP DATABASE IF EXISTS}, \texttt{DROP TABLE IF EXISTS}, and \texttt{DROP VIEW IF EXISTS} statements are always replicated, even if the database, table, or view to be dropped does not exist on the master. This is to ensure that the object to be dropped no longer exists on either the master or the slave, once the slave has caught up with the master.

Beginning with MySQL 5.0.82, \texttt{DROP ... IF EXISTS} statements for stored programs (stored procedures and functions, triggers, and events) are also replicated, even if the stored program to be dropped does not exist on the master. (Bug #13684)

16.4.1.6 Replication and DIRECTORY Table Options

If a \texttt{DATA DIRECTORY} or \texttt{INDEX DIRECTORY} table option is used in a \texttt{CREATE TABLE} statement on the master server, the table option is also used on the slave. This can cause problems if no corresponding directory exists in the slave host file system or if it exists but is not accessible to the
slave server. This can be overridden by using the NO_DIR_IN_CREATE server SQL mode on the slave, which causes the slave to ignore the DATA DIRECTORY and INDEX DIRECTORY table options when replicating CREATE TABLE statements. The result is that MyISAM data and index files are created in the table's database directory.

For more information, see Section 5.1.7, “Server SQL Modes”.

16.4.1.7 Replication and Floating-Point Values

With statement-based replication, values are converted from decimal to binary. Because conversions between decimal and binary representations of them may be approximate, comparisons involving floating-point values are inexact. This is true for operations that use floating-point values explicitly, or that use values that are converted to floating-point implicitly. Comparisons of floating-point values might yield different results on master and slave servers due to differences in computer architecture, the compiler used to build MySQL, and so forth. See Section 12.2, “Type Conversion in Expression Evaluation”, and Section B.5.4.8, “Problems with Floating-Point Values”.

16.4.1.8 Replication and FLUSH

Some forms of the FLUSH statement are not logged because they could cause problems if replicated to a slave: FLUSH LOGS, FLUSH MASTER, FLUSH SLAVE, and FLUSH TABLES WITH READ LOCK. For a syntax example, see Section 13.7.6.2, “FLUSH Syntax”. The FLUSH TABLES, ANALYZE TABLE, OPTIMIZE TABLE, and REPAIR TABLE statements are written to the binary log and thus replicated to slaves. This is not normally a problem because these statements do not modify table data.

However, this behavior can cause difficulties under certain circumstances. If you replicate the privilege tables in the mysql database and update those tables directly without using GRANT, you must issue a FLUSH PRIVILEGES on the slaves to put the new privileges into effect. In addition, if you use FLUSH TABLES when renaming a MyISAM table that is part of a MERGE table, you must issue FLUSH TABLES manually on the slaves. These statements are written to the binary log unless you specify NO_WRITE_TO_BINLOG or its alias LOCAL.

16.4.1.9 Replication and System Functions

Certain functions do not replicate well under some conditions:

- The USER(), CURRENT_USER(), UUID(), VERSION(), and LOAD_FILE() functions are replicated without change and thus do not work reliably on the slave.

- For NOW(), the binary log includes the timestamp. This means that the value as returned by the call to this function on the master is replicated to the slave. This can lead to a possibly unexpected result when replicating between MySQL servers in different time zones. Suppose that the master is located in New York, the slave is located in Stockholm, and both servers are using local time. Suppose further that, on the master, you create a table mytable, perform an INSERT statement on this table, and then select from the table, as shown here:

```
mysql> CREATE TABLE mytable (mycol TEXT);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO mytable VALUES ( NOW() );
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM mytable;
+---------------------+
| mycol               |
+---------------------+
| 2009-09-01 12:00:00 |
+---------------------+
1 row in set (0.00 sec)
```

Local time in Stockholm is 6 hours later than in New York; so, if you issue SELECT NOW() on the slave at that exact same instant, the value 2009-09-01 18:00:00 is returned. For this reason,
if you select from the slave's copy of mytable after the CREATE_TABLE and INSERT statements just shown have been replicated, you might expect mycol to contain the value 2009-09-01 18:00:00. However, this is not the case; when you select from the slave's copy of mytable, you obtain exactly the same result as on the master:

```
mysql> SELECT * FROM mytable;
+---------------------+
| mycol               |
| 2009-09-01 12:00:00 |
+---------------------+
1 row in set (0.00 sec)
```

As of MySQL 5.0.13, the SYSDATE() function is no longer equivalent to NOW(). Implications are that SYSDATE() is not replication-safe because it is not affected by SET TIMESTAMP statements in the binary log and is nondeterministic. To avoid this, you can start the server with the --sysdate-is-now option to cause SYSDATE() to be an alias for NOW().

See also Section 16.4.1.25, “Replication and Time Zones”.

- The GET_LOCK(), RELEASE_LOCK(), IS_FREE_LOCK(), and IS_USED_LOCK() functions that handle user-level locks are replicated without the slave knowing the concurrency context on the master. Therefore, these functions should not be used to insert into a master table because the content on the slave would differ. For example, do not issue a statement such as INSERT INTO mytable VALUES(GET_LOCK(...)).

As a workaround for the preceding limitations, you can use the strategy of saving the problematic function result in a user variable and referring to the variable in a later statement. For example, the following single-row INSERT is problematic due to the reference to the UUID() function:

```
INSERT INTO t VALUES(UUID());
```

To work around the problem, do this instead:

```
SET @my_uuid = UUID();
INSERT INTO t VALUES(@my_uuid);
```

That sequence of statements replicates because the value of @my_uuid is stored in the binary log as a user-variable event prior to the INSERT statement and is available for use in the INSERT.

The same idea applies to multiple-row inserts, but is more cumbersome to use. For a two-row insert, you can do this:

```
SET @my_uuid1 = UUID(); @my_uuid2 = UUID();
INSERT INTO t VALUES(@my_uuid1),(@my_uuid2);
```

However, if the number of rows is large or unknown, the workaround is difficult or impracticable. For example, you cannot convert the following statement to one in which a given individual user variable is associated with each row:

```
INSERT INTO t2 SELECT UUID(), * FROM t1;
```

Non-delayed INSERT statements that refer to RAND() or user-defined variables replicate correctly. However, changing the statements to use INSERT DELAYED can result in different results on master and slave.

Within a stored function, RAND() replicates correctly as long as it is invoked only once during the execution of the function. (You can consider the function execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)
The `FOUND_ROWS()` and `ROW_COUNT()` functions are also not replicated reliably. A workaround is to store the result of the function call in a user variable, and then use that in the `INSERT` statement. For example, if you wish to store the result in a table named `mytable`, you might normally do so like this:

```
SELECT SQL_CALC_FOUND_ROWS FROM mytable LIMIT 1;
INSERT INTO mytable VALUES( FOUND_ROWS() );
```

However, if you are replicating `mytable`, you should use `SELECT ... INTO`, and then store the variable in the table, like this:

```
SELECT SQL_CALC_FOUND_ROWS INTO @found_rows FROM mytable LIMIT 1;
INSERT INTO mytable VALUES(@found_rows);
```

In this way, the user variable is replicated as part of the context, and applied on the slave correctly.

### 16.4.1.10 Replication and LIMIT

Replication of `LIMIT` clauses in `DELETE`, `UPDATE`, and `INSERT ... SELECT` statements is not guaranteed, since the order of the rows affected is not defined. Such statements can be replicated correctly only if they also contain an `ORDER BY` clause.

### 16.4.1.11 Replication and LOAD Operations

Using `LOAD TABLE FROM MASTER` where the master is running MySQL 4.1 and the slave is running MySQL 5.0 may corrupt the table data, and is not supported. (Bug #16261)

The `LOAD DATA INFILE` statement `CONCURRENT` option is not replicated; that is, `LOAD DATA CONCURRENT` is replicated as `LOAD DATA INFILE`, and `LOAD DATA CONCURRENT LOCAL INFILE` is replicated as `LOAD DATA LOCAL INFILE`. (Bug #34628)

The following applies only if either the master or the slave is running MySQL 5.0.3 or older: If on the master a `LOAD DATA INFILE` is interrupted (integrity constraint violation, killed connection, and so on), the slave skips the `LOAD DATA INFILE` entirely. This means that if this command permanently inserted or updated table records before being interrupted, these modifications are not replicated to the slave.

### 16.4.1.12 Replication and the Slow Query Log

Replication slaves do not write replicated queries to the slow query log, even if the same queries were written to the slow query log on the master. This is a known issue. (Bug #23300)

### 16.4.1.13 Replication and REPAIR TABLE

When used on a corrupted or otherwise damaged table, it is possible for the `REPAIR TABLE` statement to delete rows that cannot be recovered. However, any such modifications of table data performed by this statement are not replicated, which can cause master and slave to lose synchronization. For this reason, in the event that a table on the master becomes damaged and you use `REPAIR TABLE` to repair it, you should first stop replication (if it is still running) before using `REPAIR TABLE`, then afterward compare the master's and slave's copies of the table and be prepared to correct any discrepancies manually, before restarting replication.

### 16.4.1.14 Replication and Master or Slave Shutdowns

It is safe to shut down a master server and restart it later. When a slave loses its connection to the master, the slave tries to reconnect immediately and retries periodically if that fails. The default is to retry every 60 seconds. This may be changed with the `CHANGE MASTER TO` statement or `--master-connect-retry` option. A slave also is able to deal with network connectivity outages. However, the slave notices the network outage only after receiving no data from the
master for \textit{slave\textunderscore net\textunderscore timeout} seconds. If your outages are short, you may want to decrease \textit{slave\textunderscore net\textunderscore timeout}. See Section 5.1.4, "Server System Variables".

An unclean shutdown (for example, a crash) on the master side can result in the master binary log having a final position less than the most recent position read by the slave, due to the master binary log file not being flushed. This can cause the slave not to be able to replicate when the master comes back up. Setting \texttt{sync\textunderscore binlog=1} in the master \texttt{my.cnf} file helps to minimize this problem because it causes the master to flush its binary log more frequently.

Unclean master shutdowns may cause inconsistencies between the content of tables and the binary log. This can be avoided by using InnoDB tables and the \texttt{--innodb\textunderscore safe\textunderscore binlog} option on the master. See Section 5.4.3, "The Binary Log".

\begin{tcolorbox}[colframe=red]
\textbf{Note}
\texttt{--innodb\textunderscore safe\textunderscore binlog} is unneeded as of MySQL 5.0.3, having been made obsolete by the introduction of XA transaction support.
\end{tcolorbox}

Shutting down a slave cleanly is safe because it keeps track of where it left off. However, be careful that the slave does not have temporary tables open; see Section 16.4.1.16, "Replication and Temporary Tables". Unclean shutdowns might produce problems, especially if the disk cache was not flushed to disk before the problem occurred:

- For transactions, the slave commits and then updates \texttt{relay-log.info}. If a crash occurs between these two operations, relay log processing will have proceeded further than the information file indicates and the slave will re-execute the events from the last transaction in the relay log after it has been restarted.

- A similar problem can occur if the slave updates \texttt{relay-log.info} but the server host crashes before the write has been flushed to disk. Writes are not forced to disk because the server relies on the operating system to flush the file from time to time.

The fault tolerance of your system for these types of problems is greatly increased if you have a good uninterruptible power supply.

\section*{16.4.1.15 Replication and MEMORY Tables}

When a master server shuts down and restarts, its \texttt{MEMORY (HEAP)} tables become empty. To replicate this effect to slaves, the first time that the master uses a given \texttt{MEMORY} table after startup, it logs an event that notifies slaves that the table must be emptied by writing a \texttt{DELETE} statement for that table to the binary log.

When a slave server shuts down and restarts, its \texttt{MEMORY} tables become empty. This causes the slave to be out of synchrony with the master and may lead to other failures or cause the slave to stop. For example, \texttt{INSERT INTO ... SELECT FROM memory_table} may insert a different set of rows on the master and slave.

The safe way to restart a slave that is replicating \texttt{MEMORY} tables is to first drop or delete all rows from the \texttt{MEMORY} tables on the master and wait until those changes have replicated to the slave. Then it is safe to restart the slave.

The size of \texttt{MEMORY} tables is limited by the value of the \texttt{max_heap_table_size} system variable, which is not replicated (see Section 16.4.1.29, "Replication and Variables"). A change in \texttt{max_heap_table_size} takes effect for \texttt{MEMORY} tables that are created or updated using \texttt{ALTER TABLE ... ENGINE = MEMORY} or \texttt{TRUNCATE TABLE} following the change, or for all \texttt{MEMORY} tables following a server restart. If you increase the value of this variable on the master without doing so on the slave, it becomes possible for a table on the master to grow larger than its counterpart on the slave, leading to inserts that succeed on the master but fail on the slave with \texttt{Table is full} errors. This is a known issue (Bug #48666). In such cases, you must set the global value of \texttt{max_heap_table_size} on the slave as well as on the master, then restart replication. It is also recommended that you restart...
Replication Features and Issues

both the master and slave MySQL servers, to insure that the new value takes complete (global) effect on each of them.

16.4.1.16 Replication and Temporary Tables

Safe slave shutdown when using temporary tables. Temporary tables are replicated except in the case where you stop the slave server (not just the slave threads) and you have replicated temporary tables that are open for use in updates that have not yet been executed on the slave. If you stop the slave server, the temporary tables needed by those updates are no longer available when the slave is restarted. To avoid this problem, do not shut down the slave while it has temporary tables open. Instead, use the following procedure:

1. Issue a `STOP SLAVE SQL_THREAD` statement.
2. Use `SHOW STATUS` to check the value of the `Slave_open_temp_tables` variable.
3. If the value is not 0, restart the slave SQL thread with `START SLAVE SQL_THREAD` and repeat the procedure later.
4. When the value is 0, issue a `mysqladmin shutdown` command to stop the slave.

Temporary tables and replication options. By default, all temporary tables are replicated; this happens whether or not there are any matching `--replicate-do-db`, `--replicate-do-table`, or `--replicate-wild-do-table` options in effect. However, the `--replicate-ignore-table` and `--replicate-wild-ignore-table` options are honored for temporary tables.

A recommended practice when using replication is to designate a prefix for exclusive use in naming temporary tables that you do not want replicated, then employ a matching `--replicate-wild-ignore-table` option. For example, you might give all such tables names beginning with `norep` (such as `norepmytable`, `norepyourtable`, and so on), then use `--replicate-wild-ignore-table=norep%` to prevent the replication of these tables.

16.4.1.17 Replication of the mysql System Database

User privileges are replicated only if the `mysql` database is replicated. That is, the `GRANT`, `REVOKE`, `SET PASSWORD`, `CREATE USER`, and `DROP USER` statements take effect on the slave only if the replication setup includes the `mysql` database.

See also Section 16.4.1.18, “Replication and User Privileges”.

16.4.1.18 Replication and User Privileges

User privileges are replicated only if the `mysql` database is replicated. That is, the `GRANT`, `REVOKE`, `SET PASSWORD`, `CREATE USER`, and `DROP USER` statements take effect on the slave only if the replication setup includes the `mysql` database.

If you are replicating all databases, but do not want statements that affect user privileges to be replicated, set up the slave not to replicate the `mysql` database, using the `--replicate-wild-ignore-table=mysql.%` option. The slave recognizes that privilege-related SQL statements have no effect, and thus it does not execute those statements.

See Section 16.4.1.17, “Replication of the mysql System Database”, for more information.

16.4.1.19 Replication and the Query Optimizer

It is possible for the data on the master and slave to become different if a statement is written in such a way that the data modification is nondeterministic; that is, left up the query optimizer. (In general, this is not a good practice, even outside of replication.) Examples of nondeterministic statements include

16.4.1.20 Replication and Reserved Words

You can encounter problems when you attempt to replicate from an older master to a newer slave and you make use of identifiers on the master that are reserved words in the newer MySQL version running on the slave. An example of this is using a table column named `condition` on a 4.1 master that is replicating to a 5.0 or higher slave because `CONDITION` is a reserved word beginning in MySQL 5.0. Replication can fail in such cases with Error 1064: 

```
You have an error in your SQL syntax..., even if a database or table named using the reserved word or a table having a column named using the reserved word is excluded from replication. This is due to the fact that each SQL event must be parsed by the slave prior to execution, so that the slave knows which database object or objects would be affected; only after the event is parsed can the slave apply any filtering rules defined by --replicate-do-db, --replicate-do-table, --replicate-ignore-db, and --replicate-ignore-table.
```

To work around the problem of database, table, or column names on the master which would be regarded as reserved words by the slave, do one of the following:

- Use one or more `ALTER TABLE` statements on the master to change the names of any database objects where these names would be considered reserved words on the slave, and change any SQL statements that use the old names to use the new names instead.

- In any SQL statements using these database object names, write the names as quoted identifiers using backtick characters (```).

For listings of reserved words by MySQL version, see Reserved Words, in the MySQL Server Version Reference. For identifier quoting rules, see Section 9.2, “Schema Object Names”.

16.4.1.21 Slave Errors During Replication

If a statement produces the same error (identical error code) on both the master and the slave, the error is logged, but replication continues.

If a statement produces different errors on the master and the slave, the slave SQL thread terminates, and the slave writes a message to its error log and waits for the database administrator to decide what to do about the error. This includes the case that a statement produces an error on the master or the slave, but not both. To address the issue, connect to the slave manually and determine the cause of the problem. `SHOW SLAVE STATUS` is useful for this. Then fix the problem and run `START SLAVE`. For example, you might need to create a nonexistent table before you can start the slave again.

If this error code validation behavior is not desirable, some or all errors can be masked out (ignored) with the `--slave-skip-errors` option.

For nontransactional storage engines such as MyISAM, it is possible to have a statement that only partially updates a table and returns an error code. This can happen, for example, on a multiple-row insert that has one row violating a key constraint, or if a long update statement is killed after updating some of the rows. If that happens on the master, the slave expects execution of the statement to result in the same error code. If it does not, the slave SQL thread stops as described previously.

If you are replicating between tables that use different storage engines on the master and slave, keep in mind that the same statement might produce a different error when run against one version of the table, but not the other, or might cause an error for one version of the table, but not the other. For example, since MyISAM ignores foreign key constraints, an `INSERT` or `UPDATE` statement accessing an InnoDB table on the master might cause a foreign key violation but the same statement performed on a MyISAM version of the same table on the slave would produce no such error, causing replication to stop.
16.4.1.22 Replication and Server SQL Mode

Using different server SQL mode settings on the master and the slave may cause the same `INSERT` statements to be handled differently on the master and the slave, leading the master and slave to diverge. For best results, you should always use the same server SQL mode on the master and on the slave.

For more information, see Section 5.1.7, “Server SQL Modes”.

16.4.1.23 Replication Retries and Timeouts

In MySQL 5.0 (starting from 5.0.3), there is a global system variable `slave_transaction_retries`:

If the slave thread fails to execute a transaction because of an InnoDB deadlock or because it exceeded the InnoDB `innodb_lock_wait_timeout` or the NDBCLUSTER `TransactionDeadlockDetectionTimeout` or `TransactionInactiveTimeout` value, the slave automatically retries the transaction `slave_transaction_retries` times before stopping with an error. The default value is 10. Starting from MySQL 5.0.4, the total retry count can be seen in the output of `SHOW STATUS`; see Section 5.1.6, “Server Status Variables”.

16.4.1.24 Replication and TIMESTAMP

Older versions of MySQL (prior to 4.1) differed significantly in several ways in their handling of the `TIMESTAMP` data type from what is supported in MySQL versions 5.0 and newer; these include syntax extensions which are deprecated in MySQL 5.1, and that no longer supported in MySQL 5.5. This can cause problems (including replication failures) when replicating between MySQL Server versions, if you are using columns that are defined using the old `TIMESTAMP(N)` syntax. See Section 2.19.1.1, “Changes Affecting Upgrades to 5.0”, for more information about the differences, how they can impact MySQL replication, and what you can do if you encounter such problems.

16.4.1.25 Replication and Time Zones

The same system time zone should be set for both master and slave. Otherwise, statements depending on the local time on the master are not replicated properly, such as statements that use the `NOW()` or `FROM_UNIXTIME()` functions. You can set the time zone in which MySQL server runs by using the `--timezonename` option of the `mysqld_safe` script or by setting the `TZ` environment variable. See also Section 16.4.1.9, “Replication and System Functions”.

`CONVERT_TZ(...,...,@@session.time_zone)` is properly replicated only if both master and slave are running MySQL 5.0.4 or newer.

16.4.1.26 Replication and Transactions

**Mixing transactional and nontransactional statements within the same transaction.** In general, you should avoid transactions that update both transactional and nontransactional tables in a replication environment. You should also avoid using any statement that accesses both transactional and nontransactional tables and writes to any of them.

In MySQL 5.0 the server uses this rule for binary logging: If the initial statements in a transaction are nontransactional, they are written to the binary log immediately. The remaining statements in the transaction are cached and not written to the binary log until the transaction is committed. (If the transaction is rolled back, the cached statements are written to the binary log only if they make nontransactional changes that cannot be rolled back. Otherwise, they are discarded.)

To apply this rule, the server considers a statement nontransactional if the first changes it makes change nontransactional tables, transactional if the first changes it makes change transactional tables. “First” applies in the sense that a statement may have several effects if it involves such things as triggers, stored functions, or multiple-table updates.

In situations where transactions mix updates to transactional and nontransactional tables, the order of statements in the binary log is correct, and all needed statements are written to the binary log even in
case of a `ROLLBACK`. However, when a second connection updates the nontransactional table before the first connection transaction is complete, statements can be logged out of order because the second connection update is written immediately after it is performed, regardless of the state of the transaction being performed by the first connection.

**Using different storage engines on master and slave.** It is possible to replicate transactional tables on the master using nontransactional tables on the slave. For example, you can replicate an InnoDB master table as a MyISAM slave table. However, if you do this, there are problems if the slave is stopped in the middle of a `BEGIN ... COMMIT` block because the slave restarts at the beginning of the `BEGIN` block.

When the storage engine type of the slave is nontransactional, transactions on the master that mix updates of transactional and nontransactional tables should be avoided because they can cause inconsistency of the data between the master transactional table and the slave nontransactional table. That is, such transactions can lead to master storage engine-specific behavior with the possible effect of replication going out of synchrony. MySQL does not issue a warning about this currently, so extra care should be taken when replicating transactional tables from the master to nontransactional tables on the slaves.

Beginning with MySQL 5.0.56, every transaction (including `autocommit` transactions) is recorded in the binary log as though it starts with a `BEGIN` statement, and ends with either a `COMMIT` or a `ROLLBACK` statement. However, this does not apply to nontransactional changes; any statements affecting tables using a nontransactional storage engine such as MyISAM are regarded for this purpose as nontransactional, even when `autocommit` is enabled. (Bug #26395)

### 16.4.1.27 Replication and Triggers

**Known issue:** In MySQL 5.0.17, the syntax for `CREATE TRIGGER` changed to include a `DEFINER` clause for specifying which access privileges to check at trigger invocation time. (See Section 13.1.11, “CREATE TRIGGER Syntax”, for more information.) However, if you attempt to replicate from a master server older than MySQL 5.0.17 to a slave running MySQL 5.0.17 through 5.0.19, replication of `CREATE TRIGGER` statements fails on the slave with a `Definer not fully qualified` error. A workaround is to create triggers on the master using a version-specific comment embedded in each `CREATE TRIGGER` statement:

```sql
CREATE /*!50017 DEFINER = 'root'@'localhost' */ TRIGGER ... ;
```

`CREATE TRIGGER` statements written this way will replicate to newer slaves, which pick up the `DEFINER` clause from the comment and execute successfully.

This slave problem is fixed as of MySQL 5.0.20.

### 16.4.1.28 Replication and Views

Views are always replicated to slaves. Views are filtered by their own name, not by the tables they refer to. This means that a view can be replicated to the slave even if the view contains a table that would normally be filtered out by `replication-ignore-table` rules. Care should therefore be taken to ensure that views do not replicate table data that would normally be filtered for security reasons.

### 16.4.1.29 Replication and Variables

The `foreign_key_checks`, `unique_checks`, and `sql_auto_is_null` variables are all replicated. `sql_mode` is also replicated except for the `NO_DIR_IN_CREATE` mode. However, when `mysqlbinlog` parses a `SET @@sql_mode = mode` statement, the full `mode` value, including `NO_DIR_IN_CREATE`, is passed to the receiving server.

The `storage_engine` system variable is not replicated, regardless of the logging mode; this is intended to facilitate replication between different storage engines.
The `read_only` system variable is not replicated. In addition, the enabling this variable has different effects with regard to temporary tables, table locking, and the `SET PASSWORD` statement in different MySQL versions.

The `max_heap_table_size` system variable is not replicated. Increasing the value of this variable on the master without doing so on the slave can lead eventually to `Table is full` errors on the slave when trying to execute `INSERT` statements on a `MEMORY` table on the master that is thus permitted to grow larger than its counterpart on the slave. For more information, see Section 16.4.1.15, “Replication and MEMORY Tables”.

Starting from MySQL 5.0.3 (master and slave), replication works even if the master and slave have different global character set variables. Starting from MySQL 5.0.4 (master and slave), replication works even if the master and slave have different global time zone variables.

Session variables are not replicated properly when used in statements that update tables. For example, the following sequence of statements will not insert the same data on the master and the slave:

```
SET max_join_size=1000;
INSERT INTO mytable VALUES(@max_join_size);
```

This does not apply to the common sequence, which replicates correctly as of MySQL 5.0.4.

```
SET time_zone=...;
INSERT INTO mytable VALUES(CONVERT_TZ(..., ..., @@time_zone));
```

Update statements that refer to user-defined variables (that is, variables of the form `@var_name`) are replicated correctly in MySQL 5.0. However, this is not true for versions prior to 4.1. Note that user variable names are case insensitive starting in MySQL 5.0. You should take this into account when setting up replication between MySQL 5.0 and older versions.

In MySQL 5.0.46 and later, the following session variables are written to the binary log and honored by the replication slave when parsing the binary log, regardless of the logging format:

- `sql_mode`
- `foreign_key_checks`
- `unique_checks`
- `character_set_client`
- `collation_connection`
- `collation_database`
- `collation_server`
- `sql_auto_is_null`

Important

Even though session variables relating to character sets and collations are written to the binary log, replication between different character sets is not supported.

It is strongly recommended that you always use the same setting for the `lower_case_table_names` system variable on both master and slave. In particular, when a case-sensitive file system is used, and this variable set to 1 on the slave, but to a different value on the master, names of databases are not converted to lowercase, which can cause replication to fail. This is a known issue, which is fixed in MySQL 5.6.
16.4.2 Replication Compatibility Between MySQL Versions

MySQL supports replication from one release series to the next higher release series. For example, you can replicate from a master running MySQL 4.1 to a slave running MySQL 5.0, from a master running MySQL 5.0 to a slave running MySQL 5.1, and so on.

However, one may encounter difficulties when replicating from an older master to a newer slave if the master uses statements or relies on behavior no longer supported in the version of MySQL used on the slave.

The use of more than two MySQL Server versions is not supported in replication setups involving multiple masters, regardless of the number of master or slave MySQL servers. This restriction applies not only to release series, but to version numbers within the same release series as well. For example, if you are using a chained or circular replication setup, you cannot use MySQL 5.0.21, MySQL 5.0.22, and MySQL 5.0.24 concurrently, although you could use any two of these releases together.

In some cases, it is also possible to replicate between a master and a slave that is more than one major release newer than the master. However, there are known issues with trying to replicate from a master running MySQL 4.1 or earlier to a slave running MySQL 5.1 or later. To work around such problems, you can insert a MySQL server running an intermediate version between the two; for example, rather than replicating directly from a MySQL 4.1 master to a MySQL 5.1 slave, it is possible to replicate from a MySQL 4.1 server to a MySQL 5.0 server, and then from the MySQL 5.0 server to a MySQL 5.1 server.

Important

It is strongly recommended to use the most recent release available within a given MySQL release series because replication (and other) capabilities are continually being improved. It is also recommended to upgrade masters and slaves that use early releases of a release series of MySQL to GA (production) releases when the latter become available for that release series.

Replication from newer masters to older slaves may be possible, but is generally not supported. This is due to a number of factors:

- **Binary log format changes.** The binary log format can change between major releases. While we attempt to maintain backward-compatibility, this is not always possible. Major changes were made in MySQL 5.0.3 (for improvements to handling of character sets and `LOAD DATA INFILE`) and 5.0.4 (for improvements to handling of time zones). Because of these changes, replication from a MySQL 5.0.3 or later master to a MySQL 5.0.2 or earlier slave is not supported. This also means that replication from a MySQL 5.0.3 (or later) master to any MySQL 4.1 (or earlier) slave is generally not supported.

  This also has significant implications for upgrading replication servers; see Section 16.4.3, “Upgrading a Replication Setup”, for more information.

- **Use of row-based replication.** Row-based replication was implemented in MySQL 5.1.5, so you cannot replicate using row-based replication from any MySQL 5.0 or later master to a slave older than MySQL 5.1.5.

  Note

  Row-based replication is not available in MySQL 5.0. For more information about row-based replication in MySQL 5.1, see Replication Formats.

- **SQL incompatibilities.** You cannot replicate from a newer master to an older slave using statement-based replication if the statements to be replicated use SQL features available on the master but not on the slave.

For more information on potential replication issues, see Section 16.4.1, “Replication Features and Issues”.
16.4.3 Upgrading a Replication Setup

When you upgrade servers that participate in a replication setup, the procedure for upgrading depends on the current server versions and the version to which you are upgrading.

This section applies to upgrading replication from older versions of MySQL to MySQL 5.0. A 4.0 server should be 4.0.3 or newer.

When you upgrade a master to 5.0 from an earlier MySQL release series, you should first ensure that all the slaves of this master are using the same 5.0.x release. If this is not the case, you should first upgrade the slaves. To upgrade each slave, shut it down, upgrade it to the appropriate 5.0.x version, restart it, and restart replication. The 5.0 slave is able to read the old relay logs written prior to the upgrade and to execute the statements they contain. Relay logs created by the slave after the upgrade are in 5.0 format.

After the slaves have been upgraded, shut down the master, upgrade it to the same 5.0.x release as the slaves, and restart it. The 5.0 master is able to read the old binary logs written prior to the upgrade and to send them to the 5.0 slaves. The slaves recognize the old format and handle it properly. Binary logs created by the master subsequent to the upgrade are in 5.0 format. These too are recognized by the 5.0 slaves.

In other words, when upgrading to MySQL 5.0, the slaves must be MySQL 5.0 before you can upgrade the master to 5.0. Note that downgrading from 5.0 to older versions does not work so simply: You must ensure that any 5.0 binary log or relay log has been fully processed, so that you can remove it before proceeding with the downgrade.

Some upgrades may require that you drop and re-create database objects when you move from one MySQL series to the next. For example, collation changes might require that table indexes be rebuilt. Such operations, if necessary, will be detailed at Section 2.19.1.1, “Changes Affecting Upgrades to 5.0”. It is safest to perform these operations separately on the slaves and the master, and to disable replication of these operations from the master to the slave. To achieve this, use the following procedure:

1. Stop all the slaves and upgrade them. Restart them with the `--skip-slave-start` option so that they do not connect to the master. Perform any table repair or rebuilding operations needed to re-create database objects, such as use of `REPAIR TABLE` or `ALTER TABLE`, or dumping and reloading tables or triggers.

2. Disable the binary log on the master. To do this without restarting the master, execute a `SET sql_log_bin = 0` statement. Alternatively, stop the master and restart it without the `--log-bin` option. If you restart the master, you might also want to disallow client connections. For example, if all clients connect using TCP/IP, use the `--skip-networking` option when you restart the master.

3. With the binary log disabled, perform any table repair or rebuilding operations needed to re-create database objects. The binary log must be disabled during this step to prevent these operations from being logged and sent to the slaves later.

4. Re-enable the binary log on the master. If you set `sql_log_bin` to 0 earlier, execute a `SET sql_log_bin = 1` statement. If you restarted the master to disable the binary log, restart it with `--log-bin`, and without `--skip-networking` so that clients and slaves can connect.

5. Restart the slaves, this time without the `--skip-slave-start` option.

16.4.4 Troubleshooting Replication

If you have followed the instructions but your replication setup is not working, the first thing to do is check the error log for messages. Many users have lost time by not doing this soon enough after encountering problems.
If you cannot tell from the error log what the problem was, try the following techniques:

- Verify that the master has binary logging enabled by issuing a `SHOW MASTER STATUS` statement. If logging is enabled, `Position` is nonzero. If binary logging is not enabled, verify that you are running the master with the `--log-bin` option.

- Verify that the master and slave both were started with the `--server-id` option and that the ID value is unique on each server.

- Verify that the slave is running. Use `SHOW SLAVE STATUS` to check whether the `Slave_IO_Running` and `Slave_SQL_Running` values are both `Yes`. If not, verify the options that were used when starting the slave server. For example, `--skip-slave-start` prevents the slave threads from starting until you issue a `START SLAVE` statement.

- If the slave is running, check whether it established a connection to the master. Use `SHOW PROCESSLIST`, find the I/O and SQL threads and check their `State` column to see what they display. See Section 16.2.1, “Replication Implementation Details”. If the I/O thread state says `Connecting to master`, check the following:

  - Verify the privileges for the user being used for replication on the master.

  - Check that the host name of the master is correct and that you are using the correct port to connect to the master. The port used for replication is the same as used for client network communication (the default is `3306`). For the host name, ensure that the name resolves to the correct IP address.

  - Check that networking has not been disabled on the master or slave. Look for the `skip-networking` option in the configuration file. If present, comment it out or remove it.

  - If the master has a firewall or IP filtering configuration, ensure that the network port being used for MySQL is not being filtered.

  - Check that you can reach the master by using `ping` or `traceroute/tracert` to reach the host.

- If the slave was running previously but has stopped, the reason usually is that some statement that succeeded on the master failed on the slave. This should never happen if you have taken a proper snapshot of the master, and never modified the data on the slave outside of the slave thread. If the slave stops unexpectedly, it is a bug or you have encountered one of the known replication limitations described in Section 16.4.1, “Replication Features and Issues”. If it is a bug, see Section 16.4.5, “How to Report Replication Bugs or Problems”, for instructions on how to report it.

- If a statement that succeeded on the master refuses to run on the slave, try the following procedure if it is not feasible to do a full database resynchronization by deleting the slave’s databases and copying a new snapshot from the master:

  1. Determine whether the affected table on the slave is different from the master table. Try to understand how this happened. Then make the slave’s table identical to the master’s and run `START SLAVE`.

  2. If the preceding step does not work or does not apply, try to understand whether it would be safe to make the update manually (if needed) and then ignore the next statement from the master.

  3. If you decide that the slave can skip the next statement from the master, issue the following statements:

     ```
     mysql> SET GLOBAL sql_slave_skip_counter = N;
     mysql> START SLAVE;
     ```

     The value of `N` should be 1 if the next statement from the master does not use `AUTO_INCREMENT` or `LAST_INSERT_ID()`. Otherwise, the value should be 2. The reason for using a value of 2 for
statements that use **AUTO_INCREMENT** or **LAST_INSERT_ID()** is that they take two events in the binary log of the master.

See also Section 13.4.2.6, "SET GLOBAL sql_slave_skip_counter Syntax".

4. If you are sure that the slave started out perfectly synchronized with the master, and that no one has updated the tables involved outside of the slave thread, then presumably the discrepancy is the result of a bug. If you are running the most recent version of MySQL, please report the problem. If you are running an older version, try upgrading to the latest production release to determine whether the problem persists.

### 16.4.5 How to Report Replication Bugs or Problems

When you have determined that there is no user error involved, and replication still either does not work at all or is unstable, it is time to send us a bug report. We need to obtain as much information as possible from you to be able to track down the bug. Please spend some time and effort in preparing a good bug report.

If you have a repeatable test case that demonstrates the bug, please enter it into our bugs database using the instructions given in Section 1.7, “How to Report Bugs or Problems”. If you have a “phantom” problem (one that you cannot duplicate at will), use the following procedure:

1. Verify that no user error is involved. For example, if you update the slave outside of the slave thread, the data goes out of synchrony, and you can have unique key violations on updates. In this case, the slave thread stops and waits for you to clean up the tables manually to bring them into synchrony. *This is not a replication problem. It is a problem of outside interference causing replication to fail.*

2. Run the slave with the **--log-slave-updates** and **--log-bin** options. These options cause the slave to log the updates that it receives from the master into its own binary logs.

3. Save all evidence before resetting the replication state. If we have no information or only sketchy information, it becomes difficult or impossible for us to track down the problem. The evidence you should collect is:
   - All binary log files from the master
   - All binary log files from the slave
   - The output of **SHOW MASTER STATUS** from the master at the time you discovered the problem
   - The output of **SHOW SLAVE STATUS** from the slave at the time you discovered the problem
   - Error logs from the master and the slave

4. Use **mysqlbinlog** to examine the binary logs. The following should be helpful to find the problem statement. **log_file** and **log_pos** are the **Master_Log_File** and **Read_Master_Log_Pos** values from **SHOW SLAVE STATUS**.

```shell> mysqlbinlog --start-position=log_pos log_file | head
```

After you have collected the evidence for the problem, try to isolate it as a separate test case first. Then enter the problem with as much information as possible into our bugs database using the instructions at Section 1.7, “How to Report Bugs or Problems”.

This chapter contains information about **MySQL Cluster**, a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. It uses the NDBCLUSTER storage engine to enable running several computers with MySQL servers and other software in a cluster. This storage engine is available in MySQL 5.0 binary releases and in RPMs compatible with most modern Linux distributions.

Beginning with MySQL 5.0.8, MySQL Cluster changes for MySQL 5.0 Server releases can be found in the MySQL 5.0 Server Release Notes. For release notes for older releases of MySQL Cluster (before 5.0.8), see MySQL Cluster 5.0 Release Notes.

**Supported Platforms.** MySQL Cluster is currently available and supported on a number of platforms. For exact levels of support available for on specific combinations of operating system versions, operating system distributions, and hardware platforms, please refer to http://www.mysql.com/support/supportedplatforms/cluster.html.

**Compatibility with standard MySQL.** While many standard MySQL schemas and applications can work using MySQL Cluster, it is also true that unmodified applications and database schemas may be slightly incompatible or have suboptimal performance when run using MySQL Cluster (see Section 17.1.5, “Known Limitations of MySQL Cluster”). Most of these issues can be overcome, but this also means that you are very unlikely to be able to switch an existing application datastore—that currently uses, for example, MyISAM or InnoDB—to use the NDB storage engine without allowing for the possibility of changes in schemas, queries, and applications.

Beginning with MySQL Cluster NDB 7.1, MySQL Cluster is available for production use on Microsoft Windows. MySQL Cluster is not available for Microsoft Windows in MySQL 5.0. For more information, see MySQL Cluster NDB 6.1 - 7.1.

This chapter represents a work in progress, and its contents are subject to revision as MySQL Cluster continues to evolve. Additional information regarding MySQL Cluster can be found on the MySQL Web site at http://www.mysql.com/products/cluster/.

**Additional Resources.** More information about MySQL Cluster can be found in the following places:

- For answers to some commonly asked questions about MySQL Cluster, see Section A.10, “MySQL 5.0 FAQ: MySQL Cluster”.
- Many MySQL Cluster users and developers blog about their experiences with MySQL Cluster, and make feeds of these available through PlanetMySQL.

# 17.1 MySQL Cluster Overview

*MySQL Cluster* is a technology that enables clustering of in-memory databases in a shared-nothing system. The shared-nothing architecture enables the system to work with very inexpensive hardware, and with a minimum of specific requirements for hardware or software.

MySQL Cluster is designed not to have any single point of failure. In a shared-nothing system, each component is expected to have its own memory and disk, and the use of shared storage mechanisms such as network shares, network file systems, and SANs is not recommended or supported.

MySQL Cluster integrates the standard MySQL server with an in-memory clustered storage engine called NDB (which stands for “Network Database”). In our documentation, the term NDB refers to the part of the setup that is specific to the storage engine, whereas “MySQL Cluster” refers to the combination of one or more MySQL servers with the NDB storage engine.

A MySQL Cluster consists of a set of computers, known as *hosts*, each running one or more processes. These processes, known as *nodes*, may include MySQL servers (for access to NDB data),
data nodes (for storage of the data), one or more management servers, and possibly other specialized
data access programs. The relationship of these components in a MySQL Cluster is shown here:

**Figure 17.1 MySQL Cluster Components**

All these programs work together to form a MySQL Cluster (see Section 17.4, “MySQL Cluster
Programs”). When data is stored by the NDB storage engine, the tables (and table data) are stored in
the data nodes. Such tables are directly accessible from all other MySQL servers (SQL nodes) in the
cluster. Thus, in a payroll application storing data in a cluster, if one application updates the salary of
an employee, all other MySQL servers that query this data can see this change immediately.

However, a MySQL server that is not connected to a MySQL Cluster cannot use the NDB storage
engine and cannot access any MySQL Cluster data.

The data stored in the data nodes for MySQL Cluster can be mirrored; the cluster can handle failures
of individual data nodes with no other impact than that a small number of transactions are aborted due
to losing the transaction state. Because transactional applications are expected to handle transaction
failure, this should not be a source of problems.

Individual nodes can be stopped and restarted, and can then rejoin the system (cluster). Rolling
restarts (in which all nodes are restarted in turn) are used in making configuration changes and
software upgrades (see Section 17.5.5, “Performing a Rolling Restart of a MySQL Cluster”). For more
information about data nodes, how they are organized in a MySQL Cluster, and how they handle and
store MySQL Cluster data, see Section 17.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and
Partitions”.

Backi ng up and restoring MySQL Cluster databases can be done using the NDB native functionality
found in the MySQL Cluster management client and the ndb_restore program included in the
MySQL Cluster distribution. For more information, see Section 17.5.3, “Online Backup of MySQL
Cluster”, and Section 17.4.14, “ndb_restore — Restore a MySQL Cluster Backup”. You can also use
the standard MySQL functionality provided for this purpose in mysqldump and the MySQL server. See
Section 4.5.4, “mysqldump — A Database Backup Program”, for more information.

MySQL Cluster nodes can use a number of different transport mechanisms for inter-node
communications, including TCP/IP using standard 100 Mbps or faster Ethernet hardware. It is also
possible to use the high-speed Scalable Coherent Interface (SCI) protocol with MySQL Cluster,
although this is not required to use MySQL Cluster. SCI requires special hardware and software; see
Section 17.3.4, “Using High-Speed Interconnects with MySQL Cluster”, for more about SCI and using it
with MySQL Cluster.

### 17.1.1 MySQL Cluster Core Concepts
**NDBCLUSTER** (also known as **NDB**) is an in-memory storage engine offering high-availability and data-persistence features.

The **NDBCLUSTER** storage engine can be configured with a range of failover and load-balancing options, but it is easiest to start with the storage engine at the cluster level. MySQL Cluster’s **NDB** storage engine contains a complete set of data, dependent only on other data within the cluster itself.

The “Cluster” portion of MySQL Cluster is configured independently of the MySQL servers. In a MySQL Cluster, each part of the cluster is considered to be a node.

---

**Note**

In many contexts, the term “node” is used to indicate a computer, but when discussing MySQL Cluster it means a process. It is possible to run multiple nodes on a single computer; for a computer on which one or more cluster nodes are being run we use the term **cluster host**.

However, MySQL 5.0 does not support the use of multiple data nodes on a single computer in a production setting. See Section 17.1.5.9, “Limitations Relating to Multiple MySQL Cluster Nodes”.

There are three types of cluster nodes, and in a minimal MySQL Cluster configuration, there will be at least three nodes, one of each of these types:

- **Management node** (MGM node): The role of this type of node is to manage the other nodes within the MySQL Cluster, performing such functions as providing configuration data, starting and stopping nodes, running backup, and so forth. Because this node type manages the configuration of the other nodes, a node of this type should be started first, before any other node. An MGM node is started with the command **ndb_mgmd**.

- **Data node**: This type of node stores cluster data. There are as many data nodes as there are replicas, times the number of fragments (see Section 17.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”). For example, with two replicas, each having two fragments, you need four data nodes. One replica is sufficient for data storage, but provides no redundancy; therefore, it is recommended to have 2 (or more) replicas to provide redundancy, and thus high availability. A data node is started with the command **ndbd** (see Section 17.4.1, “ndbd — The MySQL Cluster Data Node Daemon”).

MySQL Cluster tables in MySQL 5.0 are stored completely in memory rather than on disk (this is why we refer to MySQL cluster as an in-memory database). In MySQL 5.1, MySQL Cluster NDB 6.X, and later, some MySQL Cluster data can be stored on disk, but we do not expect to backport this functionality to MySQL 5.0; see MySQL Cluster Disk Data Tables, for more information.

- **SQL node**: This is a node that accesses the cluster data. In the case of MySQL Cluster, an SQL node is a traditional MySQL server that uses the **NDBCLUSTER** storage engine. An SQL node is a **mysqld** process started with the **--ndbcluster** and **--ndb-connectstring** options, which are explained elsewhere in this chapter, possibly with additional MySQL server options as well.

An SQL node is actually just a specialized type of **API node**, which designates any application which accesses Cluster data. Another example of an API node is the **ndb_restore** utility that is used to restore a cluster backup. It is possible to write such applications using the NDB API. For basic information about the NDB API, see Getting Started with the NDB API.

---

**Important**

It is not realistic to expect to employ a three-node setup in a production environment. Such a configuration provides no redundancy; to benefit from MySQL Cluster’s high-availability features, you must use multiple data and SQL nodes. The use of multiple management nodes is also highly recommended.
For a brief introduction to the relationships between nodes, node groups, replicas, and partitions in MySQL Cluster, see Section 17.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”.

Configuration of a cluster involves configuring each individual node in the cluster and setting up individual communication links between nodes. MySQL Cluster is currently designed with the intention that data nodes are homogeneous in terms of processor power, memory space, and bandwidth. In addition, to provide a single point of configuration, all configuration data for the cluster as a whole is located in one configuration file.

The management server (MGM node) manages the cluster configuration file and the cluster log. Each node in the cluster retrieves the configuration data from the management server, and so requires a way to determine where the management server resides. When interesting events occur in the data nodes, the nodes transfer information about these events to the management server, which then writes the information to the cluster log.

In addition, there can be any number of cluster client processes or applications. These are of two types:

- **Standard MySQL clients.** MySQL Cluster can be used with existing MySQL applications written in PHP, Perl, C, C++, Java, Python, Ruby, and so on. Such client applications send SQL statements to and receive responses from MySQL servers acting as MySQL Cluster SQL nodes in much the same way that they interact with standalone MySQL servers. However, MySQL clients using a MySQL Cluster as a data source can be modified to take advantage of the ability to connect with multiple MySQL servers to achieve load balancing and failover. For example, Java clients using Connector/J 5.0.6 and later can use `jdbc:mysql:loadbalance://` URLs (improved in Connector/J 5.1.7) to achieve load balancing transparently.

- **Management clients.** These clients connect to the management server and provide commands for starting and stopping nodes gracefully, starting and stopping message tracing (debug versions only), showing node versions and status, starting and stopping backups, and so on. Such clients—such as the `ndb_mgm` management client supplied with MySQL Cluster (see Section 17.4.3, “ndb_mgm — The MySQL Cluster Management Client”)—are written using the MGM API, a C-language API that communicates directly with one or more MySQL Cluster management servers. For more information, see The MGM API.

**Event logs.** MySQL Cluster logs events by category (startup, shutdown, errors, checkpoints, and so on), priority, and severity. A complete listing of all reportable events may be found in Section 17.5.6, “Event Reports Generated in MySQL Cluster”. Event logs are of two types:

- **Cluster log.** Keeps a record of all desired reportable events for the cluster as a whole.

- **Node log.** A separate log which is also kept for each individual node.

**Note**
Under normal circumstances, it is necessary and sufficient to keep and examine only the cluster log. The node logs need be consulted only for application development and debugging purposes.

**Checkpoint.** Generally speaking, when data is saved to disk, it is said that a checkpoint has been reached. More specific to Cluster, it is a point in time where all committed transactions are stored on disk. With regard to the NDB storage engine, there are two types of checkpoints which work together to ensure that a consistent view of the cluster's data is maintained:

- **Local Checkpoint (LCP):** This is a checkpoint that is specific to a single node; however, LCPs take place for all nodes in the cluster more or less concurrently. An LCP involves saving all of a node's data to disk, and so usually occurs every few minutes. The precise interval varies, and depends upon the amount of data stored by the node, the level of cluster activity, and other factors.

- **Global Checkpoint (GCP):** A GCP occurs every few seconds, when transactions for all nodes are synchronized and the redo-log is flushed to disk.
For more information about the files and directories created by local checkpoints and global checkpoints, see MySQL Cluster Data Node File System Directory Files.

17.1.2 MySQL Cluster Nodes, Node Groups, Replicas, and Partitions

This section discusses the manner in which MySQL Cluster divides and duplicates data for storage.

Central to an understanding of this topic are the following concepts, listed here with brief definitions:

- **(Data) Node.** An ndbd process, which stores a replica—that is, a copy of the partition (see below) assigned to the node group of which the node is a member.

  Each data node should be located on a separate computer. While it is also possible to host multiple ndbd processes on a single computer, such a configuration is not supported.

  It is common for the terms "node" and "data node" to be used interchangeably when referring to an ndbd process; where mentioned, management (MGM) nodes (ndb_mgmd processes) and SQL nodes (mysql processes) are specified as such in this discussion.

- **Node Group.** A node group consists of one or more nodes, and stores partitions, or sets of replicas (see next item).

  The number of node groups in a MySQL Cluster is not directly configurable; it is function of the number of data nodes and of the number of replicas (NoOfReplicas configuration parameter), as shown here:

  \[
  \text{[number_of_node_groups]} = \frac{\text{number_of_data_nodes}}{\text{NoOfReplicas}}
  \]

  Thus, a MySQL Cluster with 4 data nodes has 4 node groups if NoOfReplicas is set to 1 in the config.ini file, 2 node groups if NoOfReplicas is set to 2, and 1 node group if NoOfReplicas is set to 4. Replicas are discussed later in this section; for more information about NoOfReplicas, see Section 17.3.3.5, "Defining MySQL Cluster Data Nodes".

  **Note**

  All node groups in a MySQL Cluster must have the same number of data nodes.

- **Partition.** This is a portion of the data stored by the cluster. There are as many cluster partitions as nodes participating in the cluster. Each node is responsible for keeping at least one copy of any partitions assigned to it (that is, at least one replica) available to the cluster.

  A replica belongs entirely to a single node; a node can (and usually does) store several replicas.

- **Replica.** This is a copy of a cluster partition. Each node in a node group stores a replica. Also sometimes known as a partition replica. The number of replicas is equal to the number of nodes per node group.

  The following diagram illustrates a MySQL Cluster with four data nodes, arranged in two node groups of two nodes each; nodes 1 and 2 belong to node group 0, and nodes 3 and 4 belong to node group 1. Note that only data (ndbd) nodes are shown here; although a working cluster requires an ndb_mgm process for cluster management and at least one SQL node to access the data stored by the cluster, these have been omitted in the figure for clarity.
The data stored by the cluster is divided into four partitions, numbered 0, 1, 2, and 3. Each partition is stored—in multiple copies—on the same node group. Partitions are stored on alternate node groups:

- Partition 0 is stored on node group 0; a primary replica (primary copy) is stored on node 1, and a backup replica (backup copy of the partition) is stored on node 2.

- Partition 1 is stored on the other node group (node group 1); this partition's primary replica is on node 3, and its backup replica is on node 4.

- Partition 2 is stored on node group 0. However, the placing of its two replicas is reversed from that of Partition 0; for Partition 2, the primary replica is stored on node 2, and the backup on node 1.

- Partition 3 is stored on node group 1, and the placement of its two replicas are reversed from those of partition 1. That is, its primary replica is located on node 4, with the backup on node 3.

What this means regarding the continued operation of a MySQL Cluster is this: so long as each node group participating in the cluster has at least one node operating, the cluster has a complete copy of all data and remains viable. This is illustrated in the next diagram.
17.1.3 MySQL Cluster Hardware, Software, and Networking Requirements

One of the strengths of MySQL Cluster is that it can be run on commodity hardware and has no unusual requirements in this regard, other than for large amounts of RAM, due to the fact that all live data storage is done in memory. (It is possible to reduce this requirement using Disk Data tables, which are implemented in MySQL 5.1; however, we do not intend to backport this feature to MySQL 5.0.) Naturally, multiple and faster CPUs will enhance performance. Memory requirements for other MySQL Cluster processes are relatively small.

The software requirements for MySQL Cluster are also modest. Host operating systems do not require any unusual modules, services, applications, or configuration to support MySQL Cluster. For supported operating systems, a standard installation should be sufficient. The MySQL software requirements are simple: all that is needed is a production release of MySQL 5.0 to have Cluster support. It is not necessary to compile MySQL yourself merely to be able to use MySQL Cluster. We assume that you are using the server binary appropriate to your platform, available from the MySQL Cluster software downloads page at http://dev.mysql.com/downloads/cluster/.

For communication between nodes, MySQL Cluster supports TCP/IP networking in any standard topology, and the minimum expected for each host is a standard 100 Mbps Ethernet card, plus a switch, hub, or router to provide network connectivity for the cluster as a whole. We strongly recommend that a MySQL Cluster be run on its own subnet which is not shared with machines not forming part of the cluster for the following reasons:

- **Security.** Communications between MySQL Cluster nodes are not encrypted or shielded in any way. The only means of protecting transmissions within a MySQL Cluster is to run the cluster on a protected network. If you intend to use MySQL Cluster for Web applications, the cluster should definitely reside behind your firewall and not in your network’s De-Militarized Zone (DMZ) or elsewhere.

See Section 17.5.10.1, “MySQL Cluster Security and Networking Issues”, for more information.
• **Efficiency.** Setting up a MySQL Cluster on a private or protected network enables the cluster to make exclusive use of bandwidth between cluster hosts. Using a separate switch for your MySQL Cluster not only helps protect against unauthorized access to cluster data, it also ensures that MySQL Cluster nodes are shielded from interference caused by transmissions between other computers on the network. For enhanced reliability, you can use dual switches and dual cards to remove the network as a single point of failure; many device drivers support failover for such communication links.

**Network communication and latency.** MySQL Cluster requires communication between data nodes and API nodes (including SQL nodes), as well as between data nodes and other data nodes, to execute queries and updates. Communication latency between these processes can directly affect the observed performance and latency of user queries. In addition, to maintain consistency and service despite the silent failure of nodes, MySQL Cluster uses heartbeating and timeout mechanisms which treat an extended loss of communication from a node as node failure. This can lead to reduced redundancy. Recall that, to maintain data consistency, a MySQL Cluster shuts down when the last node in a node group fails. Thus, to avoid increasing the risk of a forced shutdown, breaks in communication between nodes should be avoided wherever possible.

The failure of a data or API node results in the abort of all uncommitted transactions involving the failed node. Data node recovery requires synchronization of the failed node's data from a surviving data node, and re-establishment of disk-based redo and checkpoint logs, before the data node returns to service. This recovery can take some time, during which the Cluster operates with reduced redundancy.

Heartbeating relies on timely generation of heartbeat signals by all nodes. This may not be possible if the node is overloaded, has insufficient machine CPU due to sharing with other programs, or is experiencing delays due to swapping. If heartbeat generation is sufficiently delayed, other nodes treat the node that is slow to respond as failed.

This treatment of a slow node as a failed one may or may not be desireable in some circumstances, depending on the impact of the node's slowed operation on the rest of the cluster. When setting timeout values such as `HeartbeatIntervalDbDb` and `HeartbeatIntervalDbApi` for MySQL Cluster, care must be taken to achieve quick detection, failover, and return to service, while avoiding potentially expensive false positives.

Where communication latencies between data nodes are expected to be higher than would be expected in a LAN environment (on the order of 100 µs), timeout parameters must be increased to ensure that any allowed periods of latency periods are well within configured timeouts. Increasing timeouts in this way has a corresponding effect on the worst-case time to detect failure and therefore time to service recovery.

LAN environments can typically be configured with stable low latency, and such that they can provide redundancy with fast failover. Individual link failures can be recovered from with minimal and controlled latency visible at the TCP level (where MySQL Cluster normally operates). WAN environments may offer a range of latencies, as well as redundancy with slower failover times. Individual link failures may require route changes to propagate before end-to-end connectivity is restored. At the TCP level this can appear as large latencies on individual channels. The worst-case observed TCP latency in these scenarios is related to the worst-case time for the IP layer to reroute around the failures.

**SCI support.** It is also possible to use the high-speed Scalable Coherent Interface (SCI) with MySQL Cluster, but this is not a requirement. See [Section 17.3.4, "Using High-Speed Interconnects with MySQL Cluster"](#), for more about this protocol and its use with MySQL Cluster.

### 17.1.4 What is New in MySQL Cluster

In this section, we discuss changes in the implementation of MySQL Cluster in MySQL 5.0 as compared to MySQL 4.1.

There are relatively few changes between the NDB storage engine implementations in MySQL 4.1 and in 5.0, so the upgrade path should be relatively quick and painless.
All significantly new features being developed for MySQL Cluster are going into the MySQL Cluster NDB 7.x trees. For information on changes in the Cluster implementations in MySQL versions 5.1 and later, see MySQL Cluster Development History.

MySQL Cluster in MySQL 5.0 contains a number of features added since MySQL 4.1 that are likely to be of interest:

- **Condition pushdown.** Consider the following query:

  ```sql
  SELECT * FROM t1 WHERE non_indexed_attribute = 1;
  ```

  This query uses a full table scan and the condition is evaluated in the cluster's data nodes. Thus, it is not necessary to send the records across the network for evaluation. (That is, function transport is used, rather than data transport.) Please note that this feature is currently disabled by default (pending more thorough testing), but it should work in most cases. This feature can be enabled through the use of the `SET engine_condition_pushdown = On` statement. Alternatively, you can run `mysqld` with this feature enabled by starting the MySQL server with the `--engine-condition-pushdown` option.

  A major benefit of this change is that queries can be executed in parallel. This means that queries against nonindexed columns can run faster than previously by a factor of as much as 5 to 10 times, *times the number of data nodes*, because multiple CPUs can work on the query in parallel.

  You can use `EXPLAIN` to determine when condition pushdown is being used. See Section 13.8.2, “EXPLAIN Syntax”.

- **Decreased IndexMemory Usage**: In MySQL 5.0, each record consumes approximately 25 bytes of index memory, and every unique index uses 25 bytes per record of index memory (in addition to some data memory because these are stored in a separate table). This is because the primary key is not stored in the index memory anymore.

- **Query Cache Enabled for MySQL Cluster**: See Section 8.10.3, “The MySQL Query Cache”, for information on configuring and using the query cache.

- **New optimizations.** One optimization that merits particular attention is that a batched read interface is now used in some queries. For example, consider the following query:

  ```sql
  SELECT * FROM t1 WHERE primary_key IN (1,2,3,4,5,6,7,8,9,10);
  ```

  This query will be executed 2 to 3 times more quickly than in previous MySQL Cluster versions due to the fact that all 10 key lookups are sent in a single batch rather than one at a time.

- **Limit On Number of Metadata Objects**: Beginning with MySQL 5.0.6, each Cluster database may contain a maximum of 20320 metadata objects—this includes database tables, system tables, indexes and `BLOB` values. (Previously, this number was 1600.)

### 17.1.5 Known Limitations of MySQL Cluster

In the sections that follow, we discuss known limitations of MySQL Cluster in MySQL 5.0 as compared with the features available when using the MyISAM and InnoDB storage engines. Currently, there are no plans to address these in coming releases of MySQL 5.0; however, we will attempt to supply fixes for these issues in subsequent release series. If you check the “Cluster” category in the MySQL bugs database at [http://bugs.mysql.com](http://bugs.mysql.com), you can find known bugs in the following categories under “MySQL Server;” in the MySQL bugs database at [http://bugs.mysql.com](http://bugs.mysql.com), which we intend to correct in upcoming releases of MySQL Cluster:

- Cluster
- Cluster Direct API (NDBAPI)
• Cluster Disk Data

• Cluster Replication

This information is intended to be complete with respect to the conditions just set forth. You can report any discrepancies that you encounter to the MySQL bugs database using the instructions given in Section 1.7, “How to Report Bugs or Problems”. If we do not plan to fix the problem in MySQL 5.0, we will add it to the list.

See Section 17.1.5.10, “Previous MySQL Cluster Issues Resolved in MySQL 5.0” for a list of issues in MySQL Cluster in MySQL 4.1 that have been resolved in the current version.

17.1.5.1 Noncompliance with SQL Syntax in MySQL Cluster

Some SQL statements relating to certain MySQL features produce errors when used with NDB tables, as described in the following list:

• **Temporary tables.** Temporary tables are not supported. Trying either to create a temporary table that uses the NDB storage engine or to alter an existing temporary table to use NDB fails with the error `Table storage engine 'ndbcluster' does not support the create option 'TEMPORARY'`.

• **Indexes and keys in NDB tables.** Keys and indexes on MySQL Cluster tables are subject to the following limitations:

  • **Column width.** Attempting to create an index on an NDB table column whose width is greater than 3072 bytes succeeds, but only the first 3072 bytes are actually used for the index. In such cases, a warning `Specified key was too long; max key length is 3072 bytes` is issued, and a `SHOW CREATE TABLE` statement shows the length of the index as 3072.

  • **TEXT and BLOB columns.** You cannot create indexes on NDB table columns that use any of the TEXT or BLOB data types.

  • **FULLTEXT indexes.** The NDB storage engine does not support FULLTEXT indexes, which are possible for MyISAM tables only. However, you can create indexes on VARCHAR columns of NDB tables.

  • **USING HASH keys and NULL.** Using nullable columns in unique keys and primary keys means that queries using these columns are handled as full table scans. To work around this issue, make the column NOT NULL, or re-create the index without the USING HASH option.

  • **Prefixes.** There are no prefix indexes; only entire columns can be indexed. (The size of an NDB column index is always the same as the width of the column in bytes, up to and including 3072 bytes, as described earlier in this section. Also see Section 17.1.5.6, “Unsupported or Missing Features in MySQL Cluster”, for additional information.)

  • **BIT columns.** A BIT column cannot be a primary key, unique key, or index, nor can it be part of a composite primary key, unique key, or index.

  • **AUTO_INCREMENT columns.** Like other MySQL storage engines, the NDB storage engine can handle a maximum of one AUTO_INCREMENT column per table, and this column must be indexed. However, in the case of a MySQL Cluster table with no explicit primary key, an AUTO_INCREMENT column is automatically defined and used as a “hidden” primary key. For this reason, you cannot create an NDB table having an AUTO_INCREMENT column and no explicit primary key.

  • **MySQL Cluster and geometry data types.** Geometry data types (WKT and WKB) are supported in NDB tables in MySQL 5.0. However, spatial indexes are not supported.
17.1.5.2 Limits and Differences of MySQL Cluster from Standard MySQL Limits

In this section, we list limits found in MySQL Cluster that either differ from limits found in, or that are not found in, standard MySQL.

Memory usage and recovery. Memory consumed when data is inserted into an NDB table is not automatically recovered when deleted, as it is with other storage engines. Instead, the following rules hold true:

- A DELETE statement on an NDB table makes the memory formerly used by the deleted rows available for re-use by inserts on the same table only. However, this memory can be made available for general re-use by performing a rolling restart of the cluster. See Section 17.5.5, “Performing a Rolling Restart of a MySQL Cluster”.

- A DROP TABLE or TRUNCATE TABLE operation on an NDB table frees the memory that was used by this table for re-use by any NDB table, either by the same table or by another NDB table.

Note
Recall that TRUNCATE TABLE drops and re-creates the table. See Section 13.1.21, “TRUNCATE TABLE Syntax”.

- Limits imposed by the cluster’s configuration. A number of hard limits exist which are configurable, but available main memory in the cluster sets limits. See the complete list of configuration parameters in Section 17.3.3, “MySQL Cluster Configuration Files”. Most configuration parameters can be upgraded online. These hard limits include:

  - Database memory size and index memory size (DataMemory and IndexMemory, respectively).

    DataMemory is allocated as 32KB pages. As each DataMemory page is used, it is assigned to a specific table; once allocated, this memory cannot be freed except by dropping the table.

    See Section 17.3.3.5, “Defining MySQL Cluster Data Nodes”, for further information about DataMemory and IndexMemory.

  - The maximum number of operations that can be performed per transaction is set using the configuration parameters MaxNoOfConcurrentOperations and MaxNoOfLocalOperations.

Note
Bulk loading, TRUNCATE TABLE, and ALTER TABLE are handled as special cases by running multiple transactions, and so are not subject to this limitation.

  - Different limits related to tables and indexes. For example, the maximum number of ordered indexes in the cluster is determined by MaxNoOfOrderedIndexes, and the maximum number of ordered indexes per table is 16.

  - Memory usage. All Cluster table rows are of fixed length. This means (for example) that if a table has one or more VARCHAR fields containing only relatively small values, more memory and disk space is required when using the NDB storage engine than would be the case for the same table and data using the MyISAM engine. (In other words, in the case of a VARCHAR column, the column requires the same amount of storage as a CHAR column of the same size.)

  - Node and data object maximums. The following limits apply to numbers of cluster nodes and metadata objects:

    - The maximum number of data nodes is 48.

    A data node must have a node ID in the range of 1 to 48, inclusive. (Management and API nodes may use any integer in the range of 1-63 inclusive as a node ID.)
- The total maximum number of nodes in a MySQL Cluster is 63. This number includes all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers.

- The maximum number of metadata objects in MySQL 5.0 Cluster is 20320. This limit is hard-coded.

### 17.1.5.3 Limits Relating to Transaction Handling in MySQL Cluster

A number of limitations exist in MySQL Cluster with regard to the handling of transactions. These include the following:

- **Transaction isolation level.** The NDBCLUSTER storage engine supports only the **READ COMMITTED** transaction isolation level. *(InnoDB, for example, supports **READ COMMITTED**, **READ UNCOMMITTED**, REPEATABLE READ, and **SERIALIZABLE**.) See Section 17.5.3.4, “MySQL Cluster Backup Troubleshooting”, for information on how this can affect backing up and restoring Cluster databases.

- **Transactions and BLOB or TEXT columns.** NDBCLUSTER stores only part of a column value that uses any of MySQL’s **BLOB** or **TEXT** data types in the table visible to MySQL; the remainder of the **BLOB** or **TEXT** is stored in a separate internal table that is not accessible to MySQL. This gives rise to two related issues of which you should be aware whenever executing **SELECT** statements on tables that contain columns of these types:

  1. For any **SELECT** from a MySQL Cluster table: If the **SELECT** includes a **BLOB** or **TEXT** column, the **READ COMMITTED** transaction isolation level is converted to a read with read lock. This is done to guarantee consistency.

  2. For any **SELECT** which uses a primary key lookup or unique key lookup to retrieve any columns that use any of the **BLOB** or **TEXT** data types and that is executed within a transaction, a shared read lock is held on the table for the duration of the transaction—that is, until the transaction is either committed or aborted. This does not occur for queries that use index or table scans.

For example, consider the table `t` defined by the following **CREATE TABLE** statement:

```sql
CREATE TABLE t (
    a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    b INT NOT NULL,
    c INT NOT NULL,
    d TEXT,
    INDEX i(b),
    UNIQUE KEY u(c)
) ENGINE = NDB,
```

Either of the following queries on `t` causes a shared read lock, because the first query uses a primary key lookup and the second uses a unique key lookup:

```sql
SELECT * FROM t WHERE a = 1;
SELECT * FROM t WHERE c = 1;
```

However, none of the four queries shown here causes a shared read lock:

```sql
SELECT * FROM t WHERE b = 1;
SELECT * FROM t WHERE d = '1';
SELECT * FROM t;
SELECT b,c WHERE a = 1;
```
This is because, of these four queries, the first uses an index scan, the second and third use table scans, and the fourth, while using a primary key lookup, does not retrieve the value of any BLOB or TEXT columns.

You can help minimize issues with shared read locks by avoiding queries that use primary key lookups or unique key lookups to retrieve BLOB or TEXT columns, or, in cases where such queries are not avoidable, by committing transactions as soon as possible afterward.

This limitation is lifted in MySQL Cluster NDB 7.0 (Bug #49190).

• **Rollbacks.** There are no partial transactions, and no partial rollbacks of transactions. A duplicate key or similar error aborts the entire transaction, and subsequent statements raise **ERROR 1296 (HY000): Got error 4350 'Transaction already aborted' from NDBCLUSTER.** In such cases, you must issue an explicit **ROLLBACK** and retry the entire transaction.

This behavior differs from that of other transactional storage engines such as InnoDB that may roll back individual statements.

• **Transactions and memory usage.**

As noted elsewhere in this chapter, MySQL Cluster does not handle large transactions well; it is better to perform a number of small transactions with a few operations each than to attempt a single large transaction containing a great many operations. Among other considerations, large transactions require very large amounts of memory. Because of this, the transactional behavior of a number of MySQL statements is effected as described in the following list:

• **TRUNCATE TABLE** is not transactional when used on NDB tables. If a TRUNCATE TABLE fails to empty the table, then it must be re-run until it is successful.

• **DELETE FROM** (even with no WHERE clause) is transactional. For tables containing a great many rows, you may find that performance is improved by using several DELETE FROM ... LIMIT ... statements to “chunk” the delete operation. If your objective is to empty the table, then you may wish to use TRUNCATE TABLE instead.

• **LOAD DATA statements.** **LOAD DATA INFILE** is not transactional when used on NDB tables.

  ![Important]

  When executing a **LOAD DATA INFILE** statement, the NDB engine performs commits at irregular intervals that enable better utilization of the communication network. It is not possible to know ahead of time when such commits take place.

**LOAD DATA FROM MASTER** is not supported in MySQL Cluster.

• **ALTER TABLE and transactions.** When copying an NDB table as part of an ALTER TABLE, the creation of the copy is nontransactional. (In any case, this operation is rolled back when the copy is deleted.)

### 17.1.5.4 MySQL Cluster Error Handling

Starting, stopping, or restarting a node may give rise to temporary errors causing some transactions to fail. These include the following cases:

• **Temporary errors.** When first starting a node, it is possible that you may see Error 1204

  Temporary failure, distribution changed and similar temporary errors.

• **Errors due to node failure.** The stopping or failure of any data node can result in a number of different node failure errors. (However, there should be no aborted transactions when performing a planned shutdown of the cluster.)
In either of these cases, any errors that are generated must be handled within the application. This should be done by retrying the transaction.

See also Section 17.1.5.2, “Limits and Differences of MySQL Cluster from Standard MySQL Limits”.

17.1.5.5 Limits Associated with Database Objects in MySQL Cluster

Some database objects such as tables and indexes have different limitations when using the NDBCLUSTER storage engine:

- **Identifiers.** Database names, table names and attribute names cannot be as long in NDB tables as when using other table handlers. Attribute names are truncated to 31 characters, and if not unique after truncation give rise to errors. Database names and table names can total a maximum of 122 characters. In other words, the maximum length for an NDB table name is 122 characters, less the number of characters in the name of the database of which that table is a part.

- **Table names containing special characters.** NDB tables whose names contain characters other than letters, numbers, dashes, and underscores and which are created on one SQL node may not be discovered correctly by other SQL nodes. (Bug #31470)

- **Number of tables and other database objects.** The maximum number of tables in a Cluster database in MySQL 5.0 is limited to 1792. The maximum number of all NDBCLUSTER database objects in a single MySQL Cluster—including databases, tables, and indexes—is limited to 20320.

- **Attributes per table.** The maximum number of attributes (that is, columns and indexes) per table is limited to 128.

- **Attributes per key.** The maximum number of attributes per key is 32.

- **Row size.** The maximum permitted size of any one row is 8052 bytes. Each BLOB or TEXT column contributes 256 + 8 = 264 bytes to this total.

- **BIT column storage per table.** The maximum combined width for all BIT columns used in a given NDB table is 4096.

- **Number of rows per partition.** The maximum number of rows that can be stored in a single MySQL Cluster partition varies with the number of replicas times the number of fragments. Since the number of partitions is the same as the number of data nodes in the cluster (see Section 17.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”), you can increase the number of fragments—and thus the available space—by using more data nodes.

17.1.5.6 Unsupported or Missing Features in MySQL Cluster

A number of features supported by other storage engines are not supported for NDB tables. Trying to use any of these features in MySQL Cluster does not cause errors in or of itself; however, errors may occur in applications that expects the features to be supported or enforced. Statements referencing such features, even if effectively ignored by NDB, must be syntactically and otherwise valid.

- **Foreign key constraints.** The foreign key construct is ignored, just as it is in MyISAM tables.

- **Index prefixes.** Prefixes on indexes are not supported for NDB tables. If a prefix is used as part of an index specification in a statement such as CREATE TABLE, ALTER TABLE, or CREATE INDEX, the prefix is not created by NDB.

A statement containing an index prefix, and creating or modifying an NDB table, must still be syntactically valid. For example, the following statement always fails with Error 1089 Incorrect prefix key; the used key part isn't a string, the used length is longer than the key part, or the storage engine doesn't support unique prefix keys, regardless of storage engine:

```sql
CREATE TABLE t1 (```
c1 INT NOT NULL,
c2 VARCHAR(100),
INDEX i1 (c2(500))
);

This happens on account of the SQL syntax rule that no index may have a prefix larger than itself.

- **OPTIMIZE operations.** OPTIMIZE operations are not supported.
- **LOAD TABLE ... FROM MASTER.** LOAD TABLE ... FROM MASTER is not supported.
- **Savepoints and rollbacks.** Savepoints and rollbacks to savepoints are ignored as in MyISAM.
- **Durability of commits.** There are no durable commits on disk. Commits are replicated, but there is no guarantee that logs are flushed to disk on commit.

**Replication.** Replication is not supported.

**Note**

See Section 17.1.5.3, “Limits Relating to Transaction Handling in MySQL Cluster”, for more information relating to limitations on transaction handling in NDB.

### 17.1.5.7 Limitations Relating to Performance in MySQL Cluster

The following performance issues are specific to or especially pronounced in MySQL Cluster:

- **Range scans.** There are query performance issues due to sequential access to the NDB storage engine; it is also relatively more expensive to do many range scans than it is with either MyISAM or InnoDB.

- **Reliability of Records in range.** The Records in range statistic is available but is not completely tested or officially supported. This may result in nonoptimal query plans in some cases. If necessary, you can employ USE INDEX or FORCE INDEX to alter the execution plan. See Section 8.9.2, “Index Hints”, for more information on how to do this.

- **Unique hash indexes.** Unique hash indexes created with USING HASH cannot be used for accessing a table if NULL is given as part of the key.

### 17.1.5.8 Issues Exclusive to MySQL Cluster

The following are limitations specific to the NDBCLUSTER storage engine:

- **Machine architecture.** The following issues relate to physical architecture of cluster hosts:
  
  - All machines used in the cluster must have the same architecture. That is, all machines hosting nodes must be either big-endian or little-endian, and you cannot use a mixture of both. For example, you cannot have a management node running on a PowerPC which directs a data node that is running on an x86 machine. This restriction does not apply to machines simply running mysql or other clients that may be accessing the cluster’s SQL nodes.
  
- **Adding and dropping of data nodes.** Online adding or dropping of data nodes is not currently possible. In such cases, the entire cluster must be restarted.

- **Backup and restore between architectures.** It is also not possible to perform a Cluster backup and restore between different architectures. For example, you cannot back up a cluster running on a big-endian platform and then restore from that backup to a cluster running on a little-endian system. (Bug #19255)

- **Online schema changes.** It is not possible to make online schema changes such as those accomplished using ALTER TABLE or CREATE INDEX, as the NDB Cluster engine does...
not support autodiscovery of such changes. (However, you can import or create a table that uses a different storage engine, and then convert it to NDB using ALTER TABLE tbl_name ENGINE=NDBCLUSTER. In such a case, you must issue a FLUSH TABLES statement to force the cluster to pick up the change.)

- **Binary logging.** MySQL Cluster has the following limitations or restrictions with regard to binary logging:
  - `sql_log_bin` has no effect on data operations; however, it is supported for schema operations.
  - MySQL Cluster cannot produce a binary log for tables having `BLOB` columns but no primary key.
  - Only the following schema operations are logged in a cluster binary log which is *not* on the `mysqlid` executing the statement:
    - `CREATE TABLE`
    - `ALTER TABLE`
    - `DROP TABLE`
    - `CREATE DATABASE / CREATE SCHEMA`
    - `DROP DATABASE / DROP SCHEMA`

See also Section 17.1.5.9, “Limitations Relating to Multiple MySQL Cluster Nodes”.

### 17.1.5.9 Limitations Relating to Multiple MySQL Cluster Nodes

**Multiple SQL nodes.**
The following are issues relating to the use of multiple MySQL servers as MySQL Cluster SQL nodes, and are specific to the `NDBCLUSTER` storage engine:

- **No distributed table locks.** A `LOCK TABLES` works only for the SQL node on which the lock is issued; no other SQL node in the cluster “sees” this lock. This is also true for a lock issued by any statement that locks tables as part of its operations. (See next item for an example.)

- **ALTER TABLE operations.** `ALTER TABLE` is not fully locking when running multiple MySQL servers (SQL nodes). (As discussed in the previous item, MySQL Cluster does not support distributed table locks.)

- **Replication.** MySQL replication will not work correctly if updates are done on multiple MySQL servers. However, if the database partitioning scheme is done at the application level and no transactions take place across these partitions, replication can be made to work.

- **Database autodiscovery.** Autodiscovery of databases is not supported for multiple MySQL servers accessing the same MySQL Cluster. However, autodiscovery of tables is supported in such cases. What this means is that after a database named `db_name` is created or imported using one MySQL server, you should issue a `CREATE DATABASE db_name` statement on each additional MySQL server that accesses the same MySQL Cluster. (As of MySQL 5.0.2, you may also use `CREATE SCHEMA db_name`.) Once this has been done for a given MySQL server, that server should be able to detect the database tables without error.

- **DDL operations.** DDL operations (such as `CREATE TABLE` or `ALTER TABLE`) are not safe from data node failures. If a data node fails while trying to perform one of these, the data dictionary is locked and no further DDL statements can be executed without restarting the cluster.

**Multiple management nodes.**
When using multiple management servers:

- If any of the management servers are running on the same host, you must give nodes explicit IDs in connection strings because automatic allocation of node IDs does not work across multiple...
management servers on the same host. This is not required if every management server resides on a different host.

In addition, all API nodes (including MySQL servers acting as SQL nodes), should list all management servers using the same order in their connection strings.

• You must take extreme care to have the same configurations for all management servers. No special checks for this are performed by the cluster.

• Prior to MySQL 5.0.14, all data nodes had to be restarted after bringing up the cluster for the management nodes to be able to see one another.

(See Bug #12307 and Bug #13070 for more information.)

**Multiple data node processes.** While it is possible to run multiple cluster processes concurrently on a single host, it is not always advisable to do so for reasons of performance and high availability, as well as other considerations. In particular, in MySQL 5.0, we do not support for production use any MySQL Cluster deployment in which more than one ndbd process is run on a single physical machine.

![Note](Image)

We may support multiple data nodes per host in a future MySQL release, following additional testing. However, in MySQL 5.0, such configurations can be considered experimental only.

**Multiple network addresses.** Multiple network addresses per data node are not supported. Use of these is liable to cause problems: In the event of a data node failure, an SQL node waits for confirmation that the data node went down but never receives it because another route to that data node remains open. This can effectively make the cluster inoperable.

![Note](Image)

It is possible to use multiple network hardware interfaces (such as Ethernet cards) for a single data node, but these must be bound to the same address. This also means that it not possible to use more than one [tcp] section per connection in the config.ini file. See Section 17.3.3.8, “MySQL Cluster TCP/IP Connections”, for more information.

### 17.1.5.10 Previous MySQL Cluster Issues Resolved in MySQL 5.0

The following Cluster limitations in MySQL 4.1 have been resolved in MySQL 5.0 as shown below:

• **Character set support.** The NDBCLUSTER storage engine supports all character sets and collations available in MySQL 5.0.

• **Character set directory.** Beginning with MySQL 5.0.21, it is possible to install MySQL with Cluster support to a nondefault location and change the search path for font description files using either the --basedir or --character-sets-dir options. (Previously, ndbd in MySQL 5.0 searched only the default path—typically /usr/local/mysql/share/mysql/charsets—for character sets.)

• **Metadata objects.** Prior to MySQL 5.0.6, the maximum number of metadata objects possible was 1600. Beginning with MySQL 5.0.6, this limit is increased to 20320.

• **Query cache.** Unlike the case in MySQL 4.1, the Cluster storage engine in MySQL 5.0 supports MySQL’s query cache. See Section 8.10.3, “The MySQL Query Cache”.

• **IGNORE and REPLACE functionality.**

  In MySQL 5.0.19 and earlier, INSERT IGNORE, UPDATE IGNORE, and REPLACE were supported only for primary keys, but not for unique keys. It was possible to work around this issue by removing the constraint, then dropping the unique index, performing any inserts, and then adding the unique index again.
This limitation was removed for `INSERT IGNORE` and `REPLACE` in MySQL 5.0.20. (See Bug #17431.)

- `auto_increment_increment` and `auto_increment_offset`. The `auto_increment_increment` and `auto_increment_offset` server system variables are supported for `NDBCLUSTER` tables beginning with MySQL 5.0.46.

17.2 MySQL Cluster Installation and Upgrades

This section describes the basics for planning, installing, configuring, and running a MySQL Cluster. Whereas the examples in Section 17.3, “MySQL Cluster Configuration” provide more in-depth information on a variety of clustering options and configuration, the result of following the guidelines and procedures outlined here should be a usable MySQL Cluster which meets the minimum requirements for availability and safeguarding of data.

This section covers hardware and software requirements; networking issues; installation of MySQL Cluster; configuration issues; starting, stopping, and restarting the cluster; loading of a sample database; and performing queries.

Assumptions. The following sections make a number of assumptions regarding the cluster's physical and network configuration. These assumptions are discussed in the next few paragraphs.

Cluster nodes and host computers. The cluster consists of four nodes, each on a separate host computer, and each with a fixed network address on a typical Ethernet network as shown here:

<table>
<thead>
<tr>
<th>Node</th>
<th>IP Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Management node (<code>mgmd</code>)</td>
<td>192.168.0.10</td>
</tr>
<tr>
<td>SQL node (<code>mysqld</code>)</td>
<td>192.168.0.20</td>
</tr>
<tr>
<td>Data node &quot;A&quot; (<code>ndbd</code>)</td>
<td>192.168.0.30</td>
</tr>
<tr>
<td>Data node &quot;B&quot; (<code>ndbd</code>)</td>
<td>192.168.0.40</td>
</tr>
</tbody>
</table>

This may be made clearer by the following diagram:

**Figure 17.4 MySQL Cluster Multi-Computer Setup**

Network addressing. In the interest of simplicity (and reliability), this How-To uses only numeric IP addresses. However, if DNS resolution is available on your network, it is possible to use host names.
in lieu of IP addresses in configuring Cluster. Alternatively, you can use the *hosts* file (typically /etc/hosts for Linux and other Unix-like operating systems, or your operating system's equivalent) for providing a means to do host lookup if such is available.

**Potential hosts file issues.** A common problem when trying to use host names for Cluster nodes arises because of the way in which some operating systems (including some Linux distributions) set up the system's own host name in the `/etc_hosts` during installation. Consider two machines with the host names `ndb1` and `ndb2`, both in the `cluster` network domain. Red Hat Linux (including some derivatives such as CentOS and Fedora) places the following entries in these machines' `/etc/hosts` files:

```
# ndb1 /etc/hosts:
127.0.0.1   ndb1.cluster ndb1 localhost.localdomain localhost
```

```
# ndb2 /etc/hosts:
127.0.0.1   ndb2.cluster ndb2 localhost.localdomain localhost
```

SUSE Linux (including OpenSUSE) places these entries in the machines' `/etc/hosts` files:

```
# ndb1 /etc/hosts:
127.0.0.1 localhost
127.0.0.2 ndb1.cluster ndb1
```

```
# ndb2 /etc/hosts:
127.0.0.1 localhost
127.0.0.2 ndb2.cluster ndb2
```

In both instances, `ndb1` routes `ndb1.cluster` to a loopback IP address, but gets a public IP address from DNS for `ndb2.cluster`, while `ndb2` routes `ndb2.cluster` to a loopback address and obtains a public address for `ndb1.cluster`. The result is that each data node connects to the management server, but cannot tell when any other data nodes have connected, and so the data nodes appear to hang while starting.

**Caution**

You cannot mix `localhost` and other host names or IP addresses in `config.ini`. For these reasons, the solution in such cases (other than to use IP addresses for all `config.ini HostName` entries) is to remove the fully qualified host names from `/etc/hosts` and use these in `config.ini` for all cluster hosts.

**Host computer type.** Each host computer in our installation scenario is an Intel-based desktop PC running a supported operating system installed to disk in a standard configuration, and running no unnecessary services. The core operating system with standard TCP/IP networking capabilities should be sufficient. Also for the sake of simplicity, we also assume that the file systems on all hosts are set up identically. In the event that they are not, you should adapt these instructions accordingly.

**Network hardware.** Standard 100 Mbps or 1 gigabit Ethernet cards are installed on each machine, along with the proper drivers for the cards, and that all four hosts are connected through a standard-issue Ethernet networking appliance such as a switch. (All machines should use network cards with the same throughput. That is, all four machines in the cluster should have 100 Mbps cards or all four machines should have 1 Gbps cards.) MySQL Cluster works in a 100 Mbps network; however, gigabit Ethernet provides better performance.

**Important**

MySQL Cluster is *not* intended for use in a network for which throughput is less than 100 Mbps or which experiences a high degree of latency. For this
reason (among others), attempting to run a MySQL Cluster over a wide area network such as the Internet is not likely to be successful, and is not supported in production.

**Sample data.** We use the world database which is available for download from the MySQL Web site (see http://dev.mysql.com/doc/index-other.html). We assume that each machine has sufficient memory for running the operating system, required MySQL Cluster processes, and (on the data nodes) storing the database.

For general information about installing MySQL, see Chapter 2, *Installing and Upgrading MySQL*. For information about installation of MySQL Cluster on Linux and other Unix-like operating systems, see Section 17.2.1, “Installing MySQL Cluster on Linux”.

For general information about MySQL Cluster hardware, software, and networking requirements, see Section 17.1.3, “MySQL Cluster Hardware, Software, and Networking Requirements”.

## 17.2.1 Installing MySQL Cluster on Linux

This section covers installation of MySQL Cluster on Linux and other Unix-like operating systems. While the next few sections refer to a Linux operating system, the instructions and procedures given there should be easily adaptable to other supported Unix-like platforms.

Each MySQL Cluster host computer must have the correct executable programs installed. A host running an SQL node must have installed on it a MySQL Server binary (*mysqld*). Management nodes require the management server daemon (*ndb_mgmd*); data nodes require the data node daemon (*ndbd*). It is not necessary to install the MySQL Server binary on management node hosts and data node hosts. It is recommended that you also install the management client (*ndb_mgm*) on the management server host.

Installation of MySQL Cluster on Linux can be done using precompiled binaries from Oracle (downloaded as a .tar.gz archive), with RPM packages (also available from Oracle), or from source code. All three of these installation methods are described in the section that follow.

Regardless of the method used, it is still necessary following installation of the MySQL Cluster binaries to create configuration files for all cluster nodes, before you can start the cluster. See Section 17.2.2, “Initial Configuration of MySQL Cluster”.

### 17.2.1.1 Installing a MySQL Cluster Binary Release on Linux

This section covers the steps necessary to install the correct executables for each type of Cluster node from precompiled binaries supplied by Oracle.

For setting up a cluster using precompiled binaries, the first step in the installation process for each cluster host is to download the latest MySQL 5.0 binary archive from the MySQL downloads page. We assume that you have placed this file in each machine's `/var/tmp` directory. (If you do require a custom binary, see Section 2.17.2, “Installing MySQL Using a Development Source Tree”.)

**Note**

After completing the installation, do not yet start any of the binaries. We show you how to do so following the configuration of the nodes (see Section 17.2.2, “Initial Configuration of MySQL Cluster”).

**SQL nodes.** On each of the machines designated to host SQL nodes, perform the following steps as the system root user:

1. Check your `/etc/passwd` and `/etc/group` files (or use whatever tools are provided by your operating system for managing users and groups) to see whether there is already a `mysql` group and `mysql` user on the system. Some OS distributions create these as part of the operating system
Installing MySQL Cluster on Linux

installation process. If they are not already present, create a new mysql user group, and then add a mysql user to this group:

```
shell> groupadd mysql
shell> useradd -g mysql -s /bin/false mysql
```

The syntax for useradd and groupadd may differ slightly on different versions of Unix, or they may have different names such as adduser and addgroup.

2. Change location to the directory containing the downloaded file, unpack the archive, and create a symbolic link named mysql to the mysql directory. Note that the actual file and directory names vary according to the MySQL Cluster version number.

```
shell> cd /var/tmp
shell> tar -C /usr/local -xzvf mysql-5.0.96-linux-i686-glibc23.tar.gz
shell> ln -s /usr/local/mysql-5.0.96-linux-i686-glibc23 /usr/local/mysql
```

3. Change location to the mysql directory and run the supplied script for creating the system databases:

```
shell> cd mysql
shell> scripts/mysql_install_db --user=mysql
```

4. Set the necessary permissions for the MySQL server and data directories:

```
shell> chown -R root .
shell> chown -R mysql data
shell> chgrp -R mysql .
```

5. Copy the MySQL startup script to the appropriate directory, make it executable, and set it to start when the operating system is booted up:

```
shell> cp support-files/mysql.server /etc/rc.d/init.d/
shell> chmod +x /etc/rc.d/init.d/mysql.server
shell> chkconfig --add mysql.server
```

(The startup scripts directory may vary depending on your operating system and version—for example, in some Linux distributions, it is /etc/init.d.)

Here we use Red Hat’s chkconfig for creating links to the startup scripts; use whatever means is appropriate for this purpose on your platform, such as update-rc.d on Debian.

Remember that the preceding steps must be repeated on each machine where an SQL node is to reside.

Data nodes. Installation of the data nodes does not require the mysqld binary. Only the MySQL Cluster data node executable ndbd is required. This binary can also be found in the .tar.gz archive. Again, we assume that you have placed this archive in /var/tmp.

As system root (that is, after using sudo, su root, or your system’s equivalent for temporarily assuming the system administrator account’s privileges), perform the following steps to install the data node binaries on the data node hosts:

1. Change location to the /var/tmp directory, and extract the ndbd binary from the archive into a suitable directory such as /usr/local/bin:

```
shell> cd /var/tmp
shell> tar -xzvf mysql-5.0.96-linux-i686-glibc23.tar.gz
shell> cd mysql-5.0.96-linux-i686-glibc23
shell> cp bin/ndbd /usr/local/bin/ndbd
```
Installing MySQL Cluster on Linux

(You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from /var/tmp once ndb_mgm has been copied to the executables directory.)

2. Change location to the directory into which you copied the binary, and make it executable:

```
shell> cd /usr/local/bin
shell> chmod +x ndbd
```

The preceding steps should be repeated on each data node host.

Note

The data directory on each machine hosting a data node is /usr/local/mysql/data. This piece of information is essential when configuring the management node. (See Section 17.2.2, “Initial Configuration of MySQL Cluster”.)

Management nodes. Installation of the management node does not require the mysqld binary. Only the MySQL Cluster management server (ndb_mgmd) is required; you most likely want to install the management client (ndb_mgm) as well. Both of these binaries also be found in the .tar.gz archive. Again, we assume that you have placed this archive in /var/tmp.

As system root, perform the following steps to install ndb_mgm and ndb_mgmd on the management node host:

1. Change location to the /var/tmp directory, and extract the ndb_mgm and ndb_mgmd from the archive into a suitable directory such as /usr/local/bin:

```
shell> cd /var/tmp
shell> tar -zxvf mysql-5.0.96-linux-i686-glibc23.tar.gz
shell> cd mysql-5.0.96-linux-i686-glibc23
shell> cp bin/ndb_mgm* /usr/local/bin
```

(You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from /var/tmp once ndb_mgm and ndb_mgmd have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

```
shell> cd /usr/local/bin
shell> chmod +x ndb_mgm*
```

In Section 17.2.2, “Initial Configuration of MySQL Cluster”, we create configuration files for all of the nodes in our example MySQL Cluster.

17.2.1.2 Installing MySQL Cluster from RPM

This section covers the steps necessary to install the correct executables for each type of MySQL Cluster node using RPM packages supplied by Oracle.

RPMs are available for both 32-bit and 64-bit Linux platforms. For a MySQL Cluster, three RPMs are required:

- The Server RPM (for example, MySQL-server-5.0.96-0.glibc23.i386.rpm), which supplies the core files needed to run a MySQL Server.

If you do not have your own client application capable of administering a MySQL server, you should also obtain and install the Client RPM (such as MySQL-client-5.0.96-0.sles10.i586.rpm).
Installing MySQL Cluster on Linux

- **The NDB Cluster - Storage engine RPM** (for example, `MySQL-ndb-storage-5.0.96-0.glibc23.i386.rpm`), which supplies the MySQL Cluster data node binary (`ndbd`).

- **The NDB Cluster - Storage engine management RPM** (for example, `MySQL-ndb-management-5.0.96-0.glibc23.i386.rpm`), which provides the MySQL Cluster management server binary (`ndb_mgmd`).

In addition, you should also obtain the **NDB Cluster - Storage engine basic tools RPM** (for example, `MySQL-ndb-tools-5.0.96-0.glibc23.i386.rpm`), which supplies several useful applications for working with a MySQL Cluster. The most important of these is the MySQL Cluster management client (`ndb_mgm`). The **NDB Cluster - Storage engine extra tools RPM** (for example, `MySQL-ndb-extra-5.0.96-0.glibc23.i386.rpm`) contains some additional testing and monitoring programs, but is not required to install a MySQL Cluster. (For more information about these additional programs, see Section 17.4, “MySQL Cluster Programs”.)

The MySQL version number in the RPM file names (shown here as `5.0.96`) can vary according to the version which you are actually using. *It is very important that all of the Cluster RPMs to be installed have the same MySQL version number.* The glibc version number (if present—shown here as `glibc23`), and architecture designation (shown here as `i386`) should be appropriate to the machine on which the RPM is to be installed.

**Data nodes.** On a computer that is to host a cluster data node it is necessary to install only the **NDB Cluster - Storage engine RPM**. To do so, copy this RPM to the data node host, and run the following command as the system root user, replacing the name shown for the RPM as necessary to match that of the RPM downloaded from the MySQL web site:

```
shell> rpm -Uhv MySQL-ndb-storage-5.0.96-0.glibc23.i386.rpm
```

The previous command installs the MySQL Cluster data node binary (`ndbd`) in the `/usr/sbin` directory.

**SQL nodes.** On each machine to be used for hosting a cluster SQL node, install the **Server RPM** by executing the following command as the system root user, replacing the name shown for the RPM as necessary to match the name of the RPM downloaded from the MySQL web site:

```
shell> rpm -Uhv MySQL-server-5.0.96-0.glibc23.i386.rpm
```

This installs the MySQL server binary (`mysqld`) in the `/usr/sbin` directory, as well as all needed MySQL Server support files. It also installs the `mysql.server` and `mysqld_safe` startup scripts in `/usr/share/mysql` and `/usr/bin`, respectively. The RPM installer should take care of general configuration issues (such as creating the `mysql` user and group, if needed) automatically.

**Note**

To administer the SQL node (MySQL server), you should also install the **Client RPM**, as shown here:

```
shell> rpm -Uhv MySQL-client-5.0.96-0.sles10.i586.rpm
```

This installs the `mysql` client program.

**Management nodes.** To install the MySQL Cluster management server, it is necessary only to use the **NDB Cluster - Storage engine management RPM**. Copy this RPM to the computer intended to host the management node, and then install it by running the following command as the system root user (replace the name shown for the RPM as necessary to match that of the **Storage engine management RPM** downloaded from the MySQL web site):

```
shell> rpm -Uhv MySQL-ndb-management-5.0.96-0.glibc23.i386.rpm
```
This installs the management server binary (ndb_mgmd) to the /usr/sbin directory.

You should also install the NDB management client, which is supplied by the Storage engine basic tools RPM. Copy this RPM to the same computer as the management node, and then install it by running the following command as the system root user (again, replace the name shown for the RPM as necessary to match that of the Storage engine basic tools RPM downloaded from the MySQL web site):

```
shell> rpm -Uhv MySQL-ndb-tools-5.0.96-0.sles10.i586.rpm
```

The Storage engine basic tools RPM installs the MySQL Cluster management client (ndb_mgm) to the /usr/bin directory.

Note

You can also install the Cluster storage engine extra tools RPM, if you wish, as shown here:

```
shell> rpm -Uhv MySQL-ndb-extra-5.0.96-0.sles10.i586.rpm
```

You may find the extra tools useful; however the Cluster storage engine extra tools RPM is not required to install a working MySQL Cluster.

See Section 2.12, "Installing MySQL on Linux Using RPM Packages", for general information about installing MySQL using RPMs supplied by Oracle.

After installing from RPM, you still need to configure the cluster as discussed in Section 17.2.2, "Initial Configuration of MySQL Cluster".

### 17.2.1.3 Building MySQL Cluster from Source on Linux

This section provides information about compiling MySQL Cluster on Linux and other Unix-like platforms. To build MySQL Cluster, you need the MySQL 5.0 source archive available from http://dev.mysql.com/downloads/. Building MySQL Cluster from source is similar to building the standard MySQL Server, although it differs in a few key respects discussed here. For general information about building MySQL from source, see Section 2.17, “Installing MySQL from Source”.

In addition to any other configure options you wish to use, be sure to include --with-ndbcluster. This option causes the binaries for the management nodes, data nodes, and other MySQL Cluster programs to be built; it also causes mysqld to be compiled with NDB storage engine support.

After you have run make && make install (or your system’s equivalent), the result is similar to what is obtained by unpacking a precompiled binary to the same location. However, the layout can differ. These differences are covered in the next few paragraphs.

**Management nodes.** When building from source and running the default make install, the management server binary (ndb_mgmd) is placed in /usr/local/mysql/libexec, while the management client binary (ndb_mgm) can be found in /usr/local/mysql/bin. Only ndb_mgmd is required to be present on a management node host; however, it is also a good idea to have ndb_mgm present on the same host machine. Neither of these executables requires a specific location on the host machine's file system.

**Data nodes.** The only executable required on a data node host is ndbd (mysqld, for example, does not have to be present on the host machine). By default when doing a source build, this file is placed in the directory /usr/local/mysql/libexec. For installing on multiple data node hosts, only ndbd need be copied to the other host machine or machines. (This assumes that all data node hosts use the same architecture and operating system; otherwise you may need to compile separately for each
different platform.) ndbd need not be in any particular location on the host's file system, as long as the location is known.

**SQL nodes.** If you compile MySQL with clustering support, and perform the default installation (using `make install` as the system root user), `mysqld` is placed in `/usr/local/mysql/bin`. Follow the steps given in Section 2.17, “Installing MySQL from Source” to make `mysqld` ready for use. If you want to run multiple SQL nodes, you can use a copy of the same `mysqld` executable and its associated support files on several machines. The easiest way to do this is to copy the entire `/usr/local/mysql` directory and all directories and files contained within it to the other SQL node host or hosts, then repeat the steps from Section 2.17, “Installing MySQL from Source” on each machine. If you configure the build with a nondefault `--prefix`, you need to adjust the directory accordingly.

In Section 17.2.2, “Initial Configuration of MySQL Cluster”, we create configuration files for all of the nodes in our example MySQL Cluster.

### 17.2.2 Initial Configuration of MySQL Cluster

For our four-node, four-host MySQL Cluster, it is necessary to write four configuration files, one per node host.

- Each data node or SQL node requires a `my.cnf` file that provides two pieces of information: a *connection string* that tells the node where to find the management node, and a line telling the MySQL server on this host (the machine hosting the data node) to enable the `NDBCLUSTER` storage engine.

  For more information on connection strings, see Section 17.3.3.2, “MySQL Cluster Connection Strings”.

- The management node needs a `config.ini` file telling it how many replicas to maintain, how much memory to allocate for data and indexes on each data node, where to find the data nodes, where to save data to disk on each data node, and where to find any SQL nodes.

#### Configuring the data nodes and SQL nodes.

The `my.cnf` file needed for the data nodes is fairly simple. The configuration file should be located in the `/etc` directory and can be edited using any text editor. (Create the file if it does not exist.) For example:

```shell
shell> vi /etc/my.cnf
```

**Note**

We show `vi` being used here to create the file, but any text editor should work just as well.

For each data node and SQL node in our example setup, `my.cnf` should look like this:

```ini
[mysqld]
# Options for mysqld process:
ndbcluster  # run NDB storage engine

[mysql_cluster]
# Options for MySQL Cluster processes:
ndb-connectstring=192.168.0.10  # location of management server
```

After entering the preceding information, save this file and exit the text editor. Do this for the machines hosting data node “A”, data node “B”, and the SQL node.

**Important**

Once you have started a `mysqld` process with the `ndbcluster` and `ndb-connectstring` parameters in the `[mysqld]` and `[mysql_cluster]`
Configuring the management node.  The first step in configuring the management node is to create the directory in which the configuration file can be found and then to create the file itself. For example (running as root):

```
shell> mkdir /var/lib/mysql-cluster
shell> cd /var/lib/mysql-cluster
shell> vi config.ini
```

For our representative setup, the `config.ini` file should read as follows:

```
[ndbd default]
# Options affecting ndbd processes on all data nodes:
NoOfReplicas=2    # Number of replicas
DataMemory=80M    # How much memory to allocate for data storage
IndexMemory=18M   # How much memory to allocate for index storage
# For DataMemory and IndexMemory, we have used the default values. Since the "world" database takes up only about 500KB, this should be more than enough for this example Cluster setup.

[tcp default]
# TCP/IP options:
portnumber=2202   # This the default; however, you can use any port that is free for all the hosts in the cluster
# Note: It is recommended that you do not specify the port number at all and simply allow the default value to be used instead

[ndb_mgmd]
# Management process options:
hostname=192.168.0.10           # Hostname or IP address of MGM node
datadir=/var/lib/mysql-cluster  # Directory for MGM node log files

[ndbd]
# Options for data node "A":
hostname=192.168.0.30           # Hostname or IP address
datadir=/usr/local/mysql/data   # Directory for this data node's data files

[ndbd]
# Options for data node "B":
hostname=192.168.0.40           # Hostname or IP address
datadir=/usr/local/mysql/data   # Directory for this data node's data files

[mysqld]
# SQL node options:
hostname=192.168.0.20           # Hostname or IP address
# (additional mysqld connections can be specified for this node for various purposes such as running ndb_restore)
```

Note
---

The `world` database can be downloaded from [http://dev.mysql.com/doc/index-other.html](http://dev.mysql.com/doc/index-other.html).

After all the configuration files have been created and these minimal options have been specified, you are ready to proceed with starting the cluster and verifying that all processes are running. We discuss how this is done in Section 17.2.3, “Initial Startup of MySQL Cluster”.

For more detailed information about the available MySQL Cluster configuration parameters and their uses, see Section 17.3.3, “MySQL Cluster Configuration Files”, and Section 17.3, “MySQL Cluster...”
For configuration of MySQL Cluster as relates to making backups, see Section 17.5.3.3, “Configuration for MySQL Cluster Backups”.

Note

The default port for Cluster management nodes is 1186; the default port for data nodes is 2202. Beginning with MySQL 5.0.3, this restriction is lifted, and the cluster automatically allocates ports for data nodes from those that are already free.

17.2.3 Initial Startup of MySQL Cluster

Starting the cluster is not very difficult after it has been configured. Each cluster node process must be started separately, and on the host where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes:

1. On the management host, issue the following command from the system shell to start the management node process:

```
shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
```

Note

`ndb_mgmd` must be told where to find its configuration file, using the `-f` or `--config-file` option. (See Section 17.4.2, “ndb_mgmd — The MySQL Cluster Management Server Daemon”, for details.) For additional options which can be used with `ndb_mgmd`, see Section 17.4.20, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”.

2. On each of the data node hosts, run this command to start the `ndbd` process:

```
shell> ndbd
```

3. If you used RPM files to install MySQL on the cluster host where the SQL node is to reside, you can (and should) use the supplied startup script to start the MySQL server process on the SQL node.

If all has gone well, and the cluster has been set up correctly, the cluster should now be operational. You can test this by invoking the `ndb_mgm` management node client. The output should look like that shown here, although you might see some slight differences in the output depending upon the exact version of MySQL that you are using:

```
shell> ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration

----------- [ndbd(NDB)] 2 node(s)
id=2 @192.168.0.30  (Version: 5.0.96, Nodegroup: 0, Master)
id=3 @192.168.0.40  (Version: 5.0.96, Nodegroup: 0)

----------- [ndb_mgmd(MGM)] 1 node(s)
id=1 @192.168.0.10  (Version: 5.0.96)

----------- [mysqld(API)] 1 node(s)
id=4 @192.168.0.20  (Version: 5.0.96)
```

The SQL node is referenced here as `[mysqld(API)]`, which reflects the fact that the `mysqld` process is acting as a MySQL Cluster API node.
17.2.4 MySQL Cluster Example with Tables and Data

Working with database tables and data in MySQL Cluster is not much different from doing so in standard MySQL. There are two key points to keep in mind:

• For a table to be replicated in the cluster, it must use the NDBCLUSTER storage engine. To specify this, use the ENGINE=NDBCLUSTER or ENGINE=NDB option when creating the table:

```sql
CREATE TABLE tbl_name (col_name column_definitions) ENGINE=NDBCLUSTER;
```

Alternatively, for an existing table that uses a different storage engine, use ALTER TABLE to change the table to use NDBCLUSTER:

```sql
ALTER TABLE tbl_name ENGINE=NDBCLUSTER;
```

• Every NDBCLUSTER table has a primary key. If no primary key is defined by the user when a table is created, the NDBCLUSTER storage engine automatically generates a hidden one. Such a key takes up space just as does any other table index. (It is not uncommon to encounter problems due to insufficient memory for accommodating these automatically created indexes.)

If you are importing tables from an existing database using the output of mysqldump, you can open the SQL script in a text editor and add the ENGINE option to any table creation statements, or replace any existing ENGINE (or TYPE) options. Suppose that you have the world sample database on another MySQL server that does not support MySQL Cluster, and you want to export the City table:

```shell
mysqldump --add-drop-table world City > city_table.sql
```

The resulting city_table.sql file will contain this table creation statement (and the INSERT statements necessary to import the table data):

```sql
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (  `ID` int(11) NOT NULL auto_increment,  `Name` char(35) NOT NULL default '',  `CountryCode` char(3) NOT NULL default '',  `District` char(20) NOT NULL default '',  `Population` int(11) NOT NULL default '0',  PRIMARY KEY (`ID`) ) ENGINE=MyISAM DEFAULT CHARSET=latin1;
```

You need to make sure that MySQL uses the NDBCLUSTER storage engine for this table. There are two ways that this can be accomplished. One of these is to modify the table definition before importing it into the Cluster database. Using the City table as an example, modify the ENGINE option of the definition as follows:

```sql
```

Note

The IP address shown for a given MySQL Cluster SQL or other API node in the output of SHOW is the address used by the SQL or API node to connect to the cluster data nodes, and not to any management node.
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (  
    `ID` int(11) NOT NULL auto_increment,  
    `Name` char(35) NOT NULL default '',  
    `CountryCode` char(3) NOT NULL default '',  
    `District` char(20) NOT NULL default '',  
    `Population` int(11) NOT NULL default '0',  
    PRIMARY KEY  (`ID`)  
) ENGINE=NDBCLUSTER DEFAULT CHARSET=latin1;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabol',1780000);
INSERT INTO `City` VALUES (2,'Qandahar','AFG','Qandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);

This must be done for the definition of each table that is to be part of the clustered database. The easiest way to accomplish this is to do a search-and-replace on the file that contains the definitions and replace all instances of `TYPE=engine_name` or `ENGINE=engine_name` with `ENGINE=NDBCLUSTER`. If you do not want to modify the file, you can use the unmodified file to create the tables, and then use `ALTER TABLE` to change their storage engine. The particulars are given later in this section.

Assuming that you have already created a database named `world` on the SQL node of the cluster, you can then use the `mysql` command-line client to read `city_table.sql`, and create and populate the corresponding table in the usual manner:

```
shell> mysql world < city_table.sql
```

It is very important to keep in mind that the preceding command must be executed on the host where the SQL node is running (in this case, on the machine with the IP address `192.168.0.20`).

To create a copy of the entire `world` database on the SQL node, use `mysqldump` on the noncluster server to export the database to a file named `world.sql`; for example, in the `/tmp` directory. Then modify the table definitions as just described and import the file into the SQL node of the cluster like this:

```
shell> mysql world < /tmp/world.sql
```

If you save the file to a different location, adjust the preceding instructions accordingly.

**Note**

NDBCLUSTER in MySQL 5.0 does not support autodiscovery of databases. (See Section 17.1.5, "Known Limitations of MySQL Cluster"). This means that, once the `world` database and its tables have been created on one data node, you need to issue the `CREATE DATABASE world` statement (beginning with MySQL 5.0.2, you may use `CREATE SCHEMA world` instead), followed by `FLUSH TABLES` on each SQL node in the cluster. This causes the node to recognize the database and read its table definitions.

Running `SELECT` queries on the SQL node is no different from running them on any other instance of a MySQL server. To run queries from the command line, you first need to log in to the MySQL Monitor in the usual way (specify the root password at the `Enter password:` prompt):

```
shell> mysql -u root -p
Enter password:
Welcome to the MySQL monitor.  Commands end with ; or \g.  
Your MySQL connection id is 1 to server version: 5.0.96
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
mysql>
```
We simply use the MySQL server’s root account and assume that you have followed the standard security precautions for installing a MySQL server, including setting a strong root password. For more information, see Section 2.18.4, “Securing the Initial MySQL Accounts”.

It is worth taking into account that Cluster nodes do not make use of the MySQL privilege system when accessing one another. Setting or changing MySQL user accounts (including the root account) effects only applications that access the SQL node, not interaction between nodes. See Section 17.5.10.2, “MySQL Cluster and MySQL Privileges”, for more information.

If you did not modify the ENGINE clauses in the table definitions prior to importing the SQL script, you should run the following statements at this point:

```
mysql> USE world;
mysql> ALTER TABLE City ENGINE=NDBCLUSTER;
mysql> ALTER TABLE Country ENGINE=NDBCLUSTER;
mysql> ALTER TABLE CountryLanguage ENGINE=NDBCLUSTER;
```

Selecting a database and running a SELECT query against a table in that database is also accomplished in the usual manner, as is exiting the MySQL Monitor:

```
mysql> USE world;
mysql> SELECT Name, Population FROM City ORDER BY Population DESC LIMIT 5;
+-----------+------------+
| Name      | Population |
|-----------+------------|
| Bombay    |   10500000 |
| Seoul     |    9981619 |
| São Paulo |    9968485 |
| Shanghai  |    9696300 |
| Jakarta   |    9604900 |
+-----------+------------+
5 rows in set (0.34 sec)
```

Applications that use MySQL can employ standard APIs to access NDB tables. It is important to remember that your application must access the SQL node, and not the management or data nodes. This brief example shows how we might execute the SELECT statement just shown by using the PHP 5.X mysqli extension running on a Web server elsewhere on the network:

```html
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN"
 "http://www.w3.org/TR/html4/loose.dtd">
<html>
<head>
    <meta http-equiv="Content-Type"
        content="text/html; charset=iso-8859-1">
    <title>SIMPLE mysqli SELECT</title>
</head>
<body>
<?php
    # connect to SQL node:
    $link = new mysqli('192.168.0.20', 'root', 'root_password', 'world');
    # parameters for mysqli constructor are:
    # host, user, password, database
    if( mysqli_connect_errno() )
        die("Connect failed: ". mysqli_connect_error());

    $query = "SELECT Name, Population
            FROM City
            ORDER BY Population DESC
            LIMIT 5";
```
17.2.5 Safe Shutdown and Restart of MySQL Cluster

To shut down the cluster, enter the following command in a shell on the machine hosting the management node:

```shell
ndb_mgm -e shutdown
```

The `-e` option here is used to pass a command to the `ndb_mgm` client from the shell. (See Section 17.4.20, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”, for more information about this option.) The command causes the `ndb_mgm`, `ndb_mgmd`, and any `ndbd` processes to terminate gracefully. Any SQL nodes can be terminated using `mysqladmin shutdown` and other means.

To restart the cluster, run these commands:

- On the management host (192.168.0.10 in our example setup):

  ```shell
  ndb_mgmd -f /var/lib/mysql-cluster/config.ini
  ```

- On each of the data node hosts (192.168.0.30 and 192.168.0.40):

  ```shell
  ndbd
  ```

- Use the `ndb_mgm` client to verify that both data nodes have started successfully.

- On the SQL host (192.168.0.20):
In a production setting, it is usually not desirable to shut down the cluster completely. In many cases, even when making configuration changes, or performing upgrades to the cluster hardware or software (or both), which require shutting down individual host machines, it is possible to do so without shutting down the cluster as a whole by performing a rolling restart of the cluster. For more information about doing this, see Section 17.5.5, “Performing a Rolling Restart of a MySQL Cluster”.

### 17.2.6 Upgrading and Downgrading MySQL Cluster

This section provides information about MySQL Cluster software and table file compatibility between MySQL 5.0 releases with regard to performing upgrades and downgrades as well as a compatibility matrix and notes. You are expected already to be familiar with installing and configuring a MySQL Cluster prior to attempting an upgrade or downgrade. See Section 17.3, “MySQL Cluster Configuration”.

For information regarding the rolling restart procedure used to perform an online upgrade, see Section 17.5.5, “Performing a Rolling Restart of a MySQL Cluster”.

**Important**

Only compatibility between MySQL versions with regard to NDBCLUSTER is taken into account in this section, and there are likely other issues to be considered. As with any other MySQL software upgrade or downgrade, you are strongly encouraged to review the relevant portions of the MySQL Manual for the MySQL versions from which and to which you intend to migrate, before attempting an upgrade or downgrade of the MySQL Cluster software. See Section 2.19.1, “Upgrading MySQL”.

The following table shows Cluster upgrade and downgrade compatibility between different releases of MySQL 5.0:
Cluster Upgrade and Downgrade Compatibility
Notes

- MySQL 5.0.2 was the first public release in this series.
- Direct upgrades or downgrades between MySQL Cluster 4.1 and 5.0 are not supported; you must dump all `NDBCLUSTER` tables using `mysqldump`, install the new version of the software, and then reload the tables from the dump.
- Online downgrades from MySQL Cluster 5.0.12 to 5.0.11 (or earlier) are not supported.
- You cannot restore with `ndb_restore` to a MySQL 5.0 Cluster using a backup made from a Cluster running MySQL 5.1. You must use `mysqldump` in such cases.
- There was no public release of MySQL 5.0.23.

17.3 MySQL Cluster Configuration

A MySQL server that is part of a MySQL Cluster differs in one chief respect from a normal (nonclustered) MySQL server, in that it employs the `NDB` storage engine. This engine is also referred to sometimes as `NDBCLUSTER`, although `NDB` is preferred.

To avoid unnecessary allocation of resources, the server is configured by default with the `NDB` storage engine disabled. To enable `NDB`, you must modify the server's `my.cnf` configuration file, or start the server with the `--ndbcluster` option.

This MySQL server is a part of the cluster, so it also must know how to access a management node to obtain the cluster configuration data. The default behavior is to look for the management node on `localhost`. However, should you need to specify that its location is elsewhere, this can be done in `my.cnf`, or with the `mysql` client. Before the `NDB` storage engine can be used, at least one management node must be operational, as well as any desired data nodes.

For more information about `--ndbcluster` and other `mysqld` options specific to MySQL Cluster, see `mysqld Command Options for MySQL Cluster`.

For information about installing MySQL Cluster, see Section 17.2, “MySQL Cluster Installation and Upgrades”.

17.3.1 Quick Test Setup of MySQL Cluster

To familiarize you with the basics, we will describe the simplest possible configuration for a functional MySQL Cluster. After this, you should be able to design your desired setup from the information provided in the other relevant sections of this chapter.

First, you need to create a configuration directory such as `/var/lib/mysql-cluster`, by executing the following command as the system `root` user:

```
shell> mkdir /var/lib/mysql-cluster
```

In this directory, create a file named `config.ini` that contains the following information. Substitute appropriate values for `HostName` and `DataDir` as necessary for your system.

```ini
# file "config.ini" - showing minimal setup consisting of 1 data node,
# 1 management server, and 3 SQL nodes.
# The empty default sections are not required, and are shown only for
# the sake of completeness.
# Data nodes must provide a hostname but SQL nodes are not required
# to do so.
# If you do not know the hostname for your machine, use localhost.
# The DataDir parameter also has a default value, but it is recommended to
# set it explicitly.
# Note: [db], [api], and [mgm] are aliases for [ndbd], [mysqld], and [ndb_mgmd],
# respectively. [db] is deprecated and should not be used in new installations.
```

This documentation is for an older version. If you're looking for the latest version, please visit the MySQL website.
Quick Test Setup of MySQL Cluster

You can now start the `ndb_mgmd` management server. By default, it attempts to read the `config.ini` file in its current working directory, so change location into the directory where the file is located and then invoke `ndb_mgmd`:

```
shell> cd /var/lib/mysql-cluster
shell> ndb_mgmd
```

Then start a single data node by running `ndbd`:

```
shell> ndbd
```

For command-line options which can be used when starting `ndbd`, see Section 17.4.20, "Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs".

By default, `ndbd` looks for the management server at `localhost` on port 1186.

**Note**

If you have installed MySQL from a binary tarball, you will need to specify the path of the `ndb_mgmd` and `ndbd` servers explicitly. (Normally, these will be found in `/usr/local/mysql/bin`.)

Finally, change location to the MySQL data directory (usually `/var/lib/mysql` or `/usr/local/mysql/data`), and make sure that the `my.cnf` file contains the option necessary to enable the NDB storage engine:

```
[mysqld]
ndbcluster
```

You can now start the MySQL server as usual:

```
shell> mysql_safe --user=mysql &
```

Wait a moment to make sure the MySQL server is running properly. If you see the notice `mysql ended`, check the server's `.err` file to find out what went wrong.

If all has gone well so far, you now can start using the cluster. Connect to the server and verify that the NDB storage engine is enabled:

```
shell> mysql
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 5.0.96
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
```
Try to create an NDB table:

```
shell> mysql
mysql> USE test;
Database changed
mysql> CREATE TABLE ctest (i INT) ENGINE=NDBCLUSTER;
Query OK, 0 rows affected (0.09 sec)
mysql> SHOW CREATE TABLE ctest \G
*************************** 1. row ***************************
Table: ctest
Create Table: CREATE TABLE `ctest` (`i` int(11) default NULL ) ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

To check that your nodes were set up properly, start the management client:

```
shell> ndb_mgm
```

Use the `SHOW` command from within the management client to obtain a report on the cluster's status:

```
ndb_mgm> SHOW
Cluster Configuration
---------------------
[ndbd(NDB)] 1 node(s)
id=2 @127.0.0.1 (Version: 3.5.3, Nodegroup: 0, Master)

[ndb_mgmd(MGM)] 1 node(s)
id=1 @127.0.0.1 (Version: 3.5.3)

[mysqld(API)] 3 node(s)
id=3 @127.0.0.1 (Version: 3.5.3)
id=4 (not connected, accepting connect from any host)
id=5 (not connected, accepting connect from any host)
```

At this point, you have successfully set up a working MySQL Cluster. You can now store data in the cluster by using any table created with ENGINE=NDBCLUSTER or its alias ENGINE=NDB.

### 17.3.2 Overview of MySQL Cluster Configuration Parameters, Options, and Variables

The next few sections provide summary tables of MySQL Cluster node configuration parameters used in the config.ini file to govern various aspects of node behavior, as well as options and variables read by mysqld from a my.cnf file or from the command line when run as a MySQL Cluster process. Each of the node parameter tables lists the parameters for a given type (ndbd, ndb_mgmd, mysqld, computer, tcp, shm, or sci). All tables include the data type for the parameter, option, or variable, as well as its default, minimum, and maximum values as applicable.
Considerations when restarting nodes. For node parameters, these tables also indicate what type of restart is required (node restart or system restart)—and whether the restart must be done with `--initial`—to change the value of a given configuration parameter. When performing a node restart or an initial node restart, all of the cluster's data nodes must be restarted in turn (also referred to as a rolling restart). It is possible to update cluster configuration parameters marked as node online—that is, without shutting down the cluster—in this fashion. An initial node restart requires restarting each `ndbd` process with the `--initial` option.

A system restart requires a complete shutdown and restart of the entire cluster. An initial system restart requires taking a backup of the cluster, wiping the cluster file system after shutdown, and then restoring from the backup following the restart.

In any cluster restart, all of the cluster's management servers must be restarted for them to read the updated configuration parameter values.

Important

Values for numeric cluster parameters can generally be increased without any problems, although it is advisable to do so progressively, making such adjustments in relatively small increments. Many of these can be increased online, using a rolling restart.

However, decreasing the values of such parameters—whether this is done using a node restart, node initial restart, or even a complete system restart of the cluster—is not to be undertaken lightly; it is recommended that you do so only after careful planning and testing. This is especially true with regard to those parameters that relate to memory usage and disk space, such as `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes`. In addition, it is the generally the case that configuration parameters relating to memory and disk usage can be raised using a simple node restart, but they require an initial node restart to be lowered.

Because some of these parameters can be used for configuring more than one type of cluster node, they may appear in more than one of the tables.

Note

4294967039 often appears as a maximum value in these tables. This value is defined in the `NDBCLUSTER` sources as `MAX_INT_RNIL` and is equal to `0xFFFFFEFF`, or $2^{32} - 2^8 - 1$.

17.3.2.1 MySQL Cluster Data Node Configuration Parameters

The summary table in this section provides information about parameters used in the `[ndbd]` or `[ndbd default]` sections of a `config.ini` file for configuring MySQL Cluster data nodes. For detailed descriptions and other additional information about each of these parameters, see Section 17.3.3.5, “Defining MySQL Cluster Data Nodes”.

Restart types. Changes in MySQL Cluster configuration parameters do not take effect until the cluster is restarted. The type of restart required to change a given parameter is indicated in the summary table as follows:

- **N**—Node restart: The parameter can be updated using a rolling restart (see Section 17.5.5, “Performing a Rolling Restart of a MySQL Cluster”).

- **S**—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.

- **I**—Initial restart: Data nodes must be restarted using the `--initial` option.
For more information about restart types, see Section 17.3.2, “Overview of MySQL Cluster Configuration Parameters, Options, and Variables”.

</tr>
</tbody>
</table>

**Note**

To add new data nodes to a MySQL Cluster, it is necessary to shut down the cluster completely, update the `config.ini` file, and then restart the cluster, starting all data node processes using the `--initial` option—that is, you must perform a system restart.

It is possible to add new data node groups to a running cluster online using MySQL Cluster NDB 7.0 or later (see Adding MySQL Cluster Data Nodes Online); however, we do not plan to implement this change in MySQL 5.0.

### 17.3.2.2 MySQL Cluster Management Node Configuration Parameters

The summary table in this section provides information about parameters used in the `[ndb_mgmd]` or `[mgm]` sections of a `config.ini` file for configuring MySQL Cluster management nodes. For detailed descriptions and other additional information about each of these parameters, see Section 17.3.3.4, “Defining a MySQL Cluster Management Server”.

**Restart types.** Changes in MySQL Cluster configuration parameters do not take effect until the cluster is restarted. The type of restart required to change a given parameter is indicated in the summary table as follows:

- **N**—Node restart: The parameter can be updated using a rolling restart (see Section 17.5.5, “Performing a Rolling Restart of a MySQL Cluster”).

- **S**—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.

- **I**—Initial restart: Data nodes must be restarted using the `--initial` option.

For more information about restart types, see Section 17.3.2, “Overview of MySQL Cluster Configuration Parameters, Options, and Variables”.

</tbody>
</table>

**Note**
After making changes in a management node’s configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect. See Section 17.3.3.4, “Defining a MySQL Cluster Management Server”, for more information.

To add new management servers to a running MySQL Cluster, it is also necessary perform a rolling restart of all cluster nodes after modifying any existing `config.ini` files. For more information about issues arising when using multiple management nodes, see Section 17.1.5.9, “Limitations Relating to Multiple MySQL Cluster Nodes”.

### 17.3.2.3 MySQL Cluster SQL Node and API Node Configuration Parameters

The summary table in this section provides information about parameters used in the `[mysqld]` and `[api]` sections of a `config.ini` file for configuring MySQL Cluster SQL nodes and API nodes. For detailed descriptions and other additional information about each of these parameters, see Section 17.3.3.6, “Defining SQL and Other API Nodes in a MySQL Cluster”.

**Note**
For a discussion of MySQL server options for MySQL Cluster, see `mysqld Command Options for MySQL Cluster`; for information about MySQL server system variables relating to MySQL Cluster, see MySQL Cluster System Variables.

**Restart types.** Changes in MySQL Cluster configuration parameters do not take effect until the cluster is restarted. The type of restart required to change a given parameter is indicated in the summary table as follows:

- **N**—Node restart: The parameter can be updated using a rolling restart (see Section 17.5.5, “Performing a Rolling Restart of a MySQL Cluster”).

- **S**—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.

- **I**—Initial restart: Data nodes must be restarted using the `--initial` option.

For more information about restart types, see Section 17.3.2, “Overview of MySQL Cluster Configuration Parameters, Options, and Variables”.

---

This documentation is for an older version. If you’re using the most current version, select the documentation for that version with the version switch in the upper right corner of the online documentation, or by downloading a newer PDF or EPUB file.

**Note**

To add new SQL or API nodes to the configuration of a running MySQL Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new [mysqld] or [api] sections to the `config.ini` file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.
It is not necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

### 17.3.2.4 Other MySQL Cluster Configuration Parameters

The summary tables in this section provide information about parameters used in the `[computer]`, `[tcp]`, `[shm]`, and `[sci]` sections of a `config.ini` file for configuring MySQL Cluster management nodes. For detailed descriptions and other additional information about individual parameters, see Section 17.3.3.8, “MySQL Cluster TCP/IP Connections”, Section 17.3.3.10, “MySQL Cluster Shared-Memory Connections”, or Section 17.3.3.11, “SCI Transport Connections in MySQL Cluster”, as appropriate.

#### Restart types.

Changes in MySQL Cluster configuration parameters do not take effect until the cluster is restarted. The type of restart required to change a given parameter is indicated in the summary tables as follows:

- **N**—Node restart: The parameter can be updated using a rolling restart (see Section 17.5.5, “Performing a Rolling Restart of a MySQL Cluster”).
- **S**—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.
- **I**—Initial restart: Data nodes must be restarted using the `--initial` option.

For more information about restart types, see Section 17.3.2, “Overview of MySQL Cluster Configuration Parameters, Options, and Variables”.

**DESCRIPTION:**
- Sets the granularity of the statistics by determining the number of starting and ending keys.
- Use NDB index statistics in query optimization.
- Determines how often to query data nodes instead of the statistics cache.
- Determines how an SQL node chooses a cluster data node to use as transaction coordinator.
- This is a threshold on the number of epochs to be behind before reporting binary log status.
- This is a threshold on the percentage of free memory remaining before reporting binary log status.
- Use exact row count when planning queries.
- Forces NDB to use a count of records during SELECT COUNT(*) query planning to speed up this type of query.

**DISABLED by:** `--skip-ndbcluster`
17.3.3 MySQL Cluster Configuration Files

Configuring MySQL Cluster requires working with two files:

- **my.cnf**: Specifies options for all MySQL Cluster executables. This file, with which you should be familiar from previous work with MySQL, must be accessible by each executable running in the cluster.

- **config.ini**: This file, sometimes known as the *global configuration file*, is read only by the MySQL Cluster management server, which then distributes the information contained therein to all processes participating in the cluster. *config.ini* contains a description of each node involved in the cluster. This includes configuration parameters for data nodes and configuration parameters for connections between all nodes in the cluster. For a quick reference to the sections that can appear in this file, and what sorts of configuration parameters may be placed in each section, see Sections of the *config.ini* File.

We are continuously making improvements in Cluster configuration and attempting to simplify this process. Although we strive to maintain backward compatibility, there may be times when introduce an incompatible change. In such cases we will try to let Cluster users know in advance if a change is not backward compatible. If you find such a change and we have not documented it, please report it in the MySQL bugs database using the instructions given in Section 1.7, “How to Report Bugs or Problems”.

17.3.3.1 MySQL Cluster Configuration: Basic Example

To support MySQL Cluster, you will need to update *my.cnf* as shown in the following example. You may also specify these parameters on the command line when invoking the executables.

```
# my.cnf
# example additions to my.cnf for MySQL Cluster
# (valid in MySQL 5.0)
#
# enable ndbcluster storage engine, and provide connection string for
# management server host (default port is 1186)
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com
#
# provide connection string for management server host (default port: 1186)
[ndbd]
connect-string=ndb_mgmd.mysql.com
#
# provide connection string for management server host (default port: 1186)
[ndb_mgm]
connect-string=ndb_mgmd.mysql.com
#
# provide location of cluster configuration file
[ndb_mgm]
config-file=/etc/config.ini
```

(For more information on connection strings, see Section 17.3.3.2, “MySQL Cluster Connection Strings”.)

```
# my.cnf
# example additions to my.cnf for MySQL Cluster
# (will work on all versions)
```
Important

Once you have started a `mysqld` process with the `NDBCLUSTER` and `ndb-connectstring` parameters in the `[mysqld]` in the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements will fail with an error. This is by design.

