1435
MySQL supports several storage engines that act as handlers for different table types. MySQL storage engines include both those that handle transaction-safe tables and those that handle nontransaction-safe tables.

As of MySQL 5.1, MySQL Server uses a pluggable storage engine architecture that enables storage engines to be loaded into and unloaded from a running MySQL server.

**Note**
Prior to MySQL 5.1.38, the pluggable storage engine architecture is supported on Unix platforms only and pluggable storage engines are not supported on Windows.

To determine which storage engines your server supports by using the `SHOW ENGINES` statement. The value in the **Support** column indicates whether an engine can be used. A value of **YES**, **NO**, or **DEFAULT** indicates that an engine is available, not available, or available and currently set as the default storage engine.

```
mysql> SHOW ENGINES\G
*************************** 1. row ***************************
    Engine: FEDERATED
    Support: NO
    Comment: Federated MySQL storage engine
    Transactions: NULL
    XA: NULL
    Savepoints: NULL
*************************** 2. row ***************************
    Engine: MRG_MYISAM
    Support: YES
    Comment: Collection of identical MyISAM tables
    Transactions: NO
    XA: NO
    Savepoints: NO
*************************** 3. row ***************************
    Engine: MyISAM
    Support: DEFAULT
    Comment: Default engine as of MySQL 3.23 with great performance
    Transactions: NO
    XA: NO
    Savepoints: NO
...
```

This chapter describes each of the MySQL storage engines except for **NDBCLUSTER**, which is covered in Chapter 17, *MySQL Cluster NDB 6.1 - 7.1*. It also contains a description of the pluggable storage engine architecture (see Section 14.4, “Overview of MySQL Storage Engine Architecture”).

For information about storage engine support offered in commercial MySQL Server binaries, see *MySQL Enterprise Server 5.1*, on the MySQL Web site. The storage engines available might depend on which edition of Enterprise Server you are using.

For answers to some commonly asked questions about MySQL storage engines, see Section A.2, “MySQL 5.1 FAQ: Storage Engines”.

**MySQL 5.1 supported storage engines**

- **MyISAM**: The default MySQL storage engine and the one that is used the most in Web, data warehousing, and other application environments. **MyISAM** is supported in all MySQL configurations, and is the default storage engine unless you have configured MySQL to use a different one by default.

- **InnoDB**: A transaction-safe (ACID compliant) storage engine for MySQL that has commit, rollback, and crash-recovery capabilities to protect user data. **InnoDB** row-level locking (without escalation to coarser granularity locks) and Oracle-style consistent nonlocking reads increase multi-user concurrency and performance. **InnoDB** stores user data in clustered indexes to reduce I/O for
common queries based on primary keys. To maintain data integrity, InnoDB also supports FOREIGN KEY referential-integrity constraints.

- **Memory**: Stores all data in RAM for extremely fast access in environments that require quick lookups of reference and other like data. This engine was formerly known as the HEAP engine.

- **Merge**: Enables a MySQL DBA or developer to logically group a series of identical MyISAM tables and reference them as one object. Good for VLDB environments such as data warehousing.

- **Archive**: Provides the perfect solution for storing and retrieving large amounts of seldom-referenced historical, archived, or security audit information.

- **Federated**: Offers the ability to link separate MySQL servers to create one logical database from many physical servers. Very good for distributed or data mart environments.

- **NDB (also known as NDBCLUSTER)**—This clustered database engine is particularly suited for applications that require the highest possible degree of uptime and availability.

**Note**

The NDB storage engine is not supported in standard MySQL 5.1 releases. Currently supported MySQL Cluster releases include MySQL Cluster NDB 7.0 and MySQL Cluster NDB 7.1, which are based on MySQL 5.1, and MySQL Cluster NDB 7.2, which is based on MySQL 5.5. While based on MySQL Server, these releases also contain support for NDB.

- **CSV**: The CSV storage engine stores data in text files using comma-separated values format. You can use the CSV engine to easily exchange data between other software and applications that can import and export in CSV format.

- **Blackhole**: The Blackhole storage engine accepts but does not store data and retrievals always return an empty set. The functionality can be used in distributed database design where data is automatically replicated, but not stored locally.

- **Example**: The Example storage engine is “stub” engine that does nothing. You can create tables with this engine, but no data can be stored in them or retrieved from them. The purpose of this engine is to serve as an example in the MySQL source code that illustrates how to begin writing new storage engines. As such, it is primarily of interest to developers.

It is important to remember that you are not restricted to using the same storage engine for an entire server or schema: you can use a different storage engine for each table in your schema.

**Choosing a Storage Engine**

The various storage engines provided with MySQL are designed with different use cases in mind. To use the pluggable storage architecture effectively, it is good to have an idea of the advantages and disadvantages of the various storage engines. The following table provides an overview of some storage engines provided with MySQL:

<sup>a</sup>InnoDB support for geospatial indexing is available in MySQL 5.7.5 and higher.
<sup>b</sup>InnoDB utilizes hash indexes internally for its Adaptive Hash Index feature.
<sup>c</sup>InnoDB support for FULLTEXT indexes is available in MySQL 5.6.4 and higher.
<sup>d</sup>Compressed MyISAM tables are supported only when using the compressed row format. Tables using the compressed row format with MyISAM are read only.
<sup>e</sup>Compressed InnoDB tables require the InnoDB Barracuda file format.
<sup>f</sup>Implemented in the server (via encryption functions). Data-at-rest tablespace encryption is available in MySQL 5.7 and higher.
<sup>g</sup>Implemented in the server, rather than in the storage engine.
<sup>h</sup>Implemented in the server, rather than in the storage engine.
14.1 Comparing Transaction and Nontransaction Engines

Transaction-safe tables (TSTs) have several advantages over nontransaction-safe tables (NTSTs):

- They are safer. Even if MySQL crashes or you get hardware problems, you can get your data back, either by automatic recovery or from a backup plus the transaction log.

- You can combine many statements and accept them all at the same time with the \texttt{COMMIT} statement (if autocommit is disabled).

- You can execute \texttt{ROLLBACK} to ignore your changes (if autocommit is disabled).

- If an update fails, all of your changes are reverted. (With nontransaction-safe tables, all changes that have taken place are permanent.)

- Transaction-safe storage engines can provide better concurrency for tables that get many updates concurrently with reads.

You can combine transaction-safe and nontransaction-safe tables in the same statements to get the best of both worlds. However, although MySQL supports several transaction-safe storage engines, for best results, you should not mix different storage engines within a transaction with autocommit disabled. For example, if you do this, changes to nontransaction-safe tables still are committed immediately and cannot be rolled back. For information about this and other problems that can occur in transactions that use mixed storage engines, see Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”.

Nontransaction-safe tables have several advantages of their own, all of which occur because there is no transaction overhead:

- Much faster

- Lower disk space requirements

- Less memory required to perform updates

14.2 Other Storage Engines

Other storage engines may be available from third parties and community members that have used the Custom Storage Engine interface.

Third party engines are not supported by MySQL. For further information, documentation, installation guides, bug reporting or for any help or assistance with these engines, please contact the developer of the engine directly.

For more information on developing a customer storage engine that can be used with the Pluggable Storage Engine Architecture, see MySQL Internals: Writing a Custom Storage Engine.

14.3 Setting the Storage Engine

When you create a new table, you can specify which storage engine to use by adding an \texttt{ENGINE} table option to the \texttt{CREATE TABLE} statement:

\begin{verbatim}
CREATE TABLE t (i INT) ENGINE = INNODB;
\end{verbatim}

If you omit the \texttt{ENGINE} option, the default storage engine is used. Normally, this is \texttt{MyISAM}, but you can change it by using the \texttt{--default-storage-engine} server startup option, or by setting the \texttt{default-storage-engine} option in the \texttt{my.cnf} configuration file.

You can set the default storage engine to be used during the current session by setting the \texttt{storage_engine} variable:
When MySQL is installed on Windows using the MySQL Configuration Wizard, the InnoDB or MyISAM storage engine can be selected as the default. See Section 2.3.5.5, "MySQL Server Instance Config Wizard: The Database Usage Dialog".

To convert a table from one storage engine to another, use an ALTER TABLE statement that indicates the new engine:

```
ALTER TABLE t ENGINE = MYISAM;
```

See Section 13.1.17, "CREATE TABLE Syntax", and Section 13.1.7, "ALTER TABLE Syntax".

If you try to use a storage engine that is not compiled in or that is compiled in but deactivated, MySQL instead creates a table using the default storage engine. This behavior is convenient when you want to copy tables between MySQL servers that support different storage engines. (For example, in a replication setup, perhaps your master server supports transactional storage engines for increased safety, but the slave servers use only nontransactional storage engines for greater speed.)

This automatic substitution of the default storage engine for unavailable engines can be confusing for new MySQL users. A warning is generated whenever a storage engine is automatically changed. To prevent this from happening if the desired engine is unavailable, enable the NO_ENGINE_SUBSTITUTION SQL mode. In this case, an error occurs instead of a warning and the table is not created or altered if the desired engine is unavailable. See Section 5.1.7, "Server SQL Modes".

For new tables, MySQL always creates an .frm file to hold the table and column definitions. The table's index and data may be stored in one or more other files, depending on the storage engine. The server creates the .frm file above the storage engine level. Individual storage engines create any additional files required for the tables that they manage. If a table name contains special characters, the names for the table files contain encoded versions of those characters as described in Section 9.2.3, "Mapping of Identifiers to File Names".

A database may contain tables of different types. That is, tables need not all be created with the same storage engine.

### 14.4 Overview of MySQL Storage Engine Architecture

The MySQL pluggable storage engine architecture enables a database professional to select a specialized storage engine for a particular application need while being completely shielded from the need to manage any specific application coding requirements. The MySQL server architecture isolates the application programmer and DBA from all of the low-level implementation details at the storage level, providing a consistent and easy application model and API. Thus, although there are different capabilities across different storage engines, the application is shielded from these differences.

The pluggable storage engine architecture provides a standard set of management and support services that are common among all underlying storage engines. The storage engines themselves are the components of the database server that actually perform actions on the underlying data that is maintained at the physical server level.

This efficient and modular architecture provides huge benefits for those wishing to specifically target a particular application need—such as data warehousing, transaction processing, or high availability situations—while enjoying the advantage of utilizing a set of interfaces and services that are independent of any one storage engine.

The application programmer and DBA interact with the MySQL database through Connector APIs and service layers that are above the storage engines. If application changes bring about requirements that demand the underlying storage engine change, or that one or more storage engines be added to support new needs, no significant coding or process changes are required to make things work. The
MySQL server architecture shields the application from the underlying complexity of the storage engine by presenting a consistent and easy-to-use API that applies across storage engines.

14.4.1 Pluggable Storage Engine Architecture

As of MySQL 5.1, MySQL Server uses a pluggable storage engine architecture that enables storage engines to be loaded into and unloaded from a running MySQL server.

**Note**

Prior to MySQL 5.1.38, the pluggable storage engine architecture is supported on Unix platforms only and pluggable storage engines are not supported on Windows.

**Plugging in a Storage Engine**

Before a storage engine can be used, the storage engine plugin shared library must be loaded into MySQL using the `INSTALL PLUGIN` statement. For example, if the `EXAMPLE` engine plugin is named `example` and the shared library is named `ha_example.so`, you load it with the following statement:

```
mysql> INSTALL PLUGIN example SONAME 'ha_example.so';
```

To install a pluggable storage engine, the plugin file must be located in the MySQL plugin directory, and the user issuing the `INSTALL PLUGIN` statement must have `INSERT` privilege for the `mysql.plugin` table.

The shared library must be located in the MySQL server plugin directory, the location of which is given by the `plugin_dir` system variable.

**Unplugging a Storage Engine**

To unplug a storage engine, use the `UNINSTALL PLUGIN` statement:

```
mysql> UNINSTALL PLUGIN example;
```

If you unplug a storage engine that is needed by existing tables, those tables become inaccessible, but will still be present on disk (where applicable). Ensure that there are no tables using a storage engine before you unplug the storage engine.

14.4.2 The Common Database Server Layer

A MySQL pluggable storage engine is the component in the MySQL database server that is responsible for performing the actual data I/O operations for a database as well as enabling and enforcing certain feature sets that target a specific application need. A major benefit of using specific storage engines is that you are only delivered the features needed for a particular application, and therefore you have less system overhead in the database, with the end result being more efficient and higher database performance. This is one of the reasons that MySQL has always been known to have such high performance, matching or beating proprietary monolithic databases in industry standard benchmarks.

From a technical perspective, what are some of the unique supporting infrastructure components that are in a storage engine? Some of the key feature differentiations include:

- **Concurrency**: Some applications have more granular lock requirements (such as row-level locks) than others. Choosing the right locking strategy can reduce overhead and therefore improve overall performance. This area also includes support for capabilities such as multi-version concurrency control or “snapshot” read.

- **Transaction Support**: Not every application needs transactions, but for those that do, there are very well defined requirements such as ACID compliance and more.
• **Referential Integrity**: The need to have the server enforce relational database referential integrity through DDL defined foreign keys.

• **Physical Storage**: This involves everything from the overall page size for tables and indexes as well as the format used for storing data to physical disk.

• **Index Support**: Different application scenarios tend to benefit from different index strategies. Each storage engine generally has its own indexing methods, although some (such as B-tree indexes) are common to nearly all engines.

• **Memory Caches**: Different applications respond better to some memory caching strategies than others, so although some memory caches are common to all storage engines (such as those used for user connections or MySQL’s high-speed Query Cache), others are uniquely defined only when a particular storage engine is put in play.

• **Performance Aids**: This includes multiple I/O threads for parallel operations, thread concurrency, database checkpointing, bulk insert handling, and more.

• **Miscellaneous Target Features**: This may include support for geospatial operations, security restrictions for certain data manipulation operations, and other similar features.

Each set of the pluggable storage engine infrastructure components are designed to offer a selective set of benefits for a particular application. Conversely, avoiding a set of component features helps reduce unnecessary overhead. It stands to reason that understanding a particular application's set of requirements and selecting the proper MySQL storage engine can have a dramatic impact on overall system efficiency and performance.

### 14.5 The MyISAM Storage Engine

**MyISAM** is the default storage engine. It is based on the older (and no longer available) ISAM storage engine but has many useful extensions.

#### Table 14.2 MyISAM Storage Engine Features

</table>

*a* Compressed MyISAM tables are supported only when using the compressed row format. Tables using the compressed row format with MyISAM are read only.

*b* Implemented in the server (via encryption functions). Data-at-rest tablespace encryption is available in MySQL 5.7 and higher.

*c* Implemented in the server, rather than in the storage engine.

*d* Implemented in the server, rather than in the storage engine.

Each **MyISAM** table is stored on disk in three files. The files have names that begin with the table name and have an extension to indicate the file type. An **.frm** file stores the table format. The data file has an **.MYD (MYData)** extension. The index file has an **.MYI (MYIndex)** extension.

To specify explicitly that you want a **MyISAM** table, indicate that with an **ENGINE** table option:

```
CREATE TABLE t (i INT) ENGINE = MYISAM;
```
Normally, it is unnecessary to use `ENGINE` to specify the `MyISAM` storage engine. `MyISAM` is the default engine unless the default has been changed. To ensure that `MyISAM` is used in situations where the default might have been changed, include the `ENGINE` option explicitly.

You can check or repair `MyISAM` tables with the `mysqlcheck` client or `myisamchk` utility. You can also compress `MyISAM` tables with `myisampack` to take up much less space. See Section 4.5.3, "mysqlcheck — A Table Maintenance Program", Section 4.6.3, "myisamchk — MyISAM Table-Maintenance Utility", and Section 4.6.5, "myisampack — Generate Compressed, Read-Only MyISAM Tables".

`MyISAM` tables have the following characteristics:

- All data values are stored with the low byte first. This makes the data machine and operating system independent. The only requirements for binary portability are that the machine uses two's-complement signed integers and IEEE floating-point format. These requirements are widely used among mainstream machines. Binary compatibility might not be applicable to embedded systems, which sometimes have peculiar processors.

  There is no significant speed penalty for storing data low byte first; the bytes in a table row normally are unaligned and it takes little more processing to read an unaligned byte in order than in reverse order. Also, the code in the server that fetches column values is not time critical compared to other code.

- All numeric key values are stored with the high byte first to permit better index compression.

- Large files (up to 63-bit file length) are supported on file systems and operating systems that support large files.

- There is a limit of $2^{32}$ (~4.295E+09) rows in a `MyISAM` table. If you build MySQL with the `--with-big-tables` option, the row limitation is increased to $(2^{32} \cdot 2)$ (1.844E+19) rows. See Section 2.11.4, "MySQL Source-Configuration Options". Binary distributions for Unix and Linux are built with this option.

- The maximum number of indexes per `MyISAM` table is 64. This can be changed by recompiling. Beginning with MySQL 5.1.4, you can configure the build by invoking `configure` with the `--with-max-indexes=N` option, where `N` is the maximum number of indexes to permit per `MyISAM` table. `N` must be less than or equal to 128. Before MySQL 5.1.4, you must change the source.

  The maximum number of columns per index is 16.

- The maximum key length is 1000 bytes. This can also be changed by changing the source and recompiling. For the case of a key longer than 250 bytes, a larger key block size than the default of 1024 bytes is used.

- When rows are inserted in sorted order (as when you are using an `AUTO_INCREMENT` column), the index tree is split so that the high node only contains one key. This improves space utilization in the index tree.

- Internal handling of one `AUTO_INCREMENT` column per table is supported. `MyISAM` automatically updates this column for `INSERT` and `UPDATE` operations. This makes `AUTO_INCREMENT` columns faster (at least 10%). Values at the top of the sequence are not reused after being deleted. (When an `AUTO_INCREMENT` column is defined as the last column of a multiple-column index, reuse of values deleted from the top of a sequence does occur.) The `AUTO_INCREMENT` value can be reset with `ALTER TABLE` or `myisamchk`.

- Dynamic-sized rows are much less fragmented when mixing deletes with updates and inserts. This is done by automatically combining adjacent deleted blocks and by extending blocks if the next block is deleted.

- `MyISAM` supports concurrent inserts: If a table has no free blocks in the middle of the data file, you can `INSERT` new rows into it at the same time that other threads are reading from the table. A
A free block can occur as a result of deleting rows or an update of a dynamic length row with more data than its current contents. When all free blocks are used up (filled in), future inserts become concurrent again. See Section 8.11.3, “Concurrent Inserts”.

- You can put the data file and index file in different directories on different physical devices to get more speed with the DATA DIRECTORY and INDEX DIRECTORY table options to CREATE TABLE. See Section 13.1.17, “CREATE TABLE Syntax”.

- BLOB and TEXT columns can be indexed.

- NULL values are permitted in indexed columns. This takes 0 to 1 bytes per key.

- Each character column can have a different character set. See Section 10.1, “Character Set Support”.

- There is a flag in the MyISAM index file that indicates whether the table was closed correctly. If mysqld is started with the --myisam-recover option, MyISAM tables are automatically checked when opened, and are repaired if the table wasn’t closed properly.

- myisamchk marks tables as checked if you run it with the --update-state option. myisamchk --fast checks only those tables that don’t have this mark.

- myisamchk --analyze stores statistics for portions of keys, as well as for entire keys.

- myisampack can pack BLOB and VARCHAR columns.

MyISAM also supports the following features:

- Support for a true VARCHAR type; a VARCHAR column starts with a length stored in one or two bytes.

- Tables with VARCHAR columns may have fixed or dynamic row length.

- The sum of the lengths of the VARCHAR and CHAR columns in a table may be up to 64KB.

- Arbitrary length UNIQUE constraints.

</table>

- **--myisam-recover=mode**
  Set the mode for automatic recovery of crashed MyISAM tables.

- **--delay-key-write=ALL**
  Don't flush key buffers between writes for any MyISAM table.

**Note**
If you do this, you should not access MyISAM tables from another program (such as from another MySQL server or with myisamchk) when the tables are in use. Doing so risks index corruption. Using **--external-locking** does not eliminate this risk.

The following system variables affect the behavior of MyISAM tables. For additional information, see Section 5.1.4, “Server System Variables”.

- **bulk_insert_buffer_size**
  The size of the tree cache used in bulk insert optimization.

**Note**
This is a limit per thread!

- **myisam_max_sort_file_size**
  The maximum size of the temporary file that MySQL is permitted to use while re-creating a MyISAM index (during REPAIR TABLE, ALTER TABLE, or LOAD DATA INFILE). If the file size would be larger than this value, the index is created using the key cache instead, which is slower. The value is given in bytes.

- **myisam_sort_buffer_size**
  Set the size of the buffer used when recovering tables.

Automatic recovery is activated if you start mysqld with the **--myisam-recover** option. In this case, when the server opens a MyISAM table, it checks whether the table is marked as crashed or whether
the open count variable for the table is not 0 and you are running the server with external locking
disabled. If either of these conditions is true, the following happens:

- The server checks the table for errors.

- If the server finds an error, it tries to do a fast table repair (with sorting and without re-creating the
data file).

- If the repair fails because of an error in the data file (for example, a duplicate-key error), the server
tries again, this time re-creating the data file.

- If the repair still fails, the server tries once more with the old repair option method (write row by row
without sorting). This method should be able to repair any type of error and has low disk space
requirements.

If the recovery wouldn’t be able to recover all rows from previously completed statements and you
didn’t specify FORCE in the value of the --myisam-recover option, automatic repair aborts with an
error message in the error log:

Error: Couldn't repair table: test.g00pages

If you specify FORCE, a warning like this is written instead:

Warning: Found 344 of 354 rows when repairing ./test/g00pages

If the automatic recovery value includes BACKUP, the recovery process creates files with names of the
form tbl_name-datetime.BAK. You should have a cron script that automatically moves these files
from the database directories to backup media.

14.5.2 Space Needed for Keys

MyISAM tables use B-tree indexes. You can roughly calculate the size for the index file as

\[(key_length+4)/0.67\]

summed over all keys. This is for the worst case when all keys are inserted
in sorted order and the table doesn’t have any compressed keys.

String indexes are space compressed. If the first index part is a string, it is also prefix compressed.
Space compression makes the index file smaller than the worst-case figure if a string column has a lot
of trailing space or is a VARCHAR column that is not always used to the full length. Prefix compression
is used on keys that start with a string. Prefix compression helps if there are many strings with an
identical prefix.

In MyISAM tables, you can also prefix compress numbers by specifying the PACK_KEYS=1 table option
when you create the table. Numbers are stored with the high byte first, so this helps when you have
many integer keys that have an identical prefix.

14.5.3 MyISAM Table Storage Formats

MyISAM supports three different storage formats. Two of them, fixed and dynamic format, are chosen
automatically depending on the type of columns you are using. The third, compressed format, can be
created only with the myisampack utility (see Section 4.6.5, "myisampack — Generate Compressed,
Read-Only MyISAM Tables").

When you use CREATE TABLE or ALTER TABLE for a table that has no BLOB or TEXT columns, you
can force the table format to FIXED or DYNAMIC with the ROW_FORMAT table option.

See Section 13.1.17, “CREATE TABLE Syntax”, for information about ROW_FORMAT.

You can decompress (unpack) compressed MyISAM tables using myisamchk --unpack; see
Section 4.6.3, "myisamchk — MyISAM Table-Maintenance Utility", for more information.
14.5.3.1 Static (Fixed-Length) Table Characteristics

Static format is the default for MyISAM tables. It is used when the table contains no variable-length columns (VARCHAR, VARBINARY, BLOB, or TEXT). Each row is stored using a fixed number of bytes.

Of the three MyISAM storage formats, static format is the simplest and most secure (least subject to corruption). It is also the fastest of the on-disk formats due to the ease with which rows in the data file can be found on disk: To look up a row based on a row number in the index, multiply the row number by the row length to calculate the row position. Also, when scanning a table, it is very easy to read a constant number of rows with each disk read operation.

The security is evidenced if your computer crashes while the MySQL server is writing to a fixed-format MyISAM file. In this case, myisamchk can easily determine where each row starts and ends, so it can usually reclaim all rows except the partially written one. MyISAM table indexes can always be reconstructed based on the data rows.

Note

Fixed-length row format is only available for tables without BLOB or TEXT columns. Creating a table with these columns with an explicit ROW_FORMAT clause will not raise an error or warning; the format specification will be ignored.

Static-format tables have these characteristics:

• CHAR and VARCHAR columns are space-padded to the specified column width, although the column type is not altered. BINARY and VARBINARY columns are padded with 0x00 bytes to the column width.

• Very quick.

• Easy to cache.

• Easy to reconstruct after a crash, because rows are located in fixed positions.

• Reorganization is unnecessary unless you delete a huge number of rows and want to return free disk space to the operating system. To do this, use OPTIMIZE TABLE or myisamchk -r.

• Usually require more disk space than dynamic-format tables.

14.5.3.2 Dynamic Table Characteristics

Dynamic storage format is used if a MyISAM table contains any variable-length columns (VARCHAR, VARBINARY, BLOB, or TEXT), or if the table was created with the ROW_FORMAT=DYNAMIC table option.

Dynamic format is a little more complex than static format because each row has a header that indicates how long it is. A row can become fragmented (stored in noncontiguous pieces) when it is made longer as a result of an update.

You can use OPTIMIZE TABLE or myisamchk -r to defragment a table. If you have fixed-length columns that you access or change frequently in a table that also contains some variable-length columns, it might be a good idea to move the variable-length columns to other tables just to avoid fragmentation.

Dynamic-format tables have these characteristics:

• All string columns are dynamic except those with a length less than four.

• Each row is preceded by a bitmap that indicates which columns contain the empty string (for string columns) or zero (for numeric columns). This does not include columns that contain NULL values. If a string column has a length of zero after trailing space removal, or a numeric column has a value of
zero, it is marked in the bitmap and not saved to disk. Nonempty strings are saved as a length byte plus the string contents.

- Much less disk space usually is required than for fixed-length tables.
- Each row uses only as much space as is required. However, if a row becomes larger, it is split into as many pieces as are required, resulting in row fragmentation. For example, if you update a row with information that extends the row length, the row becomes fragmented. In this case, you may have to run `OPTIMIZE TABLE` or `myisamchk -r` from time to time to improve performance. Use `myisamchk -ei` to obtain table statistics.
- More difficult than static-format tables to reconstruct after a crash, because rows may be fragmented into many pieces and links (fragments) may be missing.
- The expected row length for dynamic-sized rows is calculated using the following expression:

```latex
3 + (number of columns + 7) / 8
+ (number of char columns)
+ (packed size of numeric columns)
+ (length of strings)
+ (number of NULL columns + 7) / 8
```

There is a penalty of 6 bytes for each link. A dynamic row is linked whenever an update causes an enlargement of the row. Each new link is at least 20 bytes, so the next enlargement probably goes in the same link. If not, another link is created. You can find the number of links using `myisamchk -ed`. All links may be removed with `OPTIMIZE TABLE` or `myisamchk -r`.

### 14.5.3.3 Compressed Table Characteristics

Compressed storage format is a read-only format that is generated with the `mysampack` tool. Compressed tables can be uncompressed with `myisamchk`.

Compressed tables have the following characteristics:

- Compressed tables take very little disk space. This minimizes disk usage, which is helpful when using slow disks (such as CD-ROMs).
- Each row is compressed separately, so there is very little access overhead. The header for a row takes up one to three bytes depending on the biggest row in the table. Each column is compressed differently. There is usually a different Huffman tree for each column. Some of the compression types are:
  - Suffix space compression.
  - Prefix space compression.
  - Numbers with a value of zero are stored using one bit.
  - If values in an integer column have a small range, the column is stored using the smallest possible type. For example, a `BIGINT` column (eight bytes) can be stored as a `TINYINT` column (one byte) if all its values are in the range from `−128` to `127`.
  - If a column has only a small set of possible values, the data type is converted to `ENUM`.
  - A column may use any combination of the preceding compression types.
  - Can be used for fixed-length or dynamic-length rows.

**Note**

While a compressed table is read only, and you cannot therefore update or add rows in the table, DDL (Data Definition Language) operations are still valid. For
example, you may still use `DROP` to drop the table, and `TRUNCATE TABLE` to empty the table.

14.5.4 MyISAM Table Problems

The file format that MySQL uses to store data has been extensively tested, but there are always circumstances that may cause database tables to become corrupted. The following discussion describes how this can happen and how to handle it.

14.5.4.1 Corrupted MyISAM Tables

Even though the MyISAM table format is very reliable (all changes to a table made by an SQL statement are written before the statement returns), you can still get corrupted tables if any of the following events occur:

- The `mysqld` process is killed in the middle of a write.
- An unexpected computer shutdown occurs (for example, the computer is turned off).
- Hardware failures.
- You are using an external program (such as `myisamchk`) to modify a table that is being modified by the server at the same time.
- A software bug in the MySQL or MyISAM code.

Typical symptoms of a corrupt table are:

- You get the following error while selecting data from the table:
  ```
  Incorrect key file for table: '...'. Try to repair it
  ```
- Queries don't find rows in the table or return incomplete results.

You can check the health of a MyISAM table using the `CHECK TABLE` statement, and repair a corrupted MyISAM table with `REPAIR TABLE`. When `mysqld` is not running, you can also check or repair a table with the `myisamchk` command. See Section 13.7.2.3, “CHECK TABLE Syntax”, Section 13.7.2.6, “REPAIR TABLE Syntax”, and Section 4.6.3, “`myisamchk` — MyISAM Table-Maintenance Utility”.

If your tables become corrupted frequently, you should try to determine why this is happening. The most important thing to know is whether the table became corrupted as a result of a server crash. You can verify this easily by looking for a recent restarted `mysqld` message in the error log. If there is such a message, it is likely that table corruption is a result of the server dying. Otherwise, corruption may have occurred during normal operation. This is a bug. You should try to create a reproducible test case that demonstrates the problem. See Section B.5.3.3, “What to Do If MySQL Keeps Crashing”, and Section 22.4, “Debugging and Porting MySQL”.

14.5.4.2 Problems from Tables Not Being Closed Properly

Each MyISAM index file (`.MYI` file) has a counter in the header that can be used to check whether a table has been closed properly. If you get the following warning from `CHECK TABLE` or `myisamchk`, it means that this counter has gone out of sync:

```
clients are using or haven't closed the table properly
```

This warning doesn't necessarily mean that the table is corrupted, but you should at least check the table.
The counter works as follows:

- The first time a table is updated in MySQL, a counter in the header of the index files is incremented.
- The counter is not changed during further updates.
- When the last instance of a table is closed (because a `FLUSH TABLES` operation was performed or because there is no room in the table cache), the counter is decremented if the table has been updated at any point.
- When you repair the table or check the table and it is found to be okay, the counter is reset to zero.
- To avoid problems with interaction with other processes that might check the table, the counter is not decremented on close if it was zero.

In other words, the counter can become incorrect only under these conditions:

- A MyISAM table is copied without first issuing `LOCK TABLES` and `FLUSH TABLES`.
- MySQL has crashed between an update and the final close. (The table may still be okay because MySQL always issues writes for everything between each statement.)
- A table was modified by `myisamchk --recover` or `myisamchk --update-state` at the same time that it was in use by `mysqld`.
- Multiple `mysqld` servers are using the table and one server performed a `REPAIR TABLE` or `CHECK TABLE` on the table while it was in use by another server. In this setup, it is safe to use `CHECK TABLE`, although you might get the warning from other servers. However, `REPAIR TABLE` should be avoided because when one server replaces the data file with a new one, this is not known to the other servers.

In general, it is a bad idea to share a data directory among multiple servers. See Section 5.5, “Running Multiple MySQL Instances on One Machine”, for additional discussion.

14.6 The InnoDB Storage Engine

14.6.1 Introduction to InnoDB

Key Advantages of InnoDB

InnoDB is a high-reliability and high-performance storage engine for MySQL. Key advantages of InnoDB include:

- Its design follows the ACID model, with transactions featuring commit, rollback, and crash-recovery capabilities to protect user data.
- Row-level locking (without escalation to coarser granularity locks) and Oracle-style consistent reads increase multi-user concurrency and performance.
- InnoDB tables arrange your data on disk to optimize common queries based on primary keys. Each InnoDB table has a primary key index called the clustered index that organizes the data to minimize I/O for primary key lookups.
- To maintain data integrity, InnoDB also supports FOREIGN KEY referential-integrity constraints.
- You can freely mix InnoDB tables with tables from other MySQL storage engines, even within the same statement. For example, you can use a join operation to combine data from InnoDB and MEMORY tables in a single query.
- InnoDB has been designed for CPU efficiency and maximum performance when processing large data volumes.
Introduction to InnoDB

To determine whether your server supports InnoDB use the `SHOW ENGINES` statement. See Section 13.7.5.17, “SHOW ENGINES Syntax”.

</tr>
</tbody>
</table>

<sup>a</sup> InnoDB support for geospatial indexing is available in MySQL 5.7.5 and higher.

<sup>b</sup> InnoDB utilizes hash indexes internally for its Adaptive Hash Index feature.

<sup>c</sup> InnoDB support for FULLTEXT indexes is available in MySQL 5.6.4 and higher.

<sup>d</sup> Compressed InnoDB tables require the InnoDB Barracuda file format.

<sup>e</sup> Implemented in the server (via encryption functions). Data-at-rest tablespace encryption is available in MySQL 5.7 and higher.

<sup>f</sup> Implemented in the server, rather than in the storage engine.

<sup>g</sup> Implemented in the server, rather than in the storage engine.

The InnoDB storage engine maintains its own buffer pool for caching data and indexes in main memory. InnoDB stores its tables and indexes in a tablespace, which may consist of several files (or raw disk partitions). This is different from, for example, MyISAM tables where each table is stored using separate files. InnoDB tables can be very large even on operating systems where file size is limited to 2GB.

The Windows Essentials installer makes InnoDB the MySQL default storage engine on Windows, if the server being installed supports InnoDB.

To compare the features of InnoDB with other storage engines provided with MySQL, see the Storage Engine Features table in Chapter 14, Storage Engines.

### The InnoDB Plugin for MySQL

- At the 2008 MySQL User Conference, Innobase announced availability of an InnoDB Plugin for MySQL. This plugin for MySQL exploits the “pluggable storage engine” architecture of MySQL, to permit users to replace the “built-in” version of InnoDB in MySQL 5.1.

- As of MySQL 5.1.38, the InnoDB Plugin is included in MySQL 5.1 releases, in addition to the built-in version of InnoDB that has been included in previous releases. MySQL 5.1.42 through 5.1.45 include InnoDB Plugin 1.0.6, which is considered of Release Candidate (RC) quality. MySQL 5.1.46 and up include InnoDB Plugin 1.0.7 or higher, which is considered of General Availability (GA) quality.

- Prior to MySQL Cluster NDB 7.1.11, MySQL Cluster was not compatible with the InnoDB Plugin.

- The InnoDB Plugin offers new features, improved performance and scalability, enhanced reliability and new capabilities for flexibility and ease of use. Among the features of the InnoDB Plugin are “Fast index creation,” table and index compression, file format management, new INFORMATION_SCHEMA tables, capacity tuning, multiple background I/O threads, and group commit.

- The InnoDB Plugin is included in source and binary distributions, except RHEL3, RHEL4, SuSE 9 (x86, x86_64, ia64), and generic Linux RPM packages.
• For instructions on replacing the built-in version of InnoDB with InnoDB Plugin, see Section 14.6.2.1, “Using InnoDB Plugin Instead of the Built-In InnoDB”.

MySQL Enterprise Backup and InnoDB

The MySQL Enterprise Backup product lets you back up a running MySQL database, including InnoDB and MyISAM tables, with minimal disruption to operations while producing a consistent snapshot of the database. When MySQL Enterprise Backup is copying InnoDB tables, reads and writes to both InnoDB and MyISAM tables can continue. During the copying of MyISAM and other non-InnoDB tables, reads (but not writes) to those tables are permitted. In addition, MySQL Enterprise Backup can create compressed backup files, and back up subsets of InnoDB tables. In conjunction with the MySQL binary log, you can perform point-in-time recovery. MySQL Enterprise Backup is included as part of the MySQL Enterprise subscription.

For a more complete description of MySQL Enterprise Backup, see Section 23.2, “MySQL Enterprise Backup Overview”.

Additional Resources

• For InnoDB-related terms and definitions, see MySQL Glossary.

• A forum dedicated to the InnoDB storage engine is available here: MySQL Forums::InnoDB.

• InnoDB is published under the same GNU GPL License Version 2 (of June 1991) as MySQL. For more information on MySQL licensing, see http://www.mysql.com/company/legal/licensing/.

14.6.2 InnoDB Configuration

The first decisions to make about InnoDB configuration involve how to lay out InnoDB data files, and how much memory to allocate for the InnoDB storage engine. You record these choices either by recording them in a configuration file that MySQL reads at startup, or by specifying them as command-line options in a startup script. The full list of options, descriptions, and allowed parameter values is at Section 14.6.8, “InnoDB Startup Options and System Variables”.

Overview of InnoDB Tablespace and Log Files

Two important disk-based resources managed by the InnoDB storage engine are its tablespace data files and its log files. If you specify no InnoDB configuration options, MySQL creates an auto-extending data file, slightly larger than 10MB, named ibdata1 and two log files named ib_logfile0 and ib_logfile1 in the MySQL data directory. Their size is given by the size of the innodb_log_file_size system variable. To get good performance, explicitly provide InnoDB parameters as discussed in the following examples. Naturally, edit the settings to suit your hardware and requirements.

The examples shown here are representative. See Section 14.6.8, “InnoDB Startup Options and System Variables” for additional information about InnoDB-related configuration parameters.

Considerations for Storage Devices

In some cases, database performance improves if the data is not all placed on the same physical disk. Putting log files on a different disk from data is very often beneficial for performance. The example illustrates how to do this. It places the two data files on different disks and places the log files on the third disk. InnoDB fills the tablespace beginning with the first data file. You can also use raw disk partitions (raw devices) as InnoDB data files, which may speed up I/O. See Section 14.6.5.3, “Using Raw Disk Partitions for the System Tablespace”.

Caution

InnoDB is a transaction-safe (ACID compliant) storage engine for MySQL that has commit, rollback, and crash-recovery capabilities to protect user data.
InnoDB Configuration

However, it cannot do so if the underlying operating system or hardware does not work as advertised. Many operating systems or disk subsystems may delay or reorder write operations to improve performance. On some operating systems, the very \texttt{fsync()} system call that should wait until all unwritten data for a file has been flushed might actually return before the data has been flushed to stable storage. Because of this, an operating system crash or a power outage may destroy recently committed data, or in the worst case, even corrupt the database because of write operations having been reordered. If data integrity is important to you, perform some “pull-the-plug” tests before using anything in production. On OS X 10.3 and higher, InnoDB uses a special \texttt{fcntl()} file flush method. Under Linux, it is advisable to disable the write-back cache.

On ATA/SATA disk drives, a command such \texttt{hdparm -W0 /dev/hda} may work to disable the write-back cache. Beware that some drives or disk controllers may be unable to disable the write-back cache.

With regard to InnoDB recovery capabilities that protect user data, InnoDB uses a file flush technique involving a structure called the doublewrite buffer, which is enabled by default (\texttt{innodb_doublewrite=ON}). The doublewrite buffer adds safety to recovery following a crash or power outage, and improves performance on most varieties of Unix by reducing the need for \texttt{fsync()} operations. It is recommended that the \texttt{innodb_doublewrite} option remains enabled if you are concerned with data integrity or possible failures. For additional information about the doublewrite buffer, see Section 14.6.7, “InnoDB Disk I/O and File Space Management”.

Caution

If reliability is a consideration for your data, do not configure InnoDB to use data files or log files on NFS volumes. Potential problems vary according to OS and version of NFS, and include such issues as lack of protection from conflicting writes, and limitations on maximum file sizes.

Specifying the Location and Size for InnoDB Tablespace Files

To set up the InnoDB tablespace files, use the \texttt{innodb_data_file_path} option in the [mysqld] section of the \texttt{my.cnf} option file. On Windows, you can use \texttt{my.ini} instead. The value of \texttt{innodb_data_file_path} should be a list of one or more data file specifications. If you name more than one data file, separate them by semicolon (“;”) characters:

\begin{verbatim}
innodb_data_file_path=datafile_spec1[,datafile_spec2]...
\end{verbatim}

For example, the following setting explicitly creates a tablespace having the same characteristics as the default:

\begin{verbatim}
[mysqld]
innodb_data_file_path=ibdata1:10M:autoextend
\end{verbatim}

This setting configures a single 10MB data file named \texttt{ibdata1} that is auto-extending. No location for the file is given, so by default, InnoDB creates it in the MySQL data directory.

Sizes are specified using \texttt{K}, \texttt{M}, or \texttt{G} suffix letters to indicate units of KB, MB, or GB.

A tablespace containing a fixed-size 50MB data file named \texttt{ibdata1} and a 50MB auto-extending file named \texttt{ibdata2} in the data directory can be configured like this:

\begin{verbatim}
[mysqld]
innodb_data_file_path=datafile1:50M:autoextend,ibdata2
\end{verbatim}
InnoDB Configuration

InnoDB data file path = ibdata1:50M;ibdata2:50M:autoextend

The full syntax for a data file specification includes the file name, its size, and several optional attributes:

\[
\text{file name:file size[:autoextend[:max:max file size]]}
\]

The autoextend and max attributes can be used only for the last data file in the innodb_data_file_path line.

If you specify the autoextend option for the last data file, InnoDB extends the data file if it runs out of free space in the tablespace. The increment is 8MB at a time by default. To modify the increment, change the innodb_autoextend_increment system variable.

If the disk becomes full, you might want to add another data file on another disk. For tablespace reconfiguration instructions, see Section 14.6.5.1, “Resizing the InnoDB System Tablespace”.

InnoDB is not aware of the file system maximum file size, so be cautious on file systems where the maximum file size is a small value such as 2GB. To specify a maximum size for an auto-extending data file, use the max attribute following the autoextend attribute. Use the max attribute only in cases where constraining disk usage is of critical importance, because exceeding the maximum size causes a fatal error, possibly including a crash. The following configuration permits ibdata1 to grow up to a limit of 500MB:

```
[mysqld]
innodb_data_file_path = ibdata1:10M:autoextend:max:500M
```

InnoDB creates tablespace files in the MySQL data directory by default. To specify a location explicitly, use the innodb_data_home_dir option. For example, to use two files named ibdata1 and ibdata2 but create them in the /ibdata directory, configure InnoDB like this:

```
[mysqld]
innodb_data_home_dir = /ibdata
innodb_data_file_path = ibdata1:50M;ibdata2:50M:autoextend
```

**Note**

InnoDB does not create directories, so make sure that the /ibdata directory exists before you start the server. This is also true of any log file directories that you configure. Use the Unix or DOS mkdir command to create any necessary directories.

Make sure that the MySQL server has the proper access rights to create files in the data directory. More generally, the server must have access rights in any directory where it needs to create data files or log files.

InnoDB forms the directory path for each data file by textually concatenating the value of innodb_data_home_dir to the data file name, adding a path name separator (slash or backslash) between values if necessary. If the innodb_data_home_dir option is not specified in my.cnf at all, the default value is the “dot” directory ./, which means the MySQL data directory. (The MySQL server changes its current working directory to its data directory when it begins executing.)

If you specify innodb_data_home_dir as an empty string, you can specify absolute paths for the data files listed in the innodb_data_file_path value. The following example is equivalent to the preceding one:

```
[mysqld]
innodb_data_home_dir =
```
InnoDB Configuration

Specifying InnoDB Configuration Options

Sample my.cnf file for small systems. Suppose that you have a computer with 512MB RAM and one hard disk. The following example shows possible configuration parameters in my.cnf or my.ini for InnoDB, including the autoextend attribute. The example suits most users, both on Unix and Windows, who do not want to distribute InnoDB data files and log files onto several disks. It creates an auto-extending data file ibdata1 and two InnoDB log files ib_logfile0 and ib_logfile1 in the MySQL data directory.

```
[mysqld]
# You can write your other MySQL server options here
# ...
# Data files must be able to hold your data and indexes.
# Make sure that you have enough free disk space.
innodb_data_file_path = ibdata1:10M:autoextend
# # Set buffer pool size to 50-80% of your computer's memory
innodb_buffer_pool_size=256M
innodb_additional_mem_pool_size=20M
# # Set the log file size to about 25% of the buffer pool size
innodb_log_file_size=64M
innodb_log_buffer_size=8M
# innodb_flush_log_at_trx_commit=1
```

Note that data files must be less than 2GB in some file systems. The combined size of the log files must be less than 4GB. The combined size of data files must be at least slightly larger than 10MB.

Setting Up the InnoDB System Tablespace

When you create an InnoDB system tablespace for the first time, it is best that you start the MySQL server from the command prompt. InnoDB then prints the information about the database creation to the screen, so you can see what is happening. For example, on Windows, if mysqld is located in C:\Program Files\MySQL\MySQL Server 5.1\bin, you can start it like this:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.1\bin\mysqld" --console
```

If you do not send server output to the screen, check the server’s error log to see what InnoDB prints during the startup process.

Editing the MySQL Configuration File

You can place InnoDB options in the [mysqld] group of any option file that your server reads when it starts. The locations for option files are described in Section 4.2.6, “Using Option Files”.

If you installed MySQL on Windows using the installation and configuration wizards, the option file will be the my.ini file located in your MySQL installation directory. See Section 2.3.5.1, “Starting the MySQL Server Instance Config Wizard”.

If your PC uses a boot loader where the C: drive is not the boot drive, your only option is to use the my.ini file in your Windows directory (typically C:\WINDOWS). You can use the SET command at the command prompt in a console window to print the value of WINDIR:

```
C:\> SET WINDIR
windir=C:\WINDOWS
```

To make sure that mysqld reads options only from a specific file, use the --defaults-file option as the first option on the command line when starting the server:
**InnoDB Configuration**

```plaintext
mysqld --defaults-file=your_path_to_my_cnf
```

**Sample my.cnf file for large systems.** Suppose that you have a Linux computer with 2GB RAM and three 60GB hard disks at directory paths `/`, `/dr2` and `/dr3`. The following example shows possible configuration parameters in `my.cnf` for InnoDB.

```
[mysqld]
# You can write your other MySQL server options here
# ...
innodb_data_home_dir =
# Data files must be able to hold your data and indexes
# Set buffer pool size to 50-80% of your computer's memory,
# but make sure on Linux x86 total memory usage is < 2GB
innodb_buffer_pool_size=1G
innodb_additional_mem_pool_size=20M
innodb_log_group_home_dir = /dr3/iblogs
# Set the log file size to about 25% of the buffer pool size
innodb_log_file_size=250M
innodb_log_buffer_size=8M
innodb_flush_log_at_trx_commit=1
innodb_lock_wait_timeout=50
# Uncomment the next line if you want to use it
innodb_thread_concurrency=5
```

**Determining the Maximum Memory Allocation for InnoDB**

**Warning**

On 32-bit GNU/Linux x86, be careful not to set memory usage too high. *glibc* may permit the process heap to grow over thread stacks, which crashes your server. It is a risk if the value of the following expression is close to or exceeds 2GB:

```
innodb_buffer_pool_size
+ key_buffer_size
+ max_connections*(sort_buffer_size+read_buffer_size+binlog_cache_size)
+ max_connections*2MB
```

Each thread uses a stack (often 2MB, but only 256KB in MySQL binaries provided by Oracle Corporation.) and in the worst case also uses `sort_buffer_size + read_buffer_size` additional memory.

**Tuning other mysqld server parameters.** The following values are typical and suit most users:

```
[mysqld]
skip-external-locking
max_connections=200
read_buffer_size=1M
sort_buffer_size=1M
# Set key_buffer to 5 - 50% of your RAM depending on how much
# you use MyISAM tables, but keep key_buffer_size + InnoDB
# buffer pool size < 80% of your RAM
key_buffer_size=value
```

On Linux, if the kernel is enabled for large page support, InnoDB can use large pages to allocate memory for its buffer pool and additional memory pool. See Section 8.12.5.2, "Enabling Large Page Support".
Enabling the InnoDB Plugin

If you want to use InnoDB Plugin rather than the built-in version of InnoDB, to get the latest performance improvements and new features such as table compression and fast index creation, see Section 14.6.2.1, “Using InnoDB Plugin Instead of the Built-In InnoDB”.

Turning Off InnoDB

If you do not want to use InnoDB tables, start the server with the --innodb=OFF or --skip-innodb option to disable the InnoDB storage engine. In this case, the server will not start if the default storage engine is set to InnoDB. Use --default-storage-engine to set the default to some other engine if necessary.

14.6.2.1 Using InnoDB Plugin Instead of the Built-In InnoDB

To use InnoDB Plugin in MySQL 5.1, you must disable the built-in version of InnoDB that is also included and instruct the server to use InnoDB Plugin instead. To accomplish this, use the following lines in your my.cnf file:

```ini
[mysqld]
ignore-builtin-innodb
plugin-load=innodb=ha_innodb_plugin.so
```

For the plugin-load option, innodb is the name to associate with the plugin and ha_innodb_plugin.so is the name of the shared object library that contains the plugin code. The extension of .so applies for Unix (and similar) systems. For HP-UX on HPPA (11.11) or Windows, the extension should be .sl or .dll, respectively, rather than .so.

If the server has problems finding the plugin when it starts up, specify the pathname to the plugin directory. For example, if plugins are located in the lib/mysql/plugin directory under the MySQL installation directory and you have installed MySQL at /usr/local/mysql, use these lines in your my.cnf file:

```ini
[mysqld]
ignore-builtin-innodb
plugin-load=innodb=ha_innodb_plugin.so
plugin_dir=/usr/local/mysql/lib/mysql/plugin
```

The previous examples show how to activate the storage engine part of InnoDB Plugin, but the plugin also implements several InnoDB-related INFORMATION_SCHEMA tables. (For information about these tables, see InnoDB INFORMATION_SCHEMA Tables.) To enable these tables, include additional name=library pairs in the value of the plugin-load option:

```ini
[mysqld]
ignore-builtin-innodb
plugin-load=innodb=ha_innodb_plugin.so
;innodb_trx=ha_innodb_plugin.so
;innodb_locks=ha_innodb_plugin.so
;innodb_lock_waits=ha_innodb_plugin.so
;innodb_cmp=ha_innodb_plugin.so
;innodb_cmp_reset=ha_innodb_plugin.so
;innodb_cmpmem=ha_innodb_plugin.so
;innodb_cmpmem_reset=ha_innodb_plugin.so
```

The plugin-load option value as shown here is formatted on multiple lines for display purposes but should be written in my.cnf using a single line without spaces in the option value. On Windows, substitute .dll for each instance of the .so extension.

After the server starts, verify that InnoDB Plugin has been loaded by using the SHOW PLUGINS statement. For example, if you have loaded the storage engine and the INFORMATION_SCHEMA tables, the output should include lines similar to these:
An alternative to using the plugin-load option at server startup is to use the INSTALL PLUGIN statement at runtime. First start the server with the ignore-built-in-innodb option to disable the built-in version of InnoDB:

```sql
[mysqld]
ignore-built-in-innodb
```

Then issue an INSTALL PLUGIN statement for each plugin that you want to load:

```sql
mysql> INSTALL PLUGIN InnoDB SONAME 'ha_innodb_plugin.so';
mysql> INSTALL PLUGIN INNODB_TRX SONAME 'ha_innodb_plugin.so';
mysql> INSTALL PLUGIN INNODB_LOCKS SONAME 'ha_innodb_plugin.so';
...```

INSTALL PLUGIN need be issued only once for each plugin. Installed plugins will be loaded automatically on subsequent server restarts.

If you build MySQL from a source distribution, InnoDB Plugin is one of the storage engines that is built by default. Build MySQL the way you normally do; for example, by using the instructions at Section 2.11, “Installing MySQL from Source”. After the build completes, you should find the plugin shared object file under the storage/innodb_plugin directory, and make install should install it in the plugin directory. Configure MySQL to use InnoDB Plugin as described earlier for binary distributions.

If you use gcc, InnoDB Plugin cannot be compiled with gcc 3.x; you must use gcc 4.x instead.

**Note**

In MySQL 5.5, the InnoDB Plugin is also included, but it becomes the built-in version of InnoDB in MySQL Server, replacing the version previously included as the built-in InnoDB engine. This means that if you use InnoDB Plugin in MySQL 5.1 using the instructions just given, you will need to remove ignore-built-in-innodb and plugin-load from your startup options after an upgrade to MySQL 5.5 or the server will fail to start.

### 14.6.3 InnoDB Concepts and Architecture

#### 14.6.3.1 InnoDB Multi-Versioning

InnoDB is a multi-versioned storage engine: it keeps information about old versions of changed rows, to support transactional features such as concurrency and rollback. This information is stored in the tablespace in a data structure called a rollback segment (after an analogous data structure in Oracle). InnoDB uses the information in the rollback segment to perform the undo operations needed in a transaction rollback. It also uses the information to build earlier versions of a row for a consistent read.

Internally, InnoDB adds three fields to each row stored in the database. A 6-byte DB_TRX_ID field indicates the transaction identifier for the last transaction that inserted or updated the row. Also, a
deletion is treated internally as an update where a special bit in the row is set to mark it as deleted. Each row also contains a 7-byte `DB_ROLL_PTR` field called the roll pointer. The roll pointer points to an undo log record written to the rollback segment. If the row was updated, the undo log record contains the information necessary to rebuild the content of the row before it was updated. A 6-byte `DB_ROW_ID` field contains a row ID that increases monotonically as new rows are inserted. If InnoDB generates a clustered index automatically, the index contains row ID values. Otherwise, the `DB_ROW_ID` column does not appear in any index.

Undo logs in the rollback segment are divided into insert and update undo logs. Insert undo logs are needed only in transaction rollback and can be discarded as soon as the transaction commits. Update undo logs are used also in consistent reads, but they can be discarded only after there is no transaction present for which InnoDB has assigned a snapshot that in a consistent read could need the information in the update undo log to build an earlier version of a database row.

Commit your transactions regularly, including those transactions that issue only consistent reads. Otherwise, InnoDB cannot discard data from the update undo logs, and the rollback segment may grow too big, filling up your tablespace.

The physical size of an undo log record in the rollback segment is typically smaller than the corresponding inserted or updated row. You can use this information to calculate the space needed for your rollback segment.

In the InnoDB multi-versioning scheme, a row is not physically removed from the database immediately when you delete it with an SQL statement. InnoDB only physically removes the corresponding row and its index records when it discards the update undo log record written for the deletion. This removal operation is called a purge, and it is quite fast, usually taking the same order of time as the SQL statement that did the deletion.

If you insert and delete rows in smallish batches at about the same rate in the table, the purge thread can start to lag behind and the table can grow bigger and bigger because of all the “dead” rows, making everything disk-bound and very slow. In such a case, throttle new row operations, and allocate more resources to the purge thread by tuning the `innodb_max_purge_lag` system variable. See Section 14.6.8, “InnoDB Startup Options and System Variables” for more information.

**Multi-Versioning and Secondary Indexes**

InnoDB multiversion concurrency control (MVCC) treats secondary indexes differently than clustered indexes. Records in a clustered index are updated in-place, and their hidden system columns point undo log entries from which earlier versions of records can be reconstructed. Unlike clustered index records, secondary index records do not contain hidden system columns nor are they updated in-place.

When a secondary index column is updated, old secondary index records are delete-marked, new records are inserted, and delete-marked records are eventually purged. When a secondary index record is delete-marked or the secondary index page is updated by a newer transaction, InnoDB looks up the database record in the clustered index. In the clustered index, the record's `DB_TRX_ID` is checked, and the correct version of the record is retrieved from the undo log if the record was modified after the reading transaction was initiated.

If a secondary index record is marked for deletion or the secondary index page is updated by a newer transaction, the covering index technique is not used. Instead of returning values from the index structure, InnoDB looks up the record in the clustered index.

**14.6.3.2 InnoDB Table and Index Structures**

**Role of the .frm File**

MySQL stores its data dictionary information for tables in `.frm` files in database directories. This is true for all MySQL storage engines, but every InnoDB table also has its own entry in the InnoDB internal data dictionary inside the tablespace. When MySQL drops a table or a database, it has to delete one or
more .frm files as well as the corresponding entries inside the InnoDB data dictionary. Consequently, you cannot move InnoDB tables between databases simply by moving the .frm files.

Clustered and Secondary Indexes

Every InnoDB table has a special index called the clustered index where the data for the rows is stored. Typically, the clustered index is synonymous with the primary key. To get the best performance from queries, inserts, and other database operations, you must understand how InnoDB uses the clustered index to optimize the most common lookup and DML operations for each table.

- If you define a PRIMARY KEY on your table, InnoDB uses it as the clustered index.
- If you do not define a PRIMARY KEY for your table, MySQL picks the first UNIQUE index that has only NOT NULL columns as the primary key and InnoDB uses it as the clustered index.
- If the table has no PRIMARY KEY or suitable UNIQUE index, InnoDB internally generates a hidden clustered index on a synthetic column containing row ID values. The rows are ordered by the ID that InnoDB assigns to the rows in such a table. The row ID is a 6-byte field that increases monotonically as new rows are inserted. Thus, the rows ordered by the row ID are physically in insertion order.

How the Clustered Index Speeds Up Queries

Accessing a row through the clustered index is fast because the row data is on the same page where the index search leads. If a table is large, the clustered index architecture often saves a disk I/O operation when compared to storage organizations that store row data using a different page from the index record. (For example, MyISAM uses one file for data rows and another for index records.)

How Secondary Indexes Relate to the Clustered Index

All indexes other than the clustered index are known as secondary indexes. In InnoDB, each record in a secondary index contains the primary key columns for the row, as well as the columns specified for the secondary index. InnoDB uses this primary key value to search for the row in the clustered index.

If the primary key is long, the secondary indexes use more space, so it is advantageous to have a short primary key.

Physical Structure of an InnoDB Index

All InnoDB indexes are B-trees where the index records are stored in the leaf pages of the tree. The default size of an index page is 16KB.

When new records are inserted into an InnoDB clustered index, InnoDB tries to leave 1/16 of the page free for future insertions and updates of the index records. If index records are inserted in a sequential order (ascending or descending), the resulting index pages are about 15/16 full. If records are inserted in a random order, the pages are from 1/2 to 15/16 full. If the fill factor of an index page drops below 1/2, InnoDB tries to contract the index tree to free the page.

Changing the InnoDB page size is not a supported operation and there is no guarantee that InnoDB will function normally with a page size other than 16KB. Problems compiling or running InnoDB may occur. In particular, ROW_FORMAT=COMPRESSED in the InnoDB Plugin assumes that the page size is at most 16KB and uses 14-bit pointers.

An instance using a particular InnoDB page size cannot use data files or log files from an instance that uses a different page size.

Insert Buffering

It is a common situation in database applications that the primary key is a unique identifier and new rows are inserted in the ascending order of the primary key. Thus, insertions into the clustered index do not require random reads from a disk.
On the other hand, secondary indexes are usually nonunique, and insertions into secondary indexes happen in a relatively random order. This would cause a lot of random disk I/O operations without a special mechanism used in InnoDB.

If an index record should be inserted into a nonunique secondary index, InnoDB checks whether the secondary index page is in the buffer pool. If that is the case, InnoDB does the insertion directly to the index page. If the index page is not found in the buffer pool, InnoDB inserts the record to a special insert buffer structure. The insert buffer is kept so small that it fits entirely in the buffer pool, and insertions can be done very fast.

### Disk I/O for Flushing the Insert Buffer

Periodically, the insert buffer is merged into the secondary index trees in the database. Often, it is possible to merge several changes into the same page of the index tree, saving disk I/O operations. It has been measured that the insert buffer can speed up insertions into a table up to 15 times.

The insert buffer merging may continue to happen after the transaction has been committed. In fact, it may continue to happen after a server shutdown and restart (see Section 14.6.12.2, “Forcing InnoDB Recovery”).

Insert buffer merging may take many hours when many secondary indexes must be updated and many rows have been inserted. During this time, disk I/O will be increased, which can cause significant slowdown on disk-bound queries. Another significant background I/O operation is the purge thread (see Section 14.6.3.1, “InnoDB Multi-Versioning”).

### Adaptive Hash Indexes

If a table fits almost entirely in main memory, the fastest way to perform queries on it is to use hash indexes. InnoDB has a mechanism that monitors index searches made to the indexes defined for a table. If InnoDB notices that queries could benefit from building a hash index, it does so automatically.

The hash index is always built based on an existing B-tree index on the table. InnoDB can build a hash index on a prefix of any length of the key defined for the B-tree, depending on the pattern of searches that InnoDB observes for the B-tree index. A hash index can be partial: It is not required that the whole B-tree index is cached in the buffer pool. InnoDB builds hash indexes on demand for those pages of the index that are often accessed.

In a sense, InnoDB tailors itself through the adaptive hash index mechanism to ample main memory, coming closer to the architecture of main-memory databases.

### Physical Row Structure

The physical row structure for an InnoDB table depends on the row format specified when the table was created. For MySQL 5.1, InnoDB uses the COMPACT format by default, but the REDUNDANT format is available to retain compatibility with older versions of MySQL. To check the row format of an InnoDB table, use `SHOW TABLE STATUS`.

The compact row format decreases row storage space by about 20% at the cost of increasing CPU use for some operations. If your workload is a typical one that is limited by cache hit rates and disk speed, compact format is likely to be faster. If the workload is a rare case that is limited by CPU speed, compact format might be slower.

Rows in InnoDB tables that use REDUNDANT row format have the following characteristics:

- Each index record contains a 6-byte header. The header is used to link together consecutive records, and also in row-level locking.
- Records in the clustered index contain fields for all user-defined columns. In addition, there is a 6-byte transaction ID field and a 7-byte roll pointer field.
- If no primary key was defined for a table, each clustered index record also contains a 6-byte row ID field.
• Each secondary index record also contains all the primary key fields defined for the clustered index key that are not in the secondary index.

• A record contains a pointer to each field of the record. If the total length of the fields in a record is less than 128 bytes, the pointer is one byte; otherwise, two bytes. The array of these pointers is called the record directory. The area where these pointers point is called the data part of the record.

• Internally, InnoDB stores fixed-length character columns such as `CHAR(10)` in a fixed-length format. InnoDB does not truncate trailing spaces from `VARCHAR` columns.

• An SQL NULL value reserves one or two bytes in the record directory. Besides that, an SQL NULL value reserves zero bytes in the data part of the record if stored in a variable length column. In a fixed-length column, it reserves the fixed length of the column in the data part of the record. Reserving the fixed space for NULL values enables an update of the column from NULL to a non-NULL value to be done in place without causing fragmentation of the index page.

Rows in InnoDB tables that use COMPACT row format have the following characteristics:

• Each index record contains a 5-byte header that may be preceded by a variable-length header. The header is used to link together consecutive records, and also in row-level locking.

• The variable-length part of the record header contains a bit vector for indicating NULL columns. If the number of columns in the index that can be NULL is \( N \), the bit vector occupies \( \text{CEILING}(N/8) \) bytes. (For example, if there are anywhere from 9 to 15 columns that can be NULL, the bit vector uses two bytes.) Columns that are NULL do not occupy space other than the bit in this vector. The variable-length part of the header also contains the lengths of variable-length columns. Each length takes one or two bytes, depending on the maximum length of the column. If all columns in the index are NOT NULL and have a fixed length, the record header has no variable-length part.

• For each non-NULL variable-length field, the record header contains the length of the column in one or two bytes. Two bytes will only be needed if part of the column is stored externally in overflow pages or the maximum length exceeds 255 bytes and the actual length exceeds 127 bytes. For an externally stored column, the 2-byte length indicates the length of the internally stored part plus the 20-byte pointer to the externally stored part. The internal part is 768 bytes, so the length is 768+20. The 20-byte pointer stores the true length of the column.

• The record header is followed by the data contents of the non-NULL columns.

• Records in the clustered index contain fields for all user-defined columns. In addition, there is a 6-byte transaction ID field and a 7-byte roll pointer field.

• If no primary key was defined for a table, each clustered index record also contains a 6-byte row ID field.

• Each secondary index record also contains all the primary key fields defined for the clustered index key that are not in the secondary index. If any of these primary key fields are variable length, the record header for each secondary index will have a variable-length part to record their lengths, even if the secondary index is defined on fixed-length columns.

• Internally, InnoDB stores fixed-length character columns such as `CHAR(10)` in a fixed-length format. InnoDB does not truncate trailing spaces from `VARCHAR` columns.

• Internally, InnoDB attempts to store UTF-8 `CHAR(N)` columns in \( N \) bytes by trimming trailing spaces. (With REDUNDANT row format, such columns occupy \( 3 \times N \) bytes.) Reserving the minimum space \( N \) in many cases enables column updates to be done in place without causing fragmentation of the index page.

### 14.6.4 InnoDB Transaction Model and Locking

To implement a large-scale, busy, or highly reliable database application, to port substantial code from a different database system, or to tune MySQL performance, you must understand the notions of transactions and locking as they relate to the InnoDB storage engine.
In the InnoDB transaction model, the goal is to combine the best properties of a multi-versioning database with traditional two-phase locking. InnoDB does locking on the row level and runs queries as nonlocking consistent reads by default, in the style of Oracle. The lock information in InnoDB is stored so space-efficiently that lock escalation is not needed: Typically, several users are permitted to lock every row in InnoDB tables, or any random subset of the rows, without causing InnoDB memory exhaustion.

In InnoDB, all user activity occurs inside a transaction. If autocommit mode is enabled, each SQL statement forms a single transaction on its own. By default, MySQL starts the session for each new connection with autocommit enabled, so MySQL does a commit after each SQL statement if that statement did not return an error. If a statement returns an error, the commit or rollback behavior depends on the error. See Section 14.6.12.4, “InnoDB Error Handling”.

A session that has autocommit enabled can perform a multiple-statement transaction by starting it with an explicit START TRANSACTION or BEGIN statement and ending it with a COMMIT or ROLLBACK statement. See Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”.

If autocommit mode is disabled within a session with SET autocommit = 0, the session always has a transaction open. A COMMIT or ROLLBACK statement ends the current transaction and a new one starts.

A COMMIT means that the changes made in the current transaction are made permanent and become visible to other sessions. A ROLLBACK statement, on the other hand, cancels all modifications made by the current transaction. Both COMMIT and ROLLBACK release all InnoDB locks that were set during the current transaction.

In terms of the SQL:1992 transaction isolation levels, the default InnoDB level is REPEATABLE READ. InnoDB offers all four transaction isolation levels described by the SQL standard: READ UNCOMMITTED, READ COMMITTED, REPEATABLE READ, and SERIALIZABLE.

A user can change the isolation level for a single session or for all subsequent connections with the SET TRANSACTION statement. To set the server’s default isolation level for all connections, use the --transaction-isolation option on the command line or in an option file. For detailed information about isolation levels and level-setting syntax, see Section 13.3.6, “SET TRANSACTION Syntax”.

In row-level locking, InnoDB normally uses next-key locking. That means that besides index records, InnoDB can also lock the “gap” preceding an index record to block insertions by other sessions in the gap immediately before the index record. A next-key lock refers to a lock that locks an index record and the gap before it. A gap lock refers to a lock that locks only the gap before some index record.

For more information about row-level locking, and the circumstances under which gap locking is disabled, see Section 14.6.4.2, “InnoDB Record, Gap, and Next-Key Locks”.

14.6.4.1 InnoDB Lock Modes

InnoDB implements standard row-level locking where there are two types of locks, shared (s) locks and exclusive (x) locks. For information about record, gap, and next-key lock types, see Section 14.6.4.2, “InnoDB Record, Gap, and Next-Key Locks”.

- A shared (s) lock permits a transaction to read a row.
- An exclusive (x) lock permits a transaction to update or delete a row.

If transaction T1 holds a shared (s) lock on row r, then requests from some distinct transaction T2 for a lock on row r are handled as follows:

- A request by T2 for an s lock can be granted immediately. As a result, both T1 and T2 hold an s lock on r.
- A request by T2 for an x lock cannot be granted immediately.
If a transaction $T_1$ holds an exclusive ($X$) lock on row $r$, a request from some distinct transaction $T_2$ for a lock of either type on $r$ cannot be granted immediately. Instead, transaction $T_2$ has to wait for transaction $T_1$ to release its lock on row $r$.

### Intention Locks

Additionally, InnoDB supports *multiple granularity locking* which permits coexistence of record locks and locks on entire tables. To make locking at multiple granularity levels practical, additional types of locks called *intention locks* are used. Intention locks are table locks in InnoDB. The idea behind intention locks is for a transaction to indicate which type of lock (shared or exclusive) it will require later for a row in that table. There are two types of intention locks used in InnoDB (assume that transaction $T$ has requested a lock of the indicated type on table $t$):

- **Intention shared ($IS$)**: Transaction $T$ intends to set $S$ locks on individual rows in table $t$.
- **Intention exclusive ($IX$)**: Transaction $T$ intends to set $X$ locks on those rows.

For example, `SELECT ... LOCK IN SHARE MODE` sets an $IS$ lock and `SELECT ... FOR UPDATE` sets an $IX$ lock.

The intention locking protocol is as follows:

- Before a transaction can acquire an $S$ lock on a row in table $t$, it must first acquire an $IS$ or stronger lock on $t$.
- Before a transaction can acquire an $X$ lock on a row, it must first acquire an $IX$ lock on $t$.

These rules can be conveniently summarized by means of the following *lock type compatibility matrix*.

<table>
<thead>
<tr>
<th></th>
<th>$X$</th>
<th>$IX$</th>
<th>$S$</th>
<th>$IS$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$X$</td>
<td>Conflict</td>
<td>Conflict</td>
<td>Conflict</td>
<td>Conflict</td>
</tr>
<tr>
<td>$IX$</td>
<td>Conflict</td>
<td>Compatible</td>
<td>Conflict</td>
<td>Compatible</td>
</tr>
<tr>
<td>$S$</td>
<td>Conflict</td>
<td>Conflict</td>
<td>Compatible</td>
<td>Compatible</td>
</tr>
<tr>
<td>$IS$</td>
<td>Conflict</td>
<td>Compatible</td>
<td>Compatible</td>
<td>Compatible</td>
</tr>
</tbody>
</table>

A lock is granted to a requesting transaction if it is compatible with existing locks, but not if it conflicts with existing locks. A transaction waits until the conflicting existing lock is released. If a lock request conflicts with an existing lock and cannot be granted because it would cause deadlock, an error occurs.

Thus, intention locks do not block anything except full table requests (for example, `LOCK TABLES ... WRITE`). The main purpose of $IX$ and $IS$ locks is to show that someone is locking a row, or going to lock a row in the table.

### Deadlock Example

The following example illustrates how an error can occur when a lock request would cause a deadlock. The example involves two clients, A and B.

First, client A creates a table containing one row, and then begins a transaction. Within the transaction, A obtains an $S$ lock on the row by selecting it in share mode:

```sql
mysql> CREATE TABLE t (i INT) ENGINE = InnoDB;
Query OK, 0 rows affected (1.07 sec)

mysql> INSERT INTO t (i) VALUES(1);
Query OK, 1 row affected (0.09 sec)

mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)
```

Then, client B tries to acquire an $X$ lock on the row:

```sql
mysql> SELECT ... FOR UPDATE;
```

This request conflicts with the existing $S$ lock and cannot be granted because it would cause deadlock, an error occurs.
InnoDB Transaction Model and Locking

Next, client B begins a transaction and attempts to delete the row from the table:

mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> DELETE FROM t WHERE i = 1;

The delete operation requires an \textit{X} lock. The lock cannot be granted because it is incompatible with the \textit{S} lock that client A holds, so the request goes on the queue of lock requests for the row and client B blocks.

Finally, client A also attempts to delete the row from the table:

mysql> DELETE FROM t WHERE i = 1;
ERROR 1213 (40001): Deadlock found when trying to get lock; try restarting transaction

Deadlock occurs here because client A needs an \textit{X} lock to delete the row. However, that lock request cannot be granted because client B already has a request for an \textit{X} lock and is waiting for client A to release its \textit{S} lock. Nor can the \textit{S} lock held by A be upgraded to an \textit{X} lock because of the prior request by B for an \textit{X} lock. As a result, InnoDB generates an error for one of the clients and releases its locks. The client returns this error:

ERROR 1213 (40001): Deadlock found when trying to get lock; try restarting transaction

At that point, the lock request for the other client can be granted and it deletes the row from the table.

\textbf{Note}

If the \textit{LATEST DETECTED DEADLOCK} section of InnoDB Monitor output includes a message stating, "TOO DEEP OR LONG SEARCH IN THE LOCK TABLE WAITS-FOR GRAPH, WE WILL ROLL BACK FOLLOWING TRANSACTION," this indicates that the number of transactions on the wait-for list has reached a limit of 200, which is defined by \texttt{LOCK\_MAX\_DEPTH\_IN\_DEADLOCK\_CHECK}. A wait-for list that exceeds 200 transactions is treated as a deadlock and the transaction attempting to check the wait-for list is rolled back.

The same error may also occur if the locking thread must look at more than 1,000,000 locks owned by the transactions on the wait-for list. The limit of 1,000,000 locks is defined by \texttt{LOCK\_MAX\_N\_STEPS\_IN\_DEADLOCK\_CHECK}.

14.6.4.2 InnoDB Record, Gap, and Next-Key Locks

InnoDB has several types of record-level locks including record locks, gap locks, and next-key locks. For information about shared locks, exclusive locks, and intention locks, see Section 14.6.4.1, “InnoDB Lock Modes”.

- Record lock: This is a lock on an index record.
- Gap lock: This is a lock on a gap between index records, or a lock on the gap before the first or after the last index record.
- Next-key lock: This is a combination of a record lock on the index record and a gap lock on the gap before the index record.

**Record Locks**

Record locks always lock index records, even if a table is defined with no indexes. For such cases, InnoDB creates a hidden clustered index and uses this index for record locking. See Clustered and Secondary Indexes.

**Next-key Locks**

By default, InnoDB operates in REPEATABLE READ transaction isolation level and with the innodb_locks_unsafe_for_binlog system variable disabled. In this case, InnoDB uses next-key locks for searches and index scans, which prevents phantom rows (see Section 14.6.4.3, “Avoiding the Phantom Problem Using Next-Key Locking”).

Next-key locking combines index-row locking with gap locking. InnoDB performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index-record locks. In addition, a next-key lock on an index record also affects the “gap” before that index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the index record. If one session has a shared or exclusive lock on record \( R \) in an index, another session cannot insert a new index record in the gap immediately before \( R \) in the index order.

Suppose that an index contains the values 10, 11, 13, and 20. The possible next-key locks for this index cover the following intervals, where a round bracket denotes exclusion of the interval endpoint and a square bracket denotes inclusion of the endpoint:

\[
\begin{align*}
\text{(negative infinity, 10]} & \\
(10, 11] & \\
(11, 13] & \\
(13, 20] & \\
(20, \text{positive infinity}) & 
\end{align*}
\]

For the last interval, the next-key lock locks the gap above the largest value in the index and the “supremum” pseudo-record having a value higher than any value actually in the index. The supremum is not a real index record, so, in effect, this next-key lock locks only the gap following the largest index value.

**Gap Locks**

The next-key locking example in the previous section shows that a gap might span a single index value, multiple index values, or even be empty.

Gap locking is not needed for statements that lock rows using a unique index to search for a unique row. (This does not include the case that the search condition includes only some columns of a multiple-column unique index; in that case, gap locking does occur.) For example, if the id column has a unique index, the following statement uses only an index-record lock for the row having id value 100 and it does not matter whether other sessions insert rows in the preceding gap:

```sql
SELECT * FROM child WHERE id = 100;
```

If id is not indexed or has a nonunique index, the statement does lock the preceding gap.

It is also worth noting here that conflicting locks can be held on a gap by different transactions. For example, transaction A can hold a shared gap lock (gap S-lock) on a gap while transaction B holds an exclusive gap lock (gap X-lock) on the same gap. The reason conflicting gap locks are allowed is that if a record is purged from an index, the gap locks held on the record by different transactions must be merged.
Gap locks in InnoDB are "purely inhibitive", which means they only stop other transactions from inserting to the gap. They do not prevent different transactions from taking gap locks on the same gap. Thus, a gap X-lock has the same effect as a gap S-lock.

A type of gap lock called an insert intention gap lock is set by INSERT operations prior to row insertion. An insert intention lock signals the intent to insert in such a way that multiple transactions inserting into the same index gap need not wait for each other if they are not inserting at the same position within the gap. Suppose that there are index records with values of 4 and 7. Separate transactions that attempt to insert values of 5 and 6, respectively, both lock the gap between 4 and 7 with insert intention locks prior to obtaining the exclusive lock on the inserted row, but do not block each other because the rows are nonconflicting.

The following example demonstrates a transaction taking an insert intention lock prior to obtaining an exclusive lock on the inserted record. The example involves two clients, A and B.

Client A creates a table containing two index records (90 and 102) and then starts a transaction that places an exclusive lock on index records with an ID greater than 100. The exclusive lock includes a gap lock before record 102:

```
mysql> CREATE TABLE child (id int(11) NOT NULL, PRIMARY KEY(id)) ENGINE=InnoDB;
mysql> INSERT INTO child (id) values (90),(102);
mysql> START TRANSACTION;
mysql> SELECT * FROM child WHERE id > 100 FOR UPDATE;
+-----+
| id  |
+-----+
| 102 |
```

Client B begins a transaction to insert a record into the gap. The transaction takes an insert intention lock while it waits to obtain an exclusive lock.

```
mysql> START TRANSACTION;
mysql> INSERT INTO child (id) VALUES (101);
```

To view data about the insert intention lock, run SHOW ENGINE INNODB STATUS. Data similar to the following appears under the TRANSACTIONS heading:

```
mysql> SHOW ENGINE INNODB STATUS\G
---TRANSACTION 8731, ACTIVE 7 sec inserting
mysql tables in use 1, locked 1
LOCK WAIT 2 lock struct(s), heap size 360, 1 row lock(s)
MySql thread id 3, OS thread handle 0x7f996beac700, query id 30 localhost root update
INSERT INTO child (id) VALUES (101)
------- TRX HAS BEEN WAITING 7 SEC FOR THIS LOCK TO BE GRANTED:
RECORD LOCKS space id 31 page no 3 n bits 72 index `PRIMARY` of table `test`.`child`
trx id 8731 lock_mode X locks gap before rec insert intention waiting
Record lock, heap no 3 PHYSICAL RECORD: n_fields 3; compact format; info bits 0
0: len 4; hex 800000066; asc f;;
1: len 6; hex 00000002215; asc ";;
2: len 7; hex 90000002117; asc r;;...
```

Disabling Gap Locking

Gap locking can be disabled explicitly. This occurs if you change the transaction isolation level to READ COMMITTED or enable the innodb_locks_unsafe_for_binlog system variable. Under these circumstances, gap locking is disabled for searches and index scans and is used only for foreign-key constraint checking and duplicate-key checking.

There are also other effects of using the READ COMMITTED isolation level or enabling innodb_locks_unsafe_for_binlog: Record locks for nonmatching rows are released after MySQL has evaluated the WHERE condition. For UPDATE statements, InnoDB does a "semi-consistent"
read, such that it returns the latest committed version to MySQL so that MySQL can determine whether the row matches the `WHERE` condition of the `UPDATE`.

### 14.6.4.3 Avoiding the Phantom Problem Using Next-Key Locking

The so-called *phantom* problem occurs within a transaction when the same query produces different sets of rows at different times. For example, if a `SELECT` is executed twice, but returns a row the second time that was not returned the first time, the row is a “phantom” row.

Suppose that there is an index on the `id` column of the `child` table and that you want to read and lock all rows from the table having an identifier value larger than 100, with the intention of updating some column in the selected rows later:

```sql
SELECT * FROM child WHERE id > 100 FOR UPDATE;
```

The query scans the index starting from the first record where `id` is bigger than 100. Let the table contain rows having `id` values of 90 and 102. If the locks set on the index records in the scanned range do not lock out inserts made in the gaps (in this case, the gap between 90 and 102), another session can insert a new row into the table with an `id` of 101. If you were to execute the same `SELECT` within the same transaction, you would see a new row with an `id` of 101 (a “phantom”) in the result set returned by the query. If we regard a set of rows as a data item, the new phantom child would violate the isolation principle of transactions that a transaction should be able to run so that the data it has read does not change during the transaction.

To prevent phantoms, InnoDB uses an algorithm called *next-key locking* that combines index-row locking with gap locking. InnoDB performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index-record locks. In addition, a next-key lock on an index record also affects the “gap” before that index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the index record. If one session has a shared or exclusive lock on record `R` in an index, another session cannot insert a new index record in the gap immediately before `R` in the index order.

When InnoDB scans an index, it can also lock the gap after the last record in the index. Just that happens in the preceding example: To prevent any insert into the table where `id` would be bigger than 100, the locks set by InnoDB include a lock on the gap following `id` value 102.

You can use next-key locking to implement a uniqueness check in your application: If you read your data in share mode and do not see a duplicate for a row you are going to insert, then you can safely insert your row and know that the next-key lock set on the successor of your row during the read prevents anyone meanwhile inserting a duplicate for your row. Thus, the next-key locking enables you to “lock” the nonexistence of something in your table.

Gap locking can be disabled as discussed in Section 14.6.4.2, “InnoDB Record, Gap, and Next-Key Locks”. This may cause phantom problems because other sessions can insert new rows into the gaps when gap locking is disabled.

### 14.6.4.4 Consistent Nonlocking Reads

A consistent read means that InnoDB uses multi-versioning to present to a query a snapshot of the database at a point in time. The query sees the changes made by transactions that committed before that point of time, and no changes made by later or uncommitted transactions. The exception to this rule is that the query sees the changes made by earlier statements within the same transaction. This exception causes the following anomaly: If you update some rows in a table, a `SELECT` sees the latest version of the updated rows, but it might also see older versions of any rows. If other sessions simultaneously update the same table, the anomaly means that you might see the table in a state that never existed in the database.

If the transaction isolation level is `REPEATABLE READ` (the default level), all consistent reads within the same transaction read the snapshot established by the first such read in that transaction. You can get
InnoDB Transaction Model and Locking

a fresher snapshot for your queries by committing the current transaction and after that issuing new queries.

With **READ COMMITTED** isolation level, each consistent read within a transaction sets and reads its own fresh snapshot.

Consistent read is the default mode in which InnoDB processes **SELECT** statements in **READ COMMITTED** and **REPEATABLE READ** isolation levels. A consistent read does not set any locks on the tables it accesses, and therefore other sessions are free to modify those tables at the same time a consistent read is being performed on the table.

Suppose that you are running in the default **REPEATABLE READ** isolation level. When you issue a consistent read (that is, an ordinary **SELECT** statement), InnoDB gives your transaction a timepoint according to which your query sees the database. If another transaction deletes a row and commits after your timepoint was assigned, you do not see the row as having been deleted. Inserts and updates are treated similarly.

**Note**

The snapshot of the database state applies to **SELECT** statements within a transaction, not necessarily to **DML** statements. If you insert or modify some rows and then commit that transaction, a **DELETE** or **UPDATE** statement issued from another concurrent **REPEATABLE READ** transaction could affect those just-committed rows, even though the session could not query them. If a transaction does update or delete rows committed by a different transaction, those changes do become visible to the current transaction. For example, you might encounter a situation like the following:

```
SELECT COUNT(c1) FROM t1 WHERE c1 = 'xyz'; -- Returns 0: no rows match.
DELETE FROM t1 WHERE c1 = 'xyz'; -- Deletes several rows recently committed by other transaction.
SELECT COUNT(c2) FROM t1 WHERE c2 = 'abc'; -- Returns 0: no rows match.
UPDATE t1 SET c2 = 'cba' WHERE c2 = 'abc'; -- Affects 10 rows: another txn just committed rows with 'abc' values.
SELECT COUNT(c2) FROM t1 WHERE c2 = 'cba'; -- Returns 10: this txn can now see the rows it just updated.
```

You can advance your timepoint by committing your transaction and then doing another **SELECT** or **START TRANSACTION WITH CONSISTENT SNAPSHOT**.

This is called **multi-versioned concurrency control**.

In the following example, session A sees the row inserted by B only when B has committed the insert and A has committed as well, so that the timepoint is advanced past the commit of B.

```
<table>
<thead>
<tr>
<th>Session A</th>
<th>Session B</th>
</tr>
</thead>
<tbody>
<tr>
<td>time</td>
<td>time</td>
</tr>
<tr>
<td></td>
<td>SET autocommit=0;</td>
</tr>
<tr>
<td></td>
<td>INSERT INTO t VALUES (1, 2);</td>
</tr>
<tr>
<td></td>
<td>COMMIT;</td>
</tr>
<tr>
<td></td>
<td>COMMIT;</td>
</tr>
</tbody>
</table>
```

```
<p>| SELECT * FROM t;   |
| empty set         |
| SELECT * FROM t;   |
| empty set         |
| SELECT * FROM t;   |</p>
<table>
<thead>
<tr>
<th>empty set</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>
```
If you want to see the “freshest” state of the database, use either the `READ COMMITTED` isolation level or a locking read:

```sql
SELECT * FROM t LOCK IN SHARE MODE;
```

With `READ COMMITTED` isolation level, each consistent read within a transaction sets and reads its own fresh snapshot. With `LOCK IN SHARE MODE`, a locking read occurs instead: A `SELECT` blocks until the transaction containing the freshest rows ends (see Section 14.6.4.5, “SELECT ... FOR UPDATE and SELECT ... LOCK IN SHARE MODE Locking Reads”).

Consistent read does not work over certain DDL statements:

- Consistent read does not work over `DROP TABLE`, because MySQL cannot use a table that has been dropped and InnoDB destroys the table.
- Consistent read does not work over `ALTER TABLE`, because that statement makes a temporary copy of the original table and deletes the original table when the temporary copy is built. When you reissue a consistent read within a transaction, rows in the new table are not visible because those rows did not exist when the transaction's snapshot was taken.

The type of read varies for selects in clauses like `INSERT INTO ... SELECT, UPDATE ... (SELECT),` and `CREATE TABLE ... SELECT` that do not specify `FOR UPDATE` or `LOCK IN SHARE MODE`:

- By default, InnoDB uses stronger locks and the `SELECT` part acts like `READ COMMITTED`, where each consistent read, even within the same transaction, sets and reads its own fresh snapshot.
- To use a consistent read in such cases, enable the `innodb_locks_unsafe_for_binlog` option and set the isolation level of the transaction to `READ UNCOMMITTED`, `READ COMMITTED`, or `REPEATABLE READ` (that is, anything other than `SERIALIZABLE`). In this case, no locks are set on rows read from the selected table.

### 14.6.4.5 SELECT ... FOR UPDATE and SELECT ... LOCK IN SHARE MODE Locking Reads

If you query data and then insert or update related data within the same transaction, the regular `SELECT` statement does not give enough protection. Other transactions can update or delete the same rows you just queried. InnoDB supports two types of locking reads that offer extra safety:

- `SELECT ... LOCK IN SHARE MODE` sets a shared mode lock on any rows that are read. Other sessions can read the rows, but cannot modify them until your transaction commits. If any of these rows were changed by another transaction that has not yet committed, your query waits until that transaction ends and then uses the latest values.
- `SELECT ... FOR UPDATE` locks the rows and any associated index entries, the same as if you issued an `UPDATE` statement for those rows. Other transactions are blocked from updating those rows, from doing `SELECT ... LOCK IN SHARE MODE`, or from reading the data in certain transaction isolation levels. Consistent reads ignore any locks set on the records that exist in the read view. (Old versions of a record cannot be locked; they are reconstructed by applying undo logs on an in-memory copy of the record.)

These clauses are primarily useful when dealing with tree-structured or graph-structured data, either in a single table or split across multiple tables.

All locks set by `LOCK IN SHARE MODE` and `FOR UPDATE` queries are released when the transaction is committed or rolled back.

---

**Note**

Locking of rows for update using `SELECT FOR UPDATE` only applies when autocommit is disabled (either by beginning transaction with `START TRANSACTION` or by setting `autocommit=0`).
InnoDB Transaction Model and Locking

Usage Examples

Suppose that you want to insert a new row into a table `child`, and make sure that the child row has a parent row in table `parent`. Your application code can ensure referential integrity throughout this sequence of operations.

First, use a consistent read to query the table `PARENT` and verify that the parent row exists. Can you safely insert the child row to table `CHILD`? No, because some other session could delete the parent row in the moment between your `SELECT` and your `INSERT`, without you being aware of it.

To avoid this potential issue, perform the `SELECT` using `LOCK IN SHARE MODE`:

```
SELECT * FROM parent WHERE NAME = 'Jones' LOCK IN SHARE MODE;
```

After the `LOCK IN SHARE MODE` query returns the parent 'Jones', you can safely add the child record to the `CHILD` table and commit the transaction. Any transaction that tries to read or write to the applicable row in the `PARENT` table waits until you are finished, that is, the data in all tables is in a consistent state.

For another example, consider an integer counter field in a table `CHILD_CODES`, used to assign a unique identifier to each child added to table `CHILD`. Do not use either consistent read or a shared mode read to read the present value of the counter, because two users of the database could see the same value for the counter, and a duplicate-key error occurs if two transactions attempt to add rows with the same identifier to the `CHILD` table.

Here, `LOCK IN SHARE MODE` is not a good solution because if two users read the counter at the same time, at least one of them ends up in deadlock when it attempts to update the counter.

To implement reading and incrementing the counter, first perform a locking read of the counter using `FOR UPDATE`, and then increment the counter. For example:

```
SELECT counter_field FROM child_codes FOR UPDATE;
UPDATE child_codes SET counter_field = counter_field + 1;
```

A `SELECT ... FOR UPDATE` reads the latest available data, setting exclusive locks on each row it reads. Thus, it sets the same locks a searched SQL `UPDATE` would set on the rows.

The preceding description is merely an example of how `SELECT ... FOR UPDATE` works. In MySQL, the specific task of generating a unique identifier actually can be accomplished using only a single access to the table:

```
UPDATE child_codes SET counter_field = LAST_INSERT_ID(counter_field + 1);
SELECT LAST_INSERT_ID();
```

The `SELECT` statement merely retrieves the identifier information (specific to the current connection). It does not access any table.

14.6.4.6 Locks Set by Different SQL Statements in InnoDB

A locking read, an `UPDATE`, or a `DELETE` generally set record locks on every index record that is scanned in the processing of the SQL statement. It does not matter whether there are `WHERE` conditions in the statement that would exclude the row. InnoDB does not remember the exact `WHERE` condition, but only knows which index ranges were scanned. The locks are normally next-key locks that also block inserts into the “gap” immediately before the record. However, gap locking can be disabled explicitly, which causes next-key locking not to be used. For more information, see Section 14.6.4.2, “InnoDB Record, Gap, and Next-Key Locks”. The transaction isolation level also can affect which locks are set; see Section 13.3.6, “SET TRANSACTION Syntax”. 

1471
InnoDB Transaction Model and Locking

If a secondary index is used in a search and index record locks to be set are exclusive, InnoDB also retrieves the corresponding clustered index records and sets locks on them.

Differences between shared and exclusive locks are described in Section 14.6.4.1, "InnoDB Lock Modes".

If you have no indexes suitable for your statement and MySQL must scan the entire table to process the statement, every row of the table becomes locked, which in turn blocks all inserts by other users to the table. It is important to create good indexes so that your queries do not unnecessarily scan many rows.

For `SELECT ... FOR UPDATE` or `SELECT ... LOCK IN SHARE MODE`, locks are acquired for scanned rows, and expected to be released for rows that do not qualify for inclusion in the result set (for example, if they do not meet the criteria given in the `WHERE` clause). However, in some cases, rows might not be unlocked immediately because the relationship between a result row and its original source is lost during query execution. For example, in a `UNION`, scanned (and locked) rows from a table might be inserted into a temporary table before evaluation whether they qualify for the result set. In this circumstance, the relationship of the rows in the temporary table to the rows in the original table is lost and the latter rows are not unlocked until the end of query execution.

InnoDB sets specific types of locks as follows.

- **SELECT ... FROM** is a consistent read, reading a snapshot of the database and setting no locks unless the transaction isolation level is set to `SERIALIZABLE`. For `SERIALIZABLE` level, the search sets shared next-key locks on the index records it encounters.

- **SELECT ... FROM ... LOCK IN SHARE MODE** sets shared next-key locks on all index records the search encounters.

- For index records the search encounters, `SELECT ... FROM ... FOR UPDATE` blocks other sessions from doing `SELECT ... FROM ... LOCK IN SHARE MODE` or from reading in certain transaction isolation levels. Consistent reads will ignore any locks set on the records that exist in the read view.

- **UPDATE ... WHERE ...** sets an exclusive next-key lock on every record the search encounters.

- **DELETE FROM ... WHERE ...** sets an exclusive next-key lock on every record the search encounters.

- **INSERT** sets an exclusive lock on the inserted row. This lock is an index-record lock, not a next-key lock (that is, there is no gap lock) and does not prevent other sessions from inserting into the gap before the inserted row.

Prior to inserting the row, a type of gap lock called an insertion intention gap lock is set. This lock signals the intent to insert in such a way that multiple transactions inserting into the same index gap need not wait for each other if they are not inserting at the same position within the gap. Suppose that there are index records with values of 4 and 7. Separate transactions that attempt to insert values of 5 and 6 each lock the gap between 4 and 7 with insert intention locks prior to obtaining the exclusive lock on the inserted row, but do not block each other because the rows are nonconflicting.

If a duplicate-key error occurs, a shared lock on the duplicate index record is set. This use of a shared lock can result in deadlock should there be multiple sessions trying to insert the same row if another session already has an exclusive lock. This can occur if another session deletes the row. Suppose that an InnoDB table `t1` has the following structure:

```sql
CREATE TABLE t1 (i INT, PRIMARY KEY (i)) ENGINE = InnoDB;
```

Now suppose that three sessions perform the following operations in order:

Session 1:
InnoDB Transaction Model and Locking

Start Transaction;
INSERT INTO t1 VALUES(1);

Session 2:
START TRANSACTION;
INSERT INTO t1 VALUES(1);

Session 3:
START TRANSACTION;
INSERT INTO t1 VALUES(1);

Session 1:
ROLLBACK;

The first operation by session 1 acquires an exclusive lock for the row. The operations by sessions 2 and 3 both result in a duplicate-key error and they both request a shared lock for the row. When session 1 rolls back, it releases its exclusive lock on the row and the queued shared lock requests for sessions 2 and 3 are granted. At this point, sessions 2 and 3 deadlock: Neither can acquire an exclusive lock for the row because of the shared lock held by the other.

A similar situation occurs if the table already contains a row with key value 1 and three sessions perform the following operations in order:

Session 1:
START TRANSACTION;
DELETE FROM t1 WHERE i = 1;

Session 2:
START TRANSACTION;
INSERT INTO t1 VALUES(1);

Session 3:
START TRANSACTION;
INSERT INTO t1 VALUES(1);

Session 1:
COMMIT;

The first operation by session 1 acquires an exclusive lock for the row. The operations by sessions 2 and 3 both result in a duplicate-key error and they both request a shared lock for the row. When session 1 commits, it releases its exclusive lock on the row and the queued shared lock requests for sessions 2 and 3 are granted. At this point, sessions 2 and 3 deadlock: Neither can acquire an exclusive lock for the row because of the shared lock held by the other.

- **INSERT ... ON DUPLICATE KEY UPDATE** differs from a simple **INSERT** in that an exclusive next-key lock rather than a shared lock is placed on the row to be updated when a duplicate-key error occurs.

- **REPLACE** is done like an **INSERT** if there is no collision on a unique key. Otherwise, an exclusive next-key lock is placed on the row to be replaced.
• INSERT INTO T SELECT ... FROM S WHERE ... sets an exclusive index record lock (without a gap lock) on each row inserted into T. If the transaction isolation level is READ COMMITTED, or innodb_locks_unsafe_for_binlog is enabled and the transaction isolation level is not SERIALIZABLE, InnoDB does the search on S as a consistent read (no locks). Otherwise, InnoDB sets shared next-key locks on rows from S. InnoDB has to set locks in the latter case: In roll-forward recovery from a backup, every SQL statement must be executed in exactly the same way it was done originally.

CREATE TABLE ... SELECT ... performs the SELECT with shared next-key locks or as a consistent read, as for INSERT ... SELECT.

When a SELECT is used in the constructs REPLACE INTO t SELECT ... FROM s WHERE ... or UPDATE t ... WHERE col IN (SELECT ... FROM s ...), InnoDB sets shared next-key locks on rows from table s.

• While initializing a previously specified AUTO_INCREMENT column on a table, InnoDB sets an exclusive lock on the end of the index associated with the AUTO_INCREMENT column. In accessing the auto-increment counter, InnoDB uses a specific AUTO-INC table lock mode where the lock lasts only to the end of the current SQL statement, not to the end of the entire transaction. Other sessions cannot insert into the table while the AUTO-INC table lock is held; see Section 14.6.4, “InnoDB Transaction Model and Locking”.

InnoDB fetches the value of a previously initialized AUTO_INCREMENT column without setting any locks.

• If a FOREIGN KEY constraint is defined on a table, any insert, update, or delete that requires the constraint condition to be checked sets shared record-level locks on the records that it looks at to check the constraint. InnoDB also sets these locks in the case where the constraint fails.

• LOCK TABLES sets table locks, but it is the higher MySQL layer above the InnoDB layer that sets these locks. InnoDB is aware of table locks if innodb_table_locks = 1 (the default) and autocommit = 0, and the MySQL layer above InnoDB knows about row-level locks. Otherwise, InnoDB’s automatic deadlock detection cannot detect deadlocks where such table locks are involved. Also, because in this case the higher MySQL layer does not know about row-level locks, it is possible to get a table lock on a table where another session currently has row-level locks. However, this does not endanger transaction integrity, as discussed in Section 14.6.4.8, “Deadlock Detection and Rollback”. See also Section 14.6.6.7, “Limits on InnoDB Tables”.

14.6.4.7 Implicit Transaction Commit and Rollback

By default, MySQL starts the session for each new connection with autocommit mode enabled, so MySQL does a commit after each SQL statement if that statement did not return an error. If a statement returns an error, the commit or rollback behavior depends on the error. See Section 14.6.12.4, “InnoDB Error Handling”.

If a session that has autocommit disabled ends without explicitly committing the final transaction, MySQL rolls back that transaction.

Some statements implicitly end a transaction, as if you had done a COMMIT before executing the statement. For details, see Section 13.3.3, “Statements That Cause an Implicit Commit”.

14.6.4.8 Deadlock Detection and Rollback

InnoDB automatically detects transaction deadlocks and rolls back a transaction or transactions to break the deadlock. InnoDB tries to pick small transactions to roll back, where the size of a transaction is determined by the number of rows inserted, updated, or deleted.

InnoDB is aware of table locks if innodb_table_locks = 1 (the default) and autocommit = 0, and the MySQL layer above it knows about row-level locks. Otherwise, InnoDB cannot
detect deadlocks where a table lock set by a MySQL `LOCK TABLES` statement or a lock set by a storage engine other than InnoDB is involved. Resolve these situations by setting the value of the `innodb_lock_wait_timeout` system variable.

When InnoDB performs a complete rollback of a transaction, all locks set by the transaction are released. However, if just a single SQL statement is rolled back as a result of an error, some of the locks set by the statement may be preserved. This happens because InnoDB stores row locks in a format such that it cannot know afterward which lock was set by which statement.

As of MySQL 5.1.24, if a `SELECT` calls a stored function in a transaction, and a statement within the function fails, that statement rolls back. Furthermore, if `ROLLBACK` is executed after that, the entire transaction rolls back. Before 5.1.24, the failed statement did not roll back when it failed (even though it might ultimately get rolled back by a `ROLLBACK` later that rolls back the entire transaction).

For techniques to organize database operations to avoid deadlocks, see Section 14.6.4.9, “How to Cope with Deadlocks”.

### 14.6.4.9 How to Cope with Deadlocks

This section builds on the conceptual information about deadlocks in Section 14.6.4.8, “Deadlock Detection and Rollback”. It explains how to organize database operations to minimize deadlocks and the subsequent error handling required in applications.

Deadlocks are a classic problem in transactional databases, but they are not dangerous unless they are so frequent that you cannot run certain transactions at all. Normally, you must write your applications so that they are always prepared to re-issue a transaction if it gets rolled back because of a deadlock.

InnoDB uses automatic row-level locking. You can get deadlocks even in the case of transactions that just insert or delete a single row. That is because these operations are not really "atomic"; they automatically set locks on the (possibly several) index records of the row inserted or deleted.

You can cope with deadlocks and reduce the likelihood of their occurrence with the following techniques:

- Use `SHOW ENGINE INNODB STATUS` to determine the cause of the latest deadlock. That can help you to tune your application to avoid deadlocks.
- Always be prepared to re-issue a transaction if it fails due to deadlock. Deadlocks are not dangerous. Just try again.
- Keep transactions small and short in duration to make them less prone to collision.
- Commit transactions immediately after making a set of related changes to make them less prone to collision. In particular, do not leave an interactive `mysql` session open for a long time with an uncommitted transaction.
- If you are using locking reads (`SELECT ... FOR UPDATE` or `SELECT ... LOCK IN SHARE MODE`), try using a lower isolation level such as `READ COMMITTED`.
- When modifying multiple tables within a transaction, or different sets of rows in the same table, do those operations in a consistent order each time. Then transactions form well-defined queues and do not deadlock. For example, organize database operations into functions within your application, or call stored routines, rather than coding multiple similar sequences of `INSERT`, `UPDATE`, and `DELETE` statements in different places.
- Add well-chosen indexes to your tables. Then your queries need to scan fewer index records and consequently set fewer locks. Use `EXPLAIN SELECT` to determine which indexes the MySQL server regards as the most appropriate for your queries.
- Use less locking. If you can afford to permit a `SELECT` to return data from an old snapshot, do not add the clause `FOR UPDATE` or `LOCK IN SHARE MODE` to it. Using the `READ COMMITTED` isolation...
level is good here, because each consistent read within the same transaction reads from its own fresh snapshot.

• If nothing else helps, serialize your transactions with table-level locks. The correct way to use LOCK TABLES with transactional tables, such as InnoDB tables, is to begin a transaction with SET autocommit = 0 (not START TRANSACTION) followed by LOCK TABLES, and to not call UNLOCK TABLES until you commit the transaction explicitly. For example, if you need to write to table t1 and read from table t2, you can do this:

```sql
SET autocommit=0;
LOCK TABLES t1 WRITE, t2 READ, ...;
... do something with tables t1 and t2 here ...
COMMIT;
UNLOCK TABLES;
```

Table-level locks prevent concurrent updates to the table, avoiding deadlocks at the expense of less responsiveness for a busy system.

• Another way to serialize transactions is to create an auxiliary “semaphore” table that contains just a single row. Have each transaction update that row before accessing other tables. In that way, all transactions happen in a serial fashion. Note that the InnoDB instant deadlock detection algorithm also works in this case, because the serializing lock is a row-level lock. With MySQL table-level locks, the timeout method must be used to resolve deadlocks.

14.6.5 InnoDB Tablespace Management

14.6.5.1 Resizing the InnoDB System Tablespace

This section describes how to increase or decrease the size of the InnoDB system tablespace.

Increasing the Size of the InnoDB System Tablespace

The easiest way to increase the size of the InnoDB system tablespace is to configure it from the beginning to be auto-extending. Specify the autoextend attribute for the last data file in the tablespace definition. Then InnoDB increases the size of that file automatically in 8MB increments when it runs out of space. The increment size can be changed by setting the value of the innodb_autoextend_increment system variable, which is measured in megabytes.

You can expand the system tablespace by a defined amount by adding another data file:

1. Shut down the MySQL server.
2. If the previous last data file is defined with the keyword autoextend, change its definition to use a fixed size, based on how large it has actually grown. Check the size of the data file, round it down to the closest multiple of 1024 × 1024 bytes (= 1MB), and specify this rounded size explicitly in innodb_data_file_path.
3. Add a new data file to the end of innodb_data_file_path, optionally making that file auto-extending. Only the last data file in the innodb_data_file_path can be specified as auto-extending.
4. Start the MySQL server again.

For example, this tablespace has just one auto-extending data file ibdata1:

```sql
innodb_data_home_dir =
innodb_data_file_path = /ibdata/ibdata1:10M:autoextend
```

Suppose that this data file, over time, has grown to 988MB. Here is the configuration line after modifying the original data file to use a fixed size and adding a new auto-extending data file:
When you add a new data file to the system tablespace configuration, make sure that the filename does not refer to an existing file. InnoDB creates and initializes the file when you restart the server.

### Decreasing the Size of the InnoDB System Tablespace

You cannot remove a data file from the system tablespace. To decrease the size of your system tablespace, use this procedure:

1. Use `mysqldump` to dump all your InnoDB tables.
2. Stop the server.
3. Remove all the existing tablespace files, including the `ibdata` and `ib_log` files. If you want to keep a backup copy of the information, then copy all the `ib*` files to another location before the removing the files in your MySQL installation.
4. Remove any `.frm` files for InnoDB tables.
5. Configure a new tablespace.
6. Restart the server.
7. Import the dump files.

### 14.6.5.2 Changing the Number or Size of InnoDB Redo Log Files

To change the number or the size of your InnoDB redo log files, perform the following steps:

1. If `innodb_fast_shutdown` is set to 2, set `innodb_fast_shutdown` to 1:

   ```
   mysql> SET GLOBAL innodb_fast_shutdown = 1;
   ```

2. After ensuring that `innodb_fast_shutdown` is not set to 2, stop the MySQL server and make sure that it shuts down without errors (to ensure that there is no information for outstanding transactions in the log).

3. Copy the old log files into a safe place in case something went wrong during the shutdown and you need them to recover the tablespace.

4. Delete the old log files from the log file directory.

5. Edit `my.cnf` to change the log file configuration.

6. Start the MySQL server again. `mysqld` sees that no InnoDB log files exist at startup and creates new ones.

### 14.6.5.3 Using Raw Disk Partitions for the System Tablespace

You can use raw disk partitions as data files in the **InnoDB system tablespace**. This technique enables nonbuffered I/O on Windows and on some Linux and Unix systems without file system overhead. Perform tests with and without raw partitions to verify whether this change actually improves performance on your system.

When you use a raw disk partition, ensure that the user ID that runs the MySQL server has read and write privileges for that partition. For example, if you run the server as the `mysql` user, the partition must be readable and writeable by `mysql`. If you run the server with the `--memlock` option, the server must be run as `root`, so the partition must be readable and writeable by `root`.

The procedures described below involve option file modification. For additional information, see Section 4.2.6, “Using Option Files”.
Allocating a Raw Disk Partition on Linux and Unix Systems

1. When you create a new data file, specify the keyword `newraw` immediately after the data file size for the `innodb_data_file_path` option. The partition must be at least as large as the size that you specify. Note that 1MB in InnoDB is 1024 × 1024 bytes, whereas 1MB in disk specifications usually means 1,000,000 bytes.

   ```
   [mysqld]
   innodb_data_home_dir=
   innodb_data_file_path=/dev/hdd1:3Gnewraw;/dev/hdd2:2Gnewraw
   ```

2. Restart the server. InnoDB notices the `newraw` keyword and initializes the new partition. However, do not create or change any InnoDB tables yet. Otherwise, when you next restart the server, InnoDB reinitializes the partition and your changes are lost. (As a safety measure InnoDB prevents users from modifying data when any partition with `newraw` is specified.)

3. After InnoDB has initialized the new partition, stop the server, change `newraw` in the data file specification to `raw`:

   ```
   [mysqld]
   innodb_data_home_dir=
   innodb_data_file_path=/dev/hdd1:3Graw;/dev/hdd2:2Graw
   ```

4. Restart the server. InnoDB now permits changes to be made.

Allocating a Raw Disk Partition on Windows

On Windows systems, the same steps and accompanying guidelines described for Linux and Unix systems apply except that the `innodb_data_file_path` setting differs slightly on Windows.

1. When you create a new data file, specify the keyword `newraw` immediately after the data file size for the `innodb_data_file_path` option:

   ```
   [mysqld]
   innodb_data_home_dir=
   innodb_data_file_path=\./D::10Gnewraw
   ```

   The `\./` corresponds to the Windows syntax of `\\` for accessing physical drives. In the example above, `D:` is the drive letter of the partition.

2. Restart the server. InnoDB notices the `newraw` keyword and initializes the new partition.

3. After InnoDB has initialized the new partition, stop the server, change `newraw` in the data file specification to `raw`:

   ```
   [mysqld]
   innodb_data_home_dir=
   innodb_data_file_path=\./D::10Graw
   ```

4. Restart the server. InnoDB now permits changes to be made.

14.6.5.4 InnoDB File-Per-Table Tablespaces

You can store each InnoDB table and its indexes in its own data file. This feature is called “file-per-table tablespaces” because in effect each table has its own tablespace.

Advantages of File-Per-Table Tablespaces

- You can reclaim disk space when truncating or dropping a table stored in a file-per-table tablespace. Truncating or dropping tables stored in the system tablespace creates free space internally in the system tablespace data files (ibdata files) which can only be used for new InnoDB data.
The TRUNCATE TABLE operation is faster when run on tables stored in file-per-table tablespaces.

You can store specific tables on separate storage devices, for I/O optimization, space management, or backup purposes.

You can run OPTIMIZE TABLE to compact or recreate a file-per-table tablespace. When you run an OPTIMIZE TABLE, InnoDB creates a new .ibd file with a temporary name, using only the space required to store actual data. When the optimization is complete, InnoDB removes the old .ibd file and replaces it with the new one. If the previous .ibd file grew significantly but the actual data only accounted for a portion of its size, running OPTIMIZE TABLE can reclaim the unused space.

You can move individual InnoDB tables rather than entire databases.

You can enable compression for table and index data, using the compressed row format.

You can enable more efficient storage for tables with large BLOB or TEXT columns using the dynamic row format.

File-per-table tablespaces may improve chances for a successful recovery and save time when a corruption occurs, when a server cannot be restarted, or when backup and binary logs are unavailable.

You can back up or restore a single table quickly, without interrupting the use of other InnoDB tables, using the MySQL Enterprise Backup product. See Partial Backup and Restore Options for details.

You can exclude tables stored in file-per-table tablespaces from a backup. This is beneficial if you have tables that require backup less frequently or on a different schedule.

File-per-table tablespaces are convenient for per-table status reporting when copying or backing up tables.

You can monitor table size at a file system level, without accessing MySQL.

Common Linux file systems do not permit concurrent writes to a single file when innodb_flush_method is set to O_DIRECT. As a result, there are possible performance improvements when using innodb_file_per_table in conjunction with innodb_flush_method.

The system tablespace stores the data dictionary and undo logs, and has a 64TB size limit. By comparison, each file-per-table tablespace has a 64TB size limit, which provides you with room for growth. See Section C.7.3, “Limits on Table Size” for related information.

Potential Disadvantages of File-Per-Table Tablespaces

With file-per-table tablespaces, each table may have unused space, which can only be utilized by rows of the same table. This could lead to wasted space if not properly managed.

fsync operations must run on each open table rather than on a single file. Because there is a separate fsync operation for each file, write operations on multiple tables cannot be combined into a single I/O operation. This may require InnoDB to perform a higher total number of fsync operations.

mysqld must keep one open file handle per table, which may impact performance if you have numerous tables in file-per-table tablespaces.

More file descriptors are used.

If backward compatibility with MySQL 5.1 is a concern, be aware that enabling innodb_file_per_table means that ALTER TABLE will move InnoDB tables from the system tablespace to individual .ibd files.
InnoDB Tablespace Management

- If many tables are growing there is potential for more fragmentation which can impede `DROP TABLE` and table scan performance. However, when fragmentation is managed, having files in their own tablespace can improve performance.

- The buffer pool is scanned when dropping a file-per-table tablespace, which can take several seconds for buffer pools that are tens of gigabytes in size. The scan is performed with a broad internal lock, which may delay other operations. Tables in the system tablespace are not affected.

- The `innodb_autoextend_increment` variable, which defines increment size (in MB) for extending the size of an auto-extending shared tablespace file when it becomes full, does not apply to file-per-table tablespace files, which are auto-extending regardless of the `innodb_autoextend_increment` setting. The initial extensions are by small amounts, after which extensions occur in increments of 4MB.

Enabling and Disabling File-Per-Table Tablespaces

To enable file-per-table tablespaces, start the server with the `--innodb_file_per_table` option. For example, add a line to the `[mysqld]` section of `my.cnf`:

```
[mysqld]
innodb_file_per_table=1
```

With `innodb_file_per_table` enabled, InnoDB stores each newly created table into its own `.ibd` file in the database directory where the table belongs. This is similar to what the MyISAM storage engine does, but MyISAM divides the table into a `tbl_name.MYD` data file and an `tbl_name.MYI` index file. For InnoDB, the data and the indexes are stored together in the `.ibd` file. The `tbl_name.frm` file is still created as usual.

You cannot freely move `.ibd` files between database directories as you can with MyISAM table files. This is because the table definition that is stored in the InnoDB shared tablespace includes the database name, and because InnoDB must preserve the consistency of transaction IDs and log sequence numbers.

If you remove the `innodb_file_per_table` line from `my.cnf` and restart the server, newly created InnoDB tables are created inside the shared tablespace files again.

The `--innodb_file_per_table` option affects only table creation, not access to existing tables. If you start the server with this option, new tables are created using `.ibd` files, but you can still access tables that exist in the shared tablespace. If you start the server without this option, new tables are created in the shared tablespace, but you can still access tables created in file-per-table tablespaces.

**Note**

InnoDB requires the shared tablespace to store its internal data dictionary and undo logs. The `.ibd` files alone are not sufficient for InnoDB to operate.

To move an `.ibd` file and the associated table from one database to another, use a `RENAME TABLE` statement:

```
RENAME TABLE db1.tbl_name TO db2.tbl_name;
```

If you have a “clean” backup of an `.ibd` file, you can restore it to the MySQL installation from which it originated as follows:

1. Issue this `ALTER TABLE` statement to delete the current `.ibd` file:

   ```
   ALTER TABLE tbl_name DISCARD TABLESPACE;
   ```

2. Copy the backup `.ibd` file to the proper database directory.
InnoDB Table Management

3. Issue this ALTER TABLE statement to tell InnoDB to use the new .ibd file for the table:

```
ALTER TABLE tbl_name IMPORT TABLESPACE;
```

In this context, a “clean” .ibd file backup is one for which the following requirements are satisfied:

- There are no uncommitted modifications by transactions in the .ibd file.
- There are no unmerged insert buffer entries in the .ibd file.
- Purge has removed all delete-marked index records from the .ibd file.
- mysqld has flushed all modified pages of the .ibd file from the buffer pool to the file.

You can make a clean backup .ibd file using the following method:

1. Stop all activity from the mysqld server and commit all transactions.
2. Wait until `SHOW ENGINE INNODB STATUS` shows that there are no active transactions in the database, and the main thread status of InnoDB is `Waiting for server activity`. Then you can make a copy of the .ibd file.

Another method for making a clean copy of an .ibd file is to use the commercial MySQL Enterprise Backup product:

1. Use MySQL Enterprise Backup to back up the InnoDB installation.
2. Start a second mysqld server on the backup and let it clean up the .ibd files in the backup.

### 14.6.6 InnoDB Table Management

#### 14.6.6.1 Creating InnoDB Tables

To create an InnoDB table, specify an `ENGINE=InnoDB` option in the `CREATE TABLE` statement:

```
CREATE TABLE customers (a INT, b CHAR (20), INDEX (a)) ENGINE=InnoDB;
```

The statement creates a table and an index on column `a` in the InnoDB tablespace that consists of the data files that you specified in `my.cnf`. In addition, MySQL creates a file `customers.frm` in the `test` directory under the MySQL database directory. Internally, InnoDB adds an entry for the table to its own data dictionary. The entry includes the database name. For example, if `test` is the database in which the customers table is created, the entry is for 'test/customers'. This means you can create a table of the same name `customers` in some other database, and the table names do not collide inside InnoDB.

You can query the amount of free space in the InnoDB tablespace by issuing a `SHOW TABLE STATUS` statement for any InnoDB table. The amount of free space in the tablespace appears in the `Data_free` section in the output of `SHOW TABLE STATUS` (or the `Comment` section prior to MySQL 5.1.24). For example:

```
SHOW TABLE STATUS FROM test LIKE 'customers'
```

The statistics `SHOW` displays for InnoDB tables are only approximate. They are used in SQL optimization. Table and index reserved sizes in bytes are accurate, though.

#### 14.6.6.2 Using InnoDB with Different APIs

**Transactions in SQL**

By default, each client that connects to the MySQL server begins with `autocommit` mode enabled, which automatically commits every SQL statement as you execute it. To use multiple-statement transactions, you can switch autocommit off with the SQL statement `SET autocommit = 0` and

---

1481
end each transaction with either **COMMIT** or **ROLLBACK**. If you want to leave autocommit on, you can begin your transactions within **START TRANSACTION** and end them with **COMMIT** or **ROLLBACK**. The following example shows two transactions. The first is committed; the second is rolled back.

```
shell> mysql test
mysql> CREATE TABLE customer (a INT, b CHAR (20), INDEX (a))
    -> ENGINE=InnoDB;
Query OK, 0 rows affected (0.00 sec)
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO customer VALUES (10, 'Heikki');
Query OK, 1 row affected (0.00 sec)
mysql> COMMIT;
Query OK, 0 rows affected (0.00 sec)
mysql> SET autocommit=0;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO customer VALUES (15, 'John');
Query OK, 1 row affected (0.00 sec)
mysql> ROLLBACK;
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT * FROM customer;
+------+--------+
<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>Heikki</td>
</tr>
<tr>
<td>------</td>
<td>--------</td>
</tr>
</tbody>
</table>
1 row in set (0.00 sec)
```
14.6.4 Converting Tables from MyISAM to InnoDB

To convert a non-InnoDB table to use InnoDB use ALTER TABLE:

\[
\text{ALTER TABLE } \text{table name} \text{ ENGINE=InnoDB;}
\]

**Important**

Do not convert MySQL system tables in the `mysql` database (such as `user` or `host`) to the InnoDB type. This is an unsupported operation. The system tables must always be of the MyISAM type.

InnoDB does not have a special optimization for separate index creation the way the MyISAM storage engine does. Therefore, it does not pay to export and import the table and create indexes afterward. The fastest way to alter a table to InnoDB is to do the inserts directly to an InnoDB table. That is, use `ALTER TABLE ... ENGINE=INNODB`, or create an empty InnoDB table with identical definitions and insert the rows with `INSERT INTO ... SELECT * FROM ...`.

If you have UNIQUE constraints on secondary keys, you can speed up a table import by turning off the uniqueness checks temporarily during the import operation:

\[
\text{SET unique_checks=0;}
\]

\[
\text{... import operation ...}
\]

\[
\text{SET unique_checks=1;}
\]

For big tables, this saves disk I/O because InnoDB can use its insert buffer to write secondary index records as a batch. Be certain that the data contains no duplicate keys. `unique_checks` permits but does not require storage engines to ignore duplicate keys.

To get better control over the insertion process, you might insert big tables in pieces:

\[
\text{INSERT INTO newtable SELECT * FROM oldtable}
\]

\[
\text{WHERE yourkey > something AND yourkey <= somethingelse;}
\]

After all records have been inserted, you can rename the tables.

During the conversion of big tables, increase the size of the InnoDB buffer pool to reduce disk I/O, to a maximum of 80% of physical memory. You can also increase the sizes of the InnoDB log files.

Make sure that you do not fill up the tablespace: InnoDB tables require a lot more disk space than MyISAM tables. If an ALTER TABLE operation runs out of space, it starts a rollback, and that can take hours if it is disk-bound. For inserts, InnoDB uses the insert buffer to merge secondary index records to indexes in batches. That saves a lot of disk I/O. For rollback, no such mechanism is used, and the rollback can take 30 times longer than the insertion.

In the case of a runaway rollback, if you do not have valuable data in your database, it may be advisable to kill the database process rather than wait for millions of disk I/O operations to complete. For the complete procedure, see Section 14.6.12.2, “Forcing InnoDB Recovery”.

If you want all new user-created tables to use the InnoDB storage engine, add the line `default-storage-engine=innodb` to the [mysqld] section of your server option file.

14.6.5 AUTO_INCREMENT Handling in InnoDB

Beginning with MySQL 5.1.22, InnoDB provides a configurable locking mechanism that can significantly improve scalability and performance of SQL statements that add rows to tables with AUTO_INCREMENT columns. To use the AUTO_INCREMENT mechanism with an InnoDB table, an AUTO_INCREMENT column must be defined as part of an index such that it is possible to perform the equivalent of an indexed `SELECT MAX(ai_col)` lookup on the table to obtain the maximum column value. Typically, this is achieved by making the column the first column of some table index.
This section describes the behavior of **AUTO_INCREMENT** lock modes, usage implications for different **AUTO_INCREMENT** lock mode settings, and how InnoDB initializes the **AUTO_INCREMENT** counter.

- **InnoDB AUTO_INCREMENT Lock Modes**
- **InnoDB AUTO_INCREMENT Lock Mode Usage Implications**
- **InnoDB AUTO_INCREMENT Counter Initialization**

**InnoDB AUTO_INCREMENT Lock Modes**

This section describes the behavior of **AUTO_INCREMENT** lock modes used to generate auto-increment values, and how each lock mode affects replication. Auto-increment lock modes are configured at startup using the `innodb_autoinc_lock_mode` configuration parameter, introduced in MySQL 5.1.22.

The following terms are used in describing `innodb_autoinc_lock_mode` settings:

- “**INSERT**-like” statements
  - All statements that generate new rows in a table, including **INSERT**, **INSERT ... SELECT**, **REPLACE**, **REPLACE ... SELECT**, and **LOAD DATA**. Includes “simple-inserts”, “bulk-inserts”, and “mixed-mode” inserts.
- “Simple inserts”
  - Statements for which the number of rows to be inserted can be determined in advance (when the statement is initially processed). This includes single-row and multiple-row **INSERT** and **REPLACE** statements that do not have a nested subquery, but not **INSERT ... ON DUPLICATE KEY UPDATE**.
- “Bulk inserts”
  - Statements for which the number of rows to be inserted (and the number of required auto-increment values) is not known in advance. This includes **INSERT ... SELECT**, **REPLACE ... SELECT**, and **LOAD DATA** statements, but not plain **INSERT**. InnoDB will assign new values for the **AUTO_INCREMENT** column one at a time as each row is processed.
- “Mixed-mode inserts”
  - These are “simple insert” statements that specify the auto-increment value for some (but not all) of the new rows. An example follows, where `c1` is an **AUTO_INCREMENT** column of table `t1`:

  ```sql
  INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (5,'c'), (NULL,'d');
  ```

  Another type of “mixed-mode insert” is **INSERT ... ON DUPLICATE KEY UPDATE**, which in the worst case is in effect an **INSERT** followed by a **UPDATE**, where the allocated value for the **AUTO_INCREMENT** column may or may not be used during the update phase.

There are three possible settings for the `innodb_autoinc_lock_mode` configuration parameter. The settings are 0, 1, or 2, for “traditional”, “consecutive”, or “interleaved” lock mode, respectively.

- `innodb_autoinc_lock_mode = 0` ("traditional” lock mode)
  - The traditional lock mode provides the same behavior that existed before the `innodb_autoinc_lock_mode` configuration parameter was introduced in MySQL 5.1. The traditional lock mode option is provided for backward compatibility, performance testing, and working around issues with “mixed-mode inserts”, due to possible differences in semantics.
  - In this lock mode, all “**INSERT**-like” statements obtain a special table-level **AUTO-INC** lock for inserts into tables with **AUTO_INCREMENT** columns. This lock is normally held to the end of the statement (not to the end of the transaction) to ensure that auto-increment values are assigned in a predictable
and repeatable order for a given sequence of `INSERT` statements, and to ensure that auto-increment values assigned by any given statement are consecutive.

In the case of statement-based replication, this means that when an SQL statement is replicated on a slave server, the same values are used for the auto-increment column as on the master server. The result of execution of multiple `INSERT` statements is deterministic, and the slave reproduces the same data as on the master. If auto-increment values generated by multiple `INSERT` statements were interleaved, the result of two concurrent `INSERT` statements would be nondeterministic, and could not reliably be propagated to a slave server using statement-based replication.

To make this clear, consider an example that uses this table:

```sql
CREATE TABLE t1 (
    c1 INT(11) NOT NULL AUTO_INCREMENT,
    c2 VARCHAR(10) DEFAULT NULL,
    PRIMARY KEY (c1)
) ENGINE=InnoDB;
```

Suppose that there are two transactions running, each inserting rows into a table with an `AUTO_INCREMENT` column. One transaction is using an `INSERT ... SELECT` statement that inserts 1000 rows, and another is using a simple `INSERT` statement that inserts one row:

```
Tx1: INSERT INTO t1 (c2) SELECT 1000 rows from another table ...  
Tx2: INSERT INTO t1 (c2) VALUES ('xxx');
```

`InnoDB` cannot tell in advance how many rows will be retrieved from the `SELECT` in the `INSERT` statement in `Tx1`, and it assigns the auto-increment values one at a time as the statement proceeds. With a table-level lock, held to the end of the statement, only one `INSERT` statement referring to table `t1` can execute at a time, and the generation of auto-increment numbers by different statements is not interleaved. The auto-increment value generated by the `Tx1` `INSERT ... SELECT` statement will be consecutive, and the (single) auto-increment value used by the `INSERT` statement in `Tx2` will either be smaller or larger than all those used for `Tx1`, depending on which statement executes first.

As long as the SQL statements execute in the same order when replayed from the binary log (when using statement-based replication, or in recovery scenarios), the results will be the same as they were when `Tx1` and `Tx2` first ran. Thus, table-level locks held until the end of a statement make `INSERT` statements using auto-increment safe for use with statement-based replication. However, those table-level locks limit concurrency and scalability when multiple transactions are executing insert statements at the same time.

In the preceding example, if there were no table-level lock, the value of the auto-increment column used for the `INSERT` in `Tx2` depends on precisely when the statement executes. If the `INSERT` of `Tx2` executes while the `INSERT` of `Tx1` is running (rather than before it starts or after it completes), the specific auto-increment values assigned by the two `INSERT` statements are nondeterministic, and may vary from run to run.

Under the `consecutive` lock mode, `InnoDB` can avoid using table-level `AUTO-INC` locks for "simple insert" statements where the number of rows is known in advance, and still preserve deterministic execution and safety for statement-based replication.

If you are not using the binary log to replay SQL statements as part of recovery or replication, the `interleaved` lock mode can be used to eliminate all use of table-level `AUTO-INC` locks for even greater concurrency and performance, at the cost of permitting gaps in auto-increment numbers assigned by a statement and potentially having the numbers assigned by concurrently executing statements interleaved.

- `innodb_autoinc_lock_mode = 1` ("consecutive" lock mode)
InnoDB Table Management

This is the default lock mode. In this mode, “bulk inserts” use the special AUTO-INC table-level lock and hold it until the end of the statement. This applies to all INSERT ... SELECT, REPLACE ... SELECT, and LOAD DATA statements. Only one statement holding the AUTO-INC lock can execute at a time.

“Simple inserts” (for which the number of rows to be inserted is known in advance) avoid table-level AUTO-INC locks by obtaining the required number of auto-increment values under the control of a mutex (a light-weight lock) that is only held for the duration of the allocation process, not until the statement completes. No table-level AUTO-INC lock is used unless an AUTO-INC lock is held by another transaction. If another transaction holds an AUTO-INC lock, a “simple insert” waits for the AUTO-INC lock, as if it were a “bulk insert”.

This lock mode ensures that, in the presence of INSERT statements where the number of rows is not known in advance (and where auto-increment numbers are assigned as the statement progresses), all auto-increment values assigned by any “INSERT-like” statement are consecutive, and operations are safe for statement-based replication.

Simply put, this lock mode significantly improves scalability while being safe for use with statement-based replication. Further, as with “traditional” lock mode, auto-increment numbers assigned by any given statement are consecutive. There is no change in semantics compared to “traditional” mode for any statement that uses auto-increment, with one important exception.

The exception is for “mixed-mode inserts”, where the user provides explicit values for an AUTO_INCREMENT column for some, but not all, rows in a multiple-row “simple insert”. For such inserts, InnoDB allocates more auto-increment values than the number of rows to be inserted. However, all values automatically assigned are consecutively generated (and thus higher than) the auto-increment value generated by the most recently executed previous statement. “Excess” numbers are lost.

• `innodb_autoinc_lock_mode = 2` (“interleaved” lock mode)

In this lock mode, no “INSERT-like” statements use the table-level AUTO-INC lock, and multiple statements can execute at the same time. This is the fastest and most scalable lock mode, but it is not safe when using statement-based replication or recovery scenarios when SQL statements are replayed from the binary log.

In this lock mode, auto-increment values are guaranteed to be unique and monotonically increasing across all concurrently executing “INSERT-like” statements. However, because multiple statements can be generating numbers at the same time (that is, allocation of numbers is interleaved across statements), the values generated for the rows inserted by any given statement may not be consecutive.

If the only statements executing are “simple inserts” where the number of rows to be inserted is known ahead of time, there will be no gaps in the numbers generated for a single statement, except for “mixed-mode inserts”. However, when “bulk inserts” are executed, there may be gaps in the auto-increment values assigned by any given statement.

InnoDB AUTO_INCREMENT Lock Mode Usage Implications

• Using auto-increment with replication

If you are using statement-based replication, set `innodb_autoinc_lock_mode` to 0 or 1 and use the same value on the master and its slaves. Auto-increment values are not ensured to be the same on the slaves as on the master if you use `innodb_autoinc_lock_mode = 2` (“interleaved”) or configurations where the master and slaves do not use the same lock mode.

If you are using row-based or mixed-format replication, all of the auto-increment lock modes are safe, since row-based replication is not sensitive to the order of execution of the SQL statements (and the
mixed format uses row-based replication for any statements that are unsafe for statement-based replication).

• “Lost” auto-increment values and sequence gaps

In all lock modes (0, 1, and 2), if a transaction that generated auto-increment values rolls back, those auto-increment values are “lost”. Once a value is generated for an auto-increment column, it cannot be rolled back, whether or not the “INSERT-like” statement is completed, and whether or not the containing transaction is rolled back. Such lost values are not reused. Thus, there may be gaps in the values stored in an AUTO_INCREMENT column of a table.

• Specifying NULL or 0 for the AUTO_INCREMENT column

In all lock modes (0, 1, and 2), if a user specifies NULL or 0 for the AUTO_INCREMENT column in an INSERT, InnoDB treats the row as if the value was not specified and generates a new value for it.

• Assigning a negative value to the AUTO_INCREMENT column

In all lock modes (0, 1, and 2), the behavior of the auto-increment mechanism is not defined if you assign a negative value to the AUTO_INCREMENT column.

• If the AUTO_INCREMENT value becomes larger than the maximum integer for the specified integer type

In all lock modes (0, 1, and 2), the behavior of the auto-increment mechanism is not defined if the value becomes larger than the maximum integer that can be stored in the specified integer type.

• Gaps in auto-increment values for “bulk inserts”

With innodb_autoinc_lock_mode set to 0 (“traditional”) or 1 (“consecutive”), the auto-increment values generated by any given statement will be consecutive, without gaps, because the table-level AUTO-INC lock is held until the end of the statement, and only one such statement can execute at a time.

With innodb_autoinc_lock_mode set to 2 (“interleaved”), there may be gaps in the auto-increment values generated by “bulk inserts,” but only if there are concurrently executing “INSERT-like” statements.

For lock modes 1 or 2, gaps may occur between successive statements because for bulk inserts the exact number of auto-increment values required by each statement may not be known and overestimation is possible.

• Auto-increment values assigned by “mixed-mode inserts”

Consider a “mixed-mode insert,” where a “simple insert” specifies the auto-increment value for some (but not all) resulting rows. Such a statement will behave differently in lock modes 0, 1, and 2. For example, assume c1 is an AUTO_INCREMENT column of table t1, and that the most recent automatically generated sequence number is 100.

```sql
mysql> CREATE TABLE t1 (
    -> c1 INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
    -> c2 CHAR(1)
    -> ) ENGINE = INNODB;

mysql> INSERT INTO t1 VALUES(1,'a'),(101,'b'),(5,'c'),(102,'d');
```

Now, consider the following “mixed-mode insert” statement:

```sql
mysql> INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (5,'c'), (NULL,'d');
```

With innodb_autoinc_lock_mode set to 0 (“traditional”), the four new rows will be:
InnoDB Table Management

mysql> SELECT c1, c2 FROM t1 ORDER BY c2;
+-----+------+
| c1  | c2   |
+-----+------+
| 101 |   b  |
|   5 |   c  |
|   1 |   a  |
+-----+------+

The next available auto-increment value will be 103 because the auto-increment values are allocated one at a time, not all at once at the beginning of statement execution. This result is true whether or not there are concurrently executing “INSERT-like” statements (of any type).

With `innodb_autoinc_lock_mode` set to 1 (“consecutive”), the four new rows will also be:

mysql> SELECT c1, c2 FROM t1 ORDER BY c2;
+-----+------+
| c1  | c2   |
+-----+------+
|   1 |   a  |
| 101 |   b  |
|   5 |   c  |
| 102 |   d  |
+-----+------+

However, in this case, the next available auto-increment value will be 105, not 103 because four auto-increment values are allocated at the time the statement is processed, but only two are used. This result is true whether or not there are concurrently executing “INSERT-like” statements (of any type).

With `innodb_autoinc_lock_mode` set to mode 2 (“interleaved”), the four new rows will be:

mysql> SELECT c1, c2 FROM t1 ORDER BY c2;
+-----+------+
| c1  | c2   |
+-----+------+
|   1 |   a  |
|   x |   b  |
|   5 |   c  |
|   y |   d  |
+-----+------+

The values of \(x\) and \(y\) will be unique and larger than any previously generated rows. However, the specific values of \(x\) and \(y\) will depend on the number of auto-increment values generated by concurrently executing statements.

Finally, consider the following statement, issued when the most-recently generated sequence number was the value 4:

mysql> INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (5,'c'), (NULL,'d');

With any `innodb_autoinc_lock_mode` setting, this statement will generate a duplicate-key error 23000 (Can't write; duplicate key in table) because 5 will be allocated for the row (NULL, 'b') and insertion of the row (5, 'c') will fail.

• Modifying `AUTO_INCREMENT` column values in the middle of a sequence of `INSERT` statements

In all lock modes (0, 1, and 2), modifying an `AUTO_INCREMENT` column value in the middle of a sequence of `INSERT` statements could lead to “Duplicate entry” errors. For example, if you perform an `UPDATE` operation that changes an `AUTO_INCREMENT` column value to a value larger than the current maximum auto-increment value, subsequent `INSERT` operations that do not
specify an unused auto-increment value could encounter “Duplicate entry” errors. This behavior is demonstrated in the following example.

```sql
mysql> CREATE TABLE t1 (  
  -> c1 INT NOT NULL AUTO_INCREMENT,  
  -> PRIMARY KEY (c1)  
  -> ) ENGINE = InnoDB;

mysql> INSERT INTO t1 VALUES(0), (0), (3);

mysql> SELECT c1 FROM t1;
+----+
| c1 |
+----+
|  1 |
|  2 |
|  3 |
+----+

mysql> UPDATE t1 SET c1 = 4 WHERE c1 = 1;

mysql> SELECT c1 FROM t1;
+----+
| c1 |
+----+
|  2 |
|  3 |
|  4 |
+----+

mysql> INSERT INTO t1 VALUES(0);
ERROR 1062 (23000): Duplicate entry '4' for key 'PRIMARY'
```

### InnoDB AUTO_INCREMENT Counter Initialization

This section describes how InnoDB initializes AUTO_INCREMENT counters.

If you specify an AUTO_INCREMENT column for an InnoDB table, the table handle in the InnoDB data dictionary contains a special counter called the auto-increment counter that is used in assigning new values for the column. This counter is stored only in main memory, not on disk.

To initialize an auto-increment counter after a server restart, InnoDB executes the equivalent of the following statement on the first insert into a table containing an AUTO_INCREMENT column.

```sql
SELECT MAX(ai_col) FROM table_name FOR UPDATE;
```

InnoDB increments the value retrieved by the statement and assigns it to the column and to the auto-increment counter for the table. By default, the value is incremented by 1. This default can be overridden by the auto_increment_increment configuration setting.

If the table is empty, InnoDB uses the value 1. This default can be overridden by the auto_increment_offset configuration setting.

If a SHOW TABLE STATUS statement examines the table before the auto-increment counter is initialized, InnoDB initializes but does not increment the value. The value is stored for use by later inserts. This initialization uses a normal exclusive-locking read on the table and the lock lasts to the end of the transaction. InnoDB follows the same procedure for initializing the auto-increment counter for a newly created table.

After the auto-increment counter has been initialized, if you do not explicitly specify a value for an AUTO_INCREMENT column, InnoDB increments the counter and assigns the new value to the column. If you insert a row that explicitly specifies the column value, and the value is greater than the current counter value, the counter is set to the specified column value.
InnoDB uses the in-memory auto-increment counter as long as the server runs. When the server is stopped and restarted, InnoDB reinitializes the counter for each table for the first INSERT to the table, as described earlier.

A server restart also cancels the effect of the AUTO_INCREMENT = N table option in CREATE TABLE and ALTER TABLE statements, which you can use with InnoDB tables to set the initial counter value or alter the current counter value.

### 14.6.6 InnoDB and FOREIGN KEY Constraints

This section describes differences in the InnoDB storage engine’s handling of foreign keys as compared with that of the MySQL Server.

#### Foreign Key Definitions

Foreign key definitions for InnoDB tables are subject to the following conditions:

- **InnoDB** permits a foreign key to reference any index column or group of columns. However, in the referenced table, there must be an index where the referenced columns are listed as the first columns in the same order.

- **InnoDB** does not currently support foreign keys for tables with user-defined partitioning. This means that no user-partitioned InnoDB table may contain foreign key references or columns referenced by foreign keys.

- **InnoDB** allows a foreign key constraint to reference a non-unique key. *This is an InnoDB extension to standard SQL.*

#### Referential Actions

Referential actions for foreign keys of InnoDB tables are subject to the following conditions:

- While SET DEFAULT is allowed by the MySQL Server, it is rejected as invalid by InnoDB. CREATE TABLE and ALTER TABLE statements using this clause are not allowed for InnoDB tables.

- If there are several rows in the parent table that have the same referenced key value, InnoDB acts in foreign key checks as if the other parent rows with the same key value do not exist. For example, if you have defined a RESTRICT type constraint, and there is a child row with several parent rows, InnoDB does not permit the deletion of any of those parent rows.

- **InnoDB** performs cascading operations through a depth-first algorithm, based on records in the indexes corresponding to the foreign key constraints.

- If ON UPDATE CASCADE or ON UPDATE SET NULL recurses to update the same table it has previously updated during the cascade, it acts like RESTRICT. This means that you cannot use self-referential ON UPDATE CASCADE or ON UPDATE SET NULL operations. This is to prevent infinite loops resulting from cascaded updates. A self-referential ON DELETE SET NULL, on the other hand, is possible, as is a self-referential ON DELETE CASCADE. Cascading operations may not be nested more than 15 levels deep.

- Like MySQL in general, in an SQL statement that inserts, deletes, or updates many rows, InnoDB checks UNIQUE and FOREIGN KEY constraints row-by-row. When performing foreign key checks, InnoDB sets shared row-level locks on child or parent records it has to look at. InnoDB checks foreign key constraints immediately; the check is not deferred to transaction commit. According to the SQL standard, the default behavior should be deferred checking. That is, constraints are only checked after the entire SQL statement has been processed. Until InnoDB implements deferred constraint checking, some things will be impossible, such as deleting a record that refers to itself using a foreign key.
Foreign Key Usage and Error Information

You can obtain general information about foreign keys and their usage from querying the `INFORMATION_SCHEMA.KEY_COLUMN_USAGE` table. See also Section 13.1.17.3, "Using FOREIGN KEY Constraints".

In addition to `SHOW ERRORS`, in the event of a foreign key error involving InnoDB tables (usually Error 150 in the MySQL Server), you can obtain a detailed explanation of the most recent InnoDB foreign key error by checking the output of `SHOW ENGINE INNODB STATUS`.

14.6.6.7 Limits on InnoDB Tables

<table>
<thead>
<tr>
<th>Warning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Do not convert MySQL system tables in the <code>mysql</code> database from MyISAM to InnoDB tables. This is an unsupported operation. If you do this, MySQL does not restart until you restore the old system tables from a backup or regenerate them by reinitializing the data directory (see Section 2.12.1, &quot;Initializing the Data Directory&quot;).</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Warning</th>
</tr>
</thead>
<tbody>
<tr>
<td>It is not a good idea to configure InnoDB to use data files or log files on NFS volumes. Otherwise, the files might be locked by other processes and become unavailable for use by MySQL.</td>
</tr>
</tbody>
</table>

Maximums and Minimums

- A table can contain a maximum of 1000 columns.
- A table can contain a maximum of 64 secondary indexes.
- An index key for a single-column index can be up to 767 bytes. The same length limit applies to any index key prefix. See Section 13.1.13, "CREATE INDEX Syntax".
- The InnoDB internal maximum key length is 3500 bytes, but MySQL itself restricts this to 3072 bytes. This limit applies to the length of the combined index key in a multi-column index.
- The maximum row length, except for variable-length columns (`VARBINARY`, `VARCHAR`, `BLOB` and `TEXT`), is slightly less than half of a database page. That is, the maximum row length is about 8000 bytes. `LONGBLOB` and `LONGTEXT` columns must be less than 4GB, and the total row length, including `BLOB` and `TEXT` columns, must be less than 4GB.

If a row is less than half a page long, all of it is stored locally within the page. If it exceeds half a page, variable-length columns are chosen for external off-page storage until the row fits within half a page, as described in Section 14.6.7.2, "File Space Management".

The row size for `BLOB` columns that are chosen for external off-page storage should not exceed 10% of the combined redo log file size. If the row size exceeds 10% of the combined redo log file size, InnoDB could overwrite the most recent checkpoint which may result in lost data during crash recovery. (Bug#69477).

- Although InnoDB supports row sizes larger than 65,535 bytes internally, MySQL itself imposes a row-size limit of 65,535 for the combined size of all columns:

```sql
mysql> CREATE TABLE t (a VARCHAR(8000), b VARCHAR(10000),
                        c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
                        f VARCHAR(10000), g VARCHAR(10000)) ENGINE=InnoDB;
ERROR 1118 (42000): Row size too large. The maximum row size for the used table type, not counting BLOBs, is 65535. You have to change some columns to TEXT or BLOBs
```
InnoDB Table Management

See Section C.7.4, "Limits on Table Column Count and Row Size".

• On some older operating systems, files must be less than 2GB. This is not a limitation of InnoDB itself, but if you require a large tablespace, you will need to configure it using several smaller data files rather than one large data file.

• The combined size of the InnoDB log files must be less than 4GB.

• The minimum tablespace size is 10MB. The maximum tablespace size is four billion database pages (64TB). This is also the maximum size for a table.

• The default database page size in InnoDB is 16KB.

Note

Changing the page size is not a supported operation and there is no guarantee that InnoDB will function normally with a page size other than 16KB. Problems compiling or running InnoDB may occur. In particular, ROW_FORMAT=COMPRESSED in the InnoDB Plugin assumes that the page size is at most 16KB and uses 14-bit pointers.

A version of InnoDB built for one page size cannot use data files or log files from a version built for a different page size. This limitation could affect restore or downgrade operations using data from MySQL 5.6, which does support page sizes other than 16KB.

Index Types

• InnoDB tables do not support FULLTEXT indexes.

• InnoDB tables support spatial data types, but not indexes on them.

Restrictions on InnoDB Tables

• ANALYZE TABLE determines index cardinality (as displayed in the Cardinality column of SHOW INDEX output) by doing eight random dives to each of the index trees and updating index cardinality estimates accordingly. Because these are only estimates, repeated runs of ANALYZE TABLE may produce different numbers. This makes ANALYZE TABLE fast on InnoDB tables but not 100% accurate because it does not take all rows into account.

For InnoDB Plugin, you can change the number of random dives by modifying the innodb_stats_sample_pages system variable.

MySQL uses index cardinality estimates only in join optimization. If some join is not optimized in the right way, you can try using ANALYZE TABLE. In the few cases that ANALYZE TABLE does not produce values good enough for your particular tables, you can use FORCE INDEX with your queries to force the use of a particular index, or set the max_seeks_for_key system variable to ensure that MySQL prefers index lookups over table scans. See Section 5.1.4, “Server System Variables”, and Section B.5.5, “Optimizer-Related Issues”.

• If statements or transactions are running on a table and ANALYZE TABLE is run on the same table followed by a second ANALYZE TABLE operation, the second ANALYZE TABLE operation is blocked until the statements or transactions are completed. This behavior occurs because ANALYZE TABLE marks the currently loaded table definition as obsolete when ANALYZE TABLE is finished running. New statements or transactions (including a second ANALYZE TABLE statement) must load the new table definition into the table cache, which cannot occur until currently running statements or transactions are completed and the old table definition is purged. Loading multiple concurrent table definitions is not supported.

• SHOW TABLE STATUS does not give accurate statistics on InnoDB tables, except for the physical size reserved by the table. The row count is only a rough estimate used in SQL optimization.
InnoDB Table Management

• **InnoDB** does not keep an internal count of rows in a table because concurrent transactions might “see” different numbers of rows at the same time. To process a `SELECT COUNT(*)` FROM `t` statement, **InnoDB** scans an index of the table, which takes some time if the index is not entirely in the buffer pool. If your table does not change often, using the MySQL query cache is a good solution. To get a fast count, you have to use a counter table you create yourself and let your application update it according to the inserts and deletes it does. If an approximate row count is sufficient, `SHOW TABLE STATUS` can be used.

• On Windows, **InnoDB** always stores database and table names internally in lowercase. To move databases in a binary format from Unix to Windows or from Windows to Unix, create all databases and tables using lowercase names.

• An **AUTO_INCREMENT** column `ai_col` must be defined as part of an index such that it is possible to perform the equivalent of an indexed `SELECT MAX(ai_col)` lookup on the table to obtain the maximum column value. Typically, this is achieved by making the column the first column of some table index.

• **InnoDB** sets an exclusive lock on the end of the index associated with the **AUTO_INCREMENT** column while initializing a previously specified **AUTO_INCREMENT** column on a table.

  With `innodb_autoinc_lock_mode=0`, **InnoDB** uses a special **AUTO-INC** table lock mode where the lock is obtained and held to the end of the current SQL statement while accessing the auto-increment counter. Other clients cannot insert into the table while the **AUTO-INC** table lock is held. The same behavior occurs for “bulk inserts” with `innodb_autoinc_lock_mode=1`. Table-level **AUTO-INC** locks are not used with `innodb_autoinc_lock_mode=2`. For more information, See Section 14.6.6.5, “AUTO_INCREMENT Handling in InnoDB”.

• When you restart the MySQL server, **InnoDB** may reuse an old value that was generated for an **AUTO_INCREMENT** column but never stored (that is, a value that was generated during an old transaction that was rolled back).

• When an **AUTO_INCREMENT** integer column runs out of values, a subsequent `INSERT` operation returns a duplicate-key error. This is general MySQL behavior, similar to how **MyISAM** works.

• `DELETE FROM tbl_name` does not regenerate the table but instead deletes all rows, one by one.

• Under some conditions, `TRUNCATE tbl_name` for an **InnoDB** table is mapped to `DELETE FROM tbl_name`. See Section 13.1.34, “TRUNCATE TABLE Syntax”.

• The `LOAD TABLE FROM MASTER` statement for setting up replication slave servers does not work for **InnoDB** tables. A workaround is to alter the table to **MyISAM** on the master, then do the load, and after that alter the master table back to **InnoDB**. Do not do this if the tables use **InnoDB**-specific features such as foreign keys.

• Cascaded foreign key actions do not activate triggers.

• You cannot create a table with a column name that matches the name of an internal **InnoDB** column (including `DB_ROW_ID`, `DB_TRX_ID`, `DB_ROLL_PTR`, and `DB_MIX_ID`). In versions of MySQL before 5.1.10 this would cause a crash, since 5.1.10 the server will report error 1005 and refers to error -1 in the error message. This restriction applies only to use of the names in uppercase.

**Locking and Transactions**

• **LOCK TABLES** acquires two locks on each table if `innodb_table_locks=1` (the default). In addition to a table lock on the MySQL layer, it also acquires an **InnoDB** table lock. Versions of MySQL before 4.1.2 did not acquire **InnoDB** table locks; the old behavior can be selected by setting `innodb_table_locks=0`. If no **InnoDB** table lock is acquired, **LOCK TABLES** completes even if some records of the tables are being locked by other transactions.

• All **InnoDB** locks held by a transaction are released when the transaction is committed or aborted. Thus, it does not make much sense to invoke **LOCK TABLES** on **InnoDB** tables in `autocommit=1` mode because the acquired **InnoDB** table locks would be released immediately.
• You cannot lock additional tables in the middle of a transaction because `LOCK TABLES` performs an implicit `COMMIT` and `UNLOCK TABLES`.

• `InnoDB` has a limit of 1023 concurrent transactions that have created undo records by modifying data. Workarounds include keeping transactions as small and fast as possible, delaying changes until near the end of the transaction, and using stored routines to reduce client/server latency delays. Applications should commit transactions before doing time-consuming client-side operations.

### 14.6.7 InnoDB Disk I/O and File Space Management

#### 14.6.7.1 InnoDB Disk I/O

`InnoDB` uses simulated asynchronous disk I/O: `InnoDB` creates a number of threads to take care of I/O operations, such as read-ahead.

There are two read-ahead heuristics in `InnoDB`:

• In sequential read-ahead, if `InnoDB` notices that the access pattern to a segment in the tablespace is sequential, it posts in advance a batch of reads of database pages to the I/O system.

• In random read-ahead, if `InnoDB` notices that some area in a tablespace seems to be in the process of being fully read into the buffer pool, it posts the remaining reads to the I/O system.

`InnoDB` uses a novel file flush technique involving a structure called the doublewrite buffer, which is enabled by default (`innodb_doublewrite=ON`). It adds safety to recovery following a crash or power outage, and improves performance on most varieties of Unix by reducing the need for `fsync()` operations.

Doublewrite means that before writing pages to a data file, `InnoDB` first writes them to a contiguous tablespace area called the doublewrite buffer. Only after the write and the flush to the doublewrite buffer has completed does `InnoDB` write the pages to their proper positions in the data file. If there is an operating system, storage subsystem, or `mysqld` process crash in the middle of a page write (causing a torn page condition), `InnoDB` can later find a good copy of the page from the doublewrite buffer during recovery.

#### 14.6.7.2 File Space Management

The data files that you define in the configuration file form the `InnoDB` tablespace. The files are logically concatenated to form the tablespace. There is no striping in use. You cannot define where within the tablespace your tables are allocated. However, in a newly created tablespace, `InnoDB` allocates space starting from the first data file.

The tablespace consists of database pages with a default size of 16KB. The pages are grouped into extents of size 1MB (64 consecutive pages). The “files” inside a tablespace are called segments in `InnoDB`. The term “rollback segment” is somewhat confusing because it actually contains many tablespace segments.

When a segment grows inside the tablespace, `InnoDB` allocates the first 32 pages to it individually. After that, `InnoDB` starts to allocate whole extents to the segment. `InnoDB` can add up to 4 extents at a time to a large segment to ensure good sequentiality of data.

Two segments are allocated for each index in `InnoDB`. One is for nonleaf nodes of the B-tree, the other is for the leaf nodes. The idea here is to achieve better sequentiality for the leaf nodes, which contain the data.

Some pages in the tablespace contain bitmaps of other pages, and therefore a few extents in an `InnoDB` tablespace cannot be allocated to segments as a whole, but only as individual pages.

When you ask for available free space in the tablespace by issuing a `SHOW TABLE STATUS` statement, `InnoDB` reports the extents that are definitely free in the tablespace. `InnoDB` always reserves some extents for cleanup and other internal purposes; these reserved extents are not included in the free space.
When you delete data from a table, InnoDB contracts the corresponding B-tree indexes. Whether the freed space becomes available for other users depends on whether the pattern of deletes frees individual pages or extents to the tablespace. Dropping a table or deleting all rows from it is guaranteed to release the space to other users, but remember that deleted rows are physically removed only in an (automatic) purge operation after they are no longer needed for transaction rollbacks or consistent reads. (See Section 14.6.3.1, “InnoDB Multi-Versioning”.)

To see information about the tablespace, use the Tablespace Monitor. See Section 14.6.9, “InnoDB Monitors”.

The maximum row length, except for variable-length columns (VARBINARY, VARCHAR, BLOB and TEXT), is slightly less than half of a database page. That is, the maximum row length is about 8000 bytes. LONGBLOB and LONGTEXT columns must be less than 4GB, and the total row length, including BLOB and TEXT columns, must be less than 4GB.

If a row is less than half a page long, all of it is stored locally within the page. If it exceeds half a page, variable-length columns are chosen for external off-page storage until the row fits within half a page. For a column chosen for off-page storage, InnoDB stores the first 768 bytes locally in the row, and the rest externally into overflow pages. Each such column has its own list of overflow pages. The 768-byte prefix is accompanied by a 20-byte value that stores the true length of the column and points into the overflow list where the rest of the value is stored.

14.6.7.3 Defragmenting a Table

If there are random insertions into or deletions from the indexes of a table, the indexes may become fragmented. Fragmentation means that the physical ordering of the index pages on the disk is not close to the index ordering of the records on the pages, or that there are many unused pages in the 64-page blocks that were allocated to the index.

One symptom of fragmentation is that a table takes more space than it “should” take. How much that is exactly, is difficult to determine. All InnoDB data and indexes are stored in B-trees, and their fill factor may vary from 50% to 100%. Another symptom of fragmentation is that a table scan such as this takes more time than it “should” take:

```sql
SELECT COUNT(*) FROM t WHERE a_non_indexed_column <> 12345;
```

The preceding query requires MySQL to perform a full table scan, the slowest type of query for a large table.

It can speed up index scans if you periodically perform a “null” `ALTER TABLE` operation, which causes MySQL to rebuild the table:

```sql
ALTER TABLE tbl_name ENGINE=INNODB
```

Another way to perform a defragmentation operation is to use `mysqldump` to dump the table to a text file, drop the table, and reload it from the dump file.

If the insertions into an index are always ascending and records are deleted only from the end, the InnoDB filespace management algorithm guarantees that fragmentation in the index does not occur.

14.6.8 InnoDB Startup Options and System Variables

This section describes the InnoDB-related command options and system variables.

- System variables that are true or false can be enabled at server startup by naming them, or disabled by using a `--skip-` prefix. For example, to enable or disable InnoDB checksums, you can use `--innodb_checkums` or `--skip-innodb_checkums` on the command line, or `innodb_checkums` or `skip-innodb_checkums` in an option file.

- System variables that take a numeric value can be specified as `--var_name=value` on the command line or as `var_name=value` in option files.
Many system variables can be changed at runtime (see Section 5.1.5.2, “Dynamic System Variables”).

For information about GLOBAL and SESSION variable scope modifiers, refer to the SET statement documentation.

For more information on specifying options and system variables, see Section 4.2.3, “Specifying Program Options”.

InnoDB Command Options

- **--ignore-built-in-innodb**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.33</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><strong>--ignore-built-in-innodb</strong></td>
</tr>
</tbody>
</table>
| System Variable | **Name**: ignorebuiltin_innodb  
**Variable**: Global  
**Scope**: Dynamic |
| Permitted Values | **Type**: boolean |

This option causes the server to behave as if the built-in InnoDB is not present, which enables InnoDB Plugin to be used instead. See Section 14.6.2.1, “Using InnoDB Plugin Instead of the Built-In InnoDB”.

If this option is given but InnoDB Plugin is not used in place of the built-in InnoDB, it has the following effects:

- Other InnoDB options (including **--innodb** and **--skip-innodb**) will not be recognized and should not be used.
- The server will not start if the default storage engine is set to InnoDB. Use **--default-storage-engine** to set the default to some other engine if necessary.
- InnoDB will not appear in the output of SHOW ENGINES.

This option was added in MySQL 5.1.33.

- **--innodb[=value]**

Controls loading of the InnoDB storage engine, if the server was compiled with InnoDB support. As of MySQL 5.1.36, this option has a tristate format, with possible values of OFF, ON, or FORCE. Before MySQL 5.1.36, this is a boolean option. See Section 5.1.8.1, “Installing and Uninstalling Plugins”.

To disable InnoDB, use **--innodb=OFF** or **--skip-innodb**. In this case, the server will not start if the default storage engine is set to InnoDB. Use **--default-storage-engine** to set the default to some other engine if necessary.

- **--innodb-status-file**

| Command-Line Format | **--innodb-status-file** |
| Permitted Values | **Type**: boolean  
**Default**: OFF |

Controls whether InnoDB creates a file named innodb_status.<pid> in the MySQL data directory. If enabled, InnoDB periodically writes the output of SHOW ENGINE INNODB STATUS to this file.

By default, the file is not created. To create it, start mysqld with the **--innodb-status-file=1** option. The file is deleted during normal shutdown.

- **--skip-innodb**

Disable the InnoDB storage engine. See the description of **--innodb**.
InnoDB System Variables

• **ignore_builtin_innodb**

  | Introduced | 5.1.33 |
  | Command-Line Format | --ignore-builtin-innodb |
  | System Variable | Name | ignore_builtin_innodb |
  | | Variable | Global |
  | | Scope | Dynamic |
  | | Variable | No |
  | Permitted Values | Type | boolean |

Whether the server was started with the `--ignore-builtin-innodb` option, which causes the server to behave as if the built-in InnoDB is not present. For more information, see the description of `--ignore-builtin-innodb` under "InnoDB Command Options" earlier in this section. This variable was added in MySQL 5.1.33.

• **innodb_adaptive_flushing**

  | Introduced | 5.1.38 |
  | Command-Line Format | --innodb_adaptive_flushing=# |
  | System Variable | Name | innodb_adaptive_flushing |
  | | Variable | Global |
  | | Scope | Dynamic |
  | | Variable | Yes |
  | Permitted Values | Type | boolean |
  | Default | ON |

(InnoDB Plugin only) InnoDB Plugin 1.0.4 and up uses a heuristic to determine when to flush dirty pages in the buffer pool. This heuristic is designed to avoid bursts of I/O activity and is used when `innodb_adaptive_flushing` is enabled (which is the default).

• **innodb_adaptive_hash_index**

  | Introduced | 5.1.24 |
  | Command-Line Format | --innodb_adaptive_hash_index=# |
  | System Variable | Name | innodb_adaptive_hash_index |
  | | Variable | Global |
  | | Scope | Dynamic |
  | | Variable | No |
  | Permitted Values | Type | boolean |
  | Default | ON |

Whether the InnoDB adaptive hash index is enabled or disabled. The adaptive hash index feature is useful for some workloads, and not for others; conduct benchmarks with it both enabled and disabled, using realistic workloads. See Adaptive Hash Indexes for details. This variable is enabled by default. Use `--skip-innodb_adaptive_hash_index` at server startup to disable it. This variable was added in MySQL 5.1.24.
• \texttt{innodb_additional_mem_pool_size}

Command-Line Format: \texttt{--innodb_additional_mem_pool_size=\#}

<table>
<thead>
<tr>
<th>System Variable</th>
<th>Name</th>
<th>Variable</th>
<th>Scope</th>
<th>Dynamic</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>\texttt{innodb_additional_mem_pool_size}</td>
<td>Global</td>
<td>No</td>
<td></td>
</tr>
</tbody>
</table>

**Permitted Values**

<table>
<thead>
<tr>
<th></th>
<th>Type</th>
<th>Default</th>
<th>Min Value</th>
<th>Max Value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>integer</td>
<td>1048576</td>
<td>524288</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

The size in bytes of a memory pool \texttt{InnoDB} uses to store data dictionary information and other internal data structures. The more tables you have in your application, the more memory you need to allocate here. If \texttt{InnoDB} runs out of memory in this pool, it starts to allocate memory from the operating system and writes warning messages to the MySQL error log. The default value is 1MB for the built-in \texttt{InnoDB}, 8MB for \texttt{InnoDB Plugin}.

This variable relates to the \texttt{InnoDB} internal memory allocator, which is unused if \texttt{innodb_use_sys_malloc} is enabled.

• \texttt{innodb_autoextend_increment}

Command-Line Format: \texttt{--innodb_autoextend_increment=\#}

<table>
<thead>
<tr>
<th>System Variable</th>
<th>Name</th>
<th>Variable</th>
<th>Scope</th>
<th>Dynamic</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>\texttt{innodb_autoextend_increment}</td>
<td>Global</td>
<td>Yes</td>
<td></td>
</tr>
</tbody>
</table>

**Permitted Values**

<table>
<thead>
<tr>
<th></th>
<th>Type</th>
<th>Default</th>
<th>Min Value</th>
<th>Max Value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>integer</td>
<td>8</td>
<td>1</td>
<td>1000</td>
</tr>
</tbody>
</table>

The increment size (in MB) for extending the size of an auto-extending shared tablespace file when it becomes full. The default value is 8. This variable does not affect the per-table tablespace files that are created if you use \texttt{innodb_file_per_table=1}. Those files are auto-extending regardless of the value of \texttt{innodb_autoextend_increment}. The initial extensions are by small amounts, after which extensions occur in increments of 4MB.

• \texttt{innodb_buffer_pool_awe_mem_mb}

Removed 5.1.13

Command-Line Format: \texttt{--innodb_buffer_pool_awe_mem_mb=\#}

<table>
<thead>
<tr>
<th>System Variable</th>
<th>Name</th>
<th>Variable</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>\texttt{innodb_buffer_pool_awe_mem_mb}</td>
<td>Global</td>
<td></td>
</tr>
</tbody>
</table>
The size of the buffer pool (in MB), if it is placed in the AWE memory. If it is greater than 0, `innodb_buffer_pool_size` is the window in the 32-bit address space of `mysqld` where InnoDB maps that AWE memory. A good value for `innodb_buffer_pool_size` is 500MB. The maximum possible value is 63000.

To take advantage of AWE memory, you will need to recompile MySQL yourself. The current project settings needed for doing this can be found in the `storage/innobase/os/os0proc.c` source file.

This variable was removed in MySQL 5.1.13. Before that, it is relevant only in 32-bit Windows. If your 32-bit Windows operating system supports more than 4GB memory, using so-called “Address Windowing Extensions,” you can allocate the InnoDB buffer pool into the AWE physical memory using this variable.