You may also use a separate `[mysql_cluster]` section in the cluster `my.cnf` file for settings to be read and used by all executables:

```
# cluster-specific settings
[mysql_cluster]
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

For additional NDB variables that can be set in the `my.cnf` file, see MySQL Cluster System Variables.

The MySQL Cluster global configuration file is by convention named `config.ini` (but this is not required). It is read by `ndb_mgmd` at startup and can be placed anywhere. Its location and name are specified by using `--config-file=path_name` on the `ndb_mgmd` command line. If the configuration file is not specified, `ndb_mgmd` by default tries to read a file named `config.ini` located in the current working directory.

The global configuration file for MySQL Cluster uses INI format, which consists of sections preceded by section headings (surrounded by square brackets), followed by the appropriate parameter names and values. One deviation from the standard INI format is that the parameter name and value can be separated by a colon (";") as well as the equal sign ("="); however, the equal sign is preferred. Another deviation is that sections are not uniquely identified by section name. Instead, unique sections (such as two different nodes of the same type) are identified by a unique ID specified as a parameter within the section.

Default values are defined for most parameters, and can also be specified in `config.ini`. (Exception: The NoOfReplicas configuration parameter has no default value, and must always be specified explicitly in the [ndbd default] section.) To create a default value section, simply add the word `default` to the section name. For example, an [ndbd] section contains parameters that apply to a particular data node, whereas an [ndbd default] section contains parameters that apply to all data nodes. Suppose that all data nodes should use the same data memory size. To configure them all, create an [ndbd default] section that contains a DataMemory line to specify the data memory size.

The global configuration file must define the computers and nodes involved in the cluster and on which computers these nodes are located. An example of a simple configuration file for a cluster consisting of one management server, two data nodes and two SQL nodes is shown here:

```
# file "config.ini" - 2 data nodes and 2 SQL nodes
# This file is placed in the startup directory of ndb_mgmd (the
# management server)
# The first SQL node can be started from any host. The second
# can be started only on the host mysqld_5.mysql.com

[ndbd default]
NoOfReplicas= 2
DataDir= /var/lib/mysql-cluster

[ndbd_mgmd]
Hostname= ndb_mgmd.mysql.com
```
MySQL Cluster Configuration Files

DataDir= /var/lib/mysql-cluster

[ndbd]
HostName= ndbd_2.mysql.com

[ndbd]
HostName= ndbd_3.mysql.com

[mysqld]
[mysqld]
HostName= mysqld_5.mysql.com

Each node has its own section in the config.ini file. For example, this cluster has two data nodes, so the preceding configuration file contains two [ndbd] sections defining these nodes.

Note
Do not place comments on the same line as a section heading in the config.ini file; this causes the management server not to start because it cannot parse the configuration file in such cases.

Sections of the config.ini File

There are six different sections that you can use in the config.ini configuration file, as described in the following list:

• [computer]: Defines cluster hosts. This is not required to configure a viable MySQL Cluster, but may be used as a convenience when setting up a large cluster. See Section 17.3.3.3, “Defining Computers in a MySQL Cluster”, for more information.

• [ndbd]: Defines a cluster data node (ndbd process). See Section 17.3.3.5, “Defining MySQL Cluster Data Nodes”, for details.

• [mysqld]: Defines the cluster's MySQL server nodes (also called SQL or API nodes). For a discussion of SQL node configuration, see Section 17.3.3.6, “Defining SQL and Other API Nodes in a MySQL Cluster”.

• [mgm] or [ndb_mgmd]: Defines a cluster management server (MGM) node. For information concerning the configuration of management nodes, see Section 17.3.3.4, “Defining a MySQL Cluster Management Server”.

• [tcp]: Defines a TCP/IP connection between cluster nodes, with TCP/IP being the default connection protocol. Normally, [tcp] or [tcp default] sections are not required to set up a MySQL Cluster, as the cluster handles this automatically; however, it may be necessary in some situations to override the defaults provided by the cluster. See Section 17.3.3.8, “MySQL Cluster TCP/IP Connections”, for information about available TCP/IP configuration parameters and how to use them. (You may also find Section 17.3.3.9, “MySQL Cluster TCP/IP Connections Using Direct Connections” to be of interest in some cases.)

• [shm]: Defines shared-memory connections between nodes. In MySQL 5.0, it is enabled by default, but should still be considered experimental. For a discussion of SHM interconnects, see Section 17.3.3.10, “MySQL Cluster Shared-Memory Connections”.

• [sci]: Defines Scalable Coherent Interface connections between cluster data nodes. Such connections require software which, while freely available, is not part of the MySQL Cluster distribution, as well as specialized hardware. See Section 17.3.3.11, “SCI Transport Connections in MySQL Cluster” for detailed information about SCI interconnects.

You can define default values for each section. All Cluster parameter names are case-insensitive, which differs from parameters specified in my.cnf or my.ini files.

17.3.3.2 MySQL Cluster Connection Strings
With the exception of the MySQL Cluster management server (ndb_mgmd), each node that is part of a MySQL Cluster requires a *connection string* that points to the management server’s location. This connection string is used in establishing a connection to the management server as well as in performing other tasks depending on the node’s role in the cluster. The syntax for a connection string is as follows:

```
[nodeid=node_id, ] host-definition[, host-definition[, ...]]
host-definition:
    host_name[ :port_number]
```

*node_id* is an integer greater than or equal to 1 which identifies a node in config.ini. *host_name* is a string representing a valid Internet host name or IP address. *port_number* is an integer referring to a TCP/IP port number.

**example 1 (long):**    "nodeid=2,myhost1:1100,myhost2:1100,192.168.0.3:1200"
**example 2 (short):**   "myhost1"

`localhost:1186` is used as the default connection string value if none is provided. If *port_num* is omitted from the connection string, the default port is 1186. This port should always be available on the network because it has been assigned by IANA for this purpose (see http://www.iana.org/assignments/port-numbers for details).

By listing multiple host definitions, it is possible to designate several redundant management servers. A MySQL Cluster data or API node attempts to contact successive management servers on each host in the order specified, until a successful connection has been established.

There are a number of different ways to specify the connection string:

- Each executable has its own command-line option which enables specifying the management server at startup. (See the documentation for the respective executable.)

- It is also possible to set the connection string for all nodes in the cluster at once by placing it in a [mysql_cluster] section in the management server’s my.cnf file.

- For backward compatibility, two other options are available, using the same syntax:
  1. Set the NDB_CONNECTSTRING environment variable to contain the connection string.
  2. Write the connection string for each executable into a text file named Ndb.cfg and place this file in the executable’s startup directory.

  However, these are now deprecated and should not be used for new installations.

The recommended method for specifying the connection string is to set it on the command line or in the my.cnf file for each executable.

The maximum length of a connection string is 1024 characters.

### 17.3.3.3 Defining Computers in a MySQL Cluster

The [computer] section has no real significance other than serving as a way to avoid the need of defining host names for each node in the system. All parameters mentioned here are required.

- **Id**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>string</td>
<td>[none]</td>
<td>...</td>
<td>IS</td>
</tr>
</tbody>
</table>

This is a unique identifier, used to refer to the host computer elsewhere in the configuration file.
Important

The computer ID is not the same as the node ID used for a management, API, or data node. Unlike the case with node IDs, you cannot use `NodeId` in place of `Id` in the `[computer]` section of the `config.ini` file.

- **HostName**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>

<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>name or IP address</td>
<td>[none]</td>
<td>...</td>
<td>N</td>
</tr>
</tbody>
</table>

This is the computer's hostname or IP address.

### 17.3.3.4 Defining a MySQL Cluster Management Server

The `[ndb_mgmd]` section is used to configure the behavior of the management server. `[mgm]` can be used as an alias; the two section names are equivalent. All parameters in the following list are optional and assume their default values if omitted.

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>unsigned</td>
<td>[none]</td>
<td>1 - 63</td>
<td>IS</td>
</tr>
</tbody>
</table>

Note

If neither the `ExecuteOnComputer` nor the `HostName` parameter is present, the default value `localhost` will be assumed for both.

- **Id**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>unsigned</td>
<td>[none]</td>
<td>1 - 63</td>
<td>IS</td>
</tr>
</tbody>
</table>

Each node in the cluster has a unique identity, which is represented by an integer value in the range 1 to 63 inclusive. This ID is used by all internal cluster messages for addressing the node.

In MySQL 5.0.15 and later, `NodeId` is a synonym for this parameter, and is the preferred form. In MySQL Cluster NDB 6.2 and later, `Id` is deprecated in favor of `NodeId` for identifying management nodes.

- **NodeId**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.15</td>
<td>unsigned</td>
<td>[none]</td>
<td>1 - 63</td>
<td>IS</td>
</tr>
</tbody>
</table>

Beginning with MySQL 5.0.15, `NodeId` is available as a synonym for `Id`.

In MySQL Cluster NDB 6.2 and later, `Id` is deprecated in favor of `NodeId` for identifying management nodes.

- **ExecuteOnComputer**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>name</td>
<td>[none]</td>
<td>...</td>
<td>S</td>
</tr>
</tbody>
</table>

This refers to the `Id` set for one of the computers defined in a `[computer]` section of the `config.ini` file.
MySQL Cluster Configuration Files

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>unsigned</td>
<td>1186</td>
<td>0 - 64K</td>
<td>S</td>
</tr>
</tbody>
</table>

This is the port number on which the management server listens for configuration requests and management commands.

- **HostName**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>name or IP address</td>
<td>[none]</td>
<td>...</td>
<td>N</td>
</tr>
</tbody>
</table>

Specifying this parameter defines the hostname of the computer on which the management node is to reside. To specify a hostname other than `localhost`, either this parameter or `ExecuteOnComputer` is required.

- **LogDestination**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>[CONSOLE]</td>
<td></td>
<td>[see text]</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies where to send cluster logging information. There are three options in this regard—CONSOLE, SYSLOG, and FILE—with FILE being the default:

- **CONSOLE** outputs the log to stdout:

  CONSOLE

- **SYSLOG** sends the log to a syslog facility, possible values being one of auth, authpriv, cron, daemon, ftp, kern, lpr, mail, news, syslog, user, uucp, local0, local1, local2, local3, local4, local5, local6, or local7.

  SYSLOG:facility=syslog

- **FILE** pipes the cluster log output to a regular file on the same machine. The following values can be specified:

  - **filename**: The name of the log file.
  
  - **maxsize**: The maximum size (in bytes) to which the file can grow before logging rolls over to a new file. When this occurs, the old log file is renamed by appending `.N` to the file name, where `N` is the next number not yet used with this name.

  - **maxfiles**: The maximum number of log files.

  FILE:filename=cluster.log,maxsize=1000000,maxfiles=6

  The default value for the FILE parameter is

  FILE:filename=ndb_node_id_cluster.log,maxsize=1000000,maxfiles=6, where `node_id` is the ID of the node.
It is possible to specify multiple log destinations separated by semicolons as shown here:

```
CONSOLE;SYSLOG:facility=local0;FILE:filename=/var/log/mgmd
```

- **ArbitrationRank**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>0-2</td>
<td>1</td>
<td>0 - 2</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is used to define which nodes can act as arbitrators. Only management nodes and SQL nodes can be arbitrators. *ArbitrationRank* can take one of the following values:

- **0**: The node will never be used as an arbitrator.
- **1**: The node has high priority; that is, it will be preferred as an arbitrator over low-priority nodes.
- **2**: Indicates a low-priority node which be used as an arbitrator only if a node with a higher priority is not available for that purpose.

Normally, the management server should be configured as an arbitrator by setting its *ArbitrationRank* to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

- **ArbitrationDelay**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>milliseconds</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

An integer value which causes the management server's responses to arbitration requests to be delayed by that number of milliseconds. By default, this value is 0; it is normally not necessary to change it.

- **DataDir**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>path</td>
<td>.</td>
<td>...</td>
<td>N</td>
</tr>
</tbody>
</table>

This specifies the directory where output files from the management server will be placed. These files include cluster log files, process output files, and the daemon's process ID (PID) file. (For log files, this location can be overridden by setting the `FILE` parameter for `LogDestination` as discussed previously in this section.)

The default value for this parameter is the directory in which `ndb_mgmd` is located.

- **PortNumberStats**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>unsigned</td>
<td>[none]</td>
<td>0 - 64K</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies the port number used to obtain statistical information from a MySQL Cluster management server. It has no default value.

---

**Note**

After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect.
To add new management servers to a running MySQL Cluster, it is also necessary to perform a rolling restart of all cluster nodes after modifying any existing `config.ini` files. For more information about issues arising when using multiple management nodes, see Section 17.1.5.9, “Limitations Relating to Multiple MySQL Cluster Nodes”.

### 17.3.3.5 Defining MySQL Cluster Data Nodes

The `[ndbd]` and `[ndbd default]` sections are used to configure the behavior of the cluster's data nodes.

There are many parameters which control buffer sizes, pool sizes, timeouts, and so forth. The only mandatory parameters are:

- Either `ExecuteOnComputer` or `HostName`, which must be defined in the local `[ndbd]` section.
- The parameter `NoOfReplicas`, which must be defined in the `[ndbd default]` section, as it is common to all Cluster data nodes.

Most data node parameters are set in the `[ndbd default]` section. Only those parameters explicitly stated as being able to set local values are permitted to be changed in the `[ndbd]` section. Where present, `HostName`, `Id` and `ExecuteOnComputer` must be defined in the local `[ndbd]` section, and not in any other section of `config.ini`. In other words, settings for these parameters are specific to one data node.

For those parameters affecting memory usage or buffer sizes, it is possible to use K, M, or G as a suffix to indicate units of 1024, 1024×1024, or 1024×1024×1024. (For example, 100K means 100 × 1024 = 102400.) Parameter names and values are currently case-sensitive.

#### Identifying data nodes

The `Id` value (that is, the data node identifier) can be allocated on the command line when the node is started or in the configuration file.

- **Id**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>unsigned</td>
<td>[none]</td>
<td>1 - 48</td>
<td>IS</td>
</tr>
</tbody>
</table>

This is the node ID used as the address of the node for all cluster internal messages. For data nodes, this is an integer in the range 1 to 48 inclusive. Each node in the cluster must have a unique identifier.

In MySQL 5.0.15 and later, `NodeId` is a synonym for this parameter, and is the preferred form. In MySQL Cluster NDB 6.2 and later, `Id` is deprecated in favor of `NodeId` for identifying data nodes.

- **NodeId**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.15</td>
<td>unsigned</td>
<td>[none]</td>
<td>1 - 48</td>
<td>IS</td>
</tr>
</tbody>
</table>

Beginning with MySQL 5.0.15, `NodeId` is available as a synonym for `Id`.

In MySQL Cluster NDB 6.2 and later, `Id` is deprecated in favor of `NodeId` for identifying management nodes.

- **ExecuteOnComputer**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>name</td>
<td>[none]</td>
<td>...</td>
<td>S</td>
</tr>
</tbody>
</table>
This refers to the Id set for one of the computers defined in a [computer] section.

- **HostName**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>name or IP address</td>
<td>localhost</td>
<td>...</td>
<td>N</td>
</tr>
</tbody>
</table>

Specifying this parameter defines the hostname of the computer on which the data node is to reside. To specify a hostname other than localhost, either this parameter or ExecuteOnComputer is required.

- **ServerPort**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>unsigned</td>
<td>[none]</td>
<td>1 - 64K</td>
<td>S</td>
</tr>
</tbody>
</table>

Each node in the cluster uses a port to connect to other nodes. By default, this port is allocated dynamically in such a way as to ensure that no two nodes on the same host computer receive the same port number, so it should normally not be necessary to specify a value for this parameter.

However, if you need to be able to open specific ports in a firewall to permit communication between data nodes and API nodes (including SQL nodes), you can set this parameter to the number of the desired port in an [ndbd] section or (if you need to do this for multiple data nodes) the [ndbd default] section of the config.ini file, and then open the port having that number for incoming connections from SQL nodes, API nodes, or both.

**Note**

Connections from data nodes to management nodes is done using the ndb_mgmd management port (the management server’s PortNumber; see Section 17.3.3.4, “Defining a MySQL Cluster Management Server”) so outgoing connections to that port from any data nodes should always be permitted.

- **NoOfReplicas**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>integer</td>
<td>[none]</td>
<td>1 - 4</td>
<td>IS</td>
</tr>
</tbody>
</table>

This global parameter can be set only in the [ndbd default] section, and defines the number of replicas for each table stored in the cluster. This parameter also specifies the size of node groups. A node group is a set of nodes all storing the same information.

Node groups are formed implicitly. The first node group is formed by the set of data nodes with the lowest node IDs, the next node group by the set of the next lowest node identities, and so on. By way of example, assume that we have 4 data nodes and that NoOfReplicas is set to 2. The four data nodes have node IDs 2, 3, 4 and 5. Then the first node group is formed from nodes 2 and 3, and the second node group by nodes 4 and 5. It is important to configure the cluster in such a manner that nodes in the same node groups are not placed on the same computer because a single hardware failure would cause the entire cluster to fail.

If no node IDs are provided, the order of the data nodes will be the determining factor for the node group. Whether or not explicit assignments are made, they can be viewed in the output of the management client’s SHOW command.

There is no default value for NoOfReplicas; the recommended value is 2 for most common usage scenarios.
The maximum possible value is 4; currently, only the values 1 and 2 are actually supported.

---

**Important**

Setting `NoOfReplicas` to 1 means that there is only a single copy of all Cluster data; in this case, the loss of a single data node causes the cluster to fail because there are no additional copies of the data stored by that node.

The value for this parameter must divide evenly into the number of data nodes in the cluster. For example, if there are two data nodes, then `NoOfReplicas` must be equal to either 1 or 2, since 2/3 and 2/4 both yield fractional values; if there are four data nodes, then `NoOfReplicas` must be equal to 1, 2, or 4.

- **DataDir**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>path</td>
<td></td>
<td>...</td>
<td>IN</td>
</tr>
</tbody>
</table>

This parameter specifies the directory where trace files, log files, pid files and error logs are placed. The default is the data node process working directory.

- **FileSystemPath**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>path</td>
<td>DataDir</td>
<td>...</td>
<td>IN</td>
</tr>
</tbody>
</table>

This parameter specifies the directory where all files created for metadata, REDO logs, UNDO logs, and data files are placed. The default is the directory specified by `DataDir`.

**Note**

This directory must exist before the `ndbd` process is initiated.

The recommended directory hierarchy for MySQL Cluster includes `/var/lib/mysql-cluster`, under which a directory for the node's file system is created. The name of this subdirectory contains the node ID. For example, if the node ID is 2, this subdirectory is named `ndb_2_fs`.

- **BackupDataDir**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>path</td>
<td>[see text]</td>
<td>...</td>
<td>IN</td>
</tr>
</tbody>
</table>

This parameter specifies the directory in which backups are placed.

**Important**

The string `'/BACKUP'` is always appended to this value. For example, if you set the value of `BackupDataDir` to `/var/lib/cluster-data`, then all backups are stored under `/var/lib/cluster-data/BACKUP`. This also means that the effective default backup location is the directory named `BACKUP` under the location specified by the `FileSystemPath` parameter.

**Data memory, index memory, and string memory.** DataMemory and IndexMemory are [ndbd](https://dev.mysql.com/doc/refman/8.0/en/mysql-cluster.html) parameters specifying the size of memory segments used to store the actual records and their indexes. In setting values for these, it is important to understand how DataMemory and IndexMemory are used, as they usually need to be updated to reflect actual usage by the cluster.
**DataMemory**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>bytes</td>
<td>80M</td>
<td>1M - 1024G</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter defines the amount of space (in bytes) available for storing database records. The entire amount specified by this value is allocated in memory, so it is extremely important that the machine has sufficient physical memory to accommodate it.

The memory allocated by `DataMemory` is used to store both the actual records and indexes. Each record is currently of fixed size. (Even `VARCHAR` columns are stored as fixed-width columns.) There is a 16-byte overhead on each record; an additional amount for each record is incurred because it is stored in a 32KB page with 128 byte page overhead (see below). There is also a small amount wasted per page due to the fact that each record is stored in only one page.

The maximum record size is currently 8052 bytes.

The memory space defined by `DataMemory` is also used to store ordered indexes, which use about 10 bytes per record. Each table row is represented in the ordered index. A common error among users is to assume that all indexes are stored in the memory allocated by `IndexMemory`, but this is not the case: Only primary key and unique hash indexes use this memory; ordered indexes use the memory allocated by `DataMemory`. However, creating a primary key or unique hash index also creates an ordered index on the same keys, unless you specify `USING HASH` in the index creation statement. This can be verified by running `ndb_desc -d db_name table_name` in the management client.

MySQL Cluster can use a maximum of 512 MB for hash indexes per partition, which means in some cases it is possible to get `Table is full` errors in MySQL client applications even when `ndb_mgm -e "ALL REPORT MEMORYUSAGE"` shows significant free `DataMemory`. This can also pose a problem with data node restarts on nodes that are heavily loaded with data. You can force NDB to create extra partitions for MySQL Cluster tables and thus have more memory available for hash indexes by using the `MAX_ROWS` option for `CREATE TABLE`. In general, setting `MAX_ROWS` to twice the number of rows that you expect to store in the table should be sufficient.

The memory space allocated by `DataMemory` consists of 32KB pages, which are allocated to table fragments. Each table is normally partitioned into the same number of fragments as there are data nodes in the cluster. Thus, for each node, there are the same number of fragments as are set in `NoOfReplicas`.

In addition, due to the way in which new pages are allocated when the capacity of the current page is exhausted, there is an additional overhead of approximately 18.75%. When more `DataMemory` is required, more than one new page is allocated, according to the following formula:

\[
\text{number of new pages} = \text{FLOOR}(\text{number of current pages} \times 0.1875) + 1
\]

For example, if 15 pages are currently allocated to a given table and an insert to this table requires additional storage space, the number of new pages allocated to the table is `FLOOR(15 \times 0.1875) + 1 = FLOOR(2.8125) + 1 = 2 + 1 = 3`. Now 15 + 3 = 18 memory pages are allocated to the table. When the last of these 18 pages becomes full, `FLOOR(18 \times 0.1875) + 1 = FLOOR(3.3750) + 1 = 3 + 1 = 4` new pages are allocated, so the total number of pages allocated to the table is now 22.

Once a page has been allocated, it is currently not possible to return it to the pool of free pages, except by deleting the table. (This also means that `DataMemory` pages, once allocated to a given table, cannot be used by other tables.) Performing a node recovery also compresses the partition because all records are inserted into empty partitions from other live nodes.
The DataMemory memory space also contains UNDO information: For each update, a copy of the unaltered record is allocated in the DataMemory. There is also a reference to each copy in the ordered table indexes. Unique hash indexes are updated only when the unique index columns are updated, in which case a new entry in the index table is inserted and the old entry is deleted upon commit. For this reason, it is also necessary to allocate enough memory to handle the largest transactions performed by applications using the cluster. In any case, performing a few large transactions holds no advantage over using many smaller ones, for the following reasons:

- Large transactions are not any faster than smaller ones
- Large transactions increase the number of operations that are lost and must be repeated in event of transaction failure
- Large transactions use more memory

The default value for DataMemory is 80MB; the minimum is 1MB. There is no maximum size, but in reality the maximum size has to be adapted so that the process does not start swapping when the limit is reached. This limit is determined by the amount of physical RAM available on the machine and by the amount of memory that the operating system may commit to any one process. 32-bit operating systems are generally limited to 2–4GB per process; 64-bit operating systems can use more. For large databases, it may be preferable to use a 64-bit operating system for this reason.

- IndexMemory

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>bytes</td>
<td>18M</td>
<td>1M - 1T</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter controls the amount of storage used for hash indexes in MySQL Cluster. Hash indexes are always used for primary key indexes, unique indexes, and unique constraints. Note that when defining a primary key and a unique index, two indexes will be created, one of which is a hash index used for all tuple accesses as well as lock handling. It is also used to enforce unique constraints.

The size of the hash index is 25 bytes per record, plus the size of the primary key. For primary keys larger than 32 bytes another 8 bytes is added.

The default value for IndexMemory is 18MB. The minimum is 1MB.

- StringMemory

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>% or bytes</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>S</td>
</tr>
</tbody>
</table>

This parameter determines how much memory is allocated for strings such as table names, and is specified in an [ndbd] or [ndbd default] section of the config.ini file. A value between 0 and 100 inclusive is interpreted as a percent of the maximum default value, which is calculated based on a number of factors including the number of tables, maximum table name size, maximum size of .FRM files, MaxNoOfTriggers, maximum column name size, and maximum default column value. In general it is safe to assume that the maximum default value is approximately 5 MB for a MySQL Cluster having 1000 tables.

A value greater than 100 is interpreted as a number of bytes.

In MySQL 5.0, the default value is 100—that is, 100 percent of the default maximum, or roughly 5 MB. It is possible to reduce this value safely, but it should never be less than 5 percent. If you encounter Error 773 Out of string memory, please modify StringMemory config parameter: Permanent error: Schema error, this means that means that you have set the...
StringMemory value too low. 25 (25 percent) is not excessive, and should prevent this error from recurring in all but the most extreme conditions, as when there are hundreds or thousands of NDB tables with names whose lengths and columns whose number approach their permitted maximums.

The following example illustrates how memory is used for a table. Consider this table definition:

```
CREATE TABLE example (
  a INT NOT NULL,
  b INT NOT NULL,
  c INT NOT NULL,
  PRIMARY KEY(a),
  UNIQUE(b)
) ENGINE=NDBCLUSTER;
```

For each record, there are 12 bytes of data plus 12 bytes overhead. Having no nullable columns saves 4 bytes of overhead. In addition, we have two ordered indexes on columns a and b consuming roughly 10 bytes each per record. There is a primary key hash index on the base table using roughly 29 bytes per record. The unique constraint is implemented by a separate table with b as primary key and a as a column. This other table consumes an additional 29 bytes of index memory per record in the example table as well 8 bytes of record data plus 12 bytes of overhead.

Thus, for one million records, we need 58MB for index memory to handle the hash indexes for the primary key and the unique constraint. We also need 64MB for the records of the base table and the unique index table, plus the two ordered index tables.

You can see that hash indexes takes up a fair amount of memory space; however, they provide very fast access to the data in return. They are also used in MySQL Cluster to handle uniqueness constraints.

The only partitioning algorithm is hashing and ordered indexes are local to each node. Thus, ordered indexes cannot be used to handle uniqueness constraints in the general case.

An important point for both IndexMemory and DataMemory is that the total database size is the sum of all data memory and all index memory for each node group. Each node group is used to store replicated information, so if there are four nodes with two replicas, there will be two node groups. Thus, the total data memory available is 2 × DataMemory for each data node.

It is highly recommended that DataMemory and IndexMemory be set to the same values for all nodes. Data distribution is even over all nodes in the cluster, so the maximum amount of space available for any node can be no greater than that of the smallest node in the cluster.

DataMemory and IndexMemory can be changed, but decreasing either of these can be risky; doing so can easily lead to a node or even an entire MySQL Cluster that is unable to restart due to there being insufficient memory space. Increasing these values should be acceptable, but it is recommended that such upgrades are performed in the same manner as a software upgrade, beginning with an update of the configuration file, and then restarting the management server followed by restarting each data node in turn.

Updates do not increase the amount of index memory used. Inserts take effect immediately; however, rows are not actually deleted until the transaction is committed.

**Transaction parameters.** The next three [ndbd] parameters that we discuss are important because they affect the number of parallel transactions and the sizes of transactions that can be handled by the system. MaxNoOfConcurrentTransactions sets the number of parallel transactions possible in a node. MaxNoOfConcurrentOperations sets the number of records that can be in update phase or locked simultaneously.

Both of these parameters (especially MaxNoOfConcurrentOperations) are likely targets for users setting specific values and not using the default value. The default value is set for systems using small transactions, to ensure that these do not use excessive memory.

- MaxNoOfConcurrentTransactions
Each cluster data node requires a transaction record for each active transaction in the cluster. The task of coordinating transactions is distributed among all of the data nodes. The total number of transaction records in the cluster is the number of transactions in any given node times the number of nodes in the cluster.

Transaction records are allocated to individual SQL nodes. Each such connection requires at least one transaction record, plus an additional transaction object per table accessed by that connection. This means that a reasonable minimum for this parameter is

\[
\text{MaxNoOfConcurrentTransactions} = (\text{maximum number of tables accessed in any single transaction} + 1) \times \text{number of cluster SQL nodes}
\]

Suppose that there are 10 SQL nodes using the cluster. A single join involving 10 tables requires 11 transaction records; if there are 10 such joins in a transaction, then 10 * 11 = 110 transaction records are required for this transaction, per SQL node, or 110 * 10 = 1100 transaction records total. Each data node can be expected to handle \(\frac{\text{TotalNoOfConcurrentTransactions}}{\text{number of data nodes}}\). For a MySQL Cluster having 4 data nodes, this would mean setting \(\text{MaxNoOfConcurrentTransactions}\) on each data node to \(\frac{1100}{4} = 275\). In addition, you should provide for failure recovery by insuring that a single node group can accommodate all concurrent transactions; in other words, that each data node's \(\text{MaxNoOfConcurrentTransactions}\) is sufficient to cover a number of transaction equal to \(\frac{\text{TotalNoOfConcurrentTransactions}}{\text{number of node groups}}\). If this cluster has a single node group, then \(\text{MaxNoOfConcurrentTransactions}\) should be set to 1100 (the same as the total number of concurrent transactions for the entire cluster).

In addition, each transaction involves at least one operation; for this reason, the value set for \(\text{MaxNoOfConcurrentTransactions}\) should always be no more than the value of \(\text{MaxNoOfConcurrentOperations}\).

This parameter must be set to the same value for all cluster data nodes. This is due to the fact that, when a data node fails, the oldest surviving node re-creates the transaction state of all transactions that were ongoing in the failed node.

It is possible to change this value using a rolling restart, but the amount of traffic on the cluster must be such that no more transactions occur than the lower of the old and new levels while this is taking place.

The default value is 4096.

- \(\text{MaxNoOfConcurrentOperations}\)

It is a good idea to adjust the value of this parameter according to the size and number of transactions. When performing transactions which involve only a few operations and records, the default value for this parameter is usually sufficient. Performing large transactions involving many records usually requires that you increase its value.

Records are kept for each transaction updating cluster data, both in the transaction coordinator and in the nodes where the actual updates are performed. These records contain state information needed to find UNDO records for rollback, lock queues, and other purposes.
This parameter should be set to the number of records to be updated simultaneously in transactions, divided by the number of cluster data nodes. For example, in a cluster which has four data nodes and which is expected to handle one million concurrent updates using transactions, you should set this value to 1000000 / 4 = 250000. To help provide resiliency against failures, it is suggested that you set this parameter to a value that is high enough to permit an individual data node to handle the load for its node group. In other words, you should set the value equal to \( \frac{\text{total number of concurrent operations}}{\text{number of node groups}} \). (In the case where there is a single node group, this is the same as the total number of concurrent operations for the entire cluster.)

Because each transaction always involves at least one operation, the value of `MaxNoOfConcurrentOperations` should always be greater than or equal to the value of `MaxNoOfConcurrentTransactions`.

Read queries which set locks also cause operation records to be created. Some extra space is allocated within individual nodes to accommodate cases where the distribution is not perfect over the nodes.

When queries make use of the unique hash index, there are actually two operation records used per record in the transaction. The first record represents the read in the index table and the second handles the operation on the base table.

The default value is 32768.

This parameter actually handles two values that can be configured separately. The first of these specifies how many operation records are to be placed with the transaction coordinator. The second part specifies how many operation records are to be local to the database.

A very large transaction performed on an eight-node cluster requires as many operation records in the transaction coordinator as there are reads, updates, and deletes involved in the transaction. However, the operation records of the are spread over all eight nodes. Thus, if it is necessary to configure the system for one very large transaction, it is a good idea to configure the two parts separately. `MaxNoOfConcurrentOperations` will always be used to calculate the number of operation records in the transaction coordinator portion of the node.

It is also important to have an idea of the memory requirements for operation records. These consume about 1kB per record.

- `MaxNoOfLocalOperations`

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>integer</td>
<td>UNDEFINED</td>
<td>32 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

By default, this parameter is calculated as \( 1.1 \times \text{MaxNoOfConcurrentOperations} \). This fits systems with many simultaneous transactions, none of them being very large. If there is a need to handle one very large transaction at a time and there are many nodes, it is a good idea to override the default value by explicitly specifying this parameter.

Transaction temporary storage. The next set of `[ndbd]` parameters is used to determine temporary storage when executing a statement that is part of a Cluster transaction. All records are released when the statement is completed and the cluster is waiting for the commit or rollback.

The default values for these parameters are adequate for most situations. However, users with a need to support transactions involving large numbers of rows or operations may need to increase these values to enable better parallelism in the system, whereas users whose applications require relatively small transactions can decrease the values to save memory.

- `MaxNoOfConcurrentIndexOperations`
For queries using a unique hash index, another temporary set of operation records is used during a query's execution phase. This parameter sets the size of that pool of records. Thus, this record is allocated only while executing a part of a query. As soon as this part has been executed, the record is released. The state needed to handle aborts and commits is handled by the normal operation records, where the pool size is set by the parameter MaxNoOfConcurrentOperations.

The default value of this parameter is 8192. Only in rare cases of extremely high parallelism using unique hash indexes should it be necessary to increase this value. Using a smaller value is possible and can save memory if the DBA is certain that a high degree of parallelism is not required for the cluster.

- MaxNoOfFiredTriggers

The memory affected by this parameter is used for tracking operations fired when updating index tables and reading unique indexes. This memory is used to store the key and column information for these operations. It is only very rarely that the value for this parameter needs to be altered from the default.

The default value for MaxNoOfFiredTriggers is 4000, which is sufficient for most situations. In some cases it can even be decreased if the DBA feels certain the need for parallelism in the cluster is not high.

A record is created when an operation is performed that affects a unique hash index. Inserting or deleting a record in a table with unique hash indexes or updating a column that is part of a unique hash index fires an insert or a delete in the index table. The resulting record is used to represent this index table operation while waiting for the original operation that fired it to complete. This operation is short-lived but can still require a large number of records in its pool for situations with many parallel write operations on a base table containing a set of unique hash indexes.

- TransactionBufferMemory

The memory affected by this parameter is used for tracking operations fired when updating index tables and reading unique indexes. This memory is used to store the key and column information for these operations. It is only very rarely that the value for this parameter needs to be altered from the default.

The default value for TransactionBufferMemory is 1MB.

Normal read and write operations use a similar buffer, whose usage is even more short-lived. The compile-time parameter ZATTRBUF_FILESIZE (found in ndb/src/kernel/blocks/Dbtc/Dbtc.hpp) set to 4000 × 128 bytes (500KB). A similar buffer for key information, ZDATABUF_FILE_SIZE, set by default to 10000*16 bytes (roughly 156KB) of buffer space. Dbtc is the module that handles transaction coordination.

Scans and buffering. There are additional [ndbd] parameters in the Dblqh module (in ndb/src/kernel/blocks/Dblqh/Dblqh.hpp) that affect reads and updates. These include ZATTRINBUF_FILESIZE, set by default to 10000 × 128 bytes (1250KB) and ZDATABUF_FILE_SIZE, set by default to 10000*16 bytes (roughly 156KB) of buffer space. To date, there have been neither any reports from users nor any results from our own extensive tests suggesting that either of these compile-time limits should be increased.
• MaxNoOfConcurrentScans

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>integer</td>
<td>256</td>
<td>2 - 500</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is used to control the number of parallel scans that can be performed in the cluster. Each transaction coordinator can handle the number of parallel scans defined for this parameter. Each scan query is performed by scanning all partitions in parallel. Each partition scan uses a scan record in the node where the partition is located, the number of records being the value of this parameter times the number of nodes. The cluster should be able to sustain MaxNoOfConcurrentScans scans concurrently from all nodes in the cluster.

Scans are actually performed in two cases. The first of these cases occurs when no hash or ordered indexes exist to handle the query, in which case the query is executed by performing a full table scan. The second case is encountered when there is no hash index to support the query but there is an ordered index. Using the ordered index means executing a parallel range scan. The order is kept on the local partitions only, so it is necessary to perform the index scan on all partitions.

The default value of MaxNoOfConcurrentScans is 256. The maximum value is 500.

• MaxNoOfLocalScans

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>integer</td>
<td>[see text]</td>
<td>32 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

Specifies the number of local scan records if many scans are not fully parallelized. If the number of local scan records is not provided, it is calculated as the product of MaxNoOfConcurrentScans and the number of data nodes in the system, plus 2. The minimum value is 32.

• BatchSizePerLocalScan

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>integer</td>
<td>64</td>
<td>1 - 992</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is used to calculate the number of lock records used to handle concurrent scan operations.

BatchSizePerLocalScan has a strong connection to the BatchSize defined in the SQL nodes.

• LongMessageBuffer

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>bytes</td>
<td>1M</td>
<td>512K - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

This is an internal buffer used for passing messages within individual nodes and between nodes. Although it is highly unlikely that this would need to be changed, it is configurable. By default, it is set to 1MB.

Logging and checkpointing. The following nbd parameters control log and checkpoint behavior.
This parameter sets the number of REDO log files for the node, and thus the amount of space allocated to REDO logging. Because the REDO log files are organized in a ring, it is extremely important that the first and last log files in the set (sometimes referred to as the “head” and “tail” log files, respectively) do not meet. When these approach one another too closely, the node begins aborting all transactions encompassing updates due to a lack of room for new log records.

A REDO log record is not removed until three local checkpoints have been completed since that log record was inserted. Checkpointing frequency is determined by its own set of configuration parameters discussed elsewhere in this chapter.

How these parameters interact and proposals for how to configure them are discussed in Section 17.3.3.12, “Configuring MySQL Cluster Parameters for Local Checkpoints”.

The default parameter value is 8, which means 8 sets of 4 16MB files for a total of 512MB. In other words, REDO log space is always allocated in blocks of 64MB. In scenarios requiring a great many updates, the value for `NoOfFragmentLogFiles` may need to be set as high as 300 or even higher to provide sufficient space for REDO logs.

If the checkpointing is slow and there are so many writes to the database that the log files are full and the log tail cannot be cut without jeopardizing recovery, all updating transactions are aborted with internal error code 410 (`Out of log file space temporarily`). This condition prevails until a checkpoint has completed and the log tail can be moved forward.

Important

This parameter cannot be changed “on the fly”; you must restart the node using `--initial`. If you wish to change this value for all data nodes in a running cluster, you can do so using a rolling node restart (using `--initial` when starting each data node).

- **MaxNoOfOpenFiles**

This parameter sets a ceiling on how many internal threads to allocate for open files. *Any situation requiring a change in this parameter should be reported as a bug.*

The default value is 40.

- **MaxNoOfSavedMessages**

This parameter sets the maximum number of trace files that are kept before overwriting old ones. Trace files are generated when, for whatever reason, the node crashes.

The default is 25 trace files.

**Metadata objects.** The next set of `[ndbd]` parameters defines pool sizes for metadata objects, used to define the maximum number of attributes, tables, indexes, and trigger objects used by indexes,
events, and replication between clusters. Note that these act merely as “suggestions” to the cluster, and any that are not specified revert to the default values shown.

- **MaxNoOfAttributes**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>integer</td>
<td>1000</td>
<td>32 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter sets a suggested maximum number of attributes that can be defined in the cluster; like **MaxNoOfTables**, it is not intended to function as a hard upper limit.

A known issue in MySQL Cluster in MySQL 5.0 is that this parameter is occasionally treated as a hard limit for certain operations. This can lead to confusion when it is sometimes possible (or not possible, depending on the circumstances) to create more than **MaxNoOfAttributes** attributes. This is fixed in MySQL Cluster NDB 6.3 and later. (Bug #61684)

The default value is 1000, with the minimum possible value being 32. The maximum is 4294967039. Each attribute consumes around 200 bytes of storage per node due to the fact that all metadata is fully replicated on the servers.

When setting **MaxNoOfAttributes**, it is important to prepare in advance for any `ALTER TABLE` statements that you might want to perform in the future. This is due to the fact, during the execution of `ALTER TABLE` on a Cluster table, 3 times the number of attributes as in the original table are used, and a good practice is to permit double this amount. For example, if the MySQL Cluster table having the greatest number of attributes (`greatest_number_of_attributes`) has 100 attributes, a good starting point for the value of **MaxNoOfAttributes** would be $6 \times greatest_number_of_attributes = 600$.

You should also estimate the average number of attributes per table and multiply this by the total number of MySQL Cluster tables. If this value is larger than the value obtained in the previous paragraph, you should use the larger value instead.

Assuming that you can create all desired tables without any problems, you should also verify that this number is sufficient by trying an actual `ALTER TABLE` after configuring the parameter. If this is not successful, increase **MaxNoOfAttributes** by another multiple of **MaxNoOfTables** and test it again.

- **MaxNoOfTables**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>integer</td>
<td>128</td>
<td>8 - 1600</td>
<td>N</td>
</tr>
<tr>
<td>MySQL 5.0.0</td>
<td>integer</td>
<td>128</td>
<td>8 - 20320</td>
<td>N</td>
</tr>
</tbody>
</table>

A table object is allocated for each table and for each unique hash index in the cluster. This parameter sets a suggested maximum number of table objects for the cluster as a whole; like **MaxNoOfAttributes**, it is not intended to function as a hard upper limit.

A known issue in MySQL Cluster in MySQL 5.0 is that this parameter is occasionally treated as a hard limit for certain operations. This can lead to confusion when it is sometimes possible (or not possible, depending on the circumstances) to create more than **MaxNoOfTables** tables. This is fixed in MySQL Cluster NDB 6.3 and later. (Bug #61684)

For each attribute that has a **BLOB** data type an extra table is used to store most of the **BLOB** data. These tables also must be taken into account when defining the total number of tables.

The default value of this parameter is 128. The minimum is 8 and the maximum is 20320. (This is a change from MySQL 4.1.) Each table object consumes approximately 20KB per node.
Note

The sum of `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes` must not exceed $2^{32} - 2$ (4294967294).

- **MaxNoOfOrderedIndexes**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>integer</td>
<td>128</td>
<td>0 - 4294967039</td>
<td>N</td>
</tr>
</tbody>
</table>

For each ordered index in the cluster, an object is allocated describing what is being indexed and its storage segments. By default, each index so defined also defines an ordered index. Each unique index and primary key has both an ordered index and a hash index. `MaxNoOfOrderedIndexes` sets the total number of hash indexes that can be in use in the system at any one time.

The default value of this parameter is 128. Each hash index object consumes approximately 10KB of data per node.

Note

The sum of `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes` must not exceed $2^{32} - 2$ (4294967294).

- **MaxNoOfUniqueHashIndexes**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>integer</td>
<td>64</td>
<td>0 - 4294967039</td>
<td>N</td>
</tr>
</tbody>
</table>

For each unique index that is not a primary key, a special table is allocated that maps the unique key to the primary key of the indexed table. By default, an ordered index is also defined for each unique index. To prevent this, you must specify the `USING HASH` option when defining the unique index.

The default value is 64. Each index consumes approximately 15KB per node.

Note

The sum of `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes` must not exceed $2^{32} - 2$ (4294967294).

- **MaxNoOfTriggers**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>integer</td>
<td>768</td>
<td>0 - 4294967039</td>
<td>N</td>
</tr>
</tbody>
</table>

Internal update, insert, and delete triggers are allocated for each unique hash index. (This means that three triggers are created for each unique hash index.) However, an ordered index requires only a single trigger object. Backups also use three trigger objects for each normal table in the cluster.

This parameter sets the maximum number of trigger objects in the cluster.

The default value is 768.

- **MaxNoOfIndexes**

This parameter is deprecated. You should use `MaxNoOfOrderedIndexes` and `MaxNoOfUniqueHashIndexes` instead.
This parameter is used only by unique hash indexes. There needs to be one record in this pool for each unique hash index defined in the cluster.

The default value of this parameter is 128.

**Boolean parameters.** The behavior of data nodes is also affected by a set of [ndbd] parameters taking on boolean values. These parameters can each be specified as **TRUE** by setting them equal to 1 or **Y**, and as **FALSE** by setting them equal to 0 or **N**.

- **LockPagesInMainMemory**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>true</td>
<td>false (1</td>
<td>0)</td>
<td>0</td>
</tr>
<tr>
<td>MySQL 5.0.0</td>
<td>true</td>
<td>false (1</td>
<td>0)</td>
<td>0</td>
</tr>
<tr>
<td>MySQL 5.0.36</td>
<td>numeric</td>
<td>0</td>
<td>0 - 2</td>
<td>N</td>
</tr>
</tbody>
</table>

For a number of operating systems, including Solaris and Linux, it is possible to lock a process into memory and so avoid any swapping to disk. This can be used to help guarantee the cluster's real-time characteristics.

Beginning with MySQL 5.0.36, this parameter takes one of the integer values 0, 1, or 2, which act as follows:

- **0**: Disables locking. This is the default value.
- **1**: Performs the lock after allocating memory for the process.
- **2**: Performs the lock before memory for the process is allocated.

Previously, this parameter was a Boolean. **0** or **false** was the default setting, and disabled locking. **1** or **true** enabled locking of the process after its memory was allocated.

---

**Important**

Beginning with MySQL 5.0.36, it is no longer possible to use **true** or **false** for the value of this parameter; when upgrading from a previous version, you must change the value to **0**, **1**, or **2**.

**Note**

If the operating system is not configured to permit unprivileged users to lock pages, then the data node process making use of this parameter may have to be run as system root. **LockPagesInMainMemory** uses the **mlockall** function. From Linux kernel 2.6.9, unprivileged users can lock memory as limited by **max locked memory**. For more information, see **ulimit -l** and [http://linux.die.net/man/2/mlock](http://linux.die.net/man/2/mlock).

---

**Important**

Beginning with **glibc** 2.10, **glibc** uses per-thread arenas to reduce lock contention on a shared pool, which consumes real memory. In general, a data node process does not need per-thread arenas, since it does not perform any memory allocation after startup. (This difference in allocators does not appear to affect performance significantly.)

The **glibc** behavior is intended to be configurable via the **MALLOC_ARENA_MAX** environment variable, but a bug in this this mechanism prior to **glibc** 2.16 meant that this variable could not be set to less than 8, so...
that the wasted memory could not be reclaimed. (Bug #15907219; see also http://sourceware.org/bugzilla/show_bug.cgi?id=13137 for more information concerning this issue.)

One possible workaround for this problem is to use the LD_PRELOAD environment variable to preload a jemalloc memory allocation library to take the place of that supplied with glibc.

• **StopOnError**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>boolean</td>
<td>1</td>
<td>0, 1</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies whether a data node process should exit or perform an automatic restart when an error condition is encountered.

This parameter's default value is 1; this means that, by default, an error causes the data node process to halt.

• **Diskless**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>true</td>
<td>false (1</td>
<td>0)</td>
<td>false</td>
</tr>
</tbody>
</table>

It is possible to specify MySQL Cluster tables as *diskless*, meaning that tables are not checkpointed to disk and that no logging occurs. Such tables exist only in main memory. A consequence of using diskless tables is that neither the tables nor the records in those tables survive a crash. However, when operating in diskless mode, it is possible to run ndbd on a diskless computer.

![Important]

This feature causes the *entire* cluster to operate in diskless mode.

When this feature is enabled, Cluster online backup is disabled. In addition, a partial start of the cluster is not possible.

**Diskless** is disabled by default.

• **RestartOnErrorInsert**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>error code</td>
<td>2</td>
<td>0 - 4</td>
<td>N</td>
</tr>
</tbody>
</table>

This feature is accessible only when building the debug version where it is possible to insert errors in the execution of individual blocks of code as part of testing.

This feature is disabled by default.

**Controlling timeouts, intervals, and disk paging.** There are a number of [ndbd] parameters specifying timeouts and intervals between various actions in Cluster data nodes. Most of the timeout values are specified in milliseconds. Any exceptions to this are mentioned where applicable.

• **TimeBetweenWatchDogCheck**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>milliseconds</td>
<td>6000</td>
<td>70 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>
To prevent the main thread from getting stuck in an endless loop at some point, a “watchdog” thread checks the main thread. This parameter specifies the number of milliseconds between checks. If the process remains in the same state after three checks, the watchdog thread terminates it.

This parameter can easily be changed for purposes of experimentation or to adapt to local conditions. It can be specified on a per-node basis although there seems to be little reason for doing so.

The default timeout is 4000 milliseconds (4 seconds).

• **StartPartialTimeout**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>milliseconds</td>
<td>30000</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies how long the Cluster waits for all data nodes to come up before the cluster initialization routine is invoked. This timeout is used to avoid a partial Cluster startup whenever possible.

This parameter is overridden when performing an initial start or initial restart of the cluster.

The default value is 30000 milliseconds (30 seconds). 0 disables the timeout, in which case the cluster may start only if all nodes are available.

• **StartPartitionedTimeout**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>milliseconds</td>
<td>60000</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

If the cluster is ready to start after waiting for **StartPartialTimeout** milliseconds but is still possibly in a partitioned state, the cluster waits until this timeout has also passed. If **StartPartitionedTimeout** is set to 0, the cluster waits indefinitely.

This parameter is overridden when performing an initial start or initial restart of the cluster.

The default timeout is 60000 milliseconds (60 seconds).

• **StartFailureTimeout**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>milliseconds</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

If a data node has not completed its startup sequence within the time specified by this parameter, the node startup fails. Setting this parameter to 0 (the default value) means that no data node timeout is applied.

For nonzero values, this parameter is measured in milliseconds. For data nodes containing extremely large amounts of data, this parameter should be increased. For example, in the case of a data node containing several gigabytes of data, a period as long as $10^{-15}$ minutes (that is, 600000 to 1000000 milliseconds) might be required to perform a node restart.

• **HeartbeatIntervalDbDb**
One of the primary methods of discovering failed nodes is by the use of heartbeats. This parameter states how often heartbeat signals are sent and how often to expect to receive them. After missing three heartbeat intervals in a row, the node is declared dead. Thus, the maximum time for discovering a failure through the heartbeat mechanism is four times the heartbeat interval.

The default heartbeat interval is 1500 milliseconds (1.5 seconds). This parameter must not be changed drastically and should not vary widely between nodes. If one node uses 5000 milliseconds and the node watching it uses 1000 milliseconds, obviously the node will be declared dead very quickly. This parameter can be changed during an online software upgrade, but only in small increments.

See also Network communication and latency.

• **HeartbeatIntervalDbApi**

Each data node sends heartbeat signals to each MySQL server (SQL node) to ensure that it remains in contact. If a MySQL server fails to send a heartbeat in time it is declared “dead,” in which case all ongoing transactions are completed and all resources released. The SQL node cannot reconnect until all activities initiated by the previous MySQL instance have been completed. The three-heartbeat criteria for this determination are the same as described for **HeartbeatIntervalDbDb**.

The default interval is 1500 milliseconds (1.5 seconds). This interval can vary between individual data nodes because each data node watches the MySQL servers connected to it, independently of all other data nodes.

For more information, see Network communication and latency.

• **TimeBetweenLocalCheckpoints**

This parameter is an exception in that it does not specify a time to wait before starting a new local checkpoint; rather, it is used to ensure that local checkpoints are not performed in a cluster where relatively few updates are taking place. In most clusters with high update rates, it is likely that a new local checkpoint is started immediately after the previous one has been completed.

The size of all write operations executed since the start of the previous local checkpoints is added. This parameter is also exceptional in that it is specified as the base-2 logarithm of the number of 4-byte words, so that the default value 20 means 4MB \((4 \times 2^{20})\) of write operations, 21 would mean 8MB, and so on up to a maximum value of 31, which equates to 8GB of write operations.

All the write operations in the cluster are added together. Setting **TimeBetweenLocalCheckpoints** to 6 or less means that local checkpoints will be executed continuously without pause, independent of the cluster's workload.

• **TimeBetweenGlobalCheckpoints**
When a transaction is committed, it is committed in main memory in all nodes on which the data is mirrored. However, transaction log records are not flushed to disk as part of the commit. The reasoning behind this behavior is that having the transaction safely committed on at least two autonomous host machines should meet reasonable standards for durability.

It is also important to ensure that even the worst of cases—a complete crash of the cluster—is handled properly. To guarantee that this happens, all transactions taking place within a given interval are put into a global checkpoint, which can be thought of as a set of committed transactions that has been flushed to disk. In other words, as part of the commit process, a transaction is placed in a global checkpoint group. Later, this group's log records are flushed to disk, and then the entire group of transactions is safely committed to disk on all computers in the cluster.

This parameter defines the interval between global checkpoints. The default is 2000 milliseconds.

**TimeBetweenInactiveTransactionAbortCheck**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>milliseconds</td>
<td>1000</td>
<td>1000 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

Timeout handling is performed by checking a timer on each transaction once for every interval specified by this parameter. Thus, if this parameter is set to 1000 milliseconds, every transaction will be checked for timing out once per second.

The default value is 1000 milliseconds (1 second).

**TransactionInactiveTimeout**

This parameter states the maximum time that is permitted to lapse between operations in the same transaction before the transaction is aborted.

The default for this parameter is 4G (also the maximum). For a real-time database that needs to ensure that no transaction keeps locks for too long, this parameter should be set to a relatively small value. The unit is milliseconds.

**TransactionDeadlockDetectionTimeout**

When a node executes a query involving a transaction, the node waits for the other nodes in the cluster to respond before continuing. A failure to respond can occur for any of the following reasons:

- The node is “dead”
- The operation has entered a lock queue
- The node requested to perform the action could be heavily overloaded.
This timeout parameter states how long the transaction coordinator waits for query execution by another node before aborting the transaction, and is important for both node failure handling and deadlock detection. In MySQL 5.0.20 and earlier versions, setting it too high could cause undesirable behavior in situations involving deadlocks and node failure. Beginning with MySQL 5.0.21, active transactions occurring during node failures are actively aborted by the MySQL Cluster Transaction Coordinator, and so high settings are no longer an issue with this parameter.

The default timeout value is 1200 milliseconds (1.2 seconds). The effective minimum value is 100 milliseconds; it is possible to set it as low as 50 milliseconds, but any such value is treated as 100 ms. (Bug #44099)

• **NoOfDiskPagesToDiskAfterRestartTUP**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>8K pages/100 milliseconds</td>
<td>40</td>
<td>1 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

When executing a local checkpoint, the algorithm flushes all data pages to disk. Merely doing so as quickly as possible without any moderation is likely to impose excessive loads on processors, networks, and disks. To control the write speed, this parameter specifies how many pages per 100 milliseconds are to be written. In this context, a “page” is defined as 8KB. This parameter is specified in units of 80KB per second, so setting `NoOfDiskPagesToDiskAfterRestartTUP` to a value of 20 entails writing 1.6MB in data pages to disk each second during a local checkpoint. This value includes the writing of UNDO log records for data pages. That is, this parameter handles the limitation of writes from data memory. UNDO log records for index pages are handled by the parameter `NoOfDiskPagesToDiskAfterRestartACC`. (See the entry for `IndexMemory` for information about index pages.)

In short, this parameter specifies how quickly to execute local checkpoints. It operates in conjunction with `NoOfFragmentLogFiles`, `DataMemory`, and `IndexMemory`.

For more information about the interaction between these parameters and possible strategies for choosing appropriate values for them, see Section 17.3.3.12, “Configuring MySQL Cluster Parameters for Local Checkpoints”.

The default value is 40 (3.2MB of data pages per second).

• **NoOfDiskPagesToDiskAfterRestartACC**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>8K pages/100 milliseconds</td>
<td>20</td>
<td>1 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter uses the same units as `NoOfDiskPagesToDiskAfterRestartTUP` and acts in a similar fashion, but limits the speed of writing index pages from index memory.

The default value of this parameter is 20 (1.6MB of index memory pages per second).

• **NoOfDiskPagesToDiskDuringRestartTUP**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>8K pages/100 milliseconds</td>
<td>40</td>
<td>1 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is used in a fashion similar to `NoOfDiskPagesToDiskAfterRestartTUP` and `NoOfDiskPagesToDiskAfterRestartACC`, only it does so with regard to local checkpoints executed in the node when a node is restarting. A local checkpoint is always performed as part of
all node restarts. During a node restart it is possible to write to disk at a higher speed than at other times, because fewer activities are being performed in the node.

This parameter covers pages written from data memory.

The default value is 40 (3.2MB per second).

- `NoOfDiskPagesToDiskDuringRestartACC`

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>8K pages/100 milliseconds</td>
<td>20</td>
<td>1 - 4294967039</td>
<td>N</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>(0xFFFFFEFF)</td>
<td></td>
</tr>
</tbody>
</table>

Controls the number of index memory pages that can be written to disk during the local checkpoint phase of a node restart.

As with `NoOfDiskPagesToDiskAfterRestartTUP` and `NoOfDiskPagesToDiskAfterRestartACC`, values for this parameter are expressed in terms of 8KB pages written per 100 milliseconds (80KB/second).

The default value is 20 (1.6MB per second).

- `ArbitrationTimeout`

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>milliseconds</td>
<td>3000</td>
<td>10 - 4294967039</td>
<td>N</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>(0xFFFFFEFF)</td>
<td></td>
</tr>
</tbody>
</table>

This parameter specifies how long data nodes wait for a response from the arbitrator to an arbitration message. If this is exceeded, the network is assumed to have split.

The default value is 1000 milliseconds (1 second).

**Buffering and logging.** Several [ndbd] configuration parameters corresponding to former compile-time parameters were introduced in MySQL 4.1.5. These enable the advanced user to have more control over the resources used by node processes and to adjust various buffer sizes at need.

These buffers are used as front ends to the file system when writing log records to disk. If the node is running in diskless mode, these parameters can be set to their minimum values without penalty due to the fact that disk writes are “faked” by the NDB storage engine’s file system abstraction layer.

- `UndoIndexBuffer`

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>unsigned</td>
<td>2M</td>
<td>1M - 4294967039</td>
<td>N</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>(0xFFFFFEFF)</td>
<td></td>
</tr>
</tbody>
</table>

The UNDO index buffer, whose size is set by this parameter, is used during local checkpoints. The NDB storage engine uses a recovery scheme based on checkpoint consistency in conjunction with an operational REDO log. To produce a consistent checkpoint without blocking the entire system for writes, UNDO logging is done while performing the local checkpoint. UNDO logging is activated on a single table fragment at a time. This optimization is possible because tables are stored entirely in main memory.

The UNDO index buffer is used for the updates on the primary key hash index. Inserts and deletes rearrange the hash index; the NDB storage engine writes UNDO log records that map all physical changes to an index page so that they can be undone at system restart. It also logs all active insert operations for each fragment at the start of a local checkpoint.
Reads and updates set lock bits and update a header in the hash index entry. These changes are handled by the page-writing algorithm to ensure that these operations need no UNDO logging.

This buffer is 2MB by default. The minimum value is 1MB, which is sufficient for most applications. For applications doing extremely large or numerous inserts and deletes together with large transactions and large primary keys, it may be necessary to increase the size of this buffer. If this buffer is too small, the NDB storage engine issues internal error code 677 (Index UNDO buffers overloaded).

![Important]

It is not safe to decrease the value of this parameter during a rolling restart.

- **UndoDataBuffer**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>unsigned</td>
<td>16M</td>
<td>1M - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter sets the size of the UNDO data buffer, which performs a function similar to that of the UNDO index buffer, except the UNDO data buffer is used with regard to data memory rather than index memory. This buffer is used during the local checkpoint phase of a fragment for inserts, deletes, and updates.

Because UNDO log entries tend to grow larger as more operations are logged, this buffer is also larger than its index memory counterpart, with a default value of 16MB.

This amount of memory may be unnecessarily large for some applications. In such cases, it is possible to decrease this size to a minimum of 1MB.

It is rarely necessary to increase the size of this buffer. If there is such a need, it is a good idea to check whether the disks can actually handle the load caused by database update activity. A lack of sufficient disk space cannot be overcome by increasing the size of this buffer.

If this buffer is too small and gets congested, the NDB storage engine issues internal error code 891 (Data UNDO buffers overloaded).

![Important]

It is not safe to decrease the value of this parameter during a rolling restart.

- **RedoBuffer**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>bytes</td>
<td>8M</td>
<td>1M - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

All update activities also need to be logged. The REDO log makes it possible to replay these updates whenever the system is restarted. The NDB recovery algorithm uses a “fuzzy” checkpoint of the data together with the UNDO log, and then applies the REDO log to play back all changes up to the restoration point.

RedoBuffer sets the size of the buffer in which the REDO log is written, and is 8MB by default. The minimum value is 1MB.

If this buffer is too small, the NDB storage engine issues error code 1221 (REDO log buffers overloaded).
Important

It is not safe to decrease the value of this parameter during a rolling restart.

Controlling log messages. In managing the cluster, it is very important to be able to control the number of log messages sent for various event types to `stdout`. For each event category, there are 16 possible event levels (numbered 0 through 15). Setting event reporting for a given event category to level 15 means all event reports in that category are sent to `stdout`; setting it to 0 means that there will be no event reports made in that category.

By default, only the startup message is sent to `stdout`, with the remaining event reporting level defaults being set to 0. The reason for this is that these messages are also sent to the management server’s cluster log.

An analogous set of levels can be set for the management client to determine which event levels to record in the cluster log.

• **LogLevelStartup**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>integer</td>
<td>1</td>
<td>0 - 15</td>
<td>N</td>
</tr>
</tbody>
</table>

The reporting level for events generated during startup of the process.

The default level is 1.

• **LogLevelShutdown**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>

<td>0 - 15</td>
<td>N</td>
</tr>
</tbody>
</table>

The reporting level for events generated by errors and warnings by the cluster as a whole. These errors do not cause any node failure but are still considered worth reporting.

The default level is 0.

- **LogLevelCongestion**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>levelr</td>
<td>0</td>
<td>0 - 15</td>
<td>N</td>
</tr>
</tbody>
</table>

The reporting level for events generated by congestion. These errors do not cause node failure but are still considered worth reporting.

The default level is 0.

- **LogLevelInfo**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>integer</td>
<td>0</td>
<td>0 - 15</td>
<td>N</td>
</tr>
</tbody>
</table>

The reporting level for events generated for information about the general state of the cluster.

The default level is 0.

**Backup parameters.** The [ndbd] parameters discussed in this section define memory buffers set aside for execution of online backups.

- **BackupDataBufferSize**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>bytes</td>
<td>2M</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
<tr>
<td>NDB 7.5.0</td>
<td>bytes</td>
<td>16M</td>
<td>2M - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

In creating a backup, there are two buffers used for sending data to the disk. The backup data buffer is used to fill in data recorded by scanning a node's tables. Once this buffer has been filled to the level specified as **BackupWriteSize** (see below), the pages are sent to disk. While flushing data to disk, the backup process can continue filling this buffer until it runs out of space. When this happens,
the backup process pauses the scan and waits until some disk writes have completed freeing up memory so that scanning may continue.

The default value is 2MB.

- **BackupLogBufferSize**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>bytes</td>
<td>2M</td>
<td>0 - 4294967039</td>
<td>N</td>
</tr>
</tbody>
</table>

The backup log buffer fulfills a role similar to that played by the backup data buffer, except that it is used for generating a log of all table writes made during execution of the backup. The same principles apply for writing these pages as with the backup data buffer, except that when there is no more space in the backup log buffer, the backup fails. For that reason, the size of the backup log buffer must be large enough to handle the load caused by write activities while the backup is being made. See Section 17.5.3.3, “Configuration for MySQL Cluster Backups”.

The default value for this parameter should be sufficient for most applications. In fact, it is more likely for a backup failure to be caused by insufficient disk write speed than it is for the backup log buffer to become full. If the disk subsystem is not configured for the write load caused by applications, the cluster is unlikely to be able to perform the desired operations.

It is preferable to configure cluster nodes in such a manner that the processor becomes the bottleneck rather than the disks or the network connections.

The default value is 2MB.

- **BackupMemory**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>bytes</td>
<td>4M</td>
<td>0 - 4294967039</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is simply the sum of **BackupDataBufferSize** and **BackupLogBufferSize**.

The default value is 2MB + 2MB = 4MB.

---

**Important**

If **BackupDataBufferSize** and **BackupLogBufferSize** taken together exceed 4MB, then this parameter must be set explicitly in the `config.ini` file to their sum.

- **BackupWriteSize**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>bytes</td>
<td>32K</td>
<td>2K - 4294967039</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies the default size of messages written to disk by the backup log and backup data buffers.

The default value is 32KB.
### MySQL Cluster Configuration Files

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>bytes</td>
<td>256K</td>
<td>2K - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies the maximum size of messages written to disk by the backup log and backup data buffers.

The default value is 256KB.

**Important**

When specifying these parameters, the following relationships must hold true. Otherwise, the data node will be unable to start.

- \( \text{BackupDataBufferSize} \geq \text{BackupWriteSize} + 188\text{KB} \)
- \( \text{BackupLogBufferSize} \geq \text{BackupWriteSize} + 16\text{KB} \)
- \( \text{BackupMaxWriteSize} \geq \text{BackupWriteSize} \)

**Note**

To add new data nodes to a MySQL Cluster, it is necessary to shut down the cluster completely, update the `config.ini` file, and then restart the cluster (that is, you must perform a system restart). All data node processes must be started with the `--initial` option.

Beginning with MySQL Cluster NDB 7.0, it is possible to add new data node groups to a running cluster online; however, we do not plan to implement this change in MySQL 5.0.

#### 17.3.3.6 Defining SQL and Other API Nodes in a MySQL Cluster

The `[mysqld]` and `[api]` sections in the `config.ini` file define the behavior of the MySQL servers (SQL nodes) and other applications (API nodes) used to access cluster data. None of the parameters shown is required. If no computer or host name is provided, any host can use this SQL or API node.

Generally speaking, a `[mysqld]` section is used to indicate a MySQL server providing an SQL interface to the cluster, and an `[api]` section is used for applications other than `mysqld` processes accessing cluster data, but the two designations are actually synonymous; you can, for instance, list parameters for a MySQL server acting as an SQL node in an `[api]` section.

**Note**

For a discussion of MySQL server options for MySQL Cluster, see `mysqld Command Options for MySQL Cluster`; for information about MySQL server system variables relating to MySQL Cluster, see `MySQL Cluster System Variables`.

- **Id**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>unsigned</td>
<td>[none]</td>
<td>1 - 63</td>
<td>IS</td>
</tr>
</tbody>
</table>

The `Id` is an integer value used to identify the node in all cluster internal messages. It must be an integer in the range 1 to 63 inclusive, and must be unique among all node IDs within the cluster.

In MySQL 5.0.15 and later, `NodeId` is a synonym for this parameter, and is the preferred form. In MySQL Cluster NDB 6.2 and later, `Id` is deprecated in favor of `NodeId` for identifying SQL and other API nodes.
MySQL Cluster Configuration Files

- **NodeId**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.15</td>
<td>unsigned</td>
<td>[none]</td>
<td>1 - 63</td>
<td>IS</td>
</tr>
</tbody>
</table>

  Beginning with MySQL 5.0.15, `NodeId` is available as a synonym for `Id`.

  In MySQL Cluster NDB 6.2 and later, `Id` is deprecated in favor of `NodeId` for identifying SQL and API nodes.

- **ExecuteOnComputer**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>name</td>
<td>[none]</td>
<td>...</td>
<td>S</td>
</tr>
</tbody>
</table>

  This refers to the `Id` set for one of the computers (hosts) defined in a `[computer]` section of the configuration file.

- **HostName**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>name or IP address</td>
<td>[none]</td>
<td>...</td>
<td>N</td>
</tr>
</tbody>
</table>

  Specifying this parameter defines the hostname of the computer on which the SQL node (API node) is to reside. To specify a hostname, either this parameter or `ExecuteOnComputer` is required.

  If no `HostName` or `ExecuteOnComputer` is specified in a given `[mysql]` or `[api]` section of the `config.ini` file, then an SQL or API node may connect using the corresponding "slot" from any host which can establish a network connection to the management server host machine. This differs from the default behavior for data nodes, where `localhost` is assumed for `HostName` unless otherwise specified.

- **ArbitrationRank**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>0-2</td>
<td>0</td>
<td>0 - 2</td>
<td>N</td>
</tr>
</tbody>
</table>

  This parameter defines which nodes can act as arbitrators. Both management nodes and SQL nodes can be arbitrators. A value of 0 means that the given node is never used as an arbitrator, a value of 1 gives the node high priority as an arbitrator, and a value of 2 gives it low priority. A normal configuration uses the management server as arbitrator, setting its `ArbitrationRank` to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

- **ArbitrationDelay**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>milliseconds</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

  Setting this parameter to any other value than 0 (the default) means that responses by the arbitrator to arbitration requests will be delayed by the stated number of milliseconds. It is usually not necessary to change this value.
For queries that are translated into full table scans or range scans on indexes, it is important for best performance to fetch records in properly sized batches. It is possible to set the proper size both in terms of number of records (BatchSize) and in terms of bytes (BatchByteSize). The actual batch size is limited by both parameters.

The speed at which queries are performed can vary by more than 40% depending upon how this parameter is set.

This parameter is measured in bytes. The default value is 32K.

- **BatchSize**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>bytes</td>
<td>32K</td>
<td>1024 - 1M</td>
<td>N</td>
</tr>
</tbody>
</table>

You can obtain some information from a MySQL server running as a Cluster SQL node using `SHOW STATUS` in the `mysql` client, as shown here:

```
mysql> SHOW STATUS LIKE 'ndb\%';
+-----------------------------+---------------+
| Variable_name               | Value         |
+-----------------------------+---------------+
| Ndb_cluster_node_id         | 5             |

```

For information about these Cluster system status variables, see Section 5.1.6, "Server Status Variables".

**Note**

To add new SQL or API nodes to the configuration of a running MySQL Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new [mysqld] or [api] sections to the config.ini file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.
It is not necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

### 17.3.3.7 MySQL Server Options and Variables for MySQL Cluster

This section provides information about MySQL server options, server and status variables that are specific to MySQL Cluster. For general information on using these, and for other options and variables not specific to MySQL Cluster, see Section 5.1, “The MySQL Server”.

For MySQL Cluster configuration parameters used in the cluster configuration file (usually named `config.ini`), see Section 17.3, “MySQL Cluster Configuration”.

#### mysqld Command Options for MySQL Cluster

This section provides descriptions of `mysqld` server options relating to MySQL Cluster. For information about `mysqld` options not specific to MySQL Cluster, and for general information about the use of options with `mysqld`, see Section 5.1.3, “Server Command Options”.

For information about command-line options used with other MySQL Cluster processes (`ndbd`, `ndb_mgmd`, and `ndb_mgm`), see Section 17.4.20, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”. For information about command-line options used with NDB utility programs (such as `ndb_desc`, `ndb_size.pl`, and `ndb_show_tables`), see Section 17.4, “MySQL Cluster Programs”.

- `--ndbcluster`

**Table 17.9 Type and value information for ndbcluster**

<table>
<thead>
<tr>
<th>Command Line</th>
<th>System Variable</th>
<th>Status Variable</th>
</tr>
</thead>
<tbody>
<tr>

<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td></td>
<td>MySQL 5.0</td>
<td>boolean</td>
</tr>
<tr>
<td></td>
<td>FALSE</td>
<td></td>
</tr>
</tbody>
</table>

**DESCRIPTION:** Enable NDB Cluster (if this version of MySQL supports it)

Disabled by `--skip-ndbcluster`

The **NDBCLUSTER** storage engine is necessary for using MySQL Cluster. If a `mysqld` binary includes support for the **NDBCLUSTER** storage engine, the engine is disabled by default. Use the `--ndbcluster` option to enable it. Use `--skip-ndbcluster` to explicitly disable the engine.

- `--ndb-connectstring=connection_string`

**Table 17.10 Type and value information for ndb-connectstring**

<table>
<thead>
<tr>
<th>Command Line</th>
<th>System Variable</th>
<th>Status Variable</th>
</tr>

<td>localhost:1186</td>
</tr>
</tbody>
</table>

**DESCRIPTION:** Set the host (and port, if desired) for connecting to management server.

Can be used to set the host and port number of a single management server for the program to connect to. If the program requires node IDs or references to multiple management servers (or both) in its connection information, use the `--ndb-connectstring` option instead.

- `--ndb-nodeid=#`

**Table 17.12 Type and value information for ndb-nodeid**

<table>
<thead>
<tr>
<th>Command Line</th>
<th>System Variable</th>
<th>Status Variable</th>
</tr>
</thead>
<tbody>
<tr>

<td>Yes</td>
</tr>
<tr>
<td>Yes</td>
<td>Global</td>
<td>No</td>
</tr>
<tr>
<td>5.0.45</td>
<td>integer</td>
<td>/ 1 - 63</td>
</tr>
</tbody>
</table>

**DESCRIPTION:** MySQL Cluster node ID for this MySQL server.

Set this MySQL server's node ID in a MySQL Cluster. This can be used instead of specifying the node ID as part of the connection string or in the `config.ini` file, or permitting the cluster to determine an arbitrary node ID. If you use this option, then `--ndb-nodeid` must be specified before `--ndb-connectstring`. If `--ndb-nodeid` is used and a node ID is specified in the configuration file, the node ID from the configuration file is ignored.
connection string, then the MySQL server will not be able to connect to the cluster. In addition, if --nodeid is used, then either a matching node ID must be found in a [mysqld] or [api] section of config.ini, or there must be an “open” [mysqld] or [api] section in the file (that is, a section without an Id parameter specified).

Regardless of how the node ID is determined, its is shown as the value of the global status variable Ndb_cluster_node_id in the output of SHOW STATUS, and as cluster_node_id in the connection row of the output of SHOW ENGINE NDDBCLUSTER STATUS.

For more information about node IDs for MySQL Cluster SQL nodes, see Section 17.3.3.6, “Defining SQL and Other API Nodes in a MySQL Cluster”.

• --skip-ndbcluster

### Table 17.13 Type and value information for skip-ndbcluster

<tr>
<td>Yes</td>
<td>Both</td>
</tr>
<tr>
<td>MySQL 5.0</td>
<td>integer</td>
</tr>
<tr>
<td>5.0.56</td>
<td>integer</td>
</tr>
</tbody>
</table>

**DESCRIPTION:** NDB auto-increment prefetch size

Determines the probability of gaps in an autoincremented column. Set it to 1 to minimize this. Setting it to a high value for optimization—makes inserts faster, but decreases the likelihood that consecutive autoincrement numbers will be used in a batch of inserts. Default value: 32. Minimum value: 1.

Beginning with MySQL 5.0.56, this variable affects the number of `AUTO_INCREMENT` IDs that are fetched between statements only. Within a statement, at least 32 IDs are now obtained at a time. In MySQL 5.0.56 and later, the default value is 1. (Bug #31956)

**Important**

This variable does not affect inserts performed using `INSERT ... SELECT`.

- **ndb_cache_check_time**

<table>
<thead>
<tr>
<th>Command Line</th>
<th>System Variable</th>
<th>Status Variable</th>

<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>ndb_cache_check_time</td>
<td>Yes</td>
</tr>
<tr>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Yes</td>
<td>Global</td>
</tr>
<tr>
<td>MySQL 5.0</td>
<td>integer</td>
</tr>
</tbody>
</table>

**DESCRIPTION:** Number of milliseconds between checks of cluster SQL nodes made by the MySQL query cache

The number of milliseconds that elapse between checks of MySQL Cluster SQL nodes by the MySQL query cache. Setting this to 0 (the default and minimum value) means that the query cache checks for validation on every query.
The recommended maximum value for this variable is 1000, which means that the check is performed once per second. A larger value means that the check is performed and possibly invalidated due to updates on different SQL nodes less often. It is generally not desirable to set this to a value greater than 2000.

- **ndb_force_send**

**Table 17.17 Type and value information for ndb_force_send**

<table>
<thead>
<tr>
<th>Command Line</th>
<th>System Variable</th>
<th>Status Variable</th>

</tr>
</tbody>
</table>

**Notes**
- Yes
- Global
- MySQL 5.0

**ndb_optimized_node_selection**

Description: Determines how an SQL node chooses a cluster data node to use as transaction coordinator.

Causes an SQL node to use the “closest” data node as transaction coordinator. For this purpose, a data node having a shared memory connection with the SQL node is considered to be “closest” to the SQL node; the next closest (in order of decreasing proximity) are: TCP connection to localhost; SCI connection; TCP connection from a host other than localhost.

This option is enabled by default. Set to **0** or **OFF** to disable it, in which case the SQL node uses each data node in the cluster in succession. When this option is disabled each SQL thread attempts to use a given data node 8 times before proceeding to the next one.
• **ndb_report_thresh_binlog_epoch_slip**

</table>

Notes

ndb_report_thresh_binlog_epoch_slip

Yes No No

Yes No

MySQL 5.0 integer 3 / 0 - 256

DESCRIPTION: This is a threshold on the number of epochs to be behind before reporting binary log status.

This is a threshold on the number of epochs to be behind before reporting binary log status. For example, a value of 3 (the default) means that if the difference between which epoch has been received from the storage nodes and which epoch has been applied to the binary log is 3 or more, a status message will be sent to the cluster log.

• **ndb_report_thresh_binlog_mem_usage**

<td>Default, Range</td>
</tr>
</tbody>
</table>

Notes

ndb_report_thresh_binlog_mem_usage

Yes No No

Yes No

MySQL 5.0 integer 10 / 0 - 10

DESCRIPTION: This is a threshold on the percentage of free memory remaining before reporting binary log status.

This is a threshold on the percentage of free memory remaining before reporting binary log status. For example, a value of 10 (the default) means that if the amount of available memory for receiving binary log data from the data nodes falls below 10%, a status message will be sent to the cluster log.

No Yes No

No Both Yes
MySQL Cluster Status Variables

This section provides detailed information about MySQL server status variables that relate to MySQL Cluster and the NDB storage engine. For status variables not specific to MySQL Cluster, and for general information on using status variables, see Section 5.1.6, “Server Status Variables”.

• **Handler_discover**

  An SQL node can ask the NDB storage engine if it knows about a table with a given name. This is called discovery. `Handler_discover` indicates the number of times that tables have been discovered using this mechanism.

• **Ndb_cluster_node_id**

  If the server is acting as a MySQL Cluster node, then the value of this variable its node ID in the cluster.

  If the server is not part of a MySQL Cluster, then the value of this variable is 0.

• **Ndb_config_from_host**

  If the server is part of a MySQL Cluster, the value of this variable is the host name or IP address of the Cluster management server from which it gets its configuration data.

  If the server is not part of a MySQL Cluster, then the value of this variable is an empty string.
Prior to MySQL 5.0.23, this variable was named `Ndb_connected_host`.

- **Ndb_config_from_port**

  If the server is part of a MySQL Cluster, the value of this variable is the number of the port through which it is connected to the Cluster management server from which it gets its configuration data.

  If the server is not part of a MySQL Cluster, then the value of this variable is 0.

  Prior to MySQL 5.0.23, this variable was named `Ndb_connected_port`.

- **Ndb_number_of_data_nodes**

  If the server is part of a MySQL Cluster, the value of this variable is the number of data nodes in the cluster.

  If the server is not part of a MySQL Cluster, then the value of this variable is 0.

  Prior to MySQL 5.0.29, this variable was named `Ndb_number_of_storage_nodes`.

### 17.3.3.8 MySQL Cluster TCP/IP Connections

TCP/IP is the default transport mechanism for all connections between nodes in a MySQL Cluster. Normally it is not necessary to define TCP/IP connections; MySQL Cluster automatically sets up such connections for all data nodes, management nodes, and SQL or API nodes.

**Note**

For an exception to this rule, see Section 17.3.3.9, “MySQL Cluster TCP/IP Connections Using Direct Connections”.

To override the default connection parameters, it is necessary to define a connection using one or more `[tcp]` sections in the `config.ini` file. Each `[tcp]` section explicitly defines a TCP/IP connection between two MySQL Cluster nodes, and must contain at a minimum the parameters `NodeId1` and `NodeId2`, as well as any connection parameters to override.

It is also possible to change the default values for these parameters by setting them in the `[tcp default]` section.

**Important**

Any `[tcp]` sections in the `config.ini` file should be listed *last*, following all other sections in the file. However, this is not required for a `[tcp default]` section. This requirement is a known issue with the way in which the `config.ini` file is read by the MySQL Cluster management server.

Connection parameters which can be set in `[tcp]` and `[tcp default]` sections of the `config.ini` file are listed here:

- **NodeId1**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>numeric</td>
<td>[none]</td>
<td>...</td>
<td>N</td>
</tr>
</tbody>
</table>

To identify a connection between two nodes it is necessary to provide their node IDs in the `[tcp]` section of the configuration file as the values of `NodeId1` and `NodeId2`. These are the same unique `Id` values for each of these nodes as described in Section 17.3.3.6, “Defining SQL and Other API Nodes in a MySQL Cluster”.

- **NodeId2**
To identify a connection between two nodes it is necessary to provide their node IDs in the `tcp` section of the configuration file as the values of `NodeId1` and `NodeId2`. These are the same unique `Id` values for each of these nodes as described in Section 17.3.3.6, “Defining SQL and Other API Nodes in a MySQL Cluster”.

**HostName1**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>name or IP address</td>
<td>[none]</td>
<td>...</td>
<td>N</td>
</tr>
</tbody>
</table>

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given TCP connection between two nodes. The values used for these parameters can be host names or IP addresses.

**HostName2**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>name or IP address</td>
<td>[none]</td>
<td>...</td>
<td>N</td>
</tr>
</tbody>
</table>

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given TCP connection between two nodes. The values used for these parameters can be host names or IP addresses.

**SendBufferMemory**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>unsigned</td>
<td>256K</td>
<td>64K - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

TCP transporters use a buffer to store all messages before performing the send call to the operating system. When this buffer reaches 64KB its contents are sent; these are also sent when a round of messages have been executed. To handle temporary overload situations it is also possible to define a bigger send buffer.

The default size of the send buffer is 256 KB; 2MB is recommended in most situations in which it is necessary to set this parameter. The minimum size is 64 KB; the theoretical maximum is 4 GB.

**SendSignalId**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>boolean</td>
<td>[see text]</td>
<td>true, false</td>
<td>N</td>
</tr>
</tbody>
</table>

To be able to retrace a distributed message datagram, it is necessary to identify each message. When this parameter is set to `Y`, message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in `-debug` builds.

**Checksum**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>boolean</td>
<td>false</td>
<td>true, false</td>
<td>N</td>
</tr>
</tbody>
</table>
This parameter is a boolean parameter (enabled by setting it to Y or 1, disabled by setting it to N or 0). It is disabled by default. When it is enabled, checksums for all messages are calculated before they placed in the send buffer. This feature ensures that messages are not corrupted while waiting in the send buffer, or by the transport mechanism.

- **PortNumber (OBSOLETE)**

  This formerly specified the port number to be used for listening for connections from other nodes. This parameter should no longer be used.

- **ReceiveBufferMemory**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>bytes</td>
<td>64K</td>
<td>16K - 4294967039</td>
<td>N</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>(0xFFFFFEFF)</td>
<td></td>
</tr>
</tbody>
</table>

  Specifies the size of the buffer used when receiving data from the TCP/IP socket.

  The default value of this parameter from its of 64 KB; 1M is recommended in most situations where the size of the receive buffer needs to be set. The minimum possible value is 16K; theoretical maximum is 4G.

### 17.3.3.9 MySQL Cluster TCP/IP Connections Using Direct Connections

Setting up a cluster using direct connections between data nodes requires specifying explicitly the crossover IP addresses of the data nodes so connected in the [tcp] section of the cluster config.ini file.

In the following example, we envision a cluster with at least four hosts, one each for a management server, an SQL node, and two data nodes. The cluster as a whole resides on the 172.23.72.* subnet of a LAN. In addition to the usual network connections, the two data nodes are connected directly using a standard crossover cable, and communicate with one another directly using IP addresses in the 1.1.0.* address range as shown:

```ini
# Management Server
[ndb_mgmd]
Id=1
HostName=172.23.72.20

# SQL Node
[mysqld]
Id=2
HostName=172.23.72.21

# Data Nodes
[ndbd]
Id=3
HostName=172.23.72.22
[ndbd]
Id=4
HostName=172.23.72.23

# TCP/IP Connections
[tcp]
NodeId1=3
NodeId2=4
HostName1=1.1.0.1
HostName2=1.1.0.2
```

The `HostName1` and `HostName2` parameters are used only when specifying direct TCP connections.
The use of direct TCP connections between data nodes can improve the cluster's overall efficiency by enabling the data nodes to bypass an Ethernet device such as a switch, hub, or router, thus cutting down on the cluster's latency. It is important to note that to take the best advantage of direct connections in this fashion with more than two data nodes, you must have a direct connection between each data node and every other data node in the same node group.

### 17.3.3.10 MySQL Cluster Shared-Memory Connections

MySQL Cluster attempts to use the shared memory transporter and configure it automatically where possible. (In very early versions of MySQL Cluster, shared memory segments functioned only when the server binary was built using `--with-ndb-shm`.) Sections in the `config.ini` file explicitly define shared-memory connections between nodes in the cluster. When explicitly defining shared memory as the connection method, it is necessary to define at least `NodeId1`, `NodeId2`, and `ShmKey`. All other parameters have default values that should work well in most cases.

---

**Important**

*SHM functionality is considered experimental only.* It is not officially supported in any current MySQL Cluster release, and testing results indicate that SHM performance is not appreciably greater than when using TCP/IP for the transporter.

For these reasons, you must determine for yourself or by using our free resources (forums, mailing lists) whether SHM can be made to work correctly in your specific case.

- **NodeId1**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>

<td>[none]</td>
<td>...</td>
<td>N</td>
</tr>
</tbody>
</table>

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- **HostName1**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>name or IP address</td>
<td>[none]</td>
<td>...</td>
<td>N</td>
</tr>
</tbody>
</table>

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given SHM connection between two nodes. The values used for these parameters can be host names or IP addresses.

- **HostName2**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>name or IP address</td>
<td>[none]</td>
<td>...</td>
<td>N</td>
</tr>
</tbody>
</table>
The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given SHM connection between two nodes. The values used for these parameters can be host names or IP addresses.

- **ShmKey**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>unsigned</td>
<td>[none]</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

When setting up shared memory segments, a node ID, expressed as an integer, is used to identify uniquely the shared memory segment to use for the communication. There is no default value.

- **ShmSize**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>bytes</td>
<td>1M</td>
<td>64K - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

Each SHM connection has a shared memory segment where messages between nodes are placed by the sender and read by the reader. The size of this segment is defined by `ShmSize`. The default value is 1MB.

- **SendSignalId**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>boolean</td>
<td>false</td>
<td>true, false</td>
<td>N</td>
</tr>
</tbody>
</table>

To retrace the path of a distributed message, it is necessary to provide each message with a unique identifier. Setting this parameter to `Y` causes these message IDs to be transported over the network as well. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- **Checksum**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>boolean</td>
<td>true</td>
<td>true, false</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is a boolean (`Y/N`) parameter which is disabled by default. When it is enabled, checksums for all messages are calculated before being placed in the send buffer. This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

- **SigNum**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>unsigned</td>
<td>[none]</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

When using the shared memory transporter, a process sends an operating system signal to the other process when there is new data available in the shared memory. Should that signal conflict with an existing signal, this parameter can be used to change it. This is a possibility when using SHM due to the fact that different operating systems use different signal numbers.

The default value of `SigNum` is 0; therefore, it must be set to avoid errors in the cluster log when using the shared memory transporter. Typically, this parameter is set to 10 in the `[shm default]` section of the `config.ini` file.
17.3.3.11 SCI Transport Connections in MySQL Cluster

`[sci]` sections in the `config.ini` file explicitly define SCI (Scalable Coherent Interface) connections between cluster nodes. Using SCI transporters in MySQL Cluster is supported only when the MySQL binaries are built using `--with-ndb-sci=/your/path/to/SCI`. The path should point to a directory that contains at a minimum `lib` and `include` directories containing SISCI libraries and header files. (See Section 17.3.4, “Using High-Speed Interconnects with MySQL Cluster” for more information about SCI.)

In addition, SCI requires specialized hardware.

It is strongly recommended to use SCI Transporters only for communication between `ndbd` processes. Note also that using SCI Transporters means that the `ndbd` processes never sleep. For this reason, SCI Transporters should be used only on machines having at least two CPUs dedicated for use by `ndbd` processes. There should be at least one CPU per `ndbd` process, with at least one CPU left in reserve to handle operating system activities.

- **NodeId1**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>numeric</td>
<td>[none]</td>
<td>...</td>
<td>N</td>
</tr>
</tbody>
</table>

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- **NodeId2**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>numeric</td>
<td>[none]</td>
<td>...</td>
<td>N</td>
</tr>
</tbody>
</table>

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- **Host1SciId0**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>unsigned</td>
<td>[none]</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

This identifies the SCI node ID on the first Cluster node (identified by `NodeId1`).

- **Host1SciId1**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>unsigned</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

It is possible to set up SCI Transporters for failover between two SCI cards which then should use separate networks between the nodes. This identifies the node ID and the second SCI card to be used on the first node.

- **Host2SciId0**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>unsigned</td>
<td>[none]</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

This identifies the SCI node ID on the second Cluster node (identified by `NodeId2`).
• **Host2SciId1**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>unsigned</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

When using two SCI cards to provide failover, this parameter identifies the second SCI card to be used on the second node.

• **HostName1**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>name or IP address</td>
<td>[none]</td>
<td>...</td>
<td>N</td>
</tr>
</tbody>
</table>

The **HostName1** and **HostName2** parameters can be used to specify specific network interfaces to be used for a given SCI connection between two nodes. The values used for these parameters can be host names or IP addresses.

• **HostName2**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>name or IP address</td>
<td>[none]</td>
<td>...</td>
<td>N</td>
</tr>
</tbody>
</table>

The **HostName1** and **HostName2** parameters can be used to specify specific network interfaces to be used for a given SCI connection between two nodes. The values used for these parameters can be host names or IP addresses.

• **SharedBufferSize**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>unsigned</td>
<td>10M</td>
<td>64K - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

Each SCI transporter has a shared memory segment used for communication between the two nodes. Setting the size of this segment to the default value of 1MB should be sufficient for most applications. Using a smaller value can lead to problems when performing many parallel inserts; if the shared buffer is too small, this can also result in a crash of the ndbd process.

• **SendLimit**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>unsigned</td>
<td>8K</td>
<td>128 - 32K</td>
<td>N</td>
</tr>
</tbody>
</table>

A small buffer in front of the SCI media stores messages before transmitting them over the SCI network. By default, this is set to 8KB. Our benchmarks show that performance is best at 64KB but 16KB reaches within a few percent of this, and there was little if any advantage to increasing it beyond 8KB.

• **SendSignalId**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>boolean</td>
<td>true</td>
<td>true, false</td>
<td>N</td>
</tr>
</tbody>
</table>
To trace a distributed message it is necessary to identify each message uniquely. When this parameter is set to 1, message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in -debug builds.

- **Checksum**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.0.0</td>
<td>boolean</td>
<td>false</td>
<td>true, false</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is a boolean value, and is disabled by default. When **Checksum** is enabled, checksums are calculated for all messages before they are placed in the send buffer. This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

17.3.3.12 Configuring MySQL Cluster Parameters for Local Checkpoints

The parameters discussed in **Logging and Checkpointing** and in **Data Memory, Index Memory, and String Memory** that are used to configure local checkpoints for a MySQL Cluster do not exist in isolation, but rather are very much interdependent on each other. In this section, we illustrate how these parameters—including **DataMemory**, **IndexMemory**, **NoOfDiskPagesToDiskAfterRestartTUP**, **NoOfDiskPagesToDiskAfterRestartACC**, and **NoOfFragmentLogFiles**—relate to one another in a working Cluster.

In this example, we assume that our application performs the following numbers of types of operations per hour:

- 50000 selects
- 15000 inserts
- 15000 updates
- 15000 deletes

We also make the following assumptions about the data used in the application:

- We are working with a single table having 40 columns.
- Each column can hold up to 32 bytes of data.
- A typical **UPDATE** run by the application affects the values of 5 columns.
- No **NULL** values are inserted by the application.

A good starting point is to determine the amount of time that should elapse between local checkpoints (LCPs). It is worth noting that, in the event of a system restart, it takes 40-60 percent of this interval to execute the REDO log—for example, if the time between LCPs is 5 minutes (300 seconds), then it should take 2 to 3 minutes (120 to 180 seconds) for the REDO log to be read.

The maximum amount of data per node can be assumed to be the size of the **DataMemory** parameter. In this example, we assume that this is 2 GB. The **NoOfDiskPagesToDiskAfterRestartTUP** parameter represents the amount of data to be checkpointed per unit time—however, this parameter is actually expressed as the number of 8K memory pages to be checkpointed per 100 milliseconds. 2 GB per 300 seconds is approximately 6.8 MB per second, or 700 KB per 100 milliseconds, which works out to roughly 85 pages per 100 milliseconds.

Similarly, we can calculate **NoOfDiskPagesToDiskAfterRestartACC** in terms of the time for local checkpoints and the amount of memory required for indexes—that is, the **IndexMemory**. Assuming that we permit 512 MB for indexes, this works out to approximately 20 8-KB pages per 100 milliseconds for this parameter.
Next, we need to determine the number of REDO log files required—that is, fragment log files—the corresponding parameter being `NoOfFragmentLogFiles`. We need to make sure that there are sufficient REDO log files for keeping records for at least 3 local checkpoints. In a production setting, there are always uncertainties—for instance, we cannot be sure that disks always operate at top speed or with maximum throughput. For this reason, it is best to err on the side of caution, so we double our requirement and calculate a number of fragment log files which should be enough to keep records covering 6 local checkpoints.

It is also important to remember that the disk also handles writes to the REDO log and UNDO log, so if you find that the amount of data being written to disk as determined by the values of `NoOfDiskPagesToDiskAfterRestartACC` and `NoOfDiskPagesToDiskAfterRestartTUP` is approaching the amount of disk bandwidth available, you may wish to increase the time between local checkpoints.

Given 5 minutes (300 seconds) per local checkpoint, this means that we need to support writing log records at maximum speed for 6 * 300 = 1800 seconds. The size of a REDO log record is 72 bytes plus 4 bytes per updated column value plus the maximum size of the updated column, and there is one REDO log record for each table record updated in a transaction, on each node where the data reside. Using the numbers of operations set out previously in this section, we derive the following:

- 50000 select operations per hour yields 0 log records (and thus 0 bytes), since `SELECT` statements are not recorded in the REDO log.

- 15000 `DELETE` statements per hour is approximately 5 delete operations per second. (Since we wish to be conservative in our estimate, we round up here and in the following calculations.) No columns are updated by deletes, so these statements consume only 5 operations * 72 bytes per operation = 360 bytes per second.

- 15000 `UPDATE` statements per hour is roughly the same as 5 updates per second. Each update uses 72 bytes, plus 4 bytes per column * 5 columns updated, plus 32 bytes per column * 5 columns—this works out to 72 + 20 + 160 = 252 bytes per operation, and multiplying this by 5 operation per second yields 1260 bytes per second.

- 15000 `INSERT` statements per hour is equivalent to 5 insert operations per second. Each insert requires REDO log space of 72 bytes, plus 4 bytes per record * 40 columns, plus 32 bytes per column * 40 columns, which is 72 + 160 + 1280 = 1512 bytes per operation. This times 5 operations per second yields 7560 bytes per second.

So the total number of REDO log bytes being written per second is approximately 0 + 360 + 1260 + 7560 = 9180 bytes. Multiplied by 1800 seconds, this yields 16524000 bytes required for REDO logging, or approximately 15.75 MB. The unit used for `NoOfFragmentLogFiles` represents a set of 4 16-MB log files—that is, 64 MB. Thus, the minimum value (3) for this parameter is sufficient for the scenario envisioned in this example, since 3 times 64 = 192 MB, or about 12 times what is required; the default value of 8 (or 512 MB) is more than ample in this case.

A copy of each altered table record is kept in the UNDO log. In the scenario discussed above, the UNDO log would not require any more space than what is provided by the default settings. However, given the size of disks, it is sensible to allocate at least 1 GB for it.

### 17.3.4 Using High-Speed Interconnects with MySQL Cluster

Even before design of `NDBCLUSTER` began in 1996, it was evident that one of the major problems to be encountered in building parallel databases would be communication between the nodes in the network. For this reason, `NDBCLUSTER` was designed from the very beginning to permit the use of a number of different data transport mechanisms. In this Manual, we use the term `transporter` for these.

The MySQL Cluster codebase includes support for four different transporters:

- **TCP/IP using 100 Mbps or gigabit Ethernet**, as discussed in Section 17.3.3.8, “MySQL Cluster TCP/IP Connections”.

This documentation is for an older version.
If you're using [MySQL](https://dev.mysql.com), select the documentation for that version with the version switch in the upper right corner of the online documentation, or by downloading a newer PDF or EPUB file.
• **Direct (machine-to-machine) TCP/IP**: although this transporter uses the same TCP/IP protocol as mentioned in the previous item, it requires setting up the hardware differently and is configured differently as well. For this reason, it is considered a separate transport mechanism for MySQL Cluster. See Section 17.3.3.9, “MySQL Cluster TCP/IP Connections Using Direct Connections”, for details.

• **Shared memory (SHM)**. For more information about SHM, see Section 17.3.3.10, “MySQL Cluster Shared-Memory Connections”.

  ![Note]
  
  SHM is considered experimental only, and is not officially supported.

• **Scalable Coherent Interface (SCI)**, as described in the next section of this chapter, Section 17.3.3.11, “SCI Transport Connections in MySQL Cluster”.

Most users today employ TCP/IP over Ethernet because it is ubiquitous. TCP/IP is also by far the best-tested transporter for use with MySQL Cluster.

We are working to make sure that communication with the ndbd process is made in “chunks” that are as large as possible because this benefits all types of data transmission.

For users who desire it, it is also possible to use cluster interconnects to enhance performance even further. There are two ways to achieve this: Either a custom transporter can be designed to handle this case, or you can use socket implementations that bypass the TCP/IP stack to one extent or another. We have experimented with both of these techniques using the SCI (Scalable Coherent Interface) technology developed by Dolphin Interconnect Solutions.

### 17.3.4.1 Configuring MySQL Cluster to use SCI Sockets

It is possible employing Scalable Coherent Interface (SCI) technology to achieve a significant increase in connection speeds and throughput between MySQL Cluster data and SQL nodes. To use SCI, it is necessary to obtain and install Dolphin SCI network cards and to use the drivers and other software supplied by Dolphin. You can get information on obtaining these, from Dolphin Interconnect Solutions. SCI SuperSocket or SCI Transporter support is available for 32-bit and 64-bit Linux, Solaris, and other platforms. See the Dolphin documentation referenced later in this section for more detailed information regarding platforms supported for SCI.

![Note]

Prior to MySQL 5.0.66, there were issues with building MySQL Cluster with SCI support (see Bug #25470), but these have been resolved due to work contributed by Dolphin. SCI Sockets are now correctly supported for MySQL Cluster hosts running recent versions of Linux using the --max builds, and versions of MySQL Cluster with SCI Transporter support can be built using either of compile-amd64-max-sci or compile-pentium64-max-sci. Both of these build scripts can be found in the BUILD directory of the MySQL Cluster source trees; it should not be difficult to adapt them for other platforms. Generally, all that is necessary is to compile MySQL Cluster with SCI Transporter support is to configure the MySQL Cluster build using --with-ndb-sci=/opt/DIS.

Once you have acquired the required Dolphin hardware and software, you can obtain detailed information on how to adapt a MySQL Cluster configured for normal TCP/IP communication to use SCI from the from the Dolphin SCI online documentation.

### 17.3.4.2 MySQL Cluster Interconnects and Performance

The ndbd process has a number of simple constructs which are used to access the data in a MySQL Cluster. We have created a very simple benchmark to check the performance of each of these and the effects which various interconnects have on their performance.
There are four access methods:

- **Primary key access.** This is access of a record through its primary key. In the simplest case, only one record is accessed at a time, which means that the full cost of setting up a number of TCP/IP messages and a number of costs for context switching are borne by this single request. In the case where multiple primary key accesses are sent in one batch, those accesses share the cost of setting up the necessary TCP/IP messages and context switches. If the TCP/IP messages are for different destinations, additional TCP/IP messages need to be set up.

- **Unique key access.** Unique key accesses are similar to primary key accesses, except that a unique key access is executed as a read on an index table followed by a primary key access on the table. However, only one request is sent from the MySQL Server, and the read of the index table is handled by ndbd. Such requests also benefit from batching.

- **Full table scan.** When no indexes exist for a lookup on a table, a full table scan is performed. This is sent as a single request to the ndbd process, which then divides the table scan into a set of parallel scans on all cluster ndbd processes. In future versions of MySQL Cluster, an SQL node will be able to filter some of these scans.

- **Range scan using ordered index**

  When an ordered index is used, it performs a scan in the same manner as the full table scan, except that it scans only those records which are in the range used by the query transmitted by the MySQL server (SQL node). All partitions are scanned in parallel when all bound index attributes include all attributes in the partitioning key.

With benchmarks developed internally by MySQL for testing simple and batched primary and unique key accesses, we have found that using SCI sockets improves performance by approximately 100% over TCP/IP, except in rare instances when communication performance is not an issue. This can occur when scan filters make up most of processing time or when very large batches of primary key accesses are achieved. In that case, the CPU processing in the ndbd processes becomes a fairly large part of the overhead.

Using the SCI transporter instead of SCI Sockets is only of interest in communicating between ndbd processes. Using the SCI transporter is also only of interest if a CPU can be dedicated to the ndbd process because the SCI transporter ensures that this process will never go to sleep. It is also important to ensure that the ndbd process priority is set in such a way that the process does not lose priority due to running for an extended period of time, as can be done by locking processes to CPUs in Linux 2.6. If such a configuration is possible, the ndbd process will benefit by 10−70% as compared with using SCI sockets. (The larger figures will be seen when performing updates and probably on parallel scan operations as well.)

There are several other optimized socket implementations for computer clusters, including Myrinet, Gigabit Ethernet, Infiniband and the VIA interface. However, we have tested MySQL Cluster so far only with SCI sockets. See Section 17.3.4.1, “Configuring MySQL Cluster to use SCI Sockets”, for information on how to set up SCI sockets using ordinary TCP/IP for MySQL Cluster.

### 17.4 MySQL Cluster Programs

Using and managing a MySQL Cluster requires several specialized programs, which we describe in this chapter. We discuss the purposes of these programs in a MySQL Cluster, how to use the programs, and what startup options are available for each of them.

These programs include the MySQL Cluster data, management, and SQL node processes (ndbd, ndb_mgmd, and mysqld) and the management client (ndb_mgm).

For information about using mysqld as a MySQL Cluster process, see Section 17.5.4, “MySQL Server Usage for MySQL Cluster”.
Other NDB utility, diagnostic, and example programs are included with the MySQL Cluster distribution. These include ndb_restore, ndb_show_tables, and ndb_config. These programs are also covered in this section.

The final portion of this section contains tables of options that are common to all the various MySQL Cluster programs.

17.4.1 ndbd — The MySQL Cluster Data Node Daemon

ndbd is the process that is used to handle all the data in tables using the NDB Cluster storage engine. This is the process that empowers a data node to accomplish distributed transaction handling, node recovery, checkpointing to disk, online backup, and related tasks.

In a MySQL Cluster, a set of ndbd processes cooperate in handling data. These processes can execute on the same computer (host) or on different computers. The correspondences between data nodes and Cluster hosts is completely configurable.

The following table includes command options specific to the MySQL Cluster data node program ndbd. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including ndbd), see Section 17.4.20, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”.

Table 17.26 This table describes command-line options for the ndbd program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--initial</td>
<td>Perform initial start of ndbd, including cleaning the file system. Consult the documentation before using this option</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td>--nostart, -n</td>
<td>Don’t start ndbd immediately; ndbd waits for command to start from ndb_mgmd</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td>--daemon, -d</td>
<td>Start ndbd as daemon (default); override with --nodaemon</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td>--nodaemon</td>
<td>Do not start ndbd as daemon; provided for testing purposes</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td>--foreground</td>
<td>Run ndbd in foreground, provided for debugging purposes (implies --nodaemon)</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td>--nowait-nodes=list</td>
<td>Do not wait for these data nodes to start (takes comma-separated list of node IDs). Also requires --ndb-nodeid to be used.</td>
<td>ADDED: 5.0.21</td>
</tr>
<tr>
<td>--initial-start</td>
<td>Perform partial initial start (requires --nowait-nodes)</td>
<td>ADDED: 5.0.21</td>
</tr>
<tr>
<td>--bind-address=name</td>
<td>Local bind address</td>
<td>ADDED: 5.0.29</td>
</tr>
</tbody>
</table>

• --bind-address

| Introduced  | 5.0.29 |
| Command-Line Format | --bind-address=name |
| Permitted Values   | Type string |
| Default            |         |
Causes `ndbd` to bind to a specific network interface (host name or IP address). This option has no default value.

This option was added in MySQL 5.0.29.

- **--daemon**, `-d`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--daemon</code></td>
<td>Type boolean</td>
</tr>
<tr>
<td></td>
<td>Default TRUE</td>
</tr>
</tbody>
</table>

Instructs `ndbd` to execute as a daemon process. This is the default behavior. `--nodaemon` can be used to prevent the process from running as a daemon.

- **--initial**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--initial</code></td>
<td>Type boolean</td>
</tr>
<tr>
<td></td>
<td>Default FALSE</td>
</tr>
</tbody>
</table>

Instructs `ndbd` to perform an initial start. An initial start erases any files created for recovery purposes by earlier instances of `ndbd`. It also re-creates recovery log files. Note that on some operating systems this process can take a substantial amount of time.

An `--initial` start is to be used only when starting the `ndbd` process under very special circumstances; this is because this option causes all files to be removed from the Cluster file system and all redo log files to be re-created. These circumstances are listed here:

- When performing a software upgrade which has changed the contents of any files.
- When restarting the node with a new version of `ndbd`.
- As a measure of last resort when for some reason the node restart or system restart repeatedly fails. In this case, be aware that this node can no longer be used to restore data due to the destruction of the data files.

Use of this option prevents the `StartPartialTimeout` and `StartPartitionedTimeout` configuration parameters from having any effect.

**Important**

This option does not affect any backup files that have already been created by the affected node.

This option also has no effect on recovery of data by a data node that is just starting (or restarting) from data nodes that are already running. This recovery of data occurs automatically, and requires no user intervention in a MySQL Cluster that is running normally.

It is permissible to use this option when starting the cluster for the very first time (that is, before any data node files have been created); however, it is not necessary to do so.

- **--initial-start**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>Command-Line Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.0.21</td>
<td><code>--initial-start</code></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type boolean</td>
</tr>
</tbody>
</table>
This option is used when performing a partial initial start of the cluster. Each node should be started with this option, as well as --nowait-nodes.

Suppose that you have a 4-node cluster whose data nodes have the IDs 2, 3, 4, and 5, and you wish to perform a partial initial start using only nodes 2, 4, and 5—that is, omitting node 3:

```
shell> ndbd --ndb-nodeid=2 --nowait-nodes=3 --initial-start
shell> ndbd --ndb-nodeid=4 --nowait-nodes=3 --initial-start
shell> ndbd --ndb-nodeid=5 --nowait-nodes=3 --initial-start
```

This option was added in MySQL 5.0.21.

- --nowait-nodes=node_id_1[, node_id_2[, ...]]

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.0.21</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--nowait-nodes=list</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type string</td>
</tr>
<tr>
<td>Default</td>
<td></td>
</tr>
</tbody>
</table>

This option takes a list of data nodes which for which the cluster will not wait for before starting.

This can be used to start the cluster in a partitioned state. For example, to start the cluster with only half of the data nodes (nodes 2, 3, 4, and 5) running in a 4-node cluster, you can start each ndbd process with --nowait-nodes=3,5. In this case, the cluster starts as soon as nodes 2 and 4 connect, and does not wait StartPartitionedTimeout milliseconds for nodes 3 and 5 to connect as it would otherwise.

If you wanted to start up the same cluster as in the previous example without one ndbd—say, for example, that the host machine for node 3 has suffered a hardware failure—then start nodes 2, 4, and 5 with --nowait-nodes=3. Then the cluster will start as soon as nodes 2, 4, and 5 connect and will not wait for node 3 to start.

When using this option, you must also specify the node ID for the data node being started with the --ndb-nodeid option.

This option was added in MySQL 5.0.21.

- --nodaemon

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--nodaemon</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>Type boolean</td>
</tr>
<tr>
<td>Default</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Instructs ndbd not to start as a daemon process. This is useful when ndbd is being debugged and you want output to be redirected to the screen.

- --foreground

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--foreground</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>Type boolean</td>
</tr>
<tr>
<td>Default</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Causes ndbd to execute as a foreground process, primarily for debugging purposes. This option implies the --nodaemon option.
--nostart, -n

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--nostart</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>Type</td>
</tr>
<tr>
<td></td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Instructs ndbd not to start automatically. When this option is used, ndbd connects to the management server, obtains configuration data from it, and initializes communication objects. However, it does not actually start the execution engine until specifically requested to do so by the management server. This can be accomplished by issuing the proper START command in the management client (see Section 17.5.2, “Commands in the MySQL Cluster Management Client”).

ndbd generates a set of log files which are placed in the directory specified by DataDir in the config.ini configuration file.

These log files are listed below. node_id is the node's unique identifier. Note that node_id represents the node's unique identifier. For example, ndb_2_error.log is the error log generated by the data node whose node ID is 2.

- **ndb_node_id_error.log** is a file containing records of all crashes which the referenced ndbd process has encountered. Each record in this file contains a brief error string and a reference to a trace file for this crash. A typical entry in this file might appear as shown here:

    Date/Time: Saturday 30 July 2004 - 00:20:01
    Type of error: error
    Message: Internal program error (failed ndbrequire)
    Fault ID: 2341
    Problem data: DbtupFixAlloc.cpp
    Object of reference: DBTUP (Line: 173)
    ProgramName: NDB Kernel
    ProcessID: 14909
    TraceFile: ndb_2_trace.log.2
    ***EOM***

    Listings of possible ndbd exit codes and messages generated when a data node process shuts down prematurely can be found in ndbd Error Messages.

    **Important**
    
    The last entry in the error log file is not necessarily the newest one (nor is it likely to be). Entries in the error log are not listed in chronological order; rather, they correspond to the order of the trace files as determined in the ndb_node_id_trace.log.next file (see below). Error log entries are thus overwritten in a cyclical and not sequential fashion.

- **ndb_node_id_trace.log.trace_id** is a trace file describing exactly what happened just before the error occurred. This information is useful for analysis by the MySQL Cluster development team.

    It is possible to configure the number of these trace files that will be created before old files are overwritten. trace_id is a number which is incremented for each successive trace file.

- **ndb_node_id_trace.log.next** is the file that keeps track of the next trace file number to be assigned.

- **ndb_node_id_out.log** is a file containing any data output by the ndbd process. This file is created only if ndbd is started as a daemon, which is the default behavior.

- **ndb_node_id.pid** is a file containing the process ID of the ndbd process when started as a daemon. It also functions as a lock file to avoid the starting of nodes with the same identifier.
• ndb_node_id_signal.log is a file used only in debug versions of ndbd, where it is possible to trace all incoming, outgoing, and internal messages with their data in the ndbd process.

It is recommended not to use a directory mounted through NFS because in some environments this can cause problems whereby the lock on the .pid file remains in effect even after the process has terminated.

To start ndbd, it may also be necessary to specify the host name of the management server and the port on which it is listening. Optionally, one may also specify the node ID that the process is to use.

```shell
ndbd --connect-string="nodeid=2;host=ndb_mgmd.mysql.com:1186"
```

See Section 17.3.3.2, “MySQL Cluster Connection Strings”, for additional information about this issue. Section 17.4.20, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”, describes other command-line options which can be used with ndbd. For information about data node configuration parameters, see Section 17.3.3.5, “Defining MySQL Cluster Data Nodes”.

When ndbd starts, it actually initiates two processes. The first of these is called the “angel process”; its only job is to discover when the execution process has been completed, and then to restart the ndbd process if it is configured to do so. Thus, if you attempt to kill ndbd using the Unix kill command, it is necessary to kill both processes, beginning with the angel process. The preferred method of terminating an ndbd process is to use the management client and stop the process from there.

The execution process uses one thread for reading, writing, and scanning data, as well as all other activities. This thread is implemented asynchronously so that it can easily handle thousands of concurrent actions. In addition, a watch-dog thread supervises the execution thread to make sure that it does not hang in an endless loop. A pool of threads handles file I/O, with each thread able to handle one open file. Threads can also be used for transporter connections by the transporters in the ndbd process. In a multi-processor system performing a large number of operations (including updates), the ndbd process can consume up to 2 CPUs if permitted to do so.

For a machine with many CPUs it is possible to use several ndbd processes which belong to different node groups; however, such a configuration is still considered experimental and is not supported for MySQL 5.0 in a production setting. See Section 17.1.5, “Known Limitations of MySQL Cluster”.

### 17.4.2 ndb_mgmd — The MySQL Cluster Management Server Daemon

The management server is the process that reads the cluster configuration file and distributes this information to all nodes in the cluster that request it. It also maintains a log of cluster activities. Management clients can connect to the management server and check the cluster's status.

The following table includes options that are specific to the MySQL Cluster management server program ndb_mgmd. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including ndb_mgmd), see Section 17.4.20, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”.

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--config-file=file, -f</td>
<td>Specify the cluster configuration file; in NDB-6.4.0 and later, needs --reload or --initialize to override configuration cache if present</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td>-c</td>
<td>Print full configuration and exit</td>
<td>ADDED: 5.0.10</td>
</tr>
<tr>
<td>--print-full-config, -P</td>
<td>Run ndb_mgmd in daemon mode (default)</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td>--daemon</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Format</td>
<td>Description</td>
<td>Added or Removed</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>----------------------------------------</td>
</tr>
<tr>
<td>-d</td>
<td>Do not run ndb_mgmd as a daemon</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td>--nodaemon</td>
<td>Run ndb_mgmd in interactive mode (not officially supported in production; for testing purposes only)</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td>--interactive</td>
<td>Do not provide any node id checks</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td>--mycnf</td>
<td>Read cluster configuration data from the my.cnf file</td>
<td>All MySQL 5.0 based releases</td>
</tr>
</tbody>
</table>

### --no-nodeid-checks

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--no-nodeid-checks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>Type boolean</td>
</tr>
<tr>
<td>Default</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Do not perform any checks of node IDs.

### --config-file=filename, -f filename

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--config-file=file</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>Type file name</td>
</tr>
<tr>
<td>Default</td>
<td>./config.ini</td>
</tr>
</tbody>
</table>

Instructs the management server as to which file it should use for its configuration file. By default, the management server looks for a file named config.ini in the same directory as the ndb_mgmd executable; otherwise the file name and location must be specified explicitly.

This option also can be given as -c file_name, but this shortcut is obsolete and should not be used in new installations.

### --mycnf

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--mycnf</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>Type boolean</td>
</tr>
<tr>
<td>Default</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Read configuration data from the my.cnf file.

### --daemon, -d

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--daemon</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>Type boolean</td>
</tr>
<tr>
<td>Default</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

Instructs ndb_mgmd to start as a daemon process. This is the default behavior.

### --interactive

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--interactive</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>Type boolean</td>
</tr>
</tbody>
</table>
**ndb_mgm** — The MySQL Cluster Management Client

---

<table>
<thead>
<tr>
<th>Default</th>
<th>FALSE</th>
</tr>
</thead>
</table>

Starts `ndb_mgmd` in interactive mode; that is, an `ndb_mgm` client session is started as soon as the management server is running. This option does not start any other MySQL Cluster nodes.

- **--nodaemon**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--nodaemon</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>Type boolean</td>
</tr>
<tr>
<td>Default</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Instructs `ndb_mgmd` not to start as a daemon process.

- **--print-full-config, -P**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.0.10</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--print-full-config</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type boolean</td>
</tr>
<tr>
<td>Default</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Shows extended information regarding the configuration of the cluster. With this option on the command line the `ndb_mgmd` process prints information about the cluster setup including an extensive list of the cluster configuration sections as well as parameters and their values. Normally used together with the `--config-file (-f)` option.

It is not strictly necessary to specify a connection string when starting the management server. However, if you are using more than one management server, a connection string should be provided and each node in the cluster should specify its node ID explicitly.

See Section 17.3.3.2, “MySQL Cluster Connection Strings”, for information about using connection strings. Section 17.4.2, “ndb_mgmd — The MySQL Cluster Management Server Daemon”, describes other options for `ndb_mgmd`.

The following files are created or used by `ndb_mgmd` in its starting directory, and are placed in the `DataDir` as specified in the `config.ini` configuration file. In the list that follows, `node_id` is the unique node identifier.

- **config.ini** is the configuration file for the cluster as a whole. This file is created by the user and read by the management server. Section 17.3, “MySQL Cluster Configuration”, discusses how to set up this file.

- **ndb_node_id_cluster.log** is the cluster events log file. Examples of such events include checkpoint startup and completion, node startup events, node failures, and levels of memory usage. A complete listing of cluster events with descriptions may be found in Section 17.5, “Management of MySQL Cluster”.

By default, when the size of the cluster log reaches one million bytes, the file is renamed to `ndb_node_id_cluster.log.seq_id`, where `seq_id` is the sequence number of the cluster log file. (For example: If files with the sequence numbers 1, 2, and 3 already exist, the next log file is named using the number 4.) You can change the size and number of files, and other characteristics of the cluster log, using the `LogDestination` configuration parameter.

- **ndb_node_id_out.log** is the file used for stdout and stderr when running the management server as a daemon.

- **ndb_node_id.pid** is the process ID file used when running the management server as a daemon.

**17.4.3 ndb_mgm** — The MySQL Cluster Management Client
The **ndb_mgm** management client process is actually not needed to run the cluster. Its value lies in providing a set of commands for checking the cluster’s status, starting backups, and performing other administrative functions. The management client accesses the management server using a C API. Advanced users can also employ this API for programming dedicated management processes to perform tasks similar to those performed by **ndb_mgm**.

To start the management client, it is necessary to supply the host name and port number of the management server:

```
shell> ndb_mgm [host_name [port_num]]
```

For example:

```
shell> ndb_mgm ndb_mgmd.mysql.com 1186
```

The default host name and port number are **localhost** and 1186, respectively.

The following table includes options that are specific to the MySQL Cluster management client program **ndb_mgm**. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including **ndb_mgm**), see Section 17.4.20, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”.

Table 17.28 This table describes command-line options for the **ndb_mgm** program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--try-reconnect=number</code></td>
<td>Set the number of times to retry a connection before giving up; synonym for <code>--connect-retries</code></td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td><code>-t</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--execute=name</code></td>
<td>Execute command and exit</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td><code>-e</code></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

* **--execute=command, -e command**

This option can be used to send a command to the MySQL Cluster management client from the system shell. For example, either of the following is equivalent to executing `SHOW` in the management client:

```
shell> ndb_mgm -e "SHOW"
shell> ndb_mgm --execute="SHOW"
```

This is analogous to how the `--execute` or `-e` option works with the **mysql** command-line client. See Section 4.2.4, “Using Options on the Command Line”.

**Note**

If the management client command to be passed using this option contains any space characters, then the command must be enclosed in quotation marks. Either single or double quotation marks may be used. If the management client command contains no space characters, the quotation marks are optional.

* **--try-reconnect=number**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--try-reconnect=number</code></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Permitted Values</strong></td>
<td><strong>Type</strong> integer</td>
</tr>
</tbody>
</table>
If the connection to the management server is broken, the node tries to reconnect to it every 5 seconds until it succeeds. By using this option, it is possible to limit the number of attempts to \texttt{number} before giving up and reporting an error instead.

Additional information about using \texttt{ndb_mgm} can be found in Section 17.5.2, “Commands in the MySQL Cluster Management Client”.

17.4.4 \texttt{ndb_config} — Extract MySQL Cluster Configuration Information

This tool extracts configuration information for data nodes, SQL nodes, and API nodes from a cluster management node (and possibly its \texttt{config.ini} file).

The following table includes options that are specific to \texttt{ndb_config}. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including \texttt{ndb_config}), see Section 17.4.20, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”.

Table 17.29 This table describes command-line options for the \texttt{ndb_config} program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{--nodes}</td>
<td>Print node information ([ndbd] or [ndbd default] section of cluster configuration file) only. Cannot be used with \texttt{--system} or \texttt{--connections}.</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td>\texttt{--query=string,}</td>
<td>One or more query options (attributes)</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td>\texttt{-q}</td>
<td>Specifying host</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td>\texttt{--type=name}</td>
<td>Specify node type</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td>\texttt{--nodeid,}</td>
<td>Get configuration of node with this ID</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td>\texttt{--fields=string,}</td>
<td>Field separator</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td>\texttt{-f}</td>
<td>Row separator</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td>\texttt{--rows=string,}</td>
<td>Set the path to config.ini file</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td>\texttt{--config-file=file_name}</td>
<td>Read configuration data from my.cnf file</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td>\texttt{--mycnf}</td>
<td>Short form for \texttt{--ndb-connectstring}</td>
<td>ADDED: 5.0.33</td>
</tr>
</tbody>
</table>

Table 17.30 \texttt{ndb_config} Command Line Options

<table>
<thead>
<tr>

<tr>
<td>--type</td>
<td>Specify node type</td>
</tr>
</tbody>
</table>

- **--usage, --help, or --?**

Command-Line Format
```
--help
--usage
```

Causes `ndb_config` to print a list of available options, and then exit.

- **--version, -V**

Command-Line Format
```
--version
```

Causes `ndb_config` to print a version information string, and then exit.

- **--ndb-connectstring=connection_string**

Command-Line Format
```
--ndb-connectstring=connectstring
--connect-string=connectstring
```

Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>localhost:1186</td>
</tr>
</tbody>
</table>

Specifies the connection string to use in connecting to the management server. The format for the connection string is the same as described in Section 17.3.3.2, "MySQL Cluster Connection Strings", and defaults to `localhost:1186`.

The use of `-c` as a short version for this option is supported for `ndb_config` beginning with MySQL 5.0.29.

- **--config-file=path-to-file**

Command-Line Format
```
--config-file=file_name
```

Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>file name</td>
<td></td>
</tr>
</tbody>
</table>

Gives the path to the management server's configuration file (`config.ini`). This may be a relative or absolute path. If the management node resides on a different host from the one on which `ndb_config` is invoked, then an absolute path must be used.

- **--mycnf**

Command-Line Format
```
--mycnf
```

Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
</tr>
</tbody>
</table>
Read configuration data from the `my.cnf` file.

- `--query=query-options`, `-q query-options`

**Command-Line Format**

```
--query=string
```

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td></td>
</tr>
</tbody>
</table>

This is a comma-delimited list of `query options`—that is, a list of one or more node attributes to be returned. These include `id` (node ID), `type` (node type—that is, `ndbd`, `mysqld`, or `ndb_mgmd`), and any configuration parameters whose values are to be obtained.

For example, `--query=id,type,indexmemory,datamemory` returns the node ID, node type, `DataMemory`, and `IndexMemory` for each node.

**Note**

If a given parameter is not applicable to a certain type of node, than an empty string is returned for the corresponding value. See the examples later in this section for more information.

- `--host=hostname`

**Command-Line Format**

```
--host=name
```

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td></td>
</tr>
</tbody>
</table>

Specifies the host name of the node for which configuration information is to be obtained.

**Note**

While the hostname `localhost` usually resolves to the IP address `127.0.0.1`, this may not necessarily be true for all operating platforms and configurations. This means that it is possible, when `localhost` is used in `config.ini`, for `ndb_config --host=localhost` to fail if `ndb_config` is run on a different host where `localhost` resolves to a different address (for example, on some versions of SUSE Linux, this is `127.0.0.2`). In general, for best results, you should use numeric IP addresses for all MySQL Cluster configuration values relating to hosts, or verify that all MySQL Cluster hosts handle `localhost` in the same fashion.

- `--id=node_id`

**Command-Line Format**

```
--ndb-nodeid=#
```

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>numeric</td>
<td>0</td>
</tr>
</tbody>
</table>

Either of these options can be used to specify the node ID of the node for which configuration information is to be obtained. `--nodeid` is the preferred form.

- `--nodes`

**Command-Line Format**

```
--nodes
```

This documentation is for an older version. If you're using the most current version, select the documentation for that version with the version switch in the upper right corner of the online documentation, or by downloading a newer PDF or EPUB file.
**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

In MySQL 5.0, this option has no affect.

- **--connections**

This option (not listed in the table) is present but has no affect in MySQL 5.0. It is reserved for use in a future version of MySQL Cluster.

- **--type=node_type**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--type=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>Type</td>
</tr>
<tr>
<td></td>
<td>enumeration</td>
</tr>
<tr>
<td></td>
<td>Default</td>
</tr>
<tr>
<td></td>
<td>[none]</td>
</tr>
</tbody>
</table>

Valid Values

- ndbd
- mysqlld
- ndb_mgmd

Filters results so that only configuration values applying to nodes of the specified `node_type` (ndbd, mysqlld, or ndb_mgmd) are returned.

- **--fields=delimiter, -f delimiter**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--fields=string</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>Type</td>
</tr>
<tr>
<td></td>
<td>string</td>
</tr>
<tr>
<td></td>
<td>Default</td>
</tr>
</tbody>
</table>

Specifies a `delimiter` string used to separate the fields in the result. The default is “,” (the comma character).

**Note**

If the `delimiter` contains spaces or escapes (such as \n for the linefeed character), then it must be quoted.

- **--rows=separator, -r separator**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--rows=string</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>Type</td>
</tr>
<tr>
<td></td>
<td>string</td>
</tr>
<tr>
<td></td>
<td>Default</td>
</tr>
</tbody>
</table>

Specifies a `separator` string used to separate the rows in the result. The default is a space character.

**Note**

If the `separator` contains spaces or escapes (such as \n for the linefeed character), then it must be quoted.

**Examples**

1. To obtain the node ID and type of each node in the cluster:

```
shell> ./ndb_config --query=id,type --fields=':' --rows='
' ndbd
```
In this example, we used the `--fields` options to separate the ID and type of each node with a colon character (:`), and the `--rows` options to place the values for each node on a new line in the output.

2. To produce a connection string that can be used by data, SQL, and API nodes to connect to the management server:

   ```shell
   ./ndb_config --config-file=usr/local/mysql/cluster-data/config.ini --query=hostname,portnumber --fields=: --rows=, --type=ndb_mgmd
   192.168.0.179:1186
   ```

3. This invocation of `ndb_config` checks only data nodes (using the `--type` option), and shows the values for each node’s ID and host name, and its `DataMemory`, `IndexMemory`, and `DataDir` parameters:

   ```shell
   ./ndb_config --type=ndbd --query=id,host,datamemory,indexmemory,datadir -f ' : ' -r '
   ```

   In this example, we used the short options `-f` and `-r` for setting the field delimiter and row separator, respectively.

4. To exclude results from any host except one in particular, use the `--host` option:

   ```shell
   ./ndb_config --host=192.168.0.176 -f : -r '\n' -q id,type
   3:ndbd
   5:ndb_mgmd
   ```

   In this example, we also used the short form `-q` to determine the attributes to be queried.

   Similarly, you can limit results to a node with a specific ID using the `--id` or `--nodeid` option.

### 17.4.5 ndb_cpcd — Automate Testing for NDB Development

This utility is found in the `libexec` directory. It is part of an internal automated test framework used in testing and debugging MySQL Cluster. Because it can control processes on remote systems, it is not advisable to use `ndb_cpcd` in a production cluster.

The source files for `ndb_cpcd` may be found in the directory `storage/ndb/src/cw/cpcd`, in the MySQL source tree.

### 17.4.6 ndb_delete_all — Delete All Rows from an NDB Table

`ndb_delete_all` deletes all rows from the given NDB table. In some cases, this can be much faster than `DELETE` or even `TRUNCATE TABLE`.

**Usage**

```
ndb_delete_all -c connection_string tbl_name -d db_name
```
This deletes all rows from the table named `tbl_name` in the database named `db_name`. It is exactly equivalent to executing `TRUNCATE `db_name`.tbl_name` in MySQL.

The following table includes options that are specific to `ndb_delete_all`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndb_delete_all`), see Section 17.4.20, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”.

### Table 17.31 This table describes command-line options for the `ndb_delete_all` program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--database=dbname,</code></td>
<td>Name of the database in which the table is found</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td><code>-d</code></td>
<td>Perform the delete in a single transaction (may run out of operations)</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td><code>--transactional,</code></td>
<td>Run tup scan</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td><code>-t</code></td>
<td>Run disk scan</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td><code>--tupscan</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--diskscan</code></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- `--transactional,-t`

  Use of this option causes the delete operation to be performed as a single transaction.

  **Warning**
  
  With very large tables, using this option may cause the number of operations available to the cluster to be exceeded.

### 17.4.7 `ndb_desc` — Describe NDB Tables

`ndb_desc` provides a detailed description of one or more NDB tables.

**Usage**

```
ndb_desc -c connection_string tbl_name -d db_name [options]
```

Additional options that can be used with `ndb_desc` are listed later in this section.

**Sample Output**

MySQL table creation and population statements:

```
USE test;

CREATE TABLE fish (  
    id INT(11) NOT NULL AUTO_INCREMENT,  
    name VARCHAR(20),  
    PRIMARY KEY pk (id),  
    UNIQUE KEY uk (name)  
) ENGINE=NDBCLUSTER;

INSERT INTO fish VALUES  
    ('','guppy'), ('','tuna'), ('','shark'),  
    ('','manta ray'), ('','grouper'), ('','puffer');
```

Output from `ndb_desc`:

```
shell> ./ndb_desc -c localhost fish -d test -p
```
Information about multiple tables can be obtained in a single invocation of `ndb_desc` by using their names, separated by spaces. All of the tables must be in the same database.

The `Version` column in the output contains the table’s schema object version. For information about interpreting this value, see `NDB Schema Object Versions`.

The following table includes options that are specific to `ndb_desc`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndb_desc`), see Section 17.4.20, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”.

**Table 17.32** This table describes command-line options for the `ndb_desc` program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--database=dbname</code>, <code>--database=dbname</code>, <code>-d</code></td>
<td>Name of database containing table</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td><code>--extra-partition-info</code>, <code>--extra-partition-info</code>, <code>-p</code></td>
<td>Display information about partitions</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td><code>--retries=#</code>, <code>--retries=#</code>, <code>-r</code></td>
<td>Number of times to retry the connection (once per second)</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td><code>--unqualified</code>, <code>--unqualified</code>, <code>-u</code></td>
<td>Use unqualified table names</td>
<td>All MySQL 5.0 based releases</td>
</tr>
</tbody>
</table>

- **`--database=db_name`, `-d`**
  Specify the database in which the table should be found.

- **`--extra-partition-info`, `-p`**
  Print additional information about the table’s partitions.
• `--retries=#,-r`
  Try to connect this many times before giving up. One connect attempt is made per second.

• `--unqualified,-u`
  Use unqualified table names.

### 17.4.8 `ndb_drop_index` — Drop Index from an NDB Table

`ndb_drop_index` drops the specified index from an NDB table. It is recommended that you use this utility only as an example for writing NDB API applications—see the Warning later in this section for details.

**Usage**

```
ndb_drop_index -c connection_string table_name index -d db_name
```

The statement shown above drops the index named `index` from the `table` in the `database`.

The following table includes options that are specific to `ndb_drop_index`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndb_drop_index`), see Section 17.4.20, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”.

**Table 17.33** This table describes command-line options for the `ndb_drop_index` program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--database=dbname, -d</code></td>
<td>Name of the database in which the table is found</td>
<td>All MySQL 5.0 based releases</td>
</tr>
</tbody>
</table>

**Warning**

Operations performed on Cluster table indexes using the NDB API are not visible to MySQL and make the table unusable by a MySQL server. If you use this program to drop an index, then try to access the table from an SQL node, an error results, as shown here:

```
shell> ./ndb_drop_index -c localhost dogs ix -d ctest1
Dropping index dogs/idx...OK
NDBT_ProgramExit: 0 - OK
shell> ./mysql -u jon -p ctest1
Enter password: *******
Reading table information for completion of table and column names
You can turn off this feature to get a quicker startup with -A
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 7 to server version: 5.0.96
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
mysql> SHOW TABLES;
```

```
+------------------+
| Tables_in_ctest1 |
+------------------+
| a                |
| btl              |
| bt2              |
| dogs             |
| employees        |
```
In such a case, your only option for making the table available to MySQL again is to drop the table and re-create it. You can use either the SQL statement `DROP TABLE` or the `ndb_drop_table` utility (see Section 17.4.9, “ndb_drop_table — Drop an NDB Table”) to drop the table.

## 17.4.9 ndb_drop_table — Drop an NDB Table

`ndb_drop_table` drops the specified NDB table. (If you try to use this on a table created with a storage engine other than NDB, the attempt fails with the error 723: No such table exists.) This operation is extremely fast; in some cases, it can be an order of magnitude faster than using a MySQL `DROP TABLE` statement on an NDB table.

### Usage

```
ndb_drop_table -c connection_string tbl_name -d db_name
```

The following table includes options that are specific to `ndb_drop_table`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndb_drop_table`), see Section 17.4.20, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”.

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--database=dbname, -d</td>
<td>Name of the database in which the table is found</td>
<td>All MySQL 5.0 based releases</td>
</tr>
</tbody>
</table>

## 17.4.10 ndb_error_reporter — NDB Error-Reporting Utility

`ndb_error_reporter` creates an archive from data node and management node log files that can be used to help diagnose bugs or other problems with a cluster. It is highly recommended that you make use of this utility when filing reports of bugs in MySQL Cluster.

The following table includes command options specific to the MySQL Cluster program `ndb_error_reporter`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndb_error_reporter`), see Section 17.4.20, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”.

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--fs</td>
<td>Include file system data in error report; can use a large amount of disk space</td>
<td>All MySQL 5.0 based releases</td>
</tr>
</tbody>
</table>

### Usage

```
ndb_error_reporter path/to/config-file [username] [--fs]
```

This utility is intended for use on a management node host, and requires the path to the management host configuration file (`config.ini`). Optionally, you can supply the name of a user that is able to access the cluster's data nodes using SSH, to copy the data node log files. `ndb_error_reporter` then includes all of these files in archive that is created in the same directory in which it is run. The archive
is named `ndb_error_report_YYYYMMDDHHMMSS.tar.bz2`, where `YYYYMMDDHHMMSS` is a datetime string.

If the `--fs` is used, then the data node file systems are also copied to the management host and included in the archive that is produced by this script. As data node file systems can be extremely large even after being compressed, we ask that you please do not send archives created using this option to Oracle unless you are specifically requested to do so.

### Command-Line Format

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--fs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>Type boolean</td>
</tr>
<tr>
<td></td>
<td>Default FALSE</td>
</tr>
</tbody>
</table>

#### 17.4.11 ndb_print_backup_file — Print NDB Backup File Contents

`ndb_print_backup_file` obtains diagnostic information from a cluster backup file.

**Usage**

```
ndb_print_backup_file file_name
```

`file_name` is the name of a cluster backup file. This can be any of the files (.Data, .ctl, or .log file) found in a cluster backup directory. These files are found in the data node's backup directory under the subdirectory `BACKUP-#`, where `#` is the sequence number for the backup. For more information about cluster backup files and their contents, see Section 17.5.3.1, “MySQL Cluster Backup Concepts”.

Like `ndb_print_schema_file` and `ndb_print_sys_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_backup_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

**Additional Options**

None.

#### 17.4.12 ndb_print_schema_file — Print NDB Schema File Contents

`ndb_print_schema_file` obtains diagnostic information from a cluster schema file.

**Usage**

```
ndb_print_schema_file file_name
```

`file_name` is the name of a cluster schema file. For more information about cluster schema files, see MySQL Cluster Data Node File System Directory Files.

Like `ndb_print_backup_file` and `ndb_print_sys_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_schema_backup_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

**Additional Options**

None.

#### 17.4.13 ndb_print_sys_file — Print NDB System File Contents
ndb_restore — Restore a MySQL Cluster Backup

Usage

```
ndb_print_sys_file file_name
```

`file_name` is the name of a cluster system file (sysfile). Cluster system files are located in a data node's data directory (`DataDir`); the path under this directory to system files matches the pattern `ndb_#_fs/D/#/DBDIH/P/#.sysfile`. In each case, the `#` represents a number (not necessarily the same number). For more information, see MySQL Cluster Data Node File System Directory Files.

Like `ndb_print_backup_file` and `ndb_print_schema_file` (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) `ndb_print_backup_file` must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options

None.

17.4.14 `ndb_restore` — Restore a MySQL Cluster Backup

The cluster restoration program is implemented as a separate command-line utility `ndb_restore`, which can normally be found in the MySQL `bin` directory. This program reads the files created as a result of the backup and inserts the stored information into the database.

`ndb_restore` must be executed once for each of the backup files that were created by the START BACKUP command used to create the backup (see Section 17.5.3.2, “Using The MySQL Cluster Management Client to Create a Backup”). This is equal to the number of data nodes in the cluster at the time that the backup was created.

**Note**

Before using `ndb_restore`, it is recommended that the cluster be running in single user mode, unless you are restoring multiple data nodes in parallel. See Section 17.5.8, “MySQL Cluster Single User Mode”, for more information.

The following table includes options that are specific to the MySQL Cluster native backup restoration program `ndb_restore`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndb_restore`), see Section 17.4.20, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”.

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--connect</code></td>
<td>Alias for <code>--connectstring</code>.</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td><code>-c</code></td>
<td>Restore backup files to node with this ID</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td><code>--nodeid=#</code></td>
<td>Restore backup files to node with this ID</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td><code>-n</code></td>
<td>Restore from the backup with the given ID</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td><code>--backupid=#</code></td>
<td>Restore table data and logs into NDB Cluster using the NDB API</td>
<td>All MySQL 5.0 based releases</td>
</tr>
</tbody>
</table>
Format | Description | Added or Removed
--- | --- | ---
--restore_meta, -m | Restore metadata to NDB Cluster using the NDB API | All MySQL 5.0 based releases
--parallelism=#, -p | Number of parallel transactions to use while restoring data | All MySQL 5.0 based releases
--print | Print metadata, data and log to stdout (equivalent to --print_meta --print_data --print_log) | All MySQL 5.0 based releases
--print_meta | Print metadata to stdout | All MySQL 5.0 based releases
--print_data | Print data to stdout | All MySQL 5.0 based releases
--print_log | Print to stdout | All MySQL 5.0 based releases
--backup_path=dir_name | Path to backup files directory | ADDED: 5.0.38
--dont_ignore_systab_0, -f | Do not ignore system table during restore. Experimental only; not for production use | All MySQL 5.0 based releases
--fields-enclosed-by=char | Fields are enclosed with the indicated character | ADDED: 5.0.40
--fields-terminated-by=char | Fields are terminated by the indicated character | ADDED: 5.0.40
--fields-optionally-enclosed-by | Fields are optionally enclosed with the indicated character | ADDED: 5.0.40
--lines-terminated-by=char | Lines are terminated by the indicated character | ADDED: 5.0.40
--hex | Print binary types in hexadecimal format | ADDED: 5.0.40
--tab=dir_name, -T dir_name | Creates a tab-separated .txt file for each table in the given path | ADDED: 5.0.40
--append | Append data to a tab-delimited file | ADDED: 5.0.40
--verbose=# | Level of verbosity in output | All MySQL 5.0 based releases

Typical options for this utility are shown here:

```
ndb_restore [-c connection_string] -n node_id -b backup_id \n[-m] -r --backup_path=/path/to/backup/files
```

Normally, when restoring from a MySQL Cluster backup, `ndb_restore` requires at least a minimum the `--nodeid` (short form: `-n`), `--backupid` (short form: `-b`), and `--backup_path` options.

The `-c` option is used to specify a connection string which tells `ndb_restore` where to locate the cluster management server. (See Section 17.3.3.2, “MySQL Cluster Connection Strings”, for information on connection strings.) If this option is not used, then `ndb_restore` attempts to connect to a management server on `localhost:1186`. This utility acts as a cluster API node, and so requires a free connection “slot” to connect to the cluster management server. This means that there must be at least one `[api]` or `[mysqld]` section that can be used by it in the cluster `config.ini` file. It is a good idea to keep at least one empty `[api]` or `[mysqld]` section in `config.ini` that is not being used for a MySQL server or other application for this reason (see Section 17.3.3.6, “Defining SQL and Other API Nodes in a MySQL Cluster”).
You can verify that `ndb_restore` is connected to the cluster by using the `SHOW` command in the `ndb_mgm` management client. You can also accomplish this from a system shell, as shown here:

```
shell> ndb_mgm -e "SHOW"
```

The `--nodeid` or `-n` is used to specify the node ID of the data node on which the backup should be restored.

The first time you run the `ndb_restore` restoration program, you also need to restore the metadata. In other words, you must re-create the database tables—this can be done by running it with the `--restore_meta (-m)` option. Restoring the metadata need be done only on a single data node; this is sufficient to restore it to the entire cluster. Note that the cluster should have an empty database when starting to restore a backup. (In other words, you should start `ndbd` with `--initial` prior to performing the restore.)

The `--` option is used to specify the ID or sequence number of the backup, and is the same number shown by the management client in the Backup `backup_id` completed message displayed upon completion of a backup. (See Section 17.5.3.2, “Using The MySQL Cluster Management Client to Create a Backup”.)

**Important**

When restoring cluster backups, you must be sure to restore all data nodes from backups having the same backup ID. Using files from different backups will at best result in restoring the cluster to an inconsistent state, and may fail altogether.

The path to the backup directory is required; this is supplied to `ndb_restore` using the `--backup_path` option, and must include the subdirectory corresponding to the ID backup of the backup to be restored. For example, if the data node's DataDir is `/var/lib/mysql-cluster`, then the backup directory is `/var/lib/mysql-cluster/BACKUP`, and the backup files for the backup with the ID 3 can be found in `/var/lib/mysql-cluster/BACKUP/BACKUP-3`. The path may be absolute or relative to the directory in which the `ndb_restore` executable is located, and may be optionally prefixed with `backup_path=`.

**Note**

Previous to MySQL 5.0.38, the path to the backup directory was specified as shown here, with `backup_path=` being optional:

```
[backup_path=]/path/to/backup/files
```

Beginning with MySQL 5.0.38, this syntax changed to `--backup_path=/path/to/backup/files`, to conform more closely with options used by other MySQL programs; `--backup_id` is required, and there is no short form for this option.

It is possible to restore a backup to a database with a different configuration than it was created from. For example, suppose that a backup with backup ID 12, created in a cluster with two database nodes having the node IDs 2 and 3, is to be restored to a cluster with four nodes. Then `ndb_restore` must be run twice—one for each database node in the cluster where the backup was taken. However, `ndb_restore` cannot always restore backups made from a cluster running one version of MySQL to a cluster running a different MySQL version. See Section 17.2.6, “Upgrading and Downgrading MySQL Cluster”, for more information.

**Important**

It is not possible to restore a backup made from a newer version of MySQL Cluster using an older version of `ndb_restore`. You can restore a backup...
made from a newer version of MySQL to an older cluster, but you must use a copy of `ndb_restore` from the newer MySQL Cluster version to do so.

For example, to restore a cluster backup taken from a cluster running MySQL 5.0.45 to a cluster running MySQL Cluster 5.0.41, you must use a copy of `ndb_restore` from the 5.0.45 distribution.

For more rapid restoration, the data may be restored in parallel, provided that there is a sufficient number of cluster connections available. That is, when restoring to multiple nodes in parallel, you must have an [api] or [mysqld] section in the cluster config.ini file available for each concurrent `ndb_restore` process. However, the data files must always be applied before the logs.