• **innodb_autoinc_lock_mode**

  - Introduced 5.1.22
  - Command-Line Format `--innodb_autoinc_lock_mode=#`
  - System Variable Name `innodb_autoinc_lock_mode`
  - Variable Global
  - Scope Dynamic
  - No Variable
  - Permitted Values Type integer
  - Default 1
  - Min Value 0
  - Max Value 2

  The locking mode to use for generating auto-increment values. The permissible values are 0, 1, or 2, for “traditional”, “consecutive”, or “interleaved” lock mode, respectively. Section 14.6.6.5, “AUTO_INCREMENT Handling in InnoDB”, describes the characteristics of these modes.

  This variable was added in MySQL 5.1.22 with a default of 1 (“consecutive” lock mode). Before 5.1.22, InnoDB uses “traditional” lock mode.

• **innodb_buffer_pool_size**

  - Command-Line Format `--innodb_buffer_pool_size=#`
  - System Variable Name `innodb_buffer_pool_size`
  - Variable Global
  - Scope
The size in bytes of the memory buffer InnoDB uses to cache data and indexes of its tables. The default value is 128MB, increased from a historical default of 8MB. In MySQL 5.1.28 and later, the maximum value depends on the CPU architecture; the maximum is 4294967295 (2^{32}-1) on 32-bit systems and 18446744073709551615 (2^{64}-1) on 64-bit systems. On 32-bit systems, the CPU architecture and operating system may impose a lower practical maximum size than the stated maximum.

A larger buffer pool requires less disk I/O to access the same table data more than once. On a dedicated database server, you might set the buffer pool size to 80% of the machine's physical memory size. Be aware of the following potential issues when configuring buffer pool size, and be prepared to scale back the size of the buffer pool if necessary.

- Competition for physical memory can cause paging in the operating system.
- InnoDB reserves additional memory for buffers and control structures, so that the total allocated space is approximately 10% greater than the specified buffer pool size.
- Address space for the buffer pool must be contiguous, which can be an issue on Windows systems with DLLs that load at specific addresses.
- The time to initialize the buffer pool is roughly proportional to its size. On large installations, initialization time might be significant. For example, on a modern Linux x86_64 server, initialization of a 10GB buffer pool takes approximately 6 seconds. See Section 8.10.2, “The InnoDB Buffer Pool”.

- `innodb_change_buffering`

<table>

- `innodb_change_buffering`

**Introduced** 5.1.38

**Command-Line Format** `--innodb_change_buffering=#`

**System Variable**

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
<th>Global Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>innodb_change_buffering</td>
<td></td>
<td>Dynamic Yes</td>
</tr>
</tbody>
</table>

### InnoDB Startup Options and System Variables

#### Permitted Values

<table>
<thead>
<tr>
<th>Permitted Values</th>
<th>Type</th>
<th>Default</th>
<th>Valid Values</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>enumeration</td>
<td>inserts</td>
<td>inserts, none</td>
</tr>
</tbody>
</table>

(\textit{InnoDB Plugin} only) Whether InnoDB performs insert buffering. The permitted values \texttt{none} (do not buffer any operations) and \texttt{inserts} (buffer insert operations). The default is \texttt{inserts}. For details, see \texttt{Insert Buffering}.

- \texttt{innodb_change_buffering_debug}

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.53</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>\texttt{--innodb_change_buffering_debug=#}</td>
</tr>
<tr>
<td>System Variable</td>
<td>Name: \texttt{innodb_change_buffering_debug}</td>
</tr>
<tr>
<td></td>
<td>Variable: Global</td>
</tr>
<tr>
<td></td>
<td>Dynamic: Yes</td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td>Type: integer</td>
</tr>
<tr>
<td></td>
<td>Default: 0</td>
</tr>
<tr>
<td></td>
<td>Max Value: 2</td>
</tr>
</tbody>
</table>

Sets a debug flag for InnoDB change buffering. A value of 1 forces all changes to the change buffer. A value of 2 causes a crash at merge. A default value of 0 indicates that the change buffering debug flag is not set. This option is only available when debugging support is compiled in using the \texttt{WITH_DEBUG CMake} option.

- \texttt{innodb_checksums}

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>\texttt{--innodb_checksums}</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name: \texttt{innodb_checksums}</td>
</tr>
<tr>
<td></td>
<td>Variable: Global</td>
</tr>
<tr>
<td></td>
<td>Dynamic: No</td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td>Type: boolean</td>
</tr>
<tr>
<td></td>
<td>Default: ON</td>
</tr>
</tbody>
</table>

InnoDB can use checksum validation on all pages read from the disk to ensure extra fault tolerance against broken hardware or data files. This validation is enabled by default. However, under some rare circumstances (such as when running benchmarks) this extra safety feature is unneeded and can be disabled with \texttt{--skip-innodb-checksums}.

- \texttt{innodb_commit_concurrency}

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>\texttt{--innodb_commit_concurrency=#}</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name: \texttt{innodb_commit_concurrency}</td>
</tr>
<tr>
<td></td>
<td>Variable: Global</td>
</tr>
</tbody>
</table>

InnoDB Startup Options and System Variables

**innodb_commit_concurrency**

<table>
<thead>
<tr>
<th>Dynamic</th>
<th>Yes</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Variable</th>
<th>Type</th>
<th>Default</th>
<th>Min Value</th>
<th>Max Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>innodb_commit_concurrency</td>
<td>integer</td>
<td>0</td>
<td>0</td>
<td>1000</td>
</tr>
</tbody>
</table>

The number of threads that can commit at the same time. A value of 0 (the default) permits any number of transactions to commit simultaneously.

As of MySQL 5.1.36, the value of **innodb_commit_concurrency** cannot be changed at runtime from zero to nonzero or vice versa. The value can still be changed from one nonzero value to another.

- **innodb_concurrency_tickets**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>Name</th>
<th>Variable</th>
<th>Scope</th>
<th>Dynamic</th>
<th>Yes</th>
</tr>
</thead>
<tbody>
<tr>
<td>--innodb_concurrency_tickets=#</td>
<td>innodb_concurrency_tickets</td>
<td>innodb_concurrency_tickets</td>
<td>Global</td>
<td>Yes</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>
<th>Type</th>
<th>Default</th>
<th>Min Value</th>
<th>Max Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>innodb_concurrency_tickets</td>
<td>integer</td>
<td>500</td>
<td>1</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

The number of threads that can enter InnoDB concurrently is determined by the **innodb_thread_concurrency** variable. A thread is placed in a queue when it tries to enter InnoDB if the number of threads has already reached the concurrency limit. When a thread is permitted to enter InnoDB, it is given a number of “free tickets” equal to the value of **innodb_concurrency_tickets**, and the thread can enter and leave InnoDB freely until it has used up its tickets. After that point, the thread again becomes subject to the concurrency check (and possible queuing) the next time it tries to enter InnoDB. The default value is 500.

With a small **innodb_concurrency_tickets** value, small transactions that only need to process a few rows compete fairly with larger transactions that process many rows. The disadvantage of a small **innodb_concurrency_tickets** value is that large transactions must loop through the queue many times before they can complete, which extends the length of time required to complete their task.

With a large **innodb_concurrency_tickets** value, large transactions spend less time waiting for a position at the end of the queue (controlled by **innodb_thread_concurrency**) and more time retrieving rows. Large transactions also require fewer trips through the queue to complete their task. The disadvantage of a large **innodb_concurrency_tickets** value is that too many large transactions running at the same time can starve smaller transactions by making them wait a longer time before executing.

With a non-zero **innodb_thread_concurrency** value, you may need to adjust the **innodb_concurrency_tickets** value up or down to find the optimal balance between larger
and smaller transactions. The SHOW ENGINE INNODB STATUS report shows the number of tickets remaining for an executing transaction in its current pass through the queue.

- **innodb_data_file_path**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb_data_file_path=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name innodb_data_file_path</td>
</tr>
<tr>
<td>Variable</td>
<td>Global</td>
</tr>
<tr>
<td>Scope</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type string</td>
</tr>
<tr>
<td>Default</td>
<td>ibdata1:10M:autoextend</td>
</tr>
</tbody>
</table>

  The paths to individual data files and their sizes. The full directory path to each data file is formed by concatenating innodb_data_home_dir to each path specified here. The file sizes are specified MB or GB (1024MB) by appending M or G to the size value. The sum of the sizes of the files must be at least slightly larger than 10MB. If you do not specify innodb_data_file_path, the default behavior is to create a single auto-extending data file, slightly larger than 10MB, named ibdata1. The size limit of individual files is determined by your operating system. You can set the file size to more than 4GB on those operating systems that support big files. You can also use raw disk partitions as data files. For detailed information on configuring InnoDB tablespace files, see Section 14.6.2, “InnoDB Configuration”.

- **innodb_data_home_dir**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb_data_home_dir=dir_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name innodb_data_home_dir</td>
</tr>
<tr>
<td>Variable</td>
<td>Global</td>
</tr>
<tr>
<td>Scope</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type directory name</td>
</tr>
</tbody>
</table>

  The common part of the directory path for all InnoDB data files in the shared tablespace. This setting does not affect the location of per-file tablespaces when innodb_file_per_table is enabled. The default value is the MySQL data directory. If you specify the value as an empty string, you can use absolute file paths in innodb_data_file_path.

- **innodb_doublewrite**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-doublewrite</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name innodb_doublewrite</td>
</tr>
<tr>
<td>Variable</td>
<td>Global</td>
</tr>
<tr>
<td>Scope</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type boolean</td>
</tr>
<tr>
<td>Default</td>
<td>ON</td>
</tr>
</tbody>
</table>

  If this variable is enabled (the default), InnoDB stores all data twice, first to the doublewrite buffer, and then to the actual data files. This variable can be turned off with --skip-
InnoDB Startup Options and System Variables

- **innodb_doublewrite** for benchmarks or cases when top performance is needed rather than concern for data integrity or possible failures.

- **innodb_fast_shutdown**

  **Command-Line Format**
  
  --innodb_fast_shutdown[=#]

  **System Variable**
  
  Name: innodb_fast_shutdown
  
  **Variable Scope**
  
  Global
  
  Dynamic: Yes
  
  **Permitted Values**
  
  Type: integer
  
  Default: 1
  
  Valid Values:
  
  0
  
  1
  
  2

  The InnoDB shutdown mode. By default, the value is 1, which causes a “fast” shutdown (the normal type of shutdown). If the value is 0, InnoDB does a full purge and an insert buffer merge before a shutdown. These operations can take minutes, or even hours in extreme cases. If the value is 1, InnoDB skips these operations at shutdown. If the value is 2, InnoDB will just flush its logs and then shut down cold, as if MySQL had crashed; no committed transaction will be lost, but crash recovery will be done at the next startup. A value of 2 cannot be used on NetWare.

- **innodb_file_format**

  **Introduced** 5.1.38

  **Command-Line Format**
  
  --innodb_file_format=#

  **System Variable**
  
  Name: innodb_file_format
  
  **Variable Scope**
  
  Global
  
  Dynamic: Yes
  
  **Permitted Values**
  
  Type: string
  
  Default: Antelope
  
  Valid Values:
  
  Antelope
  
  Barracuda

  (InnoDB Plugin only) The file format to use for new InnoDB tables. Currently Antelope and Barracuda are supported. This applies only for tables that have their own tablespace, so for it to have an effect innodb_file_per_table must be enabled. The Barracuda file format is required for certain InnoDB features such as table compression.

- **innodb_file_format_check**

  **Introduced** 5.1.38

  **Command-Line Format**
  
  --innodb_file_format_check=#

  **System Variable**
  
  Name: innodb_file_format_check
  
  **Variable Scope**
  
  Global
InnoDB Startup Options and System Variables

<table>
<thead>
<tr>
<th>Permitted Values (&lt;= 5.1.41)</th>
<th>Type</th>
<th>string</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>Antelope</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values (&gt;= 5.1.42)</th>
<th>Type</th>
<th>string</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>Barracuda</td>
<td></td>
</tr>
</tbody>
</table>

(InnoDB Plugin only) This variable can be set to 1 or 0 at server startup to enable or disable whether InnoDB checks the file format tag in the shared tablespace (for example, Antelope or Barracuda). If the tag is checked and is higher than that supported by the current version of InnoDB, an error occurs and InnoDB does not start. If the tag is not higher, InnoDB sets the value of innodb_file_format_check to the file format tag, which is the value seen at runtime.

- **innodb_file_io_threads**

  **Command-Line Format**

  --innodb_file_io_threads=#

  **System Variable**

  Name innodb_file_io_threads

  Variable Global

  Dynamic No

  **Permitted Values**

  Type integer

  Default 4

  Min Value 4

  Max Value 64

  The number of file I/O threads in InnoDB. Normally, this should be left at the default value of 4, but disk I/O on Windows may benefit from a larger number. On Unix, increasing the number has no effect; InnoDB always uses the default value.

  With InnoDB Plugin, this variable is unused. Use innodb_read_io_threads and innodb_write_io_threads instead.

- **innodb_file_per_table**

  **Command-Line Format**

  --innodb_file_per_table

  **System Variable**

  Name innodb_file_per_table

  Variable Global

  Dynamic No

  **Permitted Values**

  Type boolean

  Default OFF

  If innodb_file_per_table is disabled (the default), InnoDB creates tables in the system tablespace. If innodb_file_per_table is enabled, InnoDB creates each new table using its own .ibd file for storing data and indexes, rather than in the system tablespace. See Section 14.6.5.4, “InnoDB File-Per-Table Tablespaces” for information about advantages, disadvantages, and features, such as InnoDB table compression, that only work for tables stored in separate tablespaces.
InnoDB Startup Options and System Variables

- **innodb_flush_log_at_trx_commit**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb_flush_log_at_trx_commit[=#]</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name innodb_flush_log_at_trx_commit</td>
</tr>
<tr>
<td></td>
<td>Variable Global</td>
</tr>
<tr>
<td></td>
<td>Scope Dynamic</td>
</tr>
<tr>
<td></td>
<td>DynamicYes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type enumeration</td>
</tr>
<tr>
<td></td>
<td>Default 1</td>
</tr>
<tr>
<td></td>
<td>Valid 0</td>
</tr>
<tr>
<td></td>
<td>Values 0</td>
</tr>
<tr>
<td></td>
<td>Values 1</td>
</tr>
<tr>
<td></td>
<td>Values 2</td>
</tr>
</tbody>
</table>

  If the value of `innodb_flush_log_at_trx_commit` is 0, the log buffer is written out to the log file once per second and the flush to disk operation is performed on the log file, but nothing is done at a transaction commit. When the value is 1 (the default), the log buffer is written out to the log file at each transaction commit and the flush to disk operation is performed on the log file. When the value is 2, the log buffer is written out to the file at each commit, but the flush to disk operation is not performed on it. However, the flushing on the log file takes place once per second also when the value is 2. Note that the once-per-second flushing is not 100% guaranteed to happen every second, due to process scheduling issues.

The default value of 1 is required for full ACID compliance. You can achieve better performance by setting the value different from 1, but then you can lose up to one second worth of transactions in a crash. With a value of 0, any `mysqld` process crash can erase the last second of transactions. With a value of 2, only an operating system crash or a power outage can erase the last second of transactions. InnoDB's crash recovery works regardless of the value.

For the greatest possible durability and consistency in a replication setup using InnoDB with transactions, use `innodb_flush_log_at_trx_commit=1` and `sync_binlog=1` in your master server `my.cnf` file.

Caution

Many operating systems and some disk hardware fool the flush-to-disk operation. They may tell `mysqld` that the flush has taken place, even though it has not. Then the durability of transactions is not guaranteed even with the setting 1, and in the worst case a power outage can even corrupt the InnoDB database. Using a battery-backed disk cache in the SCSI disk controller or in the disk itself speeds up file flushes, and makes the operation safer. You can also try using the Unix command `hdparm` to disable the caching of disk writes in hardware caches, or use some other command specific to the hardware vendor.

- **innodb_flush_method**

<table>
<thead>

<td>async_unbuffered</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>normal</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>unbuffered</td>
</tr>
</tbody>
</table>

Defines the method used to flush data to the InnoDB data files and log files, which can affect I/O throughput.

If innodb_flush_method=NULL on a Unix-like system, the fsync option is used by default. If innodb_flush_method=NULL on Windows, the async_unbuffered option is used by default.

The innodb_flush_method options for Unix-like systems include:

- **fsync**: InnoDB uses the fsync() system call to flush both the data and log files. fsync is the default setting.
- **O_DSYNC**: InnoDB uses O_SYNC to open and flush the log files, and fsync() to flush the data files. InnoDB does not use O_DSYNC directly because there have been problems with it on many varieties of Unix.
- **littlesync**: This option is used for internal performance testing and is currently unsupported. Use at your own risk.
- **nosync**: This option is used for internal performance testing and is currently unsupported. Use at your own risk.
- **O_DIRECT**: InnoDB uses O_DIRECT (or directio() on Solaris) to open the data files, and uses fsync() to flush both the data and log files. This option is available on some GNU/Linux versions, FreeBSD, and Solaris.

The innodb_flush_method options for Windows systems include:

- **async_unbuffered**: InnoDB uses Windows asynchronous I/O and non-buffered I/O. async_unbuffered is the default setting on Windows systems.
- **normal**: InnoDB uses a simulated asynchronous I/O and buffered I/O. This option is used for internal performance testing and is currently unsupported. Use at your own risk.
• **unbuffered**: *InnoDB* uses a simulated asynchronous I/O and non-buffered I/O. This option is used for internal performance testing and is currently unsupported. Use at your own risk.

How each settings affects performance depends on hardware configuration and workload. Benchmark your particular configuration to decide which setting to use, or whether to keep the default setting. Examine the `innodb_data_fsyncs` status variable to see the overall number of `fsync()` calls for each setting. The mix of read and write operations in your workload can affect how a setting performs. For example, on a system with a hardware RAID controller and battery-backed write cache, `O_DIRECT` can help to avoid double buffering between the *InnoDB* buffer pool and the operating system's file system cache. On some systems where *InnoDB* data and log files are located on a SAN, the default value or `O_DSYNC` might be faster for a read-heavy workload with mostly `SELECT` statements. Always test this parameter with hardware and workload that reflect your production environment.

Prior to MySQL 5.1.24, the default `innodb_flush_method` option was named `fdatasync`. When `fdatasync` was specified, *InnoDB* used the `fsync()` system call to flush both the data and log files. To avoid confusing the `fdatasync` option name with the `fdatasync()` system call, the option name was changed to `fsync` in MySQL 5.1.24.

• **innodb_force_recovery**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb_force_recovery=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>

InnoDB Startup Options and System Variables

**Permitted Values (32-bit platforms)**

<table>
<thead>
<tr>
<th>Type</th>
<th>Default</th>
<th>Min Value</th>
<th>Max Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>200</td>
<td>100</td>
<td>2**32-1</td>
</tr>
</tbody>
</table>

**Permitted Values (64-bit platforms)**

<table>
<thead>
<tr>
<th>Type</th>
<th>Default</th>
<th>Min Value</th>
<th>Max Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>200</td>
<td>100</td>
<td>2**64-1</td>
</tr>
</tbody>
</table>

(InnoDB Plugin only) An upper limit on the I/O activity performed by the InnoDB background tasks, such as flushing pages from the buffer pool and merging data from the insert buffer. The default value is 200. For busy systems capable of higher I/O rates, you can set a higher value at server startup, to help the server handle the background maintenance work associated with a high rate of row changes. For systems with individual 5400 RPM or 7200 RPM drives, you might lower the value to the former default of 100.

This parameter should be set to approximately the number of I/O operations that the system can perform per second. Ideally, keep this setting as low as practical, but not so low that these background activities fall behind. If the value is too high, data is removed from the buffer pool and insert buffer too quickly to provide significant benefit from the caching.

The value represents an estimated proportion of the I/O operations per second (IOPS) available to older-generation disk drives that could perform about 100 IOPS. The current default of 200 reflects that modern storage devices are capable of much higher I/O rates.

In general, you can increase the value as a function of the number of drives used for InnoDB I/O, particularly fast drives capable of high numbers of IOPS. For example, systems that use multiple disks or solid-state disks for InnoDB are likely to benefit from the ability to control this parameter.

Although you can specify a very high number, in practice such large values have little if any benefit; for example, a value of one million would be considered very high.

You can set the innodb_io_capacity value to any number 100 or greater, and the default value is 200. You can set the value of this parameter in the MySQL option file (my.cnf or my.ini) or change it dynamically with the SET GLOBAL command, which requires the SUPER privilege.

See Configuring the InnoDB Master Thread I/O Rate for more guidelines about this option. For general information about InnoDB I/O performance, see Section 8.6.7, “Optimizing InnoDB Disk I/O”.

This variable was added in MySQL 5.1.38.

- innodb_limit_optimistic_insert_debug
InnoDB Startup Options and System Variables

<table>
<thead>
<tr>
<th>Permitted Values</th>
<th>Type</th>
<th>Default</th>
<th>Min Value</th>
<th>Max Value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>integer</td>
<td>0</td>
<td>0</td>
<td>(2^{32}-1)</td>
</tr>
</tbody>
</table>

Limits the number of records per B-tree page. A default value of 0 means that no limit is imposed. This option is only available if debugging support is compiled in using the `WITH_DEBUG` CMake option.

- `innodb_lock_wait_timeout`

### Command-Line Format

```
--innodb_lock_wait_timeout=#
```

### System Variable

**(<= 5.1.37)**

<table>
<thead>
<tr>
<th>Name</th>
<th>Variable</th>
<th>Scope</th>
<th>Dynamic Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>innodb_lock_wait_timeout</td>
<td>Global</td>
<td></td>
<td>No</td>
</tr>
</tbody>
</table>

**(>= 5.1.38)**

<table>
<thead>
<tr>
<th>Name</th>
<th>Variable</th>
<th>Scope</th>
<th>Dynamic Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>innodb_lock_wait_timeout</td>
<td>Global, Session</td>
<td></td>
<td>No</td>
</tr>
</tbody>
</table>

### Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
<th>Default</th>
<th>Min Value</th>
<th>Max Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>50</td>
<td>1</td>
<td>1073741824</td>
</tr>
</tbody>
</table>

The timeout in seconds an InnoDB transaction waits for a row lock before giving up. The default value is 50 seconds. A transaction that tries to access a row that is locked by another InnoDB transaction waits at most this many seconds for write access to the row before issuing the following error:

```
ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction
```

When a lock wait timeout occurs, the current statement is rolled back (not the entire transaction). To have the entire transaction roll back, start the server with the `--innodb_rollback_on_timeout` option. See also [Section 14.6.12.4, “InnoDB Error Handling”](#).

You might decrease this value for highly interactive applications or OLTP systems, to display user feedback quickly or put the update into a queue for processing later. You might increase this value for long-running back-end operations, such as a transform step in a data warehouse that waits for other large insert or update operations to finish.

`innodb_lock_wait_timeout` applies to InnoDB row locks only. A MySQL table lock does not happen inside InnoDB and this timeout does not apply to waits for table locks.

InnoDB does detect transaction deadlocks in its own lock table immediately and rolls back one transaction. The lock wait timeout value does not apply to such a wait.
For the built-in InnoDB, this variable can be set only at server startup. For InnoDB Plugin, it can be set at startup or changed at runtime, and has both global and session values.

- `innodb_locks_unsafe_for_binlog`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb_locks_unsafe_for_binlog</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name: <code>innodb_locks_unsafe_for_binlog</code></td>
</tr>
<tr>
<td></td>
<td>Variable: Global Scope: No Dynamic Variable</td>
</tr>
<tr>
<td></td>
<td>Permitted Values: Type: boolean Default: OFF</td>
</tr>
</tbody>
</table>

This variable affects how InnoDB uses gap locking for searches and index scans. Normally, InnoDB uses an algorithm called *next-key locking* that combines index-row locking with gap locking. InnoDB performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index-record locks. In addition, a next-key lock on an index record also affects the “gap” before that index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the index record. If one session has a shared or exclusive lock on record R in an index, another session cannot insert a new index record in the gap immediately before R in the index order. See Section 14.6.4.2, “InnoDB Record, Gap, and Next-Key Locks”.

By default, the value of `innodb_locks_unsafe_for_binlog` is 0 (disabled), which means that gap locking is enabled: InnoDB uses next-key locks for searches and index scans. To enable the variable, set it to 1. This causes gap locking to be disabled: InnoDB uses only index-record locks for searches and index scans.

Enabling `innodb_locks_unsafe_for_binlog` does not disable the use of gap locking for foreign-key constraint checking or duplicate-key checking.

The effect of enabling `innodb_locks_unsafe_for_binlog` is similar to but not identical to setting the transaction isolation level to `READ COMMITTED`:

- Enabling `innodb_locks_unsafe_for_binlog` is a global setting and affects all sessions, whereas the isolation level can be set globally for all sessions, or individually per session.

- `innodb_locks_unsafe_for_binlog` can be set only at server startup, whereas the isolation level can be set at startup or changed at runtime.

`READ COMMITTED` therefore offers finer and more flexible control than `innodb_locks_unsafe_for_binlog`. For additional details about the effect of isolation level on gap locking, see Section 13.3.6, “SET TRANSACTION Syntax”.

Enabling `innodb_locks_unsafe_for_binlog` may cause phantom problems because other sessions can insert new rows into the gaps when gap locking is disabled. Suppose that there is an index on the `id` column of the `child` table and that you want to read and lock all rows from the table having an identifier value larger than 100, with the intention of updating some column in the selected rows later:

```sql
SELECT * FROM child WHERE id > 100 FOR UPDATE;
```

The query scans the index starting from the first record where `id` is greater than 100. If the locks set on the index records in that range do not lock out inserts made in the gaps, another session
can insert a new row into the table. Consequently, if you were to execute the same \texttt{SELECT} again within the same transaction, you would see a new row in the result set returned by the query. This also means that if new items are added to the database, InnoDB does not guarantee serializability. Therefore, if \texttt{innodb_locksUnsafeForBinlog} is enabled, InnoDB guarantees at most an isolation level of \texttt{READ COMMITTED}. (Conflict serializability is still guaranteed.) For additional information about phantoms, see Section 14.6.4.3, “Avoiding the Phantom Problem Using Next-Key Locking”.

Enabling \texttt{innodb_locksUnsafeForBinlog} has additional effects:

- For \texttt{UPDATE} or \texttt{DELETE} statements, InnoDB holds locks only for rows that it updates or deletes. Record locks for nonmatching rows are released after MySQL has evaluated the \texttt{WHERE} condition. This greatly reduces the probability of deadlocks, but they can still happen.

- For \texttt{UPDATE} statements, if a row is already locked, InnoDB performs a “semi-consistent” read, returning the latest committed version to MySQL so that MySQL can determine whether the row matches the \texttt{WHERE} condition of the \texttt{UPDATE}. If the row matches (must be updated), MySQL reads the row again and this time InnoDB either locks it or waits for a lock on it.

Consider the following example, beginning with this table:

```sql
CREATE TABLE t (a INT NOT NULL, b INT) ENGINE = InnoDB;
INSERT INTO t VALUES (1,2),(2,3),(3,2),(4,3),(5,2);
COMMIT;
```

In this case, table has no indexes, so searches and index scans use the hidden clustered index for record locking (see Clustered and Secondary Indexes).

Suppose that one client performs an \texttt{UPDATE} using these statements:

```sql
SET autocommit = 0;
UPDATE t SET b = 5 WHERE b = 3;
```

Suppose also that a second client performs an \texttt{UPDATE} by executing these statements following those of the first client:

```sql
SET autocommit = 0;
UPDATE t SET b = 4 WHERE b = 2;
```

As InnoDB executes each \texttt{UPDATE}, it first acquires an exclusive lock for each row, and then determines whether to modify it. If InnoDB does not modify the row and \texttt{innodb_locksUnsafeForBinlog} is enabled, it releases the lock. Otherwise, InnoDB retains the lock until the end of the transaction. This affects transaction processing as follows.

If \texttt{innodb_locksUnsafeForBinlog} is disabled, the first \texttt{UPDATE} acquires x-locks and does not release any of them:

```
x-lock(1,2); retain x-lock
x-lock(2,3); update(2,3) to (2,5); retain x-lock
x-lock(3,2); retain x-lock
x-lock(4,3); update(4,3) to (4,5); retain x-lock
x-lock(5,2); retain x-lock
```

The second \texttt{UPDATE} blocks as soon as it tries to acquire any locks (because first update has retained locks on all rows), and does not proceed until the first \texttt{UPDATE} commits or rolls back:

```
x-lock(1,2); block and wait for first UPDATE to commit or roll back
```
InnoDB Startup Options and System Variables

If `innodb_locks_unsafe_for_binlog` is enabled, the first `UPDATE` acquires x-locks and releases those for rows that it does not modify:

```plaintext
x-lock(1,2); unlock(1,2)
x-lock(2,3); update(2,3) to (2,5); retain x-lock
x-lock(3,2); unlock(3,2)
x-lock(4,3); update(4,3) to (4,5); retain x-lock
x-lock(5,2); unlock(5,2)
```

For the second `UPDATE`, InnoDB does a “semi-consistent” read, returning the latest committed version of each row to MySQL so that MySQL can determine whether the row matches the `WHERE` condition of the `UPDATE`:

```plaintext
x-lock(1,2); update(1,2) to (1,4); retain x-lock
x-lock(2,3); unlock(2,3)
x-lock(3,2); update(3,2) to (3,4); retain x-lock
x-lock(4,3); unlock(4,3)
x-lock(5,2); update(5,2) to (5,4); retain x-lock
```

Semi-consistent read is available as of MySQL 5.1.5. Before 5.1.5, the second `UPDATE` proceeds part way before it blocks. It begins acquiring x-locks, and blocks when it tries to acquire one for a row still locked by first `UPDATE`. The second `UPDATE` does not proceed until the first `UPDATE` commits or rolls back:

```plaintext
x-lock(1,2); update(1,2) to (1,4); retain x-lock
x-lock(2,3); block and wait for first UPDATE to commit or rollback
```

In this case, the second `UPDATE` must wait for a commit or rollback of the first `UPDATE`, even though it affects different rows. The first `UPDATE` has an exclusive lock on row (2,3) that it has not released. As the second `UPDATE` scans rows, it tries to acquire an exclusive lock for that same row, which it cannot have. Thus, before MySQL 5.1.5, enabling `innodb_locks_unsafe_for_binlog` still does not permit operations such as `UPDATE` to overtake other similar operations (such as another `UPDATE`) even when they affect different rows.

- `innodb_log_arch_dir`
  This variable is deprecated, and was removed in MySQL 5.1.21.
- `innodb_log_archive`
  This variable is deprecated, and was removed in MySQL 5.1.18.
- `innodb_log_buffer_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb_log_buffer_size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name innodb_log_buffer_size</td>
</tr>
<tr>
<td></td>
<td>Variable Global Scope</td>
</tr>
<tr>
<td></td>
<td>Dynamic No Variable</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type integer</td>
</tr>
<tr>
<td></td>
<td>Default 1048576</td>
</tr>
<tr>
<td></td>
<td>Min Value 1048576</td>
</tr>
<tr>
<td></td>
<td>Max Value 4294967295</td>
</tr>
</tbody>
</table>
The size in bytes of the buffer that InnoDB uses to write to the log files on disk. The default value is 1MB for the built-in InnoDB, 8MB for InnoDB Plugin. Sensible values range from 1MB to 8MB. A large log buffer enables large transactions to run without a need to write the log to disk before the transactions commit. Thus, if you have big transactions, making the log buffer larger saves disk I/O.

• `innodb_log_file_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb_log_file_size=##</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name innodb_log_file_size</td>
</tr>
<tr>
<td></td>
<td>Variable Global Scope</td>
</tr>
<tr>
<td></td>
<td>Dynamic No Variable</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type integer</td>
</tr>
<tr>
<td></td>
<td>Default 5242880</td>
</tr>
<tr>
<td></td>
<td>Min Value 1048576</td>
</tr>
<tr>
<td></td>
<td>Max Value 4GB / innodb_log_files_in_group</td>
</tr>
</tbody>
</table>

The size in bytes of each log file in a log group. The combined size of log files (`innodb_log_file_size * innodb_log_files_in_group`) cannot exceed a maximum value that is slightly less than 4GB. A pair of 2047 MB log files, for example, would allow you to approach the range limit but not exceed it. The default value is 5MB. Sensible values range from 1MB to \( \frac{1}{N} \)th of the size of the buffer pool, where \( N \) is the number of log files in the group. The larger the value, the less checkpoint flush activity is needed in the buffer pool, saving disk I/O. But larger log files also mean that recovery is slower in case of a crash.

• `innodb_log_files_in_group`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb_log_files_in_group=##</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name innodb_log_files_in_group</td>
</tr>
<tr>
<td></td>
<td>Variable Global Scope</td>
</tr>
<tr>
<td></td>
<td>Dynamic No Variable</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type integer</td>
</tr>
<tr>
<td></td>
<td>Default 2</td>
</tr>
<tr>
<td></td>
<td>Min Value 2</td>
</tr>
<tr>
<td></td>
<td>Max Value 100</td>
</tr>
</tbody>
</table>

The number of log files in the log group. InnoDB writes to the files in a circular fashion. The default (and recommended) value is 2.

• `innodb_log_group_home_dir`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb_log_group_home_dir=dir_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name innodb_log_group_home_dir</td>
</tr>
<tr>
<td></td>
<td>Variable Global Scope</td>
</tr>
</tbody>
</table>
InnoDB Startup Options and System Variables

<table>
<thead>
<tr>
<th>Dynamic No Variable</th>
<th>Type</th>
<th>directory name</th>
</tr>
</thead>
</table>

The directory path to the InnoDB log files. If you do not specify any InnoDB log variables, the default is to create two files named `ib_logfile0` and `ib_logfile1` in the MySQL data directory. Their size is given by the size of the `innodb_log_file_size` system variable.

- **innodb_max_dirty_pages_pct**

  **Command-Line Format**
  
  --innodb_max_dirty_pages_pct=#

  **System Variable**
  
<table>
<thead>
<tr>
<th>Name</th>
<th>Variable Scope</th>
<th>Dynamic Variable</th>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>innodb_max_dirty_pages_pct</td>
<td>Global</td>
<td>Yes</td>
<td>Type</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Default</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Min Value</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Max Value</td>
</tr>
</tbody>
</table>

  This is an integer in the range from 0 to 100. The default value is 90 for the built-in InnoDB, 75 for InnoDB Plugin. The main thread in InnoDB tries to write pages from the buffer pool so that the percentage of dirty (not yet written) pages will not exceed this value.

- **innodb_max_purge_lag**

  **Command-Line Format**
  
  --innodb_max_purge_lag=#

  **System Variable**
  
<table>
<thead>
<tr>
<th>Name</th>
<th>Variable Scope</th>
<th>Dynamic Variable</th>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>innodb_max_purge_lag</td>
<td>Global</td>
<td>Yes</td>
<td>Type</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Default</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Min Value</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Max Value</td>
</tr>
</tbody>
</table>

  This variable controls how to delay INSERT, UPDATE, and DELETE operations when purge operations are lagging (see Section 14.6.3.1, “InnoDB Multi-Versioning”). The default value 0 (no delays).

  The InnoDB transaction system maintains a list of transactions that have index records delete-marked by UPDATE or DELETE operations. Let the length of this list be `purge_lag`. When `purge_lag` exceeds `innodb_max_purge_lag`, each INSERT, UPDATE, and DELETE operation is delayed by 

  $((purge_lag/innodb_max_purge_lag) \times 10) \approx 5$ milliseconds.

  The delay is computed in the beginning of a purge batch, every ten seconds. The operations are not delayed if purge cannot run because of an old consistent read view that could see the rows to be purged.
A typical setting for a problematic workload might be 1 million, assuming that transactions are small, only 100 bytes in size, and it is permissible to have 100MB of unpurged InnoDB table rows.

The lag value is displayed as the history list length in the TRANSACTIONS section of InnoDB Monitor output. For example, if the output includes the following lines, the lag value is 20:

```
------------
TRANSACTIONS
------------
Trx id counter 0 290328385
Purge done for trx’s n:o < 0 290315608 undo n:o < 0 17
History list length 20
```

- `innodb_mirrored_log_groups`
  Has no effect.

- `innodb_old_blocks_pct`

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.41</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--innodb_old_blocks_pct=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td>Name <code>innodb_old_blocks_pct</code></td>
</tr>
<tr>
<td></td>
<td>Variable Global</td>
</tr>
<tr>
<td></td>
<td>Scope DynamicYes</td>
</tr>
<tr>
<td></td>
<td>Variable</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type <code>integer</code></td>
</tr>
<tr>
<td></td>
<td>Default 37</td>
</tr>
<tr>
<td></td>
<td>Min Value 5</td>
</tr>
<tr>
<td></td>
<td>Max Value 95</td>
</tr>
</tbody>
</table>

(InnoDB Plugin only) Specifies the approximate percentage of the InnoDB buffer pool used for the old block sublist. The range of values is 5 to 95. The default value is 37 (that is, 3/8 of the pool). See Section 8.10.2, “The InnoDB Buffer Pool” for information about buffer pool management, such as the LRU algorithm and eviction policies.

This variable was added in MySQL 5.1.41.

- `innodb_old_blocks_time`

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.41</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--innodb_old_blocks_time=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td>Name <code>innodb_old_blocks_time</code></td>
</tr>
<tr>
<td></td>
<td>Variable Global</td>
</tr>
<tr>
<td></td>
<td>Scope DynamicYes</td>
</tr>
<tr>
<td></td>
<td>Variable</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type <code>integer</code></td>
</tr>
<tr>
<td></td>
<td>Default 0</td>
</tr>
<tr>
<td></td>
<td>Min Value 0</td>
</tr>
<tr>
<td></td>
<td>Max Value</td>
</tr>
</tbody>
</table>
(InnoDB Plugin only) Specifies how long in milliseconds (ms) a block inserted into the old sublist must stay there after its first access before it can be moved to the new sublist. The default value is 0: A block inserted into the old sublist moves immediately to the new sublist the first time it is accessed, no matter how soon after insertion the access occurs. If the value is greater than 0, blocks remain in the old sublist until an access occurs at least that many ms after the first access. For example, a value of 1000 causes blocks to stay in the old sublist for 1 second after the first access before they become eligible to move to the new sublist.

This variable is often used in combination with innodb_old_blocks_pct. See Section 8.10.2, “The InnoDB Buffer Pool” for information about buffer pool management, such as the LRU algorithm and eviction policies.

This variable was added in MySQL 5.1.41.

• innodb_open_files

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb_open_files=</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name innodb_open_files</td>
</tr>
<tr>
<td>Variable Global Scope</td>
<td></td>
</tr>
<tr>
<td>Dynamic No Variable</td>
<td></td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type integer</td>
</tr>
<tr>
<td>Default 300</td>
<td></td>
</tr>
<tr>
<td>Min Value 10</td>
<td></td>
</tr>
<tr>
<td>Max Value 4294967295</td>
<td></td>
</tr>
</tbody>
</table>

This variable is relevant only if you use multiple InnoDB tablespaces. It specifies the maximum number of .ibd files that MySQL can keep open at one time. The minimum value is 10. The default value is 300.

The file descriptors used for .ibd files are for InnoDB tables only. They are independent of those specified by the --open-files-limit server option, and do not affect the operation of the table cache.

• innodb_random_read_ahead

| Introduced | 5.1.59 |
| Command-Line Format | --innodb_random_read_ahead=|
| System Variable     | Name innodb_random_read_ahead |
| Variable Global Scope |                     |
| Dynamic Yes Variable |                     |
| Permitted Values    | Type boolean |
| Default OFF |                          |

Enables the random read-ahead technique for optimizing InnoDB I/O. Random read-ahead functionality was removed from the InnoDB Plugin (version 1.0.4) and was therefore not
included in MySQL 5.5.0 when InnoDB Plugin became the “built-in” version of InnoDB. Random read-ahead was reintroduced in MySQL 5.1.59 and 5.5.16 and higher along with the innodb_random_read_ahead configuration option, which is disabled by default.

See Configuring InnoDB Buffer Pool Prefetching (Read-Ahead) for details about the performance considerations for the different types of read-ahead requests. For general I/O tuning advice, see Section 8.6.7, “Optimizing InnoDB Disk I/O”.

- **innodb_read_ahead_threshold**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.38</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--innodb_read_ahead_threshold=#</td>
</tr>
<tr>
<td>System Variable</td>
<td>Name innodb_read_ahead_threshold</td>
</tr>
<tr>
<td></td>
<td>Variable Global</td>
</tr>
<tr>
<td></td>
<td>Dynamic Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type integer</td>
</tr>
<tr>
<td></td>
<td>Default 56</td>
</tr>
<tr>
<td></td>
<td>Min Value 0</td>
</tr>
<tr>
<td></td>
<td>Max Value 64</td>
</tr>
</tbody>
</table>

(InnoDB Plugin only) Controls the sensitivity of linear read-ahead that InnoDB uses to prefetch pages into the buffer pool. If InnoDB reads at least innodb_read_ahead_threshold pages sequentially from an extent (64 pages), it initiates an asynchronous read for the entire following extent. The permissible range of values is 0 to 64. The default is 56: InnoDB must read at least 56 pages sequentially from an extent to initiate an asynchronous read for the following extent.

This variable was added in MySQL 5.1.38.

- **innodb_read_io_threads**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.38</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--innodb_read_io_threads=#</td>
</tr>
<tr>
<td>System Variable</td>
<td>Name innodb_read_io_threads</td>
</tr>
<tr>
<td></td>
<td>Variable Global</td>
</tr>
<tr>
<td></td>
<td>Dynamic No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type integer</td>
</tr>
<tr>
<td></td>
<td>Default 4</td>
</tr>
<tr>
<td></td>
<td>Min Value 1</td>
</tr>
<tr>
<td></td>
<td>Max Value 64</td>
</tr>
</tbody>
</table>

(InnoDB Plugin only) The number of I/O threads for read operations in InnoDB. The default value is 4.
On Linux systems, running multiple MySQL servers (typically more than 12) with default settings for `innodb_read_io_threads`, `innodb_write_io_threads`, and the Linux `aio-max-nr` setting can exceed system limits. Ideally, increase the `aio-max-nr` setting; as a workaround, you might reduce the settings for one or both of the MySQL configuration options.

This variable was added in MySQL 5.1.38.

- `innodb_replication_delay`

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.38</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--innodb_replication_delay=#</code></td>
</tr>
<tr>
<td>System Variable</td>
<td>Name <code>innodb_replication_delay</code></td>
</tr>
<tr>
<td></td>
<td>Variable Global</td>
</tr>
<tr>
<td></td>
<td>Scope DynamicYes</td>
</tr>
<tr>
<td></td>
<td>Variable</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type <code>integer</code></td>
</tr>
<tr>
<td></td>
<td>Default 0</td>
</tr>
<tr>
<td></td>
<td>Min Value 0</td>
</tr>
<tr>
<td></td>
<td>Max Value 4294967295</td>
</tr>
</tbody>
</table>

(InnoDB Plugin only) The replication thread delay (in ms) on a slave server if `innodb_thread_concurrency` is reached.

This variable was added in MySQL 5.1.38.

- `innodb_rollback_on_timeout`

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.15</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--innodb_rollback_on_timeout</code></td>
</tr>
<tr>
<td>System Variable</td>
<td>Name <code>innodb_rollback_on_timeout</code></td>
</tr>
<tr>
<td></td>
<td>Variable Global</td>
</tr>
<tr>
<td></td>
<td>Scope DynamicNo</td>
</tr>
<tr>
<td></td>
<td>Variable</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type <code>boolean</code></td>
</tr>
<tr>
<td></td>
<td>Default <code>OFF</code></td>
</tr>
</tbody>
</table>

In MySQL 5.1, InnoDB rolls back only the last statement on a transaction timeout by default. If `--innodb_rollback_on_timeout` is specified, a transaction timeout causes InnoDB to abort and roll back the entire transaction (the same behavior as in MySQL 4.1). This variable was added in MySQL 5.1.15.

- `innodb_spin_wait_delay`

| Introduced | 5.1.38 |
InnoDB Startup Options and System Variables

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb_spin_wait_delay=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name innodb_spin_wait_delay</td>
</tr>
<tr>
<td></td>
<td>Variable Global</td>
</tr>
<tr>
<td></td>
<td>Scope Dynamic</td>
</tr>
<tr>
<td></td>
<td>Variable Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type integer</td>
</tr>
<tr>
<td></td>
<td>Default 6</td>
</tr>
<tr>
<td></td>
<td>Min Value 0</td>
</tr>
<tr>
<td></td>
<td>Max Value 2**32-1</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type integer</td>
</tr>
<tr>
<td></td>
<td>Default 6</td>
</tr>
<tr>
<td></td>
<td>Min Value 0</td>
</tr>
<tr>
<td></td>
<td>Max Value 2**64-1</td>
</tr>
</tbody>
</table>

(InnoDB Plugin only) The maximum delay between polls for a spin lock. The low-level implementation of this mechanism varies depending on the combination of hardware and operating system, so the delay does not correspond to a fixed time interval. The default value is 6.

This variable was added in MySQL 5.1.38.

• innodb_stats_method

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.56</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--innodb_stats_method=name</td>
</tr>
<tr>
<td>System Variable</td>
<td>Name innodb_stats_method</td>
</tr>
<tr>
<td></td>
<td>Variable Global</td>
</tr>
<tr>
<td></td>
<td>Scope Dynamic</td>
</tr>
<tr>
<td></td>
<td>Variable Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type enumeration</td>
</tr>
<tr>
<td></td>
<td>Default nulls_equal</td>
</tr>
<tr>
<td></td>
<td>Valid nulls_equal</td>
</tr>
<tr>
<td></td>
<td>nulls_unequal</td>
</tr>
<tr>
<td></td>
<td>nulls_ignored</td>
</tr>
</tbody>
</table>

How the server treats NULL values when collecting statistics about the distribution of index values for InnoDB tables. This variable has three possible values, nulls_equal, nulls_unequal, and nulls_ignored. For nulls_equal, all NULL index values are considered equal and form a single value group that has a size equal to the number of NULL values. For nulls_unequal, NULL values are considered unequal, and each NULL forms a distinct value group of size 1. For nulls_ignored, NULL values are ignored.

The method that is used for generating table statistics influences how the optimizer chooses indexes for query execution, as described in Section 8.3.7, “InnoDB and MyISAM Index Statistics Collection”.

• innodb_stats_on_metadata
### Introduced

<table>
<thead>
<tr>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.1.17</td>
</tr>
</tbody>
</table>

#### Command-Line Format

```
--innodb_stats_on_metadata
```

### System Variable

<table>
<thead>
<tr>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;= 5.1.31</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Name</th>
<th>Global</th>
</tr>
</thead>
<tbody>
<tr>
<td>innodb_stats_on_metadata</td>
<td></td>
</tr>
</tbody>
</table>

#### Dynamic

No

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type boolean</td>
</tr>
<tr>
<td>Default ON</td>
</tr>
</tbody>
</table>

When this variable is enabled (which is the default, as before the variable was created), InnoDB updates statistics during metadata statements such as `SHOW TABLE STATUS` or `SHOW INDEX`, or when accessing the `INFORMATION_SCHEMA` tables `TABLES` or `STATISTICS`. (These updates are similar to what happens for `ANALYZE TABLE`.) When disabled, InnoDB does not update statistics during these operations. Disabling this variable can improve access speed for schemas that have a large number of tables or indexes. It can also improve the stability of execution plans for queries that involve InnoDB tables.

This variable was added in MySQL 5.1.17.

- **innodb_stats_sample_pages**

#### Introduced

<table>
<thead>
<tr>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.1.38</td>
</tr>
</tbody>
</table>

#### Command-Line Format

```
--innodb_stats_sample_pages=#
```

<table>
<thead>
<tr>
<th>Name</th>
<th>innodb_stats_sample_pages</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable</td>
<td>Global</td>
</tr>
<tr>
<td>Scope</td>
<td></td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
</tbody>
</table>

#### Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
<th>Min Value</th>
<th>Max Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>1</td>
<td>2**64-1</td>
</tr>
</tbody>
</table>

(InnoDB Plugin only) The number of index pages to sample for index distribution statistics such as calculated by `ANALYZE TABLE`. The default value is 8.

This variable was added in MySQL 5.1.38.

- **innodb_strict_mode**

#### Introduced

<table>
<thead>
<tr>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.1.38</td>
</tr>
</tbody>
</table>

#### Command-Line Format

```
--innodb_strict_mode=#
```
InnoDB Startup Options and System Variables

<table>
<thead>
<tr>
<th>System Variable</th>
<th>Name</th>
<th>innodb_strict_mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable</td>
<td>Global, Session</td>
<td></td>
</tr>
<tr>
<td>Scope</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
<td></td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Default</td>
<td>OFF</td>
<td></td>
</tr>
</tbody>
</table>

When `innodb_strict_mode` is ON, InnoDB returns errors rather than warnings for certain conditions. The default value is OFF.

**Strict mode** helps guard against ignored typos and syntax errors in SQL, or other unintended consequences of various combinations of operational modes and SQL statements. When `innodb_strict_mode` is ON, InnoDB raises error conditions in certain cases, rather than issuing a warning and processing the specified statement (perhaps with unintended behavior). This is analogous to `sql_mode` in MySQL, which controls what SQL syntax MySQL accepts, and determines whether it silently ignores errors, or validates input syntax and data values.

The `innodb_strict_mode` setting affects the handling of syntax errors for `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements. `innodb_strict_mode` also enables a record size check, so that an `INSERT` or `UPDATE` never fails due to the record being too large for the selected page size.

Oracle recommends enabling `innodb_strict_mode` when using `ROW_FORMAT` and `KEY_BLOCK_SIZE` clauses on `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements. When `innodb_strict_mode` is OFF, InnoDB ignores conflicting clauses and creates the table or index, with only a warning in the message log. The resulting table might have different behavior than you intended, such as having no compression when you tried to create a compressed table. When `innodb_strict_mode` is ON, such problems generate an immediate error and the table or index is not created, avoiding a troubleshooting session later.

You can turn `innodb_strict_mode` ON or OFF on the command line when you start mysqld, or in the configuration file `my.cnf` or `my.ini`. You can also enable or disable `innodb_strict_mode` at runtime with the statement `SET [GLOBAL|SESSION] innodb_strict_mode=mode`, where `mode` is either ON or OFF. Changing the `GLOBAL` setting requires the SUPER privilege and affects the operation of all clients that subsequently connect. Any client can change the `SESSION` setting for `innodb_strict_mode`, and the setting affects only that client.

• **innodb_support_xa**

    | Command-Line Format | --innodb_support_xa |
    |---------------------|---------------------|
    | System Variable     | Name                | innodb_support_xa |
    |                     | Variable            | Global, Session   |
    |                     | Scope               |                   |
    |                     | Dynamic Variable    | Yes               |
    | Permitted Values    | Type                | boolean           |
    | Default             | TRUE                |

Enables InnoDB support for two-phase commit in XA transactions, causing an extra disk flush for transaction preparation. This setting is the default. The XA mechanism is used internally and is essential for any server that has its binary log turned on and is accepting changes to its data from more than one thread. If you turn it off, transactions can be written to the binary log in a different order from the one in which the live database is committing them. This can produce different data when the binary log is replayed in disaster recovery or on a replication slave. Do not turn it off on a
replication master server unless you have an unusual setup where only one thread is able to change data.

For a server that is accepting data changes from only one thread, it is safe and recommended to turn off this option to improve performance for InnoDB tables. For example, you can turn it off on replication slaves where only the replication SQL thread is changing data.

You can also turn off this option if you do not need it for safe binary logging or replication, and you also do not use an external XA transaction manager.

- **innodb_sync_spin_loops**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb_sync_spin_loops=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name innodb_sync_spin_loops</td>
</tr>
<tr>
<td></td>
<td>Variable Global</td>
</tr>
<tr>
<td></td>
<td>Scope</td>
</tr>
<tr>
<td></td>
<td>DynamicYes</td>
</tr>
<tr>
<td></td>
<td>Variable</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type integer</td>
</tr>
<tr>
<td></td>
<td>Default 20</td>
</tr>
<tr>
<td></td>
<td>Min Value 0</td>
</tr>
<tr>
<td></td>
<td>Max Value 4294967295</td>
</tr>
</tbody>
</table>

  The number of times a thread waits for an InnoDB mutex to be freed before the thread is suspended. The default value is 20 for the built-in InnoDB, 30 for InnoDB Plugin.

- **innodb_table_locks**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb_table_locks</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name innodb_table_locks</td>
</tr>
<tr>
<td></td>
<td>Variable Global, Session</td>
</tr>
<tr>
<td></td>
<td>Scope</td>
</tr>
<tr>
<td></td>
<td>DynamicYes</td>
</tr>
<tr>
<td></td>
<td>Variable</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type boolean</td>
</tr>
<tr>
<td></td>
<td>Default TRUE</td>
</tr>
</tbody>
</table>

  If autocommit = 0, InnoDB honors LOCK TABLES; MySQL does not return from LOCK TABLES ... WRITE until all other threads have released all their locks to the table. The default value of innodb_table_locks is 1, which means that LOCK TABLES causes InnoDB to lock a table internally if autocommit = 0.

- **innodb_thread_concurrency**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb_thread_concurrency=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name innodb_thread_concurrency</td>
</tr>
<tr>
<td></td>
<td>Variable Global</td>
</tr>
<tr>
<td></td>
<td>Scope</td>
</tr>
<tr>
<td></td>
<td>DynamicYes</td>
</tr>
<tr>
<td></td>
<td>Variable</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type integer</td>
</tr>
</tbody>
</table>

  |
InnoDB Startup Options and System Variables

<table>
<thead>
<tr>
<th>Default</th>
<th>Min Value</th>
<th>Max Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>0</td>
<td>1000</td>
</tr>
</tbody>
</table>

InnoDB tries to keep the number of operating system threads concurrently inside InnoDB less than or equal to the limit given by this variable (InnoDB uses operating system threads to process user transactions). Once the number of threads reaches this limit, additional threads are placed into a “First In, First Out” (FIFO) queue for execution. Threads waiting for locks are not counted in the number of concurrently executing threads.

The range of this variable is 0 to 1000. A value of 20 or higher is interpreted as infinite concurrency before MySQL 5.1.12. From 5.1.12 on, you can disable thread concurrency checking by setting the value to 0. Disabling thread concurrency checking enables InnoDB to create as many threads as it needs. A value of 0 also disables the queries inside InnoDB and queries in queue counters in the ROW OPERATIONS section of SHOW ENGINE INNODB STATUS output.

The default value for the built-in InnoDB is 20 before MySQL 5.1.11 and 8 from 5.1.11 on. The default for the InnoDB Plugin is 0.

Consider setting this variable if your MySQL instance shares CPU resources with other applications, or if your workload or number of concurrent users is growing. The correct setting depends on workload, computing environment, and the version of MySQL that you are running. You will need to test a range of values to determine the setting that provides the best performance. innodb_thread_concurrency is a dynamic variable, which allows you to experiment with different settings on a live test system. If a particular setting performs poorly, you can quickly set innodb_thread_concurrency back to 0.

Use the following guidelines to help find and maintain an appropriate setting:

- If the number of concurrent user threads for a workload is less than 64, set innodb_thread_concurrency=0.

- If your workload is consistently heavy or occasionally spikes, start by setting innodb_thread_concurrency=128, and lowering the value to 96, 80, 64, and so on, until you find the number of threads that provides the best performance. For example, suppose your system typically has 40 to 50 users, but periodically the number increases to 60, 70, or even 200. You find that performance is stable at 80 concurrent users but starts to show a regression above this number. In this case, you would set innodb_thread_concurrency=80 to avoid impacting performance.

- If you do not want InnoDB to use more than a certain number of vCPUs for user threads (20 vCPUs for example), set innodb_thread_concurrency to this number (or possibly lower, depending on performance results). If your goal is to isolate MySQL from other applications, you may consider binding the mysql process exclusively to the vCPUs. Be aware, however, that exclusive binding could result in non-optimal hardware usage if the mysql process is not consistently busy. In this case, you might bind the mysql process to the vCPUs but also allow other applications to use some or all of the vCPUs.

**Note**

From an operating system perspective, using a resource management solution (if available) to manage how CPU time is shared among applications may be preferable to binding the mysql process. For example, you could assign 90% of vCPU time to a given application while other critical process are not running, and scale that value back to 40% when other critical processes are running.
• \texttt{innodb_thread_concurrency} values that are too high can cause performance regression due to increased contention on system internals and resources.

• In some cases, the optimal \texttt{innodb_thread_concurrency} setting can be smaller than the number of vCPUs.

• Monitor and analyze your system regularly. Changes to workload, number of users, or computing environment may require that you adjust the \texttt{innodb_thread_concurrency} setting.

• \texttt{innodb_thread_sleep_delay}

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb_thread_sleep_delay=#</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>System Variable</strong></td>
<td><strong>Name</strong> \texttt{innodb_thread_sleep_delay}</td>
</tr>
<tr>
<td><strong>Variable</strong> Global</td>
<td><strong>Scope</strong> Dynamic</td>
</tr>
<tr>
<td><strong>Yes</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Type</strong> integer</td>
<td></td>
</tr>
<tr>
<td><strong>Default</strong> 10000</td>
<td></td>
</tr>
<tr>
<td><strong>Min Value</strong> 0</td>
<td></td>
</tr>
<tr>
<td><strong>Max Value</strong> 4294967295</td>
<td></td>
</tr>
</tbody>
</table>

How long InnoDB threads sleep before joining the InnoDB queue, in microseconds. The default value is 10,000. A value of 0 disables sleep.

• \texttt{innodb_trx_purge_view_update_only_debug}

| Introduced | 5.1.68 |
| Command-Line Format | --innodb_trx_purge_view_update_only_debug=# |
| **System Variable** | **Name** \texttt{innodb_trx_purge_view_update_only_debug} |
| **Variable** Global  | **Scope** Dynamic |
| **Yes** |
| **Type** boolean |
| **Default** OFF |

Pauses purging of delete-marked records while allowing the purge view to be updated. This option artificially creates a situation in which the purge view is updated but purges have not yet been performed. This option is only available if debugging support is compiled in using the \texttt{WITH_DEBUG CMake} option.

• \texttt{innodb_trx_rseg_n_slots_debug}
## InnoDB Startup Options and System Variables

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.62</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--innodb_trx_rseg_n_slots_debug=#</code></td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td>Name: <code>innodb_trx_rseg_n_slots_debug</code>&lt;br&gt;Variable: <code>innodb_trx_rseg_n_slots_debug</code>&lt;br&gt;Scope: Global&lt;br&gt;Dynamic: Yes&lt;br&gt;Variable: <code>innodb_trx_rseg_n_slots_debug</code>&lt;br&gt;Permitted Values: &lt;br&gt;Type: integer&lt;br&gt;Default: 0&lt;br&gt;Max Value: 1024</td>
</tr>
</tbody>
</table>

Sets a debug flag that limits `TRX_RSEG_N_SLOTS` to a given value for the `trx_rsegf_undo_find_free` function which looks for a free slot for an undo log segment. This option is only available if debugging support is compiled in using the `WITH_DEBUG` CMake option.

- **innodb_use_legacy_cardinality_algorithm**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.35</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--innodb_use_legacy_cardinality_algorithm=#</code></td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td>Name: <code>innodb_use_legacy_cardinality_algorithm</code>&lt;br&gt;Variable: <code>innodb_use_legacy_cardinality_algorithm</code>&lt;br&gt;Scope: Global&lt;br&gt;Dynamic: Yes&lt;br&gt;Variable: <code>innodb_use_legacy_cardinality_algorithm</code>&lt;br&gt;Permitted Values: &lt;br&gt;Type: boolean&lt;br&gt;Default: ON</td>
</tr>
</tbody>
</table>

InnoDB uses random numbers to generate dives into indexes for calculating index cardinality. However, under certain conditions, the algorithm does not generate random numbers, so `ANALYZE TABLE` sometimes does not update cardinality estimates properly. An alternative algorithm was introduced in MySQL 5.1.35 with better randomization properties, and the `innodb_use_legacy_cardinality_algorithm`, system variable which algorithm to use. The default value of the variable is 1 (ON), to use the original algorithm for compatibility with existing applications. The variable can be set to 0 (OFF) to use the new algorithm with improved randomness.

This variable is not used in InnoDB Plugin because the improved algorithm is used by default. Also, the number of random dives can be changed by modifying the `innodb_stats_sample_pages` system variable.

- **innodb_use_sys_malloc**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.38</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--innodb_use_sys_malloc=#</code></td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td>Name: <code>innodb_use_sys_malloc</code>&lt;br&gt;Variable: <code>innodb_use_sys_malloc</code>&lt;br&gt;Scope: Global&lt;br&gt;Dynamic: No&lt;br&gt;Variable: <code>innodb_use_sys_malloc</code>&lt;br&gt;Permitted Values: &lt;br&gt;Type: boolean</td>
</tr>
</tbody>
</table>
InnoDB Monitors

<table>
<thead>
<tr>
<th>Default</th>
<th>ON</th>
</tr>
</thead>
</table>

(InnoDB Plugin only) Whether InnoDB uses the operating system memory allocator (ON) or its own (OFF). The default value is ON.

This variable was added in MySQL 5.1.38.

- **innodb_version**

  (InnoDB Plugin only) The InnoDB version number. Starting in 5.1.68, the separate numbering for InnoDB is discontinued and this value is the same as for the version variable.

  This variable was added in MySQL 5.1.38.

- **innodb_write_io_threads**

  Introduced 5.1.38

  Command-Line Format
  --innodb_write_io_threads=#

  System Variable
  Name innodb_write_io_threads

  Variable Global
  Scope DynamicNo
  Variable

  Permitted Values
  Type integer
  Default 4
  Min Value 1
  Max Value 64

  (InnoDB Plugin only) The number of I/O threads for write operations in InnoDB. The default value is 4.

  Note
  On Linux systems, running multiple MySQL servers (typically more than 12) with default settings for innodb_read_io_threads, innodb_write_io_threads, and the Linux aio-max-nr setting can exceed system limits. Ideally, increase the aio-max-nr setting; as a workaround, you might reduce the settings for one or both of the MySQL configuration options.

  This variable was added in MySQL 5.1.38.

  You should also take into consideration the value of sync_binlog, which controls synchronization of the binary log to disk.

### 14.6.9 InnoDB Monitors

InnoDB Monitors provide information about the InnoDB internal state. This information is useful for performance tuning. Each Monitor can be enabled by creating a table with a special name, which causes InnoDB to write Monitor output periodically. Output for the standard InnoDB Monitor is also available on demand through the SHOW ENGINE INNODB STATUS SQL statement. Additionally, to assist with troubleshooting, InnoDB temporarily enables standard InnoDB Monitor output under certain conditions. For more information, see Section 14.6.12, “InnoDB Troubleshooting”.

There are several types of InnoDB Monitors:
InnoDB Monitors

- The standard InnoDB Monitor displays the following types of information:
  - Table and record locks held by each active transaction.
  - Lock waits of a transaction.
  - Semaphore waits of threads.
  - Pending file I/O requests.
  - Buffer pool statistics.
  - Purge and insert buffer merge activity of the main InnoDB thread.

For a discussion of InnoDB lock modes, see Section 14.6.4.1, “InnoDB Lock Modes”.

To enable the standard InnoDB Monitor for periodic output, create a table named `innodb_monitor`. To obtain Monitor output on demand, use the `SHOW ENGINE INNODB STATUS` SQL statement to fetch the output to your client program. If you are using the `mysql` interactive client, the output is more readable if you replace the usual semicolon statement terminator with `\G`:

```
mysql> SHOW ENGINE INNODB STATUS\G
```

- The InnoDB Lock Monitor prints additional lock information as part of the standard InnoDB Monitor output. To enable the InnoDB Lock Monitor, create a table named `innodb_lock_monitor`.

- The InnoDB Tablespace Monitor prints a list of file segments in the shared tablespace and validates the tablespace allocation data structures. To enable this Monitor for periodic output, create a table named `innodb_tablespace_monitor`.

- The InnoDB Table Monitor prints the contents of the InnoDB internal data dictionary. To enable this Monitor for periodic output, create a table named `innodb_table_monitor`.

To enable an InnoDB Monitor for periodic output, use a `CREATE TABLE` statement to create the table associated with the Monitor. For example, to enable the standard InnoDB Monitor, create the `innodb_monitor` table:

```
CREATE TABLE innodb_monitor (a INT) ENGINE=INNODB;
```

To stop the Monitor, drop the table:

```
DROP TABLE innodb_monitor;
```

The `CREATE TABLE` syntax is just a way to pass a command to the InnoDB engine through MySQL’s SQL parser: The only things that matter are the table name `innodb_monitor` and that it be an InnoDB table. The structure of the table is not relevant at all for the InnoDB Monitor. If you shut down the server, the Monitor does not restart automatically when you restart the server. Drop the Monitor table and issue a new `CREATE TABLE` statement to start the Monitor. (This syntax may change in a future release.)

As of MySQL 5.1.24, the PROCESS privilege is required to start or stop the InnoDB Monitor tables.

When you enable InnoDB Monitors for periodic output, InnoDB writes their output to the `mysqld` server standard error output (`stderr`). In this case, no output is sent to clients. When switched on, InnoDB Monitors print data about every 15 seconds. Server output usually is directed to the error log (see Section 5.4.2, “The Error Log”). This data is useful in performance tuning. On Windows, start the server from a command prompt in a console window with the `--console` option if you want to direct the output to the window rather than to the error log.

InnoDB sends diagnostic output to `stderr` or to files rather than to `stdout` or fixed-size memory buffers, to avoid potential buffer overflows. As a side effect, the output of `SHOW ENGINE INNODB
**InnoDB Monitors**

`innodb_status` is written to a status file in the MySQL data directory every fifteen seconds. The name of the file is `innodb_status.pid`, where `pid` is the server process ID. InnoDB removes the file for a normal shutdown. If abnormal shutdowns have occurred, instances of these status files may be present and must be removed manually. Before removing them, you might want to examine them to see whether they contain useful information about the cause of abnormal shutdowns. The `innodb_status.pid` file is created only if the configuration option `innodb-status-file=1` is set.

InnoDB Monitors should be enabled only when you actually want to see Monitor information because output generation does result in some performance decrement. Also, if you enable monitor output by creating the associated table, your error log may become quite large if you forget to remove the table later.

For additional information about InnoDB monitors, see:

- Mark Leith: *InnoDB Table and Tablespace Monitors*

Each monitor begins with a header containing a timestamp and the monitor name. For example:

```
141017  9:57:58 INNODB MONITOR OUTPUT
```

The header for the standard Monitor (`INNODB MONITOR OUTPUT`) is also used for the Lock Monitor because the latter produces the same output with the addition of extra lock information.

The following sections describe the output for each Monitor.

### 14.6.9.1 InnoDB Standard Monitor and Lock Monitor Output

The Lock Monitor is the same as the standard Monitor except that it includes additional lock information. Enabling either monitor for periodic output by creating the associated InnoDB table turns on the same output stream, but the stream includes the extra information if the Lock Monitor is enabled. For example, if you create the `innodb_monitor` and `innodb_lock_monitor` tables, that turns on a single output stream. The stream includes extra lock information until you disable the Lock Monitor by removing the `innodb_lock_monitor` table.

Example InnoDB Monitor output (as of MySQL 5.1.72):

```sql
mysql> SHOW ENGINE INNODB STATUS\G
*************************** 1. row ***************************
Type: InnoDB
Name:
Status:
Per second averages calculated from the last 9 seconds
SEMAPHORES
OS WAIT ARRAY INFO: reservation count 416, signal count 413
Mutex spin waits 0, rounds 4630, OS waits 153
RW-shared spins 516, OS waits 258; RW-excl spins 9, OS waits 5
LATEST FOREIGN KEY ERROR
```

```sql

InnoDB Monitor output is limited to 64,000 bytes when produced using the `SHOW ENGINE INNODB STATUS` statement. This limit does not apply to output written to the server's error output.

Some notes on the output sections:

**Status**

This section shows the timestamp, the monitor name, and the number of seconds that per-second averages are based on. The number of seconds is the elapsed time between the current time and the last time InnoDB Monitor output was printed.

**BACKGROUND THREAD**

The `srv_master_thread` lines shows work done by the main background thread. This section is displayed only by InnoDB Plugin.

**SEMAPHORES**

This section reports threads waiting for a semaphore and statistics on how many times threads have needed a spin or a wait on a mutex or a rw-lock semaphore. A large number of threads waiting for semaphores may be a result of disk I/O, or contention problems inside InnoDB. Contention can be due to heavy parallelism of queries or problems in operating system thread scheduling. Setting the `innodb_thread_concurrency` system variable smaller than the default value might help in such situations. The `Spin rounds per wait` line (InnoDB Plugin only) shows the number of spinlock rounds per OS wait for a mutex.

**LATEST FOREIGN KEY ERROR**

This section provides information about the most recent foreign key constraint error. It is not present if no such error has occurred. The contents include the statement that failed as well as information about the constraint that failed and the referenced and referencing tables.

**LATEST DETECTED DEADLOCK**

This section provides information about the most recent deadlock. It is not present if no deadlock has occurred. The contents show which transactions are involved, the statement each was attempting to execute, the locks they have and need, and which transaction InnoDB decided to roll back to break the deadlock. The lock modes reported in this section are explained in Section 14.6.4.1, “InnoDB Lock Modes”.

**TRANSACTIONS**

If this section reports lock waits, your applications might have lock contention. The output can also help to trace the reasons for transaction deadlocks.

**FILE I/O**

This section provides information about threads that InnoDB uses to perform various types of I/O. The first few of these are dedicated to general InnoDB processing. The contents also display information for pending I/O operations and statistics for I/O performance.
On Unix, the number of threads is always 4. On Windows, the number depends on the setting of the `innodb_file_io_threads` system variable.

**INSERT BUFFER AND ADAPTIVE HASH INDEX**

This section shows the status of the InnoDB insert buffer and adaptive hash index. (See Insert Buffering, and Adaptive Hash Indexes.) The contents include the number of operations performed for each, plus statistics for hash index performance.

**LOG**

This section displays information about the InnoDB log. The contents include the current log sequence number, how far the log has been flushed to disk, and the position at which InnoDB last took a checkpoint. (See Section 14.6.10.2, “InnoDB Checkpoints”.) The section also displays information about pending writes and write performance statistics.

**BUFFER POOL AND MEMORY**

This section gives you statistics on pages read and written. You can calculate from these numbers how many data file I/O operations your queries currently are doing.

For additional information about the operation of the buffer pool, see Section 8.10.2, “The InnoDB Buffer Pool”.

**ROW OPERATIONS**

This section shows what the main thread is doing, including the number and performance rate for each type of row operation.

### 14.6.9.2 InnoDB Tablespace Monitor Output

The InnoDB Tablespace Monitor prints information about the file segments in the shared tablespace and validates the tablespace allocation data structures. If you use individual tablespaces by enabling `innodb_file_per_table`, the Tablespace Monitor does not describe those tablespaces.

Example InnoDB Tablespace Monitor output:

```
090408 21:28:09 INNODB TABLESPACE MONITOR OUTPUT
FILE SPACE INFO: id 0
size 13440, free limit 3136, free extents 28
not full frag extents 2; used pages 78, full frag extents 3
first seg id not used 0 23845
SEGMENT id 0 1 space 0; page 2; res 96 used 46; full ext 0
fragm pages 32; free extents 0; not full extents 1: pages 14
SEGMENT id 0 2 space 0; page 2; res 1 used 1; full ext 0
fragm pages 1; free extents 0; not full extents 0: pages 0
SEGMENT id 0 3 space 0; page 2; res 1 used 1; full ext 0
fragm pages 1; free extents 0; not full extents 0: pages 0
... SEGMENT id 0 15 space 0; page 2; res 160 used 160; full ext 2
fragm pages 32; free extents 0; not full extents 0: pages 0
SEGMENT id 0 488 space 0; page 2; res 1 used 1; full ext 0
fragm pages 1; free extents 0; not full extents 0: pages 0
SEGMENT id 0 17 space 0; page 2; res 1 used 1; full ext 0
fragm pages 1; free extents 0; not full extents 0: pages 0
... SEGMENT id 0 171 space 0; page 2; res 592 used 481; full ext 7
fragm pages 16; free extents 0; not full extents 2: pages 17
SEGMENT id 0 172 space 0; page 2; res 1 used 1; full ext 0
fragm pages 1; free extents 0; not full extents 0: pages 0
SEGMENT id 0 173 space 0; page 2; res 96 used 44; full ext 0
fragm pages 32; free extents 0; not full extents 1: pages 12
... SEGMENT id 0 601 space 0; page 2; res 1 used 1; full ext 0
```
InnoDB Monitors

```
fragm pages 1; free extents 0; not full extents 0: pages 0
NUMBER of file segments: 73
Validating tablespace
Validation ok
END OF INNODB TABLESPACE MONITOR OUTPUT
```

The Tablespace Monitor output includes information about the shared tablespace as a whole, followed by a list containing a breakdown for each segment within the tablespace.

The tablespace consists of database pages with a default size of 16KB. The pages are grouped into extents of size 1MB (64 consecutive pages).

The initial part of the output that displays overall tablespace information has this format:

```
FILE SPACE INFO: id 0
size 13440, free limit 3136, free extents 28
not full frag extents 2: used pages 78, full frag extents 3
first seg id not used 0 23845
```

Overall tablespace information includes these values:

- **id**: The tablespace ID. A value of 0 refers to the shared tablespace.
- **size**: The current tablespace size in pages.
- **free limit**: The minimum page number for which the free list has not been initialized. Pages at or above this limit are free.
- **free extents**: The number of free extents.
- **not full frag extents, used pages**: The number of fragment extents that are not completely filled, and the number of pages in those extents that have been allocated.
- **full frag extents**: The number of completely full fragment extents.
- **first seg id not used**: The first unused segment ID.

Individual segment information has this format:

```
SEGMENT id 0 15 space 0; page 2; res 160 used 160; full ext 2
fragm pages 32; free extents 0; not full extents 0: pages 0
```

Segment information includes these values:

- **id**: The segment ID.
- **space, page**: The tablespace number and page within the tablespace where the segment “inode” is located. A tablespace number of 0 indicates the shared tablespace. InnoDB uses inodes to keep track of segments in the tablespace. The other fields displayed for a segment (id, res, and so forth) are derived from information in the inode.
- **res**: The number of pages allocated (reserved) for the segment.
- **used**: The number of allocated pages in use by the segment.
- **full ext**: The number of extents allocated for the segment that are completely used.
- **fragm pages**: The number of initial pages that have been allocated to the segment.
- **free extents**: The number of extents allocated for the segment that are completely unused.
- **not full extents**: The number of extents allocated for the segment that are partially used.
- **pages**: The number of pages used within the not-full extents.
When a segment grows, it starts as a single page, and InnoDB allocates the first pages for it individually, up to 32 pages (this is the fragm pages value). After that, InnoDB allocates complete 64-page extents. InnoDB can add up to 4 extents at a time to a large segment to ensure good sequentiality of data.

For the example segment shown earlier, it has 32 fragment pages, plus 2 full extents (64 pages each), for a total of 160 pages used out of 160 pages allocated. The following segment has 32 fragment pages and one partially full extent using 14 pages for a total of 46 pages used out of 96 pages allocated:

```
SEGMENT id 0 1 space 0; page 2; res 96 used 46; full ext 0
fragm pages 32; free extents 0; not full extents 1: pages 14
```

It is possible for a segment that has extents allocated to it to have a fragm pages value less than 32 if some of the individual pages have been deallocated subsequent to extent allocation.

### 14.6.9.3 InnoDB Table Monitor Output

The InnoDB Table Monitor prints the contents of the InnoDB internal data dictionary.

The output contains one section per table. The SYS_FOREIGN and SYS_FOREIGN_COLS sections are for internal data dictionary tables that maintain information about foreign keys. There are also sections for the Table Monitor table and each user-created InnoDB table. Suppose that the following two tables have been created in the test database:

```sql
CREATE TABLE parent
(
    par_id INT NOT NULL,
    fname CHAR(20),
    lname CHAR(20),
    PRIMARY KEY (par_id),
    UNIQUE INDEX (lname, fname)
) ENGINE = INNODB;

CREATE TABLE child
(
    par_id INT NOT NULL,
    child_id INT NOT NULL,
    name VARCHAR(40),
    birth DATE,
    weight DECIMAL(10,2),
    misc_info VARCHAR(255),
    last_update TIMESTAMP,
    PRIMARY KEY (par_id, child_id),
    INDEX (name),
    FOREIGN KEY (par_id) REFERENCES parent (par_id)
    ON DELETE CASCADE
    ON UPDATE CASCADE
) ENGINE = INNODB;
```

Then the Table Monitor output will look something like this (reformatted slightly):

```
--------------------------------------
TABLE: name SYS_FOREIGN, id 0 11, columns 7, indexes 3, appr.rows 1
COLUMNS: ID DATAVARCHAR DATA_ENGLISH len 0;
FOR_NAME DATAVARCHAR DATA_ENGLISH len 0;
REF_NAME DATAVARCHAR DATA_ENGLISH len 0;
N_COLS DATAINT len 4;
DB_ROW_ID DATA_SYS prtype 256 len 6;
DB_TRX_ID DATA_SYS prtype 257 len 6;
INDEX: name ID_IND, id 0 11, fields 1/6, uniq 1, type 3
root page 46, appr.key vals 1, leaf pages 1, size pages 1
FIELDS: ID DB_TRA_ID DB_ROLL_PTR FOR_NAME REF_NAME N_COLS
```
For each table, Table Monitor output contains a section that displays general information about the table and specific information about its columns, indexes, and foreign keys.

The general information for each table includes the table name (in `db_name/tbl_name` format except for internal tables), its ID, the number of columns and indexes, and an approximate row count.

The `COLUMNS` part of a table section lists each column in the table. Information for each column indicates its name and data type characteristics. Some internal columns are added by InnoDB, such
as `DB_ROW_ID` (row ID), `DB_TRX_ID` (transaction ID), and `DB_ROLL_PTR` (a pointer to the rollback/undo data).

- **DATA.xxx**: These symbols indicate the data type. There may be multiple `DATA.xxx` symbols for a given column.
- **prtype**: The column’s “precise” type. This field includes information such as the column data type, character set code, nullability, signedness, and whether it is a binary string. This field is described in the `innobase/include/data0type.h` source file.
- **len**: The column length in bytes.

Each `INDEX` part of the table section provides the name and characteristics of one table index:

- **name**: The index name. If the name is `PRIMARY`, the index is a primary key. If the name is `GEN_CLUST_INDEX`, the index is the clustered index that is created automatically if the table definition doesn't include a primary key or non-`NULL` unique index. See Clustered and Secondary Indexes.
- **id**: The index ID.
- **fields**: The number of fields in the index, as a value in `m/n` format:
  - `m` is the number of user-defined columns; that is, the number of columns you would see in the index definition in a `CREATE TABLE` statement.
  - `n` is the total number of index columns, including those added internally. For the clustered index, the total includes the other columns in the table definition, plus any columns added internally. For a secondary index, the total includes the columns from the primary key that are not part of the secondary index.
- **uniq**: The number of leading fields that are enough to determine index values uniquely.
- **type**: The index type. This is a bit field. For example, 1 indicates a clustered index and 2 indicates a unique index, so a clustered index (which always contains unique values), will have a `type` value of 3. An index with a `type` value of 0 is neither clustered nor unique. The flag values are defined in the `innobase/include/dict0mem.h` source file.
- **root page**: The index root page number.
- **appr. key vals**: The approximate index cardinality.
- **leaf pages**: The approximate number of leaf pages in the index.
- **size pages**: The approximate total number of pages in the index.
- **FIELDS**: The names of the fields in the index. For a clustered index that was generated automatically, the field list begins with the internal `DB_ROW_ID` (row ID) field. `DB_TRX_ID` and `DB_ROLL_PTR` are always added internally to the clustered index, following the fields that comprise the primary key. For a secondary index, the final fields are those from the primary key that are not part of the secondary index.

The end of the table section lists the `FOREIGN KEY` definitions that apply to the table. This information appears whether the table is a referencing or referenced table.

### 14.6.10 InnoDB Backup and Recovery

The key to safe database management is making regular backups. Depending on your data volume, number of MySQL servers, and database workload, you can use these techniques, alone or in combination: hot backup with MySQL Enterprise Backup; cold backup by copying files while the MySQL server is shut down; physical backup for fast operation (especially for restore); logical backup with `mysqldump` for smaller data volumes or to record the structure of schema objects.
InnoDB Backup and Recovery

Hot Backups

The `mysqlbackup` command, part of the MySQL Enterprise Backup component, lets you back up a running MySQL instance, including InnoDB and MyISAM tables, with minimal disruption to operations while producing a consistent snapshot of the database. When `mysqlbackup` is copying InnoDB tables, reads and writes to both InnoDB and MyISAM tables can continue. During the copying of MyISAM tables, reads (but not writes) to those tables are permitted. MySQL Enterprise Backup can also create compressed backup files, and back up subsets of tables and databases. In conjunction with MySQL’s binary log, users can perform point-in-time recovery. MySQL Enterprise Backup is part of the MySQL Enterprise subscription. For more details, see Section 23.2, “MySQL Enterprise Backup Overview”.

Cold Backups

If you can shut down your MySQL server, you can make a binary backup that consists of all files used by InnoDB to manage its tables. Use the following procedure:

1. Do a **slow shutdown** of the MySQL server and make sure that it stops without errors.
2. Copy all InnoDB data files (`ibdata` files and `.ibd` files) into a safe place.
3. Copy all the `.frm` files for InnoDB tables to a safe place.
4. Copy all InnoDB log files (`ib_logfile` files) to a safe place.
5. Copy your `my.cnf` configuration file or files to a safe place.

Alternative Backup Types

In addition to making binary backups as just described, regularly make dumps of your tables with `mysqldump`. A binary file might be corrupted without you noticing it. Dumped tables are stored into text files that are human-readable, so spotting table corruption becomes easier. Also, because the format is simpler, the chance for serious data corruption is smaller. `mysqldump` also has a `--single-transaction` option for making a consistent snapshot without locking out other clients. See Section 7.3.1, “Establishing a Backup Policy”.

Replication works with InnoDB tables, so you can use MySQL replication capabilities to keep a copy of your database at database sites requiring high availability.

Performing Recovery

To recover your InnoDB database to the present from the time at which the binary backup was made, you must run your MySQL server with binary logging turned on, even before taking the backup. To achieve point-in-time recovery after restoring a backup, you can apply changes from the binary log that occurred after the backup was made. See Section 7.5, “Point-in-Time (Incremental) Recovery Using the Binary Log”.

To recover from a crash of your MySQL server, the only requirement is to restart it. InnoDB automatically checks the logs and performs a roll-forward of the database to the present. InnoDB automatically rolls back uncommitted transactions that were present at the time of the crash. During recovery, `mysqld` displays output something like this:

```sql
InnoDB: Database was not shut down normally.
InnoDB: Starting recovery from log files...
InnoDB: Starting log scan based on checkpoint at
InnoDB: log sequence number 0 13674004
InnoDB: Doing recovery: scanned up to log sequence number 0 13739520
InnoDB: Doing recovery: scanned up to log sequence number 0 13805056
InnoDB: Doing recovery: scanned up to log sequence number 0 13870592
InnoDB: Doing recovery: scanned up to log sequence number 0 13936128
...
InnoDB: Doing recovery: scanned up to log sequence number 0 20555264
InnoDB: Doing recovery: scanned up to log sequence number 0 20620800
InnoDB: Doing recovery: scanned up to log sequence number 0 20664692
```
InnoDB Backup and Recovery

If your database becomes corrupted or disk failure occurs, you must perform the recovery using a backup. In the case of corruption, first find a backup that is not corrupted. After restoring the base backup, do a point-in-time recovery from the binary log files using `mysqlbinlog` and `mysql` to restore the changes that occurred after the backup was made.

In some cases of database corruption, it is enough just to dump, drop, and re-create one or a few corrupt tables. You can use the `CHECK TABLE` SQL statement to check whether a table is corrupt, although `CHECK TABLE` naturally cannot detect every possible kind of corruption. You can use the Tablespace Monitor to check the integrity of the file space management inside the tablespace files.

In some cases, apparent database page corruption is actually due to the operating system corrupting its own file cache, and the data on disk may be okay. It is best first to try restarting your computer. Doing so may eliminate errors that appeared to be database page corruption. If MySQL still has trouble starting because of InnoDB consistency problems, see Section 14.6.12.2, “Forcing InnoDB Recovery” for steps to start the instance in a diagnostic mode where you can dump the data.

### 14.6.10.1 The InnoDB Recovery Process

**InnoDB crash recovery** consists of several steps:

- **Applying the redo log**: Redo log application is the first step and is performed during initialization, before accepting any connections. If all changes were flushed from the buffer pool to the tablespaces (`ibdata*` and `*.ibd` files) at the time of the shutdown or crash, the redo log application can be skipped. If the redo log files are missing at startup, InnoDB skips the redo log application.

  Removing redo logs to speed up the recovery process is not recommended, even if some data loss is acceptable. Removing redo logs should only be considered an option after a clean shutdown is performed, with `innodb_fast_shutdown` set to 0 or 1.

- **Rolling back incomplete transactions**: Any transactions that were active at the time of crash or fast shutdown. The time it takes to roll back an incomplete transaction can be three or four times the amount of time a transaction is active before it is interrupted, depending on server load.

  You cannot cancel transactions that are in the process of being rolled back. In extreme cases, when rolling back transactions is expected to take an exceptionally long time, it may be faster to start InnoDB with an `innodb_force_recovery` setting of 3 or greater. See Section 14.6.12.2, “Forcing InnoDB Recovery” for more information.

- **Insert buffer merge**: Applying changes from the insert buffer (part of the system tablespace) to leaf pages of secondary indexes, as the index pages are read to the buffer pool.

- **Purge**: Deleting delete-marked records that are no longer visible for any active transaction.

The steps that follow redo log application do not depend on the redo log (other than for logging the writes) and are performed in parallel with normal processing. Of these, only rollback of incomplete transactions is special to crash recovery. The insert buffer merge and the purge are performed during normal processing.

After redo log application, InnoDB attempts to accept connections as early as possible, to reduce downtime. As part of crash recovery, InnoDB rolls back any transactions that were not committed or in `XA PREPARE` state when the server crashed. The rollback is performed by a background thread, executed in parallel with transactions from new connections. Until the rollback operation is completed, new connections may encounter locking conflicts with recovered transactions.
In most situations, even if the MySQL server was killed unexpectedly in the middle of heavy activity, the recovery process happens automatically and no action is needed from the DBA. If a hardware failure or severe system error corrupted InnoDB data, MySQL might refuse to start. In that case, see Section 14.6.12.2, “Forcing InnoDB Recovery” for the steps to troubleshoot such an issue.

For information about the binary log and InnoDB crash recovery, see Section 5.4.4, “The Binary Log”.

14.6.10.2 InnoDB Checkpoints

InnoDB implements a checkpoint mechanism known as “fuzzy” checkpointing. InnoDB flushes modified database pages from the buffer pool in small batches. There is no need to flush the buffer pool in one single batch, which would in practice stop processing of user SQL statements during the checkpointing process.

During crash recovery, InnoDB looks for a checkpoint label written to the log files. It knows that all modifications to the database before the label are present in the disk image of the database. Then InnoDB scans the log files forward from the checkpoint, applying the logged modifications to the database.

InnoDB writes to its log files on a rotating basis. It also writes checkpoint information to the first log file at each checkpoint. All committed modifications that make the database pages in the buffer pool different from the images on disk must be available in the log files in case InnoDB has to do a recovery. This means that when InnoDB starts to reuse a log file, it has to make sure that the database page images on disk contain the modifications logged in the log file that InnoDB is going to reuse. In other words, InnoDB must create a checkpoint and this often involves flushing of modified database pages to disk.

The preceding description explains why making your log files very large may reduce disk I/O in checkpointing. It often makes sense to set the total size of the log files as large as the buffer pool or even larger. The disadvantage of using large log files is that crash recovery can take longer because there is more logged information to apply to the database.

14.6.11 InnoDB and MySQL Replication

MySQL replication works for InnoDB tables as it does for MyISAM tables. It is also possible to use replication in a way where the storage engine on the slave is not the same as the original storage engine on the master. For example, you can replicate modifications to an InnoDB table on the master to a MyISAM table on the slave.

To set up a new slave for a master, make a copy of the InnoDB tablespace and the log files, as well as the .frm files of the InnoDB tables, and move the copies to the slave. If the innodb_file_per_table option is enabled, copy the .ibd files as well. For the proper procedure to do this, see Section 14.6.10, “InnoDB Backup and Recovery”.

To make a new slave without taking down the master or an existing slave, use the MySQL Enterprise Backup product. If you can shut down the master or an existing slave, take a cold backup of the InnoDB tablespaces and log files and use that to set up a slave.

You cannot set up replication for InnoDB using the LOAD TABLE FROM MASTER statement, which works only for MyISAM tables. There are two possible workarounds:

• Dump the table on the master and import the dump file into the slave.

• Use ALTER TABLE tbl_name ENGINE=MyISAM on the master before setting up replication with LOAD TABLE tbl_name FROM MASTER, and then use ALTER TABLE to convert the master table back to InnoDB afterward. However, this should not be done for tables that have foreign key definitions because the definitions will be lost.

Transactions that fail on the master do not affect replication at all. MySQL replication is based on the binary log where MySQL writes SQL statements that modify data. A transaction that fails (for example,
because of a foreign key violation, or because it is rolled back) is not written to the binary log, so it is not sent to slaves. See Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”.

**Replication and CASCADE.** Cascading actions for InnoDB tables on the master are replicated on the slave only if the tables sharing the foreign key relation use InnoDB on both the master and slave. This is true whether you are using statement-based or row-based replication. Suppose that you have started replication, and then create two tables on the master using the following `CREATE TABLE` statements:

```sql
CREATE TABLE fc1 (  
i INT PRIMARY KEY,  
j INT  
) ENGINE = InnoDB;

CREATE TABLE fc2 (  
m INT PRIMARY KEY,  
n INT,  
FOREIGN KEY ni (n) REFERENCES fc1 (i)  
ON DELETE CASCADE  
) ENGINE = InnoDB;
```

Suppose that the slave does not have InnoDB support enabled. If this is the case, then the tables on the slave are created, but they use the MyISAM storage engine, and the `FOREIGN KEY` option is ignored. Now we insert some rows into the tables on the master:

```sql
master> INSERT INTO fc1 VALUES (1, 1), (2, 2);  
Query OK, 2 rows affected (0.09 sec)  
Records: 2 Duplicates: 0 Warnings: 0

master> INSERT INTO fc2 VALUES (1, 1), (2, 2), (3, 1);  
Query OK, 3 rows affected (0.19 sec)  
Records: 3 Duplicates: 0 Warnings: 0
```

At this point, on both the master and the slave, table `fc1` contains 2 rows, and table `fc2` contains 3 rows, as shown here:

```sql
master> SELECT * FROM fc1;  
+---+------+  
| i | j    |  
+---+------+  
| 1 |    1 |  
| 2 |    2 |  
+---+------+  
2 rows in set (0.00 sec)

master> SELECT * FROM fc2;  
+---+------+  
| m | n    |  
+---+------+  
| 1 |    1 |  
| 2 |    2 |  
| 3 |    1 |  
+---+------+  
3 rows in set (0.00 sec)

slave> SELECT * FROM fc1;  
+---+------+  
| i | j    |  
+---+------+  
| 1 |    1 |  
| 2 |    2 |  
+---+------+  
2 rows in set (0.00 sec)

slave> SELECT * FROM fc2;  
+---+------+  
| m | n    |  
+---+------+  
```
Now suppose that you perform the following DELETE statement on the master:

```
master> DELETE FROM fc1 WHERE i=1;
Query OK, 1 row affected (0.09 sec)
```

Due to the cascade, table `fc2` on the master now contains only 1 row:

```
master> SELECT * FROM fc2;
+---+---+
| m | n |
+---+---+
| 2 | 2 |
+---+---+
1 row in set (0.00 sec)
```

However, the cascade does not propagate on the slave because on the slave the DELETE for `fc1` deletes no rows from `fc2`. The slave's copy of `fc2` still contains all of the rows that were originally inserted:

```
slave> SELECT * FROM fc2;
+---+---+
| m | n |
+---+---+
| 1 | 1 |
| 3 | 1 |
| 2 | 2 |
+---+---+
3 rows in set (0.00 sec)
```

This difference is due to the fact that the cascading deletes are handled internally by the InnoDB storage engine, which means that none of the changes are logged.

### 14.6.12 InnoDB Troubleshooting

The following general guidelines apply to troubleshooting InnoDB problems:

- When an operation fails or you suspect a bug, look at the MySQL server error log (see Section 5.4.2, “The Error Log”). Section B.3, “Server Error Codes and Messages” provides troubleshooting information for some of the common InnoDB-specific errors that you may encounter.

- Issues relating to the InnoDB data dictionary include failed CREATE TABLE statements (orphan table files), inability to open `.InnoDB` files, and system cannot find the path specified errors. For information about these sorts of problems and errors, see Section 14.6.12.3, “Troubleshooting InnoDB Data Dictionary Operations”.

- When troubleshooting, it is usually best to run the MySQL server from the command prompt, rather than through `mysqld_safe` or as a Windows service. You can then see what `mysqld` prints to the console, and so have a better grasp of what is going on. On Windows, start `mysqld` with the `--console` option to direct the output to the console window.

- Enable the InnoDB Monitors to obtain information about a problem (see Section 14.6.9, “InnoDB Monitors”). If the problem is performance-related, or your server appears to be hung, you should enable the standard Monitor to print information about the internal state of InnoDB. If the problem is with locks, enable the Lock Monitor. If the problem is in creation of tables or other data dictionary operations, enable the Table Monitor to print the contents of the InnoDB internal data dictionary. To see tablespace information enable the Tablespace Monitor.
InnoDB temporarily enables standard InnoDB Monitor output under the following conditions:

- A long semaphore wait
- InnoDB cannot find free blocks in the buffer pool
- Over 67% of the buffer pool is occupied by lock heaps or the adaptive hash index
- If you suspect that a table is corrupt, run `CHECK TABLE` on that table.

### 14.6.12.1 Dealing with InnoDB Initialization Problems

If InnoDB prints an operating system error during a file operation, usually the problem has one of the following causes:

- You did not create the InnoDB data file directory or the InnoDB log directory.
- `mysqld` does not have access rights to create files in those directories.
- `mysqld` cannot read the proper `my.cnf` or `my.ini` option file, and consequently does not see the options that you specified.
- The disk is full or a disk quota is exceeded.
- You have created a subdirectory whose name is equal to a data file that you specified, so the name cannot be used as a file name.
- There is a syntax error in the `innodb_data_home_dir` or `innodb_data_file_path` value.

If something goes wrong when InnoDB attempts to initialize its tablespace or its log files, delete all files created by InnoDB. This means all `ibdata` files and all `ib_logfile` files. In case you have already created some InnoDB tables, delete the corresponding `.frm` files for these tables (and any `.ibd` files if you are using multiple tablespaces) from the MySQL database directories as well. Then you can try the InnoDB database creation again. It is best to start the MySQL server from a command prompt so that you see what is happening.

### 14.6.12.2 Forcing InnoDB Recovery

If there is database page corruption, you may want to dump your tables from the database with `SELECT ... INTO OUTFILE`. Usually, most of the data obtained in this way is intact. However, it is possible that the corruption might cause `SELECT * FROM tbl_name` statements or InnoDB background operations to crash or assert, or even cause InnoDB roll-forward recovery to crash. In such cases, you can use the `innodb_force_recovery` option to force the InnoDB storage engine to start up while preventing background operations from running, so that you can dump your tables. For example, you can add the following line to the `[mysqld]` section of your option file before restarting the server:

```
[mysqld]
innoadb_force_recovery = 1
```

**Warning**

Only set `innodb_force_recovery` to a value greater than 0 in an emergency situation, so that you can start InnoDB and dump your tables. Before doing so, ensure that you have a backup copy of your database in case you need to recreate it. Values of 4 or greater can permanently corrupt data files. Only use an `innodb_force_recovery` setting of 4 or greater on a production server instance after you have successfully tested the setting on separate physical copy of your database. When forcing InnoDB recovery, you should always start with `innodb_force_recovery=1` and only increase the value incrementally, as necessary.
InnoDB Troubleshooting

`innodb_force_recovery` is 0 by default (normal startup without forced recovery). The permissible nonzero values for `innodb_force_recovery` are 1 to 6. A larger value includes the functionality of lesser values. For example, a value of 3 includes all of the functionality of values 1 and 2.

If you are able to dump your tables with an `innodb_force_recovery` value of 3 or less, then you are relatively safe that only some data on corrupt individual pages is lost. A value of 4 or greater is considered dangerous because data files can be permanently corrupted. A value of 6 is considered drastic because database pages are left in an obsolete state, which in turn may introduce more corruption into B-trees and other database structures.

As a safety measure, InnoDB prevents users from performing INSERT, UPDATE, or DELETE operations when `innodb_force_recovery` is greater than 0.

- **1 (SRV_FORCE_IGNORE_CORRUPT)**
  
  Let the server run even if it detects a corrupt page. Try to make `SELECT * FROM tbl_name` jump over corrupt index records and pages, which helps in dumping tables.

- **2 (SRV_FORCE_NO_BACKGROUND)**
  
  Prevent the master thread from running. If a crash would occur during the purge operation, this recovery value prevents it.

- **3 (SRV_FORCE_NO_TRX_UNDO)**
  
  Do not run transaction rollbacks after crash recovery.

- **4 (SRV_FORCE_NO_IBUF_MERGE)**
  
  Prevent insert buffer merge operations. If they would cause a crash, do not do them. Do not calculate table statistics. This value can permanently corrupt data files. After using this value, be prepared to drop and recreate all secondary indexes.

- **5 (SRV_FORCE_NO_UNDO_LOG_SCAN)**
  
  Do not look at undo logs when starting the database: InnoDB treats even incomplete transactions as committed. This value can permanently corrupt data files.

- **6 (SRV_FORCE_NO_LOG_REDO)**
  
  Do not do the redo log roll-forward in connection with recovery. This value can permanently corrupt data files. Leaves database pages in an obsolete state, which in turn may introduce more corruption into B-trees and other database structures.

You can `SELECT` from tables to dump them, or `DROP` or `CREATE` tables even if forced recovery is used. If you know that a given table is causing a crash on rollback, you can drop it. You can also use this to stop a runaway rollback caused by a failing mass import or `ALTER TABLE`. You can kill the `mysqlld` process and set `innodb_force_recovery` to 3 to bring the database up without the rollback, then `DROP` the table that is causing the runaway rollback.

If corruption within the table data prevents you from dumping the entire table contents, a query with an `ORDER BY primary_key DESC` clause might be able to dump the portion of the table after the corrupted part.

If a high `innodb_force_recovery` value is required to start InnoDB, there may be corrupted data structures that could cause complex queries (queries containing `WHERE`, `ORDER BY`, or other clauses) to fail. In this case, you may only be able to run basic `SELECT * FROM t` queries.

### 14.6.12.3 Troubleshooting InnoDB Data Dictionary Operations

A specific issue with tables is that the MySQL server keeps data dictionary information in `.frm` files it stores in the database directories, whereas InnoDB also stores the information into its own data
dictionary inside the tablespace files. If you move .frm files around, or if the server crashes in the middle of a data dictionary operation, the locations of the .frm files may end up out of synchrony with the locations recorded in the InnoDB internal data dictionary.

If a data dictionary corruption or consistency issue prevents you from starting InnoDB, see Section 14.6.12.2, “Forcing InnoDB Recovery” for information about manual recovery.

**CREATE TABLE Failure Due to Orphan Table**

A symptom of an out-of-sync data dictionary is that a CREATE TABLE statement fails. If this occurs, look in the server’s error log. If the log says that the table already exists inside the InnoDB internal data dictionary, you have an orphan table inside the InnoDB tablespace files that has no corresponding .frm file. The error message looks like this:

```
InnoDB: Error: table test/parent already exists in InnoDB internal
InnoDB: data dictionary. Have you deleted the .frm file
InnoDB: and not used DROP TABLE? Have you used DROP DATABASE
InnoDB: for InnoDB tables in MySQL version <= 3.23.43?
InnoDB: See the Restrictions section of the InnoDB manual.
InnoDB: You can drop the orphaned table inside InnoDB by
InnoDB: creating an InnoDB table with the same name in another
InnoDB: database and moving the .frm file to the current database.
InnoDB: Then MySQL thinks the table exists, and DROP TABLE will
InnoDB: succeed.
```

You can drop the orphan table by following the instructions given in the error message. If you are still unable to use DROP TABLE successfully, the problem may be due to name completion in the mysql client. To work around this problem, start the mysql client with the --skip-auto-rehash option and try DROP TABLE again. (With name completion on, mysql tries to construct a list of table names, which fails when a problem such as just described exists.)

**Cannot Open File Error**

Another symptom of an out-of-sync data dictionary is that MySQL prints an error that it cannot open an InnoDB file:

```
ERROR 1016: Can't open file: 'child2.ibd'. (errno: 1)
```

In the error log you can find a message like this:

```
InnoDB: Cannot find table test/child2 from the internal data dictionary
InnoDB: of InnoDB though the .frm file for the table exists. Maybe you
InnoDB: have deleted and recreated InnoDB data files but have forgotten
InnoDB: to delete the corresponding .frm files of InnoDB tables?
```

This means that there is an orphan .frm file without a corresponding table inside InnoDB. You can drop the orphan .frm file by deleting it manually.

**Orphan Temporary Tables**

If MySQL exits in the middle of an ALTER TABLE operation, you may be left with an orphan temporary table that takes up space on your system. This section describes how to identify and remove orphan temporary tables.

Orphan temporary table names begin with an #sql- prefix (e.g., #sql-540_3). The accompanying .frm file has the same base name as the orphan temporary table.

**Note**

If there is no .frm file, you can recreate it. The .frm file must have the same table schema as the orphan temporary table (it must have the same columns and indexes) and must be placed in the database directory of the orphan temporary table.
To identify orphan temporary tables on your system, you can view Table Monitor output. Look for table names that begin with `#sql`. If the original table resides in a file-per-table tablespace, the tablespace file (the `#sql-*` file) for the orphan temporary table should be visible in the database directory.

To remove an orphan temporary table, drop the table by issuing a `DROP TABLE` statement, prefixing the name of the table with `#mysql50#` and enclosing the table name in backticks. For example:

```
mysql> DROP TABLE `#mysql50##sql-540_3`;
```

The `#mysql50#` prefix tells MySQL to ignore file name safe encoding introduced in MySQL 5.1. Enclosing the table name in backticks is required to perform SQL statements on table names with special characters such as “#”.

**Tablespace Does Not Exist**

With `innodb_file_per_table` enabled, the following message might occur if the `.frm` or `.ibd` files (or both) are missing:

```
InnoDB: in InnoDB data dictionary has tablespace id N,
InnoDB: but tablespace with that id or name does not exist. Have
InnoDB: you deleted or moved .ibd files?
InnoDB: This may also be a table created with CREATE TEMPORARY TABLE
InnoDB: whose .ibd and .frm files MySQL automatically removed, but the
InnoDB: table still exists in the InnoDB internal data dictionary.
```

If this occurs, try the following procedure to resolve the problem:

1. Create a matching `.frm` file in some other database directory and copy it to the database directory where the orphan table is located.

2. Issue `DROP TABLE` for the original table. That should successfully drop the table and InnoDB should print a warning to the error log that the `.ibd` file was missing.

**14.6.12.4 InnoDB Error Handling**

The following items describe how InnoDB performs error handling. InnoDB sometimes rolls back only the statement that failed, other times it rolls back the entire transaction.

- If you run out of file space in the tablespace, a MySQL Table is full error occurs and InnoDB rolls back the SQL statement.

- A transaction deadlock causes InnoDB to roll back the entire transaction. Retry the whole transaction when this happens.

A lock wait timeout causes InnoDB to roll back only the single statement that was waiting for the lock and encountered the timeout. (To have the entire transaction roll back, start the server with the `--innodb_rollback_on_timeout` option, available as of MySQL 5.1.15.) Retry the statement if using the current behavior, or the entire transaction if using `--innodb_rollback_on_timeout`.

Both deadlocks and lock wait timeouts are normal on busy servers and it is necessary for applications to be aware that they may happen and handle them by retrying. You can make them less likely by doing as little work as possible between the first change to data during a transaction and the commit, so the locks are held for the shortest possible time and for the smallest possible number of rows. Sometimes splitting work between different transactions may be practical and helpful.

When a transaction rollback occurs due to a deadlock or lock wait timeout, it cancels the effect of the statements within the transaction. But if the start-transaction statement was `START TRANSACTION` or `BEGIN` statement, rollback does not cancel that statement. Further SQL statements become part of the transaction until the occurrence of `COMMIT, ROLLBACK`, or some SQL statement that causes an implicit commit.
The IBMDB2I Storage Engine

- A duplicate-key error rolls back the SQL statement, if you have not specified the `IGNORE` option in your statement.

- A `row too long error` rolls back the SQL statement.

- Other errors are mostly detected by the MySQL layer of code (above the InnoDB storage engine level), and they roll back the corresponding SQL statement. Locks are not released in a rollback of a single SQL statement.

During implicit rollbacks, as well as during the execution of an explicit `ROLLBACK` SQL statement, `SHOW PROCESSLIST` displays `Rolling back` in the `State` column for the relevant connection.

14.7 The IBMDB2I Storage Engine

The IBMDB2I storage engine is designed as a fully featured transaction-capable storage engine that enables MySQL to store its data in DB2 tables running on IBM i. With the IBMDB2I storage engine, data can be shared between MySQL applications and applications coded for native DB2 for i interfaces.

IBMDB2I provides ACID-compliant transactions, support for foreign key constraints, full crash recovery, radix-tree-based indexes, and the unique ability to enable DB2 for i applications to see and update table data in real time.

More information about the storage engine and its interaction with DB2 for i can be found in IBM's Using DB2 for i as a Storage Engine for MySQL Redbook publication, at IBM DB2 for i a Storage Engine for MySQL Redbook.

**Note**

The IBMDB2I storage engine was introduced in MySQL 5.1.33 and considered GA in MySQL 5.1.35. It was removed in MySQL 5.1.54.

14.7.1 Installation

Because it relies on features specific to the IBM i operating system running on IBM Power systems, the IBMDB2I storage engine is only available on builds of MySQL specifically created for the IBM i operating system.

IBM i 5.4 or later is required to run IBMDB2I. Some features may require IBM i 6.1 or later versions. As well, a set of program temporary fixes (PTFs) must be installed. Information about the specific PTF numbers can be obtained from [http://www-912.ibm.com/n_dir/nas4apar.nsf/c79815e083182fec862564c00079d117/67d12878076e4827862574e2003c6d4a?OpenDocument](http://www-912.ibm.com/n_dir/nas4apar.nsf/c79815e083182fec862564c00079d117/67d12878076e4827862574e2003c6d4a?OpenDocument).

The engine is built as a dynamic plugin and so must be installed by using the following command:

```
mysql> INSTALL PLUGIN ibmdb2i SONAME ha_ibmdb2i.so;
```

• **ibmdb2i_assume_exclusive_use**

| Introduced | 5.1.33 |
| Command-Line Format | ibmdb2i_assume_exclusive_use |
| System Variable | Name ibmdb2i_assume_exclusive_use |
| | Variable Global |
| | Scope |
| | DynamicYes |
| | Variable |
| Permitted Values (IBM System i) | Type boolean |
| | Default off |

Specifies whether an external interface (such as DB2 for i) may be altering the data accessible by the IBMDB2I engine. This is an advisory value that may improve performance when correctly set to ON. When the value is ON, IBMDB2I may perform some internal caching of table statistics. When the value is set to OFF, IBMDB2I must assume that the table rows could be inserted and deleted without its direct knowledge and must call DB2 to obtain accurate statistics before each operation.

Default Value: OFF

• **ibmdb2i_async_enabled**

| Introduced | 5.1.33 |
| Command-Line Format | ibmdb2i_async_enabled |
| System Variable | Name ibmdb2i_async_enabled |
| | Variable Global, Session |
| | Scope |
| | DynamicYes |
| | Variable |
| Permitted Values (IBM System i) | Type boolean |
| | Default on |

Specifies whether buffering between IBMDB2I and the QSQSRVR jobs responsible for fetching row data should be done in an asynchronous manner. Asynchronous reads are enabled by default and provide optimal performance. Under normal circumstances, this value will never need to be modified.

Default Value: ON

• **ibmdb2i_create_index_option**

| Introduced | 5.1.33 |
| Command-Line Format | ibmdb2i_create_index_option |
**Configuration Options**

<table>
<thead>
<tr>
<th>System Variable</th>

<td>Global, Session</td>
<td>Dynamic Variable</td>
<td>numeric</td>
<td></td>
<td></td>
<td>0</td>
</tr>
</tbody>
</table>

Controls whether additional indexes are created for use by traditional DB2 for i interfaces. When the value is 0, no additional indexes will be created. When the value is 1 and the index created on behalf of MySQL is ASCII-based, an additional index is created based on EBCDIC hexadecimal sorting. The additional index may be useful for traditional DB2 for i interfaces which expect indexes to use EBCDIC-based sort sequences.

Default Value: 0

- **ibmdb2i_compat_opt_time_as_duration**

  **Introduced** 5.1.33

  **Command-Line Format** ibmdb2i_compat_opt_time_as_duration

  **System Variable**

<table>
<thead>
<tr>

<td>Dynamic Variable</td>
<td>boolean</td>
<td></td>
<td></td>
<td>off</td>
</tr>
</tbody>
</table>

Controls how MySQL TIME columns are mapped to DB2 data types when creating or altering an IBMDB2I table. When the value is **ON**, the column is mapped to an **INTEGER** type in DB2 and supports the full range of values defined by MySQL for **TIME** types. When the value is **OFF**, the column is mapped to a DB2 **TIME** type and supports values in the range of '00:00:00' to '23:59:59'. This option is provided to provide enhanced interoperability with DB2 for i interfaces.

Default Value: OFF

- **ibmdb2i_system_trace_level**

  **Introduced** 5.1.33

  **Command-Line Format** ibmdb2i_system_trace_level

  **System Variable**

<table>
<thead>
<tr>
<th>Name</th>
<th>Variable</th>
<th>Scope</th>
<th>Dynamic</th>
<th>Type</th>
<th>Permitted Values (IBM System i)</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>ibmdb2i_system_trace_level</td>
<td>Global</td>
<td>Dynamic Variable</td>
<td>boolean</td>
<td></td>
<td></td>
<td>0</td>
</tr>
</tbody>
</table>

Specifies what kind of debugging information is to be gathered for **QSQSRVR** jobs servicing MySQL connections. Multiple sources of information may be specified by summing the respective values. Changes to this option only affect new connections. Valid values include

- **0**: No information (Default)
The most useful sources of information are DSPJOBLOG, which will capture the job log for each QSQSRVR job in a spoolfile, and STRDBG, which will increase the diagnostic information in each job log.

Default Value: 0

• ibmdb2i_compat_opt_allow_zero_date_vals

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.33</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>

</tr>
<tr>
<td></td>
<td>Default</td>
</tr>
</tbody>
</table>

Specifies whether the storage engine should permit the 0000-00-00 date in DATETIME, TIMESTAMP and DATE columns. When the option is 0, attempts to insert a row containing this zero date into an IBMDB2I table will fail. As well, a warning will be generated when creating a column with this zero value as the default value. When this option is 1, the zero value will be substituted with 0001-01-01 when stored in DB2, and a 0001-01-01 value will be translated to 0000-00-00 when read from DB2. Similarly, when a column with a default zero value is created, the DB2 default value will be '0001-01-01'. Users must be aware that, when this option is 1, all values of 0001-01-01 in DB2 will be interpreted as 0000-00-00. This option is primarily added for compatibility with applications which rely on the zero date.

Default Value: 0

• ibmdb2i_propagate_default_col_vals

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.33</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>ibmdb2i_propagate_default_col_vals</td>
</tr>

</tr>
<tr>
<td></td>
<td>Dynamic</td>
</tr>
<tr>
<td>Permitted Values (IBM System i)</td>
<td>Type</td>
</tr>
<tr>
<td></td>
<td>Default</td>
</tr>
</tbody>
</table>

Controls how YEAR columns are stored in DB2. The default is 0 and causes YEAR columns to be created as CHAR(4) CCSID 1208 columns in DB2. Setting this option to 1 causes the YEAR columns to be created as SMALLINT columns. This provides a slight performance increase and enables indexes that combine a YEAR column with a character column.

Default Value: 0

- **ibmdb2i_lob_alloc_size**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.33</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>ibmdb2i_lob_alloc_size</td>
</tr>
<tr>

<tr>
<td>Permitted Values (IBM System i)</td>
<td>Type</td>
</tr>
<tr>
<td></td>
<td>Default</td>
</tr>
</tbody>
</table>

Controls how much space is allocated by default for reading data from a BLOB or TEXT field. If an application consistently uses BLOB or TEXT fields that contain more than 2 MB of data, read performance may be improved if this value is increased. Conversely, an application which uses smaller BLOB or TEXT fields may find that the MySQL memory footprint is reduced if a smaller value is specified for this option.

Default Value: 2 MB

- **ibmdb2i_compat_opt_blob_cols**
Configuration Options

<table>
<thead>
<tr>
<th>Permitted Values (IBM System i)</th>
<th>Type</th>
<th>numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

Specifies how MySQL TEXT and BLOB columns larger than 255 characters are mapped when creating IBMDB2I tables. When the value is 0, TEXT columns are mapped to CLOB or DBCLOB columns for DB2 for i. This enables the column to contain the maximum size documented for TEXT columns (64K characters), but the column can not be included in an index. When the value is 1, TEXT columns are mapped to LONG VARCHAR/VARGRAPHIC columns, and BLOB columns are mapped to LONG VARBINARY. This permits indexes to be created over the column, but it reduces the amount of storage available to the column below the documented maximum for TEXT columns. This option was provided to enable applications which relied on the ability to create prefix indexes over TEXT columns.

Default Value: 0

• **ibmdb2i_max_read_buffer_size**

<table>

<table>
<thead>
<tr>
<th>Permitted Values (IBM System i)</th>
<th>Type</th>
<th>numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>8MB</td>
<td></td>
</tr>
</tbody>
</table>

Controls the maximum amount of memory allocated for buffering row data when inserting multiple rows into an IBMDB2I table. This buffering is done independently of any row buffering done within MySQL proper. Setting this value too low may reduce write performance, while setting it too high may increase memory usage.

Default Value: 8 MB

• **ibmdb2i_rdb_name**
### Creating schemas and tables

**IBMDB2I** tables are created by specifying the `ENGINE=IBMDB2I` option on a `CREATE TABLE` or `ALTER TABLE` statement. These tables are stored as DB2 for i objects in the QSYS.LIB file system. Therefore, in contrast to the behavior of other storage engines, **IBMDB2I** table and index data does not reside beneath the datadir directory with other MySQL table data.

When the first **IBMDB2I** table is created in a MySQL schema, the corresponding DB2 for i schema will be created (if it does not already exist).

---

| Introduced | 5.1.33 |
| Command-Line Format | `ibmdb2i_rdb_name` |
| System Variable | Name | `ibmdb2i_rdb_name` |
| | Variable | Global |
| | Scope | Dynamic |

**Permitted Values** (IBM System i)

| Type | String |
| Default | "<blank>" |

The name of a local DB2 for i relational database that will act as a container for all **IBMDB2I** tables. This enables an independent auxiliary storage pool (IASP) to be selected for usage. If no value is specified, the system database (*SYSBAS) is used.

**Default Value:** `<blank>`

- **`ibmdb2i_transaction_unsafe`**

| Introduced | 5.1.33 |
| Command-Line Format | `ibmdb2i_transaction_unsafe` |
| System Variable | Name | `ibmdb2i_transaction_unsafe` |
| | Variable | Global, Session |
| | Dynamic | Yes |

**Permitted Values** (IBM System i)

| Type | Boolean |
| Default | "off" |

Controls whether **IBMDB2I** honors the transactional commands and isolation levels specified for MySQL. If the value is OFF, transactions are fully supported. If the value is ON, transactional behavior is not implemented. This may provide a moderate performance increase for applications that do not rely on transactional guarantees.

**Default Value:** "OFF"

---

The values specified for `ibmdb2i_create_index_option`, `ibmdb2i_create_time_columns_as_tod`, `ibmdb2i_map_blob_to_varchar`, `ibmdb2i_compat_opt_allow_zero_date_vals`, `ibmdb2i_propagate_default_col_vals`, and `ibmdb2i_propagate_default_col_val` will be applied whenever an **IBMDB2I** table is created. Tables are implicitly destroyed and re-created when an `offline ALTER TABLE` is performed on an **IBMDB2I** table. Therefore it is highly recommended that the values of these variables be consistent across the lifetime of a table to prevent an `ALTER TABLE` from running under a different set of options than were used to originally create the table. If this recommendation is not followed, the `ALTER TABLE` may fail upon encountering incompatible data when re-creating the table.

---

**14.7.3 Creating schemas and tables**

---

---
Note that if the user profile running MySQL has sufficient authority dropping a MySQL schema will drop a DB2 schema of the same name even if the schema never contained any IBMDB2I tables and contains objects not related to MySQL. Therefore, it is recommended that extreme caution be used when dropping MySQL schemas when the IBMDB2I plugin is installed.

### 14.7.3.1 Identifier names

DB2 for i file objects have both a short (10-character) system name and an SQL name. The DB2 for i SQL name is always the same as the MySQL name. However, because MySQL's sensitivity to the lettercase of schema and table names depends on the file system containing the datadir, mapping the MySQL name to the system name of the corresponding DB2 for i object must account for several factors, described below.

When MySQL is operating in a case-sensitive mode (that is, datadir is in a case-sensitive file-system like /QOpenSys), the case of the system name of the IBMDB2I object reflects the case of the name specified to MySQL. If the object has all uppercase characters and is equal to or less than 10 characters in length, the system name will be undelimited and in uppercase.If the object name has mixed or lower-case letters, the IBM i system name will contain up to 8 characters of the name in the specified case and will be delimited by surrounding quotation marks. If the MySQL name has more characters than can fit in the delimited system name, the system name will be generated as a mangled name delimited by surrounding quotation marks.

Examples of this naming behavior are given below:

**Table 14.7 Naming Behavior in DB2 Storage Engine**

<table>
<thead>
<tr>
<th>MySQL name</th>
<th>DB2 for i SQL name</th>
<th>IBM i System name</th>
</tr>
</thead>
<tbody>
<tr>
<td>mytable</td>
<td>mytable</td>
<td>&quot;mytable&quot;</td>
</tr>
<tr>
<td>mylongertable</td>
<td>mylongertable</td>
<td>&quot;mylo0001&quot;</td>
</tr>
<tr>
<td>UPPERTABLE</td>
<td>UPPERTABLE</td>
<td>UPPERTABLE</td>
</tr>
<tr>
<td>UPPERLONGTABLE</td>
<td>UPPERLONGTABLE</td>
<td>UPPER00001</td>
</tr>
<tr>
<td>MixedTab</td>
<td>MixedTab</td>
<td>&quot;MixedTab&quot;</td>
</tr>
<tr>
<td>MixedlongerTab</td>
<td>MixedlongerTab</td>
<td>&quot;Mixe0001&quot;</td>
</tr>
</tbody>
</table>

If MySQL is operating in a case-insensitive mode, the IBM i system name will contain up to 8 characters of the name in lower case and will be delimited by surrounding quotation marks. If the MySQL name has more characters than can fit in the delimited system name, the system name will be generated as a mangled name delimited by surrounding quotation marks.

Note that IBM i system names are not changed when a RENAME TABLE command is executed. Only the DB2 for i SQL name changes.

### 14.7.3.2 Index names

Unlike MySQL, DB2 for i requires that index names be unique to an entire schema. To support MySQL indexes, IBMDB2I creates the DB2 for i indexes with modified file names. The generated name is a concatenation of the index name, three underscores (_), and the table name. For example, **CREATE INDEX idx1 ON tab1 (a, b)** would create a DB2 index named **idx___tab1**. If the ibmdb2i_create_index_option value is set to 1, an additional index may be created which is named with an additional **H_** marker between the index and table names (for example, **idx___H_tab1**). These generated names are then mangled to create the an IBM i system name, as described above.

If a table is renamed, the indexes will also be renamed.

This index name generation scheme also has implications for the length of index and table names; to permit the generated name and allow for delimiting quotation marks, the combined length of the index and table names must be less than or equal to 121 characters.
Data type mapping

When creating a table, IBMDB2I may map the MySQL types specified on a CREATE TABLE statement into a corresponding or compatible DB2 for i type. Examples include the BIT type, which is stored as a BINARY field, or the MEDIUMINT type, which is stored as an INTEGER field. For most data types, this mapping is transparent. Data types which have restrictions unique to IBMDB2I are documented in Section 14.7.7, “Notes and Limitations”.

14.7.4 Database/metadata management

When an IBMDB2I table is created, a File Level ID (FID) file is created in the database directory. This file has an extension .FID and contains the last known FID of the associated DB2 for i physical file. The IBMDB2I engine uses this FID value to determine whether incompatible changes have been made to the table by an external (non-MySQL) interface. If the physical file is altered, DB2 for i automatically generates a new FID. The next time IBMDB2I attempts to access the file, it will detect that the new FID does not match the known FID, and it will prevent MySQL from using the table.

In some cases, the changes to the physical file that cause the FID to be updated may not adversely affect access through MySQL and IBMDB2I. In this case, a user may wish to override the FID check that IBMDB2I performs. A user with appropriate permissions may do so simply by deleting the .FID file associated with the table and performing a FLUSH TABLE statement against the table. IBMDB2I will then regenerate the file with the new FID the next time the table is accessed from MySQL.

If triggers or constraints are applied to the table from a native DB2 interface, they will be respected when accessing the table from MySQL, but MySQL will have no knowledge of the triggers or constraints. Likewise, views and indexes can be created over the tables from a DB2 interface, but the indexes will not be accessible from MySQL.

14.7.5 Transaction behavior

The IBMDB2I storage engine supports row-level transaction management. All MySQL isolation levels are supported by the engine, and where highest performance is required, transaction support can be disabled globally or per session by modifying the ibmdb2i_transaction_unsafe configuration option.

IBMDB2I uses the underlying DB2 for i transaction support to implement MySQL isolation levels. DB2 for i uses table and row locks to implement the various isolation levels, as described below:

<table>
<thead>
<tr>
<th>Isolation level</th>
<th>Read-only (SELECT)</th>
<th>Read-write (UPDATE, DELETE)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Lock enforcement</td>
<td>Visibility of uncommitted work on behalf of other connections</td>
</tr>
<tr>
<td>SERIALIZABLE</td>
<td>Table is locked until end of transaction. Other connections may read rows while locked.</td>
<td>N/A</td>
</tr>
<tr>
<td>REPEATABLE READ</td>
<td>Rows that have been read are locked until end of transaction. Other connections may read and insert rows while locked.</td>
<td>Rows cannot be read until work is committed.</td>
</tr>
</tbody>
</table>
### Principles and Terminology

<table>
<thead>
<tr>
<th>Isolation level</th>
<th>Read-only (SELECT)</th>
<th>Read-write (UPDATE, DELETE)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Lock enforcement</td>
<td>Visibility of uncommitted work on behalf of other connections</td>
</tr>
<tr>
<td>READ COMMITTED</td>
<td>Row is locked while cursor is positioned on that row. Other connections may read and insert rows while locked.</td>
<td>Rows cannot be read until work is committed.</td>
</tr>
<tr>
<td>READ UNCOMMITTED</td>
<td>Row is locked while cursor is positioned on that row. Other connections may read and insert rows while locked.</td>
<td>Rows can be read before work is committed.</td>
</tr>
<tr>
<td>transaction_unsafe</td>
<td>Full access</td>
<td>Table is locked until end of transaction. Other connections may read rows while locked.</td>
</tr>
</tbody>
</table>

Attempts to access locked rows time out according to the timeout value associated with the underlying DB2 physical file. This timeout wait is 30 seconds by default. Refer to [http://publib.boulder.ibm.com/infocenter/iseries/v5r4/index.jsp?topic=/dbp/rbafoconcrec.htm](http://publib.boulder.ibm.com/infocenter/iseries/v5r4/index.jsp?topic=/dbp/rbafoconcrec.htm) for more information.

Because IBMDB2I does not multi-version rows under commitment control, row lock contention may occur under certain scenarios. In particular, when multiple connections attempt to read overlapping ranges of rows while performing a statement that does updates, the connections may contend for the same row locks. This may lead to delays until the row lock timeout expires. Creating appropriate indexes and increasing query selectivity to reduce range overlap may help to alleviate this contention.

#### 14.7.6 Principles and Terminology

**AUTO_INCREMENT**

The MySQL auto_increment column attribute can be used to generate a unique identity for new rows. The IBMDB2I storage engine maps the MySQL auto_increment attribute to the DB2 for i identity attribute.

For most MySQL storage engines, the auto_increment value is determined by adding one to the maximum value stored in the table for the column. For the IBMDB2I storage engine, DB2 for i generates the identity value by adding one to the last generated value. Following are some example MySQL statements to illustrate the point.

```sql
create table t1 (a int auto increment, primary key(a)) engine = ibmdb2i;
insert into t1 values(3);
insert into t1 values(null),(null);
```

For the first INSERT statement, an explicit value of 3 is specified for the auto_increment column, so the value 3 is stored in the inserted row. For the second INSERT statement null is specified, so generated values 1 and 2 will be stored in the rows.

Duplicate key failures can occur in DB2 for i if a MySQL application mixes explicit auto_increment values with generated values within a table. For the example above, if one more record is inserted
into the table for which an auto_increment value is generated, a duplicate key error will occur because the value 3 (that is, the last generated value plus one) already exists in the table. To effect the MySQL behavior for auto_increment columns, the IBMDB2I storage engine will detect a duplicate key error, alter the restart value for the DB2 identity column to the maximum value plus one, and retry the failed insert, but only if the following conditions are true:

- The duplicate key error occurred on an index for which the auto_increment column is a key field
- An exclusive (LENR) lock can be acquired on the table
- The error occurred on the first or only row of the INSERT statement.

The IBMDB2I storage engine does not support the following usage of auto_increment columns:

1. Any MySQL global or session variable that affects the start, increment, or offset for generated auto_increment values.
2. Any MySQL feature that returns the next value to be used for an auto_increment column.
3. An auto_increment column on a MySQL partitioned table.

14.7.7 Notes and Limitations

- When using multiples instances of MySQL on a single i5 host you should be aware that the two independent instances will access the same database within the DB2 environment. This can lead to namespace collisions and issues. To get round this limitation, you should configure different IBM i independent auxiliary storage pools (ISAPs) for each MySQL server, and then use the ibmdb2i_rdb_name option to MySQL to configure which IASP should be used for each MySQL instance.

- Indexes over VARBINARY columns may not provide accurate estimates the optimizer. Queries over such indexes may produce error 2027 in the error log but will succeed. This affects only the performance of these queries, not the correctness of the results.

- Setting ibmdb2i_system_trace_level = 16 (STRTRC) may cause unpredictable failures including error 2088 on some operations. This is unlikely to affect any users, as this value is recommended only for serviceability purposes.

- IBMDB2I honors the CASCADE/RESTRICT option on the DROP TABLE statement.

- The use of FLUSH TABLES WITH READ LOCK is discouraged when using IBMDB2I tables. Due to differences in internal locking implementations, FLUSH TABLES WITH READ LOCK may produce deadlocks on IBMDB2I tables.

- Row-based replication is supported by IBMDB2I. Statement-based replication is not supported.

- Schema name lengths are limited to 10 characters in IBM i 5.4 and 30 characters in IBM i 6.1. If the schema name is mixed- or lower-case, two characters must be subtracted from the limit to account for surrounding quotation marks.

- The RENAME TABLE command cannot be used to move IBMDB2I tables from one database to another.

- The maximum length of the internal row format for IBMDB2I is 32767 bytes. Because the internal row format may differ from the MySQL row format due to data mapping differences (see Creating schemas and tables section), anticipating this limit may be difficult.

- The combined length of the index and table names must be less than or equal to 121 characters.

- Indexes over TEXT or BLOB columns with a maximum length greater than 255 characters are not supported. The ibmdb2i_map_blob_to_varchar option can be used to work around this limitation for TEXT fields up to 64K characters.

- Specific restrictions apply to certain data types as described in the following chart:
Table 14.9 Data Type Restrictions in IBMDB2I

<table>
<thead>
<tr>
<th>MySQL data type</th>
<th>Restriction</th>
</tr>
</thead>
<tbody>
<tr>
<td>LONGBLOB or LONGTEXT</td>
<td>The maximum length of a DB2 BLOB data type is 2GB.</td>
</tr>
<tr>
<td>DATE</td>
<td>IBMDB2I does not support the special date value of '0000-00-00'. The restrictions on DATE and DATETIME columns can be removed by setting the value of ibmdb2i_compat_opt_allow_zero_date vals to 1.</td>
</tr>
<tr>
<td>DATETIME</td>
<td>IBMDB2I does not support the special datetime value of '0000-00-00 00:00:00'. The restrictions on DATE and DATETIME columns can be removed by setting the value of ibmdb2i_compat_opt_allow_zero_date vals to 1.</td>
</tr>
<tr>
<td>DECIMAL(p, s) or NUMERIC(p, s)</td>
<td>If p is greater than 63 and s is greater than (p-63), the field definition is truncated to DECIMAL(63, s-(p-63)). If p is greater than 63 and s is less than or equal to (p-63), the definition is not supported.</td>
</tr>
<tr>
<td>TIME</td>
<td>By default, IBMDB2I only supports times in the range '00:00:00' to '23:59:59.' See the ibmdb2i_create_time_columns_as_tod option for more information.</td>
</tr>
</tbody>
</table>

- These MySQL statements are not supported by the IBMDB2I Engine:
  - CACHE INDEX and LOAD INDEX INTO CACHE
  - HANDLER
  - CHECK TABLE
  - REPAIR TABLE
  - BACKUP-RESTORE TABLE
- The ucs2_spanish2_ci and utf8_spanish2_ci collations are not supported by IBMDB2I. There are no plans to support these collations.
- The ucs2_swedish_ci and utf8_swedish_ci collations were added in MySQL 5.1.35, supported by IBMDB2I. As with other language-specific unicode collations, the support will be only be available on IBM i 6.1 and later releases.

14.7.8 Character sets and collations

DB2 for i only supports a single collation per index or foreign key constraint. A foreign key constraint must have the same collation as a primary key constraint, if one exists.

Character sets and collations supported by IBMDB2I are described in the list below. IBM i 6.1 is required for the most comprehensive collation support. Note that Chinese, Japanese, and Korean character sets are converted to UTF-16 for storage in DB2 for i; utf8_general_ci is converted to UCS2 for storage in DB2 for i.

Table 14.10 Collation Compatibility in IBMDB2I and MySQL

14.7.9 Error codes and trouble-shooting information

Errors reported by the `IBMDB2I` engine may originate from two locations. Error values under 2500 originate in DB2 for i. Error values over 2500 originate in the storage engine itself. Occasionally, errors are reported by `IBMDB2I` but, due to the architecture of MySQL, cannot be directly exposed to MySQL client interfaces. In these cases, issuing a `SHOW ERRORS` statement or referring to the MySQL error log may be necessary to determine the cause of a failure. Errors which originate in DB2 for i are usually encountered in the DB2 for i SQL Server Mode job (QSQSRVR) which services the MySQL client connection; additional information about failures can often be found by looking in the job log of the associated QSQSRVR job.

Following is the list of codes and messages for errors that occur in DB2 for i that are reported by the `IBMDB2I` engine. %d and %s represent numbers and strings, respectively, that are replaced when the message is displayed.

<table>

</table>

Following is the list of error codes and messages that occur within the **IBMDB2I** storage engine.

**Table 14.12 Error Codes and Messages in IBMDB2I**

<table>
<thead>
<tr>
<th>Error Code Number</th>
<th>Error Message Text</th>
</tr>
</thead>
<tbody>
<tr>
<td>2501</td>
<td>Error opening codeset conversion from %.64s to %.64s (errno = %d). <strong>Resolution:</strong> Alter the table definition to specify a character set that is supported by the <strong>IBMDB2I</strong> engine.</td>
</tr>
<tr>
<td>2502</td>
<td>Invalid %-.10s name %-.128s. <strong>Resolution:</strong> If a field name, ensure that it is less than the maximum length of 126 characters. If an index name, ensure that the length of the index name plus the length of the table name is less than 121 characters.</td>
</tr>
<tr>
<td>2503</td>
<td>Unsupported move from %-.128s to %-.128s' on RENAME TABLE statement. <strong>Resolution:</strong> Moving a table from one schema to another is not supported by the <strong>IBMDB2I</strong> engine. Create a new table in the 'to' schema, copy the data to the new table, and then drop the old table.</td>
</tr>
<tr>
<td>Error Code Number</td>
<td>Error Message Text</td>
</tr>
<tr>
<td>-------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>2504</td>
<td>The %-.64s character set is not supported. <strong>Resolution:</strong> Try using another character set.</td>
</tr>
<tr>
<td>2505</td>
<td>Auto_increment is not allowed for a partitioned table. <strong>Resolution:</strong> Remove the auto_increment attribute from the table or do not partition the table.</td>
</tr>
<tr>
<td>2506</td>
<td>Character set conversion error due to unknown encoding scheme %d. <strong>Resolution:</strong> Alter the table definition to ensure that character sets assigned to columns are supported by the IBMDB2I engine.</td>
</tr>
<tr>
<td>2508</td>
<td>Table '%-.128s' was not found by the storage engine. <strong>Resolution:</strong> A table definition exists in MySQL, but the corresponding table in DB2 for i is not found. Delete the MySQL table or restore the DB2 table.</td>
</tr>
<tr>
<td>2509</td>
<td>Could not resolve to %-.128s in library %-.10s type %-.10s (errno = %d). <strong>Resolution:</strong> Restore the missing IBM i object to the system.</td>
</tr>
<tr>
<td>2510</td>
<td>Error on _PGMCALL for program %-.10s in library %-.10s (error = %d). <strong>Resolution:</strong> This is an internal error.</td>
</tr>
<tr>
<td>2511</td>
<td>Error on _ILEDCALL for API '%.128s' (error = %d). <strong>Resolution:</strong> This is an internal error.</td>
</tr>
<tr>
<td>2512</td>
<td>Error in iconv() function during character set conversion (errno = %d). <strong>Resolution:</strong> Ensure the text being inserted contains only valid code points for the associated character set. This may be caused by using ENCRYPT or COMPRESS on a text field, resulting in binary data containing invalid characters.</td>
</tr>
<tr>
<td>2513</td>
<td>Error from Get Encoding Scheme (QTQGESP) API: %d, %d, %d <strong>Resolution:</strong> This is an internal error.</td>
</tr>
<tr>
<td>2514</td>
<td>Error from Get Related Default CCSID (QTQGRDC) API: %d, %d, %d. <strong>Resolution:</strong> This is an internal error.</td>
</tr>
<tr>
<td>2515</td>
<td>Data out of range for column '%.192s'. <strong>Resolution:</strong> DB2 for i does not support a zero value for DATE and DATETIME data types. Specify a new value for the column.</td>
</tr>
<tr>
<td>2516</td>
<td>Schema name '%.128s' exceeds maximum length of %d characters. <strong>Resolution:</strong> Change the schema name so that its length does not exceed the maximum. For mixed case or lowercase names, permit 2 characters for outer quotation marks.</td>
</tr>
<tr>
<td>2517</td>
<td>Multiple collations not supported in a single index. <strong>Resolution:</strong> DB2 for i only supports sort sequences at the table or index level, so all character-based columns in the primary key or index must be using the same collation. Alter the table definition so that all columns use the same collation.</td>
</tr>
<tr>
<td>2518</td>
<td>Sort sequence was not found. <strong>Resolution:</strong> Alter the table to use a collation that is supported by the IBMDB2I engine.</td>
</tr>
<tr>
<td>2519</td>
<td>One or more characters in column %.128s were substituted during conversion. <strong>Resolution:</strong> This is a warning that during the conversion of data from MySQL to DB2 some characters were replaced with substitute characters.</td>
</tr>
<tr>
<td>2520</td>
<td>A decimal column exceeded the maximum precision. Data may be truncated. <strong>Resolution:</strong> A decimal column specified on a CREATE TABLE or ALTER TABLE command has greater precision than DB2 permits. Data stored in this column may be truncated. Change the column specification to have a precision less than or equal to 63.</td>
</tr>
<tr>
<td>2521</td>
<td>Some data returned by DB2 for table %s could not be converted for MySQL. <strong>Resolution:</strong> This is a warning that some data could not be converted from DB2 to MySQL. Data was likely inserted into the table using DB2 interfaces that is valid data for DB2 but is invalid for MySQL.</td>
</tr>
<tr>
<td>2523</td>
<td>Column %.128s contains characters that cannot be converted. <strong>Resolution:</strong> An error occurred converting data from the MySQL character set to the associated DB2 coded character set identifier (CCSID). Omit the incompatible characters or alter the table to specify a different character set for the column.</td>
</tr>
</tbody>
</table>
The MERGE Storage Engine

14.8 The MERGE Storage Engine

The MERGE storage engine, also known as the MRG_MyISAM engine, is a collection of identical MyISAM tables that can be used as one. “Identical” means that all tables have identical column and index information. You cannot merge MyISAM tables in which the columns are listed in a different order, do not have exactly the same columns, or have the indexes in different order. However, any or all of the MyISAM tables can be compressed with myisampack. See Section 4.6.5, "myisampack — Generate Compressed, Read-Only MyISAM Tables". Differences in table options such as AVG_ROW_LENGTH, MAX_ROWS, or PACK_KEYS do not matter.

An alternative to a MERGE table is a partitioned table, which stores partitions of a single table in separate files. Partitioning enables some operations to be performed more efficiently and is not limited to the MyISAM storage engine. For more information, see Chapter 18, Partitioning.

When you create a MERGE table, MySQL creates two files on disk. The files have names that begin with the table name and have an extension to indicate the file type. An .frm file stores the table format, and an .MRG file contains the names of the underlying MyISAM tables that should be used as one. The tables do not have to be in the same database as the MERGE table.

You can use SELECT, DELETE, UPDATE, and INSERT on MERGE tables. You must have SELECT, DELETE, and UPDATE privileges on the MyISAM tables that you map to a MERGE table.

Note

The use of MERGE tables entails the following security issue: If a user has access to MyISAM table \( t \), that user can create a MERGE table \( m \) that accesses \( t \). However, if the user’s privileges on \( t \) are subsequently revoked, the user can continue to access \( t \) by doing so through \( m \).

Use of DROP TABLE with a MERGE table drops only the MERGE specification. The underlying tables are not affected.

To create a MERGE table, you must specify a UNION=(list-of-tables) option that indicates which MyISAM tables to use. You can optionally specify an INSERT_METHOD option to control how inserts into the MERGE table take place. Use a value of FIRST or LAST to cause inserts to be made in the first or last underlying table, respectively. If you specify no INSERT_METHOD option or if you specify it with a value of NO, inserts into the MERGE table are not permitted and attempts to do so result in an error.

The following example shows how to create a MERGE table:

```sql
mysql> CREATE TABLE t1 (
    -> a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    -> message CHAR(20)) ENGINE=MyISAM;
mysql> CREATE TABLE t2 (
    -> a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    -> message CHAR(20)) ENGINE=MyISAM;
mysql> INSERT INTO t1 (message) VALUES ('Testing'), ('table'), ('t1');
mysql> INSERT INTO t2 (message) VALUES ('Testing'), ('table'), ('t2');
mysql> CREATE TABLE total (
    -> a INT NOT NULL AUTO_INCREMENT,
```

<table>
<thead>
<tr>
<th>Error Code Number</th>
<th>Error Message Text</th>
<th>Resolution</th>
</tr>
</thead>
<tbody>
<tr>
<td>2524</td>
<td>An invalid name was specified for ibmdb2i_rdb_name.</td>
<td>Specify a valid relational database (RDB) name.</td>
</tr>
<tr>
<td>2525</td>
<td>A duplicate key was encountered for index '%.128s'.</td>
<td>Specify a unique key value for the row.</td>
</tr>
<tr>
<td>2528</td>
<td>Some attribute(s) defined for column '%.128s' may not be honored by accesses from DB2.</td>
<td></td>
</tr>
</tbody>
</table>
Column \texttt{a} is indexed as a \texttt{PRIMARY KEY} in the underlying \texttt{MyISAM} tables, but not in the \texttt{MERGE} table. There it is indexed but not as a \texttt{PRIMARY KEY} because a \texttt{MERGE} table cannot enforce uniqueness over the set of underlying tables. (Similarly, a column with a \texttt{UNIQUE} index in the underlying tables should be indexed in the \texttt{MERGE} table but not as a \texttt{UNIQUE} index.)

After creating the \texttt{MERGE} table, you can use it to issue queries that operate on the group of tables as a whole:

```sql
mysql> SELECT * FROM total;
+---+---------+
| a | message |
+---+---------+
| 1 | Testing |
| 2 | table   |
| 3 | t1      |
| 1 | Testing |
| 2 | table   |
| 3 | t2      |
+---+---------+
```

To remap a \texttt{MERGE} table to a different collection of \texttt{MyISAM} tables, you can use one of the following methods:

- \textbf{DROP} the \texttt{MERGE} table and re-create it.
- \textbf{Use} \texttt{ALTER TABLE tbl_name UNION=(...)} to change the list of underlying tables.

Beginning with MySQL 5.1.24, it is also possible to use \texttt{ALTER TABLE ... UNION=()} (that is, with an empty \texttt{UNION} clause) to remove all of the underlying tables. However, in this case, the table is effectively empty and inserts fail because there is no underlying table to take new rows. Such a table might be useful as a template for creating new \texttt{MERGE} tables with \texttt{CREATE TABLE ... LIKE}.

As of MySQL 5.1.15, the underlying table definitions and indexes must conform more closely than previously to the definition of the \texttt{MERGE} table. Conformance is checked when a table that is part of a \texttt{MERGE} table is opened, not when the \texttt{MERGE} table is created. If any table fails the conformance checks, the operation that triggered the opening of the table fails. This means that changes to the definitions of tables within a \texttt{MERGE} may cause a failure when the \texttt{MERGE} table is accessed. The conformance checks applied to each table are:

- The underlying table and the \texttt{MERGE} table must have the same number of columns.
- The column order in the underlying table and the \texttt{MERGE} table must match.
- Additionally, the specification for each corresponding column in the parent \texttt{MERGE} table and the underlying tables are compared and must satisfy these checks:
  - The column type in the underlying table and the \texttt{MERGE} table must be equal.
  - The column length in the underlying table and the \texttt{MERGE} table must be equal.
  - The column of the underlying table and the \texttt{MERGE} table can be \texttt{NULL}.
  - The underlying table must have at least as many indexes as the \texttt{MERGE} table. The underlying table may have more indexes than the \texttt{MERGE} table, but cannot have fewer.

\textbf{Note}

A known issue exists where indexes on the same columns must be in identical order, in both the \texttt{MERGE} table and the underlying \texttt{MyISAM} table. See Bug \#33653.
Each index must satisfy these checks:

- The index type of the underlying table and the `MERGE` table must be the same.
- The number of index parts (that is, multiple columns within a compound index) in the index definition for the underlying table and the `MERGE` table must be the same.
- For each index part:
  - Index part lengths must be equal.
  - Index part types must be equal.
  - Index part languages must be equal.
  - Check whether index parts can be `NULL`.

For information about the table checks applied prior to MySQL 5.1.15, see Section 14.8.2, “MERGE Table Problems”.

As of MySQL 5.1.20, if a `MERGE` table cannot be opened or used because of a problem with an underlying table, `CHECK TABLE` displays information about which table caused the problem.

**Additional Resources**

### 14.8.1 MERGE Table Advantages and Disadvantages

`MERGE` tables can help you solve the following problems:

- Easily manage a set of log tables. For example, you can put data from different months into separate tables, compress some of them with `myisampack`, and then create a `MERGE` table to use them as one.

- Obtain more speed. You can split a large read-only table based on some criteria, and then put individual tables on different disks. A `MERGE` table structured this way could be much faster than using a single large table.

- Perform more efficient searches. If you know exactly what you are looking for, you can search in just one of the underlying tables for some queries and use a `MERGE` table for others. You can even have many different `MERGE` tables that use overlapping sets of tables.

- Perform more efficient repairs. It is easier to repair individual smaller tables that are mapped to a `MERGE` table than to repair a single large table.

- Instantly map many tables as one. A `MERGE` table need not maintain an index of its own because it uses the indexes of the individual tables. As a result, `MERGE` table collections are very fast to create or remap. (You must still specify the index definitions when you create a `MERGE` table, even though no indexes are created.)

- If you have a set of tables from which you create a large table on demand, you can instead create a `MERGE` table from them on demand. This is much faster and saves a lot of disk space.

- Exceed the file size limit for the operating system. Each `MyISAM` table is bound by this limit, but a collection of `MyISAM` tables is not.

- You can create an alias or synonym for a `MyISAM` table by defining a `MERGE` table that maps to that single table. There should be no really notable performance impact from doing this (only a couple of indirect calls and `memcpy()` calls for each read).
The disadvantages of **MERGE** tables are:

- You can use only identical **MyISAM** tables for a **MERGE** table.

- Some **MyISAM** features are unavailable in **MERGE** tables. For example, you cannot create **FULLTEXT** indexes on **MERGE** tables. (You can create **FULLTEXT** indexes on the underlying **MyISAM** tables, but you cannot search the **MERGE** table with a full-text search.)

- If the **MERGE** table is non-temporary, all underlying **MyISAM** tables must be non-temporary. If the **MERGE** table is temporary, the **MyISAM** tables can be any mix of temporary and non-temporary.

- **MERGE** tables use more file descriptors than **MyISAM** tables. If 10 clients are using a **MERGE** table that maps to 10 tables, the server uses $(10 \times 10) + 10$ file descriptors. (10 data file descriptors for each of the 10 clients, and 10 index file descriptors shared among the clients.)

- Index reads are slower. When you read an index, the **MERGE** storage engine needs to issue a read on all underlying tables to check which one most closely matches a given index value. To read the next index value, the **MERGE** storage engine needs to search the read buffers to find the next value. Only when one index buffer is used up does the storage engine need to read the next index block. This makes **MERGE** indexes much slower on **eq_ref** searches, but not much slower on **ref** searches. For more information about **eq_ref** and **ref**, see Section 13.8.2, “EXPLAIN Syntax”.

### 14.8.2 MERGE Table Problems

The following are known problems with **MERGE** tables:

- In versions of MySQL Server prior to 5.1.23, it was possible to create temporary merge tables with non-temporary child **MyISAM** tables.

  From versions 5.1.23, **MERGE** children were locked through the parent table. If the parent was temporary, it was not locked and so the children were not locked either. Parallel use of the **MyISAM** tables corrupted them.

- If you use **ALTER TABLE** to change a **MERGE** table to another storage engine, the mapping to the underlying tables is lost. Instead, the rows from the underlying **MyISAM** tables are copied into the altered table, which then uses the specified storage engine.

- The **INSERT_METHOD** table option for a **MERGE** table indicates which underlying **MyISAM** table to use for inserts into the **MERGE** table. However, use of the **AUTO_INCREMENT** table option for that **MyISAM** table has no effect for inserts into the **MERGE** table until at least one row has been inserted directly into the **MyISAM** table.

- A **MERGE** table cannot maintain uniqueness constraints over the entire table. When you perform an **INSERT**, the data goes into the first or last **MyISAM** table (as determined by the **INSERT_METHOD** option). MySQL ensures that unique key values remain unique within that **MyISAM** table, but not over all the underlying tables in the collection.

- Because the **MERGE** engine cannot enforce uniqueness over the set of underlying tables, **REPLACE** does not work as expected. The two key facts are:
  - **REPLACE** can detect unique key violations only in the underlying table to which it is going to write (which is determined by the **INSERT_METHOD** option). This differs from violations in the **MERGE** table itself.
  - If **REPLACE** detects a unique key violation, it will change only the corresponding row in the underlying table it is writing to; that is, the first or last table, as determined by the **INSERT_METHOD** option.

  Similar considerations apply for **INSERT ... ON DUPLICATE KEY UPDATE**.

- **MERGE** tables do not support partitioning. That is, you cannot partition a **MERGE** table, nor can any of a **MERGE** table's underlying **MyISAM** tables be partitioned.
• You should not use ANALYZE TABLE, REPAIR TABLE, OPTIMIZE TABLE, ALTER TABLE, DROP TABLE, DELETE without a WHERE clause, or TRUNCATE TABLE on any of the tables that are mapped into an open MERGE table. If you do so, the MERGE table may still refer to the original table and yield unexpected results. To work around this problem, ensure that no MERGE tables remain open by issuing a FLUSH TABLES statement prior to performing any of the named operations.

The unexpected results include the possibility that the operation on the MERGE table will report table corruption. If this occurs after one of the named operations on the underlying MyISAM tables, the corruption message is spurious. To deal with this, issue a FLUSH TABLES statement after modifying the MyISAM tables.

• DROP TABLE on a table that is in use by a MERGE table does not work on Windows because the MERGE storage engine’s table mapping is hidden from the upper layer of MySQL. Windows does not permit open files to be deleted, so you first must flush all MERGE tables (with FLUSH TABLES) or drop the MERGE table before dropping the table.

• As of MySQL 5.1.15, the definition of the MyISAM tables and the MERGE table are checked when the tables are accessed (for example, as part of a SELECT or INSERT statement). The checks ensure that the definitions of the tables and the parent MERGE table definition match by comparing column order, types, sizes and associated indexes. If there is a difference between the tables, an error is returned and the statement fails. Because these checks take place when the tables are opened, any changes to the definition of a single table, including column changes, column ordering, and engine alterations will cause the statement to fail.

Prior to MySQL 5.1.15, table checks are applied as follows:

• When you create or alter MERGE table, there is no check to ensure that the underlying tables are existing MyISAM tables and have identical structures. When the MERGE table is used, MySQL checks that the row length for all mapped tables is equal, but this is not foolproof. If you create a MERGE table from dissimilar MyISAM tables, you are very likely to run into strange problems.

• Similarly, if you create a MERGE table from non-MyISAM tables, or if you drop an underlying table or alter it to be a non-MyISAM table, no error for the MERGE table occurs until later when you attempt to use it.

• Because the underlying MyISAM tables need not exist when the MERGE table is created, you can create the tables in any order, as long as you do not use the MERGE table until all of its underlying tables are in place. Also, if you can ensure that a MERGE table will not be used during a given period, you can perform maintenance operations on the underlying tables, such as backing up or restoring them, altering them, or dropping and recreating them. It is not necessary to redefine the MERGE table temporarily to exclude the underlying tables while you are operating on them.

• The order of indexes in the MERGE table and its underlying tables should be the same. If you use ALTER TABLE to add a UNIQUE index to a table used in a MERGE table, and then use ALTER TABLE to add a nonunique index on the MERGE table, the index ordering is different for the tables if there was already a nonunique index in the underlying table. (This happens because ALTER TABLE puts UNIQUE indexes before nonunique indexes to facilitate rapid detection of duplicate keys.) Consequently, queries on tables with such indexes may return unexpected results.

• If you encounter an error message similar to ERROR 1017 (HY000): Can't find file: 'tbl_name.MRG' (errno: 2), it generally indicates that some of the underlying tables do not use the MyISAM storage engine. Confirm that all of these tables are MyISAM.

• The maximum number of rows in a MERGE table is \(2^{64}\) (~1.844E+19); the same as for a MyISAM table), provided that the server was built using the --with-big-tables option. (All standard MySQL 5.1 standard binaries are built with this option; for more information, see Section 2.11.4, “MySQL Source-Configuration Options”.) It is not possible to merge multiple MyISAM tables into a single MERGE table that would have more than this number of rows.

• The MERGE storage engine does not support INSERT DELAYED statements.
The MEMORY Storage Engine

- Use of underlying MyISAM tables of differing row formats with a parent MERGE table is currently known to fail. See Bug #32364.

- As of MySQL 5.1.23, you cannot change the union list of a nontemporary MERGE table when LOCK TABLES is in effect. The following does not work:

  ```sql
  CREATE TABLE m1 ... ENGINE=MRG_MYISAM ...
  LOCK TABLES t1 WRITE, t2 WRITE, m1 WRITE;
  ALTER TABLE m1 ... UNION=(t1,t2) ...
  ```

  However, you can do this with a temporary MERGE table.

- As of MySQL 5.1.23, you cannot create a MERGE table with CREATE ... SELECT, neither as a temporary MERGE table, nor as a nontemporary MERGE table. For example:

  ```sql
  CREATE TABLE m1 ... ENGINE=MRG_MYISAM ... SELECT ...;
  ```

  Attempts to do this result in an error: `tbl_name` is not `BASE TABLE`.

- In some cases, differing PACK_KEYS table option values among the MERGE and underlying tables cause unexpected results if the underlying tables contain CHAR or BINARY columns. As a workaround, use ALTER TABLE to ensure that all involved tables have the same PACK_KEYS value. (Bug #50646)

14.9 The MEMORY Storage Engine

The MEMORY storage engine (formerly known as HEAP) creates special-purpose tables with contents that are stored in memory. Because the data is vulnerable to crashes, hardware issues, or power outages, only use these tables as temporary work areas or read-only caches for data pulled from other tables.

<table>

**When to Use MEMORY or MySQL Cluster.** Developers looking to deploy applications that use the MEMORY storage engine for important, highly available, or frequently updated data should consider whether MySQL Cluster is a better choice. A typical use case for the MEMORY engine involves these characteristics:

- Operations involving transient, non-critical data such as session management or caching. When the MySQL server halts or restarts, the data in MEMORY tables is lost.

- In-memory storage for fast access and low latency. Data volume can fit entirely in memory without causing the operating system to swap out virtual memory pages.
Performance Characteristics

• A read-only or read-mostly data access pattern (limited updates).

MySQL Cluster offers the same features as the MEMORY engine with higher performance levels, and provides additional features not available with MEMORY:

• Row-level locking and multiple-thread operation for low contention between clients.

• Scalability even with statement mixes that include writes.

• Optional disk-backed operation for data durability.

• Shared-nothing architecture and multiple-host operation with no single point of failure, enabling 99.999% availability.

• Automatic data distribution across nodes; application developers need not craft custom sharding or partitioning solutions.

• Support for variable-length data types (including BLOB and TEXT) not supported by MEMORY.

For a white paper with more detailed comparison of the MEMORY storage engine and MySQL Cluster, see Scaling Web Services with MySQL Cluster: An Alternative to the MySQL Memory Storage Engine. This white paper includes a performance study of the two technologies and a step-by-step guide describing how existing MEMORY users can migrate to MySQL Cluster.

Performance Characteristics

MEMORY performance is constrained by contention resulting from single-thread execution and table lock overhead when processing updates. This limits scalability when load increases, particularly for statement mixes that include writes.

Despite the in-memory processing for MEMORY tables, they are not necessarily faster than InnoDB tables on a busy server, for general-purpose queries, or under a read/write workload. In particular, the table locking involved with performing updates can slow down concurrent usage of MEMORY tables from multiple sessions.

Depending on the kinds of queries performed on a MEMORY table, you might create indexes as either the default hash data structure (for looking up single values based on a unique key), or a general-purpose B-tree data structure (for all kinds of queries involving equality, inequality, or range operators such as less than or greater than). The following sections illustrate the syntax for creating both kinds of indexes. A common performance issue is using the default hash indexes in workloads where B-tree indexes are more efficient.

Physical Characteristics of MEMORY Tables

The MEMORY storage engine associates each table with one disk file, which stores the table definition (not the data). The file name begins with the table name and has an extension of .frm.

MEMORY tables have the following characteristics:

• Space for MEMORY tables is allocated in small blocks. Tables use 100% dynamic hashing for inserts. No overflow area or extra key space is needed. No extra space is needed for free lists. Deleted rows are put in a linked list and are reused when you insert new data into the table. MEMORY tables also have none of the problems commonly associated with deletes plus inserts in hashed tables.

• MEMORY tables use a fixed-length row-storage format. Variable-length types such as VARCHAR are stored using a fixed length.

• MEMORY tables cannot contain BLOB or TEXT columns.

• MEMORY includes support for AUTO_INCREMENT columns.

• Non-TEMPORARY MEMORY tables are shared among all clients, just like any other non-TEMPORARY table.
DDL Operations for MEMORY Tables

To create a MEMORY table, specify the clause `ENGINE=MEMORY` on the `CREATE TABLE` statement.

```sql
CREATE TABLE t (i INT) ENGINE = MEMORY;
```

As indicated by the engine name, MEMORY tables are stored in memory. They use hash indexes by default, which makes them very fast for single-value lookups, and very useful for creating temporary tables. However, when the server shuts down, all rows stored in MEMORY tables are lost. The tables themselves continue to exist because their definitions are stored in .frm files on disk, but they are empty when the server restarts.

This example shows how you might create, use, and remove a MEMORY table:

```sql
mysql> CREATE TABLE test ENGINE=MEMORY
    
    --> SELECT ip,SUM(downloads) AS down
    
    --> FROM log_table GROUP BY ip;

mysql> SELECT COUNT(ip),AVG(down) FROM test;

mysql> DROP TABLE test;
```

The maximum size of MEMORY tables is limited by the `max_heap_table_size` system variable, which has a default value of 16MB. To enforce different size limits for MEMORY tables, change the value of this variable. The value in effect for `CREATE TABLE`, or a subsequent `ALTER TABLE` or `TRUNCATE TABLE`, is the value used for the life of the table. A server restart also sets the maximum size of existing MEMORY tables to the global `max_heap_table_size` value. You can set the size for individual tables as described later in this section.

Indexes

The MEMORY storage engine supports both HASH and BTREE indexes. You can specify one or the other for a given index by adding a `USING` clause as shown here:

```sql
CREATE TABLE lookup
    (id INT, INDEX USING HASH (id))
ENGINE = MEMORY;
CREATE TABLE lookup
    (id INT, INDEX USING BTREE (id))
ENGINE = MEMORY;
```

For general characteristics of B-tree and hash indexes, see Section 8.3.1, "How MySQL Uses Indexes".

MEMORY tables can have up to 64 indexes per table, 16 columns per index and a maximum key length of 3072 bytes.

If a MEMORY table hash index has a high degree of key duplication (many index entries containing the same value), updates to the table that affect key values and all deletes are significantly slower. The degree of this slowdown is proportional to the degree of duplication (or, inversely proportional to the index cardinality). You can use a BTREE index to avoid this problem.

MEMORY tables can have nonunique keys. (This is an uncommon feature for implementations of hash indexes.)

Columns that are indexed can contain NULL values.

User-Created and Temporary Tables

MEMORY table contents are stored in memory, which is a property that MEMORY tables share with internal temporary tables that the server creates on the fly while processing queries. However, the two
types of tables differ in that MEMORY tables are not subject to storage conversion, whereas internal temporary tables are:

- If an internal temporary table becomes too large, the server automatically converts it to on-disk storage, as described in Section 8.4.4, “Internal Temporary Table Use in MySQL”.
- User-created MEMORY tables are never converted to disk tables.

Loading Data

To populate a MEMORY table when the MySQL server starts, you can use the --init-file option. For example, you can put statements such as `INSERT INTO ... SELECT` or `LOAD DATA INFILE` into this file to load the table from a persistent data source. See Section 5.1.3, “Server Command Options”, and Section 13.2.6, “LOAD DATA INFILE Syntax”.

For loading data into MEMORY tables accessed by other sessions concurrently, MEMORY supports INSERT DELAYED. See Section 13.2.5.2, “INSERT DELAYED Syntax”.

MEMORY Tables and Replication

A server's MEMORY tables become empty when it is shut down and restarted. If the server is a replication master, its slaves are not aware that these tables have become empty, so you see out-of-date content if you select data from the tables on the slaves. To synchronize master and slave MEMORY tables, when a MEMORY table is used on a master for the first time since it was started, a DELETE statement is written to the master's binary log, to empty the table on the slaves also. The slave still has outdated data in the table during the interval between the master's restart and its first use of the table. To avoid this interval when a direct query to the slave could return stale data, use the --init-file option to populate the MEMORY table on the master at startup.

Managing Memory Use

The server needs sufficient memory to maintain all MEMORY tables that are in use at the same time.

Memory is not reclaimed if you delete individual rows from a MEMORY table. Memory is reclaimed only when the entire table is deleted. Memory that was previously used for deleted rows is re-used for new rows within the same table. To free all the memory used by a MEMORY table when you no longer require its contents, execute DELETE or TRUNCATE TABLE to remove all rows, or remove the table altogether using DROP TABLE. To free up the memory used by deleted rows, use ALTER TABLE ENGINE=MEMORY to force a table rebuild.

The memory needed for one row in a MEMORY table is calculated using the following expression:

```plaintext
SUM_OVER_ALL_BTREE_KEYS(max_length_of_key + sizeof(char*) * 4)
+ SUM_OVER_ALL_HASH_KEYS(sizeof(char*) * 2)
+ ALIGN(length_of_row+1, sizeof(char*))
```

ALIGN() represents a round-up factor to cause the row length to be an exact multiple of the char pointer size. sizeof(char*) is 4 on 32-bit machines and 8 on 64-bit machines.

As mentioned earlier, the max_heap_table_size system variable sets the limit on the maximum size of MEMORY tables. To control the maximum size for individual tables, set the session value of this variable before creating each table. (Do not change the global max_heap_table_size value unless you intend the value to be used for MEMORY tables created by all clients.) The following example creates two MEMORY tables, with a maximum size of 1MB and 2MB, respectively:

```plaintext
mysql> SET max_heap_table_size = 1024*1024;
Query OK, 0 rows affected (0.00 sec)
```
Both tables revert to the server’s global `max_heap_table_size` value if the server restarts.

You can also specify a `MAX_ROWS` table option in `CREATE TABLE` statements for `MEMORY` tables to provide a hint about the number of rows you plan to store in them. This does not enable the table to grow beyond the `max_heap_table_size` value, which still acts as a constraint on maximum table size. For maximum flexibility in being able to use `MAX_ROWS`, set `max_heap_table_size` at least as high as the value to which you want each `MEMORY` table to be able to grow.

### Additional Resources

### 14.10 The EXAMPLE Storage Engine

The `EXAMPLE` storage engine is a stub engine that does nothing. Its purpose is to serve as an example in the MySQL source code that illustrates how to begin writing new storage engines. As such, it is primarily of interest to developers.

To enable the `EXAMPLE` storage engine if you build MySQL from source, invoke `configure` with the `--with-example-storage-engine` option.

To examine the source for the `EXAMPLE` engine, look in the `storage/example` directory of a MySQL source distribution.

When you create an `EXAMPLE` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. No other files are created. No data can be stored into the table. Retrievals return an empty result.

```sql
mysql> CREATE TABLE test (i INT) ENGINE = EXAMPLE;
Query OK, 0 rows affected (0.78 sec)

mysql> INSERT INTO test VALUES(1),(2),(3);
ERROR 1031 (HY000): Table storage engine for 'test' doesn't have this option

mysql> SELECT * FROM test;
Empty set (0.31 sec)
```

The `EXAMPLE` storage engine does not support indexing.

### 14.11 The FEDERATED Storage Engine

The `FEDERATED` storage engine lets you access data from a remote MySQL database without using replication or cluster technology. Querying a local `FEDERATED` table automatically pulls the data from the remote (federated) tables. No data is stored on the local tables.

To include the `FEDERATED` storage engine if you build MySQL from source, invoke `configure` with the `--with-federated-storage-engine` option.

Beginning with MySQL 5.1.26, the `FEDERATED` storage engine is not enabled by default in the running server; to enable `FEDERATED`, you must start the MySQL server binary using the `--federated` option.
To examine the source for the FEDERATED engine, look in the storage/federated directory of a MySQL source distribution.

14.11.1 FEDERATED Storage Engine Overview

When you create a table using one of the standard storage engines (such as MyISAM, CSV or InnoDB), the table consists of the table definition and the associated data. When you create a FEDERATED table, the table definition is the same, but the physical storage of the data is handled on a remote server.

A FEDERATED table consists of two elements:

- A remote server with a database table, which in turn consists of the table definition (stored in the .frm file) and the associated table. The table type of the remote table may be any type supported by the remote mysqld server, including MyISAM or InnoDB.

- A local server with a database table, where the table definition matches that of the corresponding table on the remote server. The table definition is stored within the .frm file. However, there is no data file on the local server. Instead, the table definition includes a connection string that points to the remote table.

When executing queries and statements on a FEDERATED table on the local server, the operations that would normally insert, update or delete information from a local data file are instead sent to the remote server for execution, where they update the data file on the remote server or return matching rows from the remote server.

The basic structure of a FEDERATED table setup is shown in Figure 14.1, “FEDERATED Table Structure”.

Figure 14.1 FEDERATED Table Structure

When a client issues an SQL statement that refers to a FEDERATED table, the flow of information between the local server (where the SQL statement is executed) and the remote server (where the data is physically stored) is as follows:

1. The storage engine looks through each column that the FEDERATED table has and constructs an appropriate SQL statement that refers to the remote table.

2. The statement is sent to the remote server using the MySQL client API.

3. The remote server processes the statement and the local server retrieves any result that the statement produces (an affected-rows count or a result set).

4. If the statement produces a result set, each column is converted to internal storage engine format that the FEDERATED engine expects and can use to display the result to the client that issued the original statement.
The local server communicates with the remote server using MySQL client C API functions. It invokes `mysql_real_query()` to send the statement. To read a result set, it uses `mysql_store_result()` and fetches rows one at a time using `mysql_fetch_row()`.

### 14.11.2 How to Create FEDERATED Tables

To create a FEDERATED table you should follow these steps:

1. Create the table on the remote server. Alternatively, make a note of the table definition of an existing table, perhaps using the `SHOW CREATE TABLE` statement.

2. Create the table on the local server with an identical table definition, but adding the connection information that links the local table to the remote table.

For example, you could create the following table on the remote server:

```sql
CREATE TABLE test_table (
    id     INT(20) NOT NULL AUTO_INCREMENT,
    name   VARCHAR(32) NOT NULL DEFAULT '',
    other  INT(20) NOT NULL DEFAULT '0',
    PRIMARY KEY  (id),
    INDEX name (name),
    INDEX other_key (other)
) ENGINE=MyISAM
DEFAULT CHARSET=latin1;
```

To create the local table that will be federated to the remote table, there are two options available. You can either create the local table and specify the connection string (containing the server name, login, password) to be used to connect to the remote table using the `CONNECTION`, or you can use an existing connection that you have previously created using the `CREATE SERVER` statement.

**Important**

When you create the local table it must have an identical field definition to the remote table.

**Note**

You can improve the performance of a FEDERATED table by adding indexes to the table on the host. The optimization will occur because the query sent to the remote server will include the contents of the `WHERE` clause and will be sent to the remote server and subsequently executed locally. This reduces the network traffic that would otherwise request the entire table from the server for local processing.

#### 14.11.2.1 Creating a FEDERATED Table Using CONNECTION

To use the first method, you must specify the `CONNECTION` string after the engine type in a `CREATE TABLE` statement. For example:

```sql
CREATE TABLE federated_table (
    id     INT(20) NOT NULL AUTO_INCREMENT,
    name   VARCHAR(32) NOT NULL DEFAULT '',
    other  INT(20) NOT NULL DEFAULT '0',
    PRIMARY KEY  (id),
    INDEX name (name),
    INDEX other_key (other)
) ENGINE=FEDERATED
DEFAULT CHARSET=latin1
CONNECTION='mysql://fed_user@remote_host:9306/federated/test_table';
```
How to Create FEDERATED Tables

Note

CONNECTION replaces the COMMENT used in some previous versions of MySQL.

The CONNECTION string contains the information required to connect to the remote server containing the table that will be used to physically store the data. The connection string specifies the server name, login credentials, port number and database/table information. In the example, the remote table is on the server remote_host, using port 9306. The name and port number should match the host name (or IP address) and port number of the remote MySQL server instance you want to use as your remote table.

The format of the connection string is as follows:

```
scheme://user_name[password]@host_name[port_num]/db_name/tbl_name
```

Where:

- **scheme**: A recognized connection protocol. Only `mysql` is supported as the `scheme` value at this point.
- **user_name**: The user name for the connection. This user must have been created on the remote server, and must have suitable privileges to perform the required actions (`SELECT`, `INSERT`, `UPDATE`, and so forth) on the remote table.
- **password**: (Optional) The corresponding password for `user_name`.
- **host_name**: The host name or IP address of the remote server.
- **port_num**: (Optional) The port number for the remote server. The default is 3306.
- **db_name**: The name of the database holding the remote table.
- **tbl_name**: The name of the remote table. The name of the local and the remote table do not have to match.

Sample connection strings:

- `CONNECTION='mysql://username:password@hostname:port/database/tablename'`
- `CONNECTION='mysql://username@hostname/database/tablename'`
- `CONNECTION='mysql://username:password@hostname/database/tablename'`

**14.11.2.2 Creating a FEDERATED Table Using CREATE SERVER**

If you are creating a number of FEDERATED tables on the same server, or if you want to simplify the process of creating FEDERATED tables, you can use the `CREATE SERVER` statement to define the server connection parameters, just as you would with the `CONNECTION` string.

The format of the `CREATE SERVER` statement is:

```
CREATE SERVER server_name
FOREIGN DATA WRAPPER wrapper_name
OPTIONS (option [, option] ...)
```

The `server_name` is used in the connection string when creating a new FEDERATED table.

For example, to create a server connection identical to the `CONNECTION` string:

```
CONNECTION='mysql://fed_user@remote_host:9306/federated/test_table';
```

You would use the following statement:

```
CREATE SERVER fedlink
```
FOREIGN DATA WRAPPER mysql
OPTIONS (USER 'fed_user', HOST 'remote_host', PORT 9306, DATABASE 'federated');

To create a FEDERATED table that uses this connection, you still use the CONNECTION keyword, but specify the name you used in the CREATE SERVER statement.

```sql
CREATE TABLE test_table (
    id     INT(20) NOT NULL AUTO_INCREMENT,
    name   VARCHAR(32) NOT NULL DEFAULT '',
    other  INT(20) NOT NULL DEFAULT '0',
    PRIMARY KEY  (id),
    INDEX name (name),
    INDEX other_key (other)
) ENGINE=FEDERATED
DEFAULT CHARSET=latin1
CONNECTION='fedlink/test_table';
```

The connection name in this example contains the name of the connection (fedlink) and the name of the table (test_table) to link to, separated by a slash. If you specify only the connection name without a table name, the table name of the local table is used instead.

For more information on CREATE_SERVER, see Section 13.1.16, “CREATE SERVER Syntax”.

The CREATE_SERVER statement accepts the same arguments as the CONNECTION string. The CREATE_SERVER statement updates the rows in the mysql.servers table. See the following table for information on the correspondence between parameters in a connection string, options in the CREATE_SERVER statement, and the columns in the mysql.servers table. For reference, the format of the CONNECTION string is as follows:

```
scheme://user_name[:password]@host_name[:port_num]/db_name/tbl_name
```

<table>

14.11.3 FEDERATED Storage Engine Notes and Tips

You should be aware of the following points when using the FEDERATED storage engine:

- **FEDERATED** tables may be replicated to other slaves, but you must ensure that the slave servers are able to use the user/password combination that is defined in the CONNECTION string (or the row in the mysql.servers table) to connect to the remote server.

The following items indicate features that the FEDERATED storage engine does and does not support:

- The remote server must be a MySQL server.
- The remote table that a FEDERATED table points to must exist before you try to access the table through the FEDERATED table.
- It is possible for one FEDERATED table to point to another, but you must be careful not to create a loop.
- A FEDERATED table does not support indexes in the usual sense; because access to the table data is handled remotely, it is actually the remote table that makes use of indexes. This means that, for a
query that cannot use any indexes and so requires a full table scan, the server fetches all rows from
the remote table and filters them locally. This occurs regardless of any WHERE or LIMIT used with
this SELECT statement; these clauses are applied locally to the returned rows.

Queries that fail to use indexes can thus cause poor performance and network overload. In addition,
since returned rows must be stored in memory, such a query can also lead to the local server
swapping, or even hanging.

• Care should be taken when creating a FEDERATED table since the index definition from an equivalent
MyISAM or other table may not be supported. For example, creating a FEDERATED table with an
index prefix on VARCHAR, TEXT or BLOB columns will fail. The following definition in MyISAM is valid:

```
CREATE TABLE `T1`(`A` VARCHAR(100),UNIQUE KEY(`A`(30))) ENGINE=MYISAM;
```

The key prefix in this example is incompatible with the FEDERATED engine, and the equivalent
statement will fail:

```
CREATE TABLE `T1`(`A` VARCHAR(100),UNIQUE KEY(`A`(30))) ENGINE=FEDERATED
  CONNECTION='MYSQL://127.0.0.1:3306/TEST/T1';
```

If possible, you should try to separate the column and index definition when creating tables on both
the remote server and the local server to avoid these index issues.

• Internally, the implementation uses SELECT, INSERT, UPDATE, and DELETE, but not HANDLER.

• The FEDERATED storage engine supports SELECT, INSERT, UPDATE, DELETE, TRUNCATE TABLE,
and indexes. It does not support ALTER TABLE, or any Data Definition Language statements that
directly affect the structure of the table, other than DROP TABLE. The current implementation does
not use prepared statements.

• FEDERATED accepts INSERT ... ON DUPLICATE KEY UPDATE statements, but if a duplicate-key
violation occurs, the statement fails with an error.

• Performance on a FEDERATED table when performing bulk inserts (for example, on a INSERT
INTO ... SELECT ... statement) is slower than with other table types because each selected
row is treated as an individual INSERT statement on the FEDERATED table.

• Transactions are not supported.

• Before MySQL 5.1.21, for a multiple-row insert into a FEDERATED table that refers to a remote
transactional table, if the insert failed for a row due to constraint failure, the remote table would
contain a partial commit (the rows preceding the failed one) instead of rolling back the statement
completely. This occurred because the rows were treated as individual inserts.

As of MySQL 5.1.21, FEDERATED performs bulk-insert handling such that multiple rows are sent
to the remote table in a batch. This provides a performance improvement and enables the remote
table to perform improvement. Also, if the remote table is transactional, it enables the remote storage
engine to perform statement rollback properly should an error occur. This capability has the following
limitations:

• The size of the insert cannot exceed the maximum packet size between servers. If the insert
exceeds this size, it is broken into multiple packets and the rollback problem can occur.

• Bulk-insert handling does not occur for INSERT ... ON DUPLICATE KEY UPDATE.

• There is no way for the FEDERATED engine to know if the remote table has changed. The reason for
this is that this table must work like a data file that would never be written to by anything other than
the database system. The integrity of the data in the local table could be breached if there was any
change to the remote database.

• When using a CONNECTION string, you cannot use an '@' character in the password. You can get
round this limitation by using the CREATE SERVER statement to create a server connection.
FEDERATED Storage Engine Resources

- The `insert_id` and `timestamp` options are not propagated to the data provider.
- Any `DROP TABLE` statement issued against a FEDERATED table drops only the local table, not the remote table.
- FEDERATED tables do not work with the query cache.
- User-defined partitioning is not supported for FEDERATED tables. Beginning with MySQL 5.1.15, it is no longer possible to create such tables at all.

### 14.11.4 FEDERATED Storage Engine Resources

The following additional resources are available for the FEDERATED storage engine:

### 14.12 The ARCHIVE Storage Engine

The ARCHIVE storage engine is used for storing large amounts of data without indexes in a very small footprint.

#### Table 14.14 ARCHIVE Storage Engine Features

</table>

---

The ARCHIVE engine supports `INSERT`, `REPLACE`, and `SELECT`, but not `DELETE` or `UPDATE`. It does support `ORDER BY` operations, `BLOB` columns, and basically all but spatial data types (see Section 11.5.1, “Spatial Data Types”). The ARCHIVE engine uses row-level locking.
As of MySQL 5.1.6, the ARCHIVE engine supports the AUTO_INCREMENT column attribute. The AUTO_INCREMENT column can have either a unique or nonunique index. Attempting to create an index on any other column results in an error. The ARCHIVE engine also supports the AUTO_INCREMENT table option in CREATE TABLE statements to specify the initial sequence value for a new table or reset the sequence value for an existing table, respectively.

ARCHIVE does not support inserting a value into an AUTO_INCREMENT column less than the current maximum column value. Attempts to do so result in an ER_DUP_KEY error.

As of MySQL 5.1.6, the ARCHIVE engine ignores BLOB columns if they are not requested and scans past them while reading. Formerly, the following two statements had the same cost, but as of 5.1.6, the second is much more efficient than the first:

```sql
SELECT a, b, blob_col FROM archive_table;
SELECT a, b FROM archive_table;
```

Storage: Rows are compressed as they are inserted. The ARCHIVE engine uses zlib lossless data compression (see http://www.zlib.net/). You can use OPTIMIZE TABLE to analyze the table and pack it into a smaller format (for a reason to use OPTIMIZE TABLE, see later in this section). The engine also supports CHECK TABLE. There are several types of insertions that are used:

- An INSERT statement just pushes rows into a compression buffer, and that buffer flushes as necessary. The insertion into the buffer is protected by a lock. A SELECT forces a flush to occur, unless the only insertions that have come in were INSERT DELAYED (those flush as necessary). See Section 13.2.5.2, “INSERT DELAYED Syntax”.

- A bulk insert is visible only after it completes, unless other inserts occur at the same time, in which case it can be seen partially. A SELECT never causes a flush of a bulk insert unless a normal insert occurs while it is loading.

Retrieval: On retrieval, rows are uncompressed on demand; there is no row cache. A SELECT operation performs a complete table scan: When a SELECT occurs, it finds out how many rows are currently available and reads that number of rows. SELECT is performed as a consistent read. Note that lots of SELECT statements during insertion can deteriorate the compression, unless only bulk or delayed inserts are used. To achieve better compression, you can use OPTIMIZE TABLE or REPAIR TABLE. The number of rows in ARCHIVE tables reported by SHOW TABLE STATUS is always accurate. See Section 13.7.2.5, “OPTIMIZE TABLE Syntax”, Section 13.7.2.6, “REPAIR TABLE Syntax”, and Section 13.7.5.38, “SHOW TABLE STATUS Syntax”.

Warning

Known issue: After a binary upgrade to MySQL 5.1 from a MySQL 5.0 installation that contains ARCHIVE tables:

- Before MySQL 5.1.42, accessing those tables will cause the server to crash, even if you have run mysql_upgrade or CHECK TABLE ... FOR UPGRADE.

- As of MySQL 5.1.42, the server will not open 5.0 ARCHIVE tables at all.

In either case, the solution is to use mysqlshutdown to dump all 5.0 ARCHIVE tables before upgrading, and reload them into MySQL 5.1 after upgrading. This problem is fixed in MySQL 5.6.4: The server can open ARCHIVE tables created in MySQL 5.0. However, it remains the recommended upgrade procedure to dump 5.0 ARCHIVE tables before upgrading and reload after upgrading.

Additional Resources

The CSV Storage Engine

14.13 The CSV Storage Engine

The CSV storage engine stores data in text files using comma-separated values format.

To enable the CSV storage engine if you build MySQL from source, invoke configure with the --with-csv-storage-engine option.

To examine the source for the CSV engine, look in the storage/csv directory of a MySQL source distribution.

When you create a CSV table, the server creates a table format file in the database directory. The file begins with the table name and has an .frm extension. The storage engine also creates a data file. Its name begins with the table name and has a .CSV extension. The data file is a plain text file. When you store data into the table, the storage engine saves it into the data file in comma-separated values format.

```
mysql> CREATE TABLE test (i INT NOT NULL, c CHAR(10) NOT NULL)  
    ->  ENGINE = CSV;
Query OK, 0 rows affected (0.12 sec)
mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
Records: 2  Duplicates: 0  Warnings: 0
mysql> SELECT * FROM test;
+------+------------+
<table>
<thead>
<tr>
<th>i</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>record one</td>
</tr>
<tr>
<td>2</td>
<td>record two</td>
</tr>
</tbody>
</table>
+------+------------+
2 rows in set (0.00 sec)
```

Starting with MySQL 5.1.9, creating a CSV table also creates a corresponding Metafile that stores the state of the table and the number of rows that exist in the table. The name of this file is the same as the name of the table with the extension CSM.

If you examine the test.CSV file in the database directory created by executing the preceding statements, its contents should look like this:

```
"1","record one"
"2","record two"
```

This format can be read, and even written, by spreadsheet applications such as Microsoft Excel or StarOffice Calc.

14.13.1 Repairing and Checking CSV Tables

Functionality introduced in version 5.1.9

The CSV storage engines supports the CHECK and REPAIR statements to verify and if possible repair a damaged CSV table.

When running the CHECK statement, the CSV file will be checked for validity by looking for the correct field separators, escaped fields (matching or missing quotation marks), the correct number of fields compared to the table definition and the existence of a corresponding CSV metafile. The first invalid row discovered will report an error. Checking a valid table produces output like that shown below:

```
mysql> check table csvtest;
+----------+-----+----------+----------+
<table>
<thead>
<tr>
<th>Table</th>
<th>Op</th>
<th>Msg_type</th>
<th>Msg_text</th>
</tr>
</thead>
<tbody>
<tr>
<td>test.csvtest</td>
<td>check</td>
<td>status</td>
<td>OK</td>
</tr>
</tbody>
</table>
```
CSV Limitations

1 row in set (0.00 sec)

A check on a corrupted table returns a fault:

```sql
mysql> check table csvtest;
+--------------+-------+----------+----------+
| Table        | Op    | Msg_type | Msg_text |
+--------------+-------+----------+----------+
| test.csvtest | check | error    | Corrupt  |
+--------------+-------+----------+----------+
1 row in set (0.01 sec)
```

If the check fails, the table is marked as crashed (corrupt). Once a table has been marked as corrupt, it is automatically repaired when you next run `CHECK` or execute a `SELECT` statement. The corresponding corrupt status and new status will be displayed when running `CHECK`:

```sql
mysql> check table csvtest;
+--------------+-------+----------+----------------------------+
| Table        | Op    | Msg_type | Msg_text                   |
+--------------+-------+----------+----------------------------+
| test.csvtest | check | warning  | Table is marked as crashed |
| test.csvtest | check | status   | OK                         |
+--------------+-------+----------+----------------------------+
2 rows in set (0.08 sec)
```

To repair a table you can use `REPAIR`, this copies as many valid rows from the existing CSV data as possible, and then replaces the existing CSV file with the recovered rows. Any rows beyond the corrupted data are lost.

```sql
mysql> repair table csvtest;
+--------------+--------+----------+----------+
| Table        | Op     | Msg_type | Msg_text |
+--------------+--------+----------+----------+
| test.csvtest | repair | status   | OK       |
+--------------+--------+----------+----------+
1 row in set (0.02 sec)
```

**Warning**

During repair, only the rows from the CSV file up to the first damaged row are copied to the new table. All other rows from the first damaged row to the end of the table are removed, even valid rows.

### 14.13.2 CSV Limitations

The **CSV** storage engine does not support indexing.

Partitioning is not supported for tables using the **CSV** storage engine. Beginning with MySQL 5.1.12, it is no longer possible to create partitioned **CSV** tables. (See Bug #19307)

Beginning with MySQL 5.1.23, all tables that you create using the **CSV** storage engine must have the **NOT NULL** attribute on all columns. However, for backward compatibility, you can continue to use tables with nullable columns that were created in previous MySQL releases. (Bug #32050)

### 14.14 The BLACKHOLE Storage Engine

The **BLACKHOLE** storage engine acts as a “black hole” that accepts data but throws it away and does not store it. Retrievals always return an empty result:

```sql
mysql> CREATE TABLE test(i INT, c CHAR(10)) ENGINE = BLACKHOLE;
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
```
The BLACKHOLE Storage Engine

To enable the BLACKHOLE storage engine if you build MySQL from source, invoke configure with the --with-blackhole-storage-engine option.

To examine the source for the BLACKHOLE engine, look in the sql directory of a MySQL source distribution.

When you create a BLACKHOLE table, the server creates a table format file in the database directory. The file begins with the table name and has an .frm extension. There are no other files associated with the table.

The BLACKHOLE storage engine supports all kinds of indexes. That is, you can include index declarations in the table definition.

You can check whether the BLACKHOLE storage engine is available with the SHOW ENGINES statement.

Inserts into a BLACKHOLE table do not store any data, but if statement based binary logging is enabled, the SQL statements are logged and replicated to slave servers. This can be useful as a repeater or filter mechanism.

Note
When using the row based format for the binary log, updates and deletes are skipped, and neither logged nor applied. For this reason, you should use STATEMENT for the binary logging format, and not ROW or MIXED.

Suppose that your application requires slave-side filtering rules, but transferring all binary log data to the slave first results in too much traffic. In such a case, it is possible to set up on the master host a “dummy” slave process whose default storage engine is BLACKHOLE, depicted as follows:

The master writes to its binary log. The “dummy” mysqld process acts as a slave, applying the desired combination of replicate-do-* and replicate-ignore-* rules, and writes a new, filtered binary log of its own. (See Section 16.1.3, “Replication and Binary Logging Options and Variables”.) This filtered log is provided to the slave.

The dummy process does not actually store any data, so there is little processing overhead incurred by running the additional mysqld process on the replication master host. This type of setup can be repeated with additional replication slaves.
**The BLACKHOLE Storage Engine**

*INSERT* triggers for *BLACKHOLE* tables work as expected. However, because the *BLACKHOLE* table does not actually store any data, *UPDATE* and *DELETE* triggers are not activated: The *FOR EACH ROW* clause in the trigger definition does not apply because there are no rows.

Other possible uses for the *BLACKHOLE* storage engine include:

- Verification of dump file syntax.
- Measurement of the overhead from binary logging, by comparing performance using *BLACKHOLE* with and without binary logging enabled.
- *BLACKHOLE* is essentially a "no-op" storage engine, so it could be used for finding performance bottlenecks not related to the storage engine itself.

The *BLACKHOLE* storage engine does not support *INSERT DELAYED*, *LOCK TABLES*, or *UNLOCK TABLES* statements prior to MySQL 5.1.19.

As of MySQL 5.1.4, the *BLACKHOLE* engine is transaction-aware, in the sense that committed transactions are written to the binary log and rolled-back transactions are not.

### Blackhole Engine and Auto Increment Columns

The Blackhole engine is a no-op engine. Any operations performed on a table using Blackhole will have no effect. This should be born in mind when considering the behavior of primary key columns that auto increment. The engine will not automatically increment field values, and does not retain auto increment field state. This has important implications in replication.

Consider the following replication scenario where all three of the following conditions apply:

1. On a master server there is a blackhole table with an auto increment field that is a primary key.
2. On a slave the same table exists but using the MyISAM engine.
3. Inserts are performed into the master's table without explicitly setting the auto increment value in the *INSERT* statement itself or through using a *SET INSERT_ID* statement.

In this scenario replication will fail with a duplicate entry error on the primary key column.

In statement based replication, the value of *INSERT_ID* in the context event will always be the same. Replication will therefore fail due to trying insert a row with a duplicate value for a primary key column.

In row based replication, the value that the engine returns for the row always be the same for each insert. This will result in the slave attempting to replay two insert log entries using the same value for the primary key column, and so replication will fail.

### Column Filtering

When using row-based replication, (*binlog_format=ROW*), a slave where the last columns are missing from a table is supported, as described in the section *Section 16.4.1.10, "Replication with Differing Table Definitions on Master and Slave"*. This filtering works on the slave side, that is, the columns are copied to the slave before they are filtered out. There are at least two cases where it is not desirable to copy the columns to the slave:

1. If the data is confidential, so the slave server should not have access to it.
2. If the master has many slaves, filtering before sending to the slaves may reduce network traffic.

Master column filtering can be achieved using the *BLACKHOLE* engine. This is carried out in a way similar to how master table filtering is achieved - by using the *BLACKHOLE* engine and the *--replicate-do-table* or *--replicate-ignore-table* option.
The setup for the master is:

```sql
CREATE TABLE t1 (public_col_1, ..., public_col_N,
                 secret_col_1, ..., secret_col_M) ENGINE=MyISAM;
```

The setup for the trusted slave is:

```sql
CREATE TABLE t1 (public_col_1, ..., public_col_N) ENGINE=BLACKHOLE;
```

The setup for the untrusted slave is:

```sql
CREATE TABLE t1 (public_col_1, ..., public_col_N) ENGINE=MyISAM;
```

Data is the currency of today’s web, mobile, social, enterprise and cloud applications. Ensuring data is always available is a top priority for any organization. Minutes of downtime can result in significant loss of revenue and reputation.

There is no “one size fits all” approach to delivering High Availability (HA). Unique application attributes, business requirements, operational capabilities and legacy infrastructure can all influence HA technology selection. And technology is only one element in delivering HA: people and processes are just as critical as the technology itself.

MySQL is deployed into many applications demanding availability and scalability. Availability refers to the ability to cope with, and if necessary recover from, failures on the host, including failures of MySQL, the operating system, or the hardware and maintenance activity that may otherwise cause downtime. Scalability refers to the ability to spread both the database and the load of your application queries across multiple MySQL servers.

Because each application has different operational and availability requirements, MySQL offers a range of certified and supported solutions, delivering the appropriate levels of High Availability (HA) and scalability to meet service level requirements. Such solutions extend from replication, through virtualization and geographically redundant, multi-data center solutions delivering 99.999% uptime.

Selecting the right high availability solution for an application largely depends on:

- The level of availability required.
- The type of application being deployed.
- Accepted best practices within your own environment.

The primary solutions supported by MySQL include:

- MySQL Replication. Learn more: Chapter 16, Replication.
- MySQL Fabric. Learn more: MySQL Fabric.
- Oracle Clusterware Agent for MySQL. Learn more about Oracle Clusterware.
- MySQL with Solaris Cluster. Learn more about Solaris Cluster.
Further options are available using third-party solutions.

Each architecture used to achieve highly available database services is differentiated by the levels of uptime it offers. These architectures can be grouped into three main categories:

- Data Replication.
- Clustered & Virtualized Systems.
- Shared-Nothing, Geographically-Replicated Clusters.

As illustrated in the following figure, each of these architectures offers progressively higher levels of uptime, which must be balanced against potentially greater levels of cost and complexity that each can incur. Simply deploying a high availability architecture is not a guarantee of actually delivering HA. In fact, a poorly implemented and maintained shared-nothing cluster could easily deliver lower levels of availability than a simple data replication solution.

**Figure 15.1 Tradeoffs: Cost and Complexity versus Availability**

The following table compares the HA and Scalability capabilities of the various MySQL solutions:

**Table 15.1 Feature Comparison of MySQL HA Solutions**

15.1 Using MySQL within an Amazon EC2 Instance

The Amazon Elastic Compute Cloud (EC2) service provides virtual servers that you can build and deploy to run a variety of different applications and services, including MySQL. The EC2 service is based around the Xen framework, supporting x86, Linux based, platforms with individual instances of a virtual machine referred to as an Amazon Machine Image (AMI). You have complete (root) access to the AMI instance that you create, enabling you to configure and install your AMI in any way you choose.

To use EC2, you create an AMI based on the configuration and applications that you intend to use, and upload the AMI to the Amazon Simple Storage Service (S3). From the S3 resource, you can deploy one or more copies of the AMI to run as an instance within the EC2 environment. The EC2 environment provides management and control of the instance and contextual information about the instance while it is running.

Because you can create and control the AMI, the configuration, and the applications, you can deploy and create any environment you choose. This includes a basic MySQL server in addition to more extensive replication, HA and scalability scenarios that enable you to take advantage of the EC2 environment, and the ability to deploy additional instances as the demand for your MySQL services and applications grow.

To aid the deployment and distribution of work, three different Amazon EC2 instances are available, small (identified as ml.small), large (ml.large) and extra large (ml.xlarge). The different types provide different levels of computing power measured in EC2 computer units (ECU). A summary of the different instance configurations is shown in the following table.

<table>
<thead>
<tr>
<th>EC2 Attribute</th>

The typical model for deploying and using MySQL within the EC2 environment is to create a basic AMI that you can use to hold your database data and application. Once the basic environment for
your database and application has been created you can then choose to deploy the AMI to a suitable instance. Here the flexibility of having an AMI that can be re-deployed from the small to the large or extra large EC2 instance makes it easy to upgrade the hardware environment without rebuilding your application or database stack.

To get started with MySQL on EC2, including information on how to set up and install MySQL within an EC2 installation and how to port and migrate your data to the running instance, see Section 15.1.1, “Setting Up MySQL on an EC2 AMI”.

For tips and advice on how to create a scalable EC2 environment using MySQL, including guides on setting up replication, see Section 15.1.3, “Deploying a MySQL Database Using EC2”.

### 15.1.1 Setting Up MySQL on an EC2 AMI

There are many different ways of setting up an EC2 AMI with MySQL, including using any of the pre-configured AMIs supplied by Amazon.

The default Getting Started AMI provided by Amazon uses Fedora Core 4, and you can install MySQL by using `yum`:

```
shell> yum install mysql
```

This installs both the MySQL server and the Perl DBD::mysql driver for the Perl DBI API.

Alternatively, you can use one of the AMIs that include MySQL within the standard installation.

Finally, you can also install a standard version of MySQL downloaded from the MySQL Web site. The installation process and instructions are identical to any other installation of MySQL on Linux. See Chapter 2, *Installing and Upgrading MySQL*.

The standard configuration for MySQL places the data files in the default location, `/var/lib/mysql`. The default data directory on an EC2 instance is `/mnt` (although on the large and extra large instance you can alter this configuration). You must edit `/etc/my.cnf` to set the `datadir` option to point to the larger storage area.

**Important**

The first time you use the main storage location within an EC2 instance it needs to be initialized. The initialization process starts automatically the first time you write to the device. You can start using the device right away, but the write performance of the new device is significantly lower on the initial writes until the initialization process has finished.

To avoid this problem when setting up a new instance, you should start the initialization process before populating your MySQL database. One way to do this is to use `dd` to write to the file system:

```
root-shell> dd if=/dev/zero of=initialize bs=1024M count=50
```

The preceding creates a 50GB on the file system and starts the initialization process. Delete the file once the process has finished.

The initialization process can be time-consuming. On the small instance, initialization takes between two and three hours. For the large and extra large drives, the initialization can be 10 or 20 hours, respectively.

In addition to configuring the correct storage location for your MySQL data files, also consider setting the following other settings in your instance before you save the instance configuration for deployment:
EC2 Instance Limitations

- Set the MySQL server ID, so that when you use it for replication, the ID information is set correctly.

- Enabling binary logging, so that replication can be initialized without starting and stopping the server.

- Set the caching and memory parameters for your storage engines. There are no limitations or restrictions on what storage engines you use in your EC2 environment. Choose a configuration, possibly using one of the standard configurations provided with MySQL appropriate for the instance on which you expect to deploy. The large and extra large instances have RAM that can be dedicated to caching. Be aware that if you choose to install memcached on the servers as part of your application stack you must ensure there is enough memory for both MySQL and memcached.

Once you have configured your AMI with MySQL and the rest of your application stack, save the AMI so that you can deploy and reuse the instance.

Once you have your application stack configured in an AMI, populating your MySQL database with data should be performed by creating a dump of your database using mysqldump, transferring the dump to the EC2 instance, and then reloading the information into the EC2 instance database.

Before using your instance with your application in a production situation, be aware of the limitations of the EC2 instance environment. See Section 15.1.2, “EC2 Instance Limitations”. To begin using your MySQL AMI, consult the notes on deployment. See Section 15.1.3, “Deploying a MySQL Database Using EC2”.

15.1.2 EC2 Instance Limitations

Be aware of the following limitations of the EC2 instances before deploying your applications. Although these shouldn’t affect your ability to deploy within the Amazon EC2 environment, they may alter the way you setup and configure your environment to support your application.

- Data stored within instances is not persistent. If you create an instance and populate the instance with data, then the data only remains in place while the machine is running, and does not survive a reboot. If you shut down the instance, any data it contained is lost.

To ensure that you do not lose information, take regular backups using mysqldump. If the data being stored is critical, consider using replication to keep a “live” backup of your data in the event of a failure. When creating a backup, write the data to the Amazon S3 service to avoid the transfer charges applied when copying data offsite.

- EC2 instances are not persistent. If the hardware on which an instance is running fails, the instance is shut down. This can lead to loss of data or service.

However, if you use EBS, you can attach an EBS storage volume to an EC2 instance, and that EBS volume is persistent. Like a disk, an EBS volume can fail, but it is possible to create point-in-time snapshots of the volume. Snapshots are persisted to Amazon S3 and can be used to restore data in the event of volume failure.

- To replicate your EC2 instances to a non-EC2 environment, be aware of the transfer costs to and from the EC2 service. Data transfer between different EC2 instances is free, so using replication within the EC2 environment does not incur additional charges.

- Certain HA features are either not directly supported, or have limiting factors or problems that could reduce their utility. For example, using DRBD or MySQL Cluster might not work. The default storage configuration is also not redundant. You can use software-based RAID to improve redundancy, but this implies a further performance hit.

15.1.3 Deploying a MySQL Database Using EC2

Because you cannot guarantee the uptime and availability of your EC2 instances, when deploying MySQL within the EC2 environment, use an approach that enables you to easily distribute work among
your EC2 instances. There are a number of ways of doing this. Using sharding techniques, where you split the application across multiple servers dedicating specific blocks of your dataset and users to different servers is an effective way of doing this. As a general rule, it is easier to create more EC2 instances to support more users than to upgrade the instance to a larger machine.

The EC2 architecture works best when you treat the EC2 instances as temporary, cache-based solutions, rather than as a long-term, high availability solution. In addition to using multiple machines, take advantage of other services, such as memcached to provide additional caching for your application to help reduce the load on the MySQL server so that it can concentrate on writes. On the large and extra large instances within EC2, the RAM available can provide a large memory cache for data.

Most types of scale-out topology that you would use with your own hardware can be used and applied within the EC2 environment. However, use the limitations and advice already given to ensure that any potential failures do not lose you any data. Also, because the relative power of each EC2 instance is so low, be prepared to alter your application to use sharding and add further EC2 instances to improve the performance of your application.

For example, take the typical scale-out environment shown following, where a single master replicates to one or more slaves (three in this example), with a web server running on each replication slave.

![Scale-out environment diagram]

You can reproduce this structure completely within the EC2 environment, using an EC2 instance for the master, and one instance for each of the web and MySQL slave servers.

Note

Within the EC2 environment, internal (private) IP addresses used by the EC2 instances are constant. Always use these internal addresses and names when communicating between instances. Only use public IP addresses when communicating with the outside world - for example, when publicizing your application.

To ensure reliability of your database, add at least one replication slave dedicated to providing an active backup and storage to the Amazon S3 facility. You can see an example of this in the following topology.
Deploying a MySQL Database Using EC2

Using memcached within your EC2 instances should provide better performance. The large and extra large instances have a significant amount of RAM. To use memcached in your application, when loading information from the database, first check whether the item exists in the cache. If the data you are looking for exists in the cache, use it. If not, reload the data from the database and populate the cache.

Sharding divides up data in your entire database by allocating individual machines or machine groups to provide a unique set of data according to an appropriate group. For example, you might put all users with a surname ending in the letters A-D onto a single server. When a user connects to the application and their surname is known, queries can be redirected to the appropriate MySQL server.

When using sharding with EC2, separate the web server and MySQL server into separate EC2 instances, and then apply the sharding decision logic into your application. Once you know which MySQL server you should be using for accessing the data you then distribute queries to the appropriate server. You can see a sample of this in the following illustration.
Warning

With sharding and EC2, be careful that the potential for failure of an instance does not affect your application. If the EC2 instance that provides the MySQL server for a particular shard fails, then all of the data on that shard becomes unavailable.

15.2 Using ZFS Replication

To support high availability environments, providing an instant copy of the information on both the currently active machine and the hot backup is a critical part of the HA solution. There are many solutions to this problem, such as Chapter 16, Replication.

The ZFS file system provides functionality to create a snapshot of the file system contents, transfer the snapshot to another machine, and extract the snapshot to recreate the file system. You can create a snapshot at any time, and you can create as many snapshots as you like. By continually creating, transferring, and restoring snapshots, you can provide synchronization between one or more machines in a fashion similar to DRBD.

The following example shows a simple Solaris system running with a single ZFS pool, mounted at `/scratchpool`:

<table>
<thead>
<tr>
<th>Filesystem</th>
<th>size</th>
<th>used</th>
<th>avail</th>
<th>capacity</th>
<th>Mounted on</th>
</tr>
</thead>
<tbody>
<tr>
<td>/dev/dsk/c0d0s0</td>
<td>4.6G</td>
<td>3.7G</td>
<td>886M</td>
<td>82%</td>
<td>/</td>
</tr>
<tr>
<td>/devices</td>
<td>0K</td>
<td>0K</td>
<td>0K</td>
<td>0%</td>
<td>/devices</td>
</tr>
<tr>
<td>ctrfs</td>
<td>0K</td>
<td>0K</td>
<td>0K</td>
<td>0%</td>
<td>/system/contract</td>
</tr>
<tr>
<td>proc</td>
<td>0K</td>
<td>0K</td>
<td>0K</td>
<td>0%</td>
<td>/proc</td>
</tr>
<tr>
<td>mnttab</td>
<td>0K</td>
<td>0K</td>
<td>0K</td>
<td>0%</td>
<td>/etc/mnttab</td>
</tr>
<tr>
<td>swap</td>
<td>1.4G</td>
<td>892K</td>
<td>1.4G</td>
<td>1%</td>
<td>/etc/svc/volatile</td>
</tr>
<tr>
<td>objfs</td>
<td>0K</td>
<td>0K</td>
<td>0K</td>
<td>0%</td>
<td>/system/object</td>
</tr>
</tbody>
</table>
The MySQL data is stored in a directory on `/scratchpool`. To help demonstrate some of the basic replication functionality, there are also other items stored in `/scratchpool` as well:

```
total 17
drwxr-xr-x  31 root     bin           50 Jul 21 07:32 DTT/
drwxr-xr-x  4 root     bin            5 Jul 21 07:32 SUNWmlib/
drwxr-xr-x 14 root     sys           16 Nov  5 09:56 SUNWspro/
drwxrwxrwx 19 1000     1000          40 Nov  6 19:16 emacs-22.1/
```

To create a snapshot of the file system, you use `zfs snapshot`, specifying the pool and the snapshot name:

```
root-shell> zfs snapshot scratchpool@snap1
```

To list the snapshots already taken:

```
root-shell> zfs list -t snapshot
```

```
NAME                USED  AVAIL  REFER  MOUNTPOINT
scratchpool@snap1      0      -  24.5K  -
scratchpool@snap2      0      -  24.5K  -
```

The snapshots themselves are stored within the file system metadata, and the space required to keep them varies as time goes on because of the way the snapshots are created. The initial creation of a snapshot is very quick, because instead of taking an entire copy of the data and metadata required to hold the entire snapshot, ZFS records only the point in time and metadata of when the snapshot was created.

As more changes to the original file system are made, the size of the snapshot increases because more space is required to keep the record of the old blocks. If you create lots of snapshots, say one per day, and then delete the snapshots from earlier in the week, the size of the newer snapshots might also increase, as the changes that make up the newer state have to be included in the more recent snapshots, rather than being spread over the seven snapshots that make up the week.

You cannot directly back up the snapshots because they exist within the file system metadata rather than as regular files. To get the snapshot into a format that you can copy to another file system, tape, and so on, you use the `zfs send` command to create a stream version of the snapshot.

For example, to write the snapshot out to a file:

```
root-shell> zfs send scratchpool@snap1 >/backup/scratchpool-snap1
```

Or tape:

```
root-shell> zfs send scratchpool@snap1 >/dev/rmt/0
```

You can also write out the incremental changes between two snapshots using `zfs send`:

```
root-shell> zfs send scratchpool@snap1 scratchpool@snap2 >/backup/scratchpool-changes
```

To recover a snapshot, you use `zfs recv`, which applies the snapshot information either to a new file system, or to an existing one.
15.2.1 Using ZFS for File System Replication

Because `zfs send` and `zfs recv` use streams to exchange data, you can use them to replicate information from one system to another by combining `zfs send`, `ssh`, and `zfs recv`.

For example, to copy a snapshot of the `scratchpool` file system to a new file system called `slavepool` on a new server, you would use the following command. This sequence combines the snapshot of `scratchpool`, the transmission to the slave machine (using `ssh` with login credentials), and the recovery of the snapshot on the slave using `zfs recv`:

```bash
root-shell> zfs send scratchpool@snap1 | ssh id@host pfexec zfs recv -F slavepool
```

The first part of the pipeline, `zfs send scratchpool@snap1`, streams the snapshot. The `ssh` command, and the command that it executes on the other server, `pfexec zfs recv -F slavepool`, receives the streamed snapshot data and writes it to `slavepool`. In this instance, I've specified the `-F` option which forces the snapshot data to be applied, and is therefore destructive. This is fine, as I'm creating the first version of my replicated file system.

On the slave machine, the replicated file system contains the exact same content:

```bash
root-shell> ls -al /slavepool/
```

```
 total 23
 drwxr-xr-x 6 root root 7 Nov 8 09:13 ./
 drwxr-xr-x 29 root root 34 Nov 9 07:06 ../
 drwxr-xr-x 31 root bin 50 Jul 21 07:32 DTT/
 drwxr-xr-x 4 root bin 5 Jul 21 07:32 SUNWmlib/
 drwxr-xr-x 14 root sys 16 Nov 5 09:56 SUNWspro/
 drwxrwxrwx 19 1000 1000 40 Nov 6 19:16 emacs-22.1/
```

Once a snapshot has been created, to synchronize the file system again, you create a new snapshot and then use the incremental snapshot feature of `zfs send` to send the changes between the two snapshots to the slave machine again:

```bash
root-shell> zfs send -i scratchpool@snapshot1 scratchpool@snapshot2 | ssh id@host pfexec zfs recv slavepool
```

This operation only succeeds if the file system on the slave machine has not been modified at all. You cannot apply the incremental changes to a destination file system that has changed. In the example above, the `ls` command would cause problems by changing the metadata, such as the last access time for files or directories.

To prevent changes on the slave file system, set the file system on the slave to be read-only:

```bash
root-shell> zfs set readonly=on slavepool
```

Setting `readonly` means that you cannot change the file system on the slave by normal means, including the file system metadata. Operations that would normally update metadata (like our `ls`) silently perform their function without attempting to update the file system state.

In essence, the slave file system is nothing but a static copy of the original file system. However, even when configured to be read-only, a file system can have snapshots applied to it. With the file system set to read only, re-run the initial copy:

```bash
root-shell> zfs send scratchpool@snap1 | ssh id@host pfexec zfs recv -F slavepool
```

Now you can make changes to the original file system and replicate them to the slave.

15.2.2 Configuring MySQL for ZFS Replication

Configuring MySQL on the source file system is a case of creating the data on the file system that you intend to replicate. The configuration file in the example below has been updated to use `/scratchpool/mysql-data` as the data directory, and now you can initialize the tables:
To synchronize the initial information, perform a new snapshot and then send an incremental snapshot to the slave using `zfs send`:

```bash
root-shell> zfs snapshot scratchpool@snap2
root-shell> zfs send -i scratchpool@snap1 scratchpool@snap2|ssh id@host pexec zfs recv slavepool
```

Doublecheck that the slave has the data by looking at the MySQL data directory on the `slavepool`:

```bash
root-shell> ls -al /slavepool/mysql-data/
```

Now you can start up MySQL, create some data, and then replicate the changes using `zfs send`/`zfs recv` to the slave to synchronize the changes.

The rate at which you perform the synchronization depends on your application and environment. The limitation is the speed required to perform the snapshot and then to send the changes over the network.

To automate the process, create a script that performs the snapshot, send, and receive operation, and use `cron` to synchronize the changes at set times or intervals.

### 15.2.3 Handling MySQL Recovery with ZFS

When using ZFS replication to provide a constant copy of your data, ensure that you can recover your tables, either manually or automatically, in the event of a failure of the original system.

In the event of a failure, follow this sequence:

1. Stop the script on the master, if it is still up and running.
2. Set the slave file system to be read/write:

   ```bash
   root-shell> zfs set readonly=off slavepool
   ```

3. Start up `mysql` on the slave. If you are using `InnoDB`, you get auto-recovery, if it is needed, to make sure the table data is correct, as shown here when I started up from our mid-INSERT snapshot:

   ```
   InnoDB: The log sequence number in ibdata files does not match
   InnoDB: the log sequence number in the ib_logfiles!
   081109 15:59:59  InnoDB: Database was not shut down normally!
   InnoDB: Starting crash recovery.
   InnoDB: Reading tablespace information from the .ibd files...
   InnoDB: Restoring possible half-written data pages from the doublewrite
   InnoDB: buffer...
   081109 16:00:03  InnoDB: Started; log sequence number 0 1142807951
   081109 16:00:03  [Note] /slavepool/mysql-5.0.67-solaris10-i386/bin/mysql: ready for connections. Version: '5.0.67' socket: '/tmp/mysql.sock' port: 3306 MySQL Community Server (GPL)
   ```

Use `InnoDB` tables and a regular synchronization schedule to reduce the risk for significant data loss. On MyISAM tables, you might need to run `REPAIR TABLE`, and you might even have lost some information.

### 15.3 Using MySQL with `memcached`

`memcached` is a simple, highly scalable key-based cache that stores data and objects wherever dedicated or spare RAM is available for quick access by applications, without going through layers of parsing or disk I/O. To use, you run the `memcached` command on one or more hosts and then use the shared cache to store objects. For more usage instructions, see Section 15.3.2, “Using `memcached`”
Benefits of using `memcached` include:

- Because all information is stored in RAM, the access speed is faster than loading the information each time from disk.

- Because the “value” portion of the key-value pair does not have any data type restrictions, you can cache data such as complex structures, documents, images, or a mixture of such things.

- If you use the in-memory cache to hold transient information, or as a read-only cache for information also stored in a database, the failure of any `memcached` server is not critical. For persistent data, you can fall back to an alternative lookup method using database queries, and reload the data into RAM on a different server.

The typical usage environment is to modify your application so that information is read from the cache provided by `memcached`. If the information is not in `memcached`, then the data is loaded from the MySQL database and written into the cache so that future requests for the same object benefit from the cached data.

For a typical deployment layout, see Figure 15.2, "memcached Architecture Overview".

**Figure 15.2 memcached Architecture Overview**

In the example structure, any of the clients can contact one of the `memcached` servers to request a given key. Each client is configured to talk to all of the servers shown in the illustration. Within the client, when the request is made to store the information, the key used to reference the data is hashed and this hash is then used to select one of the `memcached` servers. The selection of the `memcached` server takes place on the client before the server is contacted, keeping the process lightweight.

The same algorithm is used again when a client requests the same key. The same key generates the same hash, and the same `memcached` server is selected as the source for the data. Using this method, the cached data is spread among all of the `memcached` servers, and the cached information is accessible from any client. The result is a distributed, memory-based, cache that can return information, particularly complex data and structures, much faster than natively reading the information from the database.

The data held within a traditional `memcached` server is never stored on disk (only in RAM, which means there is no persistence of data), and the RAM cache is always populated from the backing store (a MySQL database). If a `memcached` server fails, the data can always be recovered from the MySQL database.

### 15.3.1 Installing memcached

You can build and install `memcached` from the source code directly, or you can use an existing operating system package or installation.

**Installing memcached from a Binary Distribution**
Installing memcached

To install memcached on a Red Hat, or Fedora host, use yum:

root-shell> yum install memcached

Note
On CentOS, you may be able to obtain a suitable RPM from another source, or use the source tarball.

To install memcached on a Debian or Ubuntu host, use apt-get:

root-shell> apt-get install memcached

To install memcached on a Gentoo host, use emerge:

root-shell> emerge install memcached

Building memcached from Source

On other Unix-based platforms, including Solaris, AIX, HP-UX and OS X, and Linux distributions not mentioned already, you must install from source. For Linux, make sure you have a 2.6-based kernel, which includes the improved epoll interface. For all platforms, ensure that you have libevent 1.1 or higher installed. You can obtain libevent from libevent web page.

You can obtain the source for memcached from memcached Web site.

To build memcached, follow these steps:

1. Extract the memcached source package:

   shell> gunzip -c memcached-1.2.5.tar.gz | tar xf -

2. Change to the memcached-1.2.5 directory:

   shell> cd memcached-1.2.5

3. Run configure

   shell> ./configure

Some additional options you might specify to the configure:

• --prefix

   To specify a different installation directory, use the --prefix option:

   shell> ./configure --prefix=/opt

   The default is to use the /usr/local directory.

• --with-libevent

   If you have installed libevent and configure cannot find the library, use the --with-libevent option to specify the location of the installed library.

• --enable-64bit

   To build a 64-bit version of memcached (which enables you to use a single instance with a large RAM allocation), use --enable-64bit.
Using **memcached**

- **--enable-threads**
  
  To enable multi-threading support in **memcached**, which improves the response times on servers with a heavy load, use **--enable-threads**. You must have support for the POSIX threads within your operating system to enable thread support. For more information on the threading support, see Section 15.3.2.8, "**memcached** Thread Support".

- **--enable-dtrace**

  **memcached** includes a range of DTrace threads that can be used to monitor and benchmark a **memcached** instance. For more information, see Section 15.3.2.6, "Using **memcached** and DTrace".

4. Run `make` to build **memcached**:

    ```
    shell> make
    ```

5. Run `make install` to install **memcached**:

    ```
    shell> make install
    ```

### 15.3.2 Using **memcached**

To start using **memcached**, start the **memcached** service on one or more servers. Running **memcached** sets up the server, allocates the memory and starts listening for connections from clients.

**Note**

You do not need to be a privileged user (**root**) to run **memcached** except to listen on one of the privileged TCP/IP ports (below 1024). You must, however, use a user that has not had their memory limits restricted using `setrlimit` or similar.

To start the server, run **memcached** as a nonprivileged (that is, non-**root**) user:

```
shell> memcached
```

By default, **memcached** uses the following settings:

- Memory allocation of 64MB
- Listens for connections on all network interfaces, using port 11211
- Supports a maximum of 1024 simultaneous connections

Typically, you would specify the full combination of options that you want when starting **memcached**, and normally provide a startup script to handle the initialization of **memcached**. For example, the following line starts **memcached** with a maximum of 1024MB RAM for the cache, listening on port 11211 on the IP address 192.168.0.110, running as a background daemon:

```
shell> memcached -d -m 1024 -p 11211 -l 192.168.0.110
```

To ensure that **memcached** is started up on boot, check the init script and configuration parameters.

### 15.3.2.1 **memcached** Command-Line Options

**memcached** supports the following options:

- **-u user**

  If you start **memcached** as **root**, use the **-u** option to specify the user for executing **memcached**.
Using memcached

shell> memcached -u memcache

- **-m memory**

Set the amount of memory allocated to memcached for object storage. Default is 64MB.

To increase the amount of memory allocated for the cache, use the **-m** option to specify the amount of RAM to be allocated (in megabytes). The more RAM you allocate, the more data you can store and therefore the more effective your cache is.

**Warning**

Do not specify a memory allocation larger than your available RAM. If you specify too large a value, then some RAM allocated for memcached uses swap space, and not physical RAM. This may lead to delays when storing and retrieving values, because data is swapped to disk, instead of storing the data directly in RAM.

You can use the output of the **vmstat** command to get the free memory, as shown in **free** column:

```
shell> vmstat
```

For example, to allocate 3GB of RAM:

shell> memcached -m 3072

On 32-bit x86 systems where you are using PAE to access memory above the 4GB limit, you cannot allocate RAM beyond the maximum process size. You can get around this by running multiple instances of memcached, each listening on a different port:

shell> memcached -m 1024 -p11211
shell> memcached -m 1024 -p11212
shell> memcached -m 1024 -p11213

**Note**

On all systems, particularly 32-bit, ensure that you leave enough room for both memcached application in addition to the memory setting. For example, if you have a dedicated memcached host with 4GB of RAM, do not set the memory size above 3500MB. Failure to do this may cause either a crash or severe performance issues.

- **-l interface**

Specify a network interface/address to listen for connections. The default is to listen on all available address (INADDR_ANY).

shell> memcached -l 192.168.0.110

Support for IPv6 address support was added in memcached 1.2.5.

- **-p port**

Specify the TCP port to use for connections. Default is 18080.
Using `memcached`

```
shell> memcached -p 18080
```

- `-U port`
  Specify the UDP port to use for connections. Default is 11211, 0 switches UDP off.

```
shell> memcached -U 18080
```

- `-s socket`
  Specify a Unix socket to listen on.
  
  If you are running `memcached` on the same server as the clients, you can disable the network interface and use a local Unix socket using the `-s` option:

```
shell> memcached -s /tmp/memcached
```

Using a Unix socket automatically disables network support, and saves network ports (allowing more ports to be used by your web server or other process).

- `-a mask`
  Specify the access mask to be used for the Unix socket, in octal. Default is 0700.

- `-c connections`
  Specify the maximum number of simultaneous connections to the `memcached` service. The default is 1024.

```
shell> memcached -c 2048
```

Use this option, either to reduce the number of connections (to prevent overloading `memcached` service) or to increase the number to make more effective use of the server running `memcached` server.

- `-t threads`
  Specify the number of threads to use when processing incoming requests.

  By default, `memcached` is configured to use 4 concurrent threads. The threading improves the performance of storing and retrieving data in the cache, using a locking system to prevent different threads overwriting or updating the same values. To increase or decrease the number of threads, use the `-t` option:

```
shell> memcached -t 8
```

- `-d`
  Run `memcached` as a daemon (background) process:

```
shell> memcached -d
```

- `-r`
  Maximize the size of the core file limit. In the event of a failure, this attempts to dump the entire memory space to disk as a core file, up to any limits imposed by `setrlimit`.

- `-M`
Return an error to the client when the memory has been exhausted. This replaces the normal behavior of removing older items from the cache to make way for new items.

- **-k**
  Lock down all paged memory. This reserves the memory before use, instead of allocating new slabs of memory as new items are stored in the cache.

  **Note**
  There is a user-level limit on how much memory you can lock. Trying to allocate more than the available memory fails. You can set the limit for the user you started the daemon with (not for the `-u user user`) within the shell by using `ulimit -S -l NUM_KB`

- **-v**
  Verbose mode. Prints errors and warnings while executing the main event loop.

- **-vv**
  Very verbose mode. In addition to information printed by `-v`, also prints each client command and the response.

- **-vvv**
  Extremely verbose mode. In addition to information printed by `-vv`, also show the internal state transitions.

- **-h**
  Print the help message and exit.

- **-i**
  Print the `memcached` and `libevent` license.

- **-I mem**
  Specify the maximum size permitted for storing an object within the `memcached` instance. The size supports a unit postfix (`k` for kilobytes, `m` for megabytes). For example, to increase the maximum supported object size to 32MB:

```shell
shell> memcached -I 32m
```

The maximum object size you can specify is 128MB, the default remains at 1MB.

This option was added in 1.4.2.

- **-b**
  Set the backlog queue limit. The backlog queue configures how many network connections can be waiting to be processed by `memcached`. Increasing this limit may reduce errors received by the client that it is not able to connect to the `memcached` instance, but does not improve the performance of the server. The default is 1024.

- **-P pidfile**
  Save the process ID of the `memcached` instance into `file`.

- **-f**
Set the chunk size growth factor. When allocating new memory chunks, the allocated size of new
chunks is determined by multiplying the default slab size by this factor.

To see the effects of this option without extensive testing, use the -vv command-line option to show
the calculated slab sizes. For more information, see Section 15.3.2.9, “memcached Logs”.

• -n bytes

The minimum space allocated for the key+value+flags information. The default is 48 bytes.

• -L

On systems that support large memory pages, enables large memory page use. Using large memory
pages enables memcached to allocate the item cache in one large chunk, which can improve the
performance by reducing the number misses when accessing memory.

• -C

Disable the use of compare and swap (CAS) operations.

This option was added in memcached 1.3.x.

• -D char

Set the default character to be used as a delimiter between the key prefixes and IDs. This is used for
the per-prefix statistics reporting (see Section 15.3.4, “Getting memcached Statistics”). The default
is the colon (:). If this option is used, statistics collection is turned on automatically. If not used, you
can enable stats collection by sending the stats detail on command to the server.

This option was added in memcached 1.3.x.

• -R num

Sets the maximum number of requests per event process. The default is 20.

• -B protocol

Set the binding protocol, that is, the default memcached protocol support for client connections.
Options are ascii, binary or auto. Automatic (auto) is the default.

This option was added in memcached 1.4.0.

15.3.2.2 memcached Deployment

When using memcached you can use a number of different potential deployment strategies and
topologies. The exact strategy to use depends on your application and environment. When developing
a system for deploying memcached within your system, keep in mind the following points:

• memcached is only a caching mechanism. It shouldn't be used to store information that you cannot
  otherwise afford to lose and then load from a different location.

• There is no security built into the memcached protocol. At a minimum, make sure that the servers
  running memcached are only accessible from inside your network, and that the network ports being
  used are blocked (using a firewall or similar). If the information on the memcached servers that is
  being stored is any sensitive, then encrypt the information before storing it in memcached.

• memcached does not provide any sort of failover. Because there is no communication between
  different memcached instances. If an instance fails, your application must capable of removing it from
  the list, reloading the data and then writing data to another memcached instance.
• Latency between the clients and the **memcached** can be a problem if you are using different physical machines for these tasks. If you find that the latency is a problem, move the **memcached** instances to be on the clients.

• Key length is determined by the **memcached** server. The default maximum key size is 250 bytes.

• Try to use at least two **memcached** instances, especially for multiple clients, to avoid having a single point of failure. Ideally, create as many **memcached** nodes as possible. When adding and removing **memcached** instances from a pool, the hashing and distribution of key/value pairs may be affected. For information on how to avoid problems, see Section 15.3.2.5, “**memcached** Hashing/Distribution Types”.

### 15.3.2.3 Using Namespaces

The **memcached** cache is a very simple massive key/value storage system, and as such there is no way of compartmentalizing data automatically into different sections. For example, if you are storing information by the unique ID returned from a MySQL database, then storing the data from two different tables could run into issues because the same ID might be valid in both tables.

Some interfaces provide an automated mechanism for creating namespaces when storing information into the cache. In practice, these namespaces are merely a prefix before a given ID that is applied every time a value is stored or retrieve from the cache.

You can implement the same basic principle by using keys that describe the object and the unique identifier within the key that you supply when the object is stored. For example, when storing user data, prefix the ID of the user with `user:` or `user-`.

**Note**

Using namespaces or prefixes only controls the keys stored/retrieved. There is no security within **memcached**, and therefore no way to enforce that a particular client only accesses keys with a particular namespace. Namespaces are only useful as a method of identifying data and preventing corruption of key/value pairs.

### 15.3.2.4 Data Expiry

There are two types of data expiry within a **memcached** instance. The first type is applied at the point when you store a new key/value pair into the **memcached** instance. If there is not enough space within a suitable slab to store the value, then an existing least recently used (LRU) object is removed (evicted) from the cache to make room for the new item.

The LRU algorithm ensures that the object that is removed is one that is either no longer in active use or that was used so long ago that its data is potentially out of date or of little value. However, in a system where the memory allocated to **memcached** is smaller than the number of regularly used objects required in the cache, a lot of expired items could be removed from the cache even though they are in active use. You use the statistics mechanism to get a better idea of the level of evictions (expired objects). For more information, see Section 15.3.4, “Getting **memcached** Statistics”.

You can change this eviction behavior by setting the `-M` command-line option when starting **memcached**. This option forces an error to be returned when the memory has been exhausted, instead of automatically evicting older data.

The second type of expiry system is an explicit mechanism that you can set when a key/value pair is inserted into the cache, or when deleting an item from the cache. Using an expiration time can be a useful way of ensuring that the data in the cache is up to date and in line with your application needs and requirements.

A typical scenario for explicitly setting the expiry time might include caching session data for a user when accessing a Web site. **memcached** uses a lazy expiry mechanism where the explicit expiry time that has been set is compared with the current time when the object is requested. Only objects that have not expired are returned.
You can also set the expiry time when explicitly deleting an object from the cache. In this case, the expiry time is really a timeout and indicates the period when any attempts to set the value for a given key are rejected.

### 15.3.2.5 memcached Hashing/Distribution Types

The memcached client interface supports a number of different distribution algorithms that are used in multi-server configurations to determine which host should be used when setting or getting data from a given memcached instance. When you get or set a value, a hash is constructed from the supplied key and then used to select a host from the list of configured servers. Because the hashing mechanism uses the supplied key as the basis for the hash, the same server is selected during both set and get operations.

You can think of this process as follows. Given an array of servers (a, b, and c), the client uses a hashing algorithm that returns an integer based on the key being stored or retrieved. The resulting value is then used to select a server from the list of servers configured in the client. Most standard client hashing within memcache clients uses a simple modulus calculation on the value against the number of configured memcached servers. You can summarize the process in pseudocode as:

```plaintext
@memcservers = ['a.memc','b.memc','c.memc'];
$value = hash($key);
$chosen = $value % length(@memcservers);
```

Replacing the above with values:

```plaintext
@memcservers = ['a.memc','b.memc','c.memc'];
$value = hash('myid');
$chosen = 7009 % 3;
```

In the above example, the client hashing algorithm chooses the server at index 1 (7009 % 3 = 1), and store or retrieve the key and value with that server.

**Note**

This selection and hashing process is handled automatically by the memcached client you are using; you need only provide the list of memcached servers to use.

You can see a graphical representation of this below in Figure 15.3, “memcached Hash Selection”.

**Figure 15.3 memcached Hash Selection**

The same hashing and selection process takes place during any operation on the specified key within the memcached client.

Using this method provides a number of advantages:

- The hashing and selection of the server to contact is handled entirely within the client. This eliminates the need to perform network communication to determine the right machine to contact.
Using **memcached**

- Because the determination of the memcached server occurs entirely within the client, the server can be selected automatically regardless of the operation being executed (set, get, increment, etc.).

- Because the determination is handled within the client, the hashing algorithm returns the same value for a given key; values are not affected or reset by differences in the server environment.

- Selection is very fast. The hashing algorithm on the key value is quick and the resulting selection of the server is from a simple array of available machines.

- Using client-side hashing simplifies the distribution of data over each memcached server. Natural distribution of the values returned by the hashing algorithm means that keys are automatically spread over the available servers.

Providing that the list of servers configured within the client remains the same, the same stored key returns the same value, and therefore selects the same server.

However, if you do not use the same hashing mechanism then the same data may be recorded on different servers by different interfaces, both wasting space on your memcached and leading to potential differences in the information.

### Note

One way to use a multi-interface compatible hashing mechanism is to use the libmemcached library and the associated interfaces. Because the interfaces for the different languages (including C, Ruby, Perl and Python) use the same client library interface, they always generate the same hash code from the ID.

The problem with client-side selection of the server is that the list of the servers (including their sequential order) must remain consistent on each client using the memcached servers, and the servers must be available. If you try to perform an operation on a key when:

- A new memcached instance has been added to the list of available instances
- A memcached instance has been removed from the list of available instances
- The order of the memcached instances has changed

When the hashing algorithm is used on the given key, but with a different list of servers, the hash calculation may choose a different server from the list.

If a new memcached instance is added into the list of servers, as new.memc is in the example below, then a GET operation using the same key, myid, can result in a cache-miss. This is because the same value is computed from the key, which selects the same index from the array of servers, but index 2 now points to the new server, not the server c.memc where the data was originally stored. This would result in a cache miss, even though the key exists within the cache on another memcached instance.

**Figure 15.4** memcached Hash Selection with New memcached instance

This means that servers c.memc and new.memc both contain the information for key myid, but the information stored against the key in eachs server may be different in each instance. A more significant
problem is a much higher number of cache-misses when retrieving data, as the addition of a new
server changes the distribution of keys, and this in turn requires rebuilding the cached data on the
memcached instances, causing an increase in database reads.

The same effect can occur if you actively manage the list of servers configured in your clients, adding
and removing the configured memcached instances as each instance is identified as being available.
For example, removing a memcached instance when the client notices that the instance can no longer
be contacted can cause the server selection to fail as described here.

To prevent this causing significant problems and invalidating your cache, you can select the hashing
algorithm used to select the server. There are two common types of hashing algorithm, consistent and
modula.

With consistent hashing algorithms, the same key when applied to a list of servers always uses the
same server to store or retrieve the keys, even if the list of configured servers changes. This means
that you can add and remove servers from the configure list and always use the same server for a
given key. There are two types of consistent hashing algorithms available, Ketama and Wheel. Both
types are supported by libmemcached, and implementations are available for PHP and Java.

Any consistent hashing algorithm has some limitations. When you add servers to an existing list of
configured servers, keys are distributed to the new servers as part of the normal distribution. When you
remove servers from the list, the keys are re-allocated to another server within the list, meaning that
the cache needs to be re-populated with the information. Also, a consistent hashing algorithm does not
resolve the issue where you want consistent selection of a server across multiple clients, but where
each client contains a different list of servers. The consistency is enforced only within a single client.

With a modula hashing algorithm, the client selects a server by first computing the hash and then
choosing a server from the list of configured servers. As the list of servers changes, so the server
selected when using a modula hashing algorithm also changes. The result is the behavior described
above; changes to the list of servers mean that different servers are selected when retrieving data,
leading to cache misses and increase in database load as the cache is re-seeded with information.

If you use only a single memcached instance for each client, or your list of memcached servers
configured for a client never changes, then the selection of a hashing algorithm is irrelevant, as it has
no noticeable effect.

If you change your servers regularly, or you use a common set of servers that are shared among a
large number of clients, then using a consistent hashing algorithm should help to ensure that your
cache data is not duplicated and the data is evenly distributed.

### 15.3.2.6 Using memcached and DTrace

memcached includes a number of different DTrace probes that can be used to monitor the operation of
the server. The probes included can monitor individual connections, slab allocations, and modifications
to the hash table when a key/value pair is added, updated, or removed.

For more information on DTrace and writing DTrace scripts, read the [DTrace User Guide](#).

Support for DTrace probes was added to memcached 1.2.6 includes a number of DTrace probes that
can be used to help monitor your application. DTrace is supported on Solaris 10, OpenSolaris, OS X
10.5 and FreeBSD. To enable the DTrace probes in memcached, build from source and use the
--enable-dtrace option. For more information, see Section 15.3.1, “Installing memcached”.

The probes supported by memcached are:

- **conn-allocate(connid)**
  
  Fired when a connection object is allocated from the connection pool.

- **connid**: The connection ID.

- **conn-release(connid)**

1612
Fired when a connection object is released back to the connection pool.

Arguments:
- **connid**: The connection ID.

**conn-create(ptr)**

Fired when a new connection object is being created (that is, there are no free connection objects in the connection pool).

Arguments:
- **ptr**: A pointer to the connection object

**conn-destroy(ptr)**

Fired when a connection object is being destroyed.

Arguments:
- **ptr**: A pointer to the connection object.

**conn-dispatch(connid, threadid)**

Fired when a connection is dispatched from the main or connection-management thread to a worker thread.

Arguments:
- **connid**: The connection ID.
- **threadid**: The thread ID.

**slabs-allocate(size, slabclass, slabsize, ptr)**

Allocate memory from the slab allocator.

Arguments:
- **size**: The requested size.
- **slabclass**: The allocation is fulfilled in this class.
- **slabsize**: The size of each item in this class.
- **ptr**: A pointer to allocated memory.

**slabs-allocate-failed(size, slabclass)**

Failed to allocate memory (out of memory).

Arguments:
- **size**: The requested size.
- **slabclass**: The class that failed to fulfill the request.

**slabs-slabclass-allocate(slabclass)**

Fired when a slab class needs more space.

Arguments:
Using memcached

- **slabclass**: The class that needs more memory.

- **slabs-slabclass-allocate-failed(slabclass)**
  
  Failed to allocate memory (out of memory).
  
  Arguments:
  
  - **slabclass**: The class that failed to grab more memory.

- **slabs-free(size, slabclass, ptr)**
  
  Release memory.
  
  Arguments:
  
  - **size**: The amount of memory to release, in bytes.
  - **slabclass**: The class the memory belongs to.
  - **ptr**: A pointer to the memory to release.

- **assoc-find(key, depth)**
  
  Fired when we have searched the hash table for a named key. These two elements provide an insight into how well the hash function operates. Traversals are a sign of a less optimal function, wasting CPU capacity.
  
  Arguments:
  
  - **key**: The key searched for.
  - **depth**: The depth in the list of hash table.

- **assoc-insert(key, nokeys)**
  
  Fired when a new item has been inserted.
  
  Arguments:
  
  - **key**: The key just inserted.
  - **nokeys**: The total number of keys currently being stored, including the key for which insert was called.

- **assoc-delete(key, nokeys)**
  
  Fired when a new item has been removed.
  
  Arguments:
  
  - **key**: The key just deleted.
  - **nokeys**: The total number of keys currently being stored, excluding the key for which delete was called.

- **item-link(key, size)**
  
  Fired when an item is being linked in the cache.
  
  Arguments:
  
  - **key**: The items key.
• **size**: The size of the data.

- **item-unlink(key, size)**

  Fired when an item is being deleted.

  Arguments:
  - **key**: The item's key.
  - **size**: The size of the data.

- **item-remove(key, size)**

  Fired when the refcount for an item is reduced.

  Arguments:
  - **key**: The item's key.
  - **size**: The size of the data.

- **item-update(key, size)**

  Fired when the "last referenced" time is updated.

  Arguments:
  - **key**: The item's key.
  - **size**: The size of the data.

- **item-replace(oldkey, oldsize, newkey, newsize)**

  Fired when an item is being replaced with another item.

  Arguments:
  - **oldkey**: The key of the item to replace.
  - **oldsize**: The size of the old item.
  - **newkey**: The key of the new item.
  - **newsize**: The size of the new item.

- **process-command-start(connid, request, size)**

  Fired when the processing of a command starts.

  Arguments:
  - **connid**: The connection ID.
  - **request**: The incoming request.
  - **size**: The size of the request.

- **process-command-end(connid, response, size)**

  Fired when the processing of a command is done.

  Arguments:
- **connid**: The connection ID.
- **response**: The response to send back to the client.
- **size**: The size of the response.

**command-get(connid, key, size)**

Fired for a **get** command.

Arguments:
- **connid**: The connection ID.
- **key**: The requested key.
- **size**: The size of the key's data (or -1 if not found).

**command-gets(connid, key, size, casid)**

Fired for a **gets** command.

Arguments:
- **connid**: The connection ID.
- **key**: The requested key.
- **size**: The size of the key's data (or -1 if not found).
- **casid**: The casid for the item.

**command-add(connid, key, size)**

Fired for a **add** command.

Arguments:
- **connid**: The connection ID.
- **key**: The requested key.
- **size**: The new size of the key's data (or -1 if not found).

**command-set(connid, key, size)**

Fired for a **set** command.

Arguments:
- **connid**: The connection ID.
- **key**: The requested key.
- **size**: The new size of the key's data (or -1 if not found).

**command-replace(connid, key, size)**

Fired for a **replace** command.

Arguments:
- **connid**: The connection ID.
- **key**: The requested key.
- **size**: The new size of the key's data (or -1 if not found).

- **command-prepend(connid, key, size)**
  Fired for a **prepend** command.
  Arguments:
  - **connid**: The connection ID.
  - **key**: The requested key.
  - **size**: The new size of the key's data (or -1 if not found).

- **command-append(connid, key, size)**
  Fired for a **append** command.
  Arguments:
  - **connid**: The connection ID.
  - **key**: The requested key.
  - **size**: The new size of the key's data (or -1 if not found).

- **command-cas(connid, key, size, casid)**
  Fired for a **cas** command.
  Arguments:
  - **connid**: The connection ID.
  - **key**: The requested key.
  - **size**: The size of the key's data (or -1 if not found).
  - **casid**: The cas ID requested.

- **command-incr(connid, key, val)**
  Fired for **incr** command.
  Arguments:
  - **connid**: The connection ID.
  - **key**: The requested key.
  - **val**: The new value.

- **command-decr(connid, key, val)**
  Fired for **decr** command.
  Arguments:
  - **connid**: The connection ID.
  - **key**: The requested key.
Using memcached

- **val**: The new value.

- **command-delete(connid, key, exptime)**
  Fired for a **delete** command.
  
  Arguments:
  - **connid**: The connection ID.
  - **key**: The requested key.
  - **exptime**: The expiry time.

### 15.3.2.7 Memory Allocation within **memcached**

When you first start **memcached**, the memory that you have configured is not automatically allocated. Instead, **memcached** only starts allocating and reserving physical memory once you start saving information into the cache.

When you start to store data into the cache, **memcached** does not allocate the memory for the data on an item by item basis. Instead, a slab allocation is used to optimize memory usage and prevent memory fragmentation when information expires from the cache.

With slab allocation, memory is reserved in blocks of 1MB. The slab is divided up into a number of blocks of equal size. When you try to store a value into the cache, **memcached** checks the size of the value that you are adding to the cache and determines which slab contains the right size allocation for the item. If a slab with the item size already exists, the item is written to the block within the slab.

If the new item is bigger than the size of any existing blocks, then a new slab is created, divided up into blocks of a suitable size. If an existing slab with the right block size already exists, but there are no free blocks, a new slab is created. If you update an existing item with data that is larger than the existing block allocation for that key, then the key is re-allocated into a suitable slab.

For example, the default size for the smallest block is 88 bytes (40 bytes of value, and the default 48 bytes for the key and flag data). If the size of the first item you store into the cache is less than 40 bytes, then a slab with a block size of 88 bytes is created and the value stored.

If the size of the data that you intend to store is larger than this value, then the block size is increased by the chunk size factor until a block size large enough to hold the value is determined. The block size is always a function of the scale factor, rounded up to a block size which is exactly divisible into the chunk size.

For a sample of the structure, see Figure 15.5, “Memory Allocation in **memcached**”.

**Figure 15.5 Memory Allocation in **memcached**

![Diagram of memory allocation in memcached]

The result is that you have multiple pages allocated within the range of memory allocated to **memcached**. Each page is 1MB in size (by default), and is split into a different number of chunks, according to the chunk size required to store the key/value pairs. Each instance has multiple pages...
allocated, and a page is always created when a new item needs to be created requiring a chunk of a particular size. A slab may consist of multiple pages, and each page within a slab contains an equal number of chunks.

The chunk size of a new slab is determined by the base chunk size combined with the chunk size growth factor. For example, if the initial chunks are 104 bytes in size, and the default chunk size growth factor is used (1.25), then the next chunk size allocated would be the best power of 2 fit for 104*1.25, or 136 bytes.

Allocating the pages in this way ensures that memory does not get fragmented. However, depending on the distribution of the objects that you store, it may lead to an inefficient distribution of the slabs and chunks if you have significantly different sized items. For example, having a relatively small number of items within each chunk size may waste a lot of memory with just few chunks in each allocated page.

You can tune the growth factor to reduce this effect by using the \(-f\) command line option, which adapts the growth factor applied to make more effective use of the chunks and slabs allocated. For information on how to determine the current slab allocation statistics, see Section 15.3.4.2, "memcached Slabs Statistics".

If your operating system supports it, you can also start memcached with the \(-L\) command line option. This option preallocates all the memory during startup using large memory pages. This can improve performance by reducing the number of misses in the CPU memory cache.

15.3.2.8 memcached Thread Support

If you enable the thread implementation within when building memcached from source, then memcached uses multiple threads in addition to the libevent system to handle requests.

When enabled, the threading implementation operates as follows:

- Threading is handled by wrapping functions within the code to provide basic protection from updating the same global structures at the same time.

- Each thread uses its own instance of the libevent to help improve performance.

- TCP/IP connections are handled with a single thread listening on the TCP/IP socket. Each connection is then distributed to one of the active threads on a simple round-robin basis. Each connection then operates solely within this thread while the connection remains open.

- For UDP connections, all the threads listen to a single UDP socket for incoming requests.Threads that are not currently dealing with another request ignore the incoming packet. One of the remaining, nonbusy, threads reads the request and sends the response. This implementation can lead to increased CPU load as threads wake from sleep to potentially process the request.

Using threads can increase the performance on servers that have multiple CPU cores available, as the requests to update the hash table can be spread between the individual threads. To minimize overhead from the locking mechanism employed, experiment with different thread values to achieve the best performance based on the number and type of requests within your given workload.

15.3.2.9 memcached Logs

If you enable verbose mode, using the \(-v\), \(-vv\), or \(-vvv\) options, then the information output by memcached includes details of the operations being performed.

Without the verbose options, memcached normally produces no output during normal operating.

- Output when using \(-v\)
  
  The lowest verbosity level shows you:

  - Errors and warnings
  
  - Transient errors
Using **memcached**

- Protocol and socket errors, including exhausting available connections
- Each registered socket, including the socket descriptor number and the protocol used.

For example:

32: Client using the ascii protocol
33: Client using the ascii protocol

The socket descriptor is only valid while the client remains connected. Non-persistent connections may not be effectively represented.

Examples of the error messages output at this level include:

```plaintext
<%d send buffer was %d, now %d
Can't listen for events on fd %d
Can't read from libevent pipe
Catastrophic: event fd doesn't match conn fd!
Couldn't build response
Couldn't realloc input buffer
Couldn't update event
Failed to build UDP headers
Failed to read, and not due to blocking
Too many open connections
Unexpected state %d
```

- **Output when using **-vv**

When using the second level of verbosity, you get more detailed information about protocol operations, keys updated, chunk and network operations and details.

During the initial start-up of **memcached** with this level of verbosity, you are shown the sizes of the individual slab classes, the chunk sizes, and the number of entries per slab. These do not show the allocation of the slabs, just the slabs that would be created when data is added. You are also given information about the listen queues and buffers used to send information. A sample of the output generated for a TCP/IP based system with the default memory and growth factors is given below:

```
shell> memcached -vv
slab class   1: chunk size     80 perslab 13107
slab class   2: chunk size    104 perslab 10082
slab class   3: chunk size    136 perslab  7710
slab class   4: chunk size    176 perslab  5957
slab class   5: chunk size    224 perslab  4681
slab class   6: chunk size    280 perslab  3744
slab class   7: chunk size    352 perslab  2978
slab class   8: chunk size    440 perslab  2383
slab class   9: chunk size    552 perslab  1899
slab class  10: chunk size    696 perslab  1506
slab class  11: chunk size    872 perslab  1202
slab class  12: chunk size   1096 perslab   956
slab class  13: chunk size   1376 perslab   762
slab class  14: chunk size   1720 perslab   609
slab class  15: chunk size   2152 perslab   487
slab class  16: chunk size   2696 perslab   388
slab class  17: chunk size   3376 perslab   310
slab class  18: chunk size   4224 perslab   248
slab class  19: chunk size   5280 perslab   198
slab class  20: chunk size   6600 perslab   158
slab class  21: chunk size   8256 perslab   127
slab class  22: chunk size  10320 perslab   101
slab class  23: chunk size  12904 perslab    81
slab class  24: chunk size  16136 perslab    64
slab class  25: chunk size  20176 perslab    51
slab class  26: chunk size  25224 perslab    41
slab class  27: chunk size  31536 perslab    33
```
Using this verbosity level can be a useful way to check the effects of the growth factor used on slabs with different memory allocations, which in turn can be used to better tune the growth factor to suit the data you are storing in the cache. For example, if you set the growth factor to 4 (quadrupling the size of each slab):

```
shell> memcached -f 4 -m 1g -vv
```

During use of the cache, this verbosity level also prints out detailed information on the storage and recovery of keys and other information. An example of the output during a typical set/get and increment/decrement operation is shown below.

```
32: Client using the ascii protocol
<32 set my_key 0 0 10
>32 STORED
<32 set object_key 1 0 36
>32 STORED
<32 get my_key
>32 sending key my_key
>32 END
<32 get object_key
>32 sending key object_key
>32 END
<32 set key 0 0 6
>32 STORED
<32 incr key 1
>32 789544
<32 decre key 1
>32 789543
<32 incr key 2
>32 789545
<32 set my_key 0 0 10
>32 STORED
<32 set object_key 1 0 36
>32 STORED
<32 get my_key
```
Developing a **memcached** Application

During client communication, for each line, the initial character shows the direction of flow of the information. The `<` for communication from the client to the **memcached** server and `>` for communication back to the client. The number is the numeric socket descriptor for the connection.

- **Output when using --vvv**

This level of verbosity includes the transitions of connections between different states in the event library while reading and writing content to/from the clients. It should be used to diagnose and identify issues in client communication. For example, you can use this information to determine if **memcached** is taking a long time to return information to the client, during the read of the client operation or before returning and completing the operation. An example of the typical sequence for a set operation is provided below:

```
<32 new auto-negotiating client connection
32: going from conn_new_cmd to conn_waiting
32: going from conn_waiting to conn_read
32: going from conn_read to conn_parse_cmd
32: Client using the ascii protocol
<32 set my_key 0 0 10
32: going from conn_parse_cmd to conn_nread
> NOT FOUND my_key
>32 STORED
32: going from conn_nread to conn_write
32: going from conn_write to conn_new_cmd
32: going from conn_new_cmd to conn_waiting
32: going from conn_waiting to conn_read
32: going from conn_read to conn_closing
<32 connection closed.
```

All of the verbosity levels in **memcached** are designed to be used during debugging or examination of issues. The quantity of information generated, particularly when using --vvv, is significant, particularly on a busy server. Also be aware that writing the error information out, especially to disk, may negate some of the performance gains you achieve by using **memcached**. Therefore, use in production or deployment environments is not recommended.

### 15.3.3 Developing a **memcached** Application

A number of language interfaces let applications store and retrieve information with **memcached** servers. You can write **memcached** applications in popular languages such as Perl, PHP, Python, Ruby, C, and Java.

Data stored into a **memcached** server is referred to by a single string (the key), with storage into the cache and retrieval from the cache using the key as the reference. The cache therefore operates like a large associative array or hash table. It is not possible to structure or otherwise organize the information stored in the cache. To emulate database notions such as multiple tables or composite key values, you must encode the extra information into the strings used as keys. For example, to store or look up the address corresponding to a specific latitude and longitude, you might turn those two numeric values into a single comma-separated string to use as a key.
15.3.3.1 Basic `memcached` Operations

The interface to `memcached` supports the following methods for storing and retrieving information in the cache, and these are consistent across all the different APIs, although the language specific mechanics might be different:

- **get(key)**: Retrieves information from the cache. Returns the value associated with the key if the specified key exists. Returns `NULL`, `nil`, `undefined`, or the closest equivalent in the corresponding language, if the specified key does not exist.

- **set(key, value [, expiry])**: Sets the item associated with a key in the cache to the specified value. This either updates an existing item if the key already exists, or adds a new key/value pair if the key doesn't exist. If the expiry time is specified, then the item expires (and is deleted) when the expiry time is reached. The time is specified in seconds, and is taken as a relative time if the value is less than 30 days (30*24*60*60), or an absolute time (epoch) if larger than this value.

- **add(key, value [, expiry])**: Adds the key and associated value to the cache, if the specified key does not already exist.

- **replace(key, value [, expiry])**: Replaces the item associated with the specified key, only if the key already exists. The new value is given by the value parameter.

- **delete(key [, time])**: Deletes the key and its associated item from the cache. If you supply a time, then adding another item with the specified key is blocked for the specified period.

- **incr(key , value)**: Increments the item associated with the key by the specified value.

- **decr(key , value)**: Decrements the item associated with the key by the specified value.

- **flush_all**: Invalidates (or expires) all the current items in the cache. Technically they still exist (they are not deleted), but they are silently destroyed the next time you try to access them.

In all implementations, most or all of these functions are duplicated through the corresponding native language interface.

When practical, use `memcached` to store full items, rather than caching a single column value from the database. For example, when displaying a record about an object (invoice, user history, or blog post), load all the data for the associated entry from the database, and compile it into the internal structure that would normally be required by the application. Save the complete object in the cache.

Complex data structures cannot be stored directly. Most interfaces serialize the data for you, that is, put it in a textual form that can reconstruct the original pointers and nesting. Perl uses `Storable`, PHP uses `serialize`, Python uses `cPickle` (or `Pickle`) and Java uses the `Serializable` interface. In most cases, the serialization interface used is customizable. To share data stored in `memcached` instances between different language interfaces, consider using a common serialization solution such as JSON (Javascript Object Notation).

15.3.3.2 Using `memcached` as a MySQL Caching Layer

When using `memcached` to cache MySQL data, your application must retrieve data from the database and load the appropriate key-value pairs into the cache. Then, subsequent lookups can be done directly from the cache.

Because MySQL has its own in-memory caching mechanisms for queried data, such as the InnoDB buffer pool and the MySQL query cache, look for opportunities beyond loading individual column values or rows into the cache. Prefer to cache composite values, such as those retrieved from multiple tables through a join query, or result sets assembled from multiple rows.

**Caution**

Limit the information in the cache to non-sensitive data, because there is no security required to access or update the information within a `memcached`
Developing a memcached Application

instance. Anybody with access to the machine has the ability to read, view and potentially update the information. To keep the data secure, encrypt the information before caching it. To restrict the users capable of connecting to the server, either disable network access, or use IPTables or similar techniques to restrict access to the memcached ports to a select set of hosts.

You can introduce memcached to an existing application, even if caching was not part of the original design. In many languages and environments the changes to the application will be just a few lines, first to attempt to read from the cache when loading data, fall back to the old method if the information is not cached, and to update the cache with information once the data has been read.

The general sequence for using memcached in any language as a caching solution for MySQL is as follows:

1. Request the item from the cache.
2. If the item exists, use the item data.
3. If the item does not exist, load the data from MySQL, and store the value into the cache. This means the value is available to the next client that requests it from the cache.

For a flow diagram of this sequence, see Figure 15.6, “Typical memcached Application Flowchart”.

Figure 15.6 Typical memcached Application Flowchart

Adapting Database Best Practices to memcached Applications

The most direct way to cache MySQL data is to use a 2-column table, where the first column is a primary key. Because of the uniqueness requirements for memcached keys, make sure your database schema makes appropriate use of primary keys and unique constraints.

If you combine multiple column values into a single memcached item value, choose data types to make it easy to parse the value back into its components, for example by using a separator character between numeric values.

The queries that map most easily to memcached lookups are those with a single WHERE clause, using an = or IN operator. For complicated WHERE clauses, or those using operators such as <, >, BETWEEN, or LIKE, memcached does not provide a simple or efficient way to scan through or filter the keys.
or associated values, so typically you perform those operations as SQL queries on the underlying database.

### 15.3.3.3 Using `libmemcached` with C and C++

The `libmemcached` library provides both C and C++ interfaces to `memcached` and is also the basis for a number of different additional API implementations, including Perl, Python and Ruby. Understanding the core `libmemcached` functions can help when using these other interfaces.

The C library is the most comprehensive interface library for `memcached` and provides functions and operational systems not always exposed in interfaces not based on the `libmemcached` library.

The different functions can be divided up according to their basic operation. In addition to functions that interface to the core API, a number of utility functions provide extended functionality, such as appending and prepending data.

To build and install `libmemcached`, download the `libmemcached` package, run `configure`, and then build and install:

```bash
tar xjf libmemcached-0.21.tar.gz
cd libmemcached-0.21
./configure
make
make install
```

On many Linux operating systems, you can install the corresponding `libmemcached` package through the usual `yum`, `apt-get`, or similar commands.

To build an application that uses the library, first set the list of servers. Either directly manipulate the servers configured within the main `memcached_st` structure, or separately populate a list of servers, and then add this list to the `memcached_st` structure. The latter method is used in the following example. Once the server list has been set, you can call the functions to store or retrieve data. A simple application for setting a preset value to `localhost` is provided here:

```c
#include <stdio.h>
#include <string.h>
#include <unistd.h>
#include <libmemcached/memcached.h>

int main(int argc, char *argv[])
{
    memcached_server_st *servers = NULL;
    memcached_st *memc;
    memcached_return rc;
    char *key = "keystring";
    char *value = "keyvalue"

    servers = memcached_server_st *memcached_servers_parse (char *server_strings);
    memc = memcached_create (NULL);
    servers = memcached_server_list_append (servers, "localhost", 11211, &rc);
    rc = memcached_server_push (memc, servers);
    if (rc == MEMCACHED_SUCCESS)
        fprintf(stderr,"Added server successfully
");
    else
        fprintf(stderr,"Couldn't add server: %s\n",memcached_strerror (memc, rc));

    rc = memcached_set (memc, key, strlen(key), value, strlen(value), (time_t)0, (uint32_t)0);
    if (rc == MEMCACHED_SUCCESS)
        fprintf(stderr,"Key stored successfully\n");
    else
        fprintf(stderr,"Couldn't store key: %s\n",memcached_strerror (memc, rc));
}
```
To test the success of an operation, use the return value, or populated result code, for a given function. The value is always set to `MEMCACHED_SUCCESS` if the operation succeeded. In the event of a failure, use the `memcached_strerror()` function to translate the result code into a printable string.

To build the application, specify the `memcached` library:

```
shell> gcc -o memc_basic memc_basic.c -lmemcached
```

Running the above sample application, after starting a `memcached` server, should return a success message:

```
shell> memc_basic
Added server successfully
Key stored successfully
```

### libmemcached Base Functions

The base `libmemcached` functions let you create, destroy and clone the main `memcached_st` structure that is used to interface with the `memcached` servers. The main functions are defined below:

```c
memcached_st *memcached_create (memcached_st *ptr);
```

Creates a new `memcached_st` structure for use with the other `libmemcached` API functions. You can supply an existing, static, `memcached_st` structure, or `NULL` to have a new structured allocated. Returns a pointer to the created structure, or `NULL` on failure.

```c
void memcached_free (memcached_st *ptr);
```

Frees the structure and memory allocated to a previously created `memcached_st` structure.

```c
memcached_st *memcached_clone(memcached_st *clone, memcached_st *source);
```

Clones an existing `memcached` structure from the specified `source`, copying the defaults and list of servers defined in the structure.

### libmemcached Server Functions

The `libmemcached` API uses a list of servers, stored within the `memcached_server_st` structure, to act as the list of servers used by the rest of the functions. To use `memcached`, you first create the server list, and then apply the list of servers to a valid `libmemcached` object.

Because the list of servers, and the list of servers within an active `libmemcached` object can be manipulated separately, you can update and manage server lists while an active `libmemcached` interface is running.

The functions for manipulating the list of servers within a `memcached_st` structure are:

```c
memcached_return
    memcached_server_add (memcached_st *ptr,
                          char *hostname,
                          unsigned int port);
```

Adds a server, using the given `hostname` and `port` into the `memcached_st` structure given in `ptr`. 
Developing a memcached Application

```c
memcached_server_add_unix_socket (memcached_st *ptr,
char *socket);
```

Adds a Unix socket to the list of servers configured in the `memcached_st` structure.

```c
unsigned int memcached_server_count (memcached_st *ptr);
```

Returns a count of the number of configured servers within the `memcached_st` structure.

```c
memcached_server_st *
memcached_server_list (memcached_st *ptr);
```

Returns an array of all the defined hosts within a `memcached_st` structure.

```c
memcached_return
memcached_server_push (memcached_st *ptr,
memcached_server_st *list);
```

Pushes an existing list of servers onto list of servers configured for a current `memcached_st` structure. This adds servers to the end of the existing list, and duplicates are not checked.

The `memcached_server_st` structure can be used to create a list of `memcached` servers which can then be applied individually to `memcached_st` structures.

```c
memcached_server_st *
memcached_server_list_append (memcached_server_st *ptr,
char *hostname,
unsigned int port,
memcached_return *error);
```

Adds a server, with `hostname` and `port`, to the server list in `ptr`. The result code is handled by the `error` argument, which should point to an existing `memcached_return` variable. The function returns a pointer to the returned list.

```c
unsigned int memcached_server_list_count (memcached_server_st *ptr);
```

Returns the number of the servers in the server list.

```c
void memcached_server_list_free (memcached_server_st *ptr);
```

Frees the memory associated with a server list.

```c
memcached_server_st *memcached_servers_parse (char *server_strings);
```

Parses a string containing a list of servers, where individual servers are separated by a comma, space, or both, and where individual servers are of the form `server[:port]`. The return value is a server list structure.

### libmemcached Set Functions

The set-related functions within `libmemcached` provide the same functionality as the core functions supported by the `memcached` protocol. The full definition for the different functions is the same for all the base functions (`add`, `replace`, `prepend`, `append`). For example, the function definition for `memcached_set()` is:

```c
memcached_return
memcached_set (memcached_st *ptr,
const char *key,
```
Developing a **memcached** Application

```c
size_t key_length,
const char *value,
size_t value_length,
time_t expiration,
uint32_t flags);
```

The `ptr` is the `memcached_st` structure. The `key` and `key_length` define the key name and length, and `value` and `value_length` the corresponding value and length. You can also set the expiration and optional flags. For more information, see Controlling `libmemcached` Behaviors.

This table outlines the remainder of the set-related `libmemcached` functions and the equivalent core functions supported by the `memcached` protocol.

<table>
<thead>
<tr>
<th><code>libmemcached</code> Function</th>
<th>Equivalent Core Function</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>memcached_set(memc, key, key_length, value, value_length, expiration, flags)</code></td>
<td>Generic <code>set()</code> operation.</td>
</tr>
<tr>
<td><code>memcached_add(memc, key, key_length, value, value_length, expiration, flags)</code></td>
<td>Generic <code>add()</code> function.</td>
</tr>
<tr>
<td><code>memcached_replace(memc, key, key_length, value, value_length, expiration, flags)</code></td>
<td>Generic <code>replace()</code>.</td>
</tr>
<tr>
<td><code>memcached_prepend(memc, key, key_length, value, value_length, expiration, flags)</code></td>
<td>Prepends the specified <code>value</code> before the current value of the specified <code>key</code>.</td>
</tr>
<tr>
<td><code>memcached_append(memc, key, key_length, value, value_length, expiration, flags)</code></td>
<td>Appends the specified <code>value</code> after the current value of the specified <code>key</code>.</td>
</tr>
<tr>
<td><code>memcached_cas(memc, key, key_length, value, value_length, expiration, flags, cas)</code></td>
<td>Overwrites the data for a given key as long as the corresponding <code>cas</code> value is still the same within the server.</td>
</tr>
<tr>
<td><code>memcached_set_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code></td>
<td>Similar to the generic <code>set()</code>, but has the option of an additional master key that can be used to identify an individual server.</td>
</tr>
<tr>
<td><code>memcached_add_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code></td>
<td>Similar to the generic <code>add()</code>, but has the option of an additional master key that can be used to identify an individual server.</td>
</tr>
<tr>
<td><code>memcached_replace_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code></td>
<td>Similar to the generic <code>replace()</code>, but has the option of an additional master key that can be used to identify an individual server.</td>
</tr>
<tr>
<td><code>memcached_prepend_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code></td>
<td>Similar to the <code>memcached_prepend()</code>, but has the option of an additional master key that can be used to identify an individual server.</td>
</tr>
<tr>
<td><code>memcached_append_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code></td>
<td>Similar to the <code>memcached_append()</code>, but has the option of an additional master key that can be used to identify an individual server.</td>
</tr>
<tr>
<td><code>memcached_cas_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code></td>
<td>Similar to the <code>memcached_cas()</code>, but has the option of an additional master key that can be used to identify an individual server.</td>
</tr>
</tbody>
</table>
Developing a **memcached** Application

<table>
<thead>
<tr>
<th><strong>libmemcached</strong> Function</th>
<th>Equivalent Core Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>key_length, value, value_length, expiration, flags)</td>
<td></td>
</tr>
</tbody>
</table>

The **by_key** methods add two further arguments that define the master key, to be used and applied during the hashing stage for selecting the servers. You can see this in the following definition:

```c
memcached_return memcached_set_by_key(memcached_st *ptr, const char *master_key, size_t master_key_length, const char *key, size_t key_length, const char *value, size_t value_length, time_t expiration, uint32_t flags);
```

All the functions return a value of type **memcached_return**, which you can compare against the **MEMCACHED_SUCCESS** constant.

### libmemcached Get Functions

The **libmemcached** functions provide both direct access to a single item, and a multiple-key request mechanism that provides much faster responses when fetching a large number of keys simultaneously.

The main get-style function, which is equivalent to the generic `get()` is `memcached_get()`. This function returns a string pointer, pointing to the value associated with the specified key.

```c
char *memcached_get (memcached_st *ptr, const char *key, size_t key_length, size_t *value_length, uint32_t *flags, memcached_return *error);
```

A multi-key get, `memcached_mget()`, is also available. Using a multiple key get operation is much quicker to do in one block than retrieving the key values with individual calls to `memcached_get()`. To start the multi-key get, call `memcached_mget()`:

```c
memcached_return memcached_mget (memcached_st *ptr, char **keys, size_t *key_length, unsigned int number_of_keys);
```

The return value is the success of the operation. The `keys` parameter should be an array of strings containing the keys, and `key_length` an array containing the length of each corresponding key. `number_of_keys` is the number of keys supplied in the array.

To fetch the individual values, use `memcached_fetch()` to get each corresponding value.

```c
char *memcached_fetch (memcached_st *ptr, const char *key, size_t *key_length, size_t *value_length, uint32_t *flags, memcached_return *error);
```

The function returns the key value, with the `key`, `key_length` and `value_length` parameters being populated with the corresponding key and length information. The function returns `NULL` when there are no more values to be returned. A full example, including the populating of the key data and the return of the information is provided here.
#include <stdio.h>
#include <string.h>
#include <unistd.h>
#include <libmemcached/memcached.h>

int main(int argc, char *argv[])
{
    memcached_server_st *servers = NULL;
    memcached_st *memc;
    memcached_return rc;
    char *keys[] = {"huey", "dewey", "louie"};
    size_t key_length[3];
    char *values[] = {"red", "blue", "green"};
    size_t value_length[3];
    unsigned int x;
    uint32_t flags;
    char return_key[MEMCACHED_MAX_KEY];
    size_t return_key_length;
    char *return_value;
    size_t return_value_length;

    memc = memcached_create(NULL);

    servers = memcached_server_list_append(servers, "localhost", 11211, &rc);
    rc = memcached_server_push(memc, servers);
    if (rc == MEMCACHED_SUCCESS)
        fprintf(stderr,"Added server successfully\n");
    else
        fprintf(stderr,"Couldn't add server: %s",memcached_strerror(memc, rc));

    for(x = 0; x < 3; x++)
    {
        key_length[x] = strlen(keys[x]);
        value_length[x] = strlen(values[x]);

        rc = memcached_set(memc, keys[x], key_length[x], values[x],
            value_length[x], (time_t)0, (uint32_t)0);
        if (rc == MEMCACHED_SUCCESS)
            fprintf(stderr,"Key %s stored successfully\n",keys[x]);
        else
            fprintf(stderr,"Couldn't store key: %s\n",memcached_strerror(memc, rc));
    }

    rc = memcached_mget(memc, keys, key_length, 3);
    if (rc == MEMCACHED_SUCCESS)
    {
        while ((return_value = memcached_fetch(memc, return_key, &return_key_length,
            &return_value_length, &flags, &rc)) != NULL)
        {
            if (rc == MEMCACHED_SUCCESS)
                fprintf(stderr,"Key %s returned %s\n",return_key, return_value);
        }
    }

    return 0;
}

Running the above application produces the following output:

```
shell> memc_multi_fetch
Added server successfully
Key huey stored successfully
Key dewey stored successfully
Key louie stored successfully
Key huey returned red
```
Developing a `memcached` Application

Controlling `libmemcached` Behaviors

The behavior of `libmemcached` can be modified by setting one or more behavior flags. These can either be set globally, or they can be applied during the call to individual functions. Some behaviors also accept an additional setting, such as the hashing mechanism used when selecting servers.

To set global behaviors:

```c
memcached_return
    memcached_behavior_set (memcached_st *ptr,
                     memcached_behavior flag,
                     uint64_t data);
```

To get the current behavior setting:

```c
uint64_t
    memcached_behavior_get (memcached_st *ptr,
                     memcached_behavior flag);
```

The following table describes `libmemcached` behavior flags.

<table>
<thead>
<tr>
<th>Behavior</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MEMCACHED_BEHAVIOR_NO_BLOCK</td>
<td>Caused <code>libmemcached</code> to use asynchronous I/O.</td>
</tr>
<tr>
<td>MEMCACHED_BEHAVIOR_TCP_NODELAY</td>
<td>Turns on no-delay for network sockets.</td>
</tr>
<tr>
<td>MEMCACHED_BEHAVIOR_HASH</td>
<td>Without a value, sets the default hashing algorithm for keys to use MD5. Other valid values include MEMCACHED_HASH_DEFAULT, MEMCACHED_HASH_MD5, MEMCACHED_HASH_CRC, MEMCACHED_HASH_FNV1_64, MEMCACHED_HASH_FNV1A_64, MEMCACHED_HASH_FNV1_32, and MEMCACHED_HASH_FNV1A_32.</td>
</tr>
<tr>
<td>MEMCACHED_BEHAVIOR_DISTRIBUTION</td>
<td>Changes the method of selecting the server used to store a given value. The default method is MEMCACHED_DISTRIBUTION_MODULA. You can enable consistent hashing by setting MEMCACHED_DISTRIBUTION_CONSISTENT. MEMCACHED_DISTRIBUTION_CONSISTENT is an alias for the value MEMCACHED_DISTRIBUTION_CONSISTENT_KETAMA.</td>
</tr>
<tr>
<td>MEMCACHED_BEHAVIOR_CACHE_LOOKUPS</td>
<td>Cache the lookups made to the DNS service. This can improve the performance if you are using names instead of IP addresses for individual hosts.</td>
</tr>
<tr>
<td>MEMCACHED_BEHAVIOR_SUPPORT_CAS</td>
<td>Support CAS operations. By default, this is disabled because it imposes a performance penalty.</td>
</tr>
<tr>
<td>MEMCACHED_BEHAVIOR_KETAMA</td>
<td>Sets the default distribution to MEMCACHED_DISTRIBUTION_CONSISTENT_KETAMA and the hash to MEMCACHED_HASH_MD5.</td>
</tr>
<tr>
<td>MEMCACHED_BEHAVIOR_POLL_TIMEOUT</td>
<td>Modify the timeout value used by <code>poll()</code>. Supply a signed <code>int</code> pointer for the timeout value.</td>
</tr>
<tr>
<td>MEMCACHED_BEHAVIOR_BUFFER_REQUESTS</td>
<td>Buffers IO requests instead of them being sent. A get operation, or closing the connection causes the data to be flushed.</td>
</tr>
<tr>
<td>MEMCACHED_BEHAVIOR_VERIFY_KEY</td>
<td>Forces <code>libmemcached</code> to verify that a specified key is valid.</td>
</tr>
</tbody>
</table>
Developing a **memcached** Application

<table>
<thead>
<tr>
<th>Behavior</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MEMCACHED_BEHAVIOR_SORT_HOSTS</td>
<td>If set, hosts added to the list of configured hosts for a memcached structure are placed into the host list in sorted order. This breaks consistent hashing if that behavior has been enabled.</td>
</tr>
<tr>
<td>MEMCACHED_BEHAVIOR_CONNECT_TIMEOUT</td>
<td>In nonblocking mode this changes the value of the timeout during socket connection.</td>
</tr>
</tbody>
</table>

**libmemcached Command-Line Utilities**

In addition to the main C library interface, **libmemcached** also includes a number of command-line utilities that can be useful when working with and debugging **memcached** applications.

All of the command-line tools accept a number of arguments, the most critical of which is **servers**, which specifies the list of servers to connect to when returning information.

The main tools are:

- **memcat**: Display the value for each ID given on the command line:

  ```
  shell> memcat --servers=localhost hwkey
  Hello world
  ```

- **memcp**: Copy the contents of a file into the cache, using the file name as the key:

  ```
  shell> echo "Hello World" > hwkey
  shell> memcp --servers=localhost hwkey
  shell> memcat --servers=localhost hwkey
  Hello world
  ```

- **memrm**: Remove an item from the cache:

  ```
  shell> memcat --servers=localhost hwkey
  Hello world
  shell> memrm --servers=localhost hwkey
  shell> memcat --servers=localhost hwkey
  ```

- **memslap**: Test the load on one or more **memcached** servers, simulating get/set and multiple client operations. For example, you can simulate the load of 100 clients performing get operations:

  ```
  shell> memslap --servers=localhost --concurrency=100 --flush --test=get
  memslap --servers=localhost --concurrency=100 --flush --test=set Threads connecting to servers 100
  Took 13.571 seconds to read data
  ```

- **memflush**: Flush (empty) the contents of the **memcached** cache.

  ```
  shell> memflush --servers=localhost
  ```

**15.3.3.4 Using MySQL and **memcached** with Perl**

The **Cache::Memcached** module provides a native interface to the Memcache protocol, and provides support for the core functions offered by **memcached**. Install the module using your operating system’s package management system, or using **CPAN**:

```
root-shell> perl -MCPAN -e 'install Cache::Memcached'
```

To use **memcached** from Perl through the **Cache::Memcached** module, first create a new **Cache::Memcached** object that defines the list of servers and other parameters for the connection.
The only argument is a hash containing the options for the cache interface. For example, to create a new instance that uses three memcached servers:

```perl
use Cache::Memcached;
my $cache = new Cache::Memcached {
    'servers' => [
        '192.168.0.100:11211',
        '192.168.0.101:11211',
        '192.168.0.102:11211',
    ],
};
```

**Note**

When using the Cache::Memcached interface with multiple servers, the API automatically performs certain operations across all the servers in the group. For example, getting statistical information through Cache::Memcached returns a hash that contains data on a host-by-host basis, as well as generalized statistics for all the servers in the group.

You can set additional properties on the cache object instance when it is created by specifying the option as part of the option hash. Alternatively, you can use a corresponding method on the instance:

- **servers** or method `set_servers()`: Specifies the list of the servers to be used. The servers list should be a reference to an array of servers, with each element as the address and port number combination (separated by a colon). You can also specify a local connection through a Unix socket (for example /tmp/sock/memcached). To specify the server with a weight (indicating how much more frequently the server should be used during hashing), specify an array reference with the memcached server instance and a weight number. Higher numbers give higher priority.

- **compress_threshold** or method `set_compress_threshold()`: Specifies the threshold when values are compressed. Values larger than the specified number are automatically compressed (using zlib) during storage and retrieval.

- **no_rehash** or method `set_norehash()`: Disables finding a new server if the original choice is unavailable.

- **readonly** or method `set_readonly()`: Disables writes to the memcached servers.

Once the Cache::Memcached object instance has been configured, you can use the set() and get() methods to store and retrieve information from the memcached servers. Objects stored in the cache are automatically serialized and deserialized using the Storable module.

The Cache::Memcached interface supports the following methods for storing/retrieving data, and relate to the generic methods as shown in the table.

<table>
<thead>
<tr>
<th>Cache::Memcached Function</th>
<th>Equivalent Generic Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>get()</td>
<td>Generic get().</td>
</tr>
<tr>
<td>get_multi(keys)</td>
<td>Gets multiple keys from memcache using just one query. Returns a hash reference of key/value pairs.</td>
</tr>
<tr>
<td>set()</td>
<td>Generic set().</td>
</tr>
<tr>
<td>add()</td>
<td>Generic add().</td>
</tr>
<tr>
<td>replace()</td>
<td>Generic replace().</td>
</tr>
<tr>
<td>delete()</td>
<td>Generic delete().</td>
</tr>
<tr>
<td>incr()</td>
<td>Generic incr().</td>
</tr>
</tbody>
</table>
Developing a `memcached` Application

### Cache::Memcached Function  Equivalent Generic Method

| `decr()`                      | Generic `decr()` |

Below is a complete example for using `memcached` with Perl and the `Cache::Memcached` module:

```perl
#!/usr/bin/perl
use Cache::Memcached;
use DBI;
use Data::Dumper;

# Configure the memcached server
my $cache = new Cache::Memcached {
    'servers' => ['localhost:11211'],
};

# Get the film name from the command line
# memcached keys must not contain spaces, so create
# a key name by replacing spaces with underscores
my $filmname = shift or die 'Must specify the film name\n';
my $filmkey = $filmname;
$filmkey =~ s/ /_/;

# Load the data from the cache
my $filmdata = $cache->get($filmkey);

# If the data wasn't in the cache, then we load it from the database
if (!defined($filmdata))
{
    $filmdata = load_filmdata($filmname);
    if (defined($filmdata))
    {
        # Set the data into the cache, using the key
        if ($cache->set($filmkey,$filmdata))
        {
            print STDERR "Film data loaded from database and cached\n";
        }
        else
        {
            print STDERR "Couldn't store to cache\n";
        }
    }
    else
    {
        die "Couldn't find $filmname\n";
    }
}
else
{
    print STDERR "Film data loaded from Memcached\n";
}

sub load_filmdata
{
    my ($filmname) = @_;
    my $dsn = "DBI:mysql:database=sakila;host=localhost;port=3306";
    $dbh = DBI->connect($dsn, 'sakila','password');
    my ($filmbase) = $dbh->selectrow_hashref(sprintf('select * from film where title = %s', $filmname));
    $filmdata = $filmbase;
}
```

```
Developing a **memcached** Application

```php
$dbh->quote($filmname));

if (!defined($filmname))
{
  return (undef);
}

$filmbase->{stars} =
$dbh->selectall_arrayref(sprintf('select concat(first_name," ",last_name) ' .
  'from film_actor left join (actor) ' .
  'on (film_actor.actor_id = actor.actor_id) ' .
  ' where film_id=%s',
  $dbh->quote($filmbase->{film_id})));

return($filmbase);
}
```

The example uses the Sakila database, obtaining film data from the database and writing a composite record of the film and actors to **memcached**. When calling it for a film does not exist, you get this result:

```
shell> memcached-sakila.pl "ROCK INSTINCT"
Film data loaded from database and cached
```

When accessing a film that has already been added to the cache:

```
shell> memcached-sakila.pl "ROCK INSTINCT"
Film data loaded from Memcached
```

15.3.3.5 Using MySQL and **memcached** with Python

The Python **memcache** module interfaces to **memcached** servers, and is written in pure Python (that is, without using one of the C APIs). You can download and install a copy from **Python Memcached**.

To install, download the package and then run the Python installer:

```
python setup.py install
running install
running bdist_egg
running egg_info
creating python_memcached.egg-info
...,
removing 'build/bdist.linux-x86_64/egg' (and everything under it)
Processing python_memcached-1.43-py2.4.egg
creating /usr/lib64/python2.4/site-packages/python_memcached-1.43-py2.4.egg
Extracting python_memcached-1.43-py2.4.egg to /usr/lib64/python2.4/site-packages
Adding python-memcached 1.43 to easy-install.pth file
Installed /usr/lib64/python2.4/site-packages/python_memcached-1.43-py2.4.egg
Processing dependencies for python-memcached==1.43
Finished processing dependencies for python-memcached==1.43
```

Once installed, the **memcache** module provides a class-based interface to your **memcached** servers. When you store Python data structures as **memcached** items, they are automatically serialized (turned into string values) using the Python **cPickle** or **pickle** modules.

To create a new **memcache** interface, import the **memcache** module and create a new instance of the **memcache.Client** class. For example, if the **memcached** daemon is running on localhost using the default port:

```
import memcache
memc = memcache.Client(["127.0.0.1:11211"])
```

The first argument is an array of strings containing the server and port number for each **memcached** instance to use. To enable debugging, set the optional **debug** parameter to 1.
By default, the hashing mechanism used to divide the items among multiple servers is \texttt{crc32}. To change the function used, set the value of \texttt{memcache.serverHashFunction} to the alternate function to use. For example:

```python
from zlib import adler32
memcache.serverHashFunction = adler32
```

Once you have defined the servers to use within the \texttt{memcache} instance, the core functions provide the same functionality as in the generic interface specification. The following table provides a summary of the supported functions:

<table>
<thead>
<tr>
<th>Python \texttt{memcache} Function</th>
<th>Equivalent Generic Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{get()}</td>
<td>Generic \texttt{get().}</td>
</tr>
<tr>
<td>\texttt{get_multi(keys)}</td>
<td>Gets multiple values from the supplied array of keys. Returns a hash reference of key/value pairs.</td>
</tr>
<tr>
<td>\texttt{set()}</td>
<td>Generic \texttt{set().}</td>
</tr>
<tr>
<td>\texttt{set_multi(dict [, expiry [, key_prefix]])}</td>
<td>Sets multiple key/value pairs from the supplied dict.</td>
</tr>
<tr>
<td>\texttt{add()}</td>
<td>Generic \texttt{add().}</td>
</tr>
<tr>
<td>\texttt{replace()}</td>
<td>Generic \texttt{replace().}</td>
</tr>
<tr>
<td>\texttt{prepend(key, value [, expiry])}</td>
<td>Prepends the supplied value to the value of the existing key.</td>
</tr>
<tr>
<td>\texttt{append(key, value [, expiry]}</td>
<td>Appends the supplied value to the value of the existing key.</td>
</tr>
<tr>
<td>\texttt{delete()}</td>
<td>Generic \texttt{delete().}</td>
</tr>
<tr>
<td>\texttt{delete_multi(keys [, expiry [, key_prefix]])}</td>
<td>Deletes all the keys from the hash matching each string in the array keys.</td>
</tr>
<tr>
<td>\texttt{incr()}</td>
<td>Generic \texttt{incr().}</td>
</tr>
<tr>
<td>\texttt{decr()}</td>
<td>Generic \texttt{decr().}</td>
</tr>
</tbody>
</table>

\textbf{Note}

Within the Python \texttt{memcache} module, all the \texttt{*_multi()} functions support an optional \texttt{key_prefix} parameter. If supplied, then the string is used as a prefix to all key lookups. For example, if you call:

```python
memc.get_multi(['a','b'], key_prefix='users:')
```

The function retrieves the keys \texttt{users:a} and \texttt{users:b} from the servers.

Here is an example showing the storage and retrieval of information to a \texttt{memcache} instance, loading the raw data from MySQL:

```python
import sys
import MySQLdb
import memcache

memc = memcache.Client(['127.0.0.1:11211'], debug=1);
try:
    conn = MySQLdb.connect (host = "localhost",
                           user = "sakila",
                           passwd = "password",
                           db = "sakila")
except MySQLdb.Error, e:
```
print "Error %d: %s" % (e.args[0], e.args[1])
sys.exit (1)

popularfilms = memc.get('top5films')

if not popularfilms:
    cursor = conn.cursor()
    cursor.execute('select film_id,title from film order by rental_rate desc limit 5')
    rows = cursor.fetchall()
    memc.set('top5films',rows,60)
    print "Updated memcached with MySQL data"
else:
    print "Loaded data from memcached"
    for row in popularfilms:
        print "%s, %s" % (row[0], row[1])

When executed for the first time, the data is loaded from the MySQL database and stored to the memcached server.

shell> python memc_python.py
Updated memcached with MySQL data

Because the data is automatically serialized using cPickle/pickle, when you load the data back from memcached, you can use the object directly. In the example above, the information stored to memcached is in the form of rows from a Python DB cursor. When accessing the information (within the 60 second expiry time), the data is loaded from memcached and dumped:

shell> python memc_python.py
Loaded data from memcached
2, ACE GOLDFINGER
7, AIRPLANE SIERRA
8, AIRPORT POLLOCK
10, ALADDIN CALENDAR
13, ALI FOREVER

The serialization and deserialization happens automatically. Because serialization of Python data may be incompatible with other interfaces and languages, you can change the serialization module used during initialization. For example, you might use JSON format when you store complex data structures using a script written in one language, and access them in a script written in a different language.

15.3.3.6 Using MySQL and memcached with PHP

PHP provides support for the Memcache functions through a PECL extension. To enable the PHP memcache extensions, build PHP using the --enable-memcache option to configure when building from source.

If you are installing on a Red Hat-based server, you can install the php-pecl-memcache RPM:

root-shell> yum --install php-pecl-memcache

On Debian-based distributions, use the php-memcache package.

To set global runtime configuration options, specify the configuration option values within your php.ini file. The following table provides the name, default value, and a description for each global runtime configuration option.

<table>
<thead>
<tr>
<th>Configuration option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>memcache.allow_failover</td>
<td>1</td>
<td>Specifies whether another server in the list should be queried if the first server selected fails.</td>
</tr>
<tr>
<td>memcache.max_failover_attempts</td>
<td>20</td>
<td>Specifies the number of servers to try before returning a failure.</td>
</tr>
</tbody>
</table>
Developing a `memcached` Application

<table>
<thead>
<tr>
<th>Configuration option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>memcache.chunk_size</code></td>
<td>8192</td>
<td>Defines the size of network chunks used to exchange data with the <code>memcached</code> server.</td>
</tr>
<tr>
<td><code>memcache.default_port</code></td>
<td>11211</td>
<td>Defines the default port to use when communicating with the <code>memcached</code> servers.</td>
</tr>
<tr>
<td><code>memcache.hash_strategy</code></td>
<td>standard</td>
<td>Specifies which hash strategy to use. Set to <code>consistent</code> to enable servers to be added or removed from the pool without causing the keys to be remapped to other servers. When set to <code>standard</code>, an older (modula) strategy is used that potentially uses different servers for storage.</td>
</tr>
<tr>
<td><code>memcache.hash_function</code></td>
<td>crc32</td>
<td>Specifies which function to use when mapping keys to servers. <code>crc32</code> uses the standard CRC32 hash. <code>fnv</code> uses the FNV-1a hashing algorithm.</td>
</tr>
</tbody>
</table>

To create a connection to a `memcached` server, create a new `Memcache` object and then specify the connection options. For example:

```php
<?php
    $cache = new Memcache;
    $cache->connect('localhost',11211);
?>
```

This opens an immediate connection to the specified server.

To use multiple `memcached` servers, you need to add servers to the memcache object using `addServer()`:

```php
bool Memcache::addServer ( string $host [, int $port [, bool $persistent [, int $weight [, int $timeout [, int $retry_interval [, bool $status [, callback $failure_callback ]]]]]]] )
```

The server management mechanism within the `php-memcache` module is a critical part of the interface as it controls the main interface to the `memcached` instances and how the different instances are selected through the hashing mechanism.

To create a simple connection to two `memcached` instances:

```php
<?php
    $cache = new Memcache;
    $cache->addServer('192.168.0.100',11211);
    $cache->addServer('192.168.0.101',11211);
?>
```

In this scenario, the instance connection is not explicitly opened, but only opened when you try to store or retrieve a value. To enable persistent connections to `memcached` instances, set the `$persistent` argument to true. This is the default setting, and causes the connections to remain open.

To help control the distribution of keys to different instances, use the global `memcache.hash_strategy` setting. This sets the hashing mechanism used to select. You can also add another weight to each server, which effectively increases the number of times the instance entry appears in the instance list, therefore increasing the likelihood of the instance being chosen over other instances. To set the weight, set the value of the `$weight` argument to more than one.
The functions for setting and retrieving information are identical to the generic functional interface offered by memcached, as shown in this table:

<table>
<thead>
<tr>
<th>PECL memcache Function</th>
<th>Generic Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>get()</td>
<td>Generic get().</td>
</tr>
<tr>
<td>set()</td>
<td>Generic set().</td>
</tr>
<tr>
<td>add()</td>
<td>Generic add().</td>
</tr>
<tr>
<td>replace()</td>
<td>Generic replace().</td>
</tr>
<tr>
<td>delete()</td>
<td>Generic delete().</td>
</tr>
<tr>
<td>increment()</td>
<td>Generic incr().</td>
</tr>
<tr>
<td>decrement()</td>
<td>Generic decr().</td>
</tr>
</tbody>
</table>

A full example of the PECL memcache interface is provided below. The code loads film data from the Sakila database when the user provides a film name. The data stored into the memcached instance is recorded as a mysqli result row, and the API automatically serializes the information for you.

```php
<?php
$memc = new Memcache;
$memc->addServer('localhost','11211');
if(empty($_POST['film'])) {
} else {
    echo "Loading data...
";
    $film   = htmlspecialchars($_POST['film'], ENT_QUOTES, 'UTF-8');
    $mfilms = $memc->get($film);
    if ($mfilms) {
        printf("Film data for %s loaded from memcache\n", $mfilms['title']);
        foreach (array_keys($mfilms) as $key) {
            printf("%s: %s\n", $key, $mfilms[$key]);
        }
    } else {
        $mysqli = mysqli('localhost','sakila','password','sakila');
        if (mysqli_connect_error()) {
            sprintf("Database error: (%d) %s", mysqli_connect_errno(), mysqli_connect_error());
            exit;
        }
        $sql = sprintf('SELECT * FROM film WHERE title="%s"', $mysqli->real_escape_string($film));
        $result = $mysqli->query($sql);
```
With PHP, the connections to the memcached instances are kept open as long as the PHP and associated Apache instance remain running. When adding or removing servers from the list in a running instance (for example, when starting another script that mentions additional servers), the connections are shared, but the script only selects among the instances explicitly configured within the script.

To ensure that changes to the server list within a script do not cause problems, make sure to use the consistent hashing mechanism.

15.3.3.7 Using MySQL and memcached with Ruby

There are a number of different modules for interfacing to memcached within Ruby. The Ruby-MemCache client library provides a native interface to memcached that does not require any external libraries, such as libmemcached. You can obtain the installer package from [http://www.deveiate.org/projects/RMemCache](http://www.deveiate.org/projects/RMemCache).

To install, extract the package and then run `install.rb`:

```
shell> install.rb
```

If you have RubyGems, you can install the Ruby-MemCache gem:

```
shell> gem install Ruby-MemCache
Bulk updating Gem source index for: http://gems.rubyforge.org
Install required dependency io-reactor? [Yn]  y
Successfully installed Ruby-MemCache-0.0.1
Successfully installed io-reactor-0.05
Installing ri documentation for io-reactor-0.05...
Installing RDoc documentation for io-reactor-0.05...
```

To use a memcached instance from within Ruby, create a new instance of the MemCache object:

```
require 'memcache'
memc = MemCache::new '192.168.0.100:11211'
```

You can add a weight to each server to increase the likelihood of the server being selected during hashing by appending the weight count to the server host name/port string:

```
require 'memcache'
memc = MemCache::new '192.168.0.100:11211:3'
```

To add servers to an existing list, you can append them directly to the MemCache object:

```
memc += ['192.168.0.101:11211']
```
To set data into the cache, you can just assign a value to a key within the new cache object, which works just like a standard Ruby hash object:

```ruby
memc["key"] = "value"
```

Or to retrieve the value:

```ruby
print memc["key"]
```

For more explicit actions, you can use the method interface, which mimics the main `memcached` API functions, as summarized in the following table:

<table>
<thead>
<tr>
<th>Ruby  Method</th>
<th>Equivalent <code>memcached</code> API Functions</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>get()</code></td>
<td>Generic <code>get()</code></td>
</tr>
<tr>
<td><code>get_many</code></td>
<td>Get the values of multiple keys, returning the information as a hash of the keys and their values.</td>
</tr>
<tr>
<td><code>set()</code></td>
<td>Generic <code>set()</code></td>
</tr>
<tr>
<td><code>set_many</code></td>
<td>Set the values of the keys and values in the hash pairs.</td>
</tr>
<tr>
<td><code>add()</code></td>
<td>Generic <code>add()</code></td>
</tr>
<tr>
<td><code>delete()</code></td>
<td>Generic <code>delete()</code></td>
</tr>
<tr>
<td><code>incr()</code></td>
<td>Generic <code>incr()</code></td>
</tr>
<tr>
<td><code>decr()</code></td>
<td>Generic <code>decr()</code></td>
</tr>
</tbody>
</table>

### 15.3.3.8 Using MySQL and `memcached` with Java

The `com.danga.MemCached` class within Java provides a native interface to `memcached` instances. You can obtain the client from https://github.com/gwhalin/Memcached-Java-Client/downloads. The Java class uses hashes that are compatible with `libmemcached`, so you can mix and match Java and `libmemcached` applications accessing the same `memcached` instances. The serialization between Java and other interfaces are not compatible. If this is a problem, use JSON or a similar nonbinary serialization format.

On most systems, you can download the package and use the `jar` directly.

To use the `com.danga.MemCached` interface, you create a `MemCachedClient` instance and then configure the list of servers by configuring the `SockIOPool`. Through the pool specification you set up the server list, weighting, and the connection parameters to optimized the connections between your client and the `memcached` instances that you configure.

Generally, you can configure the `memcached` interface once within a single class, then use this interface throughout the rest of your application.

For example, to create a basic interface, first configure the `MemCachedClient` and base `SockIOPool` settings:

```java
public class MyClass {
    protected static MemCachedClient mcc = new MemCachedClient();

    static {
        String[] servers = {
            "localhost:11211",
        };
```
Developing a **memcached** Application

In the above sample, the list of servers is configured by creating an array of the **memcached** instances to use. You can then configure individual weights for each server.

The remainder of the properties for the connection are optional, but you can set the connection numbers (initial connections, minimum connections, maximum connections, and the idle timeout) by setting the pool parameters:

```java
pool.setInitConn( 5 );
pool.setMinConn( 5 );
pool.setMaxConn( 250 );
pool.setMaxIdle( 1000 * 60 * 60 * 6
```

Once the parameters have been configured, initialize the connection pool:

```java
pool.initialize();
```

The pool, and the connection to your **memcached** instances should now be ready to use.

To set the hashing algorithm used to select the server used when storing a given key, use `pool.setHashingAlg()`:

```java
pool.setHashingAlg( SockIOPool.NEW_COMPAT_HASH );
```

Valid values are `NEW_COMPAT_HASH`, `OLD_COMPAT_HASH` and `NATIVE_HASH` are also basic modula hashing algorithms. For a consistent hashing algorithm, use `CONSISTENT_HASH`. These constants are equivalent to the corresponding hash settings within `libmemcached`.

The following table outlines the Java `com.danga.MemCached` methods and the equivalent generic methods in the `memcached` interface specification.

<table>

### 15.3.3.9 Using the **memcached** TCP Text Protocol

Communicating with a **memcached** server can be achieved through either the TCP or UDP protocols. When using the TCP protocol, you can use a simple text based interface for the exchange of information.
When communicating with memcached, you can connect to the server using the port configured for the server. You can open a connection with the server without requiring authorization or login. As soon as you have connected, you can start to send commands to the server. When you have finished, you can terminate the connection without sending any specific disconnection command. Clients are encouraged to keep their connections open to decrease latency and improve performance.

Data is sent to the memcached server in two forms:

- Text lines, which are used to send commands to the server, and receive responses from the server.
- Unstructured data, which is used to receive or send the value information for a given key. Data is returned to the client in exactly the format it was provided.

Both text lines (commands and responses) and unstructured data are always terminated with the string `\r\n`. Because the data being stored may contain this sequence, the length of the data (returned by the client before the unstructured data is transmitted should be used to determine the end of the data.

Commands to the server are structured according to their operation:

- **Storage commands**: set, add, replace, append, prepend, cas

  Storage commands to the server take the form:

  ```
  command key [flags] [exptime] length [noreply]
  ```

  Or when using compare and swap (cas):

  ```
  cas key [flags] [exptime] length [casunique] [noreply]
  ```

  Where:

  - **command**: The command name.
    - **set**: Store value against key
    - **add**: Store this value against key if the key does not already exist
    - **replace**: Store this value against key if the key already exists
    - **append**: Append the supplied value to the end of the value for the specified key. The flags and exptime arguments should not be used.
    - **prepend**: Append value currently in the cache to the end of the supplied value for the specified key. The flags and exptime arguments should not be used.
    - **cas**: Set the specified key to the supplied value, only if the supplied casunique matches. This is effectively the equivalent of change the information if nobody has updated it since I last fetched it.
  - **key**: The key. All data is stored using a the specific key. The key cannot contain control characters or whitespace, and can be up to 250 characters in size.
  - **flags**: The flags for the operation (as an integer). Flags in memcached are transparent. The memcached server ignores the contents of the flags. They can be used by the client to indicate any type of information. In memcached 1.2.0 and lower the value is a 16-bit integer value. In memcached 1.2.1 and higher the value is a 32-bit integer.
  - **exptime**: The expiry time, or zero for no expiry.
  - **length**: The length of the supplied value block in bytes, excluding the terminating `\r\n` characters.
• **casunique**: A unique 64-bit value of an existing entry. This is used to compare against the existing value. Use the value returned by the `gets` command when issuing `cas` updates.

• **noreply**: Tells the server not to reply to the command.

For example, to store the value `abcdef` into the key `xyzkey`, you would use:

```plaintext
set xyzkey 0 0 6\r\nabcdef\r\n```

The return value from the server is one line, specifying the status or error information. For more information, see Table 15.3, "memcached Protocol Responses".

• **Retrieval commands**: `get`, `gets`

Retrieval commands take the form:

```plaintext
get key1 [key2 .... keyn]
gets key1 [key2 ... keyn]
```

You can supply multiple keys to the commands, with each requested key separated by whitespace.

The server responds with an information line of the form:

```plaintext
VALUE key flags bytes [casunique]
```

Where:

• **key**: The key name.

• **flags**: The value of the flag integer supplied to the `memcached` server when the value was stored.

• **bytes**: The size (excluding the terminating `\r\n` character sequence) of the stored value.

• **casunique**: The unique 64-bit integer that identifies the item.

The information line is immediately followed by the value data block. For example:

```plaintext
get xyzkey\r\nVALUE xyzkey 0 6\r\nabcdef\r\n```

If you have requested multiple keys, an information line and data block is returned for each key found. If a requested key does not exist in the cache, no information is returned.

• **Delete commands**: `delete`

Deletion commands take the form:

```plaintext
delete key [time] [noreply]
```

Where:

• **key**: The key name.

• **time**: The time in seconds (or a specific Unix time) for which the client wishes the server to refuse `add` or `replace` commands on this key. All `add`, `replace`, `get`, and `gets` commands fail during this period. `set` operations succeed. After this period, the key is deleted permanently and all commands are accepted.
If not supplied, the value is assumed to be zero (delete immediately).

- **noreply**: Tells the server not to reply to the command.

Responses to the command are either **DELETED** to indicate that the key was successfully removed, or **NOT_FOUND** to indicate that the specified key could not be found.

- **Increment/Decrement**: **incr**, **decr**

The increment and decrement commands change the value of a key within the server without performing a separate get/set sequence. The operations assume that the currently stored value is a 64-bit integer. If the stored value is not a 64-bit integer, then the value is assumed to be zero before the increment or decrement operation is applied.

Increment and decrement commands take the form:

```
incr key value [noreply]
decr key value [noreply]
```

Where:

- **key**: The key name.
- **value**: An integer to be used as the increment or decrement value.
- **noreply**: Tells the server not to reply to the command.

The response is:

- **NOT_FOUND**: The specified key could not be located.
- **value**: The new value associated with the specified key.

Values are assumed to be unsigned. For **decr** operations, the value is never decremented below 0. For **incr** operations, the value wraps around the 64-bit maximum.

- **Statistics commands**: **stats**

The **stats** command provides detailed statistical information about the current status of the **memcached** instance and the data it is storing.

Statistics commands take the form:

```
STAT [name] [value]
```

Where:

- **name**: The optional name of the statistics to return. If not specified, the general statistics are returned.
- **value**: A specific value to be used when performing certain statistics operations.

The return value is a list of statistics data, formatted as follows:

```
STAT name value
```

The statistics are terminated with a single line, **END**.

For more information, see Section 15.3.4, “Getting **memcached** Statistics”.
For reference, a list of the different commands supported and their formats is provided below.

Table 15.2 memcached Command Reference

<table>
<thead>
<tr>
<th>Command</th>
<th>Command Formats</th>

15.3.4 Getting **memcached** Statistics

The `memcached` system has a built-in statistics system that collects information about the data being stored into the cache, cache hit ratios, and detailed information on the memory usage and distribution of information through the slab allocation used to store individual items. Statistics are provided at both a basic level that provide the core statistics, and more specific statistics for specific areas of the `memcached` server.

This information can be useful to ensure that you are getting the correct level of cache and memory usage, and that your slab allocation and configuration properties are set at an optimal level.

The stats interface is available through the standard `memcached` protocol, so the reports can be accessed by using `telnet` to connect to the `memcached`. The supplied `memcached-tool` includes support for obtaining the Section 15.3.4.2, "`memcached` Slabs Statistics" and Section 15.3.4.1, "`memcached` General Statistics" information. For more information, see Section 15.3.4.6, "Using `memcached-tool`".

Alternatively, most of the language API interfaces provide a function for obtaining the statistics from the server.

For example, to get the basic stats using `telnet`:

```
shell> telnet localhost 11211
Trying ::1...
Connected to localhost.
Escape character is '"].
stats
STAT pid 23599
STAT uptime 675
STAT time 1211439587
STAT version 1.2.5
STAT pointer_size 32
STAT rusage_user 1.404992
STAT rusage_system 4.694685
STAT curr_items 32
STAT total_items 56361
STAT bytes 2642
STAT curr_connections 53
STAT total_connections 438
STAT connection_structures 55
STAT cmd_get 113482
STAT cmd_set 80519
STAT get_hits 78926
STAT get_misses 34556
STAT evictions 0
STAT bytes_read 6379783
STAT bytes_written 4860179
STAT limit_maxbytes 67108864
STAT threads 1
END
```

When using Perl and the `Cache::Memcached` module, the `stats()` function returns information about all the servers currently configured in the connection object, and total statistics for all the `memcached` servers as a whole.

For example, the following Perl script obtains the stats and dumps the hash reference that is returned:

```perl
use Cache::Memcached;
use Data::Dumper;

my $memc = new Cache::Memcached;
```
Getting memcached Statistics

```perl
$memc->set_servers(@ARGV);
print Dumper($memc->stats());
```

When executed on the same memcached as used in the Telnet example above we get a hash reference with the host by host and total statistics:

```perl
$VAR1 = {
    'hosts' => {
        'localhost:11211' => {
            'misc' => {
                'bytes' => '2421',
                'curr_connections' => '3',
                'connection_structures' => '56',
                'pointer_size' => '32',
                'time' => '1211440166',
                'total_items' => '410956',
                'cmd_set' => '588167',
                'bytes_written' => '35715151',
                'evictions' => '0',
                'curr_items' => '31',
                'pid' => '23599',
                'limit_maxbytes' => '67108864',
                'uptime' => '1254',
                'rusage_user' => '9.857805',
                'cmd_get' => '838451',
                'rusage_system' => '34.096988',
                'version' => '1.2.5',
                'get_hits' => '581511',
                'bytes_read' => '46665716',
                'threads' => '1',
                'total_connections' => '3104',
                'get_misses' => '256940'
            },
            'sizes' => {
                '128' => '16',
                '64' => '15'
            }
        }
    },
    'self' => {},
    'total' => {
        'cmd_get' => '838451',
        'bytes' => '2421',
        'get_hits' => '581511',
        'connection_structures' => '56',
        'bytes_read' => '46665716',
        'total_items' => '410956',
        'total_connections' => '3104',
        'cmd_set' => '588167',
        'bytes_written' => '35715151',
        'curr_items' => '31',
        'get_misses' => '256940'
    }
};
```

The statistics are divided up into a number of distinct sections, and then can be requested by adding the type to the `stats` command. Each statistics output is covered in more detail in the following sections:

- General statistics, see Section 15.3.4.1, “memcached General Statistics”.
- Slab statistics (slabs), see Section 15.3.4.2, “memcached Slabs Statistics”.
- Item statistics (items), see Section 15.3.4.3, “memcached Item Statistics”.
- Size statistics (sizes), see Section 15.3.4.4, “memcached Size Statistics”.
- Detailed status (detail), see Section 15.3.4.5, “memcached Detail Statistics”.
15.3.4.1 **memcached** General Statistics

The output of the general statistics provides an overview of the performance and use of the **memcached** instance. The statistics returned by the command and their meaning is shown in the following table.

The following terms are used to define the value type for each statistics value:

- **32u**: 32-bit unsigned integer
- **64u**: 64-bit unsigned integer
- **32u:32u**: Two 32-bit unsigned integers separated by a colon
- **String**: Character string

<tr>
<td>conn_yields</td>
<td>64u</td>
<td>Number of yields for connections (related to the (-R) option).</td>
<td>1.4.0</td>
</tr>
</tbody>
</table>

The most useful statistics from those given here are the number of cache hits, misses, and evictions.

A large number of `get_misses` may just be an indication that the cache is still being populated with information. The number should, over time, decrease in comparison to the number of cache `get_hits`. If, however, you have a large number of cache misses compared to cache hits after an extended period of execution, it may be an indication that the size of the cache is too small and you either need to increase the total memory size, or increase the number of the `memcached` instances to improve the hit ratio.

A large number of `evictions` from the cache, particularly in comparison to the number of items stored, is a sign that your cache is too small to hold the amount of information that you regularly want to keep cached. Instead of items being retained in the cache, items are being evicted to make way for new items keeping the turnover of items in the cache high, reducing the efficiency of the cache.

#### 15.3.4.2 memcached Slabs Statistics

To get the `slabs` statistics, use the `stats slabs` command, or the API equivalent.

The slab statistics provide you with information about the slabs that have created and allocated for storing information within the cache. You get information both on each individual slab-class and total statistics for the whole slab.

```plaintext
STAT 1:chunk_size 104
STAT 1:chunks_per_page 10082
STAT 1:total_pages 1
STAT 1:total_chunks 10082
STAT 1:used_chunks 10081
STAT 1:free_chunks 1
STAT 1:free_chunks_end 10079
STAT 9:chunk_size 696
STAT 9:chunks_per_page 1506
STAT 9:total_pages 63
STAT 9:total_chunks 94878
STAT 9:used_chunks 94878
STAT 9:free_chunks 0
STAT 9:free_chunks_end 0
STAT active_slabs 2
```
Individual stats for each slab class are prefixed with the slab ID. A unique ID is given to each allocated slab from the smallest size up to the largest. The prefix number indicates the slab class number in relation to the calculated chunk from the specified growth factor. Hence in the example, 1 is the first chunk size and 9 is the 9th chunk allocated size.

The parameters returned for each chunk size and a description of each parameter are provided in the following table.

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>chunk_size</td>
<td>Space allocated to each chunk within this slab class.</td>
<td></td>
</tr>
<tr>
<td>chunks_per_page</td>
<td>Number of chunks within a single page for this slab class.</td>
<td></td>
</tr>
<tr>
<td>total_pages</td>
<td>Number of pages allocated to this slab class.</td>
<td></td>
</tr>
<tr>
<td>total_chunks</td>
<td>Number of chunks allocated to the slab class.</td>
<td></td>
</tr>
<tr>
<td>used_chunks</td>
<td>Number of chunks allocated to an item.</td>
<td></td>
</tr>
<tr>
<td>free_chunks</td>
<td>Number of chunks not yet allocated to items.</td>
<td></td>
</tr>
<tr>
<td>free_chunks_end</td>
<td>Number of free chunks at the end of the last allocated page.</td>
<td></td>
</tr>
<tr>
<td>get_hits</td>
<td>Number of get hits to this chunk</td>
<td>1.3.x</td>
</tr>
<tr>
<td>cmd_set</td>
<td>Number of set commands on this chunk</td>
<td>1.3.x</td>
</tr>
<tr>
<td>delete_hits</td>
<td>Number of delete hits to this chunk</td>
<td>1.3.x</td>
</tr>
<tr>
<td>incr_hits</td>
<td>Number of increment hits to this chunk</td>
<td>1.3.x</td>
</tr>
<tr>
<td>decr_hits</td>
<td>Number of decrement hits to this chunk</td>
<td>1.3.x</td>
</tr>
<tr>
<td>cas_hits</td>
<td>Number of CAS hits to this chunk</td>
<td>1.3.x</td>
</tr>
<tr>
<td>cas_badval</td>
<td>Number of CAS hits on this chunk where the existing value did not match</td>
<td>1.3.x</td>
</tr>
<tr>
<td>mem_requested</td>
<td>The true amount of memory of memory requested within this chunk</td>
<td>1.4.1</td>
</tr>
</tbody>
</table>

The following additional statistics cover the information for the entire server, rather than on a chunk by chunk basis:

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>active_slabs</td>
<td>Total number of slab classes allocated.</td>
<td></td>
</tr>
<tr>
<td>total_malloced</td>
<td>Total amount of memory allocated to slab pages.</td>
<td></td>
</tr>
</tbody>
</table>

The key values in the slab statistics are the chunk_size, and the corresponding total_chunks and used_chunks parameters. These given an indication of the size usage of the chunks within the system. Remember that one key/value pair is placed into a chunk of a suitable size.

From these stats, you can get an idea of your size and chunk allocation and distribution. If you store many items with a number of largely different sizes, consider adjusting the chunk size growth factor to increase in larger steps to prevent chunk and memory wastage. A good indication of a bad growth factor is a high number of different slab classes, but with relatively few chunks actually in use within each slab. Increasing the growth factor creates fewer slab classes and therefore makes better use of the allocated pages.

**15.3.4.3 memcached Item Statistics**

To get the items statistics, use the stats items command, or the API equivalent.
The **items** statistics give information about the individual items allocated within a given slab class.

```
STAT items:2:number 1
STAT items:2:age 452
STAT items:2:evicted 0
STAT items:2:evicted_nonzero 0
STAT items:2:evicted_time 2
STAT items:2:outofmemory 0
STAT items:2:tailrepairs 0
...
STAT items:27:number 1
STAT items:27:age 452
STAT items:27:evicted 0
STAT items:27:evicted_nonzero 0
STAT items:27:evicted_time 2
STAT items:27:outofmemory 0
STAT items:27:tailrepairs 0
```

The prefix number against each statistics relates to the corresponding chunk size, as returned by the `stats slabs` statistics. The result is a display of the number of items stored within each chunk within each slab size, and specific statistics about their age, eviction counts, and out of memory counts. A summary of the statistics is given in the following table.

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>number</td>
<td>The number of items currently stored in this slab class.</td>
</tr>
<tr>
<td>age</td>
<td>The age of the oldest item within the slab class, in seconds.</td>
</tr>
<tr>
<td>evicted</td>
<td>The number of items evicted to make way for new entries.</td>
</tr>
<tr>
<td>evicted_time</td>
<td>The time of the last evicted entry</td>
</tr>
<tr>
<td>evicted_nonzero</td>
<td>The time of the last evicted non-zero entry</td>
</tr>
<tr>
<td>outofmemory</td>
<td>The number of items for this slab class that have triggered an out of memory error (only value when the <code>-M</code> command line option is in effect).</td>
</tr>
<tr>
<td>tailrepairs</td>
<td>Number of times the entries for a particular ID need repairing</td>
</tr>
</tbody>
</table>

Item level statistics can be used to determine how many items are stored within a given slab and their freshness and recycle rate. You can use this to help identify whether there are certain slab classes that are triggering a much larger number of evictions that others.

### 15.3.4.4 memcached Size Statistics

To get size statistics, use the `stats sizes` command, or the API equivalent.

The size statistics provide information about the sizes and number of items of each size within the cache. The information is returned as two columns, the first column is the size of the item (rounded up to the nearest 32 byte boundary), and the second column is the count of the number of items of that size within the cache:

```
96 35
128 38
160 807
192 804
224 410
256 222
288 83
320 39
352 53
384 33
416 64
448 51
```
Caution

Running this statistic locks up your cache as each item is read from the cache and its size calculated. On a large cache, this may take some time and prevent any set or get operations until the process completes.

The item size statistics are useful only to determine the sizes of the objects you are storing. Since the actual memory allocation is relevant only in terms of the chunk size and page size, the information is only useful during a careful debugging or diagnostic session.

15.3.4.5 memcached Detail Statistics

For `memcached` 1.3.x and higher, you can enable and obtain detailed statistics about the get, set, and `del` operations on the individual keys stored in the cache, and determine whether the attempts hit (found) a particular key. These operations are only recorded while the detailed stats analysis is turned on.

To enable detailed statistics, you must send the `stats detail on` command to the `memcached` server:

```
$ telnet localhost 11211
Trying 127.0.0.1...
Connected to tiger.
Escape character is '^]'.
stats detail on
OK
```

Individual statistics are recorded for every `get`, `set` and `del` operation on a key, including keys that are not currently stored in the server. For example, if an attempt is made to obtain the value of key `abckey` and it does not exist, the `get` operating on the specified key are recorded while detailed statistics are in effect, even if the key is not currently stored. The `hits`, that is, the number of `get` or `del` operations for a key that exists in the server are also counted.

To turn detailed statistics off, send the `stats detail off` command to the `memcached` server:

```
$ telnet localhost 11211
Trying 127.0.0.1...
Connected to tiger.
Escape character is '^]'.
stats detail on
OK
```

To obtain the detailed statistics recorded during the process, send the `stats detail dump` command to the `memcached` server:

```
stats detail dump
PREFIX hykkey get 0 hit 0 set 1 del 0
PREFIX xyzkey get 0 hit 0 set 1 del 0
PREFIX yukkey get 1 hit 0 set 0 del 0
PREFIX abckey get 3 hit 3 set 1 del 0
END
```

You can use the detailed statistics information to determine whether your `memcached` clients are using a large number of keys that do not exist in the server by comparing the `hit` and `get` or `del` counts. Because the information is recorded by key, you can also determine whether the failures or operations are clustered around specific keys.
15.3.4.6 Using **memcached-tool**

The **memcached-tool**, located within the **scripts** directory within the **memcached** source directory. The tool provides convenient access to some reports and statistics from any **memcached** instance.