```
--dont_ignore_systab_0
```

Normally, when restoring table data and metadata, `ndb_restore` ignores the copy of the NDB system table that is present in the backup. `--dont_ignore_systab_0` causes the system table to be restored. This option is intended for experimental and development use only, and is not recommended in a production environment.

```
--parallelism=#, -p
```

Determines the maximum number of parallel transactions that `ndb_restore` tries to use. By default, this is 128; the minimum is 1, and the maximum is 1024.

```
--restore_data
```

This option causes `ndb_restore` to output NDB table data and logs.

```
--restore_meta
```

This option causes `ndb_restore` to print NDB table metadata. Generally, you need only use this option when restoring the first data node of a cluster; additional data nodes can obtain the metadata from the first one.

```
--print_meta
```

This option causes `ndb_restore` to print all metadata to stdout.

```
--print_log
```

The `--print_log` option causes `ndb_restore` to output its log to stdout.

```
--print
```

Causes `ndb_restore` to print all data, metadata, and logs to stdout. Equivalent to using the `--print_data`, `--print_meta`, and `--print_log` options together.

```
--print_data
```

This option causes `ndb_restore` to direct its output to stdout.

Text and BLOB column values are always truncated to the first 256 bytes in the output; this cannot currently be overridden when using `--print_data`.

Beginning with MySQL 5.0.40, several additional options are available for use with the `--print_data` option in generating data dumps, either to stdout, or to a file. These are similar to some of the options used with `mysqldump`, and are shown in the following list:
- **--tab, -T**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.0.40</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--tab=dir_name</code></td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type</td>
</tr>
</tbody>
</table>

This option causes `--print_data` to create dump files, one per table, each named `tbl_name.txt`. It requires as its argument the path to the directory where the files should be saved; use `.` for the current directory.

- **--fields-enclosed-by=string**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.0.40</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--fields-enclosed-by=char</code></td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type</td>
</tr>
<tr>
<td>Default</td>
<td></td>
</tr>
</tbody>
</table>

Each column values are enclosed by the string passed to this option (regardless of data type; see next item).

- **--fields-optionally-enclosed-by=string**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.0.40</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--fields-optionally-enclosed-by</code></td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type</td>
</tr>
<tr>
<td>Default</td>
<td></td>
</tr>
</tbody>
</table>

The string passed to this option is used to enclose column values containing character data (such as `CHAR`, `VARCHAR`, `BINARY`, `TEXT`, or `ENUM`).

- **--fields-terminated-by=string**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.0.40</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--fields-terminated-by=char</code></td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type</td>
</tr>
<tr>
<td>Default</td>
<td>\t (tab)</td>
</tr>
</tbody>
</table>

The string passed to this option is used to separate column values. The default value is a tab character (`\t`).

- **--hex**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.0.40</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--hex</code></td>
</tr>
</tbody>
</table>

If this option is used, all binary values are output in hexadecimal format.

- **--fields-terminated-by=string**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.0.40</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--fields-terminated-by=char</code></td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type</td>
</tr>
<tr>
<td>Default</td>
<td>\t (tab)</td>
</tr>
</tbody>
</table>
This option specifies the string used to end each line of output. The default is a linefeed character (\n).

- **--append**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.0.40</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><strong>--append</strong></td>
</tr>
</tbody>
</table>

When used with the **--tab** and **--print_data** options, this causes the data to be appended to any existing files having the same names.

**Note**

If a table has no explicit primary key, then the output generated when using the **--print_data** option includes the table's hidden primary key.

**--verbose=**

Sets the level for the verbosity of the output. The minimum is 0; the maximum is 255. The default value is 1.

Beginning with MySQL 5.0.40, it is possible to restore selected databases, or to restore selected tables from a given database using the syntax shown here:

```bash
ndb_restore other_options db_name, [db_name, ...] | tbl_name[, tbl_name][, ...]
```

In other words, you can specify either of the following to be restored:

- All tables from one or more databases
- One or more tables from a single database

**Error reporting.**

**ndb_restore** reports both temporary and permanent errors. In the case of temporary errors, it may be able to recover from them. Beginning with MySQL 5.0.29, it reports Restore successful, but encountered temporary error, please look at configuration in such cases.

### 17.4.15 ndb_select_all — Print Rows from an NDB Table

**ndb_select_all** prints all rows from an NDB table to stdout.

**Usage**

```bash
ndb_select_all -c connection_string tbl_name -d db_name [> file_name]
```

The following table includes options that are specific to the MySQL Cluster native backup restoration program **ndb_select_all**. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including **ndb_select_all**), see Section 17.4.20, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”.

**Table 17.37** This table describes command-line options for the **ndb_select_all** program

<table>
<thead>
<tr>

</tr>
<tr>
<td>-x</td>
<td></td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td>--delimiter=char,</td>
<td>Set a column delimiter</td>
<td></td>
</tr>
<tr>
<td>-D</td>
<td></td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td>--disk</td>
<td>Print disk references (useful only for Disk Data tables having nonindexed columns)</td>
<td></td>
</tr>
<tr>
<td>--rowid</td>
<td>Print rowid</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td>--gci</td>
<td>Include GCI in output</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td>--gci64</td>
<td>Include GCI and row epoch in output</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td>--tup,</td>
<td>Scan in tup order</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td>-t</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--nodata</td>
<td>Do not print table column data</td>
<td>All MySQL 5.0 based releases</td>
</tr>
</tbody>
</table>

- **--database=dbname, -d dbname**
  
  Name of the database in which the table is found. The default value is TEST_DB.

- **parallelism=#, -p #**
  
  Specifies the degree of parallelism.

- **--lock=lock_type, -l lock_type**
  
  Employs a lock when reading the table. Possible values for lock_type are:
  
  - 0: Read lock
  - 1: Read lock with hold
  - 2: Exclusive read lock
  
  There is no default value for this option.

- **--order=index_name, -o index_name**
  
  Orders the output according to the index named index_name. Note that this is the name of an index, not of a column, and that the index must have been explicitly named when created.

- **--descending, -z**
  
  Sorts the output in descending order. This option can be used only in conjunction with the -o (--order) option.
• --header=FALSE

Excludes column headers from the output.

• --useHexFormat -x

Causes all numeric values to be displayed in hexadecimal format. This does not affect the output of numerals contained in strings or datatime values.

• --delimiter=character, -D character

Causes the character to be used as a column delimiter. Only table data columns are separated by this delimiter.

The default delimiter is the tab character.

• --rowid

Adds a ROWID column providing information about the fragments in which rows are stored.

• --gci

Adds a GCI column to the output showing the global checkpoint at which each row was last updated. See Section 17.1, “MySQL Cluster Overview”, and Section 17.5.6.2, “MySQL Cluster Log Events”, for more information about checkpoints.

• --gci64

Adds a ROW$GCI64 column to the output showing the global checkpoint at which each row was last updated, as well as the number of the epoch in which this update occurred.

• --tupscan, -t

Scan the table in the order of the tuples.

• --nodata

Causes any table data to be omitted.

Sample Output

Output from a MySQL SELECT statement:

```
mysql> SELECT * FROM ctest1.fish;
+----+-----------+
<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>shark</td>
</tr>
<tr>
<td>6</td>
<td>puffer</td>
</tr>
<tr>
<td>2</td>
<td>tuna</td>
</tr>
<tr>
<td>4</td>
<td>manta ray</td>
</tr>
<tr>
<td>5</td>
<td>grouper</td>
</tr>
<tr>
<td>1</td>
<td>guppy</td>
</tr>
</tbody>
</table>
+----+-----------+
6 rows in set (0.04 sec)
```

Output from the equivalent invocation of ndb_select_all:

```
shell> ./ndb_select_all -c localhost fish -d ctest1
id  name
  3  [shark]
  6  [puffer]
  2  [tuna]
  4  [manta ray]
```

17.4.16 `ndb_select_count` — Print Row Counts for NDB Tables

`ndb_select_count` prints the number of rows in one or more NDB tables. With a single table, the result is equivalent to that obtained by using the MySQL statement `SELECT COUNT(*) FROM tbl_name`.

Usage

```bash
ndb_select_count [-c connection_string] -d db_name tbl_name[, tbl_name2[, ...]]
```

The following table includes options that are specific to the MySQL Cluster native backup restoration program `ndb_select_count`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndb_select_count`), see Section 17.4.20, "Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs".

Table 17.38 This table describes command-line options for the `ndb_select_count` program
You can obtain row counts from multiple tables in the same database by listing the table names separated by spaces when invoking this command, as shown under **Sample Output**.

### Sample Output

```
shell> /ndb_select_count -c localhost -d ctest1 fish dogs
6 records in table fish
4 records in table dogs
NDBT_ProgramExit: 0 - OK
```

#### 17.4.17 ndb_show_tables — Display List of NDB Tables

The following table includes options that are specific to the MySQL Cluster native backup restoration program `ndb_show_tables`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndb_show_tables`), see Section 17.4.20, "Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs".

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--database=string</code>, -d</td>
<td>Specifies the database in which the table is found</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td><code>--loops=#</code>, -l</td>
<td>Number of times to repeat output</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td><code>--type=#</code>, -t</td>
<td>Limit output to objects of this type</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td><code>--unqualified</code>, -u</td>
<td>Do not qualify table names</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td><code>--parsable</code>, -p</td>
<td>Return output suitable for MySQL LOAD DATA INFILE statement</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td><code>--show-temp-status</code></td>
<td>Show table temporary flag</td>
<td>All MySQL 5.0 based releases</td>
</tr>
</tbody>
</table>

#### Usage

```
ndb_show_tables [-c connection_string]
```

- **--database, -d**
  
  Specifies the name of the database in which the tables are found.

- **--loops, -l**
  
  Specifies the number of times the utility should execute. This is 1 when this option is not specified, but if you do use the option, you must supply an integer argument for it.

- **--parsable, -p**
  
  Using this option causes the output to be in a format suitable for use with `LOAD DATA INFILE`.  

---

This documentation is for an older version. If you're using the most current version, select the documentation for that version with the version switch in the upper right corner of the online documentation, or by downloading a newer PDF or EPUB file.
17.4.18 ndb_size.pl — NDBCLUSTER Size Requirement Estimator

This is a Perl script that can be used to estimate the amount of space that would be required by a MySQL database if it were converted to use the NDBCLUSTER storage engine. Unlike the other utilities discussed in this section, it does not require access to a MySQL Cluster (in fact, there is no reason for it to do so). However, it does need to access the MySQL server on which the database to be tested resides.

Requirements

• A running MySQL server. The server instance does not have to provide support for MySQL Cluster.

• A working installation of Perl.

• The DBI and HTML::Template modules, both of which can be obtained from CPAN if they are not already part of your Perl installation. (Many Linux and other operating system distributions provide their own packages for one or both of these libraries.)

• The ndb_size.tmpl template file, which you should be able to find in the share/mysql directory of your MySQL installation. This file should be copied or moved into the same directory as ndb_size.pl—if it is not there already—before running the script.

• A MySQL user account having the necessary privileges. If you do not wish to use an existing account, then creating one using GRANT USAGE ON `db_name`.*—where `db_name` is the name of the database to be examined—is sufficient for this purpose.

ndb_size.pl and ndb_size.tmpl can also be found in the MySQL sources in storage/ndb/tools.

Usage

```
perl ndb_size.pl db_name hostname username password > file_name.html
```
The command shown connects to the MySQL server at \texttt{hostname} using the account of the user \texttt{username} having the password \texttt{password}, analyzes all of the tables in database \texttt{db_name}, and generates a report in HTML format which is directed to the file \texttt{file_name.html}. (Without the redirection, the output is sent to \texttt{stdout}.)

The output from this script includes the following information:

- Minimum values for the DataMemory, IndexMemory, MaxNoOfTables, MaxNoOfAttributes, MaxNoOfOrderedIndexes, MaxNoOfUniqueHashIndexes, and MaxNoOfTriggers configuration parameters required to accommodate the tables analyzed.

- Memory requirements for all of the tables, attributes, ordered indexes, and unique hash indexes defined in the database.

- The IndexMemory and DataMemory required per table and table row.

### 17.4.19 \texttt{ndb\_waiter} — Wait for MySQL Cluster to Reach a Given Status

\texttt{ndb\_waiter} repeatedly (each 100 milliseconds) prints out the status of all cluster data nodes until either the cluster reaches a given status or the \texttt{--timeout} limit is exceeded, then exits. By default, it waits for the cluster to achieve \texttt{STARTED} status, in which all nodes have started and connected to the cluster. This can be overridden using the \texttt{--no-contact} and \texttt{--not-started} options (see \texttt{Additional Options}).

The node states reported by this utility are as follows:

- \texttt{NO\_CONTACT}: The node cannot be contacted.

- \texttt{UNKNOWN}: The node can be contacted, but its status is not yet known. Usually, this means that the node has received a \texttt{START} or \texttt{RESTART} command from the management server, but has not yet acted on it.

- \texttt{NOT\_STARTED}: The node has stopped, but remains in contact with the cluster. This is seen when restarting the node using the management client's \texttt{RESTART} command.

- \texttt{STARTING}: The node's \texttt{ndbd} process has started, but the node has not yet joined the cluster.

- \texttt{STARTED}: The node is operational, and has joined the cluster.

- \texttt{SHUTTING\_DOWN}: The node is shutting down.

- \texttt{SINGLE\_USER\_MODE}: This is shown for all cluster data nodes when the cluster is in single user mode.

The following table includes options that are specific to the MySQL Cluster native backup restoration program \texttt{ndb\_waiter}. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including \texttt{ndb\_waiter}), seeSection 17.4.20, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”.

\begin{table}
\centering
\begin{tabular}{|c|l|l|}
\hline
\textbf{Format} & \textbf{Description} & \textbf{Added or Removed} \\
\hline
\texttt{--no-contact,} & Wait for cluster to reach NO CONTACT state & All MySQL 5.0 based releases \\
\texttt{-n} & & \\
\texttt{--not-started} & Wait for cluster to reach NOT STARTED state & All MySQL 5.0 based releases \\
\texttt{--single-user} & Wait for cluster to enter single user mode & All MySQL 5.0 based releases \\
\texttt{--timeout=\#,} & Wait this many seconds, then exit whether or not cluster has & All MySQL 5.0 based releases \\
\hline
\end{tabular}
\end{table}
### ndb_waiter — Wait for MySQL Cluster to Reach a Given Status

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>-t</td>
<td>reached desired state; default is 2 minutes (120 seconds)</td>
<td></td>
</tr>
</tbody>
</table>

### Usage

```bash
ndb_waiter [-c connection_string]
```

### Additional Options

- **--no-contact, -n**
  
  Instead of waiting for the **STARTED** state, `ndb_waiter` continues running until the cluster reaches **NO_CONTACT** status before exiting.

- **--not-started**

  Instead of waiting for the **STARTED** state, `ndb_waiter` continues running until the cluster reaches **NOT_STARTED** status before exiting.

- **--timeout=seconds, -t seconds**

  Time to wait. The program exits if the desired state is not achieved within this number of seconds. The default is 120 seconds (1200 reporting cycles).

- **--single-user**

  The program waits for the cluster to enter single user mode.

### Sample Output

Shown here is the output from `ndb_waiter` when run against a 4-node cluster in which two nodes have been shut down and then started again manually. Duplicate reports (indicated by "...") are omitted.

```
shell> ./ndb_waiter -c localhost

Connecting to mgmsrv at (localhost)
State node 1 STARTED
State node 2 NO_CONTACT
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED
...
State node 1 STARTED
State node 2 UNKNOWN
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED
...
State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED
...
State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 UNKNOWN
```
Waiting for cluster enter state STARTED

State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED

State node 1 STARTED
State node 2 STARTED
State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED

State node 1 STARTED
State node 2 STARTED
State node 3 STARTED
State node 4 STARTED
Waiting for cluster enter state STARTED

NDBT_ProgramExit: 0 - OK

Note
If no connection string is specified, then ndb_waiter tries to connect to a management on localhost, and reports Connecting to mgmsrv at (null).

17.4.20 Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs

All MySQL Cluster programs accept the options described in this section, with the following exceptions:

- `mysqld`
- `ndb_print_backup_file`
- `ndb_print_schema_file`
- `ndb_print_sys_file`

Users of earlier MySQL Cluster versions should note that some of these options have been changed to make them consistent with one another as well as with `mysqld`. You can use the `--help` option with any MySQL Cluster program—with the exception of `ndb_print_backup_file`, `ndb_print_schema_file`, and `ndb_print_sys_file`—to view a list of the options which the program supports.

The options in the following table are common to all MySQL Cluster executables (except those noted previously in this section).

Table 17.41 This table describes command-line options common to all MySQL Cluster programs

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--help, --usage, -?</td>
<td>Display help message and exit</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td>Format</td>
<td>Description</td>
<td>Added or Removed</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
<td>------------------</td>
</tr>
<tr>
<td>--character-sets-dir=dir_name</td>
<td>Directory where character sets are installed</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td>--core-file</td>
<td>Write core on errors (defaults to TRUE in debug builds)</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td>--debug=options</td>
<td>Enable output from debug calls. Can be used only for versions compiled with debugging enabled</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td>--ndb-connectstring=connectstring</td>
<td>Set connection string for connecting to ndb_mgmd. Syntax: [nodeid=&lt;id&gt;]; [host=]&lt;hostname&gt;[:&lt;port&gt;].</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td>--connect-string=connectstring, -c</td>
<td>Overrides entries specified in NDB_CONNECTSTRING or my.cnf.</td>
<td></td>
</tr>
<tr>
<td>--ndb-mgmd-host=host[:port]</td>
<td>Set the host (and port, if desired) for connecting to management server.</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td>--ndb-nodeid=#</td>
<td>Set node id for this node</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td>--ndb-optimized-node-selection</td>
<td>Select nodes for transactions in a more optimal way.</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td>--ndb-shm</td>
<td>Allow for optimization using shared memory connections where available (was EXPERIMENTAL, later REMOVED).</td>
<td>All MySQL 5.0 based releases</td>
</tr>
<tr>
<td>--version, -V</td>
<td>Output version information and exit</td>
<td>All MySQL 5.0 based releases</td>
</tr>
</tbody>
</table>

For options specific to individual MySQL Cluster programs, see Section 17.4, “MySQL Cluster Programs”.

See `mysqld Command Options for MySQL Cluster`, for `mysqld` options relating to MySQL Cluster.

- **--help, --usage, -?**

  **Command-Line Format**

  ```
  --help
  --usage
  ```

  Prints a short list with descriptions of the available command options.

- **--ndb-connectstring=connection_string, --connect-string=connection_string, -c connection_string**

  **Command-Line Format**

  ```
  --ndb-connectstring=connectstring
  --connect-string=connectstring
  ```

  **Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>localhost:1186</td>
</tr>
</tbody>
</table>

  This option takes a MySQL Cluster connection string that specifies the management server for the application to connect to, as shown here:
**--ndb-mgmd-host=host[:port]**

Command-Line Format: `--ndb-mgmd-host=host[:port]`

<table>
<thead>
<tr>
<th>Permitted Values</th>
<th>Type</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>string</td>
<td>localhost:1186</td>
</tr>
</tbody>
</table>

Can be used to set the host and port number of a single management server for the program to connect to. If the program requires node IDs or references to multiple management servers (or both) in its connection information, use the `--ndb-connectstring` option instead.

**--character-sets-dir=dir_name**

Command-Line Format: `--character-sets-dir=dir_name`

<table>
<thead>
<tr>
<th>Permitted Values</th>
<th>Type</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>directory name</td>
<td></td>
</tr>
</tbody>
</table>

Tells the program where to find character set information.

**--connect-string=connection_string, -c connection_string**

Command-Line Format: `--ndb-connectstring=connectstring`

<table>
<thead>
<tr>
<th>Permitted Values</th>
<th>Type</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>string</td>
<td>localhost:1186</td>
</tr>
</tbody>
</table>

`connection_string` sets the connection string to the management server as a command option.

**--core-file**

Command-Line Format: `--core-file`

<table>
<thead>
<tr>
<th>Permitted Values</th>
<th>Type</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>boolean</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Write a core file if the program dies. The name and location of the core file are system-dependent. (For MySQL Cluster programs nodes running on Linux, the default location is the program's working directory—for a data node, this is the node's `DataDir`.) For some systems, there may be restrictions or limitations; for example, it might be necessary to execute `ulimit -c unlimited` before starting the server. Consult your system documentation for detailed information.

If MySQL Cluster was built using the `--debug` option for `configure`, then `--core-file` is enabled by default. For regular builds, `--core-file` is disabled by default.

**--debug[=options]**

Command-Line Format: `--debug=options`

<table>
<thead>
<tr>
<th>Permitted Values</th>
<th>Type</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>string</td>
<td>d:t:0,/tmp/ndb_restore.trace</td>
</tr>
</tbody>
</table>
This option can be used only for versions compiled with debugging enabled. It is used to enable output from debug calls in the same manner as for the `mysqld` process.

- **--ndb-nodeid=#**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-nodeid=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>Type numeric</td>
</tr>
<tr>
<td></td>
<td>Default 0</td>
</tr>
</tbody>
</table>

Sets this node's MySQL Cluster node ID. The range of permitted values depends on the type of the node (data, management, or API) and the version of the MySQL Cluster software which is running on it. See Section 17.1.5.2, “Limits and Differences of MySQL Cluster from Standard MySQL Limits”, for more information.

- **--ndb-optimized-node-selection**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-optimized-node-selection</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>Type boolean</td>
</tr>
<tr>
<td></td>
<td>Default TRUE</td>
</tr>
</tbody>
</table>

Optimize selection of nodes for transactions. Enabled by default.

- **--version, -V**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--version</th>
</tr>
</thead>
</table>

Prints the MySQL Cluster version number of the executable. The version number is relevant because not all versions can be used together, and the MySQL Cluster startup process verifies that the versions of the binaries being used can co-exist in the same cluster. This is also important when performing an online (rolling) software upgrade or downgrade of MySQL Cluster.

See Section 17.5.5, “Performing a Rolling Restart of a MySQL Cluster”), for more information.

- **--ndb-shm**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ndb-shm</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>Type boolean</td>
</tr>
<tr>
<td></td>
<td>Default FALSE</td>
</tr>
</tbody>
</table>

In MySQL 5.0, this experimental option allows an application to use shared memory for optimization when this is available. It is not intended for production use. **--ndb-shm** is deprecated in MySQL 5.1, and is removed from all MySQL Cluster programs in MySQL Cluster NDB 7.0 and later.

### 17.5 Management of MySQL Cluster

Managing a MySQL Cluster involves a number of tasks, the first of which is to configure and start MySQL Cluster. This is covered in Section 17.3, “MySQL Cluster Configuration”, and Section 17.4, “MySQL Cluster Programs”.

The next few sections cover the management of a running MySQL Cluster.

For information about security issues relating to management and deployment of a MySQL Cluster, see Section 17.5.10, “MySQL Cluster Security Issues”.

There are essentially two methods of actively managing a running MySQL Cluster. The first of these is through the use of commands entered into the management client whereby cluster status can be
checked, log levels changed, backups started and stopped, and nodes stopped and started. The second method involves studying the contents of the cluster log ndb_node_id_cluster.log; this is usually found in the management server’s DataDir directory, but this location can be overridden using the LogDestination option—see Section 17.3.3.4, “Defining a MySQL Cluster Management Server”, for details. (Recall that node_id represents the unique identifier of the node whose activity is being logged.) The cluster log contains event reports generated by ndbd. It is also possible to send cluster log entries to a Unix system log.

In addition, some aspects of the cluster’s operation can be monitored from an SQL node using the SHOW ENGINE NDB STATUS statement. See Section 13.7.5.12, “SHOW ENGINE Syntax”, for more information.

17.5.1 Summary of MySQL Cluster Start Phases

This section provides a simplified outline of the steps involved when MySQL Cluster data nodes are started. More complete information can be found in MySQL Cluster Start Phases.

These phases are the same as those reported in the output from the node_id STATUS command in the management client. (See Section 17.5.2, “Commands in the MySQL Cluster Management Client”, for more information about this command.)

Start types. There are several different startup types and modes, as shown here:

• Initial Start. The cluster starts with a clean file system on all data nodes. This occurs either when the cluster started for the very first time, or when all data nodes are restarted using the --initial option.

  **Note**

Disk Data files are not removed when restarting a node using --initial.

• System Restart. The cluster starts and reads data stored in the data nodes. This occurs when the cluster has been shut down after having been in use, when it is desired for the cluster to resume operations from the point where it left off.

• Node Restart. This is the online restart of a cluster node while the cluster itself is running.

• Initial Node Restart. This is the same as a node restart, except that the node is reinitialized and started with a clean file system.

Setup and initialization (Phase -1). Prior to startup, each data node (ndbd process) must be initialized. Initialization consists of the following steps:

1. Obtain a node ID
2. Fetch configuration data
3. Allocate ports to be used for inter-node communications
4. Allocate memory according to settings obtained from the configuration file

When a data node or SQL node first connects to the management node, it reserves a cluster node ID. To make sure that no other node allocates the same node ID, this ID is retained until the node has managed to connect to the cluster and at least one ndbd reports that this node is connected. This retention of the node ID is guarded by the connection between the node in question and ndb_mgmd.

Normally, in the event of a problem with the node, the node disconnects from the management server, the socket used for the connection is closed, and the reserved node ID is freed. However, if a node is disconnected abruptly—for example, due to a hardware failure in one of the cluster hosts, or because of network issues—the normal closing of the socket by the operating system may not take place. In
this case, the node ID continues to be reserved and not released until a TCP timeout occurs 10 or so
minutes later.

To take care of this problem, you can use PURGE STALE SESSIONS. Running this statement forces
all reserved node IDs to be checked; any that are not being used by nodes actually connected to the
cluster are then freed.

Beginning with MySQL 5.1.11, timeout handling of node ID assignments is implemented. This performs
the ID usage checks automatically after approximately 20 seconds, so that PURGE STALE SESSIONS
should no longer be necessary in a normal Cluster start.

After each data node has been initialized, the cluster startup process can proceed. The stages which
the cluster goes through during this process are listed here:

• **Phase 0.** The NDBFS and NDBCNTR blocks start (see NDB Kernel Blocks). The cluster file system
  is cleared, if the cluster was started with the `--initial` option.

• **Phase 1.** In this stage, all remaining NDB kernel blocks are started. Cluster connections are set
  up, inter-block communications are established, and Cluster heartbeats are started. In the case of a
  node restart, API node connections are also checked.

  **Note**
  When one or more nodes hang in Phase 1 while the remaining node or
  nodes hang in Phase 2, this often indicates network problems. One possible
  cause of such issues is one or more cluster hosts having multiple network
  interfaces. Another common source of problems causing this condition is the
  blocking of TCP/IP ports needed for communications between cluster nodes.
  In the latter case, this is often due to a misconfigured firewall.

• **Phase 2.** The NDBCNTR kernel block checks the states of all existing nodes. The master node is
  chosen, and the cluster schema file is initialized.

• **Phase 3.** The DBLQH and DBTC kernel blocks set up communications between them. The startup
  type is determined; if this is a restart, the DBDIH block obtains permission to perform the restart.

• **Phase 4.** For an initial start or initial node restart, the redo log files are created. The number of
  these files is equal to NoOfFragmentLogFiles.

  For a system restart:
  • Read schema or schemas.
  • Read data from the local checkpoint.
  • Apply all redo information until the latest restorable global checkpoint has been reached.

  For a node restart, find the tail of the redo log.

• **Phase 5.** Most of the database-related portion of a data node start is performed during this phase.
  For an initial start or system restart, a local checkpoint is executed, followed by a global checkpoint.
  Periodic checks of memory usage begin during this phase, and any required node takeovers are
  performed.

• **Phase 6.** In this phase, node groups are defined and set up.

• **Phase 7.** The arbitrator node is selected and begins to function. The next backup ID is set, as
  is the backup disk write speed. Nodes reaching this start phase are marked as Started. It is now
  possible for API nodes (including SQL nodes) to connect to the cluster. connect.

• **Phase 8.** If this is a system restart, all indexes are rebuilt (by DBDIH).

• **Phase 9.** The node internal startup variables are reset.
17.5.2 Commands in the MySQL Cluster Management Client

In addition to the central configuration file, a cluster may also be controlled through a command-line interface available through the management client ndb_mgm. This is the primary administrative interface to a running cluster.

Commands for the event logs are given in Section 17.5.6, “Event Reports Generated in MySQL Cluster”; commands for creating backups and restoring from them are provided in Section 17.5.3, “Online Backup of MySQL Cluster”.

The management client has the following basic commands. In the listing that follows, node_id denotes either a database node ID or the keyword ALL, which indicates that the command should be applied to all of the cluster's data nodes.

17.5.3 Online Backup of MySQL Cluster

The next few sections describe how to prepare for and then to create a MySQL Cluster backup using the functionality for this purpose found in the ndb_mgm management client. To distinguish this type of backup from a backup made using mysqldump, we sometimes refer to it as a “native” MySQL Cluster backup. (For information about the creation of backups with mysqldump, see Section 4.5.4, “mysqldump — A Database Backup Program”.) Restoration of MySQL Cluster backups is done using the ndb_restore utility provided with the MySQL Cluster distribution; for information about ndb_restore and its use in restoring MySQL Cluster backups, see Section 17.4.14, “ndb_restore — Restore a MySQL Cluster Backup”.

17.5.3.1 MySQL Cluster Backup Concepts

A backup is a snapshot of the database at a given time. The backup consists of three main parts:

- **Metadata.** The names and definitions of all database tables
- **Table records.** The data actually stored in the database tables at the time that the backup was made
- **Transaction log.** A sequential record telling how and when data was stored in the database

- **Phase 100 (OBSOLETE).** Formerly, it was at this point during a node restart or initial node restart that API nodes could connect to the node and begin to receive events. Currently, this phase is empty.

- **Phase 101.** At this point in a node restart or initial node restart, event delivery is handed over to the node joining the cluster. The newly joined node takes over responsibility for delivering its primary data to subscribers. This phase is also referred to as SUMA handover phase.

After this process is completed for an initial start or system restart, transaction handling is enabled. For a node restart or initial node restart, completion of the startup process means that the node may now act as a transaction coordinator.
A control file containing control information and metadata. Each node saves the same table definitions (for all tables in the cluster) to its own version of this file.

- **BACKUP-backup_id-0.node_id.data**

A data file containing the table records, which are saved on a per-fragment basis. That is, different nodes save different fragments during the backup. The file saved by each node starts with a header that states the tables to which the records belong. Following the list of records there is a footer containing a checksum for all records.

- **BACKUP-backup_id.node_id.log**

A log file containing records of committed transactions. Only transactions on tables stored in the backup are stored in the log. Nodes involved in the backup save different records because different nodes host different database fragments.

In the listing above, *backup_id* stands for the backup identifier and *node_id* is the unique identifier for the node creating the file.

### 17.5.3.2 Using The MySQL Cluster Management Client to Create a Backup

Before starting a backup, make sure that the cluster is properly configured for performing one. (See Section 17.5.3.3, “Configuration for MySQL Cluster Backups”.)

The `START BACKUP` command is used to create a backup:

```sql
START BACKUP [backup_id] [wait_option]
```

**wait_option**:
- `WAIT {STARTED | COMPLETED} | NOWAIT`

Successive backups are automatically identified sequentially, so the *backup_id*, an integer greater than or equal to 1, is optional; if it is omitted, the next available value is used. If an existing *backup_id* value is used, the backup fails with the error `Backup failed: file already exists`. If used, the *backup_id* must follow `START BACKUP` immediately, before any other options are used.

The maximum supported value for *backup_id* in MySQL 5.0 is 2147483648 ($2^{31}$). (Bug #43042)

**Note**

If you start a backup using `ndb_mgm -e "START BACKUP"`, the *backup_id* is required.

The `wait_option` can be used to determine when control is returned to the management client after a `START BACKUP` command is issued, as shown in the following list:

- `WAIT STARTED`
- `WAIT COMPLETED`
- `WAIT NOWAIT`

`WAIT COMPLETED` is the default.

The procedure for creating a backup consists of the following steps:

1. Start the management client (`ndb_mgm`), if it not running already.
2. Execute the `START BACKUP` command. This produces several lines of output indicating the progress of the backup, as shown here:

```sql
ndb_mgm> START BACKUP
Waiting for completed, this may take several minutes
Node 2: Backup 1 started from node 1
```
3.  The management client indicates with a message like this one that the backup has started:

   ```
   Node 2: Backup 1 started from node 1 completed
   StartGCP: 177 StopGCP: 180
   #Records: 7362 #LogRecords: 0
   Data: 453648 bytes Log: 0 bytes
   ndb_mgm>
   ```

4.  As is the case for the notification that the backup has started, `backup_id` is the unique identifier for this particular backup, and `node_id` is the node ID of the management server that is coordinating the backup with the data nodes. This output is accompanied by additional information including relevant global checkpoints, the number of records backed up, and the size of the data, as shown here:

   ```
   Node 2: Backup 1 started from node 1 completed
   StartGCP: 177 StopGCP: 180
   #Records: 7362 #LogRecords: 0
   Data: 453648 bytes Log: 0 bytes
   ndb_mgm>
   ```

It is also possible to perform a backup from the system shell by invoking `ndb_mgm` with the `-e` or `--execute` option, as shown in this example:

   ```
   shell> ndb_mgm -e "START BACKUP 6 WAIT COMPLETED"
   ```

When using `START BACKUP` in this way, you must specify the backup ID.

Cluster backups are created by default in the `BACKUP` subdirectory of the `DataDir` on each data node. This can be overridden for one or more data nodes individually, or for all cluster data nodes in the `config.ini` file using the `BackupDataDir` configuration parameter as discussed in Identifying Data Nodes. The backup files created for a backup with a given `backup_id` are stored in a subdirectory named `BACKUP-backup_id` in the backup directory.

To abort a backup that is already in progress:

1. Start the management client.

2. Execute this command:

   ```
   ndb_mgm> ABORT BACKUP backup_id
   ```

   The number `backup_id` is the identifier of the backup that was included in the response of the management client when the backup was started (in the message `Backup backup_id started from node management_node_id`).

3. The management client will acknowledge the abort request with `Abort of backup backup_id ordered`.

   **Note**

   At this point, the management client has not yet received a response from the cluster data nodes to this request, and the backup has not yet actually been aborted.

4. After the backup has been aborted, the management client will report this fact in a manner similar to what is shown here:

   ```
   Node 1: Backup 3 started from 5 has been aborted.
   Error: 1321 - Backup aborted by user request: Permanent error: User defined error
   ```
Node 3: Backup 3 started from 5 has been aborted.
  Error: 1323 - 1323: Permanent error: Internal error
Node 2: Backup 3 started from 5 has been aborted.
  Error: 1323 - 1323: Permanent error: Internal error
Node 4: Backup 3 started from 5 has been aborted.
  Error: 1323 - 1323: Permanent error: Internal error

In this example, we have shown sample output for a cluster with 4 data nodes, where the sequence number of the backup to be aborted is 3, and the management node to which the cluster management client is connected has the node ID 5. The first node to complete its part in aborting the backup reports that the reason for the abort was due to a request by the user. (The remaining nodes report that the backup was aborted due to an unspecified internal error.)

Note
There is no guarantee that the cluster nodes respond to an ABORT BACKUP command in any particular order.

The Backup backup_id started from node management_node_id has been aborted messages mean that the backup has been terminated and that all files relating to this backup have been removed from the cluster file system.

It is also possible to abort a backup in progress from a system shell using this command:

shell> ndb_mgm -e "$ABORT BACKUP backup_id"

Note
If there is no backup having the ID backup_id running when an ABORT BACKUP is issued, the management client makes no response, nor is it indicated in the cluster log that an invalid abort command was sent.

17.5.3.3 Configuration for MySQL Cluster Backups

Five configuration parameters are essential for backup:

- **BackupDataBufferSize**
  The amount of memory used to buffer data before it is written to disk.

- **BackupLogBufferSize**
  The amount of memory used to buffer log records before these are written to disk.

- **BackupMemory**
  The total memory allocated in a database node for backups. This should be the sum of the memory allocated for the backup data buffer and the backup log buffer.

- **BackupWriteSize**
  The default size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

- **BackupMaxWriteSize**
  The maximum size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.
More detailed information about these parameters can be found in Backup Parameters.

17.5.3.4 MySQL Cluster Backup Troubleshooting

If an error code is returned when issuing a backup request, the most likely cause is insufficient memory or disk space. You should check that there is enough memory allocated for the backup.

Important

If you have set BackupDataBufferSize and BackupLogBufferSize and their sum is greater than 4MB, then you must also set BackupMemory as well. See BackupMemory.

You should also make sure that there is sufficient space on the hard drive partition of the backup target.

NDB does not support repeatable reads, which can cause problems with the restoration process. Although the backup process is “hot”, restoring a MySQL Cluster from backup is not a 100% “hot” process. This is due to the fact that, for the duration of the restore process, running transactions get nonrepeatable reads from the restored data. This means that the state of the data is inconsistent while the restore is in progress.

17.5.4 MySQL Server Usage for MySQL Cluster

`mysqld` is the traditional MySQL server process. To be used with MySQL Cluster, `mysqld` needs to be built with support for the NDBCLUSTER storage engine, as it is in the precompiled binaries available from http://dev.mysql.com/downloads/. If you build MySQL from source, you must invoke configure with the `--with-ndbcluster` option to enable NDB Cluster storage engine support.

For information about other MySQL server options and variables relevant to MySQL Cluster in addition to those discussed in this section, see Section 17.3.3.7, “MySQL Server Options and Variables for MySQL Cluster”.

If the `mysqld` binary has been built with Cluster support, the NDBCLUSTER storage engine is still disabled by default. You can use either of two possible options to enable this engine:

- Use `--ndbcluster` as a startup option on the command line when starting `mysqld`.
- Insert a line containing `NDBCLUSTER` in the `[mysqld]` section of your `my.cnf` file.

An easy way to verify that your server is running with the NDBCLUSTER storage engine enabled is to issue the `SHOW ENGINES` statement in the MySQL Monitor (`mysql`). You should see the value `YES` as the Support value in the row for NDBCLUSTER. If you see `NO` in this row or if there is no such row displayed in the output, you are not running an NDB-enabled version of MySQL. If you see `DISABLED` in this row, you need to enable it in either one of the two ways just described.

To read cluster configuration data, the MySQL server requires at a minimum three pieces of information:

- The MySQL server's own cluster node ID
- The host name or IP address for the management server (MGM node)
- The number of the TCP/IP port on which it can connect to the management server

Node IDs can be allocated dynamically, so it is not strictly necessary to specify them explicitly.

The `mysqld` parameter `ndb-connectstring` is used to specify the connection string either on the command line when starting `mysqld` or in `my.cnf`. The connection string contains the host name or IP address where the management server can be found, as well as the TCP/IP port it uses.
Performing a Rolling Restart of a MySQL Cluster

In the following example, `ndb_mgmd.mysql.com` is the host where the management server resides, and the management server listens for cluster messages on port 1186:

```
shell> mysqld --ndbcluster --ndb-connectstring=ndb_mgmd.mysql.com:1186
```

See Section 17.3.3.2, “MySQL Cluster Connection Strings”, for more information on connection strings.

Given this information, the MySQL server will be a full participant in the cluster. (We often refer to a `mysqld` process running in this manner as an SQL node.) It will be fully aware of all cluster data nodes as well as their status, and will establish connections to all data nodes. In this case, it is able to use any data node as a transaction coordinator and to read and update node data.

You can see in the `mysql` client whether a MySQL server is connected to the cluster using `SHOW PROCESSLIST`. If the MySQL server is connected to the cluster, and you have the `PROCESS` privilege, then the first row of the output is as shown here:

```
mysql> SHOW PROCESSLIST \G
*************************** 1. row ***************************
Id: 1
User: system user
Host: 
db: 
Command: Daemon
Time: 1
State: Waiting for event from ndbcluster
Info: NULL
```

17.5.5 Performing a Rolling Restart of a MySQL Cluster

This section discusses how to perform a rolling restart of a MySQL Cluster installation, so called because it involves stopping and starting (or restarting) each node in turn, so that the cluster itself remains operational. This is often done as part of a rolling upgrade or rolling downgrade, where high availability of the cluster is mandatory and no downtime of the cluster as a whole is permissible. Where we refer to upgrades, the information provided here also generally applies to downgrades as well.

There are a number of reasons why a rolling restart might be desirable. These are described in the next few paragraphs.

**Configuration change.**
To make a change in the cluster's configuration, such as adding an SQL node to the cluster, or setting a configuration parameter to a new value.

**MySQL Cluster software upgrade or downgrade.** To upgrade the cluster to a newer version of the MySQL Cluster software (or to downgrade it to an older version). This is usually referred to as a “rolling upgrade” (or “rolling downgrade”, when reverting to an older version of MySQL Cluster).

**Change on node host.** To make changes in the hardware or operating system on which one or more MySQL Cluster node processes are running.
System reset (cluster reset).
To reset the cluster because it has reached an undesirable state. In such cases it is often desirable to
reload the data and metadata of one or more data nodes. This can be done any of three ways:

- Start each data node process (`ndbd`) with the `--initial` option, which forces the data node to
clear its file system and to reload all MySQL Cluster data and metadata from the other data nodes.

- Create a backup using the `ndb_mgm` client `BACKUP` command prior to performing the restart.
Following the upgrade, restore the node or nodes using `ndb_restore`.

See Section 17.5.3, “Online Backup of MySQL Cluster”, and Section 17.4.14, “`ndb_restore` —
Restore a MySQL Cluster Backup”, for more information.

- Use `mysqldump` to create a backup prior to the upgrade; afterward, restore the dump using `LOAD
DATA INFILE`.

Resource Recovery.
To free memory previously allocated to a table by successive `INSERT` and `DELETE` operations, for re-
use by other MySQL Cluster tables.

The process for performing a rolling restart may be generalized as follows:

1. Stop all cluster management nodes (`ndb_mgmd` processes), reconfigure them, then restart them.
2. Stop, reconfigure, then restart each cluster data node (`ndbd` process) in turn.
3. Stop, reconfigure, then restart each cluster SQL node (`mysqld` process) in turn.

The specifics for implementing a given rolling upgrade depend upon the changes being made. A more
detailed view of the process is presented here:

Figure 17.6 MySQL Cluster Rolling Restarts By Type

<table>
<thead>
<tr>
<th>RESTART TYPE:</th>
<th>Cluster Configuration Change</th>
<th>Cluster Software Upgrade or Degradation</th>
<th>Change on Node Host</th>
<th>Cluster Reset</th>
</tr>
</thead>
<tbody>
<tr>
<td>A. Management node (ndbd and ndb_mgmd processes)...</td>
<td>1. Stop all ndb_mgmd processes</td>
<td>Replace ndbd binary with new version</td>
<td>1. Stop all ndb_mgmd processes</td>
<td>1. Stop all ndb_mgmd processes</td>
</tr>
<tr>
<td></td>
<td>2. Make changes in global configuration file(s)</td>
<td>3. Start all ndb_mgmd processes</td>
<td></td>
<td>2. Make changes in hardware, operating system, or both</td>
</tr>
<tr>
<td></td>
<td>5. Start all ndbd and ndb_mgmd processes</td>
<td></td>
<td></td>
<td>4. Start all ndbd and ndb_mgmd processes</td>
</tr>
<tr>
<td></td>
<td>6. Start all ndbd and ndb_mgmd processes</td>
<td></td>
<td></td>
<td>5. Start all ndbd and ndb_mgmd processes</td>
</tr>
</tbody>
</table>

B. For each data node (ndbd process)... (OR)

| | 1. Stop ndbd | Restart ndbd | 1. Stop ndbd | 1. Stop ndbd |
| | 2. Make changes in hardware, operating system, or both | 3. Start ndbd | | 2. Make changes in hardware, operating system, or both |

C. For each SQL node (mysqld process)... (OR)

| | 1. Stop mysqld | Restart mysqld | 1. Stop mysqld | 1. Stop mysqld |
| | 2. Replace mysqld binary with new version | 3. Start mysqld | | 2. Replace mysqld binary with new version |
In the previous diagram, the **Stop** and **Start** steps indicate that the process must be stopped completely using a shell command (such as `kill` on most Unix systems) or the management client **STOP** command, then started again from a system shell by invoking the `ndbd` or `ndb_mgmd` executable as appropriate.

**Restart** indicates that the process may be restarted using the `ndb_mgm` management client **RESTART** command (see Section 17.5.2, “Commands in the MySQL Cluster Management Client”).

---

**Important**

When performing an upgrade or downgrade of the MySQL Cluster software, you must upgrade or downgrade the management nodes first, then the data nodes, and finally the SQL nodes. Doing so in any other order may leave the cluster in an unusable state.

### 17.5.6 Event Reports Generated in MySQL Cluster

In this section, we discuss the types of event logs provided by MySQL Cluster, and the types of events that are logged.

MySQL Cluster provides two types of event log:

- **The cluster log**, which includes events generated by all cluster nodes. The cluster log is the log recommended for most uses because it provides logging information for an entire cluster in a single location.

  By default, the cluster log is saved to a file named `ndb_node_id_cluster.log` (where `node_id` is the node ID of the management server) in the management server's `DataDir`.

  Cluster logging information can also be sent to `stdout` or a `syslog` facility in addition to or instead of being saved to a file, as determined by the values set for the `DataDir` and `LogDestination` configuration parameters. See Section 17.3.3.4, “Defining a MySQL Cluster Management Server”, for more information about these parameters.

- **Node logs** are local to each node.

  Output generated by node event logging is written to the file `ndb_node_id_out.log` (where `node_id` is the node's node ID) in the node's `DataDir`. Node event logs are generated for both management nodes and data nodes.

  Node logs are intended to be used only during application development, or for debugging application code.

Both types of event logs can be set to log different subsets of events.

Each reportable event can be distinguished according to three different criteria:

- **Category**: This can be any one of the following values: **STARTUP**, **SHUTDOWN**, **STATISTICS**, **CHECKPOINT**, **NODERESTART**, **CONNECTION**, **ERROR**, or **INFO**.

- **Priority**: This is represented by one of the numbers from 0 to 15 inclusive, where 0 indicates “most important” and 15 “least important.”

- **Severity Level**: This can be any one of the following values: **ALERT**, **CRITICAL**, **ERROR**, **WARNING**, **INFO**, or **DEBUG**.

Both the cluster log and the node log can be filtered on these properties.

The format used in the cluster log is as shown here:
2007-01-26 19:35:55 [MgmSrvr] INFO -- Node 1: Data usage is 2%(60 32K pages of total 2560)

Each line in the cluster log contains the following information:

• A timestamp in `YYYY-MM-DD HH:MM:SS` format.
• The type of node which is performing the logging. In the cluster log, this is always `[MgmSrvr]`.
• The severity of the event.
• The ID of the node reporting the event.
• A description of the event. The most common types of events to appear in the log are connections and disconnections between different nodes in the cluster, and when checkpoints occur. In some cases, the description may contain status information.

### 17.5.6.1 MySQL Cluster Logging Management Commands

`ndb_mgm` supports a number of management commands related to the cluster log. In the listing that follows, `node_id` denotes either a database node ID or the keyword `ALL`, which indicates that the command should be applied to all of the cluster's data nodes.

- **CLUSTERLOG ON**
  Turns the cluster log on.

- **CLUSTERLOG OFF**
  Turns the cluster log off.

- **CLUSTERLOG INFO**
  Provides information about cluster log settings.

  - `node_id CLUSTERLOG category=threshold`
    Logs `category` events with priority less than or equal to `threshold` in the cluster log.

  - **CLUSTERLOG FILTER severity_level**
    Toggles cluster logging of events of the specified `severity_level`.

The following table describes the default setting (for all data nodes) of the cluster log category threshold. If an event has a priority with a value lower than or equal to the priority threshold, it is reported in the cluster log.
Note that events are reported per data node, and that the threshold can be set to different values on different nodes.

<table>
<thead>
<tr>
<th>Category</th>
<th>Default threshold (All data nodes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>STARTUP</td>
<td>7</td>
</tr>
<tr>
<td>SHUTDOWN</td>
<td>7</td>
</tr>
<tr>
<td>STATISTICS</td>
<td>7</td>
</tr>
<tr>
<td>CHECKPOINT</td>
<td>7</td>
</tr>
<tr>
<td>NODERESTART</td>
<td>7</td>
</tr>
<tr>
<td>CONNECTION</td>
<td>7</td>
</tr>
<tr>
<td>ERROR</td>
<td>15</td>
</tr>
<tr>
<td>INFO</td>
<td>7</td>
</tr>
</tbody>
</table>

The **STATISTICS** category can provide a great deal of useful data. See Section 17.5.6.3, “Using CLUSTERLOG STATISTICS in the MySQL Cluster Management Client”, for more information.

Thresholds are used to filter events within each category. For example, a **STARTUP** event with a priority of 3 is not logged unless the threshold for **STARTUP** is set to 3 or higher. Only events with priority 3 or lower are sent if the threshold is 3.

The following table shows the event severity levels.

<table>
<thead>
<tr>
<th>Severity Level Value</th>
<th>Severity</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>ALERT</td>
<td>A condition that should be corrected immediately, such as a corrupted system database</td>
</tr>
<tr>
<td>2</td>
<td>CRITICAL</td>
<td>Critical conditions, such as device errors or insufficient resources</td>
</tr>
<tr>
<td>3</td>
<td>ERROR</td>
<td>Conditions that should be corrected, such as configuration errors</td>
</tr>
<tr>
<td>4</td>
<td>WARNING</td>
<td>Conditions that are not errors, but that might require special handling</td>
</tr>
<tr>
<td>5</td>
<td>INFO</td>
<td>Informational messages</td>
</tr>
<tr>
<td>6</td>
<td>DEBUG</td>
<td>Debugging messages used for NDBCLUSTER development</td>
</tr>
</tbody>
</table>

Event severity levels can be turned on or off (using **CLUSTERLOG FILTER**—see above). If a severity level is turned on, then all events with a priority less than or equal to the category thresholds are logged. If the severity level is turned off then no events belonging to that severity level are logged.

**Important**

Cluster log levels are set on a per **ndb_mgmd**, per subscriber basis. This means that, in a MySQL Cluster with multiple management servers, using a **CLUSTERLOG** command in an instance of **ndb_mgm** connected to one management server affects only logs generated by that management server but not by any of the others. This also means that, should one of the management servers be restarted, only logs generated by that management server are affected by the resetting of log levels caused by the restart.
Event Reports Generated in MySQL Cluster

17.5.6.2 MySQL Cluster Log Events

An event report reported in the event logs has the following format:

```
datetime [string] severity -- message
```

For example:

```
```

This section discusses all reportable events, ordered by category and severity level within each category.

In the event descriptions, GCP and LCP mean “Global Checkpoint” and “Local Checkpoint”, respectively.

**CONNECTION Events**

These events are associated with connections between Cluster nodes.

<table>
<thead>
<tr>
<th>Event</th>
<th>Priority</th>
<th>Severity Level</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data nodes connected</td>
<td>8</td>
<td>INFO</td>
<td>Data nodes connected</td>
</tr>
<tr>
<td>data nodes disconnected</td>
<td>8</td>
<td>INFO</td>
<td>Data nodes disconnected</td>
</tr>
<tr>
<td>Communication closed</td>
<td>8</td>
<td>INFO</td>
<td>SQL node or data node connection closed</td>
</tr>
<tr>
<td>Communication opened</td>
<td>8</td>
<td>INFO</td>
<td>SQL node or data node connection opened</td>

</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• Lost arbitrator node (X) &lt;error msg&gt; [state=(Y)]</td>
</tr>
</tbody>
</table>

#### STATISTICS Events

The following events are of a statistical nature. They provide information such as numbers of transactions and other operations, amount of data sent or received by individual nodes, and memory usage.

<table>
<thead>
<tr>
<th>Event</th>
<th>Priority</th>
<th>Severity</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Report job scheduling statistics</td>
<td>9</td>
<td>INFO</td>
<td>Mean internal job scheduling statistics</td>
</tr>
<tr>
<td>Sent number of bytes</td>
<td>9</td>
<td>INFO</td>
<td>Mean number of bytes sent to node (X)</td>
</tr>
<tr>
<td>Received # of bytes</td>
<td>9</td>
<td>INFO</td>
<td>Mean number of bytes received from node (X)</td>
</tr>
<tr>
<td>Report transaction statistics</td>
<td>8</td>
<td>INFO</td>
<td>Numbers of: transactions, commits, reads, simple reads, writes, concurrent operations, attribute information, and aborts</td>
</tr>
<tr>
<td>Report operations</td>
<td>8</td>
<td>INFO</td>
<td>Number of operations</td>
</tr>
<tr>
<td>Report table create</td>
<td>7</td>
<td>INFO</td>
<td></td>
</tr>
<tr>
<td>Memory usage</td>
<td>5</td>
<td>INFO</td>
<td>Data and index memory usage (80%, 90%, and 100%)</td>
</tr>
</tbody>
</table>

#### ERROR Events

This documentation is for an older version. If you're
These events relate to Cluster errors and warnings. The presence of one or more of these generally indicates that a major malfunction or failure has occurred.

<table>
<thead>
<tr>
<th>Event</th>
<th>Priority</th>
<th>Severity</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dead due to missed heartbeat</td>
<td>8</td>
<td>ALERT</td>
<td>Node X declared “dead” due to missed heartbeat</td>
</tr>
<tr>
<td>Transporter errors</td>
<td>2</td>
<td>ERROR</td>
<td></td>
</tr>
<tr>
<td>Transporter warnings</td>
<td>8</td>
<td>WARNING</td>
<td></td>
</tr>
<tr>
<td>Missed heartbeats</td>
<td>8</td>
<td>WARNING</td>
<td>Node X missed heartbeat #Y</td>
</tr>
<tr>
<td>General warning events</td>
<td>2</td>
<td>WARNING</td>
<td></td>
</tr>
</tbody>
</table>

**INFO Events**

These events provide general information about the state of the cluster and activities associated with Cluster maintenance, such as logging and heartbeat transmission.

<table>
<thead>
<tr>
<th>Event</th>
<th>Priority</th>
<th>Severity</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sent heartbeat</td>
<td>12</td>
<td>INFO</td>
<td>Heartbeat sent to node X</td>
</tr>
<tr>
<td>Create log bytes</td>
<td>11</td>
<td>INFO</td>
<td>Log part, log file, MB</td>
</tr>
<tr>
<td>General information</td>
<td>2</td>
<td>INFO</td>
<td>events</td>
</tr>
</tbody>
</table>

**Note**

Sent heartbeat events are available only if MySQL Cluster was compiled with **VM_TRACE** enabled.

### 17.5.6.3 Using CLUSTERLOG STATISTICS in the MySQL Cluster Management Client

The **NDB** management client's **CLUSTERLOG STATISTICS** command can provide a number of useful statistics in its output. Counters providing information about the state of the cluster are updated at 5-second reporting intervals by the transaction coordinator (TC) and the local query handler (LQH), and written to the cluster log.

**Transaction coordinator statistics.** Each transaction has one transaction coordinator, which is chosen by one of the following methods:

- In a round-robin fashion
- By communication proximity

**Note**

You can determine which TC selection method is used for transactions started from a given SQL node using the **ndb_optimized_node_selection** system variable. For more information, see MySQL Cluster System Variables.

All operations within the same transaction use the same transaction coordinator, which reports the following statistics:

- **Trans count.** This is the number transactions started in the last interval using this TC as the transaction coordinator. Any of these transactions may have committed, have been aborted, or remain uncommitted at the end of the reporting interval.

**Note**

Transactions do not migrate between TCs.
- **Commit count.** This is the number of transactions using this TC as the transaction coordinator that were committed in the last reporting interval. Because some transactions committed in this reporting interval may have started in a previous reporting interval, it is possible for Commit count to be greater than Trans count.

- **Read count.** This is the number of primary key read operations using this TC as the transaction coordinator that were started in the last reporting interval, including simple reads. This count also includes reads performed as part of unique index operations. A unique index read operation generates 2 primary key read operations—1 for the hidden unique index table, and 1 for the table on which the read takes place.

- **Simple read count.** This is the number of simple read operations using this TC as the transaction coordinator that were started in the last reporting interval. This is a subset of Read count. Because the value of Simple read count is incremented at a different point in time from Read count, it can lag behind Read count slightly, so it is conceivable that Simple read count is not equal to Read count for a given reporting interval, even if all reads made during that time were in fact simple reads.

- **Write count.** This is the number of primary key write operations using this TC as the transaction coordinator that were started in the last reporting interval. This includes all inserts, updates, writes and deletes, as well as writes performed as part of unique index operations.

  **Note**

  A unique index update operation can generate multiple PK read and write operations on the index table and on the base table.

- **AttrInfoCount.** This is the number of 32-bit data words received in the last reporting interval for primary key operations using this TC as the transaction coordinator. For reads, this is proportional to the number of columns requested. For inserts and updates, this is proportional to the number of columns written, and the size of their data. For delete operations, this is usually zero. Unique index operations generate multiple PK operations and so increase this count. However, data words sent to describe the PK operation itself, and the key information sent, are not counted here. Attribute information sent to describe columns to read for scans, or to describe ScanFilters, is also not counted in AttrInfoCount.

- **Concurrent Operations.** This is the number of primary key or scan operations using this TC as the transaction coordinator that were started during the last reporting interval but that were not completed. Operations increment this counter when they are started and decrement it when they are completed; this occurs after the transaction commits. Dirty reads and writes—as well as failed operations—decrement this counter. The maximum value that Concurrent Operations can have is the maximum number of operations that a TC block can support; currently, this is \((2 \times \text{MaxNoOfConcurrentOperations}) + 16 + \text{MaxNoOfConcurrentTransactions}\). (For more information about these configuration parameters, see the Transaction Parameters section of Section 17.3.3.5, “Defining MySQL Cluster Data Nodes”.)

- **Abort count.** This is the number of transactions using this TC as the transaction coordinator that were aborted during the last reporting interval. Because some transactions that were aborted in the last reporting interval may have started in a previous reporting interval, Abort count can sometimes be greater than Trans count.

- **Scans.** This is the number of table scans using this TC as the transaction coordinator that were started during the last reporting interval. This does not include range scans (that is, ordered index scans).

- **Range scans.** This is the number of ordered index scans using this TC as the transaction coordinator that were started in the last reporting interval.

**Local query handler statistics (Operations).** There is 1 cluster event per local query handler block (that is, 1 per data node process). Operations are recorded in the LQH where the data they are operating on resides.
A single transaction may operate on data stored in multiple LQH blocks.

The **Operations** statistic provides the number of local operations performed by this LQH block in the last reporting interval, and includes all types of read and write operations (insert, update, write, and delete operations). This also includes operations used to replicate writes—for example, in a 2-replica cluster, the write to the primary replica is recorded in the primary LQH, and the write to the backup will be recorded in the backup LQH. Unique key operations may result in multiple local operations; however, this does *not* include local operations generated as a result of a table scan or ordered index scan, which are not counted.

**Process scheduler statistics.** In addition to the statistics reported by the transaction coordinator and local query handler, each *ndbd* process has a scheduler which also provides useful metrics relating to the performance of a MySQL Cluster. This scheduler runs in an infinite loop; during each loop the scheduler performs the following tasks:

1. Read any incoming messages from sockets into a job buffer.
2. Check whether there are any timed messages to be executed; if so, put these into the job buffer as well.
3. Execute (in a loop) any messages in the job buffer.
4. Send any distributed messages that were generated by executing the messages in the job buffer.
5. Wait for any new incoming messages.

Process scheduler statistics include the following:

- **Mean Loop Counter.** This is the number of loops executed in the third step from the preceding list. This statistic increases in size as the utilization of the TCP/IP buffer improves. You can use this to monitor changes in performance as you add new data node processes.

- **Mean send size and Mean receive size.** These statistics enable you to gauge the efficiency of, respectively writes and reads between nodes. The values are given in bytes. Higher values mean a lower cost per byte sent or received; the maximum value is 64K.

To cause all cluster log statistics to be logged, you can use the following command in the *ndb* management client:

```
ndb_mgm> ALL CLUSTERLOG STATISTICS=15
```

Setting the threshold for **STATISTICS** to 15 causes the cluster log to become very verbose, and to grow quite rapidly in size, in direct proportion to the number of cluster nodes and the amount of activity in the MySQL Cluster.

For more information about MySQL Cluster management client commands relating to logging and reporting, see Section 17.5.6.1, “MySQL Cluster Logging Management Commands”.

### 17.5.7 MySQL Cluster Log Messages

This section contains information about the messages written to the cluster log in response to different cluster log events. It provides additional, more specific information on *ndb* transporter errors.

#### 17.5.7.1 MySQL Cluster: Messages in the Cluster Log

The following table lists the most common *ndb* cluster log messages. For information about the cluster log, log events, and event types, see Section 17.5.6, “Event Reports Generated in MySQL Cluster”.

These log messages also correspond to log event types in the MGM API; see The Ndb_logevent_type Type, for related information of interest to Cluster API developers.

<table>

17.5.8 MySQL Cluster Single User Mode

Single user mode enables the database administrator to restrict access to the database system to a single API node, such as a MySQL server (SQL node) or an instance of ndb_restore. When entering single user mode, connections to all other API nodes are closed gracefully and all running transactions are aborted. No new transactions are permitted to start.

Once the cluster has entered single user mode, only the designated API node is granted access to the database.

You can use the ALL STATUS command to see when the cluster has entered single user mode.

Example:

```
ndb_mgm> ENTER SINGLE USER MODE 5
```

After this command has executed and the cluster has entered single user mode, the API node whose node ID is 5 becomes the cluster's only permitted user.

The node specified in the preceding command must be an API node; attempting to specify any other type of node will be rejected.

Note

When the preceding command is invoked, all transactions running on the designated node are aborted, the connection is closed, and the server must be restarted.

The command EXIT SINGLE USER MODE changes the state of the cluster's data nodes from single user mode to normal mode. API nodes—such as MySQL Servers—waiting for a connection (that is, waiting for the cluster to become ready and available), are again permitted to connect. The API node denoted as the single-user node continues to run (if still connected) during and after the state change.

Example:

```
ndb_mgm> EXIT SINGLE USER MODE
```

There are two recommended ways to handle a node failure when running in single user mode:

- Method 1:
  1. Finish all single user mode transactions
  2. Issue the EXIT SINGLE USER MODE command
3. Restart the cluster’s data nodes

- Method 2:
  Restart database nodes prior to entering single user mode.

17.5.9 Quick Reference: MySQL Cluster SQL Statements

This section discusses several SQL statements that can prove useful in managing and monitoring a MySQL server that is connected to a MySQL Cluster, and in some cases provide information about the cluster itself.

- **SHOW ENGINE NDB STATUS, SHOW ENGINE NDBCLUSTER STATUS**

  The output of this statement contains information about the server’s connection to the cluster, creation and usage of MySQL Cluster objects, and binary logging for MySQL Cluster replication.

  See Section 13.7.5.12, “SHOW ENGINE Syntax”, for a usage example and more detailed information.

- **SHOW ENGINES [LIKE 'NDB%']**

  This statement can be used to determine whether or not clustering support is enabled in the MySQL server, and if so, whether it is active.

  See Section 13.7.5.13, “SHOW ENGINES Syntax”, for more detailed information.

- **SHOW VARIABLES LIKE 'NDB%'**

  This statement provides a list of most server system variables relating to the NDB storage engine, and their values, as shown here:

  ```
  mysql> SHOW VARIABLES LIKE 'NDB%';
  +-----------------+-------+
  | Variable_name   | Value |
  +-----------------+-------+
  | ndb_autoincrement_prefetch_sz | 32    |
  | ndb_cache_check_time       | 0     |
  | ndb_extra_logging         | 0     |
  | ndb_force_send            | ON    |
  | ndb_index_stat_cache_entries | 32    |
  | ndb_index_stat_enable     | OFF   |
  | ndb_index_stat_update_freq | 20    |
  | ndb_report_thresh_binlog_epoch_slip | 3     |
  | ndb_report_thresh_binlog_mem_usage | 10   |
  | ndb_use_copying_alter_table | OFF   |
  | ndb_use_exact_count       | ON    |
  | ndb_use_transactions     | ON    |
  +-----------------+-------+
  ```

  See Section 5.1.4, “Server System Variables”, for more information.

- **SHOW STATUS LIKE 'NDB%'

  This statement shows at a glance whether or not the MySQL server is acting as a cluster SQL node, and if so, it provides the MySQL server’s cluster node ID, the host name and port for the cluster management server to which it is connected, and the number of data nodes in the cluster, as shown here:

  ```
  mysql> SHOW STATUS LIKE 'NDB%';
  ```
If the MySQL server was built with clustering support, but it is not connected to a cluster, all rows in
the output of this statement contain a zero or an empty string:

```
mysql> SHOW STATUS LIKE 'NDB\%';
```

If the MySQL server was built with clustering support, but it is not connected to a cluster, all rows in
the output of this statement contain a zero or an empty string:

```
mysql> SHOW STATUS LIKE 'NDB\%';
```

See also Section 13.7.5.32, “SHOW STATUS Syntax”.

17.5.10 MySQL Cluster Security Issues

This section discusses security considerations to take into account when setting up and running
MySQL Cluster.

Topics covered in this chapter include the following:

- MySQL Cluster and network security issues
- Configuration issues relating to running MySQL Cluster securely
- MySQL Cluster and the MySQL privilege system
- MySQL standard security procedures as applicable to MySQL Cluster

17.5.10.1 MySQL Cluster Security and Networking Issues

In this section, we discuss basic network security issues as they relate to MySQL Cluster. It is
extremely important to remember that MySQL Cluster “out of the box” is not secure; you or your
network administrator must take the proper steps to ensure that your cluster cannot be compromised
over the network.

Cluster communication protocols are inherently insecure, and no encryption or similar security
measures are used in communications between nodes in the cluster. Because network speed and
latency have a direct impact on the cluster’s efficiency, it is also not advisable to employ SSL or
other encryption to network connections between nodes, as such schemes will effectively slow
communications.

It is also true that no authentication is used for controlling API node access to a MySQL Cluster. As
with encryption, the overhead of imposing authentication requirements would have an adverse impact
on Cluster performance.

In addition, there is no checking of the source IP address for either of the following when accessing the
cluster:

- SQL or API nodes using “free slots” created by empty [mysqld] or [api] sections in the
  config.ini file

This means that, if there are any empty [mysqld] or [api] sections in the config.ini file, then
any API nodes (including SQL nodes) that know the management server’s host name (or IP address)
and port can connect to the cluster and access its data without restriction. (See Section 17.5.10.2, “MySQL Cluster and MySQL Privileges”, for more information about this and related issues.)

**Note**

You can exercise some control over SQL and API node access to the cluster by specifying a `HostName` parameter for all `[mysqld]` and `[api]` sections in the `config.ini` file. However, this also means that, should you wish to connect an API node to the cluster from a previously unused host, you need to add an `[api]` section containing its host name to the `config.ini` file.

More information is available elsewhere in this chapter about the `HostName` parameter. Also see Section 17.3.1, “Quick Test Setup of MySQL Cluster”, for configuration examples using `HostName` with API nodes.

- Any `ndb_mgm` client

This means that any cluster management client that is given the management server's host name (or IP address) and port (if not the standard port) can connect to the cluster and execute any management client command. This includes commands such as `ALL STOP` and `SHUTDOWN`.

For these reasons, it is necessary to protect the cluster on the network level. The safest network configuration for Cluster is one which isolates connections between Cluster nodes from any other network communications. This can be accomplished by any of the following methods:

1. Keeping Cluster nodes on a network that is physically separate from any public networks. This option is the most dependable; however, it is the most expensive to implement.

   We show an example of a MySQL Cluster setup using such a physically segregated network here:

   **Figure 17.7 MySQL Cluster with Hardware Firewall**

   ![MySQL Cluster with Hardware Firewall](image)

   This setup has two networks, one private (solid box) for the Cluster management servers and data nodes, and one public (dotted box) where the SQL nodes reside. (We show the management and data nodes connected using a gigabit switch since this provides the best performance.) Both networks are protected from the outside by a hardware firewall, sometimes also known as a network-based firewall.

   This network setup is safest because no packets can reach the cluster's management or data nodes from outside the network—and none of the cluster's internal communications can reach the outside—without going through the SQL nodes, as long as the SQL nodes do not permit any
packets to be forwarded. This means, of course, that all SQL nodes must be secured against hacking attempts.

**Important**

With regard to potential security vulnerabilities, an SQL node is no different from any other MySQL server. See Section 6.1.3, “Making MySQL Secure Against Attackers”, for a description of techniques you can use to secure MySQL servers.

2. Using one or more software firewalls (also known as host-based firewalls) to control which packets pass through to the cluster from portions of the network that do not require access to it. In this type of setup, a software firewall must be installed on every host in the cluster which might otherwise be accessible from outside the local network.

The host-based option is the least expensive to implement, but relies purely on software to provide protection and so is the most difficult to keep secure.

This type of network setup for MySQL Cluster is illustrated here:

**Figure 17.8 MySQL Cluster with Software Firewalls**

Using this type of network setup means that there are two zones of MySQL Cluster hosts. Each cluster host must be able to communicate with all of the other machines in the cluster, but only those hosting SQL nodes (dotted box) can be permitted to have any contact with the outside, while those in the zone containing the data nodes and management nodes (solid box) must be isolated from any machines that are not part of the cluster. Applications using the cluster and user of those applications must *not* be permitted to have direct access to the management and data node hosts.

To accomplish this, you must set up software firewalls that limit the traffic to the type or types shown in the following table, according to the type of node that is running on each cluster host computer:
<table>
<thead>
<tr>
<th>Type of Node to be Accessed</th>
<th>Traffic to Permit</th>
</tr>
</thead>
</table>
| SQL or API node            | • It originates from the IP address of a management or data node (using any TCP or UDP port).  
                           | • It originates from within the network in which the cluster resides and is on the port that your application is using. |
| Data node or Management node | • It originates from the IP address of a management or data node (using any TCP or UDP port).  
                              | • It originates from the IP address of an SQL or API node. |

Any traffic other than that shown in the table for a given node type should be denied.

The specifics of configuring a firewall vary from firewall application to firewall application, and are beyond the scope of this Manual. `iptables` is a very common and reliable firewall application, which is often used with `APF` as a front end to make configuration easier. You can (and should) consult the documentation for the software firewall that you employ, should you choose to implement a MySQL Cluster network setup of this type, or of a “mixed” type as discussed under the next item.

3. It is also possible to employ a combination of the first two methods, using both hardware and software to secure the cluster—that is, using both network-based and host-based firewalls. This is between the first two schemes in terms of both security level and cost. This type of network setup keeps the cluster behind the hardware firewall, but permits incoming packets to travel beyond the router connecting all cluster hosts to reach the SQL nodes.

One possible network deployment of a MySQL Cluster using hardware and software firewalls in combination is shown here:

**Figure 17.9 MySQL Cluster with a Combination of Hardware and Software Firewalls**

In this case, you can set the rules in the hardware firewall to deny any external traffic except to SQL nodes and API nodes, and then permit traffic to them only on the ports required by your application.

Whatever network configuration you use, remember that your objective from the viewpoint of keeping the cluster secure remains the same—to prevent any unessential traffic from reaching the cluster while ensuring the most efficient communication between the nodes in the cluster.
Because MySQL Cluster requires large numbers of ports to be open for communications between nodes, the recommended option is to use a segregated network. This represents the simplest way to prevent unwanted traffic from reaching the cluster.

**Note**

If you wish to administer a MySQL Cluster remotely (that is, from outside the local network), the recommended way to do this is to use `ssh` or another secure login shell to access an SQL node host. From this host, you can then run the management client to access the management server safely, from within the Cluster's own local network.

Even though it is possible to do so in theory, it is not recommended to use `ndb_mgm` to manage a Cluster directly from outside the local network on which the Cluster is running. Since neither authentication nor encryption takes place between the management client and the management server, this represents an extremely insecure means of managing the cluster, and is almost certain to be compromised sooner or later.

### 17.5.10.2 MySQL Cluster and MySQL Privileges

In this section, we discuss how the MySQL privilege system works in relation to MySQL Cluster and the implications of this for keeping a MySQL Cluster secure.

Standard MySQL privileges apply to MySQL Cluster tables. This includes all MySQL privilege types (`SELECT` privilege, `UPDATE` privilege, `DELETE` privilege, and so on) granted on the database, table, and column level. As with any other MySQL Server, user and privilege information is stored in the `mysql` system database. The SQL statements used to grant and revoke privileges on `NDB` tables, databases containing such tables, and columns within such tables are identical in all respects with the `GRANT` and `REVOKE` statements used in connection with database objects involving any (other) MySQL storage engine. The same thing is true with respect to the `CREATE USER` and `DROP USER` statements.

It is important to keep in mind that the MySQL grant tables use the MyISAM storage engine. Because of this, those tables are not duplicated or shared among MySQL servers acting as SQL nodes in a MySQL Cluster. By way of example, suppose that two SQL nodes A and B are connected to the same MySQL Cluster, which has an `NDB` table named `mytable` in a database named `mydb`, and that you execute an SQL statement on server A that creates a new user `jon@localhost` and grants this user the `SELECT` privilege on that table:

```sql
mysql> GRANT SELECT ON mydb.mytable -> TO jon@localhost IDENTIFIED BY 'mypass';
```

This user is *not* created on server B. For this to take place, the statement must also be run on server B. Similarly, statements run on server A and affecting the privileges of existing users on server A do not affect users on server B unless those statements are actually run on server B as well.

In other words, *changes in users and their privileges do not automatically propagate between SQL nodes*. Synchronization of privileges between SQL nodes must be done either manually or by scripting an application that periodically synchronizes the privilege tables on all SQL nodes in the cluster.

Conversely, because there is no way in MySQL to deny privileges (privileges can either be revoked or not granted in the first place, but not denied as such), there is no special protection for `NDB` tables on one SQL node from users that have privileges on another SQL node. The most far-reaching example of this is the MySQL `root` account, which can perform any action on any database object. In combination with empty `[mysqld]` or `[api]` sections of the `config.ini` file, this account can be especially dangerous. To understand why, consider the following scenario:

- The `config.ini` file contains at least one empty `[mysqld]` or `[api]` section. This means that the Cluster management server performs no checking of the host from which a MySQL Server (or other API node) accesses the MySQL Cluster.
MySQL Cluster Security Issues

- There is no firewall, or the firewall fails to protect against access to the Cluster from hosts external to the network.

- The host name or IP address of the Cluster's management server is known or can be determined from outside the network.

If these conditions are true, then anyone, anywhere can start a MySQL Server with 

```bash
--ndbcluster
--ndb-connectstring=management_host
```

and access the Cluster. Using the MySQL root account, this person can then perform the following actions:

- Execute a `SHOW DATABASES` statement to obtain a list of all databases that exist in the cluster
- Execute a `SHOW TABLES FROM some_database` statement to obtain a list of all NDB tables in a given database
- Run any legal MySQL statements on any of those tables, such as:
  - `SELECT * FROM some_table` to read all the data from any table
  - `DELETE FROM some_table` to delete all the data from a table
  - `DESCRIBE some_table` or `SHOW CREATE TABLE some_table` to determine the table schema
  - `UPDATE some_table SET column1 = any_value1` to fill a table column with “garbage” data; this could actually cause much greater damage than simply deleting all the data

Even more insidious variations might include statements like these:

```sql
UPDATE some_table SET an_int_column = an_int_column + 1
```

or

```sql
UPDATE some_table SET a_varchar_column = REVERSE(a_varchar_column)
```

Such malicious statements are limited only by the imagination of the attacker.

The only tables that would be safe from this sort of mayhem would be those tables that were created using storage engines other than NDB, and so not visible to a “rogue” SQL node.

Note

A user who can log in as root can also access the INFORMATION_SCHEMA database and its tables, and so obtain information about databases, tables, stored routines, scheduled events, and any other database objects for which metadata is stored in INFORMATION_SCHEMA.

It is also a very good idea to use different passwords for the root accounts on different cluster SQL nodes.

In sum, you cannot have a safe MySQL Cluster if it is directly accessible from outside your local network.

Important

*Never leave the MySQL root account password empty.* This is just as true when running MySQL as a MySQL Cluster SQL node as it is when running it as a standalone (non-Cluster) MySQL Server, and should be done as part of the MySQL installation process before configuring the MySQL Server as an SQL node in a MySQL Cluster.
You should never convert the system tables in the mysql database to use the NDB storage engine. There are a number of reasons why you should not do this, but the most important reason is this: *Many of the SQL statements that affect mysql tables storing information about user privileges, stored routines, scheduled events, and other database objects cease to function if these tables are changed to use any storage engine other than MyISAM.* This is a consequence of various MySQL Server internals which are not expected to change in the foreseeable future.

If you need to synchronize mysql system tables between SQL nodes, you can use standard MySQL replication to do so, or employ a script to copy table entries between the MySQL servers.

**Summary.** The two most important points to remember regarding the MySQL privilege system with regard to MySQL Cluster are:

1. Users and privileges established on one SQL node do not automatically exist or take effect on other SQL nodes in the cluster.

   Conversely, removing a user or privilege on one SQL node in the cluster does not remove the user or privilege from any other SQL nodes.

2. Once a MySQL user is granted privileges on an NDB table from one SQL node in a MySQL Cluster, that user can “see” any data in that table regardless of the SQL node from which the data originated.

### 17.5.10.3 MySQL Cluster and MySQL Security Procedures

In this section, we discuss MySQL standard security procedures as they apply to running MySQL Cluster.

In general, any standard procedure for running MySQL securely also applies to running a MySQL Server as part of a MySQL Cluster. First and foremost, you should always run a MySQL Server as the mysql system user; this is no different from running MySQL in a standard (non-Cluster) environment. The mysql system account should be uniquely and clearly defined. Fortunately, this is the default behavior for a new MySQL installation. You can verify that the mysqld process is running as the system user mysql by using the system command such as the one shown here:

```
shell> ps aux | grep mysql
root     10467  0.0  0.1   3616  1380 pts/3    S    11:53   0:00 /bin/sh ./mysqld_safe --ndbcluster --ndb-connectstring=localhost:1186
mysql    10512  0.2  2.5  58528 26636 pts/3    Sl   11:53   0:00 /usr/local/mysql/libexec/mysqld --basedir=/usr/local/mysql --datadir=/usr/local/mysql/var --user=mysql --ndbcluster --ndb-connectstring=localhost:1186 --pid-file=/usr/local/mysql/var/mothra.pid --log-error=/usr/local/mysql/var/mothra.err
jon      10579  0.0  0.0   2736   688 pts/0    S+   11:54   0:00 grep mysql
```

If the mysqld process is running as any other user than mysql, you should immediately shut it down and restart it as the mysql user. If this user does not exist on the system, the mysql user account should be created, and this user should be part of the mysql user group; in this case, you should also make sure that the MySQL DataDir on this system is owned by the mysql user, and that the SQL node’s my.cnf file includes user=mysql in the [mysqld] section. Alternatively, you can start the server with --user=mysql on the command line, but it is preferable to use the my.cnf option, since you might forget to use the command-line option and so have mysqld running as another user unintentionally. The mysqld_safe startup script forces MySQL to run as the mysql user.

!!! Important

Never run mysqld as the system root user. Doing so means that potentially any file on the system can be read by MySQL, and thus—should MySQL be compromised—by an attacker.

As mentioned in the previous section (see *Section 17.5.10.2, “MySQL Cluster and MySQL Privileges”*), you should always set a root password for the MySQL Server as soon as you have it running. You
should also delete the anonymous user account that is installed by default. You can accomplish these tasks using the following statements:

```
shell> mysql -u root
mysql> UPDATE mysql.user
   ->   SET Password=PASSWORD('secure_password')
   ->   WHERE User='root';
mysql> DELETE FROM mysql.user
   ->   WHERE User='';
mysql> FLUSH PRIVILEGES;
```

Be very careful when executing the `DELETE` statement not to omit the `WHERE` clause, or you risk deleting all MySQL users. Be sure to run the `FLUSH PRIVILEGES` statement as soon as you have modified the `mysql.user` table, so that the changes take immediate effect. Without `FLUSH PRIVILEGES`, the changes do not take effect until the next time that the server is restarted.

Note

Many of the MySQL Cluster utilities such as `ndb_show_tables`, `ndb_desc`, and `ndb_select_all` also work without authentication and can reveal table names, schemas, and data. By default these are installed on Unix-style systems with the permissions `wxr-xr-x` (755), which means they can be executed by any user that can access the `mysql/bin` directory.

See Section 17.4, "MySQL Cluster Programs", for more information about these utilities.

18.6 Binary Logging of Stored Programs ..................................................... 1739

This chapter discusses stored programs and views, which are database objects defined in terms of SQL code that is stored on the server for later execution.

Stored programs include these objects:

• Stored routines, that is, stored procedures and functions. A stored procedure is invoked using the `CALL` statement. A procedure does not have a return value but can modify its parameters for later inspection by the caller. It can also generate result sets to be returned to the client program. A stored function is used much like a built-in function. you invoke it in an expression and it returns a value during expression evaluation.

• Triggers. A trigger is a named database object that is associated with a table and that is activated when a particular event occurs for the table, such as an insert or update.

Views are stored queries that when referenced produce a result set. A view acts as a virtual table.

This chapter describes how to use stored programs and views. The following sections provide additional information about SQL syntax for statements related to these objects:

• For each object type, there are `CREATE`, `ALTER`, and `DROP` statements that control which objects exist and how they are defined. See Section 13.1, “Data Definition Statements”.

• The `CALL` statement is used to invoke stored procedures. See Section 13.2.1, “CALL Syntax”.

• Stored program definitions include a body that may use compound statements, loops, conditionals, and declared variables. See Section 13.6, “MySQL Compound-Statement Syntax”.

18.1 Defining Stored Programs

Each stored program contains a body that consists of an SQL statement. This statement may be a compound statement made up of several statements separated by semicolon (\;\;) characters. For example, the following stored procedure has a body made up of a `BEGIN ... END` block that contains a `SET` statement and a `REPEAT` loop that itself contains another `SET` statement:

```
CREATE PROCEDURE dorepeat(p1 INT)
```
BEGIN
    SET @x = 0;
    REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
END;

If you use the `mysql` client program to define a stored program containing semicolon characters, a problem arises. By default, `mysql` itself recognizes the semicolon as a statement delimiter, so you must redefine the delimiter temporarily to cause `mysql` to pass the entire stored program definition to the server.

To redefine the `mysql` delimiter, use the `delimiter` command. The following example shows how to do this for the `dorepeat()` procedure just shown. The delimiter is changed to `//` to enable the entire definition to be passed to the server as a single statement, and then restored to `;` before invoking the procedure. This enables the `;` delimiter used in the procedure body to be passed through to the server rather than being interpreted by `mysql` itself.

```
mysql> delimiter //
mysql> CREATE PROCEDURE dorepeat(p1 INT) -> BEGIN
mysql>    -> SET @x = 0;
mysql>    -> REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
mysql>    -> END
mysql>    -> //
Query OK, 0 rows affected (0.00 sec)
mysql> delimiter ;
mysql> CALL dorepeat(1000);
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT @x;
+------+
<table>
<thead>
<tr>
<th>@x</th>
</tr>
</thead>
<tbody>
<tr>
<td>1001</td>
</tr>
</tbody>
</table>
+------+
1 row in set (0.00 sec)
```

You can redefine the delimiter to a string other than `//`, and the delimiter can consist of a single character or multiple characters. You should avoid the use of the backslash (`\`) character because that is the escape character for MySQL.

The following is an example of a function that takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use `delimiter` because the function definition contains no internal `;` statement delimiters:

```
mysql> CREATE FUNCTION hello (s CHAR(20))
mysql> RETURNS CHAR(50) DETERMINISTIC
mysql>    RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT hello('world');
+----------------+
<table>
<thead>
<tr>
<th>hello('world')</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hello, world!</td>
</tr>
</tbody>
</table>
+----------------+
1 row in set (0.00 sec)
```

### 18.2 Using Stored Routines (Procedures and Functions)

Stored routines (procedures and functions) are supported in MySQL 5.0. A stored routine is a set of SQL statements that can be stored in the server. Once this has been done, clients don't need to keep reissuing the individual statements but can refer to the stored routine instead.
Stored routines require the `proc` table in the `mysql` database. This table is created during the MySQL 5.0 installation procedure. If you are upgrading to MySQL 5.0 from an earlier version, be sure to update your grant tables to make sure that the `proc` table exists. See Section 4.4.9, "mysql_upgrade — Check Tables for MySQL Upgrade".

Stored routines can be particularly useful in certain situations:

- When multiple client applications are written in different languages or work on different platforms, but need to perform the same database operations.

- When security is paramount. Banks, for example, use stored procedures and functions for all common operations. This provides a consistent and secure environment, and routines can ensure that each operation is properly logged. In such a setup, applications and users would have no access to the database tables directly, but can only execute specific stored routines.

Stored routines can provide improved performance because less information needs to be sent between the server and the client. The tradeoff is that this does increase the load on the database server because more of the work is done on the server side and less is done on the client (application) side. Consider this if many client machines (such as Web servers) are serviced by only one or a few database servers.

Stored routines also enable you to have libraries of functions in the database server. This is a feature shared by modern application languages that enable such design internally (for example, by using classes). Using these client application language features is beneficial for the programmer even outside the scope of database use.

MySQL follows the SQL:2003 syntax for stored routines, which is also used by IBM's DB2. All syntax described here is supported and any limitations and extensions are documented where appropriate.

**Additional Resources**

- You may find the Stored Procedures User Forum of use when working with stored procedures and functions.

- For answers to some commonly asked questions regarding stored routines in MySQL, see Section A.4, "MySQL 5.0 FAQ: Stored Procedures and Functions".

- There are some restrictions on the use of stored routines. See Section C.1, “Restrictions on Stored Programs”.

- Binary logging for stored routines takes place as described in Section 18.6, “Binary Logging of Stored Programs”.

**18.2.1 Stored Routine Syntax**

A stored routine is either a procedure or a function. Stored routines are created with the `CREATE PROCEDURE` and `CREATE FUNCTION` statements (see Section 13.1.9, “CREATE PROCEDURE and CREATE FUNCTION Syntax”). A procedure is invoked using a `CALL` statement (see Section 13.2.1, “CALL Syntax”), and can only pass back values using output variables. A function can be called from inside a statement just like any other function (that is, by invoking the function's name), and can return a scalar value. The body of a stored routine can use compound statements (see Section 13.6, “MySQL Compound-Statement Syntax”).

Stored routines can be dropped with the `DROP PROCEDURE` and `DROP FUNCTION` statements (see Section 13.1.16, “DROP PROCEDURE and DROP FUNCTION Syntax”), and altered with the `ALTER PROCEDURE` and `ALTER FUNCTION` statements (see Section 13.1.3, “ALTER PROCEDURE Syntax”).

As of MySQL 5.0.1, a stored procedure or function is associated with a particular database. This has several implications:

- When the routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). `USE` statements within stored routines are not permitted.
• You can qualify routine names with the database name. This can be used to refer to a routine that is not in the current database. For example, to invoke a stored procedure `p` or function `f` that is associated with the `test` database, you can say `CALL test.p()` or `test.f()`.

• When a database is dropped, all stored routines associated with it are dropped as well.

(In MySQL 5.0.0, stored routines are global and not associated with a database. They inherit the default database from the caller. If a `USE db_name` is executed within the routine, the original default database is restored upon routine exit.)

Stored functions cannot be recursive.

Recursion in stored procedures is permitted but disabled by default. To enable recursion, set the `max_sp_recursion_depth` server system variable to a value greater than zero. Stored procedure recursion increases the demand on thread stack space. If you increase the value of `max_sp_recursion_depth`, it may be necessary to increase thread stack size by increasing the value of `thread_stack` at server startup. See Section 5.1.4, “Server System Variables”, for more information.

MySQL supports a very useful extension that enables the use of regular `SELECT` statements (that is, without using cursors or local variables) inside a stored procedure. The result set of such a query is simply sent directly to the client. Multiple `SELECT` statements generate multiple result sets, so the client must use a MySQL client library that supports multiple result sets. This means the client must use a client library from a version of MySQL at least as recent as 4.1. The client should also specify the `CLIENT_MULTI_RESULTS` option when it connects. For C programs, this can be done with the `mysql_real_connect()` C API function. See Section 20.6.7.52, “mysql_real_connect()”, and Section 20.6.16, “C API Support for Multiple Statement Execution”.

### 18.2.2 Stored Routines and MySQL Privileges

Beginning with MySQL 5.0.3, the grant system takes stored routines into account as follows:

• The `CREATE ROUTINE` privilege is needed to create stored routines.

• The `ALTER ROUTINE` privilege is needed to alter or drop stored routines. This privilege is granted automatically to the creator of a routine if necessary, and dropped from the creator when the routine is dropped.

• The `EXECUTE` privilege is required to execute stored routines. However, this privilege is granted automatically to the creator of a routine if necessary (and dropped from the creator when the routine is dropped). Also, the default `SQL SECURITY` characteristic for a routine is `DEFINER`, which enables users who have access to the database with which the routine is associated to execute the routine.

• If the `automatic_sp_privileges` system variable is 0, the `EXECUTE` and `ALTER ROUTINE` privileges are not automatically granted to and dropped from the routine creator.

• The creator of a routine is the account used to execute the `CREATE` statement for it. This might not be the same as the account named as the `DEFINER` in the routine definition.

The server manipulates the `mysql.proc` table in response to statements that create, alter, or drop stored routines. It is not supported that the server will notice manual manipulation of this table.

### 18.2.3 Stored Routine Metadata

Metadata about stored routines can be obtained as follows:

• Query the `ROUTINES` table of the `INFORMATION_SCHEMA` database. See Section 19.8, “The `INFORMATION_SCHEMA ROUTINES` Table”.

• Use the `SHOW CREATE PROCEDURE` and `SHOW CREATE FUNCTION` statements to see routine definitions. See Section 13.7.5.8, “SHOW CREATE PROCEDURE Syntax”.

This documentation is for an older version.
If you’re using the most current version, select the documentation for that version with the version switch in the upper right corner of the online documentation, or by downloading a newer PDF or EPUB file.
18.2.4 Stored Procedures, Functions, Triggers, and LAST_INSERT_ID()

Within the body of a stored routine (procedure or function) or a trigger, the value of LAST_INSERT_ID() changes the same way as for statements executed outside the body of these kinds of objects (see Section 12.13, “Information Functions”). The effect of a stored routine or trigger upon the value of LAST_INSERT_ID() that is seen by following statements depends on the kind of routine:

• If a stored procedure executes statements that change the value of LAST_INSERT_ID(), the changed value is seen by statements that follow the procedure call.

• For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so following statements do not see a changed value. (Before MySQL 5.0.12, the value is not restored and following statements do see a changed value.)

18.3 Using Triggers

Support for triggers is included beginning with MySQL 5.0.2. A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. Some uses for triggers are to perform checks of values to be inserted into a table or to perform calculations on values involved in an update.

A trigger is defined to activate when a statement inserts, updates, or deletes rows in the associated table. These row operations are trigger events. For example, rows can be inserted by INSERT or LOAD DATA statements, and an insert trigger activates for each inserted row. A trigger can be set to activate either before or after the trigger event. For example, you can have a trigger activate before each row that is inserted into a table or after each row that is updated.

Important

MySQL triggers activate only for changes made to tables by SQL statements. They do not activate for changes in tables made by APIs that do not transmit SQL statements to the MySQL Server; in particular, they are not activated by updates made using the NDB API.

To use triggers if you have upgraded to MySQL 5.0 from an older release that did not support triggers, you should upgrade your grant tables so that they contain the trigger-related privileges. See Section 4.4.9, “mysql_upgrade — Check Tables for MySQL Upgrade”.

The following sections describe the syntax for creating and dropping triggers, show some examples of how to use them, and indicate how to obtain trigger metadata.

Additional Resources

• You may find the Triggers User Forum of use when working with triggers.

• For answers to commonly asked questions regarding triggers in MySQL, see Section A.5, “MySQL 5.0 FAQ: Triggers”.

• There are some restrictions on the use of triggers; see Section C.1, “Restrictions on Stored Programs”.

If you're using the most current version, select the documentation for that version with the version switch in the upper right corner of the online documentation, or by downloading a newer PDF or EPUB file.
• Binary logging for triggers takes place as described in Section 18.6, “Binary Logging of Stored Programs”.

18.3.1 Trigger Syntax and Examples

To create a trigger or drop a trigger, use the `CREATE TRIGGER` or `DROP TRIGGER` statement, described in Section 13.1.11, “CREATE TRIGGER Syntax”, and Section 13.1.18, “DROP TRIGGER Syntax”.

Here is a simple example that associates a trigger with a table, to activate for `INSERT` operations. The trigger acts as an accumulator, summing the values inserted into one of the columns of the table.

```sql
mysql> CREATE TABLE account (acct_num INT, amount DECIMAL(10,2));
Query OK, 0 rows affected (0.03 sec)

mysql> CREATE TRIGGER ins_sum BEFORE INSERT ON account
    -> FOR EACH ROW SET @sum = @sum + NEW.amount;
Query OK, 0 rows affected (0.06 sec)
```

The `CREATE TRIGGER` statement creates a trigger named `ins_sum` that is associated with the `account` table. It also includes clauses that specify the trigger action time, the triggering event, and what to do when the trigger activates:

• The keyword `BEFORE` indicates the trigger action time. In this case, the trigger activates before each row inserted into the table. The other permitted keyword here is `AFTER`.

• The keyword `INSERT` indicates the trigger event; that is, the type of operation that activates the trigger. In the example, `INSERT` operations cause trigger activation. You can also create triggers for `DELETE` and `UPDATE` operations.

• The statement following `FOR EACH ROW` defines the trigger body; that is, the statement to execute each time the trigger activates, which occurs once for each row affected by the triggering event. In the example, the trigger body is a simple `SET` that accumulates into a user variable the values inserted into the `amount` column. The statement refers to the column as `NEW.amount` which means “the value of the `amount` column to be inserted into the new row.”

To use the trigger, set the accumulator variable to zero, execute an `INSERT` statement, and then see what value the variable has afterward:

```sql
mysql> SET @sum = 0;
mysql> INSERT INTO account VALUES(137,14.98),(141,1937.50),(97,-100.00);
mysql> SELECT @sum AS 'Total amount inserted';
```

```
+-----------------------+
| Total amount inserted |
| 1852.48               |
+-----------------------+
```

In this case, the value of `@sum` after the `INSERT` statement has executed is `14.98 + 1937.50 - 100`, or `1852.48`.

To destroy the trigger, use a `DROP TRIGGER` statement. You must specify the schema name if the trigger is not in the default schema:

```sql
mysql> DROP TRIGGER test.ins_sum;
```

If you drop a table, any triggers for the table are also dropped.

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

In addition to the requirement that trigger names be unique for a schema, there are other limitations on the types of triggers you can create. In particular, there cannot be multiple triggers for a given table
that have the same trigger event and action time. For example, you cannot have two `BEFORE UPDATE` triggers for a table. To work around this, you can define a trigger that executes multiple statements by using the `BEGIN ... END` compound statement construct after `FOR EACH ROW`. (An example appears later in this section.)

Within the trigger body, the `OLD` and `NEW` keywords enable you to access columns in the rows affected by a trigger. `OLD` and `NEW` are MySQL extensions to triggers; they are not case sensitive.

In an `INSERT` trigger, only `NEW.col_name` can be used; there is no old row. In a `DELETE` trigger, only `OLD.col_name` can be used; there is no new row. In an `UPDATE` trigger, you can use `OLD.col_name` to refer to the columns of a row before it is updated and `NEW.col_name` to refer to the columns of the row after it is updated.

A column named with `OLD` is read only. You can refer to it (if you have the `SELECT` privilege), but not modify it. You can refer to a column named with `NEW` if you have the `SELECT` privilege for it. In a `BEFORE` trigger, you can also change its value with `SET NEW.col_name = value` if you have the `UPDATE` privilege for it. This means you can use a trigger to modify the values to be inserted into a new row or used to update a row. (Such a `SET` statement has no effect in an `AFTER` trigger because the row change will have already occurred.)

In a `BEFORE` trigger, the `NEW` value for an `AUTO_INCREMENT` column is 0, not the sequence number that is generated automatically when the new row actually is inserted.

By using the `BEGIN ... END` construct, you can define a trigger that executes multiple statements. Within the `BEGIN` block, you also can use other syntax that is permitted within stored routines such as conditionals and loops. However, just as for stored routines, if you use the `mysql` program to define a trigger that executes multiple statements, it is necessary to redefine the `mysql` statement delimiter so that you can use the `;` statement delimiter within the trigger definition. The following example illustrates these points. It defines an `UPDATE` trigger that checks the new value to be used for updating each row, and modifies the value to be within the range from 0 to 100. This must be a `BEFORE` trigger because the value must be checked before it is used to update the row:

```
mysql> delimiter //
mysql> CREATE TRIGGER upd_check BEFORE UPDATE ON account
-> FOR EACH ROW
-> BEGIN
-> IF NEW.amount < 0 THEN
-> SET NEW.amount = 0;
-> ELSEIF NEW.amount > 100 THEN
-> SET NEW.amount = 100;
-> END IF;
-> END; //
mysql> delimiter ;
```

It can be easier to define a stored procedure separately and then invoke it from the trigger using a simple `CALL` statement. This is also advantageous if you want to execute the same code from within several triggers.

There are limitations on what can appear in statements that a trigger executes when activated:

- The trigger cannot use the `CALL` statement to invoke stored procedures that return data to the client or that use dynamic SQL. (Stored procedures are permitted to return data to the trigger through `OUT` or `INOUT` parameters.)

- The trigger cannot use statements that explicitly or implicitly begin or end a transaction, such as `START TRANSACTION`, `COMMIT`, or `ROLLBACK`. (`ROLLBACK` to `SAVEPOINT` is permitted because it does not end a transaction.).

- Prior to MySQL 5.0.10, triggers cannot contain direct references to tables by name.

See also Section C.1, “Restrictions on Stored Programs”.

MySQL handles errors during trigger execution as follows:
• If a **BEFORE** trigger fails, the operation on the corresponding row is not performed.

• A **BEFORE** trigger is activated by the *attempt* to insert or modify the row, regardless of whether the attempt subsequently succeeds.

• An **AFTER** trigger is executed only if any **BEFORE** triggers and the row operation execute successfully.

• An error during either a **BEFORE** or **AFTER** trigger results in failure of the entire statement that caused trigger invocation.

• For transactional tables, failure of a statement should cause rollback of all changes performed by the statement. Failure of a trigger causes the statement to fail, so trigger failure also causes rollback. For nontransactional tables, such rollback cannot be done, so although the statement fails, any changes performed prior to the point of the error remain in effect.

Before MySQL 5.0.10, triggers cannot contain direct references to tables by name. Beginning with MySQL 5.0.10, you can write triggers such as the one named `testref` shown in this example:

```sql
CREATE TABLE test1(a1 INT);
CREATE TABLE test2(a2 INT);
CREATE TABLE test3(a3 INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
CREATE TABLE test4(
    a4 INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    b4 INT DEFAULT 0
);
delimiter |
CREATE TRIGGER testref BEFORE INSERT ON test1
    FOR EACH ROW
BEGIN
    INSERT INTO test2 SET a2 = NEW.a1;
    DELETE FROM test3 WHERE a3 = NEW.a1;
    UPDATE test4 SET b4 = b4 + 1 WHERE a4 = NEW.a1;
END;
|
delimiter ;
```

Suppose that you insert the following values into table `test1` as shown here:

```sql
mysql> INSERT INTO test1 VALUES
    -> (1), (3), (1), (7), (1), (8), (4), (4);
Query OK, 8 rows affected (0.01 sec)
Records: 8  Duplicates: 0  Warnings: 0
```

As a result, the four tables contain the following data:

```sql
mysql> SELECT * FROM test1;
+------+
| a1   |
+------+
| 1    |
| 3    |
| 1    |
| 7    |
| 1    |
| 8    |
| 4    |
```
18.3.2 Trigger Metadata

Metadata about triggers can be obtained as follows:

- Query the TRIGGERS table of the INFORMATION_SCHEMA database. See Section 19.15, “The INFORMATION_SCHEMA TRIGGERS Table”.

- Use the SHOW TRIGGERS statement. See Section 13.7.5.35, “SHOW TRIGGERS Syntax”.

18.4 Using Views

MySQL supports views, including updatable views. Views are stored queries that when invoked produce a result set. A view acts as a virtual table.

To use views if you have upgraded to MySQL 5.0.1 from an older release, you should upgrade your grant tables so that they contain the view-related privileges. See Section 4.4.9, “mysql_upgrade — Check Tables for MySQL Upgrade”.

The following discussion describes the syntax for creating and dropping views, and shows some examples of how to use them.
Additional Resources

- You may find the Views User Forum of use when working with views.
- For answers to some commonly asked questions regarding views in MySQL, see Section A.6, “MySQL 5.0 FAQ: Views”.
- There are some restrictions on the use of views; see Section C.4, “Restrictions on Views”.

18.4.1 View Syntax

The CREATE VIEW statement creates a new view (see Section 13.1.12, “CREATE VIEW Syntax”). To alter the definition of a view or drop a view, use ALTER VIEW (see Section 13.1.5, “ALTER VIEW Syntax”), or DROP VIEW (see Section 13.1.19, “DROP VIEW Syntax”).

A view can be created from many kinds of SELECT statements. It can refer to base tables or other views. It can use joins, UNION, and subqueries. The SELECT need not even refer to any tables. The following example defines a view that selects two columns from another table, as well as an expression calculated from those columns:

```
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50), (5, 60);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+------+-------+-------+
<table>
<thead>
<tr>
<th>qty</th>
<th>price</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>50</td>
<td>150</td>
</tr>
<tr>
<td>5</td>
<td>60</td>
<td>300</td>
</tr>
</tbody>
</table>
+------+-------+-------+
mysql> SELECT * FROM v WHERE qty = 5;
+------+-------+-------+
<table>
<thead>
<tr>
<th>qty</th>
<th>price</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>60</td>
<td>300</td>
</tr>
</tbody>
</table>
+------+-------+-------+
```

18.4.2 View Processing Algorithms

The optional ALGORITHM clause for CREATE VIEW or ALTER VIEW is a MySQL extension to standard SQL. It affects how MySQL processes the view. ALGORITHM takes three values: MERGE, TEMPTABLE, or UNDEFINED.

- For MERGE, the text of a statement that refers to the view and the view definition are merged such that parts of the view definition replace corresponding parts of the statement.
- For TEMPTABLE, the results from the view are retrieved into a temporary table, which then is used to execute the statement.
- For UNDEFINED, MySQL chooses which algorithm to use. It prefers MERGE over TEMPTABLE if possible, because MERGE is usually more efficient and because a view cannot be updatable if a temporary table is used.
- If no ALGORITHM clause is present, UNDEFINED is the default algorithm.

A reason to specify TEMPTABLE explicitly is that locks can be released on underlying tables after the temporary table has been created and before it is used to finish processing the statement. This might result in quicker lock release than the MERGE algorithm so that other clients that use the view are not blocked as long.

A view algorithm can be UNDEFINED for three reasons:

- No ALGORITHM clause is present in the CREATE VIEW statement.
• The **CREATE VIEW** statement has an explicit **ALGORITHM = UNDEFINED** clause.

• **ALGORITHM = MERGE** is specified for a view that can be processed only with a temporary table. In this case, MySQL generates a warning and sets the algorithm to **UNDEFINED**.

As mentioned earlier, **MERGE** is handled by merging corresponding parts of a view definition into the statement that refers to the view. The following examples briefly illustrate how the **MERGE** algorithm works. The examples assume that there is a view **v_merge** that has this definition:

```sql
CREATE ALGORITHM = MERGE VIEW v_merge (vc1, vc2) AS
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 1: Suppose that we issue this statement:

```sql
SELECT * FROM v_merge;
```

MySQL handles the statement as follows:

• **v_merge** becomes **t**

• ***** becomes **vc1, vc2**, which corresponds to **c1, c2**

• The view **WHERE** clause is added

The resulting statement to be executed becomes:

```sql
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 2: Suppose that we issue this statement:

```sql
SELECT * FROM v_merge WHERE vc1 < 100;
```

This statement is handled similarly to the previous one, except that **vc1 < 100** becomes **c1 < 100** and the view **WHERE** clause is added to the statement **WHERE** clause using an **AND** connective (and parentheses are added to make sure the parts of the clause are executed with correct precedence). The resulting statement to be executed becomes:

```sql
SELECT c1, c2 FROM t WHERE (c3 > 100) AND (c1 < 100);
```

Effectively, the statement to be executed has a **WHERE** clause of this form:

```sql
WHERE (select WHERE) AND (view WHERE)
```

If the **MERGE** algorithm cannot be used, a temporary table must be used instead. **MERGE** cannot be used if the view contains any of the following constructs:

• Aggregate functions (**SUM()**, **MIN()**, **MAX()**, **COUNT()**, and so forth)

• **DISTINCT**

• **GROUP BY**

• **HAVING**

• **LIMIT**

• **UNION** or **UNION ALL**

• Subquery in the select list

• Assignment to user variables

• Refers only to literal values (in this case, there is no underlying table)
18.4.3 Updatable and Insertable Views

Some views are updatable and references to them can be used to specify tables to be updated in data change statements. That is, you can use them in statements such as **UPDATE**, **DELETE**, or **INSERT** to update the contents of the underlying table.

For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view nonupdatable. To be more specific, a view is not updatable if it contains any of the following:

- Aggregate functions (**SUM()**, **MIN()**, **MAX()**, **COUNT()**, and so forth)
- **DISTINCT**
- **GROUP BY**
- **HAVING**
- **UNION** or **UNION ALL**
- Subquery in the select list
- Certain joins (see additional join discussion later in this section)
- Reference to nonupdatable view in the **FROM** clause
- Subquery in the **WHERE** clause that refers to a table in the **FROM** clause
- Refers only to literal values (in this case, there is no underlying table to update)
- **ALGORITHM = TEMPTABLE** (use of a temporary table always makes a view nonupdatable)
- Multiple references to any column of a base table

It is sometimes possible for a multiple-table view to be updatable, assuming that it can be processed with the **MERGE** algorithm. For this to work, the view must use an inner join (not an outer join or a **UNION**). Also, only a single table in the view definition can be updated, so the **SET** clause must name only columns from one of the tables in the view. Views that use **UNION ALL** are not permitted even though they might be theoretically updatable.

With respect to insertability (being updatable with **INSERT** statements), an updatable view is insertable if it also satisfies these additional requirements for the view columns:

- There must be no duplicate view column names.
- The view must contain all columns in the base table that do not have a default value.
- The view columns must be simple column references. They must not be expressions or composite expressions, such as these:

  ```
  3.14159
  col1 + 3
  UPPER(col2)
  col3 / col4
  (subquery)
  ```

MySQL sets a flag, called the view updatability flag, at **CREATE VIEW** time. The flag is set to **YES** (true) if **UPDATE** and **DELETE** (and similar operations) are legal for the view. Otherwise, the flag is set to **NO** (false). The **IS_UPDATABLE** column in the **INFORMATION_SCHEMA.VIEWS** table displays the status of this flag. It means that the server always knows whether a view is updatable.

If a view is not updatable, statements such **UPDATE**, **DELETE**, and **INSERT** are illegal and are rejected. (Note that even if a view is updatable, it might not be possible to insert into it, as described elsewhere in this section.)
The view updateability of views may be affected by the value of the `updatable_views_with_limit` system variable. See Section 5.1.4, “Server System Variables”.

Earlier discussion in this section pointed out that a view is not insertable if not all columns are simple column references (for example, if it contains columns that are expressions or composite expressions). Although such a view is not insertable, it can be updateable if you update only columns that are not expressions. Consider this view:

```sql
CREATE VIEW v AS SELECT col1, 1 AS col2 FROM t;
```

This view is not insertable because `col2` is an expression. But it is updateable if the update does not try to update `col2`. This update is permissible:

```sql
UPDATE v SET col1 = 0;
```

This update is not permissible because it attempts to update an expression column:

```sql
UPDATE v SET col2 = 0;
```

For a multiple-table updatable view, `INSERT` can work if it inserts into a single table. `DELETE` is not supported.

`INSERT DELAYED` is not supported for views.

If a table contains an `AUTO_INCREMENT` column, inserting into an insertable view on the table that does not include the `AUTO_INCREMENT` column does not change the value of `LAST_INSERT_ID()`, because the side effects of inserting default values into columns not part of the view should not be visible.

18.4.4 The View WITH CHECK OPTION Clause

The `WITH CHECK OPTION` clause can be given for an updatable view to prevent inserts to rows for which the `WHERE` clause in the `select_statement` is not true. It also prevents updates to rows for which the `WHERE` clause is true but the update would cause it to be not true (in other words, it prevents visible rows from being updated to nonvisible rows).

In a `WITH CHECK OPTION` clause for an updatable view, the `LOCAL` and `CASCADED` keywords determine the scope of check testing when the view is defined in terms of another view. When neither keyword is given, the default is `CASCADED`. The `LOCAL` keyword restricts the `CHECK OPTION` only to the view being defined. `CASCADED` causes the checks for underlying views to be evaluated as well.

Consider the definitions for the following table and set of views:

```sql
CREATE TABLE t1 (a INT);
CREATE VIEW v1 AS SELECT * FROM t1 WHERE a < 2
WITH CHECK OPTION;
CREATE VIEW v2 AS SELECT * FROM v1 WHERE a > 0
WITH LOCAL CHECK OPTION;
CREATE VIEW v3 AS SELECT * FROM v1 WHERE a > 0
WITH CASCADED CHECK OPTION;
```

Here the `v2` and `v3` views are defined in terms of another view, `v1`. `v2` has a `LOCAL` check option, so inserts are tested only against the `v2` check. `v3` has a `CASCADED` check option, so inserts are tested not only against its own check, but against those of underlying views. The following statements illustrate these differences:

```sql
mysql> INSERT INTO v2 VALUES (2);
Query OK, 1 row affected (0.00 sec)
mysql> INSERT INTO v3 VALUES (2);
ERROR 1369 (HY000): CHECK OPTION failed 'test.v3'
```
18.4.5 View Metadata

Metadata about views can be obtained as follows:

- Query the VIEWS table of the INFORMATION_SCHEMA database. See Section 19.17, “The INFORMATION_SCHEMA VIEWS Table”.
- Use the SHOW CREATE VIEW statement. See Section 13.7.5.10, “SHOW CREATE VIEW Syntax”.

18.5 Access Control for Stored Programs and Views

Stored programs and views are defined prior to use and, when referenced, execute within a security context that determines their privileges. These privileges are controlled by their DEFINER attribute, and, if there is one, their SQL SECURITY characteristic.

All stored programs (procedures, functions, and triggers) and views can have a DEFINER attribute that names a MySQL account. If the DEFINER attribute is omitted from a stored program or view definition, the default account is the user who creates the object.

In addition, stored routines (procedures and functions) and views can have a SQL SECURITY characteristic with a value of DEFINER or INVOKER to specify whether the object executes in definor or invoker context. If the SQL SECURITY characteristic is omitted, the default is definor context.

Triggers have no SQL SECURITY characteristic and always execute in definor context. The server invokes these objects automatically as necessary, so there is no invoking user.

Definer and invoker security contexts differ as follows:

- A stored program or view that executes in definor security context executes with the privileges of the account named by its DEFINER attribute. These privileges may be entirely different from those of the invoking user. The invoker must have appropriate privileges to reference the object (for example, EXECUTE to call a stored procedure or SELECT to select from a view), but when the object executes, the invoker's privileges are ignored and only the DEFINER account privileges matter. If this account has few privileges, the object is correspondingly limited in the operations it can perform. If the DEFINER account is highly privileged (such as a root account), the object can perform powerful operations no matter who invokes it.

- A stored routine or view that executes in invoker security context can perform only operations for which the invoker has privileges. The DEFINER attribute can be specified but has no effect for objects that execute in invoker context.

Consider the following stored procedure:

```sql
CREATE DEFINER = 'admin'@'localhost' PROCEDURE p1()
SQL SECURITY DEFINER
BEGIN
  UPDATE t1 SET counter = counter + 1;
END;
```

Any user who has the EXECUTE privilege for p1 can invoke it with a CALL statement. However, when p1 executes, it does so in DEFINER security context and thus executes with the privileges of 'admin'@'localhost', the account named in the DEFINER attribute. This account must have the EXECUTE privilege for p1 as well as the UPDATE privilege for the table t1. Otherwise, the procedure fails.

Now consider this stored procedure, which is identical to p1 except that its SQL SECURITY characteristic is INVOKER:

```sql
CREATE DEFINER = 'admin'@'localhost' PROCEDURE p2()
SQL SECURITY INVOKER
BEGIN
```

This documentation is for an older version. If you're using the most current version, select the documentation for that version with the version switch in the upper right corner of the online documentation, or by downloading a newer PDF or EPUB file.
UPDATE t1 SET counter = counter + 1;
END;

p2, unlike p1, executes in INVOKER security context. The DEFINER attribute is irrelevant and p2 executes with the privileges of the invoking user. p2 fails if the invoker lacks the EXECUTE privilege for p2 or the UPDATE privilege for the table t1.

MySQL uses the following rules to control which accounts a user can specify in an object DEFINER attribute:

• You can specify a DEFINER value other than your own account only if you have the SUPER privilege.

• If you do not have the SUPER privilege, the only legal user value is your own account, either specified literally or by using CURRENT_USER. You cannot set the definer to some other account.

To minimize the risk potential for stored program and view creation and use, follow these guidelines:

• For a stored routine or view, use SQL SECURITY INVOKER in the object definition when possible so that it can be used only by users with permissions appropriate for the operations performed by the object.

• If you create definer-context stored programs or views while using an account that has the SUPER privilege, specify an explicit DEFINER attribute that names an account possessing only the privileges required for the operations performed by the object. Specify a highly privileged DEFINER account only when absolutely necessary.

• Administrators can prevent users from specifying highly privileged DEFINER accounts by not granting them the SUPER privilege.

• Definer-context objects should be written keeping in mind that they may be able to access data for which the invoking user has no privileges. In some cases, you can prevent reference to these objects by not granting unauthorized users particular privileges:

  • A stored procedure or function cannot be referenced by a user who does not have the EXECUTE privilege for it.

  • A view cannot be referenced by a user who does not have the appropriate privilege for it (SELECT to select from it, INSERT to insert into it, and so forth).

However, no such control exists for triggers because users do not reference them directly. A trigger always executes in DEFINER context and is activated by access to the table with which it is associated, even ordinary table accesses by users with no special privileges. If the DEFINER account is highly privileged, the trigger can perform sensitive or dangerous operations. This remains true if the SUPER privilege needed to create the trigger is revoked from the account of the user who created it. Administrators should be especially careful about granting users that privilege.

18.6 Binary Logging of Stored Programs

The binary log contains information about SQL statements that modify database contents. This information is stored in the form of “events” that describe the modifications. The binary log has two important purposes:

• For replication, the binary log is used on master replication servers as a record of the statements to be sent to slave servers. The master server sends the events contained in its binary log to its slaves, which execute those events to make the same data changes that were made on the master. See Section 16.2, “Replication Implementation”.

• Certain data recovery operations require use of the binary log. After a backup file has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See Section 7.3.2, “Using Backups for Recovery”.

This documentation is for an older version.
If you're using the most current version, select the documentation for that version with the version switch in the upper right corner of the online documentation, or by downloading a newer PDF or EPUB file.
However, there are certain binary logging issues that apply with respect to stored programs (stored procedures and functions, and triggers):

- Logging occurs at the statement level. In some cases, it is possible that a statement will affect different sets of rows on a master and a slave.

- Replicated statements executed on a slave are processed by the slave SQL thread, which has full privileges. It is possible for a procedure to follow different execution paths on master and slave servers, so a user can write a routine containing a dangerous statement that will execute only on the slave where it is processed by a thread that has full privileges.

- If a stored program that modifies data is nondeterministic, it is not repeatable. This can result in different data on a master and slave, or cause restored data to differ from the original data.

This section describes how MySQL 5.0 handles binary logging for stored programs. The discussion first states the current conditions that the implementation places on the use of stored programs, and what you can do to avoid problems. Then it summarizes the changes that have taken place in the logging implementation. Finally, implementation details are given that provide information about when and why various changes were made. These details show how several aspects of the current logging behavior were implemented in response to shortcomings identified in earlier versions of MySQL.

In general, the issues described here occur due to the fact that binary logging occurs at the SQL statement level. MySQL 5.1 implements row-level binary logging, which solves or alleviates these issues because the log contains changes made to individual rows as a result of executing SQL statements.

Unless noted otherwise, the remarks here assume that you have enabled binary logging by starting the server with the `--log-bin` option. (See Section 5.4.3, “The Binary Log”.) If the binary log is not enabled, replication is not possible, nor is the binary log available for data recovery.

The current conditions on the use of stored functions in MySQL 5.0 can be summarized as follows. These conditions do not apply to stored procedures and they do not apply unless binary logging is enabled.

- To create or alter a stored function, you must have the `SUPER` privilege, in addition to the `CREATE ROUTINE` or `ALTER ROUTINE` privilege that is normally required. (Depending on the `DEFINER` value in the function definition, `SUPER` might be required regardless of whether binary logging is enabled. See Section 13.1.9, “CREATE PROCEDURE and CREATE FUNCTION Syntax”.)

- When you create a stored function, you must declare either that it is deterministic or that it does not modify data. Otherwise, it may be unsafe for data recovery or replication.

By default, for a `CREATE FUNCTION` statement to be accepted, at least one of `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL, or READS SQL DATA in its declaration and binary logging is enabled
(you *might* want to use the less safe log_bin_trust_function_creators variable)
```

This function is deterministic (and does not modify data), so it is safe:

```
CREATE FUNCTION f1(i INT)
RETURNS INT
DETERMINISTIC
READS SQL DATA
BEGIN
RETURN i;
END;
```

This function uses `UUID()`, which is not deterministic, so the function also is not deterministic and is not safe:
This function modifies data, so it may not be safe:

```sql
CREATE FUNCTION f3(p_id INT)
RETURNS INT
BEGIN
  UPDATE t SET modtime = NOW() WHERE id = p_id;
  RETURN ROW_COUNT();
END;
```

Assessment of the nature of a function is based on the “honesty” of the creator: MySQL does not check that a function declared `DETERMINISTIC` is free of statements that produce nondeterministic results.