The basic format of the command is:

```
shell> ./memcached-tool hostname:port [command]
```

The default output produces a list of the slab allocations and usage. For example:

```
shell> memcached-tool localhost:11211 display
```

<td>0</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The output shows a summarized version of the output from the **slabs** statistics. The columns provided in the output are shown below:

- **#**: The slab number
- **Item_Size**: The size of the slab
- **Max_age**: The age of the oldest item in the slab
- **Pages**: The number of pages allocated to the slab
• **Count**: The number of items in this slab
• **Full?**: Whether the slab is fully populated
• **Evicted**: The number of objects evicted from this slab
• **Evict_Time**: The time (in seconds) since the last eviction
• **OOM**: The number of items that have triggered an out of memory error

You can also obtain a dump of the general statistics for the server using the `stats` command:

```
shell> memcached-tool localhost:11211 stats
#localhost:11211   Field       Value
accepting_conns           1
bytes         162

15.3.5.13 Can we implement different types of memcached as different nodes in the same server, so can there be deterministic and non-deterministic in the same server? ................. 1657
15.3.5.14 What are best practices for testing an implementation, to ensure that it improves performance, and to measure the impact of memcached configuration changes? And would you recommend keeping the configuration very simple to start? .......................... 1658

15.3.5.15 Can memcached be run on a Windows environment?

No. Currently memcached is available only on the Unix/Linux platform. There is an unofficial port available, see http://www.codeplex.com/memcachedproviders.

15.3.5.2 What is the maximum size of an object you can store in memcached? Is that configurable?

The default maximum object size is 1MB. In memcached 1.4.2 and later, you can change the maximum size of an object using the -I command line option.

For versions before this, to increase this size, you have to re-compile memcached. You can modify the value of the POWER_BLOCK within the slabs.c file within the source.

In memcached 1.4.2 and higher, you can configure the maximum supported object size by using the -I command-line option. For example, to increase the maximum object size to 5MB:

```bash
$ memcached -I 5m
```

If an object is larger than the maximum object size, you must manually split it. memcached is very simple: you give it a key and some data, it tries to cache it in RAM. If you try to store more than the default maximum size, the value is just truncated for speed reasons.

15.3.5.3 Is it true memcached will be much more effective with db-read-intensive applications than with db-write-intensive applications?

Yes. memcached plays no role in database writes, it is a method of caching data already read from the database in RAM.

15.3.5.4 Is there any overhead in not using persistent connections? If persistent is always recommended, what are the downsides (for example, locking up)?

If you don’t use persistent connections when communicating with memcached, there will be a small increase in the latency of opening the connection each time. The effect is comparable to use nonpersistent connections with MySQL.

In general, the chance of locking or other issues with persistent connections is minimal, because there is very little locking within memcached. If there is a problem, eventually your request will time out and return no result, so your application will need to load from MySQL again.

15.3.5.5 How is an event such as a crash of one of the memcached servers handled by the memcached client?

There is no automatic handling of this. If your client fails to get a response from a server, code a fallback mechanism to load the data from the MySQL database.

The client APIs all provide the ability to add and remove memcached instances on the fly. If within your application you notice that memcached server is no longer responding, you can remove the server from the list of servers, and keys will automatically be redistributed to another memcached server in the list. If retaining the cache content on all your servers is important, make sure you use an API that supports a consistent hashing algorithm. For more information, see Section 15.3.2.5, “memcached Hashing/Distribution Types”.

1656
15.3.5.6. What is a recommended hardware configuration for a memcached server?

Memcached has a very low processing overhead. All that is required is spare physical RAM capacity. A memcached server does not require a dedicated machine. If you have web, application, or database servers that have spare RAM capacity, then use them with memcached.

To build and deploy a dedicated memcached server, use a relatively low-power CPU, lots of RAM, and one or more Gigabit Ethernet interfaces.

15.3.5.7. Memcached more effective for video and audio as opposed to textual read/writes?

Memcached works equally well for all kinds of data. To memcached, any value you store is just a stream of data. Remember, though, that the maximum size of an object you can store in memcached is 1MB, but can be configured to be larger by using the -I option in memcached 1.4.2 and later, or by modifying the source in versions before 1.4.2. If you plan on using memcached with audio and video content, you will probably want to increase the maximum object size. Also remember that memcached is a solution for caching information for reading. It shouldn't be used for writes, except when updating the information in the cache.

15.3.5.8. Can memcached work with ASPX?

There are ports and interfaces for many languages and environments. ASPX relies on an underlying language such as C# or VisualBasic, and if you are using ASP.NET then there is a C# memcached library. For more information, see https://sourceforge.net/projects/memcacheddotnet/.

15.3.5.9. How expensive is it to establish a memcache connection? Should those connections be pooled?

Opening the connection is relatively inexpensive, because there is no security, authentication or other handshake taking place before you can start sending requests and getting results. Most APIs support a persistent connection to a memcached instance to reduce the latency. Connection pooling would depend on the API you are using, but if you are communicating directly over TCP/IP, then connection pooling would provide some small performance benefit.

15.3.5.10. How is the data handled when the memcached server is down?

The behavior is entirely application dependent. Most applications fall back to loading the data from the database (just as if they were updating the memcached information). If you are using multiple memcached servers, you might also remove a downed server from the list to prevent it from affecting performance. Otherwise, the client will still attempt to communicate with the memcached server that corresponds to the key you are trying to load.

15.3.5.11. How are auto-increment columns in the MySQL database coordinated across multiple instances of memcached?

They aren't. There is no relationship between MySQL and memcached unless your application (or, if you are using the MySQL UDFs for memcached, your database definition) creates one.

If you are storing information based on an auto-increment key into multiple instances of memcached, the information is only stored on one of the memcached instances anyway. The client uses the key value to determine which memcached instance to store the information. It doesn't store the same information across all the instances, as that would be a waste of cache memory.

15.3.5.12. Compression available?

Yes. Most of the client APIs support some sort of compression, and some even allow you to specify the threshold at which a value is deemed appropriate for compression during storage.

15.3.5.13. Can we implement different types of memcached as different nodes in the same server, so can there be deterministic and non-deterministic in the same server?
Yes. You can run multiple instances of memcached on a single server, and in your client configuration you choose the list of servers you want to use.

15.3.5. What are best practices for testing an implementation, to ensure that it improves performance, and to measure the impact of memcached configuration changes? And would you recommend keeping the configuration very simple to start?

The best way to test the performance is to start up a memcached instance. First, modify your application so that it stores the data just before the data is about to be used or displayed into memcached. Since the APIs handle the serialization of the data, it should just be a one-line modification to your code. Then, modify the start of the process that would normally load that information from MySQL with the code that requests the data from memcached. If the data cannot be loaded from memcached, default to the MySQL process.

All of the changes required will probably amount to just a few lines of code. To get the best benefit, make sure you cache entire objects (for example, all the components of a web page, blog post, discussion thread, and so on), rather than using memcached as a simple cache of individual rows of MySQL tables.

Keeping the configuration simple at the start, or even over the long term, is easy with memcached. Once you have the basic structure up and running, often the only ongoing change is to add more servers into the list of servers used by your applications. You don't need to manage the memcached servers, and there is no complex configuration; just add more servers to the list and let the client API and the memcached servers make the decisions.

Replication enables data from one MySQL database server (the master) to be replicated to one or more MySQL database servers (the slaves). Replication is asynchronous - slaves need not be connected permanently to receive updates from the master. This means that updates can occur over long-distance connections and even over temporary or intermittent connections such as a dial-up service. Depending on the configuration, you can replicate all databases, selected databases, or even selected tables within a database.

For answers to some questions often asked by those who are new to MySQL Replication, see Section A.13, “MySQL 5.1 FAQ: Replication”.

The target uses for replication in MySQL include:

- Scale-out solutions - spreading the load among multiple slaves to improve performance. In this environment, all writes and updates must take place on the master server. Reads, however, may take place on one or more slaves. This model can improve the performance of writes (since the master is dedicated to updates), while dramatically increasing read speed across an increasing number of slaves.

- Data security - because data is replicated to the slave, and the slave can pause the replication process, it is possible to run backup services on the slave without corrupting the corresponding master data.

- Analytics - live data can be created on the master, while the analysis of the information can take place on the slave without affecting the performance of the master.

- Long-distance data distribution - if a branch office would like to work with a copy of your main data, you can use replication to create a local copy of the data for their use without requiring permanent access to the master.
Replication in MySQL features support for one-way, asynchronous replication, in which one server acts as the master, while one or more other servers act as slaves. This is in contrast to the synchronous replication which is a characteristic of MySQL Cluster (see Chapter 17, MySQL Cluster NDB 6.1 - 7.1).

There are a number of solutions available for setting up replication between two servers, but the best method to use depends on the presence of data and the engine types you are using. For more information on the available options, see Section 16.1.1, “How to Set Up Replication”.

There are two core types of replication format, Statement Based Replication (SBR), which replicates entire SQL statements, and Row Based Replication (RBR), which replicates only the changed rows. You may also use a third variety, Mixed Based Replication (MBR). For more information on the different replication formats, see Section 16.1.2, “Replication Formats”. From MySQL 5.1.12 to MySQL 5.1.28, mixed format is the default. Beginning with MySQL 5.1.29, statement-based format is the default.

Replication is controlled through a number of different options and variables. These control the core operation of the replication, timeouts, and the databases and filters that can be applied on databases and tables. For more information on the available options, see Section 16.1.3, “Replication and Binary Logging Options and Variables”.

You can use replication to solve a number of different problems, including problems with performance, supporting the backup of different databases, and as part of a larger solution to alleviate system failures. For information on how to address these issues, see Section 16.3, “Replication Solutions”.

For notes and tips on how different data types and statements are treated during replication, including details of replication features, version compatibility, upgrades, and problems and their resolution, including an FAQ, see Section 16.4, “Replication Notes and Tips”.

For detailed information on the implementation of replication, how replication works, the process and contents of the binary log, background threads and the rules used to decide how statements are recorded and replication, see Section 16.2, “Replication Implementation”.

16.1 Replication Configuration

Replication between servers in MySQL is based on the binary logging mechanism. The MySQL instance operating as the master (the source of the database changes) writes updates and changes as “events” to the binary log. The information in the binary log is stored in different logging formats according to the database changes being recorded. Slaves are configured to read the binary log from the master and to execute the events in the binary log on the slave's local database.

The master is “dumb” in this scenario. Once binary logging has been enabled, all statements are recorded in the binary log. Each slave receives a copy of the entire contents of the binary log. It is the responsibility of the slave to decide which statements in the binary log should be executed; you cannot configure the master to log only certain events. If you do not specify otherwise, all events in the master binary log are executed on the slave. If required, you can configure the slave to process only events that apply to particular databases or tables.

Each slave keeps a record of the binary log coordinates: The file name and position within the file that it has read and processed from the master. This means that multiple slaves can be connected to the master and executing different parts of the same binary log. Because the slaves control this process, individual slaves can be connected and disconnected from the server without affecting the master's operation. Also, because each slave remembers the position within the binary log, it is possible for slaves to be disconnected, reconnect and then “catch up” by continuing from the recorded position.

Both the master and each slave must be configured with a unique ID (using the server-id option). In addition, each slave must be configured with information about the master host name, log file name, and position within that file. These details can be controlled from within a MySQL session using the CHANGE MASTER TO statement on the slave. The details are stored within the slave's master.info file.
This section describes the setup and configuration required for a replication environment, including step-by-step instructions for creating a new replication environment. The major components of this section are:

- For a guide to setting up two or more servers for replication, Section 16.1.1, "How to Set Up Replication", deals with the configuration of the systems and provides methods for copying data between the master and slaves.

- Events in the binary log are recorded using a number of formats. These are referred to as statement-based replication (SBR) or row-based replication (RBR). A third type, mixed-format replication (MIXED), uses SBR or RBR replication automatically to take advantage of the benefits of both SBR and RBR formats when appropriate. The different formats are discussed in Section 16.1.2, "Replication Formats".

- Detailed information on the different configuration options and variables that apply to replication is provided in Section 16.1.3, "Replication and Binary Logging Options and Variables".

- Once started, the replication process should require little administration or monitoring. However, for advice on common tasks that you may want to execute, see Section 16.1.4, "Common Replication Administration Tasks".

### 16.1.1 How to Set Up Replication

This section describes how to set up complete replication of a MySQL server. There are a number of different methods for setting up replication, and the exact method to use depends on how you are setting up replication, and whether you already have data within your master database.

There are some generic tasks that are common to all replication setups:

- On the master, you must enable binary logging and configure a unique server ID. This might require a server restart. See Section 16.1.1.1, "Setting the Replication Master Configuration".

- On each slave that you want to connect to the master, you must configure a unique server ID. This might require a server restart. See Section 16.1.1.2, "Setting the Replication Slave Configuration".

- You may want to create a separate user that will be used by your slaves to authenticate with the master to read the binary log for replication. The step is optional. See Section 16.1.1.3, "Creating a User for Replication".

- Before creating a data snapshot or starting the replication process, you should record the position of the binary log on the master. You will need this information when configuring the slave so that the slave knows where within the binary log to start executing events. See Section 16.1.1.4, "Obtaining the Replication Master Binary Log Coordinates".

- If you already have data on your master and you want to use it to synchronize your slave, you will need to create a data snapshot. You can create a snapshot using `mysqldump` (see Section 16.1.1.5, "Creating a Data Snapshot Using mysqldump") or by copying the data files directly (see Section 16.1.1.6, "Creating a Data Snapshot Using Raw Data Files").

- You will need to configure the slave with settings for connecting to the master, such as the host name, login credentials, and binary log file name and position. See Section 16.1.1.10, "Setting the Master Configuration on the Slave".

Once you have configured the basic options, you will need to follow the instructions for your replication setup. A number of alternatives are provided:

- If you are establishing a new MySQL master and one or more slaves, you need only set up the configuration, as you have no data to exchange. For guidance on setting up replication in this situation, see Section 16.1.1.7, "Setting Up Replication with New Master and Slaves".

- If you are already running a MySQL server, and therefore already have data that must be transferred to your slaves before replication starts, have not previously configured the binary log and are able to
shut down your MySQL server for a short period during the process, see Section 16.1.8, “Setting Up Replication with Existing Data”.

• If you are adding slaves to an existing replication environment, you can set up the slaves without affecting the master. See Section 16.1.9, “Introducing Additional Slaves to an Existing Replication Environment”.

If you will be administering MySQL replication servers, we suggest that you read this entire chapter through and try all statements mentioned in Section 13.4.1, “SQL Statements for Controlling Master Servers”, and Section 13.4.2, “SQL Statements for Controlling Slave Servers”. You should also familiarize yourself with the replication startup options described in Section 16.1.3, “Replication and Binary Logging Options and Variables”.

Note
Note that certain steps within the setup process require the `SUPER` privilege. If you do not have this privilege, it might not be possible to enable replication.

16.1.1.1 Setting the Replication Master Configuration

On a replication master, you must enable binary logging and establish a unique server ID. If this has not already been done, this part of master setup requires a server restart.

Binary logging must be enabled on the master because the binary log is the basis for sending data changes from the master to its slaves. If binary logging is not enabled, replication will not be possible.

Each server within a replication group must be configured with a unique server ID. This ID is used to identify individual servers within the group, and must be a positive integer between 1 and $2^{32} - 1$. How you organize and select the numbers is entirely up to you.

To configure the binary log and server ID options, you will need to shut down your MySQL server and edit the `my.cnf` or `my.ini` file. Add the following options to the configuration file within the `[mysqld]` section. If these options already exist, but are commented out, uncomment the options and alter them according to your needs. For example, to enable binary logging using a log file name prefix of `mysql-bin`, and configure a server ID of 1, use these lines:

```
[mysqld]
log-bin=mysql-bin
server-id=1
```

After making the changes, restart the server.

Note
If you omit `server-id` (or set it explicitly to its default value of 0), a master refuses connections from all slaves.

Note
For the greatest possible durability and consistency in a replication setup using InnoDB with transactions, you should use `innodb_flush_log_at_trx_commit=1` and `sync_binlog=1` in the master `my.cnf` file.

Note
Ensure that the `skip-networking` option is not enabled on your replication master. If networking has been disabled, your slave will not able to communicate with the master and replication will fail.
16.1.1.2 Setting the Replication Slave Configuration

On a replication slave, you must establish a unique server ID. If this has not already been done, this part of slave setup requires a server restart.

If the slave server ID is not already set, or the current value conflicts with the value that you have chosen for the master server, you should shut down your slave server and edit the configuration to specify a unique server ID. For example:

```
[mysqld]
server-id=2
```

After making the changes, restart the server.

If you are setting up multiple slaves, each one must have a unique `server-id` value that differs from that of the master and from each of the other slaves. Think of `server-id` values as something similar to IP addresses: These IDs uniquely identify each server instance in the community of replication partners.

**Note**

If you omit `server-id` (or set it explicitly to its default value of 0), a slave refuses to connect to a master.

You do not have to enable binary logging on the slave for replication to be enabled. However, if you enable binary logging on the slave, you can use the binary log for data backups and crash recovery on the slave, and also use the slave as part of a more complex replication topology (for example, where the slave acts as a master to other slaves).

16.1.1.3 Creating a User for Replication

Each slave must connect to the master using a MySQL user name and password, so there must be a user account on the master that the slave can use to connect. Any account can be used for this operation, providing it has been granted the `REPLICATION SLAVE` privilege. You may wish to create a different account for each slave, or connect to the master using the same account for each slave.

You need not create an account specifically for replication. However, you should be aware that the user name and password will be stored in plain text within the `master.info` file (see Section 16.2.2.2, “Slave Status Logs”). Therefore, you may want to create a separate account that has privileges only for the replication process, to minimize the possibility of compromise to other accounts.

To create a new account, use `CREATE USER`. To grant this account the privileges required for replication, use the `GRANT` statement. If you create an account solely for the purposes of replication, that account needs only the `REPLICATION SLAVE` privilege. For example, to set up a new user, `repl`, that can connect for replication from any host within the `mydomain.com` domain, issue these statements on the master:

```
mysql> CREATE USER 'repl'@'%.mydomain.com' IDENTIFIED BY 'slavepass';
mysql> GRANT REPLICATION SLAVE ON *.* TO 'repl'@'%.mydomain.com';
```

See Section 13.7.1, “Account Management Statements”, for more information on statements for manipulation of user accounts.

16.1.1.4 Obtaining the Replication Master Binary Log Coordinates

To configure replication on the slave you must determine the master’s current coordinates within its binary log. You will need this information so that when the slave starts the replication process, it is able to start processing events from the binary log at the correct point.

If you have existing data on your master that you want to synchronize on your slaves before starting the replication process, you must stop processing statements on the master, and then obtain its
current binary log coordinates and dump its data, before permitting the master to continue executing statements. If you do not stop the execution of statements, the data dump and the master status information that you use will not match and you will end up with inconsistent or corrupted databases on the slaves.

To obtain the master binary log coordinates, follow these steps:

1. Start a session on the master by connecting to it with the command-line client, and flush all tables and block write statements by executing the `FLUSH TABLES WITH READ LOCK` statement:
   
   ```
   mysql> FLUSH TABLES WITH READ LOCK;
   ```

   For InnoDB tables, note that `FLUSH TABLES WITH READ LOCK` also blocks `COMMIT` operations.

   **Warning**
   Leave the client from which you issued the `FLUSH TABLES` statement running so that the read lock remains in effect. If you exit the client, the lock is released.

2. In a different session on the master, use the `SHOW MASTER STATUS` statement to determine the current binary log file name and position:
   
   ```
   mysql > SHOW MASTER STATUS;
   +------------------+----------+--------------+------------------+
   | File             | Position | Binlog_Do_DB | Binlog_Ignore_DB |
   +------------------+----------+--------------+------------------+
   | mysql-bin.000003 | 73       | test         | manual,mysql     |
   +------------------+----------+--------------+------------------+
   ```

   The `File` column shows the name of the log file and `Position` shows the position within the file. In this example, the binary log file is `mysql-bin.000003` and the position is 73. Record these values. You need them later when you are setting up the slave. They represent the replication coordinates at which the slave should begin processing new updates from the master.

   If the master has been running previously without binary logging enabled, the log file name and position values displayed by `SHOW MASTER STATUS` or `mysqldump --master-data` will be empty. In that case, the values that you need to use later when specifying the slave's log file and position are the empty string (`''`) and 4.

You now have the information you need to enable the slave to start reading from the binary log in the correct place to start replication.

If you have existing data that needs to be synchronized with the slave before you start replication, leave the client running so that the lock remains in place and then proceed to Section 16.1.1.5, “Creating a Data Snapshot Using mysqldump”, or Section 16.1.1.6, “Creating a Data Snapshot Using Raw Data Files”. The idea here is to prevent any further changes so that the data copied to the slaves is in synchrony with the master.

If you are setting up a brand new master and slave replication group, you can exit the first session to release the read lock.

### 16.1.1.5 Creating a Data Snapshot Using mysqldump

One way to create a snapshot of the data in an existing master database is to use the `mysqldump` tool to create a dump of all the databases you want to replicate. Once the data dump has been completed, you then import this data into the slave before starting the replication process.

The example shown here dumps all databases to a file named `dbdump.db`, and includes the `--master-data` option which automatically appends the `CHANGE MASTER TO` statement required on the slave to start the replication process:
How to Set Up Replication

shell> mysqldump --all-databases --master-data > dbdump.db

If you do not use --master-data, then it is necessary to lock all tables in a separate session manually (using FLUSH TABLES WITH READ LOCK) prior to running mysqldump, then exiting or running UNLOCK TABLES from the second session to release the locks. You must also obtain binary log position information matching the snapshot, using SHOW MASTER STATUS, and use this to issue the appropriate CHANGE MASTER TO statement when starting the slave.

When choosing databases to include in the dump, remember that you need to filter out databases on each slave that you do not want to include in the replication process.

To import the data, either copy the dump file to the slave, or access the file from the master when connecting remotely to the slave.

16.1.1.6 Creating a Data Snapshot Using Raw Data Files

If your database is large, copying the raw data files can be more efficient than using mysqldump and importing the file on each slave. This technique skips the overhead of updating indexes as the INSERT statements are replayed.

Using this method with tables in storage engines with complex caching or logging algorithms requires extra steps to produce a perfect “point in time” snapshot: the initial copy command might leave out cache information and logging updates, even if you have acquired a global read lock. How the storage engine responds to this depends on its crash recovery abilities.

This method also does not work reliably if the master and slave have different values for ft_stopword_file, ft_min_word_len, or ft_max_word_len and you are copying tables having full-text indexes.

If you use InnoDB tables, you can use the mysqlbackup command from the MySQL Enterprise Backup component to produce a consistent snapshot. This command records the log name and offset corresponding to the snapshot to be later used on the slave. MySQL Enterprise Backup is a commercial product that is included as part of a MySQL Enterprise subscription. See Section 23.2, “MySQL Enterprise Backup Overview” for detailed information.

Otherwise, use the cold backup technique to obtain a reliable binary snapshot of InnoDB tables: copy all data files after doing a slow shutdown of the MySQL Server.

To create a raw data snapshot of MyISAM tables, you can use standard copy tools such as cp or copy, a remote copy tool such as scp or rsync, an archiving tool such as zip or tar, or a file system snapshot tool such as dump, providing that your MySQL data files exist on a single file system. If you are replicating only certain databases, copy only those files that relate to those tables. (For InnoDB, all tables in all databases are stored in the system tablespace files, unless you have the innodb_file_per_table option enabled.)

You might want to specifically exclude the following files from your archive:

- Files relating to the mysql database.
- The master.info file.
- The master's binary log files.
- Any relay log files.

To get the most consistent results with a raw data snapshot, shut down the master server during the process, as follows:

1. Acquire a read lock and get the master's status. See Section 16.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”.

2. In a separate session, shut down the master server:
3. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:

   shell> tar cf /tmp/db.tar ./data
   shell> zip -r /tmp/db.zip ./data
   shell> rsync --recursive ./data /tmp/dbdata

4. Restart the master server.

   If you are not using InnoDB tables, you can get a snapshot of the system from a master without shutting down the server as described in the following steps:

   1. Acquire a read lock and get the master's status. See Section 16.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”.
   2. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:

       shell> tar cf /tmp/db.tar ./data
       shell> zip -r /tmp/db.zip ./data
       shell> rsync --recursive ./data /tmp/dbdata

   3. In the client where you acquired the read lock, release the lock:

       mysql> UNLOCK TABLES;

   Once you have created the archive or copy of the database, copy the files to each slave before starting the slave replication process.

16.1.1.7 Setting Up Replication with New Master and Slaves

   The easiest and most straightforward method for setting up replication is to use new master and slave servers.

   You can also use this method if you are setting up new servers but have an existing dump of the databases from a different server that you want to load into your replication configuration. By loading the data into a new master, the data will be automatically replicated to the slaves.

   To set up replication between a new master and slave:

   1. Configure the MySQL master with the necessary configuration properties. See Section 16.1.1.1, “Setting the Replication Master Configuration”.
   2. Start up the MySQL master.
   3. Set up a user. See Section 16.1.1.3, “Creating a User for Replication”.
   4. Obtain the master status information. See Section 16.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”.
   5. On the master, release the read lock:

       mysql> UNLOCK TABLES;

   6. On the slave, edit the MySQL configuration. See Section 16.1.1.2, “Setting the Replication Slave Configuration”.
   7. Start up the MySQL slave.
How to Set Up Replication

8. Execute a `CHANGE MASTER TO` statement to set the master replication server configuration. See Section 16.1.1.10, “Setting the Master Configuration on the Slave”.

Perform the slave setup steps on each slave.

Because there is no data to load or exchange on a new server configuration you do not need to copy or import any information.

If you are setting up a new replication environment using the data from a different existing database server, you will now need to run the dump file generated from that server on the new master. The database updates will automatically be propagated to the slaves:

```shell
shell> mysql -h master < fulldb.dump
```

### 16.1.1.8 Setting Up Replication with Existing Data

When setting up replication with existing data, you will need to decide how best to get the data from the master to the slave before starting the replication service.

The basic process for setting up replication with existing data is as follows:

1. With the MySQL master running, create a user to be used by the slave when connecting to the master during replication. See Section 16.1.1.3, “Creating a User for Replication”.

2. If you have not already configured the `server-id` and enabled binary logging on the master server, you will need to shut it down to configure these options. See Section 16.1.1.1, “Setting the Replication Master Configuration”.

   If you have to shut down your master server, this is a good opportunity to take a snapshot of its databases. You should obtain the master status (see Section 16.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”) before taking down the master, updating the configuration and taking a snapshot. For information on how to create a snapshot using raw data files, see Section 16.1.1.6, “Creating a Data Snapshot Using Raw Data Files”.

3. If your master server is already correctly configured, obtain its status (see Section 16.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”) and then use `mysqldump` to take a snapshot (see Section 16.1.1.5, “Creating a Data Snapshot Using mysqldump”) or take a raw snapshot of the live server using the guide in Section 16.1.1.6, “Creating a Data Snapshot Using Raw Data Files”.

4. Update the configuration of the slave. See Section 16.1.1.2, “Setting the Replication Slave Configuration”.

5. The next step depends on how you created the snapshot of data on the master.

   If you used `mysqldump`:

   a. Start the slave, using the `--skip-slave-start` option so that replication does not start.

   b. Import the dump file:

      ```shell
      shell> mysql < fulldb.dump
      ```

   If you created a snapshot using the raw data files:

   a. Extract the data files into your slave data directory. For example:

      ```shell
      shell> tar xvf dbdump.tar
      ```

   You may need to set permissions and ownership on the files so that the slave server can access and modify them.
b. Start the slave, using the `--skip-slave-start` option so that replication does not start.

6. Configure the slave with the replication coordinates from the master. This tells the slave the binary log file and position within the file where replication needs to start. Also, configure the slave with the login credentials and host name of the master. For more information on the `CHANGE MASTER TO` statement required, see Section 16.1.1.10, “Setting the Master Configuration on the Slave”.

7. Start the slave threads:

```
mysql> START SLAVE;
```

After you have performed this procedure, the slave should connect to the master and catch up on any updates that have occurred since the snapshot was taken.

If you have forgotten to set the `server-id` option for the master, slaves cannot connect to it.

If you have forgotten to set the `server-id` option for the slave, you get the following error in the slave's error log:

```
Warning: You should set server-id to a non-0 value if master_host is set; we will force server id to 2, but this MySQL server will not act as a slave.
```

You also find error messages in the slave's error log if it is not able to replicate for any other reason.

Once a slave is replicating, you can find in its data directory one file named `master.info` and another named `relay-log.info`. The slave uses these two files to keep track of how much of the master's binary log it has processed. Do not remove or edit these files unless you know exactly what you are doing and fully understand the implications. Even in that case, it is preferred that you use the `CHANGE MASTER TO` statement to change replication parameters. The slave will use the values specified in the statement to update the status files automatically.

**Note**

The content of `master.info` overrides some of the server options specified on the command line or in `my.cnf`. See Section 16.1.3, “Replication and Binary Logging Options and Variables”, for more details.

A single snapshot of the master suffices for multiple slaves. To set up additional slaves, use the same master snapshot and follow the slave portion of the procedure just described.

**16.1.1.9 Introducing Additional Slaves to an Existing Replication Environment**

To add another slave to an existing replication configuration, you can do so without stopping the master. Instead, set up the new slave by making a copy of an existing slave, except that you configure the new slave with a different `server-id` value.

To duplicate an existing slave:

1. Shut down the existing slave:

```
shell> mysqladmin shutdown
```

2. Copy the data directory from the existing slave to the new slave. You can do this by creating an archive using `tar` or `WinZip`, or by performing a direct copy using a tool such as `cp` or `rsync`. Ensure that you also copy the log files and relay log files.

A common problem that is encountered when adding new replication slaves is that the new slave fails with a series of warning and error messages like these:
How to Set Up Replication

This is due to the fact that, if the --relay-log option is not specified, the relay log files contain the host name as part of their file names. (This is also true of the relay log index file if the --relay-log-index option is not used. See Section 16.1.3, “Replication and Binary Logging Options and Variables”, for more information about these options.)

To avoid this problem, use the same value for --relay-log on the new slave that was used on the existing slave. (If this option was not set explicitly on the existing slave, use existing_slave_hostname-relay-bin.) If this is not feasible, copy the existing slave's relay log index file to the new slave and set the --relay-log-index option on the new slave to match what was used on the existing slave. (If this option was not set explicitly on the existing slave, use existing_slave_hostname-relay-bin.index.) Alternatively—if you have already tried to start the new slave (after following the remaining steps in this section) and have encountered errors like those described previously—then perform the following steps:

a. If you have not already done so, issue a STOP SLAVE on the new slave.

   If you have already started the existing slave again, issue a STOP SLAVE on the existing slave as well.

b. Copy the contents of the existing slave's relay log index file into the new slave's relay log index file, making sure to overwrite any content already in the file.

c. Proceed with the remaining steps in this section.

3. Copy the master.info and relay-log.info files from the existing slave to the new slave if they were not located in the data directory. These files hold the current log coordinates for the master's binary log and the slave's relay log.

4. Start the existing slave.

5. On the new slave, edit the configuration and give the new slave a unique server-id not used by the master or any of the existing slaves.

6. Start the new slave. The slave will use the information in its master.info file to start the replication process.

16.1.1.10 Setting the Master Configuration on the Slave

To set up the slave to communicate with the master for replication, you must tell the slave the necessary connection information. To do this, execute the following statement on the slave, replacing the option values with the actual values relevant to your system:

```sql
mysql> CHANGE MASTER TO
   -> MASTER_HOST='master_host_name',
   -> MASTER_USER='replication_user_name',
   -> MASTER_PASSWORD='replication_password',
   -> MASTER_LOG_FILE='recorded_log_file_name',
   -> MASTER_LOG_POS=recorded_log_position;
```

Note

Replication cannot use Unix socket files. You must be able to connect to the master MySQL server using TCP/IP.
The `CHANGE MASTER TO` statement has other options as well. For example, it is possible to set up secure replication using SSL. For a full list of options, and information about the maximum permissible length for the string-valued options, see Section 13.4.2.1, “CHANGE MASTER TO Syntax”.

### 16.1.2 Replication Formats

Replication works because events written to the binary log are read from the master and then processed on the slave. The events are recorded within the binary log in different formats according to the type of event. The different replication formats used correspond to the binary logging format used when the events were recorded in the master’s binary log. The correlation between binary logging formats and the terms used during replication are:

- Replication capabilities in MySQL originally were based on propagation of SQL statements from master to slave. This is called `statement-based replication` (often abbreviated as `SBR`), which corresponds to the standard statement-based binary logging format. In MySQL 5.1.4 and earlier, binary logging and replication used this format exclusively.

- Row-based binary logging logs changes in individual table rows. When used with MySQL replication, this is known as `row-based replication` (often abbreviated as `RBR`). In row-based replication, the master writes events to the binary log that indicate how individual table rows are changed.

- As of MySQL 5.1.8, the server can change the binary logging format in real time according to the type of event using `mixed-format logging`.

  When the mixed format is in effect, statement-based logging is used by default, but automatically switches to row-based logging in particular cases as described later. Replication using the mixed format is often referred to as `mixed-based replication` or `mixed-format replication`. For more information, see Section 5.4.4.3, “Mixed Binary Logging Format”.

From MySQL 5.1.12 to MySQL 5.1.28, mixed format is the default. Beginning with MySQL 5.1.29, statement-based format is the default.

**MySQL Cluster.** The default binary logging format in all MySQL Cluster NDB 6.x and 7.x releases is `ROW`. MySQL Cluster Replication always uses row-based replication, and the `NDBCLUSTER` storage engine is incompatible with statement-based replication. Using `NDBCLUSTER` sets row-based logging format automatically. See Section 17.6.2, “General Requirements for MySQL Cluster Replication”, for more information.

Starting with MySQL 5.1.20, when using `MIXED` format, the binary logging format is determined in part by the storage engine being used and the statement being executed. For more information on mixed-format logging and the rules governing the support of different logging formats, see Section 5.4.4.3, “Mixed Binary Logging Format”.

The logging format in a running MySQL server is controlled by setting the `binlog_format` server system variable. This variable can be set with session or global scope. The rules governing when and how the new setting takes effect are the same as for other MySQL server system variables—setting the variable for the current session lasts only until the end of that session, and the change is not visible to other sessions; setting the variable globally requires a restart of the server to take effect. For more information, see Section 13.7.4.1, “SET Syntax for Variable Assignment”.

There are conditions under which you cannot change the binary logging format at runtime or doing so causes replication to fail. See Section 5.4.4.2, “Setting The Binary Log Format”.

You must have the `SUPER` privilege to set the global `binlog_format` value. Starting with MySQL 5.1.29, you must have the `SUPER` privilege to set either the global or session `binlog_format` value. (Bug #39106)

The statement-based and row-based replication formats have different issues and limitations. For a comparison of their relative advantages and disadvantages, see Section 16.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

---

1670
With statement-based replication, you may encounter issues with replicating stored routines or triggers. You can avoid these issues by using row-based replication instead. For more information, see Section 19.7, “Binary Logging of Stored Programs”.

16.1.2.1 Advantages and Disadvantages of Statement-Based and Row-Based Replication

Each binary logging format has advantages and disadvantages. For most users, the mixed replication format should provide the best combination of data integrity and performance. If, however, you want to take advantage of the features specific to the statement-based or row-based replication format when performing certain tasks, you can use the information in this section, which provides a summary of their relative advantages and disadvantages, to determine which is best for your needs.

• Advantages of statement-based replication
• Disadvantages of statement-based replication
• Advantages of row-based replication
• Disadvantages of row-based replication

Advantages of statement-based replication

• Proven technology that has existed in MySQL since 3.23.
• Less data written to log files. When updates or deletes affect many rows, this results in much less storage space required for log files. This also means that taking and restoring from backups can be accomplished more quickly.
• Log files contain all statements that made any changes, so they can be used to audit the database.

Disadvantages of statement-based replication

• Statements that are unsafe for SBR.
  Not all statements which modify data (such as INSERT DELETE, UPDATE, and REPLACE statements) can be replicated using statement-based replication. Any nondeterministic behavior is difficult to replicate when using statement-based replication. Examples of such DML (Data Modification Language) statements include the following:
  • A statement that depends on a UDF or stored program that is nondeterministic, since the value returned by such a UDF or stored program or depends on factors other than the parameters supplied to it. (Row-based replication, however, simply replicates the value returned by the UDF or stored program, so its effect on table rows and data is the same on both the master and slave.) See Section 16.4.1.12, “Replication of Invoked Features”, for more information.
  • DELETE and UPDATE statements that use a LIMIT clause without an ORDER BY are nondeterministic. See Section 16.4.1.16, “Replication and LIMIT”.
  • Statements using any of the following functions cannot be replicated properly using statement-based replication:
    • LOAD_FILE()
    • UUID(), UUID_SHORT()
    • USER()
    • FOUND_ROWS()
    • SYSDATE() (unless both the master and the slave are started with the --sysdate-is-now option)
    • GET_LOCK()}
• \texttt{IS\_FREE\_LOCK()}
• \texttt{IS\_USED\_LOCK()}
• \texttt{MASTER\_POS\_WAIT()}
• \texttt{RAND()}
• \texttt{RELEASE\_LOCK()}
• \texttt{SLEEP()}
• \texttt{VERSION()}

However, all other functions are replicated correctly using statement-based replication, including \texttt{NOW()} and so forth.

For more information, see Section 16.4.1.15, “Replication and System Functions”.

Statements that cannot be replicated correctly using statement-based replication are logged with a warning like the one shown here:

\begin{verbatim}
[Warning] Statement is not safe to log in statement format.
\end{verbatim}

A similar warning is also issued to the client in such cases. The client can display it using \texttt{SHOW WARNINGS}.

• \texttt{INSERT \ldots SELECT} requires a greater number of row-level locks than with row-based replication.
• \texttt{UPDATE} statements that require a table scan (because no index is used in the \texttt{WHERE} clause) must lock a greater number of rows than with row-based replication.
• For \texttt{InnoDB}: An \texttt{INSERT} statement that uses \texttt{AUTO_INCREMENT} blocks other nonconflicting \texttt{INSERT} statements.
• For complex statements, the statement must be evaluated and executed on the slave before the rows are updated or inserted. With row-based replication, the slave only has to modify the affected rows, not execute the full statement.
• If there is an error in evaluation on the slave, particularly when executing complex statements, statement-based replication may slowly increase the margin of error across the affected rows over time. See Section 16.4.1.29, “Slave Errors During Replication”.
• Stored functions execute with the same \texttt{NOW()} value as the calling statement. However, this is not true of stored procedures.
• Deterministic UDFs must be applied on the slaves.
• Table definitions must be (nearly) identical on master and slave. See Section 16.4.1.10, “Replication with Differing Table Definitions on Master and Slave”, for more information.

\textbf{Advantages of Row-Based Replication}

• All changes can be replicated. This is the safest form of replication.

For MySQL versions earlier than 5.1.14, DDL (Data Definition Language) statements such as \texttt{CREATE TABLE} are replicated using statement-based replication, while DML statements, as well as \texttt{GRANT} and \texttt{REVOKE} statements, are replicated using row-based replication.

In MySQL 5.1.14 and later, the \texttt{mysql} database is not replicated. The \texttt{mysql} database is instead seen as a node-specific database. Row-based replication is not supported on tables in this database.
Instead, statements that would normally update this information—such as `GRANT`, `REVOKE` and the manipulation of triggers, stored routines (including stored procedures), and views—are all replicated to slaves using statement-based replication.

For statements such as `CREATE TABLE ... SELECT`, a `CREATE` statement is generated from the table definition and replicated using statement-based format, while the row insertions are replicated using row-based format.

- The technology is the same as in most other database management systems; knowledge about other systems transfers to MySQL.
- Fewer row locks are required on the master, which thus achieves higher concurrency, for the following types of statements:
  - `INSERT ... SELECT`
  - `INSERT` statements with `AUTO_INCREMENT`
  - `UPDATE` or `DELETE` statements with `WHERE` clauses that do not use keys or do not change most of the examined rows.
- Fewer row locks are required on the slave for any `INSERT`, `UPDATE`, or `DELETE` statement.

**Disadvantages of Row-Based Replication**

- RBR tends to generate more data that must be logged. To replicate a DML statement (such as an `UPDATE` or `DELETE` statement), statement-based replication writes only the statement to the binary log. By contrast, row-based replication writes each changed row to the binary log. If the statement changes many rows, row-based replication may write significantly more data to the binary log; this is true even for statements that are rolled back. This also means that taking and restoring from backup can require more time. In addition, the binary log is locked for a longer time to write the data, which may cause concurrency problems.

- Deterministic UDFs that generate large `BLOB` values take longer to replicate with row-based replication than with statement-based replication. This is because the `BLOB` column value is logged, rather than the statement generating the data.

- You cannot examine the logs to see what statements were executed, nor can you see on the slave what statements were received from the master and executed.

  However, beginning with MySQL 5.1.29, you can see what data was changed using `mysqlbinlog` with the options `--base64-output=DECODE-ROWS` and `--verbose`.

- For tables using the MyISAM storage engine, a stronger lock is required on the slave for `INSERT` statements when applying them as row-based events to the binary log than when applying them as statements. This means that concurrent inserts on MyISAM tables are not supported when using row-based replication.

- Formerly, when performing a bulk operation that includes nontransactional storage engines, changes were applied as the statement executed. With row-based logging, this meant that the binary log was written while the statement was running. On the master, this does not cause problems with concurrency, because tables are locked until the bulk operation terminates. On the slave server, tables were not locked while the slave applied changes, because the slave did not know that those changes were part of a bulk operation.

  In such cases, if you retrieved data from a table on the master (for example, using `SELECT * FROM table_name`), the server waited for the bulk operation to complete before executing the `SELECT` statement, because the table was read-locked. On the slave, the server did not wait (because there was no lock). This meant that, until the bulk operation on the slave completed, different results were obtained for the same `SELECT` query on the master and on the slave.

  This issue was resolved in MySQL 5.1.24. (Bug #29020)
16.1.2.2 Usage of Row-Based Logging and Replication

Major changes in the replication environment and in the behavior of applications can result from using row-based logging (RBL) or row-based replication (RBR) rather than statement-based logging or replication. This section describes a number of issues known to exist when using row-based logging or replication, and discusses some best practices for taking advantage of row-based logging and replication.

For additional information, see Section 16.1.2, “Replication Formats”, and Section 16.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

For information about issues specific to MySQL Cluster Replication (which depends on row-based replication), see Section 17.6.3, “Known Issues in MySQL Cluster Replication”.

- **RBL, RBR, and temporary tables.** As noted in Section 16.4.1.23, “Replication and Temporary Tables”, temporary tables are not replicated when using row-based format. When mixed format is in effect, “safe” statements involving temporary tables are logged using statement-based format. For more information, see Section 16.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

Temporary tables are not replicated when using row-based format because there is no need. In addition, because temporary tables can be read only from the thread which created them, there is seldom if ever any benefit obtained from replicating them, even when using statement-based format.

- **RBL and the BLACKHOLE storage engine.** Prior to MySQL 5.1.29, DELETE and UPDATE statements for BLACKHOLE tables did not work with RBL. (Bug #38360)

- **RBL and synchronization of nontransactional tables.** When many rows are affected, the set of changes is split into several events; when the statement commits, all of these events are written to the binary log if the statement is an initial nontransactional statement (occurring in the transaction before any transactional statements). When executing on the slave, a table lock is taken on all tables involved, and then the rows are applied in batch mode. (This may or may not be effective, depending on the engine used for the slave's copy of the table.)

- **Latency and binary log size.** Because RBL writes changes for each row to the binary log, its size can increase quite rapidly. In a replication environment, this can significantly increase the time required to make changes on the slave that match those on the master. You should be aware of the potential for this delay in your applications.

- **Reading the binary log.** mysqlbinlog displays row-based events in the binary log using the BINLOG statement (see Section 13.7.6.1, “BINLOG Syntax”). This statement displays an event in printable form, but as a base 64-encoded string the meaning of which is not evident. As of MySQL 5.1.28, when invoked with the --base64-output=DECODE-ROWS and --verbose options, mysqlbinlog formats the contents of the binary log in a manner that is easily human readable. This is helpful when binary log events were written in row-based format if you want to read or recover from a replication or database failure using the contents of the binary log. For more information, see Section 4.6.7.2, “mysqlbinlog Row Event Display”.

- **Binary log execution errors and slave_exec_mode.** If slave_exec_mode is IDEMPOTENT, a failure to apply changes from RBL because the original row cannot be found does not trigger an error or cause replication to fail. This means that it is possible that updates are not applied on the slave, so that the master and slave are no longer synchronized. Latency issues and use of nontransactional tables with RBR when slave_exec_mode is IDEMPOTENT can cause the master and slave to diverge even further. For more information about slave_exec_mode, see Section 5.1.4, “Server System Variables”.

**Note**

slave_exec_mode=IDEMPOTENT is generally useful only for circular replication or multi-master replication with MySQL Cluster, for which
Replication Formats

IDEMPOTENT is the default value (see Section 17.6, “MySQL Cluster Replication”).

For other scenarios, setting slave_exec_mode to STRICT is normally sufficient; this is the default value for storage engines other than NDB.

- **Lack of binary log checksums.** RBL uses no checksums. This means that network, disk, and other errors may not be identified when processing the binary log. To ensure that data is transmitted without network corruption, you may want to consider using SSL, which adds another layer of checksumming, for replication connections. The CHANGE MASTER TO statement has options to enable replication over SSL. See also Section 13.4.2.1, “CHANGE MASTER TO Syntax”, for general information about setting up MySQL with SSL.

- **Filtering based on server ID not supported.** A common practice is to filter out changes on some slaves by using a WHERE clause that includes the relation @@server_id <> id_value clause with UPDATE and DELETE statements, a simple example of such a clause being WHERE @@server_id <> 1. However, this does not work correctly with row-based logging. If you must use the server_id system variable for statement filtering, you must also use --binlog_format=STATEMENT.

- **Database-level replication options.** The effects of the --replicate-do-db, --replicate-ignore-db, and --replicate-rewrite-db options differ considerably depending on whether row-based or statement-based logging is used. Because of this, it is recommended to avoid database-level options and instead use table-level options such as --replicate-do-table and --replicate-ignore-table. For more information about these options and the impact that your choice of replication format has on how they operate, see Section 16.1.3, “Replication and Binary Logging Options and Variables”.

- **RBL, nontransactional tables, and stopped slaves.** When using row-based logging, if the slave server is stopped while a slave thread is updating a nontransactional table, the slave database may reach an inconsistent state. For this reason, it is recommended that you use a transactional storage engine such as InnoDB for all tables replicated using the row-based format.

Use of STOP SLAVE (or STOP SLAVE SQL_THREAD in MySQL 5.1.55 and later) prior to shutting down the slave MySQL server helps prevent such issues from occurring, and is always recommended regardless of the logging format or storage engines employed.

### 16.1.2.3 Determination of Safe and Unsafe Statements in Binary Logging

When speaking of the “safeness” of a statement in MySQL Replication, we are referring to whether a statement and its effects can be replicated correctly using statement-based format. If this is true of the statement, we refer to the statement as *safe*; otherwise, we refer to it as *unsafe*.

In general, a statement is safe if it deterministic, and unsafe if it is not. However, certain nondeterministic functions are not considered unsafe (see *Nondeterministic functions not considered unsafe*, later in this section). In addition, statements using results from floating-point math functions—which are hardware-dependent—are always considered unsafe (see Section 16.4.1.13, “Replication and Floating-Point Values”).

**Handling of safe and unsafe statements.** A statement is treated differently depending on whether the statement is considered safe, and with respect to the binary logging format (that is, the current value of binlog_format).

- **No distinction is made in the treatment of safe and unsafe statements when the binary logging mode is ROW.**

- **If the binary logging format is MIXED, statements flagged as unsafe are logged using the row-based format; statements regarded as safe are logged using the statement-based format.**

- **If the binary logging format is STATEMENT, statements flagged as being unsafe generate a warning to this effect. (Safe statements are logged normally.)**
For more information, see Section 16.1.2, “Replication Formats”.

Statements considered unsafe.

Statements having the following characteristics are considered unsafe:

- **Statements containing system functions that may return a different value on slave.**
  These functions include `FOUND_ROWS()`, `GET_LOCK()`, `IS_FREE_LOCK()`, `IS_USED_LOCK()`, `LOAD_FILE()`, `MASTER_POS_WAIT()`, `RELEASE_LOCK()`, `ROW_COUNT()`, `SESSION_USER()`, `SLEEP()`, `SYSDATE()`, `SYSTEM_USER()`, `USER()`, `UUID()`, and `UUID_SHORT()`.

  In MySQL 5.1.43 and later, `RAND()` is also treated as unsafe. (Bug #11757207, Bug #49222)

- **Nondeterministic functions not considered unsafe.** Although these functions are not deterministic, they are treated as safe for purposes of logging and replication: `CONNECTION_ID()`, `CURDATE()`, `CURRENT_DATE()`, `CURRENT_TIME()`, `CURRENT_TIMESTAMP()`, `CURTIME()`, `LOCALTIME()`, `LOCALTIMESTAMP()`, `NOW()`, `UNIX_TIMESTAMP()`, `UTC_DATE()`, `UTC_TIME()`, `UTC_TIMESTAMP()`, and `LAST_INSERT_ID()`.

  For more information, see Section 16.4.1.15, “Replication and System Functions”.

- **References to system variables.** Most system variables are not replicated correctly using the statement-based format. For exceptions, see Section 5.4.4.3, “Mixed Binary Logging Format”.

  See Section 16.4.1.38, “Replication and Variables”.

- **UDFs.** Since we have no control over what a UDF does, we must assume that it is executing unsafe statements.

- **Updates a table having an AUTO_INCREMENT column.** This is unsafe because the order in which the rows are updated may differ on the master and the slave.

  In addition, an `INSERT` into a table that has a composite primary key containing an `AUTO_INCREMENT` column that is not the first column of this composite key is unsafe.

  For more information, see Section 16.4.1.1, “Replication and AUTO_INCREMENT”.

- **INSERT DELAYED statement.** This statement is considered unsafe because the insertion of the rows may interleave with concurrently executing statements.

- **INSERT ... ON DUPLICATE KEY UPDATE statements on tables with multiple primary or unique keys.** When executed against a table that contains more than one primary or unique key, this statement is considered unsafe, being sensitive to the order in which the storage engine checks the keys, which is not deterministic, and on which the choice of rows updated by the MySQL Server depends.

  Thus, such statements are considered unsafe.

- **Updates using LIMIT.** The order in which rows are retrieved is not specified.

  See Section 16.4.1.16, “Replication and LIMIT”.

- **Accesses or references log tables.** The contents of the system log table may differ between master and slave.

- **Nontransactional operations after transactional operations.** Within a transaction, allowing any nontransactional reads or writes to execute after any transactional reads or writes is considered unsafe.

  For more information, see Section 16.4.1.35, “Replication and Transactions”.

- **Accesses or references self-logging tables.** All reads and writes to self-logging tables are considered unsafe. Within a transaction, any statement following a read or write to self-logging tables is also considered unsafe.
Replication and Binary Logging Options and Variables

- LOAD DATA INFILE statements. Beginning with MySQL 5.1.50, LOAD DATA INFILE is considered unsafe, it causes a warning in statement-based mode, and a switch to row-based format when using mixed-format logging. See Section 16.4.1.17, “Replication and LOAD DATA INFILE”.

For additional information, see Section 16.4.1, “Replication Features and Issues”.

16.1.3 Replication and Binary Logging Options and Variables

The next few sections contain information about mysqld options and server variables that are used in replication and for controlling the binary log. Options and variables for use on replication masters and replication slaves are covered separately, as are options and variables relating to binary logging. A set of quick-reference tables providing basic information about these options and variables is also included (in the next section following this one).

Of particular importance is the --server-id option.

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--server-id=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>server_id</td>
</tr>
<tr>
<td>Variable</td>
<td>server_id</td>
</tr>
<tr>
<td>Global Scope</td>
<td>server_id</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>server_id</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>integer</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Min Value</td>
<td>0</td>
</tr>
<tr>
<td>Max Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

This option is common to both master and slave replication servers, and is used in replication to enable master and slave servers to identify themselves uniquely. For additional information, see Section 16.1.3.2, “Replication Master Options and Variables”, and Section 16.1.3.3, “Replication Slave Options and Variables”.

On the master and each slave, you must use the --server-id option to establish a unique replication ID in the range from 1 to $2^{32} - 1$. “Unique”, means that each ID must be different from every other ID in use by any other replication master or slave. Example: server-id=3.

If you omit --server-id, the default ID is 0, in which case the master refuses connections from all slaves, and slaves refuse to connect to the master. In MySQL 5.1, whether the server ID is set to 0 explicitly or the default is allowed to be used, the server sets the server_id system variable to 1; this is a known issue that is fixed in MySQL 5.7.

For more information, see Section 16.1.1.2, “Setting the Replication Slave Configuration”.

16.1.3.1 Replication and Binary Logging Option and Variable Reference

The following tables list basic information about the MySQL command-line options and system variables applicable to replication and the binary log.

Table 16.1 Summary of Replication options and variables in MySQL 5.1

#### relay-log-info-file

<table>
<thead>
<tr>
<th>Yes</th>
<th>Yes</th>
<th>No</th>
<th>No</th>
<th>Yes</th>
<th>Yes</th>
</tr>
</thead>
</table>

**DESCRIPTION:** The location and name of the file that remembers where the SQL replication thread is in the relay logs.

#### relay_log_index

<table>
<thead>
<tr>
<th>Yes</th>
<th>Yes</th>
<th>No</th>
<th>No</th>
<th>Yes</th>
<th>Global</th>
</tr>
</thead>
</table>

**DESCRIPTION:** The name of the relay log index file.

#### relay_log_info_file

<table>
<thead>
<tr>
<th>Yes</th>
<th>Yes</th>
<th>No</th>
<th>No</th>
<th>Yes</th>
<th>Global</th>
</tr>
</thead>
</table>

**DESCRIPTION:** The name of the file in which the slave records information about the relay logs.

#### relay_log_purge

<table>
<thead>
<tr>
<th>Yes</th>
<th>Yes</th>
<th>No</th>
<th>No</th>
<th>Yes</th>
<th>Global</th>
</tr>
</thead>
</table>

**DESCRIPTION:** Determines whether relay logs are purged.

#### relay_log_space_limit

<table>
<thead>
<tr>
<th>Yes</th>
<th>Yes</th>
<th>No</th>
<th>No</th>
<th>Yes</th>
<th>Global</th>
</tr>
</thead>
</table>

**DESCRIPTION:** Maximum space to use for all relay logs.

#### replicate-do-db

<table>
<thead>
<tr>
<th>Yes</th>
<th>No</th>
<th>No</th>
<th>No</th>

DESCRIPTION: Option used by mysql-test for debugging and testing of replication

Section 16.1.3.4, “Binary Log Options and Variables”, provides more detailed information about options and variables relating to binary logging. For additional general information about the binary log, see Section 5.4.4, “The Binary Log”.

For information about the `sql_log_bin` and `sql_log_off` variables, see Section 5.1.4, “Server System Variables”.

For a table showing all command-line options, system and status variables used with `mysqld`, see Section 5.1.1, “Server Option and Variable Reference”.

#### 16.1.3.2 Replication Master Options and Variables

This section describes the server options and system variables that you can use on replication master servers. You can specify the options either on the command line or in an option file. You can specify system variable values using `SET`.

On the master and each slave, you must use the `server-id` option to establish a unique replication ID. For each server, you should pick a unique positive integer in the range from 1 to $2^{32} - 1$, and each ID must be different from every other ID in use by any other replication master or slave. Example: `server-id=3`.

For options used on the master for controlling binary logging, see Section 16.1.3.4, “Binary Log Options and Variables”.

### System Variables Used on Replication Masters

The following system variables are used in controlling replication masters:

- **`auto_increment_increment`**

<table>
<thead>
<tr>
<th>System Variable</th>
<th>Name</th>
<th>auto_increment_increment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable</td>
<td>Global, Session</td>
<td></td>
</tr>
<tr>
<td>Scope</td>
<td>DynamicYes</td>
<td></td>
</tr>
<tr>
<td>Variable</td>
<td>integer</td>
<td></td>
</tr>
<tr>
<td>Default</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>Min Value</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>Max Value</td>
<td>65535</td>
<td></td>
</tr>
</tbody>
</table>

`auto_increment_increment` and `auto_increment_offset` are intended for use with master-to-master replication, and can be used to control the operation of `AUTO_INCREMENT` columns. Both variables have global and session values, and each can assume an integer value between 1 and 65,535 inclusive. Setting the value of either of these two variables to 0 causes its value to be set to 1 instead. Attempting to set the value of either of these two variables to an integer greater than 65,535 or less than 0 causes its value to be set to 65,535 instead. Attempting to set the value of
**auto_increment_increment** or **auto_increment_offset** to a noninteger value gives rise to an error, and the actual value of the variable remains unchanged.

**Note**

**auto_increment_increment** is supported for use with **NDB** tables beginning with MySQL 5.1.20, MySQL Cluster NDB 6.2.5, and MySQL Cluster NDB 6.3.2. Previously, setting it when using MySQL Cluster tables or MySQL Cluster Replication produced unpredictable results.

These two variables affect **AUTO_INCREMENT** column behavior as follows:

- **auto_increment_increment** controls the interval between successive column values. For example:

  ```
  mysql> SHOW VARIABLES LIKE 'auto_inc%';
  +--------------------------+-------+
  | Variable_name            | Value |
  +--------------------------+-------+
  | auto_increment_increment | 1     |
  | auto_increment_offset    | 1     |
  +--------------------------+-------+
  2 rows in set (0.00 sec)
  
  mysql> CREATE TABLE autoincl
  -> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
  Query OK, 0 rows affected (0.04 sec)
  
  mysql> SET @@auto_increment_increment=10;
  Query OK, 0 rows affected (0.00 sec)
  
  mysql> SHOW VARIABLES LIKE 'auto_inc%';
  +--------------------------+-------+
  | Variable_name            | Value |
  +--------------------------+-------+
  | auto_increment_increment | 10    |
  | auto_increment_offset    | 1     |
  +--------------------------+-------+
  2 rows in set (0.01 sec)
  
  mysql> INSERT INTO autoincl VALUES (NULL), (NULL), (NULL), (NULL);
  Query OK, 4 rows affected (0.00 sec)
  Records: 4  Duplicates: 0  Warnings: 0
  
  mysql> SELECT col FROM autoincl;
  +-----+
  | col  |
  +-----+
  | 1    |
  | 11   |
  | 21   |
  | 31   |
  +-----+
  4 rows in set (0.00 sec)
  ```

- **auto_increment_offset** determines the starting point for the **AUTO_INCREMENT** column value. Consider the following, assuming that these statements are executed during the same session as the example given in the description for **auto_increment_increment**:

  ```
  mysql> SET @@auto_increment_offset=5;
  Query OK, 0 rows affected (0.00 sec)
  
  mysql> SHOW VARIABLES LIKE 'auto_inc%';
  +--------------------------+-------+
  | Variable_name            | Value |
  +--------------------------+-------+
  | auto_increment_increment | 10    |
  | auto_increment_offset    | 5     |
  +--------------------------+-------+
  2 rows in set (0.00 sec)
  ```
Replication and Binary Logging Options and Variables

| auto_increment_offset | 5 |
+-----------------------+---+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoinc2
  -> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO autoinc2 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT col FROM autoinc2;

+-----+
| col |
+-----+
| 15  |
| 25  |
| 35  |
+-----+
4 rows in set (0.02 sec)

If the value of `auto_increment_offset` is greater than that of `auto_increment_increment`, the value of `auto_increment_offset` is ignored.

Should one or both of these variables be changed and then new rows inserted into a table containing an `AUTO_INCREMENT` column, the results may seem counterintuitive because the series of `AUTO_INCREMENT` values is calculated without regard to any values already present in the column, and the next value inserted is the least value in the series that is greater than the maximum existing value in the `AUTO_INCREMENT` column. In other words, the series is calculated like so:

\[
\text{auto_increment_offset} + N \times \text{auto_increment_increment}
\]

where \( N \) is a positive integer value in the series \([1, 2, 3, \ldots]\). For example:

mysql> SHOW VARIABLES LIKE 'auto_inc%';

+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| auto_increment_increment | 10    |
| auto_increment_offset    | 5     |
+--------------------------+-------+
2 rows in set (0.00 sec)

mysql> SELECT col FROM autoinc1;

+-----+
| col |
+-----+
| 1   |
| 11  |
| 21  |
| 31  |
+-----+
4 rows in set (0.00 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT col FROM autoinc1;

+-----+
| col |
+-----+
| 1   |
| 11  |
| 21  |
| 31  |
| 35  |
+-----+
5 rows in set (0.02 sec)
The values shown for `auto_increment_increment` and `auto_increment_offset` generate the series \( 5 + N \times 10 \), that is, \([5, 15, 25, 35, 45, \ldots]\). The greatest value present in the `col` column prior to the `INSERT` is 31, and the next available value in the `AUTO_INCREMENT` series is 35, so the inserted values for `col` begin at that point and the results are as shown for the `SELECT` query.

It is not possible to confine the effects of these two variables to a single table, and thus they do not take the place of the sequences offered by some other database management systems; these variables control the behavior of all `AUTO_INCREMENT` columns in all tables on the MySQL server. If the global value of either variable is set, its effects persist until the global value is changed or overridden by setting the session value, or until `mysqld` is restarted. If the local value is set, the new value affects `AUTO_INCREMENT` columns for all tables into which new rows are inserted by the current user for the duration of the session, unless the values are changed during that session.

The default value of `auto_increment_increment` is 1. See Section 16.4.1.1, “Replication and `AUTO_INCREMENT`”.

- `auto_increment_offset`

<table>
<thead>
<tr>
<th>System Variable</th>
<th>Name</th>
<th>auto_increment_offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
<td></td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
<td></td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type</td>
<td>integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>Min Value</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>Max Value</td>
<td>65535</td>
<td></td>
</tr>
</tbody>
</table>

This variable has a default value of 1. For particulars, see the description for `auto_increment_increment`.

Note

`auto_increment_offset` is supported for use with NDB tables beginning with MySQL 5.1.20, MySQL Cluster NDB 6.2.5, and MySQL Cluster NDB 6.3.2. Previously, setting it when using MySQL Cluster tables or MySQL Cluster Replication produced unpredictable results.

16.1.3.3 Replication Slave Options and Variables

**Startup Options for Replication Slaves**

**System Variables Used on Replication Slaves**

This section describes the server options and system variables that apply to slave replication servers. You can specify the options either on the command line or in an option file. Many of the options can be set while the server is running by using the `CHANGE MASTER TO` statement. You can specify system variable values using `SET`.

1690
**Server ID.** On the master and each slave, you must use the `server-id` option to establish a unique replication ID in the range from 1 to $2^{32} - 1$. “Unique” means that each ID must be different from every other ID in use by any other replication master or slave. Example `my.cnf` file:

```ini
[mysqld]
server-id=3
```

**Important**

Certain `--master-xxx` options are handled in a special way to ensure that the active replication configuration is not inadvertently altered or affected:

- `--master-host`
- `--master-user`
- `--master-password`
- `--master-port`
- `--master-connect-retry`
- `--master-ssl`
- `--master-ssl-ca`
- `--master-ssl-capath`
- `--master-ssl-cert`
- `--master-ssl-cipher`
- `--master-ssl-key`

Before MySQL 5.1.17, these options are silently ignored if given unless there is no `master.info` file. If that file exists, the MySQL server has already previously been configured for replication, so the information in the file is used instead. Because the server gives an existing `master.info` file precedence over the startup options just described, you might elect not to use startup options for these values at all, and instead to specify the replication parameters associated with them by using the `CHANGE MASTER TO` statement. See Section 13.4.2.1, “CHANGE MASTER TO Syntax”.

Beginning with MySQL 5.1.17, these options are deprecated and have no effect when `mysqld` is started. If they are used, an appropriate warning is written to the error log. Instead, you must use `CHANGE MASTER TO` to set the values corresponding to the deprecated options. These options are removed in MySQL 5.5.

The `master.info` file format in MySQL 5.1 includes as its first line the number of lines in the file. (See Section 16.2.2, “Replication Relay and Status Logs”.) If you upgrade an older server (before MySQL 4.1.1) to a newer version, the new server upgrades the `master.info` file to the new format automatically when it starts. However, if you downgrade a newer server to an older version, you should remove the first line manually before starting the older server for the first time.

If no `master.info` file exists when the slave server starts, it uses the values for those options that are specified in option files or on the command line. This occurs when you start the server as a replication slave for the very first time, when you use `CHANGE MASTER TO`, or when you have run `RESET SLAVE` and then have shut down and restarted the slave.
Because the server uses `master.info` file contents and ignores any startup options that correspond to the values listed in the file, if you start the slave server with different values of the startup options that correspond to values in the file, the different values have no effect. To use different values, the preferred method is to use the `CHANGE MASTER TO` statement to reset the values while the slave is running. Alternatively, you can stop the server, remove the `master.info` file, and restart the server with different option values.

Suppose that you specify this option in your `my.cnf` file to configure a pre-5.1.17 slave server:

```
[mysqld]
master-host=some_host
```

The first time you start the server as a replication slave, it reads and uses that option from the `my.cnf` file. The server then records the value in the `master.info` file. The next time you start the server, it reads the master host value from the `master.info` file only and ignores the value in the option file. If you modify the `my.cnf` file to specify a different master host value of `some_other_host`, the change has no effect. Instead, use `CHANGE MASTER TO` to change the value.

This example shows a more extensive use of startup options to configure a pre-5.1.17 slave server:

```
[mysqld]
server-id=2
master-host=db-master.mycompany.com
master-port=3306
master-user=pertinax
master-password=freitag
master-connect-retry=60
report-host=db-slave.mycompany.com
```

As of 5.1.17, the `master-xxx` options are ignored and result in warnings in the error log.

### Startup Options for Replication Slaves

The following list describes startup options for controlling replication slave servers. Many of these options can be set while the server is running by using the `CHANGE MASTER TO` statement. Others, such as the `--replicate-*` options, can be set only when the slave server starts. Replication-related system variables are discussed later in this section.

- **--abort-slave-event-count**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--abort-slave-event-count=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>Type integer</td>
</tr>
<tr>
<td></td>
<td>Default 0</td>
</tr>
<tr>
<td></td>
<td>Min 0</td>
</tr>
<tr>
<td></td>
<td>Value</td>
</tr>
</tbody>
</table>

  When this option is set to some positive integer `value` other than 0 (the default) it affects replication behavior as follows: After the slave SQL thread has started, value log events are permitted to be executed; after that, the slave SQL thread does not receive any more events, just as if the network connection from the master were cut. The slave thread continues to run, and the output from `SHOW SLAVE STATUS` displays `Yes` in both the `Slave_IO_Running` and the `Slave_SQL_Running` columns, but no further events are read from the relay log.

  This option is used internally by the MySQL test suite for replication testing and debugging. It is not intended for use in a production setting.

- **--disconnect-slave-event-count**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--disconnect-slave-event-count=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>Type integer</td>
</tr>
</tbody>
</table>

  This option is used internally by the MySQL test suite for replication testing and debugging. It is not intended for use in a production setting.
Replication and Binary Logging Options and Variables

| Default | 0 |

This option is used internally by the MySQL test suite for replication testing and debugging.

- **--log-slave-updates**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--log-slave-updates</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name</td>
</tr>
<tr>
<td></td>
<td>log_slave_updates</td>
</tr>
<tr>
<td></td>
<td>Variable</td>
</tr>
<tr>
<td></td>
<td>Global</td>
</tr>
<tr>
<td></td>
<td>Scope</td>
</tr>
<tr>
<td></td>
<td>Dynamic</td>
</tr>
<tr>
<td></td>
<td>No</td>
</tr>
<tr>
<td></td>
<td>Variable</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type</td>
</tr>
<tr>
<td></td>
<td>boolean</td>
</tr>
<tr>
<td></td>
<td>Default</td>
</tr>
<tr>
<td></td>
<td>OFF</td>
</tr>
</tbody>
</table>

Normally, a slave does not log to its own binary log any updates that are received from a master server. This option tells the slave to log the updates performed by its SQL thread to its own binary log. For this option to have any effect, the slave must also be started with the **--log-bin** option to enable binary logging. **--log-slave-updates** is used when you want to chain replication servers. For example, you might want to set up replication servers using this arrangement:

```
A -> B -> C
```

Here, A serves as the master for the slave B, and B serves as the master for the slave C. For this to work, B must be both a master and a slave. You must start both A and B with **--log-bin** to enable binary logging, and B with the **--log-slave-updates** option so that updates received from A are logged by B to its binary log.

When using MySQL Cluster Replication prior to MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.13, records for "empty" epochs—that is, epochs in which no changes to NDBCLUSTER data or tables took place—were inserted into the ndb_apply_status and ndb_binlog_index tables on the slave even when **--log-slave-updates** was disabled (Bug #37472). Beginning with MySQL Cluster NDB 6.3.33, MySQL Cluster NDB 7.0.14, and MySQL Cluster NDB 7.1.3, it is possible to re-enable the older behavior by using the **--ndb-log-empty-epochs** option.

**Note**

The **--ndb-log-empty-epochs** option was first implemented in MySQL Cluster NDB 6.3.21 and MySQL Cluster NDB 6.4.1, but did not work correctly before the versions cited previously.

- **--log-slow-slave-statements**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.21</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--log-slow-slave-statements</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type</td>
</tr>
<tr>
<td></td>
<td>boolean</td>
</tr>
<tr>
<td></td>
<td>Default</td>
</tr>
<tr>
<td></td>
<td>OFF</td>
</tr>
</tbody>
</table>

When the slow query log is enabled, this option enables logging for queries that have taken more than long_query_time seconds to execute on the slave.

This option was added in MySQL 5.1.21.

- **--log-warnings[=level]**

  | Command-Line Format | --log-warnings[=#] |

</tr>
</tbody>
</table>

This option causes a server to print more messages to the error log about what it is doing. With respect to replication, the server generates warnings that it succeeded in reconnecting after a network/connection failure, and informs you as to how each slave thread started. This option is enabled (1) by default; to disable it, use `--log-warnings=0`. Aborted connections are not logged to the error log unless the value is greater than 1.

Note that the effects of this option are not limited to replication. It produces warnings across a spectrum of server activities.

- `--master-connect-retry=seconds`

  **Deprecated** 5.1.17

  **Command-Line Format**
  
  `--master-connect-retry=#`

  **Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
</tr>
</tbody>
</table>

  Default 60

  The number of seconds that the slave thread sleeps before trying to reconnect to the master in case the master goes down or the connection is lost. The value in the `master.info` file takes precedence if it can be read. If not set, the default is 60. Connection retries are not invoked until the slave times out reading data from the master according to the value of `--slave-net-timeout`. The number of reconnection attempts is limited by the `--master-retry-count` option.

  This option is deprecated as of MySQL 5.1.17 and is removed in MySQL 5.5.

- `slave-max-allowed-packet=bytes`

  **Introduced** 5.1.64

  **Command-Line Format**

  `--slave-max-allowed-packet=#`

  **Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
</tr>
</tbody>
</table>

  Default 1073741824

  Min 1024
In MySQL 5.1.64 and later, this option sets the maximum packet size in bytes for the slave SQL and I/O threads, so that large updates using row-based replication do not cause replication to fail because an update exceeded `max_allowed_packet`. (Bug #12400221, Bug #60926)

The corresponding server variable `slave_max_allowed_packet` always has a value that is a positive integer multiple of 1024; if you set it to some value that is not such a multiple, the value is automatically rounded down to the next highest multiple of 1024. (For example, if you start the server with `--slave-max-allowed-packet=10000`, the value used is 9216; setting 0 as the value causes 1024 to be used.) A truncation warning is issued in such cases.

The maximum (and default) value is 1073741824 (1 GB); the minimum is 1024.

- `--master-host=host_name`

<table>
<thead>
<tr>
<th>Deprecated</th>
<th>5.1.17</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--master-host=name</code></td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type  string</td>
</tr>
</tbody>
</table>

The host name or IP address of the master replication server. The value in `master.info` takes precedence if it can be read. If no master host is specified, the slave thread does not start.

This option is deprecated as of MySQL 5.1.17 and is removed in MySQL 5.5.

- `--master-info-file=file_name`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--master-info-file=file_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>Type  file name</td>
</tr>
<tr>
<td>Default</td>
<td>master.info</td>
</tr>
</tbody>
</table>

The name to use for the file in which the slave records information about the master. The default name is `master.info` in the data directory. For information about the format of this file, see Section 16.2.2.2, “Slave Status Logs”.

- `--master-password=password`

<table>
<thead>
<tr>
<th>Deprecated</th>
<th>5.1.17</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--master-password=name</code></td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type  string</td>
</tr>
</tbody>
</table>

The password of the account that the slave thread uses for authentication when it connects to the master. The value in the `master.info` file takes precedence if it can be read. If not set, an empty password is assumed.

This option is deprecated as of MySQL 5.1.17 and is removed in MySQL 5.5.

- `--master-port=port_number`

<table>
<thead>
<tr>
<th>Deprecated</th>
<th>5.1.17</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--master-port=#</code></td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type  integer</td>
</tr>
<tr>
<td>Default</td>
<td>3306</td>
</tr>
</tbody>
</table>

Default
The TCP/IP port number that the master is listening on. The value in the `master.info` file takes precedence if it can be read. If not set, the compiled-in setting is assumed (normally 3306).

This option is deprecated as of MySQL 5.1.17 and is removed in MySQL 5.5.

- `--master-retry-count=count`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--master-retry-count=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values (32-bit platforms)</td>
<td>Type integer</td>
</tr>
<tr>
<td></td>
<td>Default 86400</td>
</tr>
<tr>
<td></td>
<td>Min Value 0</td>
</tr>
<tr>
<td></td>
<td>Max Value 4294967295</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values (64-bit platforms)</th>
<th>Type integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default 86400</td>
<td></td>
</tr>
<tr>
<td>Min Value 0</td>
<td></td>
</tr>
<tr>
<td>Max Value 18446744073709551615</td>
<td></td>
</tr>
</tbody>
</table>

The number of times that the slave tries to connect to the master before giving up. Reconnects are attempted at intervals set by the `--master-connect-retry` option (or the `MASTER_CONNECT_RETRY` option of the `CHANGE MASTER TO` statement) and reconnects are triggered when data reads by the slave time out according to the `--slave-net-timeout` option. The default value is 86400. A value of 0 means “infinite”; the slave attempts to connect forever.

- `--master-user=user_name`

<table>
<thead>
<tr>
<th>Deprecated</th>
<th>5.1.17</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--master-user=name</code></td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type string</td>
</tr>
<tr>
<td></td>
<td>Default test</td>
</tr>
</tbody>
</table>

The user name of the account that the slave thread uses for authentication when it connects to the master. This account must have the `REPLICATION SLAVE` privilege. The value in the `master.info` file takes precedence if it can be read. If the master user name is not set, the name `test` is assumed.

This option is deprecated as of MySQL 5.1.17 and is removed in MySQL 5.5.

- `--max-relay-log-size=size`
### Command-Line Format

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>--max_relay_log_size=</td>
<td>#</td>
</tr>
</tbody>
</table>

### System Variable

</thead>
</table>

<table>
<thead>
<tr>
<th>Min Value</th>
<th>0</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Max Value</th>
<th>1073741824</th>
</tr>
</thead>
</table>

The size at which the server rotates relay log files automatically. If this value is nonzero, the relay log is rotated automatically when its size exceeds this value. If this value is zero (the default), the size at which relay log rotation occurs is determined by the value of `max_binlog_size`. For more information, see Section 16.2.2.1, “The Slave Relay Log”.

- `--relay-log=file_name`

### Command-Line Format

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>--relay-log=</td>
<td>file_name</td>
</tr>
</tbody>
</table>

### System Variable

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>relay_log</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Variable</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>Global</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Dynamic</th>
<th>No</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Variable</th>
<th>Yes</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Type</th>
<th>0</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Min Value</th>
<th>0</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Max Value</th>
<th>host_name-relay-bin</th>
</tr>
</thead>
</table>

The base name for the relay log. The default base name is `host_name-relay-bin`. The server writes the file in the data directory unless the base name is given with a leading absolute path name to specify a different directory. The server creates relay log files in sequence by adding a numeric suffix to the base name.

Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; the default base name is used only if the option is not actually specified. If you use the `--relay-log` option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see Section 4.2.3, “Specifying Program Options”.

If you specify this option, the value specified is also used as the base name for the relay log index file. You can override this behavior by specifying a different relay log index file base name using the `--relay-log-index` option.

You may find the `--relay-log` option useful in performing the following tasks:

- Creating relay logs whose names are independent of host names.
- If you need to put the relay logs in some area other than the data directory because your relay logs tend to be very large and you do not want to decrease `max_relay_log_size`.
- To increase speed by using load-balancing between disks.

- `--relay-log-index=file_name`
Replication and Binary Logging Options and Variables

**Command-Line Format**

```
--relay-log-index=file_name
```

**System Variable**

<table>
<thead>
<tr>
<th>Name</th>
<th>Variable</th>
<th>Scope</th>
<th>Dynamic</th>
</tr>
</thead>
<tbody>
<tr>
<td>relay_log_index</td>
<td>Global</td>
<td></td>
<td>No</td>
</tr>
</tbody>
</table>

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>file name</td>
</tr>
</tbody>
</table>

The name to use for the relay log index file. The default name is `host_name-relay-bin.index` in the data directory, where `host_name` is the name of the slave server.

Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; *the default base name is used only if the option is not actually specified*. If you use the `--relay-log-index` option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see Section 4.2.3, "Specifying Program Options".

If you specify this option, the value specified is also used as the base name for the relay logs. You can override this behavior by specifying a different relay log file base name using the `--relay-log` option.

- `--relay-log-info-file=file_name`

**Command-Line Format**

```
--relay-log-info-file=file_name
```

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>file name</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>relay-log.info</td>
</tr>
</tbody>
</table>

The name to use for the file in which the slave records information about the relay logs. The default name is `relay-log.info` in the data directory. For information about the format of this file, see Section 16.2.2.2, "Slave Status Logs".

- `--relay-log-purge={0|1}`

**Command-Line Format**

```
--relay_log_purge=N
```

**System Variable**

<table>
<thead>
<tr>
<th>Name</th>
<th>Variable</th>
<th>Scope</th>
<th>Dynamic</th>
</tr>
</thead>
<tbody>
<tr>
<td>relay_log_purge</td>
<td>Global</td>
<td></td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRUE</td>
</tr>
</tbody>
</table>

Disable or enable automatic purging of relay logs as soon as they are no longer needed. The default value is 1 (enabled). This is a global variable that can be changed dynamically with `SET GLOBAL relay_log_purge = N`.

- `--relay-log-space-limit=size`

**Command-Line Format**

```
--relay_log_space_limit=#
```

**System Variable**

<table>
<thead>
<tr>
<th>Name</th>
<th>Variable</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>relay_log_space_limit</td>
<td>Global</td>
<td></td>
</tr>
</tbody>
</table>

The name to use for the file in which the slave records information about the relay logs.
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Dynamic No Variable</th>
<th>Type</th>
<th>Default</th>
<th>Min Value</th>
<th>Max Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values (32-bit platforms)</td>

<td>0</td>
<td>0</td>
<td>4294967295</td>
</tr>
<tr>
<td>Permitted Values (64-bit platforms)</td>
<td>integer</td>
<td>0</td>
<td>0</td>
<td>18446744073709551616</td>
</tr>
</tbody>
</table>

This option places an upper limit on the total size in bytes of all relay logs on the slave. A value of 0 means “no limit.” This is useful for a slave server host that has limited disk space. When the limit is reached, the I/O thread stops reading binary log events from the master server until the SQL thread has caught up and deleted some unused relay logs. Note that this limit is not absolute: There are cases where the SQL thread needs more events before it can delete relay logs. In that case, the I/O thread exceeds the limit until it becomes possible for the SQL thread to delete some relay logs because not doing so would cause a deadlock. You should not set `--relay-log-space-limit` to less than twice the value of `--max-relay-log-size` (or `--max-binlog-size` if `--max-relay-log-size` is 0). In that case, there is a chance that the I/O thread waits for free space because `--relay-log-space-limit` is exceeded, but the SQL thread has no relay log to purge and is unable to satisfy the I/O thread. This forces the I/O thread to ignore `--relay-log-space-limit` temporarily.

- **`--replicate-do-db=db_name`**

| Command-Line Format | `--replicate-do-db=name` | Permitted Values | Type | string |

The effects of this option depend on whether statement-based or row-based replication is in use.

**Statement-based replication.** Tell the slave SQL thread to restrict replication to statements where the default database (that is, the one selected by `USE`) is `db_name`. To specify more than one database, use this option multiple times, once for each database; however, doing so does not replicate cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` while a different database (or no database) is selected.

**Warning**
To specify multiple databases you must use multiple instances of this option. Because database names can contain commas, if you supply a comma separated list then the list will be treated as the name of a single database.

An example of what does not work as you might expect when using statement-based replication: If the slave is started with `--replicate-do-db=sales` and you issue the following statements on the master, the `UPDATE` statement is not replicated:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```
The main reason for this “check just the default database” behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table DELETE statements or multiple-table UPDATE statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

**Row-based replication.** Tells the slave SQL thread to restrict replication to database `db_name`. Only tables belonging to `db_name` are changed; the current database has no effect on this. Suppose that the slave is started with `--replicate-do-db=sales` and row-based replication is in effect, and then the following statements are run on the master:

```sql
USE prices;
UPDATE sales.february SET amount=amount+100;
```

The `february` table in the `sales` database on the slave is changed in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, issuing the following statements on the master has no effect on the slave when using row-based replication and `--replicate-do-db=sales`:

```sql
USE prices;
UPDATE prices.march SET amount=amount-25;
```

Even if the statement `USE prices` were changed to `USE sales`, the `UPDATE` statement's effects would still not be replicated.

Another important difference in how `--replicate-do-db` is handled in statement-based replication as opposed to row-based replication occurs with regard to statements that refer to multiple databases. Suppose that the slave is started with `--replicate-do-db=db1`, and the following statements are executed on the master:

```sql
USE db1;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

If you are using statement-based replication, then both tables are updated on the slave. However, when using row-based replication, only `table1` is affected on the slave; since `table2` is in a different database, `table2` on the slave is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

```sql
USE db4;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

In this case, the `UPDATE` statement would have no effect on the slave when using statement-based replication. However, if you are using row-based replication, the `UPDATE` would change `table1` on the slave, but not `table2`—in other words, only tables in the database named by `--replicate-do-db` are changed, and the choice of default database has no effect on this behavior.

If you need cross-database updates to work, use `--replicate-wild-do-table=db_name.%` instead. See Section 16.2.3, “How Servers Evaluate Replication Filtering Rules”.

**Note**

This option affects replication in the same manner that `--binlog-do-db` affects binary logging, and the effects of the replication format on how `--replicate-do-db` affects replication behavior are the same as those of the logging format on the behavior of `--binlog-do-db`.

Beginning with MySQL 5.1.35, this option has no effect on `BEGIN`, `COMMIT`, or `ROLLBACK` statements. (Bug #43263)
• **--replicate-ignore-db=db_name**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--replicate-ignore-db=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>Type string</td>
</tr>
</tbody>
</table>

As with **--replicate-do-db**, the effects of this option depend on whether statement-based or row-based replication is in use.

**Statement-based replication.** Tells the slave SQL thread not to replicate any statement where the default database (that is, the one selected by `USE`) is `db_name`.

**Row-based replication.** Tells the slave SQL thread not to update any tables in the database `db_name`. The default database has no effect.

When using statement-based replication, the following example does not work as you might expect. Suppose that the slave is started with **--replicate-ignore-db=sales** and you issue the following statements on the master:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The `UPDATE` statement is replicated in such a case because **--replicate-ignore-db** applies only to the default database (determined by the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based replication, the `UPDATE` statement's effects are not propagated to the slave, and the slave's copy of the `sales.january` table is unchanged; in this instance, **--replicate-ignore-db=sales** causes all changes made to tables in the master's copy of the `sales` database to be ignored by the slave.

To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, if you supply a comma separated list then the list will be treated as the name of a single database.

You should not use this option if you are using cross-database updates and you do not want these updates to be replicated. See **Section 16.2.3, “How Servers Evaluate Replication Filtering Rules”**.

If you need cross-database updates to work, use **--replicate-wild-ignore-table=db_name. %** instead. See **Section 16.2.3, “How Servers Evaluate Replication Filtering Rules”**.

**Note**

This option affects replication in the same manner that **--binlog-ignore-db** affects binary logging, and the effects of the replication format on how **--replicate-ignore-db** affects replication behavior are the same as those of the logging format on the behavior of **--binlog-ignore-db**.

Beginning with MySQL 5.1.35, this option has no effect on `BEGIN`, `COMMIT`, or `ROLLBACK` statements. (Bug #43263)

• **--replicate-do-table=db_name.tbl_name**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--replicate-do-table=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>Type string</td>
</tr>
</tbody>
</table>

Tells the slave SQL thread to restrict replication to the specified table. To specify more than one table, use this option multiple times, once for each table. This works for both cross-database updates and default database updates, in contrast to **--replicate-do-db**. See **Section 16.2.3, “How Servers Evaluate Replication Filtering Rules”**.
Replication and Binary Logging Options and Variables

This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the `--replicate-*-db` options.

- **--replicate-ignore-table=db_name.tbl_name**

  **Command-Line Format**
  
  `--replicate-ignore-table=name`

  **Permitted Values**
  
<table>
<thead>
<tr>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
</tr>
</tbody>
</table>

  Tells the slave SQL thread not to replicate any statement that updates the specified table, even if any other tables might be updated by the same statement. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates, in contrast to `--replicate-ignore-db`. See Section 16.2.3, "How Servers Evaluate Replication Filtering Rules".

  This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the `--replicate-*-db` options.

- **--replicate-rewrite-db=from_name->to_name**

  **Command-Line Format**
  
  `--replicate-rewrite-db=old_name->new_name`

  **Permitted Values**
  
<table>
<thead>
<tr>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
</tr>
</tbody>
</table>

  Tells the slave to translate the default database (that is, the one selected by `USE`) to `to_name` if it was `from_name` on the master. Only statements involving tables are affected (not statements such as `CREATE_DATABASE`, `DROP_DATABASE`, and `ALTER_DATABASE`), and only if `from_name` is the default database on the master. To specify multiple rewrites, use this option multiple times. The server uses the first one with a `from_name` value that matches. The database name translation is done before the `--replicate-*` rules are tested.

  Statements in which table names are qualified with database names when using this option do not work with table-level replication filtering options such as `--replicate-do-table`. Suppose we have a database named `a` on the master, one named `b` on the slave, each containing a table `t`, and have started the master with `--replicate-rewrite-db='a->b'`. At a later point in time, we execute `DELETE FROM a.t`.

  In this case, no relevant filtering rule works, for the reasons shown here:

  1. `--replicate-do-table=a.t` does not work because the slave has table `t` in database `b`.
  2. `--replicate-do-table=b.t` does not match the original statement and so is ignored.
  3. `--replicate-do-table=*.t` is handled identically to `--replicate-do-table=a.t`, and thus does not work, either.

  Similarly, the `--replication-rewrite-db` option does not work with cross-database updates.

  If you use this option on the command line and the ">" character is special to your command interpreter, quote the option value. For example:

  ```
  shell> mysql --replicate-rewrite-db="olddb->newdb"
  ```

- **--replicate-same-server-id**

  **Command-Line Format**
  
  `--replicate-same-server-id`

  **Permitted Values**
  
<table>
<thead>
<tr>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>FALSE</td>
</tr>
</tbody>
</table>

  This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the `--replicate-*-db` options.
To be used on slave servers. Usually you should use the default setting of 0, to prevent infinite loops caused by circular replication. If set to 1, the slave does not skip events having its own server ID. Normally, this is useful only in rare configurations. Cannot be set to 1 if --log-slave-updates is used. By default, the slave I/O thread does not write binary log events to the relay log if they have the slave’s server ID (this optimization helps save disk usage). If you want to use --replicate-same-server-id, be sure to start the slave with this option before you make the slave read its own events that you want the slave SQL thread to execute.

- **--replicate-wild-do-table=db_name.tbl_name**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--replicate-wild-do-table=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>string</td>
</tr>
</tbody>
</table>

Tells the slave thread to restrict replication to statements where any of the updated tables match the specified database and table name patterns. Patterns can contain the “%” and “_” wildcard characters, which have the same meaning as for the LIKE pattern-matching operator. To specify more than one table, use this option multiple times, once for each table. This works for cross-database updates. See Section 16.2.3, “How Servers Evaluate Replication Filtering Rules”.

This option applies to tables, views, and triggers. It does not apply to stored procedures and functions, or events. To filter statements operating on the latter objects, use one or more of the --replicate-*-db options.

Example: **--replicate-wild-do-table=foo%.bar%** replicates only updates that use a table where the database name starts with foo and the table name starts with bar.

If the table name pattern is %, it matches any table name and the option also applies to database-level statements (CREATE DATABASE, DROP DATABASE, and ALTER DATABASE). For example, if you use **--replicate-wild-do-table=foo%.%**, database-level statements are replicated if the database name matches the pattern foo%.

To include literal wildcard characters in the database or table name patterns, escape them with a backslash. For example, to replicate all tables of a database that is named my_own%db, but not replicate tables from the my1ownAABCdb database, you should escape the “_” and “%” characters like this: **--replicate-wild-do-table=my\_own\%db**. If you use the option on the command line, you might need to double the backslashes or quote the option value, depending on your command interpreter. For example, with the bash shell, you would need to type **--replicate-wild-do-table=my\_own\%db**.

- **--replicate-wild-ignore-table=db_name.tbl_name**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--replicate-wild-ignore-table=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>string</td>
</tr>
</tbody>
</table>

Tells the slave thread not to replicate a statement where any table matches the given wildcard pattern. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates. See Section 16.2.3, “How Servers Evaluate Replication Filtering Rules”.

Example: **--replicate-wild-ignore-table=foo%.bar%** does not replicate updates that use a table where the database name starts with foo and the table name starts with bar.

For information about how matching works, see the description of the --replicate-wild-do-table option. The rules for including literal wildcard characters in the option value are the same as for --replicate-wild-ignore-table as well.

- **--report-host=host_name**
### Command-Line Format

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--report-host=host_name</code></td>
<td>The host name or IP address of the slave to be reported to the master during slave registration. This value appears in the output of <code>SHOW SLAVE HOSTS</code> on the master server. Leave the value unset if you do not want the slave to register itself with the master. Note that it is not sufficient for the master to simply read the IP address of the slave from the TCP/IP socket after the slave connects. Due to NAT and other routing issues, that IP may not be valid for connecting to the slave from the master or other hosts.</td>
</tr>
</tbody>
</table>

- `--report-password=password`

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--report-password=name</code></td>
<td>An arbitrary account password to be reported by the slave to the master during slave registration. This value appears in the output of <code>SHOW SLAVE HOSTS</code> on the master server if the <code>--show-slave-auth-info</code> option is given. Although the name of this option might imply otherwise, <code>--report-password</code> is not connected to the MySQL user privilege system and so is not necessarily (or even likely to be) the same as the password for the MySQL replication user account.</td>
</tr>
</tbody>
</table>

- `--report-port=slave_port_num`

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--report-port=#</code></td>
<td>The TCP/IP port number for connecting to the slave, to be reported to the master during slave registration. Set this only if the slave is listening on a nondefault port or if you have a special tunnel from the master or other clients to the slave. If you are not sure, do not use this option.</td>
</tr>
</tbody>
</table>
• **--report-user=user_name**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--report-user=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td></td>
</tr>
<tr>
<td>(&gt;=5.1.24)</td>
<td></td>
</tr>
<tr>
<td>Name report_user</td>
<td></td>
</tr>
<tr>
<td>Variable</td>
<td>report_user</td>
</tr>
<tr>
<td>Global Scope</td>
<td></td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>string</td>
</tr>
</tbody>
</table>

The account user name of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the `--show-slave-auth-info` option is given.

Although the name of this option might imply otherwise, `--report-user` is not connected to the MySQL user privilege system and so is not necessarily (or even likely to be) the same as the name of the MySQL replication user account.

• **--show-slave-auth-info**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--show-slave-auth-info</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>Type boolean</td>
</tr>
<tr>
<td>Default</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Display slave user names and passwords in the output of `SHOW SLAVE HOSTS` on the master server for slaves started with the `--report-user` and `--report-password` options.

• **--skip-slave-start**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--skip-slave-start</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>Type boolean</td>
</tr>
<tr>
<td>Default</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Tells the slave server not to start the slave threads when the server starts. To start the threads later, use a `START SLAVE` statement.

• **--slave_compressed_protocol={0|1}**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--slave_compressed_protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name slave_compressed_protocol</td>
</tr>
<tr>
<td>Variable</td>
<td>Global protocol</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type boolean</td>
</tr>
<tr>
<td>Default</td>
<td>OFF</td>
</tr>
</tbody>
</table>

If this option is set to 1, use compression for the slave/master protocol if both the slave and the master support it. The default is 0 (no compression).

• **--slave-load-tmpdir=dir_name**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--slave-load-tmpdir=dir_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name slave_load_tmpdir</td>
</tr>
</tbody>
</table>
**Replication and Binary Logging Options and Variables**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Scope</th>
<th>Dynamic</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Global</td>
<td>No</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>
<th>Type</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>directory name</td>
<td>/tmp</td>
</tr>
</tbody>
</table>

The name of the directory where the slave creates temporary files. This option is by default equal to the value of the `tmpdir` system variable. When the slave SQL thread replicates a `LOAD DATA INFILE` statement, it extracts the file to be loaded from the relay log into temporary files, and then loads these into the table. If the file loaded on the master is huge, the temporary files on the slave are huge, too. Therefore, it might be advisable to use this option to tell the slave to put temporary files in a directory located in some file system that has a lot of available space. In that case, the relay logs are huge as well, so you might also want to use the `--relay-log` option to place the relay logs in that file system.

The directory specified by this option should be located in a disk-based file system (not a memory-based file system) because the temporary files used to replicate `LOAD DATA INFILE` must survive machine restarts. The directory also should not be one that is cleared by the operating system during the system startup process.

- `--slave-net-timeout=seconds`

  **Command-Line Format**

  `--slave-net-timeout=#`

  **System Variable**

<table>
<thead>
<tr>
<th>Name</th>
<th><code>slave_net_timeout</code></th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Variable</th>
<th>Scope</th>
<th>Dynamic</th>
<th>Permitted Values</th>
<th>Type</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Global</td>
<td>Yes</td>
<td></td>
<td>integer</td>
<td>3600</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Min Value</td>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>

  The number of seconds to wait for more data from the master before the slave considers the connection broken, aborts the read, and tries to reconnect. The first retry occurs immediately after the timeout. The interval between retries is controlled by the `MASTER_CONNECT_RETRY` option for the `CHANGE MASTER TO` statement or `--master-connect-retry` option, and the number of reconnection attempts is limited by the `--master-retry-count` option. The default is 3600 seconds (one hour).

- `--slave-skip-errors=[err_code1, err_code2, ...|all]`

  *(MySQL Cluster NDB 7.0.33 and later; MySQL Cluster NDB 7.1.22 and later:)*

  **Command-Line Format**

  `--slave-skip-errors=name`

  **System Variable**

<table>
<thead>
<tr>
<th>Name</th>
<th><code>slave_skip_errors</code></th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Variable</th>
<th>Scope</th>
<th>Dynamic</th>
<th>Permitted Values</th>
<th>Type</th>
<th>(<em>&lt;= 5.1.61-ndb-7.0.32</em>)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Global</td>
<td>No</td>
<td></td>
<td>string</td>
<td></td>
</tr>
</tbody>
</table>
Normally, replication stops when an error occurs on the slave. This gives you the opportunity to resolve the inconsistency in the data manually. This option tells the slave SQL thread to continue replication when a statement returns any of the errors listed in the option value.

Do not use this option unless you fully understand why you are getting errors. If there are no bugs in your replication setup and client programs, and no bugs in MySQL itself, an error that stops replication should never occur. Indiscriminate use of this option results in slaves becoming hopelessly out of synchrony with the master, with you having no idea why this has occurred.

Prior to MySQL 5.1.35, this option had no effect with row-based logging. (Bug #39393)

For error codes, you should use the numbers provided by the error message in your slave error log and in the output of `SHOW SLAVE STATUS`. Appendix B, Errors, Error Codes, and Common Problems, lists server error codes.

You can also (but should not) use the very nonrecommended value of `all` to cause the slave to ignore all error messages and keeps going regardless of what happens. Needless to say, if you use `all`, there are no guarantees regarding the integrity of your data. Please do not complain (or file bug reports) in this case if the slave's data is not anywhere close to what it is on the master. You have been warned.

For MySQL Cluster Replication in MySQL Cluster NDB 7.0 beginning with version 7.0.33 and MySQL Cluster NDB 7.1 beginning with version 7.1.22, an additional shorthand value `ddl_exist_errors` is supported for use with the enhanced failover mechanism which is implemented in that and later version of MySQL Cluster NDB 7.2. This value is equivalent to the error code list `1007,1008,1050,1051,1054,1060,1061,1068,1094,1146`. This value is not
Replication and Binary Logging Options and Variables

supported by the mysqld binary included with the MySQL Server 5.1 distribution. (Bug #11762277, Bug #54854) For more information, see Section 17.6.8, “Implementing Failover with MySQL Cluster Replication”.

Examples:

```
--slave-skip-errors=1062,1053
--slave-skip-errors=all
--slave-skip-errors=ddl_exist_errors
```

System Variables Used on Replication Slaves

The following list describes system variables for controlling replication slave servers. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used with replication slaves are listed earlier in this section.

- `init_slave`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--init-slave=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name init_slave</td>
</tr>
<tr>
<td>Variable</td>
<td>Global</td>
</tr>
<tr>
<td>Scope</td>
<td>Dynamic</td>
</tr>
<tr>
<td>Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Permitted Values: Type string

This variable is similar to `init_connect`, but is a string to be executed by a slave server each time the SQL thread starts. The format of the string is the same as for the `init_connect` variable.

**Note**

The SQL thread sends an acknowledgment to the client before it executes `init_slave`. Therefore, it is not guaranteed that `init_slave` has been executed when `START SLAVE` returns. See Section 13.4.2.7, “START SLAVE Syntax”, for more information.

- `relay_log`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--relay-log=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name relay_log</td>
</tr>
<tr>
<td>Variable</td>
<td>Global</td>
</tr>
<tr>
<td>Scope</td>
<td>Dynamic</td>
</tr>
<tr>
<td>Variable</td>
<td>No</td>
</tr>
</tbody>
</table>

Permitted Values: Type file name

The name of the relay log file.

- `relay_log_index`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--relay-log-index</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name relay_log_index</td>
</tr>
<tr>
<td>Variable</td>
<td>Global</td>
</tr>
<tr>
<td>Scope</td>
<td></td>
</tr>
</tbody>
</table>

1708
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Dynamic No Variable</th>
<th>Permitted Values</th>
<th>Type</th>
<th>file name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td><em>host_name</em>-relay-bin.index</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The name of the relay log index file. The default name is `host_name-relay-bin.index` in the data directory, where `host_name` is the name of the slave server.

- **relay_log_info_file**

  | Command-Line Format | --relay-log-info-file=file_name |
  | System Variable    | Name | relay_log_info_file |
  | Variable           | Global Scope |
  | Variable           | Dynamic No Variable |
  | Permitted Values   | Type | file name |
  | Default            | relay-log.info |

The name of the file in which the slave records information about the relay logs. The default name is `relay-log.info` in the data directory.

- **rpl_recovery_rank**

  This variable is unused, and is removed in MySQL 5.6.

- **slave_compressed_protocol**

  | Command-Line Format | --slave_compressed_protocol |
  | System Variable    | Name | slave_compressed_protocol |
  | Variable           | Global Scope |
  | Variable           | Dynamic Yes Variable |
  | Permitted Values   | Type | boolean |
  | Default            | OFF |

Whether to use compression of the slave/master protocol if both the slave and the master support it.

- **slave_exec_mode**

  | Introduced | 5.1.24 |
  | Command-Line Format | --slave-exec-mode=mode |
  | System Variable    | Name | slave_exec_mode |
  | Variable           | Global Scope |
  | Variable           | Dynamic Yes Variable |
  | Permitted Values   | Type | enumeration |
  | Default            | STRICT (ALL) |
  | Default            | IDEMPOTENT (NDB) |
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Valid Values</th>
<th>IDEMPOTENT</th>
<th>STRICT</th>
</tr>
</thead>
</table>

Controls whether **IDEMPOTENT** or **STRICT** mode is used in replication conflict resolution and error checking. **IDEMPOTENT** mode causes suppression of duplicate-key and no-key-found errors.

This mode is needed for multi-master replication, circular replication, and some other special replication scenarios for MySQL Cluster Replication. (See Section 17.6.10, “MySQL Cluster Replication: Multi-Master and Circular Replication”, and Section 17.6.11, “MySQL Cluster Replication Conflict Resolution”, for more information.) The `mysqld` supplied with MySQL Cluster ignores any value explicitly set for `slave_exec_mode`, and always treats it as **IDEMPOTENT**.

In MySQL Server 5.1, **STRICT** mode is the default value. This should not be changed; currently, **IDEMPOTENT** mode is supported only by NDB.

- **slave_max_allowed_packet**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.64</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>
<th>Type</th>
<th>integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>1073741824</td>
<td></td>
</tr>
<tr>
<td>Min Value</td>
<td>1024</td>
<td></td>
</tr>
<tr>
<td>Max Value</td>
<td>1073741824</td>
<td></td>
</tr>
</tbody>
</table>

In MySQL 5.1.64 and later, this variable sets the maximum packet size for the slave SQL and I/O threads, so that large updates using row-based replication do not cause replication to fail because an update exceeded `max_allowed_packet`.

This global variable always has a value that is a positive integer multiple of 1024; if you set it to some value that is not, the value is rounded down to the next highest multiple of 1024 for it is stored or used; setting `slave_max_allowed_packet` to 0 causes 1024 to be used. (A truncation warning is issued in all such cases.) The default and maximum value is 1073741824 (1 GB); the minimum is 1024.

`slave_max_allowed_packet` can also be set at startup, using the `--slave-max-allowed-packet` option.

- **slave_load_tmpdir**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--slave-load-tmpdir=dir_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>
<th>Type</th>
<th>directory name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>/tmp</td>
<td></td>
</tr>
</tbody>
</table>
The name of the directory where the slave creates temporary files for replicating `LOAD DATA INFILE` statements.

- **slave_net_timeout**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--slave-net-timeout=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>System Variable</strong></td>
<td><strong>Name</strong> <code>slave_net_timeout</code></td>
</tr>
<tr>
<td></td>
<td><strong>Variable</strong> Global</td>
</tr>
<tr>
<td></td>
<td><strong>Scope</strong> Dynamic</td>
</tr>
<tr>
<td></td>
<td><strong>Variable</strong> Yes</td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td><strong>Type</strong> <code>integer</code></td>
</tr>
<tr>
<td></td>
<td><strong>Default</strong> 3600</td>
</tr>
<tr>
<td></td>
<td><strong>Min</strong> 1</td>
</tr>
<tr>
<td></td>
<td><strong>Value</strong></td>
</tr>
</tbody>
</table>

The number of seconds to wait for more data from a master/slave connection before aborting the read. Before MySQL 5.1.41, this timeout applies only to TCP/IP connections, not to connections made through Unix socket files, named pipes, or shared memory.

- **slave_skip_errors**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--slave-skip-errors=name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>System Variable</strong></td>
<td><strong>Name</strong> <code>slave_skip_errors</code></td>
</tr>
<tr>
<td></td>
<td><strong>Variable</strong> Global</td>
</tr>
<tr>
<td></td>
<td><strong>Scope</strong> Dynamic</td>
</tr>
<tr>
<td></td>
<td><strong>Variable</strong> No</td>
</tr>
<tr>
<td><strong>Permitted Values (&lt;= 5.1.61-ndb-7.0.32)</strong></td>
<td><strong>Type</strong> <code>string</code></td>
</tr>
<tr>
<td></td>
<td><strong>Default</strong> OFF</td>
</tr>
<tr>
<td></td>
<td><strong>Valid Values</strong> OFF</td>
</tr>
<tr>
<td></td>
<td><code>[list of error codes]</code></td>
</tr>
<tr>
<td></td>
<td><code>all</code></td>
</tr>
<tr>
<td><strong>Permitted Values (&gt;= 5.1.61-ndb-7.0.33)</strong></td>
<td><strong>Type</strong> <code>string</code></td>
</tr>
<tr>
<td></td>
<td><strong>Default</strong> OFF</td>
</tr>
<tr>
<td></td>
<td><strong>Valid Values</strong> OFF</td>
</tr>
<tr>
<td></td>
<td><code>[list of error codes]</code></td>
</tr>
<tr>
<td></td>
<td><code>all</code></td>
</tr>
<tr>
<td></td>
<td><code>ddl_exist_errors</code></td>
</tr>
<tr>
<td><strong>Permitted Values (&gt;= 5.1.39-ndb-7.1.0, &lt;= 5.1.61-ndb-7.1.21)</strong></td>
<td><strong>Type</strong> <code>string</code></td>
</tr>
<tr>
<td></td>
<td><strong>Default</strong> OFF</td>
</tr>
<tr>
<td></td>
<td><strong>Valid Values</strong> OFF</td>
</tr>
<tr>
<td></td>
<td><code>[list of error codes]</code></td>
</tr>
<tr>
<td></td>
<td><code>all</code></td>
</tr>
<tr>
<td><strong>Permitted Values (&gt;= 5.1.61-ndb-7.1.22)</strong></td>
<td><strong>Type</strong> <code>string</code></td>
</tr>
<tr>
<td></td>
<td><strong>Default</strong> OFF</td>
</tr>
</tbody>
</table>
Normally, replication stops when an error occurs on the slave. This gives you the opportunity to resolve the inconsistency in the data manually. This variable tells the slave SQL thread to continue replication when a statement returns any of the errors listed in the variable value.

- **slave_transaction_retries**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--slave_transaction_retries=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>slave_transaction_retries</td>
</tr>
<tr>
<td>Name</td>
<td>slave_transaction_retries</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10</td>
</tr>
<tr>
<td>Min Value</td>
<td>0</td>
</tr>
<tr>
<td>Max Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

If a replication slave SQL thread fails to execute a transaction because of an InnoDB deadlock or because the transaction's execution time exceeded InnoDB's `innodb_lock_wait_timeout` or `NDBCLUSTER`'s `TransactionDeadlockDetectionTimeout` or `TransactionInactiveTimeout`, it automatically retries `slave_transaction_retries` times before stopping with an error. The default value is 10.

- **slave_type_conversions**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.44-ndb-7.1.3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--slave_type_conversions=set</td>
</tr>
<tr>
<td>System Variable</td>
<td>slave_type_conversions</td>
</tr>
<tr>
<td>Name</td>
<td>slave_type_conversions</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>set</td>
</tr>
<tr>
<td>Default Value</td>
<td>ALL_LOSSY</td>
</tr>
<tr>
<td>Valid Values</td>
<td>ALL_NON_LOSSY</td>
</tr>
</tbody>
</table>
Replication and Binary Logging Options and Variables

Controls the type conversion mode in effect on the slave when using MySQL Cluster Replication. Its value is a comma-delimited set of zero or more elements from the list: ALL_LOSSY, ALL_NON_LOSSY. Set this variable to an empty string to disallow type conversions between the master and the slave. Changes require a restart of the slave to take effect.

For additional information on type conversion modes applicable to MySQL Cluster replication attribute promotion and demotion, see Attribute promotion and demotion (MySQL Cluster).

This variable was added in MySQL Cluster NDB 6.3.33, 7.0.14, and 7.1.3.

- `sql_slave_skip_counter`

<table>
<thead>
<tr>
<th>System Variable</th>
<th>Name</th>
<th>sql_slave_skip_counter</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable</td>
<td>Global</td>
<td></td>
</tr>
<tr>
<td>Scope</td>
<td>DynamicYes</td>
<td></td>
</tr>
<tr>
<td>DynamicVariable</td>
<td>Yes</td>
<td></td>
</tr>
</tbody>
</table>

The number of events from the master that a slave server should skip.

⚠️ Important

If skipping the number of events specified by setting this variable would cause the slave to begin in the middle of an event group, the slave continues to skip until it finds the beginning of the next event group and begins from that point. For more information, see Section 13.4.2.6, “SET GLOBAL sql_slave_skip_counter Syntax”.

16.1.3.4 Binary Log Options and Variables

Startup Options Used with Binary Logging

System Variables Used with Binary Logging

You can use the `mysqld` options and system variables that are described in this section to affect the operation of the binary log as well as to control which statements are written to the binary log. For additional information about the binary log, see Section 5.4.4, “The Binary Log”. For additional information about using MySQL server options and system variables, see Section 5.1.3, “Server Command Options”, and Section 5.1.4, “Server System Variables”.

Startup Options Used with Binary Logging

The following list describes startup options for enabling and configuring the binary log. System variables used with binary logging are discussed later in this section.

- `--binlog-row-event-max-size=N`

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.5</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--binlog-row-event-max-size=#</code></td>
</tr>
<tr>
<td>Permitted Values (32-bit platforms)</td>
<td>Type: <code>integer</code></td>
</tr>
<tr>
<td>Default</td>
<td>1024</td>
</tr>
<tr>
<td>Min Value</td>
<td>256</td>
</tr>
<tr>
<td>Max Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>
Replication and Binary Logging Options and Variables

**Permitted Values (64-bit platforms)**

<table>
<thead>
<tr>
<th>Type</th>
<th>Default</th>
<th>Min Value</th>
<th>Max Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>1024</td>
<td>256</td>
<td>18446744073709547520</td>
</tr>
</tbody>
</table>

Specify the maximum size of a row-based binary log event, in bytes. Rows are grouped into events smaller than this size if possible. The value should be a multiple of 256. The default is 1024. See Section 16.1.2, “Replication Formats”. This option was added in MySQL 5.1.5.

- **--log-bin [=base_name]**

  **Command-Line Format**
  --log-bin

  **System Variable**
  Name log_bin

  **Variable Global Scope**

  **Permitted Values**
  Type file name

  Enable binary logging. The server logs all statements that change data to the binary log, which is used for backup and replication. See Section 5.4.4, “The Binary Log”.

  The option value, if given, is the base name for the log sequence. The server creates binary log files in sequence by adding a numeric suffix to the base name. It is recommended that you specify a base name (see Section B.5.7, “Known Issues in MySQL”, for the reason). Otherwise, MySQL uses host_name-bin as the base name.

  Setting this option causes the log_bin system variable to be set to ON (or 1), and not to the base name. This is a known issue; see Bug #19614 for more information.

- **--log-bin-index [=file_name]**

  **Command-Line Format**
  --log-bin-index=file_name

  **Permitted Values**
  Type file name

  The index file for binary log file names. See Section 5.4.4, “The Binary Log”. If you omit the file name, and if you did not specify one with --log-bin, MySQL uses host_name-bin.index as the file name.

- **--log-bin-trust-function-creators [=0|1]**

  **Command-Line Format**
  --log-bin-trust-function-creators

  **System Variable**
  Name log_bin_trust_function_creators

  **Variable Global Scope**

  **Permitted Values**
  Type boolean

  Default FALSE

  This option sets the corresponding log_bin_trust_function_creators system variable. If no argument is given, the option sets the variable to 1. log_bin_trust_function_creators affects
how MySQL enforces restrictions on stored function and trigger creation. See Section 19.7, “Binary Logging of Stored Programs”.

Note

Previously, this option was known as `--log-bin-trust-routine-creators`, which is now deprecated.

• `--log-bin-use-v1-row-events=[0|1]`

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.56-ndb-7.1.16</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--log-bin-use-v1-row-events=[0</td>
</tr>
<tr>
<td>System Variable</td>
<td>Name <code>log_bin_use_v1_row_events</code></td>
</tr>
<tr>
<td></td>
<td>Variable Global</td>
</tr>
<tr>
<td></td>
<td>Scope</td>
</tr>
<tr>
<td></td>
<td>Dynamic No</td>
</tr>
<tr>
<td></td>
<td>Variable</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type boolean</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Default 1</td>
</tr>
</tbody>
</table>

Version 2 binary log row events are available beginning with MySQL Cluster NDB 7.0.27 and MySQL Cluster NDB 7.1.16; however, Version 2 events cannot be read by previous MySQL Cluster releases. Setting `--log-bin-use-v1-row-events` to 0 causes `mysqld` to use Version 2 binary log events. Setting this option to 1 (the default) causes `mysqld` to write the binary log using Version 1 logging events, which is the only version of binary log events used in previous releases, and thus produce binary logs that can be read by older slaves.

The value used for this option can be obtained from the read-only `log_bin_use_v1_row_events` system variable.

`--log-bin-use-v1-row-events` is chiefly of interest when setting up replication conflict detection and resolution using `NDB$EPOCH_TRANS()` as the conflict detection function, which requires Version 2 binary log row events. Thus, this option and `--ndb-log-transaction-id` are not compatible.

Note

MySQL Cluster NDB 7.2.1 and later use Version 2 binary log events by default (and so the default value for this option changes to 0 in those versions). You should keep this mind when planning upgrades for setups using MySQL Cluster Replication.

`--log-bin-use-v1-row-events` is not supported in mainline MySQL Server 5.1 releases.

For more information, see Section 17.6.11, “MySQL Cluster Replication Conflict Resolution”.

Statement selection options. The options in the following list affect which statements are written to the binary log, and thus sent by a replication master server to its slaves. There are also options for slave servers that control which statements received from the master should be executed or ignored. For details, see Section 16.1.3.3, “Replication Slave Options and Variables”.

• `--binlog-do-db=db_name`

Command-Line Format `--binlog-do-db=name`
Permitted Values | Type  | string
---|---|---

This option affects binary logging in a manner similar to the way that `--replicate-do-db` affects replication.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-do-db` depend on whether statement-based or row-based replication is in use. You should keep in mind that the format used to log a given statement may not necessarily be the same as that indicated by the value of `binlog_format`. For example, DDL statements such as `CREATE TABLE` and `ALTER TABLE` are always logged as statements, without regard to the logging format in effect, so the following statement-based rules for `--binlog-do-db` always apply in determining whether or not the statement is logged.

**Statement-based logging.** Only those statements are written to the binary log where the default database (that is, the one selected by `USE`) is `db_name`. To specify more than one database, use this option multiple times, once for each database; however, doing so does not cause cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` to be logged while a different database (or no database) is selected.

**Warning**

To specify multiple databases you *must* use multiple instances of this option. Because database names can contain commas, the list will be treated as the name of a single database if you supply a comma-separated list.

An example of what does not work as you might expect when using statement-based logging: If the server is started with `--binlog-do-db=sales` and you issue the following statements, the `UPDATE` statement is *not* logged:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this “just check the default database” behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` statements or multiple-table `UPDATE` statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

Another case which may not be self-evident occurs when a given database is replicated even though it was not specified when setting the option. If the server is started with `--binlog-do-db=sales`, the following `UPDATE` statement is logged even though `prices` was not included when setting `--binlog-do-db`:

```
USE sales;
UPDATE prices.discounts SET percentage = percentage + 10;
```

Because `sales` is the default database when the `UPDATE` statement is issued, the `UPDATE` is logged.

**Row-based logging.** Logging is restricted to database `db_name`. Only changes to tables belonging to `db_name` are logged; the default database has no effect on this. Suppose that the server is started with `--binlog-do-db=sales` and row-based logging is in effect, and then the following statements are executed:

```
USE prices;
UPDATE sales.febuary SET amount=amount+100;
```

The changes to the `febuary` table in the `sales` database are logged in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, when using
the row-based logging format and \texttt{--binlog-do-db=sales}, changes made by the following \texttt{UPDATE} are not logged:

\begin{verbatim}
USE prices;
UPDATE prices.march SET amount=amount-25;
\end{verbatim}

Even if the \texttt{USE prices} statement were changed to \texttt{USE sales}, the \texttt{UPDATE} statement's effects would still not be written to the binary log.

Another important difference in \texttt{--binlog-do-db} handling for statement-based logging as opposed to the row-based logging occurs with regard to statements that refer to multiple databases. Suppose that the server is started with \texttt{--binlog-do-db=db1}, and the following statements are executed:

\begin{verbatim}
USE db1;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
\end{verbatim}

If you are using statement-based logging, the updates to both tables are written to the binary log. However, when using the row-based format, only the changes to \texttt{table1} are logged; \texttt{table2} is in a different database, so it is not changed by the \texttt{UPDATE}. Now suppose that, instead of the \texttt{USE db1} statement, a \texttt{USE db4} statement had been used:

\begin{verbatim}
USE db4;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
\end{verbatim}

In this case, the \texttt{UPDATE} statement is not written to the binary log when using statement-based logging. However, when using row-based logging, the change to \texttt{table1} is logged, but not that to \texttt{table2}—in other words, only changes to tables in the database named by \texttt{--binlog-do-db} are logged, and the choice of default database has no effect on this behavior.

- \texttt{--binlog-ignore-db=db_name}

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>\texttt{--binlog-ignore-db}=	exttt{name}</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>Type: string</td>
</tr>
</tbody>
</table>

This option affects binary logging in a manner similar to the way that \texttt{--replicate-ignore-db} affects replication.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of \texttt{--replicate-ignore-db} depend on whether statement-based or row-based replication is in use. You should keep in mind that the format used to log a given statement may not necessarily be the same as that indicated by the value of \texttt{binlog_format}.

For example, DDL statements such as \texttt{CREATE TABLE} and \texttt{ALTER TABLE} are always logged as statements, without regard to the logging format in effect, so the following statement-based rules for \texttt{--binlog-ignore-db} always apply in determining whether or not the statement is logged.

**Statement-based logging.** Tells the server to not log any statement where the default database (that is, the one selected by \texttt{USE}) is \texttt{db_name}.

Prior to MySQL 5.1.70, this option caused any statements containing fully qualified table names not to be logged if there was no default database specified (that is, when \texttt{SELECT DATABASE()} returned \texttt{NULL}). In MySQL 5.1.70 and later, when there is no default database, no \texttt{--binlog-ignore-db} options are applied, and such statements are always logged. (Bug #11829838, Bug #60188)

**Row-based format.** Tells the server not to log updates to any tables in the database \texttt{db_name}. The current database has no effect.
When using statement-based logging, the following example does not work as you might expect. Suppose that the server is started with `--binlog-ignore-db=sales` and you issue the following statements:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The `UPDATE` statement is logged in such a case because `--binlog-ignore-db` applies only to the default database (determined by the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based logging, the `UPDATE` statement's effects are not written to the binary log, which means that no changes to the `sales.january` table are logged; in this instance, `--binlog-ignore-db=sales` causes all changes made to tables in the master’s copy of the `sales` database to be ignored for purposes of binary logging.

To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, the list will be treated as the name of a single database if you supply a comma-separated list.

You should not use this option if you are using cross-database updates and you do not want these updates to be logged.

**Testing and debugging options.** The following binary log options are used in replication testing and debugging. They are not intended for use in normal operations.

- `--max-binlog-dump-events=N`

  **Command-Line Format**  
  `--max-binlog-dump-events=`

  **Permitted Values**
  
<table>
<thead>
<tr>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
</tr>
</tbody>
</table>

  **Default** 0

  This option is used internally by the MySQL test suite for replication testing and debugging.

- `--sporadic-binlog-dump-fail`

  **Command-Line Format**  
  `--sporadic-binlog-dump-fail`

  **Permitted Values**
  
<table>
<thead>
<tr>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
</tr>
</tbody>
</table>

  **Default** FALSE

  This option is used internally by the MySQL test suite for replication testing and debugging.

**System Variables Used with Binary Logging**

The following list describes system variables for controlling binary logging. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used to control binary logging are listed earlier in this section. For information about the `sql_log_bin` and `sql_log_off` variables, see Section 5.1.4, “Server System Variables”.

- `binlog_cache_size`

  **Command-Line Format**  
  `--binlog_cache_size=`

  **System Variable**
  
<table>
<thead>
<tr>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>binlog_cache_size</code></td>
</tr>
</tbody>
</table>

  **Variable** Global
  
  **Scope**
  
  **Dynamic** Yes
  
  **Variable**
The size of the cache to hold the SQL statements for the binary log during a transaction. A binary log cache is allocated for each client if the server supports any transactional storage engines and if the server has the binary log enabled (\--log-bin option). If you often use large, multiple-statement transactions, you can increase this cache size to get better performance. The \texttt{Binlog_cache_use} and \texttt{Binlog_cache_disk_use} status variables can be useful for tuning the size of this variable. See Section 5.4.4, “The Binary Log”.

- \texttt{binlog_direct_non_transactional_updates}

| Introduced | 5.1.44 |
| Command-Line Format | \texttt{--binlog_direct_non_transactional_updates [=value]} |
| System Variable | Name \texttt{binlog_direct_non_transactional_updates} |
| | Variable Global, Session |
| | Scope |
| | DynamicYes |
| | Variable |
| Permitted Values | Type boolean |
| | Default OFF |

Due to concurrency issues, a slave can become inconsistent when a transaction contains updates to both transactional and nontransactional tables. MySQL tries to preserve causality among these statements by writing nontransactional statements to the transaction cache, which is flushed upon commit. However, problems arise when modifications done to nontransactional tables on behalf of a transaction become immediately visible to other connections because these changes may not be written immediately into the binary log.

Beginning with MySQL 5.1.44, the \texttt{binlog_direct_non_transactional_updates} variable offers one possible workaround to this issue. By default, this variable is disabled. Enabling \texttt{binlog_direct_non_transactional_updates} causes updates to nontransactional tables to be written directly to the binary log, rather than to the transaction cache.

\texttt{binlog_direct_non_transactional_updates} works only for statements that are replicated using the statement-based binary logging format; that is, it works only when the value of \texttt{binlog_format} is \texttt{STATEMENT}, or when \texttt{binlog_format} is \texttt{MIXED} and a given statement is being replicated using the statement-based format. This variable has no effect when the binary log format is \texttt{ROW}, or when \texttt{binlog_format} is set to \texttt{MIXED} and a given statement is replicated using the row-based format.
Important

Before enabling this variable, you must make certain that there are no dependencies between transactional and nontransactional tables; an example of such a dependency would be the statement `INSERT INTO myisam_table SELECT * FROM innodb_table`. Otherwise, such statements are likely to cause the slave to diverge from the master.

- **binlog_format**

<table>

<tr>
<td></td>
<td>Default MIXED</td>
</tr>
<tr>
<td></td>
<td>Valid Values ROW STATEMENT</td>
</tr>
</tbody>
</table>
This variable sets the binary logging format, and can be any one of `STATEMENT`, `ROW`, or `MIXED`. See Section 16.1.2, "Replication Formats". `binlog_format` is set by the `--binlog-format` option at startup, or by the `binlog_format` variable at runtime.

**Note**
While you can change the logging format at runtime, it is *not* recommended that you change it while replication is ongoing. This is due in part to the fact that slaves do not honor the master's `binlog_format` setting; a given MySQL Server can change only its own logging format.

The startup variable was added in MySQL 5.1.5, and the runtime variable in MySQL 5.1.8. `MIXED` was added in MySQL 5.1.8.

`STATEMENT` was used by default prior to MySQL 5.1.12; in MySQL 5.1.12, the default was changed to `MIXED`. In MySQL 5.1.29, the default was changed back to `STATEMENT`.

You must have the `SUPER` privilege to set the global `binlog_format` value. Starting with MySQL 5.1.29, you must have the `SUPER` privilege to set either the global or session `binlog_format` value. (Bug #39106)

The rules governing when changes to this variable take effect and how long the effect lasts are the same as for other MySQL server system variables. For more information, see Section 13.7.4.1, “SET Syntax for Variable Assignment”.

When `MIXED` is specified, statement-based replication is used, except for cases where only row-based replication is guaranteed to lead to proper results. For example, this happens when statements contain user-defined functions (UDF) or the `UUID()` function. An exception to this rule is that `MIXED` always uses statement-based replication for stored functions and triggers.

There are exceptions when you cannot switch the replication format at runtime:

- From within a stored function or a trigger.
- If the `NDBCLUSTER` storage engine is enabled.
- If the session is currently in row-based replication mode and has open temporary tables.
Trying to switch the format in those cases results in an error.

Before MySQL 5.1.8, switching to row-based replication format would implicitly set `--log-bin-trust-function-creators=1` and `--innodb_locks_unsafe_for_binlog`. This does not occur for MySQL 5.1.8 and later.

The binary log format affects the behavior of the following server options:

- `--replicate-do-db`
- `--replicate-ignore-db`
- `--binlog-do-db`
- `--binlog-ignore-db`

These effects are discussed in detail in the descriptions of the individual options.

- `log_bin`

<table>
<thead>
<tr>
<th>System Variable</th>
<th>Name</th>
<th>Variable</th>
<th>Scope</th>
<th>Dynamic No</th>
<th>Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>log_bin</td>
<td>Global</td>
<td>No</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Whether the binary log is enabled. If the `--log-bin` option is used, then the value of this variable is `ON`; otherwise it is `OFF`. This variable reports only on the status of binary logging (enabled or disabled); it does not actually report the value to which `--log-bin` is set.

See Section 5.4.4, “The Binary Log”.

- `log_bin_use_v1_row_events`

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.56-ndb-7.1.16</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--log-bin-use-v1-row-events[={0</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>System Variable</th>

<th>Scope</th>
<th>Dynamic No</th>
<th>Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>log_bin_use_v1_row_events</td>
<td>Global</td>
<td>No</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Types whether Version 2 binary logging, available beginning with MySQL Cluster NDB 7.0.27 and MySQL Cluster NDB 7.1.16, is in use. A value of 1 shows that the server is writing the binary log using Version 1 logging events (the only version of binary log events used in previous releases), and thus producing a binary log that can be read by older slaves. 0 indicates that Version 2 binary log events are in use.

This variable is read-only. To switch between Version 1 and Version 2 binary event binary logging, it is necessary to restart `mysqld` with the `--log-bin-use-v1-row-events` option.
Other than when performing upgrades of MySQL Cluster Replication, `--log-bin-use-v1-events` is chiefly of interest when setting up replication conflict detection and resolution using `NDB $EPOCH_TRANS()`, which requires Version 2 binary row event logging. Thus, this option and `--ndb-log-transaction-id` are not compatible.

**Note**

MySQL Cluster NDB 7.2.1 and later use Version 2 binary log row events by default (and so the default value for this variable changes to 0 in those versions). You should keep this mind when planning upgrades for setups using MySQL Cluster Replication.

This variable is not supported in mainline MySQL Server 5.1.

For more information, see Section 17.6.11, “MySQL Cluster Replication Conflict Resolution”.

- **log_slave_updates**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--log-slave-updates</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name: <code>log_slave_updates</code></td>
</tr>
<tr>
<td>Variable</td>
<td>Global Scope</td>
</tr>
<tr>
<td></td>
<td>Dynamic No Variable</td>
</tr>
<tr>

<td>Type: <code>boolean</code></td>
</tr>
<tr>
<td></td>
<td>Default: <code>FALSE</code></td>
</tr>
</tbody>
</table>

Whether updates received by a slave server from a master server should be logged to the slave's own binary log. Binary logging must be enabled on the slave for this variable to have any effect. See Section 16.1.3, “Replication and Binary Logging Options and Variables”.

- **max_binlog_cache_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--max_binlog_cache_size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name: <code>max_binlog_cache_size</code></td>
</tr>
<tr>
<td>Variable</td>
<td>Global Scope</td>
</tr>
<tr>
<td></td>
<td>Dynamic Yes Variable</td>
</tr>
<tr>
<td>Permitted Values (&gt;= 5.1.36)</td>
<td>Type: <code>integer</code></td>
</tr>
<tr>
<td></td>
<td>Default: <code>18446744073709547520</code></td>
</tr>
<tr>
<td></td>
<td>Min Value: <code>4096</code></td>
</tr>
<tr>
<td></td>
<td>Max Value: <code>18446744073709547520</code></td>
</tr>
<tr>
<td>Permitted Values (32-bit platforms, &lt;= 5.1.35)</td>
<td>Type: <code>integer</code></td>
</tr>
<tr>
<td></td>
<td>Default: <code>4294967295</code></td>
</tr>
<tr>
<td></td>
<td>Min Value: <code>4096</code></td>
</tr>
<tr>
<td></td>
<td>Max Value: <code>4294967295</code></td>
</tr>
</tbody>
</table>
If a multiple-statement transaction requires more than this many bytes of memory, the server generates a Multi-statement transaction required more than 'max_binlog_cache_size' bytes of storage error. The minimum value is 4096. The maximum and default values are 4GB on 32-bit platforms and 16EB (exabytes) on 64-bit platforms. As of MySQL 5.1.36, the maximum value is 16EB (exabytes) on all platforms. The maximum recommended value is 4GB; this is due to the fact that MySQL currently cannot work with binary log positions greater than 4GB.

In MySQL 5.1, a change in `max_binlog_cache_size` takes immediate effect for all active sessions.

- **max_binlog_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max_binlog_size=##</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name: <em>max_binlog_size</em></td>
</tr>
<tr>
<td></td>
<td>Variable: Global Scope</td>
</tr>
<tr>
<td></td>
<td>Dynamic: Yes Variable</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type: integer</td>
</tr>
<tr>
<td></td>
<td>Default: 1073741824</td>
</tr>
<tr>
<td></td>
<td>Min Value: 4096</td>
</tr>
<tr>
<td></td>
<td>Max Value: 1073741824</td>
</tr>
</tbody>
</table>

If a write to the binary log causes the current log file size to exceed the value of this variable, the server rotates the binary logs (closes the current file and opens the next one). The minimum value is 4096 bytes. The maximum and default value is 1GB.

A transaction is written in one chunk to the binary log, so it is never split between several binary logs. Therefore, if you have big transactions, you might see binary log files larger than `max_binlog_size`.

If `max_relay_log_size` is 0, the value of `max_binlog_size` applies to relay logs as well.

- **sync_binlog**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--sync-binlog=##</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>Name: <em>sync_binlog</em></td>
</tr>
<tr>
<td></td>
<td>Variable: Global Scope</td>
</tr>
<tr>
<td></td>
<td>Dynamic: Yes Variable</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type: integer</td>
</tr>
<tr>
<td></td>
<td>Default: 0</td>
</tr>
</tbody>
</table>

If `max_relay_log_size` is 0, the value of `max_binlog_size` applies to relay logs as well.
If the value of this variable is greater than 0, the MySQL server synchronizes its binary log to disk (using `fdatasync()`) after every `sync_binlog` writes to the binary log. There is one write to the binary log per statement if autocommit is enabled, and one write per transaction otherwise. The default value of `sync_binlog` is 0, which does no synchronizing to disk—in this case, the server relies on the operating system to flush the binary log’s contents from time to time as for any other file. A value of 1 is the safest choice because in the event of a crash you lose at most one statement or transaction from the binary log. However, it is also the slowest choice (unless the disk has a battery-backed cache, which makes synchronization very fast).

### 16.1.4 Common Replication Administration Tasks

Once replication has been started it should execute without requiring much regular administration. Depending on your replication environment, you will want to check the replication status of each slave periodically, daily, or even more frequently.

#### 16.1.4.1 Checking Replication Status

The most common task when managing a replication process is to ensure that replication is taking place and that there have been no errors between the slave and the master. The primary statement for this is `SHOW SLAVE STATUS`, which you must execute on each slave:

```sql
mysql> SHOW SLAVE STATUS\G
*************************** 1. row ***************************
Slave_IO_State: Waiting for master to send event
Master_Host: master1
Master_User: root
Master_Port: 3306
Connect_Retry: 60
Master_Log_File: mysql-bin.000004
Read_Master_Log_Pos: 931
Relay_Log_File: slave1-relay-bin.000056
Relay_Log_Pos: 950
Relay_Master_Log_File: mysql-bin.000004
Slave_IO_Running: Yes
Slave_SQL_Running: Yes
Replicate_Do_DB: 
Replicate_Ignore_DB: 
Replicate_Do_Table: 
Replicate_Ignore_Table: 
Replicate_Wild_Do_Table: 
Replicate_Wild_Ignore_Table: 
Last_Errno: 0
Last_Error: 
Skip_Counter: 0
Exec_Master_Log_Pos: 931
Relay_Log_Space: 1365
Until_Condition: None
Until_Log_File: 
Until_Log_Pos: 0
Master_SSL_Allowed: No
Master_SSL_CA_File: 
Master_SSL_Cert: 
`SHOW SLAVE STATUS` outputs important information about the replication status of the slave, including the state of the slave, the host and user of the master, the port number, and the status of the replication process. This information is crucial for monitoring and troubleshooting any issues that may arise during replication.
The key fields from the status report to examine are:

- **Slave_IO_State**: The current status of the slave. See Section 8.14.6, “Replication Slave I/O Thread States”, and Section 8.14.7, “Replication Slave SQL Thread States”, for more information.

- **Slave_IO_Running**: Whether the I/O thread for reading the master's binary log is running. Normally, you want this to be Yes unless you have not yet started replication or have explicitly stopped it with STOP SLAVE.

- **Slave_SQL_Running**: Whether the SQL thread for executing events in the relay log is running. As with the I/O thread, this should normally be Yes.

- **Last_IO_Error, Last_SQL_Error**: The last errors registered by the I/O and SQL threads when processing the relay log. Ideally these should be blank, indicating no errors.

- **Seconds_Behind_Master**: The number of seconds that the slave SQL thread is behind processing the master binary log. A high number (or an increasing one) can indicate that the slave is unable to handle events from the master in a timely fashion.

A value of 0 for Seconds_Behind_Master can usually be interpreted as meaning that the slave has caught up with the master, but there are some cases where this is not strictly true. For example, this can occur if the network connection between master and slave is broken but the slave I/O thread has not yet noticed this—that is, slave_net_timeout has not yet elapsed.

It is also possible that transient values for Seconds_Behind_Master may not reflect the situation accurately. When the slave SQL thread has caught up on I/O, Seconds_Behind_Master displays 0; but when the slave I/O thread is still queuing up a new event, Seconds_Behind_Master may show a large value until the SQL thread finishes executing the new event. This is especially likely when the events have old timestamps; in such cases, if you execute SHOW SLAVE STATUS several times in a relatively short period, you may see this value change back and forth repeatedly between 0 and a relatively large value.

Several pairs of fields provide information about the progress of the slave in reading events from the master binary log and processing them in the relay log:

- **(Master_Log_file, Read_Master_Log_Pos)**: Coordinates in the master binary log indicating how far the slave I/O thread has read events from that log.

- **(Relay_Master_Log_File, Exec_Master_Log_Pos)**: Coordinates in the master binary log indicating how far the slave SQL thread has executed events received from that log.

- **(Relay_Log_File, Relay_Log_Pos)**: Coordinates in the slave relay log indicating how far the slave SQL thread has executed the relay log. These correspond to the preceding coordinates, but are expressed in slave relay log coordinates rather than master binary log coordinates.

On the master, you can check the status of connected slaves using SHOW PROCESSLIST to examine the list of running processes. Slave connections have Binlog Dump in the Command field:

```sql
code
mysql> SHOW PROCESSLIST \G;
*************************** 4. row ***************************
    Id: 10
    User: root
    Host: slave1:58371
```
Because it is the slave that drives the replication process, very little information is available in this report.

For slaves that were started with the `--report-host` option and are connected to the master, the `SHOW SLAVE HOSTS` statement on the master shows basic information about the slaves. The output includes the ID of the slave server, the value of the `--report-host` option, the connecting port, and master ID:

```
mysql> SHOW SLAVE HOSTS;
+-----------+--------+------+-------------------+-----------+
| Server_id | Host   | Port | Rpl_recovery_rank | Master_id |
+-----------+--------+------+-------------------+-----------+
|        10 | slave1 | 3306 |                 0 |         1 |
+-----------+--------+------+-------------------+-----------+
1 row in set (0.00 sec)
```

### 16.1.4.2 Pausing Replication on the Slave

You can stop and start the replication of statements on the slave using the `STOP SLAVE` and `START SLAVE` statements.

To stop processing of the binary log from the master, use `STOP SLAVE`:

```
mysql> STOP SLAVE;
```

When replication is stopped, the slave I/O thread stops reading events from the master binary log and writing them to the relay log, and the SQL thread stops reading events from the relay log and executing them. You can pause the I/O or SQL thread individually by specifying the thread type:

```
mysql> STOP SLAVE IO_THREAD;
mysql> STOP SLAVE SQL_THREAD;
```

To start execution again, use the `START SLAVE` statement:

```
mysql> START SLAVE;
```

To start a particular thread, specify the thread type:

```
mysql> START SLAVE IO_THREAD;
mysql> START SLAVE SQL_THREAD;
```

For a slave that performs updates only by processing events from the master, stopping only the SQL thread can be useful if you want to perform a backup or other task. The I/O thread will continue to read events from the master but they are not executed. This makes it easier for the slave to catch up when you restart the SQL thread.

Stopping only the I/O thread enables the events in the relay log to be executed by the SQL thread up to the point where the relay log ends. This can be useful when you want to pause execution to catch up with events already received from the master, when you want to perform administration on the slave but also ensure that it has processed all updates to a specific point. This method can also be used to pause event receipt on the slave while you conduct administration on the master. Stopping the I/O thread but permitting the SQL thread to run helps ensure that there is not a massive backlog of events to be executed when replication is started again.

### 16.2 Replication Implementation
Replication is based on the master server keeping track of all changes to its databases (updates, deletes, and so on) in its binary log. The binary log serves as a written record of all events that modify database structure or content (data) from the moment the server was started. Typically, `SELECT` statements are not recorded because they modify neither database structure nor content.

Each slave that connects to the master requests a copy of the binary log. That is, it pulls the data from the master, rather than the master pushing the data to the slave. The slave also executes the events from the binary log that it receives. This has the effect of repeating the original changes just as they were made on the master. Tables are created or their structure modified, and data is inserted, deleted, and updated according to the changes that were originally made on the master.

Because each slave is independent, the replaying of the changes from the master's binary log occurs independently on each slave that is connected to the master. In addition, because each slave receives a copy of the binary log only by requesting it from the master, the slave is able to read and update the copy of the database at its own pace and can start and stop the replication process at will without affecting the ability to update to the latest database status on either the master or slave side.

For more information on the specifics of the replication implementation, see Section 16.2.1, “Replication Implementation Details”.

Masters and slaves report their status in respect of the replication process regularly so that you can monitor them. See Section 8.14, “Examining Thread Information”, for descriptions of all replicated-related states.

The master binary log is written to a local relay log on the slave before it is processed. The slave also records information about the current position with the master's binary log and the local relay log. See Section 16.2.2, “Replication Relay and Status Logs”.

Database changes are filtered on the slave according to a set of rules that are applied according to the various configuration options and variables that control event evaluation. For details on how these rules are applied, see Section 16.2.3, “How Servers Evaluate Replication Filtering Rules”.

### 16.2.1 Replication Implementation Details

MySQL replication capabilities are implemented using three threads, one on the master server and two on the slave:

- **Binlog dump thread.** The master creates a thread to send the binary log contents to a slave when the slave connects. This thread can be identified in the output of `SHOW PROCESSLIST` on the master as the Binlog Dump thread.

  The binary log dump thread acquires a lock on the master's binary log for reading each event that is to be sent to the slave. As soon as the event has been read, the lock is released, even before the event is sent to the slave.

- **Slave I/O thread.** When a `START SLAVE` statement is issued on a slave server, the slave creates an I/O thread, which connects to the master and asks it to send the updates recorded in its binary logs.

  The slave I/O thread reads the updates that the master’s Binlog Dump thread sends (see previous item) and copies them to local files that comprise the slave's relay log.

  The state of this thread is shown as Slave_IO_running in the output of `SHOW SLAVE STATUS` or as Slave_running in the output of `SHOW STATUS`.

- **Slave SQL thread.** The slave creates an SQL thread to read the relay log that is written by the slave I/O thread and execute the events contained therein.

  In the preceding description, there are three threads per master/slave connection. A master that has multiple slaves creates one binary log dump thread for each currently connected slave, and each slave has its own I/O and SQL threads.
A slave uses two threads to separate reading updates from the master and executing them into independent tasks. Thus, the task of reading statements is not slowed down if statement execution is slow. For example, if the slave server has not been running for a while, its I/O thread can quickly fetch all the binary log contents from the master when the slave starts, even if the SQL thread lags far behind. If the slave stops before the SQL thread has executed all the fetched statements, the I/O thread has at least fetched everything so that a safe copy of the statements is stored locally in the slave’s relay logs, ready for execution the next time that the slave starts. This enables the master server to purge its binary logs sooner because it no longer needs to wait for the slave to fetch their contents.

The `SHOW PROCESSLIST` statement provides information that tells you what is happening on the master and on the slave regarding replication. For information on master states, see Section 8.14.5, “Replication Master Thread States”. For slave states, see Section 8.14.6, “Replication Slave I/O Thread States”, and Section 8.14.7, “Replication Slave SQL Thread States”.

The following example illustrates how the three threads show up in the output from `SHOW PROCESSLIST`.

On the master server, the output from `SHOW PROCESSLIST` looks like this:

```sql
mysql> SHOW PROCESSLIST
*************************** 1. row ***************************
    Id: 2
    User: root
    Host: localhost:32931
    db: NULL
    Command: Binlog Dump
    Time: 94
    State: Has sent all binlog to slave; waiting for binlog to be updated
    Info: NULL
```

Here, thread 2 is a Binlog Dump replication thread that services a connected slave. The State information indicates that all outstanding updates have been sent to the slave and that the master is waiting for more updates to occur. If you see no Binlog Dump threads on a master server, this means that replication is not running; that is, no slaves are currently connected.

On a slave server, the output from `SHOW PROCESSLIST` looks like this:

```sql
mysql> SHOW PROCESSLIST
*************************** 1. row ***************************
    Id: 10
    User: system user
    Host: 
    db: NULL
    Command: Connect
    Time: 11
    State: Waiting for master to send event
    Info: NULL
```

```sql
*************************** 2. row ***************************
    Id: 11
    User: system user
    Host: 
    db: NULL
    Command: Connect
    Time: 11
    State: Has read all relay log; waiting for the slave I/O thread to update it
    Info: NULL
```

The State information indicates that thread 10 is the I/O thread that is communicating with the master server, and thread 11 is the SQL thread that is processing the updates stored in the relay logs. At the time that `SHOW PROCESSLIST` was run, both threads were idle, waiting for further updates.
The value in the Time column can show how late the slave is compared to the master. See Section A.13, “MySQL 5.1 FAQ: Replication”. If sufficient time elapses on the master side without activity on the Binlog Dump thread, the master determines that the slave is no longer connected. As for any other client connection, the timeouts for this depend on the values of net_write_timeout and net_retry_count; for more information about these, see Section 5.1.4, “Server System Variables”.

The SHOW SLAVE STATUS statement provides additional information about replication processing on a slave server. See Section 16.1.4.1, “Checking Replication Status”.

16.2.2 Replication Relay and Status Logs

During replication, a slave server creates several logs that hold the binary log events relayed from the master to the slave, and to record information about the current status and location within the relay log. There are three types of logs used in the process, listed here:

- The relay log consists of the events read from the binary log of the master and written by the slave I/O thread. Events in the relay log are executed on the slave as part of the SQL thread.

- The master info log contains status and current configuration information for the slave's connection to the master. This log holds information on the master host name, login credentials, and coordinates indicating how far the slave has read from the master's binary log.

- The relay log info log holds status information about the execution point within the slave's relay log.

16.2.2.1 The Slave Relay Log

The relay log, like the binary log, consists of a set of numbered files containing events that describe database changes, and an index file that contains the names of all used relay log files.

The term “relay log file” generally denotes an individual numbered file containing database events. The term “relay log” collectively denotes the set of numbered relay log files plus the index file.

Relay log files have the same format as binary log files and can be read using mysqlbinlog (see Section 4.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”).

By default, relay log file names have the form host_name-relay-bin.nnnnnn in the data directory, where host_name is the name of the slave server host and nnnnnn is a sequence number. Successive relay log files are created using successive sequence numbers, beginning with 000001. The slave uses an index file to track the relay log files currently in use. The default relay log index file name is host_name-relay-bin.index in the data directory.

The default relay log file and relay log index file names can be overridden with, respectively, the --relay-log and --relay-log-index server options (see Section 16.1.3, “Replication and Binary Logging Options and Variables”).

If a slave uses the default host-based relay log file names, changing a slave’s host name after replication has been set up can cause replication to fail with the errors Failed to open the relay log and Could not find target log during relay log initialization. This is a known issue (see Bug #2122). If you anticipate that a slave’s host name might change in the future (for example, if networking is set up on the slave such that its host name can be modified using DHCP), you can avoid this issue entirely by using the --relay-log and --relay-log-index options to specify relay log file names explicitly when you initially set up the slave. This will make the names independent of server host name changes.

If you encounter the issue after replication has already begun, one way to work around it is to stop the slave server, prepend the contents of the old relay log index file to the new one, and then restart the slave. On a Unix system, this can be done as shown here:

shell> cat new_relay_log_name.index >> old_relay_log_name.index
shell> mv old_relay_log_name.index new_relay_log_name.index
A slave server creates a new relay log file under the following conditions:

- Each time the I/O thread starts.
- When the logs are flushed; for example, with `FLUSH LOGS` or `mysqladmin flush-logs`.
- When the size of the current relay log file becomes “too large,” determined as follows:
  - If the value of `max_relay_log_size` is greater than 0, that is the maximum relay log file size.
  - If the value of `max_relay_log_size` is 0, `max_binlog_size` determines the maximum relay log file size.

The SQL thread automatically deletes each relay log file as soon as it has executed all events in the file and no longer needs it. There is no explicit mechanism for deleting relay logs because the SQL thread takes care of doing so. However, `FLUSH LOGS` rotates relay logs, which influences when the SQL thread deletes them.

### 16.2.2.2 Slave Status Logs

A replication slave server creates two logs. By default, these logs are files named `master.info` and `relay-log.info` and created in the data directory. The names and locations of these files can be changed by using the `--master-info-file` and `--relay-log-info-file` options, respectively. See Section 16.1.3, “Replication and Binary Logging Options and Variables”.

The two status logs contain information like that shown in the output of the `SHOW SLAVE STATUS` statement, which is discussed in Section 13.4.2, “SQL Statements for Controlling Slave Servers”. Because the status logs are stored on disk, they survive a slave server’s shutdown. The next time the slave starts up, it reads the two logs to determine how far it has proceeded in reading binary logs from the master and in processing its own relay logs.

The master info log should be protected because it contains the password for connecting to the master. See Section 6.1.2.3, “Passwords and Logging”.

The slave I/O thread updates the master info log. The following table shows the correspondence between the lines in the `master.info` file and the columns displayed by `SHOW SLAVE STATUS`.

<table>
<thead>
<tr>
<th>Line in master.info</th>
<th>SHOW SLAVE STATUS Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td></td>
<td>Number of lines in the file</td>
</tr>
<tr>
<td>2</td>
<td>Master_Log_File</td>
<td>The name of the master binary log currently being read from the master</td>
</tr>

The slave SQL thread updates the relay log info log. The following table shows the correspondence between the lines in the relay-log.info file and the columns displayed by SHOW SLAVE STATUS.

<table>
<thead>
<tr>
<th>Line in relay-log.info</th>
<th>SHOW SLAVE STATUS Column</th>

</tr>
</tbody>
</table>

The contents of the relay-log.info file and the states shown by the SHOW SLAVE STATUS statement might not match if the relay-log.info file has not been flushed to disk. Ideally, you should only view relay-log.info on a slave that is offline (that is, mysqld is not running). For a running system, SHOW SLAVE STATUS should be used.

When you back up the slave’s data, you should back up these two status logs, along with the relay log files. The status logs are needed to resume replication after you restore the data from the slave. If you lose the relay logs but still have the relay log info log, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use CHANGE MASTER TO with the MASTER_LOG_FILE and MASTER_LOG_POS options to tell the slave to re-read the binary logs from that point. Of course, this requires that the binary logs still exist on the master.

16.2.3 How Servers Evaluate Replication Filtering Rules

If a master server does not write a statement to its binary log, the statement is not replicated. If the server does log the statement, the statement is sent to all slaves and each slave determines whether to execute it or ignore it.

On the master, you can control which databases to log changes for by using the --binlog-do-db and --binlog-ignore-db options to control binary logging. For a description of the rules that servers use in evaluating these options, see Section 16.2.3.1, “Evaluation of Database-Level Replication and Binary Logging Options”. You should not use these options to control which databases and tables are replicated. Instead, use filtering on the slave to control the events that are executed on the slave.

On the slave side, decisions about whether to execute or ignore statements received from the master are made according to the --replicate-* options that the slave was started with. (See Section 16.1.3, “Replication and Binary Logging Options and Variables”.)
In the simplest case, when there are no `--replicate-*` options, the slave executes all statements that it receives from the master. Otherwise, the result depends on the particular options given.

Database-level options (`--replicate-do-db`, `--replicate-ignore-db`) are checked first; see Section 16.2.3.1, “Evaluation of Database-Level Replication and Binary Logging Options”, for a description of this process. If no database-level options are used, option checking proceeds to any table-level options that may be in use (see Section 16.2.3.2, “Evaluation of Table-Level Replication Options”, for a discussion of these). If one or more database-level options are used but none are matched, the statement is not replicated.

To make it easier to determine what effect an option set will have, it is recommended that you avoid mixing “do” and “ignore” options, or wildcard and nonwildcard options. An example of the latter that may have unintended effects is the use of `--replicate-do-db` and `--replicate-wild-do-table` together, where `--replicate-wild-do-table` uses a pattern for the database name that matches the name given for `--replicate-do-db`. Suppose a replication slave is started with `--replicate-do-db=dbx --replicate-wild-do-table=db%.t1`. Then, suppose that on the master, you issue the statement `CREATE DATABASE dbx`. Although you might expect it, this statement is not replicated because it does not reference a table named `t1`.

If any `--replicate-rewrite-db` options were specified, they are applied before the `--replicate-*` filtering rules are tested.

**Note**

Database-level filtering options are case-sensitive on platforms supporting case sensitivity in filenames, whereas table-level filtering options are not (regardless of platform). This is true regardless of the value of the `lower_case_table_names` system variable. These are known issues which are fixed in MySQL 5.5.

### 16.2.3.1 Evaluation of Database-Level Replication and Binary Logging Options

When evaluating replication options, the slave begins by checking to see whether there are any `--replicate-do-db` or `--replicate-ignore-db` options that apply. When using `--binlog-do-db` or `--binlog-ignore-db`, the process is similar, but the options are checked on the master.

With statement-based replication, the default database is checked for a match. With row-based replication, the database where data is to be changed is the database that is checked. Regardless of the binary logging format, checking of database-level options proceeds as shown in the following diagram.
The steps involved are listed here:

1. **Are there any** \texttt{--replicate-do-db} **options?**
   - **Yes.** Do any of them match the database?
     - **Yes.** Execute the statement and exit.
     - **No.** Ignore the statement and exit.
   - **No.** Continue to step 2.

2. **Are there any** \texttt{--replicate-ignore-db} **options?**
   - **Yes.** Do any of them match the database?
     - **Yes.** Ignore the statement and exit.
     - **No.** Continue to step 3.
   - **No.** Continue to step 3.

3. Proceed to checking the table-level replication options, if there are any. For a description of how these options are checked, see Section 16.2.3.2, “Evaluation of Table-Level Replication Options”. 
How Servers Evaluate Replication Filtering Rules

Important
A statement that is still permitted at this stage is not yet actually executed. The statement is not executed until all table-level options (if any) have also been checked, and the outcome of that process permits execution of the statement.

For binary logging, the steps involved are listed here:

1. Are there any `--binlog-do-db` or `--binlog-ignore-db` options?
   • Yes. Continue to step 2.
   • No. Log the statement and exit.

2. Is there a default database (has any database been selected by `USE`)?
   • Yes. Continue to step 3.
   • No. Ignore the statement and exit.

3. There is a default database. Are there any `--binlog-do-db` options?
   • Yes. Do any of them match the database?
     • Yes. Log the statement and exit.
     • No. Ignore the statement and exit.
   • No. Continue to step 4.

4. Do any of the `--binlog-ignore-db` options match the database?
   • Yes. Ignore the statement and exit.
   • No. Log the statement and exit.

Important
For statement-based logging, an exception is made in the rules just given for the `CREATE DATABASE`, `ALTER DATABASE`, and `DROP DATABASE` statements. In those cases, the database being created, altered, or dropped replaces the default database when determining whether to log or ignore updates.

`--binlog-do-db` can sometimes mean “ignore other databases”. For example, when using statement-based logging, a server running with only `--binlog-do-db=sales` does not write to the binary log statements for which the default database differs from `sales`. When using row-based logging with the same option, the server logs only those updates that change data in `sales`.

16.2.3.2 Evaluation of Table-Level Replication Options

The slave checks for and evaluates table options only if either of the following two conditions is true:

• No matching database options were found.

• One or more database options were found, and were evaluated to arrive at an “execute” condition according to the rules described in the previous section (see Section 16.2.3.1, “Evaluation of Database-Level Replication and Binary Logging Options”).

First, as a preliminary condition, the slave checks whether statement-based replication is enabled. If so, and the statement occurs within a stored function, the slave executes the statement and exits.
If row-based replication is enabled, the slave does not know whether a statement occurred within a stored function on the master, so this condition does not apply.

**Note**

For statement-based replication, replication events represent statements (all changes making up a given event are associated with a single SQL statement); for row-based replication, each event represents a change in a single table row (thus a single statement such as `UPDATE mytable SET mycol = 1` may yield many row-based events). When viewed in terms of events, the process of checking table options is the same for both row-based and statement-based replication.

Having reached this point, if there are no table options, the slave simply executes all events. If there are any `--replicate-do-table` or `--replicate-wild-do-table` options, the event must match one of these if it is to be executed; otherwise, it is ignored. If there are any `--replicate-ignore-table` or `--replicate-wild-ignore-table` options, all events are executed except those that match any of these options. This process is illustrated in the following diagram.
How Servers Evaluate Replication Filtering Rules

The following steps describe this evaluation in more detail:

1. Are there any table options?
   - **Yes.**  Continue to step 2.
   - **No.**  Execute the event and exit.

2. Are there any `--replicate-do-table` options?
16.2.3.3 Replication Rule Application

This section provides additional explanation and examples of usage for different combinations of replication filtering options.

Some typical combinations of replication filter rule types are given in the following table:

<table>
<thead>
<tr>
<th>Condition (Types of Options)</th>
<th>Outcome</th>
</tr>
</thead>
<tbody>
<tr>
<td>No <code>--replicate-*</code> options at all:</td>
<td>The slave executes all events that it receives from the master.</td>
</tr>
<tr>
<td><code>--replicate-*-db</code> options, but no table options:</td>
<td>The slave accepts or ignores events using the database options. It executes all events permitted by those options because there are no table restrictions.</td>
</tr>
<tr>
<td><code>--replicate-*-table</code> options, but no database options:</td>
<td>All events are accepted at the database-checking stage because there are no database conditions. The slave</td>
</tr>
</tbody>
</table>
A more complex example follows, in which we examine the outcomes for both statement-based and row-based settings.

Suppose that we have two tables `mytbl1` in database `db1` and `mytbl2` in database `db2` on the master, and the slave is running with the following options (and no other replication filtering options):

```
replicate-ignore-db = db1
replicate-do-table  = db2.tbl2
```

Now we execute the following statements on the master:

```
USE db1;
INSERT INTO db2.tbl2 VALUES (1);
```

The results on the slave vary considerably depending on the binary log format, and may not match initial expectations in either case.

**Statement-based replication.** The `USE` statement causes `db1` to be the default database. Thus the `--replicate-ignore-db` option matches, and the `INSERT` statement is ignored. The table options are not checked.

**Row-based replication.** The default database has no effect on how the slave reads database options when using row-based replication. Thus, the `USE` statement makes no difference in how the `--replicate-ignore-db` option is handled: the database specified by this option does not match the database where the `INSERT` statement changes data, so the slave proceeds to check the table options. The table specified by `--replicate-do-table` matches the table to be updated, and the row is inserted.

### 16.3 Replication Solutions

Replication can be used in many different environments for a range of purposes. This section provides general notes and advice on using replication for specific solution types.

For information on using replication in a backup environment, including notes on the setup, backup procedure, and files to back up, see **Section 16.3.1, “Using Replication for Backups”**.

For advice and tips on using different storage engines on the master and slaves, see **Section 16.3.2, “Using Replication with Different Master and Slave Storage Engines”**.

Using replication as a scale-out solution requires some changes in the logic and operation of applications that use the solution. See **Section 16.3.3, “Using Replication for Scale-Out”**.

For performance or data distribution reasons, you may want to replicate different databases to different replication slaves. See **Section 16.3.4, “Replicating Different Databases to Different Slaves”**.

As the number of replication slaves increases, the load on the master can increase and lead to reduced performance (because of the need to replicate the binary log to each slave). For tips on improving your replication performance, including using a single secondary server as a replication master, see **Section 16.3.5, “Improving Replication Performance”**.

<th>Outcome</th>
</tr>
</thead>
<tbody>
<tr>
<td>A combination of database and table options:</td>
<td>The slave accepts or ignores events using the database options. Then it evaluates all events permitted by those options according to the table options. This can sometimes lead to results that seem counterintuitive, and that may be different depending on whether you are using statement-based or row-based replication; see the text for an example.</td>
</tr>
</tbody>
</table>
For guidance on switching masters, or converting slaves into masters as part of an emergency failover solution, see Section 16.3.6, “Switching Masters During Failover”.

To secure your replication communication, you can encrypt the communication channel. For step-by-step instructions, see Section 16.3.7, “Setting Up Replication to Use Secure Connections”.

16.3.1 Using Replication for Backups

To use replication as a backup solution, replicate data from the master to a slave, and then back up the data slave. The slave can be paused and shut down without affecting the running operation of the master, so you can produce an effective snapshot of “live” data that would otherwise require the master to be shut down.

How you back up a database depends on its size and whether you are backing up only the data, or the data and the replication slave state so that you can rebuild the slave in the event of failure. There are therefore two choices:

• If you are using replication as a solution to enable you to back up the data on the master, and the size of your database is not too large, the mysqldump tool may be suitable. See Section 16.3.1.1, “Backing Up a Slave Using mysqldump”.

• For larger databases, where mysqldump would be impractical or inefficient, you can back up the raw data files instead. Using the raw data files option also means that you can back up the binary and relay logs that will enable you to recreate the slave in the event of a slave failure. For more information, see Section 16.3.1.2, “Backing Up Raw Data from a Slave”.

Another backup strategy, which can be used for either master or slave servers, is to put the server in a read-only state. The backup is performed against the read-only server, which then is changed back to its usual read/write operational status. See Section 16.3.1.3, “Backing Up a Master or Slave by Making It Read Only”.

16.3.1.1 Backing Up a Slave Using mysqldump

Using mysqldump to create a copy of a database enables you to capture all of the data in the database in a format that enables the information to be imported into another instance of MySQL Server (see Section 4.5.4, “mysqldump — A Database Backup Program”). Because the format of the information is SQL statements, the file can easily be distributed and applied to running servers in the event that you need access to the data in an emergency. However, if the size of your data set is very large, mysqldump may be impractical.

When using mysqldump, you should stop replication on the slave before starting the dump process to ensure that the dump contains a consistent set of data:

1. Stop the slave from processing requests. You can stop replication completely on the slave using mysqladmin:

   shell> mysqladmin stop-slave

   Alternatively, you can stop only the slave SQL thread to pause event execution:

   shell> mysql -e 'STOP SLAVE SQL_THREAD;'

   This enables the slave to continue to receive data change events from the master’s binary log and store them in the relay logs using the I/O thread, but prevents the slave from executing these events and changing its data. Within busy replication environments, permitting the I/O thread to run during backup may speed up the catch-up process when you restart the slave SQL thread.

2. Run mysqldump to dump your databases. You may either dump all databases or select databases to be dumped. For example, to dump all databases:

   shell> mysqldump --all-databases > fulldb.dump

3. Once the dump has completed, start slave operations again:
In the preceding example, you may want to add login credentials (user name, password) to the commands, and bundle the process up into a script that you can run automatically each day.

If you use this approach, make sure you monitor the slave replication process to ensure that the time taken to run the backup does not affect the slave's ability to keep up with events from the master. See Section 16.1.4.1, “Checking Replication Status”. If the slave is unable to keep up, you may want to add another slave and distribute the backup process. For an example of how to configure this scenario, see Section 16.3.4, “Replicating Different Databases to Different Slaves”.

### 16.3.1.2 Backing Up Raw Data from a Slave

To guarantee the integrity of the files that are copied, backing up the raw data files on your MySQL replication slave should take place while your slave server is shut down. If the MySQL server is still running, background tasks may still be updating the database files, particularly those involving storage engines with background processes such as InnoDB. With InnoDB, these problems should be resolved during crash recovery, but since the slave server can be shut down during the backup process without affecting the execution of the master it makes sense to take advantage of this capability.

To shut down the server and back up the files:

1. Shut down the slave MySQL server:

   ```shell
   mysqladmin shutdown
   ```

2. Copy the data files. You can use any suitable copying or archive utility, including `cp`, `tar` or `WinZip`. For example, assuming that the data directory is located under the current directory, you can archive the entire directory as follows:

   ```shell
   tar cf /tmp/dbbackup.tar ./data
   ```

3. Start the MySQL server again. Under Unix:

   ```shell
   mysqld_safe &
   ```

   Under Windows:

   ```
   C:\> "C:\Program Files\MySQL\MySQL Server 5.1\bin\mysqld"
   ```

Normally you should back up the entire data directory for the slave MySQL server. If you want to be able to restore the data and operate as a slave (for example, in the event of failure of the slave), then in addition to the slave's data, you should also back up the slave status files, `master.info` and `relay-log.info`, along with the relay log files. These files are needed to resume replication after you restore the slave's data.

If you lose the relay logs but still have the `relay-log.info` file, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use `CHANGE MASTER TO` with the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options to tell the slave to re-read the binary logs from that point. This requires that the binary logs still exist on the master server.

If your slave is replicating `LOAD DATA INFILE` statements, you should also back up any `SQL_LOAD-*` files that exist in the directory that the slave uses for this purpose. The slave needs these files to resume replication of any interrupted `LOAD DATA INFILE` operations. The location of this directory is the value of the `--slave-load-tmpdir` option. If the server was not started with that option, the directory location is the value of the `tmpdir` system variable.

### 16.3.1.3 Backing Up a Master or Slave by Making It Read Only

It is possible to back up either master or slave servers in a replication setup by acquiring a global read lock and manipulating the `read_only` system variable to change the read-only state of the server to be backed up:
1. Make the server read-only, so that it processes only retrievals and blocks updates.

2. Perform the backup.

3. Change the server back to its normal read/write state.

**Note**

The instructions in this section place the server to be backed up in a state that is safe for backup methods that get the data from the server, such as `mysqldump` (see Section 4.5.4, "mysqldump — A Database Backup Program"). You should not attempt to use these instructions to make a binary backup by copying files directly because the server may still have modified data cached in memory and not flushed to disk.

These instructions also require MySQL 5.1.15 or higher. For earlier versions, setting `read_only` does not block while table locks or outstanding transactions are pending, so data changes can still occur during the backup operation and produce inconsistent backup results.

The following instructions describe how to do this for a master server and for a slave server. For both scenarios discussed here, suppose that you have the following replication setup:

- A master server M1
- A slave server S1 that has M1 as its master
- A client C1 connected to M1
- A client C2 connected to S1

In either scenario, the statements to acquire the global read lock and manipulate the `read_only` variable are performed on the server to be backed up and do not propagate to any slaves of that server.

**Scenario 1: Backup with a Read-Only Master**

Put the master M1 in a read-only state by executing these statements on it:

```sql
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

While M1 is in a read-only state, the following properties are true:

- Requests for updates sent by C1 to M1 will block because the server is in read-only mode.
- Requests for query results sent by C1 to M1 will succeed.
- Making a backup on M1 is safe.
- Making a backup on S1 is not safe. This server is still running, and might be processing the binary log or update requests coming from client C2

While M1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on M1 completes, restore M1 to its normal operational state by executing these statements:

```sql
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```
Using Replication with Different Master and Slave Storage Engines

Although performing the backup on M1 is safe (as far as the backup is concerned), it is not optimal for performance because clients of M1 are blocked from executing updates.

This strategy applies to backing up a master server in a replication setup, but can also be used for a single server in a nonreplication setting.

**Scenario 2: Backup with a Read-Only Slave**

Put the slave S1 in a read-only state by executing these statements on it:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

While S1 is in a read-only state, the following properties are true:

- The master M1 will continue to operate, so making a backup on the master is not safe.
- The slave S1 is stopped, so making a backup on the slave S1 is safe.

These properties provide the basis for a popular backup scenario: Having one slave busy performing a backup for a while is not a problem because it does not affect the entire network, and the system is still running during the backup. In particular, clients can still perform updates on the master server, which remains unaffected by backup activity on the slave.

While S1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on S1 completes, restore S1 to its normal operational state by executing these statements:

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

After the slave is restored to normal operation, it again synchronizes to the master by catching up with any outstanding updates from the binary log of the master.

### 16.3.2 Using Replication with Different Master and Slave Storage Engines

It does not matter for the replication process whether the source table on the master and the replicated table on the slave use different engine types. In fact, the system variables `storage_engine` and `table_type` are not replicated.

This provides a number of benefits in the replication process in that you can take advantage of different engine types for different replication scenarios. For example, in a typical scale-out scenario (see Section 16.3.3, “Using Replication for Scale-Out”), you want to use InnoDB tables on the master to take advantage of the transactional functionality, but use MyISAM on the slaves where transaction support is not required because the data is only read. When using replication in a data-logging environment you may want to use the Archive storage engine on the slave.

Configuring different engines on the master and slave depends on how you set up the initial replication process:

- If you used `mysqldump` to create the database snapshot on your master, you could edit the dump file text to change the engine type used on each table.

Another alternative for `mysqldump` is to disable engine types that you do not want to use on the slave before using the dump to build the data on the slave. For example, you can add the `--skip-innodb` option on your slave to disable the InnoDB engine. If a specific engine does not exist for a table to be created, MySQL will use the default engine type, usually MyISAM. (This requires that the
Using Replication for Scale-Out

NO ENGINE SUBSTITUTION SQL mode is not enabled.) If you want to disable additional engines in this way, you may want to consider building a special binary to be used on the slave that only supports the engines you want.

- If you are using raw data files (a binary backup) to set up the slave, you will be unable to change the initial table format. Instead, use ALTER TABLE to change the table types after the slave has been started.

- For new master/slave replication setups where there are currently no tables on the master, avoid specifying the engine type when creating new tables.

If you are already running a replication solution and want to convert your existing tables to another engine type, follow these steps:

1. Stop the slave from running replication updates:

```
mysql> STOP SLAVE;
```

   This will enable you to change engine types without interruptions.

2. Execute an ALTER TABLE ... ENGINE='engine_type' for each table to be changed.

3. Start the slave replication process again:

```
mysql> START SLAVE;
```

Although the storage_engine and table_type variables are not replicated, be aware that CREATE TABLE and ALTER TABLE statements that include the engine specification will be correctly replicated to the slave. For example, if you have a CSV table and you execute:

```
mysql> ALTER TABLE csvtable Engine='MyISAM';
```

The above statement will be replicated to the slave and the engine type on the slave will be converted to MyISAM, even if you have previously changed the table type on the slave to an engine other than CSV. If you want to retain engine differences on the master and slave, you should be careful to use the storage_engine variable on the master when creating a new table. For example, instead of:

```
mysql> CREATE TABLE tablea (columna int) Engine=MyISAM;
```

Use this format:

```
mysql> SET storage_engine=MyISAM;
mysql> CREATE TABLE tablea (columna int);
```

When replicated, the storage_engine variable will be ignored, and the CREATE TABLE statement will execute on the slave using the slave’s default engine.

16.3.3 Using Replication for Scale-Out

You can use replication as a scale-out solution; that is, where you want to split up the load of database queries across multiple database servers, within some reasonable limitations.

Because replication works from the distribution of one master to one or more slaves, using replication for scale-out works best in an environment where you have a high number of reads and low number of writes/updates. Most Web sites fit into this category, where users are browsing the Web site, reading articles, posts, or viewing products. Updates only occur during session management, or when making a purchase or adding a comment/message to a forum.
Replicating Different Databases to Different Slaves

Replication in this situation enables you to distribute the reads over the replication slaves, while still enabling your web servers to communicate with the replication master when a write is required. You can see a sample replication layout for this scenario in Figure 16.1, “Using Replication to Improve Performance During Scale-Out”.

**Figure 16.1 Using Replication to Improve Performance During Scale-Out**

If the part of your code that is responsible for database access has been properly abstracted/modularized, converting it to run with a replicated setup should be very smooth and easy. Change the implementation of your database access to send all writes to the master, and to send reads to either the master or a slave. If your code does not have this level of abstraction, setting up a replicated system gives you the opportunity and motivation to clean it up. Start by creating a wrapper library or module that implements the following functions:

- `safe_writer_connect()`
- `safe_reader_connect()`
- `safe_reader_statement()`
- `safe_writer_statement()`

`safe_` in each function name means that the function takes care of handling all error conditions. You can use different names for the functions. The important thing is to have a unified interface for connecting for reads, connecting for writes, doing a read, and doing a write.

Then convert your client code to use the wrapper library. This may be a painful and scary process at first, but it pays off in the long run. All applications that use the approach just described are able to take advantage of a master/slave configuration, even one involving multiple slaves. The code is much easier to maintain, and adding troubleshooting options is trivial. You need to modify only one or two functions; for example, to log how long each statement took, or which statement among those issued gave you an error.

If you have written a lot of code, you may want to automate the conversion task by using the `replace` utility that comes with standard MySQL distributions, or write your own conversion script. Ideally, your code uses consistent programming style conventions. If not, then you are probably better off rewriting it anyway, or at least going through and manually regularizing it to use a consistent style.

### 16.3.4 Replicating Different Databases to Different Slaves

There may be situations where you have a single master and want to replicate different databases to different slaves. For example, you may want to distribute different sales data to different departments.
to help spread the load during data analysis. A sample of this layout is shown in Figure 16.2, “Using Replication to Replicate Databases to Separate Replication Slaves”.

Figure 16.2 Using Replication to Replicate Databases to Separate Replication Slaves

You can achieve this separation by configuring the master and slaves as normal, and then limiting the binary log statements that each slave processes by using the **--replicate-wild-do-table** configuration option on each slave.

**Important**

You should not use **--replicate-do-db** for this purpose when using statement-based replication, since statement-based replication causes this option's affects to vary according to the database that is currently selected. This applies to mixed-format replication as well, since this enables some updates to be replicated using the statement-based format.

However, it should be safe to use **--replicate-do-db** for this purpose if you are using row-based replication only, since in this case the currently selected database has no effect on the option's operation.

For example, to support the separation as shown in Figure 16.2, “Using Replication to Replicate Databases to Separate Replication Slaves”, you should configure each replication slave as follows, before executing **START SLAVE**:

- Replication slave 1 should use **--replicate-wild-do-table=databaseA.%**.
- Replication slave 2 should use **--replicate-wild-do-table=databaseB.%**.
- Replication slave 3 should use **--replicate-wild-do-table=databaseC.%**.

Each slave in this configuration receives the entire binary log from the master, but executes only those events from the binary log that apply to the databases and tables included by the **--replicate-wild-do-table** option in effect on that slave.

If you have data that must be synchronized to the slaves before replication starts, you have a number of choices:

- Synchronize all the data to each slave, and delete the databases, tables, or both that you do not want to keep.
- Use **mysqldump** to create a separate dump file for each database and load the appropriate dump file on each slave.
- Use a raw data file dump and include only the specific files and databases that you need for each slave.

**Note**

This does not work with **InnoDB** databases unless you use **innodb_file_per_table**.
16.3.5 Improving Replication Performance

As the number of slaves connecting to a master increases, the load, although minimal, also increases, as each slave uses a client connection to the master. Also, as each slave must receive a full copy of the master binary log, the network load on the master may also increase and create a bottleneck.

If you are using a large number of slaves connected to one master, and that master is also busy processing requests (for example, as part of a scale-out solution), then you may want to improve the performance of the replication process.

One way to improve the performance of the replication process is to create a deeper replication structure that enables the master to replicate to only one slave, and for the remaining slaves to connect to this primary slave for their individual replication requirements. A sample of this structure is shown in Figure 16.3, “Using an Additional Replication Host to Improve Performance”.

Figure 16.3 Using an Additional Replication Host to Improve Performance

For this to work, you must configure the MySQL instances as follows:

- Master 1 is the primary master where all changes and updates are written to the database. Binary logging should be enabled on this machine.
- Master 2 is the slave to the Master 1 that provides the replication functionality to the remainder of the slaves in the replication structure. Master 2 is the only machine permitted to connect to Master 1. Master 2 also has binary logging enabled, and the `--log-slave-updates` option so that replication instructions from Master 1 are also written to Master 2's binary log so that they can then be replicated to the true slaves.
- Slave 1, Slave 2, and Slave 3 act as slaves to Master 2, and replicate the information from Master 2, which actually consists of the upgrades logged on Master 1.

The above solution reduces the client load and the network interface load on the primary master, which should improve the overall performance of the primary master when used as a direct database solution.

If your slaves are having trouble keeping up with the replication process on the master, there are a number of options available:

- If possible, put the relay logs and the data files on different physical drives. To do this, use the `--relay-log` option to specify the location of the relay log.
- If the slaves are significantly slower than the master, you may want to divide up the responsibility for replicating different databases to different slaves. See Section 16.3.4, “Replicating Different Databases to Different Slaves”.
- If your master makes use of transactions and you are not concerned about transaction support on your slaves, use MyISAM or another nontransactional engine on the slaves. See Section 16.3.2, “Using Replication with Different Master and Slave Storage Engines”.
- If your slaves are not acting as masters, and you have a potential solution in place to ensure that you can bring up a master in the event of failure, then you can switch off `--log-slave-updates`. This prevents “dumb” slaves from also logging events they have executed into their own binary log.
16.3.6 Switching Masters During Failover

There is in MySQL 5.1 no official solution for providing failover between master and slaves in the event of a failure. Instead, you must set up a master and one or more slaves; then, you need to write an application or script that monitors the master to check whether it is up, and instructs the slaves and applications to change master in case of failure. This section discusses some of the issues encountered when setting up failover in this fashion.

**Note**

The MySQL Utilities include a `mysqlfailover` tool that provides failover capability using GTIDs, support for which requires MySQL 5.6 or later. For more information, see `mysqlfailover` — Automatic replication health monitoring and failover, and Replication with Global Transaction Identifiers.

You can tell a slave to change to a new master using the `CHANGE MASTER TO` statement. The slave does not check whether the databases on the master are compatible with those on the slave; it simply begins reading and executing events from the specified coordinates in the new master's binary log. In a failover situation, all the servers in the group are typically executing the same events from the same binary log file, so changing the source of the events should not affect the structure or integrity of the database, provided that you exercise care in making the change.

Slaves should be run with the `--log-bin` option and without `--log-slave-updates`. In this way, the slave is ready to become a master without restarting the slave `mysqld`. Assume that you have the structure shown in Figure 16.4, “Redundancy Using Replication, Initial Structure”.

![Figure 16.4 Redundancy Using Replication, Initial Structure](image)

In this diagram, the MySQL Master holds the master database, the MySQL Slave hosts are replication slaves, and the Web Client machines are issuing database reads and writes. Web clients that issue only reads (and would normally be connected to the slaves) are not shown, as they do not need to switch to a new server in the event of failure. For a more detailed example of a read/write scale-out replication structure, see Section 16.3.3, “Using Replication for Scale-Out”.

Each MySQL Slave (Slave 1, Slave 2, and Slave 3) is a slave running with `--log-bin` and without `--log-slave-updates`. Because updates received by a slave from the master are not logged in the binary log unless `--log-slave-updates` is specified, the binary log on each slave is empty initially. If for some reason MySQL Master becomes unavailable, you can pick one of the slaves to become the new master. For example, if you pick Slave 1, all Web Clients should be redirected to Slave 1, which writes the updates to its binary log. Slave 2 and Slave 3 should then replicate from Slave 1.
The reason for running the slave without `--log-slave-updates` is to prevent slaves from receiving updates twice in case you cause one of the slaves to become the new master. If `Slave 1` has `--log-slave-updates` enabled, it writes any updates that it receives from `Master` in its own binary log. This means that, when `Slave 2` changes from `Master` to `Slave 1` as its master, it may receive updates from `Slave 1` that it has already received from `Master`.

Make sure that all slaves have processed any statements in their relay log. On each slave, issue `STOP SLAVE IO_THREAD`, then check the output of `SHOW PROCESSLIST` until you see `Has read all relay log`. When this is true for all slaves, they can be reconfigured to the new setup. On the slave `Slave 1` being promoted to become the master, issue `STOP SLAVE` and `RESET MASTER`.

On the other slaves `Slave 2` and `Slave 3`, use `STOP SLAVE` and `CHANGE MASTER TO MASTER_HOST='Slave1'` (where `Slave1` represents the real host name of `Slave 1`). To use `CHANGE MASTER TO`, add all information about how to connect to `Slave 1` from `Slave 2` or `Slave 3` (`user, password, port`). When issuing the `CHANGE MASTER TO` statement in this, there is no need to specify the name of the `Slave 1` binary log file or log position to read from, since the first binary log file and position 4, are the defaults. Finally, execute `START SLAVE` on `Slave 2` and `Slave 3`.

Once the new replication setup is in place, you need to tell each `Web Client` to direct its statements to `Slave 1`. From that point on, all updates statements sent by `Web Client` to `Slave 1` are written to the binary log of `Slave 1`, which then contains every update statement sent to `Slave 1` since `Master` died.

The resulting server structure is shown in Figure 16.5, “Redundancy Using Replication, After Master Failure”.

Figure 16.5 Redundancy Using Replication, After Master Failure

![Diagram showing server structure](image)

When `Master` becomes available again, you should make it a slave of `Slave 1`. To do this, issue on `Master` the same `CHANGE MASTER TO` statement as that issued on `Slave 2` and `Slave 3` previously. `Master` then becomes a slave of `Slave 1` and picks up the `Web Client` writes that it missed while it was offline.

To make `Master` a master again, use the preceding procedure as if `Slave 1` was unavailable and `Master` was to be the new master. During this procedure, do not forget to run `RESET MASTER` on `Master` before making `Slave 1`, `Slave 2`, and `Slave 3` slaves of `Master`. If you fail to do this, the slaves may pick up stale writes from the `Web Client` applications dating from before the point at which `Master` became unavailable.
You should be aware that there is no synchronization between slaves, even when they share the same master, and thus some slaves might be considerably ahead of others. This means that in some cases the procedure outlined in the previous example might not work as expected. In practice, however, relay logs on all slaves should be relatively close together.

One way to keep applications informed about the location of the master is to have a dynamic DNS entry for the master. With `bind` you can use `nsupdate` to update the DNS dynamically.

### 16.3.7 Setting Up Replication to Use Secure Connections

To use a secure connection for encrypting the transfer of the binary log required during replication, both the master and the slave servers must support encrypted network connections. If either server does not support secure connections (because it has not been compiled or configured for them), replication through an encrypted connection is not possible.

Setting up secure connections for replication is similar to doing so for client/server connections. You must obtain (or create) a suitable security certificate that you can use on the master, and a similar certificate (from the same certificate authority) on each slave. You must also obtain suitable key files.

For more information on setting up a server and client for secure connections, see Section 6.4.4, “Configuring MySQL to Use Secure Connections”.

To enable secure connections on the master, you must create or obtain suitable certificate and key files, and then add the following configuration options to the master’s configuration within the `[mysqld]` section of the master’s `my.cnf` file, changing the file names as necessary:

```
[mysqld]
ssl-ca=cacert.pem
ssl-cert=server-cert.pem
ssl-key=server-key.pem
```

The paths to the files may be relative or absolute; we recommend that you always use complete paths for this purpose.

The options are as follows:

- **ssl-ca** identifies the Certificate Authority (CA) certificate.
- **ssl-cert** identifies the server public key certificate. This can be sent to the client and authenticated against the CA certificate that it has.
- **ssl-key** identifies the server private key.

On the slave, there are two ways to specify the information required for connecting securely to the master. You can either name the slave certificate and key files in the `[client]` section of the slave’s `my.cnf` file, or you can explicitly specify that information using the `CHANGE MASTER TO` statement:

- To name the slave certificate and key files using an option file, add the following lines to the `[client]` section of the slave’s `my.cnf` file, changing the file names as necessary:

```
[client]
ssl-ca=cacert.pem
ssl-cert=client-cert.pem
ssl-key=client-key.pem
```

Restart the slave server, using the `--skip-slave-start` option to prevent the slave from connecting to the master. Use `CHANGE MASTER TO` to specify the master configuration, using the `MASTER_SSL` option to connect securely:

```
mysql> CHANGE MASTER TO
    -> MASTER_HOST='master_hostname',
```
Replication Notes and Tips

To specify the certificate and key names using the CHANGE MASTER TO statement, append the appropriate MASTER_SSL_xxx options:

```
mysql> CHANGE MASTER TO
    -> MASTER_HOST='master_hostname',
    -> MASTER_USER='replicate',
    -> MASTER_PASSWORD='password',
    -> MASTER_SSL=1,
    -> MASTER_SSL_CA = 'ca_file_name',
    -> MASTER_SSL_CAPATH = 'ca_directory_name',
    -> MASTER_SSL_CERT = 'cert_file_name',
    -> MASTER_SSL_KEY = 'key_file_name';
```

After the master information has been updated, start the slave replication process:

```
mysql> START SLAVE;
```

You can use the SHOW SLAVE STATUS statement to confirm that a secure connection was established successfully.

For more information on the CHANGE MASTER TO statement, see Section 13.4.2.1, “CHANGE MASTER TO Syntax”.

If you want to enforce the use of secure connections during replication, then create a user with the REPLICATION SLAVE privilege and use the REQUIRE SSL option for that user. For example:

```
mysql> CREATE USER 'repl'@'%.mydomain.com' IDENTIFIED BY 'slavepass';
mysql> GRANT REPLICATION SLAVE ON *.*
    -> TO 'repl'@'%.mydomain.com' REQUIRE SSL;
```

If the account already exists, you can add REQUIRE SSL to it with this statement:

```
mysql> GRANT USAGE ON *.*
    -> TO 'repl'@'%.mydomain.com' REQUIRE SSL;
```

16.4 Replication Notes and Tips

16.4.1 Replication Features and Issues

The following sections provide information about what is supported and what is not in MySQL replication, and about specific issues and situations that may occur when replicating certain statements.

Statement-based replication depends on compatibility at the SQL level between the master and slave. In others, successful SBR requires that any SQL features used be supported by both the master and the slave servers. For example, if you use a feature on the master server that is available only in MySQL 5.1 (or later), you cannot replicate to a slave that uses MySQL 5.0 (or earlier).

Such incompatibilities also can occur within a release series when using pre-production releases of MySQL. For example, the SLEEP() function is available beginning with MySQL 5.0.12. If you use this function on the master, you cannot replicate to a slave that uses MySQL 5.0.11 or earlier.

For this reason, use Generally Available (GA) releases of MySQL for statement-based replication in a production setting, since we do not introduce new SQL statements or change their behavior within a given release series once that series reaches GA release status.

If you are planning to use statement-based replication between MySQL 5.1 and a previous MySQL release series, it is also a good idea to consult the edition of the MySQL Reference Manual...
corresponding to the earlier release series for information regarding the replication characteristics of that series.

With MySQL's statement-based replication, there may be issues with replicating stored routines or triggers. You can avoid these issues by using MySQL's row-based replication instead. For a detailed list of issues, see Section 19.7, "Binary Logging of Stored Programs". For more information about row-based logging and row-based replication, see Section 5.4.1.1, "Binary Logging Formats", and Section 16.1.2, "Replication Formats".

For additional information specific to replication and InnoDB, see Section 14.6.1.1, "InnoDB and MySQL Replication". For information relating to replication with MySQL Cluster, see Section 17.6, "MySQL Cluster Replication".

16.4.1.1 Replication and AUTO_INCREMENT

Statement-based replication of `AUTO_INCREMENT`, `LAST_INSERT_ID()` , and `TIMESTAMP` values is done correctly, subject to the following exceptions:

- When using statement-based replication, `AUTO_INCREMENT` columns in tables on the slave must match the same columns on the master; that is, `AUTO_INCREMENT` columns must be replicated to `AUTO_INCREMENT` columns.

  This is a known issue which is fixed in MySQL 5.5. (Bug #12669186)

- Prior to MySQL 5.1.12, a stored procedure that uses `LAST_INSERT_ID()` does not replicate properly using statement-based binary logging.

- Prior to MySQL 5.1.12, when a stored routine or trigger caused an INSERT into an `AUTO_INCREMENT` column, the generated `AUTO_INCREMENT` value was not written into the binary log, so a different value could in some cases be inserted on the slave.

- An insert into an `AUTO_INCREMENT` column caused by a stored routine or trigger running on a master that uses MySQL 5.0.60 or earlier does not replicate correctly to a slave running MySQL 5.1.12 through 5.1.23 (inclusive). (Bug #33029)

  A statement invoking a trigger or function that causes an update to an `AUTO_INCREMENT` column is not replicated correctly using statement-based replication. Beginning with MySQL 5.1.40, such statements are marked as unsafe. (Bug #45677)

- The `AUTO_INCREMENT` table option was not replicated correctly prior to MySQL 5.1.31. (Bug #41986)

- An INSERT into a table that has a composite primary key that includes an `AUTO_INCREMENT` column that is not the first column of this composite key is not safe for statement-based logging or replication. Beginning with MySQL 5.1.64, such statements are marked as unsafe. (Bug #11754117, Bug #45670)

  This issue does not affect tables using the InnoDB storage engine, since an InnoDB table with an `AUTO_INCREMENT` column requires at least one key where the auto-increment column is the only or leftmost column.

- Adding an `AUTO_INCREMENT` column to a table with `ALTER TABLE` might not produce the same ordering of the rows on the slave and the master. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the master and slave, the rows must be ordered before assigning an `AUTO_INCREMENT` number. Assuming that you want to add an `AUTO_INCREMENT` column to a table `t1` that has columns `col1` and `col2`, the following statements produce a new table `t2` identical to `t1` but with an `AUTO_INCREMENT` column:

```sql
CREATE TABLE t2 LIKE t1;
```
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;

---

Important

To guarantee the same ordering on both master and slave, the ORDER BY clause must name all columns of t1.

The instructions just given are subject to the limitations of CREATE TABLE ... LIKE: Foreign key definitions are ignored, as are the DATA DIRECTORY and INDEX DIRECTORY table options. If a table definition includes any of those characteristics, create t2 using a CREATE TABLE statement that is identical to the one used to create t1, but with the addition of the AUTO_INCREMENT column.

Regardless of the method used to create and populate the copy having the AUTO_INCREMENT column, the final step is to drop the original table and then rename the copy:

```
DROP t1;
ALTER TABLE t2 RENAME t1;
```

See also Section B.5.6.1, "Problems with ALTER TABLE".

### 16.4.1.2 Replication and BLACKHOLE Tables

The BLACKHOLE storage engine accepts data but discards it and does not store it. When performing binary logging, all inserts to such tables are always logged, regardless of the logging format in use. Updates and deletes are handled differently depending on whether statement based or row based logging is in use. With the statement based logging format, all statements affecting BLACKHOLE tables are logged, but their effects ignored. When using row-based logging, updates and deletes to such tables are simply skipped—they are not written to the binary log.

For this reason we recommend when you replicate to tables using the BLACKHOLE storage engine that you have the binlog_format server variable set to STATEMENT, and not to either ROW or MIXED.

### 16.4.1.3 Replication and Character Sets

The following applies to replication between MySQL servers that use different character sets:

- If the master has databases with a character set different from the global character_set_server value, you should design your CREATE TABLE statements so that they do not implicitly rely on the database default character set. A good workaround is to state the character set and collation explicitly in CREATE TABLE statements.

### 16.4.1.4 Replication and CHECKSUM TABLE

CHECKSUM TABLE returns a checksum that is calculated row by row, using a method that depends on the table row storage format, which is not guaranteed to remain the same between MySQL release series. For example, the storage format for VARCHAR changed between MySQL 4.1 and 5.0, so if a 4.1 table is upgraded to MySQL 5.0, the checksum value may change.

### 16.4.1.5 Replication of CREATE ... IF NOT EXISTS Statements

This section discusses the rules that are applied when various CREATE ... IF NOT EXISTS statements are replicated.

**Previous to MySQL 5.1.38.** CREATE DATABASE IF NOT EXISTS was replicated only if the database named in the statement did not exist on the master. CREATE TABLE IF NOT EXISTS was replicated only if the table named in the statement did not exist on the master.

**MySQL 5.1.39 and later.** Every CREATE DATABASE IF NOT EXISTS statement is replicated, whether or not the database already exists on the master. Similarly, every CREATE TABLE IF NOT EXISTS statement is replicated, whether or not the table already exists on the master. This includes
CREATE TABLE IF NOT EXISTS ... LIKE. However, replication of CREATE TABLE IF NOT EXISTS ... SELECT follows somewhat different rules; see Section 16.4.1.6, “Replication of CREATE TABLE ... SELECT Statements”, for more information.

Replication of CREATE EVENT IF NOT EXISTS. CREATE EVENT IF NOT EXISTS is always replicated, whether or not the event named in the statement already exists on the master. This is true for all MySQL 5.1 releases beginning with MySQL 5.1.6, when this statement was introduced.

See also Bug #45574.

16.4.1.6 Replication of CREATE TABLE ... SELECT Statements

This section discusses how MySQL replicates CREATE TABLE ... SELECT statements.

These behaviors are not dependent on MySQL version:

• CREATE TABLE ... SELECT always performs an implicit commit (Section 13.3.3, “Statements That Cause an Implicit Commit”).

• If destination table does not exist, logging occurs as follows. It does not matter whether IF NOT EXISTS is present.
  • STATEMENT or MIXED format: The statement is logged as written.
  • ROW format: The statement is logged as a CREATE TABLE statement followed by a series of insert-row events.

• If the statement fails, nothing is logged. This includes the case that the destination table exists and IF NOT EXISTS is not given.

When the destination table exists and IF NOT EXISTS is given, MySQL handles the statement in a version-dependent way.

In MySQL 5.1 before 5.1.51 and in MySQL 5.5 before 5.5.6 (this is the original behavior):

• STATEMENT or MIXED format: The statement is logged as written.

• ROW format: The statement is logged as a CREATE TABLE statement followed by a series of insert-row events.

In MySQL 5.1 as of 5.1.51:

• STATEMENT or MIXED format: The statement is logged as the equivalent pair of CREATE TABLE and INSERT INTO ... SELECT statements.

• ROW format: The statement is logged as a CREATE TABLE statement followed by a series of insert-row events.

In MySQL 5.5 as of 5.5.6:

• Nothing is inserted or logged.

These version dependencies arise due to a change in MySQL 5.5.6 in handling of CREATE TABLE ... SELECT not to insert rows if the destination table already exists, and a change made in MySQL 5.1.51 to preserve forward compatibility in replication of such statements from a 5.1 master to a 5.5 slave. For details, see Section 13.1.17.2, “CREATE TABLE ... SELECT Syntax”.

16.4.1.7 Replication of CURRENT_USER()

The following statements support use of the CURRENT_USER() function to take the place of the name of (and, possibly, the host for) an affected user or a definer; in such cases, CURRENT_USER() is expanded where and as needed:
- DROP USER
- RENAME USER
- GRANT
- REVOKE
- CREATE FUNCTION
- CREATE PROCEDURE
- CREATE TRIGGER
- CREATE EVENT
- CREATE VIEW
- ALTER EVENT
- ALTER VIEW
- SET PASSWORD

In all MySQL 5.1 releases, when CURRENT_USER() or CURRENT_USER is used as the definer in any of the statements CREATE FUNCTION, CREATE PROCEDURE, CREATE TRIGGER, CREATE EVENT, CREATE VIEW, or ALTER VIEW when binary logging is enabled, the function reference is expanded before it is written to the binary log, so that the statement refers to the same user on both the master and the slave when the statement is replicated. Beginning with MySQL 5.1.49, CURRENT_USER() or CURRENT_USER is also expanded prior to being written to the binary log when used in DROP USER, RENAME USER, GRANT, REVOKE, or ALTER EVENT. (Bug #48321)

16.4.1.8 Replication of CREATE SERVER, ALTER SERVER, and DROP SERVER

In MySQL 5.1, the statements CREATE SERVER, ALTER SERVER, and DROP SERVER are logged only when binlog_format is equal to ROW. These statements are not written to the binary log when using either the statement-based or mixed logging format.

16.4.1.9 Replication of DROP ... IF EXISTS Statements

The DROP DATABASE IF EXISTS, DROP TABLE IF EXISTS, and DROP VIEW IF EXISTS statements are always replicated, even if the database, table, or view to be dropped does not exist on the master. This is to ensure that the object to be dropped no longer exists on either the master or the slave, once the slave has caught up with the master.

Beginning with MySQL 5.1.33, DROP ... IF EXISTS statements for stored programs (stored procedures and functions, triggers, and events) are also replicated, even if the stored program to be dropped does not exist on the master. (Bug #13684)

16.4.1.10 Replication with Differing Table Definitions on Master and Slave

Starting with MySQL 5.1.21, source and target tables for replication do not have to be identical. A table on the master can have more or fewer columns than the slave's copy of the table. In addition, corresponding table columns on the master and the slave can use different data types, subject to certain conditions.

Note

Replication between tables which are partitioned differently from one another is not supported. See Section 16.4.1.26, "Replication and Partitioning".
In all cases where the source and target tables do not have identical definitions, the database and table names must be the same on both the master and the slave. Additional conditions are discussed, with examples, in the following two sections.

**Replication with More Columns on Master or Slave**

Starting with MySQL 5.1.21, you can replicate a table from the master to the slave such that the master and slave copies of the table have differing numbers of columns, subject to the following conditions:

- Columns common to both versions of the table must be defined in the same order on the master and the slave.
  
  (This is true even if both tables have the same number of columns.)

- Columns common to both versions of the table must be defined before any additional columns.

  This means that executing a `ALTER TABLE` statement on the slave where a new column is inserted into the table within the range of columns common to both tables causes replication to fail, as shown in the following example:

  Suppose that a table `t`, existing on the master and the slave, is defined by the following `CREATE TABLE` statement:

  ```sql
  CREATE TABLE t {
    c1 INT,
    c2 INT,
    c3 INT
  };
  ```

  Suppose that the `ALTER TABLE` statement shown here is executed on the slave:

  ```sql
  ALTER TABLE t ADD COLUMN cnew1 INT AFTER c3;
  ```

  The previous `ALTER TABLE` is permitted on the slave because the columns `c1`, `c2`, and `c3` that are common to both versions of table `t` remain grouped together in both versions of the table, before any columns that differ.

  However, the following `ALTER TABLE` statement cannot be executed on the slave without causing replication to break:

  ```sql
  ALTER TABLE t ADD COLUMN cnew2 INT AFTER c2;
  ```

  Replication fails after execution on the slave of the `ALTER TABLE` statement just shown, because the new column `cnew2` comes between columns common to both versions of `t`.

- Each “extra” column in the version of the table having more columns must have a default value.

  **Note**

  A column's default value is determined by a number of factors, including its type, whether it is defined with a `DEFAULT` option, whether it is declared as `NULL`, and the server SQL mode in effect at the time of its creation; for more information, see Section 11.6, “Data Type Default Values”).

  In addition, when the slave's copy of the table has more columns than the master's copy, each column common to the tables must use the same data type in both tables.

  **Examples.** The following examples illustrate some valid and invalid table definitions:

  **More columns on the master.** The following table definitions are valid and replicate correctly:
The following table definitions would raise an error because the definitions of the columns common to both versions of the table are in a different order on the slave than they are on the master:

```
master> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT);
```

The following table definitions would also raise an error because the definition of the extra column on the master appears before the definitions of the columns common to both versions of the table:

```
master> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
slave> CREATE TABLE t1 (c2 INT, c1 INT);
```

More columns on the slave. The following table definitions are valid and replicate correctly:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

The following definitions raise an error because the columns common to both versions of the table are not defined in the same order on both the master and the slave:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c2 INT, c1 INT, c3 INT);
```

The following table definitions also raise an error because the definition for the extra column in the slave's version of the table appears before the definitions for the columns which are common to both versions of the table:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
```

The following table definitions fail because the slave's version of the table has additional columns compared to the master's version, and the two versions of the table use different data types for the common column `c2`:

```
master> CREATE TABLE t1 (c1 INT, c2 INT, c2 BIGINT);
slave> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

Replication of Columns Having Different Data Types

Corresponding columns on the master's and the slave's copies of the same table ideally should have the same data type. However, beginning with MySQL 5.1.21, this is not always strictly enforced, as long as certain conditions are met.

All other things being equal, it is always possible to replicate from a column of a given data type to another column of the same type and same size or width, where applicable, or larger. For example, you can replicate from a `CHAR(10)` column to another `CHAR(10)`, or from a `CHAR(10)` column to a `CHAR(25)` column without any problems. In certain cases, it also possible to replicate from a column having one data type (on the master) to a column having a different data type (on the slave); when the data type of the master's version of the column is promoted to a type that is the same size or larger on the slave, this is known as *attribute promotion*.

Attribute promotion can be used with both statement-based and row-based replication, and is not dependent on the storage engine used by either the master or the slave. However, the choice of
logging format does have an effect on the type conversions that are permitted; the particulars are discussed later in this section.

---

### Important

Whether you use statement-based or row-based replication, the slave’s copy of the table cannot contain more columns than the master’s copy if you wish to employ attribute promotion.

#### Statement-based replication.

When using statement-based replication, a simple rule of thumb to follow is, “If the statement run on the master would also execute successfully on the slave, it should also replicate successfully”. In other words, if the statement uses a value that is compatible with the type of a given column on the slave, the statement can be replicated. For example, you can insert any value that fits in a `TINYINT` column into a `BIGINT` column as well; it follows that, even if you change the type of a `TINYINT` column in the slave’s copy of a table to `BIGINT`, any insert into that column on the master that succeeds should also succeed on the slave, since it is impossible to have a legal `TINYINT` value that is large enough to exceed a `BIGINT` column.

When using statement-based replication, `AUTO_INCREMENT` columns must be the same on both the master and the slave; otherwise, updates may be applied to the wrong table on the slave. This is a known issue which is fixed in MySQL 5.5. (Bug #12669186)

#### Note

The restrictions described in the next few paragraphs do not apply to MySQL Cluster Replication, beginning with MySQL Cluster NDB 6.3.33, 7.0.14, and 7.1.3. These and later versions of MySQL Cluster support attribute promotion and demotion (such as `TINYINT` to `BIGINT`, and `VARCHAR(50)` to `CHAR(25)`, respectively) in replication; see [Attribute promotion and demotion (MySQL Cluster)](http://dev.mysql.com/doc/refman/5.5/en/attribute-promotion-demotion.html), for more information.

#### Row-based replication.

For row-based replication, the case is not so simple, due to the fact that changes rather than statements are replicated, and these changes are transmitted from master to slave using formats that do not always map directly to MySQL server column data types. For example, with row-based binary logging, you cannot replicate between different INT subtypes, such as from `TINYINT` to `BIGINT`, because changes to columns of these types are represented differently from one another in the binary log when using row-based logging. However, you can replicate from `BLOB` to `TEXT` using row-based replication because changes to `BLOB` and `TEXT` columns are represented using the same format in the binary log.

Supported conversions for attribute promotion when using row-based replication are shown in the following table:

<table>
<thead>
<tr>
<th>From (Master)</th>
<th>To (Slave)</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>BINARY</code></td>
<td><code>CHAR</code></td>
</tr>
<tr>
<td><code>BLOB</code></td>
<td><code>TEXT</code></td>
</tr>
<tr>
<td><code>CHAR</code></td>
<td><code>BINARY</code></td>
</tr>
<tr>
<td><code>DECIMAL</code></td>
<td><code>NUMERIC</code></td>
</tr>
<tr>
<td><code>NUMERIC</code></td>
<td><code>DECIMAL</code></td>
</tr>
<tr>
<td><code>TEXT</code></td>
<td><code>BLOB</code></td>
</tr>
<tr>
<td><code>VARBINARY</code></td>
<td><code>VARCHAR</code></td>
</tr>
<tr>
<td><code>VARCHAR</code></td>
<td><code>VARBINARY</code></td>
</tr>
</tbody>
</table>

#### Note

In all cases, the size or width of the column on the slave must be equal to or greater than that of the column on the master. For example, you can replicate...
Replication Features and Issues

from a `CHAR(10)` column on the master to a column that uses `BINARY(10)` or `BINARY(25)` on the slave, but you cannot replicate from a `CHAR(10)` column on the master to `BINARY(5)` column on the slave.

Any unique index (including primary keys) having a prefix must use a prefix of the same length on both master and slave; in such cases, differing prefix lengths are disallowed. It is possible to use a nonunique index whose prefix length differs between master and slave, but this can cause serious performance issues, particularly when the prefix used on the master is longer. This is due to the fact that 2 unique prefixes of a given length may no longer be unique at a shorter length; for example, the words `catalogue` and `catamount` have the 5-character prefixes `catal` and `catam`, respectively, but share the same 4-character prefix (`cata`). This can lead to queries that use such indexes executing less efficiently on the slave, when a shorter prefix is employed in the slave’s definition of the same index than on the master.

For `DECIMAL` and `NUMERIC` columns, both the mantissa (\(M\)) and the number of decimals (\(D\)) must be the same size or larger on the slave as compared with the master. For example, replication from a `NUMERIC(5,4)` to a `DECIMAL(6,4)` works, but not from a `NUMERIC(5,4)` to a `DECIMAL(5,3)`.

MySQL (except for MySQL Cluster) does not support attribute promotion of any of the following data types to or from any other data type when using row-based replication:

- `INT` (including `TINYINT`, `SMALLINT`, `MEDIUMINT`, `BIGINT`).

Promotion between `INT` subtypes—for example, from `SMALLINT` to `BIGINT`—is also not supported.

- `SET` or `ENUM`.

- `FLOAT` or `DOUBLE`.

- All of the data types relating to dates, times, or both: `DATE`, `TIME`, `DATETIME`, `TIMESTAMP`, and `YEAR`.

Attribute promotion and demotion (MySQL Cluster). Beginning with MySQL Cluster NDB 6.3.33, 7.0.14, and 7.1.3, MySQL Cluster Replication supports attribute promotion and demotion between smaller data types and larger types. It is also possible to specify whether or not to permit lossy (truncated) or non-lossy conversions of demoted column values, as explained later in this section.

Lossy and non-lossy conversions. In the event that the target type cannot represent the value being inserted, a decision must be made on how to handle the conversion. If we permit the conversion but truncate (or otherwise modify) the source value to achieve a “fit” in the target column, we make what is known as a lossy conversion. A conversion which does not require truncation or similar modifications to fit the source column value in the target column is a non-lossy conversion.

Type conversion modes (`slave_type_conversions` variable). The setting of the `slave_type_conversions` global server variable controls the type conversion mode used on the slave. This variable takes a set of values from the following table, which shows the effects of each mode on the slave’s type-conversion behavior:

<table>
<thead>
<tr>
<th>Mode</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL_LOSSY</td>
<td>In this mode, type conversions that would mean loss of information are permitted. This does not imply that non-lossy conversions are permitted, merely that only cases requiring either lossy conversions or no conversion at all are permitted; for example, enabling only this mode permits an <code>INT</code> column to be converted to <code>TINYINT</code> (a lossy conversion), but not a <code>TINYINT</code> column to an <code>INT</code> column</td>
</tr>
</tbody>
</table>
Replication Features and Issues

<table>
<thead>
<tr>
<th>Mode</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>(non-lossy). Attempting the latter conversion in this case would cause replication to stop with an error on the slave.</td>
<td></td>
</tr>
<tr>
<td>ALL_NON_LOSSY</td>
<td>This mode permits conversions that do not require truncation or other special handling of the source value; that is, it permits conversions where the target type has a wider range than the source type.</td>
</tr>
<tr>
<td>Setting this mode has no bearing on whether lossy conversions are permitted; this is controlled with the ALL_LOSSY mode. If only ALL_NON_LOSSY is set, but not ALL_LOSSY, then attempting a conversion that would result in the loss of data (such as INT to TINYINT, or CHAR(25) to VARCHAR(20)) causes the slave to stop with an error.</td>
<td></td>
</tr>
<tr>
<td>ALL_LOSSY, ALL_NON_LOSSY</td>
<td>When this mode is set, all supported type conversions are permitted, whether or not they are lossy conversions.</td>
</tr>
<tr>
<td>[empty]</td>
<td>When slave_type_conversions is not set, no attribute promotion or demotion is permitted; this means that all columns in the source and target tables must be of the same types.</td>
</tr>
<tr>
<td>This mode is the default.</td>
<td></td>
</tr>
</tbody>
</table>

Changing the type conversion mode requires restarting the slave with the new slave_type_conversions setting.

**Supported conversions.** Supported conversions between different but similar data types are shown in the following list:

- Between any of the integer types TINYINT, SMALLINT, MEDIUMINT, INT, and BIGINT.

  This includes conversions between the signed and unsigned versions of these types.

  Lossy conversions are made by truncating the source value to the maximum (or minimum) permitted by the target column. For insuring non-lossy conversions when going from unsigned to signed types, the target column must be large enough to accommodate the range of values in the source column. For example, you can demote TINYINT UNSIGNED non-lossily to SMALLINT, but not to TINYINT.

- Between any of the decimal types DECIMAL, FLOAT, DOUBLE, and NUMERIC.

  FLOAT to DOUBLE is a non-lossy conversion; DOUBLE to FLOAT can only be handled lossily. A conversion from DECIMAL(M, D) to DECIMAL(M', D') where D' >= D and (M' - D') >= (M - D) are non-lossy; for any case where M' < M, D' < D, or both, only a lossy conversion can be made.

  For any of the decimal types, if a value to be stored cannot be fit in the target type, the value is rounded down according to the rounding rules defined for the server elsewhere in the documentation. See Section 12.18.4, "Rounding Behavior", for information about how this is done for decimal types.

- Between any of the string types CHAR, VARCHAR, and TEXT, including conversions between different widths.

  Conversion of a CHAR, VARCHAR, or TEXT to a CHAR, VARCHAR, or TEXT column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first N characters of the string on the slave, where N is the width of the target column.

**Important**

Replication between columns using different character sets is not supported.
• Between any of the binary data types *BINARY*, *VARBINARY*, and *BLOB*, including conversions between different widths.

Conversion of a *BINARY*, *VARBINARY*, or *BLOB* to a *BINARY*, *VARBINARY*, or *BLOB* column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first $N$ bytes of the string on the slave, where $N$ is the width of the target column.

• Between any 2 *BIT* columns of any 2 sizes.

When inserting a value from a *BIT($M$)* column into a *BIT($M'$)* column, where $M' > M$, the most significant bits of the *BIT($M'$)* columns are cleared (set to zero) and the $M$ bits of the *BIT($M$)* value are set as the least significant bits of the *BIT($M'$)* column.

When inserting a value from a source *BIT($M$)* column into a target *BIT($M'$)* column, where $M' < M$, the maximum possible value for the *BIT($M'$)* column is assigned; in other words, an “all-set” value is assigned to the target column.

Conversions between types not in the previous list are not permitted.

**16.4.1.11 Replication and DIRECTORY Table Options**

If a *DATA DIRECTORY* or *INDEX DIRECTORY* table option is used in a *CREATE TABLE* statement on the master server, the table option is also used on the slave. This can cause problems if no corresponding directory exists in the slave host file system or if it exists but is not accessible to the slave server. This can be overridden by using the *NO_DIR_IN_CREATE* server SQL mode on the slave, which causes the slave to ignore the *DATA DIRECTORY* and *INDEX DIRECTORY* table options when replicating *CREATE TABLE* statements. The result is that *MyISAM* data and index files are created in the table's database directory.

For more information, see *Section 5.1.7, “Server SQL Modes”*.

**16.4.1.12 Replication of Invoked Features**

Replication of invoked features such as user-defined functions (UDFs) and stored programs (stored procedures and functions, triggers, and events) was re-implemented in MySQL 5.1.18 to provide the following characteristics:

• The effects of the feature are always replicated.

• The following statements are replicated using statement-based replication:
  
  • *CREATE EVENT*
  • *ALTER EVENT*
  • *DROP EVENT*
  • *CREATE PROCEDURE*
  • *DROP PROCEDURE*
  • *CREATE FUNCTION*
  • *DROP FUNCTION*
  • *CREATE TRIGGER*
  • *DROP TRIGGER*

However, the *effects* of features created, modified, or dropped using these statements are replicated using row-based replication.
Note

Attempting to replicate invoked features using statement-based replication produces the warning `Statement may not be safe to log in statement format`. (Prior to MySQL 5.1.36, this was `Statement is not safe to log in statement format`; see Bug #42415.) For example, trying to replicate a UDF with statement-based replication generates this warning because it currently cannot be determined by the MySQL server whether the UDF is deterministic. If you are absolutely certain that the invoked feature's effects are deterministic, you can safely disregard such warnings.

• In the case of `CREATE EVENT` and `ALTER EVENT`:
  • The status of the event is set to `SLAVESIDE_DISABLED` on the slave regardless of the state specified (this does not apply to `DROP EVENT`).
  • The master on which the event was created is identified on the slave by its server ID. The `ORIGINATOR` column in `INFORMATION_SCHEMA.EVENTS` and the `originator` column in `mysql.event` were added to these tables in MySQL 5.1.18 to store this information. See Section 20.7, “The INFORMATION_SCHEMA EVENTS Table”, and Section 13.7.5.19, “SHOW EVENTS Syntax”, for more information.
  • The feature implementation resides on the slave in a renewable state so that if the master fails, the slave can be used as the master without loss of event processing.

To determine whether there are any scheduled events on a MySQL server that were created on a different server (that was acting as a replication master), query the `INFORMATION_SCHEMA.EVENTS` table in a manner similar to what is shown here:

```
SELECT EVENT_SCHEMA, EVENT_NAME
FROM INFORMATION_SCHEMA.EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED';
```

Alternatively, you can use the `SHOW EVENTS` statement, like this:

```
SHOW EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED';
```

When promoting a replication slave having such events to a replication master, you must enable each event using `ALTER EVENT event_name ENABLE`, where `event_name` is the name of the event.

If more than one master was involved in creating events on this slave, and you wish to identify events that were created only on a given master having the server ID `master_id`, modify the previous query on the `EVENTS` table to include the `ORIGINATOR` column, as shown here:

```
SELECT EVENT_SCHEMA, EVENT_NAME, ORIGINATOR
FROM INFORMATION_SCHEMA.EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED'
AND ORIGINATOR = 'master_id'
```

You can employ `ORIGINATOR` with the `SHOW EVENTS` statement in a similar fashion:

```
SHOW EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED'
AND ORIGINATOR = 'master_id'
```

Before enabling events that were replicated from the master, you should disable the MySQL Event Scheduler on the slave (using a statement such as `SET GLOBAL event_scheduler = OFF;`), run
any necessary `ALTER EVENT` statements, restart the server, then re-enable the Event Scheduler on
the slave afterward (using a statement such as `SET GLOBAL event_scheduler = ON;`).

If you later demote the new master back to being a replication slave, you must disable manually all
events enabled by the `ALTER EVENT` statements. You can do this by storing in a separate table the
event names from the `SELECT` statement shown previously, or using `ALTER EVENT` statements to
rename the events with a common prefix such as `replicated_` to identify them.

If you rename the events, then when demoting this server back to being a replication slave, you can
identify the events by querying the `EVENTS` table, as shown here:

```sql
SELECT CONCAT(EVENT_SCHEMA, '.', EVENT_NAME) AS 'Db.Event'
FROM INFORMATION_SCHEMA.EVENTS
WHERE INSTR(EVENT_NAME, 'replicated_') = 1;
```

### 16.4.1.13 Replication and Floating-Point Values

With statement-based replication, values are converted from decimal to binary. Because conversions
between decimal and binary representations of them may be approximate, comparisons involving
floating-point values are inexact. This is true for operations that use floating-point values explicitly,
or that use values that are converted to floating-point implicitly. Comparisons of floating-point values
might yield different results on master and slave servers due to differences in computer architecture,
the compiler used to build MySQL, and so forth. See Section 12.2, “Type Conversion in Expression
Evaluation”, and Section B.5.4.8, “Problems with Floating-Point Values”.

### 16.4.1.14 Replication and FLUSH

Some forms of the `FLUSH` statement are not logged because they could cause problems if replicated
to a slave: `FLUSH LOGS`, `FLUSH MASTER`, `FLUSH SLAVE`, and `FLUSH TABLES WITH READ LOCK`.
For a syntax example, see Section 13.7.6.3, “FLUSH Syntax”. The `FLUSH TABLES`, `ANALYZE TABLE`,
`OPTIMIZE TABLE`, and `REPAIR TABLE` statements are written to the binary log and thus replicated to
slaves. This is not normally a problem because these statements do not modify table data.

However, this behavior can cause difficulties under certain circumstances. If you replicate the privilege
tables in the `mysql` database and update those tables directly without using `GRANT`, you must issue
`FLUSH PRIVILEGES` on the slaves to put the new privileges into effect. In addition, if you use
`FLUSH TABLES` when renaming a `MyISAM` table that is part of a `MERGE` table, you must issue `FLUSH
TABLES` manually on the slaves. These statements are written to the binary log unless you specify
`NO_WRITE_TO_BINLOG` or its alias `LOCAL`.

### 16.4.1.15 Replication and System Functions

Certain functions do not replicate well under some conditions:

- The `USER()`, `CURRENT_USER()` (or `CURRENT_USER`), `UUID()`, `VERSION()`, `LOAD_FILE()`, and
  `RAND()` functions are replicated without change and thus do not work reliably on the slave unless
  row-based replication is enabled. (See Section 16.1.2, “Replication Formats”.)

  For early implementations of mixed-format logging, stored functions, triggers, and views that use
  these functions in their body do not replicate reliably in mixed-format logging mode because the
  logging did not switch from statement-based to row-based format. For example, `INSERT INTO t
  SELECT FROM v`, where `v` is a view that selects `UUID()` could cause problems. This limitation is
  lifted in MySQL 5.1.12.

  Beginning with MySQL 5.1.23, `USER()` and `CURRENT_USER()` are automatically replicated using
  row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (Bug
  #28086) (See also Section 16.4.1.7, “Replication of CURRENT_USER()”)

  Beginning with MySQL 5.1.42, `VERSION()` is also automatically replicated using row-based
  replication when using `MIXED` mode, and generates a warning in `STATEMENT` mode. (Bug #47995)

  Beginning with MySQL 5.1.43, this is also true with regard to the `RAND()` function. (Bug #49222)
Replication Features and Issues

• For \texttt{NOW()}, the binary log includes the timestamp. This means that the value \textit{as returned by the call to this function on the master} is replicated to the slave. This can lead to a possibly unexpected result when replicating between MySQL servers in different time zones. Suppose that the master is located in New York, the slave is located in Stockholm, and both servers are using local time. Suppose further that, on the master, you create a table \texttt{mytable}, perform an \texttt{INSERT} statement on this table, and then select from the table, as shown here:

\begin{verbatim}
mysql> CREATE TABLE mytable (mycol TEXT);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO mytable VALUES ( NOW() );
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM mytable;
+---------------------+
| mycol               |
+---------------------+
| 2009-09-01 12:00:00 |
+---------------------+
1 row in set (0.00 sec)
\end{verbatim}

Local time in Stockholm is 6 hours later than in New York; so, if you issue \texttt{SELECT NOW()} on the slave at that exact same instant, the value \texttt{2009-09-01 18:00:00} is returned. For this reason, if you select from the slave's copy of \texttt{mytable} after the \texttt{CREATE TABLE} and \texttt{INSERT} statements just shown have been replicated, you might expect \texttt{mycol} to contain the value \texttt{2009-09-01 18:00:00}. However, this is not the case; when you select from the slave's copy of \texttt{mytable}, you obtain exactly the same result as on the master:

\begin{verbatim}
mysql> SELECT * FROM mytable;
+---------------------+
| mycol               |
+---------------------+
| 2009-09-01 12:00:00 |
+---------------------+
1 row in set (0.00 sec)
\end{verbatim}

Unlike \texttt{NOW()}, the \texttt{SYSDATE()} function is not replication-safe because it is not affected by \texttt{SET TIMESTAMP} statements in the binary log and is nondeterministic if statement-based logging is used. This is not a problem if row-based logging is used.

An alternative is to use the \texttt{--sysdate-is-now} option to cause \texttt{SYSDATE()} to be an alias for \texttt{NOW()}. This must be done on the master and the slave to work correctly. In such cases, a warning is still issued by this function, but can safely be ignored as long as \texttt{--sysdate-is-now} is used on both the master and the slave.

Beginning with MySQL 5.1.42, \texttt{SYSDATE()} is automatically replicated using row-based replication when using \texttt{MIXED} mode, and generates a warning in \texttt{STATEMENT} mode. (Bug #47995)

See also Section 16.4.1.34, “Replication and Time Zones”.

• \textit{The following restriction applies to statement-based replication only, not to row-based replication.} The \texttt{GET_LOCK()}, \texttt{RELEASE_LOCK()}, \texttt{IS_FREE_LOCK()}, and \texttt{IS_USED_LOCK()} functions that handle user-level locks are replicated without the slave knowing the concurrency context on the master. Therefore, these functions should not be used to insert into a master table because the content on the slave would differ. For example, do not issue a statement such as \texttt{INSERT INTO mytable VALUES(GET_LOCK(...))}.

Beginning with MySQL 5.1.42, these functions are automatically replicated using row-based replication when using \texttt{MIXED} mode, and generate a warning in \texttt{STATEMENT} mode. (Bug #47995)

As a workaround for the preceding limitations when statement-based replication is in effect, you can use the strategy of saving the problematic function result in a user variable and referring to the variable
in a later statement. For example, the following single-row INSERT is problematic due to the reference to the UUID() function:

```sql
INSERT INTO t VALUES(UUID());
```

To work around the problem, do this instead:

```sql
SET @my_uuid = UUID();
INSERT INTO t VALUES(@my_uuid);
```

That sequence of statements replicates because the value of @my_uuid is stored in the binary log as a user-variable event prior to the INSERT statement and is available for use in the INSERT.

The same idea applies to multiple-row inserts, but is more cumbersome to use. For a two-row insert, you can do this:

```sql
SET @my_uuid1 = UUID(); @my_uuid2 = UUID();
INSERT INTO t VALUES(@my_uuid1),(@my_uuid2);
```

However, if the number of rows is large or unknown, the workaround is difficult or impracticable. For example, you cannot convert the following statement to one in which a given individual user variable is associated with each row:

```sql
INSERT INTO t2 SELECT UUID(), * FROM t1;
```

Within a stored function, RAND() replicates correctly as long as it is invoked only once during the execution of the function. (You can consider the function execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

The FOUND_ROWS() and ROW_COUNT() functions are not replicated reliably using statement-based replication. A workaround is to store the result of the function call in a user variable, and then use that in the INSERT statement. For example, if you wish to store the result in a table named mytable, you might normally do so like this:

```sql
SELECT SQL_CALC_FOUND_ROWS FROM mytable LIMIT 1;
INSERT INTO mytable VALUES( FOUND_ROWS() );
```

However, if you are replicating mytable, you should use SELECT ... INTO, and then store the variable in the table, like this:

```sql
SELECT SQL_CALC_FOUND_ROWS INTO @found_rows FROM mytable LIMIT 1;
INSERT INTO mytable VALUES(@found_rows);
```

In this way, the user variable is replicated as part of the context, and applied on the slave correctly.

Beginning with MySQL 5.1.23, these functions are automatically replicated using row-based replication when using MIXED mode, and generate a warning in STATEMENT mode. (Bug #12092, Bug #30244)

Prior to MySQL 5.1.73, the value of LAST_INSERT_ID() was not replicated correctly if any filtering options such as --replicate-ignore-db and --replicate-do-table were enabled on the slave. (Bug #17234370, BUG# 69861)

### 16.4.1.16 Replication and LIMIT

Statement-based replication of LIMIT clauses in DELETE, UPDATE, and INSERT ... SELECT statements is unsafe since the order of the rows affected is not defined. (Such statements can be replicated correctly with statement-based replication only if they also contain an ORDER BY clause.) Beginning with MySQL 5.1.24, when such a statement is encountered:
• When using **STATEMENT** mode, a warning that the statement is not safe for statement-based replication is now issued.

When using **STATEMENT** mode, warnings are issued for DML statements containing **LIMIT** even when they also have an **ORDER BY** clause (and so are made deterministic). This is a known issue. (Bug #42851)

• When using **MIXED** mode, the statement is now automatically replicated using row-based mode.

### 16.4.1.17 Replication and LOAD DATA INFILE

The **LOAD DATA INFILE** statement was not always replicated correctly to a slave running MySQL 5.1.42 or earlier from a master running MySQL 4.0 or earlier. When using statement-based replication, the **LOAD DATA INFILE** statement **CONCURRENT** option was not replicated. This issue was fixed in MySQL 5.1.43. This issue does not have any impact on **CONCURRENT** option handling when using row-based replication in MySQL 5.1 or later. (Bug #34628)

In MySQL 5.1.52 and later, **LOAD DATA INFILE** is considered unsafe (see Section 16.1.2.3, “Determination of Safe and Unsafe Statements in Binary Logging”). It causes a warning when using statement-based logging format, and is logged using row-based format when using mixed-format logging.

### 16.4.1.18 Replication and the Slow Query Log

Prior to MySQL 5.1.45, replication slaves did not write replicated queries to the slow query log, even if the same queries were written to the slow query log on the master. (Bug #23300)

### 16.4.1.19 Replication and REPAIR TABLE

When used on a corrupted or otherwise damaged table, it is possible for the **REPAIR TABLE** statement to delete rows that cannot be recovered. However, any such modifications of table data performed by this statement are not replicated, which can cause master and slave to lose synchronization. For this reason, in the event that a table on the master becomes damaged and you use **REPAIR TABLE** to repair it, you should first stop replication (if it is still running) before using **REPAIR TABLE**, then afterward compare the master’s and slave’s copies of the table and be prepared to correct any discrepancies manually, before restarting replication.

### 16.4.1.20 Replication and Master or Slave Shutdowns

It is safe to shut down a master server and restart it later. When a slave loses its connection to the master, the slave tries to reconnect immediately and retries periodically if that fails. The default is to retry every 60 seconds. This may be changed with the **CHANGE MASTER TO** statement or **--master-connect-retry** option. A slave also is able to deal with network connectivity outages. However, the slave notices the network outage only after receiving no data from the master for **slave_net_timeout** seconds. If your outages are short, you may want to decrease **slave_net_timeout**. See Section 5.1.4, “Server System Variables”.

An unclean shutdown (for example, a crash) on the master side can result in the master binary log having a final position less than the most recent position read by the slave, due to the master binary log file not being flushed. This can cause the slave not to be able to replicate when the master comes back up. Setting **sync_binlog=1** in the master **my.cnf** file helps to minimize this problem because it causes the master to flush its binary log more frequently.

Shutting down a slave cleanly is safe because it keeps track of where it left off. However, be careful that the slave does not have temporary tables open; see Section 16.4.1.23, “Replication and Temporary Tables”. Unclean shutdowns might produce problems, especially if the disk cache was not flushed to disk before the problem occurred:

• For transactions, the slave commits and then updates **relay-log.info**. If a crash occurs between these two operations, relay log processing will have proceeded further than the information file
indicates and the slave will re-execute the events from the last transaction in the relay log after it has been restarted.

- A similar problem can occur if the slave updates relay-log.info but the server host crashes before the write has been flushed to disk. Writes are not forced to disk because the server relies on the operating system to flush the file from time to time.

The fault tolerance of your system for these types of problems is greatly increased if you have a good uninterruptible power supply.

**16.4.1.21 Replication and max_allowed_packet**

*max_allowed_packet* sets an upper limit on the size of any single message between the MySQL server and clients, including replication slaves. If you are replicating large column values (such as might be found in TEXT or BLOB columns) and *max_allowed_packet* is too small on the master, the master fails with an error, and the slave shuts down the I/O thread. If *max_allowed_packet* is too small on the slave, this also causes the slave to stop the I/O thread.

Prior to MySQL 5.1.40, `Last_IO_Error` and `Last_IO_Errno` in the output of `SHOW SLAVE STATUS` were not set in the event that replication failed due to exceeding *max_allowed_packet* (Bug #42914).

Row-based replication currently sends all columns and column values for updated rows from the master to the slave, including values of columns that were not actually changed by the update. This means that, when you are replicating large column values using row-based replication, you must take care to set *max_allowed_packet* large enough to accommodate the largest row in any table to be replicated, even if you are replicating updates only, or you are inserting only relatively small values.

**16.4.1.22 Replication and MEMORY Tables**

When a master server shuts down and restarts, its MEMORY tables become empty. To replicate this effect to slaves, the first time that the master uses a given MEMORY table after startup, it logs an event that notifies slaves that the table must to be emptied by writing a DELETE statement for that table to the binary log.

When a slave server shuts down and restarts, its MEMORY tables become empty. This causes the slave to be out of synchrony with the master and may lead to other failures or cause the slave to stop:

- Row-format updates and deletes received from the master may fail with *Can't find record in 'memory_table'*.
- Statements such as `INSERT INTO ... SELECT FROM memory_table` may insert a different set of rows on the master and slave.

The safe way to restart a slave that is replicating MEMORY tables is to first drop or delete all rows from the MEMORY tables on the master and wait until those changes have replicated to the slave. Then it is safe to restart the slave.

An alternative restart method may apply in some cases. When `binlog_format=ROW`, you can prevent the slave from stopping if you set `slave_exec_mode=IDEMPOTENT` before you start the slave again. This allows the slave to continue to replicate, but its MEMORY tables will still be different from those on the master. This can be okay if the application logic is such that the contents of MEMORY tables can be safely lost (for example, if the MEMORY tables are used for caching). `slave_exec_mode=IDEMPOTENT` applies globally to all tables, so it may hide other replication errors in non-MEMORY tables.

(The method just described is not applicable in MySQL Cluster, where `slave_exec_mode` is always IDEMPOTENT, and cannot be changed.)

The size of MEMORY tables is limited by the value of the `max_heap_table_size` system variable, which is not replicated (see Section 16.4.1.38, “Replication and Variables”). A change in `max_heap_table_size` takes effect for MEMORY tables that are created or updated using `ALTER`
**TABLE ... ENGINE = MEMORY or TRUNCATE TABLE** following the change, or for all MEMORY tables following a server restart. If you increase the value of this variable on the master without doing so on the slave, it becomes possible for a table on the master to grow larger than its counterpart on the slave, leading to inserts that succeed on the master but fail on the slave with Table is full errors. This is a known issue (Bug #48666). In such cases, you must set the global value of max_heap_table_size on the slave as well as on the master, then restart replication. It is also recommended that you restart both the master and slave MySQL servers, to insure that the new value takes complete (global) effect on each of them.

See Section 14.9, “The MEMORY Storage Engine”, for more information about MEMORY tables.

### 16.4.1.23 Replication and Temporary Tables

The discussion in the following paragraphs does not apply when binlog_format=ROW because, in that case, temporary tables are not replicated; this means that there are never any temporary tables on the slave to be lost in the event of an unplanned shutdown by the slave. The remainder of this section applies only when using statement-based or mixed-format replication. Loss of replicated temporary tables on the slave can be an issue, whenever binlog_format is STATEMENT or MIXED, for statements involving temporary tables that can be logged safely using statement-based format. For more information about row-based replication and temporary tables, see RBL, RBR, and temporary tables.

**Safe slave shutdown when using temporary tables.** Temporary tables are replicated except in the case where you stop the slave server (not just the slave threads) and you have replicated temporary tables that are open for use in updates that have not yet been executed on the slave. If you stop the slave server, the temporary tables needed by those updates are no longer available when the slave is restarted. To avoid this problem, do not shut down the slave while it has temporary tables open. Instead, use the following procedure:

1. Issue a **STOP SLAVE SQL_THREAD** statement.
2. Use **SHOW STATUS** to check the value of the Slave_open_temp_tables variable.
3. If the value is not 0, restart the slave SQL thread with **START SLAVE SQL_THREAD** and repeat the procedure later.
4. When the value is 0, issue a **mysqladmin shutdown** command to stop the slave.

**Temporary tables and replication options.** By default, all temporary tables are replicated; this happens whether or not there are any matching --replicate-do-db, --replicate-do-table, or --replicate-wild-do-table options in effect. However, the --replicate-ignore-table and --replicate-wild-ignore-table options are honored for temporary tables.

A recommended practice when using statement-based or mixed-format replication is to designate a prefix for exclusive use in naming temporary tables that you do not want replicated, then employ a --replicate-wild-ignore-table option to match that prefix. For example, you might give all such tables names beginning with norep (such as norepmytable, norepyourtable, and so on), then use --replicate-wild-ignore-table=norep% to prevent them from being replicated.

### 16.4.1.24 Replication of the mysql System Database

**MySQL 5.1.14 and later.** Data modification statements made to tables in the mysql database are replicated according to the value of binlog_format; if this value is MIXED, these statements are replicated using the row-based format. However, statements that would normally update this information indirectly—such GRANT, REVOKE, and statements manipulating triggers, stored routines, and views—are replicated to slaves using statement-based replication.

**MySQL 5.1.13 and earlier.** User privileges are replicated only if the mysql database is replicated. That is, the GRANT, REVOKE, SET PASSWORD, CREATE USER, and DROP USER statements take effect on the slave only if the replication setup includes the mysql database.
16.4.1.25 Replication and the Query Optimizer

It is possible for the data on the master and slave to become different if a statement is written in such a way that the data modification is nondeterministic; that is, left up to the query optimizer. (In general, this is not a good practice, even outside of replication.) Examples of nondeterministic statements include \texttt{DELETE} or \texttt{UPDATE} statements that use \texttt{LIMIT} with no \texttt{ORDER BY} clause; see Section 16.4.1.16, “Replication and LIMIT”, for a detailed discussion of these.

16.4.1.26 Replication and Partitioning

Replication is supported between partitioned tables as long as they use the same partitioning scheme and otherwise have the same structure except where an exception is specifically allowed (see Section 16.4.1.10, “Replication with Differing Table Definitions on Master and Slave”).

Replication between tables having different partitioning is generally not supported. This because statements (such as \texttt{ALTER TABLE ... DROP PARTITION}) acting directly on partitions in such cases may produce different results on master and slave. In the case where a table is partitioned on the master but not on the slave, any statements operating on partitions on the master’s copy of the slave fail on the slave. When the slave’s copy of the table is partitioned but the master’s copy is not, statements acting on partitions cannot be run on the master without causing errors there.

Due to these dangers of causing replication to fail entirely (on account of failed statements) and of inconsistencies (when the result of a partition-level SQL statement produces different results on master and slave), we recommend that ensure that the partitioning of any tables to be replicated from the master is matched by the slave’s versions of these tables.

16.4.1.27 Replication and Reserved Words

You can encounter problems when you attempt to replicate from an older master to a newer slave and you make use of identifiers on the master that are reserved words in the newer MySQL version running on the slave. An example of this is using a table column named \texttt{range} on a 5.0 master that is replicating to a 5.1 or higher slave because \texttt{RANGE} is a reserved word beginning in MySQL 5.1. Replication can fail in such cases with Error 1064 \texttt{You have an error in your SQL syntax...}, \texttt{even if a database or table named using the reserved word or a table having a column named using the reserved word is excluded from replication}. This is due to the fact that each SQL event must be parsed by the slave prior to execution, so that the slave knows which database object or objects would be affected: only after the event is parsed can the slave apply any filtering rules defined by \texttt{--replicate-do-db}, \texttt{--replicate-do-table}, \texttt{--replicate-ignore-db}, and \texttt{--replicate-ignore-table}.

To work around the problem of database, table, or column names on the master which would be regarded as reserved words by the slave, do one of the following:

- Use one or more \texttt{ALTER TABLE} statements on the master to change the names of any database objects where these names would be considered reserved words on the slave, and change any SQL statements that use the old names to use the new names instead.

- In any SQL statements using these database object names, write the names as quoted identifiers using backtick characters (`).

For listings of reserved words by MySQL version, see Reserved Words, in the MySQL Server Version Reference. For identifier quoting rules, see Section 9.2, “Schema Object Names”.

16.4.1.28 SET PASSWORD and Row-Based Replication

Row-based replication of \texttt{SET PASSWORD} statements from a MySQL 5.1 master to a MySQL 5.5 slave did not work correctly prior to MySQL 5.1.53 on the master and MySQL 5.5.7 on the slave (see Bug #57098, Bug #57357).

16.4.1.29 Slave Errors During Replication
If a statement produces the same error (identical error code) on both the master and the slave, the error is logged, but replication continues.

If a statement produces different errors on the master and the slave, the slave SQL thread terminates, and the slave writes a message to its error log and waits for the database administrator to decide what to do about the error. This includes the case that a statement produces an error on the master or the slave, but not both. To address the issue, connect to the slave manually and determine the cause of the problem. `SHOW SLAVE STATUS` is useful for this. Then fix the problem and run `START SLAVE`. For example, you might need to create a nonexistent table before you can start the slave again.

If this error code validation behavior is not desirable, some or all errors can be masked out (ignored) with the `--slave-skip-errors` option.

For nontransactional storage engines such as MyISAM, it is possible to have a statement that only partially updates a table and returns an error code. This can happen, for example, on a multiple-row insert that has one row violating a key constraint, or if a long update statement is killed after updating some of the rows. If that happens on the master, the slave expects execution of the statement to result in the same error code. If it does not, the slave SQL thread stops as described previously.

If you are replicating between tables that use different storage engines on the master and slave, keep in mind that the same statement might produce a different error when run against one version of the table, but not the other, or might cause an error for one version of the table, but not the other. For example, since MyISAM ignores foreign key constraints, an `INSERT` or `UPDATE` statement accessing an InnoDB table on the master might cause a foreign key violation but the same statement performed on a MyISAM version of the same table on the slave would produce no such error, causing replication to stop.

### 16.4.1.30 Replication of Server-Side Help Tables

The server maintains tables in the `mysql` database that store information for the `HELP` statement (see Section 13.8.3, “HELP Syntax”). These tables can be loaded manually as described at Section 5.1.9, “Server-Side Help”.

Help table content is derived from the MySQL Reference Manual. There are versions of the manual specific to each MySQL release series, so help content is specific to each series as well. Normally, you load a version of help content that matches the server version. This has implications for replication. For example, you would load MySQL 5.5 help content into a MySQL 5.5 master server, but not necessarily replicate that content to a MySQL 5.6 slave server for which 5.6 help content is more appropriate.

This section describes how to manage help table content upgrades when your servers participate in replication. Server versions are one factor in this task. Another is that help table structure may differ between the master and the slave.

Assume that help content is stored in a file named `fill_help_tables.sql`. In MySQL distributions, this file is located under the `share` or `share/mysql` directory, and the most recent version is always available for download from [http://dev.mysql.com/doc/index-other.html](http://dev.mysql.com/doc/index-other.html).

To upgrade help tables, using the following procedure. Connection parameters are not shown for the `mysql` commands discussed here; in all cases, connect to the server using an account such as `root` that has privileges for modifying tables in the `mysql` database.

1. Upgrade your servers by running `mysql_upgrade`, first on the slaves and then on the master. This is the usual principle of upgrading slaves first.

2. Decide whether you want to replicate help table content from the master to its slaves. If not, load the content on the master and each slave individually. Otherwise, check for and resolve any incompatibilities between help table structure on the master and its slaves, then load the content into the master and let it replicate to the slaves.

More detail about these two methods of loading help table content follows.
Loading Help Table Content Without Replication to Slaves

To load help table content without replication, run this command on the master and each slave individually, using a `fill_help_tables.sql` file containing content appropriate to the server version (enter the command on one line):

```bash
mysql --init-command="SET sql_log_bin=0"
mysql < fill_help_tables.sql
```

Use the `--init-command` option on each server, including the slaves, in case a slave also acts as a master to other slaves in your replication topology. The `SET` statement suppresses binary logging. After the command has been run on each server to be upgraded, you are done.

Loading Help Table Content With Replication to Slaves

If you do want to replicate help table content, check for help table incompatibilities between your master and its slaves. The `url` column in the `help_category` and `help_topic` tables was originally `CHAR(128)`, but is `TEXT` in newer MySQL versions to accommodate longer URLs. To check help table structure, use this statement:

```sql
SELECT TABLE_NAME, COLUMN_NAME, COLUMN_TYPE
FROM INFORMATION_SCHEMA.COLUMNS
WHERE TABLE_SCHEMA = 'mysql'
AND COLUMN_NAME = 'url';
```

For tables with the old structure, the statement produces this result:

<table>
<thead>
<tr>
<th>TABLE_NAME</th>
<th>COLUMN_NAME</th>
<th>COLUMN_TYPE</th>
</tr>
</thead>
<tbody>
<tr>
<td>help_category</td>
<td>url</td>
<td>char(128)</td>
</tr>
<tr>
<td>help_topic</td>
<td>url</td>
<td>char(128)</td>
</tr>
</tbody>
</table>

For tables with the new structure, the statement produces this result:

<table>
<thead>
<tr>
<th>TABLE_NAME</th>
<th>COLUMN_NAME</th>
<th>COLUMN_TYPE</th>
</tr>
</thead>
<tbody>
<tr>
<td>help_category</td>
<td>url</td>
<td>text</td>
</tr>
<tr>
<td>help_topic</td>
<td>url</td>
<td>text_topic</td>
</tr>
</tbody>
</table>

If the master and slave both have the old structure or both have the new structure, they are compatible and you can replicate help table content by executing this command on the master:

```bash
mysql mysql < fill_help_tables.sql
```

The table content will load into the master, then replicate to the slaves.

If the master and slave have incompatible help tables (one server has the old structure and the other has the new), you have a choice between not replicating help table content after all, or making the table structures compatible so that you can replicate the content.

- If you decide not to replicate the content after all, upgrade the master and slaves individually using `mysql` with the `--init-command` option, as described previously.

- If instead you decide to make the table structures compatible, upgrade the tables on the server that has the old structure. Suppose that your master server has the old table structure. Upgrade its tables to the new structure manually by executing these statements (binary logging is disabled here to prevent replication of the changes to the slaves, which already have the new structure):
Replication Features and Issues

SET sql_log_bin=0;
ALTER TABLE mysql.help_category ALTER COLUMN url TEXT;
ALTER TABLE mysql.help_topic ALTER COLUMN url TEXT;

Then run this command on the master:

mysql mysql < fill_help_tables.sql

The table content will load into the master, then replicate to the slaves.

16.4.1.31 Replication and Server SQL Mode

Using different server SQL mode settings on the master and the slave may cause the same INSERT statements to be handled differently on the master and the slave, leading the master and slave to diverge. For best results, you should always use the same server SQL mode on the master and on the slave. This advice applies whether you are using statement-based or row-based replication.

If you are replicating partitioned tables, using different SQL modes on the master and the slave is likely to cause issues. At a minimum, this is likely to cause the distribution of data among partitions to be different in the master’s and slave’s copies of a given table. It may also cause inserts into partitioned tables that succeed on the master to fail on the slave.

For more information, see Section 5.1.7, “Server SQL Modes”.

16.4.1.32 Replication Retries and Timeouts

The global system variable slave_transaction_retries affects replication as follows:
If the slave SQL thread fails to execute a transaction because of an InnoDB deadlock or because it exceeded the InnoDB innodb_lock_wait_timeout value, or the NDBCLUSTER TransactionDeadlockDetectionTimeout or TransactionInactiveTimeout value, the slave automatically retries the transaction slave_transaction_retries times before stopping with an error. The default value is 10. The total retry count can be seen in the output of SHOW STATUS; see Section 5.1.6, “Server Status Variables”.

16.4.1.33 Replication and TIMESTAMP

Older versions of MySQL (prior to 4.1) differed significantly in several ways in their handling of the TIMESTAMP data type from what is supported in MySQL versions 5.1 and newer; these include syntax extensions which are deprecated in MySQL 5.1, and that no longer supported in MySQL 5.5. This can cause problems (including replication failures) when replicating between MySQL Server versions, if you are using columns that are defined using the old TIMESTAMP(N) syntax. See Section 2.13.1.1, “Changes Affecting Upgrades to 5.1”, for more information about the differences, how they can impact MySQL replication, and what you can do if you encounter such problems.

16.4.1.34 Replication and Time Zones

The same system time zone should be set for both master and slave. Otherwise, statements depending on the local time on the master are not replicated properly, such as statements that use the NON() or FROM_UNIXTIME() functions. You can set the time zone in which MySQL server runs by using the --timezone=timezone_name option of the mysqld_safe script or by setting the TZ environment variable. See also Section 16.4.1.15, “Replication and System Functions”.

CONVERT_TZ(...,...,@@session.time_zone) is properly replicated only if both master and slave are running MySQL 5.0.4 or newer.

16.4.1.35 Replication and Transactions

Mixing transactional and nontransactional statements within the same transaction. In general, you should avoid transactions that update both transactional and nontransactional tables in a replication environment. You should also avoid using any statement that accesses both transactional (or temporary) and nontransactional tables and writes to any of them.
As of MySQL 5.1.44, the server uses these rules for binary logging:

- If the initial statements in a transaction are nontransactional, they are written to the binary log immediately. The remaining statements in the transaction are cached and not written to the binary log until the transaction is committed. (If the transaction is rolled back, the cached statements are written to the binary log only if they make nontransactional changes that cannot be rolled back. Otherwise, they are discarded.)

- For statement-based logging, logging of nontransactional statements is affected by the `binlog_direct_non_transactional_updates` system variable. When this variable is OFF (the default), logging is as just described. When this variable is ON, logging occurs immediately for nontransactional statements occurring anywhere in the transaction (not just initial nontransactional statements). Other statements are kept in the transaction cache and logged when the transaction commits. `binlog_direct_non_transactional_updates` has no effect for row-format or mixed-format binary logging.

**Transactional, nontransactional, and mixed statements.**

To apply those rules, the server considers a statement nontransactional if it changes only nontransactional tables, and transactional if it changes only transactional tables. A statement that changes both nontransactional and transactional tables is considered “mixed”. Mixed statements, like transactional statements, are cached and logged when the transaction commits.

**Note**

A mixed statement is unrelated to mixed binary logging format.

Before MySQL 5.1.44, the rules for binary logging are similar to those just described, except that there is no `binlog_direct_non_transactional_updates` system variable to affect logging of transactional statements. Thus, the server immediately logs only the initial nontransactional statements in a transaction and caches the rest until commit time.

Before MySQL 5.1.31, the effect of the rules differs because the definition of transactional statement is different: In these earlier versions, a statement is nontransactional if the first changes it makes change nontransactional tables, transactional if the first changes it makes change transactional tables. “First” applies in the sense that a statement may have several effects if it involves such things as triggers, stored functions, or multiple-table updates. A mixed statement that changes both nontransactional and transactional tables is handled as nontransactional or transactional depending on the type of changes it makes first.

In situations where transactions mix updates to transactional and nontransactional tables, the order of statements in the binary log is correct, and all needed statements are written to the binary log even in case of a ROLLBACK. However, when a second connection updates the nontransactional table before the first connection transaction is complete, statements can be logged out of order because the second connection update is written immediately after it is performed, regardless of the state of the transaction being performed by the first connection.

**Using different storage engines on master and slave.**

It is possible to replicate transactional tables on the master using nontransactional tables on the slave. For example, you can replicate an InnoDB master table as a MyISAM slave table. However, if you do this, there are problems if the slave is stopped in the middle of a BEGIN ... COMMIT block because the slave restarts at the beginning of the BEGIN block.

Beginning with MySQL 5.1.48, it is also safe to replicate transactions from MyISAM tables on the master to transactional tables—such as tables that use the InnoDB storage engine—on the slave. In such cases (beginning with MySQL 5.1.48), an AUTOCOMMIT=1 statement issued on the master is replicated, thus enforcing AUTOCOMMIT mode on the slave.

When the storage engine type of the slave is nontransactional, transactions on the master that mix updates of transactional and nontransactional tables should be avoided because they can cause inconsistency of the data between the master transactional table and the slave nontransactional table.
That is, such transactions can lead to master storage engine-specific behavior with the possible effect of replication going out of synchrony. MySQL does not issue a warning about this currently, so extra care should be taken when replicating transactional tables from the master to nontransactional tables on the slaves.

Beginning with MySQL Cluster NDB 6.2.14 and MySQL 5.1.24, every transaction (including autocommit transactions) is recorded in the binary log as though it starts with a `BEGIN` statement, and ends with either a `COMMIT` or a `ROLLBACK` statement. However, this does not apply to nontransactional changes; any statements affecting tables using a nontransactional storage engine such as MyISAM are regarded for this purpose as nontransactional, even when autocommit is enabled. (Bug #26395)

16.4.1.36 Replication and Triggers

With statement-based replication, triggers executed on the master also execute on the slave. With row-based replication, triggers executed on the master do not execute on the slave. Instead, the row changes on the master resulting from trigger execution are replicated and applied on the slave.

This behavior is by design. If under row-based replication the slave applied the triggers as well as the row changes caused by them, the changes would in effect be applied twice on the slave, leading to different data on the master and the slave.

If you want triggers to execute on both the master and the slave—perhaps because you have different triggers on the master and slave—you must use statement-based replication. However, to enable slave-side triggers, it is not necessary to use statement-based replication exclusively. It is sufficient to switch to statement-based replication only for those statements where you want this effect, and to use row-based replication the rest of the time.

Before MySQL 5.1.31, a trigger that was defined on a transactional table but that updated a nontransactional table could cause updates on the transactional table to be replicated before they were actually committed on the master, and not be rolled back correctly on the slave if they were rolled back on the master. (Bug #40116) See also Section 16.4.1.35, “Replication and Transactions”.

A statement invoking a trigger (or function) that causes an update to an `AUTO_INCREMENT` column is not replicated correctly using statement-based replication. Beginning with MySQL 5.1.40, such statements are marked as unsafe. (Bug #45677)

16.4.1.37 Replication and TRUNCATE TABLE

`TRUNCATE TABLE` is normally regarded as a DML statement, and so would be expected to be logged and replicated using row-based format when the binary logging mode is `ROW` or `MIXED`. However this caused issues when logging or replicating, in `STATEMENT` or `MIXED` mode, tables that used transactional storage engines such as InnoDB when the transaction isolation level was `READ COMMITTED` or `READ UNCOMMITTED`, which precludes statement-based logging.

Beginning with MySQL 5.1.32, `TRUNCATE TABLE` is treated for purposes of logging and replication as DDL rather than DML so that it can be logged and replicated as a statement. However, the effects of the statement as applicable to InnoDB and other transactional tables on replication slaves still follow the rules described in Section 13.1.34, “TRUNCATE TABLE Syntax” governing such tables. (Bug #36763)

16.4.1.38 Replication and Variables

System variables are not replicated correctly when using `STATEMENT` mode, except for the following variables when they are used with session scope:

- `auto_increment_increment`
- `auto_increment_offset`
- `character_set_client`
• character_set_connection
• character_set_database
• character_set_server
• collation_connection
• collation_database
• collation_server
• foreign_key_checks
• identity
• last_insert_id
• lc_time_names
• pseudo_thread_id
• sql_auto_is_null
• time_zone
• timestamp
• unique_checks

When MIXED mode is used, the variables in the preceding list, when used with session scope, cause a switch from statement-based to row-based logging. See Section 5.4.4.3, “Mixed Binary Logging Format”.

sql_mode is also replicated except for the NO_DIR_IN_CREATE mode; the slave always preserves its own value for NO_DIR_IN_CREATE, regardless of changes to it on the master. This is true for all replication formats.

However, when mysqlbinlog parses a SET @@sql_mode = mode statement, the full mode value, including NO_DIR_IN_CREATE, is passed to the receiving server. For this reason, replication of such a statement may not be safe when STATEMENT mode is in use.

The storage_engine system variable is not replicated, regardless of the logging mode; this is intended to facilitate replication between different storage engines.

The read_only system variable is not replicated. In addition, the enabling this variable has different effects with regard to temporary tables, table locking, and the SET PASSWORD statement in different MySQL versions.

The max_heap_table_size system variable is not replicated. Increasing the value of this variable on the master without doing so on the slave can lead eventually to Table is full errors on the slave when trying to execute INSERT statements on a MEMORY table on the master that is thus permitted to grow larger than its counterpart on the slave. For more information, see Section 16.4.1.22, “Replication and MEMORY Tables”.

In statement-based replication, session variables are not replicated properly when used in statements that update tables. For example, the following sequence of statements will not insert the same data on the master and the slave:

```
SET max_join_size=1000;
INSERT INTO mytable VALUES(@@max_join_size);
```

This does not apply to the common sequence:
Replication of session variables is not a problem when row-based replication is being used, in which case, session variables are always replicated safely. See Section 16.1.2, “Replication Formats”.

In MySQL 5.1.20 and later (and in MySQL 5.0.46 and later in MySQL 5.0, for backward compatibility), the following session variables are written to the binary log and honored by the replication slave when parsing the binary log, regardless of the logging format:

- `sql_mode`
- `foreign_key_checks`
- `unique_checks`
- `character_set_client`
- `collation_connection`
- `collation_database`
- `collation_server`
- `sql_auto_is_null`

**Important**

Even though session variables relating to character sets and collations are written to the binary log, replication between different character sets is not supported.

It is strongly recommended that you always use the same setting for the `lower_case_table_names` system variable on both master and slave. In particular, when a case-sensitive file system is used, setting this variable to 1 on the slave, but to a different value on the master, can cause two types of problems: Names of databases are not converted to lowercase; in addition, when using row-based replication names of tables are also not converted. Either of these problems can cause replication to fail. This is a known issue, which is fixed in MySQL 5.6.

### 16.4.1.39 Replication and Views

Views are always replicated to slaves. Views are filtered by their own name, not by the tables they refer to. This means that a view can be replicated to the slave even if the view contains a table that would normally be filtered out by `replication-ignore-table` rules. Care should therefore be taken to ensure that views do not replicate table data that would normally be filtered for security reasons.

Replication from a table to a same-named view is supported using statement-based logging, but not when using row-based logging. In MySQL 5.1.69 and later, trying to do so when row-based logging is in effect causes an error. (Bug #11752707, Bug #43975)

### 16.4.2 Replication Compatibility Between MySQL Versions

MySQL supports replication from one release series to the next higher release series. For example, you can replicate from a master running MySQL 5.0 to a slave running MySQL 5.1, from a master running MySQL 5.1 to a slave running MySQL 5.5, and so on.

However, one may encounter difficulties when replicating from an older master to a newer slave if the master uses statements or relies on behavior no longer supported in the version of MySQL used on the slave.

The use of more than two MySQL Server versions is not supported in replication setups involving multiple masters, regardless of the number of master or slave MySQL servers. This restriction applies
not only to release series, but to version numbers within the same release series as well. For example, if you are using a chained or circular replication setup, you cannot use MySQL 5.1.31, MySQL 5.1.32, and MySQL 5.1.34 concurrently, although you could use any two of these releases together.

**Important**

It is strongly recommended to use the most recent release available within a given MySQL release series because replication (and other) capabilities are continually being improved. It is also recommended to upgrade masters and slaves that use early releases of a release series of MySQL to GA (production) releases when the latter become available for that release series.

Replication from newer masters to older slaves may be possible, but is generally not supported. This is due to a number of factors:

- **Binary log format changes.** The binary log format can change between major releases. While we attempt to maintain backward compatibility, this is not always possible. For example, the binary log format implemented in MySQL 5.0 changed considerably from that used in previous versions, especially with regard to handling of character sets, `LOAD DATA INFILE`, and time zones. This means that replication from a MySQL 5.0 (or later) master to a MySQL 4.1 (or earlier) slave is generally not supported.

  This also has significant implications for upgrading replication servers; see Section 16.4.3, "Upgrading a Replication Setup", for more information.

- **Use of row-based replication.** Row-based replication was implemented in MySQL 5.1.5, so you cannot replicate using row-based replication from any MySQL 5.1 or later master to a slave older than MySQL 5.1.5.

  For more information about row-based replication, see Section 16.1.2, “Replication Formats”.

- **SQL incompatibilities.** You cannot replicate from a newer master to an older slave using statement-based replication if the statements to be replicated use SQL features available on the master but not on the slave.

  However, if both the master and the slave support row-based replication, and there are no data definition statements to be replicated that depend on SQL features found on the master but not on the slave, you can use row-based replication to replicate the effects of data modification statements even if the DDL run on the master is not supported on the slave.

  For more information on potential replication issues, see Section 16.4.1, “Replication Features and Issues”.

### 16.4.3 Upgrading a Replication Setup

When you upgrade servers that participate in a replication setup, the procedure for upgrading depends on the current server versions and the version to which you are upgrading. This section provides information about how upgrading affects replication. For general information about upgrading MySQL, see Section 2.13.1, “Upgrading MySQL”

When you upgrade a master to 5.1 from an earlier MySQL release series, you should first ensure that all the slaves of this master are using the same 5.1.x release. If this is not the case, you should first upgrade the slaves. To upgrade each slave, shut it down, upgrade it to the appropriate 5.1.x version, restart it, and restart replication. The 5.1 slave is able to read the old relay logs written prior to the upgrade and to execute the statements they contain. Relay logs created by the slave after the upgrade are in 5.1 format.

After the slaves have been upgraded, shut down the master, upgrade it to the same 5.1.x release as the slaves, and restart it. The 5.1 master is able to read the old binary logs written prior to the upgrade and to send them to the 5.1 slaves. The slaves recognize the old format and handle it properly.
Troubleshooting Replication

logs created by the master subsequent to the upgrade are in 5.1 format. These too are recognized by the 5.1 slaves.

In other words, when upgrading to MySQL 5.1, the slaves must be MySQL 5.1 before you can upgrade the master to 5.1. Note that downgrading from 5.1 to older versions does not work so simply: You must ensure that any 5.1 binary log or relay log has been fully processed, so that you can remove it before proceeding with the downgrade.

Downgrading a replication setup to a previous version cannot be done once you have switched from statement-based to row-based replication, and after the first row-based statement has been written to the binary log. See Section 16.1.2, “Replication Formats”.

Some upgrades may require that you drop and re-create database objects when you move from one MySQL series to the next. For example, collation changes might require that table indexes be rebuilt. Such operations, if necessary, are detailed at Section 2.13.1.1, “Changes Affecting Upgrades to 5.1”. It is safest to perform these operations separately on the slaves and the master, and to disable replication of these operations from the master to the slave. To achieve this, use the following procedure:

1. Stop all the slaves and upgrade them. Restart them with the --skip-slave-start option so that they do not connect to the master. Perform any table repair or rebuilding operations needed to re-create database objects, such as use of REPAIR TABLE or ALTER TABLE, or dumping and reloading tables or triggers.

2. Disable the binary log on the master. To do this without restarting the master, execute a SET sql_log_bin = 0 statement. Alternatively, stop the master and restart it without the --log-bin option. If you restart the master, you might also want to disallow client connections. For example, if all clients connect using TCP/IP, use the --skip-networking option when you restart the master.

3. With the binary log disabled, perform any table repair or rebuilding operations needed to re-create database objects. The binary log must be disabled during this step to prevent these operations from being logged and sent to the slaves later.

4. Re-enable the binary log on the master. If you set sql_log_bin to 0 earlier, execute a SET sql_log_bin = 1 statement. If you restarted the master to disable the binary log, restart it with --log-bin, and without --skip-networking so that clients and slaves can connect.

5. Restart the slaves, this time without the --skip-slave-start option.

16.4.4 Troubleshooting Replication

If you have followed the instructions but your replication setup is not working, the first thing to do is check the error log for messages. Many users have lost time by not doing this soon enough after encountering problems.

If you cannot tell from the error log what the problem was, try the following techniques:

- Verify that the master has binary logging enabled by issuing a SHOW MASTER STATUS statement. If logging is enabled, Position is nonzero. If binary logging is not enabled, verify that you are running the master with the --log-bin option.

- Verify that the master and slave both were started with the --server-id option and that the ID value is unique on each server.

- Verify that the slave is running. Use SHOW SLAVE STATUS to check whether the Slave_IO_Running and Slave_SQL_Running values are both Yes. If not, verify the options that were used when starting the slave server. For example, --skip-slave-start prevents the slave threads from starting until you issue a START SLAVE statement.

- If the slave is running, check whether it established a connection to the master. Use SHOW PROCESSLIST, find the I/O and SQL threads and check their State column to see what they
display. See Section 16.2.1, “Replication Implementation Details”. If the I/O thread state says Connecting to master, check the following:

- Verify the privileges for the user being used for replication on the master.
- Check that the host name of the master is correct and that you are using the correct port to connect to the master. The port used for replication is the same as used for client network communication (the default is 3306). For the host name, ensure that the name resolves to the correct IP address.
- Check that networking has not been disabled on the master or slave. Look for the skip-networking option in the configuration file. If present, comment it out or remove it.
- If the master has a firewall or IP filtering configuration, ensure that the network port being used for MySQL is not being filtered.
- Check that you can reach the master by using ping or traceroute/tracert to reach the host.
- If the slave was running previously but has stopped, the reason usually is that some statement that succeeded on the master failed on the slave. This should never happen if you have taken a proper snapshot of the master, and never modified the data on the slave outside of the slave thread. If the slave stops unexpectedly, it is a bug or you have encountered one of the known replication limitations described in Section 16.4.1, “Replication Features and Issues”. If it is a bug, see Section 16.4.5, “How to Report Replication Bugs or Problems”, for instructions on how to report it.
- If a statement that succeeded on the master refuses to run on the slave, try the following procedure if it is not feasible to do a full database resynchronization by deleting the slave’s databases and copying a new snapshot from the master:

1. Determine whether the affected table on the slave is different from the master table. Try to understand how this happened. Then make the slave’s table identical to the master’s and run START SLAVE.
2. If the preceding step does not work or does not apply, try to understand whether it would be safe to make the update manually (if needed) and then ignore the next statement from the master.
3. If you decide that the slave can skip the next statement from the master, issue the following statements:

```sql
mysql> SET GLOBAL sql_slave_skip_counter = N;
mysql> START SLAVE;
```

The value of $N$ should be 1 if the next statement from the master does not use AUTO_INCREMENT or LAST_INSERT_ID(). Otherwise, the value should be 2. The reason for using a value of 2 for statements that use AUTO_INCREMENT or LAST_INSERT_ID() is that they take two events in the binary log of the master.

See also Section 13.4.2.6, “SET GLOBAL sql_slave_skip_counter Syntax”.

4. If you are sure that the slave started out perfectly synchronized with the master, and that no one has updated the tables involved outside of the slave thread, then presumably the discrepancy is the result of a bug. If you are running the most recent version of MySQL, please report the problem. If you are running an older version, try upgrading to the latest production release to determine whether the problem persists.

### 16.4.5 How to Report Replication Bugs or Problems

When you have determined that there is no user error involved, and replication still either does not work at all or is unstable, it is time to send us a bug report. We need to obtain as much information as
possible from you to be able to track down the bug. Please spend some time and effort in preparing a good bug report.

If you have a repeatable test case that demonstrates the bug, please enter it into our bugs database using the instructions given in Section 1.7, “How to Report Bugs or Problems”. If you have a “phantom” problem (one that you cannot duplicate at will), use the following procedure:

1. Verify that no user error is involved. For example, if you update the slave outside of the slave thread, the data goes out of synchrony, and you can have unique key violations on updates. In this case, the slave thread stops and waits for you to clean up the tables manually to bring them into synchrony. This is not a replication problem. It is a problem of outside interference causing replication to fail.

2. Run the slave with the `--log-slave-updates` and `--log-bin` options. These options cause the slave to log the updates that it receives from the master into its own binary logs.

3. Save all evidence before resetting the replication state. If we have no information or only sketchy information, it becomes difficult or impossible for us to track down the problem. The evidence you should collect is:
   - All binary log files from the master
   - All binary log files from the slave
   - The output of `SHOW MASTER STATUS` from the master at the time you discovered the problem
   - The output of `SHOW SLAVE STATUS` from the slave at the time you discovered the problem
   - Error logs from the master and the slave

4. Use `mysqlbinlog` to examine the binary logs. The following should be helpful to find the problem statement. `log_file` and `log_pos` are the `Master_Log_File` and `Read_Master_Log_Pos` values from `SHOW SLAVE STATUS`.

   ```shell
   mysqlbinlog --start-position=log_pos log_file | head
   ```

After you have collected the evidence for the problem, try to isolate it as a separate test case first. Then enter the problem with as much information as possible into our bugs database using the instructions at Section 1.7, “How to Report Bugs or Problems”.

  17.5.1 Summary of MySQL Cluster Start Phases ......................................................................... 2118
  17.5.2 Commands in the MySQL Cluster Management Client .................................................... 2120
This chapter contains information about MySQL Cluster, which is a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. Current releases of MySQL Cluster use versions 6 and 7 of the NDB storage engine (also known as NDBCLUSTER) to enable running several computers with MySQL servers and other software in a cluster.

Beginning with MySQL 5.1.24, support for the NDBCLUSTER storage engine was removed from the standard MySQL server binaries built by MySQL. Instead, users of MySQL Cluster binaries built by MySQL should upgrade to the most recent binary release of MySQL Cluster NDB 7.0 or MySQL Cluster 7.1 for supported platforms—these include RPMs that should work with most Linux distributions. MySQL Cluster users who build from source should be aware that, also beginning with MySQL 5.1.24, NDBCLUSTER sources in the standard MySQL 5.1 tree are no longer maintained; these users should use the sources provided for MySQL Cluster NDB 7.0 or later. (Locations where the sources can be obtained are listed later in this section.)

Note
MySQL Cluster NDB 6.1, 6.2, and 6.3 were formerly known as “MySQL Cluster Carrier Grade Edition”. Beginning with MySQL Cluster NDB 6.2.15 and MySQL Cluster NDB 6.3.14, this term is no longer applied to the MySQL Cluster software—which is now known simply as “MySQL Cluster”—but rather to a commercial licensing and support package. You can learn more about available options for commercial licensing of MySQL Cluster from http://mysql.com/products/database/cluster/features.html, on the MySQL web site.

This chapter contains information about MySQL Cluster in MySQL 5.1 mainline releases through MySQL 5.1.23, MySQL Cluster NDB 6.2 releases through 5.1.51-ndb-6.2.19, MySQL Cluster NDB 6.3 releases through 5.1.73-ndb-6.3.55, MySQL Cluster NDB 7.0 releases through 5.1.73-ndb-7.0.42 and MySQL Cluster NDB 7.1 releases through 5.1.77-ndb-7.1.37. Currently, the MySQL Cluster NDB 7.3 and MySQL Cluster NDB 7.4 release series are both Generally Available (GA). MySQL Cluster NDB 7.2 is a previous GA release series; although this series is still supported, we recommend that new deployments use MySQL Cluster NDB 7.4. For information about MySQL Cluster NDB 7.4, see MySQL
Cluster NDB 7.3 and MySQL Cluster NDB 7.4, in the MySQL 5.6 Manual. MySQL Cluster NDB 7.5 is also available as a Developer Preview; see MySQL Cluster NDB 7.5.

This chapter also contains historical information about MySQL Cluster NDB 6.1 and MySQL Cluster NDB 6.2, although these release series are no longer in active development, and no longer supported for new deployments. You should upgrade to a MySQL Cluster NDB 7.1 or later release series as soon as possible.

Release notes for the changes in each release of MySQL Cluster are located at MySQL Cluster 7.1 Release Notes.

Supported Platforms. MySQL Cluster is currently available and supported on a number of platforms. For exact levels of support available for on specific combinations of operating system versions, operating system distributions, and hardware platforms, please refer to http://www.mysql.com/support/supportedplatforms/cluster.html.

Availability. MySQL Cluster binary and source packages are available for supported platforms from http://dev.mysql.com/downloads/cluster/.

Note

Binary releases and RPMs were not available for MySQL Cluster NDB 6.2 prior to MySQL Cluster NDB 6.2.15.

MySQL Cluster release numbers. Starting with MySQL Cluster NDB 6.1 and MySQL Cluster NDB 6.2, MySQL Cluster follows a somewhat different release pattern from the mainline MySQL 5.1 Cluster series of releases. In this Manual and other MySQL documentation, we identify these and later MySQL Cluster releases employing a version number that begins with "NDB". This version number is that of the NDBCLUSTER storage engine used in the release, and not of the MySQL server version on which the MySQL Cluster release is based.

Version strings used in MySQL Cluster NDB 6.x and 7.x software. The version string displayed by MySQL Cluster NDB 6.x and 7.x software uses this format:

```
mysql-mysql_server_version-ndb-ndb_engine_version
```

`mysql_server_version` represents the version of the MySQL Server on which the MySQL Cluster release is based. For all MySQL Cluster NDB 6.x and 7.x releases, this is "5.1". `ndb_engine_version` is the version of the NDB storage engine used by this release of the MySQL Cluster software. You can see this format used in the mysql client, as shown here:

```
shell> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 2
Server version: 5.1.77-ndb-7.1.37 Source distribution
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
mysql> SELECT VERSION()\G
*************************** 1. row ***************************
VERSION(): 5.1.77-ndb-7.1.37
1 row in set (0.00 sec)
```

This version string is also displayed in the output of the SHOW command in the ndb_mgm client:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
[ndbd(NDB)] 2 node(s)
id=1 @10.0.10.6 (5.1.77-ndb-7.1.37, Nodegroup: 0, *)
```
The version string identifies the mainline MySQL version from which the MySQL Cluster release was branched and the version of the NDBCLUSTER storage engine used. For example, the full version string for MySQL Cluster NDB 7.0.5 (the first GA MySQL Cluster NDB 7.0 binary release) was mysql-5.1.32-ndb-7.0.5. From this we can determine the following:

- Since the portion of the version string preceding "-ndb-" is the base MySQL Server version, this means that MySQL Cluster NDB 7.0.5 derives from the MySQL 5.1.32, and contains all feature enhancements and bugfixes from MySQL 5.1 up to and including MySQL 5.1.32.

- Since the portion of the version string following "-ndb-" represents the version number of the NDB (or NDBCLUSTER) storage engine, MySQL Cluster NDB 7.0.5 uses version 7.0.5 of the NDBCLUSTER storage engine.

New MySQL Cluster releases are numbered according to updates in the NDB storage engine, and do not necessarily correspond in a linear fashion with mainline MySQL Server releases. For example, MySQL Cluster NDB 7.0.5 (as previously noted) is based on MySQL 5.1.32, and MySQL Cluster NDB 7.0.6 is based on MySQL 5.1.34 (version string: mysql-5.1.34-ndb-7.0.6).

**Compatibility with standard MySQL 5.1 releases.** While many standard MySQL schemas and applications can work using MySQL Cluster, it is also true that unmodified applications and database schemas may be slightly incompatible or have suboptimal performance when run using MySQL Cluster (see Section 17.1.6, “Known Limitations of MySQL Cluster”). Most of these issues can be overcome, but this also means that you are very unlikely to be able to switch an existing application datastore—that currently uses, for example, MyISAM or InnoDB—to use the NDB storage engine without allowing for the possibility of changes in schemas, queries, and applications. Moreover, from MySQL 5.1.24 onwards, the MySQL Server and MySQL Cluster codebases diverge considerably (and NDB storage engine support dropped from subsequent MySQL Server releases), so that the standard mysql cannot function as a dropin replacement for the version of mysql that is supplied with MySQL Cluster.

**MySQL Cluster development source trees.** MySQL Cluster development trees can also be accessed from [https://github.com/mysql/mysql-server](https://github.com/mysql/mysql-server). The MySQL Cluster development sources maintained at [https://github.com/mysql/mysql-server](https://github.com/mysql/mysql-server) are licensed under the GPL. For information about obtaining MySQL sources using Bazaar and building them yourself, see Section 2.11.3, “Installing MySQL Using a Development Source Tree”.

Currently, MySQL Cluster NDB 7.3 and MySQL Cluster NDB 7.4 releases are Generally Available (GA). We recommend that new deployments use MySQL Cluster NDB 7.4. MySQL Cluster NDB 7.1 and earlier versions are no longer in active development. For an overview of major features added in MySQL Cluster NDB 7.4, see What is New in MySQL Cluster NDB 7.4. For similar information about MySQL Cluster NDB 7.3, see What is New in MySQL Cluster NDB 7.3. MySQL Cluster NDB 7.2 is a past GA series that is still supported; see What is New in MySQL Cluster. MySQL Cluster NDB 7.5 is also available as a Developer Preview for testing of new features; for more information, see MySQL Cluster NDB 7.5.

This chapter represents a work in progress, and its contents are subject to revision as MySQL Cluster continues to evolve. Additional information regarding MySQL Cluster can be found on the MySQL Website at [http://www.mysql.com/products/cluster/](http://www.mysql.com/products/cluster/).

**Additional Resources.** More information about MySQL Cluster can be found in the following places:
MySQL Cluster Overview

- For answers to some commonly asked questions about MySQL Cluster, see Section A.10, “MySQL 5.1 FAQ: MySQL Cluster”.
- Many MySQL Cluster users and developers blog about their experiences with MySQL Cluster, and make feeds of these available through PlanetMySQL.

17.1 MySQL Cluster Overview

MySQL Cluster is a technology that enables clustering of in-memory databases in a shared-nothing system. The shared-nothing architecture enables the system to work with very inexpensive hardware, and with a minimum of specific requirements for hardware or software.

MySQL Cluster is designed not to have any single point of failure. In a shared-nothing system, each component is expected to have its own memory and disk, and the use of shared storage mechanisms such as network shares, network file systems, and SANs is not recommended or supported.

MySQL Cluster integrates the standard MySQL server with an in-memory clustered storage engine called NDB (which stands for “Network DataBase”). In our documentation, the term NDB refers to the part of the setup that is specific to the storage engine, whereas “MySQL Cluster” refers to the combination of one or more MySQL servers with the NDB storage engine.

A MySQL Cluster consists of a set of computers, known as hosts, each running one or more processes. These processes, known as nodes, may include MySQL servers (for access to NDB data), data nodes (for storage of the data), one or more management servers, and possibly other specialized data access programs. The relationship of these components in a MySQL Cluster is shown here:

Figure 17.1 MySQL Cluster Components

All these programs work together to form a MySQL Cluster (see Section 17.4, “MySQL Cluster Programs”). When data is stored by the NDB storage engine, the tables (and table data) are stored in the data nodes. Such tables are directly accessible from all other MySQL servers (SQL nodes) in the cluster. Thus, in a payroll application storing data in a cluster, if one application updates the salary of an employee, all other MySQL servers that query this data can see this change immediately.

Although a MySQL Cluster SQL node uses the mysqld server daemon, it differs in a number of critical respects from the mysqld binary supplied with the MySQL 5.1 distributions, and the two versions of mysqld are not interchangeable.
In addition, a MySQL server that is not connected to a MySQL Cluster cannot use the NDB storage engine and cannot access any MySQL Cluster data.

The data stored in the data nodes for MySQL Cluster can be mirrored; the cluster can handle failures of individual data nodes with no other impact than that a small number of transactions are aborted due to losing the transaction state. Because transactional applications are expected to handle transaction failure, this should not be a source of problems.

Individual nodes can be stopped and restarted, and can then rejoin the system (cluster). Rolling restarts (in which all nodes are restarted in turn) are used in making configuration changes and software upgrades (see Section 17.5.5, “Performing a Rolling Restart of a MySQL Cluster”). In MySQL Cluster NDB 7.0 and later, rolling restarts are also used as part of the process of adding new data nodes online (see Section 17.5.13, “Adding MySQL Cluster Data Nodes Online”). For more information about data nodes, how they are organized in a MySQL Cluster, and how they handle and store MySQL Cluster data, see Section 17.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”.

Backing up and restoring MySQL Cluster databases can be done using the NDB-native functionality found in the MySQL Cluster management client and the ndb_restore program included in the MySQL Cluster distribution. For more information, see Section 17.5.3, “Online Backup of MySQL Cluster”, and Section 17.4.20, “ndb_restore — Restore a MySQL Cluster Backup”. You can also use the standard MySQL functionality provided for this purpose in mysqldump and the MySQL server. See Section 4.5.4, “mysqldump — A Database Backup Program”, for more information.

MySQL Cluster nodes can use a number of different transport mechanisms for inter-node communications, including TCP/IP using standard 100 Mbps or faster Ethernet hardware. It is also possible to use the high-speed Scalable Coherent Interface (SCI) protocol with MySQL Cluster, although this is not required to use MySQL Cluster. SCI requires special hardware and software; see Section 17.3.4, “Using High-Speed Interconnects with MySQL Cluster”, for more about SCI and using it with MySQL Cluster.

17.1.1 MySQL Cluster Core Concepts

NDBCLUSTER (also known as NDB) is an in-memory storage engine offering high-availability and data-persistence features.

The NDBCLUSTER storage engine can be configured with a range of failover and load-balancing options, but it is easiest to start with the storage engine at the cluster level. MySQL Cluster’s NDB storage engine contains a complete set of data, dependent only on other data within the cluster itself.

The “Cluster” portion of MySQL Cluster is configured independently of the MySQL servers. In a MySQL Cluster, each part of the cluster is considered to be a node.

Note

In many contexts, the term “node” is used to indicate a computer, but when discussing MySQL Cluster it means a process. It is possible to run multiple nodes on a single computer; for a computer on which one or more cluster nodes are being run we use the term cluster host.

There are three types of cluster nodes, and in a minimal MySQL Cluster configuration, there will be at least three nodes, one of each of these types:

- **Management node**: The role of this type of node is to manage the other nodes within the MySQL Cluster, performing such functions as providing configuration data, starting and stopping nodes, running backup, and so forth. Because this node type manages the configuration of the other nodes, a node of this type should be started first, before any other node. An MGM node is started with the command ndb_mgmd.

- **Data node**: This type of node stores cluster data. There are as many data nodes as there are replicas, times the number of fragments (see Section 17.1.2, “MySQL Cluster Nodes, Node Groups,
Replicas, and Partitions”). For example, with two replicas, each having two fragments, you need four data nodes. One replica is sufficient for data storage, but provides no redundancy; therefore, it is recommended to have 2 (or more) replicas to provide redundancy, and thus high availability. A data node is started with the command `ndbd` (see Section 17.4.1, “ndbd — The MySQL Cluster Data Node Daemon”). In MySQL Cluster NDB 7.0 and later, `ndbmtd` can also be used for the data node process; see Section 17.4.3, “ndbmtd — The MySQL Cluster Data Node Daemon (Multi-Threaded)”, for more information.

MySQL Cluster tables are normally stored completely in memory rather than on disk (this is why we refer to MySQL Cluster as an in-memory database). In MySQL 5.1, MySQL Cluster NDB 6.X, and later, some MySQL Cluster data can be stored on disk; see Section 17.5.12, “MySQL Cluster Disk Data Tables”, for more information.

• **SQL node**: This is a node that accesses the cluster data. In the case of MySQL Cluster, an SQL node is a traditional MySQL server that uses the NDBCLUSTER storage engine. An SQL node is a `mysqld` process started with the `--ndbcluster` and `--ndb-connectstring` options, which are explained elsewhere in this chapter, possibly with additional MySQL server options as well.

An SQL node is actually just a specialized type of **API node**, which designates any application which accesses MySQL Cluster data. Another example of an API node is the `ndb_restore` utility that is used to restore a cluster backup. It is possible to write such applications using the NDB API. For basic information about the NDB API, see Getting Started with the NDB API.

**Important**

It is not realistic to expect to employ a three-node setup in a production environment. Such a configuration provides no redundancy; to benefit from MySQL Cluster’s high-availability features, you must use multiple data and SQL nodes. The use of multiple management nodes is also highly recommended.

For a brief introduction to the relationships between nodes, node groups, replicas, and partitions in MySQL Cluster, see Section 17.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”.

Configuration of a cluster involves configuring each individual node in the cluster and setting up individual communication links between nodes. MySQL Cluster is currently designed with the intention that data nodes are homogeneous in terms of processor power, memory space, and bandwidth. In addition, to provide a single point of configuration, all configuration data for the cluster as a whole is located in one configuration file.

The management server manages the cluster configuration file and the cluster log. Each node in the cluster retrieves the configuration data from the management server, and so requires a way to determine where the management server resides. When interesting events occur in the data nodes, the nodes transfer information about these events to the management server, which then writes the information to the cluster log.

In addition, there can be any number of cluster client processes or applications. These include standard MySQL clients, NDB-specific API programs, and management clients. These are described in the next few paragraphs.

**Standard MySQL clients.** MySQL Cluster can be used with existing MySQL applications written in PHP, Perl, C, C++, Java, Python, Ruby, and so on. Such client applications send SQL statements to and receive responses from MySQL servers acting as MySQL Cluster SQL nodes in much the same way that they interact with standalone MySQL servers.

MySQL clients using a MySQL Cluster as a data source can be modified to take advantage of the ability to connect with multiple MySQL servers to achieve load balancing and failover. For example, Java clients using Connector/J 5.0.6 and later can use `jdbc:mysql:loadbalance://` URLs (improved in Connector/J 5.1.7) to achieve load balancing transparently; for more information about using Connector/J with MySQL Cluster, see Using Connector/J with MySQL Cluster.
NDB client programs. Client programs can be written that access MySQL Cluster data directly from the NDBCLUSTER storage engine, bypassing any MySQL Servers that may be connected to the cluster, using the NDB API, a high-level C++ API. Such applications may be useful for specialized purposes where an SQL interface to the data is not needed. For more information, see The NDB API.

Beginning with MySQL Cluster NDB 7.1, NDB-specific Java applications can also be written for MySQL Cluster, using the MySQL Cluster Connector for Java. This MySQL Cluster Connector includes ClusterJ, a high-level database API similar to object-relational mapping persistence frameworks such as Hibernate and JPA that connect directly to NDBCLUSTER, and so does not require access to a MySQL Server. Support is also provided in MySQL Cluster NDB 7.1 and later for ClusterJPA, an OpenJPA implementation for MySQL Cluster that leverages the strengths of ClusterJ and JDBC; ID lookups and other fast operations are performed using ClusterJ (bypassing the MySQL Server), while more complex queries that can benefit from MySQL’s query optimizer are sent through the MySQL Server, using JDBC. See Java and MySQL Cluster, and The ClusterJ API and Data Object Model, for more information.

Management clients. These clients connect to the management server and provide commands for starting and stopping nodes gracefully, starting and stopping message tracing (debug versions only), showing node versions and status, starting and stopping backups, and so on. An example of this type of program is the ndb_mgm management client supplied with MySQL Cluster (see Section 17.4.5, “ndb_mgm — The MySQL Cluster Management Client”). Such applications can be written using the MGM API, a C-language API that communicates directly with one or more MySQL Cluster management servers. For more information, see The MGM API.

Oracle also makes available MySQL Cluster Manager, which provides an advanced command-line interface simplifying many complex MySQL Cluster management tasks, such restarting a MySQL Cluster with a large number of nodes. The MySQL Cluster Manager client also supports commands for getting and setting the values of most node configuration parameters as well as mysqld server options and variables relating to MySQL Cluster. See MySQL™ Cluster Manager 1.3.6 User Manual, for more information.

Event logs. MySQL Cluster logs events by category (startup, shutdown, errors, checkpoints, and so on), priority, and severity. A complete listing of all reportable events may be found in Section 17.5.6, “Event Reports Generated in MySQL Cluster”. Event logs are of the two types listed here:

• **Cluster log**: Keeps a record of all desired reportable events for the cluster as a whole.

• **Node log**: A separate log which is also kept for each individual node.

**Note**

Under normal circumstances, it is necessary and sufficient to keep and examine only the cluster log. The node logs need be consulted only for application development and debugging purposes.

Checkpoint. Generally speaking, when data is saved to disk, it is said that a checkpoint has been reached. More specific to MySQL Cluster, a checkpoint is a point in time where all committed transactions are stored on disk. With regard to the NDB storage engine, there are two types of checkpoints which work together to ensure that a consistent view of the cluster’s data is maintained. These are shown in the following list:

• **Local Checkpoint (LCP)**: This is a checkpoint that is specific to a single node; however, LCPs take place for all nodes in the cluster more or less concurrently. An LCP involves saving all of a node’s data to disk, and so usually occurs every few minutes. The precise interval varies, and depends upon the amount of data stored by the node, the level of cluster activity, and other factors.

• **Global Checkpoint (GCP)**: A GCP occurs every few seconds, when transactions for all nodes are synchronized and the redo-log is flushed to disk.

For more information about the files and directories created by local checkpoints and global checkpoints, see MySQL Cluster Data Node File System Directory Files.
17.1.2 MySQL Cluster Nodes, Node Groups, Replicas, and Partitions

This section discusses the manner in which MySQL Cluster divides and duplicates data for storage.

A number of concepts central to an understanding of this topic are discussed in the next few paragraphs.

(Data) Node. An ndbd process, which stores a replica —that is, a copy of the partition (see below) assigned to the node group of which the node is a member.

Each data node should be located on a separate computer. While it is also possible to host multiple ndbd processes on a single computer, such a configuration is not supported.

It is common for the terms “node” and “data node” to be used interchangeably when referring to an ndbd process; where mentioned, management nodes (ndb_mgmd processes) and SQL nodes (mysqld processes) are specified as such in this discussion.

Node Group. A node group consists of one or more nodes, and stores partitions, or sets of replicas (see next item).

The number of node groups in a MySQL Cluster is not directly configurable; it is a function of the number of data nodes and of the number of replicas (NoOfReplicas configuration parameter), as shown here:

\[
\text{number of node groups} = \frac{\text{number of data nodes}}{\text{NoOfReplicas}}
\]

Thus, a MySQL Cluster with 4 data nodes has 4 node groups if NoOfReplicas is set to 1 in the config.ini file, 2 node groups if NoOfReplicas is set to 2, and 1 node group if NoOfReplicas is set to 4. Replicas are discussed later in this section; for more information about NoOfReplicas, see Section 17.3.3.6, “Defining MySQL Cluster Data Nodes”.

Note
All node groups in a MySQL Cluster must have the same number of data nodes.

Prior to MySQL Cluster NDB 7.0, it was not possible to add new data nodes to a MySQL Cluster without shutting down the cluster completely and reloading all of its data. In MySQL Cluster NDB 7.0 (beginning with MySQL Cluster version NDB 6.4.0), you can add new node groups (and thus new data nodes) to a running MySQL Cluster—see Section 17.5.13, “Adding MySQL Cluster Data Nodes Online”, for information about how this can be done.

Partition. This is a portion of the data stored by the cluster. There are as many cluster partitions as nodes participating in the cluster. Each node is responsible for keeping at least one copy of any partitions assigned to it (that is, at least one replica) available to the cluster.

A replica belongs entirely to a single node; a node can (and usually does) store several replicas.

NDB and user-defined partitioning. MySQL Cluster normally partitions NDBCLUSTER tables automatically. However, in MySQL 5.1 and later MySQL Cluster releases, it is possible to employ user-defined partitioning with NDBCLUSTER tables. This is subject to the following limitations:

1. Only the KEY and LINEAR KEY partitioning schemes are supported in production with NDB tables.

2. When using ndbd, the maximum number of partitions that may be defined explicitly for any NDB table is \(8 \times \text{[number of node groups]}\). (The number of node groups in a MySQL Cluster is determined as discussed previously in this section.)

When using ndbmtd, this maximum is also affected by the number of local query handler threads, which is determined by the value of the MaxNoOfExecutionThreads configuration parameter.
In such cases, the maximum number of partitions that may be defined explicitly for an NDB table is equal to \(4 \times \text{MaxNoOfExecutionThreads} \times \text{[number of node groups]}\).

See Section 17.4.3, “ndbmt — The MySQL Cluster Data Node Daemon (Multi-Threaded)”, for more information.

For more information relating to MySQL Cluster and user-defined partitioning, see Section 17.1.6, “Known Limitations of MySQL Cluster”, and Section 18.5.2, “Partitioning Limitations Relating to Storage Engines”.

**Replica.** This is a copy of a cluster partition. Each node in a node group stores a replica. Also sometimes known as a partition replica. The number of replicas is equal to the number of nodes per node group.

The following diagram illustrates a MySQL Cluster with four data nodes, arranged in two node groups of two nodes each; nodes 1 and 2 belong to node group 0, and nodes 3 and 4 belong to node group 1. Note that only data (ndbd) nodes are shown here; although a working cluster requires an ndb_mgm process for cluster management and at least one SQL node to access the data stored by the cluster, these have been omitted in the figure for clarity.

**Figure 17.2 MySQL Cluster with Two Node Groups**

The data stored by the cluster is divided into four partitions, numbered 0, 1, 2, and 3. Each partition is stored—in multiple copies—on the same node group. Partitions are stored on alternate node groups as follows:

- Partition 0 is stored on node group 0; a primary replica (primary copy) is stored on node 1, and a backup replica (backup copy of the partition) is stored on node 2.

- Partition 1 is stored on the other node group (node group 1); this partition's primary replica is on node 3, and its backup replica is on node 4.

- Partition 2 is stored on node group 0. However, the placing of its two replicas is reversed from that of Partition 0; for Partition 2, the primary replica is stored on node 2, and the backup on node 1.
• Partition 3 is stored on node group 1, and the placement of its two replicas are reversed from those of partition 1. That is, its primary replica is located on node 4, with the backup on node 3.

What this means regarding the continued operation of a MySQL Cluster is this: so long as each node group participating in the cluster has at least one node operating, the cluster has a complete copy of all data and remains viable. This is illustrated in the next diagram.

**Figure 17.3 Nodes Required for a 2x2 Cluster**

In this example, where the cluster consists of two node groups of two nodes each, any combination of at least one node in node group 0 and at least one node in node group 1 is sufficient to keep the cluster “alive” (indicated by arrows in the diagram). However, if both nodes from either node group fail, the remaining two nodes are not sufficient (shown by the arrows marked out with an X); in either case, the cluster has lost an entire partition and so can no longer provide access to a complete set of all cluster data.

### 17.1.3 MySQL Cluster Hardware, Software, and Networking Requirements

One of the strengths of MySQL Cluster is that it can be run on commodity hardware and has no unusual requirements in this regard, other than for large amounts of RAM, due to the fact that all live data storage is done in memory. (It is possible to reduce this requirement using Disk Data tables—see Section 17.5.12, “MySQL Cluster Disk Data Tables”, for more information about these.) Naturally, multiple and faster CPUs can enhance performance. Memory requirements for other MySQL Cluster processes are relatively small.

The software requirements for MySQL Cluster are also modest. Host operating systems do not require any unusual modules, services, applications, or configuration to support MySQL Cluster. For supported operating systems, a standard installation should be sufficient. The MySQL software requirements are simple: all that is needed is a production release of MySQL Cluster. It is not strictly necessary to compile MySQL yourself merely to be able to use MySQL Cluster. We assume that you are using the binaries appropriate to your platform, available from the MySQL Cluster software downloads page at http://dev.mysql.com/downloads/cluster/.

For communication between nodes, MySQL Cluster supports TCP/IP networking in any standard topology, and the minimum expected for each host is a standard 100 Mbps Ethernet card, plus a switch, hub, or router to provide network connectivity for the cluster as a whole. We strongly recommend that a MySQL Cluster be run on its own subnet which is not shared with machines not forming part of the cluster for the following reasons:
• Security. Communications between MySQL Cluster nodes are not encrypted or shielded in any way. The only means of protecting transmissions within a MySQL Cluster is to run your MySQL Cluster on a protected network. If you intend to use MySQL Cluster for Web applications, the cluster should definitely reside behind your firewall and not in your network’s De-Militarized Zone (DMZ) or elsewhere.

See Section 17.5.11.1, “MySQL Cluster Security and Networking Issues”, for more information.

• Efficiency. Setting up a MySQL Cluster on a private or protected network enables the cluster to make exclusive use of bandwidth between cluster hosts. Using a separate switch for your MySQL Cluster not only helps protect against unauthorized access to MySQL Cluster data, it also ensures that MySQL Cluster nodes are shielded from interference caused by transmissions between other computers on the network. For enhanced reliability, you can use dual switches and dual cards to remove the network as a single point of failure; many device drivers support failover for such communication links.

Network communication and latency. MySQL Cluster requires communication between data nodes and API nodes (including SQL nodes), as well as between data nodes and other data nodes, to execute queries and updates. Communication latency between these processes can directly affect the observed performance and latency of user queries. In addition, to maintain consistency and service despite the silent failure of nodes, MySQL Cluster uses heartbeating and timeout mechanisms which treat an extended loss of communication from a node as node failure. This can lead to reduced redundancy. Recall that, to maintain data consistency, a MySQL Cluster shuts down when the last node in a node group fails. Thus, to avoid increasing the risk of a forced shutdown, breaks in communication between nodes should be avoided wherever possible.

The failure of a data or API node results in the abort of all uncommitted transactions involving the failed node. Data node recovery requires synchronization of the failed node’s data from a surviving data node, and re-establishment of disk-based redo and checkpoint logs, before the data node returns to service. This recovery can take some time, during which the Cluster operates with reduced redundancy.

Heartbeating relies on timely generation of heartbeat signals by all nodes. This may not be possible if the node is overloaded, has insufficient machine CPU due to sharing with other programs, or is experiencing delays due to swapping. If heartbeat generation is sufficiently delayed, other nodes treat the node that is slow to respond as failed.

This treatment of a slow node as a failed one may or may not be desirable in some circumstances, depending on the impact of the node’s slowed operation on the rest of the cluster. When setting timeout values such as HeartbeatIntervalDbDb and HeartbeatIntervalDbApi for MySQL Cluster, care must be taken to achieve quick detection, failover, and return to service, while avoiding potentially expensive false positives.

Where communication latencies between data nodes are expected to be higher than would be expected in a LAN environment (on the order of 100 µs), timeout parameters must be increased to ensure that any allowed periods of latency periods are well within configured timeouts. Increasing timeouts in this way has a corresponding effect on the worst-case time to detect failure and therefore time to service recovery.

LAN environments can typically be configured with stable low latency, and such that they can provide redundancy with fast failover. Individual link failures can be recovered from with minimal and controlled latency visible at the TCP level (where MySQL Cluster normally operates). WAN environments may offer a range of latencies, as well as redundancy with slower failover times. Individual link failures may require route changes to propagate before end-to-end connectivity is restored. At the TCP level this can appear as large latencies on individual channels. The worst-case observed TCP latency in these scenarios is related to the worst-case time for the IP layer to reroute around the failures.

SCI support. It is also possible to use the high-speed Scalable Coherent Interface (SCI) with MySQL Cluster, but this is not a requirement. See Section 17.3.4, “Using High-Speed Interconnects with MySQL Cluster”, for more about this protocol and its use with MySQL Cluster.
17.1.4 MySQL Cluster Development History

In this section, we discuss changes in the implementation of MySQL Cluster in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x, as compared to earlier MySQL Cluster releases.

There are a number of significant changes in the implementation of the NDBCLUSTER storage engine in mainline MySQL 5.1 releases up to and including MySQL 5.1.23 as compared to that in MySQL 5.0; MySQL Cluster NDB 6.x and 7.x make further changes and improvements in MySQL Cluster in addition to these. The changes and features most likely to be of interest are shown in the following tables:

### MySQL Cluster NDB 7.2
- Distribution of MySQL users and privileges across MySQL Cluster SQL nodes
- Distributed pushed-down joins, with greatly improved performance for many joins that can thus be pushed down and executed in parallel on the data nodes.
- Improved default values for data node configuration parameters.

### MySQL Cluster NDB 7.1
- Production-level support for MySQL Cluster on Microsoft Windows platforms.
  - ndbinfo meta-information database
  - MySQL Cluster Connector for Java, including ClusterJ and OpenJPA (ClusterJPA) support
  - Native support for default column values

### MySQL Cluster NDB 7.0
- Multi-threaded data nodes (ndbmtd data node daemon)
- Online addition of data nodes; online data redistribution
- MySQL on Windows (alpha; source releases only)
- Configuration cache
- Backup snapshots (`START BACKUP ... SNAPSHOTSTART, START BACKUP ... SNAPSHOTEND` commands)
- IPv6 support for geo-replication
- Protected DDL operations
- Dynamic buffering for NDB transporters
- Increased flexibility in determining arbitration handling, using a new `Arbitration` data node configuration parameter
- NDB API counters and associated status variables, which make it possible to observe the API-level effects of SQL statements on NDB tables from the `mysql` client.

### MySQL Cluster NDB 6.3
- Conflict detection and resolution for multi-master replication
- Compressed backups and local checkpoints
- Support for `OPTIMIZE TABLE`
- Parallel data node recovery
- Enhanced transaction coordinator selection
- Improved SQL statement performance metrics
- Transaction batching
MySQL Cluster Development History

MySQL Cluster NDB 6.3
- ndb_restore attribute promotion
- Support for epoll (Linux only)
- Distribution awareness
  - NDB thread locks; realtime extensions for multiple CPUs

MySQL Cluster NDB 6.2
- Improved backup status reporting (BackupReportFrequency, REPORT BackupStatus)
- Multiple connections per SQL node
- Data access with NdbRecord (NDB API)
- REPORT MemoryUsage command
- Memory allocation improvements
- Management client connection control
- Micro-GCPs
- Online ADD COLUMN; improved online index creation

MySQL Cluster NDB 6.1
- Greater number of cluster nodes
- Disabling of arbitration
- Additional DUMP commands
- Faster Disk Data backups
- Batched slave updates

MySQL 5.1 (through 5.1.23)
- MySQL Cluster Replication
- Disk Data storage
- Variable-size columns
- User-defined partitioning
- Autodiscovery of table schema changes
- Online adding and dropping of indexes

17.1.4.1 What is New in MySQL Cluster NDB 7.2.0

The following improvements to MySQL Cluster were made in MySQL Cluster NDB 7.2.0.

- **Distribution of MySQL users and privileges.** Automatic distribution of MySQL users and privileges across all SQL nodes in a given MySQL Cluster is now supported. To enable this support, you must first import an SQL script share/mysql/ndb_dist_priv.sql that is included with the MySQL Cluster NDB 7.2 distribution. This script creates several stored procedures which you can use to enable privilege distribution and perform related tasks.

  When a new MySQL Server joins a MySQL Cluster where privilege distribution is in effect, it also participates in the privilege distribution automatically.

  Once privilege distribution is enabled, all changes to the grant tables made on any mysqlld attached to the cluster are immediately available on any other attached MySQL Servers. This is true whether the changes are made using CREATE USER, GRANT, or any of the other statements described...
elsewhere in this Manual (see Section 13.7.1, “Account Management Statements”). This includes privileges relating to stored routines and views; however, automatic distribution of the views or stored routines themselves is not currently supported.

For more information, see Section 17.5.14, “Distributed MySQL Privileges for MySQL Cluster”.

• Distributed pushed-down joins. Many joins can now be pushed down to the NDB kernel for processing on MySQL Cluster data nodes. Previously, a join was handled in MySQL Cluster by means of repeated accesses of NDB by the SQL node; however, when pushed-down joins are enabled, a pushable join is sent in its entirety to the data nodes, where it can be distributed among the data nodes and executed in parallel on multiple copies of the data, with a single, merged result being returned to mysqld. This can reduce greatly the number of round trips between an SQL node and the data nodes required to handle such a join, leading to greatly improved performance of join processing.

It is possible to determine when joins can be pushed down to the data nodes by examining the join with EXPLAIN. A number of new system status variables (Ndb_pushed_queries_defined, Ndb_pushed_queries_dropped, Ndb_pushed_queries_executed, and Ndb_pushed_reads) and additions to the counters table (in the ndbinfo information database) can also be helpful in determining when and how well joins are being pushed down.

More information and examples are available in the description of the ndb_join_pushdown server system variable. See also the description of the status variables referenced in the previous paragraph, as well as Section 17.5.10.7, “The ndbinfo counters Table”.

• Improved default values for data node configuration parameters. In order to provide more resiliency to environmental issues and better handling of some potential failure scenarios, and to perform more reliably with increases in memory and other resource requirements brought about by recent improvements in join handling by NDB, the default values for a number of MySQL Cluster data node configuration parameters have been changed. The parameters and changes are described in the following list:

  • HeartbeatIntervalDbDb: Default increased from 1500 ms to 5000 ms.
  • ArbitrationTimeout: Default increased from 3000 ms to 7500 ms.
  • TimeBetweenEpochsTimeout: Now effectively disabled by default (default changed from 4000 ms to 0).
  • SharedGlobalMemory: Default increased from 20 MB to 128 MB.
  • MaxParallelScansPerFragment: Default increased from 32 to 256.

In addition, the value computed for MaxNoOfLocalScans when this parameter is not set in config.ini has been increased by a factor of 4.

MySQL Cluster NDB 7.2.1 and later MySQL Cluster NDB 7.2 releases are based on MySQL Server 5.5 and are not covered here. See MySQL Cluster NDB 7.2.

17.1.4.2 What is New in MySQL Cluster NDB 7.1

The following improvements to MySQL Cluster have been made in MySQL Cluster NDB 7.1.

• MySQL Cluster information database (ndbinfo). The ndbinfo information database makes it possible to obtain real-time characteristics of a MySQL Cluster by issuing queries from the mysql client or other MySQL client applications. ndbinfo provides metadata specific to MySQL Cluster similarly to how the INFORMATION_SCHEMA database provides metadata for the standard MySQL Server. This eliminates much of the need to read log files, issue REPORT or DUMP commands in the ndb_mgm client, or parse the output of ndb_config in order to get configuration and status information from a running MySQL Cluster.
For more information, see Section 17.5.10, “The ndbinfo MySQL Cluster Information Database”.

- **Java connectors for MySQL Cluster.** The MySQL Cluster distribution now includes 2 new Java user APIs, ClusterJ and ClusterJPA. ClusterJ is an object-relational interface in a manner similar to that of Java persistence frameworks such as Hibernate. Cluster JPA is a reimplementa		ion of OpenJPA. ClusterJ uses a backend library (NdbJTie) that provides access to the NDB storage engine without using a MySQL Server connection or JDBC. ClusterJPA also uses NdbJTie when it improves performance, but can also process complex queries using JDBC and a MySQL Server connection, where it can take advantage of the MySQL query optimizer.

ClusterJ and Cluster JPA can also be made to work with recent MySQL Cluster NDB 7.0 releases although the necessary library and JAR files are included only in MySQL Cluster NDB 7.1.1 and later.

For more information about using ClusterJ and ClusterJPA, see MySQL Cluster Connector for Java.

- **New CHANGE MASTER TO option for circular replication.** Beginning with MySQL Cluster NDB 7.1.0, the CHANGE MASTER TO statement supports an IGNORE_SERVER_IDS option which takes a comma-separated list of server IDs and causes events originating from the corresponding servers to be ignored. (Log rotation and log deletion events are preserved.)

See Section 13.4.2.1, “CHANGE MASTER TO Syntax”, as well as Section 13.7.5.36, “SHOW SLAVE STATUS Syntax”, for more information.

- **Native support for default column values.** Starting with MySQL Cluster NDB 7.1.4, default values for table columns are stored in the NDB kernel rather than by the MySQL server as was done previously. This means that inserts on tables having column value defaults can be smaller and faster than before, because less data must be sent from SQL nodes to NDBCLUSTER.

Tables created using previous MySQL Cluster releases can still be used in MySQL Cluster 7.1.4 and later; however, they do not support native default values until they are upgraded. You can upgrade a table with non-native default values to support native default values using an offline ALTER TABLE statement.

- **MySQL Cluster on Windows (Production).** Beginning with MySQL Cluster NDB 7.1.3, MySQL Cluster is available for production use on Microsoft Windows operating systems; MySQL Cluster NDB 7.1 binaries for Windows can be obtained from http://dev.mysql.com/downloads/cluster/.

Features and behavior are generally comparable to those found on previously supported platforms such as Linux and Solaris. However, you must install the binaries manually.

Beginning with MySQL Cluster NDB 7.1.5, MySQL Cluster processes can be run as Windows services.

If you wish to build MySQL Cluster from source on Windows, you must configure the build using the WITH_NDBCLUSTER_STORAGE_ENGINE option. For more information, see Section 2.11.7, “Installing MySQL from Source on Windows”.

- **--nowait-nodes option for management servers.** It is now possible to configure a cluster with two management servers, but to start the cluster using only one of them by starting the management node daemon with the --nowait-nodes option. The other management server can then be started at a later time to join the running MySQL Cluster.

- **Improved lock handling for primary key lookups on BLOB tables.** A MySQL Cluster table stores all but the first 256 bytes of any BLOB or TEXT column values in a separate BLOB table; when executing queries against such tables, a shared lock is obtained. Prior to MySQL Cluster NDB 7.1.1, when the query used a primary key lookup and took place within a transaction, the lock was held for the duration of the transaction, even after no more data was being read from the NDB table. Now in such cases, the lock is released when all BLOB data associated with the table has been read. (Bug #49190)
A shared lock is also taken for unique key lookups; it is still the case that this lock is held for the duration of the transaction.

• **Heartbeat thread policy and priority.** Beginning with MySQL Cluster NDB 7.1.2, a new configuration parameter `HeartbeatThreadPriority` makes it possible to set the policy and the priority for the heartbeat thread on management and API nodes.

• **Improved access to partitioning information.** The `ndb_desc` utility now provides additional information about the partitioning of data stored in MySQL Cluster. Beginning with MySQL Cluster NDB 7.1.2, the `--blob-info` option causes this program to include partition information for BLOB tables in its output. Also beginning with MySQL Cluster NDB 7.1.2, the `--extra-node-info` option causes `ndb_desc` to include information about data distribution (that is, which table fragments are stored on which data nodes). Each of these options also requires the use of the `--extra-partition-info` option.

Information about partition-to-node mappings can also be obtained using the `Table::getFragmentNodes()` method, also added in MySQL Cluster NDB 7.1.2.

• **Replication attribute promotion and demotion.** Beginning with MySQL Cluster NDB 7.1.3, MySQL Cluster Replication supports attribute promotion and demotion when replicating between columns of different but similar types on the master and the slave. For example, it is possible to promote an `INT` column on the master to a `BIGINT` column on the slave, and to demote a `TEXT` column to a `VARCHAR` column.

The implementation of type demotion distinguishes between lossy and non-lossy type conversions, and their use on the slave can be controlled by setting the `slave_type_conversions` global server system variable.

For more information, see Attribute promotion and demotion (MySQL Cluster).

• **Change in ndbinfo database.** The experimental `pools` table was removed from `ndbinfo` in MySQL Cluster NDB 7.1.3. Applications which used this table can and should be rewritten to use other `ndbinfo` tables.

• **Configuration caching control.** Beginning with MySQL Cluster NDB 7.1.4, it is possible to disable the management server’s configuration cache using the `--config-cache` option, which forces `ndb_mgmd` to read its configuration data from the `config.ini` configuration file every time it starts. For more information about configuration caching and this option, see Section 17.3.3, "MySQL Cluster Configuration Files". See also Section 17.4.4, "ndb_mgmd — The MySQL Cluster Management Server Daemon".

• **Incompatible change in NDB API event reporting.** Beginning with MySQL Cluster NDB 7.1.4, DDL events are no longer reported on `Event` objects by default. Instead the desired level of event reporting (`EventReport` value) must be set explicitly using `Event::setReport()`.

• **Number of table attributes.** Beginning with MySQL Cluster NDB 7.1.4, the maximum number of attributes (columns plus indexes) per table has been increased from 128 to 512.

• **InnoDB support in commercial binaries.** Beginning with MySQL Cluster NDB 7.1.4b, all commercial binary releases of MySQL Cluster provide support for the InnoDB storage engine.

• **Heartbeat ordering.** Beginning with MySQL Cluster NDB 7.1.5, it is possible to set a specific order for transmission of heartbeats between data nodes, using the `HeartbeatOrder` data node configuration parameter introduced in this version. This parameter can be useful in situations where multiple data nodes are running on the same host and a temporary disruption in connectivity between hosts would otherwise cause the loss of a node group (and thus failure of the cluster).

• **Relaxed ndb_restore column comparison rules.** When restoring data, `ndb_restore` compares the attributes of a column for equality with the definition of the column in the target table. However,
not all of these attributes need to be the same for ndb_restore to be meaningful, safe and useful. Beginning with MySQL Cluster NDB 7.1.5, ndb_restore automatically ignores differences in certain column attributes which do not necessarily have to match between the version of the column in a backup and the version of that column in the MySQL Cluster to which the column data is being restored. These attributes include the following:

- COLUMN_FORMAT setting (FIXED, DYNAMIC, or DEFAULT)
- STORAGE setting (MEMORY or DISK)
- The default value
- The distribution key

In such cases, ndb_restore reports any such differences to minimize any chance of user error.

- **Storage of user data in anyValue.** When writing NDB events to the binary log, MySQL Cluster uses OperationOptions::anyValue to store the server ID. Beginning with MySQL Cluster NDB 7.1.6, it is possible to store user data from an NDB API application in part of the anyValue when mysqld has been started with the --server-id-bits option set to a nondefault value. Also beginning with MySQL Cluster NDB 7.1.6, it is possible to view this data in the output of mysqlbinlog, for which its own --server-id-bits option is added.

- **--add-drop-trigger option for mysqldump.** Beginning with MySQL Cluster NDB 7.1.8, this option can be used to force all CREATE TRIGGER statements in mysqldump output to be preceded by a DROP TRIGGER IF EXISTS statement.

- **Forcing node shutdown and restart.** In MySQL Cluster NDB 7.1.8 and later, it is possible using the ndb_mgm management client or the MGM API to force a data node shutdown or restart even if this would force the shutdown or restart of the entire cluster. In the management client, this is implemented through the addition of the -f (force) option to the STOP and RESTART commands. For more information, see Section 17.5.2, “Commands in the MySQL Cluster Management Client”. The MGM API also adds two new methods for forcing such a node shutdown or restart; see ndb_mgm_stop4() , and ndb_mgm_restart4() , for more information about these methods.

- **Disk Data usage statistics (diskpagebuffer table).** MySQL Cluster 7.1.9 introduces a new table in the ndbinfo information database. The diskpagebuffer table provides real-time data on disk page buffer usage. These statistics can be used to monitor performance of MySQL Cluster Disk Data read and write operations, and can prove useful in the tuning of Disk Data parameters such as DiskPageBufferMemory.

- **InnoDB Plugin support.** Beginning with MySQL Cluster NDB 7.1.9, the MySQL Server supplied with MySQL Cluster supports the InnoDB Plugin. For more information about enabling the plugin if you are building MySQL Cluster from source, see Section 17.2, “MySQL Cluster Installation and Upgrades”.

- **Note**
  Due to a packaging issue, the InnoDB plugin was not included in RPMs for MySQL Cluster NDB 7.1.9; this issue was corrected in MySQL Cluster NDB 7.1.9a. (Bug #58283)

- **TimeBetweenEpochsTimeout and GCP stop control.** Beginning with MySQL Cluster NDB 7.1.10, it is possible to disable GCP stops by setting TimeBetweenEpochsTimeout to 0. In addition, a warning is written to the cluster log whenever the time required for a GCP save exceeds 60 seconds or the time required for a GCP commit exceeds 10 seconds. This warning includes a report of the current value of TimeBetweenEpochsTimeout. For more information, see Disk Data and GCP Stop errors.

- **Skipping corrupted tables in NDB native backups.** Beginning with MySQL Cluster NDB 7.1.10, you can cause ndb_restore to ignore tables that are corrupted due to missing blob parts tables by
using the --skip-broken-objects option. When this option is used, such tables are skipped, and the restoration of any remaining uncorrupted tables in the backup continues.

• **BLOB read and write batching.** Beginning with MySQL Cluster NDB 7.1.10, it is possible to control batching of BLOB read and write operations. For SQL nodes, this can be done using the --ndb-blob-read-batch-bytes and --ndb-blob-write-batch-bytes options for mysqld. In NDB API applications, you can control batching of BLOB reads and writes using the NdbTransaction methods setMaxPendingBlobReadBytes(), getMaxPendingBlobReadBytes(), setMaxPendingBlobWriteBytes(), and getMaxPendingBlobWriteBytes().

• **Restoring from a NDB native backup to a differently-named database.** MySQL Cluster NDB 7.1.11 adds a new --rewrite-database option to ndb_restore, which makes it possible to restore to a database having a different name from that of the database in the backup. The option can be used multiple times, and it is possible to restore from more than one source database in the backup to a single target database (although no protection against table or other object name collision is provided).

See Section 17.4.20, "ndb_restore — Restore a MySQL Cluster Backup", for more information.

• **Selective over-commit handling.** Beginning with MySQL Cluster NDB 7.1.10, it is possible to exercise more direct control over uncommitted operations from transactions aborted due to timeouts flushing redo logs to disk. This is implemented using three configuration parameters added in this version of MySQL Cluster: the data node configuration parameters RedoOverCommitCounter and RedoOverCommitLimit, and the API node configuration parameter DefaultOperationRedoProblemAction.

When an attempt to flush a given redo log takes longer than RedoOverCommitLimit seconds, and this occurs RedoOverCommitLimit times or more, the transactions contained within the redo log are aborted. Any operations left uncommitted as a result are either aborted or re-tried, according to the value of DefaultOperationRedoProblemAction.

For more information, see Redo log over-commit handling

• **INFORMATION_SCHEMA improvements.** Beginning with MySQL Cluster NDB 7.1.11, Beginning with MySQL Cluster NDB 7.0.22, INFORMATION_SCHEMA provides disk usage information for MySQL Cluster Disk Data tables. Previously, INFORMATION_SCHEMA.TABLES showed only the space usage for the in-memory data part of the table. Now, it also shows the space allocated for and used by the disk_part data of that table as well.

In addition, the INFORMATION_SCHEMA.PARTITIONS table (which did not show any statistics for NDB tables) now shows correct values in this table's TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH, MAX_DATA_LENGTH, and DATA_FREE columns, for each partition.

• **ndb_restore attribute demotion.** Beginning with MySQL Cluster NDB 7.1.11, it is possible to enable attribute demotion when restoring a MySQL Cluster from a native backup running ndb_restore with a new --lossy-conversions option.

In general, the rules governing demotion are the same as for MySQL replication, although there are some exceptions that you may need to take into account being employing this option. See Replication of Columns Having Different Data Types, for information about type conversions currently supported by attribute promotion and demotion in MySQL Cluster.

• **Improved multi-threaded order index building.** Previously, it was not possible to enable multi-threaded building of ordered indexes during initial restarts. In MySQL Cluster NDB 7.1.11, this can now be done, using the new TwoPassInitialNodeRestartCopy data node configuration parameter.

• **Configuration version information in ndbinfo.nodes.** You can see which version or versions of the MySQL Cluster configuration file are in effect on the data nodes by checking the config_generation column which is added to the nodes table in MySQL Cluster NDB 7.1.13.
 MySQL Cluster Development History

• **Configuration version information in ndbinfo.nodes.** You can see which version or versions of the MySQL Cluster configuration file are in effect on the data nodes by checking the `config_generation` column which is added to the `nodes` table in MySQL Cluster NDB 7.1.13.

• **Improvements in adding data nodes online.** Beginning with MySQL Cluster NDB 7.0.24, it is possible to add data nodes online to a running MySQL Cluster without performing a rolling restart of the cluster or starting data node processes with the `--nowait-nodes` option. This can be done by setting `Nodegroup = 65536` in the `config.ini` file for any data nodes that should be started at a later time, when first starting the cluster. The amount of time the cluster waits before doing this can be controlled using the `StartNoNodeGroupTimeout` data node configuration parameter.

• **Unique key updates in replication.** It is possible in MySQL Cluster NDB 7.1.14 and later to employ operations that update unique keys when replicating NDB tables. Previously this could lead to duplicate key errors when trying to execute the binary log (due to the fact that row events in the binary log were ordered according to the partitioning of the base table, and could differ in order within the epoch for that in which they were executed).

  Important

  Master and slave tables must both be using the NDB storage engine for this to work.

• Starting with MySQL Cluster NDB 7.1.17, the NDB kernel implements a number of statistical counters relating to actions performed by or affecting Ndb objects. Such events include starting, closing, and aborting transactions; operations using primary keys or unique keys; table, range, and pruned scans; blocking of threads by incomplete operations; and data and events sent and received by MySQL Cluster nodes. NDB API statistics counters are incremented inside the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes. A MySQL Server running as an SQL node in the cluster can access the values of these counters as system status variables, as seen in the output of `SHOW STATUS`, or in the results of queries against the `SESSION_STATUS` or `GLOBAL_STATUS` table in the `INFORMATION_SCHEMA` database. By comparing the values of these status variables before and after the execution of statements affecting NDB tables, you can observe the corresponding actions taken on the NDB API level. This can be highly useful when monitoring and tuning MySQL Cluster.

  For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”. See also MySQL Cluster Status Variables, for information about the individual status variables.

• **Version 2 binary log row events.** New versions of the `WRITE_ROW`, `UPDATE_ROW`, and `DELETE_ROW` events have been implemented in MySQL Cluster NDB 7.1.16, extending them with additional information intended to support future enhancements; these are referred to as “Version 2” binary log events.

  Version 2 log events are not backward compatible, and cannot be read by older slaves. A new `mysqld` option `--log-bin-use-v1-row-events` can be employed to force use of Version 1 events when writing the binary log. This can be used during upgrades to make a newer `mysqld` generate Version 1 binary log events that can be read by older slaves.

• **Circular replication: Primary wins first conflict detection.** Two new conflict detection functions `NDB$EPOCH()` and `NDB$EPOCH_TRANS()` can be useful in “active-active” circular replication scenarios with two MySQL Clusters. For each case, we designate one cluster as primary and one as secondary, and implement a “primary always wins” rule for determining whether to accept conflicting changes. When using `NDB$EPOCH()`, conflicting rows on the secondary are realigned with those on the primary; when using `NDB$EPOCH_TRANS()`, it is transactions containing rows in conflict (and any transactions which depend on them) on the secondary that are realigned.

  When using `NDB$EPOCH_TRANS()` as the conflict detection function, the binary log must be written using Version 2 binary logging row events; that is, the `mysqld` processes on both the primary and the secondary must be started with `--log-bin-use-v1-row-events=0`. In addition, the...
secondary’s binary log must include transaction IDs for all rows, that is, by setting `--ndb-log-transaction-id=1`.

You can monitor conflict detection and resolution performed using these functions by reading a number of related server status variables, including `Ndb_conflict_fn_epoch`, `Ndb_conflict_fn_epoch_trans`, and `Ndb_conflict_trans_row_conflict_count` (among others). See MySQL Cluster Status Variables.

For more information, see Section 17.6.11, “MySQL Cluster Replication Conflict Resolution”.

- **Fail-fast data node capability.** Beginning with MySQL Cluster NDB 7.1.17, it is possible to enable fail-fast behavior for data nodes by enabling the `CrashOnCorruptedTuple` configuration parameter introduced in this version (disabled by default). Doing so causes data nodes to fail whenever they detect a corrupted tuple.

- **Rows per partition limit removed.** Previously it was possible to store a maximum of 46137488 rows in a single MySQL Cluster partition—that is, per data node. Beginning with MySQL Cluster NDB 7.0.36 and MySQL Cluster NDB 7.1.25, this limitation has been lifted, and there is no longer any practical upper limit to this number. (Bug #13844405, Bug #14000373)

MySQL Cluster NDB 7.1 is also supported by MySQL Cluster Manager, which provides an advanced command-line interface that can simplify many complex MySQL Cluster management tasks. See MySQL™ Cluster Manager 1.3.6 User Manual, for more information.

### 17.1.4.3 What is New in MySQL Cluster NDB 7.0

The following list provides an overview of significant feature additions and changes made in MySQL Cluster NDB 7.0. For more detailed information about all feature changes and bugfixes made in MySQL Cluster NDB 7.0, see [http://dev.mysql.com/doc/relnotes/mysql-cluster/7.1/en/mysql-cluster-news-7-0.html](http://dev.mysql.com/doc/relnotes/mysql-cluster/7.1/en/mysql-cluster-news-7-0.html).

---

**Important**

Early development versions of MySQL Cluster NDB 7.0 were known as “MySQL Cluster NDB 6.4”, and the first four releases in this series were identified as MySQL Cluster NDB 6.4.0 through 6.4.3. Any information relating to these MySQL Cluster NDB 6.4.x releases appearing in this documentation apply to MySQL Cluster NDB 7.0.

MySQL Cluster NDB 7.0.4 is the fifth MySQL Cluster NDB 7.0 release; it is the successor to MySQL Cluster NDB 6.4.3.

- **MySQL Cluster on Windows (alpha).** MySQL Cluster NDB 7.0 is available on an experimental basis for Windows operating systems (for production use on Windows, you should use MySQL Cluster NDB 7.1.3 or later). Features and behavior comparable to those found on platforms that are already supported—such as Linux and Solaris—are planned for MySQL Cluster on Windows. In MySQL Cluster NDB 7.0, you must build from source (Windows binaries are available for MySQL Cluster NDB 7.1 releases). To enable MySQL Cluster support on Windows when building from source, you must configure the build using the `WITH_NDBCLUSTER_STORAGE_ENGINE` option. For more information, see Section 2.11.7, “Installing MySQL from Source on Windows”.

- **Ability to add nodes and node groups online.** Beginning with MySQL Cluster NDB 6.4.0, it is possible to add new node groups (and thus new data nodes) to a running MySQL Cluster without shutting down and reloading the cluster. As part of enabling this feature, a new command `CREATE NODEGROUP` has been added to the cluster management client and the functionality of the `ALTER ONLINE TABLE ... REORGANIZE PARTITION` SQL statement has been extended. For more information, see Section 17.5.13, “Adding MySQL Cluster Data Nodes Online”.

- **Data node multi-threading support.** Beginning with MySQL Cluster NDB 6.4.0, a multi-threaded version of the data node daemon, named `ndbmtd`, is available for use on data node hosts.
with multiple CPU cores. This binary is built automatically when compiling with MySQL Cluster support; no additional options other than those needed to provide MySQL Cluster support are needed when configuring the build. In most respects, ndbmtd functions in the same way as ndbd, and can use the same command-line options and configuration parameters. In addition, the new MaxNoOfExecutionThreads configuration parameter can be used to determine the number of data node process threads for ndbmtd. For more information, see Section 17.4.3, “ndbmtd — The MySQL Cluster Data Node Daemon (Multi-Threaded)”.

Note

Disk Data tables are not yet supported for use with ndbmtd.

• Configuration cache. Formerly, MySQL Cluster configuration was stateless—that is, configuration information was reloaded from the cluster's global configuration file (usually config.ini) each time ndb_mgmd was started. Beginning with MySQL Cluster NDB 6.4.0, the cluster’s configuration is cached internally, and the global configuration file is no longer automatically re-read when the management server is restarted. This behavior can be controlled using the management server options --configdir, --initial, and --reload. In MySQL Cluster NDB 7.0.15 and later, the configuration cache can be disabled using the --config-cache option. For more information about these changes, see Section 17.3.3, “MySQL Cluster Configuration Files”. For more information about the new management server options, see Section 17.4.4, “ndb_mgmd — The MySQL Cluster Management Server Daemon”.

• Detection of NDB API client connection errors. In MySQL Cluster NDB 7.0 (6.4.0 and later releases), the NDB API's Ndb_cluster_connection class adds the get_latest_error() and get_latest_error_msg() methods for catching and diagnosing problems with NDB API client connections.

• Snapshot options for backups. Beginning with MySQL Cluster NDB 6.4.0, you can determine when performing a cluster backup whether the backup matches the state of the data when the backup was started or when it was completed, using the new options SNAPSHOTSTART and SNAPSHOTEND for the management client's START BACKUP command. See Section 17.5.3.2, “Using The MySQL Cluster Management Client to Create a Backup”, for more information.

• Dynamic NDB transporter send buffer memory allocation. Previously, the NDB kernel used a fixed-size send buffer for every data node in the cluster, which was allocated when the node started. Because the size of this buffer could not be changed after the cluster was started, it was necessary to make it large enough in advance to accommodate the maximum possible load on any transporter socket. However, this was an inefficient use of memory, since much of it often went unused. Beginning with MySQL Cluster NDB 6.4.0, send buffer memory is allocated dynamically from a memory pool shared between all transporters, which means that the size of the send buffer can be adjusted as necessary. This change is reflected by the addition of the configuration parameters TotalSendBufferMemory, ReservedSendBufferMemory, and OverLoadLimit, as well as a change in how the existing SendBufferMemory configuration parameter is used. For more information, see Section 17.3.3.14, “Configuring MySQL Cluster Send Buffer Parameters”.

• Robust DDL operations. Beginning with MySQL Cluster NDB 6.4.0, DDL operations (such as CREATE TABLE or ALTER TABLE) are protected from data node failures; in the event of a data node failure, such operations are now rolled back gracefully. Previously, if a data node failed while trying to perform a DDL operation, the MySQL Cluster data dictionary became locked and no further DDL statements could be executed without restarting the cluster.

• IPv6 support in MySQL Cluster Replication. Beginning with MySQL Cluster NDB 6.4.1, IPv6 networking is supported between MySQL Cluster SQL nodes, which makes it possible to replicate between instances of MySQL Cluster using IPv6 addresses. However, IPv6 is supported only for direct connections between MySQL servers; all connections within an individual MySQL Cluster must use IPv4. For more information, see Section 17.6.3, “Known Issues in MySQL Cluster Replication”.

• Restoring specific databases, tables, or columns from a MySQL Cluster backup. It is now possible to exercise more fine-grained control when restoring a MySQL Cluster from backup using
**ndb_restore.** Beginning with MySQL Cluster NDB 6.4.3, you can choose to restore only specified tables or databases, or exclude specific tables or databases from being restored, using the new `ndb_restore` options `--include-tables`, `--include-databases`, `--exclude-tables`, and `--exclude-databases`. Beginning with MySQL Cluster NDB 7.0.7, it is also possible to restore to a table having fewer columns than the original using the `--exclude-missing-columns` option. For more information about all of these options, see Section 17.4.20, “ndb_restore — Restore a MySQL Cluster Backup”.

- **Improved Disk Data file system configuration.** As of MySQL Cluster NDB 6.4.3, you can specify default locations for MySQL Cluster Disk Data data files and undo log files using the data node configuration parameters `FileSystemPathDD`, `FileSystemPathDataFiles`, and `FileSystemPathUndoFiles`. This eliminates the need to use symbolic links to place Disk Data files separately from other files in data node file systems to improve Disk Data performance. For more information, see Disk Data file system parameters.

- **Automatic creation of Disk Data log file groups and tablespaces.** Beginning with MySQL Cluster NDB 6.4.3, using the data node configuration parameters `InitialLogFileGroup` and `InitialTablespace`, you can cause the creation of a MySQL Cluster Disk Data log file group, tablespace, or both, when the cluster is first started. When using these parameters, no SQL statements are required to create these Disk Data objects. For more information, see Disk Data object creation parameters.

- **Improved internal message passing and record handling.** MySQL Cluster NDB 7.0 contains 2 changes that optimize the use of network connections by addressing the size and number of messages passed between data nodes, and between data nodes and API nodes, which can increase MySQL Cluster and application performance:

  - **Packed reads.** Formerly, each read request signal contained a list of columns to be retrieved, each of these column identifiers using 4 bytes within the message. This meant that the message size increased as the number of columns being fetched increased. In addition, in the response from the data node, each column result was packed to a 4-byte boundary, which resulted in wasted space. In MySQL Cluster NDB 7.0, messaging for read operations is optimized in both directions, using a bitmap in the read request to specify the columns to be fetched. Where many fields are requested, this can result in a significant message size reduction as compared with the old method. In addition, the 4-byte packing in responses is no longer used, which means that smaller fields consume less space.

  - **Long signal transactions.** This enhancement reduces the number of messages and signals that are sent to data nodes for complex requests. Prior to MySQL Cluster NDB 7.0, there was a 100 byte limit on the size of the request signal, which meant that complex requests had to be split up between multiple messages prior to transmission, then reassembled on the receiving end. In addition to actual payload data, each message required its own operating system and protocol overhead such as header information. This often wasted network bandwidth and data node CPU. The maximum size of the message is now 32 KB, which is sufficient to accommodate most queries.

  Both of these optimizations are internal to the NDB API, and so is transparent to applications; this is true whether an application uses the NDB API directly or does so indirectly through an SQL node.

- **Configuration parameter data dumps.** Starting with MySQL Cluster NDB 7.0.6, the `ndb_config` utility supports a `--configinfo` option that causes it to dump a list of all configuration parameters supported by the cluster, along with brief descriptions, information about the parameters' default and permitted values, and the sections of the `config.ini` file in which the parameters apply. An additional `--xml` switch causes `ndb_config` to use XML rather than plain text output. Using `ndb_config --configinfo` or `ndb_config --configinfo --xml` requires no access to a running MySQL Cluster, any other programs, or any files. For more information and examples, see Section 17.4.7, “ndb_config — Extract MySQL Cluster Configuration Information”.

- **Per-table reporting of free space on disk.** The `INFORMATION_SCHEMA.FILES` table shows information about used and free space in MySQL Cluster Disk Data data files, but this information...
is not applicable to individual tables. In MySQL Cluster NDB 7.0.8 and later, the `ndb_desc` utility provides two additional columns in its output that show the amount of space allocated on disk for a given NDB table as well the amount of space that remains available for additional storage of disk-based column data for that table. For more information, see Section 17.4.10, "ndb_desc — Describe NDB Tables".

- **Improved restart times.** Optimizations in redo log handling and other file system operations introduced in MySQL Cluster NDB 7.0.9 have the potential to reduce considerably the time required for restarts. While actual performance benefits observed in production setups will naturally vary depending on database size, hardware, and other conditions, our own preliminary testing has shown that these improvements can yield startup times that are faster than those typical of previous MySQL Cluster NDB 7.0 releases by a factor of 50 or more.

- **Native support for default column values.** Starting with MySQL Cluster NDB 7.0.15, default values for table columns are stored in the NDB kernel rather than by the MySQL server as was done previously. This means that inserts on tables having column value defaults can be smaller and faster than before, because less data must be sent from SQL nodes to NDBCLUSTER. Tables created using previous MySQL Cluster releases can still be used in MySQL Cluster 7.0.15 and later; however, they do not support native default values until they are upgraded. You can upgrade a table with non-native default values to support native default values using an offline `ALTER TABLE` statement.

- **--nowait-nodes option for management servers.** Starting with MySQL Cluster NDB 7.0.10, it is possible to configure a cluster with two management servers, but to start the cluster using only one of them by starting the management node daemon with the `--nowait-nodes` option. The other management server can then be started at a later time to join the running MySQL Cluster.

- **Increased flexibility in online upgrade procedure.** Previously, when performing an upgrade of a running MySQL cluster, the order in which the types of cluster nodes had to be upgraded was very strict. However, beginning with MySQL Cluster NDB 7.0.10, MySQL Cluster supports online upgrading of API nodes (including MySQL servers running as SQL nodes) online upgrading management nodes, data nodes, or both.

---

**Important**

Before attempting to use this new upgrade functionality, see Section 17.5.5, "Performing a Rolling Restart of a MySQL Cluster", for additional information, especially if you are planning an online upgrade to MySQL Cluster NDB 7.0 from MySQL Cluster NDB 6.3.

- **New CHANGE MASTER TO option for circular replication.** Beginning with MySQL Cluster NDB 7.0.11, the `CHANGE MASTER TO` statement supports an `IGNORE_SERVER_IDS` option which takes a comma-separated list of server IDs and causes events originating from the corresponding servers to be ignored. (Log rotation and log deletion events are preserved.) See Section 13.4.2.1, "CHANGE MASTER TO Syntax", as well as Section 13.7.5.36, "SHOW SLAVE STATUS Syntax", for more information.

- **New replication conflict resolution strategy.** Beginning with MySQL Cluster NDB 7.0.11, the function `NDB$MAX_DELETE_WIN()` is available to implement “greatest timestamp, delete wins” conflict resolution. See `NDB$MAX_DELETE_WIN(column_name)`, for more information.

- **Improved lock handling for primary key lookups on BLOB tables.** A MySQL Cluster table stores all but the first 256 bytes of any BLOB or TEXT column values in a separate BLOB table; when executing queries against such tables, a shared lock is obtained. Prior to MySQL Cluster NDB 7.0.12, when the query used a primary key lookup and took place within a transaction, the lock was held for the duration of the transaction, even after no more data was being read from the NDB table. Now in such cases, the lock is released when all BLOB data associated with the table has been read. (Bug #49190)
Note

A shared lock is also taken for unique key lookups; it is still the case that this lock is held for the duration of the transaction.

• **Heartbeat thread policy and priority.** Beginning with MySQL Cluster NDB 7.0.13, a new configuration parameter `HeartbeatThreadPriority` makes it possible to set the policy and the priority for the heartbeat thread on management and API nodes.

• **Improved access to partitioning information.** The `ndb_desc` utility now provides additional information about the partitioning of data stored in MySQL Cluster. Beginning with MySQL Cluster NDB 7.0.13, the `--blob-info` option causes this program to include partition information for BLOB tables in its output. Beginning with MySQL Cluster NDB 7.0.14, the `--extra-node-info` option causes `ndb_desc` to include information about data distribution (that is, which table fragments are stored on which data nodes). Each of these options also requires the use of the `--extra-partition-info` option.

Information about partition-to-node mappings can also be obtained using the `Table::getFragmentNodes()` method, also added in MySQL Cluster NDB 7.0.14.

• **Replication attribute promotion and demotion.** Beginning with MySQL Cluster NDB 7.0.14, MySQL Cluster Replication supports attribute promotion and demotion when replicating between columns of different but similar types on the master and the slave. For example, it is possible to promote an `INT` column on the master to a `BIGINT` column on the slave, and to demote a `TEXT` column to a `VARCHAR` column.

The implementation of type demotion distinguishes between lossy and non-lossy type conversions, and their use on the slave can be controlled by setting the `slave_type_conversions` global server system variable.

For more information, see Attribute promotion and demotion (MySQL Cluster).

• **Incompatible change in NDB API event reporting.** Beginning with MySQL Cluster NDB 7.0.15, DDL events are no longer reported on `Event` objects by default. Instead such event reporting must be enabled explicitly using the `Event::setReport()` method. For more information, see `Event::setReport()`, and The `Event::EventReport Type`.

• **Number of table attributes.** Beginning with MySQL Cluster NDB 7.0.15, the maximum number of attributes (columns plus indexes) per table has been increased from 128 to 512.

• **Heartbeat ordering.** Beginning with MySQL Cluster NDB 7.0.16, it is possible to set a specific order for transmission of heartbeats between data nodes, using the `HeartbeatOrder` data node configuration parameter introduced in this version. This parameter can be useful in situations where multiple data nodes are running on the same host and a temporary disruption in connectivity between hosts would otherwise cause the loss of a node group (and thus failure of the cluster).

• **Relaxed ndb_restore column comparison rules.** When restoring data, `ndb_restore` compares the attributes of a column for equality with the definition of the column in the target table. However, not all of these attributes need to be the same for `ndb_restore` to be meaningful, safe and useful. Beginning with MySQL Cluster NDB 7.0.16, `ndb_restore` automatically ignores differences in certain column attributes which do not necessarily have to match between the version of the column in a backup and the version of that column in the MySQL Cluster to which the column data is being restored. These attributes include the following:

  • `COLUMN_FORMAT` setting (`FIXED`, `DYNAMIC`, or `DEFAULT`)
  • `STORAGE` setting (`MEMORY` or `DISK`)
  • The default value
MySQL Cluster Development History

- The distribution key

In such cases, ndb_restore reports any such differences to minimize any chance of user error.

- Storage of user data in anyValue. When writing NDB events to the binary log, MySQL Cluster uses OperationOptions::anyValue to store the server ID. Beginning with MySQL Cluster NDB 7.0.17, it is possible to store user data from an NDB API application in part of the anyValue when mysqld has started with the --server-id-bits option set to a nondefault value. Also beginning with MySQL Cluster NDB 7.0.17, it is possible to view this data in the output of mysqlbinlog, for which its own --server-id-bits option is added.

- --add-drop-trigger option for mysqldump. Beginning with MySQL Cluster NDB 7.0.19, this option can be used to force all CREATE TRIGGER statements in mysqldump output to be preceded by a DROP TRIGGER IF EXISTS statement.

- Forcing node shutdown and restart. In MySQL Cluster NDB 7.0.19 and later, it is possible using the ndb_mgm management client or the MGM API to force a data node shutdown or restart even if this would force the shutdown or restart of the entire cluster. In the management client, this is implemented through the addition of the -f (force) option to the STOP and RESTART commands. For more information, see Section 17.5.2, “Commands in the MySQL Cluster Management Client”. The MGM API also adds two new methods for forcing such a node shutdown or restart; see ndb_mgm_stop4(), and ndb_mgm_restart4(), for more information about these methods.

- TimeBetweenEpochsTimeout and GCP stop control. Beginning with MySQL Cluster NDB 7.0.21, it is possible to disable GCP stops by setting TimeBetweenEpochsTimeout to 0. In addition, a warning is written to the cluster log whenever the time required for a GCP save exceeds 60 seconds or the time required for a GCP commit exceeds 10 seconds. This warning includes a report of the current value of TimeBetweenEpochsTimeout. For more information, see Disk Data and GCP Stop errors.

- Skipping corrupted tables in NDB native backups. Beginning with MySQL Cluster NDB 7.0.21, you can cause ndb_restore to ignore tables that are corrupted due to missing blob parts tables by using the --skip-broken-objects option. When this option is used, such tables are skipped, and the restoration of any remaining uncorrupted tables in the backup continues.

- BLOB read and write batching. Beginning with MySQL Cluster NDB 7.0.21, it possible to control batching of BLOB read and write operations. For SQL nodes, this can be done using the --ndb-blob-read-batch-bytes and --ndb-blob-write-batch-bytes options for mysqld. In NDB API applications, you can control batching of BLOB reads and writes using the NdbTransaction methods setMaxPendingBlobReadBytes(), getMaxPendingBlobReadBytes(), setMaxPendingBlobWriteBytes(), and getMaxPendingBlobWriteBytes().

- Restoring from a NDB native backup to a differently-named database. MySQL Cluster NDB 7.0.22 adds a new --rewrite-database option to ndb_restore, which makes it possible to restore to a database having a different name from that of the database in the backup. The option can be used multiple times, and it is possible to restore from more than one source database in the backup to a single target database (although no protection against table or other object name collision is provided).

See Section 17.4.20, “ndb_restore — Restore a MySQL Cluster Backup”, for more information.

- INFORMATION_SCHEMA improvements. Beginning with MySQL Cluster NDB 7.0.22, INFORMATION_SCHEMA provides disk usage information for MySQL Cluster Disk Data tables. Previously, INFORMATION_SCHEMA.TABLES showed only the space usage for the in-memory data part of the table. Now, it also shows the space allocated for and used by the disk_part data of that table as well.

In addition, the INFORMATION_SCHEMA_PARTITIONS table (which did not show any statistics for NDB tables) now shows correct values in this table's TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH, MAX_DATA_LENGTH, and DATA_FREE columns, for each partition.
MySQL Cluster Development History

- **Configuration version information in ndbinfo.nodes.** You can see which version or versions of the MySQL Cluster configuration file are in effect on the data nodes by checking the `config_generation` column which is added to the `nodes` table in MySQL Cluster NDB 7.0.24.

- **Improvements in adding data nodes online.** Beginning with MySQL Cluster NDB 7.0.24, it is possible to add data nodes online to a running MySQL Cluster without performing a rolling restart of the cluster or starting data node processes with the `--nowait-nodes` option. This can be done by setting `Nodegroup = 65536` in the `config.ini` file for any data nodes that should be started at a later time, when first starting the cluster. The amount of time the cluster waits before doing this can be controlled using the `StartNoNodeGroupTimeout` data node configuration parameter.

- **Unique key updates in replication.** It is possible in MySQL Cluster NDB 7.0.25 and later to employ operations that update unique keys when replicating NDB tables. Previously this could lead to duplicate key errors when trying to execute the binary log (due to the fact that row events in the binary log were ordered according to the partitioning of the base table, and could differ in order within the epoch for that in which they were executed).

  ! Important

  Master and slave tables must both be using the NDB storage engine for this to work.

- **Starting with MySQL Cluster NDB 7.0.22,** the NDB kernel implements a number of statistical counters relating to actions performed by or affecting Ndb objects. Such events include starting, closing, and aborting transactions; operations using primary keys or unique keys; table, range, and pruned scans; blocking of threads by incompleted operations; and data and events sent and received by MySQL Cluster nodes. NDB API statistics counters are incremented inside the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes. A MySQL Server running as an SQL node in the cluster can access the values of these counters as system status variables, as seen in the output of `SHOW STATUS`, or in the results of queries against the `SESSION_STATUS` or `GLOBAL_STATUS` table in the `INFORMATION_SCHEMA` database. By comparing the values of these status variables before and after the execution of statements affecting NDB tables, you can observe the corresponding actions taken on the NDB API level. This can be highly useful when monitoring and tuning MySQL Cluster.

  For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”. See also MySQL Cluster Status Variables, for information about the individual status variables.

- **Version 2 binary log row events.** New versions of the `WRITE_ROW`, `UPDATE_ROW`, and `DELETE_ROW` events have been implemented in MySQL Cluster NDB 7.0.27, extending them with additional information intended to support future enhancements; these are referred to as “Version 2” binary log events.

  Version 2 log events are not backward compatible, and cannot be read by older slaves. A new `mysqllog` option `--log-bin-use-v1-row-events` can be employed to force use of Version 1 events when writing the binary log. This can be used during upgrades to make a newer `mysqllog` generate Version 1 binary log row events that can be read by older slaves.

- **Fail-fast data node capability.** Beginning with MySQL Cluster NDB 7.0.28, it is possible to enable fail-fast behavior for data nodes by enabling the `CrashOnCorruptedTuple` configuration parameter introduced in this version (disabled by default). Doing so causes data nodes to fail whenever they detect a corrupted tuple.

- **Rows per partition limit removed.** Previously it was possible to store a maximum of 46137488 rows in a single MySQL Cluster partition—that is, per data node. Beginning with MySQL Cluster NDB 7.0.36, this limitation has been lifted, and there is no longer any practical upper limit to this number.

17.1.4.4 What is New in MySQL Cluster NDB 6.3

The following list provides an overview of significant feature additions and changes first made in MySQL Cluster NDB 6.3. For more detailed information about all feature changes and bugfixes made
• **Conflict detection and resolution.** It is now possible to detect and resolve conflicts that arise in multi-master replication scenarios, such as circular replication, when different masters may try to update the same row on the slave with different data. Both “greatest timestamp wins” and “same timestamp wins” scenarios are supported. For more information, see Section 17.6.11, “MySQL Cluster Replication Conflict Resolution”.

• **Recovery of one master, many slaves replication setups.** Recovery of multi-way replication setups (“one master, many slaves”) is now supported using the --ndb-log-orig server option and changes in the mysql.ndb_binlog_index table. See Section 17.6.4, “MySQL Cluster Replication Schema and Tables”, for more information.

• **Enhanced selection options for transaction coordinator.** New values and behaviors are introduced for --ndb_optimized_node_selection, enabling greater flexibility when an SQL node chooses a transaction coordinator. For more information, see the description of ndb_optimized_node_selection in MySQL Cluster System Variables.