- To relax the preceding conditions on function creation (that you must have the `SUPER` privilege and that a function must be declared deterministic or to not modify data), set the global `log_bin_trust_function_creators` system variable to 1. By default, this variable has a value of 0, but you can change it like this:

  ```sql
  mysql> SET GLOBAL log_bin_trust_function_creators = 1;
  ```

  You can also set this variable by using the `--log-bin-trust-function-creators=1` option when starting the server.

  If binary logging is not enabled, `log_bin_trust_function_creators` does not apply. `SUPER` is not required for function creation unless, as described previously, the `DEFINER` value in the function definition requires it.

- For information about built-in functions that may be unsafe for replication (and thus cause stored functions that use them to be unsafe as well), see Section 16.4.1, “Replication Features and Issues”.

Triggers are similar to stored functions, so the preceding remarks regarding functions also apply to triggers with the following exception: `CREATE TRIGGER` does not have an optional `DETERMINISTIC` characteristic, so triggers are assumed to be always deterministic. However, this assumption might in some cases be invalid. For example, the `UUID()` function is nondeterministic (and does not replicate). You should be careful about using such functions in triggers.

Triggers can update tables, so error messages similar to those for stored functions occur with `CREATE TRIGGER` if you do not have the required privileges. On the slave side, the slave uses the trigger `DEFINER` attribute to determine which user is considered to be the creator of the trigger.

The rest of this section provides details on the development of stored routine logging. You need not read it unless you are interested in the background on the rationale for the current logging-related conditions on stored routine use.

The development of stored routine logging in MySQL 5.0 can be summarized as follows:

- Before MySQL 5.0.6: In the initial implementation of stored routine logging, statements that create stored routines and `CALL` statements are not logged. These omissions can cause problems for replication and data recovery.

- MySQL 5.0.6: Statements that create stored routines and `CALL` statements are logged. Stored function invocations are logged when they occur in statements that update data (because those statements are logged). However, function invocations are not logged when they occur in statements such as `SELECT` that do not change data, even if a data change occurs within a function itself; this
can cause problems. Under some circumstances, functions and procedures can have different effects if executed at different times or on different (master and slave) machines, and thus can be unsafe for data recovery or replication. To handle this, measures are implemented to enable identification of safe routines and to prevent creation of unsafe routines except by users with sufficient privileges.

MySQL 5.0.12: For stored functions, when a function invocation that changes data occurs within a nonlogged statement such as `SELECT`, the server logs a `DO func_name()` statement that invokes the function so that the function gets executed during data recovery or replication to slave servers. For stored procedures, the server does not log `CALL` statements. Instead, it logs individual statements within a procedure that are executed as a result of a `CALL`. This eliminates problems that may occur when a procedure would follow a different execution path on a slave than on the master.

MySQL 5.0.16: The procedure logging changes made in 5.0.12 enable the conditions on unsafe routines to be relaxed for stored procedures. Consequently, the user interface for controlling these conditions is revised to apply only to functions. Procedure creators are no longer bound by them.

MySQL 5.0.17: Logging of stored functions as `DO func_name()` statements (per the changes made in 5.0.12) are logged as `SELECT func_name()` statements instead for better control over error checking.

Routine logging before MySQL 5.0.6: Statements that create and use stored routines are not written to the binary log, but statements invoked within stored routines are logged. Suppose that you issue the following statements:

```sql
CREATE PROCEDURE mysp INSERT INTO t VALUES(1);
CALL mysp();
```

For this example, only the `INSERT` statement appears in the binary log. The `CREATE PROCEDURE` and `CALL` statements do not appear. The absence of routine-related statements in the binary log means that stored routines are not replicated correctly. It also means that for a data recovery operation, re-executing events in the binary log does not recover stored routines.

Routine logging changes in MySQL 5.0.6: To address the absence of logging for stored routine creation and `CALL` statements (and the consequent replication and data recovery concerns), the characteristics of binary logging for stored routines were changed as described here. (Some of the items in the following list point out issues that are dealt with in later versions.)

- The server writes `CREATE PROCEDURE`, `CREATE FUNCTION`, `ALTER PROCEDURE`, `ALTER FUNCTION`, `DROP PROCEDURE`, and `DROP FUNCTION` statements to the binary log. Also, the server logs `CALL` statements, not the statements executed within procedures. Suppose that you issue the following statements:

```sql
CREATE PROCEDURE mysp INSERT INTO t VALUES(1);
CALL mysp();
```

For this example, the `CREATE PROCEDURE` and `CALL` statements appear in the binary log, but the `INSERT` statement does not appear. This corrects the problem that occurred before MySQL 5.0.6 such that only the `INSERT` was logged.

- Logging `CALL` statements has a security implication for replication, which arises from two factors:
  - Statements executed on a slave are processed by the slave SQL thread which has full privileges.
  - It is possible for a procedure to follow different execution paths on master and slave servers.

The implication is that although a user must have the `CREATE ROUTINE` privilege to create a routine, the user can write a routine containing a dangerous statement that will execute only on the slave where it is processed by a thread that has full privileges. For example, if the master and slave servers have server ID values of 1 and 2, respectively, a user on the master server could create and invoke an unsafe procedure `unsafe_sp()` as follows:
The CREATE PROCEDURE and CALL statements are written to the binary log, so the slave will execute them. Because the slave SQL thread has full privileges, it will execute the DROP DATABASE statement that drops the accounting database. Thus, the CALL statement has different effects on the master and slave and is not replication-safe.

The preceding example uses a stored procedure, but similar problems can occur for stored functions that are invoked within statements that are written to the binary log: Function invocation has different effects on the master and slave.

To guard against this danger for servers that have binary logging enabled, MySQL 5.0.6 introduces the requirement that stored procedure and function creators must have the SUPER privilege, in addition to the usual CREATE ROUTINE privilege that is required. Similarly, to use ALTER PROCEDURE or ALTER FUNCTION, you must have the SUPER privilege in addition to the ALTER ROUTINE privilege. Without the SUPER privilege, an error will occur:

```
ERROR 1419 (HY000): You do not have the SUPER privilege and binary logging is enabled (you *might* want to use the less safe log_bin_trust_routine_creators variable)
```

If you do not want to require routine creators to have the SUPER privilege (for example, if all users with the CREATE ROUTINE privilege on your system are experienced application developers), set the global log_bin_trust_routine_creators system variable to 1. You can also set this variable by using the --log-bin-trust-routine-creators=1 option when starting the server.

If binary logging is not enabled, log_bin_trust_routine_creators does not apply. SUPER is not required for routine creation unless, as described previously, the DEFINER value in the routine definition requires it.

- If a routine that performs updates is nondeterministic, it is not repeatable. This can have two undesirable effects:
  - It will make a slave different from the master.
  - Restored data will be different from the original data.

To deal with these problems, MySQL enforces the following requirement: On a master server, creation and alteration of a routine is refused unless you declare the routine to be deterministic or to not modify data. Two sets of routine characteristics apply here:

- The DETERMINISTIC and NOT DETERMINISTIC characteristics indicate whether a routine always produces the same result for given inputs. The default is NOT DETERMINISTIC if neither characteristic is given. To declare that a routine is deterministic, you must specify DETERMINISTIC explicitly.

- The CONTAINS SQL, NO SQL, READS SQL DATA, and MODIFIES SQL DATA characteristics provide information about whether the routine reads or writes data. Either NO SQL or READS SQL DATA indicates that a routine does not change data, but you must specify one of these explicitly because the default is CONTAINS SQL if no characteristic is given.

By default, for a CREATE PROCEDURE or CREATE FUNCTION statement to be accepted, at least one of DETERMINISTIC, NO SQL, or READS SQL DATA must be specified explicitly. Otherwise an error occurs:
Binary Logging of Stored Programs

ERROR 1418 (HY000): This routine has none of DETERMINISTIC, NO SQL, or READS SQL DATA in its declaration and binary logging is enabled (you *might* want to use the less safe log_bin_trust_routine_creators variable)

If you set log_bin_trust_routine_creators to 1, the requirement that routines be deterministic or not modify data is dropped.

• A CALL statement is written to the binary log if the routine returns no error, but not otherwise. When a routine that modifies data fails, you get this warning:

ERROR 1417 (HY000): A routine failed and has neither NO SQL nor READS SQL DATA in its declaration and binary logging is enabled; if non-transactional tables were updated, the binary log will miss their changes.

This logging behavior has the potential to cause problems. If a routine partly modifies a nontransactional table (such as a MyISAM table) and returns an error, the binary log will not reflect these changes. To protect against this, you should use transactional tables in the routine and modify the tables within transactions.

If you use the IGNORE keyword with INSERT, DELETE, or UPDATE to ignore errors within a routine, a partial update might occur but no error will result. Such statements are logged and they replicate normally.

• Although statements normally are not written to the binary log if they are rolled back, CALL statements are logged even when they occur within a rolled-back transaction. This can result in a CALL being rolled back on the master but executed on slaves.

• If a stored function is invoked within a statement such as SELECT that does not modify data, execution of the function is not written to the binary log, even if the function itself modifies data. This logging behavior has the potential to cause problems. Suppose that a function myfunc() is defined as follows:

```
CREATE FUNCTION myfunc () RETURNS INT DETERMINISTIC
BEGIN
  INSERT INTO t (i) VALUES(1);
  RETURN 0;
END;
```

Given that definition, the following statement is not written to the binary log because it is a SELECT. Nevertheless, it modifies the table t because myfunc() modifies t:

```
SELECT myfunc();
```

A workaround for this problem is to invoke functions that do updates only within statements that do updates (and which therefore are written to the binary log). Note that although the DO statement sometimes is executed for the side effect of evaluating an expression, DO is not a workaround here because it is not written to the binary log.

• On slave servers, --replicate-* table rules do not apply to CALL statements or to statements within stored routines. These statements are always replicated. If such statements contain references to tables that do not exist on the slave, they could have undesirable effects when executed on the slave.

Routine logging changes in MySQL 5.0.12: The changes in 5.0.12 address several problems that were present in earlier versions:

• Stored function invocations in nonlogged statements such as SELECT were not being logged, even when a function itself changed data.
• Stored procedure logging at the CALL level could cause different effects on a master and slave if a procedure took different execution paths on the two machines.

• CALL statements were logged even when they occurred within a rolled-back transaction.

To deal with these issues, MySQL 5.0.12 implements the following changes to procedure and function logging:

• A stored function invocation is logged as a DO statement if the function changes data and occurs within a statement that would not otherwise be logged. This corrects the problem of nonreplication of data changes that result from use of stored functions in nonlogged statements. For example, SELECT statements are not written to the binary log, but a SELECT might invoke a stored function that makes changes. To handle this, a DO func_name() statement is written to the binary log when the given function makes a change. Suppose that the following statements are executed on the master:

```sql
CREATE FUNCTION f1(a INT) RETURNS INT
BEGIN
  IF (a < 3) THEN
    INSERT INTO t2 VALUES (a);
  END IF;
RETURN 0;
END;
CREATE TABLE t1 (a INT);
INSERT INTO t1 VALUES (1),(2),(3);
SELECT f1(a) FROM t1;
```

When the SELECT statement executes, the function f1() is invoked three times. Two of those invocations insert a row, and MySQL logs a DO statement for each of them. That is, MySQL writes the following statements to the binary log:

```sql
DO f1(1);
DO f1(2);
```

The server also logs a DO statement for a stored function invocation when the function invokes a stored procedure that causes an error. In this case, the server writes the DO statement to the log along with the expected error code. On the slave, if the same error occurs, that is the expected result and replication continues. Otherwise, replication stops.

Note: See later in this section for changes made in MySQL 5.0.19: These logged DO func_name() statements are logged as SELECT func_name() statements instead.

• Stored procedure calls are logged at the statement level rather than at the CALL level. That is, the server does not log the CALL statement, it logs those statements within the procedure that actually execute. As a result, the same changes that occur on the master will be observed on slave servers. This eliminates the problems that could result from a procedure having different execution paths on different machines. For example, the DROP DATABASE problem shown earlier for the unsafe_sp() procedure does not occur and the routine is no longer replication-unsafe because it has the same effect on master and slave servers.

In general, statements executed within a stored procedure are written to the binary log using the same rules that would apply were the statements to be executed in standalone fashion. Some special care is taken when logging procedure statements because statement execution within procedures is not quite the same as in nonprocedure context:

• A statement to be logged might contain references to local procedure variables. These variables do not exist outside of stored procedure context, so a statement that refers to such a variable cannot be logged literally. Instead, each reference to a local variable is replaced by this construct for logging purposes:
NAME_CONST(\textit{var\_name}, \textit{var\_value})

\textit{var\_name} is the local variable name, and \textit{var\_value} is a constant indicating the value that the variable has at the time the statement is logged. NAME_CONST() has a value of \textit{var\_value}, and a "name" of \textit{var\_name}. Thus, if you invoke this function directly, you get a result like this:

```
mysql> SELECT NAME_CONST('myname', 14);
+--------+
| myname |
+--------+
|    14  |
+--------+
```

NAME_CONST() enables a logged standalone statement to be executed on a slave with the same effect as the original statement that was executed on the master within a stored procedure.

The use of NAME_CONST() can result in a problem for CREATE TABLE ... SELECT statements when the source column expressions refer to local variables. Converting these references to NAME_CONST() expressions can result in column names that are different on the master and slave servers, or names that are too long to be legal column identifiers. A workaround is to supply aliases for columns that refer to local variables. Consider this statement when \textit{myvar} has a value of 1:

```
CREATE TABLE t1 SELECT myvar;
```

That will be rewritten as follows:

```
CREATE TABLE t1 SELECT NAME_CONST(myvar, 1);
```

To ensure that the master and slave tables have the same column names, write the statement like this:

```
CREATE TABLE t1 SELECT myvar AS myvar;
```

The rewritten statement becomes:

```
CREATE TABLE t1 SELECT NAME_CONST(myvar, 1) AS myvar;
```

- A statement to be logged might contain references to user-defined variables. To handle this, MySQL writes a SET statement to the binary log to make sure that the variable exists on the slave with the same value as on the master. For example, if a statement refers to a variable \texttt{\textbackslash@my\_var}, that statement will be preceded in the binary log by the following statement, where \texttt{value} is the value of \texttt{\textbackslash@my\_var} on the master:

```
SET \texttt{\textbackslash@my\_var} = \texttt{value};
```

- Procedure calls can occur within a committed or rolled-back transaction. Previously, CALL statements were logged even if they occurred within a rolled-back transaction. As of MySQL 5.0.12, transactional context is accounted for so that the transactional aspects of procedure execution are replicated correctly. That is, the server logs those statements within the procedure that actually execute and modify data, and also logs BEGIN, COMMIT, and ROLLBACK statements as necessary. For example, if a procedure updates only transactional tables and is executed within a transaction that is rolled back, those updates are not logged. If the procedure occurs within a committed transaction, BEGIN and COMMIT statements are logged with the updates. For a procedure that executes within a rolled-back transaction, its statements are logged using the same rules that would apply if the statements were executed in standalone fashion:
• Updates to transactional tables are not logged.

• Updates to nontransactional tables are logged because rollback does not cancel them.

• Updates to a mix of transactional and nontransactional tables are logged surrounded by `BEGIN` and `ROLLBACK` so that slaves will make the same changes and rollbacks as on the master.

• A stored procedure call is *not* written to the binary log at the statement level if the procedure is invoked from within a stored function. In that case, the only thing logged is the statement that invokes the function (if it occurs within a statement that is logged) or a `DO` statement (if it occurs within a statement that is not logged). For this reason, care still should be exercised in the use of stored functions that invoke a procedure, even if the procedure is otherwise safe in itself.

• Because procedure logging occurs at the statement level rather than at the `CALL` level, interpretation of the `--replicate-<table>` options is revised to apply only to stored functions. They no longer apply to stored procedures, except those procedures that are invoked from within functions.

Routine logging changes in MySQL 5.0.16: In 5.0.12, a change was introduced to log stored procedure calls at the statement level rather than at the `CALL` level. This change eliminates the requirement that procedures be identified as safe. The requirement now exists only for stored functions, because they still appear in the binary log as function invocations rather than as the statements executed within the function. To reflect the lifting of the restriction on stored procedures, the `log_bin_trust Routine creators` system variable is renamed to `log_bin_trust function creators` and the `--log-bin-trust-routine-creators` server option is renamed to `--log-bin-trust-function-creators` (For backward compatibility, the old names are recognized but result in a warning.) Error messages that now apply only to functions and not to routines in general are re-worded.

Routine logging changes in MySQL 5.0.19: In 5.0.12, a change was introduced to log a stored function invocation as `DO func_name()` if the invocation changes data and occurs within a nonlogged statement, or if the function invokes a stored procedure that produces an error. In 5.0.19, these invocations are logged as `SELECT func_name()` instead. The change to `SELECT` was made because use of `DO` was found to yield insufficient control over error code checking.

INFORMATION_SCHEMA provides access to database metadata.

Metadata is data about the data, such as the name of a database or table, the data type of a column, or access privileges. Other terms that sometimes are used for this information are data dictionary and system catalog.

INFORMATION_SCHEMA is the information database, the place that stores information about all the other databases that the MySQL server maintains. Inside INFORMATION_SCHEMA there are several read-only tables. They are actually views, not base tables, so there are no files associated with them, and you cannot set triggers on them. Also, there is no database directory with that name.

Although you can select INFORMATION_SCHEMA as the default database with a USE statement, you can only read the contents of tables, not perform INSERT, UPDATE, or DELETE operations on them.

Here is an example of a statement that retrieves information from INFORMATION_SCHEMA:

```
mysql> SELECT table_name, table_type, engine
    -> FROM information_schema.tables
    -> WHERE table_schema = 'db5'
    -> ORDER BY table_name DESC;
```

<table>
<thead>
<tr>
<th>table_name</th>
<th>table_type</th>
<th>engine</th>
</tr>
</thead>
<tbody>
<tr>
<td>v56</td>
<td>VIEW</td>
<td>NULL</td>
</tr>
<tr>
<td>v3</td>
<td>VIEW</td>
<td>NULL</td>
</tr>
<tr>
<td>v2</td>
<td>VIEW</td>
<td>NULL</td>
</tr>
<tr>
<td>v</td>
<td>VIEW</td>
<td>NULL</td>
</tr>
<tr>
<td>tables</td>
<td>BASE TABLE</td>
<td>MyISAM</td>
</tr>
<tr>
<td>t7</td>
<td>BASE TABLE</td>
<td>MyISAM</td>
</tr>
<tr>
<td>t3</td>
<td>BASE TABLE</td>
<td>MyISAM</td>
</tr>
<tr>
<td>t2</td>
<td>BASE TABLE</td>
<td>MyISAM</td>
</tr>
<tr>
<td>t</td>
<td>BASE TABLE</td>
<td>MyISAM</td>
</tr>
<tr>
<td>pk</td>
<td>BASE TABLE</td>

</tr>
<tr>
<td>loop</td>
<td>BASE TABLE</td>
<td>MyISAM</td>
</tr>
<tr>
<td>kurs</td>
<td>BASE TABLE</td>
<td>MyISAM</td>
</tr>
<tr>
<td>k</td>
<td>BASE TABLE</td>
<td>MyISAM</td>
</tr>
</tbody>
</table>
Explanations: The statement requests a list of all the tables in database `db5`, in reverse alphabetic order, showing just three pieces of information: the name of the table, its type, and its storage engine.

The definition for character columns (for example, `TABLES.TABLE_NAME`) is generally `VARCHAR(N) CHARACTER SET utf8` where `N` is at least 64. MySQL uses the default collation for this character set (`utf8_general_ci`) for all searches, sorts, comparisons, and other string operations on such columns. Values such as table names in `INFORMATION_SCHEMA` columns are treated as strings, not identifiers, and are not compared using the identifier rules described in Section 9.2.2, “Identifier Case Sensitivity”. If the result of a string operation on an `INFORMATION_SCHEMA` column differs from expectations, a workaround is to use an explicit `COLLATE` clause to force a suitable collation (Section 10.1.7.2, “Using COLLATE in SQL Statements”). You can also use the `UPPER()` or `LOWER()` function. For example, in a WHERE clause, you might use:

```
WHERE TABLE_NAME COLLATE utf8_bin = 'City'
WHERE TABLE_NAME COLLATE utf8_general_ci = 'city'
WHERE UPPER(TABLE_NAME) = 'CITY'
WHERE LOWER(TABLE_NAME) = 'city'
```

Each MySQL user has the right to access these tables, but can see only the rows in the tables that correspond to objects for which the user has the proper access privileges. In some cases (for example, the ROUTINE_DEFINITION column in the `INFORMATION_SCHEMA.ROUTINES` table), users who have insufficient privileges will see NULL.

The `SELECT ... FROM INFORMATION_SCHEMA` statement is intended as a more consistent way to provide access to the information provided by the various `SHOW` statements that MySQL supports (`SHOW DATABASES`, `SHOW TABLES`, and so forth). Using `SELECT` has these advantages, compared to `SHOW`:

- It conforms to Codd's rules. That is, all access is done on tables.
- Nobody needs to learn a new statement syntax. Because they already know how `SELECT` works, they only need to learn the object names.
- The implementor need not worry about adding keywords.
- There are millions of possible output variations, instead of just one. This provides more flexibility for applications that have varying requirements about what metadata they need.
- Migration is easier because every other DBMS does it this way.

However, because `SHOW` is popular and because it might be confusing were it to disappear, the advantages of conventional syntax are not a sufficient reason to eliminate `SHOW`. In fact, along with the implementation of `INFORMATION_SCHEMA`, there are enhancements to `SHOW` as well. These are described in Section 19.18, “Extensions to SHOW Statements”.

There is no difference between the privileges required for `SHOW` statements and those required to select information from `INFORMATION_SCHEMA`. In either case, you have to have some privilege on an object in order to see information about it.

The implementation for the `INFORMATION_SCHEMA` table structures in MySQL follows the ANSI/ISO SQL:2003 standard Part 11 Schemata. Our intent is approximate compliance with SQL:2003 core feature F021 Basic information schema.

Users of SQL Server 2000 (which also follows the standard) may notice a strong similarity. However, MySQL has omitted many columns that are not relevant for our implementation.
and added columns that are MySQL-specific. One such column is the ENGINE column in the INFORMATION_SCHEMA.TABLES table.

Although other DBMSs use a variety of names, like syscat or system, the standard name is INFORMATION_SCHEMA.

The following sections describe each of the tables and columns that are in INFORMATION_SCHEMA. For each column, there are three pieces of information:

- “INFORMATION_SCHEMA Name” indicates the name for the column in the INFORMATION_SCHEMA table. This corresponds to the standard SQL name unless the “Remarks” field says “MySQL extension.”
- “SHOW Name” indicates the equivalent field name in the closest SHOW statement, if there is one.
- “Remarks” provides additional information where applicable. If this field is NULL, it means that the value of the column is always NULL. If this field says “MySQL extension,” the column is a MySQL extension to standard SQL.

To avoid using any name that is reserved in the standard or in DB2, SQL Server, or Oracle, we changed the names of some columns marked “MySQL extension”. (For example, we changed COLLATION to TABLE_COLLATION in the TABLES table.) See the list of reserved words near the end of this article: http://web.archive.org/web/20070409075643rnm_1/www.dbazine.com/db2/db2-disarticles/gulutzan5.

Many sections indicate what SHOW statement is equivalent to a SELECT that retrieves information from INFORMATION_SCHEMA. For SHOW statements that display information for the default database if you omit a FROM db_name clause, you can often select information for the default database by adding an AND TABLE_SCHEMA = DATABASE() condition to the WHERE clause of a query that retrieves information from an INFORMATION_SCHEMA table.

For answers to questions that are often asked concerning the INFORMATION_SCHEMA database, see Section A.7, “MySQL 5.0 FAQ: INFORMATION_SCHEMA”.

19.1 The INFORMATION_SCHEMA CHARACTER_SETS Table

The CHARACTER_SETS table provides information about available character sets.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHARACTER_SET_NAME</td>
<td>Charset</td>
<td></td>
</tr>
<tr>
<td>DEFAULT_COLLATE_NAME</td>
<td>Default_collation</td>
<td></td>
</tr>
<tr>
<td>DESCRIPTION</td>
<td>Description</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>MAXLEN</td>
<td>Maxlen</td>
<td>MySQL extension</td>
</tr>
</tbody>
</table>

The following statements are equivalent:

```sql
SELECT * FROM INFORMATION_SCHEMA.CHARACTER_SETS
   [WHERE CHARACTER_SET_NAME LIKE 'wild']
```

```sql
SHOW CHARACTER SET
   [LIKE 'wild']
```

19.2 The INFORMATION_SCHEMA COLLATIONS Table

The COLLATIONS table provides information about collations for each character set.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>COLLATION_NAME</td>
<td>Collation</td>
<td></td>
</tr>
</tbody>
</table>
### The INFORMATION_SCHEMA COLLATION_CHARACTER_SET_APPLICABILITY Table

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHARACTER_SET_NAME</td>
<td>Charset</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>ID</td>
<td>Id</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>IS_DEFAULT</td>
<td>Default</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>IS_COMPILED</td>
<td>Compiled</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>SORTLEN</td>
<td>Sortlen</td>
<td>MySQL extension</td>
</tr>
</tbody>
</table>

- **COLLATION_NAME** is the collation name.
- **CHARACTER_SET_NAME** is the name of the character set with which the collation is associated.
- **ID** is the collation ID.
- **IS_DEFAULT** indicates whether the collation is the default for its character set.
- **IS_COMPILED** indicates whether the character set is compiled into the server.
- **SORTLEN** is related to the amount of memory required to sort strings expressed in the character set.

Collation information is also available from the `SHOW COLLATION` statement. The following statements are equivalent:

```sql
SELECT COLLATION_NAME FROM INFORMATION_SCHEMA.COLLATIONS
WHERE COLLATION_NAME LIKE 'wild'

SHOW COLLATION LIKE 'wild'
```

### 19.3 The INFORMATION_SCHEMA COLLATION_CHARACTER_SET_APPLICABILITY Table

The `COLLATION_CHARACTER_SET_APPLICABILITY` table indicates what character set is applicable for what collation. The columns are equivalent to the first two display fields that we get from `SHOW COLLATION`.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>COLLATION_NAME</td>
<td>Collation</td>
<td></td>
</tr>
<tr>
<td>CHARACTER_SET_NAME</td>
<td>Charset</td>
<td></td>
</tr>
</tbody>
</table>

### 19.4 The INFORMATION_SCHEMA COLUMNS Table

The `COLUMNS` table provides information about columns in tables.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_CATALOG</td>
<td>NULL</td>
<td></td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td></td>
<td></td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td></td>
<td></td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td>Field</td>
<td></td>
</tr>
<tr>
<td>ORDINAL_POSITION</td>
<td></td>
<td>see notes</td>
</tr>
<tr>
<td>COLUMN_DEFAULT</td>
<td>Default</td>
<td></td>
</tr>
<tr>
<td>IS_NULLABLE</td>
<td>Null</td>
<td></td>
</tr>
<tr>
<td>DATA_TYPE</td>
<td>Type</td>
<td></td>
</tr>
<tr>
<td>CHARACTER_MAXIMUM_LENGTH</td>
<td>Type</td>
<td></td>
</tr>
</tbody>
</table>
### The INFORMATION_SCHEMA COLUMN_PRIVILEGES Table

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHARACTER_OCTET_LENGTH</td>
<td></td>
<td></td>
</tr>
<tr>
<td>NUMERIC_PRECISION</td>
<td>Type</td>
<td></td>
</tr>
<tr>
<td>NUMERIC_SCALE</td>
<td>Type</td>
<td></td>
</tr>
<tr>
<td>CHARACTER_SET_NAME</td>
<td></td>
<td></td>
</tr>
<tr>
<td>COLLATION_NAME</td>
<td>Type</td>
<td></td>
</tr>
<tr>
<td>COLUMN_TYPE</td>
<td></td>
<td>MySQL extension</td>
</tr>
<tr>
<td>COLUMN_KEY</td>
<td>Key</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>EXTRA</td>
<td>Extra</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>PRIVILEGES</td>
<td>Privileges</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>COLUMN_COMMENT</td>
<td>Comment</td>
<td>MySQL extension</td>
</tr>
</tbody>
</table>

**Notes:**

- In **SHOW**, the **Type** display includes values from several different **COLUMNS** columns.

- **ORDINAL_POSITION** is necessary because you might want to say **ORDER BY ORDINAL_POSITION**. Unlike **SHOW**, **SELECT** does not have automatic ordering.

- **CHARACTER_OCTET_LENGTH** should be the same as **CHARACTER_MAXIMUM_LENGTH**, except for multibyte character sets.

- **CHARACTER_SET_NAME** can be derived from **Collation**. For example, if you say **SHOW FULL COLUMNS FROM t**, and you see in the **Collation** column a value of `latin1_swedish_ci`, the character set is what is before the first underscore: `latin1`.

The following statements are nearly equivalent:

```sql
SELECT COLUMN_NAME, DATA_TYPE, IS_NULLABLE, COLUMN_DEFAULT
FROM INFORMATION_SCHEMA.COLUMNS
WHERE table_name = 't'
AND table_schema = 'db'
AND column_name LIKE 'wild'
```

```sql
SHOW COLUMNS
FROM t
[FROM db]
[LIKE 'wild']
```

### 19.5 The INFORMATION_SCHEMA COLUMN_PRIVILEGES Table

The **COLUMN_PRIVILEGES** table provides information about column privileges. This information comes from the **mysql.columns_priv** grant table.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRANTEE</td>
<td></td>
<td>'user_name'@'host_name' value</td>
</tr>
<tr>
<td>TABLE_CATALOG</td>
<td></td>
<td>NULL</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td></td>
<td></td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td></td>
<td></td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td></td>
<td></td>
</tr>
<tr>
<td>PRIVILEGE_TYPE</td>
<td></td>
<td></td>
</tr>
<tr>
<td>IS_GRANTABLE</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
The INFORMATION_SCHEMA KEY_COLUMN_USAGE Table

Notes:

- In the output from `SHOW FULL COLUMNS`, the privileges are all in one field and in lowercase, for example, `select,insert,update,references`. In `COLUMN_PRIVILEGES`, there is one privilege per row, in uppercase.

- `PRIVILEGE_TYPE` can contain one (and only one) of these values: `SELECT`, `INSERT`, `UPDATE`, `REFERENCES`.

- If the user has `GRANT OPTION` privilege, `IS_GRANTABLE` should be `YES`. Otherwise, `IS_GRANTABLE` should be `NO`. The output does not list `GRANT OPTION` as a separate privilege.

The following statements are *not* equivalent:

```sql
SELECT ... FROM INFORMATION_SCHEMA.COLUMN_PRIVILEGES
SHOW GRANTS ...
```

19.6 The INFORMATION_SCHEMA KEY_COLUMN_USAGE Table

The `KEY_COLUMN_USAGE` table describes which key columns have constraints.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONSTRAINT_CATALOG</td>
<td>NULL</td>
<td></td>
</tr>
<tr>
<td>CONSTRAINT_SCHEMA</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CONSTRAINT_NAME</td>
<td></td>
<td></td>
</tr>
<tr>
<td>TABLE_CATALOG</td>
<td></td>
<td></td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td></td>
<td></td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td></td>
<td></td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ORDINAL_POSITION</td>
<td></td>
<td></td>
</tr>
<tr>
<td>POSITION_IN_UNIQUE_CONSTRAINT</td>
<td></td>
<td></td>
</tr>
<tr>
<td>REFERENCED_TABLE_SCHEMA</td>
<td></td>
<td></td>
</tr>
<tr>
<td>REFERENCED_TABLE_NAME</td>
<td></td>
<td></td>
</tr>
<tr>
<td>REFERENCED_COLUMN_NAME</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Notes:

- If the constraint is a foreign key, then this is the column of the foreign key, not the column that the foreign key references.

- The value of `ORDINAL_POSITION` is the column's position within the constraint, not the column's position within the table. Column positions are numbered beginning with 1.

- The value of `POSITION_IN_UNIQUE_CONSTRAINT` is `NULL` for unique and primary-key constraints. For foreign-key constraints, it is the ordinal position in key of the table that is being referenced.

Suppose that there are two tables name `t1` and `t3` that have the following definitions:

```sql
CREATE TABLE t1
{
  s1 INT,
  s2 INT,
  s3 INT,
  PRIMARY KEY(s3)
} ENGINE=InnoDB;
```
CREATE TABLE `t3`
(
  `s1` INT,
  `s2` INT,
  `s3` INT,
  KEY(`s1`),
  CONSTRAINT CO FOREIGN KEY (`s2`) REFERENCES t1(`s3`)
) ENGINE=InnoDB;

For those two tables, the `KEY_COLUMN_USAGE` table has two rows:

- One row with `CONSTRAINT_NAME` = 'PRIMARY', `TABLE_NAME` = 't1', `COLUMN_NAME` = 's3',
  `ORDINAL_POSITION` = 1, `POSITION_IN_UNIQUE_CONSTRAINT` = NULL.

- One row with `CONSTRAINT_NAME` = 'CO', `TABLE_NAME` = 't3', `COLUMN_NAME` = 's2',
  `ORDINAL_POSITION` = 1, `POSITION_IN_UNIQUE_CONSTRAINT` = 1.

- `REFERENCED_TABLE_SCHEMA`, `REFERENCED_TABLE_NAME`, and `REFERENCED_COLUMN_NAME`
  were added in MySQL 5.0.6.

### 19.7 The INFORMATION_SCHEMA PROFILING Table

The `PROFILING` table provides statement profiling information. Its contents correspond to the
information produced by the `SHOW PROFILES` and `SHOW PROFILE` statements (see Section 13.7.5.29,
“SHOW PROFILES Syntax”). The table is empty unless the profiling session variable is set to 1.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>

</tr>
</tbody>
</table>

**Notes:**

- The `PROFILING` table was added in MySQL 5.0.37.
- `QUERY_ID` is a numeric statement identifier.
- `SEQ` is a sequence number indicating the display order for rows with the same `QUERY_ID` value.
### 19.8 The INFORMATION_SCHEMA ROUTINES Table

The ROUTINES table provides information about stored routines (both procedures and functions). The ROUTINES table does not include user-defined functions (UDFs).

The column named "mysql.proc name" indicates the mysql.proc table column that corresponds to the INFORMATION_SCHEMA.ROUTINES table column, if any.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>mysql.proc Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPECIFIC_NAME</td>
<td>specific_name</td>
<td>NULL</td>
</tr>
<tr>
<td>ROUTINE_CATALOG</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ROUTINE_SCHEMA</td>
<td>db</td>
<td></td>
</tr>
<tr>

<td>MySQL extension</td>
</tr>
<tr>
<td>ROUTINE_COMMENT</td>
<td>comment</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>DEFINER</td>
<td>definer</td>
<td>MySQL extension</td>
</tr>
</tbody>
</table>

**Notes:**
• MySQL calculates `EXTERNAL_LANGUAGE` thus:
  • If `mysql.proc.language='SQL'`, `EXTERNAL_LANGUAGE` is `NULL`
  • Otherwise, `EXTERNAL_LANGUAGE` is what is in `mysql.proc.language`. However, we do not have external languages yet, so it is always `NULL`.

19.9 The INFORMATION_SCHEMA SCHEMATA Table

A schema is a database, so the `SCHEMATA` table provides information about databases.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>CATALOG_NAME</td>
<td></td>
<td>NULL</td>
</tr>
<tr>
<td>SCHEMA_NAME</td>
<td>Database</td>
<td></td>
</tr>
<tr>
<td>DEFAULT_CHARACTER_SET_NAME</td>
<td></td>
<td></td>
</tr>
<tr>
<td>DEFAULT_COLLATION_NAME</td>
<td></td>
<td></td>
</tr>
<tr>
<td>SQL_PATH</td>
<td></td>
<td>NULL</td>
</tr>
</tbody>
</table>

Notes:
• `DEFAULT_COLLATION_NAME` was added in MySQL 5.0.6.

The following statements are equivalent:

```sql
SELECT SCHEMA_NAME AS `Database`
FROM INFORMATION_SCHEMA.SCHEMATA
WHERE SCHEMA_NAME LIKE '
SHOW DATABASES
LIKE '
```

19.10 The INFORMATION_SCHEMA SCHEMA_PRIVILEGES Table

The `SCHEMA_PRIVILEGES` table provides information about schema (database) privileges. This information comes from the `mysql.db` grant table.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRANTEE</td>
<td></td>
<td>'user_name'@'host_name' value, MySQL extension</td>
</tr>
<tr>
<td>TABLE_CATALOG</td>
<td></td>
<td>NULL, MySQL extension</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td></td>
<td>MySQL extension</td>
</tr>
<tr>
<td>PRIVILEGE_TYPE</td>
<td></td>
<td>MySQL extension</td>
</tr>
<tr>
<td>IS_GRANTABLE</td>
<td></td>
<td>MySQL extension</td>
</tr>
</tbody>
</table>

Notes:
• This is a nonstandard table. It takes its values from the `mysql.db` table.

19.11 The INFORMATION_SCHEMA STATISTICS Table

The `STATISTICS` table provides information about table indexes.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_CATALOG</td>
<td></td>
<td>NULL</td>
</tr>
</tbody>
</table>
The INFORMATION_SCHEMA TABLES Table

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_SCHEMA</td>
<td>Table</td>
<td>= Database</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>Table</td>
<td></td>
</tr>
<tr>
<td>NON UNIQUE</td>
<td>Non_unique</td>
<td></td>
</tr>
<tr>
<td>INDEX_SCHEMA</td>
<td>Key_name</td>
<td></td>
</tr>
<tr>
<td>SEQ_IN_INDEX</td>
<td>Seq_in_index</td>
<td></td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td>Column_name</td>
<td></td>
</tr>
<tr>
<td>COLLATION</td>
<td>Collation</td>
<td></td>
</tr>
<tr>
<td>CARDINALITY</td>
<td>Cardinality</td>
<td></td>
</tr>
<tr>
<td>SUB_PART</td>
<td>Sub_part</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>PACKED</td>
<td>Packed</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>NULLABLE</td>
<td>Null</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>INDEX_TYPE</td>
<td>Index_type</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>COMMENT</td>
<td>Comment</td>
<td>MySQL extension</td>
</tr>
</tbody>
</table>

Notes:

- There is no standard table for indexes. The preceding list is similar to what SQL Server 2000 returns for `sp_statistics`, except that we replaced the name `QUALIFIER` with `CATALOG` and we replaced the name `OWNER` with `SCHEMA`.

Clearly, the preceding table and the output from `SHOW INDEX` are derived from the same parent. So the correlation is already close.

The following statements are equivalent:

```sql
SELECT * FROM INFORMATION_SCHEMA.STATISTICS
WHERE table_name = 'tbl_name'
AND table_schema = 'db_name'

SHOW INDEX
FROM tbl_name
FROM db_name
```

19.12 The INFORMATION_SCHEMA TABLES Table

The TABLES table provides information about tables in databases.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_CATALOG</td>
<td>NULL</td>
<td></td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td>Table_...</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>Table_...</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>TABLE_TYPE</td>
<td>Engine</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>ENGINE</td>
<td>Version</td>
<td>The version number of the table's .frm file, MySQL extension</td>
</tr>
<tr>
<td>VERSION</td>
<td>Version</td>
<td></td>
</tr>
<tr>
<td>ROW_FORMAT</td>
<td>Row_format</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>TABLE_ROWS</td>
<td>Rows</td>
<td>MySQL extension</td>
</tr>
</tbody>
</table>
The INFORMATION_SCHEMA TABLE_CONSTRAINTS Table

The TABLE_CONSTRAINTS table describes which tables have constraints.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONSTRAINT_CATALOG</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CONSTRAINT_SCHEMA</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CONSTRAINT_NAME</td>
<td></td>
<td></td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td></td>
<td></td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CONSTRAINT_TYPE</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Notes:

- The CONSTRAINT_TYPE value can be UNIQUE, PRIMARY KEY, or FOREIGN KEY.
• The **UNIQUE** and **PRIMARY KEY** information is about the same as what you get from the **Key_name** field in the output from **SHOW INDEX** when the **Non_unique** field is **0**.

• The **CONSTRAINT_TYPE** column can contain one of these values: **UNIQUE, PRIMARY KEY, FOREIGN KEY, CHECK**. This is a **CHAR** (not **ENUM**) column. The **CHECK** value is not available until we support **CHECK**.

### 19.14 The INFORMATION_SCHEMA TABLE_PRIVILEGES Table

The **TABLE_PRIVILEGES** table provides information about table privileges. This information comes from the **mysql.tables_priv** grant table.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRANTEE</td>
<td>'user_name'@'host_name' value</td>
<td></td>
</tr>
<tr>
<td>TABLE_CATALOG</td>
<td>NULL</td>
<td></td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td></td>
<td></td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td></td>
<td></td>
</tr>
<tr>
<td>PRIVILEGE_TYPE</td>
<td></td>
<td></td>
</tr>
<tr>
<td>IS_GRANTABLE</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Notes:**

• **PRIVILEGE_TYPE** can contain one (and only one) of these values: **SELECT, INSERT, UPDATE, REFERENCES, ALTER, INDEX, DROP, CREATE VIEW**.

The following statements are not equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.TABLE_PRIVILEGES
SHOW GRANTS ...
```

### 19.15 The INFORMATION_SCHEMA TRIGGERS Table

The **TRIGGERS** table provides information about triggers. You must have the **SUPER** privilege to access this table. You can see information only if you have the **SUPER** privilege.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRIGGER_CATALOG</td>
<td>NULL</td>
<td></td>
</tr>
<tr>
<td>TRIGGER_SCHEMA</td>
<td></td>
<td></td>
</tr>
<tr>
<td>TRIGGER_NAME</td>
<td>Trigger</td>
<td></td>
</tr>
<tr>
<td>EVENT_MANIPULATION</td>
<td>Event</td>
<td>NULL</td>
</tr>
<tr>
<td>EVENT_OBJECT_CATALOG</td>
<td></td>
<td></td>
</tr>
<tr>
<td>EVENT_OBJECT_SCHEMA</td>
<td></td>
<td></td>
</tr>
<tr>
<td>EVENT_OBJECT_TABLE</td>
<td>Table</td>
<td></td>
</tr>
<tr>
<td>ACTION_ORDER</td>
<td>0</td>
<td></td>
</tr>
<tr>
<td>ACTION_CONDITION</td>
<td>NULL</td>
<td></td>
</tr>
<tr>
<td>ACTION_STATEMENT</td>
<td>Statement</td>
<td></td>
</tr>
<tr>
<td>ACTION_ORIENTATION</td>
<td>ROW</td>
<td></td>
</tr>
<tr>
<td>ACTION_TIMING</td>
<td>Timing</td>
<td></td>
</tr>
<tr>
<td>ACTION_REFERENCE_OLD_TABLE</td>
<td>NULL</td>
<td></td>
</tr>
</tbody>
</table>
The INFORMATION_SCHEMA TRIGGERS Table

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA</th>
<th>SHOW</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACTION_REFERENCE_NEW_TABLE</td>
<td>NULL</td>
<td></td>
</tr>
<tr>
<td>ACTION_REFERENCE_OLD_ROW</td>
<td>OLD</td>
<td></td>
</tr>
<tr>
<td>ACTION_REFERENCE_NEW_ROW</td>
<td>NEW</td>
<td></td>
</tr>
<tr>
<td>CREATED</td>
<td>NULL (0)</td>
<td></td>
</tr>
<tr>
<td>SQL_MODE</td>
<td>MySQL extension</td>
<td></td>
</tr>
<tr>
<td>DEFINER</td>
<td>MySQL extension</td>
<td></td>
</tr>
</tbody>
</table>

Notes:

- The TRIGGERS table was added in MySQL 5.0.10.
- The names in the "SHOW Name" column refer to the SHOW TRIGGERS statement. See Section 13.7.5.35, "SHOW TRIGGERS Syntax".
- TRIGGER_SCHEMA and TRIGGER_NAME: The name of the database in which the trigger occurs and the trigger name, respectively.
- EVENT_MANIPULATION: The trigger event. This is the type of operation on the associated table for which the trigger activates. The value is 'INSERT' (a row was inserted), 'DELETE' (a row was deleted), or 'UPDATE' (a row was modified).
- EVENT_OBJECT_SCHEMA and EVENT_OBJECT_TABLE: As noted in Section 18.3, "Using Triggers", every trigger is associated with exactly one table. These columns indicate the database in which this table occurs, and the table name, respectively.
- ACTION_ORDER: The ordinal position of the trigger's action within the list of all similar triggers on the same table. This value is always 0, because it is not possible to have more than one trigger with the same EVENT_MANIPULATION and ACTION_TIMING on the same table.
- ACTION_STATEMENT: The trigger body; that is, the statement executed when the trigger activates. This text uses UTF-8 encoding.
- ACTION_ORIENTATION: Always contains the value 'ROW'.
- ACTION_TIMING: Whether the trigger activates before or after the triggering event. The value is 'BEFORE' or 'AFTER'.
- ACTION_REFERENCE_OLD_ROW and ACTION_REFERENCE_NEW_ROW: The old and new column identifiers, respectively. This means that ACTION_REFERENCE_OLD_ROW always contains the value 'OLD' and ACTION_REFERENCE_NEW_ROW always contains the value 'NEW'.
- SQL_MODE: The SQL mode in effect when the trigger was created, and under which the trigger executes. For the permitted values, see Section 5.1.7, "Server SQL Modes".
- DEFINER: The account of the user who created the trigger, in 'user_name'@'host_name' format. This column was added in MySQL 5.0.17.
- The following columns currently always contain NULL: TRIGGER CATALOG, EVENT_OBJECT_CATALOG, ACTION CONDITION, ACTION_REFERENCE_OLD_TABLE, ACTION_REFERENCE_NEW_TABLE, and CREATED.

Example, using the ins_sum trigger defined in Section 18.3, "Using Triggers":

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.TRIGGERS
   -> WHERE TRIGGER_SCHEMA='test' AND TRIGGER_NAME='ins_sum' \G
******************** 1. row ********************
TRIGGER_CATALOG: NULL
TRIGGER_SCHEMA: test
TRIGGER_NAME: ins_sum
```
19.16 The INFORMATION_SCHEMA USER_PRIVILEGES Table

The USER_PRIVILEGES table provides information about global privileges. This information comes from the mysql.user grant table.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRANTEE</td>
<td>'user_name'@'host_name' value, MySQL extension</td>
<td></td>
</tr>
<tr>
<td>TABLE_CATALOG</td>
<td>NULL, MySQL extension</td>
<td></td>
</tr>
<tr>
<td>PRIVILEGE_TYPE</td>
<td>MySQL extension</td>
<td></td>
</tr>
<tr>
<td>IS_GRANTABLE</td>
<td>MySQL extension</td>
<td></td>
</tr>
</tbody>
</table>

Notes:
- This is a nonstandard table. It takes its values from the mysql.user table.

19.17 The INFORMATION_SCHEMA VIEWS Table

The VIEWS table provides information about views in databases. You must have the SHOW VIEW privilege to access this table.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_CATALOG</td>
<td>NULL</td>
<td></td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td></td>
<td></td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td></td>
<td></td>
</tr>
<tr>
<td>VIEW_DEFINITION</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CHECK_OPTION</td>
<td></td>
<td></td>
</tr>
<tr>
<td>IS_UPDATABLE</td>
<td></td>
<td></td>
</tr>
<tr>
<td>DEFINER</td>
<td></td>
<td></td>
</tr>
<tr>
<td>SECURITY_TYPE</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Notes:
- The VIEW_DEFINITION column has most of what you see in the Create Table field that SHOW CREATE VIEW produces. Skip the words before SELECT and skip the words WITH CHECK OPTION. Suppose that the original statement was:

```sql
CREATE VIEW v AS
SELECT s2, s1 FROM t
WHERE s1 > 5
```
ORDER BY s1
WITH CHECK OPTION;

Then the view definition looks like this:

```
SELECT s2, s1 FROM t WHERE s1 > 5 ORDER BY s1
```

- The **CHECK_OPTION** column has a value of **NONE, CASCADE, or LOCAL**.

- MySQL sets a flag, called the view updatability flag, at **CREATE VIEW** time. The flag is set to **YES** (true) if **UPDATE** and **DELETE** (and similar operations) are legal for the view. Otherwise, the flag is set to **NO** (false). The **IS_UPDATABLE** column in the **VIEWS** table displays the status of this flag. It means that the server always knows whether a view is updatable.

If a view is not updatable, statements such as **UPDATE, DELETE, and INSERT** are illegal and will be rejected. (Note that even if a view is updatable, it might not be possible to insert into it; for details, refer to Section 18.4.3, "Updatable and Insertable Views".)

- **DEFINER**: The account of the user who created the view, in 'user_name'@'host_name' format. **SECURITY_TYPE** has a value of **DEFINER** or **INVOKER**. The **DEFINER** and **SECURITY_TYPE** columns were added in MySQL 5.0.14.

MySQL lets you use different **sql_mode** settings to tell the server the type of SQL syntax to support. For example, you might use the **ANSI** SQL mode to ensure MySQL correctly interprets the standard SQL concatenation operator, the double bar (||), in your queries. If you then create a view that concatenates items, you might worry that changing the **sql_mode** setting to a value different from **ANSI** could cause the view to become invalid. But this is not the case. No matter how you write out a view definition, MySQL always stores it the same way, in a canonical form. Here is an example that shows how the server changes a double bar concatenation operator to a **CONCAT()** function:

```sql
mysql> SET sql_mode = 'ANSI';
Query OK, 0 rows affected (0.00 sec)
mysql> CREATE VIEW test.v AS SELECT 'a' || 'b' as col1;
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT VIEW_DEFINITION FROM INFORMATION_SCHEMA.VIEWS
       -> WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME = 'v';
+----------------------------------+
| VIEW_DEFINITION                  |
+----------------------------------+
| select concat('a','b') AS `col1` |
+----------------------------------+
1 row in set (0.00 sec)
```

The advantage of storing a view definition in canonical form is that changes made later to the value of **sql_mode** will not affect the results from the view. However an additional consequence is that comments prior to **SELECT** are stripped from the definition by the server.

### 19.18 Extensions to SHOW Statements

Some extensions to **SHOW** statements accompany the implementation of **INFORMATION_SCHEMA**:

- **SHOW** can be used to get information about the structure of **INFORMATION_SCHEMA** itself.

- **SQL_MODE**: The SQL mode in effect when the routine was created or altered, and under which the routine executes. For the permitted values, see Section 5.1.7, "Server SQL Modes".

- Several **SHOW** statements accept a **WHERE** clause that provides more flexibility in specifying which rows to display.

These extensions are available beginning with MySQL 5.0.3.
**INFORMATION_SCHEMA** is an information database, so its name is included in the output from `SHOW DATABASES`. Similarly, `SHOW TABLES` can be used with `INFORMATION_SCHEMA` to obtain a list of its tables:

```sql
mysql> SHOW TABLES FROM INFORMATION_SCHEMA;
+---------------------------------------+
| Tables_in_information_schema          |
+---------------------------------------+
| CHARACTER_SETS                        |
| COLLATIONS                            |
| COLLATION_CHARACTER_SET_APPLICABILITY |
| COLUMNS                               |
| COLUMN_PRIVILEGES                     |
| KEY_COLUMN_USAGE                      |
| Routines                              |
| SCHEMATAS                             |
| SCHEMA_PRIVILEGES                     |
| STATISTICS                            |
| TABLES                                |
| TABLE_CONSTRAINTS                     |
| TABLE_PRIVILEGES                      |
| TRIGGERS                              |
| USER_PRIVILEGES                       |
| VIEWS                                 |
+---------------------------------------+
16 rows in set (0.00 sec)
```

`SHOW COLUMNS` and `DESCRIBE` can display information about the columns in individual `INFORMATION_SCHEMA` tables.

`SHOW` statements that accept a `LIKE` clause to limit the rows displayed also have been extended to permit a `WHERE` clause that specifies more general conditions that selected rows must satisfy:

```sql
SHOW CHARACTER SET
SHOW COLLATION
SHOW COLUMNS
SHOW DATABASES
SHOW FUNCTION STATUS
SHOW INDEX
SHOW OPEN TABLES
SHOW PROCEDURE STATUS
SHOW STATUS
SHOW TABLE STATUS
SHOW TABLES
SHOW VARIABLES
```

The `WHERE` clause, if present, is evaluated against the column names displayed by the `SHOW` statement. For example, the `SHOW CHARACTER SET` statement produces these output columns:

```sql
mysql> SHOW CHARACTER SET;
+--------------+-----------------------------+---------------------+--------+
| Charset      | Description                 | Default_collation   | Maxlen |
|--------------+-----------------------------+---------------------+--------+
| big5         | Big5 Traditional Chinese   | big5_chinese_ci     | 2      |
| dec8         | DEC West European           | dec8_swedish_ci     | 1      |
| cp850        | DOS West European           | cp850_general_ci    | 1      |
| hp8          | HP West European            | hp8_english_ci      | 1      |
| koi8r        | KOI8-R Relcom Russian       | koi8r_general_ci    | 1      |
| latin1       | cp1252 west European        | latin1_sweedn_ci    | 1      |
| latin2       | ISO 8859-2 Central European | latin2_general_ci   | 1      |
| ...          |                             |                     |        |
```

To use a `WHERE` clause with `SHOW CHARACTER SET`, you would refer to those column names. As an example, the following statement displays information about character sets for which the default collation contains the string 'japanese':
### Extensions to SHOW Statements

```sql
mysql> SHOW CHARACTER SET WHERE `Default collation` LIKE '%japanese%';
```
<table>
<thead>
<tr>
<th>Charset</th>
<th>Description</th>
<th>Default collation</th>
<th>Maxlen</th>
</tr>
</thead>
<tbody>
<tr>
<td>ujis</td>
<td>EUC-JP Japanese</td>
<td>ujis_japanese_ci</td>
<td>3</td>
</tr>
<tr>
<td>sjis</td>
<td>Shift-JIS Japanese</td>
<td>sjis_japanese_ci</td>
<td>2</td>
</tr>
<tr>
<td>cp932</td>
<td>SJIS for Windows Japanese</td>
<td>cp932_japanese_ci</td>
<td>2</td>
</tr>
<tr>
<td>eucjpms</td>
<td>UJIS for Windows Japanese</td>
<td>eucjpms_japanese_ci</td>
<td>3</td>
</tr>
</tbody>
</table>
```

This statement displays the multibyte character sets:

```sql
mysql> SHOW CHARACTER SET WHERE Maxlen > 1;
```
<table>
<thead>
<tr>
<th>Charset</th>
<th>Description</th>
<th>Default collation</th>
<th>Maxlen</th>
</tr>
</thead>
<tbody>
<tr>
<td>big5</td>
<td>Big5 Traditional Chinese</td>
<td>big5_chinese_ci</td>
<td>2</td>
</tr>
<tr>
<td>ujis</td>
<td>EUC-JP Japanese</td>
<td>ujis_japanese_ci</td>
<td>3</td>
</tr>
<tr>
<td>sjis</td>
<td>Shift-JIS Japanese</td>
<td>sjis_japanese_ci</td>
<td>2</td>
</tr>
<tr>
<td>euckr</td>
<td>EUC-KR Korean</td>
<td>euckr_korean_ci</td>
<td>2</td>
</tr>
<tr>
<td>gb2312</td>
<td>GB2312 Simplified Chinese</td>
<td>gb2312_chinese_ci</td>
<td>2</td>
</tr>
<tr>
<td>gbk</td>
<td>GBK Simplified Chinese</td>
<td>gbk_chinese_ci</td>
<td>2</td>
</tr>
<tr>
<td>utf8</td>
<td>UTF-8 Unicode</td>
<td>utf8_general_ci</td>
<td>3</td>
</tr>
<tr>
<td>ucs2</td>
<td>UCS-2 Unicode</td>
<td>ucs2_general_ci</td>
<td>2</td>
</tr>
<tr>
<td>cp932</td>
<td>SJIS for Windows Japanese</td>
<td>cp932_japanese_ci</td>
<td>2</td>
</tr>
<tr>
<td>eucjpms</td>
<td>UJIS for Windows Japanese</td>
<td>eucjpms_japanese_ci</td>
<td>3</td>
</tr>
</tbody>
</table>

MySQL Connectors provide connectivity to the MySQL server for client programs. APIs provide low-level access to the MySQL protocol and MySQL resources. Both Connectors and the APIs enable you to connect and execute MySQL statements from another language or environment, including ODBC, Java (JDBC), Perl, Python, PHP, Ruby, and native C and embedded MySQL instances.

Note
Connector version numbers do not correlate with MySQL Server version numbers. See Table 20.2, "MySQL Connector Versions and MySQL Server Versions".

MySQL Connectors

Oracle develops a number of connectors:

- **Connector/ODBC** provides driver support for connecting to MySQL using the Open Database Connectivity (ODBC) API. Support is available for ODBC connectivity from Windows, Unix, and OS X platforms.
The MySQL C API

• **Connector/Net** enables developers to create .NET applications that connect to MySQL. Connector/Net implements a fully functional ADO.NET interface and provides support for use with ADO.NET aware tools. Applications that use Connector/Net can be written in any supported .NET language.

The MySQL Visual Studio Plugin works with Connector/Net and Visual Studio 2005. The plugin is a MySQL DDEX Provider, which means that you can use the schema and data manipulation tools available in Visual Studio to create and edit objects within a MySQL database.

• **Connector/J** provides driver support for connecting to MySQL from Java applications using the standard Java Database Connectivity (JDBC) API.

• Connector/C++ enables C++ applications to connect to MySQL.

• **Connector/C** is a standalone replacement for the MySQL Client Library (*libmysqlclient*), to be used for C applications.

The MySQL C API

For direct access to using MySQL natively within a C application, there are two methods:

• The **C API** provides low-level access to the MySQL client/server protocol through the *libmysqlclient* client library. This is the primary method used to connect to an instance of the MySQL server, and is used both by MySQL command-line clients and many of the MySQL Connectors and third-party APIs detailed here.

  *libmysqlclient* is included in MySQL distributions and in Connector/C distributions.

• **libmysqld** is an embedded MySQL server library that enables you to embed an instance of the MySQL server into your C applications.

  *libmysqld* is included in MySQL distributions, but not in Connector/C distributions.

See also Section 20.6.1, "MySQL C API Implementations".

To access MySQL from a C application, or to build an interface to MySQL for a language not supported by the Connectors or APIs in this chapter, the **C API** is where to start. A number of programmer's utilities are available to help with the process; see Section 4.7, "MySQL Program Development Utilities".

Third-Party MySQL APIs

The remaining APIs described in this chapter provide an interface to MySQL from specific application languages. These third-party solutions are not developed or supported by Oracle. Basic information on their usage and abilities is provided here for reference purposes only.

All the third-party language APIs are developed using one of two methods, using *libmysqlclient* or by implementing a native driver. The two solutions offer different benefits:

• Using **libmysqlclient** offers complete compatibility with MySQL because it uses the same libraries as the MySQL client applications. However, the feature set is limited to the implementation and interfaces exposed through *libmysqlclient* and the performance may be lower as data is copied between the native language, and the MySQL API components.

• **Native drivers** are an implementation of the MySQL network protocol entirely within the host language or environment. Native drivers are fast, as there is less copying of data between components, and they can offer advanced functionality not available through the standard MySQL API. Native drivers are also easier for end users to build and deploy because no copy of the MySQL client libraries is needed to build the native driver components.

Table 20.1, "MySQL APIs and Interfaces" lists many of the libraries and interfaces available for MySQL. Table 20.2, "MySQL Connector Versions and MySQL Server Versions" shows which MySQL Server versions each connector supports.

20.1 MySQL Connector/ODBC

The MySQL Connector/ODBC manual is now published in standalone form, not as part of the MySQL Reference Manual. For information, see these documents:

- Main manual: MySQL Connector/ODBC Developer Guide
- Release notes: MySQL Connector/ODBC Release Notes

20.2 MySQL Connector/Net

The MySQL Connector/Net manual is now published in standalone form, not as part of the MySQL Reference Manual. For information, see these documents:

- Main manual: MySQL Connector/Net Developer Guide
20.3 MySQL Connector/J

The MySQL Connector/J manual is now published in standalone form, not as part of the MySQL Reference Manual. For information, see these documents:

- Main manual: MySQL Connector/J 5.1 Developer Guide
- Release notes: MySQL Connector/J Release Notes

20.4 MySQL Connector/C

The MySQL Connector/C manual is now published in standalone form, not as part of the MySQL Reference Manual. For information, see these documents:

- Main manual: MySQL Connector/C Developer Guide
- Release notes: MySQL Connector/C Release Notes

20.5 libmysqld, the Embedded MySQL Server Library

The embedded MySQL server library is NOT part of MySQL 5.0. It is part of previous editions and will be included in future versions, starting with MySQL 5.1. You can find appropriate documentation in the corresponding manuals for these versions. In this manual, only an overview of the embedded library is provided.

The embedded MySQL server library makes it possible to run a full-featured MySQL server inside a client application. The main benefits are increased speed and more simple management for embedded applications.

The embedded server library is based on the client/server version of MySQL, which is written in C/C++. Consequently, the embedded server also is written in C/C++. There is no embedded server available in other languages.

The API is identical for the embedded MySQL version and the client/server version. To change an old threaded application to use the embedded library, you normally only have to add calls to the following functions.

<table>
<thead>
<tr>
<th>Table 20.3 MySQL Embedded Server Library Functions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Function</td>
</tr>
<tr>
<td>mysql_library_init()</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>mysql_library_end()</td>
</tr>
<tr>
<td>mysql_thread_init()</td>
</tr>
<tr>
<td>mysql_thread_end()</td>
</tr>
</tbody>
</table>

Then, link your code with libmysqld.a instead of libmysqlclient.a. To ensure binary compatibility between your application and the server library, be sure to compile your application against headers for the same series of MySQL that was used to compile the server library. For example, if libmysqld was compiled against MySQL 4.1 headers, do not compile your application against MySQL 5.0 headers.

The mysql_library_xxx() functions are also included in libmysqlclient.a to enable you to change between the embedded and the client/server version by just linking your application with the right library. See Section 20.6.7.40, "mysql_library_init()".

One difference between the embedded server and the standalone server is that for the embedded server, authentication for connections is disabled by default. To use authentication for the embedded

This documentation is for an older version. If you're
server, specify the `--with-embedded-privilege-control` option when you invoke `configure` to configure your MySQL distribution.

## 20.6 MySQL C API

The C API provides low-level access to the MySQL client/server protocol and enables C programs to access database contents. The C API code is distributed with MySQL and implemented in the `libmysqlclient` library. See Section 20.6.1, “MySQL C API Implementations”.

Most other client APIs use the `libmysqlclient` library to communicate with the MySQL server. (Exceptions are except Connector/J and Connector/Net.) This means that, for example, you can take advantage of many of the same environment variables that are used by other client programs because they are referenced from the library. For a list of these variables, see Section 4.1, “Overview of MySQL Programs”.

For instructions on building client programs using the C API, see Section 20.6.4.1, “Building C API Client Programs”. For programming with threads, see Section 20.6.4.2, “Writing C API Threaded Client Programs”. To create a standalone application which includes the “server” and “client” in the same program (and does not communicate with an external MySQL server), see Section 20.5, “libmysqld, the Embedded MySQL Server Library”.

### Note

If, after an upgrade, you experience problems with compiled client programs, such as `Commands out of sync` or unexpected core dumps, the programs were probably compiled using old header or library files. In this case, check the date of the `mysql.h` file and `libmysqlclient.a` library used for compilation to verify that they are from the new MySQL distribution. If not, recompile the programs with the new headers and libraries. Recompilation might also be necessary for programs compiled against the shared client library if the library major version number has changed (for example, from `libmysqlclient.so.17` to `libmysqlclient.so.18`). For additional compatibility information, see Section 20.6.4.3, “Running C API Client Programs”.

Clients have a maximum communication buffer size. The size of the buffer that is allocated initially (16KB) is automatically increased up to the maximum size (16MB by default). Because buffer sizes are increased only as demand warrants, simply increasing the maximum limit does not in itself cause more resources to be used. This size check is mostly a precaution against erroneous statements and communication packets.

The communication buffer must be large enough to contain a single SQL statement (for client-to-server traffic) and one row of returned data (for server-to-client traffic). Each session’s communication buffer is dynamically enlarged to handle any query or row up to the maximum limit. For example, if you have `BLOB` values that contain up to 16MB of data, you must have a communication buffer limit of at least 16MB (in both server and client). The default maximum built into the client library is 1GB, but the default maximum in the server is 1MB. You can increase this by changing the value of the `max_allowed_packet` parameter at server startup. See Section 8.12.2, “Tuning Server Parameters”.

The MySQL server shrinks each communication buffer to `net_buffer_length` bytes after each query. For clients, the size of the buffer associated with a connection is not decreased until the connection is closed, at which time client memory is reclaimed.

### 20.6.1 MySQL C API Implementations

The MySQL C API is a C-based API that client applications written in C can use to communicate with MySQL Server. Client programs refer to C API header files at compile time and link to a C API library file at link time. The library comes in two versions, depending on how the application is intended to communicate with the server:
Simultaneous MySQL Server and Connector/C Installations

- **libmysqlclient**: The client version of the library, used for applications that communicate over a network connection as a client of a standalone server process.

- **libmysqld**: The embedded server version of the library, used for applications intended to include an embedded MySQL server within the application itself. The application communicates with its own private server instance.

Both libraries have the same interface. In terms of C API calls, an application communicates with a standalone server the same way it communicates with an embedded server. A given client can be built to communicate with a standalone or embedded server, depending on whether it is linked against `libmysqlclient` or `libmysqld` at build time.

There are two ways to obtain the C API header and library files required to build C API client programs:

- Install a MySQL Server distribution. Server distributions include both `libmysqlclient` and `libmysqld`.
- Install a Connector/C distribution. Connector/C distributions include only `libmysqlclient`. They do not include `libmysqld`.

For both MySQL Server and Connector/C, you can install a binary distribution that contains the C API files pre-built, or you can use a source distribution and build the C API files yourself.

Normally, you install either a MySQL Server distribution or a Connector/C distribution, but not both. For information about issues involved with simultaneous MySQL Server and Connector/C installations, see Section 20.6.2, “Simultaneous MySQL Server and Connector/C Installations”.

The names of the library files to use when linking C API client applications depend on the library type and platform for which a distribution is built:

- On Unix (and Unix-like) systems, the static library is `libmysqlclient.a`. The dynamic library is `libmysqlclient.so` on most Unix systems and `libmysqlclient.dylib` on OS X.

  For distributions that include embedded server libraries, the corresponding library names begin with `libmysqld` rather than `libmysqlclient`.

- On Windows, the static library is `mysqlclient.lib` and the dynamic library is `libmysql.dll`. Windows distributions also include `libmysql.lib`, a static import library needed for using the dynamic library.

  For distributions that include embedded server libraries, the corresponding library names are `mysqlserver.lib`, `libmysqld.dll`, and `libmysqld.lib`.

  Windows distributions also include a set of debug libraries. These have the same names as the nondebug libraries, but are located in the `lib/debug` library. You must use the debug libraries when compiling clients built using the debug C runtime.

### 20.6.2 Simultaneous MySQL Server and Connector/C Installations

MySQL Server and Connector/C installation packages both provide the files needed to build and run MySQL C API client programs. This section discusses when it is possible to install both products on the same system. For some packaging formats, this is possible without conflict. For others, both products cannot be installed at the same time.

This discussion assumes the use of similar package types for both products (for example, RPM packages for both products). It does not try to describe coexistence between packaging types (for example, use of RPM packages for one product and a `.tar` file package for the other). Nor does it describe coexistence of packages provided by Oracle and those provided by third-party vendors.

If you install both products, it may be necessary to adjust your development tools or runtime environment to choose one set of header files and libraries over the other. See Section 20.6.4.1, “Building C API Client Programs”, and Section 20.6.4.3, “Running C API Client Programs”.

This documentation is for an older version. If you're looking for the most current version, you can download a newer PDF or EPUB file.
**Example C API Client Programs**

Tar and Zip file packages install under the directory into which you unpack them. For example, you can unpack MySQL Server and Connector/C tar packages under /usr/local and they will unpack into distinct directory names without conflict.

Windows MSI installers use their own installation directory, so MySQL Server and Connector/C installers do not conflict.

OS X DMG packages install under the same parent directory but in a different subdirectory, so there is no conflict. For example:

```
/usr/local/mysql-5.6.11-osx10.7-x86_64/
/usr/local/mysql-connector-c-6.1.0-osx10.7-x86/
```

Solaris PKG packages install under the same parent directory but in a different subdirectory, so there is no conflict. For example:

```
/opt/mysql/mysql
/opt/mysql/connector-c
```

The Solaris Connector/C installer does not create any symlinks from system directories such as /usr/bin or /usr/lib into the installation directory. That must be done manually if desired after installation.

For RPM installations, there are several types of RPM packages. MySQL Server shared and devel RPM packages are similar to the corresponding Connector/C RPM packages. These RPM package types cannot coexist because the MySQL Server and Connector/C RPM packages use the same installation locations for the client library-related files. This means the following conditions hold:

- If MySQL Server shared and devel RPM packages are installed, they provide the C API headers and libraries, and there is no need to install the Connector/C RPM packages. To install the Connector/C packages anyway, you must first remove the corresponding MySQL Server packages.
- To install MySQL Server RPM packages if you already have Connector/C RPM packages installed, you must first remove the Connector/C RPM packages.

MySQL Server RPM packages other than shared and devel do not conflict with Connector/C packages and can be installed if Connector/C is installed. This includes the main server RPM that includes the mysqld server itself.

### 20.6.3 Example C API Client Programs

Many of the clients in MySQL source distributions are written in C, such as mysql, mysqladmin, and mysqlshow. If you are looking for examples that demonstrate how to use the C API, take a look at these clients: Obtain a source distribution and look in its client directory. See Section 2.5, "How to Get MySQL".

### 20.6.4 Building and Running C API Client Programs

The following sections provide information on building client programs that use the C API. Topics include compiling and linking clients, writing threaded clients, and troubleshooting runtime problems.

#### 20.6.4.1 Building C API Client Programs

This section provides guidelines for compiling C programs that use the MySQL C API.

**Compiling MySQL Clients on Unix**

You may need to specify an -I option when you compile client programs that use MySQL header files, so that the compiler can find them. For example, if the header files are installed in /usr/local/mysql/include, use this option in the compile command:
MySQL clients must be linked using the `-lmysqlclient` `-lz` options in the link command. You may also need to specify a `-L` option to tell the linker where to find the library. For example, if the library is installed in `/usr/local/mysql/lib`, use these options in the link command:

```
-L/usr/local/mysql/lib -lmysqlclient -lz
```

The path names may differ on your system. Adjust the `-I` and `-L` options as necessary.

To make it simpler to compile MySQL programs on Unix, use the `mysql_config` script. See Section 4.7.2, "mysql_config — Display Options for Compiling Clients".

`mysql_config` displays the options needed for compiling or linking:

```
shell> mysql_config --cflags
shell> mysql_config --libs
```

You can run those commands to get the proper options and add them manually to compilation or link commands. Alternatively, include the output from `mysql_config` directly within command lines using backticks:

```
shell> gcc -c `mysql_config --cflags` progname.c
shell> gcc -o progname progname.o `mysql_config --libs`
```

### Compiling MySQL Clients on Microsoft Windows

To specify header and library file locations, use the facilities provided by your development environment.

On Windows, you can link your code with either the dynamic or static C client library. The static library is named `mysqlclient.lib` and the dynamic library is named `libmysql.dll`. In addition, the `libmysql.lib` static import library is needed for using the dynamic library.

If you link with the static library, failure can occur unless these conditions are satisfied:

- The client application must be compiled with the same version of Visual Studio used to compile the library.
- The client application should link the C runtime statically by using the `/MT` compiler option.

If the client application is built in debug mode and uses the static debug C runtime (`/MTd` compiler option), it can link to the `mysqlclient.lib` static library if that library was built using the same option. If the client application uses the dynamic C runtime (`/MD` option, or `/MDd` option in debug mode), it must be linked to the `libmysql.dll` dynamic library. It cannot link to the static client library.

### Troubleshooting Problems Linking to the MySQL Client Library

Linking with the single-threaded library (`libmysqlclient`) may lead to linker errors related to `pthread` symbols. When using the single-threaded library, please compile your client with `MYSQL_CLIENT_NO_THREADS` defined. This can be done on the command line by using the `-D` option to the compiler, or in your source code before including the MySQL header files. This define should not be used when building for use with the thread-safe client library (`libmysqlclient_r`).

If the linker cannot find the MySQL client library, you might get undefined-reference errors for symbols that start with `mysql_`, such as those shown here:
You should be able to solve this problem by adding `-Ldir_path -lmysqlclient` at the end of your link command, where `dir_path` represents the path name of the directory where the client library is located. To determine the correct directory, try this command:

```
shell> mysql_config --libs
```

The output from `mysql_config` might indicate other libraries that should be specified on the link command as well. You can include `mysql_config` output directly in your compile or link command using backticks. For example:

```
shell> gcc -o programe programe.o `mysql_config --libs`
```

If an error occurs at link time that the `floor` symbol is undefined, link to the math library by adding `-lm` to the end of the compile/link line.

If you get `undefined reference` errors for the `uncompress` or `compress` function, add `-lz` to the end of your link command and try again.

Similarly, if you get undefined-reference errors for other functions that should exist on your system, such as `connect()`, check the manual page for the function in question to determine which libraries you should add to the link command.

If you get undefined-reference errors such as the following for functions that do not exist on your system, it usually means that your MySQL client library was compiled on a system that is not 100% compatible with yours:

```
mf_format.o(.text+0x201): undefined reference to `__lxstat'
```

In this case, you should download the latest MySQL or Connector/C source distribution and compile the MySQL client library yourself. See Section 2.17, “Installing MySQL from Source”, and MySQL Connector/C Developer Guide.

### 20.6.4.2 Writing C API Threaded Client Programs

The client library is almost thread-safe. The biggest problem is that the subroutines in `sql/net_serv.cc` that read from sockets are not interrupt-safe. This was done with the thought that you might want to have your own alarm that can break a long read to a server. If you install interrupt handlers for the `SIGPIPE` interrupt, socket handling should be thread-safe.

To avoid aborting the program when a connection terminates, MySQL blocks `SIGPIPE` on the first call to `mysql_library_init()`, `mysql_init()`, or `mysql_connect()`. To use your own `SIGPIPE` handler, first call `mysql_library_init()`, then install your handler.

Current binary distributions should have both a normal client library, `libmysqlclient`, and a thread-safe library, `libmysqlclient_r`. For threaded clients, link against the latter library. If “undefined symbol” errors occur, in most cases this is because you have not included the thread libraries on the link/compile command.

The thread-safe client library, `libmysqlclient_r`, is thread-safe per connection. You can let two threads share the same connection with the following caveats:

- Multiple threads cannot send a query to the MySQL server at the same time on the same connection. In particular, you must ensure that between calls to `mysql_query()` and
mysql_store_result() in one thread, no other thread uses the same connection. You must have a mutex lock around your pair of mysql_query() and mysql_store_result() calls. After mysql_store_result() returns, the lock can be released and other threads may query the same connection.

If you use POSIX threads, you can use pthread_mutex_lock() and pthread_mutex_unlock() to establish and release a mutex lock.

- Many threads can access different result sets that are retrieved with mysql_store_result().
- To use mysql_use_result(), you must ensure that no other thread is using the same connection until the result set is closed. However, it really is best for threaded clients that share the same connection to use mysql_store_result().

You need to know the following if you have a thread that did not create the connection to the MySQL database but is calling MySQL functions:

When you call mysql_init(), MySQL creates a thread-specific variable for the thread that is used by the debug library (among other things). If you call a MySQL function before the thread has called mysql_init(), the thread does not have the necessary thread-specific variables in place and you are likely to end up with a core dump sooner or later. To avoid problems, you must do the following:

1. Call mysql_library_init() before any other MySQL functions. It is not thread-safe, so call it before threads are created, or protect the call with a mutex.
2. Arrange for mysql_thread_init() to be called early in the thread handler before calling any MySQL function. If you call mysql_init(), it will call mysql_thread_init() for you.
3. In the thread, call mysql_thread_end() before calling pthread_exit(). This frees the memory used by MySQL thread-specific variables.

The preceding notes regarding mysql_init() also apply to mysql_connect(), which calls mysql_init().

### 20.6.4.3 Running C API Client Programs

If, after an upgrade, you experience problems with compiled client programs, such as Commands out of sync or unexpected core dumps, the programs were probably compiled using old header or library files. In this case, check the date of the mysql.h file and libmysqlclient.a library used for compilation to verify that they are from the new MySQL distribution. If not, recompile the programs with the new headers and libraries. Recompilation might also be necessary for programs compiled against the shared client library if the library major version number has changed (for example, from libmysqlclient.so.17 to libmysqlclient.so.18).

The major client library version determines compatibility. (For example, for libmysqlclient.so.18.1.0, the major version is 18.) For this reason, the libraries shipped with newer versions of MySQL are drop-in replacements for older versions that have the same major number. As long as the major library version is the same, you can upgrade the library and old applications should continue to work with it.

Undefined-reference errors might occur at runtime when you try to execute a MySQL program. If these errors specify symbols that start with mysql_or indicate that the libmysqlclient library cannot be found, it means that your system cannot find the shared libmysqlclient.so library. The solution to this problem is to tell your system to search for shared libraries in the directory where that library is located. Use whichever of the following methods is appropriate for your system:

- Add the path of the directory where libmysqlclient.so is located to the LD_LIBRARY_PATH or LD_LIBRARY environment variable.
- On OS X, add the path of the directory where libmysqlclient.dylib is located to the DYLD_LIBRARY_PATH environment variable.
• Copy the shared-library files (such as `libmysqlclient.so`) to some directory that is searched by your system, such as `/lib`, and update the shared library information by executing `ldconfig`. Be sure to copy all related files. A shared library might exist under several names, using symlinks to provide the alternate names.

Another way to solve this problem is by linking your program statically with the `-static` option, or by removing the dynamic MySQL libraries before linking your code. Before trying the second method, you should be sure that no other programs are using the dynamic libraries.

### 20.6.4.4 C API Server and Client Library Versions

The string and numeric forms of the MySQL server version are available at compile time as the values of the `MYSQL_SERVER_VERSION` and `MYSQL_VERSION_ID` macros, and at runtime as the values of the `mysql_get_server_info()` and `mysql_get_server_version()` functions.

The client library version is the MySQL version. For Connector/C, this is the MySQL version on which the Connector/C distribution is based. The string and numeric forms of this version are available at compile time as the values of the `MYSQL_SERVER_VERSION` and `MYSQL_VERSION_ID` macros, and at runtime as the values of the `mysql_get_client_info()` and `mysql_get_client_version()` functions.

### 20.6.5 C API Data Structures

This section describes C API data structures other than those used for prepared statements. For information about the latter, see Section 20.6.9, "C API Prepared Statement Data Structures".

• **MYSQL**

  This structure represents a handle to one database connection. It is used for almost all MySQL functions. Do not try to make a copy of a `MYSQL` structure. There is no guarantee that such a copy is usable.

• **MYSQL_RES**

  This structure represents the result of a query that returns rows (SELECT, SHOW, DESCRIBE, EXPLAIN). The information returned from a query is called the result set in the remainder of this section.

• **MYSQL_ROW**

  This is a type-safe representation of one row of data. It is currently implemented as an array of counted byte strings. (You cannot treat these as null-terminated strings if field values may contain binary data, because such values may contain null bytes internally.) Rows are obtained by calling `mysql_fetch_row()`.

• **MYSQL_FIELD**

  This structure contains metadata: information about a field, such as the field's name, type, and size. Its members are described in more detail later in this section. You may obtain the `MYSQL_FIELD` structures for each field by calling `mysql_fetch_field()` repeatedly. Field values are not part of this structure; they are contained in a `MYSQL_ROW` structure.

• **MYSQL_FIELD_OFFSET**

  This is a type-safe representation of an offset into a MySQL field list. (Used by `mysql_field_seek()`.) Offsets are field numbers within a row, beginning at zero.

• **my_ulonglong**

  The type used for the number of rows and for `mysql_affected_rows()`, `mysql_num_rows()`, and `mysql_insert_id()`. This type provides a range of 0 to 1.84×10^19.
Some functions that return a row count using this type return -1 as an unsigned value to indicate an error or exceptional condition. You can check for -1 by comparing the return value to (my_ulonglong)-1 (or to (my_ulonglong)-0, which is equivalent).

On some systems, attempting to print a value of type my_ulonglong does not work. To print such a value, convert it to unsigned long and use a %lu print format. Example:

```c
printf ("Number of rows: %lu\n",
        (unsigned long) mysql_num_rows(result));
```

- **my_bool**

  A boolean type, for values that are true (nonzero) or false (zero).

The **MYSQL_FIELD** structure contains the members described in the following list:

- **char * name**

  The name of the field, as a null-terminated string. If the field was given an alias with an AS clause, the value of name is the alias.

- **char * org_name**

  The name of the field, as a null-terminated string. Aliases are ignored. For expressions, the value is an empty string.

- **char * table**

  The name of the table containing this field, if it is not a calculated field. For calculated fields, the table value is an empty string. If the column is selected from a view, table names the view. If the table or view was given an alias with an AS clause, the value of table is the alias. For a UNION, the value is the empty string.

- **char * org_table**

  The name of the table, as a null-terminated string. Aliases are ignored. If the column is selected from a view, org_table names the view. For a UNION, the value is the empty string.

- **char * db**

  The name of the database that the field comes from, as a null-terminated string. If the field is a calculated field, db is an empty string. For a UNION, the value is the empty string.

- **char * catalog**

  The catalog name. This value is always "def".

- **char * def**

  The default value of this field, as a null-terminated string. This is set only if you use mysql_list_fields().

- **unsigned long length**

  The width of the field. This corresponds to the display length, in bytes.

  The server determines the length value before it generates the result set, so this is the minimum length required for a data type capable of holding the largest possible value from the result column, without knowing in advance the actual values that will be produced by the query for the result set.

- **unsigned long max_length**
The maximum width of the field for the result set (the length in bytes of the longest field value for the rows actually in the result set). If you use `mysql_store_result()` or `mysql_list_fields()`, this contains the maximum length for the field. If you use `mysql_use_result()`, the value of this variable is zero.

The value of `max_length` is the length of the string representation of the values in the result set. For example, if you retrieve a `FLOAT` column and the “widest” value is \(-12.345\), `max_length` is 7 (the length of ‘\(-12.345\)’).

If you are using prepared statements, `max_length` is not set by default because for the binary protocol the lengths of the values depend on the types of the values in the result set. (See Section 20.6.9, “C API Prepared Statement Data Structures”.) If you want the `max_length` values anyway, enable the `STMT_ATTR_UPDATE_MAX_LENGTH` option with `mysql_stmt_attr_set()` and the lengths will be set when you call `mysql_stmt_store_result()` . (See Section 20.6.11.3, “mysql_stmt_attr_set()”, and Section 20.6.11.27, “mysql_stmt_store_result()”.)

- `unsigned int name_length`
  The length of `name`.
- `unsigned int org_name_length`
  The length of `org_name`.
- `unsigned int table_length`
  The length of `table`.
- `unsigned int org_table_length`
  The length of `org_table`.
- `unsigned int db_length`
  The length of `db`.
- `unsigned int catalog_length`
  The length of `catalog`.
- `unsigned int def_length`
  The length of `def`.
- `unsigned int flags`
  Bit-flags that describe the field. The `flags` value may have zero or more of the bits set that are shown in the following table.

<table>
<thead>
<tr>
<th>Flag Value</th>
<th>Flag Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NOT_NULL_FLAG</td>
<td>Field cannot be NULL</td>
</tr>
<tr>
<td>PRI_KEY_FLAG</td>
<td>Field is part of a primary key</td>
</tr>
<tr>
<td>UNIQUE_KEY_FLAG</td>
<td>Field is part of a unique key</td>
</tr>
<tr>
<td>MULTIPLE_KEY_FLAG</td>
<td>Field is part of a nonunique key</td>
</tr>
<tr>
<td>UNSIGNED_FLAG</td>
<td>Field has the UNSIGNED attribute</td>
</tr>
<tr>
<td>ZEROFILL_FLAG</td>
<td>Field has the ZEROFILL attribute</td>
</tr>
<tr>
<td>BINARY_FLAG</td>
<td>Field has the BINARY attribute</td>
</tr>
<tr>
<td>AUTO_INCREMENT_FLAG</td>
<td>Field has the AUTO_INCREMENT attribute</td>
</tr>
</tbody>
</table>
### Flag Value Table

<table>
<thead>
<tr>
<th>Flag Value</th>
<th>Flag Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENUM_FLAG</td>
<td>Field is an ENUM</td>
</tr>
<tr>
<td>SET_FLAG</td>
<td>Field is a SET</td>
</tr>
<tr>
<td>BLOB_FLAG</td>
<td>Field is a BLOB or TEXT (deprecated)</td>
</tr>
<tr>
<td>TIMESTAMP_FLAG</td>
<td>Field is a TIMESTAMP (deprecated)</td>
</tr>
<tr>
<td>NUM_FLAG</td>
<td>Field is numeric; see additional notes following table</td>
</tr>
<tr>
<td>NO_DEFAULT_VALUE_FLAG</td>
<td>Field has no default value; see additional notes following table</td>
</tr>
</tbody>
</table>

Some of these flags indicate data type information and are superseded by or used in conjunction with the `MYSQL_TYPE_XXX` value in the `field->type` member described later:

- To check for BLOB or TIMESTAMP values, check whether `type` is `MYSQL_TYPE_BLOB` or `MYSQL_TYPE_TIMESTAMP`. (The BLOB_FLAG and TIMESTAMP_FLAG flags are unneeded.)

- ENUM and SET values are returned as strings. For these, check that the `type` value is `MYSQL_TYPE_STRING` and that the ENUM_FLAG or SET_FLAG flag is set in the `flags` value.

NUM_FLAG indicates that a column is numeric. This includes columns with a type of `MYSQL_TYPE_DECIMAL, MYSQL_TYPE_TINY, MYSQL_TYPE_SHORT, MYSQL_TYPE_LONG, MYSQL_TYPE_FLOAT, MYSQL_TYPE_DOUBLE, MYSQL_TYPE_NULL, MYSQL_TYPE_LONGLONG, MYSQL_TYPE_INT24, and MYSQL_TYPE_YEAR`.

NO_DEFAULT_VALUE_FLAG indicates that a column has no DEFAULT clause in its definition. This does not apply to NULL columns (because such columns have a default of NULL), or to AUTO_INCREMENT columns (which have an implied default value). NO_DEFAULT_VALUE_FLAG was added in MySQL 5.0.2.

The following example illustrates a typical use of the `flags` value:

```c
if (field->flags & NOT_NULL_FLAG)
  printf("Field cannot be null\n");
```

You may use the convenience macros shown in the following table to determine the boolean status of the `flags` value.

<table>
<thead>
<tr>
<th>Flag Status</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IS_NOT_NULL(flags)</td>
<td>True if this field is defined as NOT NULL</td>
</tr>
<tr>
<td>IS_PRI_KEY(flags)</td>
<td>True if this field is a primary key</td>
</tr>
<tr>
<td>IS_BLOB(flags)</td>
<td>True if this field is a BLOB or TEXT (deprecated; test field-&gt;type instead)</td>
</tr>
</tbody>
</table>

- **unsigned int decimals**

  The number of decimals for numeric fields.

- **unsigned int charsetnr**

  An ID number that indicates the character set/collation pair for the field.

Normally, character values in result sets are converted to the character set indicated by the `character_set_results` system variable. In this case, charsetnr corresponds to the character set indicated by that variable. Character set conversion can be suppressed by setting `character_set_results` to NULL. In this case, charsetnr corresponds to the character set of the original table column or expression. See also Section 10.1.4, “Connection Character Sets and Collations”.

---

**This documentation is for an older version. If you're using the most current version,** select the documentation for that version with the version switch in the upper right corner of the online documentation, or by downloading a newer PDF or EPUB file.
To distinguish between binary and nonbinary data for string data types, check whether the `charsetnr` value is 63. If so, the character set is `binary`, which indicates binary rather than nonbinary data. This enables you to distinguish `BINARY` from `CHAR`, `VARBINARY` from `VARCHAR`, and the `BLOB` types from the `TEXT` types.

`charsetnr` values are the same as those displayed in the `Id` column of the `SHOW COLLATION` statement or the `ID` column of the `INFORMATION_SCHEMA.COLLATIONS` table. You can use those information sources to see which character set and collation specific `charsetnr` values indicate:

```
mysql> SHOW COLLATION WHERE Id = 63;
+--------------------+----------------+----+---------+----------+---------+
| Collation          | Charset        | Id | Default | Compiled | Sortlen |
+--------------------+----------------+----+---------+----------+---------+
| binary             | binary         | 63 | Yes     | Yes      |       1 |
+--------------------+----------------+----+---------+----------+---------+
mysql>
```

```
mysql> SELECT COLLATION_NAME, CHARACTER_SET_NAME
        -> FROM INFORMATION_SCHEMA.COLLATIONS WHERE ID = 33;
+-----------------+--------------------+
| COLLATION_NAME   | CHARACTER_SET_NAME |
+-----------------+--------------------+
| utf8_general_ci | utf8               |
+-----------------+--------------------+
```

• `enum enum_field_types type`

The type of the field. The `type` value may be one of the `MYSQL_TYPE_` symbols shown in the following table.

<table>
<thead>
<tr>
<th>Type Value</th>
<th>Type Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MYSQL_TYPE_TINY</td>
<td>TINYINT field</td>
</tr>
<tr>
<td>MYSQL_TYPE_SHORT</td>
<td>SMALLINT field</td>
</tr>
<tr>
<td>MYSQL_TYPE_LONG</td>
<td>INTEGER field</td>
</tr>
<tr>
<td>MYSQL_TYPE_INT24</td>
<td>MEDIUMINT field</td>
</tr>
<tr>
<td>MYSQL_TYPE_LONGLONG</td>
<td>BIGINT field</td>
</tr>
<tr>
<td>MYSQL_TYPE_DECIMAL</td>
<td>DECIMAL or NUMERIC field</td>
</tr>
<tr>
<td>MYSQL_TYPE_NEWDECIMAL</td>
<td>Precision math DECIMAL or NUMERIC field (MySQL 5.0.3 and up)</td>
</tr>
<tr>
<td>MYSQL_TYPE_FLOAT</td>
<td>FLOAT field</td>
</tr>
<tr>
<td>MYSQL_TYPE_DOUBLE</td>
<td>DOUBLE or REAL field</td>
</tr>
<tr>
<td>MYSQL_TYPE_BIT</td>
<td>BIT field (MySQL 5.0.3 and up)</td>
</tr>
<tr>
<td>MYSQL_TYPE_TIMESTAMP</td>
<td>TIMESTAMP field</td>
</tr>
<tr>
<td>MYSQL_TYPE_DATE</td>
<td>DATE field</td>
</tr>
<tr>
<td>MYSQL_TYPE_TIME</td>
<td>TIME field</td>
</tr>
<tr>
<td>MYSQL_TYPE_DATETIME</td>
<td>DATETIME field</td>
</tr>
<tr>
<td>MYSQL_TYPE_YEAR</td>
<td>YEAR field</td>
</tr>
<tr>
<td>MYSQL_TYPE_STRING</td>
<td>CHAR or BINARY field</td>
</tr>
<tr>
<td>MYSQL_TYPE_VAR_STRING</td>
<td>VARCHAR or VARBINARY field</td>
</tr>
<tr>
<td>MYSQL_TYPE_BLOB</td>
<td>BLOB or TEXT field (use <code>max_length</code> to determine the maximum length)</td>
</tr>
<tr>
<td>MYSQL_TYPE_SET</td>
<td>SET field</td>
</tr>
<tr>
<td>MYSQL_TYPE_ENUM</td>
<td>ENUM field</td>
</tr>
</tbody>
</table>
### Type Value | Type Description
--- | ---
MYSQL_TYPE_GEOMETRY | Spatial field
MYSQL_TYPE_NULL | NULL-type field

You can use the `IS_NUM()` macro to test whether a field has a numeric type. Pass the `type` value to `IS_NUM()` and it evaluates to TRUE if the field is numeric:

```c
if (IS_NUM(field->type))
    printf("Field is numeric\n");
```

`ENUM` and `SET` values are returned as strings. For these, check that the `type` value is `MYSQL_TYPE_STRING` and that the `ENUM_FLAG` or `SET_FLAG` flag is set in the `flags` value.

### 20.6.6 C API Function Overview

The functions available in the C API are summarized here and described in greater detail in a later section. See Section 20.6.7, “C API Function Descriptions”.

### Table 20.4 C API Function Names and Descriptions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>my_init()</td>
<td>Initialize global variables, and thread handler in thread-safe programs</td>
</tr>
<tr>
<td>mysql_affected_rows()</td>
<td>Returns the number of rows changed/deleted/inserted by the last <code>UPDATE</code>, <code>DELETE</code>, or <code>INSERT</code> query</td>
</tr>
<tr>
<td>mysql_autocommit()</td>
<td>Toggles autocommit mode on/off</td>
</tr>
<tr>
<td>mysql_change_user()</td>
<td>Changes user and database on an open connection</td>
</tr>
<tr>
<td>mysql_character_set_name()</td>
<td>Return default character set name for current connection</td>
</tr>
<tr>
<td>mysql_close()</td>
<td>Closes a server connection</td>
</tr>
<tr>
<td>mysql_commit()</td>
<td>Commits the transaction</td>
</tr>
<tr>
<td>mysql_connect()</td>
<td>Connects to a MySQL server (this function is deprecated; use <code>mysql_real_connect()</code> instead)</td>
</tr>
<tr>
<td>mysql_create_db()</td>
<td>Creates a database (this function is deprecated; use the SQL statement <code>CREATE DATABASE</code> instead)</td>
</tr>
<tr>
<td>mysql_data_seek()</td>
<td>Seeks to an arbitrary row number in a query result set</td>
</tr>
<tr>
<td>mysql_debug()</td>
<td>Does a <code>DBUG_PUSH</code> with the given string</td>
</tr>
<tr>
<td>mysql_drop_db()</td>
<td>Drops a database (this function is deprecated; use the SQL statement <code>DROP DATABASE</code> instead)</td>
</tr>
<tr>
<td>mysql_dump_debug_info()</td>
<td>Makes the server write debug information to the log</td>
</tr>
<tr>
<td>mysql_eof()</td>
<td>Determines whether the last row of a result set has been read (this function is deprecated; <code>mysql_errno()</code> or <code>mysql_error()</code> may be used instead)</td>
</tr>
<tr>
<td>mysql_errno()</td>
<td>Returns the error number for the most recently invoked MySQL function</td>
</tr>
<tr>
<td>mysql_error()</td>
<td>Returns the error message for the most recently invoked MySQL function</td>
</tr>
<tr>
<td>mysql_escape_string()</td>
<td>Escapes special characters in a string for use in an SQL statement</td>
</tr>
<tr>
<td>mysql_fetch_field()</td>
<td>Returns the type of the next table field</td>
</tr>
<tr>
<td>mysql_fetch_field_direct()</td>
<td>Returns the type of a table field, given a field number</td>
</tr>
<tr>
<td>mysql_fetch_fields()</td>
<td>Returns an array of all field structures</td>
</tr>
</tbody>
</table>
### Function Description

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>mysql_fetch_lengths()</code></td>
<td>Returns the lengths of all columns in the current row</td>
</tr>
<tr>
<td><code>mysql_fetch_row()</code></td>
<td>Fetches the next row from the result set</td>
</tr>
<tr>
<td><code>mysql_field_count()</code></td>
<td>Returns the number of result columns for the most recent statement</td>
</tr>
<tr>
<td><code>mysql_field_seek()</code></td>
<td>Puts the column cursor on a specified column</td>
</tr>
<tr>
<td><code>mysql_field_tell()</code></td>
<td>Returns the position of the field cursor used for the last</td>
</tr>
<tr>
<td></td>
<td><code>mysql_fetch_field()</code></td>
</tr>
<tr>
<td><code>mysql_free_result()</code></td>
<td>Frees memory used by a result set</td>
</tr>
<tr>
<td><code>mysql_get_character_set_info()</code></td>
<td>Returns information about default character set</td>
</tr>
<tr>
<td><code>mysql_get_client_info()</code></td>
<td>Returns client version information as a string</td>
</tr>
<tr>
<td><code>mysql_get_client_version()</code></td>
<td>Returns client version information as an integer</td>
</tr>
<tr>
<td><code>mysql_get_host_info()</code></td>
<td>Returns a string describing the connection</td>
</tr>
<tr>
<td><code>mysql_get_proto_info()</code></td>
<td>Returns the protocol version used by the connection</td>
</tr>
<tr>
<td><code>mysql_get_server_info()</code></td>
<td>Returns the server version number</td>
</tr>
<tr>
<td><code>mysql_get_server_version()</code></td>
<td>Returns version number of server as an integer</td>
</tr>
<tr>
<td><code>mysql_get_ssl_cipher()</code></td>
<td>Return current SSL cipher</td>
</tr>
<tr>
<td><code>mysql_hex_string()</code></td>
<td>Encode string in hexadecimal format</td>
</tr>
<tr>
<td><code>mysql_info()</code></td>
<td>Returns information about the most recently executed query</td>
</tr>
<tr>
<td><code>mysql_init()</code></td>
<td>Gets or initializes a <code>MYSQL</code> structure</td>
</tr>
<tr>
<td><code>mysql_insert_id()</code></td>
<td>Returns the ID generated for an <code>AUTO_INCREMENT</code> column by the previous query</td>
</tr>
<tr>
<td><code>mysql_kill()</code></td>
<td>Kills a given thread</td>
</tr>
<tr>
<td><code>mysql_library_end()</code></td>
<td>Finalize the MySQL C API library</td>
</tr>
<tr>
<td><code>mysql_library_init()</code></td>
<td>Initialize the MySQL C API library</td>
</tr>
<tr>
<td><code>mysql_list_dbs()</code></td>
<td>Returns database names matching a simple regular expression</td>
</tr>
<tr>
<td><code>mysql_list_fields()</code></td>
<td>Returns field names matching a simple regular expression</td>
</tr>
<tr>
<td><code>mysql_list_processes()</code></td>
<td>Returns a list of the current server threads</td>
</tr>
<tr>
<td><code>mysql_list_tables()</code></td>
<td>Returns table names matching a simple regular expression</td>
</tr>
<tr>
<td><code>mysql_more_results()</code></td>
<td>Checks whether any more results exist</td>
</tr>
<tr>
<td><code>mysql_next_result()</code></td>
<td>Returns/initiates the next result in multiple-result executions</td>
</tr>
<tr>
<td><code>mysql_num_fields()</code></td>
<td>Returns the number of columns in a result set</td>
</tr>
<tr>
<td><code>mysql_num_rows()</code></td>
<td>Returns the number of rows in a result set</td>
</tr>
<tr>
<td><code>mysql_options()</code></td>
<td>Sets connect options for <code>mysql_real_connect()</code></td>
</tr>
<tr>
<td><code>mysql_ping()</code></td>
<td>Checks whether the connection to the server is working,</td>
</tr>
<tr>
<td></td>
<td>reconnecting as necessary</td>
</tr>
<tr>
<td><code>mysql_query()</code></td>
<td>Executes an SQL query specified as a null-terminated string</td>
</tr>
<tr>
<td><code>mysql_real_connect()</code></td>
<td>Connects to a MySQL server</td>
</tr>
<tr>
<td><code>mysql_real_escape_string()</code></td>
<td>Escapes special characters in a string for use in an SQL statement,</td>
</tr>
<tr>
<td></td>
<td>taking into account the current character set of the connection</td>
</tr>
<tr>
<td><code>mysql_real_query()</code></td>
<td>Executes an SQL query specified as a counted string</td>
</tr>
<tr>
<td><code>mysql_refresh()</code></td>
<td>Flush or reset tables and caches</td>
</tr>
<tr>
<td><code>mysql_reload()</code></td>
<td>Tells the server to reload the grant tables</td>
</tr>
<tr>
<td><code>mysql_rollback()</code></td>
<td>Rolls back the transaction</td>
</tr>
</tbody>
</table>
### C API Function Overview

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>mysql_row_seek()</code></td>
<td>Seeks to a row offset in a result set, using value returned from <code>mysql_row_tell()</code></td>
</tr>
<tr>
<td><code>mysql_row_tell()</code></td>
<td>Returns the row cursor position</td>
</tr>
<tr>
<td><code>mysql_select_db()</code></td>
<td>Selects a database</td>
</tr>
<tr>
<td><code>mysql_server_end()</code></td>
<td>Finalize the MySQL C API library</td>
</tr>
<tr>
<td><code>mysql_server_init()</code></td>
<td>Initialize the MySQL C API library</td>
</tr>
<tr>
<td><code>mysql_set_character_set()</code></td>
<td>Set default character set for current connection</td>
</tr>
<tr>
<td><code>mysql_set_local_infile_default()</code></td>
<td>Set the <code>LOAD DATA LOCAL INFILE</code> handler callbacks to their default values</td>
</tr>
<tr>
<td><code>mysql_set_local_infile_handler()</code></td>
<td>Install application-specific <code>LOAD DATA LOCAL INFILE</code> handler callbacks</td>
</tr>
<tr>
<td><code>mysql_set_server_option()</code></td>
<td>Sets an option for the connection (like <code>multi-statements</code>)</td>
</tr>
<tr>
<td><code>mysql_sqlstate()</code></td>
<td>Returns the SQLSTATE error code for the last error</td>
</tr>
<tr>
<td><code>mysql_shutdown()</code></td>
<td>Shuts down the database server</td>
</tr>
<tr>
<td><code>mysql_ssl_set()</code></td>
<td>Prepare to establish SSL connection to server</td>
</tr>
<tr>
<td><code>mysql_stat()</code></td>
<td>Returns the server status as a string</td>
</tr>
<tr>
<td><code>mysql_store_result()</code></td>
<td>Retrieves a complete result set to the client</td>
</tr>
<tr>
<td><code>mysql_thread_end()</code></td>
<td>Finalize thread handler</td>
</tr>
<tr>
<td><code>mysql_thread_id()</code></td>
<td>Returns the current thread ID</td>
</tr>
<tr>
<td><code>mysql_thread_init()</code></td>
<td>Initialize thread handler</td>
</tr>
<tr>
<td><code>mysql_thread_safe()</code></td>
<td>Returns 1 if the clients are compiled as thread-safe</td>
</tr>
<tr>
<td><code>mysql_use_result()</code></td>
<td>Initiates a row-by-row result set retrieval</td>
</tr>
<tr>
<td><code>mysql_warning_count()</code></td>
<td>Returns the warning count for the previous SQL statement</td>
</tr>
</tbody>
</table>

Application programs should use this general outline for interacting with MySQL:

1. Initialize the MySQL library by calling `mysql_library_init()`. This function exists in both the `libmysqlclient` C client library and the `libmysqld` embedded server library, so it is used whether you build a regular client program by linking with the `-libmysqlclient` flag, or an embedded server application by linking with the `-libmysqld` flag.

2. Initialize a connection handler by calling `mysql_init()` and connect to the server by calling `mysql_real_connect()`.

3. Issue SQL statements and process their results. (The following discussion provides more information about how to do this.)

4. Close the connection to the MySQL server by calling `mysql_close()`.

5. End use of the MySQL library by calling `mysql_library_end()`.

The purpose of calling `mysql_library_init()` and `mysql_library_end()` is to provide proper initialization and finalization of the MySQL library. For applications that are linked with the client library, they provide improved memory management. If you do not call `mysql_library_end()`, a block of memory remains allocated. (This does not increase the amount of memory used by the application, but some memory leak detectors will complain about it.) For applications that are linked with the embedded server, these calls start and stop the server.

`mysql_library_init()` and `mysql_library_end()` are available as of MySQL 5.0.3. For older versions of MySQL, you can call `mysql_server_init()` and `mysql_server_end()` instead.
In a nonmulti-threaded environment, the call to `mysql_library_init()` may be omitted, because `mysql_init()` will invoke it automatically as necessary. However, `mysql_library_init()` is not thread-safe in a multi-threaded environment, and thus neither is `mysql_init()`, which calls `mysql_library_init()`. You must either call `mysql_library_init()` prior to spawning any threads, or else use a mutex to protect the call, whether you invoke `mysql_library_init()` or indirectly through `mysql_init()`. This should be done prior to any other client library call.

To connect to the server, call `mysql_init()` to initialize a connection handler, then call `mysql_real_connect()` with that handler (along with other information such as the host name, user name, and password). Upon connection, `mysql_real_connect()` sets the `reconnect` flag (part of the `MYSQL`) to a value of 1 in versions of the API older than 5.0.3, or 0 in newer versions. A value of 1 for this flag indicates that if a statement cannot be performed because of a lost connection, to try reconnecting to the server before giving up. As of MySQL 5.0.13, you can use the `MYSQL_OPT_RECONNECT` option to `mysql_options()` to control reconnection behavior. When you are done with the connection, call `mysql_close()` to terminate it.

While a connection is active, the client may send SQL statements to the server using `mysql_query()` or `mysql_real_query()`. The difference between the two is that `mysql_query()` expects the query to be specified as a null-terminated string whereas `mysql_real_query()` expects a counted string. If the string contains binary data (which may include null bytes), you must use `mysql_real_query()`.

For each non-`SELECT` query (for example, `INSERT`, `UPDATE`, `DELETE`), you can find out how many rows were changed (affected) by calling `mysql_affected_rows()`.

For `SELECT` queries, you retrieve the selected rows as a result set. (Note that some statements are `SELECT`-like in that they return rows. These include `SHOW`, `DESCRIBE`, and `EXPLAIN`. Treat these statements the same way as `SELECT` statements.)

There are two ways for a client to process result sets. One way is to retrieve the entire result set all at once by calling `mysql_store_result()`. This function acquires from the server all the rows returned by the query and stores them in the client. The second way is for the client to initiate a row-by-row result set retrieval by calling `mysql_use_result()`. This function initializes the retrieval, but does not actually get any rows from the server.

In both cases, you access rows by calling `mysql_fetch_row()`. With `mysql_store_result()`, `mysql_fetch_row()` accesses rows that have previously been fetched from the server. With `mysql_use_result()`, `mysql_fetch_row()` actually retrieves the row from the server. Information about the size of the data in each row is available by calling `mysql_fetch_lengths()`.

After you are done with a result set, call `mysql_free_result()` to free the memory used for it.

The two retrieval mechanisms are complementary. Choose the approach that is most appropriate for each client application. In practice, clients tend to use `mysql_store_result()` more commonly.

An advantage of `mysql_store_result()` is that because the rows have all been fetched to the client, you not only can access rows sequentially, you can move back and forth in the result set using `mysql_data_seek()` or `mysql_row_seek()` to change the current row position within the result set. You can also find out how many rows there are by calling `mysql_num_rows()`. On the other hand, the memory requirements for `mysql_store_result()` may be very high for large result sets and you are more likely to encounter out-of-memory conditions.

An advantage of `mysql_use_result()` is that the client requires less memory for the result set because it maintains only one row at a time (and because there is less allocation overhead, `mysql_use_result()` can be faster). Disadvantages are that you must process each row quickly to avoid tying up the server, you do not have random access to rows within the result set (you can only access rows sequentially), and the number of rows in the result set is unknown until you have retrieved them all. Furthermore, you must retrieve all the rows even if you determine in mid-retrieval that you’ve found the information you were looking for.

The API makes it possible for clients to respond appropriately to statements (retrieving rows only as necessary) without knowing whether the statement is a `SELECT`. You can do this by
Calling `mysql_store_result()` after each `mysql_query()` (or `mysql_real_query()`). If the result set call succeeds, the statement was a `SELECT` and you can read the rows. If the result set call fails, call `mysql_field_count()` to determine whether a result was actually to be expected. If `mysql_field_count()` returns zero, the statement returned no data (indicating that it was an `INSERT`, `UPDATE`, `DELETE`, and so forth), and was not expected to return rows. If `mysql_field_count()` is nonzero, the statement should have returned rows, but did not. This indicates that the statement was a `SELECT` that failed. See the description for `mysql_field_count()` for an example of how this can be done.

Both `mysql_store_result()` and `mysql_use_result()` enable you to obtain information about the fields that make up the result set (the number of fields, their names and types, and so forth). You can access field information sequentially within the row by calling `mysql_fetch_field()` repeatedly, or by field number within the row by calling `mysql_fetch_field_direct()`. The current field cursor position may be changed by calling `mysql_field_seek()`. Setting the field cursor affects subsequent calls to `mysql_fetch_field()`. You can also get information for fields all at once by calling `mysql_fetch_fields()`.

For detecting and reporting errors, MySQL provides access to error information by means of the `mysql_errno()` and `mysql_error()` functions. These return the error code or error message for the most recently invoked function that can succeed or fail, enabling you to determine when an error occurred and what it was.

### 20.6.7 C API Function Descriptions

In the descriptions here, a parameter or return value of `NULL` means `NULL` in the sense of the C programming language, not a MySQL `NULL` value.

Functions that return a value generally return a pointer or an integer. Unless specified otherwise, functions returning a pointer return a non-`NULL` value to indicate success or a `NULL` value to indicate an error, and functions returning an integer return zero to indicate success or nonzero to indicate an error. Note that “nonzero” means just that. Unless the function description says otherwise, do not test against a value other than zero:

```c
if (result)                   /* correct */
  ... error ...            
if (result < 0)              /* incorrect */
  ... error ...            
if (result == -1)            /* incorrect */
  ... error ...            
```

When a function returns an error, the **Errors** subsection of the function description lists the possible types of errors. You can find out which of these occurred by calling `mysql_errno()`. A string representation of the error may be obtained by calling `mysql_error()`.

#### 20.6.7.1 mysql_affected_rows()

```c
my_ulonglong mysql_affected_rows(MYSQL *mysql)
```

**Description**

`mysql_affected_rows()` may be called immediately after executing a statement with `mysql_query()` or `mysql_real_query()`. It returns the number of rows changed, deleted, or inserted by the last statement if it was an `UPDATE`, `DELETE`, or `INSERT`. For `SELECT` statements, `mysql_affected_rows()` works like `mysql_num_rows()`.

For `UPDATE` statements, the affected-rows value by default is the number of rows actually changed. If you specify the `CLIENT_FOUND_ROWS` flag to `mysql_real_connect()` when connecting to `mysqld`, the affected-rows value is the number of rows “found”, that is, matched by the `WHERE` clause.
For REPLACE statements, the affected-rows value is 2 if the new row replaced an old row, because in this case, one row was inserted after the duplicate was deleted.

For INSERT ... ON DUPLICATE KEY UPDATE statements, the affected-rows value is 1 if the row is inserted as a new row and 2 if an existing row is updated.

Following a CALL statement for a stored procedure, mysql_affected_rows() returns the value that it would return for the last statement executed within the procedure, or 0 if that statement would return -1. Within the procedure, you can use ROW_COUNT() at the SQL level to obtain the affected-rows value for individual statements.

**Return Values**

An integer greater than zero indicates the number of rows affected or retrieved. Zero indicates that no records were updated for an UPDATE statement, no rows matched the WHERE clause in the query or that no query has yet been executed. -1 indicates that the query returned an error or that, for a SELECT query, mysql_affected_rows() was called prior to calling mysql_store_result().

Because mysql_affected_rows() returns an unsigned value, you can check for -1 by comparing the return value to (my_ulonglong)-1 (or to (my_ulonglong)-0, which is equivalent).

**Errors**

None.

**Example**

```c
char *stmt = "UPDATE products SET cost=cost*1.25
              WHERE group=10";
mysql_query(&mysql,stmt);
printf("%ld products updated",
        (long) mysql_affected_rows(&mysql));
```

20.6.7.2 mysql_autocommit()

```c
my_bool mysql_autocommit(MYSQL *mysql, my_bool mode)
```

**Description**

Sets autocommit mode on if mode is 1, off if mode is 0.

**Return Values**

Zero for success. Nonzero if an error occurred.

**Errors**

None.

20.6.7.3 mysql_change_user()

```c
my_bool mysql_change_user(MYSQL *mysql, const char *user, const char
                         *password, const char *db)
```

**Description**

Changes the user and causes the database specified by db to become the default (current) database on the connection specified by mysql. In subsequent queries, this database is the default for table references that include no explicit database specifier.
mysql_change_user() fails if the connected user cannot be authenticated or does not have permission to use the database. In this case, the user and database are not changed.

Pass a db parameter of NULL if you do not want to have a default database.

This function resets the session state as if one had done a new connect and reauthenticated. (See Section 20.6.15, "Controlling Automatic Reconnection Behavior".) It always performs a ROLLBACK of any active transactions, closes and drops all temporary tables, and unlocks all locked tables. Session system variables are reset to the values of the corresponding global system variables. Prepared statements are released and HANDLER variables are closed. Locks acquired with GET_LOCK() are released. These effects occur even if the user did not change.

Return Values

Zero for success. Nonzero if an error occurred.

Errors

The same that you can get from mysql_real_connect(), plus:

- **CR_COMMANDS_OUT_OF_SYNC**

  Commands were executed in an improper order.

- **CR_SERVER_GONE_ERROR**

  The MySQL server has gone away.

- **CR_SERVER_LOST**

  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**

  An unknown error occurred.

- **ER_UNKNOWN_COM_ERROR**

  The MySQL server does not implement this command (probably an old server).

- **ER_ACCESS_DENIED_ERROR**

  The user or password was wrong.

- **ER_BAD_DB_ERROR**

  The database did not exist.

- **ER_DBACCESS_DENIED_ERROR**

  The user did not have access rights to the database.

- **ER_WRONG_DB_NAME**

  The database name was too long.

Example

```c
if (mysql_change_user(&mysql, "user", "password", "new_database"))
{
  fprintf(stderr, "Failed to change user. Error: %s\n",
          mysql_error(&mysql));
```
20.6.7.4 mysql_character_set_name()

const char *mysql_character_set_name(MYSQL *mysql)

Description

Returns the default character set name for the current connection.

Return Values

The default character set name

Errors

None.

20.6.7.5 mysql_close()

void mysql_close(MYSQL *mysql)

Description

Closes a previously opened connection. mysql_close() also deallocates the connection handle pointed to by mysql if the handle was allocated automatically by mysql_init() or mysql_connect().

Return Values

None.

Errors

None.

20.6.7.6 mysql_commit()

my_bool mysql_commit(MYSQL *mysql)

Description

Commits the current transaction.

As of MySQL 5.0.3, the action of this function is subject to the value of the completion_type system variable. In particular, if the value of completion_type is 2, the server performs a release after terminating a transaction and closes the client connection. The client program should call mysql_close() to close the connection from the client side.

Return Values

Zero for success. Nonzero if an error occurred.

Errors

None.

20.6.7.7 mysql_connect()
MYSQL *mysql_connect(MYSQL *mysql, const char *host, const char *user, const char *passwd)

Description

This function is deprecated. Use `mysql_real_connect()` instead.

`mysql_connect()` attempts to establish a connection to a MySQL database engine running on `host`. `mysql_connect()` must complete successfully before you can execute any of the other API functions, with the exception of `mysql_get_client_info()`.

The meanings of the parameters are the same as for the corresponding parameters for `mysql_real_connect()` with the difference that the connection parameter may be `NULL`. In this case, the C API allocates memory for the connection structure automatically and frees it when you call `mysql_close()`. The disadvantage of this approach is that you cannot retrieve an error message if the connection fails. (To get error information from `mysql_errno()` or `mysql_error()`, you must provide a valid `MYSQL` pointer.)

Return Values

Same as for `mysql_real_connect()`.

Errors

Same as for `mysql_real_connect()`.

20.6.7.8 `mysql_create_db()`

```c
int mysql_create_db(MYSQL *mysql, const char *db)
```

Description

Creates the database named by the `db` parameter.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL `CREATE DATABASE` statement instead.

Return Values

Zero for success. Nonzero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
  Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`
  The MySQL server has gone away.
- `CR_SERVER_LOST`
  The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`
  An unknown error occurred.

Example
if(mysql_create_db(&mysql, "my_database"))
{
    fprintf(stderr, "Failed to create new database. Error: %s\n",
            mysql_error(&mysql));
}

20.6.7.9 mysql_data_seek()

    void mysql_data_seek(MYSQL_RES *result, my_ulonglong offset)

Description

    Seeks to an arbitrary row in a query result set. The offset value is a row number. Specify a value in
    the range from 0 to mysql_num_rows(result)-1.

    This function requires that the result set structure contains the entire result of the query, so
    mysql_data_seek() may be used only in conjunction with mysql_store_result(), not with
    mysql_use_result().

Return Values

    None.

Errors

    None.

20.6.7.10 mysql_debug()

    void mysql_debug(const char *debug)

Description

    Does a DBUG_PUSH with the given string. mysql_debug() uses the Fred Fish debug library. To use
    this function, you must compile the client library to support debugging. See Section 21.3.3, "The DBUG
    Package".

Return Values

    None.

Errors

    None.

Example

    The call shown here causes the client library to generate a trace file in /tmp/client.trace on the
    client machine:

    mysql_debug("d:t:O,/tmp/client.trace");

20.6.7.11 mysql_drop_db()

    int mysql_drop_db(MYSQL *mysql, const char *db)

Description

    Drops the database named by the db parameter.
This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL `DROP DATABASE` statement instead.

### Return Values

Zero for success. Nonzero if an error occurred.

### Errors

- **CR_COMMANDS_OUT_OF_SYNC**
  
  Commands were executed in an improper order.

- **CR_SERVER_GONE_ERROR**
  
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  
  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  
  An unknown error occurred.

### Example

```c
if(mysql_drop_db(&mysql, "my_database"))
    fprintf(stderr, "Failed to drop the database: Error: %s\n",
            mysql_error(&mysql));
```

**20.6.7.12 mysql_dump_debug_info()**

```c
int mysql_dump_debug_info(MYSQL *mysql)
```

### Description

Instructs the server to write debugging information to the error log. The connected user must have the `SUPER` privilege.

### Return Values

Zero for success. Nonzero if an error occurred.

### Errors

- **CR_COMMANDS_OUT_OF_SYNC**
  
  Commands were executed in an improper order.

- **CR_SERVER_GONE_ERROR**
  
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  
  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  
  An unknown error occurred.
20.6.7.13 mysql_eof()

my_bool mysql_eof(MYSQL_RES *result)

Description

This function is deprecated. mysql_errno() or mysql_error() may be used instead.

mysql_eof() determines whether the last row of a result set has been read.

If you acquire a result set from a successful call to mysql_store_result(), the client receives the entire set in one operation. In this case, a NULL return from mysql_fetch_row() always means the end of the result set has been reached and it is unnecessary to call mysql_eof(). When used with mysql_store_result(), mysql_eof() always returns true.

On the other hand, if you use mysql_use_result() to initiate a result set retrieval, the rows of the set are obtained from the server one by one as you call mysql_fetch_row() repeatedly. Because an error may occur on the connection during this process, a NULL return value from mysql_fetch_row() does not necessarily mean the end of the result set was reached normally. In this case, you can use mysql_eof() to determine what happened. mysql_eof() returns a nonzero value if the end of the result set was reached and zero if an error occurred.

Historically, mysql_eof() predates the standard MySQL error functions mysql_errno() and mysql_error(). Because those error functions provide the same information, their use is preferred over mysql_eof(), which is deprecated. (In fact, they provide more information, because mysql_eof() returns only a boolean value whereas the error functions indicate a reason for the error when one occurs.)

Return Values

Zero for success. Nonzero if the end of the result set has been reached.

Errors

None.

Example

The following example shows how you might use mysql_eof():

```c
mysql_query(&mysql,"SELECT * FROM some_table");
result = mysql_use_result(&mysql);
while((row = mysql_fetch_row(result)))
{
    // do something with data
}
if(!mysql_eof(result))  // mysql_fetch_row() failed due to an error
{
    fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
}
```

However, you can achieve the same effect with the standard MySQL error functions:

```c
mysql_query(&mysql,"SELECT * FROM some_table");
result = mysql_use_result(&mysql);
while((row = mysql_fetch_row(result)))
{
    // do something with data
}
if(mysql_errno(&mysql))  // mysql_fetch_row() failed due to an error
{
```
20.6.7.14 mysql_errno()

unsigned int mysql_errno(MYSQL *mysql)

**Description**

For the connection specified by `mysql`, `mysql_errno()` returns the error code for the most recently invoked API function that can succeed or fail. A return value of zero means that no error occurred. Client error message numbers are listed in the MySQL `errmsg.h` header file. Server error message numbers are listed in `mysqld_error.h`. Errors also are listed at Appendix B, Errors, Error Codes, and Common Problems.

**Note**

Some functions such as `mysql_fetch_row()` do not set `mysql_errno()` if they succeed. A rule of thumb is that all functions that have to ask the server for information reset `mysql_errno()` if they succeed.

MySQL-specific error numbers returned by `mysql_errno()` differ from SQLSTATE values returned by `mysql_sqlstate()`. For example, the `mysql` client program displays errors using the following format, where 1146 is the `mysql_errno()` value and '42S02' is the corresponding `mysql_sqlstate()` value:

```
shell> SELECT * FROM no_such_table;
ERROR 1146 (42S02): Table 'test.no_such_table' doesn't exist
```

**Return Values**

An error code value for the last `mysql_xxx()` call, if it failed. Zero means no error occurred.

**Errors**

None.

20.6.7.15 mysql_error()

const char *mysql_error(MYSQL *mysql)

**Description**

For the connection specified by `mysql`, `mysql_error()` returns a null-terminated string containing the error message for the most recently invoked API function that failed. If a function did not fail, the return value of `mysql_error()` may be the previous error or an empty string to indicate no error.

A rule of thumb is that all functions that have to ask the server for information reset `mysql_error()` if they succeed.

For functions that reset `mysql_error()`, either of these two tests can be used to check for an error:

```c
if(*mysql_error(&mysql)) {
    // an error occurred
}
if(mysql_error(&mysql)[0]) {
    // an error occurred
```
The language of the client error messages may be changed by recompiling the MySQL client library. You can choose error messages in several different languages. See Section 10.2, “Setting the Error Message Language”.

Return Values

A null-terminated character string that describes the error. An empty string if no error occurred.

Errors

None.

20.6.7.16 mysql_escape_string()

Note

This function should not be used. Use mysql_real_escape_string() instead.

mysql_escape_string() is identical to mysql_real_escape_string() except that mysql_real_escape_string() takes a connection handler as its first argument and escapes the string according to the current character set. mysql_escape_string() does not take a connection argument and does not respect the current character set.

20.6.7.17 mysql_fetch_field()

MYSQL_FIELD *mysql_fetch_field(MYSQL_RES *result)

Description

Returns the definition of one column of a result set as a MYSQL_FIELD structure. Call this function repeatedly to retrieve information about all columns in the result set. mysql_fetch_field() returns NULL when no more fields are left.

mysql_fetch_field() is reset to return information about the first field each time you execute a new SELECT query. The field returned by mysql_fetch_field() is also affected by calls to mysql_field_seek().

If you've called mysql_query() to perform a SELECT on a table but have not called mysql_store_result(), MySQL returns the default blob length (8KB) if you call mysql_fetch_field() to ask for the length of a BLOB field. (The 8KB size is chosen because MySQL does not know the maximum length for the BLOB. This should be made configurable sometime.) Once you've retrieved the result set, field->max_length contains the length of the largest value for this column in the specific query.

Return Values

The MYSQL_FIELD structure for the current column. NULL if no columns are left.

Errors

None.

Example

MYSQL_FIELD *field;
while((field = mysql_fetch_field(result)))
{
    printf("field name %s\n", field->name);
}

20.6.7.18 mysql_fetch_field_direct()

MYSQL_FIELD *mysql_fetch_field_direct(MYSQL_RES *result, unsigned int fieldnr)

Description

Given a field number fieldnr for a column within a result set, returns that column's field definition as a MYSQL_FIELD structure. Use this function to retrieve the definition for an arbitrary column. Specify a value for fieldnr in the range from 0 to mysql_num_fields(result)-1.

Return Values

The MYSQL_FIELD structure for the specified column.

Errors

None.

Example

unsigned int num_fields;
unsigned int i;
MYSQL_FIELD *field;
num_fields = mysql_num_fields(result);
for(i = 0; i < num_fields; i++)
{
    field = mysql_fetch_field_direct(result, i);
    printf("Field %u is %s\n", i, field->name);
}

20.6.7.19 mysql_fetch_fields()

MYSQL_FIELD *mysql_fetch_fields(MYSQL_RES *result)

Description

Returns an array of all MYSQL_FIELD structures for a result set. Each structure provides the field definition for one column of the result set.

Return Values

An array of MYSQL_FIELD structures for all columns of a result set.

Errors

None.

Example

unsigned int num_fields;
unsigned int i;
MYSQL_FIELD *fields;
num_fields = mysql_num_fields(result);
fields = mysql_fetch_fields(result);
20.6.7.20 mysql_fetch_lengths()

unsigned long *mysql_fetch_lengths(MYSQL_RES *result)

Description

Returns the lengths of the columns of the current row within a result set. If you plan to copy field values, this length information is also useful for optimization, because you can avoid calling strlen(). In addition, if the result set contains binary data, you must use this function to determine the size of the data, because strlen() returns incorrect results for any field containing null characters.

The length for empty columns and for columns containing NULL values is zero. To see how to distinguish these two cases, see the description for mysql_fetch_row().

Return Values

An array of unsigned long integers representing the size of each column (not including any terminating null bytes). NULL if an error occurred.

Errors

mysql_fetch_lengths() is valid only for the current row of the result set. It returns NULL if you call it before calling mysql_fetch_row() or after retrieving all rows in the result.

Example

MYSQL_ROW row;
unsigned long *lengths;
unsigned int num_fields;
unsigned int i;

row = mysql_fetch_row(result);
if (row)
{
    num_fields = mysql_num_fields(result);
    lengths = mysql_fetch_lengths(result);
    for(i = 0; i < num_fields; i++)
    {
        printf("Column %u is %lu bytes in length.\n",
               i, lengths[i]);
    }
}

20.6.7.21 mysql_fetch_row()

MYSQL_ROW mysql_fetch_row(MYSQL_RES *result)

Description

Retrieves the next row of a result set. When used after mysql_store_result(), mysql_fetch_row() returns NULL when there are no more rows to retrieve. When used after mysql_use_result(), mysql_fetch_row() returns NULL when there are no more rows to retrieve or if an error occurred.

The number of values in the row is given by mysql_num_fields(result). If row holds the return value from a call to mysql_fetch_row(), pointers to the values are accessed as row[0] to row[mysql_num_fields(result)-1]. NULL values in the row are indicated by NULL pointers.
The lengths of the field values in the row may be obtained by calling `mysql_fetch_lengths()`. Empty fields and fields containing `NULL` both have length 0; you can distinguish these by checking the pointer for the field value. If the pointer is `NULL`, the field is `NULL`; otherwise, the field is empty.

**Return Values**

A `MYSQL_ROW` structure for the next row. `NULL` if there are no more rows to retrieve or if an error occurred.

**Errors**

Errors are not reset between calls to `mysql_fetch_row()`

- **CR_SERVER_LOST**
  
  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  
  An unknown error occurred.

**Example**

```c
MYSQL_ROW row;
unsigned int num_fields;
unsigned int i;

num_fields = mysql_num_fields(result);
while ((row = mysql_fetch_row(result)))
{
  unsigned long *lengths;
  lengths = mysql_fetch_lengths(result);
  for(i = 0; i < num_fields; i++)
  {
    printf("[%.*s] ", (int) lengths[i],
      row[i] ? row[i] : "NULL");
  }
  printf("\n");
}
```

### 20.6.7.22 `mysql_field_count()`

`unsigned int mysql_field_count(MYSQL *mysql)`

**Description**

Returns the number of columns for the most recent query on the connection.

The normal use of this function is when `mysql_store_result()` returned `NULL` (and thus you have no result set pointer). In this case, you can call `mysql_field_count()` to determine whether `mysql_store_result()` should have produced a nonempty result. This enables the client program to take proper action without knowing whether the query was a `SELECT` (or `SELECT-like`) statement. The example shown here illustrates how this may be done.

**Return Values**

An unsigned integer representing the number of columns in a result set.

**Errors**

None.
Example

```c
MYSQL_RES *result;
unsigned int num_fields;
unsigned int num_rows;

if (mysql_query(&mysql,query_string))
{
    // error
}
else // query succeeded, process any data returned by it
{
    result = mysql_store_result(&mysql);
    if (result) // there are rows
    {
        num_fields = mysql_num_fields(result);
        // retrieve rows, then call mysql_free_result(result)
    }
    else // mysql_store_result() returned nothing; should it have?
    {
        if(mysql_field_count(&mysql) == 0)
        {
            // query does not return data
            // (it was not a SELECT)
            num_rows = mysql_affected_rows(&mysql);
        }
        else // mysql_store_result() should have returned data
        {
            fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
        }
    }
}
```

An alternative is to replace the `mysql_field_count(&mysql)` call with `mysql_errno(&mysql)`. In this case, you are checking directly for an error from `mysql_store_result()` rather than inferring from the value of `mysql_field_count()` whether the statement was a SELECT.

### 20.6.7.23 mysql_field_seek()

```c
MYSQL_FIELD_OFFSET mysql_field_seek(MYSQL_RES *result, MYSQL_FIELD_OFFSET offset)
```

**Description**

Sets the field cursor to the given offset. The next call to `mysql_fetch_field()` retrieves the field definition of the column associated with that offset.

To seek to the beginning of a row, pass an `offset` value of zero.

**Return Values**

The previous value of the field cursor.

**Errors**

None.

### 20.6.7.24 mysql_field_tell()

```c
MYSQL_FIELD_OFFSET mysql_field_tell(MYSQL_RES *result)
```

**Description**

Returns the position of the field cursor used for the last `mysql_fetch_field()`. This value can be used as an argument to `mysql_field_seek()`.
Return Values

The current offset of the field cursor.

Errors

None.

20.6.7.25 mysql_free_result()

```c
void mysql_free_result(MYSQL_RES *result)
```

Description

Frees the memory allocated for a result set by `mysql_store_result()`, `mysql_use_result()`, `mysql_list_dbs()`, and so forth. When you are done with a result set, you must free the memory it uses by calling `mysql_free_result()`.

Do not attempt to access a result set after freeing it.

Return Values

None.

Errors

None.

20.6.7.26 mysql_get_character_set_info()

```c
void mysql_get_character_set_info(MYSQL *mysql, MY_CHARSET_INFO *cs)
```

Description

This function provides information about the default client character set. The default character set may be changed with the `mysql_set_character_set()` function.

This function was added in MySQL 5.0.10.

Example

This example shows the fields that are available in the `MY_CHARSET_INFO` structure:

```c
if (!mysql_set_character_set(&mysql, "utf8"))
{
    MY_CHARSET_INFO cs;
    mysql_get_character_set_info(&mysql, &cs);
    printf("character set information:\n");
    printf("character set+collation number: %d\n", cs.number);
    printf("character set name: %s\n", cs.name);
    printf("collation name: %s\n", cs.csname);
    printf("comment: %s\n", cs.comment);
    printf("directory: %s\n", cs.dir);
    printf("multi byte character min. length: %d\n", cs.mbminlen);
    printf("multi byte character max. length: %d\n", cs.mbmaxlen);
}
```

20.6.7.27 mysql_get_client_info()

```c
const char *mysql_get_client_info(void)
```

Description

Returns a string that represents the MySQL client library version; for example, "5.0.96".
The function value is the MySQL version. For Connector/C, this is the MySQL version on which the Connector/C distribution is based. For more information, see Section 20.6.4.4, “C API Server and Client Library Versions”.

**Return Values**

A character string that represents the MySQL client library version.

**Errors**

None.

### 20.6.7.28 mysql_get_client_version()

```c
unsigned long mysql_get_client_version(void)
```

**Description**

Returns an integer that represents the MySQL client library version. The value has the format `XYYZZ` where `X` is the major version, `YY` is the release level (or minor version), and `ZZ` is the sub-version within the release level:

```
major_version*10000 + release_level*100 + sub_version
```

For example, "5.0.96" is returned as 50096.

The function value is the MySQL version. For Connector/C, this is the MySQL version on which the Connector/C distribution is based. For more information, see Section 20.6.4.4, “C API Server and Client Library Versions”.

**Return Values**

An integer that represents the MySQL client library version.

**Errors**

None.

### 20.6.7.29 mysql_get_host_info()

```c
const char *mysql_get_host_info(MYSQL *mysql)
```

**Description**

Returns a string describing the type of connection in use, including the server host name.

**Return Values**

A character string representing the server host name and the connection type.

**Errors**

None.

### 20.6.7.30 mysql_get_proto_info()

```c
unsigned int mysql_get_proto_info(MYSQL *mysql)
```

**Description**

Returns the protocol version used by current connection.
C API Function Descriptions

Return Values
An unsigned integer representing the protocol version used by the current connection.

Errors
None.

20.6.7.31 mysql_get_server_info()

const char *mysql_get_server_info(MYSQL *mysql)

Description
Returns a string that represents the MySQL server version; for example, "5.0.96".

Return Values
A character string that represents the MySQL server version.

Errors
None.

20.6.7.32 mysql_get_server_version()

unsigned long mysql_get_server_version(MYSQL *mysql)

Description
Returns an integer that represents the MySQL server version. The value has the format XYYZZ where X is the major version, YY is the release level (or minor version), and ZZ is the sub-version within the release level:

\[ \text{major_version} \times 10000 + \text{release_level} \times 100 + \text{sub_version} \]

For example, "5.0.96" is returned as 50096.

This function is useful in client programs for determining whether some version-specific server capability exists.

Return Values
An integer that represents the MySQL server version.

Errors
None.

20.6.7.33 mysql_get_ssl_cipher()

const char *mysql_get_ssl_cipher(MYSQL *mysql)

Description
mysql_get_ssl_cipher() returns the encryption cipher used for the given connection to the server. mysql is the connection handler returned from mysql_init().

This function was added in MySQL 5.0.23.
Return Values

A string naming the encryption cipher used for the connection, or NULL if no cipher is being used.

20.6.7.34 mysql_hex_string()

**unsigned long mysql_hex_string(char *to, const char *from, unsigned long length)**

Description

This function creates a legal SQL string for use in an SQL statement. See Section 9.1.1, “String Literals”.

The string in the from argument is encoded in hexadecimal format, with each character encoded as two hexadecimal digits. The result is placed in the to argument, followed by a terminating null byte.

The string pointed to by from must be length bytes long. You must allocate the to buffer to be at least length*2+1 bytes long. When mysql_hex_string() returns, the contents of to is a null-terminated string. The return value is the length of the encoded string, not including the terminating null byte.

The return value can be placed into an SQL statement using either X'value' or 0xvalue format. However, the return value does not include the X'...' or 0x. The caller must supply whichever of those is desired.

Example

```c
char query[1000],*end;
end = strmov(query,"INSERT INTO test_table values(");
end = strmov(end,"X'");
end += mysql_hex_string(end,"What is this",12);
end = strmov(end,"',X'");
end += mysql_hex_string(end,"binary data: \0\r\n",16);
end = strmov(end,"'");
if (mysql_real_query(&mysql,query,(unsigned int) (end - query)))
{
    fprintf(stderr, "Failed to insert row, Error: %s\n",
              mysql_error(&mysql));
}
```

The `strmov()` function used in the example is included in the libmysqlclient library and works like `strcpy()` but returns a pointer to the terminating null of the first parameter.

Return Values

The length of the encoded string that is placed into to, not including the terminating null character.

Errors

None.

20.6.7.35 mysql_info()

**const char *mysql_info(MYSQL *mysql)**

Description

Retrieves a string providing information about the most recently executed statement, but only for the statements listed here. For other statements, mysql_info() returns NULL. The format of the string
varies depending on the type of statement, as described here. The numbers are illustrative only; the string contains values appropriate for the statement.

- **INSERT INTO ... SELECT ...**
  
  String format: Records: 100 Duplicates: 0 Warnings: 0

- **INSERT INTO ... VALUES (...),(...) ...**
  
  String format: Records: 3 Duplicates: 0 Warnings: 0

- **LOAD DATA INFILE ...**
  
  String format: Records: 1 Deleted: 0 Skipped: 0 Warnings: 0

- **ALTER TABLE**
  
  String format: Records: 3 Duplicates: 0 Warnings: 0

- **UPDATE**
  
  String format: Rows matched: 40 Changed: 40 Warnings: 0

`mysql_info()` returns a non-NULL value for **INSERT ... VALUES** only for the multiple-row form of the statement (that is, only if multiple value lists are specified).

**Return Values**

A character string representing additional information about the most recently executed statement. NULL if no information is available for the statement.

**Errors**

None.

### 20.6.7.36 mysql_init()

```c
MYSQL *mysql_init(MYSQL *mysql)
```

**Description**

Allocates or initializes a `MYSQL` object suitable for `mysql_real_connect()`. If `mysql` is a NULL pointer, the function allocates, initializes, and returns a new object. Otherwise, the object is initialized and the address of the object is returned. If `mysql_init()` allocates a new object, it is freed when `mysql_close()` is called to close the connection.

In a nonmulti-threaded environment, `mysql_init()` invokes `mysql_library_init()` automatically as necessary. However, `mysql_library_init()` is not thread-safe in a multi-threaded environment, and thus neither is `mysql_init()`. Before calling `mysql_init()`, either call `mysql_library_init()` prior to spawning any threads, or use a mutex to protect the `mysql_library_init()` call. This should be done prior to any other client library call.

**Return Values**

An initialized `MYSQL*` handle. NULL if there was insufficient memory to allocate a new object.

**Errors**

In case of insufficient memory, NULL is returned.

### 20.6.7.37 mysql_insert_id()

```c
my_ulonglong mysql_insert_id(MYSQL *mysql)
```
Description

Returns the value generated for an `AUTO_INCREMENT` column by the previous `INSERT` or `UPDATE` statement. Use this function after you have performed an `INSERT` statement into a table that contains an `AUTO_INCREMENT` field, or have used `INSERT` or `UPDATE` to set a column value with `LAST_INSERT_ID(expr)`.

More precisely, `mysql_insert_id()` is updated under these conditions:

- `INSERT` statements that store a value into an `AUTO_INCREMENT` column. This is true whether the value is automatically generated by storing the special values `NULL` or `0` into the column, or is an explicit nonspecial value.

- In the case of a multiple-row `INSERT` statement, `mysql_insert_id()` returns the first automatically generated `AUTO_INCREMENT` value; if no such value is generated, it returns the last explicit value inserted into the `AUTO_INCREMENT` column.

  If no rows are successfully inserted, `mysql_insert_id()` returns 0.

- Starting in MySQL 5.0.54, if an `INSERT ... SELECT` statement is executed, and no automatically generated value is successfully inserted, `mysql_insert_id()` returns the ID of the last inserted row.

- `INSERT` statements that generate an `AUTO_INCREMENT` value by inserting `LAST_INSERT_ID(expr)` into any column or by updating any column to `LAST_INSERT_ID(expr)`.

- If the previous statement returned an error, the value of `mysql_insert_id()` is undefined.

`mysql_insert_id()` returns 0 if the previous statement does not use an `AUTO_INCREMENT` value. If you need to save the value for later, be sure to call `mysql_insert_id()` immediately after the statement that generates the value.

The value of `mysql_insert_id()` is not affected by statements such as `SELECT` that return a result set.

The value of `mysql_insert_id()` is affected only by statements issued within the current client connection. It is not affected by statements issued by other clients.

The `LAST_INSERT_ID()` SQL function returns the most recently generated `AUTO_INCREMENT` value, and is not reset between statements because the value of that function is maintained in the server. Another difference from `mysql_insert_id()` is that `LAST_INSERT_ID()` is not updated if you set an `AUTO_INCREMENT` column to a specific nonspecial value. See Section 12.13, “Information Functions”.

`mysql_insert_id()` returns 0 following a `CALL` statement for a stored procedure that generates an `AUTO_INCREMENT` value because in this case `mysql_insert_id()` applies to `CALL` and not the statement within the procedure. Within the procedure, you can use `LAST_INSERT_ID()` at the SQL level to obtain the `AUTO_INCREMENT` value.

The reason for the differences between `LAST_INSERT_ID()` and `mysql_insert_id()` is that `LAST_INSERT_ID()` is made easy to use in scripts while `mysql_insert_id()` tries to provide more exact information about what happens to the `AUTO_INCREMENT` column.

Return Values

Described in the preceding discussion.

Errors

None.
20.6.7.38 mysql_kill()

```c
int mysql_kill(MYSQL *mysql, unsigned long pid)
```

**Description**

Asks the server to kill the thread specified by `pid`.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL KILL statement instead.

**Return Values**

Zero for success. Nonzero if an error occurred.

**Errors**

- **CR_COMMANDS_OUT_OF_SYNC**
  Commands were executed in an improper order.

- **CR_SERVER_GONE_ERROR**
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  An unknown error occurred.

20.6.7.39 mysql_library_end()

```c
void mysql_library_end(void)
```

**Description**

This function finalizes the MySQL library. Call it when you are done using the library (for example, after disconnecting from the server). The action taken by the call depends on whether your application is linked to the MySQL client library or the MySQL embedded server library. For a client program linked against the `libmysqlclient` library by using the `-lmysqlclient` flag, `mysql_library_end()` performs some memory management to clean up. For an embedded server application linked against the `libmysqld` library by using the `-lmysqld` flag, `mysql_library_end()` shuts down the embedded server and then cleans up.

For usage information, see Section 20.6.6, “C API Function Overview”, and Section 20.6.7.40, “mysql_library_init()”.

`mysql_library_end()` was added in MySQL 5.0.3. For older versions of MySQL, call `mysql_server_end()` instead.

20.6.7.40 mysql_library_init()

```c
int mysql_library_init(int argc, char **argv, char **groups)
```

**Description**

Call this function to initialize the MySQL library before you call any other MySQL function, whether your application is a regular client program or uses the embedded server. If the application uses the
embedded server, this call starts the server and initializes any subsystems (mysys, InnoDB, and so forth) that the server uses.

After your application is done using the MySQL library, call mysql_library_end() to clean up. See Section 20.6.7.39, "mysql_library_end()".

The choice of whether the application operates as a regular client or uses the embedded server depends on whether you use the libmysqlclient or libmysqld library at link time to produce the final executable. For additional information, see Section 20.6.6, "C API Function Overview".

In a nonmulti-threaded environment, the call to mysql_library_init() may be omitted, because mysql_init() will invoke it automatically as necessary. However, mysql_library_init() is not thread-safe in a multi-threaded environment, and thus neither is mysql_init(), which calls mysql_library_init(). You must either call mysql_library_init() prior to spawning any threads, or else use a mutex to protect the call, whether you invoke mysql_library_init() or indirectly through mysql_init(). Do this prior to any other client library call.

The argc and argv arguments are analogous to the arguments to main(), and enable passing of options to the embedded server. For convenience, argc may be 0 (zero) if there are no command-line arguments for the server. This is the usual case for applications intended for use only as regular (nonembedded) clients, and the call typically is written as mysql_library_init(0, NULL, NULL).