• **Replication heartbeats.** Replication heartbeats facilitate the task of monitoring and detecting failures in master-slave connections in real time. This feature is implemented using a new MASTER_HEARTBEAT_PERIOD = value clause for the CHANGE MASTER TO statement and the addition of two status variables Slave_heartbeat_period and Slave_received_heartbeats. For more information, see Section 13.4.2.1, “CHANGE MASTER TO Syntax”.

• **NDB thread locks.** It is possible to lock NDB execution threads and maintenance threads (such as file system and other operating system threads) to specific CPUs on multiprocessor data node hosts, and to leverage real-time scheduling.

• **Improved performance of updates using primary keys or unique keys.** The number of unnecessary reads when performing a primary key or unique key update has been greatly reduced. Since it is seldom necessary to read a record prior to an update, this can yield a considerable improvement in performance. In addition, primary key columns are no longer written to when not needed during update operations.

• **Batching improvements.** Support of batched DELETE and UPDATE operations has been significantly improved. Batching of UPDATE WHERE... and multiple DELETE operations is also now implemented.

• **Improved SQL statement performance metrics.** The Ndb_execute_count system status variable measures the number of round trips made by SQL statements to the NDB kernel, providing an improved metric for determining efficiency with which statements are executed. For more information, see MySQL Cluster Status Variables: Ndb_execute_count.

• **Compressed LCPs and backups.** Compressed local checkpoints and backups can save 50% or more of the disk space used by uncompressed LCPs and backups. These can be enabled using the two new data node configuration parameters CompressedLCP and CompressedBackup, respectively.

• **OPTIMIZE TABLE support with NDBCLUSTER tables.** OPTIMIZE TABLE is supported for dynamic columns of in-memory NDB tables. In such cases, it is no longer necessary to drop (and possibly to re-create) a table, or to perform a rolling restart, in order to recover memory from deleted rows for general re-use by Cluster. The performance of OPTIMIZE on Cluster tables can be tuned by adjusting the value of the ndb_optimization_delay system variable, which controls the number of milliseconds to wait between processing batches of rows by OPTIMIZE TABLE. In addition, OPTIMIZE TABLE on an NDBCLUSTER table can be interrupted by, for example, killing the SQL thread performing the OPTIMIZE operation.

• **Batching of transactions.** It is possible to cause statements occurring within the same transaction to be run as a batch by setting the session variable transaction_allow_batching to 1 or ON. To use this feature, autocommit must be set to 0 or OFF. Batch sizes can be controlled
using the `--ndb-batch-size` option for `mysql`. For additional information, see MySQL Server Options for MySQL Cluster, and MySQL Cluster System Variables.

- **Attribute promotion with ndb_restore.** It is possible using `ndb_restore` to restore data reliably from a column of a given type to a column that uses a "larger" type. This is sometimes referred to as attribute promotion. For example, MySQL Cluster backup data that originated in a `SMALLINT` column can be restored to a `MEDIUMINT`, `INT`, or `BIGINT` column. See Section 17.4.20, "ndb_restore — Restore a MySQL Cluster Backup", for more information.

- **Parallel data node recovery.** Recovery of multiple data nodes can now be done in parallel, rather than sequentially. In other words, several data nodes can be restored concurrently, which can often result in much faster recovery times than when they are restored one at a time.

- **Increased local checkpoint efficiency.** Only 2 local checkpoints are stored, rather than 3, lowering disk space requirements and the size and number of redo log files.

- **NDBCLUSTER table persistence control.** Persistence of NDB tables can be controlled using the session variables `ndb_table_temporary` and `ndb_table_no_logging`. `ndb_table_no_logging` causes NDB tables not to be checkpointed to disk; `ndb_table_temporary` does the same, and in addition, no schema files are created. See Section 17.3.2.5, “MySQL Cluster mysqld Option and Variable Reference”.

- **Epoll support (Linux only).** `Epoll` is an improved method for handling file descriptors, which is more efficient than scanning to determine whether a file descriptor has data to be read. (The term `epoll` is specific to Linux and equivalent functionality is known by other names on other platforms such as Solaris and FreeBSD.) Currently, MySQL Cluster supports this functionality on Linux only.

- **Distribution awareness (SQL nodes).** In MySQL Cluster NDB 6.3, SQL nodes can take advantage of distribution awareness. Here we provide a brief example showing how to design a table to make a given class of queries distribution-aware. Suppose an `NDBCLUSTER` table `t1` has the following schema:

```sql
CREATE TABLE t1 (  
    userid INT NOT NULL,  
    serviceid INT NOT NULL AUTO_INCREMENT PRIMARY KEY,  
    data VARCHAR(255)  
) ENGINE=NDBCLUSTER;
```

Suppose further that most of the queries to be used in our application test values of the `userid` column of this table. The form of such a query looks something like this:

```sql
SELECT columns FROM t1  
WHERE userid relation value;
```

In this query, `relation` represents some relational operator, such as `=, <, >`, and so on. Queries using `IN` and a list of values can also be used:

```sql
SELECT columns FROM t1  
WHERE userid IN value_list;
```

To make use of distribution awareness, we need to make the `userid` column part of the table's primary key, then explicitly partition the table with this column being used as the partitioning key. (Recall that for a partitioned table having one or more unique keys, all columns of the table's partitioning key must also be part of all of the unique keys—for more information and examples, see Section 18.5.1, “Partitioning Keys, Primary Keys, and Unique Keys”.) In other words, the table schema should be equivalent to the following `CREATE TABLE` statement:

```sql
CREATE TABLE t1 (  
    userid INT NOT NULL,  
    serviceid INT NOT NULL AUTO_INCREMENT,
```

1809
When the table is partitioned in this way, all rows having the same `userid` value are found on the same node group, and the MySQL Server can immediately select the optimal node to use as the transaction coordinator.

**Realtime extensions for multiple CPUs.** When running MySQL Cluster data nodes on hosts with multiple processors, the realtime extensions make it possible to give priority to the data node process and control on which CPU cores it should operate. This can be done using the data node configuration parameters `RealtimeScheduler`, `SchedulerExecutionTimer`, and `SchedulerSpinTimer`. Doing so properly can significantly lower response times and make them much more predictable response. For more information about using these parameters, see [Defining Data Nodes: Realtime Performance Parameters](#).

**Fully automatic database discovery.** It is no longer a requirement for database autodiscovery that an SQL node already be connected to the cluster at the time that a database is created on another SQL node, or for a `CREATE DATABASE` or `CREATE SCHEMA` statement to be issued on the new SQL node after it joins the cluster.

**Detection of NDB API client connection errors.** Beginning with MySQL Cluster NDB 6.3.20, the NDB API's `Ndb_cluster_connection` class adds the `get_latest_error()` and `get_latest_error_msg()` methods for catching and diagnosing problems with NDB API client connections.

**Restoring specific databases, tables, or columns from a MySQL Cluster backup.** It is now possible to exercise more fine-grained control when restoring a MySQL Cluster from backup using `ndb_restore`. Beginning with MySQL Cluster NDB 6.3.22, you can choose to restore only specified tables or databases, or exclude specific tables or databases from being restored, using the new `ndb_restore` options `--include-tables`, `--include-databases`, `--exclude-tables`, and `--exclude-databases`. Beginning with MySQL Cluster NDB 6.3.26, it is also possible to restore to a table having fewer columns than the original using the `--exclude-missing-columns` option. For more information about all of these options, see [Section 17.4.20, “ndb_restore — Restore a MySQL Cluster Backup”](#).

**Improved Disk Data file system configuration.** As of MySQL Cluster NDB 6.3.22, you can specify default locations for MySQL Cluster Disk Data data files and undo log files using the data node configuration parameters `FileSystemPathDD`, `FileSystemPathDataFiles`, and `FileSystemPathUndoFiles`. This eliminates the need to use symbolic links to place Disk Data files separately from other files in data node file systems to improve Disk Data performance. For more information, see [Disk Data file system parameters](#).

**Automatic creation of Disk Data log file groups and tablespaces.** Beginning with MySQL Cluster NDB 6.3.22, using the data node configuration parameters `InitialLogFileGroup` and `InitialTablespace`, you can cause the creation of a MySQL Cluster Disk Data log file group, tablespace, or both, when the cluster is first started. When using these parameters, no SQL statements are required to create these Disk Data objects. For more information, see [Disk Data object creation parameters](#).

**Configuration parameter data dumps.** Starting with MySQL Cluster NDB 6.3.25, the `ndb_config` utility supports a `--configinfo` option that causes it to dump a list of all configuration parameters supported by the cluster, along with brief descriptions, information about the parameters’ default and permitted values, and the sections of the `config.ini` file in which the parameters apply. An additional `--xml` switch causes `ndb_config` to use XML rather than plain text output. Using `ndb_config --configinfo` or `ndb_config --configinfo --xml` requires no access to a running MySQL Cluster, any other programs, or any files. For more information and examples, see [Section 17.4.7, “ndb_config — Extract MySQL Cluster Configuration Information”](#).
MySQL Cluster Development History

- **Per-table reporting of free space on disk.** The `INFORMATION_SCHEMA.FILES` table shows information about used and free space in MySQL Cluster Disk Data data files, but this information is not applicable to individual tables. In MySQL Cluster NDB 6.3.27 and later, the `ndb_desc` utility provides two additional columns in its output that show the amount of space allocated on disk for a given NDB table as well the amount of space that remains available for additional storage of disk-based column data for that table. For more information, see Section 17.4.10, "ndb_desc — Describe NDB Tables".

- **Improved restart times.** Optimizations in redo log handling and other file system operations introduced in MySQL Cluster NDB 6.3.28 have the potential to reduce considerably the time required for restarts. While actual performance benefits observed in production setups will naturally vary depending on database size, hardware, and other conditions, our own preliminary testing has shown that these improvements can yield startup times that are faster than those typical of previous MySQL Cluster NDB 6.3 releases by a factor of 50 or more.

- **Increased flexibility in online upgrade procedure.** Previously, when performing an upgrade of a running MySQL cluster, the order in which the types of cluster nodes had to be upgraded was very strict. However, beginning with MySQL Cluster NDB 6.3.29, MySQL Cluster supports online upgrading of API nodes (including MySQL servers running as SQL nodes) before upgrading management nodes, data nodes, or both.

  **Important** Before attempting to use this new upgrade functionality, see Section 17.5.5, "Performing a Rolling Restart of a MySQL Cluster", for additional information, especially if you are planning an online upgrade from MySQL Cluster NDB 6.3 to MySQL Cluster NDB 7.0.

- **New replication conflict resolution strategy.** Beginning with MySQL Cluster NDB 6.3.31, the function `NDB$MAX_DELETE_WIN()` is available to implement "greatest timestamp, delete wins" conflict resolution. See `NDB$MAX_DELETE_WIN(column_name)`, for more information.

- **New CHANGE MASTER TO option for circular replication.** Beginning with MySQL Cluster NDB 6.3.31, the `CHANGE MASTER TO` statement supports an `IGNORE_SERVER_IDS` option which takes a comma-separated list of server IDs and causes events originating from the corresponding servers to be ignored. (Log rotation and log deletion events are preserved.) See Section 13.4.2.1, "CHANGE MASTER TO Syntax", as well as Section 13.7.5.36, "SHOW SLAVE STATUS Syntax", for more information.

- **Heartbeat thread policy and priority.** Beginning with MySQL Cluster NDB 6.3.32, a new configuration parameter `HeartbeatThreadPriority` makes it possible to set the policy and the priority for the heartbeat thread on management and API nodes.

- **Improved access to partitioning information.** The `ndb_desc` utility now provides additional information about the partitioning of data stored in MySQL Cluster. Beginning with MySQL Cluster NDB 6.3.32, the `--blob-info` option causes this program to include partition information for BLOB tables in its output. Beginning with MySQL Cluster NDB 6.3.33, the `--extra-node-info` option causes `ndb_desc` to include information about data distribution (that is, which table fragments are stored on which data nodes). Each of these options also requires the use of the `--extra-partition-info` option.

  Information about partition-to-node mappings can also be obtained using the `Table::getFragmentNodes()` method, also added in MySQL Cluster NDB 6.3.33.

- **Replication attribute promotion and demotion.** Beginning with MySQL Cluster NDB 6.3.33, MySQL Cluster Replication supports attribute promotion and demotion when replicating between columns of different but similar types on the master and the slave. For example, it is possible to promote an `INT` column on the master to a `BIGINT` column on the slave, and to demote a `TEXT` column to a `VARCHAR` column.
The implementation of type demotion distinguishes between lossy and non-lossy type conversions, and their use on the slave can be controlled by setting the `slave_type_conversions` global server system variable.

For more information, see [Attribute promotion and demotion (MySQL Cluster)](https://dev.mysql.com/doc/refman/8.0/en/attribute-promotion-and-demotion.html).

- **Incompatible change in NDB API event reporting.** Beginning with MySQL Cluster NDB 6.3.34, DDL events are no longer reported on `Event` objects by default. Instead such event reporting must be enabled explicitly using the `Event::setReport()` method. For more information, see `Event::setReport()` and [The Event::EventReport Type](https://dev.mysql.com/doc/refman/8.0/en/event-reporting.html).

- **Heartbeat ordering.** Beginning with MySQL Cluster NDB 6.3.35, it is possible to set a specific order for transmission of heartbeats between data nodes, using the `HeartbeatOrder` data node configuration parameter introduced in this version. This parameter can be useful in situations where multiple data nodes are running on the same host and a temporary disruption in connectivity between hosts would otherwise cause the loss of a node group (and thus failure of the cluster).

- **Relaxed ndb_restore column comparison rules.** When restoring data, `ndb_restore` compares the attributes of a column for equality with the definition of the column in the target table. However, not all of these attributes need to be the same for `ndb_restore` to be meaningful, safe and useful. Beginning with MySQL Cluster NDB 6.3.35, `ndb_restore` automatically ignores differences in certain column attributes which do not necessarily have to match between the version of the column in a backup and the version of that column in the MySQL Cluster to which the column data is being restored. These attributes include the following:
  - COLUMN_FORMAT setting (**FIXED, DYNAMIC, or DEFAULT**)
  - STORAGE setting (**MEMORY or DISK**)
  - The default value
  - The distribution key

In such cases, `ndb_restore` reports any such differences to minimize any chance of user error.

- **--add-drop-trigger option for mysqldump.** Beginning with MySQL Cluster NDB 6.3.38, this option can be used to force all `CREATE TRIGGER` statements in `mysqldump` output to be preceded by a `DROP TRIGGER IF EXISTS` statement.

- **Skipping corrupted tables in NDB native backups.** Beginning with MySQL Cluster NDB 6.3.40, you can cause `ndb_restore` to ignore tables that are corrupted due to missing blob parts tables by using the `--skip-broken-objects` option. When this option is used, such tables are skipped, and the restoration of any remaining uncorrupted tables in the backup continues.

- **Restoring from a NDB native backup to a differently-named database.** MySQL Cluster NDB 6.3.41 adds a new `--rewrite-database` option to `ndb_restore`, which makes it possible to restore to a database having a different name from that of the database in the backup. The option can be used multiple times, and it is possible to restore from more than one source database in the backup to a single target database (although no protection against table or other object name collision is provided).

17.1.4.5 What is New in MySQL Cluster NDB 6.2

The following list provides an overview of significant feature additions and changes made in MySQL Cluster NDB 6.2. All of the changes in this list are also available in MySQL Cluster NDB 6.3. For more detailed information about all feature changes and bugfixes made in MySQL Cluster NDB 6.2, see [http://dev.mysql.com/doc/refman/mysql-cluster/7.1/en/mysql-cluster-news-6-2.html](http://dev.mysql.com/doc/refman/mysql-cluster/7.1/en/mysql-cluster-news-6-2.html).
MySQL Cluster Development History

- **Enhanced backup status reporting.** Backup status reporting has been improved, aided in part by the introduction of a `BackupReportFrequency` configuration parameter.

- **Multiple cluster connections per SQL node.** A single MySQL server acting as a MySQL Cluster SQL node can employ multiple connections to the cluster using the `--ndb-cluster-connection-pool` startup option for `mysqld`. This option is described in *MySQL Cluster-Related Command Options for mysqld: --ndb-cluster-connection-pool option*.

- **New data access interface.** The `NdbRecord` interface provides a new and simplified data handler for use in NDB API applications.

- **New reporting commands.** The new management client `REPORT BackupStatus` and `REPORT MemoryUsage` commands provide better access to information about the status of MySQL Cluster backups and how much memory is being used by MySQL Cluster for data and index storage. See Section 17.5.2, "Commands in the MySQL Cluster Management Client", for more information about the `REPORT` commands. In addition, in-progress status reporting is provided by the `ndb_restore` utility; see Section 17.4.20, "ndb_restore — Restore a MySQL Cluster Backup".

- **Improved memory allocation and configuration.** Memory is now allocated by the NDB kernel to tables on a page-by-page basis, which significantly reduces the memory overhead required for maintaining `NDBCLUSTER` tables. In addition, the `MaxAllocate` configuration parameter now makes it possible to set the maximum size of the allocation unit used for table memory.

- **Choice of fixed-width or variable-width columns.** You can control whether fixed-width or variable-width storage is used for a given column of an NDB table by employing of the `COLUMN_FORMAT` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement. In addition, the ability to control whether a given column of an NDB table is stored in memory or on disk, using the `STORAGE` specifier as part of the column's definition in a `CREATE TABLE` or `ALTER TABLE` statement. For more information, see Section 13.1.17, "CREATE TABLE Syntax", and Section 13.1.7, "ALTER TABLE Syntax".

- **Controlling management client connections.** The `--bind-address` cluster management server startup option makes it possible to restrict management client connections to `ndb_mgmd` to a single host (IP address or host name) and port, which can make MySQL Cluster management operations more secure. For more information about this option, see Section 17.4.4, "ndb_mgmd — The MySQL Cluster Management Server Daemon".

- **Micro-GCPs.** Due to a change in the protocol for handling of global checkpoints (GCPs handled in this manner sometimes being referred to as "micro-GCPs"), it is now possible to control how often the GCI number is updated, and how often global checkpoints are written to disk, using the `TimeBetweenEpochs` and `TimeBetweenEpochsTimeout` configuration parameters. This improves the reliability and performance of MySQL Cluster Replication.

- **Core online schema change support.** Support for the online `ALTER TABLE` operations `ADD COLUMN`, `ADD INDEX`, and `DROP INDEX` is available. When the `ONLINE` keyword is used, the `ALTER TABLE` is noncopying, which means that indexes do not have to be re-created, which provides these benefits:
  - Single user mode is no longer required for `ALTER TABLE` operations that can be performed online.
  - Transactions can continue during `ALTER TABLE` operations that can be performed online.
  - Tables being altered online are not locked against access by other SQL nodes.
  However, such tables are locked against other operations on the same SQL node for the duration of the `ALTER TABLE`. We are working to overcome this limitation in a future MySQL Cluster release.

  Online `CREATE INDEX` and `DROP INDEX` statements are also supported. Online changes can be suppressed using the `OFFLINE` key word. See Section 13.1.7.2, "ALTER TABLE Online Operations".

- **mysql.ndb_binlog_index improvements.** More information has been added to the mysql.ndb_binlog_index table so that it is possible to determine which originating epochs have been applied inside an epoch. This is particularly useful for 3-way replication. See Section 17.6.4, “MySQL Cluster Replication Schema and Tables”, for more information.

- **Epoch lag control.** The MaxBufferedEpochs data node configuration parameter provides a means to control the maximum number of unprocessed epochs by which a subscribing node can lag. Subscribers which exceed this number are disconnected and forced to reconnect.

- **Fully automatic database discovery.** It is no longer a requirement for database autodiscovery that an SQL node already be connected to the cluster at the time that a database is created on another SQL node, or for a `CREATE DATABASE` or `CREATE SCHEMA` statement to be issued on the new SQL node after it joins the cluster.

- **Multiple data node processes per host.** In earlier MySQL Cluster release series, we did not support MySQL Cluster deployments in production where more than one ndbd process was run on a single physical machine. However, beginning with MySQL Cluster NDB 6.2.0, you can use multiple data node processes on a single host.

  **Note**

  A multi-threaded version of ndbd tailored for use on hosts with multiple CPUs or cores was introduced in MySQL Cluster NDB 7.0. See Section 17.1.4.3, “What is New in MySQL Cluster NDB 7.0”, and Section 17.4.3, “ndbmtd — The MySQL Cluster Data Node Daemon (Multi-Threaded)”, for more information.

- **Improved Disk Data file system configuration.** As of MySQL Cluster NDB 6.2.17, you can specify default locations for MySQL Cluster Disk Data data files and undo log files using the data node configuration parameters `FileSystemPathDD`, `FileSystemPathDataFiles`, and `FileSystemPathUndoFiles`. This eliminates the need to use symbolic links to place Disk Data files separately from other files in data node file systems to improve Disk Data performance. For more information, see Disk Data file system parameters.

- **Automatic creation of Disk Data log file groups and tablespaces.** Beginning with MySQL Cluster NDB 6.2.17, using the data node configuration parameters `InitialLogFileGroup` and `InitialTablespace`, you can cause the creation of a MySQL Cluster Disk Data log file group, tablespace, or both, when the cluster is first started. When using these parameters, no SQL statements are required to create these Disk Data objects.

- **Improved access to partitioning information.** The ndb_desc utility now provides additional information about the partitioning of data stored in MySQL Cluster. Beginning with MySQL Cluster NDB 6.2.19, the --extra-node-info option causes ndb_desc to include information about data distribution (that is, which table fragments are stored on which data nodes). This option also requires the use of the --extra-partition-info option.

  Information about partition-to-node mappings can also be obtained using the Table::getFragmentNodes() method, also added in MySQL Cluster NDB 6.2.19.

- **New CHANGE MASTER TO option for circular replication.** Beginning with MySQL Cluster NDB 6.2.19, the CHANGE MASTER TO statement supports an IGNORE_SERVER_IDS option which takes a comma-separated list of server IDs and causes events originating from the corresponding servers to be ignored. (Log rotation and log deletion events are preserved.)

  See Section 13.4.2.1, “CHANGE MASTER TO Syntax”, as well as Section 13.7.5.36, “SHOW SLAVE STATUS Syntax”, for more information.
17.1.4.6 What is New in MySQL Cluster NDB 6.1

The following list provides an overview of significant feature additions and changes made in MySQL Cluster NDB 6.1. All of the changes in this list are also available in MySQL Cluster NDB 6.2 and 6.3 releases. For detailed information about all changes made in MySQL Cluster NDB 6.1, see http://dev.mysql.com/doc/relnotes/mysql-cluster/7.1/en/mysql-cluster-news-6-1.html.

- **Increased number of cluster nodes.** The maximum number of all nodes in a MySQL Cluster has been increased to 255. For more information, see Section 17.1.6.10, “Limitations Relating to Multiple MySQL Cluster Nodes”.

- **Disabling arbitration.** It is now possible to disable arbitration by setting `ArbitrationRank=0` on all cluster management and SQL nodes. For more information, see Defining the Management Server: ArbitrationRank and Defining SQL and Other API Nodes: ArbitrationRank.

- **Additional DUMP commands.** New management client DUMP commands provide help with tracking transactions, scan operations, and locks. See Section 17.5.2, “Commands in the MySQL Cluster Management Client”, and MySQL Cluster Management Client DUMP Commands, for more information.

- **Faster Disk Data backups.** Improvements in backups of Disk Data tables can yield a 10 to 15% increase in backup speed of Disk Data tables.

- **Batched slave updates.** Batched slave updates are enabled using the `--slave-allow-batching` option for `mysqld`, increases replication efficiency. For more information, see Section 17.6.6, “Starting MySQL Cluster Replication (Single Replication Channel)”.

17.1.4.7 What is New in MySQL Cluster 5.1

A number of features for MySQL Cluster were implemented in MySQL 5.1 through MySQL 5.1.23, when support for MySQL Cluster was moved to MySQL Cluster NDB. All of the features in the following list are also available in all MySQL Cluster NDB (6.1 and later) releases.

- **Integration of MySQL Cluster into MySQL Replication.** MySQL Cluster Replication makes it possible to replicate from one MySQL Cluster to another. Updates on any SQL node (MySQL server) in the cluster acting as the master are replicated to the slave cluster; the state of the slave side remains consistent with the cluster acting as the master. This is sometimes referred to as asynchronous replication between clusters, providing geographic redundancy. It is also possible to replicate from a MySQL Cluster acting as the master to a standalone MySQL server acting as the slave, or from a standalone MySQL master server to a slave cluster; in either of these cases, the standalone MySQL server uses a storage engine other than NDBCLUSTER. Multi-master replication setups such as circular replication are also supported.

  See Section 17.6, “MySQL Cluster Replication”.

- **Support for storage of rows on disk.** Storage of NDBCLUSTER table data on disk is now supported. Indexed columns, including the primary key hash index, must still be stored in RAM; however, all other columns can be stored on disk.

  See Section 17.5.12, “MySQL Cluster Disk Data Tables”.

- **Variable-size columns.** In MySQL 5.0, an NDBCLUSTER table column defined as `VARCHAR(255)` used 260 bytes of storage independent of what was stored in any particular record. In MySQL 5.1 Cluster tables, only the portion of the column actually taken up by the record is stored. This makes possible a significant reduction in space requirements for such columns as compared to previous release series—by a factor of up to 5 in many cases.

- **User-defined partitioning.** Users can define partitions based on columns that are part of the primary key. It is possible to partition NDB tables based on KEY and LINEAR KEY schemes. This feature is also available for many other MySQL storage engines, which support additional partitioning types that are not available with NDBCLUSTER tables.
For additional general information about user-defined partitioning in MySQL 5.1, see Chapter 18, *Partitioning*. Specifics of partitioning types are discussed in Section 18.2, “Partitioning Types”.

The MySQL Server can also determine whether it is possible to “prune away” some of the partitions from the **WHERE** clause, which can greatly speed up some queries. See Section 18.4, “Partition Pruning”, for information about designing tables and queries to take advantage of partition pruning.

- **Autodiscovery of table schema changes.** In MySQL 5.0, it was necessary to issue a **FLUSH TABLES** statement or a “dummy” **SELECT** for new **NDBCLUSTER** tables or changes made to schemas of existing **NDBCLUSTER** tables on one SQL node to be visible on the cluster’s other SQL nodes. In MySQL 5.1, this is no longer necessary; new Cluster tables and changes in the definitions of existing **NDBCLUSTER** tables made on one SQL node are immediately visible to all SQL nodes connected to the cluster.

  - **Note**
    
    When creating a new database, it is still necessary in MySQL 5.1 to issue a **CREATE DATABASE** or **CREATE SCHEMA** statement on each SQL node in the cluster.

- **Distribution awareness (NDB API).** Distribution awareness is a mechanism by which the best data node is automatically selected to be queried for information. (Conceptually, it is similar in some ways to partition pruning (see Section 18.4, “Partition Pruning”). To take advantage of distribution awareness, you should do the following:

  1. Determine which table column is most likely to be used for finding matching records.
  2. Make this column part of the table’s primary key.
  3. Explicitly partition the table by **KEY**, using this column as the table’s partitioning key.

  Following these steps causes records with the same value for the partitioning column to be stored on the same partition (that is, in the same node group). When reading data, transactions are begun on the data node actually having the desired rows instead of this node being determined by the usual round-robin mechanism.

  - **Important**
    
    To see a measureable impact on performance, the cluster must have at least four data nodes, since, with only two data nodes, both data nodes have exactly the same data.

  Using distribution awareness can yield performance increase of as great as 45% when using four data nodes, and possibly more when using a greater number of data nodes.

  - **Note**
    
    In mainline MySQL 5.1 releases, distribution awareness was supported only when using the NDB API; support was added for SQL and API nodes in MySQL Cluster NDB 6.3 (see Section 17.1.4.4, “What is New in MySQL Cluster NDB 6.3”, which includes an example showing how to create a table to take advantage of distribution awareness).

- **Online adding and dropping of indexes.** For **ALTER TABLE** statements, **ADD INDEX** and **DROP INDEX** operations for dynamic (variable-width) columns on **NDB** tables are now performed as online operations (no table copying). This is also true for **CREATE INDEX** and **DROP INDEX**. As a result, these operations are now performed much more quickly than previously.

1816
17.1.5 MySQL Server Using InnoDB Compared with MySQL Cluster

MySQL Server offers a number of choices in storage engines. Since both NDBCLUSTER and InnoDB can serve as transactional MySQL storage engines, users of MySQL Server sometimes become interested in MySQL Cluster. They see NDB as a possible alternative or upgrade to the default InnoDB storage engine in MySQL 5.5. While NDB and InnoDB share common characteristics, there are differences in architecture and implementation, so that some existing MySQL Server applications and usage scenarios can be a good fit for MySQL Cluster, but not all of them.

In this section, we discuss and compare some characteristics of the NDB storage engine used by MySQL Cluster with InnoDB used in MySQL 5.1 and MySQL 5.5. The next few sections provide a technical comparison. In many instances, decisions about when and where to use MySQL Cluster must be made on a case-by-case basis, taking all factors into consideration. While it is beyond the scope of this documentation to provide specifics for every conceivable usage scenario, we also attempt to offer some very general guidance on the relative suitability of some common types of applications for NDB as opposed to InnoDB backends.

While it is possible to use InnoDB tables with MySQL Cluster, such tables are not clustered. MySQL Cluster NDB 7.1 releases use a mysqld based on MySQL 5.1 which includes InnoDB 1.0; MySQL Cluster NDB 7.2.1 and later are based on MySQL Server 5.5, which includes support for InnoDB 1.1. It is also not possible to use programs or libraries from a MySQL Cluster NDB 6.x or MySQL Cluster NDB 7.x distribution with MySQL Server 5.1 or MySQL Server 5.5, or the reverse.

While it is also true that some types of common business applications can be run either on MySQL Cluster or on MySQL Server (most likely using the InnoDB storage engine), there are some important architectural and implementation differences. Section 17.1.5.1, “Differences Between the NDB and InnoDB Storage Engines”, provides a summary of the these differences. Due to the differences, some usage scenarios are clearly more suitable for one engine or the other; see Section 17.1.5.2, “NDB and InnoDB Workloads”. This in turn has an impact on the types of applications that better suited for use with NDB or InnoDB. See Section 17.1.5.3, “NDB and InnoDB Feature Usage Summary", for a comparison of the relative suitability of each for use in common types of database applications.

For information about the relative characteristics of the NDB and MEMORY storage engines, see When to Use MEMORY or MySQL Cluster.

See Chapter 14, Storage Engines, for additional information about MySQL storage engines.

### 17.1.5.1 Differences Between the NDB and InnoDB Storage Engines

The MySQL Cluster NDB storage engine is implemented using a distributed, shared-nothing architecture, which causes it to behave differently from InnoDB in a number of ways. For those unaccustomed to working with NDB, unexpected behaviors can arise due to its distributed nature with regard to transactions, foreign keys, joins, and other characteristics. These are shown in the following table:

<table>
<thead>
<tr>
<th>Feature</th>
<th>InnoDB</th>
<th>MySQL Cluster</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>MySQL Server Version</strong></td>
<td>InnoDB 1.1: 5.5</td>
<td>MySQL Cluster NDB 6.3, 7.0, 7.1: 5.1</td>

### 17.1.5.2 NDB and InnoDB Workloads

MySQL Cluster has a range of unique attributes that make it ideal to serve applications requiring high availability, fast failover, high throughput, and low latency. Due to its distributed architecture and multi-node implementation, MySQL Cluster also has specific constraints that may keep some workloads from performing well. A number of major differences in behavior between the NDB and InnoDB storage engines with regard to some common types of database-driven application workloads are shown in the following table:

<table>
<thead>
<tr>
<th>Workload</th>
<th>InnoDB</th>
<th>MySQL Cluster (NDB)</th>
</tr>
</thead>
<tbody>
<tr>
<td>High-Volume OLTP Applications</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>DSS Applications (data marts, analytics)</td>
<td>Yes</td>
<td>Limited (Join operations across OLTP datasets not exceeding 3TB in size)</td>
</tr>
<tr>
<td>Custom Applications</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Packaged Applications</td>
<td>Yes</td>
<td>Limited (should be mostly primary key access).</td>
</tr>
<tr>
<td>In-Network Telecoms Applications (HLR, HSS, SDP)</td>
<td>No</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Note**

MySQL Cluster NDB 7.3 supports foreign keys.
17.1.5.3 NDB and InnoDB Feature Usage Summary

When comparing application feature requirements to the capabilities of InnoDB with NDB, some are clearly more compatible with one storage engine than the other.

The following table lists supported application features according to the storage engine to which each feature is typically better suited.

<table>
<thead>
<tr>
<th>Preferred application requirements for InnoDB</th>
<th>Preferred application requirements for NDB</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Foreign keys</td>
<td>• Write scaling</td>
</tr>
<tr>
<td>• Full table scans</td>
<td>• 99.99% uptime</td>
</tr>
<tr>
<td>• Very large databases, rows, or transactions</td>
<td>• Online addition of nodes and online schema operations</td>
</tr>
<tr>
<td>• Transactions other than READ COMMITTED</td>
<td>• Multiple SQL and NoSQL APIs (see MySQL Cluster APIs: Overview and Concepts)</td>
</tr>
</tbody>
</table>

17.1.6 Known Limitations of MySQL Cluster

In the sections that follow, we discuss known limitations in current releases of MySQL Cluster as compared with the features available when using the MyISAM and InnoDB storage engines. If you check the “Cluster” category in the MySQL bugs database at http://bugs.mysql.com, you can find known bugs in the following categories under “MySQL Server:” in the MySQL bugs database at http://bugs.mysql.com, which we intend to correct in upcoming releases of MySQL Cluster:

• MySQL Cluster
• Cluster Direct API (NDBAPI)
• Cluster Disk Data
• Cluster Replication
• ClusterJ

This information is intended to be complete with respect to the conditions just set forth. You can report any discrepancies that you encounter to the MySQL bugs database using the instructions given in Section 1.7, “How to Report Bugs or Problems”. If we do not plan to fix the problem in MySQL Cluster NDB 7.1, we will add it to the list.

See Section 17.1.6.11, “Previous MySQL Cluster Issues Resolved in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x” for a list of issues in MySQL Cluster in MySQL 5.0 that have been resolved in the current version.

Note
Limitations and other issues specific to MySQL Cluster Replication are described in Section 17.6.3, “Known Issues in MySQL Cluster Replication”.  

1820
17.1.6.1 Noncompliance with SQL Syntax in MySQL Cluster

Some SQL statements relating to certain MySQL features produce errors when used with NDB tables, as described in the following list:

- **Temporary tables.** Temporary tables are not supported. Trying either to create a temporary table that uses the NDB storage engine or to alter an existing temporary table to use NDB fails with the error `Table storage engine 'ndbcluster' does not support the create option 'TEMPORARY'`.

- **Indexes and keys in NDB tables.** Keys and indexes on MySQL Cluster tables are subject to the following limitations:
  - **Column width.** Attempting to create an index on an NDB table column whose width is greater than 3072 bytes succeeds, but only the first 3072 bytes are actually used for the index. In such cases, a warning `Specified key was too long; max key length is 3072 bytes` is issued, and a `SHOW CREATE TABLE` statement shows the length of the index as 3072.
  - **TEXT and BLOB columns.** You cannot create indexes on NDB table columns that use any of the TEXT or BLOB data types.
  - **FULLTEXT indexes.** The NDB storage engine does not support FULLTEXT indexes, which are possible for MyISAM tables only. However, you can create indexes on VARCHAR columns of NDB tables.
  - **USING HASH keys and NULL.** Using nullable columns in unique keys and primary keys means that queries using these columns are handled as full table scans. To work around this issue, make the column `NOT NULL`, or re-create the index without the USING HASH option.
  - **Prefixes.** There are no prefix indexes; only entire columns can be indexed. (The size of an NDB column index is always the same as the width of the column in bytes, up to and including 3072 bytes, as described earlier in this section. Also see Section 17.1.6.6, “Unsupported or Missing Features in MySQL Cluster”, for additional information.)
  - **BIT columns.** A BIT column cannot be a primary key, unique key, or index, nor can it be part of a composite primary key, unique key, or index.
  - **AUTO_INCREMENT columns.** Like other MySQL storage engines, the NDB storage engine can handle a maximum of one AUTO_INCREMENT column per table, and this column must be indexed. However, in the case of a MySQL Cluster table with no explicit primary key, an AUTO_INCREMENT column is automatically defined and used as a “hidden” primary key. For this reason, you cannot create an NDB table having an AUTO_INCREMENT column and no explicit primary key.

- **MySQL Cluster and geometry data types.** Geometry data types (WKT and WKB) are supported in NDB tables in MySQL 5.1 (including MySQL Cluster NDB 6.X and 7.X through 7.1). However, spatial indexes are not supported.

- **Character sets and binary log files.** Currently, the `ndb_apply_status` and `ndb_binlog_index` tables are created using the latin1 (ASCII) character set. Because names of binary logs are recorded in this table, binary log files named using non-Latin characters are not referenced correctly in these tables. This is a known issue, which we are working to fix. (Bug #50226)

To work around this problem, use only Latin-1 characters when naming binary log files or setting any the `--basedir`, `--log-bin`, or `--log-bin-index` options.

- **Creating NDB tables with user-defined partitioning.** Support for user-defined partitioning for MySQL Cluster is restricted to [LINEAR] KEY partitioning. Beginning with MySQL 5.1.12, using any
other partitioning type with `ENGINE=NDB` or `ENGINE=NDBCLUSTER` in a `CREATE TABLE` statement results in an error.

It is possible to override this restriction, but doing so is not supported for use in production settings. For details, see User-defined partitioning and the NDB storage engine (MySQL Cluster).

**Default partitioning scheme.** As of MySQL 5.1.6, all MySQL Cluster tables are by default partitioned by `KEY` using the table’s primary key as the partitioning key. If no primary key is explicitly set for the table, the “hidden” primary key automatically created by the NDBCLUSTER storage engine is used instead. For additional discussion of these and related issues, see Section 18.2.4, “KEY Partitioning”.

Beginning with MySQL Cluster NDB 6.2.18, MySQL Cluster NDB 6.3.25, and MySQL Cluster NDB 7.0.6, `CREATE TABLE` and `ALTER TABLE` statements that would cause a user-partitioned NDBCLUSTER table not to meet either or both of the following two requirements are not permitted, and fail with an error (Bug #40709):

1. The table must have an explicit primary key.
2. All columns listed in the table’s partitioning expression must be part of the primary key.

**Exception.** If a user-partitioned NDBCLUSTER table is created using an empty column-list (that is, using `PARTITION BY [LINEAR] KEY()`) then no explicit primary key is required.

**Maximum number of partitions for NDBCLUSTER tables.** The maximum number of partitions that can defined for a NDBCLUSTER table when employing user-defined partitioning is 8 per node group. (See Section 17.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”, for more information about MySQL Cluster node groups.

**DROP PARTITION not supported.** It is not possible to drop partitions from NDB tables using `ALTER TABLE ... DROP PARTITION`. The other partitioning extensions to `ALTER TABLE`—`ADD PARTITION`, `REORGANIZE PARTITION`, and `COALESCE PARTITION`—are supported for Cluster tables, but use copying and so are not optimized. See Section 18.3.1, “Management of RANGE and LIST Partitions” and Section 13.1.7, “ALTER TABLE Syntax”.

- **Row-based replication.** When using row-based replication with MySQL Cluster, binary logging cannot be disabled. That is, the NDB storage engine ignores the value of `sql_log_bin`. (Bug #16680)

### 17.1.6.2 Limits and Differences of MySQL Cluster from Standard MySQL Limits

In this section, we list limits found in MySQL Cluster that either differ from limits found in, or that are not found in, standard MySQL.

**Memory usage and recovery.** Memory consumed when data is inserted into an NDB table is not automatically recovered when deleted, as it is with other storage engines. Instead, the following rules hold true:

- A `DELETE` statement on an NDB table makes the memory formerly used by the deleted rows available for re-use by inserts on the same table only. However, this memory can be made available for general re-use by performing a rolling restart of the cluster. See Section 17.5.5, “Performing a Rolling Restart of a MySQL Cluster”.

Beginning with MySQL Cluster NDB 6.3.7, this limitation can be overcome using `OPTIMIZE TABLE`. See Section 17.1.6.11, “Previous MySQL Cluster Issues Resolved in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x”, for more information.

- A `DROP TABLE` or `TRUNCATE TABLE` operation on an NDB table frees the memory that was used by this table for re-use by any NDB table, either by the same table or by another NDB table.
Known Limitations of MySQL Cluster

- **Note**
  Recall that `TRUNCATE TABLE` drops and re-creates the table. See Section 13.1.34, "TRUNCATE TABLE Syntax".

- **Limits imposed by the cluster’s configuration.**
  A number of hard limits exist which are configurable, but available main memory in the cluster sets limits. See the complete list of configuration parameters in Section 17.3.3, "MySQL Cluster Configuration Files". Most configuration parameters can be upgraded online. These hard limits include:

  - **Database memory size and index memory size** (`DataMemory` and `IndexMemory`, respectively).
    - `DataMemory` is allocated as 32KB pages. As each `DataMemory` page is used, it is assigned to a specific table; once allocated, this memory cannot be freed except by dropping the table.
    - See Section 17.3.3.6, “Defining MySQL Cluster Data Nodes”, for more information.

  - **The maximum number of operations that can be performed per transaction** is set using the configuration parameters `MaxNoOfConcurrentOperations` and `MaxNoOfLocalOperations`.

  - **Note**
    Bulk loading, `TRUNCATE TABLE`, and `ALTER TABLE` are handled as special cases by running multiple transactions, and so are not subject to this limitation.

  - **Different limits related to tables and indexes.** For example, the maximum number of ordered indexes in the cluster is determined by `MaxNoOfOrderedIndexes`, and the maximum number of ordered indexes per table is 16.

  - **Node and data object maximums.**
    The following limits apply to numbers of cluster nodes and metadata objects:
    - The maximum number of data nodes is 48.
      - A data node must have a node ID in the range of 1 to 48, inclusive. (Previous to MySQL Cluster NDB 6.1.1, management and API nodes were restricted to the range 1 to 63 inclusive as a node ID; starting with MySQL Cluster NDB 6.1.1, management and API nodes may use node IDs in the range 1 to 255, inclusive.)
    - Prior to MySQL Cluster NDB 6.1.1, the total maximum number of nodes in a MySQL Cluster was 63. Beginning with MySQL Cluster NDB 6.1.1, the total maximum number of nodes in a MySQL Cluster is 255. In either case, this number includes all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers.
    - The maximum number of metadata objects in current versions of MySQL Cluster is 20320. This limit is hard-coded.
      - See Section 17.1.6.11, “Previous MySQL Cluster Issues Resolved in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x”, for more information.

17.1.6.3 Limits Relating to Transaction Handling in MySQL Cluster

A number of limitations exist in MySQL Cluster with regard to the handling of transactions. These include the following:

- **Transaction isolation level.**
  The `NDBCLUSTER` storage engine supports only the `READ COMMITTED` transaction isolation level. `InnoDB`, for example, supports `READ COMMITTED`, `READ UNCOMMITTED`, and `SERIALIZABLE` isolation levels.
Known Limitations of MySQL Cluster

UNCOMMITTED, REPEATABLE READ, and SERIALIZABLE.) You should keep in mind that NDB implements READ COMMITTED on a per-row basis; when a read request arrives at the data node storing the row, what is returned is the last committed version of the row at that time.

Uncommitted data is never returned, but when a transaction modifying a number of rows commits concurrently with a transaction reading the same rows, the transaction performing the read can observe “before” values, “after” values, or both, for different rows among these, due to the fact that a given row read request can be processed either before or after the commit of the other transaction.

To ensure that a given transaction reads only before or after values, you can impose row locks using SELECT ... LOCK IN SHARE MODE. In such cases, the lock is held until the owning transaction is committed. Using row locks can also cause the following issues:

• Increased frequency of lock wait timeout errors, and reduced concurrency
• Increased transaction processing overhead due to reads requiring a commit phase
• Possibility of exhausting the available number of concurrent locks, which is limited by MaxNoOfConcurrentOperations

NDB uses READ COMMITTED for all reads unless a modifier such as LOCK IN SHARE MODE or FOR UPDATE is used. LOCK IN SHARE MODE causes shared row locks to be used; FOR UPDATE causes exclusive row locks to be used. Unique key reads have their locks upgraded automatically by NDB to ensure a self-consistent read; BLOB reads also employ extra locking for consistency.

See Section 17.5.3.4, “MySQL Cluster Backup Troubleshooting”, for information on how MySQL Cluster’s implementation of transaction isolation level can affect backup and restoration of NDB databases.

Transactions and BLOB or TEXT columns. NDBCLUSTER stores only part of a column value that uses any of MySQL’s BLOB or TEXT data types in the table visible to MySQL; the remainder of the BLOB or TEXT is stored in a separate internal table that is not accessible to MySQL. This gives rise to two related issues of which you should be aware whenever executing SELECT statements on tables that contain columns of these types:

1. For any SELECT from a MySQL Cluster table: If the SELECT includes a BLOB or TEXT column, the READ COMMITTED transaction isolation level is converted to a read with read lock. This is done to guarantee consistency.

2. Prior to MySQL Cluster NDB 7.0.12, for any SELECT which used a primary key lookup or unique key lookup to retrieve any columns that used any of the BLOB or TEXT data types and that was executed within a transaction, a shared read lock was held on the table for the duration of the transaction—that is, until the transaction was either committed or aborted.

In MySQL Cluster NDB 7.0.12 and later, for primary key lookups, the lock is released as soon as all BLOB or TEXT data has been read. (Bug #49190) However, for unique key lookups, the shared lock continues to be held for the lifetime of the transaction.

This issue does not occur for queries that use index or table scans, even against NDB tables having BLOB or TEXT columns.

For example, consider the table t defined by the following CREATE TABLE statement:

```sql
CREATE TABLE t ( 
    a INT NOT NULL AUTO_INCREMENT PRIMARY KEY, 
    b INT NOT NULL, 
    c INT NOT NULL, 
    d TEXT, 
    INDEX i(b), 
    UNIQUE KEY u(c) 
) ENGINE = NDB,
```
Either of the following queries on t causes a shared read lock, because the first query uses a primary key lookup and the second uses a unique key lookup:

```sql
SELECT * FROM t WHERE a = 1;
SELECT * FROM t WHERE c = 1;
```

However, none of the four queries shown here causes a shared read lock:

```sql
SELECT * FROM t WHERE b = 1;
SELECT * FROM t WHERE d = '1';
SELECT * FROM t;
SELECT b,c WHERE a = 1;
```

This is because, of these four queries, the first uses an index scan, the second and third use table scans, and the fourth, while using a primary key lookup, does not retrieve the value of any BLOB or TEXT columns.

You can help minimize issues with shared read locks by avoiding queries that use unique key lookups (or primary key lookups in MySQL Cluster NDB 7.0.11 and earlier) that retrieve BLOB or TEXT columns, or, in cases where such queries are not avoidable, by committing transactions as soon as possible afterward.

- **Rollbacks.** There are no partial transactions, and no partial rollbacks of transactions. A duplicate key or similar error causes the entire transaction to be rolled back.

  This behavior differs from that of other transactional storage engines such as InnoDB that may roll back individual statements.

- **Transactions and memory usage.**

  As noted elsewhere in this chapter, MySQL Cluster does not handle large transactions well; it is better to perform a number of small transactions with a few operations each than to attempt a single large transaction containing a great many operations. Among other considerations, large transactions require very large amounts of memory. Because of this, the transactional behavior of a number of MySQL statements is effected as described in the following list:

  - **TRUNCATE TABLE** is not transactional when used on NDB tables. If a TRUNCATE TABLE fails to empty the table, then it must be re-run until it is successful.

  - **DELETE FROM** (even with no WHERE clause) *is* transactional. For tables containing a great many rows, you may find that performance is improved by using several `DELETE FROM ... LIMIT ...` statements to “chunk” the delete operation. If your objective is to empty the table, then you may wish to use TRUNCATE TABLE instead.

  - **LOAD DATA statements.** LOAD DATA INFILE is not transactional when used on NDB tables.

  **Important**

  When executing a LOAD DATA INFILE statement, the NDB engine performs commits at irregular intervals that enable better utilization of the communication network. It is not possible to know ahead of time when such commits take place.

  LOAD DATA FROM MASTER is not supported in MySQL Cluster.
Known Limitations of MySQL Cluster

- **ALTER TABLE and transactions.** When copying an NDB table as part of an ALTER TABLE, the creation of the copy is nontransactional. (In any case, this operation is rolled back when the copy is deleted.)

- **Transactions and the COUNT() function.** When using MySQL Cluster Replication, it is not possible to guarantee the transactional consistency of the COUNT() function on the slave. In other words, when performing on the master a series of statements (INSERT, DELETE, or both) that changes the number of rows in a table within a single transaction, executing SELECT COUNT(*) FROM table queries on the slave may yield intermediate results. This is due to the fact that SELECT COUNT(...) may perform dirty reads, and is not a bug in the NDB storage engine. (See Bug #31321 for more information.)

### 17.1.6.4 MySQL Cluster Error Handling

Starting, stopping, or restarting a node may give rise to temporary errors causing some transactions to fail. These include the following cases:

- **Temporary errors.** When first starting a node, it is possible that you may see Error 1204 Temporary failure, distribution changed and similar temporary errors.

- **Errors due to node failure.** The stopping or failure of any data node can result in a number of different node failure errors. (However, there should be no aborted transactions when performing a planned shutdown of the cluster.)

In either of these cases, any errors that are generated must be handled within the application. This should be done by retrying the transaction.

See also Section 17.1.6.2, “Limits and Differences of MySQL Cluster from Standard MySQL Limits”.

### 17.1.6.5 Limits Associated with Database Objects in MySQL Cluster

Some database objects such as tables and indexes have different limitations when using the NDBCLUSTER storage engine:

- **Database and table names.** When using the NDB storage engine, the maximum allowed length both for database names and for table names is 63 characters.

- **Table names containing special characters.** NDB tables whose names contain characters other than letters, numbers, dashes, and underscores and which are created on one SQL node were not always discovered correctly by other SQL nodes. (Bug #31470)

  **Note**

  This issue was fixed in MySQL 5.1.23, MySQL Cluster NDB 6.2.7, and MySQL Cluster NDB 6.3.4.

- **Number of database objects.** The maximum number of all NDB database objects in a single MySQL Cluster—including databases, tables, and indexes—is limited to 20320.

- **Attributes per table.** Prior to MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4, the maximum number of attributes (that is, columns and indexes) per table is limited to 128.

  Beginning with MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4, this limit is increased to 512.

- **Attributes per key.** The maximum number of attributes per key is 32.

- **Row size.** Prior to MySQL Cluster NDB 7.0, the maximum permitted size of any one row was 8052 bytes; in MySQL Cluster NDB 7.0 and later, this is 14000 bytes. Each BLOB or TEXT column contributes 256 + 8 = 264 bytes to this total.
• **BIT column storage per table.** The maximum combined width for all **BIT** columns used in a given **NDB** table is 4096.

### 17.1.6.6 Unsupported or Missing Features in MySQL Cluster

A number of features supported by other storage engines are not supported for **NDB** tables. Trying to use any of these features in MySQL Cluster does not cause errors in or of itself; however, errors may occur in applications that expects the features to be supported or enforced. Statements referencing such features, even if effectively ignored by **NDB**, must be syntactically and otherwise valid.

• **Foreign key constraints.** Prior to MySQL Cluster NDB 7.3, the foreign key construct is ignored, just as it is by **MyISAM** tables. Foreign keys are supported in MySQL Cluster NDB 7.3 and later.

• **Index prefixes.** Prefixes on indexes are not supported for **NDB** tables. If a prefix is used as part of an index specification in a statement such as **CREATE TABLE**, **ALTER TABLE**, or **CREATE INDEX**, the prefix is not created by **NDB**.

A statement containing an index prefix, and creating or modifying an **NDB** table, must still be syntactically valid. For example, the following statement always fails with Error 1089 **Incorrect prefix key; the used key part isn't a string, the used length is longer than the key part, or the storage engine doesn't support unique prefix keys**, regardless of storage engine:

```sql
CREATE TABLE t1 (
  c1 INT NOT NULL,
  c2 VARCHAR(100),
  INDEX i1 (c2(500))
);
```

This happens on account of the SQL syntax rule that no index may have a prefix larger than itself.

• **OPTIMIZE operations.** **OPTIMIZE** operations are not supported.

Beginning with MySQL Cluster NDB 6.3.7, this limitation has been lifted. See Section 17.1.6.11, “Previous MySQL Cluster Issues Resolved in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x”, for more information.

• **LOAD TABLE ... FROM MASTER.** **LOAD TABLE FROM MASTER** is not supported.

• **Savepoints and rollbacks.** Savepoints and rollbacks to savepoints are ignored as in **MyISAM**.

• **Durability of commits.** There are no durable commits on disk. Commits are replicated, but there is no guarantee that logs are flushed to disk on commit.

• **Replication.** Statement-based replication is not supported. Use **--binlog-format=ROW** (or **--binlog-format=MIXED**) when setting up cluster replication. See Section 17.6, “MySQL Cluster Replication”, for more information.

---

**Note**

See Section 17.1.6.3, “Limits Relating to Transaction Handling in MySQL Cluster”, for more information relating to limitations on transaction handling in **NDB**.

### 17.1.6.7 Limitations Relating to Performance in MySQL Cluster

The following performance issues are specific to or especially pronounced in MySQL Cluster:

• **Range scans.** There are query performance issues due to sequential access to the **NDB** storage engine; it is also relatively more expensive to do many range scans than it is with either **MyISAM** or **InnoDB**.
Known Limitations of MySQL Cluster

- **Reliability of Records in range.** The `Records in range` statistic is available but is not completely tested or officially supported. This may result in nonoptimal query plans in some cases. If necessary, you can employ `USE INDEX` or `FORCE INDEX` to alter the execution plan. See Section 8.9.3, “Index Hints”, for more information on how to do this.

- **Unique hash indexes.** Unique hash indexes created with `USING HASH` cannot be used for accessing a table if `NULL` is given as part of the key.

### 17.1.6.8 Issues Exclusive to MySQL Cluster

The following are limitations specific to the `NDBCLUSTER` storage engine:

- **Machine architecture.** All machines used in the cluster must have the same architecture. That is, all machines hosting nodes must be either big-endian or little-endian, and you cannot use a mixture of both. For example, you cannot have a management node running on a PowerPC which directs a data node that is running on an x86 machine. This restriction does not apply to machines simply running `mysql` or other clients that may be accessing the cluster's SQL nodes.

- **Binary logging.**
  MySQL Cluster has the following limitations or restrictions with regard to binary logging:

  - `sql_log_bin` has no effect on data operations; however, it is supported for schema operations.
  - MySQL Cluster cannot produce a binary log for tables having `BLOB` columns but no primary key.
  - Only the following schema operations are logged in a cluster binary log which is *not* on the `mysqld` executing the statement:
    - `CREATE TABLE`
    - `ALTER TABLE`
    - `DROP TABLE`
    - `CREATE DATABASE`/`CREATE SCHEMA`
    - `DROP DATABASE`/`DROP SCHEMA`
    - `CREATE TABLESPACE`
    - `ALTER TABLESPACE`
    - `DROP TABLESPACE`
    - `CREATE LOGFILE GROUP`
    - `ALTER LOGFILE GROUP`
    - `DROP LOGFILE GROUP`

  See also Section 17.1.6.10, “Limitations Relating to Multiple MySQL Cluster Nodes”.

### 17.1.6.9 Limitations Relating to MySQL Cluster Disk Data Storage

**Disk Data object maximums and minimums.** Disk data objects are subject to the following maximums and minimums:

- Maximum number of tablespaces: $2^{32}$ (4294967296)
- Maximum number of data files per tablespace: $2^{16}$ (65536)
Known Limitations of MySQL Cluster

- Maximum data file size: The theoretical limit is 64G; however, in MySQL 5.1 (including MySQL Cluster NDB 6.X and 7.X through 7.1), the practical upper limit is 32G. This is equivalent to 32768 extents of 1M each.

Since a MySQL Cluster Disk Data table can use at most 1 tablespace, this means that the theoretical upper limit to the amount of data (in bytes) that can be stored on disk by a single NDB table is 32G * 65536 = 2251799813685248, or approximately 2 petabytes.

- The theoretical maximum number of extents per tablespace data file is $2^{16}$ (65536); however, for practical purposes, the recommended maximum number of extents per data file is $2^{15}$ (32768).

The minimum and maximum possible sizes of extents for tablespace data files are 32K and 2G, respectively. See Section 13.1.18, “CREATE TABLESPACE Syntax”, for more information.

**Disk Data tables and diskless mode.** Use of Disk Data tables is not supported when running the cluster in diskless mode. Beginning with MySQL 5.1.12, it is prohibited altogether. (Bug #20008)

### 17.1.6.10 Limitations Relating to Multiple MySQL Cluster Nodes

**Multiple SQL nodes.**
The following are issues relating to the use of multiple MySQL servers as MySQL Cluster SQL nodes, and are specific to the NDBCLUSTER storage engine:

- **No distributed table locks.** A `LOCK TABLES` works only for the SQL node on which the lock is issued; no other SQL node in the cluster “sees” this lock. This is also true for a lock issued by any statement that locks tables as part of its operations. (See next item for an example.)

- **ALTER TABLE operations.** `ALTER TABLE` is not fully locking when running multiple MySQL servers (SQL nodes). (As discussed in the previous item, MySQL Cluster does not support distributed table locks.)

**Multiple management nodes.**
When using multiple management servers:

- If any of the management servers are running on the same host, you must give nodes explicit IDs in connection strings because automatic allocation of node IDs does not work across multiple management servers on the same host. This is not required if every management server resides on a different host.

- In MySQL Cluster NDB 7.0.7 and earlier, you must take extreme care to have the same configurations for all management servers; no special checks for consistency are performed.

Beginning with MySQL Cluster NDB 7.0.8, a management server when first starting checks for any other management server in the same MySQL Cluster, and upon successful connection to the other management server uses its configuration data. This means that the management server `--reload` and `--initial` startup options are ignored unless the management server is the only one running. It also means that, when performing a rolling restart of a MySQL Cluster with multiple management nodes, the management server reads its own configuration file if (and only if) it is the only management server running in this MySQL Cluster. See Section 17.5.5, “Performing a Rolling Restart of a MySQL Cluster”, for more information.

**Multiple network addresses.** Multiple network addresses per data node are not supported. Use of these is liable to cause problems: In the event of a data node failure, an SQL node waits for confirmation that the data node went down but never receives it because another route to that data node remains open. This can effectively make the cluster inoperable.

---

**Note**

It is possible to use multiple network hardware interfaces (such as Ethernet cards) for a single data node, but these must be bound to the same address. This also means that it not possible to use more than one `[tcp]` section per
Known Limitations of MySQL Cluster

17.6.11 Previous MySQL Cluster Issues Resolved in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x

A number of limitations and related issues existing in earlier versions of MySQL Cluster have been resolved:

- **Variable-length column support.** The NDBCLUSTER storage engine now supports variable-length column types for in-memory tables.

  Previously, for example, any Cluster table having one or more VARCHAR fields which contained only relatively small values, much more memory and disk space were required when using the NDBCLUSTER storage engine than would have been the case for the same table and data using the MyISAM engine. In other words, in the case of a VARCHAR column, such a column required the same amount of storage as a CHAR column of the same size. In MySQL 5.1, this is no longer the case for in-memory tables, where storage requirements for variable-length column types such as VARCHAR and BINARY are comparable to those for these column types when used in MyISAM tables (see Section 11.7, “Data Type Storage Requirements”).

  **Important**

  For MySQL Cluster Disk Data tables, the fixed-width limitation continues to apply. See Section 17.5.12, “MySQL Cluster Disk Data Tables”.

- **Replication with MySQL Cluster.** It is now possible to use MySQL replication with Cluster databases. For details, see Section 17.6, “MySQL Cluster Replication”.

  **Circular Replication.** Circular replication is also supported with MySQL Cluster, beginning with MySQL 5.1.18. See Section 17.6.10, “MySQL Cluster Replication: Multi-Master and Circular Replication”.

- **auto_increment_increment and auto_increment_offset.** The auto_increment_increment and auto_increment_offset server system variables are supported for Cluster replication beginning with MySQL 5.1.20, MySQL Cluster NDB 6.2.5, and MySQL Cluster 6.3.2.

- **Database autodiscovery and online schema changes.** Autodiscovery of databases is now supported for multiple MySQL servers accessing the same MySQL Cluster. Formerly, autodiscovery in MySQL Cluster 5.1 and MySQL Cluster NDB 6.x releases required that a given mysqld was already running and connected to the cluster at the time that the database was created on a different mysqld—in other words, when a mysqld process connected to the cluster after a database named db_name was created, it was necessary to issue a CREATE DATABASE db_name or CREATE SCHEMA db_name statement on the “new” MySQL server when it first accessed that MySQL Cluster. Beginning with MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.18, such a CREATE statement is no longer required. (Bug #39612)

  This also means that online schema changes in NDB tables are now possible. That is, the result of operations such as ALTER TABLE and CREATE INDEX performed on one SQL node in the cluster are now visible to the cluster’s other SQL nodes without any additional action being taken.

- **Backup and restore between architectures.** Beginning with MySQL 5.1.10, it is possible to perform a Cluster backup and restore between different architectures. Previously—for example—you could not back up a cluster running on a big-endian platform and then restore from that backup to a cluster running on a little-endian system. (Bug #19255)

- **Character set directory.** Beginning with MySQL 5.1.10, it is possible to install MySQL with Cluster support to a nondefault location and change the search path for font description files using either the --basedir or --character-sets-dir options. (Previously, ndbd in MySQL 5.1 searched only the default path—typically /usr/local/mysql/share/mysql/charset—for character sets.)
Known Limitations of MySQL Cluster

- **Multiple management servers.** In MySQL 5.1 (including all MySQL Cluster NDB 6.x and later versions), it is no longer necessary, when running multiple management servers, to restart all the cluster’s data nodes to enable the management nodes to see one another.

  Also, when using multiple management servers and starting concurrently several API nodes (possibly including one or more SQL nodes) whose connection strings listed the management servers in different order, it was possible for 2 API nodes to be assigned the same node ID. This issue is resolved in MySQL Cluster NDB 6.2.17, 6.3.23, and 6.4.3. (Bug #42973)

  If any of the management servers are running on the same host, you must give nodes explicit IDs in connection strings because automatic allocation of node IDs does not work across multiple management servers on the same host. This is not required if every management server resides on a different host.

- **Multiple data node processes per host.** Beginning with MySQL Cluster NDB 6.2.0, you can use multiple data node processes on a single host. (In MySQL Cluster NDB 6.1, MySQL 5.1, and earlier release series, we did not support production MySQL Cluster deployments in which more than one ndbd process was run on a single physical machine.)

  In addition, MySQL Cluster NDB 7.0 introduces support for multi-threaded data nodes (ndbmt.d). See Section 17.1.4.3, “What is New in MySQL Cluster NDB 7.0”, and Section 17.4.3, “ndbmt.d — The MySQL Cluster Data Node Daemon (Multi-Threaded)”, for more information.

- **Identifiers.** Formerly (in MySQL 5.0 and earlier), database names, table names and attribute names could not be as long for NDB tables as tables using other storage engines, because attribute names were truncated internally. In MySQL 5.1 and later, names of MySQL Cluster databases, tables, and table columns follow the same rules regarding length as they do for any other storage engine.

- **Length of CREATE TABLE statements.** CREATE TABLE statements may be no more than 4096 characters in length. This limitation affects MySQL 5.1.6, 5.1.7, and 5.1.8 only. (See Bug #17813)

- **IGNORE and REPLACE functionality.** In MySQL 5.1.7 and earlier, INSERT IGNORE, UPDATE IGNORE, and REPLACE were supported only for primary keys, but not for unique keys. It was possible to work around this issue by removing the constraint, then dropping the unique index, performing any inserts, and then adding the unique index again.

  This limitation was removed for INSERT IGNORE and REPLACE in MySQL 5.1.8. (See Bug #17431.)

- **AUTO_INCREMENT columns.** In MySQL 5.1.10 and earlier versions, the maximum number of tables having AUTO_INCREMENT columns—including those belonging to hidden primary keys—was 2048.

  This limitation was lifted in MySQL 5.1.11.

- **Maximum number of cluster nodes.** Prior to MySQL Cluster NDB 6.1.1, the total maximum number of nodes in a MySQL Cluster was 63, including all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers.

  Starting with MySQL Cluster NDB 6.1.1, the total maximum number of nodes in a MySQL Cluster is 255, including all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers. The total number of data nodes and management nodes beginning with this version is 63, of which up to 48 can be data nodes.

  The limitation that a data node cannot have a node ID greater than 49 continues to apply.
**Known Limitations of MySQL Cluster**

- **Recovery of memory from deleted rows.** Beginning with MySQL Cluster NDB 6.3.7, memory can be reclaimed from an NDB table for reuse with any NDB table by employing `OPTIMIZE TABLE`, subject to the following limitations:
  - Only in-memory tables are supported; the `OPTIMIZE TABLE` statement still has no effect on MySQL Cluster Disk Data tables.
  - Only variable-length columns (such as those declared as VARCHAR, TEXT, or BLOB) are supported.

  However, you can force columns defined using fixed-length data types (such as CHAR) to be dynamic using the `ROW_FORMAT` or `COLUMN_FORMAT` option with a `CREATE TABLE` or `ALTER TABLE` statement.

  See Section 13.1.17, “CREATE TABLE Syntax”, and Section 13.1.7, “ALTER TABLE Syntax”, for information on these options.

  You can regulate the effects of `OPTIMIZE` on performance by adjusting the value of the global system variable `ndb_optimization_delay`, which sets the number of milliseconds to wait between batches of rows being processed by `OPTIMIZE`. The default value is 10 milliseconds. It is possible to set a lower value (to a minimum of 0), but not recommended. The maximum is 10000 milliseconds (that is, 100 seconds).

- **Implicit Rollbacks.** Prior to MySQL Cluster NDB 6.2.17 and MySQL Cluster NDB 6.3.19, MySQL Cluster did not automatically roll back a transaction that was aborted by a duplicate key or similar error, and subsequent statements raised `ERROR 1296 (HY000): Got error 4350 'Transaction already aborted' from NDBCLUSTER`. In such cases, it was necessary to issue an explicit `ROLLBACK` statement first, and then to retry the entire transaction.

  Beginning with MySQL Cluster NDB 6.2.17 and MySQL Cluster NDB 6.3.19, this limitation has been removed; now, an error which causes a transaction to be aborted generates an implicit rollback of the entire transaction. This is logged with the warning *Storage engine NDB does not support rollback for this statement. Transaction rolled back and must be restarted.* A statement subsequent to this starts a new transaction. (Bug #32656)

- **Number of tables.** Previously, the maximum number of NDBCLUSTER tables in a single MySQL Cluster was 1792, but this is no longer the case in MySQL 5.1 and later MySQL Cluster releases. However, the number of tables is still included in the total maximum number of NDBCLUSTER database objects (20320). (See Section 17.1.6.5, “Limits Associated with Database Objects in MySQL Cluster”.)

- **DDL operations.** Beginning with MySQL Cluster NDB 6.4.0, DDL operations (such as `CREATE TABLE` or `ALTER TABLE`) are protected from data node failures. Previously, if a data node failed while trying to perform one of these, the data dictionary became locked and no further DDL statements could be executed without restarting the cluster (Bug #36718).

- **Adding and dropping of data nodes.** In MySQL Cluster NDB 6.3 and previous versions of MySQL Cluster, the online adding or dropping of data nodes was not possible; such operations required a complete shutdown and restart of the entire cluster. In MySQL Cluster NDB 7.0 (beginning with MySQL Cluster NDB 6.4.0) and later MySQL Cluster release series, it is possible to add new data nodes to a running MySQL Cluster by performing a rolling restart, so that the cluster and the data stored in it remain available to applications.

  When planning to increase the number of data nodes in the cluster online in MySQL Cluster NDB 7.0 or MySQL Cluster NDB 7.1, you should be aware of and take into account the following issues:
Known Limitations of MySQL Cluster

- New data nodes can be added online to a MySQL Cluster only as part of a new node group.
- New data nodes can be added online, but cannot yet be dropped online. Reducing the number of data nodes still requires a system restart of the cluster.
- As in previous MySQL Cluster releases, it is not possible to change online either the number of replicas (NoOfReplicas configuration parameter) or the number of data nodes per node group. These changes require a system restart.
- Redistribution of existing cluster data using the new data nodes is not automatic; however, this can be accomplished using simple SQL statements in the mysql client or other MySQL client application once the nodes have been added. During this procedure, it is not possible to perform DDL operations, although DML operations can continue as normal.

The distribution of new cluster data (that is, data stored in the cluster after the new nodes have been added) uses the new nodes without manual intervention.

For more information, see Section 17.5.13, “Adding MySQL Cluster Data Nodes Online”.

- Native support for default column values. Starting with MySQL Cluster NDB 7.1.0, default values for table columns are stored by NDBCLUSTER, rather than by the MySQL server as was previously the case. Because less data must be sent from an SQL node to the data nodes, inserts on tables having column value defaults can be performed more efficiently than before.

Tables created using previous MySQL Cluster releases can still be used in MySQL Cluster 7.1.0 and later, although they do not support native default values and continue to use defaults supplied by the MySQL server until they are upgraded. This can be done by means of an offline ALTER TABLE statement.

⚠️ Important

You cannot set or change a table column's default value using an online ALTER TABLE operation.

- InnoDB plugin support. Previously, InnoDB support in MySQL Cluster was limited to the version built in to the MySQL Server. Beginning with MySQL Cluster NDB 7.1.9, MySQL Cluster also provides support for the InnoDB Plugin. See Section 17.2, “MySQL Cluster Installation and Upgrades”, for information about enabling InnoDB storage engine and plugin support with MySQL Cluster.

- Distribution of MySQL users and privileges. Previously, MySQL users and privileges created on one SQL node were unique to that SQL node, due to the fact that the MySQL grant tables were restricted to using the MyISAM storage engine. Beginning with MySQL Cluster NDB 7.2.0, it is possible, following installation of the MySQL Cluster software and setup of the desired users and privileges on one SQL node, to convert the grant tables to use NDB and thus to distribute the users and privileges across all SQL nodes connected to the cluster. You can do this by loading and making use of a set of stored procedures defined in an SQL script supplied with the MySQL Cluster distribution. For more information, see Section 17.5.14, “Distributed MySQL Privileges for MySQL Cluster”.

- Number of rows per partition. Previously, a single MySQL Cluster partition could hold a maximum of 46137488 rows. This limitation was removed in MySQL Cluster NDB 7.0.36 and MySQL Cluster NDB 7.1.25. (Bug #13844405, Bug #14000373)

If you are still using a previous MySQL Cluster release, you can work around this limitation by taking advantage of the fact that the number of partitions is the same as the number of data nodes in the cluster (see Section 17.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”). This means that, by increasing the number of data nodes, you can increase the available space for storing data.
In MySQL Cluster NDB 7.0 and later, you can increase the number of data nodes in the cluster while the cluster remains in operation. See Section 17.5.13, “Adding MySQL Cluster Data Nodes Online”, for more information.

It is also possible to increase the number of partitions for NDB tables by using explicit KEY or LINEAR KEY partitioning (see Section 18.2.4, “KEY Partitioning”).

17.2 MySQL Cluster Installation and Upgrades

This section describes the basics for planning, installing, configuring, and running a MySQL Cluster. Whereas the examples in Section 17.3, “Configuration of MySQL Cluster NDB 6.1-7.1” provide more in-depth information on a variety of clustering options and configuration, the result of following the guidelines and procedures outlined here should be a usable MySQL Cluster which meets the minimum requirements for availability and safeguarding of data.

For information about upgrading or downgrading a MySQL Cluster between release versions, see Section 17.2.7, “Upgrading and Downgrading MySQL Cluster”.

This section covers hardware and software requirements; networking issues; installation of MySQL Cluster; configuration issues; starting, stopping, and restarting the cluster; loading of a sample database; and performing queries.

Assumptions. The following sections make a number of assumptions regarding the cluster’s physical and network configuration. These assumptions are discussed in the next few paragraphs.

Cluster nodes and host computers. The cluster consists of four nodes, each on a separate host computer, and each with a fixed network address on a typical Ethernet network as shown here:

<table>
<thead>
<tr>
<th>Node</th>
<th>IP Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Management node (mgmd)</td>
<td>192.168.0.10</td>
</tr>
<tr>
<td>SQL node (mysqld)</td>
<td>192.168.0.20</td>
</tr>
<tr>
<td>Data node &quot;A&quot; (ndbd)</td>
<td>192.168.0.30</td>
</tr>
<tr>
<td>Data node &quot;B&quot; (ndbd)</td>
<td>192.168.0.40</td>
</tr>
</tbody>
</table>

This may be made clearer by the following diagram:

Figure 17.4 MySQL Cluster Multi-Computer Setup
Network addressing. In the interest of simplicity (and reliability), this How-To uses only numeric IP addresses. However, if DNS resolution is available on your network, it is possible to use host names in lieu of IP addresses in configuring Cluster. Alternatively, you can use the hosts file (typically /etc/hosts for Linux and other Unix-like operating systems, C:\WINDOWS\system32\drivers\etc\hosts on Windows, or your operating system's equivalent) for providing a means to do host lookup if such is available.

Potential hosts file issues. A common problem when trying to use host names for Cluster nodes arises because of the way in which some operating systems (including some Linux distributions) set up the system's own host name in the /etc/hosts during installation. Consider two machines with the host names ndb1 and ndb2, both in the cluster network domain. Red Hat Linux (including some derivatives such as CentOS and Fedora) places the following entries in these machines' /etc/hosts files:

```
# ndb1 /etc/hosts:
127.0.0.1   ndb1.cluster ndb1 localhost.localdomain localhost
```

```
# ndb2 /etc/hosts:
127.0.0.1   ndb2.cluster ndb2 localhost.localdomain localhost
```

SUSE Linux (including OpenSUSE) places these entries in the machines' /etc/hosts files:

```
# ndb1 /etc/hosts:
127.0.0.1       localhost
127.0.0.2       ndb1.cluster ndb1
```

```
# ndb2 /etc/hosts:
127.0.0.1       localhost
127.0.0.2       ndb2.cluster ndb2
```

In both instances, ndb1 routes ndb1.cluster to a loopback IP address, but gets a public IP address from DNS for ndb2.cluster, while ndb2 routes ndb2.cluster to a loopback address and obtains a public address for ndb1.cluster. The result is that each data node connects to the management server, but cannot tell when any other data nodes have connected, and so the data nodes appear to hang while starting.

Caution

You cannot mix localhost and other host names or IP addresses in config.ini. For these reasons, the solution in such cases (other than to use IP addresses for all config.ini HostName entries) is to remove the fully qualified host names from /etc/hosts and use these in config.ini for all cluster hosts.

Host computer type. Each host computer in our installation scenario is an Intel-based desktop PC running a supported operating system installed to disk in a standard configuration, and running no unnecessary services. The core operating system with standard TCP/IP networking capabilities should be sufficient. Also for the sake of simplicity, we also assume that the file systems on all hosts are set up identically. In the event that they are not, you should adapt these instructions accordingly.

Network hardware. Standard 100 Mbps or 1 gigabit Ethernet cards are installed on each machine, along with the proper drivers for the cards, and that all four hosts are connected through a standard-issue Ethernet networking appliance such as a switch. (All machines should use network cards with the same throughput. That is, all four machines in the cluster should have 100 Mbps cards or all four machines should have 1 Gbps cards.) MySQL Cluster works in a 100 Mbps network; however, gigabit Ethernet provides better performance.
![Important]

MySQL Cluster is not intended for use in a network for which throughput is less than 100 Mbps or which experiences a high degree of latency. For this reason (among others), attempting to run a MySQL Cluster over a wide area network such as the Internet is not likely to be successful, and is not supported in production.

**Sample data.** We use the `world` database which is available for download from the MySQL Web site (see [http://dev.mysql.com/doc/index-other.html](http://dev.mysql.com/doc/index-other.html)). We assume that each machine has sufficient memory for running the operating system, required MySQL Cluster processes, and (on the data nodes) storing the database.

For general information about installing MySQL, see Chapter 2, *Installing and Upgrading MySQL*. For information about installation of MySQL Cluster on Linux and other Unix-like operating systems, see Section 17.2.1, “Installing MySQL Cluster on Linux”. For information about installation of MySQL Cluster on Windows operating systems, see Section 17.2.2, “Installing MySQL Cluster on Windows”.

For general information about MySQL Cluster hardware, software, and networking requirements, see Section 17.1.3, “MySQL Cluster Hardware, Software, and Networking Requirements”.

### 17.2.1 Installing MySQL Cluster on Linux

This section covers installation of MySQL Cluster on Linux and other Unix-like operating systems. While the next few sections refer to a Linux operating system, the instructions and procedures given there should be easily adaptable to other supported Unix-like platforms.

Beginning with MySQL Cluster NDB 7.1.3, MySQL Cluster is also supported for production use on Windows operating systems; for installation and setup instructions specific to Windows, see Section 17.2.2, “Installing MySQL Cluster on Windows”.

Each MySQL Cluster host computer must have the correct executable programs installed. A host running an SQL node must have installed on it a MySQL Server binary (**mysqld**). Management nodes require the management server daemon (**ndb_mgmd**); data nodes require the data node daemon (**ndbd**); in MySQL Cluster NDB 7.0 and later, you can use **ndb_mtd** instead. It is not necessary to install the MySQL Server binary on management node hosts and data node hosts. It is recommended that you also install the management client (**ndb_mgm** on the management server host.

Installation of MySQL Cluster on Linux can be done using precompiled binaries from Oracle (downloaded as a .tar.gz archive), with RPM packages (also available from Oracle), or from source code. All three of these installation methods are described in the section that follow.

Regardless of the method used, it is still necessary following installation of the MySQL Cluster binaries to create configuration files for all cluster nodes, before you can start the cluster. See Section 17.2.3, “Initial Configuration of MySQL Cluster”.

#### 17.2.1.1 Installing a MySQL Cluster Binary Release on Linux

This section covers the steps necessary to install the correct executables for each type of Cluster node from precompiled binaries supplied by Oracle.

For setting up a cluster using precompiled binaries, the first step in the installation process for each cluster host is to download the latest MySQL Cluster NDB 6.3, MySQL Cluster NDB 7.0, or MySQL Cluster NDB 7.1 binary archive (**mysql-cluster-gpl-6.3.35-linux-i686-glibc23.tar.gz**, **mysql-cluster-gpl-7.0.42-linux-i686-glibc23.tar.gz**, or **mysql-cluster-gpl-7.1.37-linux-i686-glibc23.tar.gz**, respectively) from the MySQL Cluster downloads area. We assume that you have placed this file in each machine's `/var/tmp` directory. (If you do require a custom binary, see Section 2.11.3, “Installing MySQL Using a Development Source Tree”.)
Installing MySQL Cluster on Linux

Note

After completing the installation, do not yet start any of the binaries. We show you how to do so following the configuration of the nodes (see Section 17.2.3, "Initial Configuration of MySQL Cluster").

SQL nodes. On each of the machines designated to host SQL nodes, perform the following steps as the system root user:

1. Check your /etc/passwd and /etc/group files (or use whatever tools are provided by your operating system for managing users and groups) to see whether there is already a mysql group and mysql user on the system. Some OS distributions create these as part of the operating system installation process. If they are not already present, create a new mysql user group, and then add a mysql user to this group:

```
shell> groupadd mysql
shell> useradd -g mysql -s /bin/false mysql
```

The syntax for useradd and groupadd may differ slightly on different versions of Unix, or they may have different names such as adduser and addgroup.

2. Change location to the directory containing the downloaded file, unpack the archive, and create a symbolic link named mysql to the mysql directory. Note that the actual file and directory names vary according to the MySQL Cluster version number.

```
shell> cd /var/tmp
shell> tar -C /usr/local -xzvf mysql-cluster-gpl-7.1.37-linux-i686-glibc23.tar.gz
```

3. Change location to the mysql directory and run the supplied script for creating the system databases:

```
shell> cd mysql
shell> scripts/mysql_install_db --user=mysql
```

4. Set the necessary permissions for the MySQL server and data directories:

```
shell> chown -R root .
shell> chown -R mysql data
shell> chgrp -R mysql .
```

5. Copy the MySQL startup script to the appropriate directory, make it executable, and set it to start when the operating system is booted up:

```
shell> cp support-files/mysql.server /etc/rc.d/init.d/
shell> chmod +x /etc/rc.d/init.d/mysql.server
shell> chkconfig --add mysql.server
```

(The startup scripts directory may vary depending on your operating system and version—for example, in some Linux distributions, it is /etc/init.d.)

Here we use Red Hat's chkconfig for creating links to the startup scripts; use whatever means is appropriate for this purpose on your platform, such as update-rc.d on Debian.

Remember that the preceding steps must be repeated on each machine where an SQL node is to reside.

Data nodes. Installation of the data nodes does not require the mysql binary. Only the MySQL Cluster data node executable ndbd (single-threaded) or ndbmtd (multi-threaded) is required. These
binaries can also be found in the .tar.gz archive. Again, we assume that you have placed this archive in /var/tmp.

As system root (that is, after using sudo, su root, or your system’s equivalent for temporarily assuming the system administrator account’s privileges), perform the following steps to install the data node binaries on the data node hosts:

1. Change location to the /var/tmp directory, and extract the ndbd and ndbmtd binaries from the archive into a suitable directory such as /usr/local/bin:

```shell
shell> cd /var/tmp
shell> tar -zxvf mysql-5.1.77-ndb-7.1.37-linux-i686-glibc23.tar.gz
shell> cd mysql-5.1.77-ndb-7.1.37-linux-i686-glibc23
shell> cp bin/ndbd /usr/local/bin/ndbd
shell> cp bin/ndbmtd /usr/local/bin/ndbmtd
```

(You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from /var/tmp once ndb_mgm and ndb_mgmd have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

```shell
shell> cd /usr/local/bin
shell> chmod +x ndb*
```

The preceding steps should be repeated on each data node host.

Although only one of the data node executables is required to run a MySQL Cluster data node, we have shown you how to install both ndbd and ndbmtd in the preceding instructions. We recommend that you do this when installing or upgrading MySQL Cluster, even if you plan to use only one of them, since this will save time and trouble in the event that you later decide to change from one to the other.

**Note**

The data directory on each machine hosting a data node is /usr/local/mysql/data. This piece of information is essential when configuring the management node. (See Section 17.2.3, “Initial Configuration of MySQL Cluster”.)

**Management nodes.** Installation of the management node does not require the mysqld binary. Only the MySQL Cluster management server (ndb_mgmd) is required; you most likely want to install the management client (ndb_mgm) as well. Both of these binaries also be found in the .tar.gz archive. Again, we assume that you have placed this archive in /var/tmp.

As system root, perform the following steps to install ndb_mgm and ndb_mgm on the management node host:

1. Change location to the /var/tmp directory, and extract the ndb_mgm and ndb_mgm from the archive into a suitable directory such as /usr/local/bin:

```shell
shell> cd /var/tmp
shell> tar -zxvf mysql-5.1.77-ndb-7.1.37-linux-i686-glibc23.tar.gz
shell> cd mysql-5.1.77-ndb-7.1.37-linux-i686-glibc23
shell> cp bin/ndb_mgm* /usr/local/bin
```

(You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from /var/tmp once ndb_mgm and ndb_mgm have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:
17.2.1.2 Installing MySQL Cluster from RPM

This section covers the steps necessary to install the correct executables for each type of MySQL Cluster node using RPM packages supplied by Oracle.

RPMs are available for both 32-bit and 64-bit Linux platforms. For a MySQL Cluster, three RPMs are required:

- **The Server RPM** (for example, MySQL-Cluster-gpl-server-6.3.55-0.sles10.i586.rpm, MySQL-Cluster-gpl-server-7.0.42-0.sles10.i586.rpm, or MySQL-Cluster-gpl-server-7.1.37-0.sles10.i586.rpm), which supplies the core files needed to run a MySQL Server with NDBCLUSTER storage engine support (that is, as a MySQL Cluster SQL node).

  If you do not have your own client application capable of administering a MySQL server, you should also obtain and install the **Client RPM** (for example, MySQL-Cluster-gpl-client-6.3.55-0.sles10.i586.rpm, MySQL-Cluster-gpl-client-7.0.42-0.sles10.i586.rpm, or MySQL-Cluster-gpl-client-7.1.37-0.sles10.i586.rpm).

- **The Cluster storage engine RPM** (for example, MySQL-Cluster-gpl-storage-6.3.55-0.sles10.i586.rpm, MySQL-Cluster-gpl-storage-7.0.42-0.sles10.i586.rpm, or MySQL-Cluster-gpl-storage-7.1.37-0.sles10.i586.rpm), which supplies the MySQL Cluster data node binary (ndbd).

- **The Cluster storage engine management RPM** (for example, MySQL-Cluster-gpl-management-6.3.55-0.sles10.i586.rpm, MySQL-Cluster-gpl-management-7.0.42-0.sles10.i586.rpm, or MySQL-Cluster-gpl-management-7.1.37-0.sles10.i586.rpm) which provides the MySQL Cluster management server binary (ndb_mgmd).

In addition, you should also obtain the **NDB Cluster - Storage engine basic tools RPM** (for example, MySQL-Cluster-gpl-tools-6.3.55-0.sles10.i586.rpm, MySQL-Cluster-gpl-tools-7.0.42-0.sles10.i586.rpm, or MySQL-Cluster-gpl-tools-7.1.37-0.sles10.i586.rpm), which supplies several useful applications for working with a MySQL Cluster. The most important of these is the MySQL Cluster management client (ndb_mgm). The **NDB Cluster - Storage engine extra tools RPM** (for example, MySQL-Cluster-gpl-extra-6.3.55-0.sles10.i586.rpm, MySQL-Cluster-gpl-extra-7.0.42-0.sles10.i586.rpm, or MySQL-Cluster-gpl-extra-7.1.37-0.sles10.i586.rpm) contains some additional testing and monitoring programs, but is not required to install a MySQL Cluster. (For more information about these additional programs, see Section 17.4, "MySQL Cluster Programs").

The MySQL Cluster version number in the RPM file names (shown here as 6.3.55, 7.0.42, or 7.1.37) can vary according to the version which you are actually using. *It is very important that all of the Cluster RPMs to be installed have the same version number.* The glibc version number (if present), and architecture designation (shown here as i586) should be appropriate to the machine on which the RPM is to be installed.

**Data nodes.** On a computer that is to host a cluster data node it is necessary to install only the **NDB Cluster - Storage engine RPM**. To do so, copy this RPM to the data node host, and run the following command as the system root user, replacing the name shown for the RPM as necessary to match that of the RPM downloaded from the MySQL web site:
Installing MySQL Cluster on Linux

The previous command installs the MySQL Cluster data node binary (ndbd) in the /usr/sbin directory.

**SQL nodes.** On each machine to be used for hosting a cluster SQL node, install the **Server** RPM by executing the following command as the system root user, replacing the name shown for the RPM as necessary to match the name of the RPM downloaded from the MySQL web site:

```
shell> rpm -Uhv MySQL-Cluster-gpl-server-7.1.37-0.sles10.i586.rpm
```

This installs the MySQL server binary (mysqld) in the /usr/sbin directory, as well as all needed MySQL Server support files. It also installs the mysql.server and mysqld_safe startup scripts in /usr/share/mysql and /usr/bin, respectively. The RPM installer should take care of general configuration issues (such as creating the mysql user and group, if needed) automatically.

**Management nodes.** To install the MySQL Cluster management server, it is necessary only to use the **NDB Cluster - Storage engine management** RPM. Copy this RPM to the computer intended to host the management node, and then install it by running the following command as the system root user (replace the name shown for the RPM as necessary to match that of the **Storage engine management** RPM downloaded from the MySQL web site):

```
shell> rpm -Uhv MySQL-Cluster-gpl-management-7.1.37-0.sles10.i586.rpm
```

This installs the management server binary (ndb_mgmd) to the /usr/sbin directory.

You should also install the **NDB** management client, which is supplied by the **Storage engine basic tools** RPM. Copy this RPM to the same computer as the management node, and then install it by running the following command as the system root user (again, replace the name shown for the RPM as necessary to match that of the **Storage engine basic tools** RPM downloaded from the MySQL web site):

```
shell> rpm -Uhv MySQL-Cluster-gpl-tools-7.1.37-0.sles10.i586.rpm
```

The **Storage engine basic tools** RPM installs the MySQL Cluster management client (ndb_mgm) to the /usr/bin directory.

**Note**

You can also install the **Cluster storage engine extra tools** RPM, if you wish, as shown here:

```
shell> rpm -Uhv MySQL-Cluster-gpl-extra-7.1.37-0.sles10.i586.rpm
```

You may find the extra tools useful; however the **Cluster storage engine extra tools** RPM is not required to install a working MySQL Cluster.

See Section 2.5.1, “Installing MySQL on Linux Using RPM Packages”, for general information about installing MySQL using RPMs supplied by Oracle.
After installing from RPM, you still need to configure the cluster as discussed in Section 17.2.3, “Initial Configuration of MySQL Cluster”.

17.2.1.3 Building MySQL Cluster from Source on Linux

This section provides information about compiling MySQL Cluster on Linux and other Unix-like platforms. Building MySQL Cluster from source is similar to building the standard MySQL Server, although it differs in a few key respects discussed here. For general information about building MySQL from source, see Section 2.11, “Installing MySQL from Source”. Beginning with MySQL Cluster NDB 7.1.3, MySQL Cluster is also supported on Windows platforms, and can be built on Windows from source. For information about compiling MySQL Cluster on Windows platforms, see Section 17.2.2.2, “Compiling and Installing MySQL Cluster from Source on Windows”.

Building MySQL Cluster requires using the MySQL Cluster sources. These are available from the MySQL Cluster downloads page at http://dev.mysql.com/downloads/cluster/. The archived source file should have a name similar to `mysql-cluster-gpl-6.3.55.tar.gz`, `mysql-cluster-gpl-7.0.42.tar.gz`, or `mysql-cluster-gpl-7.1.37.tar.gz`. You can also obtain MySQL development sources from launchpad.net. Attempting to build MySQL Cluster from standard MySQL 5.1 sources is not supported.

In addition to any other configure options you wish to use, be sure to include `--with-plugins=ndbcluster`, `--with-plugins=max`, or `--with-plugins=max-no-innodb`. Either of these options causes the binaries for the management nodes, data nodes, and other MySQL Cluster programs to be built; it also causes `mysqld` to be compiled with NDB storage engine support.

After you have run `make && make install` (or your system’s equivalent), the result is similar to what is obtained by unpacking a precompiled binary to the same location. However, the layout can differ. These differences are covered in the next few paragraphs.

Prior to MySQL Cluster NDB 7.1.9, MySQL Cluster was not compatible with the InnoDB Plugin; in earlier MySQL Cluster releases, only the version of InnoDB supplied with the MySQL Server could be used. Beginning with MySQL Cluster NDB 7.1.9, you can build MySQL Cluster with InnoDB storage engine or plugin support using the appropriate `--with-plugins` option for configure.

Management nodes. When building from source and running the default `make install`, the management server binary (`ndb_mgmd`) is placed in `/usr/local/mysql/libexec`, while the management client binary (`ndb_mgm`) can be found in `/usr/local/mysql/bin`. Only `ndb_mgmd` is required to be present on a management node host; however, it is also a good idea to have `ndb_mgm` present on the same host machine. Neither of these executables requires a specific location on the host machine's file system.

Data nodes. The only executable required on a data node host is `ndbd` (`mysqld`, for example, does not have to be present on the host machine). By default when doing a source build, this file is placed in the directory `/usr/local/mysql/libexec`. For installing on multiple data node hosts, only `ndbd` need be copied to the other host machine or machines. (This assumes that all data node hosts use the same architecture and operating system; otherwise you may need to compile separately for each different platform.) `ndbd` need not be in any particular location on the host’s file system, as long as the location is known.

When compiling MySQL Cluster NDB 7.0 or later from source, no special options are required for building multi-threaded data node binaries. On Unix platforms, configuring the build with any of the options `--with-plugins=ndbcluster`, `--with-plugins=max`, or `--with-plugins=max-no-innodb` causes `ndbmtd` to be built automatically; `make install` places the `ndbmtd` binary in the `libexec` directory along with `mysqld`, `ndbd`, and `ndb_mgm`.

SQL nodes. If you compile MySQL with clustering support, and perform the default installation (using `make install` as the system root user), `mysqld` is placed in `/usr/local/mysql/bin`. Follow the steps given in Section 2.11, “Installing MySQL from Source” to make `mysqld` ready for use. If you want to run multiple SQL nodes, you can use a copy of the same `mysqld` executable and its
associated support files on several machines. The easiest way to do this is to copy the entire `/usr/local/mysql` directory and all directories and files contained within it to the other SQL node host or hosts, then repeat the steps from Section 2.11, “Installing MySQL from Source” on each machine. If you configure the build with a nondefault `--prefix`, you need to adjust the directory accordingly.

In Section 17.2.3, “Initial Configuration of MySQL Cluster”, we create configuration files for all of the nodes in our example MySQL Cluster.

17.2.2 Installing MySQL Cluster on Windows

Experimental support for MySQL Cluster on Microsoft Windows operating systems was introduced in MySQL Cluster NDB 7.0. Beginning with MySQL Cluster NDB 7.1.3, production support is provided for MySQL Cluster on Windows, and MySQL Cluster binaries for Windows can be obtained from http://dev.mysql.com/downloads/cluster/. For information about installing MySQL Cluster on Windows from a binary release provided by Oracle, see Section 17.2.2.1, “Installing MySQL Cluster on Windows from a Binary Release”.

It is also possible to compile and install MySQL Cluster from source on Windows using Microsoft Visual Studio. For more information, see Section 17.2.2.2, “Compiling and Installing MySQL Cluster from Source on Windows”.

17.2.2.1 Installing MySQL Cluster on Windows from a Binary Release

This section describes a basic installation of MySQL Cluster on Windows using a binary no-install MySQL Cluster release provided by Oracle, using the same 4-node setup outlined in the beginning of this section (see Section 17.2, “MySQL Cluster Installation and Upgrades”), as shown in the following table:

<table>
<thead>
<tr>
<th>Node</th>
<th>IP Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Management (MGMD) node</td>
<td>192.168.0.10</td>
</tr>
<tr>
<td>MySQL server (SQL) node</td>
<td>192.168.0.20</td>
</tr>
<tr>
<td>Data (NDBD) node &quot;A&quot;</td>
<td>192.168.0.30</td>
</tr>
<tr>
<td>Data (NDBD) node &quot;B&quot;</td>
<td>192.168.0.40</td>
</tr>
</tbody>
</table>

As on other platforms, the MySQL Cluster host computer running an SQL node must have installed on it a MySQL Server binary (`mysqld.exe`). You should also have the MySQL client (`mysql.exe`) on this host. For management nodes and data nodes, it is not necessary to install the MySQL Server binary; however, each management node requires the management server daemon (`ndb_mgmd.exe`); each data node requires the data node daemon (`ndbd.exe` or `ndbmtdd.exe`). For this example, we refer to `ndbd.exe` as the data node executable, but you can install `ndbmtdd.exe`, the multi-threaded version of this program, instead, in exactly the same way. You should also install the management client (`ndb_mgm.exe`) on the management server host. This section covers the steps necessary to install the correct Windows binaries for each type of MySQL Cluster node.

`ndbmtdd.exe` was not included in MySQL Cluster NDB 7.1.3 binary releases for Windows, due to a problem with `make_win_bin_dist`. This issue was corrected in MySQL Cluster NDB 7.1.5.

**Note**

As with other Windows programs, MySQL Cluster executables are named with the `.exe` file extension. However, it is not necessary to include the `.exe` extension when invoking these programs from the command line. Therefore, we often simply refer to these programs in this documentation as `mysqld`, `mysql`, `ndb_mgmd`, and so on. You should understand that, whether we refer (for example) to `mysqld` or `mysqld.exe`, either name means the same thing (the MySQL Server program).
Installing MySQL Cluster on Windows

For setting up a MySQL Cluster using Oracle's no-install binaries, the first step in the installation process is to download the latest MySQL Cluster Windows binary archive from http://dev.mysql.com/downloads/cluster/. This archive has a filename of the form mysql-cluster-gpl-noinstall-ver-winarch.zip, where ver is the NDB storage engine version (such as 7.1.3), and arch is the architecture (32 for 32-bit binaries, and 64 for 64-bit binaries). For example, the MySQL Cluster NDB 7.1.3 no-install archive for 32-bit Windows systems is named mysql-cluster-gpl-noinstall-7.1.3-win32.zip.

You can run 32-bit MySQL Cluster binaries on both 32-bit and 64-bit versions of Windows; however, 64-bit MySQL Cluster binaries can be used only on 64-bit versions of Windows. If you are using a 32-bit version of Windows on a computer that has a 64-bit CPU, then you must use the 32-bit MySQL Cluster binaries.

To minimize the number of files that need to be downloaded from the Internet or copied between machines, we start with the computer where you intend to run the SQL node.

**SQL node.** We assume that you have placed a copy of the no-install archive in the directory C:\Documents and Settings\username\My Documents\Downloads on the computer having the IP address 192.168.0.20, where username is the name of the current user. (You can obtain this name using ECHO %USERNAME% on the command line.) To install and run MySQL Cluster executables as Windows services, this user should be a member of the Administrators group.

Extract all the files from the archive. The Extraction Wizard integrated with Windows Explorer is adequate for this task. (If you use a different archive program, be sure that it extracts all files and directories from the archive, and that it preserves the archive's directory structure.) When you are asked for a destination directory, enter C:\, which causes the Extraction Wizard to extract the archive to the directory C:\mysql-cluster-gpl-noinstall-ver-winarch. Rename this directory to C:\mysql.

It is possible to install the MySQL Cluster binaries to directories other than C:\mysql\bin; however, if you do so, you must modify the paths shown in this procedure accordingly. In particular, if the MySQL Server (SQL node) binary is installed to a location other than C:\mysql or C:\Program Files \MySQL\MySQL Server 5.1, or if the SQL node's data directory is in a location other than C:\mysql\data or C:\Program Files\MySQL\MySQL Server 5.1\data, extra configuration options must be used on the command line or added to the my.ini or my.cnf file when starting the SQL node. For more information about configuring a MySQL Server to run in a nonstandard location, see Section 2.3.6, “Installing MySQL on Microsoft Windows Using a noinstall Zip Archive”.

For a MySQL Server with MySQL Cluster support to run as part of a MySQL Cluster, it must be started with the options --ndbcluster and --ndb-connectstring. While you can specify these options on the command line, it is usually more convenient to place them in an option file. To do this, create a new text file in Notepad or another text editor. Enter the following configuration information into this file:

```plaintext
[mysqld]
# Options for mysqld process:
ndbcluster # run NDB storage engine
ndb-connectstring=192.168.0.10 # location of management server
```

You can add other options used by this MySQL Server if desired (see Section 2.3.6.2, “Creating an Option File”), but the file must contain the options shown, at a minimum. Save this file as C:\mysql\my.ini. This completes the installation and setup for the SQL node.

**Data nodes.** A MySQL Cluster data node on a Windows host requires only a single executable, one of either ndbd.exe or ndbmtd.exe. For this example, we assume that you are using ndbd.exe, but the same instructions apply when using ndbmtd.exe. On each computer where you wish to run a data node (the computers having the IP addresses 192.168.0.30 and 192.168.0.40), create the directories C:\mysql,C:\mysql\bin, and C:\mysql\cluster-data; then, on the computer where you downloaded and extracted the no-install archive, locate ndbd.exe in the C:\mysql\bin directory. Copy this file to the C:\mysql\bin directory on each of the two data node hosts.
To function as part of a MySQL Cluster, each data node must be given the address or hostname of the management server. You can supply this information on the command line using the --ndb-connectstring or -c option when starting each data node process. However, it is usually preferable to put this information in an option file. To do this, create a new text file in Notepad or another text editor and enter the following text:

```
[mysql_cluster]
# Options for data node process:
ndb-connectstring=192.168.0.10  # location of management server
```

Save this file as `C:\mysql\my.ini` on the data node host. Create another text file containing the same information and save it as `C:\mysql\my.ini` on the other data node host, or copy the `my.ini` file from the first data node host to the second one, making sure to place the copy in the second data node’s `C:\mysql` directory. Both data node hosts are now ready to be used in the MySQL Cluster, which leaves only the management node to be installed and configured.

**Management node.** The only executable program required on a computer used for hosting a MySQL Cluster management node is the management server program `ndb_mgmd.exe`. However, in order to administer the MySQL Cluster once it has been started, you should also install the MySQL Cluster management client program `ndb_mgm.exe` on the same machine as the management server. Locate these two programs on the machine where you downloaded and extracted the no-install archive; this should be the directory `C:\mysql\bin` on the SQL node host. Create the directory `C:\mysql\bin` on the computer having the IP address 192.168.0.10, then copy both programs to this directory.

You should now create two configuration files for use by `ndb_mgmd.exe`:

1. A local configuration file to supply configuration data specific to the management node itself. Typically, this file needs only to supply the location of the MySQL Cluster global configuration file (see item 2).

   To create this file, start a new text file in Notepad or another text editor, and enter the following information:

   ```
   [mysql_cluster]
   # Options for management node process
   config-file=C:/mysql/bin/config.ini
   ```

   Save this file as the text file `C:\mysql\bin\my.ini`.

2. A global configuration file from which the management node can obtain configuration information governing the MySQL Cluster as a whole. At a minimum, this file must contain a section for each node in the MySQL Cluster, and the IP addresses or hostnames for the management node and all data nodes (`HostName` configuration parameter). It is also advisable to include the following additional information:

   - The IP address or hostname of any SQL nodes
   - The data memory and index memory allocated to each data node (`DataMemory` and `IndexMemory` configuration parameters)
   - The number of replicas, using the `NoOfReplicas` configuration parameter (see Section 17.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”)
   - The directory where each data node stores its data and log file, and the directory where the management node keeps its log files (in both cases, the `DataDir` configuration parameter)

   Create a new text file using a text editor such as Notepad, and input the following information:

   ```
   [ndbd default]
   ```
Installing MySQL Cluster on Windows

# Options affecting ndbd processes on all data nodes:
NoOfReplicas=2                      # Number of replicas
DataDir=C:/mysql/cluster-data       # Directory for each data node's data files
# Forward slashes used in directory path,
# rather than backslashes. This is correct;
# see Important note in text
DataMemory=80M    # Memory allocated to data storage
IndexMemory=18M   # Memory allocated to index storage
# For DataMemory and IndexMemory, we have used the
# default values. Since the "world" database takes up
# only about 500KB, this should be more than enough for
# this example Cluster setup.

[ndb_mgmd]
# Management process options:
HostName=192.168.0.10               # Hostname or IP address of management node
DataDir=C:/mysql/bin/cluster-logs   # Directory for management node log files

[ndbd]
# Options for data node "A":
HostName=192.168.0.30           # Hostname or IP address

[ndbd]
# Options for data node "B":
HostName=192.168.0.40           # Hostname or IP address

[mysqld]
# SQL node options:
HostName=192.168.0.20           # Hostname or IP address

Save this file as the text file C:\mysql\bin\config.ini.

---

Important

A single backslash character (\) cannot be used when specifying directory paths in program options or configuration files used by MySQL Cluster on Windows. Instead, you must either escape each backslash character with a second backslash (\\), or replace the backslash with a forward slash character (/). For example, the following line from the [ndb_mgmd] section of a MySQL Cluster config.ini file does not work:

```
DataDir=C:\mysql\bin\cluster-logs
```

Instead, you may use either of the following:

```
DataDir=C:\\mysql\\bin\\cluster-logs  # Escaped backslashes
DataDir=C:/mysql/bin/cluster-logs     # Forward slashes
```

For reasons of brevity and legibility, we recommend that you use forward slashes in directory paths used in MySQL Cluster program options and configuration files on Windows.

---

17.2.2.2 Compiling and Installing MySQL Cluster from Source on Windows

Oracle provides precompiled MySQL Cluster binaries for Windows which should be adequate for most users. However, if you wish, it is also possible to compile MySQL Cluster for Windows from source code. The procedure for doing this is almost identical to the procedure used to compile the standard MySQL Server binaries for Windows, and uses the same tools. However, there are two major differences:

- To build MySQL Cluster, you must use the MySQL Cluster sources, which you can obtain from [http://dev.mysql.com/downloads/cluster/](http://dev.mysql.com/downloads/cluster/).
Attempting to build MySQL Cluster from the source code for the standard MySQL Server is likely not to be successful, and is not supported by Oracle.

- You must configure the build using the `WITH_NDBCLUSTER_STORAGE_ENGINE` option in addition to any other build options you wish to use before creating the Visual Studio project files. Once you have run `configure.js` with the desired options, you can create the project files and build from them in the same manner as you do when compiling the standard MySQL Server. For more information, see Section 2.11.7, “Installing MySQL from Source on Windows”.

Prior to MySQL Cluster NDB 7.1.9, MySQL Cluster was not compatible with the InnoDB Plugin; in earlier MySQL Cluster releases, only the version of InnoDB supplied with the MySQL Server could be used. Beginning with MySQL Cluster NDB 7.1.9, you can build MySQL Cluster with InnoDB storage engine or plugin support on Windows using `WITH_INNOBASE_STORAGE_ENGINE` with `configure.js`.

Once the build process is complete, you can create a Zip archive containing the compiled binaries by running `make_win_bin_dist`. The MySQL Cluster binaries can be found in the `bin` directory of the resulting archive, which is equivalent to the `no-install` archive, and which can be installed and configured in the same manner. For basic information about how to accomplish these tasks, see Section 17.2.2.1, “Installing MySQL Cluster on Windows from a Binary Release”.

On Windows, beginning with MySQL Cluster NDB 7.0.11, using `WITH_NDBCLUSTER_STORAGE_ENGINE` with `configure.js` causes `ndbmtd.exe` to be built automatically, and to be found in the `bin` directory of the archive created by `make_win_bin_dist`. (It was not possible to build `ndbmtd.exe` on Windows prior to MySQL Cluster NDB 7.0.11.)

### 17.2.2.3 Initial Startup of MySQL Cluster on Windows

Once the MySQL Cluster executables and needed configuration files are in place, performing an initial start of the cluster is simply a matter of starting the MySQL Cluster executables for all nodes in the cluster. Each cluster node process must be started separately, and on the host computer where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes.

1. On the management node host, issue the following command from the command line to start the management node process:

   ```
   C:\mysql\bin> ndb_mgmd
   2010-06-23 07:53:34 [MgmtSrvr] INFO -- Reading cluster configuration from 'config.ini'
   ```

   The management node process continues to print logging output to the console. This is normal, because the management node is not running as a Windows service. (If you have used MySQL Cluster on a Unix-like platform such as Linux, you may notice that the management node’s default behavior in this regard on Windows is effectively the opposite of its behavior on Unix systems, where it runs by default as a Unix daemon process. This behavior is also true of MySQL Cluster data node processes running on Windows.) For this reason, do not close the window in which `ndb_mgmd.exe` is running; doing so kills the management node process. (See Section 17.2.2.4, “Installing MySQL Cluster Processes as Windows Services”, where we show how to install and run MySQL Cluster processes as Windows services.)

   The required `-f` option tells the management node where to find the global configuration file `config.ini`. The long form of this option is `--config-file`.

   **Important**

   A MySQL Cluster management node caches the configuration data that it reads from `config.ini`; once it has created a configuration cache, it ignores the `config.ini` file on subsequent starts unless forced to do otherwise. This means that, if the management node fails to start due
Installing MySQL Cluster on Windows

To an error in this file, you must make the management node re-read
\texttt{config.ini} after you have corrected any errors in it. You can do this by
starting \texttt{ndb_mgmd.exe} with the \texttt{--reload} or \texttt{--initial} option on the
command line. Either of these options works to refresh the configuration
cache.

It is not necessary or advisable to use either of these options in the
management node's \texttt{my.ini} file.

For additional information about options which can be used with \texttt{ndb_mgmd}, see Section 17.4.4,
``ndb_mgmd — The MySQL Cluster Management Server Daemon``, as well as Section 17.4.26,
``Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs``.

2. On each of the data node hosts, run the command shown here to start the data node processes:

\begin{verbatim}
C:\mysql\bin> ndbd
\end{verbatim}

In each case, the first line of output from the data node process should resemble what is shown
in the preceding example, and is followed by additional lines of logging output. As with the
management node process, this is normal, because the data node is not running as a Windows
service. For this reason, do not close the console window in which the data node process is
running; doing so kills \texttt{ndbd.exe}. (For more information, see Section 17.2.2.4, "Installing MySQL
Cluster Processes as Windows Services").

3. Do not start the SQL node yet; it cannot connect to the cluster until the data nodes have finished
starting, which may take some time. Instead, in a new console window on the management
node host, start the MySQL Cluster management client \texttt{ndb_mgm.exe}, which should be in \texttt{C:\mysql\bin}
on the management node host. (Do not try to re-use the console window where
\texttt{ndb_mgm.exe} is running by typing \texttt{CTRL+C}, as this kills the management node.) The resulting
output should look like this:

\begin{verbatim}
C:\mysql\bin> ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm>
\end{verbatim}

When the prompt \texttt{ndb_mgm>} appears, this indicates that the management client is ready to receive
MySQL Cluster management commands. You can observe the status of the data nodes as they
start by entering \texttt{ALL STATUS} at the management client prompt. This command causes a running
report of the data nodes's startup sequence, which should look something like this:

\begin{verbatim}
ndb_mgm> ALL STATUS
Connected to Management Server at: localhost:1186
Node 2: starting (Last completed phase 3) (mysql-5.1.77-ndb-7.1.37)
Node 3: starting (Last completed phase 3) (mysql-5.1.77-ndb-7.1.37)

Node 2: starting (Last completed phase 4) (mysql-5.1.77-ndb-7.1.37)
Node 3: starting (Last completed phase 4) (mysql-5.1.77-ndb-7.1.37)

Node 2: Started (version 7.1.37)
Node 3: Started (version 7.1.37)
\end{verbatim}

\textbf{Note}

Commands issued in the management client are not case-sensitive; we
use uppercase as the canonical form of these commands, but you are not
required to observe this convention when inputting them into the \texttt{ndb_mgm}
client. For more information, see Section 17.5.2, "Commands in the MySQL
Cluster Management Client".
The output produced by `ALL STATUS` is likely to vary from what is shown here, according to the speed at which the data nodes are able to start, the release version number of the MySQL Cluster software you are using, and other factors. What is significant is that, when you see that both data nodes have started, you are ready to start the SQL node.

You can leave `ndb_mgm.exe` running; it has no negative impact on the performance of the MySQL Cluster, and we use it in the next step to verify that the SQL node is connected to the cluster after you have started it.

4. On the computer designated as the SQL node host, open a console window and navigate to the directory where you unpacked the MySQL Cluster binaries (if you are following our example, this is `C:\mysql\bin`).

Start the SQL node by invoking `mysqld.exe` from the command line, as shown here:

```
C:\mysql\bin> mysqld --console
```

The `--console` option causes logging information to be written to the console, which can be helpful in the event of problems. (Once you are satisfied that the SQL node is running in a satisfactory manner, you can stop it and restart it without the `--console` option, so that logging is performed normally.)

In the console window where the management client (`ndb_mgm.exe`) is running on the management node host, enter the `SHOW` command, which should produce output similar to what is shown here:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
[ndbd(NDB)]  2 node(s)
id=2    @192.168.0.30  (Version: 5.1.77-ndb-7.1.37, Nodegroup: 0, *)
id=3    @192.168.0.40  (Version: 5.1.77-ndb-7.1.37, Nodegroup: 0)
[ndb_mgmd(MGM)] 1 node(s)
id=1    @192.168.0.10  (Version: 5.1.77-ndb-7.1.37)
[mysqld(API)]  1 node(s)
id=4    @192.168.0.20  (Version: 5.1.77-ndb-7.1.37)
```

You can also verify that the SQL node is connected to the MySQL Cluster in the `mysql` client (`mysql.exe`) using the `SHOW ENGINE NDB STATUS` statement.

You should now be ready to work with database objects and data using MySQL Cluster's `NDBCLUSTER` storage engine. See Section 17.2.5, “MySQL Cluster Example with Tables and Data”, for more information and examples.

Beginning with MySQL Cluster NDB 7.0.16 and MySQL Cluster NDB 7.1.5, you can install `ndb_mgmd.exe`, `ndbd.exe`, and `ndbmtd.exe` as Windows services. For information on how to do this, see Section 17.2.2.4, “Installing MySQL Cluster Processes as Windows Services”.

### 17.2.2.4 Installing MySQL Cluster Processes as Windows Services

Once you are satisfied that MySQL Cluster is running as desired, you can—beginning with MySQL Cluster NDB 7.0.16 and MySQL Cluster NDB 7.1.5—install the management nodes and data nodes as Windows services, so that these processes are started and stopped automatically whenever Windows is started or stopped. This also makes it possible to control these processes from the command line with the appropriate `NET START` or `NET STOP` command, or using the Windows graphical Services utility.
Installing programs as Windows services usually must be done using an account that has Administrator rights on the system.

To install the management node as a service on Windows, invoke `ndb_mgmd.exe` from the command line on the machine hosting the management node, using the `--install` option, as shown here:

```bash
C:\> C:\mysql\bin\ndb_mgmd.exe --install
Installing service 'MySQL Cluster Management Server' as "C:\mysql\bin\ndbd.exe" "--service=ndb_mgmd"
Service successfully installed.
```

**Important**
When installing a MySQL Cluster program as a Windows service, you should always specify the complete path; otherwise the service installation may fail with the error *The system cannot find the file specified.*

The `--install` option must be used first, ahead of any other options that might be specified for `ndb_mgmd.exe`. However, it is preferable to specify such options in an options file instead. If your options file is not in one of the default locations as shown in the output of `ndb_mgmd.exe --help`, you can specify the location using the `--config-file` option.

Now you should be able to start and stop the management server like this:

```bash
C:\> NET START ndb_mgmd
The MySQL Cluster Management Server service is starting.
The MySQL Cluster Management Server service was started successfully.
C:\> NET STOP ndb_mgmd
The MySQL Cluster Management Server service is stopping..
The MySQL Cluster Management Server service was stopped successfully.
```

You can also start or stop the management server as a Windows service using the descriptive name, as shown here:

```bash
C:\> NET START 'MySQL Cluster Management Server'
The MySQL Cluster Management Server service is starting.
The MySQL Cluster Management Server service was started successfully.
C:\> NET STOP 'MySQL Cluster Management Server'
The MySQL Cluster Management Server service is stopping..
The MySQL Cluster Management Server service was stopped successfully.
```

However, it is usually simpler to specify a short service name or to permit the default service name to be used when installing the service, and then reference that name when starting or stopping the service. To specify a service name other than `ndb_mgmd`, append it to the `--install` option, as shown in this example:

```bash
C:\> C:\mysql\bin\ndb_mgmd.exe --install=mgmd1
Installing service 'MySQL Cluster Management Server' as "C:\mysql\bin\ndb_mgmd.exe" "--service=mgmd1"
Service successfully installed.
```

Now you should be able to start or stop the service using the name you have specified, like this:

```bash
C:\> NET START mgmd1
The MySQL Cluster Management Server service is starting.
The MySQL Cluster Management Server service was started successfully.
C:\> NET STOP mgmd1
The MySQL Cluster Management Server service is stopping..
```
The MySQL Cluster Management Server service was stopped successfully.

To remove the management node service, invoke `ndb_mgmd.exe` with the `--remove` option, as shown here:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --remove
Removing service 'MySQL Cluster Management Server'
Service successfully removed.
```

If you installed the service using a service name other than the default, you can remove the service by passing this name as the value of the `--remove` option, like this:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --remove=mgmd1
Removing service 'mgmd1'
Service successfully removed.
```

Installation of a MySQL Cluster data node process as a Windows service can be done in a similar fashion, using the `--install` option for `ndbd.exe` (or `ndbmtd.exe`), as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --install
Installing service 'MySQL Cluster Data Node Daemon' as "C:\mysql\bin\ndbd.exe" '--service=ndbd''
Service successfully installed.
```

Now you can start or stop the data node using either the default service name or the descriptive name with `net start` or `net stop`, as shown in the following example:

```
C:\> NET START ndbd
The MySQL Cluster Data Node Daemon service is starting.
The MySQL Cluster Data Node Daemon service was started successfully.

C:\> NET STOP ndbd
The MySQL Cluster Data Node Daemon service is stopping..
The MySQL Cluster Data Node Daemon service was stopped successfully.

C:\> NET START 'MySQL Cluster Data Node Daemon'
The MySQL Cluster Data Node Daemon service is starting.
The MySQL Cluster Data Node Daemon service was started successfully.

C:\> NET STOP 'MySQL Cluster Data Node Daemon'
The MySQL Cluster Data Node Daemon service is stopping..
The MySQL Cluster Data Node Daemon service was stopped successfully.
```

To remove the data node service, invoke `ndbd.exe` with the `--remove` option, as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --remove
Removing service 'MySQL Cluster Data Node Daemon'
Service successfully removed.
```

As with `ndb_mgmd.exe` (and `mysqld.exe`), when installing `ndbd.exe` as a Windows service, you can also specify a name for the service as the value of `--install`, and then use it when starting or stopping the service, like this:

```
C:\> C:\mysql\bin\ndbd.exe --install=dnode1
Installing service 'dnode1' as "C:\mysql\bin\ndbd.exe" '--service=dnode1''
Service successfully installed.

C:\> NET START dnode1
The MySQL Cluster Data Node Daemon service is starting.
The MySQL Cluster Data Node Daemon service was started successfully.

C:\> NET STOP dnode1
The MySQL Cluster Data Node Daemon service is stopping..
```

1850
The MySQL Cluster Data Node Daemon service was stopped successfully.

If you specified a service name when installing the data node service, you can use this name when removing it as well, by passing it as the value of the `--remove` option, as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --remove=dnode1
Removing service 'dnode1'
Service successfully removed.
```

Installation of the SQL node as a Windows service, starting the service, stopping the service, and removing the service are done in a similar fashion, using `mysqld --install`, `NET START`, `NET STOP`, and `mysqld --remove`. For additional information, see Section 2.3.6.7, “Starting MySQL Server as a Microsoft Windows Service”.

### 17.2.3 Initial Configuration of MySQL Cluster

For our four-node, four-host MySQL Cluster, it is necessary to write four configuration files, one per node host.

- Each data node or SQL node requires a `my.cnf` file that provides two pieces of information: a `connection string` that tells the node where to find the management node, and a line telling the MySQL server on this host (the machine hosting the data node) to enable the `NDBCLUSTER` storage engine.

  For more information on connection strings, see Section 17.3.3.3, “MySQL Cluster Connection Strings”.

- The management node needs a `config.ini` file telling it how many replicas to maintain, how much memory to allocate for data and indexes on each data node, where to find the data nodes, where to save data to disk on each data node, and where to find any SQL nodes.

#### Configuring the data nodes and SQL nodes.

The `my.cnf` file needed for the data nodes is fairly simple. The configuration file should be located in the `/etc` directory and can be edited using any text editor. (Create the file if it does not exist.) For example:

```
shell> vi /etc/my.cnf
```

*Note*

We show `vi` being used here to create the file, but any text editor should work just as well.

For each data node and SQL node in our example setup, `my.cnf` should look like this:

```
[mysqld]
# Options for mysqld process:
ndbcluster                      # run NDB storage engine

[mysql_cluster]
# Options for MySQL Cluster processes:
ndb-connectstring=192.168.0.10  # location of management server
```

After entering the preceding information, save this file and exit the text editor. Do this for the machines hosting data node “A”, data node “B”, and the SQL node.

*Important*

Once you have started a `mysqld` process with the `ndbcluster` and `ndb-connectstring` parameters in the `[mysqld]` and `[mysql_cluster]` sections of the `my.cnf` file as shown previously, you cannot execute any
**Initial Configuration of MySQL Cluster**

**CREATE TABLE** or **ALTER TABLE** statements without having actually started the cluster. Otherwise, these statements will fail with an error. This is by design.

**Configuring the management node.** The first step in configuring the management node is to create the directory in which the configuration file can be found and then to create the file itself. For example (running as **root**):

```
shell> mkdir /var/lib/mysql-cluster
shell> cd /var/lib/mysql-cluster
shell> vi config.ini
```

For our representative setup, the **config.ini** file should read as follows:

```
[ndbd default]
# Options affecting ndbd processes on all data nodes:
NoOfReplicas=2    # Number of replicas
DataMemory=80M    # How much memory to allocate for data storage
IndexMemory=18M   # How much memory to allocate for index storage
# For DataMemory and IndexMemory, we have used the
data default values. Since the "world" database takes up
only about 500KB, this should be more than enough for
this example Cluster setup.

[tcp default]
# TCP/IP options:
portnumber=2202   # This the default; however, you can use any
    # port that is free for all the hosts in the cluster
    # Note: It is recommended that you do not specify the port
    # number at all and simply allow the default value to be used
    # instead

[ndb_mgmd]
# Management process options:
hostname=192.168.0.10           # Hostname or IP address of MGM node
datadir=/var/lib/mysql-cluster  # Directory for MGM node log files

[ndbd]
# Options for data node "A":
hostname=192.168.0.30           # Hostname or IP address
datadir=/usr/local/mysql/data   # Directory for this data node's data files

[ndbd]
# Options for data node "B":
hostname=192.168.0.40           # Hostname or IP address
datadir=/usr/local/mysql/data   # Directory for this data node's data files

[mysqld]
# SQL node options:
hostname=192.168.0.20           # Hostname or IP address
# (additional mysqld connections can be
# specified for this node for various
# purposes such as running ndb_restore)
```

**Note**

The **world** database can be downloaded from [http://dev.mysql.com/doc/index-other.html](http://dev.mysql.com/doc/index-other.html).

After all the configuration files have been created and these minimal options have been specified, you are ready to proceed with starting the cluster and verifying that all processes are running. We discuss how this is done in Section 17.2.4, “Initial Startup of MySQL Cluster”.

For more detailed information about the available MySQL Cluster configuration parameters and their uses, see Section 17.3.3, “MySQL Cluster Configuration Files”, and Section 17.3, “Configuration of MySQL Cluster NDB 6.1-7.1”. For configuration of MySQL Cluster as relates to making backups, see Section 17.5.3.3, “Configuration for MySQL Cluster Backups”.
Initial Startup of MySQL Cluster

Note
The default port for Cluster management nodes is 1186; the default port for data nodes is 2202. However, the cluster can automatically allocate ports for data nodes from those that are already free.

17.2.4 Initial Startup of MySQL Cluster

Starting the cluster is not very difficult after it has been configured. Each cluster node process must be started separately, and on the host where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes:

1. On the management host, issue the following command from the system shell to start the management node process:

   \texttt{shell} > \texttt{ndb_mgmd -f /var/lib/mysql-cluster/config.ini}

   \texttt{ndb_mgmd} must be told where to find its configuration file, using the \texttt{-f} or \texttt{--config-file} option. (See Section 17.4.4, "\texttt{ndb_mgmd} — The MySQL Cluster Management Server Daemon", for details.)

   For additional options which can be used with \texttt{ndb_mgmd}, see Section 17.4.26, "Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs".

2. On each of the data node hosts, run this command to start the \texttt{ndbd} process:

   \texttt{shell} > \texttt{ndbd}

3. If you used RPM files to install MySQL on the cluster host where the SQL node is to reside, you can (and should) use the supplied startup script to start the MySQL server process on the SQL node.

   If all has gone well, and the cluster has been set up correctly, the cluster should now be operational. You can test this by invoking the \texttt{ndb_mgm} management node client. The output should look like that shown here, although you might see some slight differences in the output depending upon the exact version of MySQL that you are using:

   \texttt{shell} > \texttt{ndb_mgm}
   
   \texttt{-- NDB Cluster -- Management Client --}
   
   \texttt{ndb_mgm> SHOW}
   
   Connected to Management Server at: localhost:1186
   
   Cluster Configuration
   
   ----------------------
   
   [ndbd(NDB)]  2 node(s)
   id=2 @192.168.0.30 (Version: 5.1.77-ndb-7.1.37, Nodegroup: 0, *)
   id=3 @192.168.0.40 (Version: 5.1.77-ndb-7.1.37, Nodegroup: 0)
   
   [ndb_mgmd(MGM)] 1 node(s)
   id=1 @192.168.0.10 (Version: 5.1.77-ndb-7.1.37)

   [mysqld(API)]  1 node(s)
   id=4 @192.168.0.20 (Version: 5.1.77-ndb-7.1.37)

   The SQL node is referenced here as \texttt{[mysqld(API)]}, which reflects the fact that the \texttt{mysqld} process is acting as a MySQL Cluster API node.

   Note
   The IP address shown for a given MySQL Cluster SQL or other API node in the output of \texttt{SHOW} is the address used by the SQL or API node to connect to the cluster data nodes, and not to any management node.

   You should now be ready to work with databases, tables, and data in MySQL Cluster. See Section 17.2.5, "MySQL Cluster Example with Tables and Data", for a brief discussion.
17.2.5 MySQL Cluster Example with Tables and Data

Note

The information in this section applies to MySQL Cluster running on both Unix and Windows platforms.

Working with database tables and data in MySQL Cluster is not much different from doing so in standard MySQL. There are two key points to keep in mind:

• For a table to be replicated in the cluster, it must use the `NDBCLUSTER` storage engine. To specify this, use the `ENGINE=NDBCLUSTER` or `ENGINE=NDB` option when creating the table:

  ```sql
  CREATE TABLE tbl_name (col_name column_definitions) ENGINE=NDBCLUSTER;
  ```

  Alternatively, for an existing table that uses a different storage engine, use `ALTER TABLE` to change the table to use `NDBCLUSTER`:

  ```sql
  ALTER TABLE tbl_name ENGINE=NDBCLUSTER;
  ```

• Every `NDBCLUSTER` table has a primary key. If no primary key is defined by the user when a table is created, the `NDBCLUSTER` storage engine automatically generates a hidden one. Such a key takes up space just as does any other table index. (It is not uncommon to encounter problems due to insufficient memory for accommodating these automatically created indexes.)

If you are importing tables from an existing database using the output of `mysqldump`, you can open the SQL script in a text editor and add the `ENGINE` option to any table creation statements, or replace any existing `ENGINE` options. Suppose that you have the world sample database on another MySQL server that does not support MySQL Cluster, and you want to export the `City` table:

```bash
shell> mysqldump --add-drop-table world City > city_table.sql
```

The resulting `city_table.sql` file will contain this table creation statement (and the `INSERT` statements necessary to import the table data):

```sql
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
  `CountryCode` char(3) NOT NULL default '',
  `District` char(20) NOT NULL default '',
  `Population` int(11) NOT NULL default '0',
  PRIMARY KEY (`ID`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1;

INSERT INTO `City` VALUES (1,'Kabul','AFG','Kabol',1780000);
INSERT INTO `City` VALUES (2,'Kandahar','AFG','Kandahar',237500);
INSERT INTO `City` VALUES (3,'Herat','AFG','Herat',186800);

(remaining INSERT statements omitted)
```

You need to make sure that MySQL uses the `NDBCLUSTER` storage engine for this table. There are two ways that this can be accomplished. One of these is to modify the table definition before importing it into the Cluster database. Using the `City` table as an example, modify the `ENGINE` option of the definition as follows:

```sql
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
  `CountryCode` char(3) NOT NULL default '',
  `District` char(20) NOT NULL default '',
  PRIMARY KEY (`ID`)
) ENGINE=NDBCLUSTER;
```

1854
MySQL Cluster Example with Tables and Data

This must be done for the definition of each table that is to be part of the clustered database. The easiest way to accomplish this is to do a search-and-replace on the file that contains the definitions and replace all instances of `TYPE=engine_name` or `ENGINE=engine_name` with `ENGINE=NDBCLUSTER`. If you do not want to modify the file, you can use the unmodified file to create the tables, and then use `ALTER TABLE` to change their storage engine. The particulars are given later in this section.

Assuming that you have already created a database named `world` on the SQL node of the cluster, you can then use the `mysql` command-line client to read `city_table.sql`, and create and populate the corresponding table in the usual manner:

```
shell> mysql world < city_table.sql
```

It is very important to keep in mind that the preceding command must be executed on the host where the SQL node is running (in this case, on the machine with the IP address `192.168.0.20`).

To create a copy of the entire `world` database on the SQL node, use `mysqldump` on the noncluster server to export the database to a file named `world.sql`; for example, in the `/tmp` directory. Then modify the table definitions as just described and import the file into the SQL node of the cluster like this:

```
shell> mysql world < /tmp/world.sql
```

If you save the file to a different location, adjust the preceding instructions accordingly.

Running `SELECT` queries on the SQL node is no different from running them on any other instance of a MySQL server. To run queries from the command line, you first need to log in to the MySQL Monitor in the usual way (specify the `root` password at the `Enter password:` prompt):

```
shell> mysql -u root -p
Enter password: 
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 5.1.77-ndb-7.1.37
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
mysql>
```

We simply use the MySQL server’s `root` account and assume that you have followed the standard security precautions for installing a MySQL server, including setting a strong `root` password. For more information, see Section 2.12.4, “Securing the Initial MySQL Accounts”.

It is worth taking into account that Cluster nodes do not make use of the MySQL privilege system when accessing one another. Setting or changing MySQL user accounts (including the `root` account) effects only applications that access the SQL node, not interaction between nodes. See Section 17.5.11.2, “MySQL Cluster and MySQL Privileges”, for more information.

If you did not modify the `ENGINE` clauses in the table definitions prior to importing the SQL script, you should run the following statements at this point:

```
mysql> USE world;
mysql> ALTER TABLE city ENGINE=NDBCLUSTER;
mysql> ALTER TABLE country ENGINE=NDBCLUSTER;
mysql> ALTER TABLE countrylanguage ENGINE=NDBCLUSTER;
```
Selecting a database and running a `SELECT` query against a table in that database is also accomplished in the usual manner, as is exiting the MySQL Monitor:

```
mysql> USE world;
mysql> SELECT Name, Population FROM city ORDER BY Population DESC LIMIT 5;
+-----------+------------+
<table>
<thead>
<tr>
<th>Name</th>
<th>Population</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bombay</td>
<td>10500000</td>
</tr>
<tr>
<td>Seoul</td>
<td>9981619</td>
</tr>
<tr>
<td>São Paulo</td>
<td>9968485</td>
</tr>
<tr>
<td>Shanghai</td>
<td>9696300</td>
</tr>
<tr>
<td>Jakarta</td>
<td>9604900</td>
</tr>
</tbody>
</table>
+-----------+------------+
5 rows in set (0.34 sec)
mysql> \q
Bye
```

Applications that use MySQL can employ standard APIs to access NDB tables. It is important to remember that your application must access the SQL node, and not the management or data nodes. This brief example shows how we might execute the `SELECT` statement just shown by using the PHP 5.X `mysqli` extension running on a Web server elsewhere on the network:

```php
<?php
    # connect to SQL node:
    $link = new mysqli('192.168.0.20', 'root', 'root_password', 'world');
    # parameters for mysqli constructor are:
    # host, user, password, database
    if( mysqli_connect_errno() )
        die("Connect failed: ". mysqli_connect_error());

    $query = "SELECT Name, Population
              FROM City
              ORDER BY Population DESC
              LIMIT 5";

    # if no errors...
    if( $result = $link->query($query) )
    {
        # then display the results...
        while($row = $result->fetch_object())
            printf("<tr>
                <td align="center">%s</td><td>%d</td>
            </tr>
", $row->Name, $row->Population);
    }
</table>
# ...and verify the number of rows that were retrieved
```
We assume that the process running on the Web server can reach the IP address of the SQL node.

In a similar fashion, you can use the MySQL C API, Perl-DBI, Python-mysql, or MySQL Connectors to perform the tasks of data definition and manipulation just as you would normally with MySQL.

**17.2.6 Safe Shutdown and Restart of MySQL Cluster**

To shut down the cluster, enter the following command in a shell on the machine hosting the management node:

```
shell> ndb_mgm -e shutdown
```

The `-e` option here is used to pass a command to the `ndb_mgm` client from the shell. (See Section 17.4.26, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”, for more information about this option.) The command causes the `ndb_mgm`, `ndb_mgmd`, and any `ndbd` or `ndbmtd` processes to terminate gracefully. Any SQL nodes can be terminated using `mysqladmin shutdown` and other means. On Windows platforms, assuming that you have installed the SQL node as a Windows service, you can use `NET STOP MYSQL`.

To restart the cluster on Unix platforms, run these commands:

- On the management host (192.168.0.10 in our example setup):
  ```
  shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
  ```

- On each of the data node hosts (192.168.0.30 and 192.168.0.40):
  ```
  shell> ndbd
  ```

- Use the `ndb_mgm` client to verify that both data nodes have started successfully.

- On the SQL host (192.168.0.20):
  ```
  shell> mysql_safe &
  ```

On Windows platforms, assuming that you have installed all MySQL Cluster processes as Windows services using the default service names (see Section 17.2.4, “Installing MySQL Cluster Processes as Windows Services”), you can restart the cluster as follows:

- On the management host (192.168.0.10 in our example setup), execute the following command:
  ```
  C:\> NET START ndb_mgmd
  ```

- On each of the data node hosts (192.168.0.30 and 192.168.0.40), execute the following command:
  ```
  C:\> NET START ndbd
  ```
On the management node host, use the ndb_mgm client to verify that the management node and both data nodes have started successfully (see Section 17.2.2.3, “Initial Startup of MySQL Cluster on Windows”).

On the SQL node host (192.168.0.20), execute the following command:

C:\> NET START mysql

In a production setting, it is usually not desirable to shut down the cluster completely. In many cases, even when making configuration changes, or performing upgrades to the cluster hardware or software (or both), which require shutting down individual host machines, it is possible to do so without shutting down the cluster as a whole by performing a rolling restart of the cluster. For more information about doing this, see Section 17.5.5, “Performing a Rolling Restart of a MySQL Cluster”.

### 17.2.7 Upgrading and Downgrading MySQL Cluster

This section provides information about MySQL Cluster software and table file compatibility between MySQL 5.1.23 and earlier, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x releases with regard to performing upgrades and downgrades as well as compatibility matrices and notes. You are expected already to be familiar with installing and configuring a MySQL Cluster prior to attempting an upgrade or downgrade. See Section 17.3, “Configuration of MySQL Cluster NDB 6.1-7.1”.

For information regarding the rolling restart procedure used to perform an online upgrade, see Section 17.5.5, “Performing a Rolling Restart of a MySQL Cluster”.

---

**Important**

Only compatibility between MySQL versions with regard to NDBCLUSTER is taken into account in this section, and there are likely other issues to be considered. As with any other MySQL software upgrade or downgrade, you are strongly encouraged to review the relevant portions of the MySQL Manual for the MySQL versions from which and to which you intend to migrate, before attempting an upgrade or downgrade of the MySQL Cluster software. See Section 2.13.1, “Upgrading MySQL”.

For information about upgrades and downgrades to, from, and between different releases of MySQL Cluster NDB 7.0 and MySQL Cluster NDB 7.1, see Section 17.2.7.1, “Upgrade and downgrade compatibility: MySQL Cluster NDB 7.x”.

For information about upgrades and downgrades to, from, and between different releases of MySQL Cluster NDB 6.1, MySQL Cluster NDB 6.2, and MySQL Cluster NDB 6.3, see Section 17.2.7.2, “Upgrade and Downgrade Compatibility: MySQL Cluster NDB 6.x”.

For information about upgrades and downgrades to, from, and between different releases of MySQL Cluster NDB 7.2, see Upgrading and Downgrading MySQL Cluster NDB 7.2.

For information about upgrades and downgrades to, from, and between different editions of MySQL Cluster as found in standard MySQL 5.1.23 and earlier releases, see Section 17.2.7.3, “Upgrade and downgrade compatibility: MySQL 5.1”.

---

**Important**

Only compatibility between MySQL versions with regard to NDBCLUSTER is taken into account in this section, and there are likely other issues to be considered. As with any other MySQL software upgrade or downgrade, you are strongly encouraged to review the relevant portions of the MySQL Manual for the MySQL versions from which and to which you intend to migrate, before attempting an upgrade or downgrade of the MySQL Cluster software. See Section 2.13.1, “Upgrading MySQL”.

---
17.2.7.1 Upgrade and downgrade compatibility: MySQL Cluster NDB 7.x

The table shown here provides information on MySQL Cluster upgrade and downgrade compatibility among different releases of MySQL Cluster NDB 7.0 and 7.1. Additional notes about upgrades and downgrades to, from, or within the MySQL Cluster NDB 7.x release series can be found immediately following the table.

Figure 17.5 MySQL Cluster Upgrade and Downgrade compatibility, MySQL Cluster NDB 7.x
Notes: MySQL Cluster NDB 7.x

**Versions supported.** Online upgrades from any MySQL Cluster NDB 7.0 release up to and including MySQL Cluster NDB 7.0.4 (as well as all early releases numbered NDB 6.4.x) to MySQL Cluster NDB 7.0.5 or later are not possible. Upgrades to MySQL Cluster NDB 7.0.6 or later from MySQL Cluster NDB 6.3.8 or a later MySQL Cluster NDB 6.3 release, or from MySQL Cluster NDB 7.0.5 or later, are supported. (Bug #44294)

**Upgrading ndbd to ndbmtd.** When upgrading online from a MySQL Cluster NDB 6.3 release to a MySQL Cluster NDB 7.0 (or later) release, you should not try to upgrade the data nodes from ndbd to ndbmtd at the same time. Instead, perform the upgrade using the new ndbd executable (from the MySQL Cluster NDB 7.0 or later distribution to which you are upgrading) to replace the one in use on the data nodes. Once the version upgrade is complete, you can perform a second (online) upgrade to replace the data node executables with ndbmtd from the newer distribution. Changing the data node binary type should not be an issue when upgrading from MySQL Cluster NDB 7.0 or later version.

**Changes in default values.** In MySQL Cluster NDB 7.0.4, the default values for a number of MySQL Cluster configuration parameters relating to memory usage and buffering changed (see [http://dev.mysql.com/doc/relnotes/mysql-cluster/7.1/en/mysql-cluster-news-5-1-32-ndb-7-0-4.html](http://dev.mysql.com/doc/relnotes/mysql-cluster/7.1/en/mysql-cluster-news-5-1-32-ndb-7-0-4.html), for a list of the parameters whose defaults changed). For this reason, you may encounter issues if you try to use a configuration that does not explicitly define each of these buffers (because it was developed for a previous version of MySQL Cluster). SendBufferMemory and ReceiveBufferMemory in particular.

Other known issues include the following:

- Prior to MySQL Cluster NDB 7.0.7, DML statements failed if executed while performing an online upgrade from a MySQL Cluster NDB 6.3 release. (Bug #45917)

- Following an upgrade from any MySQL Cluster NDB 6.3.x release to MySQL Cluster NDB 7.0.6, DDL and backup operations failed. This issue was resolved in MySQL Cluster NDB 7.0.7. (Bug #46494, Bug #46563)

- In some cases, there could be problems with online upgrades from MySQL Cluster NDB 6.3 releases to MySQL Cluster NDB 7.0 releases due to a previous change in the signalling format used between nodes. This issue was corrected in MySQL Cluster NDB 7.0.9.

- Once an NDB table had an ALTER ONLINE TABLE operation performed on it using a MySQL Cluster NDB 6.3.x release, it could not be upgraded online to MySQL Cluster NDB 7.0. This issue was resolved in MySQL Cluster NDB 7.0.8. (See Bug #47542.)

- Following an upgrade from MySQL Cluster NDB 6.3 to MySQL Cluster NDB 7.0, if there were any tables having unique indexes prior to the upgrade, attempts to create unique indexes failed. This could also occur when performing offline ALTER TABLE operations on tables having indexes that were not dropped as a result of the ALTER TABLE. This issue was due to a change in the way that NDB tracked unique indexes internally, and was resolved in MySQL Cluster NDB 7.0.9. (Bug #48416)

For upgrades to MySQL Cluster NDB 7.0 releases prior to version 7.0.9, a workaround is available: Following the upgrade, execute a second rolling restart of the cluster before performing any ALTER TABLE operations involving indexes.

- Due to an issue discovered after the release of MySQL Cluster NDB 7.0.10 (Bug #50433), it is not possible to perform an online upgrade from MySQL Cluster NDB 7.0.9b and earlier MySQL Cluster NDB 7.0 releases to MySQL Cluster NDB 7.0.10. Instead, you should upgrade your MySQL Cluster NDB 7.0 installation directly to MySQL Cluster NDB 7.0.11 or later.

This issue did not appear to affect MySQL Cluster NDB 6.3, and it should be possible to upgrade online from MySQL Cluster NDB 6.3 to MySQL Cluster NDB 7.0.10 without any problems other than those noted previously.

- It was not possible to perform an online upgrade from a MySQL Cluster NDB 6.3 or 7.0 release to MySQL Cluster NDB 7.1.0 or 7.1.1. This issue was fixed in MySQL Cluster NDB 7.1.2 (see Bug #51429).
• Following an upgrade to MySQL Cluster NDB 7.0.15 or later (MySQL Cluster NDB 7.0), or to MySQL Cluster NDB 7.1.4 or later (MySQL Cluster NDB 7.1), a table created in a previous version of MySQL Cluster does not automatically support NDB-native default values. Such a table continues to use default values supplied by the MySQL server until it is upgraded by performing an offline `ALTER TABLE` on it.

When upgrading to a MySQL Cluster release that supports native default values from a MySQL Cluster release that does not, you should not attempt to create any new tables until all data nodes are using the new `ndbd` or `ndbmd` binaries. This is because the older binaries do not provide support for native default values.

**Important**

Tables created with native default value support cannot be used with versions of MySQL Cluster that do not support native default values.

• NDB API changes in MySQL Cluster NDB 7.1.16 and MySQL Cluster NDB 7.0.27 are not backward compatible. Due to these changes the version of the included NDB client library was increased from 4.0.0 to 5.0.0; NDB API applications must be recompiled as part of any upgrade to these or later MySQL Cluster releases.

In addition, NDB API programs should be updated as part of such an upgrade, in order to take into account changes in the default behavior and values for the `Ndb_cluster_connection::connect()` method.

• Due to issues discovered shortly after release, MySQL Cluster NDB 7.0.20 was withdrawn and replaced with MySQL Cluster NDB 7.0.20a. Users of MySQL Cluster NDB 7.0.19 and previous MySQL Cluster NDB 7.0 releases should upgrade to MySQL Cluster NDB 7.0.20a, or to a later MySQL Cluster NDB 7.0 release. See [http://dev.mysql.com/doc/relnotes/mysql-cluster/7.1/en/mysql-cluster-news-5-1-51-ndb-7-0-20a.html](http://dev.mysql.com/doc/relnotes/mysql-cluster/7.1/en/mysql-cluster-news-5-1-51-ndb-7-0-20a.html), for more information.

Due to issues discovered shortly after release, MySQL Cluster NDB 7.1.9 was withdrawn and replaced with MySQL Cluster NDB 7.1.9a. Users of MySQL Cluster NDB 7.1.8 and previous MySQL Cluster NDB 7.1 releases should upgrade to MySQL Cluster NDB 7.1.14 (the last release directly upgrade-compatible with MySQL Cluster 7.1.18 and earlier) before upgrading to MySQL Cluster 7.1.15a or later. See [http://dev.mysql.com/doc/relnotes/mysql-cluster/7.1/en/mysql-cluster-news-5-1-51-ndb-7-1-9a.html](http://dev.mysql.com/doc/relnotes/mysql-cluster/7.1/en/mysql-cluster-news-5-1-51-ndb-7-1-9a.html), for more information.

• When performing an online upgrade or downgrade between MySQL Cluster NDB 7.1.8 or earlier and a later release up to and including MySQL Cluster NDB 7.1.14, you must upgrade or downgrade the data nodes before upgrading or downgrading any SQL nodes; otherwise `mysql_upgrade` fails on the SQL nodes due to differences between `ndbinfo` tables used in the “old” and “new” versions of the MySQL Cluster software. You should also upgrade or downgrade the data nodes prior to the SQL nodes when performing an online upgrade or downgrade between MySQL Cluster NDB 7.1 releases where either of the versions involved is MySQL Cluster NDB 7.1.14 or earlier, and where one or more `ndbinfo` tables has more, fewer, or differing columns between the two versions.

This issue is resolved in MySQL Cluster NDB 7.1.15. (Bug #11885602)

• It was not possible to downgrade online to MySQL Cluster NDB 7.1 from some later versions of MySQL Cluster due to a change in the size used for table hash maps by NDB. (Bug #14645319) This issue was resolved in MySQL Cluster NDB 7.1.26, where the size is made configurable using the `DefaultHashMapSize` parameter. (Bug #14800539) See the description of this parameter for more information.
17.2.7.2 Upgrade and Downgrade Compatibility: MySQL Cluster NDB 6.x

The table shown here provides information on MySQL Cluster upgrade and downgrade compatibility among different releases of MySQL Cluster NDB 6.1, 6.2, and 6.3. Additional notes about upgrades and downgrades to, from, or within the MySQL Cluster NDB 6.x release series can be found immediately following the table.
Figure 17.6 MySQL Cluster Upgrade and Downgrade compatibility, MySQL Cluster NDB 6.x

KEY:
- Upgrade and downgrade possible
- Downgrades not possible
- Unreleased or withdrawn following release
- The NDB 6.1 and 6.2 series are no longer in production
- NDB 6.3.05 was a special-purpose release, not part of the normal upgrade cycle.
Notes: MySQL Cluster NDB 6.1

**Availability of older releases.** MySQL Cluster NDB 6.1 is no longer in production; information about this series of releases is of historical interest only. MySQL Cluster NDB 6.2 is still available, but is no longer supported in new deployments. If you are still using a MySQL Cluster NDB 6.1 or MySQL Cluster NDB 6.2 release, you should upgrade to the most recent MySQL Cluster NDB 7.0 or MySQL Cluster NDB 7.1 release as soon as possible.

- It is not possible to upgrade from MySQL Cluster NDB 6.1.2 (or an older 6.1 release) directly to 6.1.4 or a newer NDB 6.1 release, or to downgrade from 6.1.4 (or a newer 6.1 release) directly to 6.1.2 or an older NDB 6.1 release; in either case, you must upgrade or downgrade to MySQL Cluster NDB 6.1.3 first.
- It is not possible to perform an online downgrade from MySQL Cluster NDB 6.1.8 (or a newer 6.1 release) to MySQL Cluster NDB 6.1.7 (or an older 6.1 release).
- MySQL Cluster NDB 6.1.6 and 6.1.18 were not released.
- It is not possible to perform an online upgrade or downgrade between MySQL Cluster NDB 6.2 and any previous release series (including mainline MySQL 5.1 and MySQL Cluster NDB 6.1); it is necessary to perform a dump and reload. However, it should be possible to perform online upgrades or downgrades between any MySQL Cluster NDB 6.2 release and any MySQL Cluster NDB 6.3 release up to and including 6.3.7.

Notes: MySQL Cluster NDB 6.2 and MySQL Cluster NDB 6.3

**Internal column specification changes.** The internal specifications for columns in NDB tables changed in MySQL Cluster NDB 6.1.17 and 6.2.1 to enable compatibility with later MySQL Cluster releases implementing online adding and dropping of columns (MySQL 5.1.17 through MySQL 5.1.23; MySQL Cluster NDB 6.2.3 and later; MySQL Cluster NDB 6.3.2 and later). This change is not backward-compatible with earlier MySQL Server or MySQL Cluster releases.

To make tables created in earlier versions compatible with online adding and dropping of columns in later versions, it is necessary to force MySQL Cluster to convert the tables to the new format by following this procedure following an upgrade:

1. Upgrade the MySQL Cluster software on all data, management, and SQL nodes
2. Back up all NDB tables
3. Shut down the cluster (all data, management, and SQL nodes)
4. Restart the cluster, starting all data nodes with the `--initial` option (to clear and rebuild the data node file systems)
5. Restore the tables from backup

To minimize possible later difficulties, it is strongly advised that the procedure outlined above be followed as soon as possible after upgrading between the versions indicated. The procedure is not necessary for NDDBCLUSTER tables created in any of the following versions:

- MySQL Cluster NDB 6.1.8 or a later MySQL Cluster NDB 6.1 release
- MySQL Cluster 6.2.1 or a later MySQL Cluster NDB 6.2 release
- Any MySQL Cluster NDB 6.3 release (or later MySQL Cluster release series)

Tables created in the versions listed previously (or later versions, as indicated) are already compatible with adding and dropping of columns online (as implemented beginning with MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.2).

Additional issues encountered when upgrading or downgrading to or from MySQL Cluster NDB 6.2 and MySQL Cluster NDB 6.3 releases are listed here:
• It was not possible to perform an online upgrade between any MySQL Cluster NDB 6.2 release and MySQL Cluster NDB 6.3.8 and later MySQL Cluster 6.3 releases. This issue was fixed in MySQL Cluster NDB 6.3.21. (Bug #41435)

• Online downgrades between MySQL Cluster NDB 6.2.5 and earlier releases are not supported.

• Online downgrades between MySQL Cluster NDB 6.3.8 and earlier releases are not supported.

17.2.7.3 Upgrade and downgrade compatibility: MySQL 5.1

The table shown here provides information on MySQL Cluster upgrade and downgrade compatibility among different releases of MySQL 5.1 prior to MySQL 5.1.24. Additional notes about upgrades and downgrades to, from, or within the MySQL 5.1 release series can be found immediately following the table.

Figure 17.7 MySQL Cluster Upgrade and Downgrade compatibility, MySQL Cluster 5.1

Notes: MySQL 5.1

• MySQL 5.1.3 was the first public release in this series.

• Direct upgrades or downgrades between MySQL Cluster 5.0 and 5.1 are not supported; you must dump all NDBCLUSTER tables using mysqldump, install the new version of the software, and then reload the tables from the dump.
• You cannot downgrade a MySQL Cluster based on MySQL 5.1.6 or later and using Disk Data tables to MySQL 5.1.5 or earlier unless you convert all such tables to in-memory NDB tables first.

• MySQL 5.1.8, MySQL 5.1.10, and MySQL 5.1.13 were not released.

• Online cluster upgrades and downgrades between MySQL 5.1.11 (or an earlier version) and 5.1.12 (or a later version) are not possible due to major changes in the cluster file system. In such cases, you must perform a backup or dump, upgrade (or downgrade) the software, start each data node with `--initial`, and then restore from the backup or dump. You can use native NDB backup and restore, or `mysqldump` and `LOAD DATA INFILE` for this purpose.

• Online downgrades from MySQL 5.1.14 or later to versions previous to 5.1.14 are not supported due to incompatible changes in the cluster system tables.

MySQL Cluster Replication: changes in ndb_apply_status. Online upgrades from MySQL 5.1.17 and earlier to 5.1.18 and later MySQL 5.1.x releases are not supported for clusters using replication due to incompatible changes in the `mysql.ndb_apply_status` table. (Online upgrades from MySQL 5.1 to MySQL Cluster NDB 6.2 and later are not supported, as discussed elsewhere in this section.) However, it should not be necessary to shut down the cluster entirely, if you follow this modified rolling restart procedure:

1. Stop the management server, update the management server software, then start the management server again. For multiple management servers, repeat this step for each management server in turn.

2. For each data node in turn: Stop the data node, update the data node daemon (in MySQL Cluster NDB 7.0 and later, this can be either `ndbd` or `ndbmtd`) with the new version, then restart the data node. It should not be necessary to use `--initial` when restarting any of the data nodes after updating the software.

3. Stop all SQL nodes. Upgrade the existing MySQL server installations to the new version on all SQL nodes, then restart them. It is not necessary to start them one at a time after upgrading the MySQL server software, but there must be a time when none of them is running before starting any of them again using the 5.1.18 (or later) `mysqld`. Otherwise—due to the fact that `mysql.ndb_apply_status` uses the NDB storage engine and is thus shared between all SQL nodes—there may be conflicts between the old and new versions of the table on different SQL nodes.

You can find more information about the changes to `ndb_apply_status` in Section 17.6.4, “MySQL Cluster Replication Schema and Tables”.

Note
You should upgrade the MySQL Cluster software on each node using the same method by which it was originally installed. See Section 17.2, “MySQL Cluster Installation and Upgrades”, for more information.

As with any other MySQL Cluster version upgrade, you should also update the MySQL Cluster management client (`ndb_mgm`) and other MySQL Cluster client programs such as `ndb_config` and `ndb_error_reporter`; however, this does not have to be done in any particular order.

Internal column specification changes. The internal specifications for columns in `NDBCLUSTER` tables changed in MySQL 5.1.18 to enable compatibility with later MySQL Cluster releases that permit online adding and dropping of columns. **This change is not backward-compatible with earlier MySQL versions.**

To make tables created in MySQL 5.1.17 and earlier compatible with online adding and dropping of columns (available beginning with beginning with MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.2—see Section 13.1.7, “ALTER TABLE Syntax”, for more information), it is necessary to force MySQL 5.1.18 and later to convert the tables to the new format by following this procedure:
1. Back up all NDBCLUSTER tables.

2. Upgrade the MySQL Cluster software on all data, management, and SQL nodes.

3. Shut down the cluster completely (this includes all data, management, and API or SQL nodes).

4. Restart the cluster, starting all data nodes with the --initial option (to clear and rebuild the data node file systems).

5. Restore the NDBCLUSTER tables from backup.

It is not necessary to follow this procedure for NDBCLUSTER tables created in MySQL 5.1.18 and later; such tables are already compatible with online adding and dropping of columns (as implemented beginning with MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.2).

To minimize possible later difficulties, it is strongly advised that the procedure outlined above be followed as soon as possible after to upgrading from MySQL 5.1.17 or earlier to MySQL 5.1.18 or later.

Information about how this change effects users of MySQL Cluster NDB 6.x and 7.x is provided later in this section.

MySQL Cluster not supported in MySQL Server 5.1.24 and later. MySQL Cluster is not supported in standard MySQL 5.1 releases beginning with MySQL 5.1.24. If you are using MySQL Cluster in a standard MySQL 5.1 release, you should upgrade to the most recent MySQL Cluster NDB 7.0 or MySQL Cluster NDB 7.1 release.

17.3 Configuration of MySQL Cluster NDB 6.1-7.1

A MySQL server that is part of a MySQL Cluster differs in one chief respect from a normal (nonclustered) MySQL server, in that it employs the NDB storage engine. This engine is also referred to sometimes as NDBCLUSTER, although NDB is preferred.

To avoid unnecessary allocation of resources, the server is configured by default with the NDB storage engine disabled. To enable NDB, you must modify the server's my.cnf configuration file, or start the server with the --ndbcluster option.

This MySQL server is a part of the cluster, so it also must know how to access a management node to obtain the cluster configuration data. The default behavior is to look for the management node on localhost. However, should you need to specify that its location is elsewhere, this can be done in my.cnf, or with the mysql client. Before the NDB storage engine can be used, at least one management node must be operational, as well as any desired data nodes.

For more information about --ndbcluster and other mysqld options specific to MySQL Cluster, see MySQL Server Options for MySQL Cluster.

For information about installing MySQL Cluster, see Section 17.2, “MySQL Cluster Installation and Upgrades”.

17.3.1 Quick Test Setup of MySQL Cluster

To familiarize you with the basics, we will describe the simplest possible configuration for a functional MySQL Cluster. After this, you should be able to design your desired setup from the information provided in the other relevant sections of this chapter.

First, you need to create a configuration directory such as /var/lib/mysql-cluster, by executing the following command as the system root user:

```
shell> mkdir /var/lib/mysql-cluster
```

In this directory, create a file named config.ini that contains the following information. Substitute appropriate values for HostName and DataDir as necessary for your system.
Quick Test Setup of MySQL Cluster

```
# file "config.ini" - showing minimal setup consisting of 1 data node, 
# 1 management server, and 3 SQL nodes. 
# The empty default sections are not required, and are shown only for 
# the sake of completeness. 
# Data nodes must provide a hostname but SQL nodes are not required 
# to do so. 
# If you do not know the hostname for your machine, use localhost. 
# The DataDir parameter also has a default value, but it is recommended to 
# set it explicitly. 
# Note: [db], [api], and [mgm] are aliases for [ndbd], [mysqld], and [ndb_mgmd], 
# respectively. [db] is deprecated and should not be used in new installations.

[ndbd default]
NoOfReplicas= 1

[mysqld default]
[ndb_mgmd default]
[tcp default]

[ndb_mgmd]
HostName= myhost.example.com

[ndbd]
HostName= myhost.example.com
DataDir= /var/lib/mysql-cluster

[mysqld]

You can now start the ndb_mgmd management server. By default, it attempts to read the config.ini file in its current working directory, so change location into the directory where the file is located and then invoke ndb_mgmd:

```
shell> cd /var/lib/mysql-cluster
shell> ndb_mgmd
```

Then start a single data node by running ndbd:

```
shell> ndbd
```

For command-line options which can be used when starting ndbd, see Section 17.4.26, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”.

By default, ndbd looks for the management server at localhost on port 1186.

![Note]

If you have installed MySQL from a binary tarball, you will need to specify the path of the ndb_mgmd and ndbd servers explicitly. (Normally, these will be found in /usr/local/mysql/bin.)

Finally, change location to the MySQL data directory (usually /var/lib/mysql or /usr/local/mysql/data), and make sure that the my.cnf file contains the option necessary to enable the NDB storage engine:

```
[mysqld]
ndbcluster
```

You can now start the MySQL server as usual:

```
shell> mysql_safe --user=mysql &
```
Wait a moment to make sure the MySQL server is running properly. If you see the notice `mysql ended`, check the server’s `.err` file to find out what went wrong.

If all has gone well so far, you now can start using the cluster. Connect to the server and verify that the NDB storage engine is enabled:

```shell
shell> mysql
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 5.1.73
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
SHOW ENGINES\G
```

```
*************************** 12. row ***************************
Engine: NDBCLUSTER
Support: YES
Comment: Clustered, fault-tolerant, memory-based tables

*************************** 13. row ***************************
Engine: NDB
Support: YES
Comment: Alias for NDBCLUSTER
```

The row numbers shown in the preceding example output may be different from those shown on your system, depending upon how your server is configured.

Try to create an NDB table:

```shell
shell> mysql
mysql> USE test;
Database changed

mysql> CREATE TABLE ctest (i INT) ENGINE=NDBCLUSTER;
Query OK, 0 rows affected (0.09 sec)

mysql> SHOW CREATE TABLE ctest \G
```

```
*************************** 1. row ***************************
Table: ctest
Create Table: CREATE TABLE `ctest` (
    `i` int(11) default NULL
) ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

To check that your nodes were set up properly, start the management client:

```shell
shell> ndb_mgm
```

Use the `SHOW` command from within the management client to obtain a report on the cluster’s status:

```shell
ndb_mgm> SHOW
Cluster Configuration
---------------------
[ndbd(NDB)]  1 node(s)
id=2   @127.0.0.1  (Version: 5.1.77-ndb-7.1.37, Nodegroup: 0, *)

[ndb_mgmd(MGM)]  1 node(s)
id=1   @127.0.0.1  (Version: 5.1.77-ndb-7.1.37)

[mysqld(API)]  3 node(s)
id=3   @127.0.0.1  (Version: 5.1.77-ndb-7.1.37)
id=4  (not connected, accepting connect from any host)
id=5  (not connected, accepting connect from any host)
```

At this point, you have successfully set up a working MySQL Cluster. You can now store data in the cluster by using any table created with `ENGINE=NDBCLUSTER` or its alias `ENGINE=NDB.`
Overview of MySQL Cluster Configuration Parameters, Options, and Variables

17.3.2 Overview of MySQL Cluster Configuration Parameters, Options, and Variables

The next several sections provide summary tables of MySQL Cluster node configuration parameters used in the `config.ini` file to govern various aspects of node behavior, as well as of options and variables read by `mysqld` from a `my.cnf` file or from the command line when run as a MySQL Cluster process. Each of the node parameter tables lists the parameters for a given type (`ndbd`, `ndb_mgmd`, `mysqld`, `computer`, `tcp`, `shm`, or `sci`). All tables include the data type for the parameter, option, or variable, as well as its default, minimum, and maximum values as applicable.

Considerations when restarting nodes. For node parameters, these tables also indicate what type of restart is required (node restart or system restart)—and whether the restart must be done with `--initial`—to change the value of a given configuration parameter. When performing a node restart or an initial node restart, all of the cluster's data nodes must be restarted in turn (also referred to as a rolling restart). It is possible to update cluster configuration parameters marked as node online—that is, without shutting down the cluster—in this fashion. An initial node restart requires restarting each `ndbd` process with the `--initial` option.

A system restart requires a complete shutdown and restart of the entire cluster. An initial system restart requires taking a backup of the cluster, wiping the cluster file system after shutdown, and then restoring from the backup following the restart.

In any cluster restart, all of the cluster's management servers must be restarted for them to read the updated configuration parameter values.

### Important

Values for numeric cluster parameters can generally be increased without any problems, although it is advisable to do so progressively, making such adjustments in relatively small increments. Many of these can be increased online, using a rolling restart.

However, decreasing the values of such parameters—which this is done using a node restart, node initial restart, or even a complete system restart of the cluster—is not to be undertaken lightly; it is recommended that you do so only after careful planning and testing. This is especially true with regard to those parameters that relate to memory usage and disk space, such as `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes`. In addition, it is the generally the case that configuration parameters relating to memory and disk usage can be raised using a simple node restart, but they require an initial node restart to be lowered.

Because some of these parameters can be used for configuring more than one type of cluster node, they may appear in more than one of the tables.

### Note

4294967039 often appears as a maximum value in these tables. This value is defined in the `NDBCLUSTER` sources as `MAX_INT_RNIL` and is equal to `0xFFFFFEFF`, or $2^{32} - 2^8 - 1$.

17.3.2.1 MySQL Cluster Data Node Configuration Parameters

The summary table in this section provides information about parameters used in the `[ndbd]` or `[ndbd default]` sections of a `config.ini` file for configuring MySQL Cluster data nodes. For detailed descriptions and other additional information about each of these parameters, see Section 17.3.3.6, “Defining MySQL Cluster Data Nodes”.

1870
Beginning with MySQL Cluster NDB 6.4.0, these parameters also apply to `ndbmtd`, which is a multi-threaded version of `ndbd`. For more information, see Section 17.4.3, "`ndbmtd` — The MySQL Cluster Data Node Daemon (Multi-Threaded)".