```c
#include <mysql.h>
#include <stdlib.h>

int main(void) {
  if (mysql_library_init(0, NULL, NULL)) {
    fprintf(stderr, "could not initialize MySQL library\n");
    exit(1);
  }
  /* Use any MySQL API functions here */
  mysql_library_end();
  return EXIT_SUCCESS;
}
```

When arguments are to be passed (argc is greater than 0), the first element of argv is ignored (it typically contains the program name). mysql_library_init() makes a copy of the arguments so it is safe to destroy argv or groups after the call.

For embedded applications, if you want to connect to an external server without starting the embedded server, you have to specify a negative value for argc.

The groups argument is an array of strings that indicate the groups in option files from which to read options. See Section 4.2.6, "Using Option Files". Make the final entry in the array NULL. For convenience, if the groups argument itself is NULL, the [server] and [embedded] groups are used by default.

```c
#include <mysql.h>
#include <stdlib.h>

static char *server_args[] = {
  "this_program",       /* this string is not used */
  "--datadir=.",
  "--key_buffer_size=32M"
};
static char *server_groups[] = {
  "embedded",
  "server",
  "this_program_SERVER",
  (char *)NULL
};
```
int main(void) {
    if (mysql_library_init(sizeof(server_args) / sizeof(char *),
                           server_args, server_groups)) {
        fprintf(stderr, "could not initialize MySQL library\n");
        exit(1);
    }

    /* Use any MySQL API functions here */
    mysql_library_end();
    return EXIT_SUCCESS;
}

mysql_library_init() was added in MySQL 5.0.3. For older versions of MySQL, call
mysql_server_init() instead.

**Return Values**

Zero for success. Nonzero if an error occurred.

### 20.6.7.41 mysql_list_dbs()

```c
MYSQL_RES *mysql_list_dbs(MYSQL *mysql, const char *wild)
```

**Description**

Returns a result set consisting of database names on the server that match the simple regular
expression specified by the `wild` parameter. `wild` may contain the wildcard characters "%" or "_", or
may be a `NULL` pointer to match all databases. Calling `mysql_list_dbs()` is similar to executing the
query `SHOW DATABASES [LIKE wild]`.

You must free the result set with `mysql_free_result()`.

**Return Values**

A `MYSQL_RES` result set for success. `NULL` if an error occurred.

**Errors**

- CR_COMMANDS_OUT_OF_SYNC
  
  Commands were executed in an improper order.

- CR_OUT_OF_MEMORY
  
  Out of memory.

- CR_SERVER_GONE_ERROR
  
  The MySQL server has gone away.

- CR_SERVER_LOST
  
  The connection to the server was lost during the query.

- CR_UNKNOWN_ERROR
  
  An unknown error occurred.

### 20.6.7.42 mysql_list_fields()

```c
MYSQL_RES *mysql_list_fields(MYSQL *mysql, const char *table, const char *wild)
```
C API Function Descriptions

Description

Returns an empty result set for which the metadata provides information about the columns in the
given table that match the simple regular expression specified by the wild parameter. wild may
contain the wildcard characters "%" or "_", or may be a NULL pointer to match all fields. Calling
mysql_list_fields() is similar to executing the query SHOW COLUMNS FROM tbl_name [LIKE
wild].

It is preferable to use SHOW COLUMNS FROM tbl_name instead of mysql_list_fields().

You must free the result set with mysql_free_result().

Return Values

A MYSQL_RES result set for success. NULL if an error occurred.

Errors

- CR_COMMANDS_OUT_OF_SYNC

  Commands were executed in an improper order.

- CR_SERVER_GONE_ERROR

  The MySQL server has gone away.

- CR_SERVER_LOST

  The connection to the server was lost during the query.

- CR_UNKNOWN_ERROR

  An unknown error occurred.

Example

```c
int i;
MYSQL_RES *tbl_cols = mysql_list_fields(mysql, "mytbl", "f%");  
unsigned int field_cnt = mysql_num_fields(tbl_cols);
printf("Number of columns: %d\n", field_cnt);
for (i=0; i < field_cnt; ++i)
{  
  /* col describes i-th column of the table */
  MYSQL_FIELD *col = mysql_fetch_field_direct(tbl_cols, i);
  printf("Column %d: %s\n", i, col->name);
}
mysql_free_result(tbl_cols);
```

20.6.7.43 mysql_list_processes()

MYSQL_RES *mysql_list_processes(MYSQL *mysql)

Description

Returns a result set describing the current server threads. This is the same kind of information as that
reported by mysqladmin processlist or a SHOW PROCESSLIST query.

You must free the result set with mysql_free_result().

Return Values

A MYSQL_RES result set for success. NULL if an error occurred.
Errors

- **CR_COMMANDS_OUT_OF_SYNC**
  Commands were executed in an improper order.

- **CR_SERVER_GONE_ERROR**
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  An unknown error occurred.

20.6.7.44 mysql_list_tables()

```c
MYSQL_RES *mysql_list_tables(MYSQL *mysql, const char *wild)
```

**Description**

Returns a result set consisting of table names in the current database that match the simple regular expression specified by the `wild` parameter. `wild` may contain the wildcard characters "%" or "_", or may be a NULL pointer to match all tables. Calling `mysql_list_tables()` is similar to executing the query `SHOW TABLES [LIKE wild]`.

You must free the result set with `mysql_free_result()`.

**Return Values**

A `MYSQL_RES` result set for success. `NULL` if an error occurred.

**Errors**

- **CR_COMMANDS_OUT_OF_SYNC**
  Commands were executed in an improper order.

- **CR_SERVER_GONE_ERROR**
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  An unknown error occurred.

20.6.7.45 mysql_more_results()

```c
my_bool mysql_more_results(MYSQL *mysql)
```

**Description**

This function is used when you execute multiple statements specified as a single statement string, or when you execute `CALL` statements, which can return multiple result sets.
mysql_more_results()  true if more results exist from the currently executed statement, in which case the application must call mysql_next_result() to fetch the results.

Return Values

TRUE (1) if more results exist. FALSE (0) if no more results exist.

In most cases, you can call mysql_next_result() instead to test whether more results exist and initiate retrieval if so.

See Section 20.6.16, "C API Support for Multiple Statement Execution", and Section 20.6.7.46, "mysql_next_result()".

Errors

None.

20.6.7.46 mysql_next_result()

int mysql_next_result(MYSQL *mysql)

Description

This function is used when you execute multiple statements specified as a single statement string, or when you use CALL statements to execute stored procedures, which can return multiple result sets.

mysql_next_result() reads the next statement result and returns a status to indicate whether more results exist. If mysql_next_result() returns an error, there are no more results.

Before each call to mysql_next_result(), you must call mysql_free_result() for the current statement if it is a statement that returned a result set (rather than just a result status).

After calling mysql_next_result() the state of the connection is as if you had called mysql_store_result(), mysql_warning_count(), mysql_affected_rows(), and so forth.

If your program uses CALL statements to execute stored procedures, the CLIENT_MULTI_RESULTS flag must be enabled. This is because each CALL returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure. Because CALL can return multiple results, process them using a loop that calls mysql_next_result() to determine whether there are more results.

CLIENT_MULTI_RESULTS can be enabled when you call mysql_real_connect(), either explicitly by passing the CLIENT_MULTI_RESULTS flag itself, or implicitly by passing CLIENT_MULTI_STATEMENTS (which also enables CLIENT_MULTI_RESULTS).

It is also possible to test whether there are more results by calling mysql_more_results(). However, this function does not change the connection state, so if it returns true, you must still call mysql_next_result() to advance to the next result.

For an example that shows how to use mysql_next_result(), see Section 20.6.16, "C API Support for Multiple Statement Execution".

Return Values

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Successful and there are more results</td>
</tr>
<tr>
<td>-1</td>
<td>Successful and there are no more results</td>
</tr>
</tbody>
</table>
Return Value | Description
---|---
>0 | An error occurred

### Errors

- **CR_COMMANDS_OUT_OF_SYNC**
  
  Commands were executed in an improper order. For example, if you did not call `mysql_use_result()` for a previous result set.

- **CR_SERVER_GONE_ERROR**
  
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  
  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  
  An unknown error occurred.

#### 20.6.7.47 mysql_num_fields()

```c
unsigned int mysql_num_fields(MYSQL_RES *result)
```

To pass a `MYSQL*` argument instead, use `unsigned int mysql_field_count(MYSQL *mysql)`.

### Description

Returns the number of columns in a result set.

You can get the number of columns either from a pointer to a result set or to a connection handle. You would use the connection handle if `mysql_store_result()` or `mysql_use_result()` returned `NULL` (and thus you have no result set pointer). In this case, you can call `mysql_field_count()` to determine whether `mysql_store_result()` should have produced a nonempty result. This enables the client program to take proper action without knowing whether the query was a `SELECT` (or `SELECT`-like) statement. The example shown here illustrates how this may be done.

### Return Values

An unsigned integer representing the number of columns in a result set.

### Errors

None.

### Example

```c
MYSQL_RES *result;
unsigned int num_fields;
unsigned int num_rows;

if (mysql_query(&mysql,query_string))
{
    // error
}
else // query succeeded, process any data returned by it
{  
```
result = mysql_store_result(&mysql);
if (result)  // there are rows
{
   num_fields = mysql_num_fields(result);
   // retrieve rows, then call mysql_free_result(result)
}
else  // mysql_store_result() returned nothing; should it have?
{
   if (mysql_errno(&mysql))
   {
      fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
   }
   else if (mysql_field_count(&mysql) == 0)
   {
      // query does not return data
      // (it was not a SELECT)
      num_rows = mysql_affected_rows(&mysql);
   }
}

An alternative (if you know that your query should have returned a result set) is to replace the mysql_errno(&mysql) call with a check whether mysql_field_count(&mysql) returns 0. This happens only if something went wrong.

20.6.7.48 mysql_num_rows()

my_ulonglong mysql_num_rows(MYSQL_RES *result)

Description

Returns the number of rows in the result set.

The use of mysql_num_rows() depends on whether you use mysql_store_result() or mysql_use_result() to return the result set. If you use mysql_store_result(), mysql_num_rows() may be called immediately. If you use mysql_use_result(), mysql_num_rows() does not return the correct value until all the rows in the result set have been retrieved.

mysql_num_rows() is intended for use with statements that return a result set, such as SELECT. For statements such as INSERT, UPDATE, or DELETE, the number of affected rows can be obtained with mysql_affected_rows().

Return Values

The number of rows in the result set.

Errors

None.

20.6.7.49 mysql_options()

int mysql_options(MYSQL *mysql, enum mysql_option option, const char *arg)

Description

Can be used to set extra connect options and affect behavior for a connection. This function may be called multiple times to set several options.

Call mysql_options() after mysql_init() and before mysql_connect() or mysql_real_connect().

The option argument is the option that you want to set; the arg argument is the value for the option. If the option is an integer, specify a pointer to the value of the integer as the arg argument.
The following list describes the possible options, their effect, and how arg is used for each option. Several of the options apply only when the application is linked against the libmysqld embedded server library and are unused for applications linked against the libmysqlclient client library. For option descriptions that indicate arg is unused, its value is irrelevant; it is conventional to pass 0.

- **MYSQL_INIT_COMMAND** (argument type: char *)
  SQL statement to execute when connecting to the MySQL server. Automatically re-executed if reconnection occurs.

- **MYSQL_OPT_COMPRESS** (argument: not used)
  Use the compressed client/server protocol.

- **MYSQL_OPT_CONNECT_TIMEOUT** (argument type: unsigned int *)
  The connect timeout in seconds.

- **MYSQL_OPT_GUESS_CONNECTION** (argument: not used)
  For an application linked against the libmysqld embedded server library, this enables the library to guess whether to use the embedded server or a remote server. “Guess” means that if the host name is set and is not localhost, it uses a remote server. This behavior is the default. MYSQL_OPT_USE_EMBEDDED_CONNECTION and MYSQL_OPT_USE_REMOTE_CONNECTION can be used to override it. This option is ignored for applications linked against the libmysqlclient client library.

- **MYSQL_OPT_LOCAL_INFILE** (argument type: optional pointer to unsigned int)
  If no pointer is given or if pointer points to an unsigned int that has a nonzero value, the LOAD DATA LOCAL INFILE statement is enabled.

- **MYSQL_OPT_NAMED_PIPE** (argument: not used)
  Use a named pipe to connect to the MySQL server on Windows, if the server permits named-pipe connections.

- **MYSQL_OPT_PROTOCOL** (argument type: unsigned int *)
  Type of protocol to use. Specify one of the enum values of mysql_protocol_type defined in mysql.h.

- **MYSQL_OPT_READ_TIMEOUT** (argument type: unsigned int *)
  The timeout in seconds for each attempt to read from the server. There are retries if necessary, so the total effective timeout value is three times the option value. You can set the value so that a lost connection can be detected earlier than the TCP/IP Close_Wait_Timeout value of 10 minutes. This option works only for TCP/IP connections and, prior to MySQL 5.0.25, only for Windows.

- **MYSQL_OPT_RECONNECT** (argument type: my_bool *)
  Enable or disable automatic reconnection to the server if the connection is found to have been lost. Reconnect has been off by default since MySQL 5.0.3; this option is new in 5.0.13 and provides a way to set reconnection behavior explicitly.

  **Note:** mysql_real_connect() incorrectly reset the MYSQL_OPT_RECONNECT option to its default value before MySQL 5.0.19. Therefore, prior to that version, if you want reconnect to be enabled for each connection, you must call mysql_options() with the MYSQL_OPT_RECONNECT option after each call to mysql_real_connect(). This is not necessary as of 5.0.19: Call mysql_options() only before mysql_real_connect() as usual.

- **MYSQL_OPT_SSL_VERIFY_SERVER_CERT** (argument type: my_bool *)
Enable or disable verification of the server’s Common Name value in its certificate against the host name used when connecting to the server. The connection is rejected if there is a mismatch. For encrypted connections, this feature can be used to prevent man-in-the-middle attacks. Verification is disabled by default. Added in MySQL 5.0.23.

- **MYSQL_OPT_USE_EMBEDDED_CONNECTION** (argument: not used)
  
  For an application linked against the `libmysqld` embedded server library, this forces the use of the embedded server for the connection. This option is ignored for applications linked against the `libmysqlclient` client library.

- **MYSQL_OPT_USE_REMOTE_CONNECTION** (argument: not used)
  
  For an application linked against the `libmysqld` embedded server library, this forces the use of a remote server for the connection. This option is ignored for applications linked against the `libmysqlclient` client library.

- **MYSQL_OPT_USE_RESULT** (argument: not used)
  
  This option is unused.

- **MYSQL_OPT_WRITE_TIMEOUT** (argument type: `unsigned int` *)
  
  The timeout in seconds for each attempt to write to the server. There is a retry if necessary, so the total effective timeout value is two times the option value. This option works only for TCP/IP connections and, prior to MySQL 5.0.25, only for Windows.

- **MYSQL_READ_DEFAULT_FILE** (argument type: `char` *)
  
  Read options from the named option file instead of from `my.cnf`.

- **MYSQL_READ_DEFAULT_GROUP** (argument type: `char` *)
  
  Read options from the named group from `my.cnf` or the file specified with `MYSQL_READ_DEFAULT_FILE`.

- **MYSQL_REPORT_DATA_TRUNCATION** (argument type: `my_bool` *)
  
  Enable or disable reporting of data truncation errors for prepared statements using the `error` member of `MYSQL_BIND` structures. (Default: enabled.) Added in 5.0.3.

- **MYSQL_SECURE_AUTH** (argument type: `my_bool` *)
  
  Whether to connect to a server that does not support the password hashing used in MySQL 4.1.1 and later.

- **MYSQL_SET_CHARSET_DIR** (argument type: `char` *)
  
  The path name to the directory that contains character set definition files.

- **MYSQL_SET_CHARSET_NAME** (argument type: `char` *)
  
  The name of the character set to use as the default character set.

- **MYSQL_SET_CLIENT_IP** (argument type: `char` *)
  
  For an application linked against the `libmysqld` embedded server library (when `libmysqld` is compiled with authentication support), this means that the user is considered to have connected from the specified IP address (specified as a string) for authentication purposes. This option is ignored for applications linked against the `libmysqlclient` client library.

- **MYSQL_SHARED_MEMORY_BASE_NAME** (argument type: `char` *)
The name of the shared-memory object for communication to the server on Windows, if the server supports shared-memory connections. Specify the same value as the `--shared-memory-base-name` option used for the `mysqld` server you want to connect to.

The `client` group is always read if you use `MYSQL_READ_DEFAULT_FILE` or `MYSQL_READ_DEFAULT_GROUP`.

The specified group in the option file may contain the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>character-sets-dir=dir_name</code></td>
<td>The directory where character sets are installed.</td>
</tr>
<tr>
<td><code>compress</code></td>
<td>Use the compressed client/server protocol.</td>
</tr>
<tr>
<td><code>connect-timeout=seconds</code></td>
<td>The connect timeout in seconds. On Linux this timeout is also used for waiting for the first answer from the server.</td>
</tr>
<tr>
<td><code>database=db_name</code></td>
<td>Connect to this database if no database was specified in the connect command.</td>
</tr>
<tr>
<td><code>debug</code></td>
<td>Debug options.</td>
</tr>
<tr>
<td><code>default-character-set=charset_name</code></td>
<td>Disable use of <code>LOAD DATA LOCAL INFILE</code>.</td>
</tr>
<tr>
<td><code>host=host_name</code></td>
<td>Default host name.</td>
</tr>
<tr>
<td><code>init-command=stmt</code></td>
<td>Statement to execute when connecting to MySQL server. Automatically re-executed if reconnection occurs.</td>
</tr>
<tr>
<td><code>interactive-timeout=seconds</code></td>
<td>Same as specifying <code>CLIENT_INTERACTIVE</code> to <code>mysql_real_connect()</code>. See Section 20.6.7.52, &quot;mysql_real_connect()&quot;.</td>
</tr>
<tr>
<td>`local-infile={0</td>
<td>1}`</td>
</tr>
<tr>
<td><code>max_allowed_packet=bytes</code></td>
<td>Maximum size of packet that client can read from server.</td>
</tr>
<tr>
<td><code>multi-queries,multi-results</code></td>
<td>Enable multiple result sets from multiple-statement executions or stored procedures.</td>
</tr>
<tr>
<td><code>multi-statements</code></td>
<td>Enable the client to send multiple statements in a single string (separated by <code>;</code> characters).</td>
</tr>
<tr>
<td><code>password=password</code></td>
<td>Default password.</td>
</tr>
<tr>
<td><code>pipe</code></td>
<td>Use named pipes to connect to a MySQL server on Windows.</td>
</tr>
<tr>
<td><code>port=port_num</code></td>
<td>Default port number.</td>
</tr>
<tr>
<td>`protocol={TCP</td>
<td>SOCKET</td>
</tr>
<tr>
<td><code>return-found-rows</code></td>
<td>Tell <code>mysql_info()</code> to return found rows instead of updated rows when using <code>UPDATE</code>.</td>
</tr>
<tr>
<td><code>shared-memory-base-name=name</code></td>
<td>Shared-memory name to use to connect to server.</td>
</tr>
<tr>
<td>`socket={file_name</td>
<td>pipe_name}`</td>
</tr>
<tr>
<td><code>ssl-ca=file_name</code></td>
<td>Certificate Authority file.</td>
</tr>
<tr>
<td><code>ssl-capath=dir_name</code></td>
<td>Certificate Authority directory.</td>
</tr>
<tr>
<td><code>ssl-cert=file_name</code></td>
<td>Certificate file.</td>
</tr>
<tr>
<td><code>ssl-cipher=cipher_list</code></td>
<td>Permissible SSL ciphers.</td>
</tr>
</tbody>
</table>
### Option Description

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ssl-key=file_name</td>
<td>Key file.</td>
</tr>
<tr>
<td>timeout=seconds</td>
<td>Like connect-timeout.</td>
</tr>
<tr>
<td>user</td>
<td>Default user.</td>
</tr>
</tbody>
</table>

`timeout` has been replaced by `connect-timeout`, but `timeout` is still supported for backward compatibility.

For more information about option files used by MySQL programs, see Section 4.2.6, “Using Option Files”.

### Return Values

Zero for success. Nonzero if you specify an unknown option.

### Example

The following `mysql_options()` calls request the use of compression in the client/server protocol, cause options to be read from the [odbc] group of option files, and disable transaction autocommit mode:

```c
MYSQL mysql;
mysql_init(&mysql);
mysql_options(&mysql,MYSQL_OPT_COMPRESS,0);
mysql_options(&mysql,MYSQL_READ_DEFAULT_GROUP,"odbc");
mysql_options(&mysql,MYSQL_INIT_COMMAND,"SET autocommit=0");
if (!mysql_real_connect(&mysql,"host","user","passwd","database",0,NULL,0))
{
    fprintf(stderr, "Failed to connect to database: Error: %s\n", mysql_error(&mysql));
}
```

This code requests that the client use the compressed client/server protocol and read the additional options from the `odbc` section in the `my.cnf` file.

### 20.6.7.50 mysql_ping()

#### int mysql_ping(MYSQL *mysql)

### Description

Checks whether the connection to the server is working. If the connection has gone down and auto-reconnect is enabled an attempt to reconnect is made. If the connection is down and auto-reconnect is disabled, `mysql_ping()` returns an error.

Auto-reconnect is enabled by default before MySQL 5.0.3 and enabled from 5.0.3 on. To enable auto-connect, call `mysql_options()` with the `MYSQL_OPT_RECONNECT` option. For details, see Section 20.6.7.49, “mysql_options()”.

`mysql_ping()` can be used by clients that remain idle for a long while, to check whether the server has closed the connection and reconnect if necessary.

If `mysql_ping()` does cause a reconnect, there is no explicit indication of it. To determine whether a reconnect occurs, call `mysql_thread_id()` to get the original connection identifier before calling `mysql_ping()`, then call `mysql_thread_id()` again to see whether the identifier has changed.

If reconnect occurs, some characteristics of the connection will have been reset. For details about these characteristics, see Section 20.6.15, “Controlling Automatic Reconnection Behavior”.
Return Values

Zero if the connection to the server is active. Nonzero if an error occurred. A nonzero return does not indicate whether the MySQL server itself is down; the connection might be broken for other reasons such as network problems.

Errors

- **CR_COMMANDS_OUT_OF_SYNC**
  
  Commands were executed in an improper order.

- **CR_SERVER_GONE_ERROR**
  
  The MySQL server has gone away.

- **CR_UNKNOWN_ERROR**
  
  An unknown error occurred.

### 20.6.7.51 mysql_query()

```c
int mysql_query(MYSQL *mysql, const char *stmt_str)
```

### Description

Executes the SQL statement pointed to by the null-terminated string `stmt_str`. Normally, the string must consist of a single SQL statement without a terminating semicolon (`;`) or `\g`. If multiple-statement execution has been enabled, the string can contain several statements separated by semicolons. See Section 20.6.16, "C API Support for Multiple Statement Execution".

`mysql_query()` cannot be used for statements that contain binary data; you must use `mysql_real_query()` instead. (Binary data may contain the "\0" character, which `mysql_query()` interprets as the end of the statement string.)

If you want to know whether the statement should return a result set, you can use `mysql_field_count()` to check for this. See Section 20.6.7.22, "mysql_field_count()".

### Return Values

Zero for success. Nonzero if an error occurred.

### Errors

- **CR_COMMANDS_OUT_OF_SYNC**
  
  Commands were executed in an improper order.

- **CR_SERVER_GONE_ERROR**
  
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  
  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  
  An unknown error occurred.

### 20.6.7.52 mysql_real_connect()
MYSQL *mysql_real_connect(MYSQL *mysql, const char *host, const char *user, const char *passwd, const char *db, unsigned int port, const char *unix_socket, unsigned long client_flag)

Description

mysql_real_connect() attempts to establish a connection to a MySQL database engine running on host. mysql_real_connect() must complete successfully before you can execute any other API functions that require a valid MYSQL connection handle structure.

The parameters are specified as follows:

- For the first parameter, specify the address of an existing MYSQL structure. Before calling mysql_real_connect(), call mysql_init() to initialize the MYSQL structure. You can change a lot of connect options with the mysql_options() call. See Section 20.6.7.49, "mysql_options()".

- The value of host may be either a host name or an IP address. If host is NULL or the string "localhost", a connection to the local host is assumed. For Windows, the client connects using a shared-memory connection, if the server has shared-memory connections enabled. Otherwise, TCP/IP is used. For Unix, the client connects using a Unix socket file. For local connections, you can also influence the type of connection to use with the MYSQL_OPT_PROTOCOL or MYSQL_OPT_NAMED_PIPE options to mysql_options(). The type of connection must be supported by the server. For a host value of "." on Windows, the client connects using a named pipe, if the server has named-pipe connections enabled. If named-pipe connections are not enabled, an error occurs.

- The user parameter contains the user's MySQL login ID. If user is NULL or the empty string "", the current user is assumed. Under Unix, this is the current login name. Under Windows ODBC, the current user name must be specified explicitly. See the Connector/ODBC section of Chapter 20, Connectors and APIs.

- The passwd parameter contains the password for user. If passwd is NULL, only entries in the user table for the user that have a blank (empty) password field are checked for a match. This enables the database administrator to set up the MySQL privilege system in such a way that users get different privileges depending on whether they have specified a password.

  Note

  Do not attempt to encrypt the password before calling mysql_real_connect(); password encryption is handled automatically by the client API.

- The user and passwd parameters use whatever character set has been configured for the MYSQL object. By default, this is latin1, but can be changed by calling mysql_options(mysql, MYSQL_SET_CHARSET_NAME, "charset_name") prior to connecting.

- db is the database name. If db is not NULL, the connection sets the default database to this value.

- If port is not 0, the value is used as the port number for the TCP/IP connection. Note that the host parameter determines the type of the connection.

- If unix_socket is not NULL, the string specifies the socket or named pipe to use. Note that the host parameter determines the type of the connection.

- The value of client_flag is usually 0, but can be set to a combination of the following flags to enable certain features.

<table>
<thead>
<tr>
<th>Flag Name</th>
<th>Flag Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLIENT_COMPRESS</td>
<td>Use compression in the client/server protocol.</td>
</tr>
<tr>
<td>CLIENT_FOUND_ROWS</td>
<td>Return the number of found (matched) rows, not the number of changed rows.</td>
</tr>
</tbody>
</table>
### Flag Name

<table>
<thead>
<tr>
<th>Flag Name</th>
<th>Flag Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLIENT_IGNORE_SIGPIPE</td>
<td>Prevents the client library from installing a SIGPIPE signal handler. This can be used to avoid conflicts with a handler that the application has already installed.</td>
</tr>
<tr>
<td>CLIENT_IGNORE_SPACE</td>
<td>Permit spaces after function names. Makes all functions names reserved words.</td>
</tr>
<tr>
<td>CLIENT_INTERACTIVE</td>
<td>Permit interactive_timeout seconds of inactivity (rather than wait_timeout seconds) before closing the connection. The client's session wait_timeout variable is set to the value of the session interactive_timeout variable.</td>
</tr>
<tr>
<td>CLIENT_LOCAL_FILES</td>
<td>Enable LOAD DATA LOCAL handling.</td>
</tr>
<tr>
<td>CLIENT_MULTI_RESULTS</td>
<td>Tell the server that the client can handle multiple result sets from multiple-statement executions or stored procedures. This flag is automatically enabled if CLIENT_MULTI_STATEMENTS is enabled. See the note following this table for more information about this flag.</td>
</tr>
<tr>
<td>CLIENT_MULTI_STATEMENTS</td>
<td>Tell the server that the client may send multiple statements in a single string (separated by ; characters). If this flag is not set, multiple-statement execution is disabled. See the note following this table for more information about this flag.</td>
</tr>
<tr>
<td>CLIENT_NO_SCHEMA</td>
<td>Do not permit db_name.tbl_name.col_name syntax. This is for ODBC. It causes the parser to generate an error if you use that syntax, which is useful for trapping bugs in some ODBC programs.</td>
</tr>
<tr>
<td>CLIENT_ODBC</td>
<td>Unused.</td>
</tr>
<tr>
<td>CLIENT_SSL</td>
<td>Use SSL (encrypted protocol). Do not set this option within an application program; it is set internally in the client library. Instead, use mysql_ssl_set() before calling mysql_real_connect().</td>
</tr>
<tr>
<td>CLIENT_REMEMBER_OPTIONS</td>
<td>Remember options specified by calls to mysql_options(). Without this option, if mysql_real_connect() fails, you must repeat the mysql_options() calls before trying to connect again. With this option, the mysql_options() calls need not be repeated.</td>
</tr>
</tbody>
</table>

If your program uses CALL statements to execute stored procedures, the CLIENT_MULTI_RESULTS flag must be enabled. This is because each CALL returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure. Because CALL can return multiple results, process them using a loop that calls mysql_next_result() to determine whether there are more results.

CLIENT_MULTI_RESULTS can be enabled when you call mysql_real_connect(), either explicitly by passing the CLIENT_MULTI_RESULTS flag itself, or implicitly by passing CLIENT_MULTI_STATEMENTS (which also enables CLIENT_MULTI_RESULTS).

If you enable CLIENT_MULTI_STATEMENTS or CLIENT_MULTI_RESULTS, you should process the result for every call to mysql_query() or mysql_real_query() by using a loop that calls mysql_next_result() to determine whether there are more results. For an example, see Section 20.6.16, “C API Support for Multiple Statement Execution”.

For some parameters, it is possible to have the value taken from an option file rather than from an explicit value in the mysql_real_connect() call. To do this, call mysql_options() with the MYSQL_READ_DEFAULT_FILE or MYSQL_READ_DEFAULT_GROUP option before calling mysql_real_connect(). Then, in the mysql_real_connect() call, specify the “no-value” value for each parameter to be read from an option file.
C API Function Descriptions

- For `host`, specify a value of `NULL` or the empty string (`""`).
- For `user`, specify a value of `NULL` or the empty string.
- For `passwd`, specify a value of `NULL`. (For the password, a value of the empty string in the `mysql_real_connect()` call cannot be overridden in an option file, because the empty string indicates explicitly that the MySQL account must have an empty password.)
- For `db`, specify a value of `NULL` or the empty string.
- For `port`, specify a value of 0.
- For `unix_socket`, specify a value of `NULL`.

If no value is found in an option file for a parameter, its default value is used as indicated in the descriptions given earlier in this section.

Return Values

A `MYSQL*` connection handle if the connection was successful, `NULL` if the connection was unsuccessful. For a successful connection, the return value is the same as the value of the first parameter.

Errors

- **CR_CONN_HOST_ERROR**
  Failed to connect to the MySQL server.
- **CR_CONNECTION_ERROR**
  Failed to connect to the local MySQL server.
- **CR_IPSOCK_ERROR**
  Failed to create an IP socket.
- **CR_OUT_OF_MEMORY**
  Out of memory.
- **CR_SOCKET_CREATE_ERROR**
  Failed to create a Unix socket.
- **CR_UNKNOWN_HOST**
  Failed to find the IP address for the host name.
- **CR_VERSION_ERROR**
  A protocol mismatch resulted from attempting to connect to a server with a client library that uses a different protocol version.
- **CR_NAMEDPIPEOPEN_ERROR**
  Failed to create a named pipe on Windows.
- **CR_NAMEDPIPEWAIT_ERROR**
  Failed to wait for a named pipe on Windows.
Failed to get a pipe handler on Windows.

- **CR_SERVER_LOST**

  If `connect_timeout` > 0 and it took longer than `connect_timeout` seconds to connect to the server or if the server died while executing the `init-command`.

**Example**

```c
MYSQL mysql;
mysql_init(&mysql);
mysql_options(&mysql,MYSQL_READ_DEFAULT_GROUP,"your_prog_name");
if (!mysql_real_connect(&mysql,"host","user","passwd","database",0,NULL,0))
{
    fprintf(stderr, "Failed to connect to database: Error: %s\n",
            mysql_error(&mysql));
}
```

By using `mysql_options()` the MySQL library reads the `[client]` and `[your_prog_name]` sections in the `my.cnf` file which ensures that your program works, even if someone has set up MySQL in some nonstandard way.

Upon connection, `mysql_real_connect()` sets the `reconnect` flag (part of the `MYSQL` structure) to a value of 1 in versions of the API older than 5.0.3, or 0 in newer versions. A value of 1 for this flag indicates that if a statement cannot be performed because of a lost connection, to try reconnecting to the server before giving up. As of MySQL 5.0.13, you can use the `MYSQL_OPT_RECONNECT` option to `mysql_options()` to control reconnection behavior.

### 20.6.7.53 `mysql_real_escape_string()`

```c
unsigned long mysql_real_escape_string(MYSQL *mysql, char *to, const char *from, unsigned long length)
```

**Description**

This function creates a legal SQL string for use in an SQL statement. See Section 9.1.1, “String Literals”.

The `mysql` argument must be a valid, open connection because character escaping depends on the character set in use by the server.

The string in the `from` argument is encoded to produce an escaped SQL string, taking into account the current character set of the connection. The result is placed in the `to` argument, followed by a terminating null byte.

Characters encoded are "\", "'", "", NULL (ASCII 0), "\n", "\r", and Control+Z. Strictly speaking, MySQL requires only that backslash and the quote character used to quote the string in the query be escaped. `mysql_real_escape_string()` quotes the other characters to make them easier to read in log files. For comparison, see the quoting rules for literal strings and the `QUOTE()` SQL function in Section 9.1.1, “String Literals”, and Section 12.5, “String Functions”.

The string pointed to by `from` must be `length` bytes long. You must allocate the `to` buffer to be at least `length*2+1` bytes long. (In the worst case, each character may need to be encoded as using two bytes, and there must be room for the terminating null byte.) When `mysql_real_escape_string()` returns, the contents of `to` is a null-terminated string. The return value is the length of the encoded string, not including the terminating null byte.

If you must change the character set of the connection, use the `mysql_set_character_set()` function rather than executing a `SET NAMES` (or `SET CHARACTER SET`) statement. `mysql_set_character_set()` works like `SET NAMES` but also affects the character set used by `mysql_real_escape_string()`, which `SET NAMES` does not.
Example

The following example inserts two escaped strings into an INSERT statement, each within single quote characters:

```c
char query[1000],*end;
end = strmov(query,"INSERT INTO test_table VALUES(");
*end++ = '\';
end += mysql_real_escape_string(&mysql,end,"What is this",12);
*end++ = ',';
*end++ = '\';
end += mysql_real_escape_string(&mysql,end,"binary data: \0\r\n",16);
*end++ = '\';
*end++ = ')';
if (mysql_real_query(&mysql,query,(unsigned int) (end - query)))
{
    fprintf(stderr, "Failed to insert row, Error: %s\n",
            mysql_error(&mysql));
}
```

The `strmov()` function used in the example is included in the `libmysqlclient` library and works like `strcpy()` but returns a pointer to the terminating null of the first parameter.

Return Values

The length of the encoded string that is placed into the `to` argument, not including the terminating null character.

Errors

None.

20.6.7.54 mysql_real_query()

```c
int mysql_real_query(MYSQL *mysql, const char *stmt_str, unsigned long length)
```

Description

Executes the SQL statement pointed to by `stmt_str`, a string `length` bytes long. Normally, the string must consist of a single SQL statement without a terminating semicolon (";"") or `\g`. If multiple-statement execution has been enabled, the string can contain several statements separated by semicolons. See Section 20.6.16, “C API Support for Multiple Statement Execution”.

mysql_query() cannot be used for statements that contain binary data; you must use mysql_real_query() instead. (Binary data may contain the “\0” character, which mysql_query() interprets as the end of the statement string.) In addition, mysql_real_query() is faster than mysql_query() because it does not call strlen() on the statement string.

If you want to know whether the statement should return a result set, you can use mysql_field_count() to check for this. See Section 20.6.7.22, “mysql_field_count()”.

Return Values

Zero for success. Nonzero if an error occurred.

Errors

- CR_COMMANDS_OUT_OF_SYNC
Commands were executed in an improper order.

- **CR_SERVER_GONE_ERROR**
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  An unknown error occurred.

### 20.6.7.55 mysql_refresh()

```c
int mysql_refresh(MYSQL *mysql, unsigned int options)
```

**Description**

This function flushes tables or caches, or resets replication server information. The connected user must have the `RELOAD` privilege.

The `options` argument is a bit mask composed from any combination of the following values. Multiple values can be OR’ed together to perform multiple operations with a single call.

- **REFRESH_GRANT**
  Refresh the grant tables, like `FLUSH PRIVILEGES`.

- **REFRESH_LOG**
  Flush the logs, like `FLUSH LOGS`.

- **REFRESH_TABLES**
  Flush the table cache, like `FLUSH TABLES`.

- **REFRESH_HOSTS**
  Flush the host cache, like `FLUSH HOSTS`.

- **REFRESH_STATUS**
  Reset status variables, like `FLUSH STATUS`.

- **REFRESH_THREADS**
  Flush the thread cache.

- **REFRESH_SLAVE**
  On a slave replication server, reset the master server information and restart the slave, like `RESET SLAVE`.

- **REFRESH_MASTER**
  On a master replication server, remove the binary log files listed in the binary log index and truncate the index file, like `RESET MASTER`.

**Return Values**

Zero for success. Nonzero if an error occurred.
Errors

- **CR_COMMANDS_OUT_OF_SYNC**
  Commands were executed in an improper order.

- **CR_SERVER_GONE_ERROR**
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  An unknown error occurred.

### 20.6.7.56 mysql_reload()

```c
int mysql_reload(MYSQL *mysql)
```

**Description**

Asks the MySQL server to reload the grant tables. The connected user must have the `RELOAD` privilege.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL `FLUSH PRIVILEGES` statement instead.

**Return Values**

Zero for success. Nonzero if an error occurred.

**Errors**

- **CR_COMMANDS_OUT_OF_SYNC**
  Commands were executed in an improper order.

- **CR_SERVER_GONE_ERROR**
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  An unknown error occurred.

### 20.6.7.57 mysql_rollback()

```c
my_bool mysql_rollback(MYSQL *mysql)
```

**Description**

Rolls back the current transaction.

As of MySQL 5.0.3, the action of this function is subject to the value of the `completion_type` system variable. In particular, if the value of `completion_type` is 2, the server performs a release
after terminating a transaction and closes the client connection. The client program should call `mysql_close()` to close the connection from the client side.

**Return Values**

Zero for success. Nonzero if an error occurred.

**Errors**

None.

### 20.6.7.58 mysql_row_seek()

```c
MYSQL_ROW_OFFSET mysql_row_seek(MYSQL_RES *result, MYSQL_ROW_OFFSET offset)
```

**Description**

Sets the row cursor to an arbitrary row in a query result set. The `offset` value is a row offset, typically a value returned from `mysql_row_tell()` or from `mysql_row_seek()`. This value is not a row number; to seek to a row within a result set by number, use `mysql_data_seek()` instead.

This function requires that the result set structure contains the entire result of the query, so `mysql_row_seek()` may be used only in conjunction with `mysql_store_result()`, not with `mysql_use_result()`.

**Return Values**

The previous value of the row cursor. This value may be passed to a subsequent call to `mysql_row_seek()`.

**Errors**

None.

### 20.6.7.59 mysql_row_tell()

```c
MYSQL_ROW_OFFSET mysql_row_tell(MYSQL_RES *result)
```

**Description**

Returns the current position of the row cursor for the last `mysql_fetch_row()`. This value can be used as an argument to `mysql_row_seek()`.

Use `mysql_row_tell()` only after `mysql_store_result()`, not after `mysql_use_result()`.

**Return Values**

The current offset of the row cursor.

**Errors**

None.

### 20.6.7.60 mysql_select_db()

```c
int mysql_select_db(MYSQL *mysql, const char *db)
```

**Description**

Causes the database specified by `db` to become the default (current) database on the connection specified by `mysql`. In subsequent queries, this database is the default for table references that include no explicit database specifier.
mysql_select_db() fails unless the connected user can be authenticated as having permission to use the database.

Return Values

Zero for success. Nonzero if an error occurred.

Errors

- **CR_COMMANDS_OUT_OF_SYNC**
  Commands were executed in an improper order.
- **CR_SERVER_GONE_ERROR**
  The MySQL server has gone away.
- **CR_SERVER_LOST**
  The connection to the server was lost during the query.
- **CR_UNKNOWN_ERROR**
  An unknown error occurred.

20.6.7.61 mysql_set_character_set()

```c
int mysql_set_character_set(MYSQL *mysql, const char *csname)
```

**Description**

This function is used to set the default character set for the current connection. The string csname specifies a valid character set name. The connection collation becomes the default collation of the character set. This function works like the `SET NAMES` statement, but also sets the value of `mysql->charset`, and thus affects the character set used by `mysql_real_escape_string()`.

This function was added in MySQL 5.0.7.

**Return Values**

Zero for success. Nonzero if an error occurred.

**Example**

```c
MYSQL mysql;
mysql_init(&mysql);
if (!mysql_real_connect(&mysql, "host", "user", "passwd", "database", 0, NULL, 0))
{
    fprintf(stderr, "Failed to connect to database: Error: %s\n",
            mysql_error(&mysql));
}
if (!mysql_set_character_set(&mysql, "utf8"))
{
    printf("New client character set: %s\n",
            mysql_character_set_name(&mysql));
}
```

20.6.7.62 mysql_set_local_infile_default()

```c
void mysql_set_local_infile_default(MYSQL *mysql);
```
Description

Sets the LOAD DATA LOCAL INFILE callback functions to the defaults used internally by the C client library. The library calls this function automatically if mysql_set_local_infile_handler() has not been called or does not supply valid functions for each of its callbacks.

Return Values

None.

Errors

None.

20.6.7.63 mysql_set_local_infile_handler()

void mysql_set_local_infile_handler(MYSQL *mysql, int (*local_infile_init)(void **, const char *, void *), int (*local_infile_read)(void *, char *, unsigned int), void (*local_infile_end)(void *), int (*local_infile_error)(void *, char*, unsigned int), void *userdata);

Description

This function installs callbacks to be used during the execution of LOAD DATA LOCAL INFILE statements. It enables application programs to exert control over local (client-side) data file reading. The arguments are the connection handler, a set of pointers to callback functions, and a pointer to a data area that the callbacks can use to share information.

To use mysql_set_local_infile_handler(), you must write the following callback functions:

```c
int
local_infile_init(void **ptr, const char *filename, void *userdata);
```

The initialization function. This is called once to do any setup necessary, open the data file, allocate data structures, and so forth. The first void** argument is a pointer to a pointer. You can set the pointer (that is, *ptr) to a value that will be passed to each of the other callbacks (as a void*). The callbacks can use this pointed-to value to maintain state information. The userdata argument is the same value that is passed to mysql_set_local_infile_handler().

The initialization function should return zero for success, nonzero for an error.

```c
int
local_infile_read(void *ptr, char *buf, unsigned int buf_len);
```

The data-reading function. This is called repeatedly to read the data file. buf points to the buffer where the read data is stored, and buf_len is the maximum number of bytes that the callback can read and store in the buffer. (It can read fewer bytes, but should not read more.)

The return value is the number of bytes read, or zero when no more data could be read (this indicates EOF). Return a value less than zero if an error occurs.

```c
void
local_infile_end(void *ptr)
```

The termination function. This is called once after local_infile_read() has returned zero (EOF) or an error. Within this function, deallocate any memory allocated by local_infile_init() and perform any other cleanup necessary. It is invoked even if the initialization function returns an error.
int
local_infile_error(void *ptr,
        char *error_msg,
        unsigned int error_msg_len);

The error-handling function. This is called to get a textual error message to return to the user in case any of your other functions returns an error. error_msg points to the buffer into which the message is written, and error_msg_len is the length of the buffer. Write the message as a null-terminated string, at most error_msg_len−1 bytes long.

The return value is the error number.

Typically, the other callbacks store the error message in the data structure pointed to by ptr, so that local_infile_error() can copy the message from there into error_msg.

After calling mysql_set_local_infile_handler() in your C code and passing pointers to your callback functions, you can then issue a LOAD DATA LOCAL INFILE statement (for example, by using mysql_query()). The client library automatically invokes your callbacks. The file name specified in LOAD DATA LOCAL INFILE will be passed as the second parameter to the local_infile_init() callback.

Return Values
None.

Errors
None.

20.6.7.64 mysql_set_server_option()

int mysql_set_server_option(MYSQL *mysql, enum enum_mysql_set_option option)

Description
Enables or disables an option for the connection. option can have one of the following values.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MYSQL_OPTION_MULTI_STATEMENTS_ON</td>
<td>Enable multiple-statement support</td>
</tr>
<tr>
<td>MYSQL_OPTION_MULTI_STATEMENTS_OFF</td>
<td>Disable multiple-statement support</td>
</tr>
</tbody>
</table>

If you enable multiple-statement support, you should retrieve results from calls to mysql_query() or mysql_real_query() by using a loop that calls mysql_next_result() to determine whether there are more results. For an example, see Section 20.6.16, “C API Support for Multiple Statement Execution”.

Enabling multiple-statement support with MYSQL_OPTION_MULTI_STATEMENTS_ON does not have quite the same effect as enabling it by passing the CLIENT_MULTI_STATEMENTS flag to mysql_real_connect(): CLIENT_MULTI_STATEMENTS also enables CLIENT_MULTI_RESULTS. If you are using the CALL SQL statement in your programs, multiple-result support must be enabled; this means that MYSQL_OPTION_MULTI_STATEMENTS_ON by itself is insufficient to permit the use of CALL.

Return Values
Zero for success. Nonzero if an error occurred.

Errors
- CR_COMMANDS_OUT_OF_SYNC
Commands were executed in an improper order.

- **CR_SERVER_GONE_ERROR**
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  The connection to the server was lost during the query.

- **ER_UNKNOWN_COM_ERROR**
  The server did not support `mysql_set_server_option()` (which is the case that the server is older than 4.1.1) or the server did not support the option one tried to set.

### 20.6.7.65 mysql_shutdown()

```c
int mysql_shutdown(MYSQL *mysql, enum mysql_enum_shutdown_level shutdown_level)
```

**Description**

Asks the database server to shut down. The connected user must have the `SHUTDOWN` privilege. The `shutdown_level` argument was added in MySQL 5.0.1. MySQL servers support only one type of shutdown; `shutdown_level` must be equal to `SHUTDOWN_DEFAULT`. Dynamically linked executables which have been compiled with older versions of the `libmysqlclient` headers and call `mysql_shutdown()` need to be used with the old `libmysqlclient` dynamic library.

The shutdown process is described in Section 5.1.10, “The Server Shutdown Process”.

**Return Values**

Zero for success. Nonzero if an error occurred.

**Errors**

- **CR_COMMANDS_OUT_OF_SYNC**
  Commands were executed in an improper order.

- **CR_SERVER_GONE_ERROR**
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  An unknown error occurred.

### 20.6.7.66 mysql_sqlstate()

```c
const char *mysql_sqlstate(MYSQL *mysql)
```

**Description**

Returns a null-terminated string containing the SQLSTATE error code for the most recently executed SQL statement. The error code consists of five characters. ‘00000’ means “no error.” The values are
specified by ANSI SQL and ODBC. For a list of possible values, see Appendix B, Errors, Error Codes, and Common Problems.

SQLSTATE values returned by mysql_sqlstate() differ from MySQL-specific error numbers returned by mysql_errno(). For example, the mysql client program displays errors using the following format, where 1146 is the mysql_errno() value and '42S02' is the corresponding mysql_sqlstate() value:

```shell
shell> SELECT * FROM no_such_table;
ERROR 1146 (42S02): Table 'test.no_such_table' doesn't exist
```

Not all MySQL error numbers are mapped to SQLSTATE error codes. The value ‘HY000’ (general error) is used for unmapped error numbers.

If you call mysql_sqlstate() after mysql_real_connect() fails, mysql_sqlstate() might not return a useful value. For example, this happens if a host is blocked by the server and the connection is closed without any SQLSTATE value being sent to the client.

**Return Values**

A null-terminated character string containing the SQLSTATE error code.

**See Also**

See Section 20.6.7.14, “mysql_errno()”, Section 20.6.7.15, “mysql_error()”, and Section 20.6.11.26, “mysql_stmt_sqlstate()”.

### 20.6.7.67 mysql_ssl_set()

```c
my_bool mysql_ssl_set(MYSQL *mysql, const char *key, const char *cert, const char *ca, const char *capath, const char *cipher)
```

**Description**

mysql_ssl_set() is used for establishing secure connections using SSL. It must be called before mysql_real_connect().

mysql_ssl_set() does nothing unless SSL support is enabled in the client library.

mysql is the connection handler returned from mysql_init(). The other parameters are specified as follows:

- **key** is the path name to the key file.
- **cert** is the path name to the certificate file.
- **ca** is the path name to the certificate authority file.
- **capath** is the path name to a directory that contains trusted SSL CA certificates in PEM format.
- **cipher** is a list of permissible ciphers to use for SSL encryption.

Any unused SSL parameters may be given as NULL.

**Return Values**

This function always returns 0. If SSL setup is incorrect, mysql_real_connect() returns an error when you attempt to connect.

### 20.6.7.68 mysql_stat()

```c
const char *mysql_stat(MYSQL *mysql)
```
Description

Returns a character string containing information similar to that provided by the `mysqladmin status` command. This includes uptime in seconds and the number of running threads, questions, reloads, and open tables.

Return Values

A character string describing the server status. **NULL** if an error occurred.

Errors

- **CR_COMMANDS_OUT_OF_SYNC**
  
  Commands were executed in an improper order.

- **CR_SERVER_GONE_ERROR**
  
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  
  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  
  An unknown error occurred.

### 20.6.7.69 mysql_store_result()

**MYSQL_RES **`*mysql_store_result(MYSQL *mysql)***

Description

After invoking `mysql_query()` or `mysql_real_query()`, you must call `mysql_store_result()` or `mysql_use_result()` for every statement that successfully produces a result set (SELECT, SHOW, DESCRIBE, EXPLAIN, CHECK TABLE, and so forth). You must also call `mysql_free_result()` after you are done with the result set.

You need not call `mysql_store_result()` or `mysql_use_result()` for other statements, but it does not do any harm or cause any notable performance degradation if you call `mysql_store_result()` in all cases. You can detect whether the statement has a result set by checking whether `mysql_store_result()` returns a nonzero value (more about this later).

If you enable multiple-statement support, you should retrieve results from calls to `mysql_query()` or `mysql_real_query()` by using a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see Section 20.6.16, “C API Support for Multiple Statement Execution”.

If you want to know whether a statement should return a result set, you can use `mysql_field_count()` to check for this. See Section 20.6.7.22, “mysql_field_count()”.

`mysql_store_result()` reads the entire result of a query to the client, allocates a `MYSQL_RES` structure, and places the result into this structure.

`mysql_store_result()` returns a null pointer if the statement did not return a result set (for example, if it was an INSERT statement).

`mysql_store_result()` also returns a null pointer if reading of the result set failed. You can check whether an error occurred by checking whether `mysql_error()` returns a nonempty string, `mysql_errno()` returns nonzero, or `mysql_field_count()` returns zero.
An empty result set is returned if there are no rows returned. (An empty result set differs from a null pointer as a return value.)

After you have called `mysql_store_result()` and gotten back a result that is not a null pointer, you can call `mysql_num_rows()` to find out how many rows are in the result set.

You can call `mysql_fetch_row()` to fetch rows from the result set, or `mysql_row_seek()` and `mysql_row_tell()` to obtain or set the current row position within the result set.

**Return Values**

A `MYSQL_RES` result structure with the results. `NULL` if an error occurred.

**Errors**

`mysql_store_result()` resets `mysql_error()` and `mysql_errno()` if it succeeds.

- **CR_COMMANDS_OUT_OF_SYNC**
  Commands were executed in an improper order.

- **CR_OUT_OF_MEMORY**
  Out of memory.

- **CR_SERVER_GONE_ERROR**
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  An unknown error occurred.

---

**20.6.7.70 mysql_thread_id()**

```
unsigned long mysql_thread_id(MYSQL *mysql)
```

**Description**

Returns the thread ID of the current connection. This value can be used as an argument to `mysql_kill()` to kill the thread.

If the connection is lost and you reconnect with `mysql_ping()`, the thread ID changes. This means you should not get the thread ID and store it for later. You should get it when you need it.

**Note**

This function does not work correctly if thread IDs become larger than 32 bits, which can occur on some systems. To avoid problems with `mysql_thread_id()`, do not use it. To get the connection ID, execute a `SELECT CONNECTION_ID()` query and retrieve the result.

**Return Values**

The thread ID of the current connection.
Errors

None.

20.6.7.71 mysql_use_result()

MYSQL_RES *mysql_use_result(MYSQL *mysql)

Description

After invoking `mysql_query()` or `mysql_real_query()`, you must call `mysql_store_result()` or `mysql_use_result()` for every statement that successfully produces a result set (SELECT, SHOW, DESCRIBE, EXPLAIN, CHECK TABLE, and so forth). You must also call `mysql_free_result()` after you are done with the result set.

`mysql_use_result()` initiates a result set retrieval but does not actually read the result set into the client like `mysql_store_result()` does. Instead, each row must be retrieved individually by making calls to `mysql_fetch_row()`. This reads the result of a query directly from the server without storing it in a temporary table or local buffer, which is somewhat faster and uses much less memory than `mysql_store_result()`. The client allocates memory only for the current row and a communication buffer that may grow up to `max_allowed_packet` bytes.

On the other hand, you should not use `mysql_use_result()` for locking reads if you are doing a lot of processing for each row on the client side, or if the output is sent to a screen on which the user may type a ^S (stop scroll). This ties up the server and prevent other threads from updating any tables from which the data is being fetched.

When using `mysql_use_result()`, you must execute `mysql_fetch_row()` until a NULL value is returned, otherwise, the unfetched rows are returned as part of the result set for your next query. The C API gives the error `Commands out of sync; you can't run this command now` if you forget to do this!

You may not use `mysql_data_seek()`, `mysql_row_seek()`, `mysql_row_tell()`, `mysql_num_rows()`, or `mysql_affected_rows()` with a result returned from `mysql_use_result()`, nor may you issue other queries until `mysql_use_result()` has finished. (However, after you have fetched all the rows, `mysql_num_rows()` accurately returns the number of rows fetched.)

You must call `mysql_free_result()` once you are done with the result set.

When using the `libmysqld` embedded server, the memory benefits are essentially lost because memory usage incrementally increases with each row retrieved until `mysql_free_result()` is called.

Return Values

A `MYSQL_RES` result structure. NULL if an error occurred.

Errors

`mysql_use_result()` resets `mysql_error()` and `mysql_errno()` if it succeeds.

• `CR_COMMANDS_OUT_OF_SYNC`

  Commands were executed in an improper order.

• `CR_OUT_OF_MEMORY`

  Out of memory.

• `CR_SERVER_GONE_ERROR`
The MySQL server has gone away.

- **CR_SERVER_LOST**
  
The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  
  An unknown error occurred.

### 20.6.7.72 mysql_warning_count()

```c
unsigned int mysql_warning_count(MYSQL *mysql)
```

**Description**

Returns the number of errors, warnings, and notes generated during execution of the previous SQL statement.

**Return Values**

The warning count.

**Errors**

None.

### 20.6.8 C API Prepared Statements

The MySQL client/server protocol provides for the use of prepared statements. This capability uses the `MYSQL_STMT` statement handler data structure returned by the `mysql_stmt_init()` initialization function. Prepared execution is an efficient way to execute a statement more than once. The statement is first parsed to prepare it for execution. Then it is executed one or more times at a later time, using the statement handle returned by the initialization function.

Prepared execution is faster than direct execution for statements executed more than once, primarily because the query is parsed only once. In the case of direct execution, the query is parsed every time it is executed. Prepared execution also can provide a reduction of network traffic because for each execution of the prepared statement, it is necessary only to send the data for the parameters.

Prepared statements might not provide a performance increase in some situations. For best results, test your application both with prepared and nonprepared statements and choose whichever yields best performance.

Another advantage of prepared statements is that it uses a binary protocol that makes data transfer between client and server more efficient.

For a list of SQL statements that can be used as prepared statements, see Section 13.5, “SQL Syntax for Prepared Statements”.

### 20.6.9 C API Prepared Statement Data Structures

Prepared statements use several data structures:

- To obtain a statement handle, pass a MySQL connection handler to `mysql_stmt_init()`, which returns a pointer to a `MYSQL_STMT` data structure. This structure is used for further operations with the statement. To specify the statement to prepare, pass the `MYSQL_STMT` pointer and the statement string to `mysql_stmt_prepare()`.
• To provide input parameters for a prepared statement, set up MYSQL_BIND structures and pass them to mysql_stmt_bind_param(). To receive output column values, set up MYSQL_BIND structures and pass them to mysql_stmt_bind_result().

• The MYSQL_TIME structure is used to transfer temporal data in both directions.

The following discussion describes the prepared statement data types in detail. For examples that show how to use them, see Section 20.6.11.10, “mysql_stmt_execute()”; and Section 20.6.11.11, “mysql_stmt_fetch()”.

• MYSQL_STMT

This structure is a handle for a prepared statement. A handle is created by calling mysql_stmt_init(), which returns a pointer to a MYSQL_STMT. The handle is used for all subsequent operations with the statement until you close it with mysql_stmt_close(), at which point the handle becomes invalid.

The MYSQL_STMT structure has no members intended for application use. Applications should not try to copy a MYSQL_STMT structure. There is no guarantee that such a copy will be usable.

Multiple statement handles can be associated with a single connection. The limit on the number of handles depends on the available system resources.

• MYSQL_BIND

This structure is used both for statement input (data values sent to the server) and output (result values returned from the server):

• For input, use MYSQL_BIND structures with mysql_stmt_bind_param() to bind parameter data values to buffers for use by mysql_stmt_execute().

• For output, use MYSQL_BIND structures with mysql_stmt_bind_result() to bind buffers to result set columns, for use in fetching rows with mysql_stmt_fetch().

To use a MYSQL_BIND structure, zero its contents to initialize it, then set its members appropriately. For example, to declare and initialize an array of three MYSQL_BIND structures, use this code:

```c
MYSQL_BIND bind[3];
memset(bind, 0, sizeof(bind));
```

The MYSQL_BIND structure contains the following members for use by application programs. For several of the members, the manner of use depends on whether the structure is used for input or output.

• enum enum_field_types buffer_type

The type of the buffer. This member indicates the data type of the C language variable bound to a statement parameter or result set column. For input, buffer_type indicates the type of the variable containing the value to be sent to the server. For output, it indicates the type of the variable into which a value received from the server should be stored. For permissible buffer_type values, see Section 20.6.9.1, “C API Prepared Statement Type Codes”.

• void *buffer

A pointer to the buffer to be used for data transfer. This is the address of a C language variable.

For input, buffer is a pointer to the variable in which you store the data value for a statement parameter. When you call mysql_stmt_execute(), MySQL use the value stored in the variable in place of the corresponding parameter marker in the statement (specified with ? in the statement string).
For output, *buffer is a pointer to the variable in which to return a result set column value. When you call `mysql_stmt_fetch()`, MySQL stores a column value from the current row of the result set in this variable. You can access the value when the call returns.

To minimize the need for MySQL to perform type conversions between C language values on the client side and SQL values on the server side, use C variables that have types similar to those of the corresponding SQL values:

- For numeric data types, *buffer should point to a variable of the proper numeric C type. For integer variables (which can be `char` for single-byte values or an integer type for larger values), you should also indicate whether the variable has the `unsigned` attribute by setting the `is_unsigned` member, described later.

- For character (nonbinary) and binary string data types, *buffer should point to a character buffer.

- For date and time data types, *buffer should point to a `MYSQL_TIME` structure.

For guidelines about mapping between C types and SQL types and notes about type conversions, see Section 20.6.9.1, “C API Prepared Statement Type Codes”, and Section 20.6.9.2, “C API Prepared Statement Type Conversions”.

- `unsigned long buffer_length`

  The actual size of *buffer in bytes. This indicates the maximum amount of data that can be stored in the buffer. For character and binary C data, the `buffer_length` value specifies the length of *buffer when used with `mysql_stmt_bind_param()` to specify input values, or the maximum number of output data bytes that can be fetched into the buffer when used with `mysql_stmt_bind_result()`.

- `unsigned long *length`

  A pointer to an `unsigned long` variable that indicates the actual number of bytes of data stored in *buffer. Length is used for character or binary C data.

  For input parameter data binding, set *length to indicate the actual length of the parameter value stored in *buffer. This is used by `mysql_stmt_execute()`.

  For output value binding, MySQL sets *length when you call `mysql_stmt_fetch()`. The `mysql_stmt_fetch()` return value determines how to interpret the length:

  - If the return value is 0, *length indicates the actual length of the parameter value.

  - If the return value is `MYSQL_DATA_TRUNCATED`, *length indicates the nontruncated length of the parameter value. In this case, the minimum of *length and `buffer_length` indicates the actual length of the value.

  *length is ignored for numeric and temporal data types because the `buffer_type` value determines the length of the data value.

  If you must determine the length of a returned value before fetching it, see Section 20.6.11.11, “`mysql_stmt_fetch()`”, for some strategies.

- `my_bool *is_null`

  This member points to a `my_bool` variable that is true if a value is `NULL`, false if it is not `NULL`. For input, set *is_null to true to indicate that you are passing a `NULL` value as a statement parameter.
is_null is a pointer to a boolean scalar, not a boolean scalar, to provide flexibility in how you specify NULL values:

- If your data values are always NULL, use MYSQL_TYPE_NULL as the buffer_type value when you bind the column. The other MYSQL_BIND members, including is_null, do not matter.

- If your data values are always NOT NULL, set is_null = (my_bool*) 0, and set the other members appropriately for the variable you are binding.

- In all other cases, set the other members appropriately and set is_null to the address of a my_bool variable. Set that variable's value to true or false appropriately between executions to indicate whether the corresponding data value is NULL or NOT NULL, respectively.

For output, when you fetch a row, MySQL sets the value pointed to by is_null to true or false according to whether the result set column value returned from the statement is or is not NULL.

- my_bool is_unsigned

This member applies for C variables with data types that can be unsigned (char, short int, int, long long int). Set is_unsigned to true if the variable pointed to by buffer is unsigned and false otherwise. For example, if you bind a signed char variable to buffer, specify a type code of MYSQL_TYPE_TINY and set is_unsigned to false. If you bind an unsigned char instead, the type code is the same but is_unsigned should be true. (For char, it is not defined whether it is signed or unsigned, so it is best to be explicit about signedness by using signed char or unsigned char.)

is_unsigned applies only to the C language variable on the client side. It indicates nothing about the signedness of the corresponding SQL value on the server side. For example, if you use an int variable to supply a value for a BIGINT UNSIGNED column, is_unsigned should be false because int is a signed type. If you use an unsigned int variable to supply a value for a BIGINT column, is_unsigned should be true because unsigned int is an unsigned type. MySQL performs the proper conversion between signed and unsigned values in both directions, although a warning occurs if truncation results.

- my_bool *error

For output, set this member to point to a my_bool variable to have truncation information for the parameter stored there after a row fetching operation. When truncation reporting is enabled, mysql_stmt_fetch() returns MYSQL_DATA_TRUNCATED and *error is true in the MYSQL_BIND structures for parameters in which truncation occurred. Truncation indicates loss of sign or significant digits, or that a string was too long to fit in a column. Truncation reporting is enabled by default, but can be controlled by calling mysql_options() with the MYSQL_REPORT_DATA_TRUNCATION option. The error member was added in MySQL 5.0.3.

- MYSQL_TIME

This structure is used to send and receive DATE, TIME, DATETIME, and TIMESTAMP data directly to and from the server. Set the buffer member to point to a MYSQL_TIME structure, and set the buffer_type member of a MYSQL_BIND structure to one of the temporal types (MYSQL_TYPE_TIME, MYSQL_TYPE_DATE, MYSQL_TYPE_DATETIME, MYSQL_TYPE_TIMESTAMP).

The MYSQL_TIME structure contains the members listed in the following table.

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>unsigned int year</td>
<td>The year</td>
</tr>
<tr>
<td>unsigned int month</td>
<td>The month of the year</td>
</tr>
<tr>
<td>unsigned int day</td>
<td>The day of the month</td>
</tr>
</tbody>
</table>
### Member Description

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>unsigned int hour</td>
<td>The hour of the day</td>
</tr>
<tr>
<td>unsigned int minute</td>
<td>The minute of the hour</td>
</tr>
<tr>
<td>unsigned int second</td>
<td>The second of the minute</td>
</tr>
<tr>
<td>my_bool neg</td>
<td>A boolean flag indicating whether the time is negative</td>
</tr>
<tr>
<td>unsigned long second_part</td>
<td>The fractional part of the second in microseconds; currently unused</td>
</tr>
</tbody>
</table>

Only those parts of a `MYSQL_TIME` structure that apply to a given type of temporal value are used. The `year`, `month`, and `day` elements are used for `DATE`, `DATETIME`, and `TIMESTAMP` values. The `hour`, `minute`, and `second` elements are used for `TIME`, `DATETIME`, and `TIMESTAMP` values. See Section 20.6.18, "C API Prepared Statement Handling of Date and Time Values".

### 20.6.9.1 C API Prepared Statement Type Codes

The `buffer_type` member of `MYSQL_BIND` structures indicates the data type of the C language variable bound to a statement parameter or result set column. For input, `buffer_type` indicates the type of the variable containing the value to be sent to the server. For output, it indicates the type of the variable into which a value received from the server should be stored.

The following table shows the permissible values for the `buffer_type` member of `MYSQL_BIND` structures for input values sent to the server. The table shows the C variable types that you can use, the corresponding type codes, and the SQL data types for which the supplied value can be used without conversion. Choose the `buffer_type` value according to the data type of the C language variable that you are binding. For the integer types, you should also set the `is_unsigned` member to indicate whether the variable is signed or unsigned.

<table>
<thead>
<tr>
<th>Input Variable C Type</th>
<th><code>buffer_type</code> Value</th>
<th>SQL Type of Destination Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>signed char</code></td>
<td>MYSQL_TYPE_TINY</td>
<td>TINYINT</td>
</tr>
<tr>
<td><code>short int</code></td>
<td>MYSQL_TYPE_SHORT</td>
<td>SMALLINT</td>
</tr>
<tr>
<td><code>int</code></td>
<td>MYSQL_TYPE_LONG</td>
<td>INT</td>
</tr>
<tr>
<td><code>long long int</code></td>
<td>MYSQL_TYPE_LONGLONG</td>
<td>BIGINT</td>
</tr>
<tr>
<td><code>float</code></td>
<td>MYSQL_TYPE_FLOAT</td>
<td>FLOAT</td>
</tr>
<tr>
<td><code>double</code></td>
<td>MYSQL_TYPE_DOUBLE</td>
<td>DOUBLE</td>
</tr>
<tr>
<td><code>MYSQL_TIME</code></td>
<td>MYSQL_TYPE_TIME</td>
<td>TIME</td>
</tr>
<tr>
<td><code>MYSQL_TIME</code></td>
<td>MYSQL_TYPE_DATE</td>
<td>DATE</td>
</tr>
<tr>
<td><code>MYSQL_TIME</code></td>
<td>MYSQL_TYPE_DATETIME</td>
<td>DATETIME</td>
</tr>
<tr>
<td><code>MYSQL_TIME</code></td>
<td>MYSQL_TYPE_TIMESTAMP</td>
<td>TIMESTAMP</td>
</tr>
<tr>
<td><code>char[]</code></td>
<td>MYSQL_TYPE_STRING</td>
<td>TEXT, CHAR, VARCHAR</td>
</tr>
<tr>
<td><code>char[]</code></td>
<td>MYSQL_TYPE_BLOB</td>
<td>BLOB, BINARY, VARBINARY</td>
</tr>
<tr>
<td><code>MYSQL_TIME</code></td>
<td>MYSQL_TYPE_NULL</td>
<td>NULL</td>
</tr>
</tbody>
</table>

Use `MYSQL_TYPE_NULL` as indicated in the description for the `is_null` member in Section 20.6.9, “C API Prepared Statement Data Structures”.

For input string data, use `MYSQL_TYPE_STRING` or `MYSQL_TYPE_BLOB` depending on whether the value is a character (nonbinary) or binary string:

- `MYSQL_TYPE_STRING` indicates character input string data. The value is assumed to be in the character set indicated by the `character_set_client` system variable. If the server stores the value into a column with a different character set, it converts the value to that character set.
• MySQL_TYPE_BLOB indicates binary input string data. The value is treated as having the binary character set. That is, it is treated as a byte string and no conversion occurs.

The following table shows the permissible values for the buffer_type member of MYSQL_BIND structures for output values received from the server. The table shows the SQL types of received values, the corresponding type codes that such values have in result set metadata, and the recommended C language data types to bind to the MYSQL_BIND structure to receive the SQL values without conversion. Choose the buffer_type value according to the data type of the C language variable that you are binding. For the integer types, you should also set the is_unsigned member to indicate whether the variable is signed or unsigned.

<table>
<thead>
<tr>
<th>SQL Type of Received Value</th>
<th>buffer_type Value</th>
<th>Output Variable C Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>TINYINT</td>
<td>MYSQL_TYPE_TINY</td>
<td>signed char</td>
</tr>
<tr>
<td>SMALLINT</td>
<td>MYSQL_TYPE_SHORT</td>
<td>short int</td>
</tr>
<tr>
<td>MEDIUMINT</td>
<td>MYSQL_TYPE_INT24</td>
<td>int</td>
</tr>
<tr>
<td>INT</td>
<td>MYSQL_TYPE_LONG</td>
<td>int</td>
</tr>
<tr>
<td>BIGINT</td>
<td>MYSQL_TYPEONGLONG</td>
<td>long long int</td>
</tr>
<tr>
<td>FLOAT</td>
<td>MYSQL_TYPE_FLOAT</td>
<td>float</td>
</tr>
<tr>
<td>DOUBLE</td>
<td>MYSQL_TYPE_DOUBLE</td>
<td>double</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>MYSQL_TYPE_NEWDECIMAL</td>
<td>char[]</td>
</tr>
<tr>
<td>YEAR</td>
<td>MYSQL_TYPE_SHORT</td>
<td>short int</td>
</tr>
<tr>
<td>TIME</td>
<td>MYSQL_TYPE_TIME</td>
<td>MYSQL_TIME</td>
</tr>
<tr>
<td>DATE</td>
<td>MYSQL_TYPE_DATE</td>
<td>MYSQL_TIME</td>
</tr>
<tr>
<td>DATETIME</td>
<td>MYSQL_TYPE_DATETIME</td>
<td>MYSQL_TIME</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>MYSQL_TYPE_TIMESTAMP</td>
<td>MYSQL_TIME</td>
</tr>
<tr>
<td>CHAR, BINARY</td>
<td>MYSQL_TYPE_STRING</td>
<td>char[]</td>
</tr>
<tr>
<td>VARCHAR, VARBINARY</td>
<td>MYSQL_TYPE_VAR_STRING</td>
<td>char[]</td>
</tr>
<tr>
<td>TINYBLOB, TINYTEXT</td>
<td>MYSQL_TYPE_TINY_BLOB</td>
<td>char[]</td>
</tr>
<tr>
<td>BLOB, TEXT</td>
<td>MYSQL_TYPE_BLOB</td>
<td>char[]</td>
</tr>
<tr>
<td>MEDIUMBLOB, MEDIUMTEXT</td>
<td>MYSQL_TYPE_MEDIUM_BLOB</td>
<td>char[]</td>
</tr>
<tr>
<td>LONGBLOB, LONGTEXT</td>
<td>MYSQL_TYPE_LONG_BLOB</td>
<td>char[]</td>
</tr>
<tr>
<td>BIT</td>
<td>MYSQL_TYPE_BIT</td>
<td>char[]</td>
</tr>
</tbody>
</table>

---

20.6.9.2 C API Prepared Statement Type Conversions

Prepared statements transmit data between the client and server using C language variables on the client side that correspond to SQL values on the server side. If there is a mismatch between the C variable type on the client side and the corresponding SQL value type on the server side, MySQL performs implicit type conversions in both directions.

MySQL knows the type code for the SQL value on the server side. The buffer_type value in the MYSQL_BIND structure indicates the type code of the C variable that holds the value on the client side. The two codes together tell MySQL what conversion must be performed, if any. Here are some examples:

- If you use MySQL_TYPE_LONG with an int variable to pass an integer value to the server that is to be stored into a FLOAT column, MySQL converts the value to floating-point format before storing it.

- If you fetch an SQL MEDIUMINT column value, but specify a buffer_type value of MYSQL_TYPE_LONG and use a C variable of type long long int as the destination buffer,
MySQL converts the \texttt{MEDIUMINT} value (which requires less than 8 bytes) for storage into the \texttt{long long int} (an 8-byte variable).

- If you fetch a numeric column with a value of 255 into a \texttt{char[4]} character array and specify a \texttt{buffer_type} value of \texttt{MYSQL\_TYPE\_STRING}, the resulting value in the array is a 4-byte string \texttt{'255\0'}.

- MySQL returns \texttt{DECIMAL} values as the string representation of the original server-side value, which is why the corresponding \texttt{C} type is \texttt{char[]}. For example, \texttt{12.345} is returned to the client as \texttt{'12.345'}. If you specify \texttt{MYSQL\_TYPE\_NEWDECIMAL} and bind a string buffer to the \texttt{MYSQL\_BIND} structure, \texttt{mysql\_stmt\_fetch()} stores the value in the buffer as a string without conversion. If instead you specify a numeric variable and type code, \texttt{mysql\_stmt\_fetch()} converts the string-format \texttt{DECIMAL} value to numeric form.

- For the \texttt{MYSQL\_TYPE\_BIT} type code, \texttt{BIT} values are returned into a string buffer, which is why the corresponding \texttt{C} type is \texttt{char[]}. The value represents a bit string that requires interpretation on the client side. To return the value as a type that is easier to deal with, you can cause the value to be cast to integer using either of the following types of expressions:

\begin{verbatim}
SELECT bit_col + 0 FROM t
SELECT CAST(bit_col AS UNSIGNED) FROM t
\end{verbatim}

To retrieve the value, bind an integer variable large enough to hold the value and specify the appropriate corresponding integer type code.

Before binding variables to the \texttt{MYSQL\_BIND} structures that are to be used for fetching column values, you can check the type codes for each column of the result set. This might be desirable if you want to determine which variable types would be best to use to avoid type conversions. To get the type codes, call \texttt{mysql\_stmt\_result\_metadata()} after executing the prepared statement with \texttt{mysql\_stmt\_execute()}. The metadata provides access to the type codes for the result set as described in Section 20.6.11.22, “\texttt{mysql\_stmt\_result\_metadata()}”, and Section 20.6.5, “C API Data Structures”.

To determine whether output string values in a result set returned from the server contain binary or nonbinary data, check whether the \texttt{charsetnr} value of the result set metadata is 63 (see Section 20.6.5, “C API Data Structures”). If so, the character set is \texttt{binary}, which indicates binary rather than nonbinary data. This enables you to distinguish \texttt{BINARY} from \texttt{CHAR}, \texttt{VARBINARY} from \texttt{VARCHAR}, and the \texttt{BLOB} types from the \texttt{TEXT} types.

If you cause the \texttt{max\_length} member of the \texttt{MYSQL\_FIELD} column metadata structures to be set (by calling \texttt{mysql\_stmt\_attr\_set()}), be aware that the \texttt{max\_length} values for the result set indicate the lengths of the longest string representation of the result values, not the lengths of the binary representation. That is, \texttt{max\_length} does not necessarily correspond to the size of the buffers needed to fetch the values with the binary protocol used for prepared statements. Choose the size of the buffers according to the types of the variables into which you fetch the values. For example, a \texttt{TINYINT} column containing the value -128 might have a \texttt{max\_length} value of 4. But the binary representation of any \texttt{TINYINT} value requires only 1 byte for storage, so you can supply a \texttt{signed char} variable in which to store the value and set \texttt{is\_unsigned} to indicate that values are signed.

### 20.6.10 C API Prepared Statement Function Overview

The functions available for prepared statement processing are summarized here and described in greater detail in a later section. See Section 20.6.11, “C API Prepared Statement Function Descriptions”.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{mysql_stmt_affected_rows}</td>
<td>Returns the number of rows changed, deleted, or inserted by prepared \texttt{UPDATE}, \texttt{DELETE}, or \texttt{INSERT} statement</td>
</tr>
<tr>
<td>\texttt{mysql_stmt_attr_get()}</td>
<td>Gets value of an attribute for a prepared statement</td>
</tr>
</tbody>
</table>
### C API Prepared Statement Function Overview

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql_stmt_attr_set()</td>
<td>Sets an attribute for a prepared statement</td>
</tr>
<tr>
<td>mysql_stmt_bind_param()</td>
<td>Associates application data buffers with the parameter markers in a prepared SQL statement</td>
</tr>
<tr>
<td>mysql_stmt_bind_result()</td>
<td>Associates application data buffers with columns in a result set</td>
</tr>
<tr>
<td>mysql_stmt_close()</td>
<td>Frees memory used by a prepared statement</td>
</tr>
<tr>
<td>mysql_stmt_data_seek()</td>
<td>Seeks to an arbitrary row number in a statement result set</td>
</tr>
<tr>
<td>mysql_stmt_errno()</td>
<td>Returns the error number for the last statement execution</td>
</tr>
<tr>
<td>mysql_stmt_error()</td>
<td>Returns the error message for the last statement execution</td>
</tr>
<tr>
<td>mysql_stmt_execute()</td>
<td>Executes a prepared statement</td>
</tr>
<tr>
<td>mysql_stmt_fetch()</td>
<td>Fetches the next row of data from a result set and returns data for all bound columns</td>
</tr>
<tr>
<td>mysql_stmt_fetch_column()</td>
<td>Fetch data for one column of the current row of a result set</td>
</tr>
<tr>
<td>mysql_stmt_field_count()</td>
<td>Returns the number of result columns for the most recent statement</td>
</tr>
<tr>
<td>mysql_stmt_free_result()</td>
<td>Free the resources allocated to a statement handle</td>
</tr>
<tr>
<td>mysql_stmt_init()</td>
<td>Allocates memory for a MYSQL_STMT structure and initializes it</td>
</tr>
<tr>
<td>mysql_stmt_insert_id()</td>
<td>Returns the ID generated for an AUTO_INCREMENT column by a prepared statement</td>
</tr>
<tr>
<td>mysql_stmt_num_rows()</td>
<td>Returns the row count from a buffered statement result set</td>
</tr>
<tr>
<td>mysql_stmt_param_count()</td>
<td>Returns the number of parameters in a prepared statement</td>
</tr>
<tr>
<td>mysql_stmt_param_metadata()</td>
<td>Returns parameter metadata in the form of a result set. This function does nothing</td>
</tr>
<tr>
<td>mysql_stmt_prepare()</td>
<td>Prepares an SQL statement string for execution</td>
</tr>
<tr>
<td>mysql_stmt_reset()</td>
<td>Resets the statement buffers in the server</td>
</tr>
<tr>
<td>mysql_stmt_result_metadata()</td>
<td>Returns prepared statement metadata in the form of a result set</td>
</tr>
<tr>
<td>mysql_stmt_row_seek()</td>
<td>Seeks to a row offset in a statement result set, using value returned from mysql_stmt_row_tell()</td>
</tr>
<tr>
<td>mysql_stmt_row_tell()</td>
<td>Returns the statement row cursor position</td>
</tr>
<tr>
<td>mysql_stmt_send_long_data()</td>
<td>Sends long data in chunks to server</td>
</tr>
<tr>
<td>mysql_stmt_sqlstate()</td>
<td>Returns the SQLSTATE error code for the last statement execution</td>
</tr>
<tr>
<td>mysql_stmt_store_result()</td>
<td>Retrieves a complete result set to the client</td>
</tr>
</tbody>
</table>

Call `mysql_stmt_init()` to create a statement handle, then `mysql_stmt_prepare()` to prepare the statement string, `mysql_stmt_bind_param()` to supply the parameter data, and `mysql_stmt_execute()` to execute the statement. You can repeat the `mysql_stmt_execute()` by changing parameter values in the respective buffers supplied through `mysql_stmt_bind_param()`.

You can send text or binary data in chunks to server using `mysql_stmt_send_long_data()`. See Section 20.6.11.25, “`mysql_stmt_send_long_data()`”.

If the statement is a `SELECT` or any other statement that produces a result set, `mysql_stmt_prepare()` also returns the result set metadata information in the form of a MYSQL_RES result set through `mysql_stmt_result_metadata()`.

You can supply the result buffers using `mysql_stmt_bind_result()`, so that the `mysql_stmt_fetch()` automatically returns data to these buffers. This is row-by-row fetching.

When statement execution has been completed, close the statement handle using `mysql_stmt_close()` so that all resources associated with it can be freed.

---

This documentation is for an older version.
If you're using the most current version, select the documentation for that version in the upper right corner of the online documentation, or by downloading a newer PDF or EPUB file.
If you obtained a `SELECT` statement’s result set metadata by calling `mysql_stmt_result_metadata()`, you should also free the metadata using `mysql_free_result()`.

### Execution Steps

To prepare and execute a statement, an application follows these steps:

1. Create a prepared statement handle with `mysql_stmt_init()`. To prepare the statement on the server, call `mysql_stmt_prepare()` and pass it a string containing the SQL statement.

2. If the statement will produce a result set, call `mysql_stmt_result_metadata()` to obtain the result set metadata. This metadata is itself in the form of result set, albeit a separate one from the one that contains the rows returned by the query. The metadata result set indicates how many columns are in the result and contains information about each column.

3. Set the values of any parameters using `mysql_stmt_bind_param()`. All parameters must be set. Otherwise, statement execution returns an error or produces unexpected results.

4. Call `mysql_stmt_execute()` to execute the statement.

5. If the statement produces a result set, bind the data buffers to use for retrieving the row values by calling `mysql_stmt_bind_result()`.

6. Fetch the data into the buffers row by row by calling `mysql_stmt_fetch()` repeatedly until no more rows are found.

7. Repeat steps 3 through 6 as necessary, by changing the parameter values and re-executing the statement.

When `mysql_stmt_prepare()` is called, the MySQL client/server protocol performs these actions:

- The server parses the statement and sends the okay status back to the client by assigning a statement ID. It also sends total number of parameters, a column count, and its metadata if it is a result set oriented statement. All syntax and semantics of the statement are checked by the server during this call.

- The client uses this statement ID for the further operations, so that the server can identify the statement from among its pool of statements.

When `mysql_stmt_execute()` is called, the MySQL client/server protocol performs these actions:

- The client uses the statement handle and sends the parameter data to the server.

- The server identifies the statement using the ID provided by the client, replaces the parameter markers with the newly supplied data, and executes the statement. If the statement produces a result set, the server sends the data back to the client. Otherwise, it sends an okay status and the number of rows changed, deleted, or inserted.

When `mysql_stmt_fetch()` is called, the MySQL client/server protocol performs these actions:

- The client reads the data from the current row of the result set and places it into the application data buffers by doing the necessary conversions. If the application buffer type is same as that of the field type returned from the server, the conversions are straightforward.

If an error occurs, you can get the statement error number, error message, and SQLSTATE code using `mysql_stmt_errno()`, `mysql_stmt_error()`, and `mysql_stmt_sqlstate()`, respectively.

### Prepared Statement Logging

For prepared statements that are executed with the `mysql_stmt_prepare()` and `mysql_stmt_execute()` C API functions, the server writes `Prepare` and `Execute` lines to the general query log so that you can tell when statements are prepared and executed.
Suppose that you prepare and execute a statement as follows:

1. Call `mysql_stmt_prepare()` to prepare the statement string "SELECT ?".
2. Call `mysql_stmt_bind_param()` to bind the value 3 to the parameter in the prepared statement.
3. Call `mysql_stmt_execute()` to execute the prepared statement.

As a result of the preceding calls, the server writes the following lines to the general query log:

```
Prepare [1] SELECT ?
Execute [1] SELECT 3
```

Each `Prepare` and `Execute` line in the log is tagged with a `[N]` statement identifier so that you can keep track of which prepared statement is being logged. N is a positive integer. If there are multiple prepared statements active simultaneously for the client, N may be greater than 1. Each `Execute` line shows a prepared statement after substitution of data values for `?` parameters.

### 20.6.11 C API Prepared Statement Function Descriptions

To prepare and execute queries, use the functions described in detail in the following sections.

All functions that operate with a `MYSQL_STMT` structure begin with the prefix `mysql_stmt_`.

To create a `MYSQL_STMT` handle, use the `mysql_stmt_init()` function.

#### 20.6.11.1 `mysql_stmt_affected_rows()`

```c
my_ulonglong mysql_stmt_affected_rows(MYSQL_STMT *stmt)
```

**Description**

`mysql_stmt_affected_rows()` may be called immediately after executing a statement with `mysql_stmt_execute()`. It is like `mysql_affected_rows()` but for prepared statements. For a description of what the affected-rows value returned by this function means, see Section 20.6.7.1, "mysql_affected_rows()".

**Errors**

None.

**Example**

See the Example in Section 20.6.11.10, "mysql_stmt_execute()".

#### 20.6.11.2 `mysql_stmt_attr_get()`

```c
my_bool mysql_stmt_attr_get(MYSQL_STMT *stmt, enum enum_stmt_attr_type option, void *arg)
```

**Description**

Can be used to get the current value for a statement attribute.

The `option` argument is the option that you want to get; the `arg` should point to a variable that should contain the option value. If the option is an integer, `arg` should point to the value of the integer.

See Section 20.6.11.3, "mysql_stmt_attr_set()", for a list of options and option types.

**Note**

In MySQL 5.0, `mysql_stmt_attr_get()` uses `unsigned long *`, not `my_bool *`, for `STMT_ATTR_UPDATE_MAX_LENGTH`. This was corrected in MySQL 5.1.7.
Return Values

Zero for success. Nonzero if option is unknown.

Errors

None.

20.6.11.3 mysql_stmt_attr_set()

my_bool mysql_stmt_attr_set(MYSQL_STMT *stmt, enum enum_stmt_attr_type option, const void *arg)

Description

Can be used to affect behavior for a prepared statement. This function may be called multiple times to set several options.

The option argument is the option that you want to set. The arg argument is the value for the option. arg should point to a variable that is set to the desired attribute value. The variable type is as indicated in the following table.

The following table shows the possible option values.

<table>
<thead>
<tr>
<th>Option</th>
<th>Argument Type</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>STMT_ATTR_UPDATE_MAX_LENGTH</td>
<td>my_bool *</td>
<td>If set to 1, causes mysql_stmt_store_result() to update the metadata MYSQL_FIELD-&gt;max_length value.</td>
</tr>
<tr>
<td>STMT_ATTR_CURSOR_TYPE</td>
<td>unsigned long *</td>
<td>Type of cursor to open for statement when mysql_stmt_execute() is invoked. *arg can be CURSOR_TYPE_NO_CURSOR (the default) or CURSOR_TYPE_READ_ONLY.</td>
</tr>
<tr>
<td>STMT_ATTR_PREFETCH_ROWS</td>
<td>unsigned long *</td>
<td>Number of rows to fetch from server at a time when using a cursor. *arg can be in the range from 1 to the maximum value of unsigned long. The default is 1.</td>
</tr>
</tbody>
</table>

Note

In MySQL 5.0, mysql_stmt_attr_get() uses unsigned int *, not my_bool *, for STMT_ATTR_UPDATE_MAX_LENGTH. This is corrected in MySQL 5.1.7.

If you use the STMT_ATTR_CURSOR_TYPE option with CURSOR_TYPE_READ_ONLY, a cursor is opened for the statement when you invoke mysql_stmt_execute(). If there is already an open cursor from a previous mysql_stmt_execute() call, it closes the cursor before opening a new one. mysql_stmt_reset() also closes any open cursor before preparing the statement for re-execution. mysql_stmt_free_result() closes any open cursor.

If you open a cursor for a prepared statement, mysql_stmt_store_result() is unnecessary, because that function causes the result set to be buffered on the client side.

The STMT_ATTR_CURSOR_TYPE option was added in MySQL 5.0.2. The STMT_ATTR_PREFETCH_ROWS option was added in MySQL 5.0.6.
Return Values

Zero for success. Nonzero if `option` is unknown.

Errors

None.

Example

The following example opens a cursor for a prepared statement and sets the number of rows to fetch at a time to 5:

```c
MYSQL_STMT *stmt;
int rc;
unsigned long type;
unsigned long prefetch_rows = 5;

stmt = mysql_stmt_init(mysql);
type = (unsigned long) CURSOR_TYPE_READ_ONLY;
rc = mysql_stmt_attr_set(stmt, STMT_ATTR_CURSOR_TYPE, (void*) &type);
/* ... check return value ... */
rc = mysql_stmt_attr_set(stmt, STMT_ATTR_PREFETCH_ROWS,
                         (void*) &prefetch_rows);
/* ... check return value ... */
```

20.6.11.4 mysql_stmt_bind_param()

`my_bool mysql_stmt_bind_param(MYSQL_STMT *stmt, MYSQL_BIND *bind)`

Description

`mysql_stmt_bind_param()` is used to bind input data for the parameter markers in the SQL statement that was passed to `mysql_stmt_prepare()`. It uses `MYSQL_BIND` structures to supply the data. `bind` is the address of an array of `MYSQL_BIND` structures. The client library expects the array to contain one element for each `?` parameter marker that is present in the query.

Suppose that you prepare the following statement:

```
INSERT INTO mytbl VALUES(?,?,?)
```

When you bind the parameters, the array of `MYSQL_BIND` structures must contain three elements, and can be declared like this:

```c
MYSQL_BIND bind[3];
```

Section 20.6.9, “C API Prepared Statement Data Structures“, describes the members of each `MYSQL_BIND` element and how they should be set to provide input values.

Return Values

Zero for success. Nonzero if an error occurred.

Errors

- `CR_UNSUPPORTED_PARAM_TYPE`
  The conversion is not supported. Possibly the `buffer_type` value is illegal or is not one of the supported types.
- `CR_OUT_OF_MEMORY`
  Out of memory.
• **CR_UNKNOWN_ERROR**

An unknown error occurred.

**Example**

See the Example in Section 20.6.11.10, “mysql_stmt_execute()”.

### 20.6.11.5 mysql_stmt_bind_result()

```c
my_bool mysql_stmt_bind_result(MYSQL_STMT *stmt, MYSQL_BIND *bind)
```

**Description**

`mysql_stmt_bind_result()` is used to associate (that is, bind) output columns in the result set to data buffers and length buffers. When `mysql_stmt_fetch()` is called to fetch data, the MySQL client/server protocol places the data for the bound columns into the specified buffers.

All columns must be bound to buffers prior to calling `mysql_stmt_fetch()`. `bind` is the address of an array of `MYSQL_BIND` structures. The client library expects the array to contain one element for each column of the result set. If you do not bind columns to `MYSQL_BIND` structures, `mysql_stmt_fetch()` simply ignores the data fetch. The buffers should be large enough to hold the data values, because the protocol does not return data values in chunks.

A column can be bound or rebound at any time, even after a result set has been partially retrieved. The new binding takes effect the next time `mysql_stmt_fetch()` is called. Suppose that an application binds the columns in a result set and calls `mysql_stmt_fetch()`. The client/server protocol returns data in the bound buffers. Then suppose that the application binds the columns to a different set of buffers. The protocol places data into the newly bound buffers when the next call to `mysql_stmt_fetch()` occurs.

To bind a column, an application calls `mysql_stmt_bind_result()` and passes the type, address, and length of the output buffer into which the value should be stored. Section 20.6.9, “C API Prepared Statement Data Structures”, describes the members of each `MYSQL_BIND` element and how they should be set to receive output values.

**Return Values**

Zero for success. Nonzero if an error occurred.

**Errors**

• **CR_UNSUPPORTED_PARAM_TYPE**

The conversion is not supported. Possibly the `buffer_type` value is illegal or is not one of the supported types.

• **CR_OUT_OF_MEMORY**

Out of memory.

• **CR_UNKNOWN_ERROR**

An unknown error occurred.

**Example**

See the Example in Section 20.6.11.11, “mysql_stmt_fetch()”.

### 20.6.11.6 mysql_stmt_close()

```c
my_bool mysql_stmt_close(MYSQL_STMT *)
```
Description

Closes the prepared statement. `mysql_stmt_close()` also deallocates the statement handle pointed to by `stmt`.

If the current statement has pending or unread results, this function cancels them so that the next query can be executed.

Return Values

Zero for success. Nonzero if an error occurred.

Errors

- `CR_SERVER_GONE_ERROR`
  The MySQL server has gone away.
- `CR_UNKNOWN_ERROR`
  An unknown error occurred.

Example

See the Example in Section 20.6.11.10, “mysql_stmt_execute()”.

20.6.11.7 mysql_stmt_data_seek()

```c
void mysql_stmt_data_seek(MYSQL_STMT *stmt, my_ulonglong offset)
```

Description

Seeks to an arbitrary row in a statement result set. The `offset` value is a row number and should be in the range from 0 to `mysql_stmt_num_rows(stmt)-1`.

This function requires that the statement result set structure contains the entire result of the last executed query, so `mysql_stmt_data_seek()` may be used only in conjunction with `mysql_stmt_store_result()`.

Return Values

None.

Errors

None.

20.6.11.8 mysql_stmt_errno()

```c
unsigned int mysql_stmt_errno(MYSQL_STMT *stmt)
```

Description

For the statement specified by `stmt`, `mysql_stmt_errno()` returns the error code for the most recently invoked statement API function that can succeed or fail. A return value of zero means that no error occurred. Client error message numbers are listed in the MySQL `errmsg.h` header file. Server error message numbers are listed in `mysqld_error.h`. Errors also are listed at Appendix B, Errors, Error Codes, and Common Problems.

Return Values

An error code value. Zero if no error occurred.
Errors

None.

20.6.11.9 mysql_stmt_error()

const char *mysql_stmt_error(MYSQL_STMT *stmt)

Description

For the statement specified by stmt, mysql_stmt_error() returns a null-terminated string containing the error message for the most recently invoked statement API function that can succeed or fail. An empty string (""") is returned if no error occurred. Either of these two tests can be used to check for an error:

```c
if(*mysql_stmt_errno(stmt))
{
    // an error occurred
}
if (mysql_stmt_error(stmt)[0])
{
    // an error occurred
}
```

The language of the client error messages may be changed by recompiling the MySQL client library. You can choose error messages in several different languages.

Return Values

A character string that describes the error. An empty string if no error occurred.

Errors

None.

20.6.11.10 mysql_stmt_execute()

int mysql_stmt_execute(MYSQL_STMT *stmt)

Description

mysql_stmt_execute() executes the prepared query associated with the statement handle. The currently bound parameter marker values are sent to server during this call, and the server replaces the markers with this newly supplied data.

Statement processing following mysql_stmt_execute() depends on the type of statement:

- For an UPDATE, DELETE, or INSERT, the number of changed, deleted, or inserted rows can be found by calling mysql_stmt_affected_rows().

- For a statement such as SELECT that generates a result set, you must call mysql_stmt_fetch() to fetch the data prior to calling any other functions that result in query processing. For more information on how to fetch the results, refer to Section 20.6.11.11, “mysql_stmt_fetch()”.

Do not following invocation of mysql_stmt_execute() with a call to mysql_store_result() or mysql_use_result(). Those functions are not intended for processing results from prepared statements.

For statements that generate a result set, you can request that mysql_stmt_execute() open a cursor for the statement by calling mysql_stmt_attr_set() before executing the statement. If you execute a statement multiple times, mysql_stmt_execute() closes any open cursor before opening a new one.
Return Values

Zero for success. Nonzero if an error occurred.

Errors

- **CR_COMMANDS_OUT_OF_SYNC**
  Commands were executed in an improper order.

- **CR_OUT_OF_MEMORY**
  Out of memory.

- **CR_SERVER_GONE_ERROR**
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  An unknown error occurred.

Example

The following example demonstrates how to create and populate a table using `mysql_stmt_init()`, `mysql_stmt_prepare()`, `mysql_stmt_param_count()`, `mysql_stmt_bind_param()`, `mysql_stmt_execute()`, and `mysql_stmt_affected_rows()`. The `mysql` variable is assumed to be a valid connection handle. For an example that shows how to retrieve data, see Section 20.6.11.11, "mysql_stmt_fetch()".

```c
#define STRING_SIZE 50
#define DROP_SAMPLE_TABLE "DROP TABLE IF EXISTS test_table"
#define CREATE_SAMPLE_TABLE "CREATE TABLE test_table(col1 INT,\n  col2 VARCHAR(40),\n  col3 SMALLINT,\n  col4 TIMESTAMP)"
#define INSERT_SAMPLE "INSERT INTO \n  test_table(col1,col2,col3) \n  VALUES(?,?,?)"

MYSQL_STMT    *stmt;
MYSQL_BIND    bind[3];
my_ulonglong  affected_rows;
int           param_count;
short         small_data;
int           int_data;
char          str_data[STRING_SIZE];
unsigned long str_length;
my_bool       is_null;

if (mysql_query(mysql, DROP_SAMPLE_TABLE))
  {
    fprintf(stderr, " DROP TABLE failed\n");
    fprintf(stderr, "%s\n", mysql_error(mysql));
    exit(0);
  }
if (mysql_query(mysql, CREATE_SAMPLE_TABLE))
  {
    fprintf(stderr, " CREATE TABLE failed\n");
    fprintf(stderr, "%s\n", mysql_error(mysql));
    exit(0);
  }
```
/* Prepare an INSERT query with 3 parameters */
/* (the TIMESTAMP column is not named; the server */
/* sets it to the current date and time) */
stmt = mysql_stmt_init(mysql);
if (!stmt)
    { fprintf(stderr, " mysql_stmt_init(), out of memory\n");
      exit(0);
    }
if (mysql_stmt_prepare(stmt, INSERT_SAMPLE, strlen(INSERT_SAMPLE)))
    { fprintf(stderr, " mysql_stmt_prepare(), INSERT failed\n");
      fprintf(stderr, " %s
", mysql_stmt_error(stmt));
      exit(0);
    }
fprintf(stdout, " prepare, INSERT successful\n");
/* Get the parameter count from the statement */
param_count= mysql_stmt_param_count(stmt);
fprintf(stdout, " total parameters in INSERT: %d, param_count: %d\n", param_count);
if (param_count != 3) /* validate parameter count */
    { fprintf(stderr, " invalid parameter count returned by MySQL\n");
      exit(0);
    }
/* Bind the data for all 3 parameters */
memset(bind, 0, sizeof(bind));
/* INTEGER PARAM */
/* This is a number type, so there is no need */
to specify buffer_length */
bind[0].buffer_type= MYSQL_TYPE_LONG;
bind[0].buffer= (char *)&int_data;
bind[0].is_null= 0;
bind[0].length= 0;
/* STRING PARAM */
bind[1].buffer_type= MYSQL_TYPE_STRING;
bind[1].buffer= (char *)str_data;
bind[1].buffer_length= STRING_SIZE;
bind[1].is_null= 0;
bind[1].length= &str_length;
/* SMALLINT PARAM */
bind[2].buffer_type= MYSQL_TYPE_SHORT;
bind[2].buffer= (char *)&small_data;
bind[2].is_null= &is_null;
bind[2].length= 0;
/* Bind the buffers */
if (mysql_stmt_bind_param(stmt, bind))
    { fprintf(stderr, " mysql_stmt_bind_param() failed\n");
      fprintf(stderr, " %s
", mysql_stmt_error(stmt));
      exit(0);
    }
/* Specify the data values for the first row */
int_data= 10; /* integer */
strncpy(str_data, "MySQL", STRING_SIZE); /* string */
str_length= strlen(str_data);
/* INSERT SMALLINT data as NULL */
is_null= 1;
/* Execute the INSERT statement */
if (mysql_stmt_execute(stmt))
fprintf(stderr, " mysql_stmt_execute(), 1 failed\n");
fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
exit(0);
}

/* Get the number of affected rows */
affected_rows= mysql_stmt_affected_rows(stmt);
fprintf(stdout, " total affected rows(insert 1): %lu\n",
(unsigned long) affected_rows);
if (affected_rows != 1) /* validate affected rows */
{
    fprintf(stderr, " invalid affected rows by MySQL\n");
    exit(0);
}

/* Specify data values for second row,
then re-execute the statement */
int_data= 1000;
strncpy(str_data, "The most popular Open Source database",
STRING_SIZE);
str_length= strlen(str_data);
small_data= 1000; /* smallint */
is_null= 0; /* reset */

/* Execute the INSERT statement - 2*/
if (mysql_stmt_execute(stmt))
{
    fprintf(stderr, " mysql_stmt_execute, 2 failed\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

/* Get the total rows affected */
affected_rows= mysql_stmt_affected_rows(stmt);
fprintf(stdout, " total affected rows(insert 2): %lu\n",
(unsigned long) affected_rows);
if (affected_rows != 1) /* validate affected rows */
{
    fprintf(stderr, " invalid affected rows by MySQL\n");
    exit(0);
}

/* Close the statement */
if (mysql_stmt_close(stmt))
{
    fprintf(stderr, " failed while closing the statement\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

Note
For complete examples on the use of prepared statement functions, refer to the
file tests/mysql_client_test.c. This file can be obtained from a MySQL
source distribution or from the source repository (see Section 2.17, “Installing
MySQL from Source”).

20.6.11.11 mysql_stmt_fetch()

int mysql_stmt_fetch(MYSQL_STMT *stmt)

Description

mysql_stmt_fetch() returns the next row in the result set. It can be called only while the result set
exists; that is, after a call to mysql_stmt_execute() for a statement such as SELECT that produces
a result set.
mysql_stmt_fetch() returns row data using the buffers bound by mysql_stmt_bind_result(). It returns the data in those buffers for all the columns in the current row set and the lengths are returned to the length pointer. All columns must be bound by the application before it calls mysql_stmt_fetch().

By default, result sets are fetched unbuffered a row at a time from the server. To buffer the entire result set on the client, call mysql_stmt_store_result() after binding the data buffers and before calling mysql_stmt_fetch().

If a fetched data value is a NULL value, the *is_null value of the corresponding MYSQL_BIND structure contains TRUE (1). Otherwise, the data and its length are returned in the *buffer and *length elements based on the buffer type specified by the application. Each numeric and temporal type has a fixed length, as listed in the following table. The length of the string types depends on the length of the actual data value, as indicated by data_length.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>MYSQL_TYPE_TINY</td>
<td>1</td>
</tr>
<tr>
<td>MYSQL_TYPE_SHORT</td>
<td>2</td>
</tr>
<tr>
<td>MYSQL_TYPE_LONG</td>
<td>4</td>
</tr>
<tr>
<td>MYSQL_TYPE_LONGLONG</td>
<td>8</td>
</tr>
<tr>
<td>MYSQL_TYPE_FLOAT</td>
<td>4</td>
</tr>
<tr>
<td>MYSQL_TYPE_DOUBLE</td>
<td>8</td>
</tr>
<tr>
<td>MYSQL_TYPE_TIME</td>
<td>sizeof(MYSQL_TIME)</td>
</tr>
<tr>
<td>MYSQL_TYPE_DATE</td>
<td>sizeof(MYSQL_TIME)</td>
</tr>
<tr>
<td>MYSQL_TYPE_DATETIME</td>
<td>sizeof(MYSQL_TIME)</td>
</tr>
<tr>
<td>MYSQL_TYPE_STRING</td>
<td>data_length</td>
</tr>
<tr>
<td>MYSQL_TYPE_BLOB</td>
<td>data_length</td>
</tr>
</tbody>
</table>

In some cases you might want to determine the length of a column value before fetching it with mysql_stmt_fetch(). For example, the value might be a long string or BLOB value for which you want to know how much space must be allocated. To accomplish this, you can use these strategies:

- Before invoking mysql_stmt_fetch() to retrieve individual rows, pass
  STMT_ATTR_UPDATE_MAX_LENGTH to mysql_stmt_attr_set(), then invoke
  mysql_stmt_store_result() to buffer the entire result on the client side. Setting
  the STMT_ATTR_UPDATE_MAX_LENGTH attribute causes the maximal length of column
  values to be indicated by the max_length member of the result set metadata returned by
  mysql_stmt_result_metadata().

- Invoke mysql_stmt_fetch() with a zero-length buffer for the column in question and a pointer in
  which the real length can be stored. Then use the real length with mysql_stmt_fetch_column().

```c
real_length= 0;
bind[0].buffer= 0;
bind[0].buffer_length= 0;
bind[0].length= &real_length
mysql_stmt_bind_result(stmt, bind);

mysql_stmt_fetch(stmt);
if (real_length > 0)
{
    data= malloc(real_length);
    bind[0].buffer= data;
    bind[0].buffer_length= real_length;
    mysql_stmt_fetch_column(stmt, bind, 0, 0);
}
```
Return Values

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Successful, the data has been fetched to application data buffers.</td>
</tr>
<tr>
<td>1</td>
<td>Error occurred. Error code and message can be obtained by calling <code>mysql_stmt_errno()</code> and <code>mysql_stmt_error()</code>.</td>
</tr>
<tr>
<td>MYSQL_NO_DATA</td>
<td>No more rows/data exists</td>
</tr>
<tr>
<td>MYSQL_DATA_TRUNCATED</td>
<td>Data truncation occurred</td>
</tr>
</tbody>
</table>

`MYSQL_DATA_TRUNCATED` is returned when truncation reporting is enabled. To determine which column values were truncated when this value is returned, check the `error` members of the `MYSQL_BIND` structures used for fetching values. Truncation reporting is enabled by default, but can be controlled by calling `mysql_options()` with the `MYSQL_REPORT_DATA_TRUNCATION` option.

Errors

- CR_COMMANDS_OUT_OF_SYNC
  Commands were executed in an improper order.
- CR_OUT_OF_MEMORY
  Out of memory.
- CR_SERVER_GONE_ERROR
  The MySQL server has gone away.
- CR_SERVER_LOST
  The connection to the server was lost during the query.
- CR_UNKNOWN_ERROR
  An unknown error occurred.
- CR_UNSUPPORTED_PARAM_TYPE
  The buffer type is `MYSQL_TYPE_DATE`, `MYSQL_TYPE_TIME`, `MYSQL_TYPE_DATETIME`, or `MYSQL_TYPE_TIMESTAMP`, but the data type is not `DATE`, `TIME`, `DATETIME`, or `TIMESTAMP`.
- All other unsupported conversion errors are returned from `mysql_stmt_bind_result()`.

Example

The following example demonstrates how to fetch data from a table using `mysql_stmt_result_metadata()`, `mysql_stmt_bind_result()`, and `mysql_stmt_fetch()`.

(This example expects to retrieve the two rows inserted by the example shown in Section 20.6.11.10, “mysql_stmt_execute()”.) The `mysql` variable is assumed to be a valid connection handle.