**Restart types.** Changes in MySQL Cluster configuration parameters do not take effect until the cluster is restarted. The type of restart required to change a given parameter is indicated in the summary table as follows:

- **N**—Node restart: The parameter can be updated using a rolling restart (see Section 17.5.5, "Performing a Rolling Restart of a MySQL Cluster").

- **S**—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.

- **I**—Initial restart: Data nodes must be restarted using the `--initial` option.

For more information about restart types, see Section 17.3.2, “Overview of MySQL Cluster Configuration Parameters, Options, and Variables”.

| **ThreadConfig**                      | string        | "..."                                  | IS           | NDB 7.1.17                |
Prior to MySQL Cluster NDB 7.0, to add new data nodes to a MySQL Cluster, it is necessary to shut down the cluster completely, update the `config.ini` file, and then restart the cluster, starting all data node processes using the `--initial` option—that is, you must perform a system restart.

Beginning in MySQL Cluster NDB 7.0, it is possible to add new data node groups to a running cluster online. For more information, see Section 17.5.13, "Adding MySQL Cluster Data Nodes Online".

### 17.3.2.2 MySQL Cluster Management Node Configuration Parameters

The summary table in this section provides information about parameters used in the `[ndb_mgmd]` or `[mgm]` sections of a `config.ini` file for configuring MySQL Cluster management nodes. For detailed descriptions and other additional information about each of these parameters, see Section 17.3.3.5, "Defining a MySQL Cluster Management Server".

**Restart types.** Changes in MySQL Cluster configuration parameters do not take effect until the cluster is restarted. The type of restart required to change a given parameter is indicated in the summary table as follows:

- **N**—Node restart: The parameter can be updated using a rolling restart (see Section 17.5.5, "Performing a Rolling Restart of a MySQL Cluster").

- **S**—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.

- **I**—Initial restart: Data nodes must be restarted using the `--initial` option.

For more information about restart types, see Section 17.3.2, "Overview of MySQL Cluster Configuration Parameters, Options, and Variables".

**Note**

After making changes in a management node’s configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect. See Section 17.3.3.5, “Defining a MySQL Cluster Management Server”, for more information.

To add new management servers to a running MySQL Cluster, it is also necessary perform a rolling restart of all cluster nodes after modifying any existing `config.ini` files. For more information about issues arising when using multiple management nodes, see Section 17.1.6.10, “Limitations Relating to Multiple MySQL Cluster Nodes”.

### 17.3.2.3 MySQL Cluster SQL Node and API Node Configuration Parameters

The summary table in this section provides information about parameters used in the `[mysqld]` and `[api]` sections of a `config.ini` file for configuring MySQL Cluster SQL nodes and API nodes. For detailed descriptions and other additional information about each of these parameters, see Section 17.3.3.7, “Defining SQL and Other API Nodes in a MySQL Cluster”.

**Note**

For a discussion of MySQL server options for MySQL Cluster, see MySQL Server Options for MySQL Cluster; for information about MySQL server system variables relating to MySQL Cluster, see MySQL Cluster System Variables.

**Restart types.** Changes in MySQL Cluster configuration parameters do not take effect until the cluster is restarted. The type of restart required to change a given parameter is indicated in the summary table as follows:

- N—Node restart: The parameter can be updated using a rolling restart (see Section 17.5.5, “Performing a Rolling Restart of a MySQL Cluster”).

- S—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.

- I—Initial restart: Data nodes must be restarted using the `--initial` option.

For more information about restart types, see Section 17.3.2, “Overview of MySQL Cluster Configuration Parameters, Options, and Variables”.

**Note**

To add new SQL or API nodes to the configuration of a running MySQL Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new [mysqld] or [api] sections to the config.ini file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is not necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

**17.3.2.4 Other MySQL Cluster Configuration Parameters**
The summary tables in this section provide information about parameters used in the [computer], [tcp], [shm], and [sci] sections of a config.ini file for configuring MySQL Cluster management nodes. For detailed descriptions and other additional information about individual parameters, see Section 17.3.3.9, “MySQL Cluster TCP/IP Connections”, Section 17.3.3.11, “MySQL Cluster Shared-Memory Connections”, or Section 17.3.3.12, “SCI Transport Connections in MySQL Cluster”, as appropriate.

**Restart types.** Changes in MySQL Cluster configuration parameters do not take effect until the cluster is restarted. The type of restart required to change a given parameter is indicated in the summary tables as follows:

- **N**—Node restart: The parameter can be updated using a rolling restart (see Section 17.5.5, “Performing a Rolling Restart of a MySQL Cluster”).
- **S**—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.
- **I**—Initial restart: Data nodes must be restarted using the --initial option.

For more information about restart types, see Section 17.3.2, “Overview of MySQL Cluster Configuration Parameters, Options, and Variables”.

### 17.3.2.5 MySQL Cluster mysqld Option and Variable Reference

The following table provides a list of the command-line options, server and status variables applicable within `mysqld` when it is running as an SQL node in a MySQL Cluster. For a table showing all command-line options, server and status variables available for use with `mysqld`, see Section 5.1.1, “Server Option and Variable Reference”.

#### Table 17.9 MySQL Server Options and Variables for MySQL Cluster: MySQL 5.1, MySQL Cluster NDB 6.3-7.1

<table>

DESCRIPTION: This is a threshold on the number of epochs to be behind before reporting binary log status.

DESCRIPTION: This is a threshold on the percentage of free memory remaining before reporting binary log status.

DESCRIPTION: The total number of scans executed by NDB since the cluster was last started.

DESCRIPTION: NDB tables created when this setting is enabled are not checkpointed to disk (although table schema files are created). The setting in effect when the table is created with or altered to use NDBCLUSTER persists for the lifetime of the table.

DESCRIPTION: NDB tables are not persistent on disk: no schema files are created and the tables are not logged.

DESCRIPTION: Use exact row count when planning queries.

DESCRIPTION: Forces NDB to use a count of records during SELECT COUNT(*) query planning to speed up this type of query.

DESCRIPTION: Shows build and NDB engine version as an integer.

DESCRIPTION: Shows build information including NDB engine version in ndb-x.y.z format.

**DESCRIPTION:** Sets the number of least significant bits in the server_id actually used for identifying the server, permitting NDB API applications to store application data in the most significant bits. server_id must be less than 2 to the power of this value.
### 17.3.3 MySQL Cluster Configuration Files

Configuring MySQL Cluster requires working with two files:

- **my.cnf**: Specifies options for all MySQL Cluster executables. This file, with which you should be familiar with from previous work with MySQL, must be accessible by each executable running in the cluster.

- **config.ini**: This file, sometimes known as the *global configuration file*, is read only by the MySQL Cluster management server, which then distributes the information contained therein to all processes participating in the cluster. config.ini contains a description of each node involved in the cluster. This includes configuration parameters for data nodes and configuration parameters for connections between all nodes in the cluster. For a quick reference to the sections that can appear in this file, and what sorts of configuration parameters may be placed in each section, see Sections of the config.ini File.

#### Caching of configuration data.

Beginning with MySQL Cluster NDB 6.4.0, MySQL Cluster uses stateful configuration. The global configuration file is no longer read every time the management server is restarted. Instead, the management server caches the configuration the first time it is started, and thereafter, the global configuration file is read only when one of the following items is true:

- **The management server is started using the --initial option.** When --initial is used, the global configuration file is re-read, any existing cache files are deleted, and the management server creates a new configuration cache.

- **The management server is started using the --reload option.** The --reload option causes the management server to compare its cache with the global configuration file. If they differ, the management server creates a new configuration cache; any existing configuration cache is preserved, but not used. If the management server's cache and the global configuration file contain the same configuration data, then the existing cache is used, and no new cache is created.

- **The management server is started using --config-cache=FALSE.** Beginning with MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4, this disables --config-cache (enabled by default), and can be used to force the management server to bypass configuration caching altogether. In this case, the management server ignores any configuration files that may be present, always reading its configuration data from the config.ini file instead.
MySQL Cluster Configuration Files

• **No configuration cache is found.** In this case, the management server reads the global configuration file and creates a cache containing the same configuration data as found in the file.

**Configuration cache files.** Beginning with MySQL Cluster 6.4.0, the management server by default creates configuration cache files in a directory named `mysql-cluster` in the MySQL installation directory. (If you build MySQL Cluster from source on a Unix system, the default location is `/usr/local/mysql-cluster`.) This can be overridden at runtime by starting the management server with the `--configdir` option. Configuration cache files are binary files named according to the pattern `ndb_node_id_config.bin_seq_id`, where `node_id` is the management server's node ID in the cluster, and `seq_id` is a cache identifier. Cache files are numbered sequentially using `seq_id`, in the order in which they are created. The management server uses the latest cache file as determined by the `seq_id`.

**Note**

It is possible to roll back to a previous configuration by deleting later configuration cache files, or by renaming an earlier cache file so that it has a higher `seq_id`. However, since configuration cache files are written in a binary format, you should not attempt to edit their contents by hand.

For more information about the `--configdir`, `--config-cache`, `--initial`, and `--reload` options for the MySQL Cluster management server, see Section 17.4.4, “ndb_mgmd — The MySQL Cluster Management Server Daemon”.

We are continuously making improvements in Cluster configuration and attempting to simplify this process. Although we strive to maintain backward compatibility, there may be times when introduce an incompatible change. In such cases we will try to let Cluster users know in advance if a change is not backward compatible. If you find such a change and we have not documented it, please report it in the MySQL bugs database using the instructions given in Section 1.7, “How to Report Bugs or Problems”.

### 17.3.3.1 MySQL Cluster Configuration: Basic Example

To support MySQL Cluster, you will need to update `my.cnf` as shown in the following example. You may also specify these parameters on the command line when invoking the executables.

**Note**

The options shown here should not be confused with those that are used in `config.ini` global configuration files. Global configuration options are discussed later in this section.

```sql
# my.cnf
# example additions to my.cnf for MySQL Cluster
# (valid in MySQL 5.1)

# enable ndbcluster storage engine, and provide connection string for
# management server host (default port is 1186)
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com

# provide connection string for management server host (default port: 1186)
[ndbd]
connect-string=ndb_mgmd.mysql.com

# provide connection string for management server host (default port: 1186)
[ndb_mgm]
connect-string=ndb_mgmd.mysql.com

# provide location of cluster configuration file
[ndb_mgmd]
config-file=/etc/config.ini
```
(For more information on connection strings, see Section 17.3.3.3, “MySQL Cluster Connection Strings”.)

```ini
# my.cnf
# example additions to my.cnf for MySQL Cluster
# (will work on all versions)

# enable ndbcluster storage engine, and provide connection string for management
# server host to the default port 1186
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

**Important**

Once you have started a `mysqld` process with the `NDBCLUSTER` and `ndb-connectstring` parameters in the `[mysqld]` in the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements will fail with an error. This is by design.

You may also use a separate `[mysql_cluster]` section in the cluster `my.cnf` file for settings to be read and used by all executables:

```ini
# cluster-specific settings
[mysql_cluster]
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

For additional NDB variables that can be set in the `my.cnf` file, see MySQL Cluster System Variables.

The MySQL Cluster global configuration file is by convention named `config.ini` (but this is not required). It is read by `ndb_mgmd` at startup and can be placed in any location that can be read by it. The location and name of the configuration are specified using `--config-file=path_name` with `ndb_mgmd` on the command line. Beginning with MySQL Cluster NDB 6.4.0, this option has no default value, and is ignored if `ndb_mgmd` uses the configuration cache.

The global configuration file for MySQL Cluster uses INI format, which consists of sections preceded by section headings (surrounded by square brackets), followed by the appropriate parameter names and values. One deviation from the standard INI format is that the parameter name and value can be separated by a colon ("=") as well as the equal sign ("="); however, the equal sign is preferred. Another deviation is that sections are not uniquely identified by section name. Instead, unique sections (such as two different nodes of the same type) are identified by a unique ID specified as a parameter within the section.

Default values are defined for most parameters, and can also be specified in `config.ini`. (Prior to MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.6, there was no default value for `NoOfReplicas`, which always had to be specified explicitly in the `[ndbd default]` section. Beginning with versions just stated, the default value is 2, which is the recommended setting in most common usage scenarios.) To create a default value section, simply add the word `default` to the section name. For example, an `[ndbd]` section contains parameters that apply to a particular data node, whereas an `[ndbd default]` section contains parameters that apply to all data nodes. Suppose that all data nodes should use the same data memory size. To configure them all, create an `[ndbd default]` section that contains a `DataMemory` line to specify the data memory size.

The global configuration file must define the computers and nodes involved in the cluster and on which computers these nodes are located. An example of a simple configuration file for a cluster consisting of one management server, two data nodes and two SQL nodes is shown here:

```ini
# file "config.ini" - 2 data nodes and 2 SQL nodes
# This file is placed in the startup directory of ndb_mgmd (the
# management server)
# The first SQL node can be started from any host. The second
```
MySQL Cluster Configuration Files

```ini
# can be started only on the host mysql_5.mysql.com

[ndbd default]
NoOfReplicas= 2
DataDir= /var/lib/mysql-cluster

[ndb_mgmd]
Hostname= ndb_mgmd.mysql.com
DataDir= /var/lib/mysql-cluster

[ndbd]
HostName= ndbd_2.mysql.com

[ndbd]
HostName= ndbd_3.mysql.com

[mysqld]
[mysqld]
HostName= mysqld_5.mysql.com
```

### Note

The preceding example is intended as a minimal starting configuration for purposes of familiarization with MySQL Cluster, and is almost certain not to be sufficient for production settings. See Section 17.3.3.2, "Recommended Starting Configurations for MySQL Cluster NDB 6.2 and Later", which provides more complete example starting configurations for use with MySQL Cluster NDB 6.2 and newer versions of MySQL Cluster.

Each node has its own section in the `config.ini` file. For example, this cluster has two data nodes, so the preceding configuration file contains two [ndbd] sections defining these nodes.

### Note

Do not place comments on the same line as a section heading in the `config.ini` file; this causes the management server not to start because it cannot parse the configuration file in such cases.

### Sections of the `config.ini` File

There are six different sections that you can use in the `config.ini` configuration file, as described in the following list:

- **[computer]**: Defines cluster hosts. This is not required to configure a viable MySQL Cluster, but may be used as a convenience when setting up a large cluster. See Section 17.3.3.4, "Defining Computers in a MySQL Cluster", for more information.

- **[ndbd]**: Defines a cluster data node (ndbd process). See Section 17.3.3.6, "Defining MySQL Cluster Data Nodes", for details.

- **[mysqld]**: Defines the cluster's MySQL server nodes (also called SQL or API nodes). For a discussion of SQL node configuration, see Section 17.3.3.7, "Defining SQL and Other API Nodes in a MySQL Cluster".

- **[mgm]** or **[ndb_mgmd]**: Defines a cluster management server (MGM) node. For information concerning the configuration of management nodes, see Section 17.3.3.5, "Defining a MySQL Cluster Management Server".

- **[tcp]**: Defines a TCP/IP connection between cluster nodes, with TCP/IP being the default connection protocol. Normally, [tcp] or [tcp default] sections are not required to set up a MySQL Cluster, as the cluster handles this automatically; however, it may be necessary in some situations to override the defaults provided by the cluster. See Section 17.3.3.9, "MySQL Cluster TCP/IP Connections", for information about available TCP/IP configuration parameters and how to use them. (You may also find Section 17.3.3.10, "MySQL Cluster TCP/IP Connections Using Direct Connections" to be of interest in some cases.)
MySQL Cluster Configuration Files

- **[shm]**: Defines shared-memory connections between nodes. In MySQL 5.1, it is enabled by default, but should still be considered experimental. For a discussion of SHM interconnects, see Section 17.3.3.11, “MySQL Cluster Shared-Memory Connections”.

- **[sci]**: Defines Scalable Coherent Interface connections between cluster data nodes. Such connections require software which, while freely available, is not part of the MySQL Cluster distribution, as well as specialized hardware. See Section 17.3.3.12, “SCI Transport Connections in MySQL Cluster” for detailed information about SCI interconnects.

You can define default values for each section. All Cluster parameter names are case-insensitive, which differs from parameters specified in *my.cnf* or *my.ini* files.

### 17.3.3.2 Recommended Starting Configurations for MySQL Cluster NDB 6.2 and Later

Achieving the best performance from a MySQL Cluster depends on a number of factors including the following:

- MySQL Cluster software version
- Numbers of data nodes and SQL nodes
- Hardware
- Operating system
- Amount of data to be stored
- Size and type of load under which the cluster is to operate

Therefore, obtaining an optimum configuration is likely to be an iterative process, the outcome of which can vary widely with the specifics of each MySQL Cluster deployment. Changes in configuration are also likely to be indicated when changes are made in the platform on which the cluster is run, or in applications that use the MySQL Cluster’s data. For these reasons, it is not possible to offer a single configuration that is ideal for all usage scenarios. However, in this section, we provide recommended base configurations for MySQL Cluster NDB 6.2 and 6.3 that can serve as reasonable starting points.

**Starting configuration for MySQL Cluster NDB 6.2.** The following is a recommended starting point for configuring a cluster running MySQL Cluster NDB 6.2.

```conf
# TCP PARAMETERS
[tcp default]
SendBufferMemory=2M
ReceiveBufferMemory=2M

# Increasing the sizes of these 2 buffers beyond the default values
# helps prevent bottlenecks due to slow disk I/O.

# MANAGEMENT NODE PARAMETERS
[ndb_mgmd default]
DataDir=path/to/management/server/data/directory

# It is possible to use a different data directory for each management
# server, but for ease of administration it is preferable to be
# consistent.

[ndb_mgmd]
HostName=management-server-1-hostname
# NodeId=management-server-1-nodeid

[ndb_mgmd]
HostName=management-server-2-hostname

# Using 2 management servers helps guarantee that there is always an
# arbitrator in the event of network partitioning, and so is
# recommended for high availability. Each management server must be
```

1915
MySQL Cluster Configuration Files

# identified by a HostName. You may for the sake of convenience specify
# a node ID for any management server, although one will be allocated
# for it automatically; if you do so, it must be in the range 1-255
# inclusive and must be unique among all IDs specified for cluster
# nodes.

# DATA NODE PARAMETERS

[ndbd default]
NoOfReplicas=2

# Using 2 replicas is recommended to guarantee availability of data;
# using only 1 replica does not provide any redundancy, which means
# that the failure of a single data node causes the entire cluster to
# shut down. We do not recommend using more than 2 replicas, since 2 is
# sufficient to provide high availability, and we do not currently test
# with greater values for this parameter.

LockPagesInMainMemory=1

# On Linux and Solaris systems, setting this parameter locks data node
# processes into memory. Doing so prevents them from swapping to disk,
# which can severely degrade cluster performance.

DataMemory=3072M
IndexMemory=384M

# The values provided for DataMemory and IndexMemory assume 4 GB RAM
# per data node. However, for best results, you should first calculate
# the memory that would be used based on the data you actually plan to
# store (you may find the ndb_size.pl utility helpful in estimating
# this), then allow an extra 20% over the calculated values. Naturally,
# you should ensure that each data node host has at least as much
# physical memory as the sum of these two values.

ODirect=1

# Enabling this parameter causes NDBCLUSTER to try using O_DIRECT
# writes for local checkpoints and redo logs; this can reduce load on
# CPUs. We recommend doing so when using MySQL Cluster NDB 6.2.3 or
# newer on systems running Linux kernel 2.6 or later.

NoOfFragmentLogFiles=300
DataDir=path/to/data/node/data/directory
MaxNoOfConcurrentOperations=100000
TimeBetweenGlobalCheckpoints=1000
TimeBetweenEpochs=200
DiskCheckpointSpeed=10M
DiskCheckpointSpeedInRestart=100M
RedoBuffer=32M
# MaxNoOfLocalScans=64
MaxNoOfTables=1024
MaxNoOfOrderedIndexes=256

[ndbd]
HostName=data-node-A-hostname
# NodeId=data-node-A-nodeid

[ndbd]
HostName=data-node-B-hostname
# NodeId=data-node-B-nodeid

# You must have an [ndbd] section for every data node in the cluster;
# each of these sections must include a HostName. Each section may
# optionally include an Id for convenience, but in most cases, it is
# sufficient to allow the cluster to allocate node IDs dynamically. If
# you do specify the node ID for a data node, it must be in the range 1
# to 48 inclusive and must be unique among all IDs specified for
# cluster nodes.

# SQL NODE / API NODE PARAMETERS
[mysqld]
# HostName=SQL-node-1-hostname
# NodeId=sql-node-A-nodeid

[mysqld]

Each API or SQL node that connects to the cluster requires a [mysqld]
or [api] section of its own. Each such section defines a connection
"slot"; you should have at least as many of these sections in the
cfg.ini file as the total number of API nodes and SQL nodes that
you wish to have connected to the cluster at any given time. There is
no performance or other penalty for having extra slots available in
the case you find later that you want or need more API or SQL nodes to
connect to the cluster at the same time.
If no HostName is specified for a given [mysqld] or [api] section,
then any API or SQL node may use that slot to connect to the
cluster. You may wish to use an explicit HostName for one connection slot
to guarantee that an API or SQL node from that host can always
connect to the cluster. If you wish to prevent API or SQL nodes from
connecting from other than a desired host or hosts, then use a
HostName for every [mysqld] or [api] section in the config.ini file.
You can if you wish define a node ID (Id parameter) for any API or
SQL node, but this is not necessary; if you do so, it must be in the
range 1 to 255 inclusive and must be unique among all IDs specified
for cluster nodes.

Starting configuration for MySQL Cluster NDB 6.3. The following is a recommended starting
point for configuring a cluster running MySQL Cluster NDB 6.3. It is similar to the recommendation for
MySQL Cluster NDB 6.2, with the addition of parameters for better control of NDBCLUSTER process
threads.

# TCP PARAMETERS

[tcp default]
SendBufferMemory=2M
ReceiveBufferMemory=2M

# Increasing the sizes of these 2 buffers beyond the default values
# helps prevent bottlenecks due to slow disk I/O.

# MANAGEMENT NODE PARAMETERS

[ndb_mgmd default]
DataDir=path/to/management/server/data/directory

# It is possible to use a different data directory for each management
# server, but for ease of administration it is preferable to be
# consistent.

[ndb_mgmd]
HostName=management-server-A-hostname
# NodeId=management-server-A-nodeid

[ndb_mgmd]
HostName=management-server-B-hostname
# NodeId=management-server-B-nodeid

# Using 2 management servers helps guarantee that there is always an
# arbitrator in the event of network partitioning, and so is
# recommended for high availability. Each management server must be
# identified by a HostName. You may for the sake of convenience specify
# a NodeId for any management server, although one will be allocated
# for it automatically; if you do so, it must be in the range 1-255
# inclusive and must be unique among all IDs specified for cluster
# nodes.

# DATA NODE PARAMETERS
MySQL Cluster Configuration Files

[ndbd default]
NoOfReplicas=2

# Using 2 replicas is recommended to guarantee availability of data;
# using only 1 replica does not provide any redundancy, which means
# that the failure of a single data node causes the entire cluster to
# shut down. We do not recommend using more than 2 replicas, since 2 is
# sufficient to provide high availability, and we do not currently test
# with greater values for this parameter.

LockPagesInMainMemory=1

# On Linux and Solaris systems, setting this parameter locks data node
# processes into memory. Doing so prevents them from swapping to disk,
# which can severely degrade cluster performance.

DataMemory=3072M
IndexMemory=384M

# The values provided for DataMemory and IndexMemory assume 4 GB RAM
# per data node. However, for best results, you should first calculate
# the memory that would be used based on the data you actually plan to
# store (you may find the ndb_size.pl utility helpful in estimating
# this), then allow an extra 20% over the calculated values. Naturally,
# you should ensure that each data node host has at least as much
# physical memory as the sum of these two values.

ODirect=1

# Enabling this parameter causes NDBCLUSTER to try using O_DIRECT
# writes for local checkpoints and redo logs; this can reduce load on
# CPUs. We recommend doing so when using MySQL Cluster NDB 6.2.3 or
# newer on systems running Linux kernel 2.6 or later.

NoOfFragmentLogFiles=300
DataDir=/path/to/data/node/data/directory
MaxNoOfConcurrentOperations=100000

SchedulerSpinTimer=400
SchedulerExecutionTimer=100
RealTimeScheduler=1

# Setting these parameters allows you to take advantage of real-time scheduling
# of NDB threads (introduced in MySQL Cluster NDB 6.3.4) to achieve increased
# throughput when using ndbd. They are not needed when using ndbmtd; in
# particular, you should not set RealTimeScheduler for ndbmtd data nodes.

TimeBetweenGlobalCheckpoints=1000
TimeBetweenEpochs=200
DiskCheckpointSpeed=10M
DiskCheckpointSpeedInRestart=100M
RedoBuffer=32M

# CompressedLCP=1
# CompressedBackup=1

# Enabling CompressedLCP and CompressedBackup causes, respectively, local
# checkpoint files and backup files to be compressed, which can result in a space
# savings of up to 50% over noncompressed LCPs and backups.

# MaxNoOfLocalScans=64
# MaxNoOfTables=1024
# MaxNoOfOrderedIndexes=256

[ndbd]
HostName=data-node-A-hostname
NodeId=data-node-A-nodeid

LockExecuteThreadToCPU=1
LockMaintThreadsToCPU=0

# On systems with multiple CPUs, these parameters can be used to lock NDBCLUSTER
# threads to specific CPUs

[ndbd]
MySQL Cluster Configuration Files

HostName=data-node-B-hostname
# NodeId=data-node-B-nodeid

LockExecuteThreadToCPU=1
LockMaintThreadsToCPU=0

# You must have an [ndbd] section for every data node in the cluster;
# each of these sections must include a HostName. Each section may
# optionally include a NodeId for convenience, but in most cases, it is
# sufficient to allow the cluster to allocate node IDs dynamically. If
# you do specify the node ID for a data node, it must be in the range 1
# to 48 inclusive and must be unique among all IDs specified for
# cluster nodes.

# SQL NODE / API NODE PARAMETERS
[mysqld]
# HostName = sql-node-A-hostname
# NodeId = sql-node-A-nodeid

[mysqld]

# Each API or SQL node that connects to the cluster requires a [mysqld]
# or [api] section of its own. Each such section defines a connection
# "slot"; you should have at least as many of these sections in the
# config.ini file as the total number of API nodes and SQL nodes that
# you wish to have connected to the cluster at any given time. There is
# no performance or other penalty for having extra slots available in
# case you find later that you want or need more API or SQL nodes to
# connect to the cluster at the same time.
# If no HostName is specified for a given [mysqld] or [api] section,
# then any API or SQL node may use that slot to connect to the
# cluster. You may wish to use an explicit HostName for one connection slot
# to guarantee that an API or SQL node from that host can always
# connect to the cluster. If you wish to prevent API or SQL nodes from
# connecting from other than a desired host or hosts, then use a
# HostName for every [mysqld] or [api] section in the config.ini file.
# You can if you wish define a node ID (NodeId parameter) for any API or
# SQL node, but this is not necessary; if you do so, it must be in the
# range 1 to 255 inclusive and must be unique among all IDs specified
# for cluster nodes.

Recommended my.cnf options for SQL nodes. MySQL Servers acting as MySQL Cluster SQL
nodes must always be started with the --ndbcluster and --ndb-connectstring options, either
on the command line or in my.cnf. In addition, set the following options for all mysqld processes in
the cluster, unless your setup requires otherwise:

• --ndb-use-exact-count=0
• --ndb-index-stat-enable=0
• --ndb-force-send=1
• --engine-condition-pushdown=1

17.3.3.3 MySQL Cluster Connection Strings

With the exception of the MySQL Cluster management server (ndb_mgmd), each node that is part
of a MySQL Cluster requires a connection string that points to the management server's location.
This connection string is used in establishing a connection to the management server as well as in
performing other tasks depending on the node's role in the cluster. The syntax for a connection string is
as follows:

[nodeid=node_id, ]host-definition[, host-definition[, ...]]

host-definition:
MySQL Cluster Configuration Files

**host_name[:port_number]**

- **node_id** is an integer greater than or equal to 1 which identifies a node in `config.ini`. **host_name** is a string representing a valid Internet host name or IP address. **port_number** is an integer referring to a TCP/IP port number.

- **example 1 (long)**: "nodeid=2,myhost1:1100,myhost2:1100,192.168.0.3:1200"
- **example 2 (short)**: "myhost1"

**localhost:1186** is used as the default connection string value if none is provided. If **port_num** is omitted from the connection string, the default port is 1186. This port should always be available on the network because it has been assigned by IANA for this purpose (see [http://www.iana.org/assignments/port-numbers](http://www.iana.org/assignments/port-numbers) for details).

By listing multiple host definitions, it is possible to designate several redundant management servers. A MySQL Cluster data or API node attempts to contact successive management servers on each host in the order specified, until a successful connection has been established.

Beginning with MySQL Cluster NDB 6.3.19, it is also possible in a connection string to specify one or more bind addresses to be used by nodes having multiple network interfaces for connecting to management servers. A bind address consists of a hostname or network address and an optional port number. This enhanced syntax for connection strings is shown here:

```
[nodeid=node_id, ]
[bind-address=host-definition, ]
host-definition[; bind-address=host-definition]
host-definition[; bind-address=host-definition]
[, ...]]
host-definition:
  host_name[:port_number]
```

If a single bind address is used in the connection string prior to specifying any management hosts, then this address is used as the default for connecting to any of them (unless overridden for a given management server; see later in this section for an example). For example, the following connection string causes the node to use **192.168.178.242** regardless of the management server to which it connects:

```
bind-address=192.168.178.242, poseidon:1186, perch:1186
```

If a bind address is specified following a management host definition, then it is used only for connecting to that management node. Consider the following connection string:

```
poseidon:1186;bind-address=localhost, perch:1186;bind-address=192.168.178.242
```

In this case, the node uses **localhost** to connect to the management server running on the host named **poseidon** and **192.168.178.242** to connect to the management server running on the host named **perch**.

You can specify a default bind address and then override this default for one or more specific management hosts. In the following example, **localhost** is used for connecting to the management server running on host **poseidon**; since **192.168.178.242** is specified first (before any management server definitions), it is the default bind address and so is used for connecting to the management servers on hosts **perch** and **orca**:

```
bind-address=192.168.178.242,poseidon:1186;bind-address=localhost,perch:1186,orca:2200
```

There are a number of different ways to specify the connection string:

- Each executable has its own command-line option which enables specifying the management server at startup. (See the documentation for the respective executable.)
MySQL Cluster Configuration Files

- It is also possible to set the connection string for all nodes in the cluster at once by placing it in a [mysql_cluster] section in the management server's my.cnf file.

- For backward compatibility, two other options are available, using the same syntax:
  1. Set the NDB_CONNECTSTRING environment variable to contain the connection string.
  2. Write the connection string for each executable into a text file named Ndb.cfg and place this file in the executable’s startup directory.

However, these are now deprecated and should not be used for new installations.

The recommended method for specifying the connection string is to set it on the command line or in the my.cnf file for each executable.

Previous to MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4, the maximum length of a connection string was 1024 characters.

17.3.3.4 Defining Computers in a MySQL Cluster

The [computer] section has no real significance other than serving as a way to avoid the need of defining host names for each node in the system. All parameters mentioned here are required.

- **Id**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>string</td>
<td>[none]</td>
<td>...</td>
<td>IS</td>
</tr>
</tbody>
</table>

This is a unique identifier, used to refer to the host computer elsewhere in the configuration file.

Important

The computer ID is not the same as the node ID used for a management, API, or data node. Unlike the case with node IDs, you cannot useNodeId in place of Id in the [computer] section of the config.ini file.

- **HostName**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>name or IP address</td>
<td>[none]</td>
<td>...</td>
<td>N</td>
</tr>
</tbody>
</table>

This is the computer's hostname or IP address.

17.3.3.5 Defining a MySQL Cluster Management Server

The [ndb_mgmd] section is used to configure the behavior of the management server. If multiple management servers are employed, you can specify parameters common to all of them in an [ndb_mgmd default] section. [mgm] and [mgm default] are older aliases for these, supported for backward compatibility.

All parameters in the following list are optional and assume their default values if omitted.

Note

If neither the ExecuteOnComputer nor the HostName parameter is present, the default value localhost will be assumed for both.

- **Id**
MySQL Cluster Configuration Files

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>unsigned</td>
<td>[none]</td>
<td>1 - 63</td>
<td>IS</td>
</tr>
<tr>
<td>NDB 6.1.1</td>
<td>unsigned</td>
<td>[none]</td>
<td>1 - 255</td>
<td>IS</td>
</tr>
</tbody>
</table>

Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 63 inclusive (previous to MySQL Cluster NDB 6.1.1), or in the range 1 to 255 inclusive (MySQL Cluster NDB 6.1.1 and later). This ID is used by all internal cluster messages for addressing the node, and so must be unique for each MySQL Cluster node, regardless of the type of node.

**Note**

Data node IDs must be less than 49, regardless of the MySQL Cluster version used. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 48.

The use of the `Id` parameter for identifying management nodes is deprecated in favor of `NodeId` beginning with MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.39, MySQL Cluster NDB 7.0.20, and MySQL Cluster NDB 7.1.9. Although `Id` continues to be supported for backward compatibility, it now generates a warning.

- **NodeId**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>unsigned</td>
<td>[none]</td>
<td>1 - 63</td>
<td>IS</td>
</tr>
<tr>
<td>NDB 6.1.1</td>
<td>unsigned</td>
<td>[none]</td>
<td>1 - 255</td>
<td>IS</td>
</tr>
</tbody>
</table>

Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 63 inclusive (previous to MySQL Cluster NDB 6.1.1), or in the range 1 to 255 inclusive (MySQL Cluster NDB 6.1.1 and later). This ID is used by all internal cluster messages for addressing the node, and so must be unique for each MySQL Cluster node, regardless of the type of node.

**Note**

Data node IDs must be less than 49, regardless of the MySQL Cluster version used. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 48.

`NodeId` is the preferred parameter name to use when identifying management nodes beginning with MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.39, MySQL Cluster NDB 7.0.20, and MySQL Cluster NDB 7.1.9. Although `Id` continues to be supported for backward compatibility, it is now deprecated and generates a warning when used.

- **ExecuteOnComputer**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>name</td>
<td>[none]</td>
<td>...</td>
<td>S</td>
</tr>
</tbody>
</table>

This refers to the `Id` set for one of the computers defined in a `[computer]` section of the `config.ini` file.

- **PortNumber**
MySQL Cluster Configuration Files

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>unsigned</td>
<td>1186</td>
<td>0 - 64K</td>
<td>S</td>
</tr>
</tbody>
</table>

This is the port number on which the management server listens for configuration requests and management commands.

- **HostName**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>name or IP address</td>
<td>[none]</td>
<td>...</td>
<td>N</td>
</tr>
</tbody>
</table>

Specifying this parameter defines the hostname of the computer on which the management node is to reside. To specify a hostname other than localhost, either this parameter or ExecuteOnComputer is required.

- **LogDestination**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>{CONSOLE</td>
<td>SYSLOG</td>
<td>FILE}</td>
<td>[see text]</td>
</tr>
</tbody>
</table>

This parameter specifies where to send cluster logging information. There are three options in this regard—CONSOLE, SYSLOG, and FILE—with FILE being the default:

- **CONSOLE** outputs the log to stdout:

  CONSOLE

- **SYSLOG** sends the log to a syslog facility, possible values being one of auth, authpriv, cron, daemon, ftp, kern, lpr, mail, news, syslog, user, uucp, local0, local1, local2, local3, local4, local5, local6, or local7.

  Note

  Not every facility is necessarily supported by every operating system.

  SYSLOG:facility=syslog

- **FILE** pipes the cluster log output to a regular file on the same machine. The following values can be specified:

  - **filename**: The name of the log file.

    Prior to MySQL Cluster NDB 7.0.43 and MySQL Cluster NDB 7.1.23, the log file's default name, used if FILE was specified without also setting filename, was logger.log. Beginning with MySQL Cluster NDB 7.0.43 and MySQL Cluster NDB 7.1.23, the default log file name used in such cases is ndb_nodeid_cluster.log.

  - **maxsize**: The maximum size (in bytes) to which the file can grow before logging rolls over to a new file. When this occurs, the old log file is renamed by appending .N to the file name, where N is the next number not yet used with this name.

  - **maxfiles**: The maximum number of log files.

  FILE:filename=cluster.log,maxsize=1000000,maxfiles=6
The default value for the `FILE` parameter is `FILE:filename=ndb_node_id_cluster.log,maxsize=1000000,maxfiles=6`, where `node_id` is the ID of the node.

It is possible to specify multiple log destinations separated by semicolons as shown here:

```
CONSOLE;SYSLOG:facility=local0;FILE:filename=/var/log/mgmd
```

- **ArbitrationRank**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>0-2</td>
<td>1</td>
<td>0 - 2</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is used to define which nodes can act as arbitrators. Only management nodes and SQL nodes can be arbitrators. `ArbitrationRank` can take one of the following values:

- **0**: The node will never be used as an arbitrator.
- **1**: The node has high priority; that is, it will be preferred as an arbitrator over low-priority nodes.
- **2**: Indicates a low-priority node which be used as an arbitrator only if a node with a higher priority is not available for that purpose.

Normally, the management server should be configured as an arbitrator by setting its `ArbitrationRank` to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

Beginning with MySQL 5.1.16 and MySQL Cluster NDB 6.1.3, it is possible to disable arbitration completely by setting `ArbitrationRank` to 0 on all management and SQL nodes. In MySQL Cluster NDB 7.0.7 and later releases, you can also control arbitration by overriding this parameter; to do this, set the `Arbitration` parameter in the `[ndbd default]` section of the `config.ini` global configuration file.

- **ArbitrationDelay**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>milliseconds</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

An integer value which causes the management server's responses to arbitration requests to be delayed by that number of milliseconds. By default, this value is 0; it is normally not necessary to change it.

- **DataDir**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>path</td>
<td>.</td>
<td>...</td>
<td>N</td>
</tr>
</tbody>
</table>

This specifies the directory where output files from the management server will be placed. These files include cluster log files, process output files, and the daemon's process ID (PID) file. (For log files, this location can be overridden by setting the `FILE` parameter for `LogDestination` as discussed previously in this section.)

The default value for this parameter is the directory in which `ndb_mgmd` is located.

- **PortNumberStats**
This parameter specifies the port number used to obtain statistical information from a MySQL Cluster management server. It has no default value.

- **Wan**

```
Wan
```

Use WAN TCP setting as default. Introduced in MySQL Cluster NDB 6.1.1.

- **HeartbeatThreadPriority**

Beginning with MySQL Cluster NDB 6.3.32, MySQL Cluster NDB 7.0.13, and MySQL Cluster NDB 7.1.2, it is possible to use this parameter to set the scheduling policy and priority of heartbeat threads for management and API nodes.

The syntax for setting this parameter is shown here:

```
HeartbeatThreadPriority = policy[, priority]
policy: {FIFO | RR}
```

When setting this parameter, you must specify a policy. This is one of FIFO (first in, first out) or RR (round robin). The policy value is followed optionally by the priority (an integer).

- **ExtraSendBufferMemory**

```
ExtraSendBufferMemory
```

This parameter specifies the amount of transporter send buffer memory to allocate in addition to any that has been set using `TotalSendBufferMemory`, `SendBufferMemory`, or both. This parameter was added in MySQL Cluster NDB 7.0.39 and MySQL Cluster NDB 7.1.28. (Bug #14555359)

- **TotalSendBufferMemory**

```
TotalSendBufferMemory
```

This parameter is available beginning with MySQL Cluster NDB 6.4.0. It is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see Section 17.3.3.14, “Configuring MySQL Cluster Send Buffer Parameters”.

- **HeartbeatIntervalMgmdMgmd**
### Effective Version

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.0.40</td>
<td>milliseconds</td>
<td>1500</td>
<td>100 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
<tr>
<td>NDB 7.1.29</td>
<td>milliseconds</td>
<td>1500</td>
<td>100 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

Specify the interval between heartbeat messages used to determine whether another management node is on contact with this one. The management node waits after 3 of these intervals to declare the connection dead; thus, the default setting of 1500 milliseconds causes the management node to wait for approximately 1600 ms before timing out.

This parameter was added in MySQL Cluster NDB 7.0.40 and MySQL Cluster NDB 7.1.29. (Bug #16426805)

---

**Note**

After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect.

To add new management servers to a running MySQL Cluster, it is also necessary to perform a rolling restart of all cluster nodes after modifying any existing `config.ini` files. For more information about issues arising when using multiple management nodes, see Section 17.1.6.10, “Limitations Relating to Multiple MySQL Cluster Nodes”.

---

### 17.3.3.6 Defining MySQL Cluster Data Nodes

The `[ndbd]` and `[ndbd default]` sections are used to configure the behavior of the cluster's data nodes.

`[ndbd]` and `[ndbd default]` are always used as the section names whether you are using `ndbd` or (in MySQL Cluster NDB 6.4.0 and later) `ndbmtd` binaries for the data node processes.

There are many parameters which control buffer sizes, pool sizes, timeouts, and so forth. The only mandatory parameters are:

- Either `ExecuteOnComputer` or `HostName`, which must be defined in the local `[ndbd]` section.
- The parameter `NoOfReplicas`, which must be defined in the `[ndbd default]` section, as it is common to all Cluster data nodes.

**Note**

It is no longer strictly necessary to set `NoOfReplicas` starting with MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.6, where it acquires a default value (2). However, it remains good practice to set it explicitly.

Most data node parameters are set in the `[ndbd default]` section. Only those parameters explicitly stated as being able to set local values are permitted to be changed in the `[ndbd]` section. Where present, `HostName`, `NodeId` and `ExecuteOnComputer` must be defined in the local `[ndbd]` section, and not in any other section of `config.ini`. In other words, settings for these parameters are specific to one data node.

For those parameters affecting memory usage or buffer sizes, it is possible to use `K`, `M`, or `G` as a suffix to indicate units of 1024, 1024×1024, or 1024×1024×1024. (For example, `100K` means 100 × 1024 = 102400.) Parameter names and values are currently case-sensitive.

Information about configuration parameters specific to MySQL Cluster Disk Data tables can be found later in this section (see Disk Data Configuration Parameters).
Beginning with MySQL Cluster NDB 6.4.0, all of these parameters also apply to `ndbmtd` (the multi-threaded version of `ndbd`). Two additional data node configuration parameters—`MaxNoOfExecutionThreads` and `ThreadConfig`—apply to `ndbmtd` only; these have no effect when used with `ndbd`. For more information, see Multi-Threading Configuration Parameters (ndbmtd). See also Section 17.4.3, “ndbmtd — The MySQL Cluster Data Node Daemon (Multi-Threaded)”.

Identifying data nodes. The `NodeId` or `Id` value (that is, the data node identifier) can be allocated on the command line when the node is started or in the configuration file.

```
<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>unsigned</td>
<td>[none]</td>
<td>1 - 48</td>
<td>IS</td>
</tr>
</tbody>
</table>
```

A unique node ID is used as the node's address for all cluster internal messages. For data nodes, this is an integer in the range 1 to 48 inclusive. Each node in the cluster must have a unique identifier.

`NodeId` is the preferred parameter name to use when identifying data nodes beginning with MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.39, MySQL Cluster NDB 7.0.20, and MySQL Cluster NDB 7.1.9. Although `Id` continues to be supported for backward compatibility, it is now deprecated and generates a warning when used.

```
<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>unsigned</td>
<td>[none]</td>
<td>1 - 48</td>
<td>IS</td>
</tr>
</tbody>
</table>
```

A unique node ID is used as the node's address for all cluster internal messages. For data nodes, this is an integer in the range 1 to 48 inclusive. Each node in the cluster must have a unique identifier.

`NodeId` is the preferred parameter name to use when identifying data nodes beginning with MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.39, MySQL Cluster NDB 7.0.20, and MySQL Cluster NDB 7.1.9. Although `Id` continues to be supported for backward compatibility, it is now deprecated and generates a warning when used.

```
<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>name</td>
<td>[none]</td>
<td>...</td>
<td>S</td>
</tr>
</tbody>
</table>
```

This refers to the `Id` set for one of the computers defined in a `[computer]` section.

```
<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>name or IP address</td>
<td>localhost</td>
<td>...</td>
<td>N</td>
</tr>
</tbody>
</table>
```

Specifying this parameter defines the hostname of the computer on which the data node is to reside. To specify a hostname other than `localhost`, either this parameter or `ExecuteOnComputer` is required.

```
<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>unsigned</td>
<td>[none]</td>
<td>1 - 64K</td>
<td>S</td>
</tr>
</tbody>
</table>
```
Each node in the cluster uses a port to connect to other nodes. By default, this port is allocated dynamically in such a way as to ensure that no two nodes on the same host computer receive the same port number, so it should normally not be necessary to specify a value for this parameter.

However, if you need to be able to open specific ports in a firewall to permit communication between data nodes and API nodes (including SQL nodes), you can set this parameter to the number of the desired port in an [ndbd] section or (if you need to do this for multiple data nodes) the [ndbd default] section of the config.ini file, and then open the port having that number for incoming connections from SQL nodes, API nodes, or both.

Note
Connections from data nodes to management nodes is done using the ndb_mgmd management port (the management server's PortNumber; see Section 17.3.3.5, “Defining a MySQL Cluster Management Server”) so outgoing connections to that port from any data nodes should always be permitted.

• TcpBind_INADDR_ANY

Setting this parameter to TRUE or 1 binds IP_ADDR_ANY so that connections can be made from anywhere (for autogenerated connections). The default is FALSE (0).

This parameter was added in MySQL Cluster NDB 6.2.0.

• NodeGroup

This parameter can be used to assign a data node to a specific node group. It is read only when the cluster is started for the first time, and cannot be used to reassign a data node to a different node group online. It is generally not desirable to use this parameter in the [ndbd default] section of the config.ini file, and care must be taken not to assign nodes to node groups in such a way that an invalid numbers of nodes are assigned to any node groups.

The NodeGroup parameter is chiefly intended for use in adding a new node group to a running MySQL Cluster without having to perform a rolling restart. For this purpose, you should set it to 65536 (the maximum value). You are not required to set a NodeGroup value for all cluster data nodes, only for those nodes which are to be started and added to the cluster as a new node group at a later time. For more information, see Section 17.5.13.3, “Adding MySQL Cluster Data Nodes Online: Detailed Example”.

This parameter was added in MySQL Cluster NDB 6.4.0.

• NoOfReplicas

This global parameter can be set only in the [ndbd default] section, and defines the number of replicas for each table stored in the cluster. This parameter also specifies the size of node groups. A node group is a set of nodes all storing the same information.

Node groups are formed implicitly. The first node group is formed by the set of data nodes with the lowest node IDs, the next node group by the set of the next lowest node identities, and so on. By way
of example, assume that we have 4 data nodes and that `NoOfReplicas` is set to 2. The four data nodes have node IDs 2, 3, 4 and 5. Then the first node group is formed from nodes 2 and 3, and the second node group by nodes 4 and 5. It is important to configure the cluster in such a manner that nodes in the same node groups are not placed on the same computer because a single hardware failure would cause the entire cluster to fail.

If no node IDs are provided, the order of the data nodes will be the determining factor for the node group. Whether or not explicit assignments are made, they can be viewed in the output of the management client's `SHOW` command.

Prior to MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.6, there was no default value for `NoOfReplicas`; beginning with these versions, the default value is 2, which is the recommended setting in most common usage scenarios. (Bug #44746)

The maximum possible value is 4; currently, only the values 1 and 2 are actually supported.

---

### Important

Setting `NoOfReplicas` to 1 means that there is only a single copy of all Cluster data; in this case, the loss of a single data node causes the cluster to fail because there are no additional copies of the data stored by that node.

The value for this parameter must divide evenly into the number of data nodes in the cluster. For example, if there are two data nodes, then `NoOfReplicas` must be equal to either 1 or 2, since 2/3 and 2/4 both yield fractional values; if there are four data nodes, then `NoOfReplicas` must be equal to 1, 2, or 4.

---

### • DataDir

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>path</td>
<td>.</td>
<td>...</td>
<td>IN</td>
</tr>
</tbody>
</table>

This parameter specifies the directory where trace files, log files, pid files and error logs are placed. The default is the data node process working directory.

---

### • FileSystemPath

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>path</td>
<td>DataDir</td>
<td>...</td>
<td>IN</td>
</tr>
</tbody>
</table>

This parameter specifies the directory where all files created for metadata, REDO logs, UNDO logs (for Disk Data tables), and data files are placed. The default is the directory specified by `DataDir`.

---

**Note**

This directory must exist before the `ndbd` process is initiated.

The recommended directory hierarchy for MySQL Cluster includes `/var/lib/mysql-cluster`, under which a directory for the node’s file system is created. The name of this subdirectory contains the node ID. For example, if the node ID is 2, this subdirectory is named `ndb_2_fs`.

---

### • BackupDataDir

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>path</td>
<td>[see text]</td>
<td>...</td>
<td>IN</td>
</tr>
</tbody>
</table>

This parameter specifies the directory in which backups are placed.
Important

The string '/BACKUP' is always appended to this value. For example, if you set the value of BackupDataDir to /var/lib/cluster-data, then all backups are stored under /var/lib/cluster-data/BACKUP. This also means that the effective default backup location is the directory named BACKUP under the location specified by the FileSystemPath parameter.

Data Memory, Index Memory, and String Memory

DataMemory and IndexMemory are [ndbd] parameters specifying the size of memory segments used to store the actual records and their indexes. In setting values for these, it is important to understand how DataMemory and IndexMemory are used, as they usually need to be updated to reflect actual usage by the cluster:

- DataMemory

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>bytes</td>
<td>80M</td>
<td>1M - 1024G</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter defines the amount of space (in bytes) available for storing database records. The entire amount specified by this value is allocated in memory, so it is extremely important that the machine has sufficient physical memory to accommodate it.

The memory allocated by DataMemory is used to store both the actual records and indexes. There is a 16-byte overhead on each record; an additional amount for each record is incurred because it is stored in a 32KB page with 128 byte page overhead (see below). There is also a small amount wasted per page due to the fact that each record is stored in only one page.

For variable-size table attributes in MySQL 5.1, the data is stored on separate data pages, allocated from DataMemory. Variable-length records use a fixed-size part with an extra overhead of 4 bytes to reference the variable-size part. The variable-size part has 2 bytes overhead plus 2 bytes per attribute.

Prior to MySQL Cluster NDB 7.0, the maximum record size was 8052 bytes; in MySQL Cluster NDB 7.0 and later, it is 14000 bytes.

The memory space defined by DataMemory is also used to store ordered indexes, which use about 10 bytes per record. Each table row is represented in the ordered index. A common error among users is to assume that all indexes are stored in the memory allocated by IndexMemory, but this is not the case: Only primary key and unique hash indexes use this memory; ordered indexes use the memory allocated by DataMemory. However, creating a primary key or unique hash index also creates an ordered index on the same keys, unless you specify USING HASH in the index creation statement. This can be verified by running ndb_desc -d db_name table_name in the management client.

MySQL Cluster can use a maximum of 512 MB for hash indexes per partition, which means in some cases it is possible to get Table is full errors in MySQL client applications even when ndb_mgm -e "ALL REPORT MEMORYUSAGE" shows significant free DataMemory. This can also pose a problem with data node restarts on nodes that are heavily loaded with data. You can force NDB to create extra partitions for MySQL Cluster tables and thus have more memory available for hash indexes by using the MAX_ROWS option for CREATE TABLE. In general, setting MAX_ROWS to twice the number of rows that you expect to store in the table should be sufficient. In MySQL Cluster 7.1.18 and later, you can also use the MinFreePct configuration parameter to help avoid problems with node restarts. (Bug #13436216)

The memory space allocated by DataMemory consists of 32KB pages, which are allocated to table fragments. Each table is normally partitioned into the same number of fragments as there are data
nodes in the cluster. Thus, for each node, there are the same number of fragments as are set in `NoOfReplicas`.

In addition, due to the way in which new pages are allocated when the capacity of the current page is exhausted, there is an additional overhead of approximately 18.75%. When more `DataMemory` is required, more than one new page is allocated, according to the following formula:

\[
\text{number of new pages} = \text{FLOOR}(\text{number of current pages} \times 0.1875) + 1
\]

For example, if 15 pages are currently allocated to a given table and an insert to this table requires additional storage space, the number of new pages allocated to the table is \(\text{FLOOR}(15 \times 0.1875) + 1 = \text{FLOOR}(2.8125) + 1 = 2 + 1 = 3\). Now 15 + 3 = 18 memory pages are allocated to the table. When the last of these 18 pages becomes full, \(\text{FLOOR}(18 \times 0.1875) + 1 = \text{FLOOR}(3.3750) + 1 = 3 + 1 = 4\) new pages are allocated, so the total number of pages allocated to the table is now 22.

Note
The “18.75% + 1” overhead is no longer required beginning with MySQL Cluster NDB 6.2.3 and MySQL Cluster NDB 6.3.0.

Once a page has been allocated, it is currently not possible to return it to the pool of free pages, except by deleting the table. (This also means that `DataMemory` pages, once allocated to a given table, cannot be used by other tables.) Performing a node recovery also compresses the partition because all records are inserted into empty partitions from other live nodes.

The `DataMemory` memory space also contains UNDO information: For each update, a copy of the unaltered record is allocated in the `DataMemory`. There is also a reference to each copy in the ordered table indexes. Unique hash indexes are updated only when the unique index columns are updated, in which case a new entry in the index table is inserted and the old entry is deleted upon commit. For this reason, it is also necessary to allocate enough memory to handle the largest transactions performed by applications using the cluster. In any case, performing a few large transactions holds no advantage over using many smaller ones, for the following reasons:

- Large transactions are not any faster than smaller ones
- Large transactions increase the number of operations that are lost and must be repeated in event of transaction failure
- Large transactions use more memory

The default value for `DataMemory` is 80MB; the minimum is 1MB. There is no maximum size, but in reality the maximum size has to be adapted so that the process does not start swapping when the limit is reached. This limit is determined by the amount of physical RAM available on the machine and by the amount of memory that the operating system may commit to any one process. 32-bit operating systems are generally limited to 2–4GB per process; 64-bit operating systems can use more. For large databases, it may be preferable to use a 64-bit operating system for this reason.

### IndexMemory

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>bytes</td>
<td>18M</td>
<td>1M - 1T</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter controls the amount of storage used for hash indexes in MySQL Cluster. Hash indexes are always used for primary key indexes, unique indexes, and unique constraints. When defining a primary key or a unique index, two indexes are created, one of which is a hash index used for all tuple accesses as well as lock handling. This index is also used to enforce unique constraints.

You can estimate the size of a hash index using this formula:
size = ( (fragments * 32K) + (rows * 18) ) * replicas

fragments is the number of fragments, replicas is the number of replicas (normally 2), and rows is the number of rows. If a table has one million rows, 8 fragments, and 2 replicas, the expected index memory usage is calculated as shown here:

\[
\begin{align*}
((8 \times 32K) + (1000000 \times 18)) \times 2 &= ((8 \times 32768) + (1000000 \times 18)) \times 2 \\
&= (262144 + 18000000) \times 2 \\
&= 18262144 \times 2 = 36524288 \text{ bytes} = \sim 35\text{MB}
\end{align*}
\]

The default value for IndexMemory is 18MB. The minimum is 1MB.

- **StringMemory**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>% or bytes</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>S</td>
</tr>
<tr>
<td>MySQL 5.1.32</td>
<td>% or bytes</td>
<td>25</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>S</td>
</tr>
<tr>
<td>MySQL 5.1.6</td>
<td>% or bytes</td>
<td>5</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>S</td>
</tr>
<tr>
<td>NDB 7.2.1</td>
<td>% or bytes</td>
<td>25</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>S</td>
</tr>
</tbody>
</table>

This parameter determines how much memory is allocated for strings such as table names, and is specified in an [ndbd] or [ndbd default] section of the config.ini file. A value between 0 and 100 inclusive is interpreted as a percent of the maximum default value, which is calculated based on a number of factors including the number of tables, maximum table name size, maximum size of .FRM files, MaxNoOfTriggers, maximum column name size, and maximum default column value.

A value greater than 100 is interpreted as a number of bytes.

The default value is 25—that is, 25 percent of the default maximum. (Previously, prior to MySQL Cluster NDB 6.2.18, MySQL Cluster NDB 6.3.24, and MySQL Cluster NDB 7.0.5, the default value was 5; prior to MySQL 5.1.6, the default was 0.)

Under most circumstances, the default value should be sufficient, but when you have a great many Cluster tables (1000 or more), it is possible to get Error 773 Out of string memory, please modify StringMemory config parameter: Permanent error: Schema error, in which case you should increase this value. 25 (25 percent) is not excessive, and should prevent this error from recurring in all but the most extreme conditions.

The following example illustrates how memory is used for a table. Consider this table definition:

```sql
CREATE TABLE example ( 
  a INT NOT NULL, 
  b INT NOT NULL, 
  c INT NOT NULL, 
  PRIMARY KEY(a), 
  UNIQUE(b), 
) ENGINE=NDBCLUSTER;
```

For each record, there are 12 bytes of data plus 12 bytes overhead. Having no nullable columns saves 4 bytes of overhead. In addition, we have two ordered indexes on columns a and b consuming roughly
10 bytes each per record. There is a primary key hash index on the base table using roughly 29 bytes per record. The unique constraint is implemented by a separate table with b as primary key and a as a column. This other table consumes an additional 29 bytes of index memory per record in the example table as well 8 bytes of record data plus 12 bytes of overhead.

Thus, for one million records, we need 58MB for index memory to handle the hash indexes for the primary key and the unique constraint. We also need 64MB for the records of the base table and the unique index table, plus the two ordered index tables.

You can see that hash indexes takes up a fair amount of memory space; however, they provide very fast access to the data in return. They are also used in MySQL Cluster to handle uniqueness constraints.

The only partitioning algorithm is hashing and ordered indexes are local to each node. Thus, ordered indexes cannot be used to handle uniqueness constraints in the general case.

An important point for both `IndexMemory` and `DataMemory` is that the total database size is the sum of all data memory and all index memory for each node group. Each node group is used to store replicated information, so if there are four nodes with two replicas, there will be two node groups. Thus, the total data memory available is 2 × `DataMemory` for each data node.

It is highly recommended that `DataMemory` and `IndexMemory` be set to the same values for all nodes. Data distribution is even over all nodes in the cluster, so the maximum amount of space available for any node can be no greater than that of the smallest node in the cluster.

`DataMemory` and `IndexMemory` can be changed, but decreasing either of these can be risky; doing so can easily lead to a node or even an entire MySQL Cluster that is unable to restart due to there being insufficient memory space. Increasing these values should be acceptable, but it is recommended that such upgrades are performed in the same manner as a software upgrade, beginning with an update of the configuration file, and then restarting the management server followed by restarting each data node in turn.

`MinFreePct`. Beginning with MySQL Cluster NDB 7.0.29 and MySQL Cluster NDB 7.1.18, a proportion (5% by default) of data node resources including `DataMemory` and `IndexMemory` is kept in reserve to insure that the data node does not exhaust its memory when performing a restart. This can be adjusted using the `MinFreePct` data node configuration parameter (default 5) introduced in the same versions of MySQL Cluster.

<table>

</tr>
</tbody>
</table>

Updates do not increase the amount of index memory used. Inserts take effect immediately; however, rows are not actually deleted until the transaction is committed.

**Transaction parameters.** The next few [ndbd] parameters that we discuss are important because they affect the number of parallel transactions and the sizes of transactions that can be handled by the system. `MaxNoOfConcurrentTransactions` sets the number of parallel transactions possible in a node. `MaxNoOfConcurrentOperations` sets the number of records that can be in update phase or locked simultaneously.

Both of these parameters (especially `MaxNoOfConcurrentOperations`) are likely targets for users setting specific values and not using the default value. The default value is set for systems using small transactions, to ensure that these do not use excessive memory.

`MaxDMLOperationsPerTransaction`, added in MySQL Cluster NDB 7.0.26 and MySQL Cluster NDB 7.1.15, sets the maximum number of DML operations that can be performed in a given transaction.

- `MaxNoOfConcurrentTransactions`
Each cluster data node requires a transaction record for each active transaction in the cluster. The task of coordinating transactions is distributed among all of the data nodes. The total number of transaction records in the cluster is the number of transactions in any given node times the number of nodes in the cluster.

Transaction records are allocated to individual MySQL servers. Each connection to an SQL node requires at least one transaction record, plus an additional transaction object per table accessed by that connection. This means that a reasonable minimum for this parameter is

\[
\text{MaxNoOfConcurrentTransactions} = (\text{maximum number of tables accessed in any single transaction} + 1) \times \text{number of cluster SQL nodes}
\]

Suppose that there are 10 SQL nodes using the cluster. A single join involving 10 tables requires 11 transaction records; if there are 10 such joins in a transaction, then \(10 \times 11 = 110\) transaction records are required for this transaction, per SQL node, or \(110 \times 10 = 1100\) transaction records total. Each data node can be expected to handle \(\text{TotalNoOfConcurrentTransactions} / \text{number of data nodes}\). For a MySQL Cluster having 4 data nodes, this would mean setting \(\text{MaxNoOfConcurrentTransactions}\) on each data node to \(1100 / 4 = 275\). In addition, you should provide for failure recovery by ensuring that a single node group can accommodate all concurrent transactions; in other words, that each data node’s \(\text{MaxNoOfConcurrentTransactions}\) is sufficient to cover a number of transaction equal to \(\text{TotalNoOfConcurrentTransactions} / \text{number of node groups}\). If this cluster has a single node group, then \(\text{MaxNoOfConcurrentTransactions}\) should be set to 1100 (the same as the total number of concurrent transactions for the entire cluster).

In addition, each transaction involves at least one operation; for this reason, the value set for \(\text{MaxNoOfConcurrentTransactions}\) should always be no more than the value of \(\text{MaxNoOfConcurrentOperations}\).

This parameter must be set to the same value for all cluster data nodes. This is due to the fact that, when a data node fails, the oldest surviving node re-creates the transaction state of all transactions that were ongoing in the failed node.

It is possible to change this value using a rolling restart, but the amount of traffic on the cluster must be such that no more transactions occur than the lower of the old and new levels while this is taking place.

The default value is 4096.

\* \(\text{MaxNoOfConcurrentOperations}\)
This parameter should be set to the number of records to be updated simultaneously in transactions, divided by the number of cluster data nodes. For example, in a cluster which has four data nodes and which is expected to handle one million concurrent updates using transactions, you should set this value to 1000000 / 4 = 250000. To help provide resiliency against failures, it is suggested that you set this parameter to a value that is high enough to permit an individual data node to handle the load for its node group. In other words, you should set the value equal to total number of concurrent operations / number of node groups. (In the case where there is a single node group, this is the same as the total number of concurrent operations for the entire cluster.)

Because each transaction always involves at least one operation, the value of MaxNoOfConcurrentOperations should always be greater than or equal to the value of MaxNoOfConcurrentTransactions.

Read queries which set locks also cause operation records to be created. Some extra space is allocated within individual nodes to accommodate cases where the distribution is not perfect over the nodes.

When queries make use of the unique hash index, there are actually two operation records used per record in the transaction. The first record represents the read in the index table and the second handles the operation on the base table.

The default value is 32768.

This parameter actually handles two values that can be configured separately. The first of these specifies how many operation records are to be placed with the transaction coordinator. The second part specifies how many operation records are to be local to the database.

A very large transaction performed on an eight-node cluster requires as many operation records in the transaction coordinator as there are reads, updates, and deletes involved in the transaction. However, the operation records of the are spread over all eight nodes. Thus, if it is necessary to configure the system for one very large transaction, it is a good idea to configure the two parts separately. MaxNoOfConcurrentOperations will always be used to calculate the number of operation records in the transaction coordinator portion of the node.

It is also important to have an idea of the memory requirements for operation records. These consume about 1kB per record.

• MaxNoOfLocalOperations

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>integer</td>
<td>UNDEFINED</td>
<td>32 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

By default, this parameter is calculated as \(1.1 \times \text{MaxNoOfConcurrentOperations}\). This fits systems with many simultaneous transactions, none of them being very large. If there is a need to handle one very large transaction at a time and there are many nodes, it is a good idea to override the default value by explicitly specifying this parameter.

• MaxDMLOperationsPerTransaction

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.0.26</td>
<td>operations (DML)</td>
<td>4294967295</td>
<td>32 - 4294967295</td>
<td>N</td>
</tr>
<tr>
<td>NDB 7.1.15</td>
<td>operations (DML)</td>
<td>4294967295</td>
<td>32 - 4294967295</td>
<td>N</td>
</tr>
</tbody>
</table>

Added in MySQL Cluster NDB 7.0.26 and MySQL Cluster NDB 7.1.15, this parameter limits the size of a transaction. The transaction is aborted if it requires more than this many DML operations. The minimum number of operations per transaction is 32; however, you can set...
**MaxDMLOperationsPerTransaction** to 0 to disable any limitation on the number of DML operations per transaction. The maximum (and default) is 4294967295.

**Transaction temporary storage.** The next set of [ndbd] parameters is used to determine temporary storage when executing a statement that is part of a Cluster transaction. All records are released when the statement is completed and the cluster is waiting for the commit or rollback.

The default values for these parameters are adequate for most situations. However, users with a need to support transactions involving large numbers of rows or operations may need to increase these values to enable better parallelism in the system, whereas users whose applications require relatively small transactions can decrease the values to save memory.

- **MaxNoOfConcurrentIndexOperations**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>integer</td>
<td>8K</td>
<td>0 - 4294967039</td>
<td>N</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>(0xFFFFFEFF)</td>
<td></td>
</tr>
</tbody>
</table>

For queries using a unique hash index, another temporary set of operation records is used during a query's execution phase. This parameter sets the size of that pool of records. Thus, this record is allocated only while executing a part of a query. As soon as this part has been executed, the record is released. The state needed to handle aborts and commits is handled by the normal operation records, where the pool size is set by the parameter **MaxNoOfConcurrentOperations**.

The default value of this parameter is 8192. Only in rare cases of extremely high parallelism using unique hash indexes should it be necessary to increase this value. Using a smaller value is possible and can save memory if the DBA is certain that a high degree of parallelism is not required for the cluster.

- **MaxNoOfFiredTriggers**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>integer</td>
<td>4000</td>
<td>0 - 4294967039</td>
<td>N</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>(0xFFFFFEFF)</td>
<td></td>
</tr>
</tbody>
</table>

The default value of **MaxNoOfFiredTriggers** is 4000, which is sufficient for most situations. In some cases it can even be decreased if the DBA feels certain the need for parallelism in the cluster is not high.

A record is created when an operation is performed that affects a unique hash index. Inserting or deleting a record in a table with unique hash indexes or updating a column that is part of a unique hash index fires an insert or a delete in the index table. The resulting record is used to represent this index table operation while waiting for the original operation that fired it to complete. This operation is short-lived but can still require a large number of records in its pool for situations with many parallel write operations on a base table containing a set of unique hash indexes.

- **TransactionBufferMemory**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>bytes</td>
<td>1M</td>
<td>1K - 4294967039</td>
<td>N</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>(0xFFFFFEFF)</td>
<td></td>
</tr>
</tbody>
</table>

The memory affected by this parameter is used for tracking operations fired when updating index tables and reading unique indexes. This memory is used to store the key and column information for these operations. It is only very rarely that the value for this parameter needs to be altered from the default.

The default value for **TransactionBufferMemory** is 1MB.
Normal read and write operations use a similar buffer, whose usage is even more short-lived. The compile-time parameter `ZATTRBUF_FILESIZE` (found in `ndb/src/kernel/blocks/Dbtc/Dbtc.hpp`) set to 4000 × 128 bytes (500KB). A similar buffer for key information, `ZDATABUF_FILESIZE` (also in `Dbtc.hpp`) contains 4000 × 16 = 62.5KB of buffer space. `Dbtc` is the module that handles transaction coordination.

**Scans and buffering.** There are additional [ndbd] parameters in the `Dblqh` module (in `ndb/src/kernel/blocks/Dblqh/Dblqh.hpp`) that affect reads and updates. These include `ZATTRINBUF_FILESIZE`, set by default to 10000 × 128 bytes (1250KB) and `ZDATABUF_FILE_SIZE`, set by default to 10000*16 bytes (roughly 156KB) of buffer space. To date, there have been neither any reports from users nor any results from our own extensive tests suggesting that either of these compile-time limits should be increased.

- **MaxNoOfConcurrentScans**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>integer</td>
<td>256</td>
<td>2 - 500</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is used to control the number of parallel scans that can be performed in the cluster. Each transaction coordinator can handle the number of parallel scans defined for this parameter. Each scan query is performed by scanning all partitions in parallel. Each partition scan uses a scan record in the node where the partition is located, the number of records being the value of this parameter times the number of nodes. The cluster should be able to sustain `MaxNoOfConcurrentScans` scans concurrently from all nodes in the cluster.

Scans are actually performed in two cases. The first of these cases occurs when no hash or ordered indexes exists to handle the query, in which case the query is executed by performing a full table scan. The second case is encountered when there is no hash index to support the query but there is an ordered index. Using the ordered index means executing a parallel range scan. The order is kept on the local partitions only, so it is necessary to perform the index scan on all partitions.

The default value of `MaxNoOfConcurrentScans` is 256. The maximum value is 500.

- **MaxNoOfLocalScans**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>integer</td>
<td>[see text]</td>
<td>32 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
<tr>
<td>NDB 7.2.0</td>
<td>integer</td>
<td>[see text]</td>
<td>32 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

Specifies the number of local scan records if many scans are not fully parallelized. In MySQL Cluster NDB 7.2.0 and later, when the number of local scan records is not provided, it is calculated as shown here:

\[ 4 \times \text{MaxNoOfConcurrentScans} \times \text{[# data nodes]} + 2 \]

In MySQL Cluster NDB 7.1 and earlier, the default is calculated as the product of `MaxNoOfConcurrentScans` and the number of data nodes, plus 2. The minimum value is 32.

- **BatchSizePerLocalScan**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>integer</td>
<td>64</td>
<td>1 - 992</td>
<td>N</td>
</tr>
<tr>
<td>NDB 7.2.1</td>
<td>integer</td>
<td>256</td>
<td>1 - 992</td>
<td>N</td>
</tr>
</tbody>
</table>
This parameter is used to calculate the number of lock records used to handle concurrent scan operations.

`BatchSizePerLocalScan` has a strong connection to the `BatchSize` defined in the SQL nodes.

- **LongMessageBuffer**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>bytes</td>
<td>1M</td>
<td>512K - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
<tr>
<td>NDB 7.0.4</td>
<td>bytes</td>
<td>4M</td>
<td>512K - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
<tr>
<td>NDB 7.2.0</td>
<td>bytes</td>
<td>4M</td>
<td>512K - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
<tr>
<td>NDB 7.1.31</td>
<td>bytes</td>
<td>64M</td>
<td>512K - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

This is an internal buffer used for passing messages within individual nodes and between nodes. In MySQL Cluster NDB 6.4.3 and earlier, the default is 1MB; beginning with MySQL Cluster NDB 7.0.4, this increased to 4MB; the default increased to 64MB in MySQL Cluster NDB 7.1.31.

This parameter seldom needs to be changed from the default. However, when replicating a MySQL Cluster using `ndbmtd` for the data nodes, you may need to increase this value to 8MB (or possibly more) to prevent data node instability, because `ndbmtd` uses much more of this resource than `ndbd` does. Beginning with MySQL Cluster NDB 7.0.13 and MySQL Cluster NDB 7.1.2, this should no longer be necessary when using `ndbmtd` with MySQL Cluster Replication (Bug #46914).

- **MaxParallelScansPerFragment**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.0.23</td>
<td>bytes</td>
<td>32</td>
<td>1 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
<tr>
<td>NDB 7.1.12</td>
<td>bytes</td>
<td>32</td>
<td>1 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
<tr>
<td>NDB 7.2.0</td>
<td>bytes</td>
<td>256</td>
<td>1 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

Beginning with MySQL Cluster NDB 7.0.23 and MySQL Cluster NDB 7.1.12, it is possible to configure the maximum number of parallel scans (TUP scans and TUX scans) allowed before they begin queuing for serial handling. (Previously, the maximum number of parallel scans per fragment was fixed at 32.) You can increase this to take advantage of any unused CPU when performing large number of scans in parallel and improve their performance.

Beginning with MySQL Cluster NDB 7.2.0, the default value for this parameter is increased from 32 to 256.

**Memory Allocation**

- **MaxAllocate**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.1.19</td>
<td>unsigned</td>
<td>32M</td>
<td>1M - 1G</td>
<td>N</td>
</tr>
</tbody>
</table>
This is the maximum size of the memory unit to use when allocating memory for tables. In cases where NDB gives Out of memory errors, but it is evident by examining the cluster logs or the output of DUMP 1000 that all available memory has not yet been used, you can increase the value of this parameter (or MaxNoOfTables, or both) to cause NDB to make sufficient memory available.

This parameter was introduced in MySQL 5.1.20, MySQL Cluster NDB 6.1.12 and MySQL Cluster NDB 6.2.3.

**Hash Map Size**

```
DefaultHashMapSize
```

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.2.3</td>
<td>unsigned</td>
<td>32M</td>
<td>1M - 1G</td>
<td>N</td>
</tr>
<tr>
<td>MySQL 5.1.20</td>
<td>unsigned</td>
<td>32M</td>
<td>1M - 1G</td>
<td>N</td>
</tr>
</tbody>
</table>

Beginning with MySQL Cluster NDB 7.0.38 and MySQL Cluster NDB 7.1.26, the size of the table hash maps used by NDB is configurable using this parameter; previously this value was hard-coded. DefaultHashMapSize can take any of three possible values (0, 240, 3840). These values and their effects are described in the following table:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description / Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Use the lowest value set, if any, for this parameter among all data nodes and API nodes in the cluster; if it is not set on any data or API node, use the default value.</td>
</tr>
<tr>
<td>240</td>
<td>Original hash map size used by default in all MySQL Cluster NDB 7.1 and MySQL Cluster NDB 7.0 (and earlier) releases; effectively the only value prior to versions 7.0.38 and 7.1.26 (when this parameter was introduced).</td>
</tr>
<tr>
<td>3840</td>
<td>Larger hash map size available beginning with MySQL Cluster NDB 7.0.38 and MySQL Cluster NDB 7.1.26</td>
</tr>
</tbody>
</table>

The primary intended use for this parameter is to facilitate upgrades and especially downgrades between MySQL Cluster NDB 7.1 and later MySQL Cluster versions in which the larger hash map size (3840) is the default; by setting this parameter to 240 prior to performing an upgrade, you can cause the cluster to continue using the smaller size for table hash maps, in which case the tables remain compatible with earlier versions. DefaultHashMapSize can be set for individual data nodes, API nodes, or both, but setting it once only, in the [ndbd default] section of the config.ini file, is the recommended practice. You can also set this parameter to 0, in which case the default value is used.

After increasing this parameter, to have existing tables to take advantage of the new size, you can run ALTER TABLE ... REORGANIZE PARTITION on them, after which they can use the larger hash map size. This is in addition to performing a rolling restart, which makes the larger hash maps available to new tables, but does not enable existing tables to use them.

Decreasing this parameter online after any tables have been created or modified with DefaultHashMapSize equal to 3840 is not currently supported.

**Logging and checkpointing.** The following [ndbd] parameters control log and checkpoint behavior.

- NoOfFragmentLogFiles
This parameter sets the number of REDO log files for the node, and thus the amount of space allocated to REDO logging. Because the REDO log files are organized in a ring, it is extremely important that the first and last log files in the set (sometimes referred to as the “head” and “tail” log files, respectively) do not meet. When these approach one another too closely, the node begins aborting all transactions encompassing updates due to a lack of room for new log records.

A REDO log record is not removed until the required number of local checkpoints has been completed since that log record was inserted (prior to MySQL Cluster NDB 6.3.8, this was 3 local checkpoints; in later versions of MySQL Cluster, only 2 local checkpoints are necessary). Checkpointing frequency is determined by its own set of configuration parameters discussed elsewhere in this chapter.

How these parameters interact and proposals for how to configure them are discussed in Section 17.3.3.13, “Configuring MySQL Cluster Parameters for Local Checkpoints”.

The default parameter value is 16, which by default means 16 sets of 4 16MB files for a total of 1024MB. Beginning with MySQL Cluster NDB 6.1.1, the size of the individual log files is configurable using the `FragmentLogFileSize` parameter. In scenarios requiring a great many updates, the value for `NoOfFragmentLogFiles` may need to be set as high as 300 or even higher to provide sufficient space for REDO logs.

If the checkpointing is slow and there are so many writes to the database that the log files are full and the log tail cannot be cut without jeopardizing recovery, all updating transactions are aborted with internal error code 410 (Out of log file space temporarily). This condition prevails until a checkpoint has completed and the log tail can be moved forward.

### Important

This parameter cannot be changed “on the fly”; you must restart the node using `--initial`. If you wish to change this value for all data nodes in a running cluster, you can do so using a rolling node restart (using `--initial` when starting each data node).

- **FragmentLogFileSize**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.1.11</td>
<td>bytes</td>
<td>16M</td>
<td>4M - 1G</td>
<td>IN</td>
</tr>
</tbody>
</table>

Setting this parameter enables you to control directly the size of redo log files. This can be useful in situations when MySQL Cluster is operating under a high load and it is unable to close fragment log files quickly enough before attempting to open new ones (only 2 fragment log files can be open at one time); increasing the size of the fragment log files gives the cluster more time before having to open each new fragment log file. The default value for this parameter is 16M. `FragmentLogFileSize` was added in MySQL Cluster NDB 6.1.11.

For more information about fragment log files, see the description for `NoOfFragmentLogFiles`.

- **InitFragmentLogFiles**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.3.19</td>
<td>[see values]</td>
<td>SPARSE</td>
<td>SPARSE, FULL</td>
<td>IN</td>
</tr>
</tbody>
</table>
By default, fragment log files are created sparsely when performing an initial start of a data node—that is, depending on the operating system and file system in use, not all bytes are necessarily written to disk. Beginning with MySQL Cluster NDB 6.3.19, it is possible to override this behavior and force all bytes to be written regardless of the platform and file system type being used by mean of this parameter.

*InitFragmentLogFiles* takes one of two values:

- **SPARSE.** Fragment log files are created sparsely. This is the default value.
- **FULL.** Force all bytes of the fragment log file to be written to disk.

Depending on your operating system and file system, setting *InitFragmentLogFiles=FULL* may help eliminate I/O errors on writes to the REDO log.

*MaxNoOfOpenFiles*

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>integer</td>
<td>40</td>
<td>20 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
<tr>
<td>MySQL 5.1.16</td>
<td>unsigned</td>
<td>0</td>
<td>20 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter sets a ceiling on how many internal threads to allocate for open files. *Any situation requiring a change in this parameter should be reported as a bug.*

The default value is 0. (Prior to MySQL 5.1.16, the default was 40.) However, the minimum value to which this parameter can be set is 20.

*InitialNoOfOpenFiles*

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.9</td>
<td>files</td>
<td>27</td>
<td>20 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter sets the initial number of internal threads to allocate for open files.

The default value is 27.

*MaxNoOfSavedMessages*

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>integer</td>
<td>25</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter sets the maximum number of errors written in the error log as well as the maximum number of trace files that are kept before overwriting the existing ones. Trace files are generated when, for whatever reason, the node crashes.

The default is 25, which sets these maximums to 25 error messages and 25 trace files.

*MaxLCPStartDelay*

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.3.23</td>
<td>seconds</td>
<td>0</td>
<td>0 - 600</td>
<td>N</td>
</tr>
<tr>
<td>NDB 6.4.3</td>
<td>seconds</td>
<td>941</td>
<td>0 - 600</td>
<td>N</td>
</tr>
</tbody>
</table>
In parallel data node recovery (supported in MySQL Cluster NDB 6.3.8 and later), only table data is actually copied and synchronized in parallel; synchronization of metadata such as dictionary and checkpoint information is done in a serial fashion. In addition, recovery of dictionary and checkpoint information cannot be executed in parallel with performing of local checkpoints. This means that, when starting or restarting many data nodes concurrently, data nodes may be forced to wait while a local checkpoint is performed, which can result in longer node recovery times.

Beginning with MySQL Cluster NDB 6.3.23 and MySQL Cluster NDB 6.4.3, it is possible to force a delay in the local checkpoint to permit more (and possibly all) data nodes to complete metadata synchronization; once each data node’s metadata synchronization is complete, all of the data nodes can recover table data in parallel, even while the local checkpoint is being executed.

To force such a delay, you can set `MaxLCPStartDelay`, which determines the number of seconds the cluster can wait to begin a local checkpoint while data nodes continue to synchronize metadata. This parameter should be set in the `[ndbd default]` section of the `config.ini` file, so that it is the same for all data nodes. The maximum value is 600; the default is 0.

- **LcpScanProgressTimeout**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.0.40</td>
<td>second</td>
<td>60</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
<tr>
<td>NDB 7.1.29</td>
<td>second</td>
<td>60</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

A local checkpoint fragment scan watchdog checks periodically for no progress in each fragment scan performed as part of a local checkpoint, and shuts down the node if there is no progress after a given amount of time has elapsed. Prior to MySQL Cluster NDB 7.0.39 and MySQL Cluster NDB 7.1.29, this interval is always 60 seconds (Bug #16630410). In MySQL Cluster NDB 7.0.39, MySQL Cluster NDB 7.1.29, and later this interval can be set using the `LcpScanProgressTimeout` data node configuration parameter, which sets the maximum time for which the local checkpoint can be stalled before the LCP fragment scan watchdog shuts down the node.

The default value is 60 seconds (providing compatibility with previous releases). Setting this parameter to 0 disables the LCP fragment scan watchdog altogether.

**Metadata objects.** The next set of `[ndbd]` parameters defines pool sizes for metadata objects, used to define the maximum number of attributes, tables, indexes, and trigger objects used by indexes, events, and replication between clusters. Note that these act merely as “suggestions” to the cluster, and any that are not specified revert to the default values shown.

- **MaxNoOfAttributes**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>integer</td>
<td>1000</td>
<td>32 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter sets a suggested maximum number of attributes that can be defined in the cluster; like `MaxNoOfTables`, it is not intended to function as a hard upper limit.

Prior to MySQL Cluster NDB 6.3.45, MySQL Cluster NDB 7.0.26, and MySQL Cluster NDB 7.1.15, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with MySQL Cluster Replication, when it was possible to create more tables than could be replicated, and sometimes led to confusion when it was possible (or not possible, depending on the circumstances) to create more than `MaxNoOfAttributes` attributes. (Bug #61684)
The default value is 1000, with the minimum possible value being 32. The maximum is 4294967039. Each attribute consumes around 200 bytes of storage per node due to the fact that all metadata is fully replicated on the servers.

When setting `MaxNoOfAttributes`, it is important to prepare in advance for any `ALTER TABLE` statements that you might want to perform in the future. This is due to the fact, during the execution of `ALTER TABLE` on a Cluster table, 3 times the number of attributes as in the original table are used, and a good practice is to permit double this amount. For example, if the MySQL Cluster table having the greatest number of attributes (`greatest_number_of_attributes`) has 100 attributes, a good starting point for the value of `MaxNoOfAttributes` would be `6 * greatest_number_of_attributes = 600`.

You should also estimate the average number of attributes per table and multiply this by `MaxNoOfTables`. If this value is larger than the value obtained in the previous paragraph, you should use the larger value instead.

Assuming that you can create all desired tables without any problems, you should also verify that this number is sufficient by trying an actual `ALTER TABLE` after configuring the parameter. If this is not successful, increase `MaxNoOfAttributes` by another multiple of `MaxNoOfTables` and test it again.

- `MaxNoOfTables`

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>integer</td>
<td>128</td>
<td>8 - 20320</td>
<td>N</td>
</tr>
</tbody>
</table>

A table object is allocated for each table and for each unique hash index in the cluster. This parameter sets a suggested maximum number of table objects for the cluster as a whole; like `MaxNoOfAttributes`, it is not intended to function as a hard upper limit.

Prior to MySQL Cluster NDB 6.3.45, MySQL Cluster NDB 7.0.26, and MySQL Cluster NDB 7.1.15, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with MySQL Cluster Replication, when it was possible to create more tables than could be replicated, and sometimes led to confusion when it was possible (or not possible, depending on the circumstances) to create more than `MaxNoOfTables` tables.

For each attribute that has a `BLOB` data type an extra table is used to store most of the `BLOB` data. These tables also must be taken into account when defining the total number of tables.

The default value of this parameter is 128. The minimum is 8 and the maximum is 20320. Each table object consumes approximately 20KB per node.

Note

The sum of `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes` must not exceed $2^{32} - 2$ (4294967294).

- `MaxNoOfOrderedIndexes`

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>integer</td>
<td>128</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

For each ordered index in the cluster, an object is allocated describing what is being indexed and its storage segments. By default, each index so defined also defines an ordered index. Each unique index and primary key has both an ordered index and a hash index. `MaxNoOfOrderedIndexes` sets the total number of ordered indexes that can be in use in the system at any one time.
The default value of this parameter is 128. Each index object consumes approximately 10KB of data per node.

Note
The sum of MaxNoOfTables, MaxNoOfOrderedIndexes, and MaxNoOfUniqueHashIndexes must not exceed $2^{32} - 2 (4294967294).

- **MaxNoOfUniqueHashIndexes**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>integer</td>
<td>64</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

For each unique index that is not a primary key, a special table is allocated that maps the unique key to the primary key of the indexed table. By default, an ordered index is also defined for each unique index. To prevent this, you must specify the **USING HASH** option when defining the unique index.

The default value is 64. Each index consumes approximately 15KB per node.

Note
The sum of MaxNoOfTables, MaxNoOfOrderedIndexes, and MaxNoOfUniqueHashIndexes must not exceed $2^{32} - 2 (4294967294).

- **MaxNoOfTriggers**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>integer</td>
<td>768</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

Internal update, insert, and delete triggers are allocated for each unique hash index. (This means that three triggers are created for each unique hash index.) However, an ordered index requires only a single trigger object. Backups also use three trigger objects for each normal table in the cluster.

Replication between clusters also makes use of internal triggers.

This parameter sets the maximum number of trigger objects in the cluster.

The default value is 768.

- **MaxNoOfIndexes**

This parameter is deprecated. You should use MaxNoOfOrderedIndexes and MaxNoOfUniqueHashIndexes instead.

This parameter is used only by unique hash indexes. There needs to be one record in this pool for each unique hash index defined in the cluster.

The default value of this parameter is 128.

- **MaxNoOfSubscriptions**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.2.10</td>
<td>unsigned</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
<tr>
<td>NDB 6.3.7</td>
<td>unsigned</td>
<td>1944</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>
Each NDB table in a MySQL Cluster requires a subscription in the NDB kernel. For some NDB API applications, it may be necessary or desirable to change this parameter, which became available in MySQL Cluster NDB 6.2.10 and MySQL Cluster NDB 6.3.7. However, for normal usage with MySQL servers acting as SQL nodes, there is not any need to do so.

The default value for **MaxNoOfSubscriptions** is 0, which is treated as equal to **MaxNoOfTables**. Each subscription consumes 108 bytes.

**• MaxNoOfSubscribers**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.2.10</td>
<td>unsigned</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
<tr>
<td>NDB 6.3.7</td>
<td>unsigned</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter, added in MySQL Cluster NDB 6.2.10 and MySQL Cluster NDB 6.3.7, is of interest only when using MySQL Cluster Replication. The default value is 0, which is treated as $2 \times \text{MaxNoOfTables}$; that is, there is one subscription per NDB table for each of two MySQL servers (one acting as the replication master and the other as the slave). Each subscriber uses 16 bytes of memory.

When using circular replication, multi-master replication, and other replication setups involving more than 2 MySQL servers, you should increase this parameter to the number of **mysqld** processes included in replication (this is often, but not always, the same as the number of clusters). For example, if you have a circular replication setup using three MySQL Clusters, with one mysqld attached to each cluster, and each of these mysqld processes acts as a master and as a slave, you should set **MaxNoOfSubscribers** equal to $3 \times \text{MaxNoOfTables}$.

For more information, see Section 17.6, “MySQL Cluster Replication”.

**• MaxNoOfConcurrentSubOperations**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.2.10</td>
<td>unsigned</td>
<td>256</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
<tr>
<td>NDB 6.3.7</td>
<td>unsigned</td>
<td>256</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter sets a ceiling on the number of operations that can be performed by all API nodes in the cluster at one time. The default value (256) is sufficient for normal operations, and might need to be adjusted only in scenarios where there are a great many API nodes each performing a high volume of operations concurrently.

This parameter was added in MySQL Cluster NDB 6.2.10 and MySQL Cluster NDB 6.3.7.

**Boolean parameters.** The behavior of data nodes is also affected by a set of [ndbd] parameters taking on boolean values. These parameters can each be specified as **TRUE** by setting them equal to 1 or Y, and as **FALSE** by setting them equal to 0 or N.

**• LateAlloc**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.4.0</td>
<td>numeric</td>
<td>1</td>
<td>0 - 1</td>
<td>N</td>
</tr>
</tbody>
</table>

Allocate memory for this data node after a connection to the management server has been established. Enabled by default.
Added in MySQL Cluster NDB 6.4.0.

- **LockPagesInMainMemory**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>numeric</td>
<td>0</td>
<td>0 - 2</td>
<td>N</td>
</tr>
<tr>
<td>MySQL 5.1.0</td>
<td>true</td>
<td>false</td>
<td>0</td>
<td>0 - 1</td>
</tr>
<tr>
<td>MySQL 5.1.15</td>
<td>numeric</td>
<td>0</td>
<td>0 - 2</td>
<td>N</td>
</tr>
</tbody>
</table>

For a number of operating systems, including Solaris and Linux, it is possible to lock a process into memory and so avoid any swapping to disk. This can be used to help guarantee the cluster’s real-time characteristics.

Beginning with MySQL 5.1.15 and MySQL Cluster NDB 6.1.1, this parameter takes one of the integer values 0, 1, or 2, which act as follows:

- **0**: Disables locking. This is the default value.
- **1**: Performs the lock after allocating memory for the process.
- **2**: Performs the lock before memory for the process is allocated.

Previously, this parameter was a Boolean. 0 or `false` was the default setting, and disabled locking. 1 or `true` enabled locking of the process after its memory was allocated.

**Important**

Beginning with MySQL 5.1.15 and MySQL Cluster NDB 6.1.1, it is no longer possible to use `true` or `false` for the value of this parameter; when upgrading from a previous version, you must change the value to 0, 1, or 2.

Prior to MySQL Cluster NDB 6.3.31 and MySQL Cluster NDB 7.0.11, setting this parameter did not cause the stated memory to be allocated when the node was started, but rather only when the memory was used by the data node process for other reasons. (Bug #37430)

**Note**

If the operating system is not configured to permit unprivileged users to lock pages, then the data node process making use of this parameter may have to be run as system root. (`LockPagesInMainMemory` uses the `mlockall` function. From Linux kernel 2.6.9, unprivileged users can lock memory as limited by `max locked memory`. For more information, see `ulimit -l` and http://linux.die.net/man/2/mlock).

**Important**

Beginning with glibc 2.10, glibc uses per-thread arenas to reduce lock contention on a shared pool, which consumes real memory. In general, a data node process does not need per-thread arenas, since it does not perform any memory allocation after startup. (This difference in allocators does not appear to affect performance significantly.)

The glibc behavior is intended to be configurable via the `MALLOC_ARENA_MAX` environment variable, but a bug in this mechanism prior to glibc 2.16 meant that this variable could not be set to less than 8, so that the wasted memory could not be reclaimed. (Bug #15907219; see also http://sourceware.org/bugzilla/show_bug.cgi?id=13137 for more information concerning this issue.)
One possible workaround for this problem is to use the `LD_PRELOAD` environment variable to preload a `jemalloc` memory allocation library to take the place of that supplied with `glibc`.

- **StopOnError**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>boolean</td>
<td>1</td>
<td>0, 1</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies whether a data node process should exit or perform an automatic restart when an error condition is encountered.

This parameter’s default value is 1; this means that, by default, an error causes the data node process to halt.

Users of MySQL Cluster Manager should note that, when `StopOnError` equals 1, this prevents the MySQL Cluster Manager agent from restarting any data nodes after it has performed its own restart and recovery. See [Starting and Stopping the Agent on Linux](#), for more information.

- **CrashOnCorruptedTuple**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.0.28, 5.1.56-ndb-7.1.17</td>
<td>boolean</td>
<td>false</td>
<td>true, false</td>
<td>S</td>
</tr>
<tr>
<td>NDB 7.2.1</td>
<td>boolean</td>
<td>true</td>
<td>true, false</td>
<td>S</td>
</tr>
</tbody>
</table>

This parameter was introduced in MySQL Cluster NDB 7.0.28 and MySQL Cluster NDB 7.1.17. When enabled, it forces a data node to shut down whenever it encounters a corrupted tuple. By default, it is disabled.

- **Diskless**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>true</td>
<td>false (1</td>
<td>0)</td>
<td>false</td>
</tr>
</tbody>
</table>

It is possible to specify MySQL Cluster tables as *diskless*, meaning that tables are not checkpointed to disk and that no logging occurs. Such tables exist only in main memory. A consequence of using diskless tables is that neither the tables nor the records in those tables survive a crash. However, when operating in diskless mode, it is possible to run `ndbd` on a diskless computer.

---

Important

This feature causes the *entire* cluster to operate in diskless mode.

When this feature is enabled, Cluster online backup is disabled. In addition, a partial start of the cluster is not possible.

*Diskless* is disabled by default.

- **ODirect**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.1.11</td>
<td>boolean</td>
<td>false</td>
<td>true, false</td>
<td>N</td>
</tr>
<tr>
<td>NDB 6.2.3</td>
<td>boolean</td>
<td>false</td>
<td>true, false</td>
<td>N</td>
</tr>
<tr>
<td>NDB 6.3.0</td>
<td>boolean</td>
<td>false</td>
<td>true, false</td>
<td>N</td>
</tr>
</tbody>
</table>
Enabling this parameter causes NDB to attempt using `O_DIRECT` writes for LCP, backups, and redo logs, often lowering kswapd and CPU usage. When using MySQL Cluster on Linux, enable `ODirect` if you are using a 2.6 or later kernel.

This parameter was added in MySQL 5.1.20, MySQL Cluster NDB 6.1.11, MySQL Cluster NDB 6.2.3, and MySQL Cluster NDB 6.3.0.

`ODirect` is disabled by default.

- **RestartOnErrorInsert**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>error code</td>
<td>2</td>
<td>0 - 4</td>
<td>N</td>
</tr>
</tbody>
</table>

This feature is accessible only when building the debug version where it is possible to insert errors in the execution of individual blocks of code as part of testing.

This feature is disabled by default.

- **CompressedBackup**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.3.7</td>
<td>boolean</td>
<td>false</td>
<td>true, false</td>
<td>N</td>
</tr>
</tbody>
</table>

Setting this parameter to 1 causes backup files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store uncompressed backup files. Compressed backups can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the `[ndbd default]` section of the `config.ini` file).

**Important**

You cannot restore a compressed backup to a cluster running a MySQL version that does not support this feature.

The default value is 0 (disabled).

This parameter was introduced in MySQL Cluster NDB 6.3.7.

- **CompressedLCP**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.3.7</td>
<td>boolean</td>
<td>false</td>
<td>true, false</td>
<td>N</td>
</tr>
</tbody>
</table>

Setting this parameter to 1 causes local checkpoint files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store uncompressed checkpoint files. Compressed LCPs can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the `[ndbd default]` section of the `config.ini` file).

**Important**

You cannot restore a compressed local checkpoint to a cluster running a MySQL version that does not support this feature.

The default value is 0 (disabled).

This parameter was introduced in MySQL Cluster NDB 6.3.7.
Controlling Timeouts, Intervals, and Disk Paging

There are a number of \texttt{ndbd} parameters specifying timeouts and intervals between various actions in Cluster data nodes. Most of the timeout values are specified in milliseconds. Any exceptions to this are mentioned where applicable.

- **TimeBetweenWatchDogCheck**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>milliseconds</td>
<td>6000</td>
<td>70 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

  To prevent the main thread from getting stuck in an endless loop at some point, a “watchdog” thread checks the main thread. This parameter specifies the number of milliseconds between checks. If the process remains in the same state after three checks, the watchdog thread terminates it.

  This parameter can easily be changed for purposes of experimentation or to adapt to local conditions. It can be specified on a per-node basis although there seems to be little reason for doing so.

  The default timeout is 6000 milliseconds (6 seconds).

- **TimeBetweenWatchDogCheckInitial**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.20</td>
<td>milliseconds</td>
<td>6000</td>
<td>70 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

  This is similar to the **TimeBetweenWatchDogCheck** parameter, except that **TimeBetweenWatchDogCheckInitial** controls the amount of time that passes between execution checks inside a database node in the early start phases during which memory is allocated.

  The default timeout is 6000 milliseconds (6 seconds).

  This parameter was added in MySQL 5.1.20.

- **StartPartialTimeout**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>milliseconds</td>
<td>30000</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

  This parameter specifies how long the Cluster waits for all data nodes to come up before the cluster initialization routine is invoked. This timeout is used to avoid a partial Cluster startup whenever possible.

  This parameter is overridden when performing an initial start or initial restart of the cluster.

  The default value is 30000 milliseconds (30 seconds). 0 disables the timeout, in which case the cluster may start only if all nodes are available.

- **StartPartitionedTimeout**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>milliseconds</td>
<td>60000</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>milliseconds</td>
<td>1949</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>
If the cluster is ready to start after waiting for `StartPartialTimeout` milliseconds but is still possibly in a partitioned state, the cluster waits until this timeout has also passed. If `StartPartitionedTimeout` is set to 0, the cluster waits indefinitely.

This parameter is overridden when performing an initial start or initial restart of the cluster.

The default timeout is 60000 milliseconds (60 seconds).

- **StartFailureTimeout**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>milliseconds</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

If a data node has not completed its startup sequence within the time specified by this parameter, the node startup fails. Setting this parameter to 0 (the default value) means that no data node timeout is applied.

For nonzero values, this parameter is measured in milliseconds. For data nodes containing extremely large amounts of data, this parameter should be increased. For example, in the case of a data node containing several gigabytes of data, a period as long as 10−15 minutes (that is, 600000 to 1000000 milliseconds) might be required to perform a node restart.

- **StartNoNodeGroupTimeout**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.0.24</td>
<td>milliseconds</td>
<td>15000</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

When a data node is configured with `Nodegroup = 65536`, is regarded as not being assigned to any node group. When that is done, the cluster waits `StartNoNodegroupTimeout` milliseconds, then treats such nodes as though they had been added to the list passed to the `--nowait-nodes` option, and starts. The default value is 15000 (that is, the management server waits 15 seconds). Setting this parameter equal to 0 means that the cluster waits indefinitely.

`StartNoNodegroupTimeout` must be the same for all data nodes in the cluster; for this reason, you should always set it in the `[ndbd default]` section of the `config.ini` file, rather than for individual data nodes.

This parameter was added in MySQL Cluster NDB 7.0.24 and MySQL Cluster NDB 7.1.13. See Section 17.5.13, “Adding MySQL Cluster Data Nodes Online”, for more information.

- **HeartbeatIntervalDbDb**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>milliseconds</td>
<td>15000</td>
<td>10 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
<tr>
<td>NDB 7.2.0</td>
<td>milliseconds</td>
<td>50000</td>
<td>10 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

One of the primary methods of discovering failed nodes is by the use of heartbeats. This parameter states how often heartbeat signals are sent and how often to expect to receive them. After missing three heartbeat intervals in a row, the node is declared dead. Thus, the maximum time for discovering a failure through the heartbeat mechanism is four times the heartbeat interval.

In MySQL Cluster NDB 7.2.0 and later, the default heartbeat interval is 5000 milliseconds (5 seconds). Previously, the default was 1500 milliseconds (1.5 seconds). This parameter must not be
changed drastically and should not vary widely between nodes. If one node uses 5000 milliseconds and the node watching it uses 1000 milliseconds, obviously the node will be declared dead very quickly. This parameter can be changed during an online software upgrade, but only in small increments.

See also Network communication and latency.

- **HeartbeatIntervalDbApi**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>milliseconds</td>
<td>1500</td>
<td>100 - 4,294,967,039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

Each data node sends heartbeat signals to each MySQL server (SQL node) to ensure that it remains in contact. If a MySQL server fails to send a heartbeat in time it is declared “dead,” in which case all ongoing transactions are completed and all resources released. The SQL node cannot reconnect until all activities initiated by the previous MySQL instance have been completed. The three-heartbeat criteria for this determination are the same as described for **HeartbeatIntervalDbDb**.

The default interval is 1500 milliseconds (1.5 seconds). This interval can vary between individual data nodes because each data node watches the MySQL servers connected to it, independently of all other data nodes.

For more information, see Network communication and latency.

- **HeartbeatOrder**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.3.35</td>
<td>numeric</td>
<td>0</td>
<td>0 - 65535</td>
<td>S</td>
</tr>
<tr>
<td>NDB 7.0.16</td>
<td>numeric</td>
<td>0</td>
<td>0 - 65535</td>
<td>S</td>
</tr>
<tr>
<td>NDB 7.1.5</td>
<td>numeric</td>
<td>0</td>
<td>0 - 65535</td>
<td>S</td>
</tr>
</tbody>
</table>

Data nodes send heartbeats to one another in a circular fashion whereby each data node monitors the previous one. If a heartbeat is not detected by a given data node, this node declares the previous data node in the circle “dead” (that is, no longer accessible by the cluster). The determination that a data node is dead is done globally; in other words; once a data node is declared dead, it is regarded as such by all nodes in the cluster.

It is possible for heartbeats between data nodes residing on different hosts to be too slow compared to heartbeats between other pairs of nodes (for example, due to a very low heartbeat interval or temporary connection problem), such that a data node is declared dead, even though the node can still function as part of the cluster.

In this type of situation, it may be that the order in which heartbeats are transmitted between data nodes makes a difference as to whether or not a particular data node is declared dead. If this declaration occurs unnecessarily, this can in turn lead to the unnecessary loss of a node group and as thus to a failure of the cluster.

Consider a setup where there are 4 data nodes A, B, C, and D running on 2 host computers **host1** and **host2**, and that these data nodes make up 2 node groups, as shown in the following table:

<table>
<thead>
<tr>
<th>Node Group</th>
<th>Nodes Running on <strong>host1</strong></th>
<th>Nodes Running on <strong>host2</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Node Group 0:</strong></td>
<td>Node A</td>
<td>Node B</td>
</tr>
<tr>
<td><strong>Node Group 1:</strong></td>
<td>Node C</td>
<td>Node D</td>
</tr>
</tbody>
</table>

Suppose the heartbeats are transmitted in order A->B->C->D->A. In this case, the loss of the heartbeat between the hosts causes node B to declare node A dead and node C to declare node B...
dead. This results in loss of Node Group 0, and so the cluster fails. On the other hand, if the order of transmission is A->B->D->C->A (and all other conditions remain as previously stated), the loss of the heartbeat causes nodes A and D to be declared dead; in this case, each node group has one surviving node, and the cluster survives.

Prior to MySQL Cluster NDB 6.3.35, MySQL Cluster NDB 7.0.16, and MySQL Cluster NDB 7.1.5, the order of heartbeat transmission between data nodes was always automatically determined by NDB. However, beginning with these versions, the HeartbeatOrder configuration parameter makes the order of heartbeat transmission user-configurable.

The default value for HeartbeatOrder is zero; allowing the default value to be used on all data nodes causes the order of heartbeat transmission to be determined by NDB. If this parameter is used, it must be set to a nonzero value (maximum 65535) for every data node in the cluster, and this value must be unique for each data node; this causes the heartbeat transmission to proceed from data node to data node in the order of their HeartbeatOrder values from lowest to highest (and then directly from the data node having the highest HeartbeatOrder to the data node having the lowest value, to complete the circle). The values need not be consecutive; for example, to force the heartbeat transmission order A->B->D->C->A in the scenario outlined previously, you could set the HeartbeatOrder values as shown here:

<table>
<thead>
<tr>
<th>Node</th>
<th>HeartbeatOrder</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>10</td>
</tr>
<tr>
<td>B</td>
<td>20</td>
</tr>
<tr>
<td>C</td>
<td>30</td>
</tr>
<tr>
<td>D</td>
<td>25</td>
</tr>
</tbody>
</table>

To use this parameter to change the heartbeat transmission order in a running MySQL Cluster, you must first set HeartbeatOrder for each data node in the cluster in the global configuration (config.ini) file (or files). To cause the change to take effect, you must perform either of the following:

- A complete shutdown and restart of the entire cluster.
- 2 rolling restarts of the cluster in succession. All nodes must be restarted in the same order in both rolling restarts.

You can use DUMP 908 to observe the effect of this parameter in the data node logs.

- ConnectCheckIntervalDelay

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.1.13</td>
<td>milliseconds</td>
<td>1500</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
<tr>
<td>NDB 7.2.1</td>
<td>milliseconds</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter enables connection checking between data nodes. A data node that fails to respond within an interval of ConnectCheckIntervalDelay milliseconds is considered suspect, and is considered dead after two such intervals.

- TimeBetweenLocalCheckpoints

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>number of 4-byte words, as a base-2 logarithm</td>
<td>20</td>
<td>0 - 31</td>
<td>N</td>
</tr>
</tbody>
</table>
This parameter is an exception in that it does not specify a time to wait before starting a new local checkpoint; rather, it is used to ensure that local checkpoints are not performed in a cluster where relatively few updates are taking place. In most clusters with high update rates, it is likely that a new local checkpoint is started immediately after the previous one has been completed.

The size of all write operations executed since the start of the previous local checkpoints is added. This parameter is also exceptional in that it is specified as the base-2 logarithm of the number of 4-byte words, so that the default value 20 means 4MB \((4 \times 2^{20})\) of write operations, 21 would mean 8MB, and so on up to a maximum value of 31, which equates to 8GB of write operations.

All the write operations in the cluster are added together. Setting \texttt{TimeBetweenLocalCheckpoints} to 6 or less means that local checkpoints will be executed continuously without pause, independent of the cluster’s workload.

- \textbf{TimeBetweenGlobalCheckpoints}

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>milliseconds</td>
<td>2000</td>
<td>10 - 32000</td>
<td>N</td>
</tr>
<tr>
<td>NDB 6.2.0</td>
<td>milliseconds</td>
<td>2000</td>
<td>20 - 32000</td>
<td>N</td>
</tr>
</tbody>
</table>

When a transaction is committed, it is committed in main memory in all nodes on which the data is mirrored. However, transaction log records are not flushed to disk as part of the commit. The reasoning behind this behavior is that having the transaction safely committed on at least two autonomous host machines should meet reasonable standards for durability.

It is also important to ensure that even the worst of cases—a complete crash of the cluster—is handled properly. To guarantee that this happens, all transactions taking place within a given interval are put into a global checkpoint, which can be thought of as a set of committed transactions that has been flushed to disk. In other words, as part of the commit process, a transaction is placed in a global checkpoint group. Later, this group’s log records are flushed to disk, and then the entire group of transactions is safely committed to disk on all computers in the cluster.

This parameter defines the interval between global checkpoints. The default is 2000 milliseconds.

- \textbf{TimeBetweenEpochs}

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.2.5</td>
<td>milliseconds</td>
<td>100</td>
<td>0 - 32000</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter defines the interval between synchronization epochs for MySQL Cluster Replication. The default value is 100 milliseconds.

\texttt{TimeBetweenEpochs} is part of the implementation of “micro-GCPs”, which can be used to improve the performance of MySQL Cluster Replication. This parameter was introduced in MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.2.

- \textbf{TimeBetweenEpochsTimeout}

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.22</td>
<td>milliseconds</td>
<td>4000</td>
<td>0 - 32000</td>
<td>N</td>
</tr>
<tr>
<td>MySQL 5.1.51</td>
<td>milliseconds</td>
<td>0</td>
<td>0 - 256000</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter defines a timeout for synchronization epochs for MySQL Cluster Replication. If a node fails to participate in a global checkpoint within the time determined by this parameter, the node is shut down. In MySQL Cluster NDB 7.2.0 and later, the default value is 0; in other words, the timeout is disabled. This represents a change from previous versions of MySQL Cluster, in which the default value was 4000 milliseconds (4 seconds).
**TimeBetweenEpochsTimeout** is part of the implementation of “micro-GCPs”, which can be used to improve the performance of MySQL Cluster Replication. This parameter was introduced in MySQL Cluster NDB 6.2.7 and MySQL Cluster NDB 6.3.4.

The following changes regarding this parameter were made in MySQL Cluster NDB 7.0.21 and MySQL Cluster NDB 7.1.10:

- The maximum possible value for this parameter was increased from 32000 milliseconds to 256000 milliseconds.
- Setting this parameter to zero now has the effect of disabling GCP stops caused by save timeouts, commit timeouts, or both.
- The current value of this parameter and a warning are now written to the cluster log whenever a GCP save takes longer than 1 minute or a GCP save takes longer than 10 seconds.

*MaxBufferedEpochs*

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.2.14</td>
<td>epochs</td>
<td>100</td>
<td>0 - 100000</td>
<td>N</td>
</tr>
</tbody>
</table>

The number of unprocessed epochs by which a subscribing node can lag behind. Exceeding this number causes a lagging subscriber to be disconnected.

The default value of 100 is sufficient for most normal operations. If a subscribing node does lag enough to cause disconnections, it is usually due to network or scheduling issues with regard to processes or threads. (In rare circumstances, the problem may be due to a bug in the NDB client.) It may be desirable to set the value lower than the default when epochs are longer.

Disconnection prevents client issues from affecting the data node service, running out of memory to buffer data, and eventually shutting down. Instead, only the client is affected as a result of the disconnect (by, for example gap events in the binary log), forcing the client to reconnect or restart the process.

*MaxBufferedEpochBytes*

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.3.52</td>
<td>bytes</td>
<td>26214400</td>
<td>26214400 - 4294967039</td>
<td>N</td>
</tr>
</tbody>
</table>

The total number of bytes allocated for buffering epochs by this node.

This parameter was introduced in MySQL Cluster NDB 6.3.52, MySQL Cluster NDB 7.0.38, and MySQL Cluster NDB 7.1.27. (Bug #16203623)

*TimeBetweenInactiveTransactionAbortCheck*
Type handling is performed by checking a timer on each transaction once for every interval specified by this parameter. Thus, if this parameter is set to 1000 milliseconds, every transaction will be checked for timing out once per second.

The default value is 1000 milliseconds (1 second).

- **TransactionInactiveTimeout**

This parameter states the maximum time that is permitted to lapse between operations in the same transaction before the transaction is aborted.

The default for this parameter is 4G (also the maximum). For a real-time database that needs to ensure that no transaction keeps locks for too long, this parameter should be set to a relatively small value. The unit is milliseconds.

- **TransactionDeadlockDetectionTimeout**

When a node executes a query involving a transaction, the node waits for the other nodes in the cluster to respond before continuing. A failure to respond can occur for any of the following reasons:

  - The node is “dead”
  - The operation has entered a lock queue
  - The node requested to perform the action could be heavily overloaded.

This timeout parameter states how long the transaction coordinator waits for query execution by another node before aborting the transaction, and is important for both node failure handling and deadlock detection. In MySQL 5.1.10 and earlier versions, setting it too high could cause undesirable behavior in situations involving deadlocks and node failure. Beginning with MySQL 5.1.11, active transactions occurring during node failures are actively aborted by the MySQL Cluster Transaction Coordinator, and so high settings are no longer an issue with this parameter.

The default timeout value is 1200 milliseconds (1.2 seconds).

Prior to MySQL Cluster NDB versions 6.2.18, 6.3.24, and 7.0.5, the effective minimum for this parameter was 100 milliseconds. (Bug #44099) Beginning with these versions, the actual minimum is 50 milliseconds.

- **DiskSyncSize**
This is the maximum number of bytes to store before flushing data to a local checkpoint file. This is done to prevent write buffering, which can impede performance significantly. This parameter is not intended to take the place of `TimeBetweenLocalCheckpoints`.

**Note**

When `ODirect` is enabled, it is not necessary to set `DiskSyncSize`; in fact, in such cases its value is simply ignored.

The default value is 4M (4 megabytes).

This parameter was added in MySQL 5.1.12.

- **DiskCheckpointSpeed**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.12</td>
<td>bytes</td>
<td>10M</td>
<td>1M - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

The amount of data, in bytes per second, that is sent to disk during a local checkpoint. This allocation is shared by DML operations and backups (but not backup logging), which means that backups started during times of intensive DML may be impaired by flooding of the redo log buffer and may fail altogether if the contention is sufficiently severe.

The default value is 10M (10 megabytes per second).

This parameter was added in MySQL 5.1.12.

- **DiskCheckpointSpeedInRestart**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.12</td>
<td>bytes</td>
<td>100M</td>
<td>1M - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

The amount of data, in bytes per second, that is sent to disk during a local checkpoint as part of a restart operation.

The default value is 100M (100 megabytes per second).

This parameter was added in MySQL 5.1.12.

- **NoOfDiskPagesToDiskAfterRestartTUP**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>8K pages/100 milliseconds</td>
<td>40</td>
<td>1 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

When executing a local checkpoint, the algorithm flushes all data pages to disk. Merely doing so as quickly as possible without any moderation is likely to impose excessive loads on processors, networks, and disks. To control the write speed, this parameter specifies how many pages per 100 milliseconds are to be written. In this context, a “page” is defined as 8KB. This parameter is specified in units of 80KB per second, so setting `NoOfDiskPagesToDiskAfterRestartTUP` to a value of 20 entails writing 1.6MB in data pages to disk each second during a local checkpoint. This value includes the writing of UNDO log records for data pages. That is, this parameter handles the limitation of writes from data memory. (See the entry for `IndexMemory` for information about index pages.)
In short, this parameter specifies how quickly to execute local checkpoints. It operates in conjunction with `NoOfFragmentLogFiles`, `DataMemory`, and `IndexMemory`.

For more information about the interaction between these parameters and possible strategies for choosing appropriate values for them, see Section 17.3.3.13, "Configuring MySQL Cluster Parameters for Local Checkpoints".

The default value is 40 (3.2MB of data pages per second).

**Note**

This parameter is deprecated as of MySQL 5.1.6. For MySQL 5.1.12 and later versions, use `DiskCheckpointSpeed` and `DiskSyncSize` instead.

* `NoOfDiskPagesToDiskAfterRestartACC`

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>8K pages/100 milliseconds</td>
<td>20</td>
<td>1 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter uses the same units as `NoOfDiskPagesToDiskAfterRestartTUP` and acts in a similar fashion, but limits the speed of writing index pages from index memory.

The default value of this parameter is 20 (1.6MB of index memory pages per second).

**Note**

This parameter is deprecated as of MySQL 5.1.6. For MySQL 5.1.12 and later versions, use `DiskCheckpointSpeed` and `DiskSyncSize`.

* `NoOfDiskPagesToDiskDuringRestartTUP` (DEPRECATED)

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>8K pages/100 milliseconds</td>
<td>40</td>
<td>1 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is used in a fashion similar to `NoOfDiskPagesToDiskAfterRestartTUP` and `NoOfDiskPagesToDiskAfterRestartACC`, only it does so with regard to local checkpoints executed in the node when a node is restarting. A local checkpoint is always performed as part of all node restarts. During a node restart it is possible to write to disk at a higher speed than at other times, because fewer activities are being performed in the node.

This parameter covers pages written from data memory.

The default value is 40 (3.2MB per second).

**Note**

This parameter is deprecated as of MySQL 5.1.6. For MySQL 5.1.12 and later versions, use `DiskCheckpointSpeedInRestart` and `DiskSyncSize`.

* `NoOfDiskPagesToDiskDuringRestartACC` (DEPRECATED)

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>8K pages/100 milliseconds</td>
<td>20</td>
<td>1 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>
Controls the number of index memory pages that can be written to disk during the local checkpoint phase of a node restart.

As with `NoOfDiskPagesToDiskAfterRestartTUP` and `NoOfDiskPagesToDiskAfterRestartACC`, values for this parameter are expressed in terms of 8KB pages written per 100 milliseconds (80KB/second).

The default value is 20 (1.6MB per second).

Note
This parameter is deprecated as of MySQL 5.1.6. For MySQL 5.1.12 and later versions, use `DiskCheckpointSpeedInRestart` and `DiskSyncSize`.

- **ArbitrationTimeout**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>milliseconds</td>
<td>3000</td>
<td>10 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
<tr>
<td>NDB 7.2.0</td>
<td>milliseconds</td>
<td>7500</td>
<td>10 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies how long data nodes wait for a response from the arbitrator to an arbitration message. If this is exceeded, the network is assumed to have split.

In MySQL Cluster NDB 7.2.0 and later, the default value is 7500 milliseconds (7.5 seconds). Previously, this was 3000 milliseconds (3 seconds).

- **Arbitration**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.0.7</td>
<td>enumeration</td>
<td>Default</td>
<td>Default, Disabled, WaitExternal</td>
<td>N</td>
</tr>
</tbody>
</table>

The Arbitration parameter, added in MySQL Cluster NDB 7.0.7, enables a choice of arbitration schemes, corresponding to one of 3 possible values for this parameter:

- **Default.** This enables arbitration to proceed normally, as determined by the ArbitrationRank settings for the management and API nodes. This is the default value.

- **Disabled.** Previously, it was possible to disable arbitration only by setting ArbitrationRank to 0 on all management and API nodes. Now, you can now use Arbitration = Disabled in the [ndbd default] section of the config.ini file to accomplish this task. In this case, any ArbitrationRank settings are ignored.

- **WaitExternal.** The Arbitration parameter also makes it possible to configure arbitration in such a way that the cluster waits until after the time determined by ArbitrationTimeout has passed for an external cluster manager application to perform arbitration instead of handling arbitration internally. This can be done by setting Arbitration = WaitExternal in the [ndbd default] section of the config.ini file. For best results with the WaitExternal setting, it is recommended that ArbitrationTimeout be 2 times as long as the interval required by the external cluster manager to perform arbitration.

Important
This parameter should be used only in the [ndbd default] section of the cluster configuration file. The behavior of the cluster is unspecified when Arbitration is set to different values for individual data nodes.
Buffering and logging. Several [ndbd] configuration parameters enable the advanced user to have more control over the resources used by node processes and to adjust various buffer sizes at need.

These buffers are used as front ends to the file system when writing log records to disk. If the node is running in diskless mode, these parameters can be set to their minimum values without penalty due to the fact that disk writes are “faked” by the NDB storage engine's file system abstraction layer.

* UndoIndexBuffer

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>unsigned</td>
<td>2M</td>
<td>1M - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

The UNDO index buffer, whose size is set by this parameter, is used during local checkpoints. The NDB storage engine uses a recovery scheme based on checkpoint consistency in conjunction with an operational REDO log. To produce a consistent checkpoint without blocking the entire system for writes, UNDO logging is done while performing the local checkpoint. UNDO logging is activated on a single table fragment at a time. This optimization is possible because tables are stored entirely in main memory.

The UNDO index buffer is used for the updates on the primary key hash index. Inserts and deletes rearrange the hash index; the NDB storage engine writes UNDO log records that map all physical changes to an index page so that they can be undone at system restart. It also logs all active insert operations for each fragment at the start of a local checkpoint.

Reads and updates set lock bits and update a header in the hash index entry. These changes are handled by the page-writing algorithm to ensure that these operations need no UNDO logging.

This buffer is 2MB by default. The minimum value is 1MB, which is sufficient for most applications. For applications doing extremely large or numerous inserts and deletes together with large transactions and large primary keys, it may be necessary to increase the size of this buffer. If this buffer is too small, the NDB storage engine issues internal error code 677 (Index UNDO buffers overloaded).

**Important**

It is not safe to decrease the value of this parameter during a rolling restart.

* UndoDataBuffer

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>unsigned</td>
<td>16M</td>
<td>1M - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter sets the size of the UNDO data buffer, which performs a function similar to that of the UNDO index buffer, except the UNDO data buffer is used with regard to data memory rather than index memory. This buffer is used during the local checkpoint phase of a fragment for inserts, deletes, and updates.

Because UNDO log entries tend to grow larger as more operations are logged, this buffer is also larger than its index memory counterpart, with a default value of 16MB.

This amount of memory may be unnecessarily large for some applications. In such cases, it is possible to decrease this size to a minimum of 1MB.

It is rarely necessary to increase the size of this buffer. If there is such a need, it is a good idea to check whether the disks can actually handle the load caused by database update activity. A lack of sufficient disk space cannot be overcome by increasing the size of this buffer.
If this buffer is too small and gets congested, the NDB storage engine issues internal error code 891 (Data UNDO buffers overloaded).

Important
It is not safe to decrease the value of this parameter during a rolling restart.

- **RedoBuffer**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>bytes</td>
<td>8M</td>
<td>1M - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
<tr>
<td>NDB 7.0.4</td>
<td>bytes</td>
<td>32M</td>
<td>1M - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

All update activities also need to be logged. The REDO log makes it possible to replay these updates whenever the system is restarted. The NDB recovery algorithm uses a “fuzzy” checkpoint of the data together with the UNDO log, and then applies the REDO log to play back all changes up to the restoration point.

**RedoBuffer** sets the size of the buffer in which the REDO log is written. In MySQL Cluster NDB 6.4.3 and earlier, the default value is 8MB; beginning with MySQL Cluster NDB 7.0.4, the default is 32MB. The minimum value is 1MB.

If this buffer is too small, the NDB storage engine issues error code 1221 (REDO log buffers overloaded). For this reason, you should exercise care if you attempt to decrease the value of **RedoBuffer** as part of an online change in the cluster's configuration.

**ndbmtd** allocates a separate buffer for each LDM thread (see **ThreadConfig**). For example, with 4 LDM threads, an ndbmtd data node actually has 4 buffers and allocates **RedoBuffer** bytes to each one, for a total of 4 * **RedoBuffer** bytes.

- **EventLogBufferSize**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.0.4</td>
<td>bytes</td>
<td>8192</td>
<td>0 - 64K</td>
<td>S</td>
</tr>
</tbody>
</table>

Controls the size of the circular buffer used for NDB log events within data nodes.

Added in MySQL Cluster NDB 7.0.4.

**Controlling log messages.** In managing the cluster, it is very important to be able to control the number of log messages sent for various event types to stdout. For each event category, there are 16 possible event levels (numbered 0 through 15). Setting event reporting for a given event category to level 15 means all event reports in that category are sent to stdout; setting it to 0 means that there will be no event reports made in that category.

By default, only the startup message is sent to stdout, with the remaining event reporting level defaults being set to 0. The reason for this is that these messages are also sent to the management server’s cluster log.

An analogous set of levels can be set for the management client to determine which event levels to record in the cluster log.

- **LogLevelStartup**
The reporting level for events generated during startup of the process.

The default level is 1.

- **LogLevelShutdown**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>integer</td>
<td>0</td>
<td>0 - 15</td>
<td>N</td>
</tr>
</tbody>
</table>

The reporting level for events generated as part of graceful shutdown of a node.

The default level is 0.

- **LogLevelStatistic**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>integer</td>
<td>0</td>
<td>0 - 15</td>
<td>N</td>
</tr>
</tbody>
</table>

The reporting level for statistical events such as number of primary key reads, number of updates, number of inserts, information relating to buffer usage, and so on.

The default level is 0.

- **LogLevelCheckpoint**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>log level</td>
<td>0</td>
<td>0 - 15</td>
<td>N</td>
</tr>
</tbody>
</table>

The reporting level for events generated by local and global checkpoints.

The default level is 0.

- **LogLevelNodeRestart**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>integer</td>
<td>0</td>
<td>0 - 15</td>
<td>N</td>
</tr>
</tbody>
</table>

The reporting level for events generated during node restart.

The default level is 0.

- **LogLevelConnection**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>integer</td>
<td>0</td>
<td>0 - 15</td>
<td>N</td>
</tr>
</tbody>
</table>

The reporting level for events generated by connections between cluster nodes.

The default level is 0.

- **LogLevelError**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>integer</td>
<td>0</td>
<td>0 - 15</td>
<td>N</td>
</tr>
</tbody>
</table>
The reporting level for events generated by errors and warnings by the cluster as a whole. These errors do not cause any node failure but are still considered worth reporting.

The default level is 0.

- **LogLevelCongestion**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>levelr</td>
<td>0</td>
<td>0 - 15</td>
<td>N</td>
</tr>
</tbody>
</table>

The reporting level for events generated by congestion. These errors do not cause node failure but are still considered worth reporting.

The default level is 0.

- **LogLevelInfo**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>integer</td>
<td>0</td>
<td>0 - 15</td>
<td>N</td>
</tr>
</tbody>
</table>

The reporting level for events generated for information about the general state of the cluster.

The default level is 0.

- **MemReportFrequency**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.1.0</td>
<td>unsigned</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
<tr>
<td>MySQL 5.1.16</td>
<td>unsigned</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter controls how often data node memory usage reports are recorded in the cluster log; it is an integer value representing the number of seconds between reports.

Each data node's data memory and index memory usage is logged as both a percentage and a number of 32 KB pages of the `DataMemory` and `IndexMemory`, respectively, set in the `config.ini` file. For example, if `DataMemory` is equal to 100 MB, and a given data node is using 50 MB for data memory storage, the corresponding line in the cluster log might look like this:

```
2006-12-24 01:18:16 [MgmSrvr] INFO -- Node 2: Data usage is 50%(1280 32K pages of total 2560)
```

`MemReportFrequency` is not a required parameter. If used, it can be set for all cluster data nodes in the `[ndbd default]` section of `config.ini`, and can also be set or overridden for individual data nodes in the corresponding `[ndbd]` sections of the configuration file. The minimum value—which is also the default value—is 0, in which case memory reports are logged only when memory usage reaches certain percentages (80%, 90%, and 100%), as mentioned in the discussion of statistics events in Section 17.5.6.2, “MySQL Cluster Log Events”.

This parameter was added in MySQL Cluster 5.1.16 and MySQL Cluster NDB 6.1.0.

- **StartupStatusReportFrequency**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.4.0</td>
<td>seconds</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>
When a data node is started with the `--initial`, it initializes the redo log file during Start Phase 4 (see Section 17.5.1, “Summary of MySQL Cluster Start Phases”). When very large values are set for `NoOfFragmentLogFiles`, `FragmentLogFileSize`, or both, this initialization can take a long time. Previous to MySQL Cluster NDB 6.4.0, only the beginning and end of the redo log file initialization process were logged. Beginning with this version, it is possible to force reports on the progress of this process to be logged periodically, by means of the `StartupStatusReportFrequency` configuration parameter. In this case, progress is reported in the cluster log, in terms of both the number of files and the amount of space that have been initialized, as shown here:

```
#Total files: 80, Completed: 60
#Total MBytes: 20480, Completed: 15557
#Total files: 80, Completed: 60
#Total MBytes: 20480, Completed: 15570
```

These reports are logged each `StartupStatusReportFrequency` seconds during Start Phase 4. If `StartupStatusReportFrequency` is 0 (the default), then reports are written to the cluster log only when at the beginning and at the completion of the redo log file initialization process.

**Debugging Parameters.** Beginning with MySQL Cluster NDB 6.3.36, MySQL Cluster NDB 7.0.17, and MySQL Cluster NDB 7.1.6, it is possible to cause logging of traces for events generated by creating and dropping tables using `DictTrace`. This parameter is useful only in debugging NDB kernel code. `DictTrace` takes an integer value; currently, 0 (default - no logging) and 1 (logging enabled) are the only supported values.

**Backup parameters.** The [ndbd] parameters discussed in this section define memory buffers set aside for execution of online backups.

- **BackupDataBufferSize**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>bytes</td>
<td>2M</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
<tr>
<td>NDB 6.3.23</td>
<td>bytes</td>
<td>16M</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
<tr>
<td>NDB 7.0.4</td>
<td>bytes</td>
<td>16M</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
<tr>
<td>NDB 7.5.1</td>
<td>bytes</td>
<td>16M</td>
<td>512K - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

In creating a backup, there are two buffers used for sending data to the disk. The backup data buffer is used to fill in data recorded by scanning a node’s tables. Once this buffer has been filled to the level specified as `BackupWriteSize`, the pages are sent to disk. While flushing data to disk, the backup process can continue filling this buffer until it runs out of space. When this happens, the backup process pauses the scan and waits until some disk writes have completed freeing up memory so that scanning may continue.

In MySQL Cluster NDB 6.4.3 and earlier, the default value is 2MB; in MySQL Cluster NDB 7.0.4 and later, it is 16MB.

- **BackupLogBufferSize**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>bytes</td>
<td>2M</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>
The backup log buffer fulfills a role similar to that played by the backup data buffer, except that it is used for generating a log of all table writes made during execution of the backup. The same principles apply for writing these pages as with the backup data buffer, except that when there is no more space in the backup log buffer, the backup fails. For that reason, the size of the backup log buffer must be large enough to handle the load caused by write activities while the backup is being made. See Section 17.5.3.3, “Configuration for MySQL Cluster Backups”.

The default value for this parameter should be sufficient for most applications. In fact, it is more likely for a backup failure to be caused by insufficient disk write speed than it is for the backup log buffer to become full. If the disk subsystem is not configured for the write load caused by applications, the cluster is unlikely to be able to perform the desired operations.

It is preferable to configure cluster nodes in such a manner that the processor becomes the bottleneck rather than the disks or the network connections.

In MySQL Cluster NDB 6.4.3 and earlier, the default value is 2MB; in MySQL Cluster NDB 7.0.4 and later, it is 16MB.

• **BackupMemory**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>bytes</td>
<td>4M</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
<tr>
<td>NDB 7.0.4</td>
<td>bytes</td>
<td>32M</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is simply the sum of **BackupDataBufferSize** and **BackupLogBufferSize**.

In MySQL Cluster NDB 7.0.4 and later, the default value is 16MB + 16MB = 32MB. (Previously, it was 2MB + 2MB = 4MB.)

---

**Important**

If **BackupDataBufferSize** and **BackupLogBufferSize** taken together exceed the default value for **BackupMemory**, then this parameter must be set explicitly in the **config.ini** file to their sum.

• **BackupReportFrequency**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.2.3</td>
<td>seconds</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter controls how often backup status reports are issued in the management client during a backup, as well as how often such reports are written to the cluster log (provided cluster event logging is configured to permit it—see **Logging and checkpointing**). **BackupReportFrequency** represents the time in seconds between backup status reports.

The default value is 0.
MySQL Cluster Configuration Files

- **BackupWriteSize**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>bytes</td>
<td>32K</td>
<td>2K - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
<tr>
<td>NDB 7.0.4</td>
<td>bytes</td>
<td>256K</td>
<td>2K - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies the default size of messages written to disk by the backup log and backup data buffers.

In MySQL Cluster 6.4.3 and earlier, the default value for this parameter was 32KB; beginning with MySQL Cluster NDB 7.0.4, it is 256KB.

- **BackupMaxWriteSize**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>bytes</td>
<td>256K</td>
<td>2K - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
<tr>
<td>MySQL 5.1.32</td>
<td>bytes</td>
<td>1M</td>
<td>2K - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
<tr>
<td>NDB 7.2.1</td>
<td>bytes</td>
<td>1M</td>
<td>2K - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies the maximum size of messages written to disk by the backup log and backup data buffers.

In MySQL Cluster 6.4.3 and earlier, the default value for this parameter was 256KB; beginning with MySQL Cluster NDB 7.0.4, it is 1MB.

**Important**

When specifying these parameters, the following relationships must hold true. Otherwise, the data node will be unable to start.

- BackupDataBufferSize >= BackupWriteSize + 188KB
- BackupLogBufferSize >= BackupWriteSize + 16KB
- BackupMaxWriteSize >= BackupWriteSize

**MySQL Cluster Realtime Performance Parameters**

The [ndbd] parameters discussed in this section are used in scheduling and locking of threads to specific CPUs on multiprocessor data node hosts. They were introduced in MySQL Cluster NDB 6.3.4.

**Note**

To make use of these parameters, the data node process must be run as system root.

- **LockExecuteThreadToCPU**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.3.4</td>
<td>CPU ID</td>
<td>64K</td>
<td>0 - 64K</td>
<td>N</td>
</tr>
</tbody>
</table>

**Previous to MySQL Cluster NDB 7.0.** This parameter specifies the ID of the CPU assigned to handle the NDBCLUSTER execution thread. The value of this parameter is an integer in the range 0 to 65535 (inclusive). The default is 65535.
MySQL Cluster NDB 7.0 and later (beginning with MySQL Cluster NDB 6.4.0). When used with `ndbd`, this parameter (now a string) specifies the ID of the CPU assigned to handle the `NDBCLUSTER` execution thread.

When used with `ndbmtd`, the value of this parameter is a comma-separated list of CPU IDs assigned to handle execution threads. Each CPU ID in the list should be an integer in the range 0 to 65535 (inclusive). The number of IDs specified should match the number of execution threads determined by `MaxNoOfExecutionThreads`. However, there is no guarantee that threads are assigned to CPUs in any given order when using this parameter; beginning with in MySQL Cluster NDB 7.0.31 and MySQL Cluster NDB 7.1.20, you can obtain more finely-grained control of this type using `ThreadConfig`.

`LockExecuteThreadToCPU` has no default value.

Prior to MySQL Cluster NDB 7.0.18 and MySQL Cluster NDB 7.1.7, the effective maximum value recognized by this parameter as a valid CPU ID was 255; using a greater value caused thread locking to be disabled. (Bug #56185)

- **LockMaintThreadsToCPU**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.3.4</td>
<td>CPU ID</td>
<td>64K</td>
<td>0 - 64K</td>
<td>N</td>
</tr>
<tr>
<td>NDB 6.4.0</td>
<td>CPU ID</td>
<td>[none]</td>
<td>0 - 64K</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies the ID of the CPU assigned to handle `NDBCLUSTER` maintenance threads.

The value of this parameter is an integer in the range 0 to 65535 (inclusive). This parameter was added in MySQL Cluster NDB 6.3.4. Prior to MySQL Cluster NDB 6.4.0, the default is 65535; in MySQL Cluster NDB 7.0 and later MySQL Cluster release series, there is no default value.

- **RealtimeScheduler**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.3.4</td>
<td>boolean</td>
<td>false</td>
<td>true, false</td>
<td>N</td>
</tr>
</tbody>
</table>

Setting this parameter to 1 enables real-time scheduling of data node threads.

Prior to MySQL Cluster NDB 7.0.40 and MySQL Cluster NDB 7.1.29, this parameter did not work correctly with data nodes running `ndbmtd`. (Bug #16961971)

The default is 0 (scheduling disabled).

- **SchedulerExecutionTimer**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.3.4</td>
<td>µs</td>
<td>50</td>
<td>0 - 11000</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies the time in microseconds for threads to be executed in the scheduler before being sent. Setting it to 0 minimizes the response time; to achieve higher throughput, you can increase the value at the expense of longer response times.

The default is 50 µsec, which our testing shows to increase throughput slightly in high-load cases without materially delaying requests.

This parameter was added in MySQL Cluster NDB 6.3.4.

- **SchedulerSpinTimer**
MySQL Cluster Configuration Files

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.3.4</td>
<td>µs</td>
<td>0</td>
<td>0 - 500</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies the time in microseconds for threads to be executed in the scheduler before sleeping.

The default value is 0.

• **BuildIndexThreads**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.3.30</td>
<td>numeric</td>
<td>0</td>
<td>0 - 128</td>
<td>S</td>
</tr>
<tr>
<td>NDB 7.0.11</td>
<td>numeric</td>
<td>0</td>
<td>0 - 128</td>
<td>S</td>
</tr>
</tbody>
</table>

This parameter determines the number of threads to create when rebuilding ordered indexes during a system or node start, as well as when running `ndb_restore --rebuild-indexes`. It is supported only when there is more than one fragment for the table per data node (for example, when the `MAX_ROWS` option has been used with `CREATE TABLE`).

Setting this parameter to 0 (the default) disables multi-threaded building of ordered indexes.

This parameter was added in MySQL Cluster NDB 6.3.30 and MySQL Cluster NDB 7.0.11. Prior to MySQL Cluster NDB 7.0.16 and MySQL Cluster NDB 7.1.5, it was supported only when using `ndbd`; in these and later MySQL Cluster releases, `BuildIndexThreads` is also supported for data nodes running `ndbmtd` (see Bug #54521).

You can enable multi-threaded builds during data node initial restarts by setting the `TwoPassInitialNodeRestartCopy` data node configuration parameter to `TRUE`.

• **TwoPassInitialNodeRestartCopy**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.1.11</td>
<td>boolean</td>
<td>false</td>
<td>true, false</td>
<td>N</td>
</tr>
</tbody>
</table>

In MySQL Cluster NDB 7.1.11 and later, multi-threaded building of ordered indexes can be enabled for initial restarts of data nodes by setting this configuration parameter to `TRUE`, which enables two-pass copying of data during initial node restarts.

You must also set `BuildIndexThreads` to a nonzero value.

• **Numa**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.0.20</td>
<td>boolean</td>
<td>1</td>
<td>...</td>
<td>N</td>
</tr>
<tr>
<td>NDB 7.1.9</td>
<td>boolean</td>
<td>1</td>
<td>...</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter determines whether Non-Uniform Memory Access (NUMA) is controlled by the operating or by the data node process, whether the data node uses `ndbd` or `ndbmtd`. By default, NDB attempts to use an interleaved NUMA memory allocation policy on any data node where the host operating system provides NUMA support.

Setting `Numa = 0` means that the datanode process does not itself attempt to set a policy for memory allocation, and permits this behavior to be determined by the operating system, which may be further guided by the separate `numactl` tool. That is, `Numa = 0` yields the system default behavior, which can be customised by `numactl`. For many Linux systems, the system default behavior is to allocate socket-local memory to any given process at allocation time. This can be
problematic when using ndbmtd; this is because ndbmtd allocates all memory at startup, leading to an imbalance, giving different access speeds for different sockets, especially when locking pages in main memory.

Setting Numa = 1 means that the data node process uses libnuma to request interleaved memory allocation. (This can also be accomplished manually, on the operating system level, using numactl.) Using interleaved allocation in effect tells the data node process to ignore non-uniform memory access but does not attempt to take any advantage of fast local memory; instead, the data node process tries to avoid imbalances due to slow remote memory. If interleaved allocation is not desired, set Numa to 0 so that the desired behavior can be determined on the operating system level.

The Numa configuration parameter is supported only on Linux systems where lib numa.so is available.

Multi-Threading Configuration Parameters (ndbmtd). ndbmtd runs by default as a single-threaded process and must be configured to use multiple threads, using either of two methods, both of which require setting configuration parameters in the config.ini file. The first method is simply to set an appropriate value for the MaxNoOfExecutionThreads configuration parameter. In MySQL Cluster NDB 7.1.17 and later, a second method is also supported, whereby it is possible to set up more complex rules for ndbmtd multi-threading using ThreadConfig. The next few paragraphs provide information about these parameters and their use with multi-threaded data nodes.

- MaxNoOfExecutionThreads

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.4.0</td>
<td>integer</td>
<td>[none]</td>
<td>2 - 8</td>
<td>IS</td>
</tr>
<tr>
<td>NDB 7.0.4</td>
<td>integer</td>
<td>2</td>
<td>2 - 8</td>
<td>IS</td>
</tr>
</tbody>
</table>

This parameter controls the number of execution threads used by ndbmtd, up to a maximum of 8 threads, 4 of which can be LDM (LQH) threads. Although this parameter is set in the [ndbd] or [ndbd default] sections of the config.ini file, it is exclusive to ndbmtd and does not apply to ndbd.

Setting MaxNoOfExecutionThreads sets the number of threads by type as determined in the following table:

<table>
<thead>
<tr>
<th>MaxNoOfExecutionThreads Value</th>
<th>LDM Threads</th>
<th>TC Threads</th>
<th>Send Threads</th>
<th>Receive Threads</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 .. 3</td>
<td>1</td>
<td>1</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>4 .. 6</td>
<td>2</td>
<td>1</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>7 .. 8</td>
<td>4</td>
<td>1</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>

There is always one SUMA (replication) thread.

The thread types are described later in this section (see ThreadConfig).

Setting this parameter outside the permitted range of values causes the management server to abort on startup with the error Error line number: Illegal value value for parameter MaxNoOfExecutionThreads.

For MaxNoOfExecutionThreads, a value of 0 or 1 is rounded up internally by NDB to 2, so that 2 is considered this parameter’s default and minimum value.

MaxNoOfExecutionThreads is generally intended to be set equal to the number of CPU threads available, and to allocate a number of threads of each type suitable to typical workloads. It does not assign particular threads to specified CPUs. For cases where it is desirable to vary from the settings provided, or to bind threads to CPUs, you should use ThreadConfig instead, which allows you to allocate each thread directly to a desired type, CPU, or both.
The multi-threaded data node process always spawns at least 4 threads, listed here:

- 1 local query handler (LDM) thread
- 1 transaction coordinator (TC) thread
- 1 receive thread
- 1 subscription manager (SUMA or replication) thread

Changing the number of LDM threads always requires a system restart, whether it is changed using this parameter or \texttt{ThreadConfig}. If the cluster's \texttt{IndexMemory} usage is greater than 50%, changing this requires an initial restart of the cluster. (A maximum of 30-35\% \texttt{IndexMemory} usage is recommended in such cases.) Otherwise, resource usage and LDM thread allocation cannot be balanced between nodes, which can result in underutilized and overutilized LDM threads, and ultimately data node failures.

In MySQL Cluster NDB 7.1 and earlier, it is not possible to cause \texttt{ndbmtd} to use more than 1 TC thread. (This is possible in MySQL Cluster NDB 7.2.)

- \texttt{ThreadConfig}

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.1.17</td>
<td>string</td>
<td>&quot;</td>
<td>...</td>
<td>IS</td>
</tr>
<tr>
<td>NDB 7.2.3</td>
<td>string</td>
<td>&quot;</td>
<td>...</td>
<td>IS</td>
</tr>
</tbody>
</table>

This parameter is used with \texttt{ndbmtd} to assign threads of different types to different CPUs. Its value is a string whose format has the following syntax:

\begin{verbatim}
ThreadConfig := entry[, entry[, ...]]
entry := type=[param[, param[, ...]]]
type := ldm | main | recv | rep | io | tc | watchdog
param := count=number
         | cpubind=cpu_list
         | cpuset=cpu_list
         | spintime=number
         | realtime={0|1}
\end{verbatim}

The curly braces (\{\ldots\}) surrounding the list of parameters are required, even if there is only one parameter in the list.

A \texttt{param} (parameter) specifies any or all of the following information:

- The number of threads of the given type (\texttt{count}).

- The set of CPUs to which the threads of the given type are to be nonexclusively bound. This is determined by either one of \texttt{cpubind} or \texttt{cpuset}. \texttt{cpubind} causes each thread to be bound (nonexclusively) to a CPU in the set; \texttt{cpuset} means that each thread is bound (nonexclusively) to the set of CPUs specified.

Only one of \texttt{cpubind} or \texttt{cpuset} can be provided in a single configuration.

- \texttt{spintime} determines the wait time in microseconds the thread spins before going to sleep.

The default value for \texttt{spintime} is the value of the \texttt{SchedulerSpinTimer} data node configuration parameter.
spintime does not apply to I/O threads or watchdog threads and so cannot be set for these thread types.

- realtime can be set to 0 or 1. If it is set to 1, the threads run with real-time priority. This also means that thread_prio cannot be set.

The realtime parameter is set by default to the value of the RealtimeScheduler data node configuration parameter.

The type attribute represents an NDB thread type. The thread types supported in MySQL Cluster NDB 7.1 and the range of permitted count values for each are provided in the following list:

- ldm: Local query handler (DBLQH kernel block) that handles data. The more LDM threads that are used, the more highly partitioned the data becomes. Each LDM thread maintains its own sets of data and index partitions, as well as its own redo log. In MySQL Cluster NDB 7.1, the maximum is 4 such threads.

Important

Changing the number of LDM threads requires a system restart to be effective and safe for cluster operations. (This is also true when this is done using MaxNoOfExecutionThreads.) If IndexMemory usage is in excess of 50%, an initial restart of the cluster is required; a maximum of 30-35% IndexMemory usage is recommended in such cases. Otherwise, IndexMemory and DataMemory usage as well as the allocation of LDM threads cannot be balanced between nodes, which can ultimately lead to data node failures.

- tc: Transaction coordinator thread (DBTC kernel block) containing the state of an ongoing transaction. In MySQL Cluster NDB 7.1, there can be only 1 TC thread. (In MySQL Cluster NDB 7.2, this number is configurable.)

Range: 1 only.

- main: Data dictionary and transaction coordinator (DBDIH and DBTC kernel blocks), providing schema management. This is always handled by a single dedicated thread.

Range: 1 only.

- recv: Receive thread (CMVMI kernel block). Each receive thread handles one or more sockets for communicating with other nodes in a MySQL Cluster, with one socket per node. Previously, this was limited to a single thread, but MySQL Cluster 7.2 implements multiple receive threads (up to 8).

Range: 1 only.

- rep: Replication thread (SUMA kernel block). Asynchronous replication operations are always handled by a single, dedicated thread.

Range: 1 only.

- io: File system and other miscellaneous operations. These are not demanding tasks, and are always handled as a group by a single, dedicated I/O thread.

Range: 1 only.

Simple examples:
It is usually desirable when configuring thread usage for a data node host to reserve one or more CPUs for operating system and other tasks. Thus, for a host machine with 8 CPUs, you might want to use 8 CPU threads bound to 7 CPUs (leaving one for operating system and other functions), with 4 LDM threads, 1 TC thread, 1 receive thread, and 1 thread each for schema management, asynchronous replication, and I/O operations. (This is almost the same distribution of threads used when MaxNoOfExecutionThreads is set equal to 8.) The following ThreadConfig setting performs these assignments, additionally binding all of these threads to specific CPUs:

```
ThreadConfig=ldm={count=4,cpubind=1,2,3,4},main={cpubind=5},
  io={cpubind=6},tc={cpubind=7},recv={cpubind=8}
```

It should be possible in most cases to bind the main (schema management) thread and the I/O thread to the same CPU, as we have done in the example just shown.

In order to take advantage of the enhanced stability that the use of ThreadConfig offers, it is necessary to insure that CPUs are isolated, and that they not subject to interrupts, or to being scheduled for other tasks by the operating system. On many Linux systems, you can do this by setting `IRQBALANCE_BANNED_CPUS` in `/etc/sysconfig/irqbalance` to `0xFFFFF0`, and by using the `isolcpus` boot option in `grub.conf`. For specific information, see your operating system or platform documentation.

In MySQL Cluster NDB 7.1 and earlier, it is not possible to cause `ndbmtd` to use more than 1 TC thread; this capability is introduced in MySQL Cluster NDB 7.2.

**Disk Data Configuration Parameters.** Configuration parameters affecting Disk Data behavior include the following:

- **DiskPageBufferMemory**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.6</td>
<td>bytes</td>
<td>64M</td>
<td>4M - 1T</td>
<td>N</td>
</tr>
</tbody>
</table>

This determines the amount of space used for caching pages on disk, and is set in the `[ndbd]` or `[ndbd default]` section of the `config.ini` file. It is measured in bytes. Each page takes up 32 KB. This means that Cluster Disk Data storage always uses \( N \times 32 \) KB memory where \( N \) is some nonnegative integer.

The default value for this parameter is **64M** (2000 pages of 32 KB each).

This parameter was added in MySQL 5.1.6.

Beginning with MySQL Cluster NDB 7.1.9, you can query the `ndbinfo.diskpagebuffer` table to help determine whether the value for this parameter should be increased to minimize unnecessary disk seeks. See Section 17.5.10.8, "The ndbinfo diskpagebuffer Table", for more information.

- **SharedGlobalMemory**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>bytes</td>
<td>128M</td>
<td>0 - 64T</td>
<td>N</td>
</tr>
<tr>
<td>MySQL 5.1.6</td>
<td>bytes</td>
<td>20M</td>
<td>0 - 64T</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter determines the amount of memory that is used for log buffers, disk operations (such as page requests and wait queues), and metadata for tablespaces, log file groups, UNDO files, and data files. The shared global memory pool also provides memory used for satisfying the memory
requirements of the `UNDO_BUFFER_SIZE` option used with `CREATE LOGFILE GROUP` and `ALTER LOGFILE GROUP` statements, including any default value implied for this options by the setting of the `InitialLogFileGroup` data node configuration parameter. `SharedGlobalMemory` can be set in the `[ndbd]` or `[ndbd default]` section of the `config.ini` configuration file, and is measured in bytes.

As of MySQL Cluster NDB 7.2.0, the default value is 128M. (Previously, this was 20M.)

This parameter was added in MySQL 5.1.6.

- **DiskIOThreadPool**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.4.3</td>
<td>threads</td>
<td>8</td>
<td>0 - 4294967039 (0xFFFFFFFF)</td>
<td>N</td>
</tr>
<tr>
<td>NDB 7.0.7</td>
<td>threads</td>
<td>2</td>
<td>0 - 4294967039 (0xFFFFFFFF)</td>
<td>N</td>
</tr>
<tr>
<td>NDB 7.1.0</td>
<td>threads</td>
<td>2</td>
<td>0 - 4294967039 (0xFFFFFFFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter determines the number of unbound threads used for Disk Data file access. Before `DiskIOThreadPool` was introduced, exactly one thread was spawned for each Disk Data file, which could lead to performance issues, particularly when using very large data files. With `DiskIOThreadPool`, you can—for example—access a single large data file using several threads working in parallel.

This parameter applies to Disk Data I/O threads only.

The optimum value for this parameter depends on your hardware and configuration, and includes these factors:

- **Physical distribution of Disk Data files.** You can obtain better performance by placing data files, undo log files, and the data node file system on separate physical disks. If you do this with some or all of these sets of files, then you can set `DiskIOThreadPool` higher to enable separate threads to handle the files on each disk.

- **Disk performance and types.** The number of threads that can be accommodated for Disk Data file handling is also dependent on the speed and throughput of the disks. Faster disks and higher throughput allow for more disk I/O threads. Our test results indicate that solid-state disk drives can handle many more disk I/O threads than conventional disks, and thus higher values for `DiskIOThreadPool`.

This parameter was added in MySQL Cluster NDB 6.4.0. Previous to MySQL Cluster NDB 6.4.3, it was named `IOThreadPool`. Previous to MySQL Cluster NDB 7.0.7, the default value was 8. Beginning with MySQL Cluster NDB 7.0.7 and MySQL Cluster NDB 7.1.0, the default is 2.

- **Disk Data file system parameters.** The parameters in the following list were added in MySQL Cluster NDB 6.2.17, 6.3.22, and 6.4.3 to make it possible to place MySQL Cluster Disk Data files in specific directories without the need for using symbolic links.

- **FileSystemPathDD**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.3.22</td>
<td>filename</td>
<td>[see text]</td>
<td>...</td>
<td>IN</td>
</tr>
<tr>
<td>NDB 6.2.17</td>
<td>filename</td>
<td>[see text]</td>
<td>...</td>
<td>IN</td>
</tr>
<tr>
<td>NDB 6.4.3</td>
<td>filename</td>
<td>[see text]</td>
<td>...</td>
<td>IN</td>
</tr>
</tbody>
</table>
If this parameter is specified, then MySQL Cluster Disk Data data files and undo log files are placed in the indicated directory. This can be overridden for data files, undo log files, or both, by specifying values for `FileSystemPathDataFiles`, `FileSystemPathUndoFiles`, or both, as explained for these parameters. It can also be overridden for data files by specifying a path in the `ADD DATAFILE` clause of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement, and for undo log files by specifying a path in the `ADD UNDOFILE` clause of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement. If `FileSystemPathDD` is not specified, then `FileSystemPath` is used.

If a `FileSystemPathDD` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

- **FileSystemPathDataFiles**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.3.22</td>
<td>filename</td>
<td>[see text]</td>
<td>...</td>
<td>IN</td>
</tr>
<tr>
<td>NDB 6.2.17</td>
<td>filename</td>
<td>[see text]</td>
<td>...</td>
<td>IN</td>
</tr>
<tr>
<td>NDB 6.4.3</td>
<td>filename</td>
<td>[see text]</td>
<td>...</td>
<td>IN</td>
</tr>
</tbody>
</table>

If this parameter is specified, then MySQL Cluster Disk Data data files are placed in the indicated directory. This overrides any value set for `FileSystemPathDD`. This parameter can be overridden for a given data file by specifying a path in the `ADD DATAFILE` clause of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement used to create that data file. If `FileSystemPathDataFiles` is not specified, then `FileSystemPathDD` is used (or `FileSystemPath`, if `FileSystemPathDD` has also not been set).

If a `FileSystemPathDataFiles` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

- **FileSystemPathUndoFiles**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.3.22</td>
<td>filename</td>
<td>[see text]</td>
<td>...</td>
<td>IN</td>
</tr>
<tr>
<td>NDB 6.2.17</td>
<td>filename</td>
<td>[see text]</td>
<td>...</td>
<td>IN</td>
</tr>
<tr>
<td>NDB 6.4.3</td>
<td>filename</td>
<td>[see text]</td>
<td>...</td>
<td>IN</td>
</tr>
</tbody>
</table>

If this parameter is specified, then MySQL Cluster Disk Data undo log files are placed in the indicated directory. This overrides any value set for `FileSystemPathDD`. This parameter can be overridden for a given data file by specifying a path in the `ADD UNDOFILE` clause of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement used to create that data file. If `FileSystemPathUndoFiles` is not specified, then `FileSystemPathDD` is used (or `FileSystemPath`, if `FileSystemPathDD` has also not been set).

If a `FileSystemPathUndoFiles` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

For more information, see Section 17.5.12.1, “MySQL Cluster Disk Data Objects”.

- **Disk Data object creation parameters.** The next two parameters enable you—when starting the cluster for the first time—to cause a Disk Data log file group, tablespace, or both, to be created without the use of SQL statements.

  - **InitialLogFileGroup**
MySQL Cluster Configuration Files

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.3.22</td>
<td>string</td>
<td>[see text]</td>
<td>...</td>
<td>S</td>
</tr>
<tr>
<td>NDB 6.2.17</td>
<td>string</td>
<td>[see text]</td>
<td>...</td>
<td>S</td>
</tr>
<tr>
<td>NDB 6.4.3</td>
<td>string</td>
<td>[see text]</td>
<td>...</td>
<td>S</td>
</tr>
</tbody>
</table>

This parameter can be used to specify a log file group that is created when performing an initial start of the cluster. `InitialLogFileGroup` is specified as shown here:

```plaintext
InitialLogFileGroup = [name=name;] [undo_buffer_size=size;] file-specification-list

file-specification-list:
  file-specification[; file-specification[; ...]]

file-specification:
  filename:size
```

The `name` of the log file group is optional and defaults to `DEFAULT-LG`. The `undo_buffer_size` is also optional; if omitted, it defaults to 64M. Each `file-specification` corresponds to an undo log file, and at least one must be specified in the `file-specification-list`. Undo log files are placed according to any values that have been set for `FileSystemPath`, `FileSystemPathDD`, and `FileSystemPathUndoFiles`, just as if they had been created as the result of a `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP` statement.

Consider the following:

```
InitialLogFileGroup = name=LG1; undo_buffer_size=128M; undo1.log:250M; undo2.log:150M
```

This is equivalent to the following SQL statements:

```sql
CREATE LOGFILE GROUP LG1
  ADD UNDOFILE 'undo1.log'
  INITIAL_SIZE 250M
  UNDO_BUFFER_SIZE 128M
  ENGINE NDBCLUSTER;

ALTER LOGFILE GROUP LG1
  ADD UNDOFILE 'undo2.log'
  INITIAL_SIZE 150M
  ENGINE NDBCLUSTER;
```

This logfile group is created when the data nodes are started with `--initial`.

Resources for the initial log file group are taken from the global memory pool whose size is determined by the value of the `SharedGlobalMemory` data node configuration parameter; if this parameter is set too low and the values set in `InitialLogFileGroup` for the logfile group's initial size or undo buffer size are too high, the cluster may fail to create the default log file group when starting, or fail to start altogether.

This parameter, if used, should always be set in the `[ndbd default]` section of the `config.ini` file. The behavior of a MySQL Cluster when different values are set on different data nodes is not defined.

- `InitialTablespace`

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.3.22</td>
<td>string</td>
<td>[see text]</td>
<td>...</td>
<td>S</td>
</tr>
<tr>
<td>NDB 6.2.17</td>
<td>string</td>
<td>[see text]</td>
<td>...</td>
<td>S</td>
</tr>
</tbody>
</table>
MySQL Cluster Configuration Files

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.4.3</td>
<td>string</td>
<td>[see text]</td>
<td>...</td>
<td>S</td>
</tr>
</tbody>
</table>

This parameter can be used to specify a MySQL Cluster Disk Data tablespace that is created when performing an initial start of the cluster. `InitialTablespace` is specified as shown here:

```
InitialTablespace = [name=name;] [extent_size=size;] file-specification-list
```

The `name` of the tablespace is optional and defaults to `DEFAULT-TS`. The `extent_size` is also optional; it defaults to 1M. The `file-specification-list` uses the same syntax as shown with the `InitialLogfileGroup` parameter, the only difference being that each `file-specification` used with `InitialTablespace` corresponds to a data file. At least one must be specified in the `file-specification-list`. Data files are placed according to any values that have been set for `FileSystemPath`, `FileSystemPathDD`, and `FileSystemPathDataFiles`, just as if they had been created as the result of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement.

For example, consider the following line specifying `InitialTablespace` in the `[ndbd default]` section of the `config.ini` file (as with `InitialLogfileGroup`, this parameter should always be set in the `[ndbd default]` section, as the behavior of a MySQL Cluster when different values are set on different data nodes is not defined):

```
InitialTablespace = name=TS1; extent_size=8M; data1.dat:2G; data2.dat:4G
```

This is equivalent to the following SQL statements:

```sql
CREATE TABLESPACE TS1
  ADD DATAFILE 'data1.dat'
  EXTENT_SIZE 8M
  INITIAL_SIZE 2G
  ENGINE NDBCLUSTER;

ALTER TABLESPACE TS1
  ADD DATAFILE 'data2.dat'
  INITIAL_SIZE 4G
  ENGINE NDBCLUSTER;
```

This tablespace is created when the data nodes are started with `--initial`, and can be used whenever creating MySQL Cluster Disk Data tables thereafter.

**Disk Data and GCP Stop errors.** Errors encountered when using Disk Data tables such as `Node nodeid killed this node because GCP stop was detected (error 2303)` are often referred to as “GCP stop errors”. Such errors occur when the redo log is not flushed to disk quickly enough; this is usually due to slow disks and insufficient disk throughput.

You can help prevent these errors from occurring by using faster disks, and by placing Disk Data files on a separate disk from the data node file system. Reducing the value of `TimeBetweenGlobalCheckpoints` tends to decrease the amount of data to be written for each global checkpoint, and so may provide some protection against redo log buffer overflows when trying to write a global checkpoint; however, reducing this value also permits less time in which to write the GCP, so this must be done with caution.

In addition, adjusting the cluster configuration as discussed here can also help:

- **MySQL Cluster NDB 6.2 and 6.3.** When working with large amounts of data on disk under high load, the default value for `DiskPageBufferMemory` may not be large enough. In such cases, you should increase its value to include most of the memory available to the data nodes after accounting for index memory, data memory, internal buffers, and memory needed by the data node host operating system.
You can use this formula as a guide:

\[
\text{DiskPageBufferMemory} = 0.8 \times ([\text{total memory}] - ([\text{operating system memory}] + [\text{buffer memory}] + \text{DataMemory} + \text{IndexMemory} )
\]

Once you have established that sufficient memory is reserved for DataMemory, IndexMemory, NDB internal buffers, and operating system overhead, it is possible (and sometimes desirable) to allocate more than the above amount of the remainder to DiskPageBufferMemory.

- **MySQL Cluster NDB 7.X.** In addition to the considerations given for DiskPageBufferMemory as explained previously, it is also very important that the DiskIOThreadPool configuration parameter be set correctly; having DiskIOThreadPool set too high is very likely to cause GCP stop errors (Bug #37227).

GCP stops can be caused by save or commit timeouts; the TimeBetweenEpochsTimeout data node configuration parameter determines the timeout for commits. However, beginning with MySQL Cluster NDB 7.0.21 and MySQL Cluster NDB 7.1.10, it is possible to disable both types of timeouts by setting this parameter to 0.

**Parameters for configuring send buffer memory allocation (MySQL Cluster NDB 7.0 and later).** Beginning with MySQL Cluster NDB 6.4.0, send buffer memory is allocated dynamically from a memory pool shared between all transporters, which means that the size of the send buffer can be adjusted as necessary. (Previously, the NDB kernel used a fixed-size send buffer for every node in the cluster, which was allocated when the node started and could not be changed while the node was running.) The following data node configuration parameters were added in MySQL Cluster NDB 6.4.0 to permit the setting of limits on this memory allocation; this change is reflected by the addition of the configuration parameters TotalSendBufferMemory and OverLoadLimit, as well as a change in how the existing SendBufferMemory configuration parameter is used. For more information, see Section 17.3.3.14, “Configuring MySQL Cluster Send Buffer Parameters”.

- **ExtraSendBufferMemory**

  This parameter specifies the amount of transporter send buffer memory to allocate in addition to any set using TotalSendBufferMemory, SendBufferMemory, or both.

  This parameter was added in MySQL Cluster NDB 7.0.31 and MySQL Cluster NDB 7.1.20. (Bug #13633845, Bug #11760629, Bug #53053)

- **TotalSendBufferMemory**

  This parameter is available beginning with MySQL Cluster NDB 6.4.0. It is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

  Prior to MySQL Cluster NDB 7.0.31 and MySQL Cluster NDB 7.1.20, this parameter did not work correctly with ndbmtd. (Bug #13633845)

  If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see Section 17.3.3.14, “Configuring MySQL Cluster Send Buffer Parameters”.

- **ReservedSendBufferMemory**

  This parameter is present in NDBCLUSTER source code beginning with MySQL Cluster NDB 6.4.0. However, it is not currently enabled.
As of MySQL Cluster NDB 7.0.31 and MySQL Cluster NDB 7.1.20, this parameter is deprecated, and is subject to removal in a future release of MySQL Cluster (Bug #11760629, Bug #53053).