```c
#define STRING_SIZE 50
#define SELECT_SAMPLE "SELECT col1, col2, col3, col4 \ FROM test_table"

MYSQL_STMT    *stmt;
MYSQL_BIND    bind[4];
MYSQL_RES     *prepare_meta_result;
MYSQL_TIME    ts;
unsigned long length[4];
short         small_data;
int           int_data;
```
char str_data[STRING_SIZE];
my_bool is_null[4];
my_bool error[4];

/* Prepare a SELECT query to fetch data from test_table */
stmt = mysql_stmt_init(mysql);
if (!stmt)
{
    fprintf(stderr, " mysql_stmt_init(), out of memory\n");
    exit(0);
}
if (mysql_stmt_prepare(stmt, SELECT_SAMPLE, strlen(SELECT_SAMPLE)))
{
    fprintf(stderr, " mysql_stmt_prepare(), SELECT failed\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}
fprintf(stdout, " prepare, SELECT successful\n");

/* Get the parameter count from the statement */
param_count = mysql_stmt_param_count(stmt);
fprintf(stdout, " total parameters in SELECT: %d, param_count\n", param_count);
if (param_count != 0) /* validate parameter count */
{
    fprintf(stderr, " invalid parameter count returned by MySQL\n");
    exit(0);
}

/* Fetch result set meta information */
prepare_meta_result = mysql_stmt_result_metadata(stmt);
if (!prepare_meta_result)
{
    fprintf(stderr, " mysql_stmt_result_metadata(), \n");    fprintf(stderr, " returned no meta information\n", mysql_stmt_error(stmt));
    exit(0);
}

/* Get total columns in the query */
column_count = mysql_num_fields(prepare_meta_result);
fprintf(stdout, " total columns in SELECT statement: %d, column_count\n", column_count);
if (column_count != 4) /* validate column count */
{
    fprintf(stderr, " invalid column count returned by MySQL\n");
    exit(0);
}

/* Execute the SELECT query */
if (mysql_stmt_execute(stmt))
{
    fprintf(stderr, " mysql_stmt_execute(), failed\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

/* Bind the result buffers for all 4 columns before fetching them */
memset(bind, 0, sizeof(bind));

/* INTEGER COLUMN */
bind[0].buffer_type = MYSQL_TYPE_LONG;
bind[0].buffer = (char *)&int_data;
bind[0].is_null = &is_null[0];
bind[0].length = &length[0];
bind[0].error = &error[0];
/* STRING COLUMN */
bind[1].buffer_type= MYSQL_TYPE_STRING;
bind[1].buffer= (char *)str_data;
bind[1].buffer_length= STRING_SIZE;
bind[1].is_null= &is_null[1];
bind[1].length= &length[1];
bind[1].error= &error[1];

/* SMALLINT COLUMN */
bind[2].buffer_type= MYSQL_TYPE_SHORT;
bind[2].buffer= (char *)&small_data;
bind[2].is_null= &is_null[2];
bind[2].length= &length[2];
bind[2].error= &error[2];

/* TIMESTAMP COLUMN */
bind[3].buffer_type= MYSQL_TYPE_TIMESTAMP;
bind[3].buffer= (char *)&ts;
bind[3].is_null= &is_null[3];
bind[3].length= &length[3];
bind[3].error= &error[3];

/* Bind the result buffers */
if (mysql_stmt_bind_result(stmt, bind))
{
    fprintf(stderr, " mysql_stmt_bind_result() failed\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

/* Now buffer all results to client (optional step) */
if (mysql_stmt_store_result(stmt))
{
    fprintf(stderr, " mysql_stmt_store_result() failed\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

/* Fetch all rows */
row_count= 0;
fprintf(stdout, "Fetching results ...
");
while (!mysql_stmt_fetch(stmt))
{
    row_count++;
    fprintf(stdout, " row %d\n", row_count);

    /* column 1 */
    fprintf(stdout, " column1 (integer) : ");
    if (is_null[0])
        fprintf(stdout, " NULL\n");
    else
        fprintf(stdout, " %d(%ld)\n", int_data, length[0]);

    /* column 2 */
    fprintf(stdout, " column2 (string)   : ");
    if (is_null[1])
        fprintf(stdout, " NULL\n");
    else
        fprintf(stdout, " %s(%ld)\n", str_data, length[1]);

    /* column 3 */
    fprintf(stdout, " column3 (smallint) : ");
    if (is_null[2])
        fprintf(stdout, " NULL\n");
    else
        fprintf(stdout, " %d(%ld)\n", small_data, length[2]);

    /* column 4 */
    fprintf(stdout, " column4 (timestamp): ");
    if (is_null[3])
        fprintf(stdout, " NULL\n");
    else
        fprintf(stdout, " %04d-%02d-%02d %02d:%02d:%02d (%ld)\n",
20.6.11.12 mysql_stmt_fetch_column()

```c
int mysql_stmt_fetch_column(MYSQL_STMT *stmt, MYSQL_BIND *bind, unsigned int column, unsigned long offset)
```

**Description**

Fetch one column from the current result set row. `bind` provides the buffer where data should be placed. It should be set up the same way as for `mysql_stmt_bind_result()`. `column` indicates which column to fetch. The first column is numbered 0. `offset` is the offset within the data value at which to begin retrieving data. This can be used for fetching the data value in pieces. The beginning of the value is offset 0.

**Return Values**

Zero for success. Nonzero if an error occurred.

**Errors**

- **CR_INVALID_PARAMETER_NO**
  
  Invalid column number.

- **CR_NO_DATA**

  The end of the result set has already been reached.

20.6.11.13 mysql_stmt_field_count()

```c
unsigned int mysql_stmt_field_count(MYSQL_STMT *stmt)
```

**Description**

Returns the number of columns for the most recent statement for the statement handler. This value is zero for statements such as `INSERT` or `DELETE` that do not produce result sets.

`mysql_stmt_field_count()` can be called after you have prepared a statement by invoking `mysql_stmt_prepare()`.
Return Values

An unsigned integer representing the number of columns in a result set.

Errors

None.

20.6.11.14 mysql_stmt_free_result()

my_bool mysql_stmt_free_result(MYSQL_STMT *stmt)

Description

Releases memory associated with the result set produced by execution of the prepared statement. If there is a cursor open for the statement, mysql_stmt_free_result() closes it.

Return Values

Zero for success. Nonzero if an error occurred.

Errors

20.6.11.15 mysql_stmt_init()

MYSQL_STMT *mysql_stmt_init(MYSQL *mysql)

Description

Create a MYSQL_STMT handle. The handle should be freed with mysql_stmt_close(MYSQL_STMT *).

See also Section 20.6.9, "C API Prepared Statement Data Structures", for more information.

Return Values

A pointer to a MYSQL_STMT structure in case of success. NULL if out of memory.

Errors

• CR_OUT_OF_MEMORY

Out of memory.

20.6.11.16 mysql_stmt_insert_id()

my_ulonglong mysql_stmt_insert_id(MYSQL_STMT *stmt)

Description

Returns the value generated for an AUTO_INCREMENT column by the prepared INSERT or UPDATE statement. Use this function after you have executed a prepared INSERT statement on a table which contains an AUTO_INCREMENT field.

See Section 20.6.7.37, "mysql_insert_id()", for more information.

Return Values

Value for AUTO_INCREMENT column which was automatically generated or explicitly set during execution of prepared statement, or value generated by LAST_INSERT_ID(expr) function. Return value is undefined if statement does not set AUTO_INCREMENT value.
Errors
None.

20.6.11.17 mysql_stmt_num_rows()

my_ulonglong mysql_stmt_num_rows(MYSQL_STMT *stmt)

Description
Returns the number of rows in the result set.

The use of mysql_stmt_num_rows() depends on whether you used mysql_stmt_store_result() to buffer the entire result set in the statement handle. If you use mysql_stmt_store_result(), mysql_stmt_num_rows() may be called immediately. Otherwise, the row count is unavailable unless you count the rows as you fetch them.

mysql_stmt_num_rows() is intended for use with statements that return a result set, such as SELECT. For statements such as INSERT, UPDATE, or DELETE, the number of affected rows can be obtained with mysql_stmt_affected_rows().

Return Values
The number of rows in the result set.

Errors
None.

20.6.11.18 mysql_stmt_param_count()

unsigned long mysql_stmt_param_count(MYSQL_STMT *stmt)

Description
Returns the number of parameter markers present in the prepared statement.

Return Values
An unsigned long integer representing the number of parameters in a statement.

Errors
None.

Example
See the Example in Section 20.6.11.10, "mysql_stmt_execute()".

20.6.11.19 mysql_stmt_param_metadata()

MYSQL_RES *mysql_stmt_param_metadata(MYSQL_STMT *stmt)

Description
This function currently does nothing.

Return Values

Errors

20.6.11.20 mysql_stmt_prepare()
int mysql_stmt_prepare(MYSQL_STMT *stmt, const char *stmt_str, unsigned long length)

Description

Given the statement handle returned by mysql_stmt_init(), prepares the SQL statement pointed to by the string stmt_str and returns a status value. The string length should be given by the length argument. The string must consist of a single SQL statement. You should not add a terminating semicolon (";") or \g to the statement.

The application can include one or more parameter markers in the SQL statement by embedding question mark (?) characters into the SQL string at the appropriate positions.

The markers are legal only in certain places in SQL statements. For example, they are permitted in the VALUES() list of an INSERT statement (to specify column values for a row), or in a comparison with a column in a WHERE clause to specify a comparison value. However, they are not permitted for identifiers (such as table or column names), or to specify both operands of a binary operator such as the = equal sign. The latter restriction is necessary because it would be impossible to determine the parameter type. In general, parameters are legal only in Data Manipulation Language (DML) statements, and not in Data Definition Language (DDL) statements.

The parameter markers must be bound to application variables using mysql_stmt_bind_param() before executing the statement.

Return Values

Zero for success. Nonzero if an error occurred.

Errors

- **CR_COMMANDS_OUT_OF_SYNC**
  
  Commands were executed in an improper order.

- **CR_OUT_OF_MEMORY**
  
  Out of memory.

- **CR_SERVER_GONE_ERROR**
  
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  
  The connection to the server was lost during the query

- **CR_UNKNOWN_ERROR**
  
  An unknown error occurred.

If the prepare operation was unsuccessful (that is, mysql_stmt_prepare() returns nonzero), the error message can be obtained by calling mysql_stmt_error().

Example

See the Example in Section 20.6.11.10, “mysql_stmt_execute()”.

20.6.11.21 mysql_stmt_reset()

my_bool mysql_stmt_reset(MYSQL_STMT *stmt)
Description

Resets a prepared statement on client and server to state after prepare. It resets the statement on the server, data sent using `mysql_stmt_send_long_data()`, unbuffered result sets and current errors. It does not clear bindings or stored result sets. Stored result sets will be cleared when executing the prepared statement (or closing it).

To re-prepare the statement with another query, use `mysql_stmt_prepare()`.

Return Values

Zero for success. Nonzero if an error occurred.

Errors

- **CR_COMMANDS_OUT_OF_SYNC**
  
  Commands were executed in an improper order.

- **CR_SERVER_GONE_ERROR**
  
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  
  The connection to the server was lost during the query

- **CR_UNKNOWN_ERROR**
  
  An unknown error occurred.

20.6.11.22 `mysql_stmt_result_metadata()`

MYSQL_RES *mysql_stmt_result_metadata(MYSQL_STMT *stmt)

Description

If a statement passed to `mysql_stmt_prepare()` is one that produces a result set, `mysql_stmt_result_metadata()` returns the result set metadata in the form of a pointer to a `MYSQL_RES` structure that can be used to process the meta information such as number of fields and individual field information. This result set pointer can be passed as an argument to any of the field-based API functions that process result set metadata, such as:

- `mysql_num_fields()`
- `mysql_fetch_field()`
- `mysql_fetch_field_direct()`
- `mysql_fetch_fields()`
- `mysql_field_count()`
- `mysql_field_seek()`
- `mysql_field_tell()`
- `mysql_free_result()`

The result set structure should be freed when you are done with it, which you can do by passing it to `mysql_free_result()`. This is similar to the way you free a result set obtained from a call to `mysql_store_result()`.

This documentation is for an older version. If you’re...
The result set returned by `mysql_stmt_result_metadata()` contains only metadata. It does not contain any row results. The rows are obtained by using the statement handle with `mysql_stmt_fetch()`.

**Return Values**

A `MYSQL_RES` result structure. `NULL` if no meta information exists for the prepared query.

**Errors**

- `CR_OUT_OF_MEMORY`
  
  Out of memory.

- `CR_UNKNOWN_ERROR`
  
  An unknown error occurred.

**Example**

See the Example in Section 20.6.11.11, "mysql_stmt_fetch()".

### 20.6.11.23 mysql_stmt_row_seek()

`MYSQL_ROW_OFFSET mysql_stmt_row_seek(MYSQL_STMT *stmt, MYSQL_ROW_OFFSET offset)`

**Description**

Sets the row cursor to an arbitrary row in a statement result set. The `offset` value is a row offset that should be a value returned from `mysql_stmt_row_tell()` or from `mysql_stmt_row_seek()`. This value is not a row number; if you want to seek to a row within a result set by number, use `mysql_stmt_data_seek()` instead.

This function requires that the result set structure contains the entire result of the query, so `mysql_stmt_row_seek()` may be used only in conjunction with `mysql_stmt_store_result()`.

**Return Values**

The previous value of the row cursor. This value may be passed to a subsequent call to `mysql_stmt_row_seek()`.

**Errors**

None.

### 20.6.11.24 mysql_stmt_row_tell()

`MYSQL_ROW_OFFSET mysql_stmt_row_tell(MYSQL_STMT *stmt)`

**Description**

Returns the current position of the row cursor for the last `mysql_stmt_fetch()`. This value can be used as an argument to `mysql_stmt_row_seek()`.

You should use `mysql_stmt_row_tell()` only after `mysql_stmt_store_result()`.

**Return Values**

The current offset of the row cursor.

**Errors**

None.
### 20.6.11.25 mysql_stmt_send_long_data()

```c
my_bool mysql_stmt_send_long_data(MYSQL_STMT *stmt, unsigned int parameter_number, const char *data, unsigned long length)
```

**Description**

Enables an application to send parameter data to the server in pieces (or “chunks”). Call this function after `mysql_stmt_bind_param()` and before `mysql_stmt_execute()`. It can be called multiple times to send the parts of a character or binary data value for a column, which must be one of the TEXT or BLOB data types.

`parameter_number` indicates which parameter to associate the data with. Parameters are numbered beginning with 0. `data` is a pointer to a buffer containing data to be sent, and `length` indicates the number of bytes in the buffer.

**Note**

The next `mysql_stmt_execute()` call ignores the bind buffer for all parameters that have been used with `mysql_stmt_send_long_data()` since last `mysql_stmt_execute()` or `mysql_stmt_reset()`.

If you want to reset/forget the sent data, you can do it with `mysql_stmt_reset()`. See Section 20.6.11.21, "mysql_stmt_reset()".

**Return Values**

Zero for success. Nonzero if an error occurred.

**Errors**

- **CR_INVALID_BUFFER_USE**
  
  The parameter does not have a string or binary type.

- **CR_INVALID_PARAMETER_NO**
  
  Invalid parameter number.

- **CR_COMMANDS_OUT_OF_SYNC**
  
  Commands were executed in an improper order.

- **CR_SERVER_GONE_ERROR**
  
  The MySQL server has gone away.

- **CR_OUT_OF_MEMORY**
  
  Out of memory.

- **CR_UNKNOWN_ERROR**
  
  An unknown error occurred.

**Example**

The following example demonstrates how to send the data for a TEXT column in chunks. It inserts the data value 'MySQL - The most popular Open Source database' into the text_column column. The `mysql` variable is assumed to be a valid connection handle.
#define INSERT_QUERY "INSERT INTO \
    test_long_data(text_column) VALUES(?)"

MYSQL_BIND bind[1];
long length;
stmt = mysql_stmt_init(mysql);
if (!stmt)
{
    fprintf(stderr, " mysql_stmt_init(), out of memory\n");
    exit(0);
}
if (mysql_stmt_prepare(stmt, INSERT_QUERY, strlen(INSERT_QUERY)))
{
    fprintf(stderr, "\n    mysql_stmt_prepare(), INSERT failed");
    fprintf(stderr, "\n    %s", mysql_stmt_error(stmt));
    exit(0);
}
memset(bind, 0, sizeof(bind));
bind[0].buffer_type= MYSQL_TYPE_STRING;
bind[0].length= &length;
bind[0].is_null= 0;
/* Bind the buffers */
if (mysql_stmt_bind_param(stmt, bind))
{
    fprintf(stderr, "\n    param bind failed");
    fprintf(stderr, "\n    %s", mysql_stmt_error(stmt));
    exit(0);
}
/* Supply data in chunks to server */
if (mysql_stmt_send_long_data(stmt,0,"MySQL",5))
{
    fprintf(stderr, "\n    send_long_data failed");
    fprintf(stderr, "\n    %s", mysql_stmt_error(stmt));
    exit(0);
}
/* Supply the next piece of data */
if (mysql_stmt_send_long_data(stmt,0,
    " - The most popular Open Source database",40))
{
    fprintf(stderr, "\n    send_long_data failed");
    fprintf(stderr, "\n    %s", mysql_stmt_error(stmt));
    exit(0);
}
/* Now, execute the query */
if (mysql_stmt_execute(stmt))
{
    fprintf(stderr, "\n    mysql_stmt_execute failed");
    fprintf(stderr, "\n    %s", mysql_stmt_error(stmt));
    exit(0);
}

20.6.11.26 mysql_stmt_sqlstate()

const char *mysql_stmt_sqlstate(MYSQL_STMT *stmt)

Description

For the statement specified by stmt, mysql_stmt_sqlstate() returns a null-terminated string containing the SQLSTATE error code for the most recently invoked prepared statement API function that can succeed or fail. The error code consists of five characters. "00000" means "no error." The values are specified by ANSI SQL and ODBC. For a list of possible values, see Appendix B, Errors, Error Codes, and Common Problems.

Not all MySQL errors are mapped to SQLSTATE codes. The value "HY000" (general error) is used for unmapped errors.
Return Values

A null-terminated character string containing the SQLSTATE error code.

20.6.11.27 mysql_stmt_store_result()

```c
int mysql_stmt_store_result(MYSQL_STMT *stmt)
```

Description

Result sets are produced by calling `mysql_stmt_execute()` to executed prepared statements for SQL statements such as `SELECT`, `SHOW`, `DESCRIBE`, and `EXPLAIN`. By default, result sets for successfully executed prepared statements are not buffered on the client and `mysql_stmt_fetch()` fetches them one at a time from the server. To cause the complete result set to be buffered on the client, call `mysql_stmt_store_result()` after binding data buffers with `mysql_stmt_bind_result()` and before calling `mysql_stmt_fetch()` to fetch rows. (For an example, see Section 20.6.11.11, “mysql_stmt_fetch()”.)

`mysql_stmt_store_result()` is optional for result set processing, unless you will call `mysql_stmt_data_seek()`, `mysql_stmt_row_seek()`, or `mysql_stmt_row_tell()`. Those functions require a seekable result set.

It is unnecessary to call `mysql_stmt_store_result()` after executing an SQL statement that does not produce a result set, but if you do, it does not harm or cause any notable performance problem. You can detect whether the statement produced a result set by checking if `mysql_stmt_result_metadata()` returns `NULL`. For more information, refer to Section 20.6.11.22, “mysql_stmt_result_metadata()”.

Note

MySQL does not by default calculate `MYSQL_FIELD->max_length` for all columns in `mysql_stmt_store_result()` because calculating this would slow down `mysql_stmt_store_result()` considerably and most applications do not need `max_length`. If you want `max_length` to be updated, you can call `mysql_stmt_attr_set(MYSQL_STMT, STMT_ATTR_UPDATE_MAX_LENGTH, &flag)` to enable this. See Section 20.6.11.3, “mysql_stmt_attr_set()”.

Return Values

Zero for success. Nonzero if an error occurred.

Errors

- **CR_COMMANDS_OUT_OF_SYNC**
  
  Commands were executed in an improper order.

- **CR_OUT_OF_MEMORY**
  
  Out of memory.

- **CR_SERVER_GONE_ERROR**
  
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  
  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
An unknown error occurred.

If the application is linked to the embedded server library, runtime error messages will indicate the libmysqld rather than libmysqlclient library, but the solution to the problem is the same as just described.

### 20.6.12 C API Threaded Function Descriptions

To create a threaded client, use the functions described in the following sections. See also Section 20.6.4.2, “Writing C API Threaded Client Programs”.

#### 20.6.12.1 my_init()

```c
void my_init(void)
```

**Description**

`my_init()` initializes some global variables that MySQL needs. If you are using a thread-safe client library, it also calls `mysql_thread_init()` for this thread.

It is necessary for `my_init()` to be called early in the initialization phase of a program's use of the MySQL library. However, `my_init()` is automatically called by `mysql_init()`, `mysql_library_init()`, `mysql_server_init()`, and `mysql_connect()`. If you ensure that your program invokes one of those functions before any other MySQL calls, there is no need to invoke `my_init()` explicitly.

To access the prototype for `my_init()`, your program should include these header files:

```c
#include <my_global.h>
#include <my_sys.h>
```

**Return Values**

None.

#### 20.6.12.2 mysql_thread_end()

```c
void mysql_thread_end(void)
```

**Description**

This function needs to be called before calling `pthread_exit()` to free memory allocated by `mysql_thread_init()`.

`mysql_thread_end()` is *not invoked automatically by the client library*. It must be called explicitly to avoid a memory leak.

**Return Values**

None.

#### 20.6.12.3 mysql_thread_init()

```c
my_bool mysql_thread_init(void)
```

**Description**

This function must be called early within each created thread to initialize thread-specific variables. However, you may not necessarily need to invoke it explicitly: `mysql_thread_init()` is automatically called by `my_init()`, which itself is automatically called by `mysql_init()`,
mysql_library_init(), mysql_server_init(), and mysql_connect(). If you invoke any of those functions, mysql_thread_init() will be called for you.

Return Values
Zero for success. Nonzero if an error occurred.

20.6.12.4 mysql_thread_safe()

unsigned int mysql_thread_safe(void)

Description
This function indicates whether the client library is compiled as thread-safe.

Return Values
1 if the client library is thread-safe, 0 otherwise.

20.6.13 C API Embedded Server Function Descriptions

MySQL applications can be written to use an embedded server. See Section 20.5, “libmysqld, the Embedded MySQL Server Library”. To write such an application, you must link it against the libmysqld library by using the -lmymysqld flag rather than linking it against the libmysqlclient client library by using the -lmysqlclient flag. However, the calls to initialize and finalize the library are the same whether you write a client application or one that uses the embedded server: Call mysql_library_init() to initialize the library and mysql_library_end() when you are done with it. See Section 20.6.6, “C API Function Overview”.

mysql_library_init() and mysql_library_end() are available as of MySQL 5.0.3. For earlier versions, call mysql_server_init() and mysql_server_end() instead, which are equivalent. mysql_library_init() and mysql_library_end() actually are #define symbols that make them equivalent to mysql_server_init() and mysql_server_end(), but the names more clearly indicate that they should be called when beginning and ending use of a MySQL C API library no matter whether the application uses libmysqlclient or libmysqld.

20.6.13.1 mysql_server_init()

int mysql_server_init(int argc, char **argv, char **groups)

Description
This function initializes the MySQL library, which must be done before you call any other MySQL function.

As of MySQL 5.0.3, mysql_server_init() is deprecated and you should call mysql_library_init() instead. See Section 20.6.40, “mysql_library_init()”.

Return Values
Zero for success. Nonzero if an error occurred.

20.6.13.2 mysql_server_end()

void mysql_server_end(void)

Description
This function finalizes the MySQL library. You should call it when you are done using the library.

As of MySQL 5.0.3, mysql_server_end() is deprecated and you should call mysql_library_end() instead. See Section 20.6.39, “mysql_library_end()”.
20.6.14 Why mysql_store_result() Sometimes Returns NULL After mysql_query() Returns Success

It is possible for mysql_store_result() to return NULL following a successful call to mysql_query(). When this happens, it means one of the following conditions occurred:

- There was a malloc() failure (for example, if the result set was too large).
- The data could not be read (an error occurred on the connection).
- The query returned no data (for example, it was an INSERT, UPDATE, or DELETE).

You can always check whether the statement should have produced a nonempty result by calling mysql_field_count(). If mysql_field_count() returns zero, the result is empty and the last query was a statement that does not return values (for example, an INSERT or a DELETE). If mysql_field_count() returns a nonzero value, the statement should have produced a nonempty result. See the description of the mysql_field_count() function for an example.

You can test for an error by calling mysql_error() or mysql_errno().

20.6.14.2 What Results You Can Get from a Query

In addition to the result set returned by a query, you can also get the following information:

- mysql_affected_rows() returns the number of rows affected by the last query when doing an INSERT, UPDATE, or DELETE.
  For a fast re-create, use TRUNCATE TABLE.
- mysql_num_rows() returns the number of rows in a result set. With mysql_store_result(), mysql_num_rows() may be called as soon as mysql_store_result() returns. With mysql_use_result(), mysql_num_rows() may be called only after you have fetched all the rows with mysql_fetch_row().
- mysql_insert_id() returns the ID generated by the last query that inserted a row into a table with an AUTO_INCREMENT index. See Section 20.6.7.37, “mysql_insert_id()”.
- Some queries (LOAD DATA INFILE ..., INSERT INTO ... SELECT ..., UPDATE) return additional information. The result is returned by mysql_info(). See the description for mysql_info() for the format of the string that it returns. mysql_info() returns a NULL pointer if there is no additional information.

20.6.14.3 How to Get the Unique ID for the Last Inserted Row

If you insert a record into a table that contains an AUTO_INCREMENT column, you can obtain the value stored into that column by calling the mysql_insert_id() function.

You can check from your C applications whether a value was stored in an AUTO_INCREMENT column by executing the following code (which assumes that you've checked that the statement succeeded). It determines whether the query was an INSERT with an AUTO_INCREMENT index:

```c
if ((result = mysql_store_result(&mysql)) == 0 &&
    mysql_field_count(&mysql) == 0 &&
    mysql_insert_id(&mysql) != 0) {
    used_id = mysql_insert_id(&mysql);
} else {
    used_id = -1;
}
```
When a new AUTO_INCREMENT value has been generated, you can also obtain it by executing a `SELECT LAST_INSERT_ID()` statement with `mysql_query()` and retrieving the value from the result set returned by the statement.

For `LAST_INSERT_ID()`, the most recently generated ID is maintained in the server on a per-connection basis. It is not changed by another client. It is not even changed if you update another AUTO_INCREMENT column with a nonmagic value (that is, a value that is not `NULL` and not `0`). Using `LAST_INSERT_ID()` and `AUTO_INCREMENT` columns simultaneously from multiple clients is perfectly valid. Each client will receive the last inserted ID for the last statement that client executed.

If you want to use the ID that was generated for one table and insert it into a second table, you can use SQL statements like this:

```sql
INSERT INTO foo (auto,text) VALUES(NULL,'text');  # generate ID by inserting NULL
INSERT INTO foo2 (id,text) VALUES(LAST_INSERT_ID(),'text');  # use ID in second table
```

`mysql_insert_id()` returns the value stored into an `AUTO_INCREMENT` column, whether that value is automatically generated by storing `NULL` or `0` or was specified as an explicit value. `LAST_INSERT_ID()` returns only automatically generated `AUTO_INCREMENT` values. If you store an explicit value other than `NULL` or `0`, it does not affect the value returned by `LAST_INSERT_ID()`.

For more information on obtaining the last ID in an `AUTO_INCREMENT` column:

- For information on `LAST_INSERT_ID()`, which can be used within an SQL statement, see Section 12.13, “Information Functions”.
- For information on `mysql_insert_id()`, the function you use from within the C API, see Section 20.6.7.37, “mysql_insert_id()”.
- For information on obtaining the auto-incremented value when using Connector/J, see Retrieving AUTO_INCREMENT Column Values through JDBC.
- For information on obtaining the auto-incremented value when using Connector/ODBC, see Obtaining Auto-Increment Values.

### 20.6.15 Controlling Automatic Reconnection Behavior

The MySQL client library can perform an automatic reconnection to the server if it finds that the connection is down when you attempt to send a statement to the server to be executed. If auto-reconnect is enabled, the library tries once to reconnect to the server and send the statement again.

If it is important for your application to know that the connection has been dropped (so that it can exit or take action to adjust for the loss of state information), be sure that auto-reconnect is disabled. To ensure this, call `mysql_options()` with the `MYSQL_OPT_RECONNECT` option:

```c
my_bool reconnect = 0;
mysql_options(&mysql, MYSQL_OPT_RECONNECT, &reconnect);
```

Auto-reconnect was enabled by default until MySQL 5.0.3, and disabled by default thereafter. The `MYSQL_OPT_RECONNECT` option is available as of MySQL 5.0.13.

If the connection has gone down, the effect of `mysql_ping()` depends on the auto-reconnect state. If auto-reconnect is enabled, `mysql_ping()` performs a reconnect. Otherwise, it returns an error.

Some client programs might provide the capability of controlling automatic reconnection. For example, `mysql` reconnects by default, but the `--skip-reconnect` option can be used to suppress this behavior.
If an automatic reconnection does occur (for example, as a result of calling `mysql_ping()`), there is no explicit indication of it. To check for reconnection, call `mysql_thread_id()` to get the original connection identifier before calling `mysql_ping()`, then call `mysql_thread_id()` again to see whether the identifier changed.

Automatic reconnection can be convenient because you need not implement your own reconnect code, but if a reconnection does occur, several aspects of the connection state are reset on the server side and your application will not be notified.

The connection-related state is affected as follows:

- Any active transactions are rolled back and autocommit mode is reset.
- All table locks are released.
- All TEMPORARY tables are closed (and dropped).
- Session system variables are reinitialized to the values of the corresponding global system variables, including system variables that are set implicitly by statements such as `SET NAMES`.
- User variable settings are lost.
- Prepared statements are released.
- HANDLER variables are closed.
- The value of `LAST_INSERT_ID()` is reset to 0.
- Locks acquired with `GET_LOCK()` are released.

If the connection drops, it is possible that the session associated with the connection on the server side will still be running if the server has not yet detected that the client is no longer connected. In this case, any locks held by the original connection still belong to that session, so you may want to kill it by calling `mysql_kill()`.

### 20.6.16 C API Support for Multiple Statement Execution

By default, `mysql_query()` and `mysql_real_query()` interpret their statement string argument as a single statement to be executed, and you process the result according to whether the statement produces a result set (a set of rows, as for `SELECT`) or an affected-rows count (as for `INSERT`, `UPDATE`, and so forth).

MySQL also supports the execution of a string containing multiple statements separated by semicolon (`;`) characters. This capability is enabled by special options that are specified either when you connect to the server with `mysql_real_connect()` or after connecting by calling `mysql_set_server_option()`.

Executing a multiple-statement string can produce multiple result sets or row-count indicators. Processing these results involves a different approach than for the single-statement case: After handling the result from the first statement, it is necessary to check whether more results exist and process them in turn if so. To support multiple-result processing, the C API includes the `mysql_more_results()` and `mysql_next_result()` functions. These functions are used at the end of a loop that iterates as long as more results are available. Failure to process the result this way may result in a dropped connection to the server.

Multiple-result processing also is required if you execute `CALL` statements for stored procedures. Results from a stored procedure have these characteristics:

- Statements within the procedure may produce result sets (for example, if it executes `SELECT` statements). These result sets are returned in the order that they are produced as the procedure executes.
In general, the caller cannot know how many result sets a procedure will return. Procedure execution may depend on loops or conditional statements that cause the execution path to differ from one call to the next. Therefore, you must be prepared to retrieve multiple results.

- The final result from the procedure is a status result that includes no result set. The status indicates whether the procedure succeeded or an error occurred.

The multiple statement and result capabilities can be used only with `mysql_query()` or `mysql_real_query()`. They cannot be used with the prepared statement interface. Prepared statement handles are defined to work only with strings that contain a single statement. See Section 20.6.8, “C API Prepared Statements”.

To enable multiple-statement execution and result processing, the following options may be used:

- The `mysql_real_connect()` function has a `flags` argument for which two option values are relevant:

  - `CLIENT_MULTI_RESULTS` enables the client program to process multiple results. This option must be enabled if you execute `CALL` statements for stored procedures that produce result sets. Otherwise, such procedures result in an error Error 1312 (0A000): PROCEDURE proc_name can't return a result set in the given context.

  - `CLIENT_MULTI_STATEMENTS` enables `mysql_query()` and `mysql_real_query()` to execute statement strings containing multiple statements separated by semicolons. This option also enables `CLIENT_MULTI_RESULTS` implicitly, so a `flags` argument of `CLIENT_MULTI_STATEMENTS` to `mysql_real_connect()` is equivalent to an argument of `CLIENT_MULTI_STATEMENTS | CLIENT_MULTI_RESULTS`. That is, `CLIENT_MULTI_STATEMENTS` is sufficient to enable multiple-statement execution and all multiple-result processing.

- After the connection to the server has been established, you can use the `mysql_set_server_option()` function to enable or disable multiple-statement execution by passing it an argument of `MYSQL_OPTION_MULTI_STATEMENTS_ON` or `MYSQL_OPTION_MULTI_STATEMENTS_OFF`. Enabling multiple-statement execution with this function also enables processing of “simple” results for a multiple-statement string where each statement produces a single result, but is not sufficient to permit processing of stored procedures that produce result sets.

The following procedure outlines a suggested strategy for handling multiple statements:

1. Pass `CLIENT_MULTI_STATEMENTS` to `mysql_real_connect()`, to fully enable multiple-statement execution and multiple-result processing.
2. After calling `mysql_query()` or `mysql_real_query()` and verifying that it succeeds, enter a loop within which you process statement results.
3. For each iteration of the loop, handle the current statement result, retrieving either a result set or an affected-rows count. If an error occurs, exit the loop.
4. At the end of the loop, call `mysql_next_result()` to check whether another result exists and initiate retrieval for it if so. If no more results are available, exit the loop.

One possible implementation of the preceding strategy is shown following. The final part of the loop can be reduced to a simple test of whether `mysql_next_result()` returns nonzero. The code as written distinguishes between no more results and an error, which enables a message to be printed for the latter occurrence.

```c
/* connect to server with the CLIENT_MULTI_STATEMENTS option */
if (mysql_real_connect (mysql, host_name, user_name, password,
    db_name, port_num, socket_name, CLIENT_MULTI_STATEMENTS) == NULL) {
```
printf("mysql_real_connect() failed\n");
mysql_close(mysql);
exit(1);
}

/* execute multiple statements */
status = mysql_query(mysql,
"DROP TABLE IF EXISTS test_table;
CREATE TABLE test_table(id INT);
INSERT INTO test_table VALUES(10);
UPDATE test_table SET id=20 WHERE id=10;
SELECT * FROM test_table;
DROP TABLE test_table");
if (status)
{
    printf("Could not execute statement(s)\n");
    mysql_close(mysql);
    exit(0);
}

/* process each statement result */
do {
    /* did current statement return data? */
    result = mysql_store_result(mysql);
    if (result)
    {
        /* yes; process rows and free the result set */
        process_result_set(mysql, result);
        mysql_free_result(result);
    }
    else  /* no result set or error */
    {
        if (mysql_field_count(mysql) == 0)
        {
            printf("%lld rows affected\n", mysql_affected_rows(mysql));
        }
        else  /* some error occurred */
        {
            printf("Could not retrieve result set\n");
            break;
        }
    }
    /* more results? -1 = no, >0 = error, 0 = yes (keep looping) */
    if ((status = mysql_next_result(mysql)) > 0)
    {
        printf("Could not execute statement\n");
    }
}
while (status == 0);
mysql_close(mysql);

20.6.17 C API Prepared Statement Problems

Here follows a list of the currently known problems with prepared statements:

• **TIME, TIMESTAMP, and DATETIME** do not support parts of seconds (for example, from DATE_FORMAT()).

• When converting an integer to string, **ZEROFILL** is honored with prepared statements in some cases where the MySQL server does not print the leading zeros. (For example, with MIN(number-with-zerofill)).

• When converting a floating-point number to a string in the client, the rightmost digits of the converted value may differ slightly from those of the original value.

• **Prepared statements do not use the query cache, even in cases where a query does not contain any placeholders.** See Section 8.10.3.1, “How the Query Cache Operates”.

• Prepared statements do not support multi-statements (that is, multiple statements within a single string separated by ; characters).
• In MySQL 5.0, prepared CALL statements cannot invoke stored procedures that return result sets because prepared statements do not support multiple result sets. Nor can the calling application access a stored procedure's OUT or INOUT parameters when the procedure returns. These capabilities are supported beginning with MySQL 5.5.

### 20.6.18 C API Prepared Statement Handling of Date and Time Values

The binary (prepared statement) protocol enables you to send and receive date and time values (DATE, TIME, DATETIME, and TIMESTAMP), using the MYSQL_TIME structure. The members of this structure are described in [Section 20.6.9, "C API Prepared Statement Data Structures"].

To send temporal data values, create a prepared statement using `mysql_stmt_prepare()`. Then, before calling `mysql_stmt_execute()` to execute the statement, use the following procedure to set up each temporal parameter:

1. In the MYSQL_BIND structure associated with the data value, set the buffer_type member to the type that indicates what kind of temporal value you're sending. For DATE, TIME, DATETIME, or TIMESTAMP values, set buffer_type to MYSQL_TYPE_DATE, MYSQL_TYPE_TIME, MYSQL_TYPE_DATETIME, or MYSQL_TYPE_TIMESTAMP, respectively.

2. Set the buffer member of the MYSQL_BIND structure to the address of the MYSQL_TIME structure in which you pass the temporal value.

3. Fill in the members of the MYSQL_TIME structure that are appropriate for the type of temporal value to pass.

Use `mysql_stmt_bind_param()` to bind the parameter data to the statement. Then you can call `mysql_stmt_execute()`.

To retrieve temporal values, the procedure is similar, except that you set the buffer_type member to the type of value you expect to receive, and the buffer member to the address of a MYSQL_TIME structure into which the returned value should be placed. Use `mysql_stmt_bind_result()` to bind the buffers to the statement after calling `mysql_stmt_execute()` and before fetching the results.

Here is a simple example that inserts DATE, TIME, and TIMESTAMP data. The mysql variable is assumed to be a valid connection handle.

```c
MYSQL_TIME  ts;
MYSQL_BIND  bind[3];

### 20.6.19 C API Support for Prepared CALL Statements

In MySQL 5.0, prepared CALL statements can be used only for stored procedures that produce at most one result set. Nor can the calling application use placeholders for OUT or INOUT parameters.

MySQL 5.5 expands prepared CALL statement support for stored procedures that produce multiple result sets and to provide placeholder access to OUT and INOUT parameters.

### 20.7 MySQL PHP API

The MySQL PHP API manual is now published in standalone form, not as part of the MySQL Reference Manual. See MySQL and PHP.

### 20.8 MySQL Perl API

The Perl DBI module provides a generic interface for database access. You can write a DBI script that works with many different database engines without change. To use DBI with MySQL, install the following:

1. The DBI module.
2. The DBD::mysql module. This is the DataBase Driver (DBD) module for Perl.
3. Optionally, the DBD module for any other type of database server you want to access.

Perl DBI is the recommended Perl interface. It replaces an older interface called mysqlperl, which should be considered obsolete.

These sections contain information about using Perl with MySQL and writing MySQL applications in Perl:

- For installation instructions for Perl DBI support, see Section 2.22, “Perl Installation Notes”.
- For an example of reading options from option files, see Section 5.5.4, “Using Client Programs in a Multiple-Server Environment”.
- For secure coding tips, see Section 6.1.1, “Security Guidelines”.
- For debugging tips, see Section 21.3.1.4, “Debugging mysqld under gdb”.
- For some Perl-specific environment variables, see Section 2.21, “Environment Variables”.
- For considerations for running on OS X, see Section 2.11, “Installing MySQL on OS X”.
- For ways to quote string literals, see Section 9.1.1, “String Literals”.
DBI information is available at the command line, online, or in printed form:

- Once you have the DBI and DBD::mysql modules installed, you can get information about them at the command line with the perldoc command:

```bash
shell> perldoc DBI
shell> perldoc DBI::FAQ
shell> perldoc DBD::mysql
```

You can also use pod2man, pod2html, and so on to translate this information into other formats.

- For online information about Perl DBI, visit the DBI Web site, http://dbi.perl.org/. That site hosts a general DBI mailing list. Oracle Corporation hosts a list specifically about DBD::mysql; see Section 1.6.1, “MySQL Mailing Lists”.

### 20.9 MySQL Python API

MySQLdb is a third-party driver that provides MySQL support for Python, compliant with the Python DB API version 2.0. It can be found at http://sourceforge.net/projects/mysql-python/.

The new MySQL Connector/Python component provides an interface to the same Python API, and is built into the MySQL Server and supported by Oracle. See MySQL Connector/Python Developer Guide for details on the Connector, as well as coding guidelines for Python applications and sample Python code.

### 20.10 MySQL Ruby APIs

Two APIs are available for Ruby programmers developing MySQL applications:

- The MySQL/Ruby API is based on the libmysqlclient API library. For information on installing and using the MySQL/Ruby API, see Section 20.10.1, “The MySQL/Ruby API”.

- The Ruby/MySQL API is written to use the native MySQL network protocol (a native driver). For information on installing and using the Ruby/MySQL API, see Section 20.10.2, “The Ruby/MySQL API”.

For background and syntax information about the Ruby language, see Ruby Programming Language.

#### 20.10.1 The MySQL/Ruby API

The MySQL/Ruby module provides access to MySQL databases using Ruby through libmysqlclient.

For information on installing the module, and the functions exposed, see MySQL/Ruby.

#### 20.10.2 The Ruby/MySQL API

The Ruby/MySQL module provides access to MySQL databases using Ruby through a native driver interface using the MySQL network protocol.

For information on installing the module, and the functions exposed, see Ruby/MySQL.

### 20.11 MySQL Tcl API
MySQLtcl is a simple API for accessing a MySQL database server from the Tcl programming language. It can be found at http://www.xdobry.de/mysqltcl/.

20.12 MySQL Eiffel Wrapper

Eiffel MySQL is an interface to the MySQL database server using the Eiffel programming language, written by Michael Ravits. It can be found at http://efsa.sourceforge.net/archive/ravits/mysql.htm.

21.1 MySQL Internals

This chapter describes a lot of things that you need to know when working on the MySQL code. To track or contribute to MySQL development, follow the instructions in Section 2.17.2, “Installing MySQL Using a Development Source Tree”. If you are interested in MySQL internals, you should also subscribe to our internals mailing list. This list has relatively low traffic. For details on how to subscribe, please see Section 1.6.1, “MySQL Mailing Lists”. Many MySQL developers at Oracle Corporation are on the internals list and we help other people who are working on the MySQL code. Feel free to use this list both to ask questions about the code and to send patches that you would like to contribute to the MySQL project!

21.1.1 MySQL Threads

The MySQL server creates the following threads:

• Connection manager threads handle client connection requests on the network interfaces that the server listens to. On all platforms, one manager thread handles TCP/IP connection requests. On Unix, this manager thread also handles Unix socket file connection requests. On Windows, a manager thread handles shared-memory connection requests, and another handles named-pipe connection requests. The server does not create threads to handle interfaces that it does not listen to. For example, a Windows server that does not have support for named-pipe connections enabled does not create a thread to handle them.

• Connection manager threads associate each client connection with a thread dedicated to it that handles authentication and request processing for that connection. Manager threads create a new thread when necessary but try to avoid doing so by consulting the thread cache first to see whether it contains a thread that can be used for the connection. When a connection ends, its thread is returned to the thread cache if the cache is not full.

   For information about tuning the parameters that control thread resources, see Section 8.12.6.1, “How MySQL Uses Threads for Client Connections”.

• On a master replication server, connections from slave servers are handled like client connections: There is one thread per connected slave.

• On a slave replication server, an I/O thread is started to connect to the master server and read updates from it. An SQL thread is started to apply updates read from the master. These two threads run independently and can be started and stopped independently.

• A signal thread handles all signals. This thread also normally handles alarms and calls process_alarm() to force timeouts on connections that have been idle too long.
• If InnoDB is used, there will be 4 additional threads by default. Those are file I/O threads, controlled by the `innodb_file_io_threads` parameter. See Section 14.2.2, “InnoDB Startup Options and System Variables”.

• If mysqld is compiled with `-DUSE_ALARM_THREAD`, a dedicated thread that handles alarms is created. This is only used on some systems where there are problems with `sigwait()` or if you want to use the `thr_alarm()` code in your application without a dedicated signal handling thread.

• If the server is started with the `--flush_time=VAL` option, a dedicated thread is created to flush all tables every `VAL` seconds.

• Each table for which `INSERT DELAYED` statements are issued gets its own thread. See Section 13.2.5.2, “INSERT DELAYED Syntax”.

`mysqladmin processlist` only shows the connection, `INSERT DELAYED`, and replication threads.

### 21.1.2 The MySQL Test Suite

The test system that is included in Unix source and binary distributions makes it possible for users and developers to perform regression tests on the MySQL code. These tests can be run on Unix.

You can also write your own test cases. For information about the MySQL Test Framework, including system requirements, see the manual available at http://dev.mysql.com/doc/mysqltest/2.0/en/.

The current set of test cases doesn't test everything in MySQL, but it should catch most obvious bugs in the SQL processing code, operating system or library issues, and is quite thorough in testing replication. Our goal is to have the tests cover 100% of the code. We welcome contributions to our test suite. You may especially want to contribute tests that examine the functionality critical to your system because this ensures that all future MySQL releases work well with your applications.

The test system consists of a test language interpreter (`mysqltest`), a Perl script to run all tests (`mysql-test-run.pl`), the actual test cases written in a special test language, and their expected results. To run the test suite on your system after a build, type `make test` from the source root directory, or change location to the `mysql-test` directory and type `./mysql-test-run.pl`. If you have installed a binary distribution, change location to the `mysql-test` directory under the installation root directory (for example, `/usr/local/mysql/mysql-test`), and run `./mysql-test-run.pl`. All tests should succeed. If any do not, feel free to try to find out why and report the problem if it indicates a bug in MySQL. See Section 1.7, “How to Report Bugs or Problems”.

If one test fails, you should run `mysql-test-run.pl` with the `--force` option to check whether any other tests fail.

If you have a copy of `mysqld` running on the machine where you want to run the test suite, you do not have to stop it, as long as it is not using ports 9306 or 9307. If either of those ports is taken, you should set the `MTR_BUILD_THREAD` environment variable to an appropriate value, and the test suite will use a different set of ports for master, slave, NDB, and Instance Manager). For example:

```shell
shell> export MTR_BUILD_THREAD=31
shell> ./mysql-test-run.pl [options] [test_name]
```

In the `mysql-test` directory, you can run an individual test case with `./mysql-test-run.pl test_name`.

If you have a question about the test suite, or have a test case to contribute, send an email message to the MySQL internals mailing list. See Section 1.6.1, “MySQL Mailing Lists”.

### 21.2 Adding New Functions to MySQL

There are three ways to add new functions to MySQL:

- You can add functions through the user-defined function (UDF) interface. User-defined functions are compiled as object files and then added to and removed from the server dynamically using the
CREATE FUNCTION and DROP FUNCTION statements. See Section 13.7.3.1, “CREATE FUNCTION Syntax for User-defined Functions”.

- You can add functions as native (built-in) MySQL functions. Native functions are compiled into the mysqld server and become available on a permanent basis.

- Another way to add functions is by creating stored functions. These are written using SQL statements rather than by compiling object code. The syntax for writing stored functions is not covered here. See Section 18.2, “Using Stored Routines (Procedures and Functions)”.

Each method of creating compiled functions has advantages and disadvantages:

- If you write user-defined functions, you must install object files in addition to the server itself. If you compile your function into the server, you don't need to do that.

- Native functions require you to modify a source distribution. UDFs do not. You can add UDFs to a binary MySQL distribution. No access to MySQL source is necessary.

- If you upgrade your MySQL distribution, you can continue to use your previously installed UDFs, unless you upgrade to a newer version for which the UDF interface changes. For native functions, you must repeat your modifications each time you upgrade.

Whichever method you use to add new functions, they can be invoked in SQL statements just like native functions such as ABS() or SOUNDEX().

See Section 9.2.3, “Function Name Parsing and Resolution”, for the rules describing how the server interprets references to different kinds of functions.

The following sections describe features of the UDF interface, provide instructions for writing UDFs, discuss security precautions that MySQL takes to prevent UDF misuse, and describe how to add native MySQL functions.

For example source code that illustrates how to write UDFs, take a look at the sql/udf_example.c file that is provided in MySQL source distributions.

### 21.2.1 Features of the User-Defined Function Interface

The MySQL interface for user-defined functions provides the following features and capabilities:

- Functions can return string, integer, or real values and can accept arguments of those same types.

- You can define simple functions that operate on a single row at a time, or aggregate functions that operate on groups of rows.

- Information is provided to functions that enables them to check the number, types, and names of the arguments passed to them.

- You can tell MySQL to coerce arguments to a given type before passing them to a function.

- You can indicate that a function returns NULL or that an error occurred.

### 21.2.2 Adding a New User-Defined Function

For the UDF mechanism to work, functions must be written in C or C++ and your operating system must support dynamic loading. MySQL source distributions include a file sql/udf_example.c that defines five UDF functions. Consult this file to see how UDF calling conventions work. The include/mysql_com.h header file defines UDF-related symbols and data structures, although you need not include this header file directly; it is included by mysql.h.

A UDF contains code that becomes part of the running server, so when you write a UDF, you are bound by any and all constraints that apply to writing server code. For example, you may have problems if you attempt to use functions from the libstdc++ library. Note that these constraints may change in future versions of the server, so it is possible that server upgrades will require revisions
Adding a New User-Defined Function

to UDFs that were originally written for older servers. For information about these constraints, see Section 2.17.3, "MySQL Source-Configuration Options", and Section 2.17.4, "Dealing with Problems Compiling MySQL".

To be able to use UDFs, you must link mysqld dynamically. Don't configure MySQL using --with-mysqld-ldflags=-all-static. If you want to use a UDF that needs to access symbols from mysqld (for example, the metaphone function in sql/udf_example.c uses default_charset_info), you must link the program with -rdynamic (see man dlopen). If you plan to use UDFs, the rule of thumb is to configure MySQL with --with-mysqld-ldflags=-rdynamic unless you have a very good reason not to.

For each function that you want to use in SQL statements, you should define corresponding C (or C++) functions. In the following discussion, the name “xxx” is used for an example function name. To distinguish between SQL and C/C++ usage, XXX() (uppercase) indicates an SQL function call, and xxx() (lowercase) indicates a C/C++ function call.

Note
When using C++ you can encapsulate your C functions within:

extern "C" { ...
}

This ensures that your C++ function names remain readable in the completed UDF.

The following list describes the C/C++ functions that you write to implement the interface for a function named XXX(). The main function, xxx(), is required. In addition, a UDF requires at least one of the other functions described here, for reasons discussed in Section 21.2.2.6, "UDF Security Precautions".

• xxx()

The main function. This is where the function result is computed. The correspondence between the SQL function data type and the return type of your C/C++ function is shown here.

<table>
<thead>
<tr>
<th>SQL Type</th>
<th>C/C++ Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>STRING</td>
<td>char *</td>
</tr>
<tr>
<td>INTEGER</td>
<td>long long</td>
</tr>
<tr>
<td>REAL</td>
<td>double</td>
</tr>
</tbody>
</table>

It is also possible to declare a DECIMAL function, but currently the value is returned as a string, so you should write the UDF as though it were a STRING function. ROW functions are not implemented.

• xxx_init()

The initialization function for xxx(). If present, it can be used for the following purposes:

• To check the number of arguments to XXX().

• To verify that the arguments are of a required type or, alternatively, to tell MySQL to coerce arguments to the required types when the main function is called.

• To allocate any memory required by the main function.

• To specify the maximum length of the result.

• To specify (for REAL functions) the maximum number of decimal places in the result.

• To specify whether the result can be NULL.

• xxx_deinit()
Adding a New User-Defined Function

The deinitialization function for xxx(). If present, it should deallocate any memory allocated by the initialization function.

When an SQL statement invokes XXX(), MySQL calls the initialization function xxx_init() to let it perform any required setup, such as argument checking or memory allocation. If xxx_init() returns an error, MySQL aborts the SQL statement with an error message and does not call the main or deinitialization functions. Otherwise, MySQL calls the main function xxx() once for each row. After all rows have been processed, MySQL calls the deinitialization function xxx_deinit() so that it can perform any required cleanup.

For aggregate functions that work like SUM(), you must also provide the following functions:

- xxx_clear()

  Reset the current aggregate value but do not insert the argument as the initial aggregate value for a new group.

- xxx_add()

  Add the argument to the current aggregate value.

MySQL handles aggregate UDFs as follows:

1. Call xxx_init() to let the aggregate function allocate any memory it needs for storing results.
2. Sort the table according to the GROUP BY expression.
3. Call xxx_clear() for the first row in each new group.
4. Call xxx_add() for each row that belongs in the same group.
5. Call xxx() to get the result for the aggregate when the group changes or after the last row has been processed.
6. Repeat steps 3 to 5 until all rows has been processed
7. Call xxx_deinit() to let the UDF free any memory it has allocated.

All functions must be thread-safe. This includes not just the main function, but the initialization and deinitialization functions as well, and also the additional functions required by aggregate functions. A consequence of this requirement is that you are not permitted to allocate any global or static variables that change! If you need memory, you should allocate it in xxx_init() and free it in xxx_deinit().

21.2.2.1 UDF Calling Sequences for Simple Functions

This section describes the different functions that you need to define when you create a simple UDF. Section 21.2.2, “Adding a New User-Defined Function”, describes the order in which MySQL calls these functions.

The main xxx() function should be declared as shown in this section. Note that the return type and parameters differ, depending on whether you declare the SQL function XXX() to return STRING, INTEGER, or REAL in the CREATE FUNCTION statement:

For STRING functions:

```c
char *xxx(UDF_INIT *initid, UDF_ARGS *args, char *result, unsigned long *length, char *is_null, char *error);
```

For INTEGER functions:

```c
long long xxx(UDF_INIT *initid, UDF_ARGS *args, char *is_null, char *error);
```
For **REAL** functions:

```c
double xxx(UDF_INIT *initid, UDF_ARGS *args,
           char *is_null, char *error);
```

**DECIMAL** functions return string values and should be declared the same way as **STRING** functions. **ROW** functions are not implemented.

The initialization and deinitialization functions are declared like this:

```c
my_bool xxx_init(UDF_INIT *initid, UDF_ARGS *args, char *message);
void xxx_deinit(UDF_INIT *initid);
```

The `initid` parameter is passed to all three functions. It points to a `UDF_INIT` structure that is used to communicate information between functions. The `UDF_INIT` structure members follow. The initialization function should fill in any members that it wishes to change. (To use the default for a member, leave it unchanged.)

- **my_bool maybe_null**

  `xxx_init()` should set `maybe_null` to 1 if `xxx()` can return `NULL`. The default value is 1 if any of the arguments are declared `maybe_null`.

- **unsigned int decimals**

  The number of decimal digits to the right of the decimal point. The default value is the maximum number of decimal digits in the arguments passed to the main function. For example, if the function is passed `1.34`, `1.345`, and `1.3`, the default would be 3, because `1.345` has 3 decimal digits.

  For arguments that have no fixed number of decimals, the `decimals` value is set to 31, which is 1 more than the maximum number of decimals permitted for the **DECIMAL**, **FLOAT**, and **DOUBLE** data types.

  A `decimals` value of 31 is used for arguments in cases such as a **FLOAT** or **DOUBLE** column declared without an explicit number of decimals (for example, **FLOAT** rather than **FLOAT(10,3)**) and for floating-point constants such as `1345E-3`. It is also used for string and other nonnumber arguments that might be converted within the function to numeric form.

  The value to which the `decimals` member is initialized is only a default. It can be changed within the function to reflect the actual calculation performed. The default is determined such that the largest number of decimals of the arguments is used. If the number of decimals is 31 for even one of the arguments, that is the value used for `decimals`.

- **unsigned int max_length**

  The maximum length of the result. The default `max_length` value differs depending on the result type of the function. For string functions, the default is the length of the longest argument. For integer functions, the default is 21 digits. For real functions, the default is 13 plus the number of decimal digits indicated by `initid->decimals`. (For numeric functions, the length includes any sign or decimal point characters.)

  If you want to return a blob value, you can set `max_length` to 65KB or 16MB. This memory is not allocated, but the value is used to decide which data type to use if there is a need to temporarily store the data.

- **char *ptr**

  A pointer that the function can use for its own purposes. For example, functions can use `initid->ptr` to communicate allocated memory among themselves. `xxx_init()` should allocate the memory and assign it to this pointer.
Adding a New User-Defined Function

```c
initid->ptr = allocated_memory;
```

In `xxx()` and `xxx_deinit()`, refer to `initid->ptr` to use or deallocate the memory.

- `my_bool const_item`

  `xxx_init()` should set `const_item` to 1 if `xxx()` always returns the same value and to 0 otherwise.

### 21.2.2.2 UDF Calling Sequences for Aggregate Functions

This section describes the different functions that you need to define when you create an aggregate UDF. Section 21.2.2, “Adding a New User-Defined Function”, describes the order in which MySQL calls these functions.

- `xxx_reset()`

  This function is called when MySQL finds the first row in a new group. It should reset any internal summary variables and then use the given `UDF_ARGS` argument as the first value in your internal summary value for the group. Declare `xxx_reset()` as follows:

  ```c
  void xxx_reset(UDF_INIT *initid, UDF_ARGS *args, char *is_null, char *error);
  ```

  `xxx_reset()` is not needed or used in MySQL 5.0, in which the UDF interface uses `xxx_clear()` instead. However, you can define both `xxx_reset()` and `xxx_clear()` if you want to have your UDF work with older versions of the server. (If you do include both functions, the `xxx_reset()` function in many cases can be implemented internally by calling `xxx_clear()` to reset all variables, and then calling `xxx_add()` to add the `UDF_ARGS` argument as the first value in the group.)

- `xxx_clear()`

  This function is called when MySQL needs to reset the summary results. It is called at the beginning for each new group but can also be called to reset the values for a query where there were no matching rows. Declare `xxx_clear()` as follows:

  ```c
  void xxx_clear(UDF_INIT *initid, char *is_null, char *error);
  ```

  `is_null` is set to point to `CHAR(0)` before calling `xxx_clear()`.

  If something went wrong, you can store a value in the variable to which the `error` argument points. `error` points to a single-byte variable, not to a string buffer.

  `xxx_clear()` is required by MySQL 5.0.

- `xxx_add()`

  This function is called for all rows that belong to the same group. You should use it to add the value in the `UDF_ARGS` argument to your internal summary variable.

  ```c
  void xxx_add(UDF_INIT *initid, UDF_ARGS *args, char *is_null, char *error);
  ```

  The `xxx()` function for an aggregate UDF should be declared the same way as for a nonaggregate UDF. See Section 21.2.2.1, “UDF Calling Sequences for Simple Functions”.

For an aggregate UDF, MySQL calls the `xxx()` function after all rows in the group have been processed. You should normally never access its `UDF_ARGS` argument here but instead return a value based on your internal summary variables.
Return value handling in \texttt{xxx()} should be done the same way as for a nonaggregate UDF. See Section 21.2.2.4, "UDF Return Values and Error Handling".

The \texttt{xxx_reset()} and \texttt{xxx_add()} functions handle their \texttt{UDF_ARGS} argument the same way as functions for nonaggregate UDFs. See Section 21.2.2.3, "UDF Argument Processing".

The pointer arguments to \texttt{is_null} and \texttt{error} are the same for all calls to \texttt{xxx_reset()}, \texttt{xxx_clear()}, \texttt{xxx_add()} and \texttt{xxx()}. You can use this to remember that you got an error or whether the \texttt{xxx()} function should return \texttt{NULL}. You should not store a string into \texttt{*error}. You should not store a string into \texttt{*error}! \texttt{error} points to a single-byte variable, not to a string buffer.

\texttt{*is_null} is reset for each group (before calling \texttt{xxx_clear()}). \texttt{*error} is never reset.

If \texttt{*is_null} or \texttt{*error} are set when \texttt{xxx()} returns, MySQL returns \texttt{NULL} as the result for the group function.

### 21.2.2.3 UDF Argument Processing

The \texttt{args} parameter points to a \texttt{UDF_ARGS} structure that has the members listed here:

- \texttt{unsigned int arg_count}
  
  The number of arguments. Check this value in the initialization function if you require your function to be called with a particular number of arguments. For example:

  ```c
  if (args->arg_count != 2)
  {
      strcpy(message,"XXX() requires two arguments");
      return 1;
  }
  ```

  For other \texttt{UDF_ARGS} member values that are arrays, array references are zero-based. That is, refer to array members using index values from 0 to \texttt{args->arg_count} − 1.

- \texttt{enum Item_result *arg_type}
  
  A pointer to an array containing the types for each argument. The possible type values are \texttt{STRING_RESULT}, \texttt{INT_RESULT}, \texttt{REAL_RESULT}, and \texttt{DECIMAL_RESULT}.

  To make sure that arguments are of a given type and return an error if they are not, check the \texttt{arg_type} array in the initialization function. For example:

  ```c
  if (args->arg_type[0] != STRING_RESULT ||
      args->arg_type[1] != INT_RESULT)
  {
      strcpy(message,"XXX() requires a string and an integer");
      return 1;
  }
  ```

  Arguments of type \texttt{DECIMAL_RESULT} are passed as strings, so you should handle them the same way as \texttt{STRING_RESULT} values.

  As an alternative to requiring your function's arguments to be of particular types, you can use the initialization function to set the \texttt{arg_type} elements to the types you want. This causes MySQL to coerce arguments to those types for each call to \texttt{xxx()}. For example, to specify that the first two arguments should be coerced to string and integer, respectively, do this in \texttt{xxx_init()}:

  ```c
  args->arg_type[0] = STRING_RESULT;
  args->arg_type[1] = INT_RESULT;
  ```
Exact-value decimal arguments such as 1.3 or DECIMAL column values are passed with a type of DECIMAL_RESULT. However, the values are passed as strings. If you want to receive a number, use the initialization function to specify that the argument should be coerced to a REAL_RESULT value:

```c
args->arg_type[2] = REAL_RESULT;
```

**Note**

Prior to MySQL 5.0.3, decimal arguments were passed as REAL_RESULT values. If you upgrade to a newer version and find that your UDF now receives string values, use the initialization function to coerce the arguments to numbers as just described.

- **char **args**

  `args->args` communicates information to the initialization function about the general nature of the arguments passed to your function. For a constant argument `i`, `args->args[i]` points to the argument value. (See below for instructions on how to access the value properly.) For a nonconstant argument, `args->args[i]` is 0. A constant argument is an expression that uses only constants, such as 3 or 4*7-2 or SIN(3.14). A nonconstant argument is an expression that refers to values that may change from row to row, such as column names or functions that are called with nonconstant arguments.

For each invocation of the main function, `args->args` contains the actual arguments that are passed for the row currently being processed.

If argument `i` represents NULL, `args->args[i]` is a null pointer (0). If the argument is not NULL, functions can refer to it as follows:

- An argument of type STRING_RESULT is given as a string pointer plus a length, to enable handling of binary data or data of arbitrary length. The string contents are available as `args->args[i]` and the string length is `args->lengths[i]`. Do not assume that the string is null-terminated.

- For an argument of type INT_RESULT, you must cast `args->args[i]` to a `long long` value:

  ```c
  long long int_val;
  int_val = *((long long*) args->args[i]);
  ```

- For an argument of type REAL_RESULT, you must cast `args->args[i]` to a `double` value:

  ```c
  double    real_val;
  real_val = *((double*) args->args[i]);
  ```

- For an argument of type DECIMAL_RESULT, the value is passed as a string and should be handled like a STRING_RESULT value.

- ROW_RESULT arguments are not implemented.

- **unsigned long **lengths**

  For the initialization function, the `lengths` array indicates the maximum string length for each argument. You should not change these. For each invocation of the main function, `lengths` contains the actual lengths of any string arguments that are passed for the row currently being processed. For arguments of types INT_RESULT or REAL_RESULT, `lengths` still contains the maximum length of the argument (as for the initialization function).

- **char **maybe_null**
For the initialization function, the `maybe_null` array indicates for each argument whether the argument value might be null (0 if no, 1 if yes).

- `char **attributes`

  `args->attributes` communicates information about the names of the UDF arguments. For argument `i`, the attribute name is available as a string in `args->attributes[i]` and the attribute length is `args->attribute_lengths[i]`. Do not assume that the string is null-terminated.

  By default, the name of a UDF argument is the text of the expression used to specify the argument. For UDFs, an argument may also have an optional `[AS] alias_name clause, in which case the argument name is `alias_name`. The `attributes` value for each argument thus depends on whether an alias was given.

  Suppose that a UDF `my_udf()` is invoked as follows:

  ```sql
  SELECT my_udf(expr1, expr2 AS alias1, expr3 alias2);
  ```

  In this case, the `attributes` and `attribute_lengths` arrays will have these values:

  ```c
  args->attributes[0] = "expr1"
  args->attribute_lengths[0] = 5
  args->attributes[1] = "alias1"
  args->attribute_lengths[1] = 6
  args->attributes[2] = "alias2"
  args->attribute_lengths[2] = 6
  ```

- `unsigned long *attribute_lengths`

  The `attribute_lengths` array indicates the length of each argument name.

### 21.2.2.4 UDF Return Values and Error Handling

The initialization function should return 0 if no error occurred and 1 otherwise. If an error occurs, `xxx_init()` should store a null-terminated error message in the `message` parameter. The message is returned to the client. The message buffer is `MYSQL_ERRMSG_SIZE` characters long, but you should try to keep the message to less than 80 characters so that it fits the width of a standard terminal screen.

The return value of the main function `xxx()` is the function value, for `long long` and `double` functions. A string function should return a pointer to the result and set `*length` to the length (in bytes) of the return value. For example:

```c
memcpy(result, "result string", 13);
*length = 13;
```

MySQL passes a buffer to the `xxx()` function using the `result` parameter. This buffer is sufficiently long to hold 255 characters, which can be multibyte characters. The `xxx()` function can store the result in this buffer if it fits, in which case the return value should be a pointer to the buffer. If the function stores the result in a different buffer, it should return a pointer to that buffer.

If your string function does not use the supplied buffer (for example, if it needs to return a string longer than 255 characters), you must allocate the space for your own buffer with `malloc()` in your `xxx_init()` function or your `xxx()` function and free it in your `xxx_deinit()` function. You can store the allocated memory in the `ptr` slot in the `UDF_INIT` structure for reuse by future `xxx()` calls. See Section 21.2.2.1, “UDF Calling Sequences for Simple Functions”.

To indicate a return value of `NULL` in the main function, set `*is_null` to 1:
Adding a New User-Defined Function

This documentation is for an older version. If you're using the most current version, select the documentation for that version with the version switch in the upper right corner of the online documentation, or by downloading a newer PDF or EPUB file.

```c
*is_null = 1;

To indicate an error return in the main function, set *error to 1:

*error = 1;

If xxx() sets *error to 1 for any row, the function value is NULL for the current row and for any subsequent rows processed by the statement in which XXX() was invoked. (xxx() is not even called for subsequent rows.)
```

### 21.2.2.5 UDF Compiling and Installing

Files implementing UDFs must be compiled and installed on the host where the server runs. This process is described below for the example UDF file `sql/udf_example.c` that is included in the MySQL source distribution.

If a UDF will be referred to in statements that will be replicated to slave servers, you must ensure that every slave also has the function available. Otherwise, replication will fail on the slaves when they attempt to invoke the function.

The immediately following instructions are for Unix. Instructions for Windows are given later in this section.

The `udf_example.c` file contains the following functions:

- `metaphon()` returns a metaphon string of the string argument. This is something like a soundex string, but it is more tuned for English.
- `myfunc_double()` returns the sum of the ASCII values of the characters in its arguments, divided by the sum of the length of its arguments.
- `myfunc_int()` returns the sum of the length of its arguments.
- `sequence([const int])` returns a sequence starting from the given number or 1 if no number has been given.
- `lookup()` returns the IP address for a host name.
- `reverse_lookup()` returns the host name for an IP address. The function may be called either with a single string argument of the form `'xxx.xxx.xxx.xxx'` or with four numbers.
- `avgcost()` returns an average cost. This is an aggregate function.

A dynamically loadable file should be compiled as a sharable object file, using a command something like this:

```bash
shell> gcc -shared -o udf_example.so udf_example.c
```

If you are using `gcc` with `configure` and `libtool` (which is how MySQL is configured), you should be able to create `udf_example.so` with a simpler command:

```bash
shell> make udf_example.la
```

After you compile a shared object containing UDFs, you must install it and tell MySQL about it. Compiling a shared object from `udf_example.c` using `gcc` directly produces a file named `udf_example.so`. Compiling the shared object using `make` produces a file named something like `udf_example.so.0.0.0` in the `.libs` directory (the exact name may vary from platform to platform).

As of MySQL 5.0.67, copy the shared object to server's plugin directory and name it `udf_example.so`. This directory is given by the value of the `plugin_dir` system variable.
Prior to MySQL 5.0.67, or if the value of plugin_dir is empty, the shared object should be placed in a directory such as /usr/lib that is searched by your system's dynamic (runtime) linker, or you can add the directory in which you place the shared object to the linker configuration file (for example, /etc/ld.so.conf).

On many systems, you can also set the LD_LIBRARY or LD_LIBRARY_PATH environment variable to point to the directory where you have the files for your UDF. You should set the variable in mysql.server or mysqld_safe startup scripts and restart mysqld. You might do this if you want to place the object file in a directory accessible only to the server and not in a public directory. The dlopen manual page tells you which variable to use on your system.

The dynamic linker name is system-specific (for example, ld-elf.so.1 on FreeBSD, ld.so on Linux, or dyld on OS X). Consult your system documentation for information about the linker name and how to configure it.

On some systems, the ldconfig program that configures the dynamic linker does not recognize a shared object unless its name begins with lib. In this case you should rename a file such as udf_example.so to libudf_example.so.

On Windows, you can compile user-defined functions by using the following procedure:

1. Obtain the development source for MySQL 5.0. See Section 2.5, "How to Get MySQL".
2. Obtain the CMake build utility, if necessary, from http://www.cmake.org. (Version 2.6 or later is required).
3. In the source tree, look in the sql directory. There are files named udf_example.def udf_example.c there. Copy both files from this directory to your working directory.
4. Create a CMake makefile (CMakeLists.txt) with these contents:

```
PROJECT(udf_example)

# Path for MySQL include directory
INCLUDE_DIRECTORIES("c:/mysql/include")

ADD_DEFINITIONS("-DHAVE_DLOPEN")
ADD_LIBRARY(udf_example MODULE udf_example.c udf_example.def)
TARGET_LINK_LIBRARIES(udf_example wsock32)
```

5. Create the VC project and solution files:

```
cmake -G "<Generator>"
```

Invoking cmake --help shows you a list of valid Generators.

6. Create udf_example.dll:

```
deenv udf_example.sln /build Release
```

After the shared object file has been installed, notify mysqld about the new functions with the following statements. If object files have a suffix different from .so on your system, substitute the correct suffix throughout (for example, .dll on Windows).

```
mysql> CREATE FUNCTION metaphon RETURNS STRING SONAME 'udf_example.so';
mysql> CREATE FUNCTION myfunc_double RETURNS REAL SONAME 'udf_example.so';
mysql> CREATE FUNCTION myfunc_int RETURNS INTEGER SONAME 'udf_example.so';
mysql> CREATE FUNCTION sequence RETURNS INTEGER SONAME 'udf_example.so';
mysql> CREATE FUNCTION lookup RETURNS STRING SONAME 'udf_example.so';
mysql> CREATE FUNCTION reverse_lookup
   -> RETURNS STRING SONAME 'udf_example.so';
mysql> CREATE AGGREGATE FUNCTION avgcost
```
Adding a New Native Function

Once installed, a function remains installed until it is uninstalled.

To delete functions, use DROP FUNCTION:

```sql
mysql> DROP FUNCTION metaphon;
mysql> DROP FUNCTION myfunc_double;
mysql> DROP FUNCTION myfunc_int;
mysql> DROP FUNCTION sequence;
mysql> DROP FUNCTION lookup;
mysql> DROP FUNCTION reverse_lookup;
mysql> DROP FUNCTION avgcost;
```

The CREATE FUNCTION and DROP FUNCTION statements update the `func` system table in the `mysql` database. The function's name, type and shared library name are saved in the table. You must have the INSERT or DELETE privilege for the `mysql` database to create or drop functions, respectively.

You should not use CREATE FUNCTION to add a function that has previously been created. If you need to reinstall a function, you should remove it with DROP FUNCTION and then reinstall it with CREATE FUNCTION. You would need to do this, for example, if you recompile a new version of your function, so that mysqld gets the new version. Otherwise, the server continues to use the old version.

An active function is one that has been loaded with CREATE FUNCTION and not removed with DROP FUNCTION. All active functions are reloaded each time the server starts, unless you start mysqld with the `--skip-grant-tables` option. In this case, UDF initialization is skipped and UDFs are unavailable.

21.2.2.6 UDF Security Precautions

MySQL takes several measures to prevent misuse of user-defined functions.

UDF object files cannot be placed in arbitrary directories. They must be located in some system directory that the dynamic linker is configured to search. To enforce this restriction and prevent attempts at specifying path names outside of directories searched by the dynamic linker, MySQL checks the shared object file name specified in CREATE FUNCTION statements for path name delimiter characters. As of MySQL 5.0.3, MySQL also checks for path name delimiters in file names stored in the `mysql.func` table when it loads functions. This prevents attempts at specifying illegitimate path names through direct manipulation of the `mysql.func` table. For information about UDFs and the runtime linker, see Section 21.2.2.5, “UDF Compiling and Installing”.

To use CREATE FUNCTION or DROP FUNCTION, you must have the INSERT or DELETE privilege, respectively, for the `mysql` database. This is necessary because those statements add and delete rows from the `mysql.func` table.

UDFs should have at least one symbol defined in addition to the `xxx` symbol that corresponds to the main `xxx()` function. These auxiliary symbols correspond to the `xxx_init()`, `xxx_deinit()`, `xxx_reset()`, `xxx_clear()`, and `xxx_add()` functions. As of MySQL 5.0.3, mysqld supports an `--allow-suspicious-udfs` option that controls whether UDFs that have only an `xxx` symbol can be loaded. By default, the option is off, to prevent attempts at loading functions from shared object files other than those containing legitimate UDFs. If you have older UDFs that contain only the `xxx` symbol and that cannot be recompiled to include an auxiliary symbol, it may be necessary to specify the `--allow-suspicious-udfs` option. Otherwise, you should avoid enabling this capability.

21.2.3 Adding a New Native Function

To add a new native MySQL function, use the procedure described here, which requires that you use a source distribution. You cannot add native functions to a binary distribution because it is necessary to modify MySQL source code and compile MySQL from the modified source. If you migrate to another version of MySQL (for example, when a new version is released), you must repeat the procedure with the new version.
If the new native function will be referred to in statements that will be replicated to slave servers, you must ensure that every slave server also has the function available. Otherwise, replication will fail on the slaves when they attempt to invoke the function.

To add a new native function, follow these steps to modify source files in the `sql` directory:

1. Add one line to `lex.h` that defines the function name in the `sql_functions[]` array.

2. If the function prototype is simple (just takes zero, one, two, or three arguments), add a line to the `sql_functions[]` array in `lex.h` that specifies `SYM(FUNC_ARGN)` as the second argument (where `N` is the number of arguments the function takes). Also, add a function in `item_create.cc` that creates a function object. Look at "ABS" and `create_funcs_abs()` for an example of this.

If the function prototype is not simple (for example, if it takes a variable number of arguments), you should make two changes to `sql_yacc.yy`. One is a line that indicates the preprocessor symbol that `yacc` should define; this should be added at the beginning of the file. The other is an "item" to be added to the `simple_expr` parsing rule that defines the function parameters. You will need an item for each syntax with which the function can be called. For an example that shows how this is done, check all occurrences of `ATAN` in `sql_yacc.yy`.

3. In `item_func.h`, declare a class inheriting from `Item_num_func` or `Item_str_func`, depending on whether your function returns a number or a string.

4. In `item_func.cc`, add one of the following declarations, depending on whether you are defining a numeric or string function:

   ```
   double Item_func_newname::val()
   longlong Item_func_newname::val_int()
   String *Item_func_newname::Str(String *str)
   ```

   If you inherit your object from any of the standard items (like `Item_num_func`), you probably only have to define one of these functions and let the parent object take care of the other functions. For example, the `Item_str_func` class defines a `val()` function that executes `atof()` on the value returned by `::str()`.

5. If the function is nondeterministic, include the following statement in the item constructor to indicate that function results should not be cached:

   ```
   current_thd->lex->safe_to_cache_query=0;
   ```

   A function is nondeterministic if, given fixed values for its arguments, it can return different results for different invocations.

6. You should probably also define the following object function:

   ```
   void Item_func_newname::fix_length_and_dec()
   ```

   This function should at least calculate `max_length` based on the given arguments. `max_length` is the maximum number of characters the function may return. This function should also set `maybe_null = 0` if the main function can't return a NULL value. The function can check whether any of the function arguments can return NULL by checking the arguments' `maybe_null` variable. Look at `Item_func_mod::fix_length_and_dec` for a typical example of how to do this.

   All functions must be thread-safe. In other words, do not use any global or static variables in the functions without protecting them with mutexes.

   If you want to return NULL from `::val()`, `::val_int()`, or `::str()`, you should set `null_value` to 1 and return 0.

   For `::str()` object functions, there are additional considerations to be aware of:
• The `String *str` argument provides a string buffer that may be used to hold the result. (For more information about the `String` type, take a look at the `sql_string.h` file.)

• The `::str()` function should return the string that holds the result, or `(char*) 0` if the result is `NULL`.

• All current string functions try to avoid allocating any memory unless absolutely necessary!

## 21.3 Debugging and Porting MySQL

This section helps you port MySQL to other operating systems. Do check the list of currently supported operating systems first. See [http://www.mysql.com/support/supportedplatforms/database.html](http://www.mysql.com/support/supportedplatforms/database.html). If you have created a new port of MySQL, please let us know so that we can list it here and on our Web site ([http://www.mysql.com/](http://www.mysql.com/)), recommending it to other users.

### Note

If you create a new port of MySQL, you are free to copy and distribute it under the GPL license, but it does not make you a copyright holder of MySQL.

A working POSIX thread library is needed for the server.

Both the server and the client need a working C++ compiler. We use `gcc` on many platforms. Other compilers that are known to work are Sun Studio, HP-UX `aCC`, IBM AIX `xlC_r`, Intel ecc/icc. With previous versions on the respective platforms, we also used Irix `cc` and Compaq `cxx`.

### Important

If you are trying to build MySQL 5.0 with `icc` on the IA64 platform, and need support for MySQL Cluster, you should first ensure that you are using `icc` version 9.1.043 or later. (For details, see Bug #21875.)

To compile only the client, use `.configure --without-server`.

If you want or need to change any `Makefile` or the `configure` script, you also need GNU Automake and Autoconf. See Section 2.17.2, “Installing MySQL Using a Development Source Tree”.

All steps needed to remake everything from the most basic files.

```
/bin/rm */.deps/*.*
/bin/rm -f config.cache
aclocal
autoheader
aclocal
automake
autoconf
./configure --with-debug=full --prefix='your installation directory'

# The makefiles generated above need GNU make 3.75 or newer.
# (called gmake below)
gmake clean all install init-db
```

If you run into problems with a new port, you may have to do some debugging of MySQL! See Section 21.3.1, “Debugging a MySQL Server”.

### Note

Before you start debugging `mysqld`, first get the test programs `mysys/thr_alarm` and `mysys/thr_lock` to work. This ensures that your thread installation has even a remote chance to work!

## 21.3.1 Debugging a MySQL Server
If you are using some functionality that is very new in MySQL, you can try to run `mysqld` with the `--skip-new` option (which disables all new, potentially unsafe functionality). See Section B.5.3.3, "What to Do If MySQL Keeps Crashing".

If `mysqld` doesn't want to start, you should verify that you don't have any `my.cnf` files that interfere with your setup! You can check your `my.cnf` arguments with `mysqld --print-defaults` and avoid using them by starting with `mysqld --no-defaults` ....

If `mysqld` starts to eat up CPU or memory or if it "hangs," you can use `mysqladmin processlist status` to find out if someone is executing a query that takes a long time. It may be a good idea to run `mysqladmin -i10 processlist status` in some window if you are experiencing performance problems or problems when new clients can't connect.

The command `mysqladmin debug` dumps some information about locks in use, used memory and query usage to the MySQL log file. This may help solve some problems. This command also provides some useful information even if you haven't compiled MySQL for debugging!

If the problem is that some tables are getting slower and slower you should try to optimize the table with `OPTIMIZE TABLE` or `myisamchk`. See Chapter 5, MySQL Server Administration. You should also check the slow queries with `EXPLAIN`.

You should also read the OS-specific section in this manual for problems that may be unique to your environment. See Section 2.20, "Operating System-Specific Notes".

### 21.3.1.1 Compiling MySQL for Debugging

If you have some very specific problem, you can always try to debug MySQL. To do this you must configure MySQL with the `--with-debug` or the `--with-debug=full` option. You can check whether MySQL was compiled with debugging by doing: `mysqld --help`. If the `--debug` flag is listed with the options then you have debugging enabled. `mysqladmin ver` also lists the `mysqld` version as `mysql ... --debug` in this case.

If you are using `gcc`, the recommended `configure` line is:

```bash
CC=gcc CFLAGS="-O2" CXX=gcc CXXFLAGS="-O2 -felide-constructors 
-fno-exceptions -fno-rtti" ./configure --prefix=/usr/local/mysql 
--with-debug --with-extra-charsets=complex
```

This avoids problems with the `libstdc++` library and with C++ exceptions (many compilers have problems with C++ exceptions in threaded code) and compile a MySQL version with support for all character sets.

If you suspect a memory overrun error, you can configure MySQL with `--with-debug=full`, which installs a memory allocation (`SAFEMALLOC`) checker. However, running with `SAFEMALLOC` is quite slow, so if you get performance problems you should start `mysqld` with the `--skip-safemalloc` option. This disables the memory overrun checks for each call to `malloc()` and `free()`.

If `mysqld` stops crashing when you compile it with `--with-debug`, you probably have found a compiler bug or a timing bug within MySQL. In this case, you can try to add `-g` to the `CFLAGS` and `CXXFLAGS` variables above and not use `--with-debug`. If `mysqld` dies, you can at least attach to it with `gdb` or use `gdb` on the core file to find out what happened.

When you configure MySQL for debugging you automatically enable a lot of extra safety check functions that monitor the health of `mysqld`. If they find something "unexpected," an entry is written to `stderr`, which `mysqld_safe` directs to the error log! This also means that if you are having some unexpected problems with MySQL and are using a source distribution, the first thing you should do is to configure MySQL for debugging! (The second thing is to send mail to a MySQL mailing list and ask for help. See Section 1.6.1, "MySQL Mailing Lists". If you believe that you have found a bug, please use the instructions at Section 1.7, "How to Report Bugs or Problems".
In the Windows MySQL distribution, `mysqld.exe` is by default compiled with support for trace files. See also Section 21.3.1.2, "Creating Trace Files".

### 21.3.1.2 Creating Trace Files

If the `mysqld` server doesn't start or if you can cause it to crash quickly, you can try to create a trace file to find the problem.

To do this, you must have a `mysqld` that has been compiled with debugging support. You can check this by executing `mysqld -V`. If the version number ends with `-debug`, it is compiled with support for trace files. (On Windows, the debugging server is named `mysqld-debug` rather than `mysqld`.)

Start the `mysqld` server with a trace log in `/tmp/mysqld.trace` on Unix or `\mysqld.trace` on Windows:

```
shell> mysqld --debug
```

On Windows, you should also use the `--standalone` flag to not start `mysqld` as a service. In a console window, use this command:

```
C:\> mysqld-debug --debug --standalone
```

After this, you can use the `mysql.exe` command-line tool in a second console window to reproduce the problem. You can stop the `mysqld` server with `mysqladmin shutdown`.

The trace file can become very large! To generate a smaller trace file, you can use debugging options something like this:

```
mysqld --debug=d,info,error,query,general,where:O,/tmp/mysqld.trace
```

This only prints information with the most interesting tags to the trace file.

If you make a bug report about this, please only send the lines from the trace file to the appropriate mailing list where something seems to go wrong! If you can't locate the wrong place, you can open a bug report and upload the trace file to the report, so that a MySQL developer can take a look at it. For instructions, see Section 1.7, "How to Report Bugs or Problems".

The trace file is made with the `DBUG` package by Fred Fish. See Section 21.3.3, "The `DBUG` Package".

### 21.3.1.3 Using pdb to create a Windows crashdump

Starting with MySQL 5.0.24 the Program Database files (extension `.pdb`) are included in the Noinstall distribution of MySQL. These files provide information for debugging your MySQL installation in the event of a problem.

The PDB file contains more detailed information about `mysqld` and other tools that enables more detailed trace and dump files to be created. You can use these with Dr Watson, WinDbg and Visual Studio to debug `mysqld`.

For more information on PDB files, see Microsoft Knowledge Base Article 121366. For more information on the debugging options available, see Debugging Tools for Windows.

Dr Watson is installed with all Windows distributions, but if you have installed Windows development tools, Dr Watson may have been replaced with WinDbg, the debugger included with Visual Studio, or the debugging tools provided with Borland or Delphi.

To generate a crash file using Dr Watson, follow these steps:

1. Start Dr Watson by running `drwtsn32.exe` interactively using the `-i` option:
2. Set the **Log File Path** to the directory where you want to store trace files.

3. Make sure **Dump All Thread Contexts** and **Append To Existing Log File**.

4. Uncheck **Dump Symbol Table**, **Visual Notification**, **Sound Notification** and **Create Crash Dump File**.

5. Set the **Number of Instructions** to a suitable value to capture enough calls in the stacktrace. A value of at 25 should be enough.

Note that the file generated can become very large.

### 21.3.1.4 Debugging mysqld under gdb

On most systems you can also start `mysqld` from `gdb` to get more information if `mysqld` crashes.

With some older `gdb` versions on Linux you must use `run --one-thread` if you want to be able to debug `mysqld` threads. In this case, you can only have one thread active at a time. It is best to upgrade to `gdb 5.1` because thread debugging works much better with this version!

NPTL threads (the new thread library on Linux) may cause problems while running `mysqld` under `gdb`. Some symptoms are:

- `mysqld` hangs during startup (before it writes `ready for connections`).
- `mysqld` crashes during a `pthread_mutex_lock()` or `pthread_mutex_unlock()` call.

In this case, you should set the following environment variable in the shell before starting `gdb`:

```bash
LD_ASSUME_KERNEL=2.4.1
export LD_ASSUME_KERNEL
```

When running `mysqld` under `gdb`, you should disable the stack trace with `--skip-stack-trace` to be able to catch segfaults within `gdb`.

Use the `--gdb` option to `mysqld` to install an interrupt handler for `SIGINT` (needed to stop `mysqld` with `^C` to set breakpoints) and disable stack tracing and core file handling.

It is very hard to debug MySQL under `gdb` if you do a lot of new connections the whole time as `gdb` doesn't free the memory for old threads. You can avoid this problem by starting `mysqld` with `--thread_cache_size` set to a value equal to `max_connections + 1`. In most cases just using `--thread_cache_size=5` helps a lot!

If you want to get a core dump on Linux if `mysqld` dies with a SIGSEGV signal, you can start `mysqld` with the `--core-file` option. This core file can be used to make a backtrace that may help you find out why `mysqld` died:

```shell
shell> gdb mysqld core
gdb> backtrace full
gdb> quit
```

See Section B.5.3.3, “What to Do If MySQL Keeps Crashing”.

If you are using `gdb 4.17.x` or above on Linux, you should install a `.gdb` file, with the following information, in your current directory:

```bash
set print sevenbit off
handle SIGUSR1 nostop noprint
```
Debugging a MySQL Server

If you have problems debugging threads with `gdb`, you should download gdb 5.x and try this instead. The new `gdb` version has very improved thread handling!

Here is an example how to debug `mysqld`:

```
shell> gdb /usr/local/libexec/mysqld
gdb> run
...
backtrace full # Do this when mysqld crashes
```

Include the above output in a bug report, which you can file using the instructions in Section 1.7, “How to Report Bugs or Problems”.

If `mysqld` hangs you can try to use some system tools like `strace` or `/usr/proc/bin/pstack` to examine where `mysqld` has hung.

```
strace /tmp/log libexec/mysqld
```

If you are using the Perl `DBI` interface, you can turn on debugging information by using the `trace` method or by setting the `DBI_TRACE` environment variable.

### 21.3.1.5 Using a Stack Trace

On some operating systems, the error log contains a stack trace if `mysqld` dies unexpectedly. You can use this to find out where (and maybe why) `mysqld` died. See Section 5.4.1, “The Error Log”. To get a stack trace, you must not compile `mysqld` with the `-fomit-frame-pointer` option to gcc. See Section 21.3.1.1, “Compiling MySQL for Debugging”.

A stack trace in the error log looks something like this:

```
mysqld got signal 11;
Attempting backtrace. You can use the following information
to find out where mysqld died. If you see no messages after
this, something went terribly wrong...
stack range sanity check, ok, backtrace follows
0x40077552
0x81281a0
0x8128f47
0x8127be0
0x8127995
0x8104947
0x80ff28f
0x810131b
0x80e4bc
0x80c3c91
0x80c6b43
0x80c1fd9
0x80c1686
```

You can use the `resolve_stack_dump` utility to determine where `mysqld` died by using the following procedure:

1. Copy the preceding numbers to a file, for example `mysqld.stack`:
2. Make a symbol file for the **mysqld** server:

```shell
shell> nm -n libexec/mysqld > /tmp/mysqld.sym
```

If **mysqld** is not linked statically, use the following command instead:

```shell
shell> nm -D -n libexec/mysqld > /tmp/mysqld.sym
```

If you want to decode C++ symbols, use the `--demangle`, if available, to **nm**. If your version of **nm** does not have this option, you will need to use the **c++filt** command after the stack dump has been produced to demangle the C++ names.

3. Execute the following command:

```shell
shell> resolve_stack_dump -s /tmp/mysqld.sym -n mysqld.stack
```

If you were not able to include demangled C++ names in your symbol file, process the `resolve_stack_dump` output using **c++filt**:

```shell
shell> resolve_stack_dump -s /tmp/mysqld.sym -n mysqld.stack | c++filt
```

This prints out where **mysqld** died. If that does not help you find out why **mysqld** died, you should create a bug report and include the output from the preceding command with the bug report.

However, in most cases it does not help us to have just a stack trace to find the reason for the problem. To be able to locate the bug or provide a workaround, in most cases we need to know the statement that killed **mysqld** and preferably a test case so that we can repeat the problem! See Section 1.7, “How to Report Bugs or Problems”.

### 21.3.1.6 Using Server Logs to Find Causes of Errors in **mysqld**

Note that before starting **mysqld** with the general query log enabled, you should check all your tables with **myisamchk**. See Chapter 5, **MySQL Server Administration**.

If **mysqld** dies or hangs, you should start **mysqld** with the general query log enabled. See Section 5.4.2, “The General Query Log”. When **mysqld** dies again, you can examine the end of the log file for the query that killed **mysqld**.

If you use the default general query log file, the log is stored in the database directory as `host_name.log` In most cases it is the last query in the log file that killed **mysqld**, but if possible you should verify this by restarting **mysqld** and executing the found query from the **mysql** command-line tools. If this works, you should also test all complicated queries that didn’t complete.

You can also try the command **EXPLAIN** on all **SELECT** statements that takes a long time to ensure that **mysqld** is using indexes properly. See Section 13.8.2, “**EXPLAIN** Syntax”.

You can find the queries that take a long time to execute by starting **mysqld** with the slow query log enabled. See Section 5.4.4, “The Slow Query Log”.

This documentation is for an older version. If you're
If you find the text `mysqld` restarted in the error log file (normally named `hostname.err`) you probably have found a query that causes `mysqld` to fail. If this happens, you should check all your tables with `myisamchk` (see Chapter 5, MySQL Server Administration), and test the queries in the MySQL log files to see whether one fails. If you find such a query, try first upgrading to the newest MySQL version. If this doesn't help and you can't find anything in the `mysql` mail archive, you should report the bug to a MySQL mailing list. The mailing lists are described at http://lists.mysql.com/, which also has links to online list archives.

If you have started `mysqld` with `--myisam-recover`, MySQL automatically checks and tries to repair MyISAM tables if they are marked as 'not closed properly' or 'crashed'. If this happens, MySQL writes an entry in the `hostname.err` file 'Warning: Checking table ...' which is followed by 'Warning: Repairing table' if the table needs to be repaired. If you get a lot of these errors, without `mysqld` having died unexpectedly just before, then something is wrong and needs to be investigated further. See Section 5.1.3, "Server Command Options".

It is not a good sign if `mysqld` did die unexpectedly, but in this case, you should not investigate the Checking table... messages, but instead try to find out why `mysqld` died.

### 21.3.1.7 Making a Test Case If You Experience Table Corruption

The following procedure applies to MyISAM tables. For information about steps to take when encountering InnoDB table corruption, see Section 1.7, "How to Report Bugs or Problems".

If you encounter corrupted MyISAM tables or if `mysqld` always fails after some update statements, you can test whether the issue is reproducible by doing the following:

1. Stop the MySQL daemon with `mysqladmin shutdown`.
2. Make a backup of the tables to guard against the very unlikely case that the repair does something bad.
3. Check all tables with `myisamchk -s database/*.MYI`. Repair any corrupted tables with `myisamchk -r database/table.MYI`.
4. Make a second backup of the tables.
5. Remove (or move away) any old log files from the MySQL data directory if you need more space.
6. Start `mysqld` with the binary log enabled. If you want to find a statement that crashes `mysqld`, you should start the server with the general query log enabled as well. See Section 5.4.2, "The General Query Log", and Section 5.4.3, "The Binary Log".
7. When you have gotten a crashed table, stop the `mysqld` server.
8. Restore the backup.
9. Restart the `mysqld` server without the binary log enabled.
10. Re-execute the statements with `mysqlbinlog binary-log-file | mysql`. The binary log is saved in the MySQL database directory with the name `hostname-bin.NNNNNN`.
11. If the tables are corrupted again or you can get `mysqld` to die with the above command, you have found a reproducible bug. FTP the tables and the binary log to our bugs database using the instructions given in Section 1.7, "How to Report Bugs or Problems". If you are a support customer, you can use the MySQL Customer Support Center (http://www.mysql.com/support/) to alert the MySQL team about the problem and have it fixed as soon as possible.

You can also use the script `mysql_find_rows` to just execute some of the update statements if you want to narrow down the problem.

The preceding discussion applies only to RHEL4. The patch is unnecessary for RHEL5.
21.3.2 Debugging a MySQL Client

To be able to debug a MySQL client with the integrated debug package, you should configure MySQL with `--with-debug` or `--with-debug=full`. See Section 2.17.3, "MySQL Source-Configuration Options".

Before running a client, you should set the `MYSQL_DEBUG` environment variable:

```
shell> MYSQL_DEBUG=d:t:o,/tmp/client.trace
shell> export MYSQL_DEBUG
```

This causes clients to generate a trace file in `/tmp/client.trace`.

If you have problems with your own client code, you should attempt to connect to the server and run your query using a client that is known to work. Do this by running `mysql` in debugging mode (assuming that you have compiled MySQL with debugging on):

```
shell> mysql --debug=d:t:o,/tmp/client.trace
```

This provides useful information in case you mail a bug report. See Section 1.7, "How to Report Bugs or Problems".

If your client crashes at some 'legal' looking code, you should check that your `mysql.h` include file matches your MySQL library file. A very common mistake is to use an old `mysql.h` file from an old MySQL installation with new MySQL library.

21.3.3 The DBUG Package

The MySQL server and most MySQL clients are compiled with the DBUG package originally created by Fred Fish. When you have configured MySQL for debugging, this package makes it possible to get a trace file of what the program is doing. See Section 21.3.1.2, "Creating Trace Files".

This section summarizes the argument values that you can specify in debug options on the command line for MySQL programs that have been built with debugging support. For more information about programming with the DBUG package, see the DBUG manual in the `dbug` directory of MySQL source distributions. It's best to use a recent distribution to get the most updated DBUG manual.

The DBUG package can be used by invoking a program with the `--debug=[debug_options]` or `--# [debug_options]` option. If you specify the `--debug` or `--#` option without a `debug_options` value, most MySQL programs use a default value. The server default is `d:t:i:o,/tmp/mysqld.trace` on Unix and `d:t:i:o,\mysqld.trace` on Windows. The effect of this default is:

- `d`: Enable output for all debug macros
- `t`: Trace function calls and exits
- `i`: Add PID to output lines
- `o,/tmp/mysqld.trace,0,\mysqld.trace`: Set the debug output file.

Most client programs use a default `debug_options` value of `d:t:o,/tmp/program_name.trace`, regardless of platform.

Here are some example debug control strings as they might be specified on a shell command line:

```
--debug=d:t
--debug=d:f,main,subr1:F:L:t,20
--debug=d,input,output,files:n
--debug=d:t:i:O,\mysqld.trace
```
The `debug_options` value is a sequence of colon-separated fields:

```
field_1:field_2:...:field_N
```

Each field within the value consists of a mandatory flag character, optionally preceded by a `+` or `−` character, and optionally followed by a comma-delimited list of modifiers:

```
[+|−]flag[,modifier,modifier,...,modifier]
```

The following table describes the permitted flag characters. Unrecognized flag characters are silently ignored.

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>d</td>
<td>Enable output from <code>DEBUG_XXX</code> macros for the current state. May be followed by a list of keywords, which enables output only for the <code>DEBUG</code> macros with that keyword. An empty list of keywords enables output for all macros. In MySQL, common debug macro keywords to enable are <code>enter</code>, <code>exit</code>, <code>error</code>, <code>warning</code>, <code>info</code>, and <code>loop</code>.</td>
</tr>
<tr>
<td>D</td>
<td>Delay after each debugger output line. The argument is the delay, in tenths of seconds, subject to machine capabilities. For example, <code>D, 20</code> specifies a delay of two seconds.</td>
</tr>
<tr>
<td>f</td>
<td>Limit debugging, tracing, and profiling to the list of named functions. An empty list enables all functions. The appropriate <code>d</code> or <code>t</code> flags must still be given; this flag only limits their actions if they are enabled.</td>
</tr>
<tr>
<td>F</td>
<td>Identify the source file name for each line of debug or trace output.</td>
</tr>
<tr>
<td>i</td>
<td>Identify the process with the PID or thread ID for each line of debug or trace output.</td>
</tr>
<tr>
<td>L</td>
<td>Identify the source file line number for each line of debug or trace output.</td>
</tr>
<tr>
<td>n</td>
<td>Print the current function nesting depth for each line of debug or trace output.</td>
</tr>
<tr>
<td>N</td>
<td>Number each line of debug output.</td>
</tr>
<tr>
<td>o</td>
<td>Redirect the debugger output stream to the specified file. The default output is <code>stderr</code>.</td>
</tr>
<tr>
<td>O</td>
<td>Like <code>o</code>, but the file is really flushed between each write. When needed, the file is closed and reopened between each write.</td>
</tr>
<tr>
<td>p</td>
<td>Limit debugger actions to specified processes. A process must be identified with the <code>DBUG_PROCESS</code> macro and match one in the list for debugger actions to occur.</td>
</tr>
<tr>
<td>P</td>
<td>Print the current process name for each line of debug or trace output.</td>
</tr>
<tr>
<td>r</td>
<td>When pushing a new state, do not inherit the previous state's function nesting level. Useful when the output is to start at the left margin.</td>
</tr>
<tr>
<td>S</td>
<td>Do function <code>_sanity(_file_, _line_)</code> at each debugged function until <code>_sanity()</code> returns something that differs from 0. (Mostly used with <code>safemalloc</code> to find memory leaks.)</td>
</tr>
<tr>
<td>t</td>
<td>Enable function call/exit trace lines. May be followed by a list (containing only one modifier) giving a numeric maximum trace level, beyond which no output occurs for either debugging or tracing macros. The default is a compile time option.</td>
</tr>
</tbody>
</table>

The leading `+` or `−` character and trailing list of modifiers are used for flag characters such as `d` or `f` that can enable a debug operation for all applicable modifiers or just some of them:

- With no leading `+` or `−`, the flag value is set to exactly the modifier list as given.
- With a leading `+` or `−`, the modifiers in the list are added to or subtracted from the current modifier list.
This documentation is for an older version.
If you're using the most current version, select the documentation for that version with the version switch in the upper right corner of the online documentation, or by downloading a newer PDF or EPUB file.
MySQL Enterprise Edition is a commercial product. Like MySQL Community Edition, MySQL Enterprise Edition includes MySQL Server, a fully integrated transaction-safe, ACID-compliant database with full commit, rollback, crash-recovery, and row-level locking capabilities. In addition, MySQL Enterprise Edition includes the following components designed to provide monitoring and online backup, as well as improved security and scalability:

The following sections briefly discuss each of these components and indicate where to find more detailed information. To learn more about commercial products, see http://www.mysql.com/products/.

- MySQL Enterprise Monitor
- MySQL Enterprise Backup
- MySQL Enterprise Security
- MySQL Enterprise Encryption
- MySQL Enterprise Audit
- MySQL Enterprise Firewall
- MySQL Enterprise Thread Pool

22.1 MySQL Enterprise Monitor Overview

MySQL Enterprise Monitor is an enterprise monitoring system for MySQL that keeps an eye on your MySQL servers, notifies you of potential issues and problems, and advises you how to fix the issues. MySQL Enterprise Monitor can monitor all kinds of configurations, from a single MySQL server that is important to your business, all the way up to a huge farm of MySQL servers powering a busy web site.

The following discussion briefly summarizes the basic components that make up the MySQL Enterprise Monitor product. For more information, see the MySQL Enterprise Monitor manual, available at http://dev.mysql.com/doc/mysql-monitor/en/.

MySQL Enterprise Monitor components can be installed in various configurations depending on your database and network topology, to give you the best combination of reliable and responsive monitoring data, with minimal overhead on the database server machines. A typical MySQL Enterprise Monitor installation consists of:

- One or more MySQL servers to monitor. MySQL Enterprise Monitor can monitor both Community and Enterprise MySQL server releases.
- A MySQL Enterprise Monitor Agent for each monitored host.
- A single MySQL Enterprise Service Manager, which collates information from the agents and provides the user interface to the collected data.
MySQL Enterprise Monitor is designed to monitor one or more MySQL servers. The monitoring information is collected by using an agent, MySQL Enterprise Monitor Agent. The agent communicates with the hosts and MySQL servers that it monitors, collecting variables, status and health information, and sending this information to the MySQL Enterprise Service Manager.

The information collected by the agent about each MySQL server and host you are monitoring is sent to the MySQL Enterprise Service Manager. This server collates all of the information from the agents. As it collates the information sent by the agents, the MySQL Enterprise Service Manager continually tests the collected data, comparing the status of the server to reasonable values. When thresholds are reached, the server can trigger an event (including an alarm and notification) to highlight a potential issue, such as low memory, high CPU usage, or more complex conditions such insufficient buffer sizes and status information. We call each test, with its associated threshold value, a rule.

These rules, and the alarms and notifications, are each known as a MySQL Enterprise Advisor. Advisors form a critical part of the MySQL Enterprise Service Manager, as they provide warning information and troubleshooting advice about potential problems.

The MySQL Enterprise Service Manager includes a web server, and you interact with it through any web browser. This interface, the MySQL Enterprise Monitor User Interface, displays all of the information collected by the agents, and lets you view all of your servers and their current status as a group or individually. You control and configure all aspects of the service using the MySQL Enterprise Monitor User Interface.

The information supplied by the MySQL Enterprise Monitor Agent processes also includes statistical and query information, which you can view in the form of graphs. For example, you can view aspects such as server load, query numbers, or index usage information as a graph over time. The graph lets you pinpoint problems or potential issues on your server, and can help diagnose the impact from database or external problems (such as external system or network failure) by examining the data from a specific time interval.

The MySQL Enterprise Monitor Agent can also be configured to collect detailed information about the queries executed on your server, including the row counts and performance times for executing each query. You can correlate the detailed query data with the graphical information to identify which queries were executing when you experienced a particularly high load, index or other issue. The query data is supported by a system called Query Analyzer, and the data can be presented in different ways depending on your needs.

**22.2 MySQL Enterprise Backup Overview**

MySQL Enterprise Backup performs hot backup operations for MySQL databases. The product is architected for efficient and reliable backups of tables created by the InnoDB storage engine. For completeness, it can also back up tables from MyISAM and other storage engines.

Hot backups are performed while the database is running and applications are reading and writing to it. This type of backup does not block normal database operations, and it captures even changes that occur while the backup is happening. For these reasons, hot backups are desirable when your database “grows up” -- when the data is large enough that the backup takes significant time, and when your data is important enough to your business that you must capture every last change, without taking your application, web site, or web service offline.

MySQL Enterprise Backup does a hot backup of all tables that use the InnoDB storage engine. For tables using MyISAM or other non-InnoDB storage engines, it does a “warm” backup, where the database continues to run, but those tables cannot be modified while being backed up. For efficient backup operations, you can designate InnoDB as the default storage engine for new tables, or convert existing tables to use the InnoDB storage engine.

**22.3 MySQL Enterprise Security Overview**
MySQL Enterprise Edition provides plugins that implement authentication using external services:

- MySQL Enterprise Edition includes an authentication plugin that enables MySQL Server to use PAM (Pluggable Authentication Modules) to authenticate MySQL users. PAM enables a system to use a standard interface to access various kinds of authentication methods, such as Unix passwords or an LDAP directory. For more information, see The PAM Authentication Plugin.

- MySQL Enterprise Edition includes an authentication plugin that performs external authentication on Windows, enabling MySQL Server to use native Windows services to authenticate client connections. Users who have logged in to Windows can connect from MySQL client programs to the server based on the information in their environment without specifying an additional password. For more information, see The Windows Native Authentication Plugin.

- MySQL Enterprise Edition includes a keyring plugin that uses Oracle Key Vault for keyring backend storage. For more information, see The MySQL Keyring.

For other related Enterprise security features, see Section 22.4, “MySQL Enterprise Encryption Overview”.

### 22.4 MySQL Enterprise Encryption Overview

MySQL Enterprise Edition includes a set of encryption functions based on the OpenSSL library that expose OpenSSL capabilities at the SQL level. These functions enable Enterprise applications to perform the following operations:

- Implement added data protection using public-key asymmetric cryptography
- Create public and private keys and digital signatures
- Perform asymmetric encryption and decryption
- Use cryptographic hashing for digital signing and data verification and validation

For more information, see MySQL Enterprise Encryption Functions.

For other related Enterprise security features, see Section 22.3, “MySQL Enterprise Security Overview”.

### 22.5 MySQL Enterprise Audit Overview

MySQL Enterprise Edition includes MySQL Enterprise Audit, implemented using a server plugin. MySQL Enterprise Audit uses the open MySQL Audit API to enable standard, policy-based monitoring and logging of connection and query activity executed on specific MySQL servers. Designed to meet the Oracle audit specification, MySQL Enterprise Audit provides an out of box, easy to use auditing and compliance solution for applications that are governed by both internal and external regulatory guidelines.

When installed, the audit plugin enables MySQL Server to produce a log file containing an audit record of server activity. The log contents include when clients connect and disconnect, and what actions they perform while connected, such as which databases and tables they access.

For more information, see MySQL Enterprise Audit Log Plugin.

### 22.6 MySQL Enterprise Firewall Overview

MySQL Enterprise Edition includes MySQL Enterprise Firewall, an application-level firewall that enables database administrators to permit or deny SQL statement execution based on matching against whitelists of accepted statement patterns. This helps harden MySQL Server against attacks such as SQL injection or attempts to exploit applications by using them outside of their legitimate query workload characteristics.
Each MySQL account registered with the firewall has its own statement whitelist, enabling protection to be tailored per account. For a given account, the firewall can operate in recording or protecting mode, for training in the accepted statement patterns or protection against unacceptable statements.

For more information, see MySQL Enterprise Firewall.

22.7 MySQL Enterprise Thread Pool Overview

MySQL Enterprise Edition includes the MySQL Thread Pool, implemented using a server plugin. The default thread-handling model in MySQL Server executes statements using one thread per client connection. As more clients connect to the server and execute statements, overall performance degrades. In MySQL Enterprise Edition, a thread pool plugin provides an alternative thread-handling model designed to reduce overhead and improve performance. The plugin implements a thread pool that increases server performance by efficiently managing statement execution threads for large numbers of client connections.

For more information, see The Thread Pool Plugin.

A.1 MySQL 5.0 FAQ: General

A.1.1 Which version of MySQL is production-ready (GA)? .......................................................... 1907
A.1.2 What is the state of development (non-GA) versions? ......................................................... 1907
A.1.3 Can MySQL 5.0 do subqueries? ............................................................................................ 1908
A.1.4 Can MySQL 5.0 perform multiple-table inserts, updates, and deletes? ............................. 1908
A.1.5 Does MySQL 5.0 have a Query Cache? Does it work on Server, Instance or Database? .... 1908
A.1.6 Does MySQL 5.0 have Sequences? ....................................................................................... 1908
A.1.7 Does MySQL 5.0 have a NOW() function with fractions of seconds? ............................... 1908
A.1.8 Does MySQL 5.0 work with multi-core processors? ........................................................... 1908
A.1.9 Why do I see multiple processes for mysqld? ................................................................. 1908
A.1.10 Can MySQL 5.0 perform ACID transactions? ................................................................. 1908

A.1.1. Which version of MySQL is production-ready (GA)?

MySQL 5.7 and MySQL 5.6 are supported for production use.

MySQL 5.7 achieved General Availability (GA) status with MySQL 5.7.9, which was released for production use on 21 October 2015.

MySQL 5.6 achieved General Availability (GA) status with MySQL 5.6.10, which was released for production use on 5 February 2013.

MySQL 5.5 achieved General Availability (GA) status with MySQL 5.5.8, which was released for production use on 3 December 2010. The MySQL 5.5 series is no longer current, but still supported in production.

MySQL 5.1 achieved General Availability (GA) status with MySQL 5.1.30, which was released for production use on 14 November 2008. Active development for MySQL 5.1 has ended.

MySQL 5.0 achieved General Availability (GA) status with MySQL 5.0.15, which was released for production use on 19 October 2005. Active development for MySQL 5.0 has ended.

A.1.2. What is the state of development (non-GA) versions?

MySQL follows a milestone release model that introduces pre-production-quality features and stabilizes them to release quality (see http://dev.mysql.com/doc/mysql-development-cycle/en/index.html). This process then repeats, so releases cycle between pre-production and release quality status. Please check the change logs to identify the status of a given release.

MySQL 5.4 was a development series. Work on this series has ceased.
A successor to MySQL 5.7 is being actively developed using the milestone release methodology described above.

**A.1.3. Can MySQL 5.0 do subqueries?**

Yes. See Section 13.2.9, “Subquery Syntax”.

**A.1.4. Can MySQL 5.0 perform multiple-table inserts, updates, and deletes?**

Yes. For the syntax required to perform multiple-table updates, see Section 13.2.10, “UPDATE Syntax”; for that required to perform multiple-table deletes, see Section 13.2.2, “DELETE Syntax”.

A multiple-table insert can be accomplished using a trigger whose *FOR EACH ROW* clause contains multiple *INSERT* statements within a *BEGIN ... END* block. See Section 18.3, “Using Triggers”.

**A.1.5. Does MySQL 5.0 have a Query Cache? Does it work on Server, Instance or Database?**

Yes. The query cache operates on the server level, caching complete result sets matched with the original query string. If an exactly identical query is made (which often happens, particularly in web applications), no parsing or execution is necessary; the result is sent directly from the cache. Various tuning options are available. See Section 8.10.3, “The MySQL Query Cache”.

**A.1.6. Does MySQL 5.0 have Sequences?**

No. However, MySQL has an *AUTO_INCREMENT* system, which in MySQL 5.0 can also handle inserts in a multi-master replication setup. With the *auto_increment_increment* and *auto_increment_offset* system variables, you can set each server to generate auto-increment values that don't conflict with other servers. The *auto_increment_increment* value should be greater than the number of servers, and each server should have a unique offset.

**A.1.7. Does MySQL 5.0 have a NOW() function with fractions of seconds?**

No, but support was added in 5.6.4.

Also, MySQL does parse time strings with a fractional component. See Section 11.3.2, “The TIME Type”.

**A.1.8. Does MySQL 5.0 work with multi-core processors?**

Yes. MySQL is fully multi-threaded, and will make use of multiple CPUs, provided that the operating system supports them.

**A.1.9. Why do I see multiple processes for mysqld?**

When using LinuxThreads, you should see a minimum of three *mysqld* processes running. These are in fact threads. There is one thread for the LinuxThreads manager, one thread to handle connections, and one thread to handle alarms and signals.

**A.1.10 Can MySQL 5.0 perform ACID transactions?**

Yes. All current MySQL versions support transactions. The *InnoDB* storage engine offers full ACID transactions with row-level locking, multi-versioning, nonlocking repeatable reads, and all four SQL standard isolation levels.

The *NDB* storage engine supports the *READ COMMITTED* transaction isolation level only.

**A.2 MySQL 5.0 FAQ: Storage Engines**

**A.2.1 Where can I obtain complete documentation for MySQL storage engines?**

**A.2.2 Are there any new storage engines in MySQL 5.0?**
A.2.3 Have any storage engines been removed in MySQL 5.0? .................................................. 1909
A.2.4 What are the unique benefits of the **ARCHIVE** storage engine? ........................................... 1909
A.2.5 Do the new features in MySQL 5.0 apply to all storage engines? ............................................... 1909

### A.2.1. Where can I obtain complete documentation for MySQL storage engines?

See Chapter 14, *Storage Engines*. That chapter contains information about all MySQL storage engines except for the **NDB** storage engine used for MySQL Cluster; **NDB** is covered in Chapter 17, *MySQL Cluster*.

### A.2.2. Are there any new storage engines in MySQL 5.0?

Yes. The **FEDERATED** storage engine, new in MySQL 5.0, allows the server to access tables on other (remote) servers. See Section 14.7, “The FEDERATED Storage Engine”.

### A.2.3. Have any storage engines been removed in MySQL 5.0?

Yes. MySQL 5.0 no longer supports the **ISAM** storage engine. If you have any existing **ISAM** tables from previous versions of MySQL, you should convert these to **MyISAM** before upgrading to MySQL 5.0.

### A.2.4. What are the unique benefits of the **ARCHIVE** storage engine?

The **ARCHIVE** storage engine is ideally suited for storing large amounts of data without indexes; it has a very small footprint, and performs selects using table scans. See Section 14.8, “The **ARCHIVE** Storage Engine”, for details.

### A.2.5. Do the new features in MySQL 5.0 apply to all storage engines?

The general new features such as views, stored procedures, triggers, **INFORMATION_SCHEMA**, precision math (**DECIMAL** column type), and the **BIT** column type, apply to all storage engines. There are also additions and changes for specific storage engines.

### A.3 MySQL 5.0 FAQ: Server SQL Mode

#### A.3.1 What are server SQL modes? ................................................................. 1909
#### A.3.2 How many server SQL modes are there? ................................................. 1909
#### A.3.3 How do you determine the server SQL mode? ........................................... 1909
#### A.3.4 Is the mode dependent on the database or connection? ............................. 1909
#### A.3.5 Can the rules for strict mode be extended? .............................................. 1910
#### A.3.6 Does strict mode impact performance? ..................................................... 1910
#### A.3.7 What is the default server SQL mode when MySQL 5.0 is installed? .......... 1910

### A.3.1. What are server SQL modes?

Server SQL modes define what SQL syntax MySQL should support and what kind of data validation checks it should perform. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers. The MySQL Server apply these modes individually to different clients. For more information, see Section 5.1.7, “Server SQL Modes”.

### A.3.2. How many server SQL modes are there?

Each mode can be independently switched on and off. See Section 5.1.7, “Server SQL Modes”, for a complete list of available modes.

### A.3.3. How do you determine the server SQL mode?

You can set the default SQL mode (for **mysqld** startup) with the **--sql-mode** option. Using the statement `SET [GLOBAL|SESSION] sql_mode='modes'`, you can change the settings from within a connection, either locally to the connection, or to take effect globally. You can retrieve the current mode by issuing a `SELECT @@sql_mode` statement.

### A.3.4. Is the mode dependent on the database or connection?
A mode is not linked to a particular database. Modes can be set locally to the session (connection), or globally for the server. You can change these settings using `SET [GLOBAL|SESSION] sql_mode='modes'`.

A.3.5. Can the rules for strict mode be extended?

When we refer to strict mode, we mean a mode where at least one of the modes TRADITIONAL, STRICT_TRANS_TABLES, or STRICT_ALL_TABLES is enabled. Options can be combined, so you can add restrictions to a mode. See Section 5.1.7, “Server SQL Modes”, for more information.

A.3.6. Does strict mode impact performance?

The intensive validation of input data that some settings require more time than if the validation is not done. While the performance impact is not that great, if you do not require such validation (perhaps your application already handles all of this), then MySQL gives you the option of leaving strict mode disabled. However—if you do require it—strict mode can provide such validation.

A.3.7. What is the default server SQL mode when MySQL 5.0 is installed?

By default, no special modes are enabled. For information about all available modes and MySQL’s default behavior, see Section 5.1.7, “Server SQL Modes”.

A.4 MySQL 5.0 FAQ: Stored Procedures and Functions

A.4.1 Does MySQL 5.0 support stored procedures and functions? .............................................. 1910
A.4.2 Where can I find documentation for MySQL stored procedures and stored functions? ........ 1911
A.4.3 Is there a discussion forum for MySQL stored procedures? ............................................. 1911
A.4.4 Where can I find the ANSI SQL 2003 specification for stored procedures? ...................... 1911
A.4.5 How do you manage stored routines? ................................................................. 1911
A.4.6 Is there a way to view all stored procedures and stored functions in a given database? ........ 1911
A.4.7 Where are stored procedures stored? ................................................................. 1911
A.4.8 Is it possible to group stored procedures or stored functions into packages? ..................... 1911
A.4.9 Can a stored procedure call another stored procedure? ........................................... 1911
A.4.10 Can a stored procedure call a trigger? ............................................................... 1911
A.4.11 Can a stored procedure access tables? ............................................................... 1912
A.4.12 Do stored procedures have a statement for raising application errors? ......................... 1912
A.4.13 Do stored procedures provide exception handling? .................................................. 1912
A.4.14 Can MySQL 5.0 stored routines return result sets? ................................................. 1912
A.4.15 Is WITH RECOMPILE supported for stored procedures? ............................................ 1912
A.4.16 Is there a MySQL equivalent to using `mod_plsql` as a gateway on Apache to talk directly to a stored procedure in the database? ................................................................. 1912

A.4.19 Can I return a cursor as an OUT parameter from a stored procedure? ......................... 1912
A.4.20 Can I print out a variable’s value within a stored routine for debugging purposes? .......... 1912
A.4.21 Can I commit or roll back transactions inside a stored procedure? ................................ 1912
A.4.22 Do MySQL 5.0 stored procedures and functions work with replication? ......................... 1912
A.4.23 Are stored procedures and functions created on a master server replicated to a slave? ...... 1912
A.4.24 How are actions that take place inside stored procedures and functions replicated? ........ 1913
A.4.25 Are there special security requirements for using stored procedures and functions together with replication? ......................................................................................... 1913
A.4.26 What limitations exist for replicating stored procedure and function actions? ................. 1913
A.4.27 Do the preceding limitations affect MySQL’s ability to do point-in-time recovery? .......... 1913
A.4.28 What is being done to correct the aforementioned limitations? .................................... 1913

A.4.1. Does MySQL 5.0 support stored procedures and functions?

Yes. MySQL 5.0 supports two types of stored routines—stored procedures and stored functions.
A.4.2. Where can I find documentation for MySQL stored procedures and stored functions?

See Section 18.2, “Using Stored Routines (Procedures and Functions)".

A.4.3. Is there a discussion forum for MySQL stored procedures?

A.4.4. Where can I find the ANSI SQL 2003 specification for stored procedures?

Unfortunately, the official specifications are not freely available (ANSI makes them available for purchase). However, there are books—such as SQL-99 Complete, Really by Peter Gulutzan and Trudy Pelzer—which give a comprehensive overview of the standard, including coverage of stored procedures.

A.4.5. How do you manage stored routines?

It is always good practice to use a clear naming scheme for your stored routines. You can manage stored procedures with `CREATE [FUNCTION|PROCEDURE]`, `ALTER [FUNCTION|PROCEDURE]`, `DROP [FUNCTION|PROCEDURE]`, and `SHOW CREATE [FUNCTION|PROCEDURE]`. You can obtain information about existing stored procedures using the Routines table in the INFORMATION_SCHEMA database (see Section 19.8, “The INFORMATION_SCHEMA ROUTINES Table”).

A.4.6. Is there a way to view all stored procedures and stored functions in a given database?

Yes. For a database named `dbname`, use this query on the INFORMATION_SCHEMA ROUTINES table:

```
SELECT ROUTINE_TYPE, ROUTINE_NAME
FROM INFORMATION_SCHEMA.ROUTINES
WHERE ROUTINE_SCHEMA='dbname';
```

For more information, see Section 19.8, “The INFORMATION_SCHEMA ROUTINES Table”.

The body of a stored routine can be viewed using `SHOW CREATE FUNCTION` (for a stored function) or `SHOW CREATE PROCEDURE` (for a stored procedure). See Section 13.7.5.8, “SHOW CREATE PROCEDURE Syntax”, for more information.

A.4.7. Where are stored procedures stored?

In the proc table of the mysql system database. However, you should not access the tables in the system database directly. Instead, use `SHOW CREATE FUNCTION` to obtain information about stored functions, and `SHOW CREATE PROCEDURE` to obtain information about stored procedures. See Section 13.7.5.8, “SHOW CREATE PROCEDURE Syntax”, for more information about these statements.

You can also query the ROUTINES table in the INFORMATION_SCHEMA database—see Section 19.8, “The INFORMATION_SCHEMA ROUTINES Table”, for information about this table.

A.4.8. Is it possible to group stored procedures or stored functions into packages?

No. This is not supported in MySQL 5.0.

A.4.9. Can a stored procedure call another stored procedure?

Yes.

A.4.10. Can a stored procedure call a trigger?

A stored procedure can execute an SQL statement, such as an `UPDATE`, that causes a trigger to activate.
A.4.11 Can a stored procedure access tables?

Yes. A stored procedure can access one or more tables as required.

A.4.12 Do stored procedures have a statement for raising application errors?

Not in MySQL 5.0. The SQL standard `SIGNAL` and `RESIGNAL` statements are implemented in MySQL 5.5.

A.4.13 Do stored procedures provide exception handling?

MySQL implements `HANDLER` definitions according to the SQL standard. See Section 13.6.7.2, “DECLARE ... HANDLER Syntax”, for details.

A.4.14 Can MySQL 5.0 stored routines return result sets?

`Stored procedures` can, but stored functions cannot. If you perform an ordinary `SELECT` inside a stored procedure, the result set is returned directly to the client. You need to use the MySQL 4.1 (or above) client/server protocol for this to work. This means that—for instance—in PHP, you need to use the `mysqli` extension rather than the old `mysql` extension.

A.4.15 Is `WITH RECOMPILE` supported for stored procedures?

Not in MySQL 5.0.

A.4.16 Is there a MySQL equivalent to using `mod_plsql` as a gateway on Apache to talk directly to a stored procedure in the database?

There is no equivalent in MySQL 5.0.

A.4.17 Can I pass an array as input to a stored procedure?

Not in MySQL 5.0.

A.4.18 Can I pass a cursor as an `IN` parameter to a stored procedure?

In MySQL 5.0, cursors are available inside stored procedures only.

A.4.19 Can I return a cursor as an `OUT` parameter from a stored procedure?

In MySQL 5.0, cursors are available inside stored procedures only. However, if you do not open a cursor on a `SELECT`, the result will be sent directly to the client. You can also `SELECT INTO` variables. See Section 13.2.8, “SELECT Syntax”.

A.4.20 Can I print out a variable's value within a stored routine for debugging purposes?

Yes, you can do this in a `stored procedure`, but not in a stored function. If you perform an ordinary `SELECT` inside a stored procedure, the result set is returned directly to the client. You will need to use the MySQL 4.1 (or above) client/server protocol for this to work. This means that—for instance—in PHP, you need to use the `mysqli` extension rather than the old `mysql` extension.

A.4.21 Can I commit or roll back transactions inside a stored procedure?

Yes. However, you cannot perform transactional operations within a stored function.

A.4.22 Do MySQL 5.0 stored procedures and functions work with replication?

Yes, standard actions carried out in stored procedures and functions are replicated from a master MySQL server to a slave server. There are a few limitations that are described in detail in Section 18.6, “Binary Logging of Stored Programs”.

A.4.23 Are stored procedures and functions created on a master server replicated to a slave?
Yes, creation of stored procedures and functions carried out through normal DDL statements on a master server are replicated to a slave, so the objects will exist on both servers. \texttt{ALTER} and \texttt{DROP} statements for stored procedures and functions are also replicated.

\textbf{A.4.24} How are actions that take place inside stored procedures and functions replicated?

MySQL records each DML event that occurs in a stored procedure and replicates those individual actions to a slave server. The actual calls made to execute stored procedures are not replicated.

Stored functions that change data are logged as function invocations, not as the DML events that occur inside each function.

\textbf{A.4.25} Are there special security requirements for using stored procedures and functions together with replication?

Yes. Because a slave server has authority to execute any statement read from a master’s binary log, special security constraints exist for using stored functions with replication. If replication or binary logging in general (for the purpose of point-in-time recovery) is active, then MySQL DBAs have two security options open to them:

1. Any user wishing to create stored functions must be granted the \texttt{SUPER} privilege.
2. Alternatively, a DBA can set the \texttt{log_bin_trust_function_creators} system variable to 1, which enables anyone with the standard \texttt{CREATE ROUTINE} privilege to create stored functions.

\textbf{A.4.26} What limitations exist for replicating stored procedure and function actions?

Nondeterministic (random) or time-based actions embedded in stored procedures may not replicate properly. By their very nature, randomly produced results are not predictable and cannot be exactly reproduced, and therefore, random actions replicated to a slave will not mirror those performed on a master. Declaring stored functions to be \texttt{DETERMINISTIC} or setting the \texttt{log_bin_trust_function_creators} system variable to 0 will not allow random-valued operations to be invoked.

In addition, time-based actions cannot be reproduced on a slave because the timing of such actions in a stored procedure is not reproducible through the binary log used for replication. It records only DML events and does not factor in timing constraints.

Finally, nontransactional tables for which errors occur during large DML actions (such as bulk inserts) may experience replication issues in that a master may be partially updated from DML activity, but no updates are done to the slave because of the errors that occurred. A workaround is for a function’s DML actions to be carried out with the \texttt{IGNORE} keyword so that updates on the master that cause errors are ignored and updates that do not cause errors are replicated to the slave.

\textbf{A.4.27} Do the preceding limitations affect MySQL’s ability to do point-in-time recovery?

The same limitations that affect replication do affect point-in-time recovery.

\textbf{A.4.28} What is being done to correct the aforementioned limitations?

MySQL 5.1 implements \textit{row-based replication}, which resolves the limitations mentioned earlier.

We do not plan to backport row-based replication to MySQL 5.0. For additional information, see \textit{Replication Formats}, in the \textit{MySQL 5.1 Manual}.

\section*{A.5 MySQL 5.0 FAQ: Triggers}

\textbf{A.5.1} Where can I find the documentation for MySQL 5.0 triggers?

\textbf{A.5.2} Is there a discussion forum for MySQL Triggers?
A.5.3 Does MySQL 5.0 have statement-level or row-level triggers? .............................. 1914
A.5.4 Are there any default triggers? .............................................................................. 1914
A.5.5 How are triggers managed in MySQL? ................................................................. 1914
A.5.6 Is there a way to view all triggers in a given database? ....................................... 1914
A.5.7 Where are triggers stored? ..................................................................................... 1914
A.5.8 Can a trigger call a stored procedure? ................................................................. 1914
A.5.9 Can triggers access tables? .................................................................................... 1914
A.5.10 Can a table have multiple triggers with the same trigger event and action time? .... 1915
A.5.11 Can triggers call an external application through a UDF? ................................. 1915
A.5.12 Is it possible for a trigger to update tables on a remote server? ......................... 1915
A.5.13 Do triggers work with replication? .......................................................... 1914
A.5.14 How are actions carried out through triggers on a master replicated to a slave? ... 1915

A.5.1. Where can I find the documentation for MySQL 5.0 triggers?

See Section 18.3, “Using Triggers”.

A.5.2. Is there a discussion forum for MySQL Triggers?

A.5.3. Does MySQL 5.0 have statement-level or row-level triggers?

In MySQL 5.0, all triggers are **FOR EACH ROW**—that is, the trigger is activated for each row that is inserted, updated, or deleted. MySQL 5.0 does not support triggers using **FOR EACH STATEMENT**.

A.5.4. Are there any default triggers?

Not explicitly. MySQL does have specific special behavior for some **TIMESTAMP** columns, as well as for columns which are defined using **AUTO_INCREMENT**.

A.5.5. How are triggers managed in MySQL?

In MySQL 5.0, triggers can be created using the **CREATE TRIGGER** statement, and dropped using **DROP TRIGGER**. See Section 13.1.11, “CREATE TRIGGER Syntax”, and Section 13.1.18, “DROP TRIGGER Syntax”, for more about these statements.

Information about triggers can be obtained by querying the **INFORMATION_SCHEMA.TRIGGERS** table. See Section 19.15, “The INFORMATION_SCHEMA TRIGGERS Table”.

A.5.6. Is there a way to view all triggers in a given database?

Yes. You can obtain a listing of all triggers defined on database **dbname** using a query on the **INFORMATION_SCHEMA.TRIGGERS** table such as the one shown here:

```
SELECT TRIGGER_NAME, EVENT_MANIPULATION, EVENT_OBJECT_TABLE, ACTION_STATEMENT
FROM INFORMATION_SCHEMA.TRIGGERS
WHERE TRIGGER_SCHEMA='dbname';
```

For more information about this table, see Section 19.15, “The INFORMATION_SCHEMA TRIGGERS Table”.

You can also use the **SHOW TRIGGERS** statement, which is specific to MySQL. See Section 13.7.5.35, “SHOW TRIGGERS Syntax”.

A.5.7. Where are triggers stored?

Triggers for a table are currently stored in **.TRG** files, with one such file one per table.

A.5.8. Can a trigger call a stored procedure?

Yes.
A.5.9. Can triggers access tables?

A trigger can access both old and new data in its own table. A trigger can also affect other tables, but it is not permitted to modify a table that is already being used (for reading or writing) by the statement that invoked the function or trigger. (Before MySQL 5.0.10, a trigger cannot modify other tables.)

A.5.10. Can a table have multiple triggers with the same trigger event and action time?

In MySQL 5.0, there cannot be multiple triggers for a given table that have the same trigger event and action time. For example, you cannot have two BEFORE UPDATE triggers for a table. This limitation is lifted in MySQL 5.7.

A.5.11. Can triggers call an external application through a UDF?

Yes. For example, a trigger could invoke the `sys_exec()` UDF.

A.5.12. Is it possible for a trigger to update tables on a remote server?

Yes. A table on a remote server could be updated using the `FEDERATED` storage engine. (See Section 14.7, “The FEDERATED Storage Engine”).

A.5.13. Do triggers work with replication?

Triggers and replication in MySQL 5.0 work in the same way as in most other database systems: Actions carried out through triggers on a master are not replicated to a slave server. Instead, triggers that exist on tables that reside on a MySQL master server need to be created on the corresponding tables on any MySQL slave servers so that the triggers activate on the slaves as well as the master.

For more information, see Section 16.4.1.27, “Replication and Triggers”.

A.5.14. How are actions carried out through triggers on a master replicated to a slave?

First, the triggers that exist on a master must be re-created on the slave server. Once this is done, the replication flow works as any other standard DML statement that participates in replication. For example, consider a table `EMP` that has an `AFTER` insert trigger, which exists on a master MySQL server. The same `EMP` table and `AFTER` insert trigger exist on the slave server as well. The replication flow would be:

1. An `INSERT` statement is made to `EMP`.
2. The `AFTER` trigger on `EMP` activates.
3. The `INSERT` statement is written to the binary log.
4. The replication slave picks up the `INSERT` statement to `EMP` and executes it.
5. The `AFTER` trigger on `EMP` that exists on the slave activates.

For more information, see Section 16.4.1.27, “Replication and Triggers”.

A.6 MySQL 5.0 FAQ: Views

A.6.1. Where can I find documentation covering MySQL Views? ................................. 1915
A.6.2. Is there a discussion forum for MySQL Views? ......................................................... 1916
A.6.3. What happens to a view if an underlying table is dropped or renamed? ...................... 1916
A.6.4. Does MySQL 5.0 have table snapshots? ................................................................. 1916
A.6.5. Does MySQL 5.0 have materialized views? ............................................................. 1916
A.6.6. Can you insert into views that are based on joins? .................................................. 1916

A.6.1. Where can I find documentation covering MySQL Views?
See Section 18.4, “Using Views”.

A.6.2. Is there a discussion forum for MySQL Views?

Yes. See http://forums.mysql.com/list.php?100

A.6.3. What happens to a view if an underlying table is dropped or renamed?

After a view has been created, it is possible to drop or alter a table or view to which the definition refers. To check a view definition for problems of this kind, use the CHECK TABLE statement. (See Section 13.7.2.3, “CHECK TABLE Syntax”.)

A.6.4. Does MySQL 5.0 have table snapshots?

No.

A.6.5. Does MySQL 5.0 have materialized views?

No.

A.6.6. Can you insert into views that are based on joins?

It is possible, provided that your INSERT statement has a column list that makes it clear there is only one table involved.

You cannot insert into multiple tables with a single insert on a view.

A.7 MySQL 5.0 FAQ: INFORMATION_SCHEMA

A.7.1 Where can I find documentation for the MySQL INFORMATION_SCHEMA database?

See Chapter 19, INFORMATION_SCHEMA Tables

A.7.2 Is there a discussion forum for INFORMATION_SCHEMA?

A.7.3 Where can I find the ANSI SQL 2003 specification for INFORMATION_SCHEMA?

Unfortunately, the official specifications are not freely available. (ANSI makes them available for purchase.) However, there are books available—such as SQL-99 Complete, Really by Peter Gulutzan and Trudy Pelzer—which give a comprehensive overview of the standard, including INFORMATION_SCHEMA.

A.7.4 What is the difference between the Oracle Data Dictionary and MySQL’s INFORMATION_SCHEMA?

Both Oracle and MySQL provide metadata in tables. However, Oracle and MySQL use different table names and column names. MySQL’s implementation is more similar to those found in DB2 and SQL Server, which also support INFORMATION_SCHEMA as defined in the SQL standard.

A.7.5 Can I add to or otherwise modify the tables found in the INFORMATION_SCHEMA database?

No. Since applications may rely on a certain standard structure, this should not be modified. For this reason, we cannot support bugs or other issues which result from modifying INFORMATION_SCHEMA tables or data.
A.8 MySQL 5.0 FAQ: Migration

A.8.1 Where can I find information on how to migrate from MySQL 4.1 to MySQL 5.0? ............... 1917
A.8.2 How has storage engine (table type) support changed in MySQL 5.0 from previous versions? .................................................. 1917

A.8.1. Where can I find information on how to migrate from MySQL 4.1 to MySQL 5.0?

For detailed upgrade information, see Section 2.19.1, “Upgrading MySQL”. Do not skip a major version when upgrading, but rather complete the process in steps, upgrading from one major version to the next in each step. This may seem more complicated, but it will you save time and trouble—if you encounter problems during the upgrade, their origin will be easier to identify, either by you or—if you have a MySQL Enterprise subscription—by MySQL support.

A.8.2. How has storage engine (table type) support changed in MySQL 5.0 from previous versions?

Storage engine support has changed as follows:

• Support for ISAM tables was removed in MySQL 5.0 and you should now use the MyISAM storage engine in place of ISAM. To convert a table tblname from ISAM to MyISAM, simply issue a statement such as this one:
  
  ```
  ALTER TABLE tblname ENGINE=MYISAM;
  ```

• Internal RAID for MyISAM tables was also removed in MySQL 5.0. This was formerly used to allow large tables in file systems that did not support file sizes greater than 2GB. All modern file systems allow for larger tables; in addition, there are now other solutions such as MERGE tables and views.

• The VARCHAR column type now retains trailing spaces in all storage engines.

• MEMORY tables (formerly known as HEAP tables) can also contain VARCHAR columns.

A.9 MySQL 5.0 FAQ: Security

A.9.1 Where can I find documentation that addresses security issues for MySQL? ............... 1917
A.9.2 Does MySQL 5.0 have native support for SSL? .................................................. 1918
A.9.3 Is SSL support built into MySQL binaries, or must I recompile the binary myself to enable it? 1918
A.9.4 Does MySQL 5.0 have built-in authentication against LDAP directories? ............... 1918
A.9.5 Does MySQL 5.0 include support for Roles Based Access Control (RBAC)? ............... 1918

A.9.1. Where can I find documentation that addresses security issues for MySQL?

The best place to start is Chapter 6, Security.

Other portions of the MySQL Documentation which you may find useful with regard to specific security concerns include the following:

• Section 6.1.1, “Security Guidelines”.

• Section 6.1.3, “Making MySQL Secure Against Attackers”.

• Section B.5.3.2, “How to Reset the Root Password”.

• Section 6.1.5, “How to Run MySQL as a Normal User”.

• Section 21.2.2.6, “UDF Security Precautions”.

• Section 6.1.4, “Security-Related mysqld Options and Variables”.

• Section 6.1.6, “Security Issues with LOAD DATA LOCAL”. 
A.9.2. Does MySQL 5.0 have native support for SSL?

Most 5.0 binaries have support for SSL connections between the client and server. See Section 6.3.6, “Using Secure Connections”.

You can also tunnel a connection using SSH, if (for example) the client application does not support SSL connections. For an example, see Section 6.3.8, “Connecting to MySQL Remotely from Windows with SSH”.

A.9.3. Is SSL support built into MySQL binaries, or must I recompile the binary myself to enable it?

Most 5.0 binaries have SSL enabled for client/server connections that are secured, authenticated, or both. See Section 6.3.6, “Using Secure Connections”.

A.9.4. Does MySQL 5.0 have built-in authentication against LDAP directories?

No.

As of MySQL 5.5.16, the Enterprise edition includes a PAM Authentication Plugin that supports authentication against an LDAP directory.

A.9.5. Does MySQL 5.0 include support for Roles Based Access Control (RBAC)?

Not at this time.

A.10 MySQL 5.0 FAQ: MySQL Cluster

In the following section, we answer questions that are frequently asked about MySQL Cluster and the NDBCLUSTER storage engine.

A.10.1 Which versions of the MySQL software support Cluster? Do I have to compile from source? ................................................................. 1919

A.10.2 What do “NDB” and “NDBCLUSTER” mean? ................................................................. 1919

A.10.3 What is the difference between using MySQL Cluster versus using MySQL Replication? ... 1919

A.10.4 Do I need any special networking to run MySQL Cluster? How do computers in a cluster communicate? ......................................................... 1920

A.10.5 How many computers do I need to run a MySQL Cluster, and why? ................................. 1920

A.10.6 What do the different computers do in a MySQL Cluster? .................................................. 1920

A.10.7 With which operating systems can I use MySQL Cluster? .................................................. 1921

A.10.8 What are the hardware requirements for running MySQL Cluster? ....................................... 1921

A.10.9 How much RAM do I need to use MySQL Cluster? Is it possible to use disk memory at all? 1921

A.10.10 What file systems can I use with MySQL Cluster? What about network file systems or network shares? ........................................................................ 1922

A.10.11 Can I run MySQL Cluster nodes inside virtual machines (such as those created by VMWare, Parallels, or Xen)? ......................................................... 1923

A.10.12 I am trying to populate a MySQL Cluster database. The loading process terminates prematurely and I get an error message like this one: ......................................................... 1923

A.10.13 MySQL Cluster uses TCP/IP. Does this mean that I can run it over the Internet, with one or more nodes in remote locations? ................................................................. 1923

A.10.14 Do I have to learn a new programming or query language to use MySQL Cluster? ............... 1923

A.10.15 What programming languages and APIs are supported by MySQL Cluster? ...................... 1924

A.10.16 Does MySQL Cluster include any management tools? .......................................................... 1924

A.10.17 How do I find out what an error or warning message means when using MySQL Cluster? 1924

A.10.18 Is MySQL Cluster transaction-safe? What isolation levels are supported? .......................... 1924

A.10.19 What storage engines are supported by MySQL Cluster? .................................................... 1924

A.10.20 In the event of a catastrophic failure—say, for instance, the whole city loses power and my UPS fails—would I lose all my data? ................................................................. 1924
A.10.21 Is it possible to use FULLTEXT indexes with MySQL Cluster? ........................................ 1924
A.10.22 Can I run multiple nodes on a single computer? ............................................................ 1925
A.10.23 Can I add data nodes to a MySQL Cluster without restarting it? .................................... 1925
A.10.24 Are there any limitations that I should be aware of when using MySQL Cluster? ........... 1925
A.10.25 Does MySQL Cluster support foreign keys? ................................................................. 1926
A.10.26 How do I import an existing MySQL database into a MySQL Cluster? ......................... 1926
A.10.27 How do MySQL Cluster nodes communicate with one another? .................................. 1926
A.10.28 What is an arbitrator? ....................................................................................................... 1926
A.10.29 What data types are supported by MySQL Cluster? ....................................................... 1927
A.10.30 How do I start and stop MySQL Cluster? ...................................................................... 1927
A.10.31 What happens to MySQL Cluster data when the MySQL Cluster is shut down? .......... 1928
A.10.32 Is it a good idea to have more than one management node for a MySQL Cluster? ....... 1928
A.10.33 Can I mix different kinds of hardware and operating systems in one MySQL Cluster? ... 1928

A.10.1 Which versions of the MySQL software support Cluster? Do I have to compile from source?

MySQL Cluster is supported in all server binaries in the 5.0 release series for operating systems on which MySQL Cluster is available. See Section 4.3.1, “mysqld — The MySQL Server.” You can determine whether your server has NDB support using either of the statements SHOW VARIABLES LIKE 'have_%' or SHOW ENGINES.

Note

Linux users: NDB is not included in the standard MySQL server RPMs. Beginning with MySQL 5.0.4, there are separate RPM packages for the NDB storage engine and accompanying management and other tools; see the NDB RPM Downloads section of the MySQL 5.0 Downloads page for these. (Prior to 5.0.4, you had to use the --max binaries supplied as .tar.gz archives. This is still possible, but is not required, so you can use your Linux distribution's RPM manager if you prefer.)

You can also obtain NDB support by compiling MySQL from source, but it is not necessary to do so simply to use MySQL Cluster. To download the latest binary, RPM, or source distribution in the MySQL 5.0 series, visit http://dev.mysql.com/downloads/mysql/5.0.html.

You should use MySQL Cluster NDB 7.3 or MySQL Cluster NDB 7.4 for new deployments; if you are currently using an older version of MySQL Cluster, you should upgrade to one of these versions as soon as possible. For an overview of improvements made in MySQL Cluster NDB 7.3 and 7.4, see What is New in MySQL Cluster NDB 7.3, and What is New in MySQL Cluster NDB 7.4, respectively.

A.10.2 What do “NDB” and “NDBCLUSTER” mean?

“NDB” stands for “Network Database”, NDB and NDBCLUSTER are both names for the storage engine that enables clustering support with MySQL. NDB is preferred, but either name is correct.

A.10.3 What is the difference between using MySQL Cluster versus using MySQL Replication?

In traditional MySQL replication, a master MySQL server updates one or more slaves. Transactions are committed sequentially, and a slow transaction can cause the slave to lag behind the master. This means that if the master fails, it is possible that the slave might not have recorded the last few transactions. If a transaction-safe engine such as InnoDB is being used, a transaction will either be complete on the slave or not applied at all, but replication does not guarantee that all data on the master and the slave will be consistent at all times. In MySQL
Cluster, all data nodes are kept in synchrony, and a transaction committed by any one data node is committed for all data nodes. In the event of a data node failure, all remaining data nodes remain in a consistent state.

In short, whereas standard MySQL replication is *asynchronous*, MySQL Cluster is *synchronous*.

We have implemented (asynchronous) replication for Cluster in MySQL 5.1 and later. *MySQL Cluster Replication* (also sometimes known as “geo-replication”) includes the capability to replicate both between two MySQL Clusters, and from a MySQL Cluster to a non-Cluster MySQL server. However, we do not plan to backport this functionality to MySQL 5.0. See *MySQL Cluster Replication*.

**A.10.4** Do I need any special networking to run MySQL Cluster? How do computers in a cluster communicate?

MySQL Cluster is intended to be used in a high-bandwidth environment, with computers connecting using TCP/IP. Its performance depends directly upon the connection speed between the cluster’s computers. The minimum connectivity requirements for MySQL Cluster include a typical 100-megabit Ethernet network or the equivalent. We recommend you use gigabit Ethernet whenever available.

**A.10.5** How many computers do I need to run a MySQL Cluster, and why?

A minimum of three computers is required to run a viable cluster. However, the minimum *recommended* number of computers in a MySQL Cluster is four: one each to run the management and SQL nodes, and two computers to serve as data nodes. The purpose of the two data nodes is to provide redundancy; the management node must run on a separate machine to guarantee continued arbitration services in the event that one of the data nodes fails.

To provide increased throughput and high availability, you should use multiple SQL nodes (MySQL Servers connected to the cluster). It is also possible (although not strictly necessary) to run multiple management servers.

**A.10.6** What do the different computers do in a MySQL Cluster?

A MySQL Cluster has both a physical and logical organization, with computers being the physical elements. The logical or functional elements of a cluster are referred to as *nodes*, and a computer housing a cluster node is sometimes referred to as a *cluster host*. There are three types of nodes, each corresponding to a specific role within the cluster. These are:

- **Management node.** This node provides management services for the cluster as a whole, including startup, shutdown, backups, and configuration data for the other nodes. The management node server is implemented as the application *ndb_mgmd*; the management client used to control MySQL Cluster is *ndb_mgm*. See Section 17.4.2, "*ndb_mgmd — The MySQL Cluster Management Server Daemon*", and Section 17.4.3, "*ndb_mgm — The MySQL Cluster Management Client*", for information about these programs.

- **Data node.** This type of node stores and replicates data. Data node functionality is handled by instances of the *NDB* data node process *ndbd*. For more information, see Section 17.4.1, "*ndbd — The MySQL Cluster Data Node Daemon*".

- **SQL node.** This is simply an instance of MySQL Server (*mysqld*) that is built with support for the *NDBCLUSTER* storage engine and started with the *--ndb-cluster* option to enable the engine and the *--ndb-connectstring* option to enable it to connect to a MySQL Cluster management server. For more about these options, see *mysqld Command Options for MySQL Cluster*.

**Note**

An *API node* is any application that makes direct use of Cluster data nodes for data storage and retrieval. An SQL node can thus be
considered a type of API node that uses a MySQL Server to provide an SQL interface to the Cluster. You can write such applications (that do not depend on a MySQL Server) using the NDB API, which supplies a direct, object-oriented transaction and scanning interface to MySQL Cluster data; see MySQL Cluster API Overview: The NDB API, for more information.

A.10.7 With which operating systems can I use MySQL Cluster?

MySQL Cluster is supported on most Unix-like operating systems. Beginning with MySQL Cluster NDB 7.1.3, MySQL Cluster is also supported in production on Microsoft Windows operating systems.

Important

We do not intend to provide any level of support on Windows for MySQL Cluster in MySQL 5.0; you must use MySQL Cluster NDB 7.1.3 or later to obtain GA-level support for MySQL Cluster in a Windows environment. See What is New in MySQL Cluster NDB 7.1, for more information.

For more detailed information concerning the level of support which is offered for MySQL Cluster on various operating system versions, operating system distributions, and hardware platforms, please refer to http://www.mysql.com/support/supportedplatforms/cluster.html.

A.10.8 What are the hardware requirements for running MySQL Cluster?

MySQL Cluster should run on any platform for which NDB-enabled binaries are available. For data nodes and API nodes, faster CPUs and more memory are likely to improve performance, and 64-bit CPUs are likely to be more effective than 32-bit processors. There must be sufficient memory on machines used for data nodes to hold each node’s share of the database (see How much RAM do I Need? for more information). For a computer which is used only for running the MySQL Cluster management server, the requirements are minimal; a common desktop PC (or the equivalent) is generally sufficient for this task. Nodes can communicate through the standard TCP/IP network and hardware. They can also use the high-speed SCI protocol; however, special networking hardware and software are required to use SCI (see Section 17.3.4, “Using High-Speed Interconnects with MySQL Cluster”).

A.10.9 How much RAM do I need to use MySQL Cluster? Is it possible to use disk memory at all?

In MySQL 5.0, Cluster is in-memory only. This means that all table data (including indexes) is stored in RAM. Therefore, if your data takes up 1 GB of space and you want to replicate it once in the cluster, you need 2 GB of memory to do so (1 GB per replica). This is in addition to the memory required by the operating system and any applications running on the cluster computers.

If a data node’s memory usage exceeds what is available in RAM, then the system will attempt to use swap space up to the limit set for DataMemory. However, this will at best result in severely degraded performance, and may cause the node to be dropped due to slow response time (missed heartbeats). We do not recommend on relying on disk swapping in a production environment for this reason. In any case, once the DataMemory limit is reached, any operations requiring additional memory (such as inserts) will fail.

We have implemented disk data storage for MySQL Cluster in MySQL 5.1 and later but we have no plans to add this capability in MySQL 5.0. See MySQL Cluster Disk Data Tables, for more information.

You can use the following formula for obtaining a rough estimate of how much RAM is needed for each data node in the cluster:

\[(\text{Size of Database} \times \text{Number of Replicas} \times 1.1) / \text{Number of Data Nodes}\]
To calculate the memory requirements more exactly requires determining, for each table in the cluster database, the storage space required per row (see Section 11.7, “Data Type Storage Requirements”, for details), and multiplying this by the number of rows. You must also remember to account for any column indexes as follows:

- Each primary key or hash index created for an NDBCLUSTER table requires 21–25 bytes per record. These indexes use IndexMemory.
- Each ordered index requires 10 bytes storage per record, using DataMemory.
- Creating a primary key or unique index also creates an ordered index, unless this index is created with USING HASH. In other words:
  - A primary key or unique index on a Cluster table normally takes up 31 to 35 bytes per record.
  - However, if the primary key or unique index is created with USING HASH, then it requires only 21 to 25 bytes per record.

Creating MySQL Cluster tables with USING HASH for all primary keys and unique indexes will generally cause table updates to run more quickly—in some cases by as much as 20 to 30 percent faster than updates on tables where USING HASH was not used in creating primary and unique keys. This is due to the fact that less memory is required (because no ordered indexes are created), and that less CPU must be utilized (because fewer indexes must be read and possibly updated). However, it also means that queries that could otherwise use range scans must be satisfied by other means, which can result in slower selects.

When calculating Cluster memory requirements, you may find useful the ndb_size.pl utility which is available in recent MySQL 5.0 releases. This Perl script connects to a current (non-Cluster) MySQL database and creates a report on how much space that database would require if it used the NDBCLUSTER storage engine. For more information, see Section 17.4.18, “ndb_size.pl — NDBCLUSTER Size Requirement Estimator”.

It is especially important to keep in mind that every MySQL Cluster table must have a primary key. The NDB storage engine creates a primary key automatically if none is defined; this primary key is created without USING HASH.

There is no easy way to determine exactly how much memory is being used for storage of MySQL Cluster indexes at any given time; however, warnings are written to the cluster log when 80% of available DataMemory or IndexMemory is in use, and again when usage reaches 85%, 90%, and so on.

**A.10.10 What file systems can I use with MySQL Cluster? What about network file systems or network shares?**

Generally, any file system that is native to the host operating system should work well with MySQL Cluster. If you find that a given file system works particularly well (or not so especially well) with MySQL Cluster, we invite you to discuss your findings in the MySQL Cluster Forums.

We do not test MySQL Cluster with FAT or VFAT file systems on Linux. Because of this, and due to the fact that these are not very useful for any purpose other than sharing disk partitions between Linux and Windows operating systems on multi-boot computers, we do not recommend their use with MySQL Cluster.

MySQL Cluster is implemented as a shared-nothing solution; the idea behind this is that the failure of a single piece of hardware should not cause the failure of multiple cluster nodes, or possibly even the failure of the cluster as a whole. For this reason, the use of network shares or network file systems is not supported for MySQL Cluster. This also applies to shared storage devices such as SANs.
A.10.11 Can I run MySQL Cluster nodes inside virtual machines (such as those created by VMWare, Parallels, or Xen)?

This is possible but not recommended for a production environment with MySQL Cluster versions prior to MySQL Cluster NDB 7.2.

For deployment in virtualized environments, you should use MySQL Cluster NDB 7.2 or later.

A.10.12 I am trying to populate a MySQL Cluster database. The loading process terminates prematurely and I get an error message like this one:

```
ERROR 1114: The table 'my_cluster_table' is full
```

Why is this happening?

The cause is very likely to be that your setup does not provide sufficient RAM for all table data and all indexes, including the primary key required by the NDB storage engine and automatically created in the event that the table definition does not include the definition of a primary key.

It is also worth noting that all data nodes should have the same amount of RAM, since no data node in a cluster can use more memory than the least amount available to any individual data node. For example, if there are four computers hosting Cluster data nodes, and three of these have 3GB of RAM available to store Cluster data while the remaining data node has only 1GB RAM, then each data node can devote at most 1GB to MySQL Cluster data and indexes.

In some cases it is possible to get `Table is full` errors in MySQL client applications even when `ndb_mgm -e "ALL REPORT MEMORYUSAGE"` shows significant free `DataMemory`. You can force NDB to create extra partitions for MySQL Cluster tables and thus have more memory available for hash indexes by using the `MAX_ROWS` option for `CREATE TABLE`. In general, setting `MAX_ROWS` to twice the number of rows that you expect to store in the table should be sufficient.

For similar reasons, you can also sometimes encounter problems with data node restarts on nodes that are heavily loaded with data. In MySQL Cluster NDB 7.1 and later, the addition of the `MinFreePct` parameter helps with this issue by reserving a portion (5% by default) of `DataMemory` and `IndexMemory` for use in restarts. This reserved memory is not available for storing NDB tables or data.

A.10.13 MySQL Cluster uses TCP/IP. Does this mean that I can run it over the Internet, with one or more nodes in remote locations?

It is very unlikely that a cluster would perform reliably under such conditions, as MySQL Cluster was designed and implemented with the assumption that it would be run under conditions guaranteeing dedicated high-speed connectivity such as that found in a LAN setting using 100 Mbps or gigabit Ethernet—preferably the latter. We neither test nor warrant its performance using anything slower than this.

Also, it is extremely important to keep in mind that communications between the nodes in a MySQL Cluster are not secure; they are neither encrypted nor safeguarded by any other protective mechanism. The most secure configuration for a cluster is in a private network behind a firewall, with no direct access to any Cluster data or management nodes from outside. (For SQL nodes, you should take the same precautions as you would with any other instance of the MySQL server.) For more information, see Section 17.5.10, “MySQL Cluster Security Issues”.

A.10.14 Do I have to learn a new programming or query language to use MySQL Cluster?

No. Although some specialized commands are used to manage and configure the cluster itself, only standard (My)SQL statements are required for the following operations:

- Creating, altering, and dropping tables
• Inserting, updating, and deleting table data
• Creating, changing, and dropping primary and unique indexes

Some specialized configuration parameters and files are required to set up a MySQL Cluster—see Section 17.3.3, “MySQL Cluster Configuration Files”, for information about these.

A few simple commands are used in the MySQL Cluster management client (ndb_mgm) for tasks such as starting and stopping cluster nodes. See Section 17.5.2, “Commands in the MySQL Cluster Management Client”.

A.10.15. What programming languages and APIs are supported by MySQL Cluster?

MySQL Cluster 5.0 supports the same programming APIs and languages as the standard MySQL Server, including ODBC, .Net, the MySQL C API, and numerous drivers for popular scripting languages such as PHP, Perl, and Python. MySQL Cluster applications written using these APIs behave similarly to other MySQL applications; they transmit SQL statements to a MySQL Server (in the case of MySQL Cluster, an SQL node), and receive responses containing rows of data. For more information about these APIs, see Chapter 20, Connectors and APIs.

A.10.16. Does MySQL Cluster include any management tools?

MySQL Cluster includes a command line client for performing basic management functions. See Section 17.4.3, “ndb_mgm — The MySQL Cluster Management Client”, and Section 17.5.2, “Commands in the MySQL Cluster Management Client”.

A.10.17. How do I find out what an error or warning message means when using MySQL Cluster?

There are two ways in which this can be done:

• From within the mysql client, use SHOW ERRORS or SHOW WARNINGS immediately upon being notified of the error or warning condition.
• From a system shell prompt, use perror --ndb error_code.

A.10.18. MySQL Cluster transaction-safe? What isolation levels are supported?

Yes. For tables created with the NDB storage engine, transactions are supported. Currently, MySQL Cluster supports only the READ COMMITTED transaction isolation level.

A.10.19. What storage engines are supported by MySQL Cluster?

Clustering with MySQL is supported only by the NDB storage engine. That is, in order for a table to be shared between nodes in a MySQL Cluster, the table must be created using ENGINE=NDB (or the equivalent option ENGINE=NDBCLUSTER).

It is possible to create tables using other storage engines (such as InnoDB or MyISAM) on a MySQL server being used with a MySQL Cluster, but since these tables do not use NDB, they do not participate in clustering; each such table is strictly local to the individual MySQL server instance on which it is created.

A.10.20. In the event of a catastrophic failure—say, for instance, the whole city loses power and my UPS fails—would I lose all my data?

All committed transactions are logged. Therefore, although it is possible that some data could be lost in the event of a catastrophe, this should be quite limited. Data loss can be further reduced by minimizing the number of operations per transaction. (It is not a good idea to perform large numbers of operations per transaction in any case.)

A.10.21. Is it possible to use FULLTEXT indexes with MySQL Cluster?
**FULLTEXT** indexing is currently supported only by the **MyISAM** storage engine. See Section 12.9, "Full-Text Search Functions", for more information.

### A.10.2 Can I run multiple nodes on a single computer?

It is possible but not advisable. One of the chief reasons to run a cluster is to provide redundancy. To obtain the full benefits of this redundancy, each node should reside on a separate machine. If you place multiple nodes on a single machine and that machine fails, you lose all of those nodes. Given that MySQL Cluster can be run on commodity hardware loaded with a low-cost (or even no-cost) operating system, the expense of an extra machine or two is well worth it to safeguard mission-critical data. It also worth noting that the requirements for a cluster host running a management node are minimal. This task can be accomplished with a 300 MHz Pentium or equivalent CPU and sufficient RAM for the **ndb_mgmd** and **ndb_mgm** processes.

It is acceptable to run multiple cluster data nodes on a single host for learning about MySQL Cluster, or for testing purposes; however, this is not generally supported for production use.

### A.10.2 Can I add data nodes to a MySQL Cluster without restarting it?

Not in MySQL 5.0. While a rolling restart is all that is required for adding new management or API nodes to a MySQL Cluster (see Section 17.5.5, “Performing a Rolling Restart of a MySQL Cluster”), adding data nodes is more complex, and requires the following steps:

1. Make a complete backup of all Cluster data.
2. Completely shut down the cluster and all cluster node processes.
3. Restart the cluster, using the **--initial** startup option for all instances of **ndbd**.

**Warning**

Never use the **--initial** when starting **ndbd** except when necessary to clear the data node file system. See Section 17.4.1, "**ndbd** — The MySQL Cluster Data Node Daemon", for information about when this is required.

4. Restore all cluster data from the backup.

**Note**

Beginning with MySQL Cluster NDB 6.4, it is possible to add new data nodes to a running MySQL Cluster without taking it offline. For more information, see Adding MySQL Cluster Data Nodes Online. However, we do not plan to add this capability in MySQL 5.0.

### A.10.2 Are there any limitations that I should be aware of when using MySQL Cluster?

**Limitations on NDB** tables in MySQL 5.0 include the following:

- Temporary tables are not supported; a **CREATE TEMPORARY TABLE** statement using **ENGINE=NDB** or **ENGINE=NDBCLUSTER** fails with an error.

- **FULLTEXT** indexes are not supported.

- Index prefixes are not supported. Only complete columns may be indexed.

- As of MySQL 5.0.16, MySQL Cluster supports spatial data types. However, spatial indexes are not supported. See Section 11.5, “Extensions for Spatial Data”.

- Only complete rollbacks for transactions are supported. Partial rollbacks and rollbacks to savepoints are not supported. A failed insert due to a duplicate key or similar error causes
a transaction to abort; when this occurs, you must issue an explicit `ROLLBACK` and retry the transaction.

- The maximum number of attributes allowed per table is 128, and attribute names cannot be any longer than 31 characters. For each table, the maximum combined length of the table and database names is 122 characters.

- The maximum size for a table row is 8 kilobytes, not counting BLOB values. There is no set limit for the number of rows per NDB table. Limits on table size depend on a number of factors, in particular on the amount of RAM available to each data node.

- The NDB engine does not support foreign key constraints. As with MySQL tables, if these are specified in a `CREATE TABLE` or `ALTER TABLE` statement, they are ignored.

For a complete listing of limitations in MySQL Cluster, see Section 17.1.5, “Known Limitations of MySQL Cluster”. See also Section 17.1.5.10, “Previous MySQL Cluster Issues Resolved in MySQL 5.0”.

A.10.25. Does MySQL Cluster support foreign keys?

MySQL Cluster 5.0 does not support foreign key constraints, and ignores foreign keys in `CREATE TABLE` statements (similarly to how MyISAM treats foreign key syntax).

Foreign key support comparable to that found in the InnoDB storage engine is provided by NDB beginning with MySQL Cluster NDB 7.3. Applications requiring foreign support should use MySQL Cluster NDB 7.3 or later.

A.10.26. How do I import an existing MySQL database into a MySQL Cluster?

You can import databases into MySQL Cluster much as you would with any other version of MySQL. Other than the limitations mentioned elsewhere in this FAQ, the only other special requirement is that any tables to be included in the cluster must use the NDB storage engine. This means that the tables must be created with `ENGINE=NDB` or `ENGINE=NDBCLUSTER`.

It is also possible to convert existing tables that use other storage engines to NDBCLUSTER using one or more `ALTER TABLE` statement. However, the definition of the table must be compatible with the NDBCLUSTER storage engine prior to making the conversion. In MySQL 5.0, an additional workaround is also required; see Section 17.1.5, “Known Limitations of MySQL Cluster”, for details.

A.10.27. How do MySQL Cluster nodes communicate with one another?

Cluster nodes can communicate through any of three different transport mechanisms: TCP/IP, SHM (shared memory), and SCI (Scalable Coherent Interface). Where available, SHM is used by default between nodes residing on the same cluster host; however, this is considered experimental. SCI is a high-speed (1 gigabit per second and higher), high-availability protocol used in building scalable multi-processor systems; it requires special hardware and drivers. See Section 17.3.4, “Using High-Speed Interconnects with MySQL Cluster”, for more about using SCI as a transport mechanism for MySQL Cluster.

A.10.28. What is an arbitrator?

If one or more data nodes in a cluster fail, it is possible that not all cluster data nodes will be able to “see” one another. In fact, it is possible that two sets of data nodes might become isolated from one another in a network partitioning, also known as a “split-brain” scenario. This type of situation is undesirable because each set of data nodes tries to behave as though it is the entire cluster. An arbitrator is required to decide between the competing sets of data nodes.

When all data nodes in at least one node group are alive, network partitioning is not an issue, because no single subset of the cluster can form a functional cluster on its own. The real problem arises when no single node group has all its nodes alive, in which case
network partitioning (the “split-brain” scenario) becomes possible. Then an arbitrator is required. All cluster nodes recognize the same node as the arbitrator, which is normally the management server; however, it is possible to configure any of the MySQL Servers in the cluster to act as the arbitrator instead. The arbitrator accepts the first set of cluster nodes to contact it, and tells the remaining set to shut down. Arbitrator selection is controlled by the ArbitrationRank configuration parameter for MySQL Server and management server nodes. For more information about this parameter, see Section 17.3.3.4, “Defining a MySQL Cluster Management Server”.

The role of arbitrator does not in and of itself impose any heavy demands upon the host so designated, and thus the arbitrator host does not need to be particularly fast or to have extra memory especially for this purpose.

A.10.29 What data types are supported by MySQL Cluster?

In MySQL 5.0, MySQL Cluster supports all of the usual MySQL data types, including (beginning with MySQL 5.0.16) those associated with MySQL’s spatial extensions; however, the NDB storage engine does not support spatial indexes. (Spatial indexes are supported only by MyISAM; see Section 11.5, “Extensions for Spatial Data”, for more information.) In addition, there are some differences with regard to indexes when used with NDB tables.

Note

In MySQL 5.0, MySQL Cluster tables (that is, tables created with ENGINE=NDB or ENGINE=NBDBCLUSTER) have only fixed-width rows. This means that (for example) each record containing a VARCHAR(255) column will require space for 255 characters (as required for the character set and collation being used for the table), regardless of the actual number of characters stored therein. This issue is fixed in MySQL 5.1 and later; however, we do not plan to backport this functionality to MySQL 5.0.

See Section 17.1.5, “Known Limitations of MySQL Cluster”, for more information about these issues.

A.10.30 How do I start and stop MySQL Cluster?

It is necessary to start each node in the cluster separately, in the following order:

1. Start the management node, using the ndb_mgmd command.
   
   You must include the -f or --config-file option to tell the management node where its configuration file can be found.

2. Start each data node with the ndbd command.
   
   Each data node must be started with the -c or --ndb-connectstring option so that the data node knows how to connect to the management server.

3. Start each MySQL Server (SQL node) using your preferred startup script, such as mysqld_safe.
   
   Each MySQL Server must be started with the --ndbcluster and --ndb-connectstring options. These options cause mysqld to enable NDBCLUSTER storage engine support and how to connect to the management server.

Each of these commands must be run from a system shell on the machine housing the affected node. (You do not have to be physically present at the machine—a remote login shell can be used for this purpose.) You can verify that the cluster is running by starting the NDB management client ndb_mgm on the machine housing the management node and issuing the SHOW or ALL STATUS command.
To shut down a running cluster, issue the command `SHUTDOWN` in the management client. Alternatively, you may enter the following command in a system shell:

```
shell> ndb_mgm -e "SHUTDOWN"
```

(The quotation marks in this example are optional, since there are no spaces in the command string following the `-e` option; in addition, the `SHUTDOWN` command, like other management client commands, is not case-sensitive.)

Either of these commands causes the `ndb_mgm`, `ndb_mgm`, and any `ndbd` processes to terminate gracefully. MySQL servers running as SQL nodes can be stopped using `mysqladmin shutdown`.

For more information, see Section 17.5.2, “Commands in the MySQL Cluster Management Client”, and Section 17.2.5, “Safe Shutdown and Restart of MySQL Cluster”.

**A.10.31 What happens to MySQL Cluster data when the MySQL Cluster is shut down?**

The data that was held in memory by the cluster’s data nodes is written to disk, and is reloaded into memory the next time that the cluster is started.

**A.10.32 Is it a good idea to have more than one management node for a MySQL Cluster?**

It can be helpful as a fail-safe. Only one management node controls the cluster at any given time, but it is possible to configure one management node as primary, and one or more additional management nodes to take over in the event that the primary management node fails.

See Section 17.3.3, “MySQL Cluster Configuration Files”, for information on how to configure MySQL Cluster management nodes.

**A.10.33 Can I mix different kinds of hardware and operating systems in one MySQL Cluster?**

Yes, as long as all machines and operating systems have the same “endianness” (all big-endian or all little-endian).

It is also possible to use software from different MySQL Cluster releases on different nodes. However, we support this only as part of a rolling upgrade procedure (see Section 17.5.5, “Performing a Rolling Restart of a MySQL Cluster”).

**A.10.34 Can I run two data nodes on a single host? Two SQL nodes?**

Yes, it is possible to do this. In the case of multiple data nodes, it is advisable (but not required) for each node to use a different data directory. If you want to run multiple SQL nodes on one machine, each instance of `mysqld` must use a different TCP/IP port. However, in MySQL 5.0, running more than one cluster node of a given type per machine is generally not encouraged or supported for production use.

We also advise against running data nodes and SQL nodes together on the same host, since the `ndbd` and `mysqld` processes may compete for memory.

**A.10.35 Can I use host names with MySQL Cluster?**

Yes, it is possible to use DNS and DHCP for cluster hosts. However, if your application requires “five nines” availability, you should use fixed (numeric) IP addresses, since making communication between Cluster hosts dependent on services such as DNS and DHCP introduces additional potential points of failure.

**A.10.36 How do I handle MySQL users in a MySQL Cluster having multiple MySQL servers?**

MySQL user accounts and privileges are not automatically propagated between different MySQL servers accessing the same MySQL Cluster. Therefore, you must make sure that these are
copied between the SQL nodes yourself. You can do this manually, or automate the task with scripts.

**Warning**

Do not attempt to work around this issue by converting the MySQL system tables to use the NDBCLUSTER storage engine. Only the MyISAM storage engine is supported for these tables.

A.10.3**How do I continue to send queries in the event that one of the SQL nodes fails?**

MySQL Cluster does not provide any sort of automatic failover between SQL nodes. Your application must be prepared to handle the loss of SQL nodes and to fail over between them.

A.10.38**How do I back up and restore a MySQL Cluster?**

You can use the NDB native backup and restore functionality in the MySQL Cluster management client and the ndb_restore program. See Section 17.5.3, “Online Backup of MySQL Cluster”, and Section 17.4.14, “ndb_restore — Restore a MySQL Cluster Backup”.

You can also use the traditional functionality provided for this purpose in mysqldump and the MySQL server. See Section 4.5.4, “mysqldump — A Database Backup Program”, for more information.

A.10.39**What is an “angel process”?**

This process monitors and, if necessary, attempts to restart the data node process. If you check the list of active processes on your system after starting ndbd, you can see that there are actually 2 processes running by that name, as shown here (we omit the output from ndb_mgmd and ndbd for brevity):

```
shell> ./ndb_mgmd
shell> ps aux | grep ndb
me      23002  0.0  0.0 122948  3104 ?        Ssl  14:14   0:00 ./ndb_mgmd
me      23025  0.0  0.0   5284   820 pts/2    S+   14:14   0:00 grep ndb
shell> ./ndbd -c 127.0.0.1 --initial
shell> ps aux | grep ndb
me      23002  0.0  0.0 123080  3356 ?        Ssl  14:14   0:00 ./ndb_mgmd
me      23096  0.0  0.0  35876  2036 ?        Ss   14:14   0:00 ./ndbd -c 127.0.0.1 --initial
me      23097  1.0  2.4 524116 91096 ?        Sl   14:14   0:00 ./ndbd -c 127.0.0.1 --initial
me      23168  0.0  0.0  5284  812 pts/2    R+   14:15   0:00 grep ndb
```

The ndbd process showing 0 memory and CPU usage is the angel process. It actually does use a very small amount of each, of course. It simply checks to see if the main ndbd process (the primary data node process that actually handles the data) is running. If permitted to do so (for example, if the StopOnError configuration parameter is set to false—see Section 17.3.2.1, “MySQL Cluster Data Node Configuration Parameters”), the angel process tries to restart the primary data node process.

A.11 MySQL 5.0 FAQ: MySQL Chinese, Japanese, and Korean Character Sets

This set of Frequently Asked Questions derives from the experience of MySQL’s Support and Development groups in handling many inquiries about CJK (Chinese-Japanese-Korean) issues.

A.11.1 What CJK character sets are available in MySQL? ................................................................. 1930

A.11.2 I have inserted CJK characters into my table. Why does SELECT display them as “?” characters? .................................................................................................................. 1931

A.11.3 What problems should I be aware of when working with the Big5 Chinese character set? .. 1932
A.11.1 What CJK character sets are available in MySQL?

The list of CJK character sets may vary depending on your MySQL version. For example, the gb18030 character set was not supported prior to MySQL 5.7.4. However, since the name of the applicable language appears in the DESCRIPTION column for every entry in the INFORMATION_SCHEMA.CHARACTER_SETS table, you can obtain a current list of all the non-Unicode CJK character sets using this query:

```sql
mysql> SELECT CHARACTER_SET_NAME, DESCRIPTION
    -> FROM INFORMATION_SCHEMA.CHARACTER_SETS
    -> WHERE DESCRIPTION LIKE '%Chin%'
    -> OR DESCRIPTION LIKE '%Japanese'
    -> OR DESCRIPTION LIKE '%Korean'
    -> ORDER BY CHARACTER_SET_NAME;
```

```
+-------------------+----------------------------------+
| CHARACTER_SET_NAME | DESCRIPTION                       |
|--------------------+----------------------------------|
| big5               | Big5 Traditional Chinese         |
| cp932              | SJIS for Windows Japanese        |
| eucjms             | UJIS for Windows Japanese        |
| euckr              | EUC-KR Korean                     |
| gb18030            | China National Standard GB18030  |
| gb2312             | GB2312 Simplified Chinese        |
| gbk                | GBK Simplified Chinese           |
| sjis               | Shift-JIS Japanese               |
| ujis               | EUC-JP Japanese                  |
+-------------------+----------------------------------+
9 rows in set (0.01 sec)
```

(See Section 19.1, “The INFORMATION_SCHEMA CHARACTER_SETS Table”, for more information.)

MySQL supports three variants of the GB (Guojia Biaozhun, or National Standard, or Simplified Chinese) character sets which are official in the People's Republic of China: gb2312, gbk, and gb18030 (added in MySQL 5.7.4).

Sometimes people try to insert gbk characters into gb2312, and it works most of the time because gbk is a superset of gb2312—but eventually they try to insert a rarer Chinese character and it doesn’t work. (See Bug #16072 for an example).

Here, we try to clarify exactly what characters are legitimate in gb2312 or gbk, with reference to the official documents. Please check these references before reporting gb2312 or gbk bugs.
A.11.2 If I have inserted CJK characters into my table. Why does SELECT display them as “?” characters?

This problem is usually due to a setting in MySQL that doesn’t match the settings for the application program or the operating system. Here are some common steps for correcting these types of issues:

- **Be certain of what MySQL version you are using.**
  
  Use the statement `SELECT VERSION();` to determine this.

- **Make sure that the database is actually using the desired character set.**
  
  People often think that the client character set is always the same as either the server character set or the character set used for display purposes. However, both of these are false assumptions. You can make sure by checking the result of `SHOW CREATE TABLE tablename` or—better yet—by using this statement:

  ```sql
  SELECT character_set_name, collation_name
  FROM information_schema.columns
  WHERE table_schema = your_database_name
  AND table_name = your_table_name
  AND column_name = your_column_name;
  ```

- **Determine the hexadecimal value of the character or characters that are not being displayed correctly.**
  
  You can obtain this information for a column `column_name` in the table `tablename` using the following query:

  ```sql
  SELECT HEX(column_name)
  FROM tablename;
  ```

  3F is the encoding for the ? character; this means that ? is the character actually stored in the column. This most often happens because of a problem converting a particular character from your client character set to the target character set.

- **Make sure that a round trip possible—that is, when you select literal (or _introducer hexadecimal-value), you obtain literal as a result.**
  
  For example, the Japanese Katakana character Pe (ペ) exists in all CJK character sets, and has the code point value (hexadecimal coding) 0x30da. To test a round trip for this character, use this query:

  ```sql
  SELECT 'ペ' AS 'ペ'; /* or SELECT _ucs2 0x30da; */
  ```

  If the result is not also ペ, then the round trip has failed.
For bug reports regarding such failures, we might ask you to follow up with `SELECT HEX('^-');`. Then we can determine whether the client encoding is correct.

- **Make sure that the problem is not with the browser or other application, rather than with MySQL.**

Use the `mysql` client program (on Windows: `mysql.exe`) to accomplish this task. If `mysql` displays correctly but your application doesn't, then your problem is probably due to system settings.

To find out what your settings are, use the `SHOW VARIABLES` statement, whose output should resemble what is shown here:

```
mysql> SHOW VARIABLES LIKE 'char%';
+--------------------------+----------------------------------------+
| Variable_name            | Value                                  |
+--------------------------+----------------------------------------+
| character_set_client     | utf8                                   |
| character_set_connection | utf8                                   |
| character_set_database   | latin1                                 |
| character_set_filesystem | binary                                 |
| character_set_results    | utf8                                   |
| character_set_server     | latin1                                 |
| character_set_system     | utf8                                   |
| character_sets_dir       | /usr/local/mysql/share/mysql/charsets/ |
+--------------------------+----------------------------------------+
8 rows in set (0.03 sec)
```

These are typical character-set settings for an international-oriented client (notice the use of `utf8` Unicode) connected to a server in the West (`latin1` is a West Europe character set and a default for MySQL).

Although Unicode (usually the `utf8` variant on Unix, and the `ucs2` variant on Windows) is preferable to Latin, it is often not what your operating system utilities support best. Many Windows users find that a Microsoft character set, such as `cp932` for Japanese Windows, is suitable.

If you cannot control the server settings, and you have no idea what your underlying computer is, then try changing to a common character set for the country that you're in (`euckr` = Korea; `gb18030`, `gb2312` or `gbk` = People's Republic of China; `big5` = Taiwan; `ujis`, `sjis`, `cp932`, or `eucjpms` = Japan; `ucs2` or `utf8` = anywhere). Usually it is necessary to change only the client and connection and results settings. There is a simple statement which changes all three at once: `SET NAMES`. For example:

```
SET NAMES 'big5';
```

Once the setting is correct, you can make it permanent by editing `my.cnf` or `my.ini`. For example you might add lines looking like these:

```
[mysqld]
character-set-server=big5
[client]
default-character-set=big5
```

It is also possible that there are issues with the API configuration setting being used in your application; see *Why does my GUI front end or browser not display CJK characters correctly?* for more information.

**A.11.3** What problems should I be aware of when working with the Big5 Chinese character set?
MySQL supports the Big5 character set which is common in Hong Kong and Taiwan (Republic of China). MySQL's big5 is in reality Microsoft code page 950, which is very similar to the original big5 character set. We changed to this character set starting with MySQL version 4.1.16 / 5.0.16 (as a result of Bug #12476). For example, the following statements work in current versions of MySQL, but not in old versions:

```sql
mysql> CREATE TABLE big5 (BIG5 CHAR(1) CHARACTER SET BIG5);
Query OK, 0 rows affected (0.13 sec)

mysql> INSERT INTO big5 VALUES (0xf9dc);
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM big5;
+------+
| big5 |
|嫺   |
+------+
1 row in set (0.02 sec)
```

A feature request for adding HKSCS extensions has been filed. People who need this extension may find the suggested patch for Bug #13577 to be of interest.

### A.11.4 Why do Japanese character set conversions fail?

MySQL supports the sjis, ujis, cp932, and eucjpms character sets, as well as Unicode. A common need is to convert between character sets. For example, there might be a Unix server (typically with sjis or ujis) and a Windows client (typically with cp932).

In the following conversion table, the ucs2 column represents the source, and the sjis, cp932, ujis, and eucjpms columns represent the destinations—that is, the last 4 columns provide the hexadecimal result when we use `CONVERT(ucs2)` or we assign a ucs2 column containing the value to an sjis, cp932, ujis, or eucjpms column.

<table>
<thead>
<tr>
<th>Character Name</th>
<th>ucs2</th>
<th>sjis</th>
<th>cp932</th>
<th>ujis</th>
<th>eucjpms</th>
</tr>
</thead>
<tbody>
<tr>
<td>BROKEN BAR</td>
<td>00A6</td>
<td>3F</td>
<td>3F</td>
<td>8FA2</td>
<td>3F</td>
</tr>
<tr>
<td>FULLWIDTH BROKEN BAR</td>
<td>FFE4</td>

<td>3F</td>
</tr>
<tr>
<td>FULLWIDTH CENT SIGN</td>
<td>FFE0</td>
<td>3F</td>
<td>8191</td>
<td>3F</td>
<td>A1F1</td>
</tr>
</tbody>
</table>
Now consider the following portion of the table.

<table>
<thead>
<tr>
<th>Character Name</th>
<th>ucs2</th>
<th>sjis</th>
<th>cp932</th>
<th>ujis</th>
<th>eucjpmns</th>
</tr>
</thead>
<tbody>
<tr>
<td>POUND SIGN</td>
<td>00A3</td>
<td>8192</td>
<td>3F</td>
<td>A1F2</td>
<td>3F</td>
</tr>
<tr>
<td>FULLWIDTH POUND SIGN</td>
<td>FFE1</td>
<td>3F</td>
<td>8192</td>
<td>3F</td>
<td>A1F2</td>
</tr>
<tr>
<td>NOT SIGN</td>
<td>00AC</td>
<td>81CA</td>
<td>3F</td>
<td>A2CC</td>
<td>3F</td>
</tr>
<tr>
<td>FULLWIDTH NOT SIGN</td>
<td>FFE2</td>
<td>3F</td>
<td>81CA</td>
<td>3F</td>
<td>A2CC</td>
</tr>
</tbody>
</table>

This means that MySQL converts the NOT SIGN (Unicode U+00AC) to sjis code point 0x81CA and to cp932 code point 3F. (3F is the question mark (“?”)—this is what is always used when the conversion cannot be performed.

A.11.5 What should I do if I want to convert SJIS 81CA to cp932?

Our answer is: “?” . There are serious complaints about this: many people would prefer a “loose” conversion, so that 81CA (NOT SIGN) in sjis becomes 81CA (FULLWIDTH NOT SIGN) in cp932. We are considering a change to this behavior.

A.11.6 How does MySQL represent the Yen (¥) sign?

A problem arises because some versions of Japanese character sets (both sjis and euc) treat 5C as a reverse solidus (\)—also known as a backslash), and others treat it as a yen sign (¥).

MySQL follows only one version of the JIS (Japanese Industrial Standards) standard description. In MySQL, 5C is always the reverse solidus (\).

A.11.7 Does MySQL plan to make a separate character set where 5C is the Yen sign, as at least one other major DBMS does?

This is one possible solution to the Yen sign issue; however, this will not happen in MySQL 5.1 or 6.0.

A.11.8 Of what issues should I be aware when working with Korean character sets in MySQL?

In theory, while there have been several versions of the euckr (Extended Unix Code Korea) character set, only one problem has been noted.

We use the “ASCII” variant of EUC-KR, in which the code point 0x5c is REVERSE SOLIDUS, that is \, instead of the “KS-Roman” variant of EUC-KR, in which the code point 0x5c is WON SIGN (₩). This means that you cannot convert Unicode U+20A9 to euckr:

```sql
mysql> SELECT
    -> CONVERT('₩' USING euckr) AS euckr,
    -> HEX(CONVERT('₩' USING euckr)) AS hexeuckr;
+-------+----------+
| euckr | hexeuckr |
| ?     | 3F       |
+-------+----------+
1 row in set (0.00 sec)
```

MySQL's graphic Korean chart is here: euckr.

A.11.9 Why do I get Incorrect string value error messages?
For illustration, we’ll create a table with one Unicode (ucs2) column and one Chinese (gb2312) column.

```sql
mysql> CREATE TABLE ch
    -> (ucs2 CHAR(3) CHARACTER SET ucs2,
    -> gb2312 CHAR(3) CHARACTER SET gb2312);
Query OK, 0 rows affected (0.05 sec)
```

We’ll try to place the rare character 汌 in both columns.

```sql
mysql> INSERT INTO ch VALUES ('A

汌 B','A

汌 B');
Query OK, 1 row affected, 1 warning (0.00 sec)
```

Ah, there is a warning. Use the following statement to see what it is:

```sql
mysql> SHOW WARNINGS\G
```

```
+-----------------------+------------------------+----------+
| Level: Warning Code: 1366 | Message: Incorrect string value: '\xE6\x8C\xB' for column 'gb2312' at row 1 |
+-----------------------+------------------------+----------+
```

So it is a warning about the gb2312 column only.

```sql
mysql> SELECT ucs2,HEX(ucs2),gb2312,HEX(gb2312) FROM ch;
+-------+--------------+--------+-------------+
| ucs2  | HEX(ucs2)    | gb2312 | HEX(gb2312) |
+-------+--------------+--------+-------------+
| A

汌 B | 00416C4C0042 | A?B    | 413F42      |
+-------+--------------+--------+-------------+
```

Several things need explanation here:

1. The fact that it is a “warning” rather than an “error” is characteristic of MySQL. We like to try to do what we can, to get the best fit, rather than give up.
2. The 汌 character is not in the gb2312 character set. We described that problem earlier.
3. If you are using an old version of MySQL, you will probably see a different message.
4. With sql_mode=TRADITIONAL, there would be an error message, rather than a warning.

### A.11.10 Why does my GUI front end or browser not display CJK characters correctly in my application using Access, PHP, or another API?

Obtain a direct connection to the server using the `mysql` client (Windows: `mysql.exe`), and try the same query there. If `mysql` responds correctly, then the trouble may be that your application interface requires initialization. Use `mysql` to tell you what character set or sets it uses with the statement `SHOW VARIABLES LIKE 'char%';`. If you are using Access, then you are most likely connecting with Connector/ODBC. In this case, you should check Configuring Connector/ODBC. If, for instance, you use big5, you would enter `SET NAMES 'big5';` (Note that no ; is required in this case). If you are using ASP, you might need to add `SET NAMES` in the code. Here is an example that has worked in the past:

```html
<%
Session.CodePage=0
Dim strConnection
Dim Conn
strConnection="driver={MySQL ODBC 3.51 Driver};server=server;uid=username;" \
& "pwd=password;database=database;stmt=SET NAMES 'big5';"
Set Conn = Server.CreateObject("ADODB.Connection")
```
Conn.Open strConnection

In much the same way, if you are using any character set other than `latin1` with Connector/Net, then you must specify the character set in the connection string. See Connecting to MySQL Using Connector/Net, for more information.

If you are using PHP, try this:

```php
<?php
    $link = new mysqli($host, $usr, $pwd, $db);
    if( mysqli_connect_errno() ) {
        printf("Connect failed: %s\n", mysqli_connect_error());
        exit();
    }
    $link->query("SET NAMES 'utf8'" الدماء);
?>
```

In this case, we used `SET NAMES` to change `character_set_client` and `character_set_connection` and `character_set_results`.

Another issue often encountered in PHP applications has to do with assumptions made by the browser. Sometimes adding or changing a `<meta>` tag suffices to correct the problem: for example, to insure that the user agent interprets page content as `UTF-8`, you should include `<meta http-equiv="Content-Type" content="text/html; charset=utf-8">` in the `<head>` of the HTML page.

If you are using Connector/J, see Using Character Sets and Unicode.

A.11.11. I've upgraded to MySQL 5.0. How can I revert to behavior like that in MySQL 4.0 with regard to character sets?

In MySQL Version 4.0, there was a single _global_ character set for both server and client, and the decision as to which character to use was made by the server administrator. This changed starting with MySQL Version 4.1. What happens now is a “handshake”, as described in Section 10.1.4, “Connection Character Sets and Collations”:

When a client connects, it sends to the server the name of the character set that it wants to use. The server uses the name to set the `character_set_client`, `character_set_results`, and `character_set_connection` system variables. In effect, the server performs a `SET NAMES` operation using the character set name.

The effect of this is that you cannot control the client character set by starting `mysqld` with `--character-set-server=utf8`. However, some of our Asian customers have said that they prefer the MySQL 4.0 behavior. To make it possible to retain this behavior, we added a `mysqld` switch, `--character-set-client-handshake`, which can be turned off with `--skip-character-set-client-handshake`. If you start `mysqld` with `--skip-character-set-client-handshake`, then, when a client connects, it sends to the server the name of the character set that it wants to use—however, _the server ignores this request from the client_.

By way of example, suppose that your favorite server character set is `latin1` (unlikely in a CJK area, but this is the default value). Suppose further that the client uses `utf8` because this is what the client's operating system supports. Now, start the server with `latin1` as its default character set:

```
mysqld --character-set-server=latin1
```
And then start the client with the default character set `utf8`:

```
mysql --default-character-set=utf8
```

The current settings can be seen by viewing the output of `SHOW VARIABLES`:

```
mysql> SHOW VARIABLES LIKE 'char%';
+--------------------------+----------------------------------------+
| Variable_name            | Value                                  |
+--------------------------+----------------------------------------+
| character_set_client     | utf8                                   |
| character_set_connection | utf8                                   |
| character_set_database   | latin1                                 |
| character_set_filesystem | binary                                 |
| character_set_results    | utf8                                   |
| character_set_server     | latin1                                 |
| character_set_system     | utf8                                   |
| character_sets_dir       | /usr/local/mysql/share/mysql/charsets/ |
+--------------------------+----------------------------------------+
8 rows in set (0.01 sec)
```

Now stop the client, and then stop the server using `mysqladmin`. Then start the server again, but this time tell it to skip the handshake like so:

```
mysqld --character-set-server=utf8 --skip-character-set-client-handshake
```

Start the client with `utf8` once again as the default character set, then display the current settings:

```
mysql> SHOW VARIABLES LIKE 'char%';
+--------------------------+----------------------------------------+
| Variable_name            | Value                                  |
+--------------------------+----------------------------------------+
| character_set_client     | latin1                                 |
| character_set_connection | latin1                                 |
| character_set_database   | latin1                                 |

| character_set_system     | utf8                                   |
| character_sets_dir       | /usr/local/mysql/share/mysql/charsets/ |
+--------------------------+----------------------------------------+
8 rows in set (0.01 sec)
```

As you can see by comparing the differing results from `SHOW VARIABLES`, the server ignores the client’s initial settings if the `--skip-character-set-client-handshake` is used.

A.11.12 Why do some `LIKE` and `FULLTEXT` searches with CJK characters fail?

There is a very simple problem with `LIKE` searches on `BINARY` and `BLOB` columns: we need to know the end of a character. With multibyte character sets, different characters might have different octet lengths. For example, in `utf8`, `A` requires one byte but `彼` requires three bytes, as shown here:

```
+-------------------------+---------------------------+
| OCTET_LENGTH(_utf8 'A') | OCTET_LENGTH(_utf8 '彼') |
| 1                       | 3                        |
+-------------------------+---------------------------+
1 row in set (0.00 sec)
```
If we don't know where the first character ends, then we don't know where the second character begins, in which case even very simple searches such as `LIKE '_A%'` fail. The solution is to use a regular CJK character set in the first place, or to convert to a CJK character set before comparing.

This is one reason why MySQL cannot allow encodings of nonexistent characters. If it is not strict about rejecting bad input, then it has no way of knowing where characters end.

For **FULLTEXT** searches, we need to know where words begin and end. With Western languages, this is rarely a problem because most (if not all) of these use an easy-to-identify word boundary—the space character. However, this is not usually the case with Asian writing. We could use arbitrary halfway measures, like assuming that all Han characters represent words, or (for Japanese) depending on changes from Katakana to Hiragana due to grammatical endings. However, the only sure solution requires a comprehensive word list, which means that we would have to include a dictionary in the server for each Asian language supported. This is simply not feasible.

**A.11.13.** How do I know whether character \texttt{x} is available in all character sets?

The majority of simplified Chinese and basic nonhalfwidth Japanese Kana characters appear in all CJK character sets. This stored procedure accepts a **UCS-2** Unicode character, converts it to all other character sets, and displays the results in hexadecimal.

```
DELIMITER //

CREATE PROCEDURE p_convert(ucs2_char CHAR(1) CHARACTER SET ucs2)
BEGIN

CREATE TABLE t j
(ucs2 CHAR(1) character set ucs2,
 utf8 CHAR(1) character set utf8,
 big5 CHAR(1) character set big5,
 cp932 CHAR(1) character set cp932,
 eucjpms CHAR(1) character set eucjpms,
 euckr CHAR(1) character set euckr,
 gb2312 CHAR(1) character set gb2312,
 gbk CHAR(1) character set gbk,
 sjis CHAR(1) character set sjis,
 ujis CHAR(1) character set ujis);

INSERT INTO t j (ucs2) VALUES (ucs2_char);

UPDATE t j SET utf8=ucs2,
 big5=ucs2,
 cp932=ucs2,
 eucjpms=ucs2,
 euckr=ucs2,
 gb2312=ucs2,
 gbk=ucs2,
 sjis=ucs2,
 ujis=ucs2;

/* If there is a conversion problem, UPDATE will produce a warning. */

SELECT hex(ucs2) AS ucs2,
 hex(utf8) AS utf8,
 hex(big5) AS big5,
 hex(cp932) AS cp932,
 hex(eucjpms) AS eucjpms,
 hex(euckr) AS euckr,
 hex(gb2312) AS gb2312,
 hex(gbk) AS gbk,
 hex(sjis) AS sjis,
 hex(ujis) AS ujis
FROM t j;
```
The input can be any single \texttt{ucs2} character, or it can be the code point value (hexadecimal representation) of that character. For example, from Unicode's list of \texttt{ucs2} encodings and names (http://www.unicode.org/Public/UNIDATA/UnicodeData.txt), we know that the Katakana character \texttt{Pe} appears in all CJK character sets, and that its code point value is \texttt{0x30da}. If we use this value as the argument to \texttt{p_convert()}, the result is as shown here:

```
mysql> CALL p_convert(0x30da)//
+------+--------+------+-------+---------+-------+--------+------+------+------+
| ucs2 | utf8   | big5 | cp932 | eucjpms | euckr | gb2312 | gbk  | sjis | ujis |
+------+--------+------+-------+---------+-------+--------+------+------+------+
| 30DA | E3839A | C772 | 8379  | A5DA    | ABDA  | A5DA   | A5DA | 8379 | A5DA |
+------+--------+------+-------+---------+-------+--------+------+------+------+
1 row in set (0.04 sec)
```

Since none of the column values is \texttt{3F}—that is, the question mark character (?)—we know that every conversion worked.

**A.11.1** Why do CJK strings sort incorrectly in Unicode? (I)

Sometimes people observe that the result of a \texttt{utf8_unicode_ci} or \texttt{ucs2_unicode_ci} search, or of an \texttt{ORDER BY} sort is not what they think a native would expect. Although we never rule out the possibility that there is a bug, we have found in the past that many people do not read correctly the standard table of weights for the Unicode Collation Algorithm. MySQL uses the table found at http://www.unicode.org/Public/UCA/4.0.0/allkeys-4.0.0.txt. This is not the first table you will find by navigating from the unicode.org home page, because MySQL uses the older 4.0.0 "allkeys" table, rather than the more recent 4.1.0 table. (The newer '520' collations in MySQL 5.6 use the 5.2 “allkeys” table.) This is because we are very wary about changing ordering which affects indexes, lest we bring about situations such as that reported in Bug #16526, illustrated as follows:

```
mysql< CREATE TABLE tj (s1 CHAR(1) CHARACTER SET utf8 COLLATE utf8_unicode_ci);
Query OK, 0 rows affected (0.05 sec)

mysql> INSERT INTO tj VALUES ('が'), ('か');
Query OK, 2 rows affected (0.00 sec)
Records: 2  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM tj WHERE s1 = 'か';
+------+
| s1   |
+------+
| が   |
+------+
2 rows in set (0.00 sec)
```

The character in the first result row is not the one that we searched for. Why did MySQL retrieve it? First we look for the Unicode code point value, which is possible by reading the hexadecimal number for the \texttt{ucs2} version of the characters:

```
mysql> SELECT s1, HEX(CONVERT(s1 USING ucs2)) FROM tj;
+-----------+-----------------------------+
| s1        | HEX(CONVERT(s1 USING ucs2)) |
+-----------+-----------------------------+
| か        | 304C                        |
| が        | 304B                        |
+-----------+-----------------------------+
2 rows in set (0.03 sec)
```
Now we search for 304B and 304C in the 4.0.0 allkeys table, and find these lines:

| 304B  | [.1E57.0020.000E.304B] # HIRAGANA LETTER KA |
| 304C  | [.1E57.0020.000E.304B][.0000.0140.0002.3099] # HIRAGANA LETTER GA; QQCM |

The official Unicode names (following the “#” mark) tell us the Japanese syllabary (Hiragana), the informal classification (letter, digit, or punctuation mark), and the Western identifier (KA or GA, which happen to be voiced and unvoiced components of the same letter pair). More importantly, the primary weight (the first hexadecimal number inside the square brackets) is 1E57 on both lines. For comparisons in both searching and sorting, MySQL pays attention to the primary weight only, ignoring all the other numbers. This means that we are sorting が and か correctly according to the Unicode specification. If we wanted to distinguish them, we’d have to use a non-UCA (Unicode Collation Algorithm) collation (utf8_bin or utf8_general_ci), or to compare the HEX() values, or use ORDER BY CONVERT(s1 USING sjis). Being correct “according to Unicode” isn’t enough, of course: the person who submitted the bug was equally correct. We plan to add another collation for Japanese according to the JIS X 4061 standard, in which voiced/unvoiced letter pairs like KA/GA are distinguishable for ordering purposes.

A.11.15. Why do CJK strings sort incorrectly in Unicode? (II)

If you are using Unicode (ucs2 or utf8), and you know what the Unicode sort order is (see Section A.11, “MySQL 5.0 FAQ: MySQL Chinese, Japanese, and Korean Character Sets”), but MySQL still seems to sort your table incorrectly, then you should first verify the table character set:

```
mysql> SHOW CREATE TABLE t;
```

```
Table: t
Create Table: CREATE TABLE `t` (
  `s1` char(1) CHARACTER SET ucs2 DEFAULT NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

Since the character set appears to be correct, let’s see what information the `INFORMATION_SCHEMA.COLUMNS` table can provide about this column:

```
mysql> SELECT COLUMN_NAME, CHARACTER_SET_NAME, COLLATION_NAME
  -> FROM INFORMATION_SCHEMA.COLUMNS
  -> WHERE COLUMN_NAME = 's1'
  -> AND TABLE_NAME = 't';
```

```
+-------------+--------------------+-----------------+
| COLUMN_NAME | CHARACTER_SET_NAME | COLLATION_NAME  |
| s1          | ucs2               | ucs2_general_ci |
+-------------+--------------------+-----------------+
1 row in set (0.01 sec)
```

(See Section 19.4, “The INFORMATION_SCHEMA.COLUMNS Table”, for more information.)

You can see that the collation is `ucs2_general_ci` instead of `ucs2_unicode_ci`. The reason why this is so can be found using `SHOW CHARSET`, as shown here:

```
mysql> SHOW CHARSET LIKE 'ucs2%';
```

```
<table>
<thead>
<tr>
<th>Charset</th>
<th>Description</th>
<th>Default collation</th>
<th>Maxlen</th>
</tr>
</thead>
<tbody>
<tr>
<td>ucs2</td>
<td>UCS-2 Unicode</td>
<td>ucs2_general_ci</td>
<td>2</td>
</tr>
</tbody>
</table>
+---------+-----------------+-------------------+--------+
1 row in set (0.00 sec)
```
For **ucs2** and **utf8**, the default collation is “general”. To specify a Unicode collation, use **COLLATE ucs2_unicode_ci**.

**A.11.16** Why are my supplementary characters rejected by MySQL?

Before MySQL 5.5.3, MySQL does not support supplementary characters—that is, characters which need more than 3 bytes—for **UTF-8**. We support only what Unicode calls the **Basic Multilingual Plane / Plane 0**. Only a few very rare Han characters are supplementary; support for them is uncommon. This has led to reports such as that found in Bug #12600, which we rejected as “not a bug”. With **utf8**, we must truncate an input string when we encounter bytes that we don’t understand. Otherwise, we wouldn’t know how long the bad multibyte character is.

One possible workaround is to use **ucs2** instead of **utf8**, in which case the “bad” characters are changed to question marks; however, no truncation takes place. You can also change the data type to **BLOB** or **BINARY**, which perform no validity checking.

As of MySQL 5.5.3, Unicode support is extended to include supplementary characters by means of additional Unicode character sets: **utf16**, **utf32**, and 4-byte **utf8mb4**. These character sets support supplementary Unicode characters outside the Basic Multilingual Plane (BMP).

**A.11.17** Shouldn’t it be “CJKV”?

No. The term “CJKV” (**Chinese Japanese Korean Vietnamese**) refers to Vietnamese character sets which contain Han (originally Chinese) characters. MySQL has no plan to support the old Vietnamese script using Han characters. MySQL does of course support the modern Vietnamese script with Western characters.

As of MySQL 5.6, there are Vietnamese collations for Unicode character sets, as described in Section 10.1.13.1, “Unicode Character Sets”.

**A.11.18** Does MySQL allow CJK characters to be used in database and table names?

This issue is fixed in MySQL 5.1, by automatically rewriting the names of the corresponding directories and files.

For example, if you create a database named 楷 on a server whose operating system does not support CJK in directory names, MySQL creates a directory named `@0w@00a5@00ae`, which is just a fancy way of encoding E6A5AE—that is, the Unicode hexadecimal representation for the 楷 character. However, if you run a **SHOW DATABASES** statement, you can see that the database is listed as 楷.

**A.11.19** Where can I get help with CJK and related issues in MySQL?

The following resources are available:

- A listing of MySQL user groups can be found at [https://wikis.oracle.com/display/mysql/List+of+MySQL+User+Groups](https://wikis.oracle.com/display/mysql/List+of+MySQL+User+Groups).

**A.12 MySQL 5.0 FAQ: Connectors & APIs**

For common questions, issues, and answers relating to the MySQL Connectors and other APIs, see the following areas of the Manual:

- Section 20.6.14, “Common Questions and Problems When Using the C API”
- Common Problems with MySQL and PHP
A.13 MySQL 5.0 FAQ: Replication

In the following section, we provide answers to questions that are most frequently asked about MySQL Replication.

A.13.1 Must the slave be connected to the master all the time? .......................................................... 1942
A.13.2 Must I enable networking on my master and slave to enable replication? .............................. 1942
A.13.3 How do I know how late a slave is compared to the master? In other words, how do I know the date of the last statement replicated by the slave? .......................................................... 1942
A.13.4 How do I force the master to block updates until the slave catches up? ................................. 1943
A.13.5 What issues should I be aware of when setting up two-way replication? .................................. 1943
A.13.6 How can I use replication to improve performance of my system? ..................................... 1943
A.13.7 What should I do to prepare client code in my own applications to use performance-enhancing replication? ................................................................................................................. 1944
A.13.8 When and how much can MySQL replication improve the performance of my system? ...... 1944
A.13.9 How can I use replication to provide redundancy or high availability? ................................ 1945
A.13.10 How do I tell whether a master server is using statement-based or row-based binary logging format? .......................................................................................................................... 1945
A.13.11 How do I tell a slave to use row-based replication? ................................................................. 1945
A.13.12 How do I prevent GRANT and REVOKE statements from replicating to slave machines? .... 1945
A.13.13 Does replication work on mixed operating systems (for example, the master runs on Linux while slaves run on OS X and Windows)? ............................................................... 1945
A.13.14 Does replication work on mixed hardware architectures (for example, the master runs on a 64-bit machine while slaves run on 32-bit machines)? ................................................. 1945

A.13.1 Must the slave be connected to the master all the time?

No, it does not. The slave can go down or stay disconnected for hours or even days, and then reconnect and catch up on updates. For example, you can set up a master/slave relationship over a dial-up link where the link is up only sporadically and for short periods of time. The implication of this is that, at any given time, the slave is not guaranteed to be in synchroyny with the master unless you take some special measures.

To ensure that catchup can occur for a slave that has been disconnected, you must not remove binary log files from the master that contain information that has not yet been replicated to the slaves. Asynchronous replication can work only if the slave is able to continue reading the binary log from the point where it last read events.

A.13.2 Must I enable networking on my master and slave to enable replication?

Yes, networking must be enabled on the master and slave. If networking is not enabled, the slave cannot connect to the master and transfer the binary log. Check that the skip-networking option has not been enabled in the configuration file for either server.

A.13.3 How do I know how late a slave is compared to the master? In other words, how do I know the date of the last statement replicated by the slave?

Check the Seconds_Behind_Master column in the output from SHOW SLAVE STATUS. See Section 16.1.3.1, “Checking Replication Status”.

When the slave SQL thread executes an event read from the master, it modifies its own time to the event timestamp. (This is why TIMESTAMP is well replicated.) In the Time column in the output of SHOW PROCESSLIST, the number of seconds displayed for the slave SQL thread is
the number of seconds between the timestamp of the last replicated event and the real time of the slave machine. You can use this to determine the date of the last replicated event. Note that if your slave has been disconnected from the master for one hour, and then reconnects, you may immediately see large Time values such as 3600 for the slave SQL thread in SHOW PROCESSLIST. This is because the slave is executing statements that are one hour old. See Section 16.2.1, “Replication Implementation Details”.

A.13.4 How do I force the master to block updates until the slave catches up?

Use the following procedure:

1. On the master, execute these statements:

```sql
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SHOW MASTER STATUS;
```

Record the replication coordinates (the current binary log file name and position) from the output of the SHOW statement.

2. On the slave, issue the following statement, where the arguments to the MASTER_POS_WAIT() function are the replication coordinate values obtained in the previous step:

```sql
mysql> SELECT MASTER_POS_WAIT('log_name', log_pos);
```

The SELECT statement blocks until the slave reaches the specified log file and position. At that point, the slave is in synchrony with the master and the statement returns.

3. On the master, issue the following statement to enable the master to begin processing updates again:

```sql
mysql> UNLOCK TABLES;
```

A.13.5 What issues should I be aware of when setting up two-way replication?

MySQL replication currently does not support any locking protocol between master and slave to guarantee the atomicity of a distributed (cross-server) update. In other words, it is possible for client A to make an update to co-master 1, and in the meantime, before it propagates to co-master 2, client B could make an update to co-master 2 that makes the update of client A work differently than it did on co-master 1. Thus, when the update of client A makes it to co-master 2, it produces tables that are different from what you have on co-master 1, even after all the updates from co-master 2 have also propagated. This means that you should not chain two servers together in a two-way replication relationship unless you are sure that your updates can safely happen in any order, or unless you take care of mis-ordered updates somehow in the client code.

You should also realize that two-way replication actually does not improve performance very much (if at all) as far as updates are concerned. Each server must do the same number of updates, just as you would have a single server do. The only difference is that there is a little less lock contention because the updates originating on another server are serialized in one slave thread. Even this benefit might be offset by network delays.

A.13.6 How can I use replication to improve performance of my system?

Set up one server as the master and direct all writes to it. Then configure as many slaves as you have the budget and rackspace for, and distribute the reads among the master and the slaves. You can also start the slaves with the --skip-innodb, --low-priority-updates, and --delay-key-write=ALL options to get speed improvements on the slave end. In this case, the slave uses nontransactional MyISAM tables instead of InnoDB tables to get more speed by eliminating transactional overhead.
A.13.7 What should I do to prepare client code in my own applications to use performance-enhancing replication?

See the guide to using replication as a scale-out solution, Section 16.3.3, “Using Replication for Scale-Out”.

A.13.8 When and how much can MySQL replication improve the performance of my system?

MySQL replication is most beneficial for a system that processes frequent reads and infrequent writes. In theory, by using a single-master/multiple-slave setup, you can scale the system by adding more slaves until you either run out of network bandwidth, or your update load grows to the point that the master cannot handle it.

To determine how many slaves you can use before the added benefits begin to level out, and how much you can improve performance of your site, you must know your query patterns, and determine empirically by benchmarking the relationship between the throughput for reads and writes on a typical master and a typical slave. The example here shows a rather simplified calculation of what you can get with replication for a hypothetical system. Let reads and writes denote the number of reads and writes per second, respectively.

Let's say that system load consists of 10% writes and 90% reads, and we have determined by benchmarking that reads is 1200 - 2 * writes. In other words, the system can do 1,200 reads per second with no writes, the average write is twice as slow as the average read, and the relationship is linear. Suppose that the master and each slave have the same capacity, and that we have one master and N slaves. Then we have for each server (master or slave):

\[
\text{reads} = 1200 - 2 \times \text{writes}
\]

\[
\text{reads} = 9 \times \frac{\text{writes}}{(N + 1)} \quad \text{(reads are split, but writes replicated to all slaves)}
\]

\[
9 \times \frac{\text{writes}}{(N + 1)} + 2 \times \text{writes} = 1200
\]

\[
\text{writes} = \frac{1200}{2 + 9/(N + 1)}
\]

The last equation indicates the maximum number of writes for N slaves, given a maximum possible read rate of 1,200 per second and a ratio of nine reads per write.

This analysis yields the following conclusions:

- If \( N = 0 \) (which means we have no replication), our system can handle about 1200/11 = 109 writes per second.
- If \( N = 1 \), we get up to 184 writes per second.
- If \( N = 8 \), we get up to 400 writes per second.
- If \( N = 17 \), we get up to 480 writes per second.
- Eventually, as \( N \) approaches infinity (and our budget negative infinity), we can get very close to 600 writes per second, increasing system throughput about 5.5 times. However, with only eight servers, we increase it nearly four times.

These computations assume infinite network bandwidth and neglect several other factors that could be significant on your system. In many cases, you may not be able to perform a computation similar to the one just shown that accurately predicts what will happen on your system if you add \( N \) replication slaves. However, answering the following questions should help you decide whether and by how much replication will improve the performance of your system:

- What is the read/write ratio on your system?
- How much more write load can one server handle if you reduce the reads?
• For how many slaves do you have bandwidth available on your network?

A.13.9 How can I use replication to provide redundancy or high availability?

How you implement redundancy is entirely dependent on your application and circumstances. High-availability solutions (with automatic failover) require active monitoring and either custom scripts or third party tools to provide the failover support from the original MySQL server to the slave.

To handle the process manually, you should be able to switch from a failed master to a pre-configured slave by altering your application to talk to the new server or by adjusting the DNS for the MySQL server from the failed server to the new server.

For more information and some example solutions, see Section 16.3.6, “Switching Masters During Failover”.

A.13.10 How do I tell whether a master server is using statement-based or row-based binary logging format?

Check the value of the binlog_format system variable:

```
mysql> SHOW VARIABLES LIKE 'binlog_format';
```

The value shown will be one of STATEMENT, ROW, or MIXED. For MIXED mode, statement-based logging is used by default but replication switches automatically to row-based logging under certain conditions, such as unsafe statements. For information about when this may occur, see Mixed Binary Logging Format.

A.13.11 How do I tell a slave to use row-based replication?

Slaves automatically know which format to use.

A.13.12 How do I prevent GRANT and REVOKE statements from replicating to slave machines?

Start the server with the --replicate-wild-ignore-table=mysql.% option to ignore replication for tables in the mysql database.

A.13.13 Does replication work on mixed operating systems (for example, the master runs on Linux while slaves run on OS X and Windows)?

Yes.

A.13.14 Does replication work on mixed hardware architectures (for example, the master runs on a 64-bit machine while slaves run on 32-bit machines)?

Yes.

  B.5.7 Known Issues in MySQL .................................................................... 2018

This appendix lists common problems and errors that may occur and potential resolutions, in addition to listing the errors that may appear when you call MySQL from any host language. The first section covers problems and resolutions. Detailed information on errors is provided: One list displays server error messages. Another list displays client program messages.

B.1 Sources of Error Information

There are several sources of error information in MySQL:

- Each SQL statement executed results in an error code, an SQLSTATE value, and an error message, as described in Section B.2, "Types of Error Values". These errors are returned from the server side; see Section B.3, "Server Error Codes and Messages".

- Errors can occur on the client side, usually involving problems communicating with the server; see Section B.4, "Client Error Codes and Messages".

- SQL statement warning and error information is available through the SHOW WARNINGS and SHOW ERRORS statements. The warning_count system variable indicates the number of errors, warnings, and notes. The error_count system variable indicates the number of errors. Its value excludes warnings and notes.

- SHOW SLAVE STATUS statement output includes information about replication errors occurring on the slave side.

- SHOW ENGINE INNODB STATUS statement output includes information about the most recent foreign key error if a CREATE TABLE statement for an InnoDB table fails.

- The perror program provides information from the command line about error numbers. See Section 4.8.1, "perror — Explain Error Codes".

Descriptions of server and client errors are provided later in this Appendix. For information about errors related to InnoDB, see Section 14.2.12, "InnoDB Error Handling".

B.2 Types of Error Values

When an error occurs in MySQL, the server returns two types of error values:

- A MySQL-specific error code. This value is numeric. It is not portable to other database systems.

- An SQLSTATE value. The value is a five-character string (for example, '42S02'). The values are taken from ANSI SQL and ODBC and are more standardized.
A message string that provides a textual description of the error is also available.

When an error occurs, the MySQL error code, SQLSTATE value, and message string are available using C API functions:

- MySQL error code: Call `mysql_errno()`
- SQLSTATE value: Call `mysql_sqlstate()`
- Error message: Call `mysql_error()`

For prepared statements, the corresponding error functions are `mysql_stmt_errno()`, `mysql_stmt_sqlstate()`, and `mysql_stmt_error()`. All error functions are described in Section 20.6, "MySQL C API".

The number of errors, warnings, and notes for the previous statement can be obtained by calling `mysql_warning_count()`. See Section 20.6.7.72, "mysql_warning_count()".

The first two characters of an SQLSTATE value indicate the error class:

- Class = '00' indicates success.
- Class = '01' indicates a warning.
- Class = '02' indicates “not found.” This is relevant within the context of cursors and is used to control what happens when a cursor reaches the end of a data set. This condition also occurs for `SELECT ... INTO var_list` statements that retrieve no rows.
- Class > '02' indicates an exception.

### B.3 Server Error Codes and Messages

MySQL programs have access to several types of error information when the server returns an error. For example, the `mysql` client program displays errors using the following format:

```
shell> SELECT * FROM no_such_table;
ERROR 1146 (42S02): Table 'test.no_such_table' doesn't exist
```

The message displayed contains three types of information:

- A numeric error code (1146). This number is MySQL-specific and is not portable to other database systems.
- A five-character SQLSTATE value ('42S02'). The values are taken from ANSI SQL and ODBC and are more standardized. Not all MySQL error numbers have corresponding SQLSTATE values. In these cases, 'HY000' (general error) is used.
- A message string that provides a textual description of the error.

For error checking, use error codes, not error messages. Error messages do not change often, but it is possible. Also if the database administrator changes the language setting, that affects the language of error messages.

Error codes are stable across GA releases of a given MySQL series. Before a series reaches GA status, new codes may still be under development and subject to change.

Server error information comes from the following source files. For details about the way that error information is defined, see the MySQL Internals Manual.

- Error message information is listed in the `share/errmsg.txt` file. `%d` and `%s` represent numbers and strings, respectively, that are substituted into the Message values when they are displayed.
• The Error values listed in `share/errmsg.txt` are used to generate the definitions in the `include/mysqld_error.h` and `include/mysqld_ename.h` MySQL source files.

• The SQLSTATE values listed in `share/errmsg.txt` are used to generate the definitions in the `include/sql_state.h` MySQL source file.

Because updates are frequent, it is possible that those files will contain additional error information not listed here.

• Error: 1000 SQLSTATE: HY000 (ER_HASHCHK)
  Message: hashchk
  Unused.

• Error: 1001 SQLSTATE: HY000 (ER_NISAMCHK)
  Message: isamchk
  Unused.

• Error: 1002 SQLSTATE: HY000 (ER_NO)
  Message: NO
  Used in the construction of other messages.

• Error: 1003 SQLSTATE: HY000 (ER_YES)
  Message: YES
  Used in the construction of other messages.

  Extended EXPLAIN format generates Note messages. ER_YES is used in the Code column for these messages in subsequent SHOW WARNINGS output.

• Error: 1004 SQLSTATE: HY000 (ER_CANT_CREATE_FILE)
  Message: Can't create file '%s' (errno: %d)
  Occurs for failure to copy an .frm file to a new location, during execution of a CREATE TABLE dst LIKE src statement when the server tries to copy the source table .frm file to the destination table .frm file.
  Possible causes: Permissions problem for source .frm file; destination .frm file already exists but is not writeable.

• Error: 1005 SQLSTATE: HY000 (ER_CANT_CREATE_DB)
  Message: Can't create database '%s' (errno: %d)
  InnoDB reports this error when a table cannot be created. If the error message refers to error 150, table creation failed because a foreign key constraint was not correctly formed. If the error message refers to error -1, table creation probably failed because the table includes a column name that matched the name of an internal InnoDB table.

• Error: 1006 SQLSTATE: HY000 (ER_CANT_CREATE_TABLE)
  Message: Can't create table '%s' (errno: %d)

• Error: 1007 SQLSTATE: HY000 (ER_DB_CREATE_EXISTS)
  Message: Can't create database '%s'; database exists
An attempt to create a database failed because the database already exists.

Drop the database first if you really want to replace an existing database, or add an IF NOT EXISTS clause to the CREATE DATABASE statement if to retain an existing database without having the statement produce an error.

- **Error:** 1008 SQLSTATE: HY000 (ER_DB_DROP_EXISTS)
  Message: Can't drop database '%s'; database doesn't exist

- **Error:** 1009 SQLSTATE: HY000 (ER_DB_DROP_DELETE)
  Message: Error dropping database (can't delete '%s', errno: %d)

- **Error:** 1010 SQLSTATE: HY000 (ER_DB_DROP_RMDIR)
  Message: Error dropping database (can't rmdir '%s', errno: %d)

- **Error:** 1011 SQLSTATE: HY000 (ER_CANT_DELETE_FILE)
  Message: Error on delete of '%s' (errno: %d)

- **Error:** 1012 SQLSTATE: HY000 (ER_CANT_FIND_SYSTEM_REC)
  Message: Can't read record in system table

  Returned by InnoDB for attempts to access InnoDB INFORMATION_SCHEMA tables when InnoDB is unavailable.

- **Error:** 1013 SQLSTATE: HY000 (ER_CANT_GET_STAT)
  Message: Can't get status of '%s' (errno: %d)

- **Error:** 1014 SQLSTATE: HY000 (ER_CANT_GET_WD)
  Message: Can't get working directory (errno: %d)

- **Error:** 1015 SQLSTATE: HY000 (ER_CANT_LOCK)
  Message: Can't lock file (errno: %d)

- **Error:** 1016 SQLSTATE: HY000 (ER_CANT_OPEN_FILE)
  Message: Can't open file: '%s' (errno: %d)

  InnoDB reports this error when the table from the InnoDB data files cannot be found, even though the .frm file for the table exists. See Section 14.2.13.3, “Troubleshooting InnoDB Data Dictionary Operations”.

- **Error:** 1017 SQLSTATE: HY000 (ER_FILE_NOT_FOUND)
  Message: Can't find file: '%s' (errno: %d)

- **Error:** 1018 SQLSTATE: HY000 (ER_CANT_READ_DIR)
  Message: Can't read dir of '%s' (errno: %d)

- **Error:** 1019 SQLSTATE: HY000 (ER_CANT_SET_WD)
  Message: Can't change dir to '%s' (errno: %d)

- **Error:** 1020 SQLSTATE: HY000 (ER_CHECKREAD)
Message: Record has changed since last read in table '%s'

- Error: 1021 SQLSTATE: HY000 (ER_DISK_FULL)
  Message: Disk full (%s); waiting for someone to free some space...

- Error: 1022 SQLSTATE: 23000 (ER_DUP_KEY)
  Message: Can't write; duplicate key in table '%s'

- Error: 1023 SQLSTATE: HY000 (ER_ERROR_ON_CLOSE)
  Message: Error on close of '%s' (errno: %d)

- Error: 1024 SQLSTATE: HY000 (ER_ERROR_ON_READ)
  Message: Error reading file '%s' (errno: %d)

- Error: 1025 SQLSTATE: HY000 (ER_ERROR_ON_RENAME)
  Message: Error on rename of '%s' to '%s' (errno: %d)

  InnoDB reports this error if you attempt to drop the last index that can enforce a particular referential constraint. As of MySQL 5.5, this error message is replaced by ERROR 1553.

- Error: 1026 SQLSTATE: HY000 (ER_ERROR_ON_WRITE)
  Message: Error writing file '%s' (errno: %d)

- Error: 1027 SQLSTATE: HY000 (ER_FILE_USED)
  Message: '%s' is locked against change

- Error: 1028 SQLSTATE: HY000 (ER_FILSORT_ABORT)
  Message: Sort aborted

- Error: 1029 SQLSTATE: HY000 (ER_FORM_NOT_FOUND)
  Message: View '%s' doesn't exist for '%s'

- Error: 1030 SQLSTATE: HY000 (ER_GET_ERRNO)
  Message: Got error %d from storage engine
  Check the %d value to see what the OS error means. For example, 28 indicates that you have run out of disk space.

- Error: 1031 SQLSTATE: HY000 (ER_ILLEGAL_HA)
  Message: Table storage engine for '%s' doesn't have this option

- Error: 1032 SQLSTATE: HY000 (ER_KEY_NOT_FOUND)
  Message: Can't find record in '%s'

- Error: 1033 SQLSTATE: HY000 (ER_NOT_FORM_FILE)
  Message: Incorrect information in file: '%s'

- Error: 1034 SQLSTATE: HY000 (ER_NOT_KEYFILE)
  Message: Incorrect key file for table '%s'; try to repair it
Server Error Codes and Messages

- **Error:** 1035 SQLSTATE: HY000 (ER_OLD_KEYFILE)
  Message: Old key file for table '%s'; repair it!

- **Error:** 1036 SQLSTATE: HY000 (ER_OPEN_AS_READONLY)
  Message: Table '%s' is read only

- **Error:** 1037 SQLSTATE: HY001 (ER_OUTOFMEMORY)
  Message: Out of memory; restart server and try again (needed %d bytes)

- **Error:** 1038 SQLSTATE: HY001 (ER_OUT_OF_SORTMEMORY)
  Message: Out of sort memory; increase server sort buffer size

- **Error:** 1039 SQLSTATE: HY000 (ER_UNEXPECTED_EOF)
  Message: Unexpected EOF found when reading file '%s' (errno: %d)

- **Error:** 1040 SQLSTATE: 08004 (ER_CON_COUNT_ERROR)
  Message: Too many connections

- **Error:** 1041 SQLSTATE: HY000 (ER_OUT_OF_RESOURCES)
  Message: Out of memory; check if mysqld or some other process uses all available memory; if not, you may have to use 'ulimit' to allow mysqld to use more memory or you can add more swap space

- **Error:** 1042 SQLSTATE: 08S01 (ER_BAD_HOST_ERROR)
  Message: Can't get hostname for your address

- **Error:** 1043 SQLSTATE: 08S01 (ER_HANDSHAKE_ERROR)
  Message: Bad handshake

- **Error:** 1044 SQLSTATE: 42000 (ER_DBACCESS_DENIED_ERROR)
  Message: Access denied for user '%s'@'%s' to database '%s'

- **Error:** 1045 SQLSTATE: 28000 (ER_ACCESS_DENIED_ERROR)
  Message: Access denied for user '%s'@'%s' (using password: %s)

- **Error:** 1046 SQLSTATE: 3D000 (ER_NO_DB_ERROR)
  Message: No database selected

- **Error:** 1047 SQLSTATE: 08S01 (ER_UNKNOWN_COM_ERROR)
  Message: Unknown command

- **Error:** 1048 SQLSTATE: 23000 (ER_BAD_NULL_ERROR)
  Message: Column '%s' cannot be null

- **Error:** 1049 SQLSTATE: 42000 (ER_BAD_DB_ERROR)
  Message: Unknown database '%s'

- **Error:** 1050 SQLSTATE: 42S01 (ER_TABLE_EXISTS_ERROR)
  Message: Table '%s' already exists

- **Error:** 1051 SQLSTATE: 42S02 (ER_BAD_TABLE_ERROR)
Message: Unknown table '%s'

- Error: 1052 SQLSTATE: 23000 (ER_NON_UNIQ_ERROR)

Message: Column '%s' in %s is ambiguous

%s = column name
%s = location of column (for example, "field list")

Likely cause: A column appears in a query without appropriate qualification, such as in a select list or ON clause.

Examples:

```sql
mysql> SELECT i FROM t INNER JOIN t AS t2;
ERROR 1052 (23000): Column 'i' in field list is ambiguous
```

```sql
mysql> SELECT * FROM t LEFT JOIN t AS t2 ON i = i;
ERROR 1052 (23000): Column 'i' in on clause is ambiguous
```

Resolution:

- Qualify the column with the appropriate table name:

```sql
mysql> SELECT t2.i FROM t INNER JOIN t AS t2;
```

- Modify the query to avoid the need for qualification:

```sql
mysql> SELECT * FROM t LEFT JOIN t AS t2 USING (i);
```

- Error: 1053 SQLSTATE: 08S01 (ER_SERVER_SHUTDOWN)

Message: Server shutdown in progress

- Error: 1054 SQLSTATE: 42S22 (ER_BAD_FIELD_ERROR)

Message: Unknown column '%s' in '%s'

- Error: 1055 SQLSTATE: 42000 (ER_WRONG_FIELD_WITH_GROUP)

Message: '%s' isn't in GROUP BY

- Error: 1056 SQLSTATE: 42000 (ER_WRONG_GROUP_FIELD)

Message: Can't group on '%s'

- Error: 1057 SQLSTATE: 42000 (ER_WRONG_SUM_SELECT)

Message: Statement has sum functions and columns in same statement

- Error: 1058 SQLSTATE: 21S01 (ER_WRONG_VALUE_COUNT)

Message: Column count doesn't match value count

- Error: 1059 SQLSTATE: 42000 (ER_TOO_LONG_IDENT)

Message: Identifier name '%s' is too long

- Error: 1060 SQLSTATE: 42S21 (ER_DUP_FILENAME)

Message: Duplicate column name '%s'
Server Error Codes and Messages

- Error: 1061 SQLSTATE: 42000 (ER_DUP_KEYNAME)
  Message: Duplicate key name '%s'

- Error: 1062 SQLSTATE: 23000 (ER_DUP_ENTRY)
  Message: Duplicate entry '%s' for key %d

- Error: 1063 SQLSTATE: 42000 (ER_WRONG_FIELD_SPEC)
  Message: Incorrect column specifier for column '%s'

- Error: 1064 SQLSTATE: 42000 (ER_PARSE_ERROR)
  Message: %s near '%s' at line %d

- Error: 1065 SQLSTATE: 42000 (ER_EMPTY_QUERY)
  Message: Query was empty

- Error: 1066 SQLSTATE: 42000 (ER_NONUNIQ_TABLE)
  Message: Not unique table/alias: '%s'

- Error: 1067 SQLSTATE: 42000 (ER_INVALID_DEFAULT)
  Message: Invalid default value for '%s'

- Error: 1068 SQLSTATE: 42000 (ER_MULTIPLE_PRI_KEY)
  Message: Multiple primary key defined

- Error: 1069 SQLSTATE: 42000 (ER_TOO_MANY_KEYS)
  Message: Too many keys specified; max %d keys allowed

- Error: 1070 SQLSTATE: 42000 (ER_TOO_MANY_KEY_PARTS)
  Message: Too many key parts specified; max %d parts allowed

- Error: 1071 SQLSTATE: 42000 (ER_TOO_LONG_KEY)
  Message: Specified key was too long; max key length is %d bytes

- Error: 1072 SQLSTATE: 42000 (ER_KEY_COLUMN_DOES_NOT_EXIT)
  Message: Key column '%s' doesn't exist in table

- Error: 1073 SQLSTATE: 42000 (ER_BLOB_USED_AS_KEY)
  Message: BLOB column '%s' can't be used in key specification with the used table type

- Error: 1074 SQLSTATE: 42000 (ER_TOO_BIG_FIELDLENGTH)
  Message: Column length too big for column '%s' (max = %lu); use BLOB or TEXT instead

- Error: 1075 SQLSTATE: 42000 (ER_WRONG_AUTO_KEY)
  Message: Incorrect table definition; there can be only one auto column and it must be defined as a key

- Error: 1076 SQLSTATE: HY000 (ER_READY)
  Message: %s: ready for connections. Version: '%s' socket: '%s' port: %d
Server Error Codes and Messages

- **Error: 1077 SQLSTATE: HY000 (ER_NORMAL_SHUTDOWN)**
  Message: %s: Normal shutdown

- **Error: 1078 SQLSTATE: HY000 (ER_GOT_SIGNAL)**
  Message: %s: Got signal %d. Aborting!

- **Error: 1079 SQLSTATE: HY000 (ER_SHUTDOWN_COMPLETE)**
  Message: %s: Shutdown complete

- **Error: 1080 SQLSTATE: 08S01 (ER_FORCING_CLOSE)**
  Message: %s: Forcing close of thread %ld user: '%s'

- **Error: 1081 SQLSTATE: 08S01 (ER_IPSOCK_ERROR)**
  Message: Can't create IP socket

- **Error: 1082 SQLSTATE: 42S12 (ER_NO_SUCH_INDEX)**
  Message: Table '%s' has no index like the one used in CREATE INDEX; recreate the table

- **Error: 1083 SQLSTATE: 42000 (ER_WRONG_FIELD_TERMINATORS)**
  Message: Field separator argument is not what is expected; check the manual

- **Error: 1084 SQLSTATE: 42000 (ER_BLOBS_AND_NO_TERMINATED)**
  Message: You can't use fixed rowlength with BLOBs; please use 'fields terminated by'

- **Error: 1085 SQLSTATE: HY000 (ER_TEXTFILE_NOT_READABLE)**
  Message: The file '%s' must be in the database directory or be readable by all

- **Error: 1086 SQLSTATE: HY000 (ER_FILE_EXISTS_ERROR)**
  Message: File '%s' already exists

- **Error: 1087 SQLSTATE: HY000 (ER_LOAD_INFO)**
  Message: Records: %ld Deleted: %ld Skipped: %ld Warnings: %ld

- **Error: 1088 SQLSTATE: HY000 (ER_ALTER_INFO)**
  Message: Records: %ld Duplicates: %ld

- **Error: 1089 SQLSTATE: HY000 (ER_WRONG_SUB_KEY)**
  Message: Incorrect sub part key; the used key part isn't a string, the used length is longer than the key part, or the storage engine doesn't support unique sub keys

- **Error: 1090 SQLSTATE: 42000 (ER_CANT_REMOVE_ALL_FIELDS)**
  Message: You can't delete all columns with ALTER TABLE; use DROP TABLE instead

- **Error: 1091 SQLSTATE: 42000 (ER_CANT_DROP_FIELD_OR_KEY)**
  Message: Can't DROP '%s'; check that column/key exists

- **Error: 1092 SQLSTATE: HY000 (ER_INSERT_INFO)**
  Message: Records: %ld Duplicates: %ld Warnings: %ld
• Error: 1093 SQLSTATE: HY000 (ER_UPDATE_TABLE_USED)
  Message: You can't specify target table '%s' for update in FROM clause

• Error: 1094 SQLSTATE: HY000 (ER_NO_SUCH_THREAD)
  Message: Unknown thread id: %lu

• Error: 1095 SQLSTATE: HY000 (ER_KILL_DENIED_ERROR)
  Message: You are not owner of thread %lu

• Error: 1096 SQLSTATE: HY000 (ER_NO_TABLES_USED)
  Message: No tables used

• Error: 1097 SQLSTATE: HY000 (ER_TOO_BIG_SET)
  Message: Too many strings for column %s and SET

• Error: 1098 SQLSTATE: HY000 (ER_NO_UNIQUE_LOGFILE)
  Message: Can't generate a unique log-filename %s.(1-999)

• Error: 1099 SQLSTATE: HY000 (ER_TABLE_NOT_LOCKED_FOR_WRITE)
  Message: Table '%s' was locked with a READ lock and can't be updated

• Error: 1100 SQLSTATE: HY000 (ER_TABLE_NOT_LOCKED)
  Message: Table '%s' was not locked with LOCK TABLES

• Error: 1101 SQLSTATE: 42000 (ER_BLOB_CANT HAVE_DEFAULT)
  Message: BLOB/TEXT column '%s' can't have a default value

• Error: 1102 SQLSTATE: 42000 (ER_WRONG_DB_NAME)
  Message: Incorrect database name '%s'

• Error: 1103 SQLSTATE: 42000 (ER_WRONG_TABLE_NAME)
  Message: Incorrect table name '%s'

• Error: 1104 SQLSTATE: 42000 (ER_TOO_BIG_SELECT)
  Message: The SELECT would examine more than MAX_JOIN_SIZE rows; check your WHERE and use SET SQL_BIG_SELECTS=1 or SET SQL_MAX_JOIN_SIZE=# if the SELECT is okay

• Error: 1105 SQLSTATE: HY000 (ER_UNKNOWN_ERROR)
  Message: Unknown error

• Error: 1106 SQLSTATE: 42000 (ER_UNKNOWN_PROCEDURE)
  Message: Unknown procedure '%s'

• Error: 1107 SQLSTATE: 42000 (ER_WRONG_PARAMCOUNT_TO_PROCEDURE)
  Message: Incorrect parameter count to procedure '%s'

• Error: 1108 SQLSTATE: HY000 (ER_WRONG_PARAMETERS_TO_PROCEDURE)
  Message: Incorrect parameters to procedure '%s'
Server Error Codes and Messages

- **Error:** 1109 SQLSTATE: 42S02 (*ER_UNKNOWN_TABLE*)
  Message: Unknown table '%s' in %s

- **Error:** 1110 SQLSTATE: 42000 (*ER_FIELD_SPECIFIED_TWICE*)
  Message: Column '%s' specified twice

- **Error:** 1111 SQLSTATE: HY000 (*ER_INVALID_GROUP_FUNC_USE*)
  Message: Invalid use of group function

- **Error:** 1112 SQLSTATE: 42000 (*ER_UNSUPPORTED_EXTENSION*)
  Message: Table '%s' uses an extension that doesn't exist in this MySQL version

- **Error:** 1113 SQLSTATE: 42000 (*ER_TABLE.Must.HAVE_COLUMNS*)
  Message: A table must have at least 1 column

- **Error:** 1114 SQLSTATE: HY000 (*ER_RECORD_FILE_FULL*)
  Message: The table '%s' is full

  *InnoDB* reports this error when the system tablespace runs out of free space. Reconfigure the system tablespace to add a new data file.

- **Error:** 1115 SQLSTATE: 42000 (*ER_UNKNOWN_CHARACTER_SET*)
  Message: Unknown character set: '%s'

- **Error:** 1116 SQLSTATE: HY000 (*ER_TOO_MANY_TABLES*)
  Message: Too many tables; MySQL can only use %d tables in a join

- **Error:** 1117 SQLSTATE: HY000 (*ER_TOO_MANY_FIELDS*)
  Message: Too many columns

- **Error:** 1118 SQLSTATE: 42000 (*ER_TOO_BIG_ROWSIZE*)
  Message: Row size too large. The maximum row size for the used table type, not counting BLOBs, is %ld. You have to change some columns to TEXT or BLOBs

- **Error:** 1119 SQLSTATE: HY000 (*ER_STACK_OVERRUN*)
  Message: Thread stack overrun: Used: %ld of a %ld stack. Use 'mysqld -O thread_stack=#' to specify a bigger stack if needed

- **Error:** 1160 SQLSTATE: 08S01 (ER_NET_ERROR_ON_WRITE)
  Message: Got an error writing communication packets
- **Error:** 1161 SQLSTATE: 08S01 (ER_NET_WRITE_INTERRUPTED)
  Message: Got timeout writing communication packets
- **Error:** 1162 SQLSTATE: 42000 (ER_TOO_LONG_STRING)
  Message: Result string is longer than 'max_allowed_packet' bytes
- **Error:** 1163 SQLSTATE: 42000 (ER_TABLE_CANT.Handle_BLOB)
  Message: The used table type doesn't support BLOB/TEXT columns
- **Error:** 1164 SQLSTATE: 42000 (ER_TABLE_CANT.Handle_AUTO_INCREMENT)
  Message: The used table type doesn't support AUTO_INCREMENT columns
- **Error:** 1165 SQLSTATE: HY000 (ER_DELAYED_INSERT_TABLE_LOCKED)
  Message: INSERT DELAYED can't be used with table '%s' because it is locked with LOCK TABLES
- **Error:** 1166 SQLSTATE: 42000 (ER_WRONG_COLUMN_NAME)
  Message: Incorrect column name '%s'
- **Error:** 1167 SQLSTATE: 42000 (ER_WRONG_KEY_COLUMN)
  Message: The used storage engine can't index column '%s'
- **Error:** 1168 SQLSTATE: HY000 (ER_WRONG_MRG_TABLE)
  Message: Unable to open underlying table which is differently defined or of non-MyISAM type or doesn't exist
- **Error:** 1169 SQLSTATE: 23000 (ER_DUP_UNIQUE)
  Message: Can't write, because of unique constraint, to table '%s'
- **Error:** 1170 SQLSTATE: 42000 (ER_BLOB_KEYWITHOUT_LENGTH)
  Message: BLOB/TEXT column '%s' used in key specification without a key length
• Error: 1171 SQLSTATE: 42000 (ER_PRIMARY_CANT_HAVE_NULL)
  Message: All parts of a PRIMARY KEY must be NOT NULL; if you need NULL in a key, use UNIQUE instead
• Error: 1172 SQLSTATE: 42000 (ER_TOO_MANY_ROWS)
  Message: Result consisted of more than one row
• Error: 1173 SQLSTATE: 42000 (ER_REQUIRES_PRIMARY_KEY)
  Message: This table type requires a primary key
  
  InnoDB reports this error when you attempt to drop an implicit clustered index (the first UNIQUE NOT NULL index) if the table did not contain a PRIMARY KEY.

  InnoDB should no longer report this error as of MySQL 5.5. For tables without an explicit PRIMARY KEY, InnoDB creates an implicit clustered index using the first columns of the table that are declared UNIQUE and NOT NULL. When you drop such an index, InnoDB now automatically copies the table and rebuilds the index using a different UNIQUE NOT NULL group of columns or a system-generated key. Since this operation changes the primary key, it uses the slow method of copying the table and re-creating the index, rather than the Fast Index Creation technique from Implementation Details of Fast Index Creation.

• Error: 1174 SQLSTATE: HY000 (ER_NO_RAIDCompiled)
  Message: This version of MySQL is not compiled with RAID support
• Error: 1175 SQLSTATE: HY000 (ER_UPDATE WITHOUT KEY_IN_SAFE_MODE)
  Message: You are using safe update mode and you tried to update a table without a WHERE that uses a KEY column
• Error: 1176 SQLSTATE: HY000 (ER_KEY DOES NOT EXISTS)
  Message: Key '%s' doesn't exist in table '%s'
• Error: 1177 SQLSTATE: 42000 (ER_CHECK NO SUCH TABLE)
  Message: Can't open table
• Error: 1178 SQLSTATE: 42000 (ER_CHECK NOT IMPLEMENTED)

- **Error:** 1190 SQLSTATE: 08S01 (ER_MASTER_NET_WRITE)
  Message: Net error writing to master

- **Error:** 1191 SQLSTATE: HY000 (ER_FT_MATCHING_KEY_NOT_FOUND)
  Message: Can't find FULLTEXT index matching the column list

- **Error:** 1192 SQLSTATE: HY000 (ER_LOCK_OR_ACTIVE_TRANSACTION)
  Message: Can't execute the given command because you have active locked tables or an active transaction

- **Error:** 1193 SQLSTATE: HY000 (ER_UNKNOWN_SYSTEM_VARIABLE)
  Message: Unknown system variable '%s'

- **Error:** 1194 SQLSTATE: HY000 (ER_CRASHED_ON_USAGE)
  Message: Table '%s' is marked as crashed and should be repaired

- **Error:** 1195 SQLSTATE: HY000 (ER_CRASHED_ON_REPAIR)
  Message: Table '%s' is marked as crashed and last (automatic?) repair failed

- **Error:** 1196 SQLSTATE: HY000 (ER_WARNING_NOT_COMPLETE_ROLLBACK)
  Message: Some non-transactional changed tables couldn't be rolled back

- **Error:** 1197 SQLSTATE: HY000 (ER_TRANS_CACHE_FULL)
  Message: Multi-statement transaction required more than 'max_binlog_cache_size' bytes of storage; increase this mysqld variable and try again

- **Error:** 1198 SQLSTATE: HY000 (ER_SLAVE_MUST_STOP)
  Message: This operation cannot be performed with a running slave; run STOP SLAVE first

- **Error:** 1199 SQLSTATE: HY000 (ER_SLAVE_NOT_RUNNING)
  Message: This operation requires a running slave; configure slave and do START SLAVE
• **Error:** 1200 SQLSTATE: HY000 (**ER_BAD_SLAVE**)

  Message: The server is not configured as slave; fix in config file or with CHANGE MASTER TO

• **Error:** 1201 SQLSTATE: HY000 (**ER_MASTER_INFO**)

  Message: Could not initialize master info structure; more error messages can be found in the MySQL error log

• **Error:** 1202 SQLSTATE: HY000 (**ER_SLAVE_THREAD**)

  Message: Could not create slave thread; check system resources

• **Error:** 1203 SQLSTATE: 42000 (**ER_TOO_MANY_USER_CONNECTIONS**)

  Message: User %s already has more than 'max_user_connections' active connections

• **Error:** 1204 SQLSTATE: HY000 (**ER_SET_CONSTANTS_ONLY**)

  Message: You may only use constant expressions with SET

• **Error:** 1205 SQLSTATE: HY000 (**ER_LOCK_WAIT_TIMEOUT**)

  Message: Lock wait timeout exceeded; try restarting transaction

  *InnoDB* reports this error when lock wait timeout expires. The statement that waited too long was rolled back (not the entire transaction). You can increase the value of the *innodb_lock_wait_timeout* configuration option if SQL statements should wait longer for other transactions to complete, or decrease it if too many long-running transactions are causing locking problems and reducing concurrency on a busy system.

• **Error:** 1206 SQLSTATE: HY000 (**ER_LOCK_TABLE_FULL**)

  Message: The total number of locks exceeds the lock table size

  *InnoDB* reports this error when the total number of locks exceeds the amount of memory devoted to managing locks. To avoid this error, increase the value of *innodb_buffer_pool_size*. Within an individual application, a workaround may be to break a large operation into smaller pieces. For example, if the error occurs for a large *INSERT*, perform several smaller *INSERT* operations.

• **Error:** 1207 SQLSTATE: 25000 (**ER_READ_ONLY_TRANSACTION**)

  Message: Update locks cannot be acquired during a READ UNCOMMITTED transaction

• **Error:** 1208 SQLSTATE: HY000 (**ER_DROP_DB_WITH_READ_LOCK**)

  Message: DROP DATABASE not allowed while thread is holding global read lock

• **Error:** 1209 SQLSTATE: HY000 (**ER_CREATE_DB_WITH_READ_LOCK**)

  Message: CREATE DATABASE not allowed while thread is holding global read lock

• **Error:** 1210 SQLSTATE: HY000 (**ER_WRONG_ARGUMENTS**)

  Message: Incorrect arguments to %s

• **Error:** 1211 SQLSTATE: 42000 (**ER_NO_PERMISSION_TO_CREATE_USER**)

  Message: '%s'@'%s' is not allowed to create new users

• **Error:** 1212 SQLSTATE: HY000 (**ER_UNION_TABLES_IN_DIFFERENT_DIR**)

  Message: Incorrect table definition; all MERGE tables must be in the same database
• Error: 1213 SQLSTATE: 40001 (ER_LOCK_DEADLOCK)
Message: Deadlock found when trying to get lock; try restarting transaction

InnoDB reports this error when a transaction encounters a deadlock and is automatically rolled back so that your application can take corrective action. To recover from this error, run all the operations in this transaction again. A deadlock occurs when requests for locks arrive in inconsistent order between transactions. The transaction that was rolled back released all its locks, and the other transaction can now get all the locks it requested. Thus, when you re-run the transaction that was rolled back, it might have to wait for other transactions to complete, but typically the deadlock does not recur. If you encounter frequent deadlocks, make the sequence of locking operations (LOCK TABLES, SELECT ... FOR UPDATE, and so on) consistent between the different transactions or applications that experience the issue. See Section 14.2.8.9, "How to Cope with Deadlocks" for details.

• Error: 1214 SQLSTATE: HY000 (ER_TABLE_CANT_HANDLE_FT)
Message: The used table type doesn't support FULLTEXT indexes

• Error: 1215 SQLSTATE: HY000 (ER_CANNOT_ADD_FOREIGN)
Message: Cannot add foreign key constraint

• Error: 1216 SQLSTATE: 23000 (ER_NO_REFERENCED_ROW)
Message: Cannot add or update a child row: a foreign key constraint fails

InnoDB reports this error when you try to add a row but there is no parent row, and a foreign key constraint fails. Add the parent row first.

• Error: 1217 SQLSTATE: 23000 (ER_ROW_IS_REFERENCED)
Message: Cannot delete or update a parent row: a foreign key constraint fails

InnoDB reports this error when you try to delete a parent row that has children, and a foreign key constraint fails. Delete the children first.

• Error: 1218 SQLSTATE: 08S01 (ER_CONNECT_TO_MASTER)

• Error: **1340** SQLSTATE: **HY000** (**ER_FPARSER_TOO_BIG_FILE**)
  Message: Configuration file '%s' is too big

• Error: **1341** SQLSTATE: **HY000** (**ER_FPARSER_BAD_HEADER**)
  Message: Malformed file type header in file '%s'

• Error: **1342** SQLSTATE: **HY000** (**ER_FPARSER_EOF_IN_COMMENT**)
  Message: Unexpected end of file while parsing comment '%s'

• Error: **1343** SQLSTATE: **HY000** (**ER_FPARSER_ERROR_IN_PARAMETER**)
  Message: Error while parsing parameter '%s' (line: '%s')

• Error: **1344** SQLSTATE: **HY000** (**ER_FPARSER_EOF_IN_UNKNOWN_PARAMETER**)
  Message: Unexpected end of file while skipping unknown parameter '%s'

• Error: **1345** SQLSTATE: **HY000** (**ER_VIEW_NO_EXPLAIN**)
  Message: EXPLAIN/SHOW can not be issued; lacking privileges for underlying table

• Error: **1346** SQLSTATE: **HY000** (**ER_FRM_UNKNOWN_TYPE**)
  Message: File '%s' has unknown type '%s' in its header

• Error: **1347** SQLSTATE: **HY000** (**ER_WRONG_OBJECT**)
  Message: '%s.%s' is not %s

• Error: **1348** SQLSTATE: **HY000** (**ER_NONUPDATEABLE_COLUMN**)
  Message: Column '%s' is not updatable

• Error: **1349** SQLSTATE: **HY000** (**ER_VIEW_SELECT_DERIVED**)
Message: View's SELECT contains a subquery in the FROM clause

• Error: 1350 SQLSTATE: HY000 (ER_VIEW_SELECT_CLAUSE)

Message: View's SELECT contains a '%s' clause

• Error: 1351 SQLSTATE: HY000 (ER_VIEW_SELECT_VARIABLE)

Message: View's SELECT contains a variable or parameter

• Error: 1352 SQLSTATE: HY000 (ER_VIEW_SELECT_TMPTABLE)

Message: View's SELECT refers to a temporary table '%s'

• Error: 1353 SQLSTATE: HY000 (ER_VIEW_WRONG_LIST)

Message: View's SELECT and view's field list have different column counts

• Error: 1354 SQLSTATE: HY000 (ER_WARN_VIEW_MERGE)

Message: View merge algorithm can't be used here for now (assumed undefined algorithm)

• Error: 1355 SQLSTATE: HY000 (ER_WARN_VIEW_WITHOUT_KEY)

Message: View being updated does not have complete key of underlying table in it

• Error: 1356 SQLSTATE: HY000 (ER_VIEW_INVALID)

Message: View '%s.%s' references invalid table(s) or column(s) or function(s) or definer/invoker of view lack rights to use them

• Error: 1357 SQLSTATE: HY000 (ER_SP_NO_DROP_SP)

Message: Can't drop or alter a %s from within another stored routine

• Error: 1358 SQLSTATE: HY000 (ER_SP_GOTO_IN_HNDLR)

Message: GOTO is not allowed in a stored procedure handler

• Error: 1359 SQLSTATE: HY000 (ER_TRG_ALREADY_EXISTS)

Message: Trigger already exists

• Error: 1360 SQLSTATE: HY000 (ER_TRG_DOES_NOT_EXIST)

Message: Trigger does not exist

• Error: 1361 SQLSTATE: HY000 (ER_TRG_ON_VIEW_OR_TEMP_TABLE)

Message: Trigger's '%s' is view or temporary table

• Error: 1362 SQLSTATE: HY000 (ER_TRG_CANT_CHANGE_ROW)

Message: Updating of %s row is not allowed in %strigger

• Error: 1363 SQLSTATE: HY000 (ER_TRG_NO_SUCH_ROW_IN_TRG)

Message: There is no %s row in %s trigger

• Error: 1364 SQLSTATE: HY000 (ER_NO_DEFAULT_FOR_FIELD)

Message: Field '%s' doesn't have a default value

• Error: 1365 SQLSTATE: 22012 (ER_DIVISION_BY_ZERO)
Message: Division by 0

- Error: 1366 SQLSTATE: HY000 (ER_TRUNCATED_WRONG_VALUE_FOR_FIELD)
  Message: Incorrect %s value: '%s' for column '%s' at row %ld

- Error: 1367 SQLSTATE: 22007 (ER_ILLEGAL_VALUE_FOR_TYPE)
  Message: Illegal %s '%s' value found during parsing

- Error: 1368 SQLSTATE: HY000 (ER_VIEW_NONUPD_CHECK)
  Message: CHECK OPTION on non-updatable view '%s.%s'

- Error: 1369 SQLSTATE: HY000 (ER_VIEW_CHECK_FAILED)
  Message: CHECK OPTION failed '%s.%s'

- Error: 1370 SQLSTATE: 42000 (ER_PROCACCESS_DENIED_ERROR)

Server Error Codes and Messages

• **Error: 1414 SQLSTATE: 42000 (ER_SP_NOT_VAR_ARG)**
  Message: OUT or INOUT argument %d for routine %s is not a variable or NEW pseudo-variable in BEFORE trigger

• **Error: 1415 SQLSTATE: 0A000 (ER_SP_NO_RETSET_IN_FUNC)**
  Message: Not allowed to return a result set from a function

  In 5.0.12: **ER_SP_NO_RETSET_IN_FUNC** was renamed to **ER_SP_NO_RETSET**.
  **ER_SP_NO_RETSET_IN_FUNC** was removed after 5.0.11.

• **Error: 1415 SQLSTATE: 0A000 (ER_SP_NO_RETSET)**
  Message: Not allowed to return a result set from a %s

  In 5.0.12: **ER_SP_NO_RETSET_IN_FUNC** was renamed to **ER_SP_NO_RETSET**.
  **ER_SP_NO_RETSET** was added in 5.0.12.

• **Error: 1416 SQLSTATE: 22003 (ER_CANT_CREATE_GEOMETRY_OBJECT)**
  Message: Cannot get geometry object from data you send to the GEOMETRY field

• **Error: 1417 SQLSTATE: HY000 (ER_FAILED_ROUTINE_BREAK_BINLOG)**
  Message: A routine failed and has neither NO SQL nor READS SQL DATA in its declaration and binary logging is enabled; if non-transactional tables were updated, the binary log will miss their changes

• **Error: 1418 SQLSTATE: HY000 (ER_BINLOG_UNSAFE_ROUTINE)**
  Message: This function has none of DETERMINISTIC, NO SQL, or READS SQL DATA in its declaration and binary logging is enabled (you *might* want to use the less safe log_bin_trust_function_creators variable)

• **Error: 1419 SQLSTATE: HY000 (ER_BINLOG_CREATE_ROUTINE_NEED_SUPER)**
  Message: You do not have the SUPER privilege and binary logging is enabled (you *might* want to use the less safe log_bin_trust_function_creators variable)

• **Error: 1420 SQLSTATE: HY000 (ER_EXEC_STMT_WITH_OPEN_CURSOR)**
  Message: You can’t execute a prepared statement which has an open cursor associated with it. Reset the statement to re-execute it.

• **Error: 1421 SQLSTATE: HY000 (ER_STMT_HAS_NO_OPEN_CURSOR)**
  Message: The statement (%lu) has no open cursor.

• **Error: 1422 SQLSTATE: HY000 (ER_COMMIT_NOT_ALLOWED_IN_SF_OR_TRG)**
  Message: Explicit or implicit commit is not allowed in stored function or trigger.

• **Error: 1423 SQLSTATE: HY000 (ER_NO_DEFAULT_FOR_VIEW_FIELD)**
  Message: Field of view '%s.%s' underlying table doesn't have a default value
  **ER_NO_DEFAULT_FOR_VIEW_FIELD** was added in 5.0.9.

• **Error: 1424 SQLSTATE: HY000 (ER_SP_NO_RECURSION)**
  Message: Recursive stored functions and triggers are not allowed.
**ER_SP_NO_RECURSION** was added in 5.0.9.

- **Error:** 1425 SQLSTATE: 42000 (**ER_TOO_BIG_SCALE**)
  
  Message: Too big scale %lu specified for column '%s'. Maximum is %d.

  **ER_TOO_BIG_SCALE** was added in 5.0.10.

- **Error:** 1426 SQLSTATE: 42000 (**ER_TOO_BIG_PRECISION**)
  
  Message: Too big precision %lu specified for column '%s'. Maximum is %lu.

  **ER_TOO_BIG_PRECISION** was added in 5.0.10.

- **Error:** 1427 SQLSTATE: 42000 (**ER_SCALE_BIGGER_THAN_PRECISION**)
  
  Message: Scale may not be larger than the precision (column '%s').

  In 5.0.14: **ER_SCALE_BIGGER_THAN_PRECISION** was renamed to **ER_M_BIGGER_THAN_D**.

  **ER_SCALE_BIGGER_THAN_PRECISION** was added in 5.0.10, removed after 5.0.13.

- **Error:** 1427 SQLSTATE: 42000 (**ER_M_BIGGER_THAN_D**)
  
  Message: For float(M,D), double(M,D) or decimal(M,D), M must be >= D (column '%s').

  In 5.0.14: **ER_SCALE_BIGGER_THAN_PRECISION** was renamed to **ER_M_BIGGER_THAN_D**.

  **ER_M_BIGGER_THAN_D** was added in 5.0.14.

- **Error:** 1428 SQLSTATE: HY000 (**ER_WRONG_LOCK_OF_SYSTEM_TABLE**)
  
  Message: You can't combine write-locking of system '%s.%s' table with other tables

  **ER_WRONG_LOCK_OF_SYSTEM_TABLE** was added in 5.0.10.

- **Error:** 1429 SQLSTATE: HY000 (**ER_CONNECT_TO_FOREIGN_DATA_SOURCE**)
  
  Message: Unable to connect to foreign data source: %s

  **ER_CONNECT_TO_FOREIGN_DATA_SOURCE** was added in 5.0.10.

- **Error:** 1430 SQLSTATE: HY000 (**ER_QUERY_ON_FOREIGN_DATA_SOURCE**)
  
  Message: There was a problem processing the query on the foreign data source. Data source error: %s

  **ER_QUERY_ON_FOREIGN_DATA_SOURCE** was added in 5.0.10.

- **Error:** 1431 SQLSTATE: HY000 (**ER_FOREIGN_DATA_SOURCE_DOESNT_EXIST**)
  
  Message: The foreign data source you are trying to reference does not exist. Data source error: %s

  **ER_FOREIGN_DATA_SOURCE_DOESNT_EXIST** was added in 5.0.10.

- **Error:** 1432 SQLSTATE: HY000 (**ER_FOREIGN_DATA_STRING_INVALID_CANT_CREATE**)
  
  Message: Can't create federated table. The data source connection string '%s' is not in the correct format

  **ER_FOREIGN_DATA_STRING_INVALID_CANT_CREATE** was added in 5.0.10.

- **Error:** 1433 SQLSTATE: HY000 (**ER_FOREIGN_DATA_STRING_INVALID**)
Message: The data source connection string '%s' is not in the correct format

\texttt{ER\_FOREIGN\_DATA\_STRING\_INVALID} was added in 5.0.10.

- **Error:** 1434 SQLSTATE: \texttt{HY000 (ER\_CANT\_CREATE\_FEDERATED\_TABLE)}
  Message: Can't create federated table. Foreign data src error: %s
  \texttt{ER\_CANT\_CREATE\_FEDERATED\_TABLE} was added in 5.0.10.

- **Error:** 1435 SQLSTATE: \texttt{HY000 (ER\_TRG\_IN\_WRONG\_SCHEMA)}
  Message: Trigger in wrong schema
  \texttt{ER\_TRG\_IN\_WRONG\_SCHEMA} was added in 5.0.10.

- **Error:** 1436 SQLSTATE: \texttt{HY000 (ER\_STACK\_OVERRUN\_NEED\_MORE)}
  Message: Thread stack overrun: %ld bytes used of a %ld byte stack, and %ld bytes needed. Use 'mysqld -O thread_stack=#' to specify a bigger stack.
  \texttt{ER\_STACK\_OVERRUN\_NEED\_MORE} was added in 5.0.11.

- **Error:** 1437 SQLSTATE: \texttt{42000 (ER\_TOO\_LONG\_BODY)}
  Message: Routine body for '%s' is too long
  \texttt{ER\_TOO\_LONG\_BODY} was added in 5.0.11.

- **Error:** 1438 SQLSTATE: \texttt{HY000 (ER\_WARN\_CANT\_DROP\_DEFAULT\_KEYCACHE)}
  Message: Cannot drop default keycache
  \texttt{ER\_WARN\_CANT\_DROP\_DEFAULT\_KEYCACHE} was added in 5.0.12.

- **Error:** 1439 SQLSTATE: \texttt{42000 (ER\_TOO\_BIG\_DISPLAYWIDTH)}
  Message: Display width out of range for column '%s' (max = %lu)
  \texttt{ER\_TOO\_BIG\_DISPLAYWIDTH} was added in 5.0.12.

- **Error:** 1440 SQLSTATE: \texttt{XAE08 (ER\_XAER\_DUPID)}
  Message: XAER\_DUPID: The XID already exists
  \texttt{ER\_XAER\_DUPID} was added in 5.0.12.

- **Error:** 1441 SQLSTATE: \texttt{22008 (ER\_DATETIME\_FUNCTION\_OVERFLOW)}
  Message: Datetime function: %s field overflow
  \texttt{ER\_DATETIME\_FUNCTION\_OVERFLOW} was added in 5.0.12.

- **Error:** 1442 SQLSTATE: \texttt{HY000 (ER\_CANT\_UPDATE\_USED\_TABLE\_IN\_SF\_OR\_TRG)}
  Message: Can't update table '%s' in stored function/trigger because it is already used by statement which invoked this stored function/trigger.
  \texttt{ER\_CANT\_UPDATE\_USED\_TABLE\_IN\_SF\_OR\_TRG} was added in 5.0.12.

- **Error:** 1443 SQLSTATE: \texttt{HY000 (ER\_VIEW\_PREVENT\_UPDATE)}
  Message: The definition of table '%s' prevents operation %s on table '%s'.
**ER_VIEW_PREVENT_UPDATE** was added in 5.0.13.

- **Error:** 1444 SQLSTATE: HY000 (**ER_PS_NO_RECURSION**)  
  Message: The prepared statement contains a stored routine call that refers to that same statement. It's not allowed to execute a prepared statement in such a recursive manner  
  **ER_PS_NO_RECURSION** was added in 5.0.13.

- **Error:** 1445 SQLSTATE: HY000 (**ER_SP_CANT_SET_AUTOCOMMIT**)  
  Message: Not allowed to set autocommit from a stored function or trigger  
  **ER_SP_CANT_SET_AUTOCOMMIT** was added in 5.0.13.

- **Error:** 1446 SQLSTATE: HY000 (**ER_NO_VIEW_USER**)  
  Message: View definer is not fully qualified  
  In 5.0.17: **ER_NO_VIEW_USER** was renamed to **ER_MALFORMED_DEFINER**.  
  **ER_NO_VIEW_USER** was added in 5.0.13, removed after 5.0.16.

- **Error:** 1446 SQLSTATE: HY000 (**ER_MALFORMED_DEFINER**)  
  Message: Definer is not fully qualified  
  In 5.0.17: **ER_NO_VIEW_USER** was renamed to **ER_MALFORMED_DEFINER**.  
  **ER_MALFORMED_DEFINER** was added in 5.0.17.

- **Error:** 1447 SQLSTATE: HY000 (**ER_VIEW_FRM_NO_USER**)  
  Message: View '%s'.'%s' has no definer information (old table format). Current user is used as definer. Please recreate the view!  
  **ER_VIEW_FRM_NO_USER** was added in 5.0.13.

- **Error:** 1448 SQLSTATE: HY000 (**ER_VIEW_OTHER_USER**)  
  Message: You need the SUPER privilege for creation view with '%s'@'%s' definer  
  **ER_VIEW_OTHER_USER** was added in 5.0.13.

- **Error:** 1449 SQLSTATE: HY000 (**ER_NO_SUCH_USER**)  
  Message: There is no '%s'@'%s' registered  
  **ER_NO_SUCH_USER** was added in 5.0.13.

- **Error:** 1450 SQLSTATE: HY000 (**ER_FORBID_SCHEMA_CHANGE**)  
  Message: Changing schema from '%s' to '%s' is not allowed.  
  **ER_FORBID_SCHEMA_CHANGE** was added in 5.0.14.

- **Error:** 1451 SQLSTATE: 23000 (**ER_ROW_IS_REFERENCED_2**)  
  Message: Cannot delete or update a parent row: a foreign key constraint fails (%s)  
  **ER_ROW_IS_REFERENCED_2** was added in 5.0.14.

- **Error:** 1452 SQLSTATE: 23000 (**ER_NO_REFERENCED_ROW_2**)
Message: Cannot add or update a child row: a foreign key constraint fails (%s)

**ER_NO_REFERENCED_ROW_2 was added in 5.0.14.**

- **Error:** 1453 SQLSTATE: 42000 (**ER_SP_BAD_VAR_SHADOW**)
  Message: Variable '%s' must be quoted with `...`, or renamed
  **ER_SP_BAD_VAR_SHADOW was added in 5.0.15.**

- **Error:** 1454 SQLSTATE: HY000 (**ER_TRG_NO_DEFINER**)
  Message: No definer attribute for trigger '%s'.'%s'. The trigger will be activated under the authorization of the invoker, which may have insufficient privileges. Please recreate the trigger.

  **ER_VIEW_RECURSIVE was added in 5.0.21.**
Server Error Codes and Messages

Message: "%s`.%s` contains view recursion

ER_VIEW_RECURSIVE was added in 5.0.21.

- Error: 1463 SQLSTATE: 42000 (ER_NON_GROUPING_FIELD_USED)
  Message: non-grouping field `%s` is used in %s clause
  ER_NON_GROUPING_FIELD_USED was added in 5.0.23.

- Error: 1464 SQLSTATE: HY000 (ER_TABLE_CANT_HANDLE_SPKEYS)
  Message: The used table type doesn't support SPATIAL indexes
  ER_TABLE_CANT_HANDLE_SPKEYS was added in 5.0.23.

- Error: 1465 SQLSTATE: HY000 (ER_NO_TRIGGERS_ON_SYSTEM_SCHEMA)
  Message: Triggers can not be created on system tables
  ER_NO_TRIGGERS_ON_SYSTEM_SCHEMA was added in 5.0.23.

- Error: 1466 SQLSTATE: HY000 (ER_REMOVED_SPACES)
  Message: Leading spaces are removed from name `%s`
  ER_REMOVED_SPACES was added in 5.0.25.

- Error: 1467 SQLSTATE: HY000 (ER_AUTOINC_READ_FAILED)
  Message: Failed to read auto-increment value from storage engine
  ER_AUTOINC_READ_FAILED was added in 5.0.26.

- Error: 1468 SQLSTATE: HY000 (ER_USERNAME)
  Message: user name
  ER_USERNAME was added in 5.0.24.

- Error: 1469 SQLSTATE: HY000 (ER_HOSTNAME)
  Message: host name
  ER_HOSTNAME was added in 5.0.24.

- Error: 1470 SQLSTATE: HY000 (ER_WRONG_STRING_LENGTH)
  Message: String `%s` is too long for %s (should be no longer than %d)
  ER_WRONG_STRING_LENGTH was added in 5.0.24.

- Error: 1471 SQLSTATE: HY000 (ER_NON_INSERTABLE_TABLE)
  Message: The target table %s of the %s is not insertable-into
  ER_NON_INSERTABLE_TABLE was added in 5.0.26.

- Error: 1472 SQLSTATE: HY000 (ER_ADMIN_WRONG_MRG_TABLE)
  Message: Table `%s` is differently defined or of non-MyISAM type or doesn't exist
  ER_ADMIN_WRONG_MRG_TABLE was added in 5.0.46.
• Error: 1473 SQLSTATE: HY000 (ER_TOO_HIGH_LEVEL_OF_NESTING_FOR_SELECT)
  Message: Too high level of nesting for select
  ER_TOO_HIGH_LEVEL_OF_NESTING_FOR_SELECT was added in 5.0.48.

• Error: 1474 SQLSTATE: HY000 (ER_NAME_BECOMES_EMPTY)
  Message: Name '%s' has become "
  ER_NAME_BECOMES_EMPTY was added in 5.0.50.

• Error: 1475 SQLSTATE: HY000 (ER_AMBIGUOUS_FIELD_TERM)
  Message: First character of the FIELDS TERMINATED string is ambiguous; please use non-optional
  and non-empty FIELDS ENCLOSED BY
  ER_AMBIGUOUS_FIELD_TERM was added in 5.0.52.

• Error: 1476 SQLSTATE: HY000 (ER_LOAD_DATA_INVALID_COLUMN)
  Message: Invalid column reference ('%s') in LOAD DATA
  ER_LOAD_DATA_INVALID_COLUMN was added in 5.0.60.

• Error: 1477 SQLSTATE: HY000 (ER_LOG_PURGE_NO_FILE)
  Message: Being purged log '%s' was not found
  ER_LOG_PURGE_NO_FILE was added in 5.0.60.

• Error: 1478 SQLSTATE: XA106 (ER_XA_RBTIMEOUT)
  Message: XA_RBTIMEOUT: Transaction branch was rolled back: took too long
  ER_XA_RBTIMEOUT was added in 5.0.72.

• Error: 1479 SQLSTATE: XA102 (ER_XA_RBDEADLOCK)
  Message: XA_RBDEADLOCK: Transaction branch was rolled back: deadlock was detected
  ER_XA_RBDEADLOCK was added in 5.0.72.

• Error: 1480 SQLSTATE: HY000 (ER_TOO_MANY_CONCURRENT_TRXS)
  Message: Too many active concurrent transactions
  ER_TOO_MANY_CONCURRENT_TRXS was added in 5.0.85.

B.4 Client Error Codes and Messages

Client error information comes from the following source files:

• The Error values and the symbols in parentheses correspond to definitions in the include/errmsg.h MySQL source file.

• The Message values correspond to the error messages that are listed in the libmysql/errmsg.c file. %d and %s represent numbers and strings, respectively, that are substituted into the messages when they are displayed.

Because updates are frequent, it is possible that those files will contain additional error information not listed here.
• Error: **2000** (*CR_UNKNOWN_ERROR*)
  Message: Unknown MySQL error

• Error: **2001** (*CR_SOCKET_CREATE_ERROR*)
  Message: Can't create UNIX socket (%d)

• Error: **2002** (*CR_CONNECTION_ERROR*)
  Message: Can't connect to local MySQL server through socket '%s' (%d)

• Error: **2003** (*CR_CONN_HOST_ERROR*)
  Message: Can't connect to MySQL server on '%s' (%d)

• Error: **2004** (*CR_IPSOCK_ERROR*)
  Message: Can't create TCP/IP socket (%d)

• Error: **2005** (*CR_UNKNOWN_HOST*)
  Message: Unknown MySQL server host '%s' (%d)

• Error: **2006** (*CR_SERVER_GONE_ERROR*)
  Message: MySQL server has gone away

• Error: **2007** (*CR_VERSION_ERROR*)
  Message: Protocol mismatch; server version = %d, client version = %d

• Error: **2008** (*CR_OUT_OF_MEMORY*)
  Message: MySQL client ran out of memory

• Error: **2009** (*CR_WRONG_HOST_INFO*)
  Message: Wrong host info

• Error: **2010** (*CR_LOCALHOST_CONNECTION*)
  Message: Localhost via UNIX socket

• Error: **2011** (*CR_TCP_CONNECTION*)
  Message: %s via TCP/IP

• Error: **2012** (*CR_SERVER_HANDSHAKE_ERR*)
  Message: Error in server handshake

• Error: **2013** (*CR_SERVER_LOST*)
  Message: Lost connection to MySQL server during query

• Error: **2014** (*CR_COMMANDS_OUT_OF_SYNC*)
  Message: Commands out of sync; you can't run this command now

• Error: **2015** (*CR_NAMEDPIPE_CONNECTION*)
  Message: Named pipe: %s

• Error: **2016** (*CR_NAMEDPIPEWAIT_ERROR*)
Message: Can't wait for named pipe to host: %s pipe: %s (%lu)

• Error: 2017 (CR_NAMEDPIPEOPEN_ERROR)

Message: Can't open named pipe to host: %s pipe: %s (%lu)

• Error: 2018 (CR_NAMEDPIPESETSTATE_ERROR)

Message: Can't set state of named pipe to host: %s pipe: %s (%lu)

• Error: 2019 (CR_CANT_READ_CHARSET)

Message: Can't initialize character set %s (path: %s)

• Error: 2020 (CR_NET_PACKET_TOO_LARGE)

Message: Got packet bigger than 'max_allowed_packet' bytes

• Error: 2021 (CR.Embedded_CONNECTION)

Message: Embedded server

• Error: 2022 (CR_PROBE_SLAVE_STATUS)

Message: Error on SHOW SLAVE STATUS:

• Error: 2023 (CR_PROBE_SLAVE_HOSTS)

Message: Error on SHOW SLAVE HOSTS:

• Error: 2024 (CR_PROBE_SLAVE_CONNECT)

Message: Error connecting to slave:

• Error: 2025 (CR_PROBE_MASTER_CONNECT)

Message: Error connecting to master:

• Error: 2026 (CR_SSL_CONNECTION_ERROR)

Message: SSL connection error

• Error: 2027 (CR_MALFORMED_PACKET)

Message: Malformed packet

• Error: 2028 (CR_WRONG_LICENSE)

Message: This client library is licensed only for use with MySQL servers having '%s' license

• Error: 2029 (CR_NULL_POINTER)

Message: Invalid use of null pointer

• Error: 2030 (CR_NO_PREPARE_STMT)

Message: Statement not prepared

• Error: 2031 (CR_PARAMS_NOT_BOUND)

Message: No data supplied for parameters in prepared statement

• Error: 2032 (CR_DATA_TRUNCATED)
Message: Data truncated

- Error: 2033 (CR_NO_PARAMETERS_EXISTS)

Message: No parameters exist in the statement

- Error: 2034 (CR_INVALID_PARAMETER_NO)

Message: Invalid parameter number

The column number for `mysql_stmt_fetch_column()` was invalid.
The parameter number for `mysql_stmt_send_long_data()` was invalid.

- Error: 2035 (CR_INVALID_BUFFER_USE)

Message: Can't send long data for non-string/non-binary data types (parameter: %d)

- Error: 2036 (CR_UNSUPPORTED_PARAM_TYPE)

Message: Using unsupported buffer type: %d (parameter: %d)

- Error: 2037 (CR_SHARED_MEMORY_CONNECTION)

Message: Shared memory: %s

- Error: 2038 (CR_SHARED_MEMORY_CONNECT_REQUEST_ERROR)

Message: Can't open shared memory; client could not create request event (%lu)

- Error: 2039 (CR_SHARED_MEMORY_CONNECT_ANSWER_ERROR)

Message: Can't open shared memory; no answer event received from server (%lu)

- Error: 2040 (CR_SHARED_MEMORY_CONNECT_FILE_MAP_ERROR)

Message: Can't open shared memory; server could not allocate file mapping (%lu)

- Error: 2041 (CR_SHARED_MEMORY_CONNECT_MAP_ERROR)

Message: Can't open shared memory; server could not get pointer to file mapping (%lu)

- Error: 2042 (CR_SHARED_MEMORY_FILE_MAP_ERROR)

Message: Can't open shared memory; client could not allocate file mapping (%lu)

- Error: 2043 (CR_SHARED_MEMORY_MAP_ERROR)

Message: Can't open shared memory; client could not get pointer to file mapping (%lu)

- Error: 2044 (CR_SHARED_MEMORY_EVENT_ERROR)

Message: Can't open shared memory; client could not create %s event (%lu)

- Error: 2045 (CR_SHARED_MEMORY_CONNECT_ABANDONED_ERROR)

Message: Can't open shared memory; no answer from server (%lu)

- Error: 2046 (CR_SHARED_MEMORY_CONNECT_SET_ERROR)

Message: Can't open shared memory; cannot send request event to server (%lu)

- Error: 2047 (CR_CONN_UNKNOWN_PROTOCOL)
Problems and Common Errors

Message: Wrong or unknown protocol
• Error: 2048 (CR_INVALID_CONN_HANDLE)
  Message: Invalid connection handle
• Error: 2049 (CR_SECURE_AUTH)
  Message: Connection using old (pre-4.1.1) authentication protocol refused (client option 'secure_auth' enabled)
• Error: 2050 (CR_FETCH_CANCELED)
  Message: Row retrieval was canceled by mysql_stmt_close() call
• Error: 2051 (CR_NO_DATA)
  Message: Attempt to read column without prior row fetch
• Error: 2052 (CR_NO_STMT_METADATA)
  Message: Prepared statement contains no metadata
• Error: 2053 (CR_NO_RESULT_SET)
  Message: Attempt to read a row while there is no result set associated with the statement
• Error: 2054 (CR_NOT_IMPLEMENTED)
  Message: This feature is not implemented yet
• Error: 2055 (CR_SERVER_LOST_EXTENDED)
  Message: Lost connection to MySQL server at '%s', system error: %d

CR_SERVER_LOST_EXTENDED was added in 5.0.32.

B.5 Problems and Common Errors

This section lists some common problems and error messages that you may encounter. It describes how to determine the causes of the problems and what to do to solve them.

B.5.1 How to Determine What Is Causing a Problem

When you run into a problem, the first thing you should do is to find out which program or piece of equipment is causing it:

• If you have one of the following symptoms, then it is probably a hardware problems (such as memory, motherboard, CPU, or hard disk) or kernel problem:
  • The keyboard does not work. This can normally be checked by pressing the Caps Lock key. If the Caps Lock light does not change, you have to replace your keyboard. (Before doing this, you should try to restart your computer and check all cables to the keyboard.)
  • The mouse pointer does not move.
  • The machine does not answer to a remote machine's pings.
  • Other programs that are not related to MySQL do not behave correctly.
  • Your system restarted unexpectedly. (A faulty user-level program should never be able to take down your system.)
Common Errors When Using MySQL Programs

In this case, you should start by checking all your cables and run some diagnostic tool to check your hardware! You should also check whether there are any patches, updates, or service packs for your operating system that could likely solve your problem. Check also that all your libraries (such as glibc) are up to date.

It is always good to use a machine with ECC memory to discover memory problems early.

- If your keyboard is locked up, you may be able to recover by logging in to your machine from another machine and executing `kbd_mode -a`.

- Please examine your system log file (`/var/log/messages` or similar) for reasons for your problem. If you think the problem is in MySQL, you should also examine MySQL’s log files. See Section 5.4, “MySQL Server Logs”.

- If you do not think you have hardware problems, you should try to find out which program is causing problems. Try using `top`, `ps`, Task Manager, or some similar program, to check which program is taking all CPU or is locking the machine.

- Use `top`, `df`, or a similar program to check whether you are out of memory, disk space, file descriptors, or some other critical resource.

- If the problem is some runaway process, you can always try to kill it. If it does not want to die, there is probably a bug in the operating system.

If after you have examined all other possibilities and you have concluded that the MySQL server or a MySQL client is causing the problem, it is time to create a bug report for our mailing list or our support team. In the bug report, try to give a very detailed description of how the system is behaving and what you think is happening. You should also state why you think that MySQL is causing the problem. Take into consideration all the situations in this chapter. State any problems exactly how they appear when you examine your system. Use the “copy and paste” method for any output and error messages from programs and log files.

Try to describe in detail which program is not working and all symptoms you see. We have in the past received many bug reports that state only “the system does not work.” This provides us with no information about what could be the problem.

If a program fails, it is always useful to know the following information:

- Has the program in question made a segmentation fault (did it dump core)?

- Is the program taking up all available CPU time? Check with `top`. Let the program run for a while, it may simply be evaluating something computationally intensive.

- If the `mysqld` server is causing problems, can you get any response from it with `mysqladmin -u root ping` or `mysqladmin -u root processlist`?

- What does a client program say when you try to connect to the MySQL server? (Try with `mysql`, for example.) Does the client jam? Do you get any output from the program?

When sending a bug report, you should follow the outline described in Section 1.7, “How to Report Bugs or Problems”.

B.5.2 Common Errors When Using MySQL Programs

This section lists some errors that users frequently encounter when running MySQL programs. Although the problems show up when you try to run client programs, the solutions to many of the problems involves changing the configuration of the MySQL server.

B.5.2.1 Access denied
An *Access denied* error can have many causes. Often the problem is related to the MySQL accounts that the server permits client programs to use when connecting. See Section 6.2, “The MySQL Access Privilege System”, and Section 6.2.7, “Troubleshooting Problems Connecting to MySQL”.

### B.5.2.2 Can’t connect to [local] MySQL server

A MySQL client on Unix can connect to the *mysqld* server in two different ways: By using a Unix socket file to connect through a file in the file system (default `/tmp/mysql.sock`), or by using TCP/IP, which connects through a port number. A Unix socket file connection is faster than TCP/IP, but can be used only when connecting to a server on the same computer. A Unix socket file is used if you do not specify a host name or if you specify the special host name *localhost*.

If the MySQL server is running on Windows, you can connect using TCP/IP. If the server is started with the `--enable-named-pipe` option, you can also connect with named pipes if you run the client on the host where the server is running. The name of the named pipe is *MySQL* by default. If you do not give a host name when connecting to *mysqld*, a MySQL client first tries to connect to the named pipe. If that does not work, it connects to the TCP/IP port. You can force the use of named pipes on Windows by using `. ` as the host name.

The error (2002) *Can't connect to ...* normally means that there is no MySQL server running on the system or that you are using an incorrect Unix socket file name or TCP/IP port number when trying to connect to the server. You should also check that the TCP/IP port you are using has not been blocked by a firewall or port blocking service.

The error (2003) *Can't connect to MySQL server on 'server' (10061)* indicates that the network connection has been refused. You should check that there is a MySQL server running, that it has network connections enabled, and that the network port you specified is the one configured on the server.

Start by checking whether there is a process named *mysqld* running on your server host. (Use `ps xa | grep mysqld` on Unix or the Task Manager on Windows.) If there is no such process, you should start the server. See Section 2.18.2, “Starting the Server”.

If a *mysqld* process is running, you can check it by trying the following commands. The port number or Unix socket file name might be different in your setup. `host_ip` represents the IP address of the machine where the server is running.

```
shell> mysqladmin version
shell> mysqladmin variables
shell> mysqladmin -h `hostname` version variables
shell> mysqladmin -h `hostname` --port=3306 version
shell> mysqladmin -h host_ip version
shell> mysqladmin --protocol=SOCKET --socket=/tmp/mysql.sock version
```

Note the use of backticks rather than forward quotation marks with the `hostname` command; these cause the output of `hostname` (that is, the current host name) to be substituted into the `mysqladmin` command. If you have no `hostname` command or are running on Windows, you can manually type the host name of your machine (without backticks) following the `-h` option. You can also try `-h 127.0.0.1` to connect with TCP/IP to the local host.

Make sure that the server has not been configured to ignore network connections or (if you are attempting to connect remotely) that it has not been configured to listen only locally on its network interfaces. If the server was started with `--skip-networking`, it will not accept TCP/IP connections at all. If the server was started with `--bind-address=127.0.0.1`, it will listen for TCP/IP connections only locally on the loopback interface and will not accept remote connections.

Check to make sure that there is no firewall blocking access to MySQL. Your firewall may be configured on the basis of the application being executed, or the port number used by MySQL for communication (3306 by default). Under Linux or Unix, check your IP tables (or similar) configuration
to ensure that the port has not been blocked. Under Windows, applications such as ZoneAlarm or the Windows XP personal firewall may need to be configured not to block the MySQL port.

Here are some reasons the Can't connect to local MySQL server error might occur:

• mysqld is not running on the local host. Check your operating system's process list to ensure the mysqld process is present.

• You're running a MySQL server on Windows with many TCP/IP connections to it. If you're experiencing that quite often your clients get that error, you can find a workaround here: Connection to MySQL Server Failing on Windows.

• Someone has removed the Unix socket file that mysqld uses (/tmp/mysql.sock by default). For example, you might have a cron job that removes old files from the /tmp directory. You can always run mysqladmin version to check whether the Unix socket file that mysqladmin is trying to use really exists. The fix in this case is to change the cron job to not remove mysql.sock or to place the socket file somewhere else. See Section B.5.3.6, "How to Protect or Change the MySQL Unix Socket File".

• You have started the mysqld server with the --socket=/path/to/socket option, but forgotten to tell client programs the new name of the socket file. If you change the socket path name for the server, you must also notify the MySQL clients. You can do this by providing the same --socket option when you run client programs. You also need to ensure that clients have permission to access the mysql.sock file. To find out where the socket file is, you can do:

```
shell> netstat -ln | grep mysql
```

See Section B.5.3.6, "How to Protect or Change the MySQL Unix Socket File".

• You are using Linux and one server thread has died (dumped core). In this case, you must kill the other mysqld threads (for example, with kill or with the mysql_zap script) before you can restart the MySQL server. See Section B.5.3.3, "What to Do If MySQL Keeps Crashing".

• The server or client program might not have the proper access privileges for the directory that holds the Unix socket file or the socket file itself. In this case, you must either change the access privileges for the directory or socket file so that the server and clients can access them, or restart mysqld with a --socket option that specifies a socket file name in a directory where the server can create it and where client programs can access it.

If you get the error message Can't connect to MySQL server on some_host, you can try the following things to find out what the problem is:

• Check whether the server is running on that host by executing telnet some_host 3306 and pressing the Enter key a couple of times. (3306 is the default MySQL port number. Change the value if your server is listening to a different port.) If there is a MySQL server running and listening to the port, you should get a response that includes the server's version number. If you get an error such as telnet: Unable to connect to remote host: Connection refused, then there is no server running on the given port.

• If the server is running on the local host, try using mysqladmin -h localhost variables to connect using the Unix socket file. Verify the TCP/IP port number that the server is configured to listen to (it is the value of the port variable.)

• If you are running under Linux and Security-Enhanced Linux (SELinux) is enabled, make sure you have disabled SELinux protection for the mysqld process.

**Connection to MySQL Server Failing on Windows**

When you're running a MySQL server on Windows with many TCP/IP connections to it, and you're experiencing that quite often your clients get a Can't connect to MySQL server error, the
reason might be that Windows does not allow for enough ephemeral (short-lived) ports to serve those connections.

The purpose of \texttt{TIME\_WAIT} is to keep a connection accepting packets even after the connection has been closed. This is because Internet routing can cause a packet to take a slow route to its destination and it may arrive after both sides have agreed to close. If the port is in use for a new connection, that packet from the old connection could break the protocol or compromise personal information from the original connection. The \texttt{TIME\_WAIT} delay prevents this by ensuring that the port cannot be reused until after some time has been permitted for those delayed packets to arrive.

It is safe to reduce \texttt{TIME\_WAIT} greatly on LAN connections because there is little chance of packets arriving at very long delays, as they could through the Internet with its comparatively large distances and latencies.

Windows permits ephemeral (short-lived) TCP ports to the user. After any port is closed it will remain in a \texttt{TIME\_WAIT} status for 120 seconds. The port will not be available again until this time expires. The default range of port numbers depends on the version of Windows, with a more limited number of ports in older versions:

- Windows through Server 2003: Ports in range 1025–5000

With a small stack of available TCP ports (5000) and a high number of TCP ports being open and closed over a short period of time along with the \texttt{TIME\_WAIT} status you have a good chance for running out of ports. There are two ways to address this problem:

- Reduce the number of TCP ports consumed quickly by investigating connection pooling or persistent connections where possible
- Tune some settings in the Windows registry (see below)

\begin{table}
\centering
\begin{tabular}{|l|l|}
\hline
1. & Start Registry Editor (\texttt{Regedt32.exe}). \\
2. & Locate the following key in the registry: \\
\hline
& HKEY\_LOCAL\_MACHINE\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters \\
3. & On the \textbf{Edit} menu, click \textbf{Add Value}, and then add the following registry value: \\
\hline
& Value Name: MaxUserPort \\
& Data Type: REG\_DWORD \\
& Value: 65534 \\
4. & On the \textbf{Edit} menu, click \textbf{Add Value}, and then add the following registry value: \\
\hline
& Value Name: TcpTimedWaitDelay \\
& Data Type: REG\_DWORD \\
& Value: 30
\end{tabular}
\end{table}

This sets the number of ephemeral ports available to any user. The valid range is between 5000 and 65534 (decimal). The default value is 0x1388 (5000 decimal).
This sets the number of seconds to hold a TCP port connection in \texttt{TIME\_WAIT} state before closing. The valid range is between 30 and 300 decimal, although you may wish to check with Microsoft for the latest permitted values. The default value is 0x78 (120 decimal).

5. Quit Registry Editor.

6. Reboot the machine.

Note: Undoing the above should be as simple as deleting the registry entries you’ve created.

**B.5.2.3 Lost connection to MySQL server**

There are three likely causes for this error message.

Usually it indicates network connectivity trouble and you should check the condition of your network if this error occurs frequently. If the error message includes “during query,” this is probably the case you are experiencing.

Sometimes the “during query” form happens when millions of rows are being sent as part of one or more queries. If you know that this is happening, you should try increasing \texttt{net\_read\_timeout} from its default of 30 seconds to 60 seconds or longer, sufficient for the data transfer to complete.

More rarely, it can happen when the client is attempting the initial connection to the server. In this case, if your \texttt{connect\_timeout} value is set to only a few seconds, you may be able to resolve the problem by increasing it to ten seconds, perhaps more if you have a very long distance or slow connection. You can determine whether you are experiencing this more uncommon cause by using \texttt{SHOW\ GLOBAL\ STATUS\ LIKE}\ \%\ Aborted\_connects\%. It will increase by one for each initial connection attempt that the server aborts. You may see “reading authorization packet” as part of the error message; if so, that also suggests that this is the solution that you need.

If the cause is none of those just described, you may be experiencing a problem with \texttt{BLOB} values that are larger than \texttt{max\_allowed\_packet}, which can cause this error with some clients. Sometime you may see an \texttt{ER\_NET\_PACKET\_TOO\_LARGE} error, and that confirms that you need to increase \texttt{max\_allowed\_packet}.

**B.5.2.4 Client does not support authentication protocol**

The current implementation of the authentication protocol uses a password hashing algorithm that is incompatible with that used by older (pre-4.1) clients. Attempts to connect to a 4.1 or newer server with an older client may fail with the following message:

```
shell> mysql
Client does not support authentication protocol requested by server; consider upgrading MySQL client
```

To deal with this problem, the preferred solution is to upgrade all client programs to use a 4.1.1 or newer client library. If that is not possible, use one of the following approaches:

- To connect to the server with a pre-4.1 client program, use an account that still has a pre-4.1-style password.

- Reset the password to pre-4.1 style for each user that needs to use a pre-4.1 client program. This can be done using the \texttt{SET\ PASSWORD} statement and the \texttt{OLD\_PASSWORD()} function:

```
mysql> SET PASSWORD FOR -> 'some_user'@'some_host' = OLD_PASSWORD('new_password');
```

Substitute the password you want to use for “\texttt{new\_password}” in the preceding example. MySQL cannot tell you what the original password was, so you’ll need to pick a new one.
• Tell the server to use the older password hashing algorithm by default:

1. Start `mysqld` with the `old_passwords` system variable set to 1.

2. Assign an old-format password to each account that has had its password updated to the longer 4.1 format. You can identify these accounts with the following query:

   ```sql
   mysql> SELECT Host, User, Password FROM mysql.user
   -> WHERE LENGTH(Password) > 16;
   ```

   For each account record displayed by the query, use the `Host` and `User` values and assign a password using one of the methods described previously.

   The `Client does not support authentication protocol` error also can occur if multiple versions of MySQL are installed but client programs are dynamically linked and link to an older library. Make sure that clients use the most recent library version with which they are compatible. The procedure to do this will depend on your system.

   **Note**

   The PHP `mysql` extension does not support the authentication protocol in MySQL 4.1.1 and higher. This is true regardless of the PHP version being used. If you wish to use the `mysql` extension with MySQL 4.1 or newer, you may need to follow one of the options discussed above for configuring MySQL to work with old clients. The `mysqli` extension (stands for "MySQL, Improved"; added in PHP 5) is compatible with the improved password hashing employed in MySQL 4.1 and higher, and no special configuration of MySQL need be done to use this MySQL client library. For more information about the `mysqli` extension, see [http://php.net/mysqli](http://php.net/mysqli).

   For additional background on password hashing and authentication, see [Section 6.1.2.4, “Password Hashing in MySQL”](#).

**B.5.2.5 Password Fails When Entered Interactively**

MySQL client programs prompt for a password when invoked with a `--password` or `-p` option that has no following password value:

```shell
shell> mysql -u user_name -p
Enter password:
```

On some systems, you may find that your password works when specified in an option file or on the command line, but not when you enter it interactively at the `Enter password:` prompt. This occurs when the library provided by the system to read passwords limits password values to a small number of characters (typically eight). That is a problem with the system library, not with MySQL. To work around it, change your MySQL password to a value that is eight or fewer characters long, or put your password in an option file.

**B.5.2.6 Host 'host_name' is blocked**

If the following error occurs, it means that `mysqld` has received many connection requests from the given host that were interrupted in the middle:

```
Host 'host_name' is blocked because of many connection errors.
Unblock with 'mysqladmin flush-hosts'
```

The value of the `max_connect_errors` system variable determines how many successive interrupted connection requests are permitted. (See [Section 5.1.4, “Server System Variables”](#).) After `max_connect_errors` failed requests without a successful connection, `mysqld` assumes that...
something is wrong (for example, that someone is trying to break in), and blocks the host from further connections until you issue a `FLUSH HOSTS` statement or execute a `mysqladmin flush-hosts` command.

By default, `mysqld` blocks a host after 10 connection errors. You can adjust the value by setting `max_connect_errors` at server startup:

```shell
shell> mysqld_safe --max-connect_errors=10000 &
```

The value can also be set at runtime:

```mysql
mysql> SET GLOBAL max_connect_errors=10000;
```

If you get the `Host 'host_name' is blocked` error message for a given host, you should first verify that there is nothing wrong with TCP/IP connections from that host. If you are having network problems, it does you no good to increase the value of the `max_connect_errors` variable.

### B.5.2.7 Too many connections

If you get a `Too many connections` error when you try to connect to the `mysqld` server, this means that all available connections are in use by other clients.

The number of connections permitted is controlled by the `max_connections` system variable. Its default value is 100. If you need to support more connections, you should set a larger value for this variable.

`mysqld` actually permits `max_connections+1` clients to connect. The extra connection is reserved for use by accounts that have the `SUPER` privilege. By granting the `SUPER` privilege to administrators and not to normal users (who should not need it), an administrator can connect to the server and use `SHOW PROCESSLIST` to diagnose problems even if the maximum number of unprivileged clients are connected. See Section 13.7.5.27, “SHOW PROCESSLIST Syntax”.

The maximum number of connections MySQL can support depends on the quality of the thread library on a given platform, the amount of RAM available, how much RAM is used for each connection, the workload from each connection, and the desired response time. Linux or Solaris should be able to support at 500 to 1000 simultaneous connections routinely and as many as 10,000 connections if you have many gigabytes of RAM available and the workload from each is low or the response time target undemanding. Windows is limited to (open tables × 2 + open connections) < 2048 due to the Posix compatibility layer used on that platform.

Increasing `open-files-limit` may be necessary. Also see Section 2.20.1.4, “Linux Postinstallation Notes”, for how to raise the operating system limit on how many handles can be used by MySQL.

### B.5.2.8 Out of memory

If you issue a query using the `mysql` client program and receive an error like the following one, it means that `mysql` does not have enough memory to store the entire query result:

```mysql
mysql: Out of memory at line 42, 'malloc.c'
mysql: needed 8136 byte (8k), memory in use: 12481367 bytes (12189k)
ERROR 2008: MySQL client ran out of memory
```

To remedy the problem, first check whether your query is correct. Is it reasonable that it should return so many rows? If not, correct the query and try again. Otherwise, you can invoke `mysql` with the `--quick` option. This causes it to use the `mysql_use_result()` C API function to retrieve the result set, which places less of a load on the client (but more on the server).

### B.5.2.9 MySQL server has gone away
This section also covers the related Lost connection to server during query error.

The most common reason for the MySQL server has gone away error is that the server timed out and closed the connection. In this case, you normally get one of the following error codes (which one you get is operating system-dependent).

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CR_SERVER_GONE_ERROR</td>
<td>The client couldn't send a question to the server.</td>
</tr>
<tr>
<td>CR_SERVER_LOST</td>
<td>The client didn't get an error when writing to the server, but it didn't get a full answer (or any answer) to the question.</td>
</tr>
</tbody>
</table>

By default, the server closes the connection after eight hours if nothing has happened. You can change the time limit by setting the wait_timeout variable when you start mysqld. See Section 5.1.4, “Server System Variables”.

If you have a script, you just have to issue the query again for the client to do an automatic reconnection. This assumes that you have automatic reconnection in the client enabled (which is the default for the mysql command-line client).

Some other common reasons for the MySQL server has gone away error are:

- You (or the db administrator) has killed the running thread with a KILL statement or a mysqladmin kill command.
- You tried to run a query after closing the connection to the server. This indicates a logic error in the application that should be corrected.
- A client application running on a different host does not have the necessary privileges to connect to the MySQL server from that host.
- You got a timeout from the TCP/IP connection on the client side. This may happen if you have been using the commands: mysql_options(..., MYSQL_OPT_READ_TIMEOUT,...) or mysql_options(..., MYSQL_OPT_WRITE_TIMEOUT,...). In this case increasing the timeout may help solve the problem.
- You have encountered a timeout on the server side and the automatic reconnection in the client is disabled (the reconnect flag in the MYSQL structure is equal to 0).
- You are using a Windows client and the server had dropped the connection (probably because wait_timeout expired) before the command was issued.

The problem on Windows is that in some cases MySQL does not get an error from the OS when writing to the TCP/IP connection to the server, but instead gets the error when trying to read the answer from the connection.

Prior to MySQL 5.0.19, even if the reconnect flag in the MYSQL structure is equal to 1, MySQL does not automatically reconnect and re-issue the query as it doesn’t know if the server did get the original query or not.

The solution to this is to either do a mysql_ping() on the connection if there has been a long time since the last query (this is what Connector/ODBC does) or set wait_timeout on the mysqld server so high that it in practice never times out.

- You can also get these errors if you send a query to the server that is incorrect or too large. If mysqld receives a packet that is too large or out of order, it assumes that something has gone wrong with the client and closes the connection. If you need big queries (for example, if you are working with big BLOB columns), you can increase the query limit by setting the server's max_allowed_packet variable, which has a default value of 1MB. You may also need to increase the maximum packet size on the client end. More information on setting the packet size is given in Section B.5.2.10, “Packet Too Large”.
An **INSERT** or **REPLACE** statement that inserts a great many rows can also cause these sorts of errors. Either one of these statements sends a single request to the server irrespective of the number of rows to be inserted; thus, you can often avoid the error by reducing the number of rows sent per **INSERT** or **REPLACE**.

- You also get a lost connection if you are sending a packet 16MB or larger if your client is older than 4.0.8 and your server is 4.0.8 and above, or the other way around.

- It is also possible to see this error if host name lookups fail (for example, if the DNS server on which your server or network relies goes down). This is because MySQL is dependent on the host system for name resolution, but has no way of knowing whether it is working—from MySQL’s point of view the problem is indistinguishable from any other network timeout.

You may also see the **MySQL server has gone away** error if MySQL is started with the **--skip-networking** option.

Another networking issue that can cause this error occurs if the MySQL port (default 3306) is blocked by your firewall, thus preventing any connections at all to the MySQL server.

- You can also encounter this error with applications that fork child processes, all of which try to use the same connection to the MySQL server. This can be avoided by using a separate connection for each child process.

- You have encountered a bug where the server died while executing the query.

You can check whether the MySQL server died and restarted by executing `mysqladmin version` and examining the server’s uptime. If the client connection was broken because `mysqld` crashed and restarted, you should concentrate on finding the reason for the crash. Start by checking whether issuing the query again kills the server again. See Section B.5.3.3, “What to Do If MySQL Keeps Crashing”.

You can get more information about the lost connections by starting `mysqld` with the **--log-warnings=2** option. This logs some of the disconnected errors in the `hostname.err` file. See Section 5.4.1, “The Error Log”.

If you want to create a bug report regarding this problem, be sure that you include the following information:

- Indicate whether the MySQL server died. You can find information about this in the server error log. See Section B.5.3.3, “What to Do If MySQL Keeps Crashing”.

- If a specific query kills `mysqld` and the tables involved were checked with `CHECK TABLE` before you ran the query, can you provide a reproducible test case? See Section 21.3, “Debugging and Porting MySQL”.

- What is the value of the `wait_timeout` system variable in the MySQL server? (`mysqladmin variables` gives you the value of this variable.)

- Have you tried to run `mysqld` with the general query log enabled to determine whether the problem query appears in the log? (See Section 5.4.2, “The General Query Log”.)

See also Section B.5.2.11, “Communication Errors and Aborted Connections”, and Section 1.7, “How to Report Bugs or Problems”.

### B.5.2.10 Packet Too Large

A communication packet is a single SQL statement sent to the MySQL server, a single row that is sent to the client, or a binary log event sent from a master replication server to a slave.

The largest possible packet that can be transmitted to or from a MySQL 5.0 server or client is 1GB.
When a MySQL client or the `mysqld` server receives a packet bigger than `max_allowed_packet` bytes, it issues an `ER_NET_PACKET_TOO_LARGE` error and closes the connection. With some clients, you may also get a `Lost connection to MySQL server during query` error if the communication packet is too large.

Both the client and the server have their own `max_allowed_packet` variable, so if you want to handle big packets, you must increase this variable both in the client and in the server.

If you are using the `mysql` client program, its default `max_allowed_packet` variable is 16MB. To set a larger value, start `mysql` like this:

```
shell> mysql --max_allowed_packet=32M
```

That sets the packet size to 32MB.

The server's default `max_allowed_packet` value is 1MB. You can increase this if the server needs to handle big queries (for example, if you are working with big BLOB columns). For example, to set the variable to 16MB, start the server like this:

```
shell> mysqld --max_allowed_packet=16M
```

You can also use an option file to set `max_allowed_packet`. For example, to set the size for the server to 16MB, add the following lines in an option file:

```
[mysqld]
max_allowed_packet=16M
```

It is safe to increase the value of this variable because the extra memory is allocated only when needed. For example, `mysqld` allocates more memory only when you issue a long query or when `mysqld` must return a large result row. The small default value of the variable is a precaution to catch incorrect packets between the client and server and also to ensure that you do not run out of memory by using large packets accidentally.

You can also get strange problems with large packets if you are using large BLOB values but have not given `mysqld` access to enough memory to handle the query. If you suspect this is the case, try adding `ulimit -d 256000` to the beginning of the `mysqld_safe` script and restarting `mysqld`.

### B.5.2.11 Communication Errors and Aborted Connections

If connection problems occur such as communication errors or aborted connections, use these sources of information to diagnose problems:

- The error log. See Section 5.4.1, “The Error Log”.
- The general query log. See Section 5.4.2, “The General Query Log”.
- The `Aborted_xxx` status variables. See Section 5.1.6, “Server Status Variables”.

If you start the server with the `--log-warnings` option, you might find messages like this in your error log:

```
Aborted connection 854 to db: 'employees' user: 'josh'
```

If a client is unable even to connect, the server increments the `Aborted_connects` status variable. Unsuccessful connection attempts can occur for the following reasons:

- A client attempts to access a database but has no privileges for it.
- A client uses an incorrect password.
- A connection packet does not contain the right information.
• It takes more than `connect_timeout` seconds to obtain a connect packet. See Section 5.1.4, “Server System Variables”.

If these kinds of things happen, it might indicate that someone is trying to break into your server! If the general query log is enabled, messages for these types of problems are logged to it.

If a client successfully connects but later disconnects improperly or is terminated, the server increments the `Aborted_clients` status variable, and logs an `Aborted connection` message to the error log. The cause can be any of the following:

• The client program did not call `mysql_close()` before exiting.

• The client had been sleeping more than `wait_timeout` or `interactive_timeout` seconds without issuing any requests to the server. See Section 5.1.4, “Server System Variables”.

• The client program ended abruptly in the middle of a data transfer.

Other reasons for problems with aborted connections or aborted clients:

• The `max_allowed_packet` variable value is too small or queries require more memory than you have allocated for `mysqld`. See Section B.5.2.10, “Packet Too Large”.

• Use of Ethernet protocol with Linux, both half and full duplex. Some Linux Ethernet drivers have this bug. You should test for this bug by transferring a huge file using FTP between the client and server machines. If a transfer goes in burst-pause-burst-pause mode, you are experiencing a Linux duplex syndrome. Switch the duplex mode for both your network card and hub/switch to either full duplex or to half duplex and test the results to determine the best setting.

• A problem with the thread library that causes interrupts on reads.

• Badly configured TCP/IP.

• Faulty Ethernets, hubs, switches, cables, and so forth. This can be diagnosed properly only by replacing hardware.

See also Section B.5.2.9, “MySQL server has gone away”.

B.5.2.12 The table is full

If a table-full error occurs, it may be that the disk is full or that the table has reached its maximum size. The effective maximum table size for MySQL databases is usually determined by operating system constraints on file sizes, not by MySQL internal limits. See Section C.7.3, “Limits on Table Size”.

This error can occur sometimes for MySQL Cluster tables even when there appears to be more than sufficient data memory available. See the documentation for the `DataMemory` MySQL Cluster data node configuration parameter, as well as Section 17.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”, for more information.

B.5.2.13 Can't create/write to file

If you get an error of the following type for some queries, it means that MySQL cannot create a temporary file for the result set in the temporary directory:

```
Can't create/write to file '\sqla3fe_0.ism'.
```

The preceding error is a typical message for Windows; the Unix message is similar.

One fix is to start `mysqld` with the `--tmpdir` option or to add the option to the `[mysqld]` section of your option file. For example, to specify a directory of `C:\temp`, use these lines:

```
[mysqld]
tmpdir=C:/temp
```
The `C:\temp` directory must exist and have sufficient space for the MySQL server to write to. See Section 4.2.6, “Using Option Files”.

Another cause of this error can be permissions issues. Make sure that the MySQL server can write to the `tmpdir` directory.

Check also the error code that you get with `perror`. One reason the server cannot write to a table is that the file system is full:

```
shell> perror 28
OS error code 28: No space left on device
```

If you get an error of the following type during startup, it indicates that the file system or directory used for storing data files is write protected. Provided that the write error is to a test file, the error is not serious and can be safely ignored.

```
Can't create test file /usr/local/mysql/data/master.lower-test
```

### B.5.2.14 Commands out of sync

If you get `Commands out of sync; you can't run this command now` in your client code, you are calling client functions in the wrong order.

This can happen, for example, if you are using `mysql_use_result()` and try to execute a new query before you have called `mysql_free_result()`. It can also happen if you try to execute two queries that return data without calling `mysql_use_result()` or `mysql_store_result()` in between.

### B.5.2.15 Ignoring user

If you get the following error, it means that when `mysqld` was started or when it reloaded the grant tables, it found an account in the `user` table that had an invalid password.

```
Found wrong password for user 'some_user'@'some_host'; ignoring user
```

As a result, the account is simply ignored by the permission system.

The following list indicates possible causes of and fixes for this problem:

- You may be running a new version of `mysqld` with an old `user` table. You can check this by executing `mysqlshow mysql user` to see whether the `Password` column is shorter than 16 characters. If so, you can correct this condition by running the `scripts/add_long_password` script.

- The account has an old password (eight characters long). Update the account in the `user` table to have a new password.

- You have specified a password in the `user` table without using the `PASSWORD()` function. Use `mysql` to update the account in the `user` table with a new password, making sure to use the `PASSWORD()` function:

```
mysql> UPDATE user SET Password=PASSWORD('new_password')
   ->   WHERE User='some_user' AND Host='some_host';
```

### B.5.2.16 Table 'tbl_name' doesn't exist

If you get either of the following errors, it usually means that no table exists in the default database with the given name:

```
Table 'tbl_name' doesn't exist
Can't find file: 'tbl_name' (errno: 2)
```

In some cases, it may be that the table does exist but that you are referring to it incorrectly:
• Because MySQL uses directories and files to store databases and tables, database and table names are case sensitive if they are located on a file system that has case-sensitive file names.

• Even for file systems that are not case sensitive, such as on Windows, all references to a given table within a query must use the same lettercase.

You can check which tables are in the default database with `SHOW TABLES`. See Section 13.7.5, “SHOW Syntax”.

### B.5.2.17 Can't initialize character set

You might see an error like this if you have character set problems:

```
MySQL Connection Failed: Can't initialize character set charset_name
```

This error can have any of the following causes:

• The character set is a multibyte character set and you have no support for the character set in the client. In this case, you need to recompile the client by running `configure` with the `--with-charset=charset_name` or `--with-extra-charsets=charset_name` option. See Section 2.17.3, “MySQL Source-Configuration Options”.

All standard MySQL binaries are compiled with `--with-extra-charsets=complex` or (for Windows) `--with-extra-charsets=complex`, which enables support for all multibyte character sets. See Section 2.17.3, “MySQL Source-Configuration Options”.

• The character set is a simple character set that is not compiled into `mysqld`, and the character set definition files are not in the place where the client expects to find them.

In this case, you need to use one of the following methods to solve the problem:

• Recompile the client with support for the character set. See Section 2.17.3, “MySQL Source-Configuration Options”.

• Specify to the client the directory where the character set definition files are located. For many clients, you can do this with the `--character-sets-dir` option.

• Copy the character definition files to the path where the client expects them to be.

### B.5.2.18 File Not Found and Similar Errors

If you get `ERROR 'file_name' not found (errno: 23), Can't open file: file_name (errno: 24)`, or any other error with `errno 23` or `errno 24` from MySQL, it means that you have not allocated enough file descriptors for the MySQL server. You can use the `perror` utility to get a description of what the error number means:

```
shell> perror 23
OS error code 23:  File table overflow
shell> perror 24
OS error code 24:  Too many open files
shell> perror 11
OS error code 11:  Resource temporarily unavailable
```

The problem here is that `mysqld` is trying to keep open too many files simultaneously. You can either tell `mysqld` not to open so many files at once or increase the number of file descriptors available to `mysqld`.

To tell `mysqld` to keep open fewer files at a time, you can make the table cache smaller by reducing the value of the `table_cache` system variable (the default value is 64). This may not entirely prevent running out of file descriptors because in some circumstances the server may attempt to extend the cache size temporarily, as described in Section 8.4.3.1, “How MySQL Opens and Closes Tables”.

This documentation is for an older version. If you're

This documentation is for an older version. If you're
Reducing the value of `max_connections` also reduces the number of open files (the default value is 100).

To change the number of file descriptors available to `mysqld`, you can use the `--open-files-limit` option to `mysqld_safe` or set the `open_files_limit` system variable. See Section 5.1.4, “Server System Variables”. The easiest way to set these values is to add an option to your option file. See Section 4.2.6, “Using Option Files”. If you have an old version of `mysqld` that does not support setting the open files limit, you can edit the `mysqld_safe` script. There is a commented-out line `ulimit -n 256` in the script. You can remove the “#” character to uncomment this line, and change the number 256 to set the number of file descriptors to be made available to `mysqld`.

`--open-files-limit` and `ulimit` can increase the number of file descriptors, but only up to the limit imposed by the operating system. There is also a “hard” limit that can be overridden only if you start `mysqld_safe` or `mysqld` as root (just remember that you also need to start the server with the `--user` option in this case so that it does not continue to run as root after it starts up). If you need to increase the operating system limit on the number of file descriptors available to each process, consult the documentation for your system.

Note

If you run the `tcsh` shell, `ulimit` does not work! `tcsh` also reports incorrect values when you ask for the current limits. In this case, you should start `mysqld_safe` using `sh`.

B.5.2.19 Table-Corruption Issues

If you have started `mysqld` with `--myisam-recover`, MySQL automatically checks and tries to repair MyISAM tables if they are marked as 'not closed properly' or 'crashed'. If this happens, MySQL writes an entry in the `hostname.err` file 'Warning: Checking table ...' which is followed by 'Warning: Repairing table' if the table needs to be repaired. If you get a lot of these errors, without `mysqld` having died unexpectedly just before, then something is wrong and needs to be investigated further.

See also Section 5.1.3, “Server Command Options”, and Section 21.3.1.7, “Making a Test Case If You Experience Table Corruption”.

B.5.3 Administration-Related Issues

B.5.3.1 Problems with File Permissions

If you have problems with file permissions, the `UMASK` or `UMASK_DIR` environment variable might be set incorrectly when `mysqld` starts. For example, MySQL might issue the following error message when you create a table:

```
ERROR: Can't find file: 'path/with/filename.frm' (Errcode: 13)
```

The default `UMASK` and `UMASK_DIR` values are 0660 and 0700, respectively. MySQL assumes that the value for `UMASK` or `UMASK_DIR` is in octal if it starts with a zero. For example, setting `UMASK=0600` is equivalent to `UMASK=384` because 0600 octal is 384 decimal.

To change the default `UMASK` value, start `mysqld_safe` as follows:

```
shell> UMASK=384  # = 600 in octal
shell> export UMASK
shell> mysqld_safe &
```

By default, MySQL creates database and RAID directories with an access permission value of 0700. To modify this behavior, set the `UMASK_DIR` variable. If you set its value, new directories are created with the combined `UMASK` and `UMASK_DIR` values. For example, to give group access to all new directories, start `mysqld_safe` as follows:
B.5.3.2 How to Reset the Root Password

If you have never assigned a root password for MySQL, the server does not require a password at all for connecting as root. However, this is insecure. For instructions on assigning passwords, see Section 2.18.4, “Securing the Initial MySQL Accounts”.

If you know the root password and want to change it, see Section 13.7.1.6, “SET PASSWORD Syntax”.

If you assigned a root password previously but have forgotten it, you can assign a new password. The following sections provide instructions for Windows and Unix and Unix-like systems, as well as generic instructions that apply to any system.

Resetting the Root Password: Windows Systems

On Windows, use the following procedure to reset the password for the MySQL 'root'@'localhost' account. To change the password for a root account with a different host name part, modify the instructions to use that host name.

1. Log on to your system as Administrator.
2. Stop the MySQL server if it is running. For a server that is running as a Windows service, go to the Services manager: From the Start menu, select Control Panel, then Administrative Tools, then Services. Find the MySQL service in the list and stop it.
   If your server is not running as a service, you may need to use the Task Manager to force it to stop.
3. Create a text file containing the following statement on a single line. Replace the password with the password that you want to use.

   ```shell
   SET PASSWORD FOR 'root'@'localhost' = PASSWORD('MyNewPass');
   ```
4. Save the file. This example assumes that you name the file C:\mysql-init.txt.
5. Open a console window to get to the command prompt: From the Start menu, select Run, then enter cmd as the command to be run.
6. Start the MySQL server with the special --init-file option (notice that the backslash in the option value is doubled):

   ```shell
   C:\> cd "C:\Program Files\MySQL\MySQL Server 5.0\bin"
   C:\> mysqld-nt --init-file=C:\\mysql-init.txt
   ```
   If you installed MySQL to a different location, adjust the cd command accordingly.

   The server executes the contents of the file named by the --init-file option at startup, changing the 'root'@'localhost' account password.

   To have server output to appear in the console window rather than in a log file, add the --console option to the mysqld command.

   If you installed MySQL using the MySQL Installation Wizard, you may need to specify a --defaults-file option. For example:

   ```shell
   C:\> mysqld-nt
   ```
The appropriate --defaults-file setting can be found using the Services Manager: From the Start menu, select Control Panel, then Administrative Tools, then Services. Find the MySQL service in the list, right-click it, and choose the Properties option. The Path to executable field contains the --defaults-file setting.

7. After the server has started successfully, delete C:\mysql-init.txt.

You should now be able to connect to the MySQL server as root using the new password. Stop the MySQL server and restart it normally. If you run the server as a service, start it from the Windows Services window. If you start the server manually, use whatever command you normally use.

Resetting the Root Password: Unix and Unix-Like Systems

On Unix, use the following procedure to reset the password for the MySQL 'root'@'localhost' account. To change the password for a root account with a different host name part, modify the instructions to use that host name.

The instructions assume that you will start the MySQL server from the Unix login account that you normally use for running it. For example, if you run the server using the mysql login account, you should log in as mysql before using the instructions. Alternatively, you can log in as root, but in this case you must start mysqld with the --user=mysql option. If you start the server as root without using --user=mysql, the server may create root-owned files in the data directory, such as log files, and these may cause permission-related problems for future server startups. If that happens, you will need to either change the ownership of the files to mysql or remove them.

1. Log on to your system as the Unix user that the MySQL server runs as (for example, mysql).

2. Stop the MySQL server if it is running. Locate the .pid file that contains the server's process ID. The exact location and name of this file depend on your distribution, host name, and configuration. Common locations are /var/lib/mysql/, /var/run/mysqld/, and /usr/local/mysql/data/. Generally, the file name has an extension of .pid and begins with either mysqld or your system's host name.

Stop the MySQL server by sending a normal kill (not kill -9) to the mysqld process. Use the actual path name of the .pid file in the following command:

```bash
shell> kill `cat /mysql-data-directory/host_name.pid`
```

Use backticks (not forward quotation marks) with the cat command. These cause the output of cat to be substituted into the kill command.

3. Create a text file containing the following statement on a single line. Replace the password with the password that you want to use.

```sql
SET PASSWORD FOR 'root'@'localhost' = PASSWORD('MyNewPass');
```

4. Save the file. This example assumes that you name the file /home/me/mysql-init. The file contains the password, so do not save it where it can be read by other users. If you are not logged in as mysql (the user the server runs as), make sure that the file has permissions that permit mysql to read it.

5. Start the MySQL server with the special --init-file option:

```bash
shell> mysqld_safe --init-file=/home/me/mysql-init &
```

The server executes the contents of the file named by the --init-file option at startup, changing the 'root'@'localhost' account password.
6. After the server has started successfully, delete `/home/me/mysql-init`

You should now be able to connect to the MySQL server as `root` using the new password. Stop the server and restart it normally.

**Resetting the Root Password: Generic Instructions**

The preceding sections provide password-resetting instructions specifically for Windows and Unix and Unix-like systems. Alternatively, on any platform, you can reset the password using the `mysql` client (but this approach is less secure):

1. Stop the MySQL server if necessary, then restart it with the `--skip-grant-tables` option. This enables anyone to connect without a password and with all privileges, and disables account-management statements such as `SET PASSWORD`. Because this is insecure, you might want to use `--skip-grant-tables` in conjunction with `--skip-networking` to prevent remote clients from connecting.

2. Connect to the MySQL server using the `mysql` client; no password is necessary because the server was started with `--skip-grant-tables`:

   ```shell
   mysql
   ```

3. In the `mysql` client, tell the server to reload the grant tables so that account-management statements work:

   ```sql
   FLUSH PRIVILEGES;
   ```

   Then change the `root@localhost` account password. Replace the password with the password that you want to use. To change the password for a `root` account with a different host name part, modify the instructions to use that host name.

   ```sql
   SET PASSWORD FOR 'root'@'localhost' = PASSWORD('MyNewPass');
   ```

   You should now be able to connect to the MySQL server as `root` using the new password. Stop the server and restart it normally (without the `--skip-grant-tables` and `--skip-networking` options).

**B.5.3.3 What to Do If MySQL Keeps Crashing**

Each MySQL version is tested on many platforms before it is released. This does not mean that there are no bugs in MySQL, but if there are bugs, they should be very few and can be hard to find. If you have a problem, it always helps if you try to find out exactly what crashes your system, because you have a much better chance of getting the problem fixed quickly.

First, you should try to find out whether the problem is that the `mysqld` server dies or whether your problem has to do with your client. You can check how long your `mysqld` server has been up by executing `mysqld --version`. If `mysqld` has died and restarted, you may find the reason by looking in the server's error log. See Section 5.4.1, "The Error Log".

On some systems, you can find in the error log a stack trace of where `mysqld` died that you can resolve with the `resolve_stack_dump` program. See Section 21.3, "Debugging and Porting MySQL". Note that the variable values written in the error log may not always be 100% correct.

Many server crashes are caused by corrupted data files or index files. MySQL updates the files on disk with the `write()` system call after every SQL statement and before the client is notified about the result. (This is not true if you are running with `--delay-key-write`, in which case data files are written but not index files.) This means that data file contents are safe even if `mysqld` crashes, because the operating system ensures that the unflushed data is written to disk. You can force MySQL to flush everything to disk after every SQL statement by starting `mysqld` with the `--flush` option.
The preceding means that normally you should not get corrupted tables unless one of the following happens:

- The MySQL server or the server host was killed in the middle of an update.
- You have found a bug in `mysqld` that caused it to die in the middle of an update.
- Some external program is manipulating data files or index files at the same time as `mysqld` without locking the table properly.
- You are running many `mysqld` servers using the same data directory on a system that does not support good file system locks (normally handled by the `lockd` lock manager), or you are running multiple servers with external locking disabled.
- You have a crashed data file or index file that contains very corrupt data that confused `mysqld`.
- You have found a bug in the data storage code. This isn't likely, but it is at least possible. In this case, you can try to change the storage engine to another engine by using `ALTER TABLE` on a repaired copy of the table.

Because it is very difficult to know why something is crashing, first try to check whether things that work for others crash for you. Please try the following things:

- Stop the `mysqld` server with `mysqldadmin shutdown`, run `myisamchk --silent --force */*.MYI` from the data directory to check all MyISAM tables, and restart `mysqld`. This ensures that you are running from a clean state. See Chapter 5, *MySQL Server Administration*.

- Start `mysqld` with the general query log enabled (see Section 5.4.2, “The General Query Log”). Then try to determine from the information written to the log whether some specific query kills the server. About 95% of all bugs are related to a particular query. Normally, this is one of the last queries in the log file just before the server restarts. See Section 5.4.2, “The General Query Log”. If you can repeatedly kill MySQL with a specific query, even when you have checked all tables just before issuing it, then you have been able to locate the bug and should submit a bug report for it. See Section 1.7, “How to Report Bugs or Problems”.

- Try to make a test case that we can use to repeat the problem. See Section 21.3, “Debugging and Porting MySQL”.

- Try running the tests in the `mysql-test` directory and the MySQL benchmarks. See Section 21.1.2, “The MySQL Test Suite”. They should test MySQL rather well. You can also add code to the benchmarks that simulates your application. The benchmarks can be found in the `sql-bench` directory in a source distribution or, for a binary distribution, in the `sql-bench` directory under your MySQL installation directory.

- Try the `fork_big.pl` script. (It is located in the `tests` directory of source distributions.)

- If you configure MySQL for debugging, it is much easier to gather information about possible errors if something goes wrong. Configuring MySQL for debugging causes a safe memory allocator to be included that can find some errors. It also provides a lot of output about what is happening. Reconfigure MySQL with the `--with-debug` or `--with-debug=full` option to `configure` and then recompile. See Section 21.3, “Debugging and Porting MySQL”.

- Make sure that you have applied the latest patches for your operating system.

- Use the `--skip-external-locking` option to `mysqld`. On some systems, the `lockd` lock manager does not work properly; the `--skip-external-locking` option tells `mysqld` not to use external locking. (This means that you cannot run two `mysqld` servers on the same data directory and that you must be careful if you use `myisamchk`. Nevertheless, it may be instructive to try the option as a test.)

- Have you tried `mysqladmin -u root processlist` when `mysqld` appears to be running but not responding? Sometimes `mysqld` is not comatose even though you might think so. The problem
may be that all connections are in use, or there may be some internal lock problem. `mysqladmin -u root processlist` usually is able to make a connection even in these cases, and can provide useful information about the current number of connections and their status.

- Run the command `mysqladmin -i 5 status` or `mysqladmin -i 5 -r status` in a separate window to produce statistics while you run your other queries.

- Try the following:
  2. Run your test scripts.
  3. Print the backtrace and the local variables at the three lowest levels. In `gdb`, you can do this with the following commands when `mysqld` has crashed inside `gdb`:

```
backtrace
info local
up
info local
up
info local
```

With `gdb`, you can also examine which threads exist with `info threads` and switch to a specific thread with `thread N`, where `N` is the thread ID.

- Try to simulate your application with a Perl script to force MySQL to crash or misbehave.

- Send a normal bug report. See Section 1.7, “How to Report Bugs or Problems”. Be even more detailed than usual. Because MySQL works for many people, it may be that the crash results from something that exists only on your computer (for example, an error that is related to your particular system libraries).

- If you have a problem with tables containing dynamic-length rows and you are using only `VARCHAR` columns (not `BLOB` or `TEXT` columns), you can try to change all `VARCHAR` to `CHAR` with `ALTER TABLE`. This forces MySQL to use fixed-size rows. Fixed-size rows take a little extra space, but are much more tolerant to corruption.

The current dynamic row code has been in use for several years with very few problems, but dynamic-length rows are by nature more prone to errors, so it may be a good idea to try this strategy to see whether it helps.

- Do not rule out your server hardware when diagnosing problems. Defective hardware can be the cause of data corruption. Particular attention should be paid to your memory and disk subsystems when troubleshooting hardware.

**B.5.3.4 How MySQL Handles a Full Disk**

This section describes how MySQL responds to disk-full errors (such as “no space left on device”), and to quota-exceeded errors (such as “write failed” or “user block limit reached”).

This section is relevant for writes to MyISAM tables. It also applies for writes to binary log files and binary log index file, except that references to “row” and “record” should be understood to mean “event.”

When a disk-full condition occurs, MySQL does the following:

- It checks once every minute to see whether there is enough space to write the current row. If there is enough space, it continues as if nothing had happened.

- Every 10 minutes it writes an entry to the log file, warning about the disk-full condition.
To alleviate the problem, you can take the following actions:

- To continue, you only have to free enough disk space to insert all records.
- To abort the thread, you must use `mysqladmin kill`. The thread is aborted the next time it checks the disk (in one minute).
- Other threads might be waiting for the table that caused the disk-full condition. If you have several “locked” threads, killing the one thread that is waiting on the disk-full condition enables the other threads to continue.

Exceptions to the preceding behavior are when you use `REPAIR TABLE` or `OPTIMIZE TABLE` or when the indexes are created in a batch after `LOAD DATA INFILE` or after an `ALTER TABLE` statement. All of these statements may create large temporary files that, if left to themselves, would cause big problems for the rest of the system. If the disk becomes full while MySQL is doing any of these operations, it removes the big temporary files and mark the table as crashed. The exception is that for `ALTER TABLE`, the old table is left unchanged.

### B.5.3.5 Where MySQL Stores Temporary Files

On Unix, MySQL uses the value of the `TMPDIR` environment variable as the path name of the directory in which to store temporary files. If `TMPDIR` is not set, MySQL uses the system default, which is usually `/tmp`, `/var/tmp`, or `/usr/tmp`.

On Windows, Netware and OS2, MySQL checks in order the values of the `TMPDIR`, `TEMP`, and `TMP` environment variables. For the first one found to be set, MySQL uses it and does not check those remaining. If none of `TMPDIR`, `TEMP`, or `TMP` are set, MySQL uses the Windows system default, which is usually `C:\windows\temp\`.

If the file system containing your temporary file directory is too small, you can use the `mysqld --tmpdir` option to specify a directory in a file system where you have enough space. On replication slaves, you can use `--slave-load-tmpdir` to specify a separate directory for holding temporary files when replicating `LOAD DATA INFILE` statements.

The `--tmpdir` option can be set to a list of several paths that are used in round-robin fashion. Paths should be separated by colon characters (“:”) on Unix and semicolon characters (“;”) on Windows, NetWare, and OS/2.

**Note**

To spread the load effectively, these paths should be located on different physical disks, not different partitions of the same disk.

If the MySQL server is acting as a replication slave, you should be sure to set `--slave-load-tmpdir` not to point to a directory that is on a memory-based file system or to a directory that is cleared when the server host restarts. A replication slave needs some of its temporary files to survive a machine restart so that it can replicate temporary tables or `LOAD DATA INFILE` operations. If files in the slave temporary file directory are lost when the server restarts, replication fails.

MySQL arranges that temporary files are removed if `mysqld` is terminated. On platforms that support it (such as Unix), this is done by unlinking the file after opening it. The disadvantage of this is that the name does not appear in directory listings and you do not see a big temporary file that fills up the file system in which the temporary file directory is located. (In such cases, `lsof +L1` may be helpful in identifying large files associated with `mysqld`.)

When sorting (`ORDER BY` or `GROUP BY`), MySQL normally uses one or two temporary files. The maximum disk space required is determined by the following expression:

\[
\text{(length of what is sorted + sizeof(row pointer))} \times \text{number of matched rows}
\]
The row pointer size is usually four bytes, but may grow in the future for really big tables.

For some `SELECT` queries, MySQL also creates temporary SQL tables. These are not hidden and have names of the form `SQL_*`.

`ALTER TABLE` creates a temporary copy of the original table in the same directory as the original table.

### B.5.3.6 How to Protect or Change the MySQL Unix Socket File

The default location for the Unix socket file that the server uses for communication with local clients is `/tmp/mysql.sock`. (For some distribution formats, the directory might be different, such as `/var/lib/mysql` for RPMs.)

On some versions of Unix, anyone can delete files in the `/tmp` directory or other similar directories used for temporary files. If the socket file is located in such a directory on your system, this might cause problems.

On most versions of Unix, you can protect your `/tmp` directory so that files can be deleted only by their owners or the superuser (root). To do this, set the `sticky` bit on the `/tmp` directory by logging in as root and using the following command:

```
shell> chmod t /tmp
```

You can check whether the `sticky` bit is set by executing `ls -ld /tmp`. If the last permission character is `t`, the bit is set.

Another approach is to change the place where the server creates the Unix socket file. If you do this, you should also let client programs know the new location of the file. You can specify the file location in several ways:

- Specify the path in a global or local option file. For example, put the following lines in `/etc/my.cnf`:

  ```
  [mysqld]
  socket=/path/to/socket
  [client]
  socket=/path/to/socket
  ```

  See Section 4.2.6, “Using Option Files”.

- Specify a `--socket` option on the command line to `mysqld_safe` and when you run client programs.

- Set the `MYSQL_UNIX_PORT` environment variable to the path of the Unix socket file.

- Recompile MySQL from source to use a different default Unix socket file location. Define the path to the file with the `--with-unix-socket-path` option when you run `configure`. See Section 2.17.3, “MySQL Source-Configuration Options”.

You can test whether the new socket location works by attempting to connect to the server with this command:

```
shell> mysqladmin --socket=/path/to/socket version
```

### B.5.3.7 Time Zone Problems

If you have a problem with `SELECT NOW()` returning values in UTC and not your local time, you have to tell the server your current time zone. The same applies if `UNIX_TIMESTAMP()` returns the wrong
value. This should be done for the environment in which the server runs; for example, in `mysqld_safe` or `mysql.server`. See Section 2.21, "Environment Variables".

You can set the time zone for the server with the `--timezone=timezone_name` option to `mysqld_safe`. You can also set it by setting the `TZ` environment variable before you start `mysqld`.

The permissible values for `--timezone` or `TZ` are system dependent. Consult your operating system documentation to see what values are acceptable.

### B.5.4 Query-Related Issues

#### B.5.4.1 Case Sensitivity in String Searches

For nonbinary strings (`CHAR`, `VARCHAR`, `TEXT`), string searches use the collation of the comparison operands. For binary strings (`BINARY`, `VARBINARY`, `BLOB`), comparisons use the numeric values of the bytes in the operands; this means that for alphabetic characters, comparisons will be case sensitive.

A comparison between a nonbinary string and binary string is treated as a comparison of binary strings.

Simple comparison operations (`>=`, `>`, `=`, `<`, `<=`, sorting, and grouping) are based on each character’s “sort value.” Characters with the same sort value are treated as the same character. For example, if “é” and “ê” have the same sort value in a given collation, they compare as equal.

The default character set and collation are `latin1` and `latin1_swedish_ci`, so nonbinary string comparisons are case insensitive by default. This means that if you search with `col_name LIKE 'a %'`, you get all column values that start with A or a. To make this search case sensitive, make sure that one of the operands has a case sensitive or binary collation. For example, if you are comparing a column and a string that both have the `latin1` character set, you can use the `COLLATE` operator to cause either operand to have the `latin1_general_cs` or `latin1_bin` collation:

```
col_name COLLATE latin1_general_cs LIKE 'a %'
col_name LIKE 'a %' COLLATE latin1_general_cs
col_name COLLATE latin1_bin LIKE 'a %'
col_name LIKE 'a %' COLLATE latin1_bin
```

If you want a column always to be treated in case-sensitive fashion, declare it with a case sensitive or binary collation. See Section 13.1.10, “CREATE TABLE Syntax”.

To cause a case-sensitive comparison of nonbinary strings to be case insensitive, use `COLLATE` to name a case-insensitive collation. The strings in the following example normally are case sensitive, but `COLLATE` changes the comparison to be case insensitive:

```
mysql> SET @s1 = 'MySQL' COLLATE latin1_bin,
        @s2 = 'mysql' COLLATE latin1_bin;
mysql> SELECT @s1 = @s2;
+-----------+
| @s1 = @s2 |
+-----------+
|         0  |
+-----------+
mysql> SELECT @s1 COLLATE latin1_swedish_ci = @s2;
+-------------------------------------+
| @s1 COLLATE latin1_swedish_ci = @s2 |
+-------------------------------------+
|                                   1  |
+-------------------------------------+
```

A binary string is case sensitive in comparisons. To compare the string as case insensitive, convert it to a nonbinary string and use `COLLATE` to name a case-insensitive collation:

```
mysql> SET @s = BINARY 'MySQL';
```
To determine whether a value will compare as a nonbinary or binary string, use the `COLLATION()` function. This example shows that `VERSION()` returns a string that has a case-insensitive collation, so comparisons are case insensitive:

```sql
mysql> SELECT COLLATION(VERSION());
+----------------------+
| COLLATION(VERSION()) |
| utf8_general_ci      |
+----------------------+
```

For binary strings, the collation value is `binary`, so comparisons will be case sensitive. One context in which you will see `binary` is for compression and encryption functions, which return binary strings as a general rule: string:

```sql
mysql> SELECT COLLATION(ENCRYPT('x')), COLLATION(SHA1('x'));
+-------------------------+----------------------+
| COLLATION(ENCRYPT('x')) | COLLATION(SHA1('x')) |
| binary                  | binary               |
+-------------------------+----------------------+
```

### B.5.4.2 Problems Using DATE Columns

The format of a `DATE` value is `'YYYY-MM-DD'`. According to standard SQL, no other format is permitted. You should use this format in `UPDATE` expressions and in the `WHERE` clause of `SELECT` statements. For example:

```sql
SELECT * FROM t1 WHERE date >= '2003-05-05';
```

As a convenience, MySQL automatically converts a date to a number if the date is used in a numeric context and vice versa. MySQL also permits a “relaxed” string format when updating and in a `WHERE` clause that compares a date to a `DATE`, `DATETIME`, or `TIMESTAMP` column. “Relaxed” format means that any punctuation character may be used as the separator between parts. For example, `'2004-08-15'` and `'2004#08#15'` are equivalent. MySQL can also convert a string containing no separators (such as `'20040815'`), provided it makes sense as a date.

When you compare a `DATE`, `TIME`, `DATETIME`, or `TIMESTAMP` to a constant string with the `<`, `<=`, `=`, `>=`, `>`, or `BETWEEN` operators, MySQL normally converts the string to an internal long integer for faster comparison (and also for a bit more “relaxed” string checking). However, this conversion is subject to the following exceptions:

- When you compare two columns
- When you compare a `DATE`, `TIME`, `DATETIME`, or `TIMESTAMP` column to an expression
- When you use any comparison method other than those just listed, such as `IN` or `STRCMP()`.

For those exceptions, the comparison is done by converting the objects to strings and performing a string comparison.
To be on the safe side, assume that strings are compared as strings and use the appropriate string functions if you want to compare a temporal value to a string.

The special "zero" date '0000-00-00' can be stored and retrieved as '0000-00-00'. When a '0000-00-00' date is used through Connector/ODBC, it is automatically converted to NULL because ODBC cannot handle that kind of date.

Because MySQL performs the conversions just described, the following statements work (assume that idate is a DATE column):

```sql
INSERT INTO t1 (idate) VALUES (19970505);
INSERT INTO t1 (idate) VALUES ('19970505');
INSERT INTO t1 (idate) VALUES ('97-05-05');
INSERT INTO t1 (idate) VALUES ('1997.05.05');
INSERT INTO t1 (idate) VALUES ('1997 05 05');
INSERT INTO t1 (idate) VALUES ('0000-00-00');
SELECT idate FROM t1 WHERE idate >= '1997-05-05';
SELECT idate FROM t1 WHERE idate >= 19970505;
SELECT MOD(idate,100) FROM t1 WHERE idate >= 19970505;
SELECT idate FROM t1 WHERE idate >= '19970505';
```

However, the following statement does not work:

```sql
SELECT idate FROM t1 WHERE STRCMP(idate,'20030505')=0;
```

STRCMP() is a string function, so it converts idate to a string in 'YYYY-MM-DD' format and performs a string comparison. It does not convert '20030505' to the date '2003-05-05' and perform a date comparison.

If you enable the ALLOW_INVALID_DATES SQL mode, MySQL permits you to store dates that are given only limited checking: MySQL requires only that the day is in the range from 1 to 31 and the month is in the range from 1 to 12. This makes MySQL very convenient for Web applications where you obtain year, month, and day in three different fields and you want to store exactly what the user inserted (without date validation).

MySQL permits you to store dates where the day or month and day are zero. This is convenient if you want to store a birthdate in a DATE column and you know only part of the date. To disallow zero month or day parts in dates, enable the NO_ZERO_IN_DATE SQL mode.

MySQL permits you to store a "zero" value of '0000-00-00' as a "dummy date." This is in some cases more convenient than using NULL values. If a date to be stored in a DATE column cannot be converted to any reasonable value, MySQL stores '0000-00-00'. To disallow '0000-00-00', enable the NO_ZERO_DATE SQL mode.

To have MySQL check all dates and accept only legal dates (unless overridden by IGNORE), set the sql_mode system variable to "NO_ZERO_IN_DATE,NO_ZERO_DATE".

Date handling in MySQL 5.0.1 and earlier works like MySQL 5.0.2 with the ALLOW_INVALID_DATES SQL mode enabled.

### B.5.4.3 Problems with NULL Values

The concept of the NULL value is a common source of confusion for newcomers to SQL, who often think that NULL is the same thing as an empty string ''. This is not the case. For example, the following statements are completely different:

```sql
mysql> INSERT INTO my_table (phone) VALUES (NULL);
mysql> INSERT INTO my_table (phone) VALUES ('');
```

Both statements insert a value into the phone column, but the first inserts a NULL value and the second inserts an empty string. The meaning of the first can be regarded as "phone number is not".
known” and the meaning of the second can be regarded as “the person is known to have no phone, and thus no phone number.”

To help with NULL handling, you can use the IS NULL and IS NOT NULL operators and the IFNULL() function.

In SQL, the NULL value is never true in comparison to any other value, even NULL. An expression that contains NULL always produces a NULL value unless otherwise indicated in the documentation for the operators and functions involved in the expression. All columns in the following example return NULL:

```sql
mysql> SELECT NULL, 1+NULL, CONCAT('Invisible',NULL);
```

To search for column values that are NULL, you cannot use an expr = NULL test. The following statement returns no rows, because expr = NULL is never true for any expression:

```sql
mysql> SELECT * FROM my_table WHERE phone = NULL;
```

To look for NULL values, you must use the IS NULL test. The following statements show how to find the NULL phone number and the empty phone number:

```sql
mysql> SELECT * FROM my_table WHERE phone IS NULL;
mysql> SELECT * FROM my_table WHERE phone = '';
```

See Section 3.3.4.6, “Working with NULL Values”, for additional information and examples.

You can add an index on a column that can have NULL values if you are using the MyISAM, InnoDB, or BDB, or MEMORY storage engine. Otherwise, you must declare an indexed column NOT NULL, and you cannot insert NULL into the column.

When reading data with LOAD DATA INFILE, empty or missing columns are updated with '' . To load a NULL value into a column, use \N in the data file. The literal word “NULL” may also be used under some circumstances. See Section 13.2.6, “LOAD DATA INFILE Syntax”.

When using DISTINCT, GROUP BY, or ORDER BY, all NULL values are regarded as equal.

When using ORDER BY, NULL values are presented first, or last if you specify DESC to sort in descending order.

Aggregate (summary) functions such as COUNT(), MIN(), and SUM() ignore NULL values. The exception to this is COUNT(*) , which counts rows and not individual column values. For example, the following statement produces two counts. The first is a count of the number of rows in the table, and the second is a count of the number of non-NULL values in the age column:

```sql
mysql> SELECT COUNT(*), COUNT(age) FROM person;
```

For some data types, MySQL handles NULL values specially. If you insert NULL into a TIMESTAMP column, the current date and time is inserted. If you insert NULL into an integer or floating-point column that has the AUTO_INCREMENT attribute, the next number in the sequence is inserted.

**B.5.4.4 Problems with Column Aliases**

An alias can be used in a query select list to give a column a different name. You can use the alias in GROUP BY, ORDER BY, or HAVING clauses to refer to the column:

```sql
SELECT SQRT(a*b) AS root FROM tbl_name
GROUP BY root HAVING root > 0;
SELECT id, COUNT(*) AS cnt FROM tbl_name
GROUP BY id HAVING cnt > 0;
SELECT id AS 'Customer identity' FROM tbl_name;
```
Standard SQL disallows references to column aliases in a **WHERE** clause. This restriction is imposed because when the **WHERE** clause is evaluated, the column value may not yet have been determined. For example, the following query is illegal:

```sql
SELECT id, COUNT(*) AS cnt FROM tbl_name
    WHERE cnt > 0 GROUP BY id;
```

The **WHERE** clause determines which rows should be included in the **GROUP BY** clause, but it refers to the alias of a column value that is not known until after the rows have been selected, and grouped by the **GROUP BY** clause.

In the select list of a query, a quoted column alias can be specified using identifier or string quoting characters:

```sql
SELECT 1 AS 'one', 2 AS 'two';
```

Elsewhere in the statement, quoted references to the alias must use identifier quoting or the reference is treated as a string literal. For example, this statement groups by the values in column `id`, referenced using the alias `a`:

```sql
SELECT id AS 'a', COUNT(*) AS cnt FROM tbl_name
    GROUP BY 'a';
```

But this statement groups by the literal string `'a'` and will not work as expected:

```sql
SELECT id AS 'a', COUNT(*) AS cnt FROM tbl_name
    GROUP BY 'a';
```

### B.5.4.5 Rollback Failure for Nontransactional Tables

If you receive the following message when trying to perform a **ROLLBACK**, it means that one or more of the tables you used in the transaction do not support transactions:

```sql
Warning: Some non-transactional changed tables couldn't be rolled back
```

These nontransactional tables are not affected by the **ROLLBACK** statement.

If you were not deliberately mixing transactional and nontransactional tables within the transaction, the most likely cause for this message is that a table you thought was transactional actually is not. This can happen if you try to create a table using a transactional storage engine that is not supported by your **mysqld** server (or that was disabled with a startup option). If **mysqld** does not support a storage engine, it instead creates the table as a **MyISAM** table, which is nontransactional.

You can check the storage engine for a table by using either of these statements:

```sql
SHOW TABLE STATUS LIKE 'tbl_name';
SHOW CREATE TABLE tbl_name;
```

See Section 13.7.5.33, “SHOW TABLE STATUS Syntax”, and Section 13.7.5.9, “SHOW CREATE TABLE Syntax”.

You can check which storage engines your **mysqld** server supports by using this statement:

```sql
SHOW ENGINES;
```

You can also use the following statement, and check the value of the variable that is associated with the storage engine in which you are interested:
SHOW VARIABLES LIKE 'have_%';

For example, to determine whether the InnoDB storage engine is available, check the value of the have_innodb variable.

See Section 13.7.5.13, “SHOW ENGINES Syntax”, and Section 13.7.5.36, “SHOW VARIABLES Syntax”.

B.5.4.6 Deleting Rows from Related Tables

If the total length of the DELETE statement for related_table is more than 1MB (the default value of the max_allowed_packet system variable), you should split it into smaller parts and execute multiple DELETE statements. You probably get the fastest DELETE by specifying only 100 to 1,000 related_column values per statement if the related_column is indexed. If the related_column isn’t indexed, the speed is independent of the number of arguments in the IN clause.

B.5.4.7 Solving Problems with No Matching Rows

If you have a complicated query that uses many tables but that returns no rows, you should use the following procedure to find out what is wrong:

1. Test the query with EXPLAIN to check whether you can find something that is obviously wrong. See Section 13.8.2, “EXPLAIN Syntax”.
2. Select only those columns that are used in the WHERE clause.
3. Remove one table at a time from the query until it returns some rows. If the tables are large, it is a good idea to use LIMIT 10 with the query.
4. Issue a SELECT for the column that should have matched a row against the table that was last removed from the query.
5. If you are comparing FLOAT or DOUBLE columns with numbers that have decimals, you cannot use equality (=) comparisons. This problem is common in most computer languages because not all floating-point values can be stored with exact precision. In some cases, changing the FLOAT to a DOUBLE fixes this. See Section B.5.4.8, “Problems with Floating-Point Values”.

   Similar problems may be encountered when comparing DECIMAL values prior to MySQL 5.0.3.

6. If you still cannot figure out what is wrong, create a minimal test that can be run with mysql test < query.sql that shows your problems. You can create a test file by dumping the tables with mysqldump --quick db_name tbl_name_1 ... tbl_name_n > query.sql. Open the file in an editor, remove some insert lines (if there are more than needed to demonstrate the problem), and add your SELECT statement at the end of the file.

   Verify that the test file demonstrates the problem by executing these commands:

   ```
   shell> mysqladmin create test2
   shell> mysql test2 < query.sql
   ```

   Attach the test file to a bug report, which you can file using the instructions in Section 1.7, “How to Report Bugs or Problems”.

B.5.4.8 Problems with Floating-Point Values

Floating-point numbers sometimes cause confusion because they are approximate and not stored as exact values. A floating-point value as written in an SQL statement may not be the same as the value represented internally. Attempts to treat floating-point values as exact in comparisons may lead to problems. They are also subject to platform or implementation dependencies. The FLOAT and DOUBLE data types are subject to these issues. Before MySQL 5.0.3, DECIMAL comparison operations are approximate as well.
Prior to MySQL 5.0.3, DECIMAL columns store values with exact precision because they are represented as strings, but calculations on DECIMAL values are done using floating-point operations. As of 5.0.6, MySQL performs DECIMAL operations with a precision of 65 decimal digits (64 digits from 5.0.3 to 5.0.5), which should solve most common inaccuracy problems when it comes to DECIMAL columns. (If your server is from MySQL 5.0.3 or higher, but you have DECIMAL columns in tables that were created before 5.0.3, the old behavior still applies to those columns. To convert the tables to the newer DECIMAL format, dump them with mysqldump and reload them.)

The following example (for versions of MySQL older than 5.0.3) demonstrates the problem. It shows that even for older DECIMAL columns, calculations that are done using floating-point operations are subject to floating-point error. (Were you to replace the DECIMAL columns with FLOAT, similar problems would occur for all versions of MySQL.)

```
mysql> CREATE TABLE t1 (i INT, d1 DECIMAL(9,2), d2 DECIMAL(9,2));
mysql> INSERT INTO t1 VALUES (1, 101.40, 21.40), (1, -80.00, 0.00),
   -> (2, 0.00, 0.00), (2, -13.20, 0.00), (2, 59.60, 46.40),
   -> (2, 30.40, 30.40), (3, 37.00, 7.40), (3, -29.60, 0.00),
   -> (4, 60.00, 15.40), (4, -10.60, 0.00), (4, -34.00, 0.00),
   -> (5, 33.00, 0.00), (5, -25.80, 0.00), (5, 0.00, 7.20),
   -> (6, 0.00, 0.00), (6, -51.40, 0.00);
mysql> SELECT i, SUM(d1) AS a, SUM(d2) AS b
   -> FROM t1 GROUP BY i HAVING a <> b;
```

```
+------+--------+-------+
| i    | a      | b     |
+------+--------+-------+
|    1 |  21.40 | 21.40 |
|    2 |  76.80 | 76.80 |
|    3 |   7.40 |  7.40 |
|    4 |  15.40 | 15.40 |
|    5 |   7.20 |  7.20 |
|    6 | -51.40 |  0.00 |
+------+--------+-------+
```

The result is correct. Although the first five records look like they should not satisfy the comparison (the values of `a` and `b` do not appear to be different), they may do so because the difference between the numbers shows up around the tenth decimal or so, depending on factors such as computer architecture or the compiler version or optimization level. For example, different CPUs may evaluate floating-point numbers differently.

As of MySQL 5.0.3, you will get only the last row in the above result.

The problem cannot be solved by using `ROUND()` or similar functions, because the result is still a floating-point number:

```
mysql> SELECT i, ROUND(SUM(d1), 2) AS a, ROUND(SUM(d2), 2) AS b
   -> FROM t1 GROUP BY i HAVING a <> b;
```

```
+------+--------+-------+
| i    | a      | b     |
+------+--------+-------+
|    1 |  21.40 | 21.40 |
|    2 |  76.80 | 76.80 |
|    3 |   7.40 |  7.40 |
|    4 |  15.40 | 15.40 |
|    5 |   7.20 |  7.20 |
|    6 | -51.40 |  0.00 |
+------+--------+-------+
```

This is what the numbers in column `a` look like when displayed with more decimal places:
Depending on your computer architecture, you may or may not see similar results. For example, on some machines you may get the “correct” results by multiplying both arguments by 1, as the following example shows.

```
Warning
Never use this method in your applications. It is not an example of a trustworthy method!
```

```
mysql> SELECT i, ROUND(SUM(d1), 2)*1 AS a, ROUND(SUM(d2), 2)*1 AS b
    -> FROM t1 GROUP BY i HAVING a <> b;
```

```
+------+--------+------+
| i    | a      | b    |
+------+--------+------+
| 6    | -51.40 | 0.00 |
+------+--------+------+
```

The reason that the preceding example seems to work is that on the particular machine where the test was done, CPU floating-point arithmetic happens to round the numbers to the same value. However, there is no rule that any CPU should do so, so this method cannot be trusted.

The correct way to do floating-point number comparison is to first decide on an acceptable tolerance for differences between the numbers and then do the comparison against the tolerance value. For example, if we agree that floating-point numbers should be regarded the same if they are same within a precision of one in ten thousand (0.0001), the comparison should be written to find differences larger than the tolerance value:

```
mysql> SELECT i, SUM(d1) AS a, SUM(d2) AS b FROM t1
    -> GROUP BY i HAVING ABS(a - b) > 0.0001;
```

```
+------+-------+-------+
| i    | a     | b     |
+------+-------+-------+
| 6    | -51.40 | 0.00  |
+------+-------+-------+
1 row in set (0.00 sec)
```

Conversely, to get rows where the numbers are the same, the test should find differences within the tolerance value:

```
mysql> SELECT i, SUM(d1) AS a, SUM(d2) AS b FROM t1
    -> GROUP BY i HAVING ABS(a - b) <= 0.0001;
```

```
+-----+-----+-----+
| i   | a   | b   |
+-----+-----+-----+
| 1   | 21.40 | 21.40 |
| 2   | 76.80 | 76.80 |
| 3   | 7.40  | 7.40  |
| 4   | 15.40 | 15.40 |
| 5   | 7.20  | 7.20  |
+-----+-----+-----+
```

Floating-point values are subject to platform or implementation dependencies. Suppose that you execute the following statements:

```
CREATE TABLE t1(c1 FLOAT(53,0), c2 FLOAT(53,0));
```
INSERT INTO t1 VALUES('1e+52','-1e+52');
SELECT * FROM t1;

On some platforms, the SELECT statement returns inf and -inf. On others, it returns 0 and -0.

An implication of the preceding issues is that if you attempt to create a replication slave by dumping table contents with mysqldump on the master and reloading the dump file into the slave, tables containing floating-point columns might differ between the two hosts.

### B.5.5 Optimizer-Related Issues

MySQL uses a cost-based optimizer to determine the best way to resolve a query. In many cases, MySQL can calculate the best possible query plan, but sometimes MySQL does not have enough information about the data at hand and has to make "educated" guesses about the data.

For the cases when MySQL does not do the "right" thing, tools that you have available to help MySQL are:

- Use the EXPLAIN statement to get information about how MySQL processes a query. To use it, just add the keyword EXPLAIN to the front of your SELECT statement:

  ```sql
  mysql> EXPLAIN SELECT * FROM t1, t2 WHERE t1.i = t2.i;
  ```

  EXPLAIN is discussed in more detail in Section 13.8.2, "EXPLAIN Syntax".

- Use ANALYZE TABLE tbl_name to update the key distributions for the scanned table. See Section 13.7.2.1, “ANALYZE TABLE Syntax”.

- Use FORCE INDEX for the scanned table to tell MySQL that table scans are very expensive compared to using the given index:

  ```sql
  SELECT * FROM t1, t2 FORCE INDEX (index_for_column)
  WHERE t1.col_name=t2.col_name;
  ```

  USE INDEX and IGNORE INDEX may also be useful. See Section 8.9.2, “Index Hints”.

- Global and table-level STRAIGHTJOIN. See Section 13.2.8, “SELECT Syntax”.

- You can tune global or thread-specific system variables. For example, start mysqld with the --max-seeks-for-key=1000 option or use SET max_seeks_for_key=1000 to tell the optimizer to assume that no key scan causes more than 1,000 key seeks. See Section 5.1.4, “Server System Variables”.

### B.5.6 Table Definition-Related Issues

#### B.5.6.1 Problems with ALTER TABLE

If you get a duplicate-key error when using ALTER TABLE to change the character set or collation of a character column, the cause is either that the new column collation maps two keys to the same value or that the table is corrupted. In the latter case, you should run REPAIR TABLE on the table.

If ALTER TABLE dies with the following error, the problem may be that MySQL crashed during an earlier ALTER TABLE operation and there is an old table named A-xxx or B-xxx lying around:

```text
Error on rename of './database/name.frm' to './database/B-xxx.frm' (Errcode: 17)
```

In this case, go to the MySQL data directory and delete all files that have names starting with A- or B-.
(You may want to move them elsewhere instead of deleting them.)
**ALTER TABLE** works in the following way:

- Create a new table named `A-xxx` with the requested structural changes.
- Copy all rows from the original table to `A-xxx`.
- Rename the original table to `B-xxx`.
- Rename `A-xxx` to your original table name.
- Delete `B-xxx`.

If something goes wrong with the renaming operation, MySQL tries to undo the changes. If something goes seriously wrong (although this shouldn’t happen), MySQL may leave the old table as `B-xxx`. A simple rename of the table files at the system level should get your data back.

If you use **ALTER TABLE** on a transactional table or if you are using Windows or OS/2, **ALTER TABLE** unlocks the table if you had done a **LOCK TABLE** on it. This is done because InnoDB and these operating systems cannot drop a table that is in use.

### B.5.6.2 TEMPORARY Table Problems

The following list indicates limitations on the use of **TEMPORARY** tables:

- A **TEMPORARY** table can only be of type **MEMORY, MyISAM, MERGE,** or **InnoDB**.

  Temporary tables are not supported for MySQL Cluster.

- You cannot refer to a **TEMPORARY** table more than once in the same query. For example, the following does not work:

  ```
  mysql> SELECT * FROM temp_table, temp_table AS t2;
  ERROR 1137: Can't reopen table: 'temp_table'
  ```

  This error also occurs if you refer to a temporary table multiple times in a stored function under different aliases, even if the references occur in different statements within the function.

- The **SHOW TABLES** statement does not list **TEMPORARY** tables.

- You cannot use **RENAME** to rename a **TEMPORARY** table. However, you can use **ALTER TABLE** instead:

  ```
  mysql> ALTER TABLE orig_name RENAME new_name;
  ```

- There are known issues in using temporary tables with replication. See Section 16.4.1, “Replication Features and Issues”, for more information.

### B.5.7 Known Issues in MySQL

This section lists known issues in recent versions of MySQL.

For information about platform-specific issues, see the installation and porting instructions in Section 2.20, “Operating System-Specific Notes”, and Section 21.3, “Debugging and Porting MySQL”.

The following problems are known:

- Subquery optimization for **IN** is not as effective as for **=**.

- Even if you use `lower_case_table_names=2` (which enables MySQL to remember the case used for databases and table names), MySQL does not remember the case used for database names for the function **DATABASE()** or within the various logs (on case-insensitive systems).
Known Issues in MySQL

- Dropping a `FOREIGN KEY` constraint does not work in replication because the constraint may have another name on the slave.

- `REPLACE` (and `LOAD DATA` with the `REPLACE` option) does not trigger `ON DELETE CASCADE`.

- `DISTINCT` with `ORDER BY` does not work inside `GROUP_CONCAT()` if you do not use all and only those columns that are in the `DISTINCT` list.

- If one user has a long-running transaction and another user drops a table that is updated in the transaction, there is small chance that the binary log may contain the `DROP TABLE` statement before the table is used in the transaction itself.

- When inserting a big integer value (between $2^{63}$ and $2^{64} - 1$) into a decimal or string column, it is inserted as a negative value because the number is evaluated in a signed integer context.

- `FLUSH TABLES WITH READ LOCK` does not block `COMMIT` if the server is running without binary logging, which may cause a problem (of consistency between tables) when doing a full backup.

- `ANALYZE TABLE` on a `BDB` table may in some cases make the table unusable until you restart `mysqld`. If this happens, look for errors of the following form in the MySQL error file:

  001207 22:07:56  bdb:  log_flush: LSN past current end-of-log

- Do not execute `ALTER TABLE` on a `BDB` table on which you are running multiple-statement transactions until all those transactions complete. (The transaction might be ignored.)

- `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` may cause problems on tables for which you are using `INSERT DELAYED`.

- Performing `LOCK TABLE ...` and `FLUSH TABLES ...` does not guarantee that there isn’t a half-finished transaction in progress on the table.

- `BDB` tables are relatively slow to open. If you have many `BDB` tables in a database, it takes a long time to use the `mysql` client on the database if you are not using the `-A` option or if you are using `rehash`. This is especially noticeable when you have a large table cache.

- Replication uses query-level logging: The master writes the executed queries to the binary log. This is a very fast, compact, and efficient logging method that works perfectly in most cases.

  It is possible for the data on the master and slave to become different if a query is designed in such a way that the data modification is nondeterministic (generally not a recommended practice, even outside of replication).

  For example:

  - `CREATE TABLE ... SELECT` or `INSERT ... SELECT` statements that insert zero or `NULL` values into an `AUTO_INCREMENT` column.

  - `DELETE` if you are deleting rows from a table that has foreign keys with `ON DELETE CASCADE` properties.

  - `REPLACE ... SELECT`, `INSERT IGNORE ... SELECT` if you have duplicate key values in the inserted data.

  If and only if the preceding queries have no `ORDER BY` clause guaranteeing a deterministic order.

  For example, for `INSERT ... SELECT` with no `ORDER BY`, the `SELECT` may return rows in a different order (which results in a row having different ranks, hence getting a different number in the `AUTO_INCREMENT` column), depending on the choices made by the optimizers on the master and slave.
A query is optimized differently on the master and slave only if:

- The table is stored using a different storage engine on the master than on the slave. (It is possible to use different storage engines on the master and slave. For example, you can use InnoDB on the master, but MyISAM on the slave if the slave has less available disk space.)

- MySQL buffer sizes (key_buffer_size, and so on) are different on the master and slave.

- The master and slave run different MySQL versions, and the optimizer code differs between these versions.

This problem may also affect database restoration using mysqlbinlog|mysql.

The easiest way to avoid this problem is to add an ORDER BY clause to the aforementioned nondeterministic queries to ensure that the rows are always stored or modified in the same order.

- Log file names are based on the server host name if you do not specify a file name with the startup option. To retain the same log file names if you change your host name to something else, you must explicitly use options such as \(--log-bin=old_host_name\)-bin. Alternatively, rename the old files to reflect your host name change. If these are binary logs, you must edit the binary log index file and fix the binary log file names there as well. (The same is true for the relay logs on a slave server.)

- mysqlbinlog does not delete temporary files left after a LOAD DATA INFILE statement. See Section 4.6.7, "mysqlbinlog — Utility for Processing Binary Log Files".

- RENAME does not work with TEMPORARY tables or tables used in a MERGE table.

- Due to the way table format (.frm) files are stored, you cannot use character 255 (CHAR(255)) in table names, column names, or enumerations.

- When using SET CHARACTER SET, you cannot use translated characters in database, table, and column names.

- You cannot use "-_" or "%" with ESCAPE in LIKE ... ESCAPE.

- The server uses only the first max_sort_length bytes when comparing data values. This means that values cannot reliably be used in GROUP BY, ORDER BY, or DISTINCT if they differ only after the first max_sort_length bytes. To work around this, increase the variable value. The default value of max_sort_length is 1024 and can be changed at server startup time or at runtime.

- Numeric calculations are done with BIGINT or DOUBLE (both are normally 64 bits long). Which precision you get depends on the function. The general rule is that bit functions are performed with BIGINT precision, IF() and ELT() with BIGINT or DOUBLE precision, and the rest with DOUBLE precision. You should try to avoid using unsigned long long values if they resolve to be larger than 63 bits (9223372036854775807) for anything other than bit fields.

- You can have up to 255 ENUM and SET columns in one table.

- In MIN(), MAX(), and other aggregate functions, MySQL currently compares ENUM and SET columns by their string value rather than by the string's relative position in the set.

- mysqlqd_safe redirects all messages from mysqlqd to the mysqlqd log. One problem with this is that if you execute mysqladmin refresh to close and reopen the log, stdout and stderr are still redirected to the old log. If you use the general query log extensively, you should edit mysqlqd_safe to log to host_name.err instead of host_name.log so that you can easily reclaim the space for the old log by deleting it and executing mysqladmin refresh.

- In an UPDATE statement, columns are updated from left to right. If you refer to an updated column, you get the updated value instead of the original value. For example, the following statement increments KEY by 2, not 1:
Known Issues in MySQL

You can refer to multiple temporary tables in the same query, but you cannot refer to any given temporary table more than once. For example, the following does not work:

```sql
mysql> SELECT * FROM temp_table, temp_table AS t2;
ERROR 1137: Can't reopen table: 'temp_table'
```

The optimizer may handle `DISTINCT` differently when you are using “hidden” columns in a join than when you are not. In a join, hidden columns are counted as part of the result (even if they are not shown), whereas in normal queries, hidden columns do not participate in the `DISTINCT` comparison.

An example of this is:

```sql
SELECT DISTINCT mp3id FROM band_downloads
WHERE userid = 9 ORDER BY id DESC;
```

and

```sql
SELECT DISTINCT band_downloads.mp3id
FROM band_downloads,band_mp3
WHERE band_downloads.userid = 9
AND band_mp3.id = band_downloads.mp3id
ORDER BY band_downloads.id DESC;
```

In the second case, using MySQL Server 3.23.x, you may get two identical rows in the result set (because the values in the hidden `id` column may differ).

Note that this happens only for queries that do not have the `ORDER BY` columns in the result.

- If you execute a `PROCEDURE` on a query that returns an empty set, in some cases the `PROCEDURE` does not transform the columns.
- Creation of a table of type `MERGE` does not check whether the underlying tables are compatible types.
- If you use `ALTER TABLE` to add a `UNIQUE` index to a table used in a `MERGE` table and then add a normal index on the `MERGE` table, the key order is different for the tables if there was an old, non-`UNIQUE` key in the table. This is because `ALTER TABLE` puts `UNIQUE` indexes before normal indexes to be able to detect duplicate keys as early as possible.

The discussion here describes restrictions that apply to the use of MySQL features such as subqueries or views.

C.1 Restrictions on Stored Programs

Some of the restrictions noted here apply to all stored routines; that is, both to stored procedures and stored functions. Some of these restrictions apply to stored functions but not to stored procedures.

The restrictions for stored functions also apply to triggers.

Stored routines cannot contain arbitrary SQL statements. The following statements are not permitted:

- The table-maintenance statements **CHECK TABLE** and **OPTIMIZE TABLE**. This restriction is lifted beginning with MySQL 5.0.17.

- The locking statements **LOCK TABLES** and **UNLOCK TABLES**.

- **ALTER VIEW**. (Before MySQL 5.0.46, this restriction is enforced only for stored functions.)

- **LOAD DATA** and **LOAD TABLE**.

- SQL prepared statements (**PREPARE**, **EXECUTE**, **DEALLOCATE PREPARE**). Implication: You cannot use dynamic SQL within stored routines (where you construct dynamically statements as strings and then execute them). This restriction is lifted as of MySQL 5.0.13 for stored procedures; it still applies to stored functions and triggers.

Generally, statements not permitted in SQL prepared statements are also not permitted in stored programs. For a list of statements supported as prepared statements, see Section 13.5, “SQL Syntax for Prepared Statements”.

- Because local variables are in scope only during stored program execution, references to them are not permitted in prepared statements created within a stored program. Prepared statement scope is the current session, not the stored program, so the statement could be executed after the program ends, at which point the variables would no longer be in scope. For example, **SELECT ... INTO local_var** cannot be used as a prepared statement. This restriction also applies to stored procedure and function parameters. See Section 13.5.1, “PREPARE Syntax”.

- Inserts cannot be delayed. **INSERT DELAYED** syntax is accepted but the statement is handled as a normal **INSERT**.
Restrictions on Stored Programs

- Within stored programs (stored procedures and functions, and triggers), the parser treats `BEGIN [WORK]` as the beginning of a `BEGIN ... END` block. Begin a transaction in this context with `START TRANSACTION` instead.

For stored functions (but not stored procedures), the following additional statements or operations are not permitted:

- Statements that perform explicit or implicit commit or rollback. Support for these statements is not required by the SQL standard, which states that each DBMS vendor may decide whether to permit them.

- Statements that return a result set. This includes `SELECT` statements that do not have an `INTO var_list` clause and other statements such as `SHOW`, `EXPLAIN`, and `CHECK TABLE`. A function can process a result set either with `SELECT ... INTO var_list` or by using a cursor and `FETCH` statements. See Section 13.2.8.1, “SELECT ... INTO Syntax”, and Section 13.6.6, “Cursors”.

- `FLUSH` statements.

- Before MySQL 5.0.10, stored functions created with `CREATE FUNCTION` must not contain references to tables, with limited exceptions. They may include some `SET` statements that contain table references, for example `SET a:= (SELECT MAX(id) FROM t)`, and `SELECT` statements that fetch values directly into variables, for example `SELECT i INTO var1 FROM t`.

- Stored functions cannot be used recursively.

- Within a stored function or trigger, it is not permitted to modify a table that is already being used (for reading or writing) by the statement that invoked the function or trigger.

- If you refer to a temporary table multiple times in a stored function under different aliases, a `Can't reopen table: 'tbl_name'` error occurs, even if the references occur in different statements within the function.

- A stored function acquires table locks before executing, to avoid inconsistency in the binary log due to mismatch of the order in which statements execute and when they appear in the log. Statements that invoke a function are recorded rather than the statements executed within the function. Consequently, stored functions that update the same underlying tables do not execute in parallel. In contrast, stored procedures do not acquire table-level locks. All statements executed within stored procedures are written to the binary log. See Section 18.6, “Binary Logging of Stored Programs”.

Although some restrictions normally apply to stored functions and triggers but not to stored procedures, those restrictions do apply to stored procedures if they are invoked from within a stored function or trigger. For example, if you use `FLUSH` in a stored procedure, that stored procedure cannot be called from a stored function or trigger.

It is possible for the same identifier to be used for a routine parameter, a local variable, and a table column. Also, the same local variable name can be used in nested blocks. For example:

```sql
CREATE PROCEDURE p (i INT)
BEGIN
  DECLARE i INT DEFAULT 0;
  SELECT i FROM t;
BEGIN
  DECLARE i INT DEFAULT 1;
  SELECT i FROM t;
END;
END;
```

In such cases the identifier is ambiguous and the following precedence rules apply:

- A local variable takes precedence over a routine parameter or table column
- A routine parameter takes precedence over a table column
C.2 Restrictions on Server-Side Cursors

Server-side cursors are implemented beginning with the C API in MySQL 5.0.2 using the `mysql_stmt_attr_set()` function. A server-side cursor enables a result set to be generated on the server side, but not transferred to the client except for those rows that the client requests. For example, if a client executes a query but is only interested in the first row, the remaining rows are not transferred.

In MySQL, a server-side cursor is materialized into an internal temporary table. Initially, this is a MEMORY table, but is converted to a MyISAM table when its size exceeds the minimum value of the `max_heap_table_size` and `tmp_table_size` system variables. The same restrictions apply to internal temporary tables created to hold the result set for a cursor as for other uses of internal temporary tables. See Section 8.4.4, “Internal Temporary Table Use in MySQL”. (Beginning with MySQL 5.0.14, the same temporary-table implementation also is used for cursors in stored routines.) One limitation of the implementation is that for a large result set, retrieving its rows through a cursor might be slow.
Restrictions on Subqueries

Cursors are read only; you cannot use a cursor to update rows.

**UPDATE WHERE CURRENT OF** and **DELETE WHERE CURRENT OF** are not implemented, because updatable cursors are not supported.

Cursors are nonholdable (not held open after a commit).

Cursors are asensitive.

Cursors are nonscrollable.

Cursors are not named. The statement handler acts as the cursor ID.

You can have open only a single cursor per prepared statement. If you need several cursors, you must prepare several statements.

You cannot use a cursor for a statement that generates a result set if the statement is not supported in prepared mode. This includes statements such as **CHECK TABLE**, **HANDLER READ**, and **SHOW BINLOG EVENTS**.

### C.3 Restrictions on Subqueries

- In MySQL 5.0 before 5.0.36, if you compare a **NULL** value to a subquery using **ALL**, **ANY**, or **SOME**, and the subquery returns an empty result, the comparison might evaluate to the nonstandard result of **NULL** rather than to **TRUE** or **FALSE**.

- Subquery optimization for **IN** is not as effective as for the **=** operator or for the **IN(value_list)** operator.

  A typical case for poor **IN** subquery performance is when the subquery returns a small number of rows but the outer query returns a large number of rows to be compared to the subquery result.

  The problem is that, for a statement that uses an **IN** subquery, the optimizer rewrites it as a correlated subquery. Consider the following statement that uses an uncorrelated subquery:

  ```sql
  SELECT ... FROM t1 WHERE t1.a IN (SELECT b FROM t2);
  ```

  The optimizer rewrites the statement to a correlated subquery:

  ```sql
  SELECT ... FROM t1 WHERE EXISTS (SELECT 1 FROM t2 WHERE t2.b = t1.a);
  ```

  If the inner and outer queries return \( M \) and \( N \) rows, respectively, the execution time becomes on the order of \( O(M \times N) \), rather than \( O(M + N) \) as it would be for an uncorrelated subquery.

  An implication is that an **IN** subquery can be much slower than a query written using an **IN(value_list)** operator that lists the same values that the subquery would return.

- In general, you cannot modify a table and select from the same table in a subquery. For example, this limitation applies to statements of the following forms:

  ```sql
  DELETE FROM t WHERE ... (SELECT ... FROM t ...);
  UPDATE t ... WHERE col = (SELECT ... FROM t ...);
  {INSERT|REPLACE} INTO t (SELECT ... FROM t ...);
  ```

  Exception: The preceding prohibition does not apply if you are using a subquery for the modified table in the **FROM** clause. Example:

  ```sql
  UPDATE t ... WHERE col = (SELECT * FROM (SELECT ... FROM t...) AS _t ...);
  ```
Restrictions on Subqueries

Here the result from the subquery in the `FROM` clause is stored as a temporary table, so the relevant rows in `t` have already been selected by the time the update to `t` takes place.

- Row comparison operations are only partially supported:
  - For `expr [NOT] IN subquery`, `expr` can be an `n`-tuple (specified using row constructor syntax) and the subquery can return rows of `n`-tuples. The permitted syntax is therefore more specifically expressed as `row_constructor [NOT] IN table_subquery`
  - For `expr op {ALL|ANY|SOME} subquery`, `expr` must be a scalar value and the subquery must be a column subquery; it cannot return multiple-column rows.

In other words, for a subquery that returns rows of `n`-tuples, this is supported:

```
(expr_i, ..., expr_n) [NOT] IN table_subquery
```

But this is not supported:

```
(expr_i, ..., expr_n) op {ALL|ANY|SOME} subquery
```

The reason for supporting row comparisons for `IN` but not for the others is that `IN` is implemented by rewriting it as a sequence of `=` comparisons and `AND` operations. This approach cannot be used for `ALL`, `ANY`, or `SOME`.

- Prior to MySQL 5.0.26, row constructors were not well optimized; of the following two equivalent expressions, only the second could be optimized:

  ```
  (col1, col2, ...) = (val1, val2, ...)
  col1 = val1 AND col2 = val2 AND ...
  ```

  In MySQL 5.0.26 and later, all row equalities are converted into conjunctions of equalities between row elements, and handled by the optimizer in the same way. (Bug #16081)

- Subqueries in the `FROM` clause cannot be correlated subqueries. They are materialized in whole (evaluated to produce a result set) before evaluating the outer query, so they cannot be evaluated per row of the outer query.

- MySQL does not support `LIMIT` in subqueries for certain subquery operators:

  ```
  mysql> SELECT * FROM t1
                      -> WHERE s1 IN (SELECT s2 FROM t2 ORDER BY s1 LIMIT 1);
  ERROR 1235 (42000): This version of MySQL doesn't yet support 'LIMIT & IN/ALL/ANY/SOME subquery'
  ```

- The optimizer is more mature for joins than for subqueries, so in many cases a statement that uses a subquery can be executed more efficiently if you rewrite it as a join.

  An exception occurs for the case where an `IN` subquery can be rewritten as a `SELECT DISTINCT` join. Example:

  ```
  SELECT col FROM t1 WHERE id_col IN (SELECT id_col2 FROM t2 WHERE condition);
  ```

  That statement can be rewritten as follows:

  ```
  SELECT DISTINCT col FROM t1, t2 WHERE t1.id_col = t2.id_col AND condition;
  ```

  But in this case, the join requires an extra `DISTINCT` operation and is not more efficient than the subquery.
• MySQL permits a subquery to refer to a stored function that has data-modifying side effects such as inserting rows into a table. For example, if \( f() \) inserts rows, the following query can modify data:

```sql
SELECT ... WHERE x IN (SELECT f() ...);
```

This behavior is an extension to the SQL standard. In MySQL, it can produce indeterminate results because \( f() \) might be executed a different number of times for different executions of a given query depending on how the optimizer chooses to handle it.

For replication, one implication of this indeterminism is that such a query can produce different results on the master and its slaves.

### C.4 Restrictions on Views

View processing is not optimized:

• It is not possible to create an index on a view.

• Indexes can be used for views processed using the merge algorithm. However, a view that is processed with the temptable algorithm is unable to take advantage of indexes on its underlying tables (although indexes can be used during generation of the temporary tables).

Subqueries cannot be used in the `FROM` clause of a view.

There is a general principle that you cannot modify a table and select from the same table in a subquery. See Section C.3, “Restrictions on Subqueries”.

The same principle also applies if you select from a view that selects from the table, if the view selects from the table in a subquery and the view is evaluated using the merge algorithm. Example:

```sql
CREATE VIEW v AS
SELECT * FROM t2 WHERE EXISTS (SELECT 1 FROM t1 WHERE t1.a = t2.a);
UPDATE t1, v2 SET t1.a = 1 WHERE t1.b = v2.b;
```

If the view is evaluated using a temporary table, you can select from the table in the view subquery and still modify that table in the outer query. In this case the view will be stored in a temporary table and thus you are not really selecting from the table in a subquery and modifying it “at the same time.” (This is another reason you might wish to force MySQL to use the temptable algorithm by specifying `ALGORITHM = TEMPTABLE` in the view definition.)

You can use `DROP TABLE` or `ALTER TABLE` to drop or alter a table that is used in a view definition. No warning results from the `DROP` or `ALTER` operation, even though this invalidates the view. Instead, an error occurs later, when the view is used. `CHECK TABLE` can be used to check for views that have been invalidated by `DROP` or `ALTER` operations.

A view definition is “frozen” by certain statements:

• If a statement prepared by `PREPARE` refers to a view, the view definition seen each time the statement is executed later will be the definition of the view at the time it was prepared. This is true even if the view definition is changed after the statement is prepared and before it is executed. Example:

```sql
CREATE VIEW v AS SELECT RAND();
PREPARE s FROM 'SELECT * FROM v';
ALTER VIEW v AS SELECT NOW();
EXECUTE s;
```

The result returned by the `EXECUTE` statement is a random number, not the current date and time.
• If a statement in a stored routine refers to a view, the view definition seen by the statement are its
definition the first time that statement is executed. For example, this means that if the statement
is executed in a loop, further iterations of the statement see the same view definition, even if the
definition is changed later in the loop. Example:

```sql
CREATE VIEW v AS SELECT 1;
delimiter //
CREATE PROCEDURE p ()
BEGIN
    DECLARE i INT DEFAULT 0;
    WHILE i < 5 DO
        SELECT * FROM v;
        SET i = i + 1;
        ALTER VIEW v AS SELECT 2;
    END WHILE;
END;
//
delimiter ;
CALL p();
```

When the procedure `p()` is called, the `SELECT` returns 1 each time through the loop, even though
the view definition is changed within the loop.

As of MySQL 5.0.46, `ALTER VIEW` is prohibited within stored routines, so this restriction does not
apply.

With regard to view updatability, the overall goal for views is that if any view is theoretically updatable,
it should be updatable in practice. This includes views that have `UNION` in their definition. Not all views
that are theoretically updatable can be updated. The initial view implementation was deliberately
written this way to get usable, updatable views into MySQL as quickly as possible. Many theoretically
updatable views can be updated now, but limitations still exist:

• Updatable views with subqueries anywhere other than in the `WHERE` clause. Some views that have
  subqueries in the `SELECT` list may be updatable.

• You cannot use `UPDATE` to update more than one underlying table of a view that is defined as a join.

• You cannot use `DELETE` to update a view that is defined as a join.

There exists a shortcoming with the current implementation of views. If a user is granted the basic
privileges necessary to create a view (the `CREATE VIEW` and `SELECT` privileges), that user will be
unable to call `SHOW CREATE VIEW` on that object unless the user is also granted the `SHOW VIEW`
privilege.

That shortcoming can lead to problems backing up a database with `mysqldump`, which may fail due to
insufficient privileges. This problem is described in Bug #22062.

The workaround to the problem is for the administrator to manually grant the `SHOW VIEW` privilege to
users who are granted `CREATE VIEW`, since MySQL doesn't grant it implicitly when views are created.

Views do not have indexes, so index hints do not apply. Use of index hints when selecting from a view
is not permitted.

`SHOW CREATE VIEW` displays view definitions using an `AS alias_name` clause for each column.
If a column is created from an expression, the default alias is the expression text, which can be quite
long. As of MySQL 5.0.52, aliases for column names in `CREATE VIEW` statements are checked against
the maximum column length of 64 characters (not the maximum alias length of 256 characters). As
a result, views created from the output of `SHOW CREATE VIEW` fail if any column alias exceeds 64
characters. This can cause problems in the following circumstances for views with too-long aliases:

• View definitions fail to replicate to newer slaves that enforce the column-length restriction.
Restrictions on XA Transactions

- Dump files created with `mysqldump` cannot be loaded into servers that enforce the column-length restriction.

A workaround for either problem is to modify each problematic view definition to use aliases that provide shorter column names. Then the view will replicate properly, and can be dumped and reloaded without causing an error. To modify the definition, drop and create the view again with `DROP VIEW` and `CREATE VIEW`, or replace the definition with `CREATE OR REPLACE VIEW`.

For problems that occur when reloading view definitions in dump files, another workaround is to edit the dump file to modify its `CREATE VIEW` statements. However, this does not change the original view definitions, which may cause problems for subsequent dump operations.

C.5 Restrictions on XA Transactions

XA transaction support is limited to the InnoDB storage engine.

For “external XA,” a MySQL server acts as a Resource Manager and client programs act as Transaction Managers. For “internal XA,” storage engines within a MySQL server act as RMs, and the server itself acts as a TM. Internal XA support is limited by the capabilities of individual storage engines. Internal XA is required for handling XA transactions that involve more than one storage engine. The implementation of internal XA requires that a storage engine support two-phase commit at the table handler level, and currently this is true only for InnoDB.

For `XA START`, the `JOIN` and `RESUME` clauses are not supported.

For `XA END`, the `SUSPEND [FOR MIGRATE]` clause is not supported.

The requirement that the `bqual` part of the `xid` value be different for each XA transaction within a global transaction is a limitation of the current MySQL XA implementation. It is not part of the XA specification.

If an XA transaction has reached the `PREPARED` state and the MySQL server is killed (for example, with `kill -9` on Unix) or shuts down abnormally, the transaction can be continued after the server restarts. However, if the client reconnects and commits the transaction, the transaction will be absent from the binary log even though it has been committed. This means the data and the binary log have gone out of synchrony. An implication is that XA cannot be used safely together with replication.

It is possible that the server will roll back a pending XA transaction, even one that has reached the `PREPARED` state. This happens if a client connection terminates and the server continues to run, or if clients are connected and the server shuts down gracefully. (In the latter case, the server marks each connection to be terminated, and then rolls back the `PREPARED` XA transaction associated with it.) It should be possible to commit or roll back a `PREPARED` XA transaction, but this cannot be done without changes to the binary logging mechanism.

C.6 Restrictions on Character Sets

- Identifiers are stored in `mysql` database tables (user, db, and so forth) using `utf8`, but identifiers can contain only characters in the Basic Multilingual Plane (BMP). Supplementary characters are not permitted in identifiers.

- The `ucs2` character sets has the following restrictions:
  - It cannot be used as a client character set, which means that it does not work for `SET NAMES` or `SET CHARACTER SET`. (See Section 10.1.4, “Connection Character Sets and Collations”.)
  - It is currently not possible to use `LOAD DATA INFILE` to load data files that use this character set.
  - `FULLTEXT` indexes cannot be created on a column that this character set. However, you can perform `IN BOOLEAN MODE` searches on the column without an index.
• The `REGEXP` and `RLIKE` operators work in byte-wise fashion, so they are not multibyte safe and may produce unexpected results with multibyte character sets. In addition, these operators compare characters by their byte values and accented characters may not compare as equal even if a given collation treats them as equal.

C.7 Limits in MySQL

This section lists current limits in MySQL 5.0.

C.7.1 Limits on Joins

The maximum number of tables that can be referenced in a single join is 61. This also applies to the number of tables that can be referenced in the definition of a view.

C.7.2 Limits on Number of Databases and Tables

MySQL has no limit on the number of databases. The underlying file system may have a limit on the number of directories.

MySQL has no limit on the number of databases. The underlying file system may have a limit on the number of tables. Individual storage engines may impose engine-specific constraints. `InnoDB` permits up to 4 billion tables.

C.7.3 Limits on Table Size

The effective maximum table size for MySQL databases is usually determined by operating system constraints on file sizes, not by MySQL internal limits. The following table lists some examples of operating system file-size limits. This is only a rough guide and is not intended to be definitive. For the most up-to-date information, be sure to check the documentation specific to your operating system.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>File-size Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Win32 w/ FAT/FAT32</td>
<td>2GB/4GB</td>
</tr>
<tr>
<td>Win32 w/ NTFS</td>
<td>2TB (possibly larger)</td>
</tr>
<tr>
<td>Linux 2.2-Intel 32-bit</td>
<td>2GB (LFS: 4GB)</td>
</tr>
<tr>
<td>Linux 2.4+</td>
<td>(using ext3 file system) 4TB</td>
</tr>
<tr>
<td>Solaris 9/10</td>
<td>16TB</td>
</tr>
<tr>
<td>MacOS X w/ HFS+</td>
<td>2TB</td>
</tr>
<tr>
<td>NetWare w/NSS file system</td>
<td>8TB</td>
</tr>
</tbody>
</table>

Windows users, please note that FAT and VFAT (FAT32) are not considered suitable for production use with MySQL. Use NTFS instead.

On Linux 2.2, you can get `MyISAM` tables larger than 2GB in size by using the Large File Support (LFS) patch for the ext2 file system. Most current Linux distributions are based on kernel 2.4 or higher and include all the required LFS patches. On Linux 2.4, patches also exist for ReiserFS to get support for big files (up to 2TB). With JFS and XFS, petabyte and larger files are possible on Linux.

For a detailed overview about LFS in Linux, have a look at Andreas Jaeger's Large File Support in Linux page at http://www.suse.de/~aj/linux_lfs.html.

If you do encounter a full-table error, there are several reasons why it might have occurred:

• The disk might be full.
The InnoDB storage engine maintains InnoDB tables within a tablespace that can be created from several files. This enables a table to exceed the maximum individual file size. The tablespace can include raw disk partitions, which permits extremely large tables. The maximum tablespace size is 64TB.

If you are using InnoDB tables and run out of room in the InnoDB tablespace. In this case, the solution is to extend the InnoDB tablespace. See Section 14.2.4, “Changing the Number or Size of InnoDB Redo Log Files”.

You are using MyISAM tables on an operating system that supports files only up to 2GB in size and you have hit this limit for the data file or index file.

You are using a MyISAM table and the space required for the table exceeds what is permitted by the internal pointer size. MyISAM creates data and index table files to permit up to 4GB by default (256TB as of MySQL 5.0.6), but this limit can be changed up to the maximum permissible size of 65,536TB (256^7 – 1 bytes).

If you need a MyISAM table that is larger than the default limit and your operating system supports large files, the CREATE TABLE statement supports AVG_ROW_LENGTH and MAX_ROWS options. See Section 13.1.10, “CREATE TABLE Syntax”. The server uses these options to determine how large a table to permit.

If the pointer size is too small for an existing table, you can change the options with ALTER TABLE to increase a table's maximum permissible size. See Section 13.1.4, “ALTER TABLE Syntax”.

```
ALTER TABLE tbl_name MAX_ROWS=1000000000 AVG_ROW_LENGTH=nnn;
```

You have to specify AVG_ROW_LENGTH only for tables with BLOB or TEXT columns; in this case, MySQL can’t optimize the space required based only on the number of rows.

To change the default size limit for MyISAM tables, set the myisam_data_pointer_size, which sets the number of bytes used for internal row pointers. The value is used to set the pointer size for new tables if you do not specify the MAX_ROWS option. The value of myisam_data_pointer_size can be from 2 to 7. A value of 4 permits tables up to 4GB; a value of 6 permits tables up to 256TB.

You can check the maximum data and index sizes by using this statement:

```
SHOW TABLE STATUS FROM db_name LIKE 'tbl_name';
```

You also can use myisampack -dv /path/to/table-index-file. See Section 13.7.5, “SHOW Syntax”, or Section 4.6.5, “myisampack — Generate Compressed, Read-Only MyISAM Tables”.

Other ways to work around file-size limits for MyISAM tables are as follows:

- If your large table is read only, you can use myisampack to compress it. myisampack usually compresses a table by at least 50%, so you can have, in effect, much bigger tables. myisampack also can merge multiple tables into a single table. See Section 4.6.5, “myisampack — Generate Compressed, Read-Only MyISAM Tables”.

- MySQL includes a MERGE library that enables you to handle a collection of MyISAM tables that have identical structure as a single MERGE table. See Section 14.3, “The MERGE Storage Engine”.

- You are using the NDB storage engine, in which case you need to increase the values for the DataMemory and IndexMemory configuration parameters in your config.ini file. See Section 17.3.2.1, “MySQL Cluster Data Node Configuration Parameters”.

- You are using the MEMORY (HEAP) storage engine; in this case you need to increase the value of the max_heap_table_size system variable. See Section 5.1.4, “Server System Variables”.

C.7.4 Limits on Table Column Count and Row Size
There is a hard limit of 4096 columns per table, but the effective maximum may be less for a given table. The exact limit depends on several interacting factors.

- Every table (regardless of storage engine) has a maximum row size of 65,535 bytes. Storage engines may place additional constraints on this limit, reducing the effective maximum row size.

The maximum row size constrains the number (and possibly size) of columns because the total length of all columns cannot exceed this size. For example, utf8 characters require up to three bytes per character, so for a `CHAR(255) CHARACTER SET utf8` column, the server must allocate $255 \times 3 = 765$ bytes per value. Consequently, a table cannot contain more than $65,535 / 765 = 85$ such columns.

Storage for variable-length columns includes length bytes, which are assessed against the row size. For example, a `VARCHAR(255) CHARACTER SET utf8` column takes two bytes to store the length of the value, so each value can take up to 767 bytes.

BLOB and TEXT columns count from one to four plus eight bytes each toward the row-size limit because their contents are stored separately from the rest of the row.

Declaring columns NULL can reduce the maximum number of columns permitted. For MyISAM tables, NULL columns require additional space in the row to record whether their values are NULL. Each NULL column takes one bit extra, rounded up to the nearest byte. The maximum row length in bytes can be calculated as follows:

\[
\text{row length} = 1 + (\text{sum of column lengths}) + (\text{number of NULL columns} + \text{delete_flag} + 7)/8 + (\text{number of variable-length columns})
\]

\(\text{delete_flag}\) is 1 for tables with static row format. Static tables use a bit in the row record for a flag that indicates whether the row has been deleted. \(\text{delete_flag}\) is 0 for dynamic tables because the flag is stored in the dynamic row header. For information about MyISAM table formats, see Section 14.1.3, "MyISAM Table Storage Formats".

For InnoDB tables, storage size is the same for NULL and NOT NULL columns, so the preceding calculations do not apply.

The following statement to create table \(t1\) succeeds because the columns require 32,765 + 2 bytes and 32,766 + 2 bytes, which falls within the maximum row size of 65,535 bytes:

mysql> CREATE TABLE t1
    \-> (c1 VARCHAR(32765) NOT NULL, c2 VARCHAR(32766) NOT NULL)
    \-> ENGINE = MyISAM CHARACTER SET latin1;
Query OK, 0 rows affected (0.02 sec)

The following statement to create table \(t2\) fails because the columns are NULL and MyISAM requires additional space that causes the row size to exceed 65,535 bytes:

mysql> CREATE TABLE t2
    \-> (c1 VARCHAR(32765) NULL, c2 VARCHAR(32766) NULL)
    \-> ENGINE = MyISAM CHARACTER SET latin1;
ERROR 1118 (42000): Row size too large. The maximum row size for the used table type, not counting BLOBs, is 65535. You have to change some columns to TEXT or BLOBS

The following statement to create table \(t3\) fails because, although the column length is within the maximum length of 65,535 bytes, two additional bytes are required to record the length, which causes the row size to exceed 65,535 bytes:
Limits Imposed by .frm File Structure

Each table has an .frm file that contains the table definition. The server uses the following expression to check some of the table information stored in the file against an upper limit of 64KB:

```sql
if (info_length+(ulong) create_fields.elements*FCOMP+288+ n_length+int_length+com_length > 65535L || int_count > 255)
```

The portion of the information stored in the .frm file that is checked against the expression cannot grow beyond the 64KB limit, so if the table definition reaches this size, no more columns can be added.

The relevant factors in the expression are:

- **info_length** is space needed for “screens.” This is related to MySQL’s Unireg heritage.
- **create_fields.elements** is the number of columns.
- **FCOMP** is 17.
- **n_length** is the total length of all column names, including one byte per name as a separator.
- **int_length** is related to the list of values for **ENUM** and **SET** columns. In this context, “int” does not mean “integer.” It means “interval,” a term that refers collectively to **ENUM** and **SET** columns.
- **int_count** is the number of unique **ENUM** and **SET** definitions.
- **com_length** is the total length of column comments.

The expression just described has several implications for permitted table definitions:

- Using long column names can reduce the maximum number of columns, as can the inclusion of **ENUM** or **SET** columns, or use of column comments.

- A table can have no more than 255 unique **ENUM** and **SET** definitions. Columns with identical element lists are considered the same against this limit. For example, if a table contains these two columns, they count as one (not two) toward this limit because the definitions are identical:

```sql
e1 ENUM('a','b','c')
```
Windows Platform Limitations

The following limitations apply to use of MySQL on the Windows platform:

- **Number of file descriptors**
  The number of open file descriptors on Windows is limited to a maximum of 2048, which may limit the ability to open a large number of tables simultaneously. This limit is due not to Windows but to C runtime library compatibility functions used to open files on Windows that use the POSIX compatibility layer.

  This limitation will also cause problems if you try to set `open_files_limit` to a value greater than the 2048 file limit.

- **Process memory**
  On Windows 32-bit platforms it is not possible by default to use more than 2GB of RAM within a single process, including MySQL. This is because the physical address limit on Windows 32-bit is 4GB and the default setting within Windows is to split the virtual address space between kernel (2GB) and user/applications (2GB).

  Some versions of Windows have a boot time setting to enable larger applications by reducing the kernel application. Alternatively, to use more than 2GB, use a 64-bit version of Windows.

- **File system aliases**
  When using MyISAM tables, you cannot use aliases within Windows link to the data files on another volume and then link back to the main MySQL `datadir` location.

  This facility is often used to move the data and index files to a RAID or other fast solution, while retaining the main `.frm` files in the default data directory configured with the `datadir` option.

- **Limited number of ports**
  Windows systems have about 4,000 ports available for client connections, and after a connection on a port closes, it takes two to four minutes before the port can be reused. In situations where clients connect to and disconnect from the server at a high rate, it is possible for all available ports to be used up before closed ports become available again. If this happens, the MySQL server appears to be unresponsive even though it is running. Ports may be used by other applications running on the machine as well, in which case the number of ports available to MySQL is lower.

  For more information about this problem, see [http://support.microsoft.com/default.aspx?scid=kb;en-us;196271](http://support.microsoft.com/default.aspx?scid=kb;en-us;196271).

- **Concurrent reads**
  MySQL depends on the `pread()` and `pwrite()` system calls to be able to mix `INSERT` and `SELECT`. We use mutexes to emulate `pread()` and `pwrite()`. We intend to replace the file level interface with a virtual interface in the future so that we can use the `readfile()`/`writefile()` interface to get more speed. The current implementation limits the number of open files that MySQL 5.0 can use to 2,048, which means that you cannot run as many concurrent threads on Windows as on Unix.

  This problem is fixed in MySQL 5.5.

- **Blocking read**
MySQL uses a blocking read for each connection. That has the following implications if named-pipe connections are enabled:

- A connection is not disconnected automatically after eight hours, as happens with the Unix version of MySQL.
- If a connection hangs, it is not possible to break it without killing MySQL.
- `mysqladmin kill` does not work on a sleeping connection.
- `mysqladmin shutdown` cannot abort as long as there are sleeping connections.

These problems are fixed in MySQL 5.1. (Bug #31621)

### ALTER TABLE

While you are executing an `ALTER TABLE` statement, the table is locked from being used by other threads. This has to do with the fact that on Windows, you can't delete a file that is in use by another thread. In the future, we may find some way to work around this problem.

### DROP TABLE

`DROP TABLE` on a table that is in use by a MERGE table does not work on Windows because the MERGE handler does the table mapping hidden from the upper layer of MySQL. Because Windows does not permit dropping files that are open, you first must flush all MERGE tables (with `FLUSH TABLES`) or drop the MERGE table before dropping the table.

### DATA DIRECTORY and INDEX DIRECTORY

The `DATA DIRECTORY` and `INDEX DIRECTORY` options for `CREATE TABLE` are ignored on Windows, because MySQL does not support Windows symbolic links. These options also are ignored on systems that have a nonfunctional `realpath()` call.

### DROP DATABASE

You cannot drop a database that is in use by another session.

### Case-insensitive names

File names are not case sensitive on Windows, so MySQL database and table names are also not case sensitive on Windows. The only restriction is that database and table names must be specified using the same case throughout a given statement. See Section 9.2.2, "Identifier Case Sensitivity".

### Directory and file names

On Windows, MySQL Server supports only directory and file names that are compatible with the current ANSI code pages. For example, the following Japanese directory name will not work in the Western locale (code page 1252):

```plaintext
datadir="C:/私たちのプロジェクトのデータ"
```

The same limitation applies to directory and file names referred to in SQL statements, such as the data file path name in `LOAD DATA INFILE`.

### The “\” path name separator character

Path name components in Windows are separated by the “\” character, which is also the escape character in MySQL. If you are using `LOAD DATA INFILE` or `SELECT ... INTO OUTFILE`, use Unix-style file names with “/” characters:
Windows Platform Limitations

mysql> LOAD DATA INFILE 'C:/tmp/skr.txt' INTO TABLE skr;
mysql> SELECT * INTO OUTFILE 'C:/tmp/skr.txt' FROM skr;

Alternatively, you must double the "\" character:

mysql> LOAD DATA INFILE 'C:\tmp\skr.txt' INTO TABLE skr;
mysql> SELECT * INTO OUTFILE 'C:\tmp\skr.txt' FROM skr;

- Problems with pipes

Pipes do not work reliably from the Windows command-line prompt. If the pipe includes the character ^Z/CHAR(24), Windows thinks that it has encountered end-of-file and aborts the program.

This is mainly a problem when you try to apply a binary log as follows:

shell> mysqlbinlog binary_log_file | mysql --user=root

If you have a problem applying the log and suspect that it is because of a ^Z/CHAR(24) character, you can use the following workaround:

shell> mysqlbinlog binary_log_file --result-file=/tmp/bin.sql
shell> mysql --user=root --execute "source /tmp/bin.sql"

The latter command also can be used to reliably read in any SQL file that may contain binary data.