For more detailed information about the behavior and use of `TotalSendBufferMemory` and `ReservedSendBufferMemory`, and about configuring send buffer memory parameters in MySQL Cluster NDB 6.4.0 and later, see Section 17.3.3.14, “Configuring MySQL Cluster Send Buffer Parameters”.

**Note**

Previous to MySQL Cluster NDB 7.0, to add new data nodes to a MySQL Cluster, it was necessary to shut down the cluster completely, update the `config.ini` file, and then restart the cluster (that is, you had to perform a system restart). All data node processes had to be started with the `--initial` option.

Beginning with MySQL Cluster NDB 7.0, it is possible to add new data node groups to a running cluster online. See Section 17.5.13, “Adding MySQL Cluster Data Nodes Online”, for more information.

**Redo log over-commit handling.** Beginning with MySQL Cluster NDB 7.1.10, it is possible to control the data node's handling of operations when too much time is taken flushing redo logs to disk. This occurs when a given redo log flush takes longer than `RedoOverCommitLimit` seconds, more than `RedoOverCommitCounter` times, causing any pending transactions to be aborted. When this happens, the API node that sent the transaction can handle the operations that should have been committed either by queuing the operations and re-trying them, or by aborting them, as determined by `DefaultOperationRedoProblemAction`. The data node configuration parameters for setting the timeout and number of times it may be exceeded before the API node takes this action are described in the following list:

- **RedoOverCommitCounter**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.1.10</td>
<td>numeric</td>
<td>3</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

When `RedoOverCommitLimit` is exceeded when trying to write a given redo log to disk this many times or more, any transactions that were not committed as a result are aborted, and an API node where any of these transactions originated handles the operations making up those transactions according to its value for `DefaultOperationRedoProblemAction` (by either queuing the operations to be re-tryed, or aborting them).

`RedoOverCommitCounter` defaults to 3. Set it to 0 to disable the limit. This parameter was added in MySQL Cluster NDB 7.1.10.

- **RedoOverCommitLimit**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.1.10</td>
<td>seconds</td>
<td>20</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter sets an upper limit in seconds for trying to write a given redo log to disk before timing out. The number of times the data node tries to flush this redo log, but takes longer than `RedoOverCommitLimit`, is kept and compared with `RedoOverCommitCounter`, and when flushing takes too long more times than the value of that parameter, any transactions that were not committed as a result of the flush timeout are aborted. When this occurs, the API node where any of these transactions originated handles the operations making up those transactions according to its
DefaultOperationRedoProblemAction setting (it either queues the operations to be re-tried, or aborts them).

By default, RedoOverCommitLimit is 20 seconds. Set to 0 to disable checking for redo log flush timeouts. This parameter was added in MySQL Cluster NDB 7.1.10.

Controlling restart attempts. Beginning in MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.37, MySQL Cluster NDB 7.0.18, and MySQL Cluster NDB 7.1.7, it is possible to exercise more finely-grained control over restart attempts by data nodes when they fail to start using two data node configuration parameters added in these releases. MaxStartFailRetries limits the total number of retries made before giving up on starting the data node; StartFailRetryDelay sets the number of seconds between retry attempts, as described in the following list:

- **StartFailRetryDelay**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.3.37</td>
<td>unsigned</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
<tr>
<td>NDB 7.0.18</td>
<td>unsigned</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
<tr>
<td>NDB 7.1.7</td>
<td>unsigned</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
<tr>
<td>NDB 6.2.19</td>
<td>unsigned</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

Beginning in MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.37, MySQL Cluster NDB 7.0.18, and MySQL Cluster NDB 7.1.7, it is possible to set the number of seconds between restart attempts by the data node in the event on failure on startup. The default is 0 (no delay).

**Note**

This parameter is ignored unless StopOnError is equal to 0.

- **MaxStartFailRetries**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.3.37</td>
<td>unsigned</td>
<td>3</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
<tr>
<td>NDB 7.0.18</td>
<td>unsigned</td>
<td>3</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
<tr>
<td>NDB 7.1.7</td>
<td>unsigned</td>
<td>3</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
<tr>
<td>NDB 6.2.19</td>
<td>unsigned</td>
<td>3</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

Beginning in MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.37, MySQL Cluster NDB 7.0.18, and MySQL Cluster NDB 7.1.7, it is possible to limit the number restart attempts made by the data node in the event that it fails on startup. The default is 3 attempts.

**Note**

This parameter is ignored unless StopOnError is equal to 0.

17.3.3.7 Defining SQL and Other API Nodes in a MySQL Cluster
The \texttt{[mysqld]} and \texttt{[api]} sections in the \texttt{config.ini} file define the behavior of the MySQL servers (SQL nodes) and other applications (API nodes) used to access cluster data. None of the parameters shown is required. If no computer or host name is provided, any host can use this SQL or API node.

Generally speaking, a \texttt{[mysqld]} section is used to indicate a MySQL server providing an SQL interface to the cluster, and an \texttt{[api]} section is used for applications other than \texttt{mysqld} processes accessing cluster data, but the two designations are actually synonymous; you can, for instance, list parameters for a MySQL server acting as an SQL node in an \texttt{[api]} section.

**Note**

For a discussion of MySQL server options for MySQL Cluster, see MySQL Server Options for MySQL Cluster; for information about MySQL server system variables relating to MySQL Cluster, see MySQL Cluster System Variables.

- \textbf{Id}

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>unsigned</td>
<td>[none]</td>
<td>1 - 63</td>
<td>IS</td>
</tr>
<tr>
<td>NDB 6.1.1</td>
<td>unsigned</td>
<td>[none]</td>
<td>1 - 255</td>
<td>IS</td>
</tr>
</tbody>
</table>

The \texttt{Id} is an integer value used to identify the node in all cluster internal messages. Prior to MySQL Cluster NDB 6.1.1, the permitted range of values for this parameter was 1 to 63 inclusive. Beginning with MySQL Cluster NDB 6.1.1, the permitted range is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.

**Note**

Data node IDs must be less than 49, regardless of the MySQL Cluster version used. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 48.

\texttt{NodeId} is the preferred parameter name to use when identifying management nodes beginning with MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.39, MySQL Cluster NDB 7.0.20, and MySQL Cluster NDB 7.1.9. Although \texttt{Id} continues to be supported for backward compatibility, it is now deprecated and generates a warning when used.

- \textbf{ConnectionMap}

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.1.0</td>
<td>string</td>
<td>[none]</td>
<td>...</td>
<td>N</td>
</tr>
</tbody>
</table>

Specifies which data nodes to connect. Introduced in MySQL Cluster NDB 6.1.0.

- \textbf{NodeId}

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>unsigned</td>
<td>[none]</td>
<td>1 - 63</td>
<td>IS</td>
</tr>
<tr>
<td>NDB 6.1.1</td>
<td>unsigned</td>
<td>[none]</td>
<td>1 - 255</td>
<td>IS</td>
</tr>
</tbody>
</table>

The \texttt{NodeId} is an integer value used to identify the node in all cluster internal messages. Prior to MySQL Cluster NDB 6.1.1, the permitted range of values for this parameter was 1 to 63 inclusive. Beginning with MySQL Cluster NDB 6.1.1, the permitted range is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.
MySQL Cluster Configuration Files

Note
Data node IDs must be less than 49, regardless of the MySQL Cluster version used. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 48.

NodeId is the preferred parameter name to use when identifying management nodes beginning with MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.39, MySQL Cluster NDB 7.0.20, and MySQL Cluster NDB 7.1.9. Although Id continues to be supported for backward compatibility, it is now deprecated and generates a warning when used.

- **ExecuteOnComputer**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>name</td>
<td>[none]</td>
<td>...</td>
<td>S</td>
</tr>
</tbody>
</table>

This refers to the Id set for one of the computers (hosts) defined in a [computer] section of the configuration file.

- **HostName**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>name or IP address</td>
<td>[none]</td>
<td>...</td>
<td>N</td>
</tr>
</tbody>
</table>

Specifying this parameter defines the hostname of the computer on which the SQL node (API node) is to reside. To specify a hostname, either this parameter or ExecuteOnComputer is required.

If no HostName or ExecuteOnComputer is specified in a given [mysql] or [api] section of the config.ini file, then an SQL or API node may connect using the corresponding “slot” from any host which can establish a network connection to the management server host machine. This differs from the default behavior for data nodes, where localhost is assumed for HostName unless otherwise specified.

- **ArbitrationRank**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>0-2</td>
<td>0</td>
<td>0 - 2</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter defines which nodes can act as arbitrators. Both management nodes and SQL nodes can be arbitrators. A value of 0 means that the given node is never used as an arbitrator, a value of 1 gives the node high priority as an arbitrator, and a value of 2 gives it low priority. A normal configuration uses the management server as arbitrator, setting its ArbitrationRank to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

Beginning with MySQL 5.1.16 and MySQL Cluster NDB 6.1.3, it is possible to disable arbitration completely by setting ArbitrationRank to 0 on all management and SQL nodes. In MySQL Cluster NDB 7.0.7 and later releases, you can also control arbitration by overriding this parameter; to do this, set the Arbitration parameter in the [ndbd default] section of the config.ini global configuration file.

- **ArbitrationDelay**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>milliseconds</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>
Setting this parameter to any other value than 0 (the default) means that responses by the arbitrator to arbitration requests will be delayed by the stated number of milliseconds. It is usually not necessary to change this value.

- **BatchByteSize**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>bytes</td>
<td>32K</td>
<td>1024 - 1M</td>
<td>N</td>
</tr>
<tr>
<td>NDB 7.2.1</td>
<td>bytes</td>
<td>16K</td>
<td>1024 - 1M</td>
<td>N</td>
</tr>
</tbody>
</table>

For queries that are translated into full table scans or range scans on indexes, it is important for best performance to fetch records in properly sized batches. It is possible to set the proper size both in terms of number of records (**BatchSize**) and in terms of bytes (**BatchByteSize**). The actual batch size is limited by both parameters.

The speed at which queries are performed can vary by more than 40% depending upon how this parameter is set.

This parameter is measured in bytes. The default value is 32K.

- **BatchSize**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>records</td>
<td>64</td>
<td>1 - 992</td>
<td>N</td>
</tr>
<tr>
<td>NDB 7.2.1</td>
<td>records</td>
<td>256</td>
<td>1 - 992</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is measured in number of records and is by default set to 64. The maximum size is 992.

- **ExtraSendBufferMemory**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.0.39</td>
<td>bytes</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
<tr>
<td>NDB 7.1.28</td>
<td>bytes</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter specifies the amount of transporter send buffer memory to allocate in addition to any that has been set using **TotalSendBufferMemory**, **SendBufferMemory**, or both.

This parameter was added in MySQL Cluster NDB 7.0.39 and MySQL Cluster NDB 7.1.28. (Bug #14555359)

- **HeartbeatThreadPriority**

Beginning with MySQL Cluster NDB 6.3.32, MySQL Cluster NDB 7.0.13, and MySQL Cluster NDB 7.1.2, it is possible to use this parameter to set the scheduling policy and priority of heartbeat threads for management and API nodes.

The syntax for setting this parameter is shown here:

```plaintext
HeartbeatThreadPriority = policy[, priority]
```

```plaintext
policy:
   (FIFO | RR)
```
When setting this parameter, you must specify a policy. This is one of FIFO (first in, first in) or RR (round robin). This followed optionally by the priority (an integer).

- **MaxScanBatchSize**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>bytes</td>
<td>256K</td>
<td>32K - 16M</td>
<td>N</td>
</tr>
</tbody>
</table>

The batch size is the size of each batch sent from each data node. Most scans are performed in parallel to protect the MySQL Server from receiving too much data from many nodes in parallel; this parameter sets a limit to the total batch size over all nodes.

The default value of this parameter is set to 256KB. Its maximum size is 16MB.

- **TotalSendBufferMemory**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.4.0</td>
<td>bytes</td>
<td>0</td>
<td>256K - 4294967039 (0xFFFFFFFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is available beginning with MySQL Cluster NDB 6.4.0. It is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; 0 indicates that the parameter has not been set. For more detailed information, see Section 17.3.3.14, “Configuring MySQL Cluster Send Buffer Parameters”.

- **AutoReconnect**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.3.26</td>
<td>boolean</td>
<td>false</td>
<td>true, false</td>
<td>N</td>
</tr>
<tr>
<td>NDB 7.0.7</td>
<td>boolean</td>
<td>false</td>
<td>true, false</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is available beginning with MySQL Cluster NDB 6.3.26 and MySQL Cluster NDB 7.0.7. By default, its value is `false`, which forces disconnected API nodes (including MySQL Servers acting as SQL nodes) the use a new connection to the cluster rather than attempting to re-use an existing one, which can cause problems when using dynamically-allocated node IDs. (Bug #45921)

**Note**

This parameter can be overridden using the NDB API. For more information, see `Ndb_cluster_connection::set_auto_reconnect()` and `Ndb_cluster_connection::get_auto_reconnect()`.

- **DefaultOperationRedoProblemAction**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.1.10</td>
<td>enumeration</td>
<td>ABORT</td>
<td>ABORT, QUEUE</td>
<td>S</td>
</tr>
<tr>
<td>NDB 7.2.1</td>
<td>enumeration</td>
<td>ABORT</td>
<td>ABORT, QUEUE</td>
<td>S</td>
</tr>
</tbody>
</table>

This parameter was introduced in MySQL Cluster NDB 7.1.10 (along with `RedoOverCommitLimit` and `RedoOverCommitCounter`) for controlling the data node's handling of operations when too much time is taken flushing redo logs to disk. This occurs when a given redo log flush takes longer...
than `RedoOverCommitLimit` seconds, more than `RedoOverCommitCounter` times, causing any pending transactions to be aborted.

When this happens, the node can respond in either of two ways, according to the value of `DefaultOperationRedoProblemAction`, listed here:

- **ABORT**: Any pending operations from aborted transactions are also aborted.
- **QUEUE**: Pending operations from transactions that were aborted are queued up to be re-tried.

Prior to MySQL Cluster NDB 7.1.26, setting this parameter did not have any effect. (Bug #15855588)

- **DefaultHashMapSize**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.0.38</td>
<td>buckets</td>
<td>240</td>
<td>0 - 3840</td>
<td>N</td>
</tr>
<tr>
<td>NDB 7.1.27</td>
<td>buckets</td>
<td>240</td>
<td>0 - 3840</td>
<td>N</td>
</tr>
</tbody>
</table>

Beginning with MySQL Cluster NDB 7.0.38 and MySQL Cluster NDB 7.1.26, the size of the table hash maps used by NDB is configurable using this parameter; previously this value was hard-coded. `DefaultHashMapSize` can take any of three possible values (0, 240, 3840). These values and their effects are described in the following table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description / Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Use the lowest value set, if any, for this parameter among all data nodes and API nodes in the cluster; if it is not set on any data or API node, use the default value.</td>
</tr>
<tr>
<td>240</td>
<td>Original hash map size used by default in all MySQL Cluster NDB 7.1 and MySQL Cluster NDB 7.0 (and earlier) releases; effectively the only value prior to versions 7.0.38 and 7.1.26 (when this parameter was introduced).</td>
</tr>
<tr>
<td>3840</td>
<td>Larger hash map size available beginning with MySQL Cluster NDB 7.0.38 and MySQL Cluster NDB 7.1.26</td>
</tr>
</tbody>
</table>

The primary intended use for this parameter is to facilitate upgrades and especially downgrades between MySQL Cluster NDB 7.1 and later MySQL Cluster versions in which the larger hash map size (3840) is the default; by setting this parameter to 240 prior to performing an upgrade, you can cause the cluster to continue using the smaller size for table hash maps, in which case the tables remain compatible with earlier versions. `DefaultHashMapSize` can be set for individual data nodes, API nodes, or both, but setting it once only, in the `[ndbd default]` section of the `config.ini` file, is the recommended practice. You can also set this parameter to 0, in which case the default value is used.

After increasing this parameter, to have existing tables to take advantage of the new size, you can run `ALTER TABLE ... REORGANIZE PARTITION` on them, after which they can use the larger hash map size. This is in addition to performing a rolling restart, which makes the larger hash maps available to new tables, but does not enable existing tables to use them.

Decreasing this parameter online after any tables have been created or modified with `DefaultHashMapSize` equal to 3840 is not currently supported.

- **Wan**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.1.1</td>
<td>boolean</td>
<td>false</td>
<td>true, false</td>
<td>N</td>
</tr>
</tbody>
</table>

Use WAN TCP setting as default. Introduced in MySQL Cluster NDB 6.1.1.
You can also obtain information from a MySQL server running as a MySQL Cluster SQL node using `SHOW STATUS` in the `mysql` client, as shown here:

```
mysql> SHOW STATUS LIKE 'ndb%';
+-----------------------------+---------------+
| Variable_name               | Value         |
|-----------------------------+---------------+
| Ndb_cluster_node_id         | 5             |
| Ndb_config_from_host        | 192.168.0.112 |
| Ndb_config_from_port        | 1186          |
| Ndb_number_of_storage_nodes | 4             |
+-----------------------------+---------------+
4 rows in set (0.02 sec)
```

For information about the status variables appearing in the output from this statement, see MySQL Cluster Status Variables.

**Note**

To add new SQL or API nodes to the configuration of a running MySQL Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new `mysqld` or `api` sections to the `config.ini` file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is *not* necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

### 17.3.3.8 MySQL Server Options and Variables for MySQL Cluster

This section provides information about MySQL server options, server and status variables that are specific to MySQL Cluster. For general information on using these, and for other options and variables not specific to MySQL Cluster, see Section 5.1, “The MySQL Server”.

For MySQL Cluster configuration parameters used in the cluster configuration file (usually named `config.ini`), see Section 17.3, “Configuration of MySQL Cluster NDB 6.1-7.1”.

#### MySQL Server Options for MySQL Cluster

This section provides descriptions of `mysqld` server options relating to MySQL Cluster. For information about `mysqld` options not specific to MySQL Cluster, and for general information about the use of options with `mysqld`, see Section 5.1.3, “Server Command Options”.

For information about command-line options used with other MySQL Cluster processes (`ndbd`, `ndb_mgmd`, and `ndb_mgm`), see Section 17.4.26, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”. For information about command-line options used with NDB utility programs (such as `ndb_desc`, `ndb_size.pl`, and `ndb_show_tables`), see Section 17.4, “MySQL Cluster Programs”.

- `--ndb-batch-size=#`

<tr>
<td>65536 / 0 - 4294967295</td>
</tr>
</tbody>
</table>

DESCRIPTION: Specifies size in bytes that large BLOB reads should be batched into. 0 = no limit.

This option can be used to set the size (in bytes) for batching of BLOB data reads in MySQL Cluster applications. When this batch size is exceeded by the amount of BLOB data to be read within the current transaction, any pending BLOB read operations are immediately executed.

The maximum value for this option is 4294967295; the default is 65536. Setting it to 0 has the effect of disabling BLOB read batching.

Note

In NDB API applications, you can control BLOB write batching with the `setMaxPendingBlobReadBytes()` and `getMaxPendingBlobReadBytes()` methods.

This option was introduced in MySQL Cluster NDB 7.0.21 and MySQL Cluster NDB 7.1.10.

</tr>
</tbody>
</table>

- --ndb-cluster-connection-pool=#

By setting this option to a value greater than 1 (the default), a mysql process can use multiple connections to the cluster, effectively mimicking several SQL nodes. Each connection requires its own [api] or [mysqld] section in the cluster configuration (config.ini) file, and counts against the maximum number of API connections supported by the cluster.

Suppose that you have 2 cluster host computers, each running an SQL node whose mysql process was started with --ndb-cluster-connection-pool=4; this means that the cluster must have 8 API slots available for these connections (instead of 2). All of these connections are set up when the SQL node connects to the cluster, and are allocated to threads in a round-robin fashion.

This option is useful only when running mysql on host machines having multiple CPUs, multiple cores, or both. For best results, the value should be smaller than the total number of cores available on the host machine. Setting it to a value greater than this is likely to degrade performance severely.

Important
Because each SQL node using connection pooling occupies multiple API node slots—each slot having its own node ID in the cluster—you must not
use a node ID as part of the cluster connection string when starting any
*mysqld* process that employs connection pooling.

Setting a node ID in the connection string when using the `--ndb-cluster-
connection-pool` option causes node ID allocation errors when the SQL
node attempts to connect to the cluster.

This option was introduced in MySQL Cluster NDB 6.2.2. Beginning with MySQL Cluster NDB 6.2.16
and MySQL Cluster NDB 6.3.13, the value used for this option is available as a system variable (Bug
#35573).

Prior to MySQL Cluster NDB 7.0.23 and MySQL Cluster NDB 7.1.12, there was also a status
variable corresponding to this option; however, the status variable was removed as redundant as of
these versions. (Bug #60119)

* `--ndb-connectstring=connection_string`

| DESCRIPTION: Specifies that constraint checks on unique indexes (where these are supported)
should be deferred until commit time. Not normally needed or used; for testing purposes only. |

Controls whether or not constraint checks on unique indexes are deferred until commit time, where
such checks are supported. 0 is the default.

This option is not normally needed for operation of MySQL Cluster or MySQL Cluster Replication,
and is intended primarily for use in testing.
This option was added in MySQL Cluster NDB 7.0.28 and MySQL Cluster NDB 7.1.14.

- `--ndb-distribution=[KEYHASH|LINHASH]`

<tr>
<td>Yes</td>
</tr>
</tbody>
</table>
The **NDBCLUSTER** storage engine is necessary for using MySQL Cluster. If a **mysqld** binary includes support for the **NDBCLUSTER** storage engine, the engine is disabled by default. Use the `--ndbcluster` option to enable it. Use `--skip-ndbcluster` to explicitly disable the engine.

- `--ndb-log-apply-status`

### Table 17.19 Type and value information for ndb-log-apply-status

<table>
<thead>
<tr>
<th>Command Line</th>
<th>System Variable</th>
<th>Status Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ndb-log-apply-status</code></td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Yes</td>
<td>Global</td>
<td>No</td>
</tr>
<tr>
<td>MySQL 5.1</td>
<td>boolean</td>
<td>OFF</td>
</tr>
</tbody>
</table>

DESCRIPTION: Cause a MySQL server acting as a slave to log mysql.ndb_apply_status updates received from its immediate master in its own binary log, using its own server ID. Effective only if the server is started with the `--ndbcluster` option.

Causes a slave **mysqld** to log any updates received from its immediate master to the `mysql.ndb_apply_status` table in its own binary log using its own server ID rather than the server ID of the master. In a circular or chain replication setting, this allows such updates to propagate to the `mysql.ndb_apply_status` tables of any MySQL servers configured as slaves of the current **mysqld**.

In a chain replication setup, using this option allows downstream (slave) clusters to be aware of their positions relative to all of their upstream contributors (masters).

In a circular replication setup, this option causes changes to `ndb_apply_status` tables to complete the entire circuit, eventually propagating back to the originating MySQL Cluster. This also allows a cluster acting as a master to see when its changes (epochs) have been applied to the other clusters in the circle.

This option was added in MySQL Cluster NDB 7.0.21 and MySQL Cluster NDB 7.1.10. It has no effect unless the MySQL server is started with the `--ndbcluster` option.

- `--ndb-log-empty-epochs=[0|1]`

</tr>
</tbody>
</table>

ndb-log-empty-epochs

Yes  Yes  No
Yes  Global  Yes
MySQL 5.1  boolean  OFF

DESCRIPTION: When enabled, causes epochs in which there were no changes to be written to the ndb_apply_status and ndb_binlog_index tables, even when --log-slave-updates is enabled.

Causes epochs during which there were no changes to be written to the ndb_apply_status and ndb_binlog_index tables, even when --log-slave-updates is enabled.

By default this option is disabled. Disabling --ndb-log-empty-epochs causes epoch transactions with no changes not to be written to the binary log, although a row is still written even for an empty epoch in ndb_binlog_index (Bug #49559, Bug #11757505).

Because --ndb-log-empty-epochs=1 causes the size of ndb_binlog_index table to increase independently of the size of the binary log, users should be prepared to manage the growth of this table, even if they expect the cluster to be idle a large part of the time.

This option was introduced in MySQL Cluster NDB 6.3.21 and MySQL Cluster NDB 6.4.1. Prior to MySQL Cluster NDB 6.3.33, MySQL Cluster NDB 7.0.14, and MySQL Cluster NDB 7.1.3, setting --ndb-log-empty-epochs=0 also caused no row to be written in ndb_binlog_index for an empty epoch.

- --ndb-log-orig

</tbody>
</table>

ndb-log-orig

Yes  Yes  No
Yes  Global  No
MySQL 5.1  boolean  OFF

DESCRIPTION: Log originating server id and epoch in mysql.ndb_binlog_index table.

Log the originating server ID and epoch in the ndb_binlog_index table.

Note that this makes it possible for a given epoch to have multiple rows in ndb_binlog_index, one for each originating epoch.

For more information, see Section 17.6.4, “MySQL Cluster Replication Schema and Tables”.

- --ndb-log-transaction-id
Table 17.22 Type and value information for ndb-log-transaction-id

<table>
<thead>
<tr>
<th>Option File</th>

<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td></td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td></td>
<td>MySQL 5.1</td>
<td>OFF</td>
</tr>
</tbody>
</table>

DESCRIPTION: Write NDB transaction IDs in the binary log. Requires `--log-bin-v1-events=OFF`.

Causes a slave `mysqld` to write the NDB transaction ID in each row of the binary log. Such logging requires the use of the Version 2 event format for the binary log; thus, `--log-bin-use-v1-row-events` must be set to `FALSE` in order to use this option.

This option is available beginning with MySQL Cluster NDB 7.1.16 (and is not supported in mainline MySQL Server 5.1). It is required to enable MySQL Cluster Replication conflict detection and resolution using the `NDB$EPOCH_TRANS()` function introduced in the same MySQL Cluster release.

The default value is `FALSE`.

For more information, see Section 17.6.11, “MySQL Cluster Replication Conflict Resolution”.

- `--ndb-nodeid=\#`

</tr>
</tbody>
</table>

DESCRIPTION: MySQL Cluster node ID for this MySQL server

Set this MySQL server’s node ID in a MySQL Cluster.

Prior to MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4, this option can be used instead of specifying the node ID as part of the connection string or in the `config.ini` file, or permitting the cluster to determine an arbitrary node ID. If you use this option, then `--ndb-nodeid` must be specified before `--ndb-connectstring`. If `--ndb-nodeid` is used and a node ID is specified in the connection string, then the MySQL server cannot connect to the cluster.

Beginning with MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4, the `--ndb-nodeid` option overrides any node ID set with `--ndb-connectstring`, regardless of the order in which the two options are used.
In addition (regardless of the MySQL Cluster version), if `--ndb-nodeid` is used, then either a matching node ID must be found in a `[mysqld]` or `[api]` section of `config.ini`, or there must be an “open” `[mysqld]` or `[api]` section in the file (that is, a section without a `NodeID` or `Id` parameter specified). This is also true if the node ID is specified as part of the connection string.

Regardless of how the node ID is determined, its is shown as the value of the global status variable `Ndb_cluster_node_id` in the output of `SHOW STATUS`, and as `cluster_node_id` in the `connection` row of the output of `SHOW ENGINE NDBCLUSTER STATUS`.

For more information about node IDs for MySQL Cluster SQL nodes, see Section 17.3.3.7, “Defining SQL and Other API Nodes in a MySQL Cluster”.

• `--ndb_optimization_delay=milliseconds`

<table>
<thead>
<tr>
<th>Command Line</th>
<th>System Variable</th>
<th>Status Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option File</td>
<td>Scope</td>
<td>Dynamic</td>
</tr>
<tr>
<td>From Version</td>
<td>Type</td>
<td>Default, Range</td>
</tr>
<tr>
<td>Notes</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>ndb_optimization_delay</code></td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>No</td>
<td>Global</td>
<td>Yes</td>
</tr>
<tr>
<td>MySQL 5.1</td>
<td>integer</td>
<td>10 / 0 - 100000</td>
</tr>
</tbody>
</table>

DESCRIPTION: Sets the number of milliseconds to wait between processing sets of rows by `OPTIMIZE TABLE` statements on `NDB` tables.

Set the number of milliseconds to wait between sets of rows by `OPTIMIZE TABLE` statements on `NDB` tables. The default is 10.

• `ndb-transid-mysql-connection-map=state`

<table>
<thead>
<tr>
<th>Command Line</th>
<th>System Variable</th>
<th>Status Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option File</td>
<td>Scope</td>
<td>Dynamic</td>
</tr>
<tr>
<td>From Version</td>

<td></td>
</tr>
<tr>
<td><code>ndb-transid-mysql-connection-map</code></td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>No</td>
<td></td>
<td></td>
</tr>
<tr>
<td>MySQL 5.1</td>
<td>enumeration</td>
<td>ON / ON, OFF, FORCE</td>
</tr>
</tbody>
</table>

DESCRIPTION: Enable or disable the `ndb_transid_mysql_connection_map` plugin; that is, enable or disable the `INFORMATION_SCHEMA` table having that name.

Enables or disables the plugin that handles the `ndb_transid_mysql_connection_map` table in the `INFORMATION_SCHEMA` database. Takes one of the values `ON`, `OFF`, or `FORCE`. `ON` (the default) enables the plugin. `OFF` disables the plugin, which makes `ndb_transid_mysql_connection_map` inaccessible. `FORCE` keeps the MySQL Server from starting if the plugin fails to load and start.
You can see whether the `ndb_transid_mysql_connection_map` table plugin is running by checking the output of `SHOW PLUGINS`.

This option was added in MySQL Cluster NDB 7.1.17.

• `--ndb-wait-connected=seconds`

Table 17.26 Type and value information for ndb-wait-connected

<table>
<thead>
<tr>
<th>Command Line</th>
<th>System Variable</th>
<th>Status Variable</th>
</tr>
</thead>

<td>integer</td>
<td>0 / 0 - 31536000</td>
<td></td>
</tr>
</tbody>
</table>

**DESCRIPTION:** Time (in seconds) for the MySQL server to wait for connection to cluster management and data nodes before accepting MySQL client connections.

This option sets the period of time that the MySQL server waits for connections to MySQL Cluster management and data nodes to be established before accepting MySQL client connections. The time is specified in seconds.

Prior to MySQL Cluster NDB 7.0.27 and MySQL Cluster NDB 7.1.16, there existed a hard-coded 30-second timeout (which was removed in these versions), and the default value for this option was 0. Starting with these releases, the default value is 30, and user-supplied values are handled correctly. (Bug #12543299)

• `--ndb-wait-setup=seconds`

Table 17.27 Type and value information for ndb-wait-setup

<td>integer</td>
<td>15 / 0 - 31536000</td>
<td></td>
</tr>
</tbody>
</table>

**DESCRIPTION:** Time (in seconds) for the MySQL server to wait for NDB engine setup to complete.

This variable shows the period of time that the MySQL server waits for the NDB storage engine to complete setup before timing out and treating NDB as unavailable. The time is specified in seconds.
Prior to MySQL Cluster NDB 7.0.27 and MySQL Cluster NDB 7.1.16, the default value for this option was 15. In these and later releases, the default value is 30. (Bug #12543299)

- `--server-id-bits=#`

**Table 17.28 Type and value information for server-id-bits**

<table>
<thead>
<tr>
<th>Command Line</th>
<th>System Variable</th>

<td>Global</td>
<td>No</td>
<td></td>
</tr>
<tr>
<td>MySQL 5.1</td>
<td>integer</td>
<td>32 / 7 - 32</td>
<td></td>
</tr>
</tbody>
</table>

DESCRIPTION: Sets the number of least significant bits in the server_id actually used for identifying the server, permitting NDB API applications to store application data in the most significant bits. server_id must be less than 2 to the power of this value.

This option indicates the number of least significant bits within the 32-bit server_id which actually identify the server. Indicating that the server is actually identified by fewer than 32 bits makes it possible for some of the remaining bits to be used for other purposes, such as storing user data generated by applications using the NDB API's Event API within the AnyValue of an OperationOptions structure (MySQL Cluster uses the AnyValue to store the server ID).

When extracting the effective server ID from server_id for purposes such as detection of replication loops, the server ignores the remaining bits. The `--server-id-bits` option is used to mask out any irrelevant bits of server_id in the IO and SQL threads when deciding whether an event should be ignored based on the server ID.

This data can be read from the binary log by mysqlbinlog, provided that it is run with its own `--server-id-bits` option set to 32 (the default).

The value of server_id must be less than $2^{server_id_bits}$; otherwise, mysqld refuses to start.

This system variable was added in MySQL Cluster NDB 7.0.17 and MySQL Cluster NDB 7.1.6; it is supported only in these and later releases of MySQL Cluster. It is not supported by the standard MySQL Server.

- `--skip-ndbcluster`

<tbody>
<tr>
<td>Yes</td>
<td>No</td>
<td></td>
</tr>
</tbody>
</table>

DESCRIPTION: Disable the NDB Cluster storage engine
Disable the NDBCLUSTER storage engine. This is the default for binaries that were built with NDBCLUSTER storage engine support; the server allocates memory and other resources for this storage engine only if the --ndbcluster option is given explicitly. See Section 17.3.1, “Quick Test Setup of MySQL Cluster”, for an example.

MySQL Cluster System Variables

This section provides detailed information about MySQL server system variables that are specific to MySQL Cluster and the NDB storage engine. For system variables not specific to MySQL Cluster, see Section 5.1.4, “Server System Variables”. For general information on using system variables, see Section 5.1.5, “Using System Variables”.

• have_ndbcluster

<td>integer</td>
<td>1 / 1 - 65536</td>
</tr>
</tbody>
</table>
Determines the probability of gaps in an autoincremented column. Set it to 1 to minimize this. Setting it to a high value for optimization makes inserts faster, but decreases the likelihood that consecutive autoincrement numbers will be used in a batch of inserts. The minimum value is 1. Prior to MySQL 5.1.23, MySQL Cluster NDB 6.2.9, and MySQL Cluster NDB 6.3.7, the default value was 32; in these and all later versions, the default is 1. Prior to MySQL Cluster NDB 6.3.31 and MySQL Cluster NDB 7.0.11, the maximum value was 256; in these and all later versions of MySQL Cluster (including all MySQL Cluster NDB 7.1 releases), the maximum is 65536 (Bug #50621).

Beginning with MySQL Cluster NDB 6.2.10, MySQL Cluster NDB 6.3.7, and MySQL 5.1.23, this variable affects the number of `AUTO_INCREMENT` IDs that are fetched between statements only. Within a statement, at least 32 IDs are now obtained at a time. Also beginning with these releases, the default value is 1. (Bug #31956)

```
Important
This variable does not affect inserts performed using `INSERT ... SELECT`.
```

* `ndb_cache_check_time`

### Table 17.32 Type and value information for `ndb_cache_check_time`

<table>

<td></td>
</tr>
</tbody>
</table>

`ndb_cache_check_time`

Yes Yes No
Yes Global Yes
MySQL 5.1 integer 0 /

DESCRIPTION: Number of milliseconds between checks of cluster SQL nodes made by the MySQL query cache

The number of milliseconds that elapse between checks of MySQL Cluster SQL nodes by the MySQL query cache. Setting this to 0 (the default and minimum value) means that the query cache checks for validation on every query.

The recommended maximum value for this variable is 1000, which means that the check is performed once per second. A larger value means that the check is performed and possibly invalidated due to updates on different SQL nodes less often. It is generally not desirable to set this to a value greater than 2000.

* `ndb_deferred_constraints`
MySQL Cluster Configuration Files

</table>

**Notes**

- **ndb_deferred_constraints**
  - Yes
  - Yes
  - No
  - Yes
  - Both
  - integer
  - 0 / 0 - 1

**DESCRIPTION:** Specifies that constraint checks should be deferred (where these are supported). Not normally needed or used; for testing purposes only.

Controls whether or not constraint checks are deferred, where these are supported. 0 is the default.

This variable was added in MySQL Cluster NDB 7.0.28 and MySQL Cluster NDB 7.1.14.

This variable is not normally needed for operation of MySQL Cluster or MySQL Cluster Replication, and is intended primarily for use in testing.

DESCRIPTION: Controls logging of MySQL Cluster schema, connection, and data distribution events in the MySQL error log.

This variable enables recording in the MySQL error log of information specific to the NDB storage engine.

When this variable is set to 0, the only information specific to NDB that is written to the MySQL error log relates to transaction handling. If it set to a value greater than 0 but less than 10, NDB table schema and connection events are also logged, as well as whether or not conflict resolution is in use, and other NDB errors and information. If the value is set to 10 or more, information about NDB internals, such as the progress of data distribution among cluster nodes, is also written to the MySQL error log.

This variable was added in MySQL 5.1.6. Prior to MySQL Cluster NDB 6.3, the default value was 0; in MySQL Cluster NDB 6.3.0 and later, the default is 1.

• ndb_force_send
Table 17.37 Type and value information for ndb_force_send

Notes

ndb_index_stat_cache_entries
Yes | Yes | No
Yes | Both | Yes
MySQL 5.1 | integer | 32 / 0 - 4294967295

DESCRIPTION: Sets the granularity of the statistics by determining the number of starting and ending keys.

Sets the granularity of the statistics by determining the number of starting and ending keys to store in the statistics memory cache. Zero means no caching takes place; in this case, the data nodes are always queried directly. Default value: 32.

Note

If ndb_index_stat_enable is OFF, then setting this variable has no effect.

This variable is deprecated as of MySQL 5.1.19, and is removed from MySQL Cluster NDB 7.1.31 and later.

</tr>
</tbody>
</table>

**DESCRIPTION:** Comma-separated list of tunable options for NDB index statistics; the list should contain no spaces

This variable is used for providing tuning options for NDB index statistics generation. The list consist of comma-separated name-value pairs of option names and values. Note that this list must not contain any space characters.

Options not used when setting **ndb_index_stat_option** are not changed from their default values. For example, you can set **ndb_index_stat_option = 'loop_idle=1000ms,cache_limit=32M'**.

Time values can be optionally suffixed with **h** (hours), **m** (minutes), or **s** (seconds). Millisecond values can optionally be specified using **ms**; millisecond values cannot be specified using **h**, **m**, or **s**. Integer values can be suffixed with **K**, **M**, or **G**.

The names of the options that can be set using this variable are shown in the table that follows. The table also provides brief descriptions of the options, their default values, and (where applicable) their minimum and maximum values.

**Notes**

- MySQL 5.1: integer
  - 20 / 0 - 4294967295

**DESCRIPTION:** How often to query data nodes instead of the statistics cache.

How often to query data nodes instead of the statistics cache. For example, a value of 20 (the default) means to direct every 20th query to the data nodes.

**Note**

If `ndb_index_stat_cache_entries` is 0, then setting this variable has no effect; in this case, every query is sent directly to the data nodes.

This variable is deprecated as of MySQL 5.1.19, and is removed from MySQL Cluster NDB 7.1.31 and later.

- **ndb_join_pushdown**

**Table 17.42 Type and value information for ndb_join_pushdown**

<table>
<thead>
<tr>
<th>Command Line</th>
<th>System Variable</th>
<th>Status Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option File</td>
<td>Scope</td>
<td>Dynamic</td>
</tr>
<tr>
<td>From Version</td>

<td>Default, Range</td>
</tr>
</tbody>
</table>

**Notes**

- ndb_join_pushdown
  - No
  - Yes
  - No
  - Both
  - 5.1.51-ndb-7.2.0

**DESCRIPTION:** Enables pushing down of joins to data nodes.

Added in MySQL Cluster NDB 7.2.0, this variable controls whether joins on NDB tables are pushed down to the NDB kernel (data nodes). Previously, a join was handled using multiple accesses of NDB by the SQL node; however, when `ndb_join_pushdown` is enabled, a pushable join is sent in its entirety to the data nodes, where it can be distributed among the data nodes and executed in parallel on multiple copies of the data, with a single, merged result being returned to `mysqld`. This can reduce greatly the number of round trips between an SQL node and the data nodes required to handle such a join.

By default, `ndb_join_pushdown` is enabled.

**Conditions for NDB pushdown joins.** In order for a join to be pushable, it must meet the following conditions:

1. Only columns can be compared, and all columns to be joined must use exactly the same data type.

   This means that expressions such as `t1.a = t2.a + constant` cannot be pushed down, and that (for example) a join on an INT column and a BIGINT column also cannot be pushed down.

2. Queries referencing BLOB or TEXT columns are not supported.
3. Explicit locking is not supported; however, the NDB storage engine’s characteristic implicit row-based locking is enforced.

This means that a join using FOR UPDATE cannot be pushed down.

4. In order for a join to be pushed down, child tables in the join must be accessed using one of the ref, eq_ref, or const access methods, or some combination of these methods.

Outer joined child tables can only be pushed using eq_ref.

If the root of the pushed join is an eq_ref or const, only child tables joined by eq_ref can be appended. (A table joined by ref is likely to become the root of another pushed join.)

If the query optimizer decides on Using join cache for a candidate child table, that table cannot be pushed as a child. However, it may be the root of another set of pushed tables.

5. Joins referencing tables explicitly partitioned by [LINEAR] HASH, LIST, or RANGE currently cannot be pushed down.

You can see whether a given join can be pushed down by checking it with EXPLAIN; when the join can be pushed down, you can see references to the pushed join in the Extra column of the output, as shown in this example:

```
mysql> EXPLAIN
    
--- SELECT e.first_name, e.last_name, t.title, d.dept_name
    
FROM employees e
    
JOIN dept_emp de ON e.emp_no=de.emp_no
    
JOIN departments d ON d.dept_no=de.dept_no
    
JOIN titles t ON e.emp_no=t.emp_no

*************************** 1. row ***************************
    id: 1
    select_type: SIMPLE
    table: d
    type: ALL
    possible_keys: PRIMARY
    key: NULL
    key_len: NULL
    ref: NULL
    rows: 9
    Extra: Parent of 4 pushed join@1

*************************** 2. row ***************************
    id: 1
    select_type: SIMPLE
    table: de
    type: ref
    possible_keys: PRIMARY,emp_no,dept_no
    key: dept_no
    key_len: 4
    ref: employees.d.dept_no
    rows: 5305
    Extra: Child of 'd' in pushed join@1

*************************** 3. row ***************************
    id: 1
    select_type: SIMPLE
    table: e
    type: eq_ref
    possible_keys: PRIMARY
    key: PRIMARY
    key_len: 4
    ref: employees.de.emp_no
    rows: 1
    Extra: Child of 'de' in pushed join@1

*************************** 4. row ***************************
    id: 1
    select_type: SIMPLE
    table: t
```
Note

If inner joined child tables are joined by ref, and the result is ordered or grouped by a sorted index, this index cannot provide sorted rows, which forces writing to a sorted tempfile.

Two additional sources of information about pushed join performance are available:

1. The status variables `Ndb_pushed_queries_defined`, `Ndb_pushed_queries_dropped`, `Ndb_pushed_queries_executed`, and `Ndb_pushed_reads` (all introduced in MySQL Cluster NDB 7.2.0).

2. The counters in the `ndbinfo.counters` table that belong to the DBSPJ kernel block. (These counters and the DBSPJ block were also introduced in MySQL Cluster NDB 7.2.0). See Section 17.5.10.7, “The ndbinfo counters Table”, for information about these counters. See also The DBSPJ Block, in the MySQL Cluster API Developer Guide.

• **ndb_log_apply_status**

Table 17.43  Type and value information for ndb_log_apply_status

</table>

DESCRIPTION: Write updates to NDB tables in the binary log. Effective only if binary logging is enabled with --log-bin.

Causes updates to NDB tables to be written to the binary log. Setting this variable has no effect if binary logging is not already enabled for the server using log_bin. ndb_log_bin defaults to 1 (ON); normally, there is never any need to change this value in a production environment.

This variable was added in MySQL 5.1.6.

- ndb_log_binlog_index

**Table 17.45 Type and value information for ndb_log_binlog_index**

<table>
<thead>
<tr>
<th>Command Line</th>
<th>System Variable</th>
<th>Status Variable</th>

</tr>
<tr>
<td>MySQL 5.1</td>
<td>boolean</td>
<td>ON</td>
</tr>
</tbody>
</table>

DESCRIPTION: Insert mapping between epochs and binary log positions into the ndb_binlog_index table. Defaults to ON. Effective only if binary logging is enabled on the server.

Causes a mapping of epochs to positions in the binary log to be inserted into the ndb_binlog_index table. Setting this variable has no effect if binary logging is not already enabled for the server using log_bin. (In addition, ndb_log_bin must not be disabled.) ndb_log_binlog_index defaults to 1 (ON); normally, there is never any need to change this value in a production environment.

This variable was added in MySQL 5.1.6.

<th>ndb_log_transaction_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>No</td>
</tr>
<tr>
<td>No</td>
</tr>
<tr>
<td>MySQL 5.1</td>
</tr>
</tbody>
</table>

DESCRIPTION: Whether NDB transaction IDs are written into the binary log. (Read-only.)

This read-only, Boolean system variable shows whether a slave `mysqld` writes NDB transaction IDs in the binary log (required to use “active-active” MySQL Cluster Replication with NDB `$EPOCH_TRANS()` conflict detection). To change the setting, use the `--ndb-log-transaction-id` option.
ndb_log_transaction_id is available in MySQL Cluster NDB 7.1.16 and later. It is not supported in mainline MySQL Server 5.1.

For more information, see Section 17.6.11, “MySQL Cluster Replication Conflict Resolution”.

• ndb_optimized_node_selection

<table>

</tr>
<tr>
<td>MySQL 5.1</td>
</tr>
<tr>
<td>5.1.22-ndb-6.3.4</td>
</tr>
</tbody>
</table>

DESCRIPTION: Determines how an SQL node chooses a cluster data node to use as transaction coordinator

Prior to MySQL Cluster NDB 6.3.4. Causes an SQL node to use the “closest” data node as transaction coordinator. Enabled by default. Set to 0 or OFF to disable, in which case the SQL node uses each data node in the cluster in succession. When this option is disabled each SQL thread attempts to use a given data node 8 times before proceeding to the next one.

Beginning with MySQL Cluster NDB 6.3.4. There are two forms of optimized node selection, described here:

1. The SQL node uses proximity to determine the transaction coordinator; that is, the “closest” data node to the SQL node is chosen as the transaction coordinator. For this purpose, a data node having a shared memory connection with the SQL node is considered to be “closest” to the SQL node; the next closest (in order of decreasing proximity) are: TCP connection to localhost; SCI connection; TCP connection from a host other than localhost.

2. The SQL thread uses distribution awareness to select the data node. That is, the data node housing the cluster partition accessed by the first statement of a given transaction is used as the transaction coordinator for the entire transaction. (This is effective only if the first statement of the transaction accesses no more than one cluster partition.)

This option takes one of the integer values 0, 1, 2, or 3. 3 is the default. These values affect node selection as follows:

• 0: Node selection is not optimized. Each data node is employed as the transaction coordinator 8 times before the SQL thread proceeds to the next data node. (This is the same “round-robin” behavior as caused by setting this option to 0 or OFF in previous versions of MySQL Cluster.)

• 1: Proximity to the SQL node is used to determine the transaction coordinator. (This is the same behavior as caused by setting this option to 1 or ON in previous MySQL versions.)

• 2: Distribution awareness is used to select the transaction coordinator. However, if the first statement of the transaction accesses more than one cluster partition, the SQL node reverts to the round-robin behavior seen when this option is set to 0.
MySQL Cluster Configuration Files

• **3**: If distribution awareness can be employed to determine the transaction coordinator, then it is used; otherwise proximity is used to select the transaction coordinator. (This is the default behavior in MySQL Cluster NDB 6.3.4 and later.)

![Important]

Beginning with MySQL Cluster NDB 6.3.4, it is no longer possible to set `--ndb_optimized_node_selection` to ON or OFF; attempting to do so causes `mysqld` to abort with an error.

• **ndb_report_thresh_binlog_epoch_slip**

Table 17.50 Type and value information for ndb_report_thresh_binlog_epoch_slip

<table>
<thead>
<tr>
<th>Command Line</th>
<th>System Variable</th>
<th>Status Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>ndb_report_thresh_binlog_epoch_slip</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

This is a threshold on the number of epochs to be behind before reporting binary log status. For example, a value of 3 (the default) means that if the difference between which epoch has been received from the storage nodes and which epoch has been applied to the binary log is 3 or more, a status message is sent to the cluster log.

• **ndb_report_thresh_binlog_mem_usage**

Table 17.51 Type and value information for ndb_report_thresh_binlog_mem_usage

<table>
<thead>
<tr>
<th>Command Line</th>
<th>System Variable</th>
<th>Status Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>ndb_report_thresh_binlog_mem_usage</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

This is a threshold on the percentage of free memory remaining before reporting binary log status. For example, a value of 10 (the default) means that if the amount of available memory for receiving binary log data from the data nodes falls below 10%, a status message is sent to the cluster log.

• **ndb_table_no_logging**
Table 17.52  Type and value information for ndb_table_no_logging

<table>
<thead>
<tr>
<th>Command Line</th>
<th>System Variable</th>
<th>Status Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option File</td>
<td>Scope</td>
<td>Dynamic</td>
</tr>
<tr>
<td>From Version</td>
<td>Type</td>
<td>Default, Range</td>
</tr>
</tbody>
</table>

Notes

ndb_table_no_logging

No  Yes  No
No  Session  Yes
MySQL 5.1  boolean  FALSE

DESCRIPTION: NDB tables created when this setting is enabled are not checkpointed to disk (although table schema files are created). The setting in effect when the table is created with or altered to use NDBCLUSTER persists for the lifetime of the table.

When this variable is set to ON or 1, it causes NDB tables not to be checkpointed to disk. More specifically, this setting applies to tables which are created or altered using ENGINE NDB when ndb_table_no_logging is enabled, and continues to apply for the lifetime of the table, even if ndb_table_no_logging is later changed. Suppose that A, B, C, and D are tables that we create (and perhaps also alter), and that we also change the setting for ndb_table_no_logging as shown here:

```
SET @@ndb_table_no_logging = 1;
CREATE TABLE A ... ENGINE NDB;
CREATE TABLE B ... ENGINE MYISAM;
CREATE TABLE C ... ENGINE MYISAM;
ALTER TABLE B ENGINE NDB;
SET @@ndb_table_no_logging = 0;
CREATE TABLE D ... ENGINE NDB;
ALTER TABLE C ENGINE NDB;
SET @@ndb_table_no_logging = 1;
```

After the previous sequence of events, tables A and B are not checkpointed; A was created with ENGINE NDB and B was altered to use NDB, both while ndb_table_no Logging was enabled. However, tables C and D are logged; C was altered to use NDB and D was created using ENGINE NDB, both while ndb_table_no_logging was disabled. Setting ndb_table_no_logging back to 1 or ON does not cause table C or D to be checkpointed.

Note

ndb_table_no_logging has no effect on the creation of NDB table schema files; to suppress these, use ndb_table_temporary instead.

• ndb_table_temporary
Table 17.53  Type and value information for ndb_table_temporary

<table>
<thead>
<tr>
<th>Command Line</th>
<th>System Variable</th>
<th>Status Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option File</td>
<td>Scope</td>
<td>Dynamic</td>
</tr>
<tr>
<td>From Version</td>
<td>Type</td>
<td>Default, Range</td>
</tr>
</tbody>
</table>

Notes

ndb_table_temporary
No | Yes | No
No | Session | Yes
MySQL 5.1 | boolean | FALSE

DESCRIPTION: NDB tables are not persistent on disk: no schema files are created and the tables are not logged

When set to ON or 1, this variable causes NDB tables not to be written to disk: This means that no table schema files are created, and that the tables are not logged.

Note

Setting this variable currently has no effect in MySQL Cluster NDB 7.0 and later. This is a known issue; see Bug #34036.

- ndb_use_copying_alter_table

Table 17.54  Type and value information for ndb_use_copying_alter_table

<td>Type</td>
<td>Default, Range</td>
</tr>
</tbody>
</table>

Notes

\textit{ndb\_use\_exact\_count}

No Yes No
No Both Yes
MySQL 5.1 boolean ON
5.1.47-ndb-7.1.8 boolean OFF

DESCRIPTION: Use exact row count when planning queries

Forces NDB to use a count of records during \texttt{SELECT COUNT(*)} query planning to speed up this type of query. Prior to MySQL Cluster NDB 7.1.7, the default value for this variable was ON. Starting with MySQL Cluster NDB 7.1.8, the value of \textit{ndb\_use\_exact\_count} defaults to OFF, which allows for faster queries overall.

- \textit{ndb\_use\_transactions}
Table 17.58  Type and value information for ndb_use_transactions

<table>
<thead>
<tr>
<th>Command Line</th>
<th>System Variable</th>
<th>Status Variable</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</thead>
<tbody>
<tr>
<td>Option File</td>
<td>Scope</td>
<td>Dynamic</td>
</tr>
<tr>
<td>From Version</td>
<td>Type</td>
<td>Default, Range</td>
</tr>
</tbody>
</table>

DESCRIPTION: Forces NDB to use a count of records during SELECT COUNT(*) query planning to speed up this type of query.

You can disable NDB transaction support by setting this variable's values to OFF (not recommended). The default is ON.

Note

The setting for this variable was not honored in MySQL Cluster NDB 6.4.3 and MySQL Cluster NDB 7.0.4. (Bug #43236)

* server_id_bits

Table 17.59  Type and value information for server_id_bits

<table>
<thead>
<tr>
<th>Command Line</th>
<th>System Variable</th>
<th>Status Variable</th>
</tr>
</thead>
<tbody>
<tr>

<td>Type</td>
<td>Default, Range</td>
</tr>
</tbody>
</table>

DESCRIPTION: The effective value of server_id if the server was started with the --server-id-bits option set to a nondefault value.

The effective value of server_id if the server was started with the --server-id-bits option set to a nondefault value.

If the value of server_id is greater than or equal to 2 to the power of server_id_bits, mysqld refuses to start.

This system variable was added in MySQL Cluster NDB 7.0.17 and MySQL Cluster NDB 7.1.6; it is supported only in these and later releases of MySQL Cluster. server_id_bits is not supported by the standard MySQL Server.

* slave_allow_batching
Table 17.60 Type and value information for slave_allow_batching

<table>
<thead>
<tr>
<th>Command Line</th>
<th>System Variable</th>
<th>Status Variable</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</thead>
<tbody>
<tr>
<td>Yes</td>
<td>Global</td>
<td>Yes</td>
</tr>
<tr>
<td>MySQL 5.1</td>
<td>boolean</td>
<td>off</td>
</tr>
</tbody>
</table>

**DESCRIPTION:** Turns update batching on and off for a replication slave

Whether or not batched updates are enabled on MySQL Cluster replication slaves.

This variable is available beginning with MySQL Cluster NDB 6.2.3. It is available for `mysqld` only as supplied with MySQL Cluster or built from the MySQL Cluster sources. For more information, see Section 17.6.6, “Starting MySQL Cluster Replication (Single Replication Channel)".

- transaction_allow_batching

Table 17.61 Type and value information for transaction_allow_batching

<table>
<thead>
<tr>
<th>Command Line</th>
<th>System Variable</th>
<th>Status Variable</th>
</tr>
</thead>
<tbody>
<tr>

<th>Yes</th>
<th>No</th>
</tr>
</thead>
<tbody>
<tr>
<td>No</td>
<td>Session</td>
<td>Yes</td>
</tr>
<tr>
<td>MySQL 5.1</td>
<td>boolean</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

**DESCRIPTION:** Allows batching of statements within a transaction. Disable AUTOCOMMIT to use.

When set to 1 or ON, this variable enables batching of statements within the same transaction. To use this variable, autocommit must first be disabled by setting it to 0 or OFF; otherwise, setting transaction_allow_batching has no effect.

It is safe to use this variable with transactions that performs writes only, as having it enabled can lead to reads from the “before” image. You should ensure that any pending transactions are committed (using an explicit COMMIT if desired) before issuing a SELECT.

**Important**

transaction_allow_batching should not be used whenever there is the possibility that the effects of a given statement depend on the outcome of a previous statement within the same transaction.

This variable was added in MySQL Cluster NDB 6.3.7, and is currently supported in MySQL Cluster only.

The system variables in the following list all relate to the ndbinfo information database. They were added in MySQL Cluster NDB 7.1.1.

- ndbinfo_database
MySQL Cluster Configuration Files

Table 17.62  Type and value information for ndbinfo_database

</tbody>
</table>

Notes
DESCRIPTION: The prefix to use for naming ndbinfo internal base tables

The prefix used in naming the ndbinfo database's base tables (normally hidden, unless exposed by setting `ndbinfo_show_hidden`). This is a read-only variable whose default value is "ndb$". You can start the server with the `--ndbinfo-table-prefix` option, but this merely sets the variable and does not change the actual prefix used to name the hidden base tables; the prefix itself is determined at compile time.

- ndbinfo_version

Table 17.68 Type and value information for ndbinfo_version

<table>

</table>

DESCRIPTION: The version of the ndbinfo engine; read only.

Shows the version of the `ndbinfo` engine in use; read-only.

MySQL Cluster Status Variables

This section provides detailed information about MySQL server status variables that relate to MySQL Cluster and the NDB storage engine. For status variables not specific to MySQL Cluster, and for general information on using status variables, see Section 5.1.6, “Server Status Variables”.

- Handler_discover

The MySQL server can ask the NDBCLUSTER storage engine if it knows about a table with a given name. This is called discovery. `Handler_discover` indicates the number of times that tables have been discovered using this mechanism.

- Ndb_api_event_bytes_count

The number of bytes of events received by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- Ndb_api_bytes_sent_count_session

Amount of data (in bytes) sent to the data nodes in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.  

2016
MySQL Cluster Configuration Files

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_bytes_sent_count_slave**

  Amount of data (in bytes) sent to the data nodes by this slave.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_bytes_sent_count**

  Amount of data (in bytes) sent to the data nodes by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_bytes_received_count_session**

  Amount of data (in bytes) received from the data nodes in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_bytes_received_count_slave**

  Amount of data (in bytes) received from the data nodes by this slave.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_bytes_received_count**

  Amount of data (in bytes) received from the data nodes by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_event_bytes_count.injector**

  The number of bytes of events received by the NDB binlog injector thread.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.
This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_event_data_count_injector**

  The number of row change events received by the NDB binlog injector thread.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_event_data_count**

  The number of row change events received by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_event_nondata_count_injector**

  The number of events received, other than row change events, by the NDB binary log injector thread.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_event_nondata_count**

  The number of events received, other than row change events, by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_pk_op_count_session**

  The number of operations in this client session based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_pk_op_count_slave**

  The number of operations by this slave based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.
Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_pk_op_count**

  The number of operations by this MySQL Server (SQL node) based on or using primary keys. This includes operations on blob tables, implicit unlock operations, and auto-increment operations, as well as user-visible primary key operations.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_pruned_scan_count_session**

  The number of scans in this client session that have been pruned to a single partition.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_pruned_scan_count_slave**

  The number of scans by this slave that have been pruned to a single partition.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_pruned_scan_count**

  The number of scans by this MySQL Server (SQL node) that have been pruned to a single partition.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_range_scan_count_session**

  The number of range scans that have been started in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_range_scan_count_slave**
The number of range scans that have been started by this slave.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_range_scan_count**

  The number of range scans that have been started by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_read_row_count_session**

  The total number of rows that have been read in this client session. This includes all rows read by any primary key, unique key, or scan operation made in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this mysqld.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_read_row_count_slave**

  The total number of rows that have been read by this slave. This includes all rows read by any primary key, unique key, or scan operation made by this slave.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_read_row_count**

  The total number of rows that have been read by this MySQL Server (SQL node). This includes all rows read by any primary key, unique key, or scan operation made by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_scan_batch_count_session**

  The number of batches of rows received in this client session. 1 batch is defined as 1 set of scan results from a single fragment.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this mysqld.
This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_scan_batch_count_slave**

  The number of batches of rows received by this slave. 1 batch is defined as 1 set of scan results from a single fragment.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_scan_batch_count**

  The number of batches of rows received by this MySQL Server (SQL node). 1 batch is defined as 1 set of scan results from a single fragment.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_table_scan_count_session**

  The number of table scans that have been started in this client session, including scans of internal tables.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_table_scan_count_slave**

  The number of table scans that have been started by this slave, including scans of internal tables.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_table_scan_count**

  The number of table scans that have been started by this MySQL Server (SQL node), including scans of internal tables.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_abort_count_session**
The number of transactions aborted in this client session.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_abort_count_slave**

The number of transactions aborted by this slave.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_abort_count**

The number of transactions aborted by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_close_count_session**

The number of transactions closed in this client session. This value may be greater than the sum of `Ndb_api_trans_commit_count_session` and `Ndb_api_trans_abort_count_session`, since some transactions may have been rolled back.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_close_count_slave**

The number of transactions closed by this slave. This value may be greater than the sum of `Ndb_api_trans_commit_count_slave` and `Ndb_api_trans_abort_count_slave`, since some transactions may have been rolled back.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_close_count**

The number of transactions closed by this MySQL Server (SQL node). This value may be greater than the sum of `Ndb_api_trans_commit_count` and `Ndb_api_trans_abort_count`, since some transactions may have been rolled back.
Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_commit_count_session**
  The number of transactions committed in this client session.
  
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.
  
  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_commit_count_slave**
  The number of transactions committed by this slave.
  
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.
  
  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_commit_count**
  The number of transactions committed by this MySQL Server (SQL node).
  
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.
  
  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_local_read_row_count_session**
  The total number of rows that have been read in this client session. This includes all rows read by any primary key, unique key, or scan operation made in this client session.
  
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.
  
  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_local_read_row_count_slave**
  The total number of rows that have been read by this slave. This includes all rows read by any primary key, unique key, or scan operation made by this slave.
  
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.
  
  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_local_read_row_count**
The total number of rows that have been read by this MySQL Server (SQL node). This includes all rows read by any primary key, unique key, or scan operation made by this MySQL Server (SQL node).

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_start_count_session**

  The number of transactions started in this client session.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_start_count_slave**

  The number of transactions started by this slave.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_trans_start_count**

  The number of transactions started by this MySQL Server (SQL node).

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_uk_op_count_session**

  The number of operations in this client session based on or using unique keys.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_uk_op_count_slave**

  The number of operations by this slave based on or using unique keys.

  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.
MySQL Cluster Configuration Files

- **Ndb_api_uk_op_count**
  The number of operations by this MySQL Server (SQL node) based on or using unique keys.
  Although this variable can be read using `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.
  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_wait_exec_complete_count_session**
  The number of times a thread has been blocked in this client session while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit implicit executes for blob and auto-increment operations not visible to clients.
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this mysqld.
  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_wait_exec_complete_count_slave**
  The number of times a thread has been blocked by this slave while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit implicit executes for blob and auto-increment operations not visible to clients.
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.
  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_wait_exec_complete_count**
  The number of times a thread has been blocked by this MySQL Server (SQL node) while waiting for execution of an operation to complete. This includes all `execute()` calls as well as implicit implicit executes for blob and auto-increment operations not visible to clients.
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.
  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_wait_meta_request_count_session**
  The number of times a thread has been blocked in this client session waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this mysqld.
  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_wait_meta_request_count_slave**
  The number of times a thread has been blocked by this slave waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.
Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_meta_request_count**

The number of times a thread has been blocked by this MySQL Server (SQL node) waiting for a metadata-based signal, such as is expected for DDL requests, new epochs, and seizure of transaction records.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_nanos_count_session**

Total time (in nanoseconds) spent in this client session waiting for any type of signal from the data nodes.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_nanos_count_slave**

Total time (in nanoseconds) spent by this slave waiting for any type of signal from the data nodes.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_nanos_count**

Total time (in nanoseconds) spent by this MySQL Server (SQL node) waiting for any type of signal from the data nodes.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.

This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

• **Ndb_api_wait_scan_result_count_session**

The number of times a thread has been blocked in this client session while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.

Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it relates to the current session only, and is not affected by any other clients of this `mysqld`. 
This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_wait_scan_result_count_slave**
  The number of times a thread has been blocked by this slave while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope. If this MySQL server does not act as a replication slave, or does not use NDB tables, this value is always 0.
  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_api_wait_scan_result_count**
  The number of times a thread has been blocked by this MySQL Server (SQL node) while waiting for a scan-based signal, such as when waiting for more results from a scan, or when waiting for a scan to close.
  Although this variable can be read using either `SHOW GLOBAL STATUS` or `SHOW SESSION STATUS`, it is effectively global in scope.
  This variable was added in MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11. For more information, see Section 17.5.15, “NDB API Statistics Counters and Variables”.

- **Ndb_cluster_node_id**
  If the server is acting as a MySQL Cluster node, then the value of this variable its node ID in the cluster.
  If the server is not part of a MySQL Cluster, then the value of this variable is 0.
  Prior to MySQL 5.1.12, this variable was named `Ndb_connected_host`.

- **Ndb_config_from_host**
  If the server is part of a MySQL Cluster, the value of this variable is the host name or IP address of the Cluster management server from which it gets its configuration data.
  If the server is not part of a MySQL Cluster, then the value of this variable is an empty string.
  Prior to MySQL 5.1.12, this variable was named `Ndb_connected_port`.

- **Ndb_config_from_port**
  If the server is part of a MySQL Cluster, the value of this variable is the number of the port through which it is connected to the Cluster management server from which it gets its configuration data.
  If the server is not part of a MySQL Cluster, then the value of this variable is 0.
  Prior to MySQL 5.1.12, this variable was named `Ndb_connected_port`.

- **Ndb_conflict_fn_max**
  Used in MySQL Cluster Replication conflict resolution, this variable shows the number of times that a row was not applied on the current SQL node due to “greatest timestamp wins” conflict resolution since the last time that this `mysqld` was started.
  This variable was added in MySQL Cluster NDB 6.3.3. For more information, see Section 17.6.11, “MySQL Cluster Replication Conflict Resolution”.

- **Ndb_conflict_fn_old**
MySQL Cluster Configuration Files

Used in MySQL Cluster Replication conflict resolution, this variable shows the number of times that a row was not applied as the result of "same timestamp wins" conflict resolution on a given mysqld since the last time it was restarted.

This variable was added in MySQL Cluster NDB 6.3.4. For more information, see Section 17.6.11, “MySQL Cluster Replication Conflict Resolution”.

• Ndb_conflict_fn_epoch

Used in MySQL Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using NDB$EPOCH() conflict resolution on a given mysqld since the last time it was restarted.

This variable was added in MySQL Cluster NDB 7.1.16. For more information, see Section 17.6.11, “MySQL Cluster Replication Conflict Resolution”.

• Ndb_conflict_trans

Used in MySQL Cluster Replication conflict resolution, this variable shows the number of rows found to be in conflict using NDB$EPOCH_TRANS() conflict resolution on a given mysqld since the last time it was restarted.

This variable was added in MySQL Cluster NDB 7.1.16. For more information, see Section 17.6.11, “MySQL Cluster Replication Conflict Resolution”.

• Ndb_conflict_trans_row_conflict_count

Used in MySQL Cluster Replication conflict resolution, this status variable shows the number of rows found to be directly in-conflict by a transactional conflict function on a given mysqld since the last time it was restarted.

Currently, the only transactional conflict detection function supported by MySQL Cluster is NDB$EPOCH_TRANS(), so this status variable is effectively the same as Ndb_conflict_trans_row_conflict_count.

This variable was added in MySQL Cluster NDB 7.1.16. For more information, see Section 17.6.11, “MySQL Cluster Replication Conflict Resolution”.

• Ndb_conflict_trans_row_reject_count

Used in MySQL Cluster Replication conflict resolution, this status variable shows the total number of rows realigned due to being determined as conflicting by a transactional conflict detection function. This includes not only Ndb_conflict_trans_row_conflict_count, but any rows in or dependent on conflicting transactions.

This variable was added in MySQL Cluster NDB 7.1.16. For more information, see Section 17.6.11, “MySQL Cluster Replication Conflict Resolution”.

• Ndb_conflict_trans_reject_count

Used in MySQL Cluster Replication conflict resolution, this status variable shows the number of transactions found to be in conflict by a transactional conflict detection function.

This variable was added in MySQL Cluster NDB 7.1.16. For more information, see Section 17.6.11, “MySQL Cluster Replication Conflict Resolution”.

• Ndb_conflict_trans_detect_iter_count

Used in MySQL Cluster Replication conflict resolution, this shows the number of internal iterations required to commit an epoch transaction. Should be (slightly) greater than or equal to Ndb_conflict_trans_conflict_commit_count.
This variable was added in MySQL Cluster NDB 7.1.16. For more information, see Section 17.6.11, “MySQL Cluster Replication Conflict Resolution”.

- **Ndb_conflict_trans_conflict_commit_count**

  Used in MySQL Cluster Replication conflict resolution, this shows the number of epoch transactions committed after they required transactional conflict handling.

  This variable was added in MySQL Cluster NDB 7.1.16. For more information, see Section 17.6.11, “MySQL Cluster Replication Conflict Resolution”.

- **Ndb_execute_count**

  Provides the number of round trips to the NDB kernel made by operations. Added in MySQL Cluster NDB 6.3.6.

- **Ndb_number_of_data_nodes**

  If the server is part of a MySQL Cluster, the value of this variable is the number of data nodes in the cluster.

  If the server is not part of a MySQL Cluster, then the value of this variable is 0.

  Prior to MySQL 5.1.12, this variable was named Ndb_number_of_storage_nodes.

- **Ndb_pushed_queries_defined**

  The total number of joins pushed down to the NDB kernel for distributed handling on the data nodes. Note that joins tested using EXPLAIN that can be pushed down contribute to this number. Added in MySQL Cluster NDB 7.2.0.

- **Ndb_pushed_queries_dropped**

  The number of joins that were pushed down to the NDB kernel but that could not be handled there. Added in MySQL Cluster NDB 7.2.0.

- **Ndb_pushed_queries_executed**

  The number of joins successfully pushed down to NDB and executed there. Added in MySQL Cluster NDB 7.2.0.

- **Ndb_pushed_reads**

  The number of rows returned to mysqld from the NDB kernel by joins that were pushed down. Note that executing EXPLAIN on joins that can be pushed down to NDB does not add to this number. Added in MySQL Cluster NDB 7.2.0.

- **Ndb_pruned_scan_count**

  This variable holds a count of the number of scans executed by NDBCLUSTER since the MySQL Cluster was last started where NDBCLUSTER was able to use partition pruning.

  Using this variable together with Ndb_scan_count can be helpful in schema design to maximize the ability of the server to prune scans to a single table partition, thereby involving only a single data node.

  This variable was added in MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.5.

- **Ndb_scan_count**

  This variable holds a count of the total number of scans executed by NDBCLUSTER since the MySQL Cluster was last started.
This variable was added in MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.5.

- **Slave_heartbeat_period**

  Shows the replication heartbeat interval (in seconds) on a replication slave.

  This variable was added in MySQL Cluster NDB 6.3.4.

- **Slave_received_heartbeats**

  This counter increments with each replication heartbeat received by a replication slave since the last time that the slave was restarted or reset, or a `CHANGE MASTER TO` statement was issued.

  This variable was added in MySQL Cluster NDB 6.3.4.

### 17.3.3.9 MySQL Cluster TCP/IP Connections

TCP/IP is the default transport mechanism for all connections between nodes in a MySQL Cluster. Normally it is not necessary to define TCP/IP connections; MySQL Cluster automatically sets up such connections for all data nodes, management nodes, and SQL or API nodes.

**Note**

For an exception to this rule, see Section 17.3.3.10, “MySQL Cluster TCP/IP Connections Using Direct Connections”.

To override the default connection parameters, it is necessary to define a connection using one or more `[tcp]` sections in the `config.ini` file. Each `[tcp]` section explicitly defines a TCP/IP connection between two MySQL Cluster nodes, and must contain at a minimum the parameters `NodeId1` and `NodeId2`, as well as any connection parameters to override.

It is also possible to change the default values for these parameters by setting them in the `[tcp default]` section.

**Important**

Any `[tcp]` sections in the `config.ini` file should be listed last, following all other sections in the file. However, this is not required for a `[tcp default]` section. This requirement is a known issue with the way in which the `config.ini` file is read by the MySQL Cluster management server.

Connection parameters which can be set in `[tcp]` and `[tcp default]` sections of the `config.ini` file are listed here:

- **NodeId1**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>numeric</td>
<td>[none]</td>
<td>...</td>
<td>N</td>
</tr>
</tbody>
</table>

  To identify a connection between two nodes it is necessary to provide their node IDs in the `[tcp]` section of the configuration file as the values of `NodeId1` and `NodeId2`. These are the same unique `Id` values for each of these nodes as described in Section 17.3.3.7, “Defining SQL and Other API Nodes in a MySQL Cluster”.

- **NodeId2**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>numeric</td>
<td>[none]</td>
<td>...</td>
<td>N</td>
</tr>
</tbody>
</table>
To identify a connection between two nodes it is necessary to provide their node IDs in the \[tcp\]
section of the configuration file as the values of \texttt{NodeId1} and \texttt{NodeId2}. These are the same unique \texttt{Id} values for each of these nodes as described in Section 17.3.7, “Defining SQL and Other API Nodes in a MySQL Cluster”.

- \texttt{HostName1}

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>name or IP address</td>
<td>[none]</td>
<td>...</td>
<td>N</td>
</tr>
</tbody>
</table>

The \texttt{HostName1} and \texttt{HostName2} parameters can be used to specify specific network interfaces to be used for a given TCP connection between two nodes. The values used for these parameters can be host names or IP addresses.

- \texttt{HostName2}

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>name or IP address</td>
<td>[none]</td>
<td>...</td>
<td>N</td>
</tr>
</tbody>
</table>

The \texttt{HostName1} and \texttt{HostName2} parameters can be used to specify specific network interfaces to be used for a given TCP connection between two nodes. The values used for these parameters can be host names or IP addresses.

- \texttt{OverloadLimit}

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.4.0</td>
<td>bytes</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

Beginning in MySQL Cluster NDB 6.4.0, this parameter can be used to determine the amount of unsent data that must be present in the send buffer before the connection is considered overloaded. See Section 17.3.14, “Configuring MySQL Cluster Send Buffer Parameters”, for more information.

Prior to MySQL Cluster NDB 7.0.27 and MySQL Cluster NDB 7.1.16, the effective value of this parameter was limited by the size of \texttt{SendBufferMemory}; beginning with these releases, the actual value for \texttt{OverloadLimit} (up to the stated maximum of 4G) is used instead.

- \texttt{SendBufferMemory}

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>unsigned</td>
<td>256K</td>
<td>64K - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
<tr>
<td>NDB 7.0.4</td>
<td>unsigned</td>
<td>2M</td>
<td>256K - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

TCP transporters use a buffer to store all messages before performing the send call to the operating system. When this buffer reaches 64KB its contents are sent; these are also sent when a round of messages have been executed. To handle temporary overload situations it is also possible to define a bigger send buffer.

Prior to MySQL Cluster NDB 7.0, this parameter determines a fixed amount of memory allocated at startup for each configured TCP connection. Beginning with MySQL Cluster NDB 6.4.0, if this parameter is set explicitly, then the memory is not dedicated to each transporter; instead, the value...
used denotes the hard limit for how much memory (out of the total available memory—that is, `TotalSendBufferMemory`) that may be used by a single transporter. For more information about configuring dynamic transporter send buffer memory allocation in MySQL Cluster NDB 7.0 and later, see Section 17.3.3.14, “Configuring MySQL Cluster Send Buffer Parameters”.

In MySQL Cluster NDB 6.4.3 and earlier, the default size of the send buffer was 256 KB; in MySQL Cluster NDB 7.0.4 and later, it is 2MB, which is the size recommended in most situations. The minimum size is 64 KB; the theoretical maximum is 4 GB.

- **SendSignalId**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>boolean</td>
<td>[see text]</td>
<td>true, false</td>
<td>N</td>
</tr>
</tbody>
</table>

To be able to retrace a distributed message datagram, it is necessary to identify each message. When this parameter is set to `Y`, message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- **Checksum**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>boolean</td>
<td>false</td>
<td>true, false</td>
<td>N</td>
</tr>
</tbody>
</table>

This parameter is a boolean parameter (enabled by setting it to `Y` or `1`, disabled by setting it to `N` or `0`). It is disabled by default. When it is enabled, checksums for all messages are calculated before they placed in the send buffer. This feature ensures that messages are not corrupted while waiting in the send buffer, or by the transport mechanism.

- **PortNumber** *(OBSOLETE)*

  This formerly specified the port number to be used for listening for connections from other nodes. This parameter is deprecated as of MySQL 5.1.3 and should no longer be used; use the `ServerPort` data node configuration parameter for this purpose instead.

- **ReceiveBufferMemory**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>bytes</td>
<td>64K</td>
<td>16K - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
<tr>
<td>NDB 7.0.4</td>
<td>bytes</td>
<td>2M</td>
<td>16K - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

Specifies the size of the buffer used when receiving data from the TCP/IP socket.

In MySQL Cluster NDB 6.4.3 and earlier, the default value of this parameter was 64 KB; beginning with MySQL Cluster NDB 7.0.4, 2MB is the default. The minimum possible value is 16KB; the theoretical maximum is 4GB.

- **TCP_RCV_BUF_SIZE**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.1.1</td>
<td>unsigned</td>
<td>70080</td>
<td>1 - 2G</td>
<td>N</td>
</tr>
</tbody>
</table>

Determines the size of the receive buffer set during TCP transporter initialization. The default is recommended for most common usage cases.

`TCP_RCV_BUF_SIZE` was added in MySQL Cluster NDB 6.1.1.
• **TCP_SND_BUF_SIZE**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.1.1</td>
<td>unsigned</td>
<td>71540</td>
<td>1 - 2G</td>
<td>N</td>
</tr>
</tbody>
</table>

Determines the size of the send buffer set during TCP transporter initialization. The default is recommended for most common usage cases.  

**TCP_SND_BUF_SIZE** was added in MySQL Cluster NDB 6.1.1.

• **TCP_MAXSEG_SIZE**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 6.1.1</td>
<td>unsigned</td>
<td>0</td>
<td>0 - 2G</td>
<td>N</td>
</tr>
</tbody>
</table>

Determines the size of the memory set during TCP transporter initialization. The default is recommended for most common usage cases.  

**TCP_MAXSEG_SIZE** was added in MySQL Cluster NDB 6.1.1.

• **TcpBind_INADDR_ANY**

Setting this parameter to **TRUE** or 1 binds **IP_ADDR_ANY** so that connections can be made from anywhere (for autogenerated connections). The default is **FALSE** (0).

This parameter was added in MySQL Cluster NDB 6.2.0.

### 17.3.3.10 MySQL Cluster TCP/IP Connections Using Direct Connections

Setting up a cluster using direct connections between data nodes requires specifying explicitly the crossover IP addresses of the data nodes so connected in the `[tcp]` section of the cluster `config.ini` file.

In the following example, we envision a cluster with at least four hosts, one each for a management server, an SQL node, and two data nodes. The cluster as a whole resides on the 172.23.72.* subnet of a LAN. In addition to the usual network connections, the two data nodes are connected directly using a standard crossover cable, and communicate with one another directly using IP addresses in the 1.1.0.* address range as shown:

```
# Management Server
[ndb_mgmd]
Id=1
HostName=172.23.72.20

# SQL Node
[mysqld]
Id=2
HostName=172.23.72.21

# Data Nodes
[ndbd]
Id=3
HostName=172.23.72.22

[ndbd]
Id=4
HostName=172.23.72.23

# TCP/IP Connections
[tcp]
NodeId1=3
NodeId2=4
HostName1=1.1.0.1
```
The `HostName1` and `HostName2` parameters are used only when specifying direct connections.

The use of direct TCP connections between data nodes can improve the cluster's overall efficiency by enabling the data nodes to bypass an Ethernet device such as a switch, hub, or router, thus cutting down on the cluster's latency. It is important to note that to take the best advantage of direct connections in this fashion with more than two data nodes, you must have a direct connection between each data node and every other data node in the same node group.

### 17.3.3.11 MySQL Cluster Shared-Memory Connections

MySQL Cluster attempts to use the shared memory transporter and configure it automatically where possible. `[shm]` sections in the `config.ini` file explicitly define shared-memory connections between nodes in the cluster. When explicitly defining shared memory as the connection method, it is necessary to define at least `NodeId1`, `NodeId2`, and `ShmKey`. All other parameters have default values that should work well in most cases.

---

**Important**

*SHM functionality is considered experimental only.* It is not officially supported in any current MySQL Cluster release, and testing results indicate that SHM performance is not appreciably greater than when using TCP/IP for the transporter.

For these reasons, you must determine for yourself or by using our free resources (forums, mailing lists) whether SHM can be made to work correctly in your specific case.

<table>
<thead>
<tr>
<th>NodeId1</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Effective Version</strong></td>
</tr>
<tr>
<td><strong>Type/Units</strong></td>
</tr>
<tr>
<td><strong>Default</strong></td>
</tr>
<tr>
<td><strong>Range/Values</strong></td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
</tr>
</tbody>
</table>

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

<table>
<thead>
<tr>
<th>NodeId2</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Effective Version</strong></td>
</tr>
<tr>
<td><strong>Type/Units</strong></td>
</tr>
<tr>
<td><strong>Default</strong></td>
</tr>
<tr>
<td><strong>Range/Values</strong></td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
</tr>
</tbody>
</table>

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

<table>
<thead>
<tr>
<th>HostName1</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Effective Version</strong></td>
</tr>
<tr>
<td><strong>Type/Units</strong></td>
</tr>
<tr>
<td><strong>Default</strong></td>
</tr>
<tr>
<td><strong>Range/Values</strong></td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
</tr>
</tbody>
</table>

The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given SHM connection between two nodes. The values used for these parameters can be host names or IP addresses.

<table>
<thead>
<tr>
<th>HostName2</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Effective Version</strong></td>
</tr>
<tr>
<td><strong>Type/Units</strong></td>
</tr>
<tr>
<td><strong>Default</strong></td>
</tr>
<tr>
<td><strong>Range/Values</strong></td>
</tr>
<tr>
<td><strong>Restart Type</strong></td>
</tr>
</tbody>
</table>
The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given SHM connection between two nodes. The values used for these parameters can be host names or IP addresses.

- **OverloadLimit**

Beginning in MySQL Cluster NDB 6.4.0, this parameter can be used to determine the amount of unsent data that must be present in the send buffer before the connection is considered overloaded. See Section 17.3.3.14, “Configuring MySQL Cluster Send Buffer Parameters”, for more information.

Prior to MySQL Cluster NDB 7.0.27 and MySQL Cluster NDB 7.1.16, the effective value of this parameter was limited by the size of `SendBufferMemory`; beginning with these releases, the actual value for `OverloadLimit` (up to the stated maximum) is used instead.

- **ShmKey**

When setting up shared memory segments, a node ID, expressed as an integer, is used to identify uniquely the shared memory segment to use for the communication. There is no default value.

- **ShmSize**

Each SHM connection has a shared memory segment where messages between nodes are placed by the sender and read by the reader. The size of this segment is defined by `ShmSize`. The default value is 1MB.

- **SendSignalId**

To retrace the path of a distributed message, it is necessary to provide each message with a unique identifier. Setting this parameter to `Y` causes these message IDs to be transported over the network as well. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- **Checksum**
This parameter is a boolean (Y/N) parameter which is disabled by default. When it is enabled, checksums for all messages are calculated before being placed in the send buffer.

This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

- **SigNum**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>unsigned</td>
<td>[none]</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

When using the shared memory transporter, a process sends an operating system signal to the other process when there is new data available in the shared memory. Should that signal conflict with an existing signal, this parameter can be used to change it. This is a possibility when using SHM due to the fact that different operating systems use different signal numbers.

The default value of **SigNum** is 0; therefore, it must be set to avoid errors in the cluster log when using the shared memory transporter. Typically, this parameter is set to 10 in the [shm default] section of the config.ini file.

### 17.3.3.12 SCI Transport Connections in MySQL Cluster

[sci] sections in the config.ini file explicitly define SCI (Scalable Coherent Interface) connections between cluster nodes. Using SCI transporters in MySQL Cluster is supported only when the MySQL binaries are built using `--with-ndb-sci=your/path/to/SCI`. The path should point to a directory that contains at a minimum lib and include directories containing SISCI libraries and header files. (See Section 17.3.4, “Using High-Speed Interconnects with MySQL Cluster” for more information about SCI.)

In addition, SCI requires specialized hardware.

It is strongly recommended to use SCI Transporters only for communication between ndbd processes. Note also that using SCI Transporters means that the ndbd processes never sleep. For this reason, SCI Transporters should be used only on machines having at least two CPUs dedicated for use by ndbd processes. There should be at least one CPU per ndbd process, with at least one CPU left in reserve to handle operating system activities.

- **NodeId1**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>numeric</td>
<td>[none]</td>
<td>...</td>
<td>N</td>
</tr>
</tbody>
</table>

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as **NodeId1** and **NodeId2**.

- **NodeId2**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>numeric</td>
<td>[none]</td>
<td>...</td>
<td>N</td>
</tr>
</tbody>
</table>

To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as **NodeId1** and **NodeId2**.

- **Host1SciId0**
MySQL Cluster Configuration Files

<table>
<thead>
<tr>
<th>MySQL Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>unsigned</td>
<td>[none]</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

This identifies the SCI node ID on the first Cluster node (identified by NodeId1).

- **Host1SciId1**

<table>
<thead>
<tr>
<th>MySQL Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>unsigned</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

It is possible to set up SCI Transporters for failover between two SCI cards which then should use separate networks between the nodes. This identifies the node ID and the second SCI card to be used on the first node.

- **Host2SciId0**

<table>
<thead>
<tr>
<th>MySQL Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>unsigned</td>
<td>[none]</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

This identifies the SCI node ID on the second Cluster node (identified by NodeId2).

- **Host2SciId1**

<table>
<thead>
<tr>
<th>MySQL Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>unsigned</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
<td>N</td>
</tr>
</tbody>
</table>

When using two SCI cards to provide failover, this parameter identifies the second SCI card to be used on the second node.

- **HostName1**

<table>
<thead>
<tr>
<th>MySQL Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>name or IP address</td>
<td>[none]</td>
<td>...</td>
<td>N</td>
</tr>
</tbody>
</table>

The **HostName1** and **HostName2** parameters can be used to specify specific network interfaces to be used for a given SCI connection between two nodes. The values used for these parameters can be host names or IP addresses.

- **HostName2**

<table>
<thead>
<tr>
<th>MySQL Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th>Restart Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.1.0</td>
<td>name or IP address</td>
<td>[none]</td>
<td>...</td>
<td>N</td>
</tr>
</tbody>
</table>

The **HostName1** and **HostName2** parameters can be used to specify specific network interfaces to be used for a given SCI connection between two nodes. The values used for these parameters can be host names or IP addresses.

- **SharedBufferSize**
Each SCI transporter has a shared memory segment used for communication between the two nodes. Setting the size of this segment to the default value of 1MB should be sufficient for most applications. Using a smaller value can lead to problems when performing many parallel inserts; if the shared buffer is too small, this can also result in a crash of the ndbd process.

• **SendLimit**

A small buffer in front of the SCI media stores messages before transmitting them over the SCI network. By default, this is set to 8KB. Our benchmarks show that performance is best at 64KB but 16KB reaches within a few percent of this, and there was little if any advantage to increasing it beyond 8KB.

• **SendSignalId**

To trace a distributed message it is necessary to identify each message uniquely. When this parameter is set to Y, message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in -debug builds.

• **Checksum**

This parameter is a boolean value, and is disabled by default. When Checksum is enabled, checksums are calculated for all messages before they are placed in the send buffer. This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

• **OverloadLimit**

When more than this many unsent bytes are in the send buffer, the connection is considered overloaded. See Section 17.3.3.14, “Configuring MySQL Cluster Send Buffer Parameters”, for more information.

### 17.3.3.13 Configuring MySQL Cluster Parameters for Local Checkpoints

The parameters discussed in Logging and Checkpointing and in Data Memory, Index Memory, and String Memory that are used to configure local checkpoints for a MySQL Cluster do not exist in isolation, but rather are very much interdependent on each other. In this section, we illustrate how these parameters—including DataMemory, IndexMemory, NoOfDiskPagesToDiskAfterRestartTUP, NoOfDiskPagesToDiskAfterRestartACC, and NoOfFragmentLogFiles—relate to one another in a working Cluster.
Important

The parameters `NoOfDiskPagesToDiskAfterRestartTUP` and `NoOfDiskPagesToDiskAfterRestartACC` were deprecated in MySQL 5.1.6. From MySQL 5.1.6 through 5.1.11, disk writes during LCPs took place at the maximum speed possible. Beginning with MySQL 5.1.12, the speed and throughput for LCPs are controlled using the parameters `DiskSyncSize`, `DiskCheckpointSpeed`, and `DiskCheckpointSpeedInRestart`. See Section 17.3.3.6, “Defining MySQL Cluster Data Nodes”.

In this example, we assume that our application performs the following numbers of types of operations per hour:

- 50000 selects
- 15000 inserts
- 15000 updates
- 15000 deletes

We also make the following assumptions about the data used in the application:

- We are working with a single table having 40 columns.
- Each column can hold up to 32 bytes of data.
- A typical `UPDATE` run by the application affects the values of 5 columns.
- No `NULL` values are inserted by the application.

A good starting point is to determine the amount of time that should elapse between local checkpoints (LCPs). It is worth noting that, in the event of a system restart, it takes 40-60 percent of this interval to execute the REDO log—for example, if the time between LCPs is 5 minutes (300 seconds), then it should take 2 to 3 minutes (120 to 180 seconds) for the REDO log to be read.

The maximum amount of data per node can be assumed to be the size of the `DataMemory` parameter. In this example, we assume that this is 2 GB. The `NoOfDiskPagesToDiskAfterRestartTUP` parameter represents the amount of data to be checkpointed per unit time—however, this parameter is actually expressed as the number of 8K memory pages to be checkpointed per 100 milliseconds. 2 GB per 300 seconds is approximately 6.8 MB per second, or 700 KB per 100 milliseconds, which works out to roughly 85 pages per 100 milliseconds.

Similarly, we can calculate `NoOfDiskPagesToDiskAfterRestartACC` in terms of the time for local checkpoints and the amount of memory required for indexes—that is, the `IndexMemory`. Assuming that we permit 512 MB for indexes, this works out to approximately 20 8-KB pages per 100 milliseconds for this parameter.

Next, we need to determine the number of REDO log files required—that is, fragment log files—the corresponding parameter being `NoOfFragmentLogFiles`. We need to make sure that there are sufficient REDO log files for keeping records for at least 3 local checkpoints (in MySQL Cluster NDB 6.3.8 and later, we need only allow for 2 local checkpoints). In a production setting, there are always uncertainties—for instance, we cannot be sure that disks always operate at top speed or with maximum throughput. For this reason, it is best to err on the side of caution, so we double our requirement and calculate a number of fragment log files which should be enough to keep records covering 6 local checkpoints (in MySQL Cluster NDB 6.3.8 and later, a number of fragment log files accommodating 4 local checkpoints should be sufficient).

It is also important to remember that the disk also handles writes to the REDO log, so if you find that the amount of data being written to disk as determined by the values of `NoOfDiskPagesToDiskAfterRestartACC` and `NoOfDiskPagesToDiskAfterRestartTUP` is approaching the amount of disk bandwidth available, you may wish to increase the time between local checkpoints.
Given 5 minutes (300 seconds) per local checkpoint, this means that we need to support writing log records at maximum speed for 6 * 300 = 1800 seconds ([MySQL Cluster NDB 6.3.8 and later: 4 * 300 = 1200 seconds]). The size of a REDO log record is 72 bytes plus 4 bytes per updated column value plus the maximum size of the updated column, and there is one REDO log record for each table record updated in a transaction, on each node where the data reside. Using the numbers of operations set out previously in this section, we derive the following:

- 50000 select operations per hour yields 0 log records (and thus 0 bytes), since SELECT statements are not recorded in the REDO log.

- 15000 DELETE statements per hour is approximately 5 delete operations per second. (Since we wish to be conservative in our estimate, we round up here and in the following calculations.) No columns are updated by deletes, so these statements consume only 5 operations * 72 bytes per operation = 360 bytes per second.

- 15000 UPDATE statements per hour is roughly the same as 5 updates per second. Each update uses 72 bytes, plus 4 bytes per column * 5 columns updated, plus 32 bytes per column * 5 columns—this works out to 72 + 20 + 160 = 252 bytes per operation, and multiplying this by 5 operation per second yields 1260 bytes per second.

- 15000 INSERT statements per hour is equivalent to 5 insert operations per second. Each insert requires REDO log space of 72 bytes, plus 4 bytes per record * 40 columns, plus 32 bytes per column * 40 columns, which is 72 + 160 + 1280 = 1512 bytes per operation. This times 5 operations per second yields 7560 bytes per second.

So the total number of REDO log bytes being written per second is approximately 0 + 360 + 1260 + 7560 = 9180 bytes. Multiplied by 1800 seconds, this yields 16524000 bytes required for REDO logging, or approximately 15.75 MB. The unit used for NoOfFragmentLogFiles represents a set of 4 16-MB log files—that is, 64 MB. Thus, the minimum value (3) for this parameter is sufficient for the scenario envisioned in this example, since 3 times 64 = 192 MB, or about 12 times what is required; the default value of 8 (or 512 MB) is more than ample in this case.

17.3.3.14 Configuring MySQL Cluster Send Buffer Parameters

Formerly, the NDB kernel used a send buffer whose size was fixed at 2MB for every node in the cluster, which was allocated when the node started. Because the size of this buffer could not be changed after the cluster was started, it was necessary to make it large enough in advance to accommodate the maximum possible load on any transporter socket. However, this was an inefficient use of memory, since much of it often went unused, and could result in large amounts of resources being wasted when scaling up to many API nodes.

Beginning with MySQL Cluster NDB 7.0, this problem is solved by employing a unified send buffer whose memory is allocated dynamically from a pool shared by all transporters. This means that the size of the send buffer can be adjusted as necessary. Configuration of the unified send buffer can accomplished by setting the following parameters:

- TotalSendBufferMemory. This parameter can be set for all types of MySQL Cluster nodes—that is, it can be set in the [ndbd], [mgm], and [api] (or [mysql]) sections of the config.ini file. It represents the total amount of memory (in bytes) to be allocated by each node for which it is set for use among all configured transporters. If set, its minimum is 256KB; the maximum is 4294967039.

To be backward-compatible with existing configurations, this parameter takes as its default value the sum of the maximum send buffer sizes of all configured transporters, plus an additional 32KB (one page) per transporter. The maximum depends on the type of transporter, as shown in the following table:

<table>
<thead>
<tr>
<th>Transporter</th>
<th>Maximum Send Buffer Size (bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>SendBufferMemory (default = 2M)</td>
</tr>
<tr>
<td>SCI</td>
<td>SendLimit (default = 8K) plus 16K</td>
</tr>
</tbody>
</table>
Using High-Speed Interconnects with MySQL Cluster

### Transporters

<table>
<thead>
<tr>
<th>Transporter</th>
<th>Maximum Send Buffer Size (bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>SHM</td>
<td>20K</td>
</tr>
</tbody>
</table>

This enables existing configurations to function in close to the same way as they did with MySQL Cluster NDB 6.3 and earlier, with the same amount of memory and send buffer space available to each transporter. However, memory that is unused by one transporter is not available to other transporters.

- **OverloadLimit.** This parameter is used in the `config.ini` file `[tcp]` section, and denotes the amount of unsent data (in bytes) that must be present in the send buffer before the connection is considered overloaded. When such an overload condition occurs, transactions that affect the overloaded connection fail with NDB API Error 1218 (Send Buffers overloaded in NDB kernel) until the overload status passes. The default value is 0, in which case the effective overload limit is calculated as `SendBufferMemory * 0.8` for a given connection. The maximum value for this parameter is 4G.

- **SendBufferMemory.** In MySQL Cluster NDB 6.3 and earlier, this TCP configuration parameter represented the amount of memory allocated at startup for each configured TCP connection. Beginning with MySQL Cluster NDB 7.0, this value denotes a hard limit for the amount of memory that may be used by a single transporter out of the entire pool specified by `TotalSendBufferMemory`. However, the sum of `SendBufferMemory` for all configured transporters may be greater than the `TotalSendBufferMemory` that is set for a given node. This is a way to save memory when many nodes are in use, as long as the maximum amount of memory is never required by all transporters at the same time.

- **ReservedSendBufferMemory.** This optional data node parameter, if set, gives an amount of memory (in bytes) that is reserved for connections between data nodes; this memory is not allocated to send buffers used for communications with management servers or API nodes. This provides a way to protect the cluster against misbehaving API nodes that use excess send memory and thus cause failures in communications internally in the NDB kernel. If set, its the minimum permitted value for this parameters is 256KB; the maximum is 4294967039.

### 17.3.4 Using High-Speed Interconnects with MySQL Cluster

Even before design of NDBCLUSTER began in 1996, it was evident that one of the major problems to be encountered in building parallel databases would be communication between the nodes in the network. For this reason, NDBCLUSTER was designed from the very beginning to permit the use of a number of different data transport mechanisms. In this Manual, we use the term transporter for these.

The MySQL Cluster codebase provides for four different transporters:

- **TCP/IP using 100 Mbps or gigabit Ethernet**, as discussed in Section 17.3.3.9, “MySQL Cluster TCP/IP Connections”.

- **Direct (machine-to-machine) TCP/IP**: although this transporter uses the same TCP/IP protocol as mentioned in the previous item, it requires setting up the hardware differently and is configured differently as well. For this reason, it is considered a separate transport mechanism for MySQL Cluster. See Section 17.3.3.10, “MySQL Cluster TCP/IP Connections Using Direct Connections”, for details.

- **Shared memory (SHM)**. For more information about SHM, see Section 17.3.3.11, “MySQL Cluster Shared-Memory Connections”.

  **Note**

  SHM is considered experimental only, and is not officially supported.

- **Scalable Coherent Interface (SCI)**, as described in the next section of this chapter, Section 17.3.3.12, “SCI Transport Connections in MySQL Cluster”.

2041
Most users today employ TCP/IP over Ethernet because it is ubiquitous. TCP/IP is also by far the best-tested transporter for use with MySQL Cluster.

We are working to make sure that communication with the ndbd process is made in “chunks” that are as large as possible because this benefits all types of data transmission.

For users who desire it, it is also possible to use cluster interconnects to enhance performance even further. There are two ways to achieve this: Either a custom transporter can be designed to handle this case, or you can use socket implementations that bypass the TCP/IP stack to one extent or another. We have experimented with both of these techniques using the SCI (Scalable Coherent Interface) technology developed by Dolphin Interconnect Solutions.

### 17.3.4.1 Configuring MySQL Cluster to use SCI Sockets

It is possible employing Scalable Coherent Interface (SCI) technology to achieve a significant increase in connection speeds and throughput between MySQL Cluster data and SQL nodes. To use SCI, it is necessary to obtain and install Dolphin SCI network cards and to use the drivers and other software supplied by Dolphin. You can get information on obtaining these, from Dolphin Interconnect Solutions. SCI SuperSocket or SCI Transporter support is available for 32-bit and 64-bit Linux, Solaris, Windows, and other platforms. See the Dolphin documentation referenced later in this section for more detailed information regarding platforms supported for SCI.

**Note**

Prior to MySQL 5.1.20, there were issues with building MySQL Cluster with SCI support (see Bug #25470), but these have been resolved due to work contributed by Dolphin. SCI Sockets are now correctly supported for MySQL Cluster hosts running recent versions of Linux using the --max builds, and versions of MySQL Cluster with SCI Transporter support can be built using either of `compile-amd64-max-sci` or `compile-pentium64-max-sci`. Both of these build scripts can be found in the BUILD directory of the MySQL Cluster source trees; it should not be difficult to adapt them for other platforms. Generally, all that is necessary is to compile MySQL Cluster with SCI Transporter support is to configure the MySQL Cluster build using `--with-ndb-sci=/opt/DIS`.

Once you have acquired the required Dolphin hardware and software, you can obtain detailed information on how to adapt a MySQL Cluster configured for normal TCP/IP communication to use SCI from the Dolphin SCI online documentation.

### 17.3.4.2 MySQL Cluster Interconnects and Performance

The ndbd process has a number of simple constructs which are used to access the data in a MySQL Cluster. We have created a very simple benchmark to check the performance of each of these and the effects which various interconnects have on their performance.

There are four access methods:

- **Primary key access.** This is access of a record through its primary key. In the simplest case, only one record is accessed at a time, which means that the full cost of setting up a number of TCP/IP messages and a number of costs for context switching are borne by this single request. In the case where multiple primary key accesses are sent in one batch, those accesses share the cost of setting up the necessary TCP/IP messages and context switches. If the TCP/IP messages are for different destinations, additional TCP/IP messages need to be set up.

- **Unique key access.** Unique key accesses are similar to primary key accesses, except that a unique key access is executed as a read on an index table followed by a primary key access on the table. However, only one request is sent from the MySQL Server, and the read of the index table is handled by ndbd. Such requests also benefit from batching.
MySQL Cluster Programs

- **Full table scan.** When no indexes exist for a lookup on a table, a full table scan is performed. This is sent as a single request to the `ndbd` process, which then divides the table scan into a set of parallel scans on all cluster `ndbd` processes. In future versions of MySQL Cluster, an SQL node will be able to filter some of these scans.

- **Range scan using ordered index.** When an ordered index is used, it performs a scan in the same manner as the full table scan, except that it scans only those records which are in the range used by the query transmitted by the MySQL server (SQL node). All partitions are scanned in parallel when all bound index attributes include all attributes in the partitioning key.

With benchmarks developed internally by MySQL for testing simple and batched primary and unique key accesses, we have found that using SCI sockets improves performance by approximately 100% over TCP/IP, except in rare instances when communication performance is not an issue. This can occur when scan filters make up most of processing time or when very large batches of primary key accesses are achieved. In that case, the CPU processing in the `ndbd` processes becomes a fairly large part of the overhead.

Using the SCI transporter instead of SCI Sockets is only of interest in communicating between `ndbd` processes. Using the SCI transporter is also only of interest if a CPU can be dedicated to the `ndbd` process because the SCI transporter ensures that this process will never go to sleep. It is also important to ensure that the `ndbd` process priority is set in such a way that the process does not lose priority due to running for an extended period of time, as can be done by locking processes to CPUs in Linux 2.6. If such a configuration is possible, the `ndbd` process will benefit by 10–70% as compared with using SCI sockets. (The larger figures will be seen when performing updates and probably on parallel scan operations as well.)

There are several other optimized socket implementations for computer clusters, including Myrinet, Gigabit Ethernet, Infiniband and the VIA interface. However, we have tested MySQL Cluster so far only with SCI sockets. See Section 17.3.4.1, “Configuring MySQL Cluster to use SCI Sockets”, for information on how to set up SCI sockets using ordinary TCP/IP for MySQL Cluster.

### 17.4 MySQL Cluster Programs

Using and managing a MySQL Cluster requires several specialized programs, which we describe in this chapter. We discuss the purposes of these programs in a MySQL Cluster, how to use the programs, and what startup options are available for each of them.

These programs include the MySQL Cluster data, management, and SQL node processes (`ndbd`, `ndbmtd`, `ndb_mgmd`, and `mysqld`) and the management client (`ndb_mgm`).

For information about using `mysqld` as a MySQL Cluster process, see Section 17.5.4, “MySQL Server Usage for MySQL Cluster”.

Other `NDB` utility, diagnostic, and example programs are included with the MySQL Cluster distribution. These include `ndb_restore`, `ndb_show_tables`, and `ndb_config`. These programs are also covered in this section.

The final portion of this section contains tables of options that are common to all the various MySQL Cluster programs.

#### 17.4.1 `ndbd` — The MySQL Cluster Data Node Daemon

`ndbd` is the process that is used to handle all the data in tables using the NDB Cluster storage engine. This is the process that empowers a data node to accomplish distributed transaction handling, node recovery, checkpointing to disk, online backup, and related tasks.

In a MySQL Cluster, a set of `ndbd` processes cooperate in handling data. These processes can execute on the same computer (host) or on different computers. The correspondences between data nodes and Cluster hosts is completely configurable.
The following table includes command options specific to the MySQL Cluster data node program `ndbd`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndbd`), see Section 17.4.26, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”.

Table 17.69 This table describes command-line options for the `ndbd` program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--initial</code></td>
<td>Perform initial start of ndbd, including cleaning the file system. Consult the documentation before using this option</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td><code>--nostart, -n</code></td>
<td>Don’t start ndbd immediately; ndbd waits for command to start from ndb_mgmd</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td><code>--daemon, -d</code></td>
<td>Start ndbd as daemon (default); override with <code>--nodaemon</code></td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td><code>--nodaemon</code></td>
<td>Do not start ndbd as daemon; provided for testing purposes</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td><code>--foreground</code></td>
<td>Run ndbd in foreground, provided for debugging purposes (implies <code>--nodaemon</code>)</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td><code>--nowait-nodes=list</code></td>
<td>Do not wait for these data nodes to start (takes comma-separated list of node IDs). Also requires <code>--ndb-nodeid</code> to be used.</td>
<td>ADDED: 5.1.9</td>
</tr>
<tr>
<td><code>--initial-start</code></td>
<td>Perform partial initial start (requires <code>--nowait-nodes</code>)</td>
<td>ADDED: 5.1.11</td>
</tr>
<tr>
<td><code>--bind-address=name</code></td>
<td>Local bind address</td>
<td>ADDED: 5.1.12</td>
</tr>
<tr>
<td><code>--install[=name]</code></td>
<td>Used to install the data node process as a Windows service. Does not apply on non-Windows platforms.</td>
<td>ADDED: NDB 7.0.16, NDB 7.1.5</td>
</tr>
<tr>
<td><code>--remove[=name]</code></td>
<td>Used to remove a data node process that was previously installed as a Windows service. Does not apply on non-Windows platforms.</td>
<td>ADDED: NDB 7.0.16, NDB 7.1.5</td>
</tr>
<tr>
<td><code>--connect-retries=#</code></td>
<td>Set the number of times to retry a connection before giving up; 0 means 1 attempt only (and no retries)</td>
<td>ADDED: NDB 7.0.36, NDB 7.1.25</td>
</tr>
<tr>
<td><code>--connect-delay=#</code></td>
<td>Time to wait between attempts to contact a management server, in seconds; 0 means do not wait between attempts</td>
<td>ADDED: NDB 7.0.36, NDB 7.1.25</td>
</tr>
</tbody>
</table>

**Note**

All of these options also apply to the multi-threaded version of this program (`ndbmtcd`, available in MySQL Cluster NDB 7.0 and later) and you may substitute “`ndbmtcd`” for “`ndbd`” wherever the latter occurs in this section.
• **--bind-address**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.12</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--bind-address=name</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type: string</td>
</tr>
</tbody>
</table>

Causes `ndbd` to bind to a specific network interface (host name or IP address). This option has no default value.

This option was added in MySQL 5.1.12.

• **--daemon, -d**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--daemon</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>Type: boolean</td>
</tr>
<tr>
<td>Default</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

Instructs `ndbd` or `ndbmtd` to execute as a daemon process. This is the default behavior. `--nodaemon` can be used to prevent the process from running as a daemon.

This option has no effect when running `ndbd` or `ndbmtd` on Windows platforms.

• **--nodaemon**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--nodaemon</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>Type: boolean</td>
</tr>
<tr>
<td>Default</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Prevents `ndbd` or `ndbmtd` from executing as a daemon process. This option overrides the `--daemon` option. This is useful for redirecting output to the screen when debugging the binary.

As of MySQL Cluster NDB 7.0.8, the default behavior for `ndbd` and `ndbmtd` on Windows is to run in the foreground, making this option unnecessary on Windows platforms, where it has no effect. (Bug #45588)

• **--foreground**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--foreground</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>Type: boolean</td>
</tr>
<tr>
<td>Default</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Causes `ndbd` or `ndbmtd` to execute as a foreground process, primarily for debugging purposes. This option implies the `--nodaemon` option.

This option has no effect when running `ndbd` or `ndbmtd` on Windows platforms.

• **--initial**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--initial</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>Type: boolean</td>
</tr>
<tr>
<td>Default</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

2045
Instructs ndbd to perform an initial start. An initial start erases any files created for recovery purposes by earlier instances of ndbd. It also re-creates recovery log files. Note that on some operating systems this process can take a substantial amount of time.

An `--initial` start is to be used only when starting the ndbd process under very special circumstances; this is because this option causes all files to be removed from the MySQL Cluster file system and all redo log files to be re-created. These circumstances are listed here:

- When performing a software upgrade which has changed the contents of any files.
- When restarting the node with a new version of ndbd.
- As a measure of last resort when for some reason the node restart or system restart repeatedly fails. In this case, be aware that this node can no longer be used to restore data due to the destruction of the data files.

Use of this option prevents the `StartPartialTimeout` and `StartPartitionedTimeout` configuration parameters from having any effect.

### Important

This option does *not* affect either of the following types of files:

- Backup files that have already been created by the affected node
- MySQL Cluster Disk Data files (see Section 17.5.12, "MySQL Cluster Disk Data Tables").

This option also has no effect on recovery of data by a data node that is just starting (or restarting) from data nodes that are already running. This recovery of data occurs automatically, and requires no user intervention in a MySQL Cluster that is running normally.

It is permissible to use this option when starting the cluster for the very first time (that is, before any data node files have been created); however, it is *not* necessary to do so.

### --initial-start

| Introduced | 5.1.11 |
| Command-Line Format | `--initial-start` |
| Permitted Values | Type: boolean Default: FALSE |

This option is used when performing a partial initial start of the cluster. Each node should be started with this option, as well as `--nowait-nodes`.

Suppose that you have a 4-node cluster whose data nodes have the IDs 2, 3, 4, and 5, and you wish to perform a partial initial start using only nodes 2, 4, and 5—that is, omitting node 3:

```sh
cshell> ndbd --ndb-nodeid=2 --nowait-nodes=3 --initial-start
cshell> ndbd --ndb-nodeid=4 --nowait-nodes=3 --initial-start
cshell> ndbd --ndb-nodeid=5 --nowait-nodes=3 --initial-start
```

Prior to MySQL 5.1.19, it was not possible to perform DDL operations involving Disk Data tables on a partially started cluster. (See Bug #24631.)

When using this option, you must also specify the node ID for the data node being started with the `--ndb-nodeid` option.
This option was added in MySQL 5.1.11.

Important
Do not confuse this option with the `--nowait-nodes` option added for ndb_mgmd in MySQL Cluster NDB 7.0.10, which can be used to enable a cluster configured with multiple management servers to be started without all management servers being online.

- `--nowait-nodes=node_id_1[, node_id_2[, ...]]`

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.9</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--nowait-nodes=list</code></td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type: string</td>
</tr>
<tr>
<td>Default</td>
<td></td>
</tr>
</tbody>
</table>

This option takes a list of data nodes which for which the cluster will not wait for before starting.

This can be used to start the cluster in a partitioned state. For example, to start the cluster with only half of the data nodes (nodes 2, 3, 4, and 5) running in a 4-node cluster, you can start each ndbd process with `--nowait-nodes=3,5`. In this case, the cluster starts as soon as nodes 2 and 4 connect, and does not wait `StartPartitionedTimeout` milliseconds for nodes 3 and 5 to connect as it would otherwise.

If you wanted to start up the same cluster as in the previous example without one ndbd (say, for example, that the host machine for node 3 has suffered a hardware failure) then start nodes 2, 4, and 5 with `--nowait-nodes=3`. Then the cluster will start as soon as nodes 2, 4, and 5 connect and will not wait for node 3 to start.

This option was added in MySQL 5.1.9.

- `--nostart,-n`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--nostart</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>Type: boolean</td>
</tr>
<tr>
<td>Default</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Instructs ndbd not to start automatically. When this option is used, ndbd connects to the management server, obtains configuration data from it, and initializes communication objects. However, it does not actually start the execution engine until specifically requested to do so by the management server. This can be accomplished by issuing the proper START command in the management client (see Section 17.5.2, "Commands in the MySQL Cluster Management Client").

- `--install[=name]`

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.47-ndb-7.1.5</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--install[=name]</code></td>
</tr>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type: string</td>
</tr>
<tr>
<td>Default</td>
<td>ndbd</td>
</tr>
</tbody>
</table>

Causes ndbd to be installed as a Windows service. Optionally, you can specify a name for the service; if not set, the service name defaults to ndbd. Although it is preferable to specify other ndbd program options in a my.ini or my.cnf configuration file, it is possible to use together with --
However, in such cases, the `--install` option must be specified first, before any other options are given, for the Windows service installation to succeed.

It is generally not advisable to use this option together with the `--initial` option, since this causes the data node file system to be wiped and rebuilt every time the service is stopped and started. Extreme care should also be taken if you intend to use any of the other `ndbd` options that affect the starting of data nodes—including `--initial-start`, `--nostart`, and `--nowait-nodes`—together with `--install`, and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

The `--install` option has no effect on non-Windows platforms.

This option became available in MySQL Cluster NDB 7.0.16 and MySQL Cluster NDB 7.1.5.

• `--remove [=name]`

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.47-ndb-7.1.5</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--remove [=name]</code></td>
</tr>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type string</td>
</tr>
<tr>
<td></td>
<td>Default ndbd</td>
</tr>
</tbody>
</table>

Causes an `ndbd` process that was previously installed as a Windows service to be removed. Optionally, you can specify a name for the service to be uninstalled; if not set, the service name defaults to `ndbd`.

The `--remove` option has no effect on non-Windows platforms.

This option became available in MySQL Cluster NDB 7.0.16 and MySQL Cluster NDB 7.1.5.

• `--connect-retries=#`

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.66-ndb-7.1.25</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--connect-retries=#</code></td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type numeric</td>
</tr>
<tr>
<td></td>
<td>Default 12</td>
</tr>
<tr>
<td></td>
<td>Min Value 0</td>
</tr>
<tr>
<td></td>
<td>Max Value 65535</td>
</tr>
</tbody>
</table>

Determines the number of times that the data node attempts to contact a management server when starting. Setting this option to -1 causes the data node to keep trying to make contact indefinitely. The default is 12 attempts. The time to wait between attempts is controlled by the `--connect-delay` option.

This option was added in MySQL Cluster NDB 7.0.36 and MySQL Cluster 7.1.25.

• `--connect-delay=#`

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.66-ndb-7.1.25</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--connect-delay=#</code></td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type numeric</td>
</tr>
<tr>
<td></td>
<td>Default 5 2048</td>
</tr>
</tbody>
</table>
Determines the time to wait between attempts to contact a management server when starting (the time between attempts is controlled by the --connect-retries option). The default is 5 attempts.

This option was added in MySQL Cluster NDB 7.0.36 and MySQL Cluster 7.1.25.

`ndbd` generates a set of log files which are placed in the directory specified by `DataDir` in the `config.ini` configuration file.

These log files are listed below. `node_id` is the node’s unique identifier. Note that `node_id` represents the node’s unique identifier. For example, `ndb_2_error.log` is the error log generated by the data node whose node ID is 2.

- `ndb_node_id_error.log` is a file containing records of all crashes which the referenced `ndbd` process has encountered. Each record in this file contains a brief error string and a reference to a trace file for this crash. A typical entry in this file might appear as shown here:

```plaintext
Date/Time: Saturday 30 July 2004 - 00:20:01
Type of error: error
Message: Internal program error (failed ndbrequire)
Fault ID: 2341
Problem data: DbtupFixAlloc.cpp
Object of reference: DBTUP (Line: 173)
ProgramName: NDB Kernel
ProcessID: 14909
TraceFile: ndb_2_trace.log.2
***EOM***
```

Listings of possible `ndbd` exit codes and messages generated when a data node process shuts down prematurely can be found in `ndbd Error Messages`.

**Important**

The last entry in the error log file is not necessarily the newest one (nor is it likely to be). Entries in the error log are not listed in chronological order; rather, they correspond to the order of the trace files as determined in the `ndb_node_id_trace.log.next` file (see below). Error log entries are thus overwritten in a cyclical and not sequential fashion.

- `ndb_node_id_trace.log.trace_id` is a trace file describing exactly what happened just before the error occurred. This information is useful for analysis by the MySQL Cluster development team.

It is possible to configure the number of these trace files that will be created before old files are overwritten. `trace_id` is a number which is incremented for each successive trace file.

- `ndb_node_id_trace.log.next` is the file that keeps track of the next trace file number to be assigned.

- `ndb_node_id_out.log` is a file containing any data output by the `ndbd` process. This file is created only if `ndbd` is started as a daemon, which is the default behavior.

- `ndb_node_id.pid` is a file containing the process ID of the `ndbd` process when started as a daemon. It also functions as a lock file to avoid the starting of nodes with the same identifier.

- `ndb_node_id_signal.log` is a file used only in debug versions of `ndbd`, where it is possible to trace all incoming, outgoing, and internal messages with their data in the `ndbd` process.
It is recommended not to use a directory mounted through NFS because in some environments this can cause problems whereby the lock on the .pid file remains in effect even after the process has terminated.

To start ndbd, it may also be necessary to specify the host name of the management server and the port on which it is listening. Optionally, one may also specify the node ID that the process is to use.

```
shell> ndbd --connect-string="nodeid=2;host=ndb_mgmd.mysql.com:1186"
```

See Section 17.3.3.3, “MySQL Cluster Connection Strings”, for additional information about this issue. Section 17.4.26, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”, describes other command-line options which can be used with ndbd. For information about data node configuration parameters, see Section 17.3.3.6, “Defining MySQL Cluster Data Nodes”.

When ndbd starts, it actually initiates two processes. The first of these is called the “angel process”; its only job is to discover when the execution process has been completed, and then to restart the ndbd process if it is configured to do so. Thus, if you attempt to kill ndbd using the Unix kill command, it is necessary to kill both processes, beginning with the angel process. The preferred method of terminating an ndbd process is to use the management client and stop the process from there.

The execution process uses one thread for reading, writing, and scanning data, as well as all other activities. This thread is implemented asynchronously so that it can easily handle thousands of concurrent actions. In addition, a watch-dog thread supervises the execution thread to make sure that it does not hang in an endless loop. A pool of threads handles file I/O, with each thread able to handle one open file. Threads can also be used for transporter connections by the transporters in the ndbd process. In a multi-processor system performing a large number of operations (including updates), the ndbd process can consume up to 2 CPUs if permitted to do so.

For a machine with many CPUs it is possible to use several ndbd processes which belong to different node groups; however, such a configuration is still considered experimental and is not supported for MySQL 5.1 in a production setting. See Section 17.1.6, “Known Limitations of MySQL Cluster”.

**17.4.2 ndbinfo_select_all — Select From ndbinfo Tables**

ndbinfo_select_all is a client program that selects all rows and columns from one or more tables in the ndbinfo database. It is included with the MySQL Cluster distribution beginning with MySQL Cluster NDB 7.1.17.

Not all ndbinfo tables can be accessed by this program. ndbinfo_select_all can access the counters, diskpagebuffer, logbuffers, logspaces, nodes, resources, threadblocks, threadstat, and transporters tables.

To select from one or more ndbinfo tables using ndbinfo_select_all, it is necessary to supply the names of the tables when invoking the program as shown here:

```
shell> ndbinfo_select_all table_name1 [table_name2] [...]
```

For example:

```
shell> ndbinfo_select_all logbuffers logspaces
== logbuffers ==
node_id log_type log_id log_part total used high
5 0 0 0 33554432 262144 0
6 0 0 0 33554432 262144 0
7 0 0 0 33554432 262144 0
8 0 0 0 33554432 262144 0
== logspaces ==
node_id log_type log_id log_part total used high
5 0 0 0 268435456 0 0
5 0 0 1 268435456 0 0
```

17.4.2 ndbinfo_select_all — Select From ndbinfo Tables

ndbinfo_select_all is a client program that selects all rows and columns from one or more tables in the ndbinfo database. It is included with the MySQL Cluster distribution beginning with MySQL Cluster NDB 7.1.17.

Not all ndbinfo tables can be accessed by this program. ndbinfo_select_all can access the counters, diskpagebuffer, logbuffers, logspaces, nodes, resources, threadblocks, threadstat, and transporters tables.

To select from one or more ndbinfo tables using ndbinfo_select_all, it is necessary to supply the names of the tables when invoking the program as shown here:

```
shell> ndbinfo_select_all table_name1 [table_name2] [...]
```

For example:

```
shell> ndbinfo_select_all logbuffers logspaces
== logbuffers ==
node_id log_type log_id log_part total used high
5 0 0 0 33554432 262144 0
6 0 0 0 33554432 262144 0
7 0 0 0 33554432 262144 0
8 0 0 0 33554432 262144 0
== logspaces ==
node_id log_type log_id log_part total used high
5 0 0 0 268435456 0 0
5 0 0 1 268435456 0 0
```

2050
The following table includes options that are specific to `ndbinfo_select_all`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndbinfo_select_all`), see Section 17.4.26, "Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs".

Table 17.70 This table describes command-line options for the ndbinfo_select_all program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--delay=#</code></td>
<td>Set the delay in seconds between loops. Default is 5.</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td><code>--loops=number</code>, <code>-l</code></td>
<td>Set the number of times to perform the select. Default is 1.</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td><code>--database=db_name, -d</code></td>
<td>Name of the database where the table located.</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td><code>--parallelism=#</code>, <code>-p</code></td>
<td>Set the degree of parallelism.</td>
<td>All MySQL 5.1 based releases</td>
</tr>
</tbody>
</table>

- **`--delay=seconds`**
  
  **Command-Line Format**
  
  `--delay=#`
  
  **Permitted Values**
  
<table>
<thead>
<tr>
<th>Type</th>
<th>numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>5</td>
</tr>
<tr>
<td>Min Value</td>
<td>0</td>
</tr>
<tr>
<td>Max Value</td>
<td>MAX_INT</td>
</tr>
</tbody>
</table>
  
  This option sets the number of seconds to wait between executing loops. Has no effect if `--loops` is set to 0 or 1.

- **`--loops=number, -l number`**
  
  **Command-Line Format**
  
  `--loops=#`
  
  **Permitted Values**
  
<table>
<thead>
<tr>
<th>Type</th>
<th>numeric</th>
</tr>

<tbody>
<tr>
<td>Default</td>
<td>1</td>
</tr>
<tr>
<td>Min Value</td>
<td>0</td>
</tr>
<tr>
<td>Max Value</td>
<td>MAX_INT</td>
</tr>
</tbody>
</table>
  
  This option sets the number of times to perform the select. Default is 1.
This option sets the number of times to execute the select. Use --delay to set the time between loops.

### 17.4.3 ndbmtd — The MySQL Cluster Data Node Daemon (Multi-Threaded)

ndbmtd is a multi-threaded version of ndbd, the process that is used to handle all the data in tables using the NDBCLUSTER storage engine. ndbmtd is intended for use on host computers having multiple CPU cores. Except where otherwise noted, ndbmtd functions in the same way as ndbd; therefore, in this section, we concentrate on the ways in which ndbmtd differs from ndbd, and you should consult Section 17.4.1, "ndbd — The MySQL Cluster Data Node Daemon", for additional information about running MySQL Cluster data nodes that apply to both the single-threaded and multi-threaded versions of the data node process.

Command-line options and configuration parameters used with ndbd also apply to ndbmtd. For more information about these options and parameters, see Section 17.4.1, "ndbd — The MySQL Cluster Data Node Daemon", and Section 17.3.3.6, "Defining MySQL Cluster Data Nodes", respectively.

ndbmtd is also file system-compatible with ndbd. In other words, a data node running ndbd can be stopped, the binary replaced with ndbmtd, and then restarted without any loss of data. (However, when doing this, you must make sure that MaxNoOfExecutionThreads is set to an appropriate value before restarting the node if you wish for ndbmtd to run in multi-threaded fashion.) Similarly, an ndbmtd binary can be replaced with ndbd simply by stopping the node and then starting ndbd in place of the multi-threaded binary. It is not necessary when switching between the two to start the data node binary using --initial.

Prior to MySQL Cluster NDB 7.0.6, there were known issues when using ndbmtd with MySQL Cluster Disk Data tables. If you wish to use multi-threaded data nodes with disk-based NDB tables, you should ensure that you are running MySQL Cluster NDB 7.0.6 or later (see Bug #41915 and Bug #44915)

Using ndbmtd differs from using ndbd in two key respects:

1. Because ndbmtd runs by default in single-threaded mode (that is, it behaves like ndbd), you must configure it to use multiple threads. This can be done by setting an appropriate value in the config.ini file for the MaxNoOfExecutionThreads configuration parameter. For more information about this parameter and its use, see Multi-Threading Configuration Parameters (ndbmtd).

2. Trace files are generated by critical errors in ndbmtd processes in a somewhat different fashion from how these are generated by ndbd failures. These differences are discussed in more detail in the next few paragraphs.

Like ndbd, ndbmtd generates a set of log files which are placed in the directory specified by DataDir in the config.ini configuration file. Except for trace files, these are generated in the same way and have the same names as those generated by ndbd.

In the event of a critical error, ndbmtd generates trace files describing what happened just prior to the error’s occurrence. These files, which can be found in the data node's DataDir, are useful for analysis of problems by the MySQL Cluster Development and Support teams. One trace file is generated for each ndbmtd thread. The names of these files have the following pattern:

```
ndb_node_id_trace.log.trace_id_tthread_id,
```

In this pattern, node_id stands for the data node's unique node ID in the cluster, trace_id is a trace sequence number, and thread_id is the thread ID. For example, in the event of the failure of an ndbmtd process running as a MySQL Cluster data node having the node ID 3 and with MaxNoOfExecutionThreads equal to 4, four trace files are generated in the data node’s data directory. If the is the first time this node has failed, then these files are named ndb_3_trace.log.1_t1, ndb_3_trace.log.1_t2, ndb_3_trace.log.1_t3, and ndb_3_trace.log.1_t4. Internally, these trace files follow the same format as ndbd trace files.
The `ndbd` exit codes and messages that are generated when a data node process shuts down prematurely are also used by `ndbmd`. See `ndbd Error Messages`, for a listing of these.

Note
It is possible to use `ndbd` and `ndbmd` concurrently on different data nodes in the same MySQL Cluster. However, such configurations have not been tested extensively; thus, we cannot recommend doing so in a production setting at this time.

### 17.4.4 ndb_mgmd — The MySQL Cluster Management Server Daemon

The management server is the process that reads the cluster configuration file and distributes this information to all nodes in the cluster that request it. It also maintains a log of cluster activities. Management clients can connect to the management server and check the cluster's status.

The following table includes options that are specific to the MySQL Cluster management server program `ndb_mgmd`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndb_mgmd`), see Section 17.4.26, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”.

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--config-file=file</code></td>
<td>Specify the cluster configuration file; in NDB-6.4.0 and later, needs <code>--reload</code> or <code>--initial</code> to override configuration cache if present.</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td><code>-f</code></td>
<td></td>
<td></td>
</tr>

### ndb_mgmd — The MySQL Cluster Management Server Daemon

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>--initial</strong></td>
<td>Causes the management server reload its configuration data from the configuration file, bypassing the configuration cache</td>
<td>ADDED: NDB 6.4.0</td>
</tr>
<tr>
<td><strong>--nowait-nodes=list</strong></td>
<td>Do not wait for these management nodes when starting this management server. Also requires --ndb-nodeid to be used.</td>
<td>ADDED: NDB 7.0.10, NDB 7.1.0</td>
</tr>
<tr>
<td>**--config-cache=[TRUE</td>
<td>FALSE]**</td>
<td>Enable the management server configuration cache; TRUE by default.</td>
</tr>
<tr>
<td><strong>--install=[name]</strong></td>
<td>Used to install the management server process as a Windows service. Does not apply on non-Windows platforms.</td>
<td>ADDED: NDB 7.0.16, NDB 7.1.5</td>
</tr>
<tr>
<td><strong>--remove=[name]</strong></td>
<td>Used to remove a management server process that was previously installed as a Windows service, optionally specifying the name of the service to be removed. Does not apply on non-Windows platforms.</td>
<td>ADDED: NDB 7.0.16, NDB 7.1.5</td>
</tr>
</tbody>
</table>

- **--bind-address=host[:port]**

  **Introduced**  5.1.22-ndb-6.3.2  
  **Command-Line Format**  **--bind-address=ip_address**  
  **Permitted Values**  | **Type** string  | **Default** [none]  

  When specified, this option limits management server connections by management clients to clients at the specified host name or IP address (and possibly port, if this is also specified). In such cases, a management client attempting to connect to the management server from any other address fails with the error `Unable to setup port: host:port`!

  If the *port* is not specified, the management client attempts to use port 1186.

  This option was added in MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.2.

- **--no-nodeid-checks**

  **Command-Line Format**  **--no-nodeid-checks**  
  **Permitted Values**  | **Type** boolean  | **Default** FALSE  

  Do not perform any checks of node IDs.

- **--configdir=dir_name**

  **Introduced**  5.1.30-ndb-6.4.0  
  **Command-Line Format**  **--configdirectory**
In MySQL Cluster NDB 7.0 and later, specifies the cluster management server's configuration cache directory. Starting with MySQL Cluster NDB 7.0.8, `--config-dir` is accepted as an alias for this option.

- `--config-cache`

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.44-ndb-7.1.4</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>`--config-cache[=TRUE</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type boolean</td>
</tr>
<tr>
<td>Default</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

This option, whose default value is 1 (or TRUE, or ON), can be used to disable the management server's configuration cache, so that it reads its configuration from `config.ini` every time it starts (see Section 17.3.3, "MySQL Cluster Configuration Files"). You can do this by starting the `ndb_mgmd` process with any one of the following options:

- `--config-cache=0`
- `--config-cache=FALSE`
- `--config-cache=OFF`
- `--skip-config-cache`

Using one of the options just listed is effective only if the management server has no stored configuration at the time it is started. If the management server finds any configuration cache files, then the `--config-cache` option or the `--skip-config-cache` option is ignored. Therefore, to disable configuration caching, the option should be used the first time that the management server is started. Otherwise—that is, if you wish to disable configuration caching for a management server that has already created a configuration cache—you must stop the management server, delete any existing configuration cache files manually, then restart the management server with `--skip-config-cache` (or with `--config-cache` set equal to 0, OFF, or FALSE).

Configuration cache files are normally created in a directory named `mysql-cluster` under the installation directory (unless this location has been overridden using the `--configdir` option). Each time the management server updates its configuration data, it writes a new cache file. The files are named sequentially in order of creation using the following format:

```
ndb_node-id_config.bin.seq-number
```

`node-id` is the management server's node ID; `seq-number` is a sequence number, beginning with 1. For example, if the management server's node ID is 5, then the first three configuration cache files would, when they are created, be named `ndb_5_config.bin.1`, `ndb_5_config.bin.2`, and `ndb_5_config.bin.3`.

If your intent is to purge or reload the configuration cache without actually disabling caching, you should start `ndb_mgmd` with one of the options `--reload` or `--initial` instead of `--skip-config-cache`.

To re-enable the configuration cache, simply restart the management server, but without the `--config-cache` or `--skip-config-cache` option that was used previously to disable the configuration cache.
This option was added in MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4.

Beginning with MySQL Cluster NDB 7.0.31 and MySQL Cluster NDB 7.1.20, \texttt{ndb_mgmd} no longer checks for the configuration directory (\texttt{--configdir}) or attempts to create one when \texttt{--skip-config-cache} is used. (Bug #13428853)

\begin{itemize}
\item \texttt{--config-file=filename, -f filename}
\end{itemize}

\begin{tabular}{|l|l|}
\hline
\textbf{Command-Line Format} & \texttt{--config-file=file} \\
\hline
\textbf{Permitted Values} & \textbf{Type} file name \\
\hline
\textbf{Default} & ./config.ini \\
\hline
\end{tabular}

\begin{tabular}{|l|l|}
\hline
\multicolumn{2}{|l|}{
\textbf{Permitted Values (\geq 5.1.30-ndb-6.4.0)}
} \\
\hline
\textbf{Type} & file name \\
\hline
\textbf{Default} & [none] \\
\hline
\end{tabular}

Instructs the management server as to which file it should use for its configuration file. By default, the management server looks for a file named \texttt{config.ini} in the same directory as the \texttt{ndb_mgmd} executable; otherwise the file name and location must be specified explicitly.

Beginning with MySQL Cluster NDB 6.4.0, this option has no default value, and is ignored unless the management server is forced to read the configuration file, either because \texttt{ndb_mgmd} was started with the \texttt{--reload} or \texttt{--initial} option, or because the management server could not find any configuration cache. Beginning with MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4, this option is also read if \texttt{ndb_mgmd} was started with \texttt{--config-cache=OFF}. See Section 17.3.3, “MySQL Cluster Configuration Files”, for more information.

Formerly, using this option together with \texttt{--initial} caused removal of the configuration cache even if the file was not found. This issue was resolved in MySQL Cluster NDB 7.0.38 and MySQL Cluster NDB 7.1.27. (Bug #1299289)

\begin{itemize}
\item \texttt{--mycnf}
\end{itemize}

\begin{tabular}{|l|l|}
\hline
\textbf{Command-Line Format} & \texttt{--mycnf} \\
\hline
\textbf{Permitted Values} & \textbf{Type} boolean \\
\hline
\textbf{Default} & FALSE \\
\hline
\end{tabular}

Read configuration data from the \texttt{my.cnf} file.

\begin{itemize}
\item \texttt{--daemon, -d}
\end{itemize}

\begin{tabular}{|l|l|}
\hline
\textbf{Command-Line Format} & \texttt{--daemon} \\
\hline
\textbf{Permitted Values} & \textbf{Type} boolean \\
\hline
\textbf{Default} & TRUE \\
\hline
\end{tabular}

Instructs \texttt{ndb_mgmd} to start as a daemon process. This is the default behavior.

This option has no effect when running \texttt{ndb_mgmd} on Windows platforms.

\begin{itemize}
\item \texttt{--interactive}
\end{itemize}

\begin{tabular}{|l|l|}
\hline
\textbf{Command-Line Format} & \texttt{--interactive} \\
\hline
\textbf{Permitted Values} & \textbf{Type} boolean \\
\hline
\textbf{Default} & FALSE \\
\hline
\end{tabular}

Starts \texttt{ndb_mgmd} in interactive mode; that is, an \texttt{ndb_mgm} client session is started as soon as the management server is running. This option does not start any other MySQL Cluster nodes.
• **--initial**

  **Introduced** 5.1.30-ndb-6.4.0

  **Command-Line Format** `--initial`

  **Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

  Beginning with MySQL Cluster NDB 6.4.0, configuration data is cached internally rather than being read from the cluster global configuration file each time the management server is started (see Section 17.3.3, “MySQL Cluster Configuration Files”). Using this option overrides this behavior, by forcing the management server to delete any existing cache files, and then to re-read the configuration data from the cluster configuration file and to build a new cache.

  This differs in two ways from the `--reload` option. First, `--reload` forces the server to check the configuration file against the cache and reload its data only if the contents of the file are different from the cache. Second, `--reload` does not delete any existing cache files.

  If `ndb_mgmd` is invoked with `--initial` but cannot find a global configuration file, the management server cannot start.

  In MySQL Cluster NDB 7.0.8 and later, when starting, the management server checks for another management server in the same MySQL Cluster and tries to use its configuration data. In other words, `ndb_mgmd` ignores `--initial` unless it is the only management server running. This behavior has implications when performing a rolling restart of a MySQL Cluster with multiple management nodes. See Section 17.5.5, “Performing a Rolling Restart of a MySQL Cluster”, for more information.

  Formerly, using this option together with the `--config-file` option caused removal of the configuration cache even if the file was not found. Starting with MySQL Cluster NDB 7.0.38 and MySQL Cluster NDB 7.1.27, the cache is cleared in such cases only if the configuration file is actually found. (Bug #1299289)

  This option was introduced in MySQL Cluster NDB 6.4.0.

• **--log-name=name**

  **Introduced** 5.1.37-ndb-7.0.8

  **Command-Line Format** `--log-name=name`

  **Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td>MgmtSrvr</td>
</tr>
</tbody>
</table>

  Provides a name to be used for this node in the cluster log.

  This option was added in MySQL Cluster NDB 7.0.8.

• **--nodaemon**

  **Introduced** 5.1.37-ndb-7.0.8

  **Command-Line Format** `--nodaemon`

  **Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

  Instructs `ndb_mgmd` not to start as a daemon process.

  As of MySQL Cluster NDB 7.0.8, the default behavior for `ndb_mgmd` on Windows is to run in the foreground, making this option unnecessary on Windows platforms. (Bug #45588)
- **--print-full-config, -P**

  **Command-Line Format**  
  `--print-full-config`
  
  **Permitted Values**  
  Type: boolean  
  Default: FALSE

  Shows extended information regarding the configuration of the cluster. With this option on the command line the `ndb_mgmd` process prints information about the cluster setup including an extensive list of the cluster configuration sections as well as parameters and their values. Normally used together with the `--config-file (-f)` option.

- **--reload**

  **Introduced**  
  5.1.30-ndb-6.4.0

  **Command-Line Format**  
  `--reload`
  
  **Permitted Values**  
  Type: boolean  
  Default: FALSE

  Beginning with MySQL Cluster NDB 6.4.0, configuration data is stored internally rather than being read from the cluster global configuration file each time the management server is started (see Section 17.3.3, “MySQL Cluster Configuration Files”). Using this option forces the management server to check its internal data store against the cluster configuration file and to reload the configuration if it finds that the configuration file does not match the cache. Existing configuration cache files are preserved, but not used.

  This differs in two ways from the `--initial` option. First, `--initial` causes all cache files to be deleted. Second, `--initial` forces the management server to re-read the global configuration file and construct a new cache.

  If the management server cannot find a global configuration file, then the `--reload` option is ignored.

  In MySQL Cluster NDB 7.0.8 and later, when starting, the management server checks for another management server in the same MySQL Cluster and tries to use its configuration data. In other words, `ndb_mgmd` ignores `--reload` unless it is the only management server running. This behavior has implications when performing a rolling restart of a MySQL Cluster with multiple management nodes. See Section 17.5.5, “Performing a Rolling Restart of a MySQL Cluster”, for more information.

  This option was introduced in MySQL Cluster NDB 6.4.0.

- **--nowait-nodes**

  **Introduced**  
  5.1.39-ndb-7.1.0

  **Command-Line Format**  
  `--nowait-nodes=list`
  
  **Permitted Values**  
  Type: numeric  
  Default: 1  
  Min Value: 1  
  Max Value: 255

  When starting a MySQL Cluster is configured with two management nodes and running MySQL Cluster NDB 7.0 and later, each management server normally checks to see whether the other `ndb_mgmd` is also operational and whether the other management server's configuration is identical to its own. However, it is sometimes desirable to start the cluster with only one management node
(and perhaps to allow the other ndb_mgmd to be started later). This option causes the management node to bypass any checks for any other management nodes whose node IDs are passed to this option, permitting the cluster to start as though configured to use only the management node that was started.

For purposes of illustration, consider the following portion of a config.ini file (where we have omitted most of the configuration parameters that are not relevant to this example):

```
[nbdb]
NodeId = 1
HostName = 192.168.0.101

[nbdb]
NodeId = 2
HostName = 192.168.0.102

[nbdb]
NodeId = 3
HostName = 192.168.0.103

[nbdb]
NodeId = 4
HostName = 192.168.0.104

[ndb_mgmd]
NodeId = 10
HostName = 192.168.0.150

[ndb_mgmd]
NodeId = 11
HostName = 192.168.0.151

[api]
NodeId = 20
HostName = 192.168.0.200

[api]
NodeId = 21
HostName = 192.168.0.201
```

Assume that you wish to start this cluster using only the management server having node ID 10 and running on the host having the IP address 192.168.0.150. (Suppose, for example, that the host computer on which you intend to the other management server is temporarily unavailable due to a hardware failure, and you are waiting for it to be repaired.) To start the cluster in this way, use a command line on the machine at 192.168.0.150 to enter the following command:

```
shell> ndb_mgmd --ndb-nodeid=10 --nowait-nodes=11
```

As shown in the preceding example, when using --nowait-nodes, you must also use the --ndb-nodeid option to specify the node ID of this ndb_mgmd process.

You can then start each of the cluster's data nodes in the usual way. If you wish to start and use the second management server in addition to the first management server at a later time without restarting the data nodes, you must start each data node with a connection string that references both management servers, like this:

```
shell> ndbd -c 192.168.0.150,192.168.0.151
```

The same is true with regard to the connection string used with any mysqld processes that you wish to start as MySQL Cluster SQL nodes connected to this cluster. See Section 17.3.3.3, “MySQL Cluster Connection Strings”, for more information.
When used with `ndb_mgmd`, this option affects the behavior of the management node with regard to other management nodes only. Do not confuse it with the `--nowait-nodes` option used with `ndbd` (or `ndbmd` in MySQL Cluster NDB 7.0 and later) to permit a cluster to start with fewer than its full complement of data nodes; when used with data nodes, this option affects their behavior only with regard to other data nodes.

Multiple management node IDs may be passed to this option as a comma-separated list. Each node ID must be no less than 1 and no greater than 255. In practice, it is quite rare to use more than two management servers for the same MySQL Cluster (or to have any need for doing so); in most cases you need to pass to this option only the single node ID for the one management server that you do not wish to use when starting the cluster.

![Note]

When you later start the "missing" management server, its configuration must match that of the management server that is already in use by the cluster. Otherwise, it fails the configuration check performed by the existing management server, and does not start.

This option was introduced in MySQL Cluster NDB 7.0.10 and MySQL Cluster NDB 7.1.0.

It is not strictly necessary to specify a connection string when starting the management server. However, if you are using more than one management server, a connection string should be provided and each node in the cluster should specify its node ID explicitly.

See Section 17.3.3.3, “MySQL Cluster Connection Strings”, for information about using connection strings. Section 17.4.4, “`ndb_mgmd` — The MySQL Cluster Management Server Daemon”, describes other options for `ndb_mgmd`.

The following files are created or used by `ndb_mgmd` in its starting directory, and are placed in the `DataDir` as specified in the `config.ini` configuration file. In the list that follows, `node_id` is the unique node identifier.

- `config.ini` is the configuration file for the cluster as a whole. This file is created by the user and read by the management server. See Section 17.3, “Configuration of MySQL Cluster NDB 6.1-7.1”, discusses how to set up this file.

- `ndb_node_id_cluster.log` is the cluster events log file. Examples of such events include checkpoint startup and completion, node startup events, node failures, and levels of memory usage. A complete listing of cluster events with descriptions may be found in Section 17.5, “Management of MySQL Cluster”.

  By default, when the size of the cluster log reaches one million bytes, the file is renamed to `ndb_node_id_cluster.log.seq_id`, where `seq_id` is the sequence number of the cluster log file. (For example: If files with the sequence numbers 1, 2, and 3 already exist, the next log file is named using the number 4.) You can change the size and number of files, and other characteristics of the cluster log, using the `LogDestination` configuration parameter.

- `ndb_node_id_out.log` is the file used for `stdout` and `stderr` when running the management server as a daemon.

- `ndb_node_id.pid` is the process ID file used when running the management server as a daemon.

- `--install[=name]`
Causes \texttt{ndb\_mgmd} to be installed as a Windows service. Optionally, you can specify a name for the service; if not set, the service name defaults to \texttt{ndb\_mgmd}. Although it is preferable to specify other \texttt{ndb\_mgmd} program options in a \texttt{my.ini} or \texttt{my.cnf} configuration file, it is possible to use them together with \texttt{--install}. However, in such cases, the \texttt{--install} option must be specified first, before any other options are given, for the Windows service installation to succeed.

It is generally not advisable to use this option together with the \texttt{--initial} option, since this causes the configuration cache to be wiped and rebuilt every time the service is stopped and started. Care should also be taken if you intend to use any other \texttt{ndb\_mgmd} options that affect the starting of the management server, and you should make absolutely certain you fully understand and allow for any possible consequences of doing so.

The \texttt{--install} option has no effect on non-Windows platforms.

This option became available in MySQL Cluster NDB 7.0.16 and MySQL Cluster NDB 7.1.5.

\begin{itemize}
\item \texttt{--remove [=name]}
\end{itemize}

\begin{table}
\begin{tabular}{|l|l|}
\hline
\textbf{Introduced} & 5.1.47-ndb-7.1.5 \\
\hline
\textbf{Command-Line Format} & \texttt{--remove [=name]} \\
\hline
\textbf{Platform Specific} & Windows \\
\hline
\textbf{Permitted Values} & Type string \\
\hline
\textbf{Default} & \texttt{ndb\_mgmd} \\
\hline
\end{tabular}
\end{table}

Causes an \texttt{ndb\_mgmd} process that was previously installed as a Windows service to be removed. Optionally, you can specify a name for the service to be uninstalled; if not set, the service name defaults to \texttt{ndb\_mgmd}.

The \texttt{--remove} option has no effect on non-Windows platforms.

This option became available in MySQL Cluster NDB 7.0.16 and MySQL Cluster NDB 7.1.5.

\section*{17.4.5 \texttt{ndb\_mgm} — The MySQL Cluster Management Client}

The \texttt{ndb\_mgm} management client process is actually not needed to run the cluster. Its value lies in providing a set of commands for checking the cluster's status, starting backups, and performing other administrative functions. The management client accesses the management server using a C API. Advanced users can also employ this API for programming dedicated management processes to perform tasks similar to those performed by \texttt{ndb\_mgm}.

To start the management client, it is necessary to supply the host name and port number of the management server:

\begin{verbatim}
shell> ndb\_mgm [host\_name [port\_num]]
\end{verbatim}

For example:

\begin{verbatim}
shell> ndb\_mgm ndb\_mgmd.mysql.com 1186
\end{verbatim}

The default host name and port number are \texttt{localhost} and 1186, respectively.

The following table includes options that are specific to the MySQL Cluster management client program \texttt{ndb\_mgm}. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including \texttt{ndb\_mgm}), see Section 17.4.26, "Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs".
Table 17.72 This table describes command-line options for the ndb_mgm program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--try-reconnect=#,</td>
<td>Set the number of times to retry a connection before giving up; synonym</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--execute=name,</td>
<td>Execute command and exit</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>-t</td>
<td></td>
<td></td>
</tr>
<tr>
<td>-e</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- **--execute=command, -e command**

Command-Line Format

This option can be used to send a command to the MySQL Cluster management client from the system shell. For example, either of the following is equivalent to executing `SHOW` in the management client:

```
shell> ndb_mgm -e "SHOW"
shell> ndb_mgm --execute="SHOW"
```

This is analogous to how the `--execute` or `-e` option works with the `mysql` command-line client. See Section 4.2.4, “Using Options on the Command Line”.

**Note**

If the management client command to be passed using this option contains any space characters, then the command must be enclosed in quotation marks. Either single or double quotation marks may be used. If the management client command contains no space characters, the quotation marks are optional.

- **--try-reconnect=number**

Command-Line Format

```
--try-reconnect=
```

Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
<th>Default</th>
<th>Min Value</th>
<th>Max Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>3</td>
<td>0</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

If the connection to the management server is broken, the node tries to reconnect to it every 5 seconds until it succeeds. By using this option, it is possible to limit the number of attempts to `number` before giving up and reporting an error instead.

Additional information about using `ndb_mgm` can be found in Section 17.5.2, "Commands in the MySQL Cluster Management Client".

17.4.6 ndb_blob_tool — Check and Repair BLOB and TEXT columns of MySQL Cluster Tables

This tool, which is available in MySQL Cluster NDB 7.0.4 and later, can be used to check for and remove orphaned BLOB column parts from NDB tables, as well as to generate a file listing any orphaned parts. It is sometimes useful in diagnosing and repairing corrupted or damaged NDB tables containing BLOB or TEXT columns.
The basic syntax for `ndb_blob_tool` is shown here:

```
ndb_blob_tool [options] table [column, ...]
```

Unless you use the `--help` option, you must specify an action to be performed by including one or more of the options `--check-orphans`, `--delete-orphans`, or `--dump-file`. These options cause `ndb_blob_tool` to check for orphaned BLOB parts, remove any orphaned BLOB parts, and generate a dump file listing orphaned BLOB parts, respectively, and are described in more detail later in this section.

You must also specify the name of a table when invoking `ndb_blob_tool`. In addition, you can optionally follow the table name with the (comma-separated) names of one or more BLOB or TEXT columns from that table. If no columns are listed, the tool works on all of the table's BLOB and TEXT columns. If you need to specify a database, use the `--database (-d)` option.

The `--verbose` option provides additional information in the output about the tool's progress.

The following table includes options that are specific to `ndb_blob_tool`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndb_blob_tool`), see Section 17.4.26, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”.

Table 17.73 This table describes command-line options for the ndb_blob_tool program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--check-orphans</code></td>
<td>Check for orphan blob parts</td>
<td>ADDED: NDB 7.0.4</td>
</tr>
<tr>
<td><code>--database=db_name, -d</code></td>
<td>Database to find the table in.</td>
<td>ADDED: NDB 7.0.4</td>
</tr>
<tr>
<td><code>--delete-orphans</code></td>
<td>Delete orphan blob parts</td>
<td>ADDED: NDB 7.0.4</td>
</tr>
<tr>
<td><code>--dump-file=file</code></td>
<td>Write orphan keys to specified</td>
<td>ADDED: NDB 7.0.4</td>
</tr>
<tr>
<td><code>--verbose, -v</code></td>
<td>Verbose output</td>
<td>ADDED: NDB 7.0.4</td>
</tr>
</tbody>
</table>

- **`--check-orphans`**
  
  **Introduced** 5.1.32-ndb-7.0.4
  
  **Command-Line Format** `--check-orphans`
  
  **Permitted Values (>= 5.1.32-ndb-7.0.4)** Type boolean
  
  **Default** FALSE
  
  Check for orphaned BLOB parts in MySQL Cluster tables.

- **`--database=db_name, -d`**
  
  **Introduced** 5.1.32-ndb-7.0.4
  
  **Command-Line Format** `--database=db_name`
  
  **Permitted Values (>= 5.1.32-ndb-7.0.4)** Type string
  
  **Default** [none]
  
  Specify the database to find the table in.

- **`--delete-orphans`**
  
  **Introduced** 5.1.32-ndb-7.0.4
ndb_blob_tool — Check and Repair BLOB and TEXT columns of MySQL Cluster Tables

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--delete-orphans</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values (&gt;= 5.1.32-ndb-7.0.4)</td>
<td>Type boolean</td>
</tr>
<tr>
<td>Default FALSE</td>
<td></td>
</tr>
</tbody>
</table>

Remove orphaned BLOB parts from MySQL Cluster tables.

- **--dump-file=file**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.32-ndb-7.0.4</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--dump-file=file</td>
</tr>
<tr>
<td>Permitted Values (&gt;= 5.1.32-ndb-7.0.4)</td>
<td>Type file name</td>
</tr>
<tr>
<td>Default [none]</td>
<td></td>
</tr>
</tbody>
</table>

Writes a list of orphaned BLOB column parts to file. The information written to the file includes the table key and BLOB part number for each orphaned BLOB part.

- **--verbose**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.32-ndb-7.0.4</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--verbose</td>
</tr>
<tr>
<td>Permitted Values (&gt;= 5.1.32-ndb-7.0.4)</td>
<td>Type boolean</td>
</tr>
<tr>
<td>Default FALSE</td>
<td></td>
</tr>
</tbody>
</table>

Provide extra information in the tool’s output regarding its progress.

**Example**

First we create an NDB table in the test database, using the CREATE TABLE statement shown here:

```sql
USE test;
CREATE TABLE btest (
    c0 BIGINT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
    c1 TEXT,
    c2 BLOB
) ENGINE=NDB;
```

Then we insert a few rows into this table, using a series of statements similar to this one:

```
INSERT INTO btest VALUES (NULL, 'x', REPEAT('x', 1000));
```

When run with **--check-orphans** against this table, ndb_blob_tool generates the following output:

```bash
shell> ndb_blob_tool --check-orphans --verbose -d test btest
connected
processing 2 blobs
processing blob #0 c1 NDB$BLOB_19_1
NDB$BLOB_19_1: nextResult: res=1
NDB$BLOB_19_1: nextResult: res=0
NDB$BLOB_19_1: nextResult: res=0
NDB$BLOB_19_1: nextResult: res=0
NDB$BLOB_19_1: nextResult: res=0
NDB$BLOB_19_1: nextResult: res=0
NDB$BLOB_19_1: nextResult: res=0
NDB$BLOB_19_1: nextResult: res=0
processing blob #1 c2 NDB$BLOB_19_2
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=0
```

2064
NDB$BLOB_19_2: nextResult: res=0
NDB$BLOB_19_2: nextResult: res=1
total parts: 10
orphan parts: 0
disconnected
NDBT_ProgramExit: 0 - OK

The tool reports that there are no NDB BLOB column parts associated with column c1, even though c1 is a TEXT column. This is due to the fact that, in an NDB table, only the first 256 bytes of a BLOB or TEXT column value are stored inline, and only the excess, if any, is stored separately; thus, if there are no values using more than 256 bytes in a given column of one of these types, no BLOB column parts are created by NDB for this column. See Section 11.7, “Data Type Storage Requirements”, for more information.

17.4.7 ndb_config — Extract MySQL Cluster Configuration Information

This tool extracts current configuration information for data nodes, SQL nodes, and API nodes from one of a number of sources: a MySQL Cluster management node, or its config.ini or my.cnf file. By default, the management node is the source for the configuration data; to override the default, execute ndb_config with the --config-file or --mycnf option. Beginning with MySQL Cluster NDB 7.0.27 and MySQL Cluster NDB 7.1.16, it is also possible to use a data node as the source by specifying its node ID using --config_from_node=node_id.

Beginning with MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.6, ndb_config can also provide an offline dump of all configuration parameters which can be used, along with their default, maximum, and minimum values and other information. The dump can be produced in either text or XML format; for more information, see the discussion of the --configinfo and --xml options later in this section.

Beginning with MySQL Cluster NDB 7.0.27 and MySQL Cluster NDB 7.1.16, you can filter the results by section (DB, SYSTEM, or CONNECTIONS) using one of the options --nodes, --system, or --connections.

The following table includes options that are specific to ndb_config. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including ndb_config), see Section 17.4.26, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”.

Table 17.74 This table describes command-line options for the ndb_config program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--nodes</td>
<td>Print node information ([ndbd] or [ndbd default] section of cluster configuration file) only. Cannot be used with --system or --connections.</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--connections</td>
<td>Print connections information ([tcp], [tcp default], [sci], [sci default], [shm], or [shm default] sections of cluster configuration file) only. Cannot be used with --system or --nodes.</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--query=string,</td>
<td>One or more query options (attributes)</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>-q</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--host=name</td>
<td>Specify host</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--type=name</td>
<td>Specify node type</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--nodeid,</td>
<td>Get configuration of node with this ID</td>
<td>All MySQL 5.1 based releases</td>
</tr>
</tbody>

### ndb_config — Extract MySQL Cluster Configuration Information

#### Format

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--id</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--fields=string,</td>
<td>Field separator</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>-f</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--rows=string,</td>
<td>Row separator</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>-r</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--config-file=file_name</td>
<td>Set the path to config.ini file</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--mycnf</td>
<td>Read configuration data from my.cnf file</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>-c</td>
<td>Short form for --ndb-connectstring</td>
<td>ADDED: 5.1.12</td>
</tr>
<tr>
<td>--configinfo</td>
<td>Dumps information about all NDB configuration parameters in text format with default, maximum, and minimum values. Use with --xml to obtain XML output.</td>
<td>ADDED: NDB 6.3.25, NDB 7.0.6</td>
</tr>
<tr>
<td>--configinfo --xml</td>
<td>Use --xml with --configinfo to obtain a dump of all NDB configuration parameters in XML format with default, maximum, and minimum values.</td>
<td>ADDED: NDB 6.3.25, NDB 7.0.6</td>
</tr>
<tr>
<td>--system</td>
<td>Print SYSTEM section information only (see ndb_config --configinfo output). Cannot be used with --nodes or --connections.</td>
<td>ADDED: NDB 7.0.27, NDB 7.1.16</td>
</tr>
<tr>
<td>--config_from_node=#</td>
<td>Obtain configuration data from the node having this ID (must be a data node).</td>
<td>ADDED: NDB 7.0.27, NDB 7.1.16</td>
</tr>
</tbody>
</table>

- --usage, --help, or -?

#### Command-Line Format

- `--help`
- `--usage`

Causes `ndb_config` to print a list of available options, and then exit.

- `--config_from_node=#`

#### Introduced

- 5.1.56-ndb-7.1.16

#### Command-Line Format

- `--config_from_node=#`

#### Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>none</td>
</tr>
<tr>
<td>Min Value</td>
<td>1</td>
</tr>
<tr>
<td>Max Value</td>
<td>48</td>
</tr>
</tbody>
</table>

Obtain the cluster's configuration data from the data node that has this ID.
If the node having this ID is not a data node, `ndb_config` fails with an error. (To obtain configuration data from the management node instead, simply omit this option.)

`--config_from_node` was added in MySQL Cluster NDB 7.0.27 and MySQL NDB 7.1.16.

- `--version, -V`

**Command-Line Format**

```
--version
```

Causes `ndb_config` to print a version information string, and then exit.

- `--ndb-connectstring=connection_string`

**Command-Line Format**

```
--ndb-connectstring=connection_string
--connect-string=connection_string
```

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>string</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td><code>localhost:1186</code></td>
</tr>
</tbody>
</table>

Specifies the connection string to use in connecting to the management server. The format for the connection string is the same as described in Section 17.3.3.3, "MySQL Cluster Connection Strings", and defaults to `localhost:1186`.

The use of `-c` as a short version for this option is supported for `ndb_config` beginning with MySQL 5.1.12.

- `--config-file=path-to-file`

**Command-Line Format**

```
--config-file=file_name
```

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td></td>
</tr>
</tbody>
</table>

Gives the path to the management server’s configuration file (`config.ini`). This may be a relative or absolute path. If the management node resides on a different host from the one on which `ndb_config` is invoked, then an absolute path must be used.

- `--mycnf`

**Command-Line Format**

```
--mycnf
```

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>boolean</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Read configuration data from the `my.cnf` file.

- `--query=query-options, -q query-options`

**Command-Line Format**

```
--query=string
```

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>string</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td></td>
</tr>
</tbody>
</table>

This is a comma-delimited list of `query options`—that is, a list of one or more node attributes to be returned. These include `id` (node ID), `type` (node type—that is, `ndbd`, `mysqld`, or `ndb_mgmd`), and any configuration parameters whose values are to be obtained.

For example, `--query=id, type, indexmemory, datamemory` returns the node ID, node type, `DataMemory`, and `IndexMemory` for each node.
### ndb_config — Extract MySQL Cluster Configuration Information

**Note**

If a given parameter is not applicable to a certain type of node, than an empty string is returned for the corresponding value. See the examples later in this section for more information.

- **--host=hostname**

  **Command-Line Format**
  ```
  --host=name
  ```

  **Permitted Values**
  - **Type**: string
  - **Default**:

  Specifies the host name of the node for which configuration information is to be obtained.

  **Note**
  While the hostname `localhost` usually resolves to the IP address `127.0.0.1`, this may not necessarily be true for all operating platforms and configurations. This means that it is possible, when `localhost` is used in `config.ini`, for `ndb_config --host=localhost` to fail if `ndb_config` is run on a different host where `localhost` resolves to a different address (for example, on some versions of SUSE Linux, this is `127.0.0.2`). In general, for best results, you should use numeric IP addresses for all MySQL Cluster configuration values relating to hosts, or verify that all MySQL Cluster hosts handle `localhost` in the same fashion.

- **--id=node_id**
  - **--nodeid=node_id**

  **Command-Line Format**
  ```
  --ndb-nodeid=#
  ```

  **Permitted Values**
  - **Type**: numeric
  - **Default**: 0

  Either of these options can be used to specify the node ID of the node for which configuration information is to be obtained. `--nodeid` is the preferred form.

- **--nodes**

  **Command-Line Format**
  ```
  --nodes
  ```

  **Permitted Values**
  - **Type**: boolean
  - **Default**: FALSE

  Tells `ndb_config` to print information relating only to parameters defined in an [ndbd] or [ndbd default] section of the cluster configuration file (see Section 17.3.6, "Defining MySQL Cluster Data Nodes"). Prior to MySQL Cluster NDB 7.0.27 and MySQL Cluster NDB 7.1.16, this option had no affect.

  This option is mutually exclusive with `--connections` and `--system`; only one of these 3 options can be used.

- **--connections**

  **Command-Line Format**
  ```
  --connections
  ```

  **Permitted Values**
  - **Type**: boolean
  - **Default**: FALSE
Tells `ndb_config` to print CONNECTIONS information only—that is, information about parameters found in the [tcp], [tcp default], [sci], [sci default], [shm], or [shm default] sections of the cluster configuration file (see Section 17.3.3.9, “MySQL Cluster TCP/IP Connections”, Section 17.3.3.12, “SCI Transport Connections in MySQL Cluster”, and Section 17.3.3.11, “MySQL Cluster Shared-Memory Connections”, for more information). This option existed prior to MySQL Cluster NDB 7.0.27 and MySQL Cluster NDB 7.1.16, but had no affect before then.

This option is mutually exclusive with `--nodes` and `--system`; only one of these 3 options can be used.

- **--system**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.56-ndb-7.1.16</th>
</tr>
</thead>
</table>

  Tells `ndb_config` to print SYSTEM information only. This consists of system variables that cannot be changed at run time; thus, there is no corresponding section of the cluster configuration file for them. They can be seen (prefixed with "***** SYSTEM *****") in the output of `ndb_config --configinfo`. The `--system` option was introduced in MySQL Cluster NDB 7.0.27 and MySQL Cluster NDB 7.1.16.

  This option is mutually exclusive with `--nodes` and `--connections`; only one of these 3 options can be used.

- **--type=node_type**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--type=name</th>
</tr>
</thead>
</table>

  Filters results so that only configuration values applying to nodes of the specified node_type (ndbd, mysqld, or ndb_mgmd) are returned.

- **--fields=delimiter, -f delimiter**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--fields=string</th>
</tr>
</thead>
</table>

  Specifies a delimiter string used to separate the fields in the result. The default is “,” (the comma character).

  **Note**

  If the delimiter contains spaces or escapes (such as \n for the linefeed character), then it must be quoted.

- **--rows=separator, -r separator**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--rows=string</th>
</tr>
</thead>
</table>
**ndb_config** — Extract MySQL Cluster Configuration Information

<table>
<thead>
<tr>
<th>Permitted Values</th>
<th>Type</th>
<th>string</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Specifies a `separator` string used to separate the rows in the result. The default is a space character.

**Note**
If the `separator` contains spaces or escapes (such as `\n` for the linefeed character), then it must be quoted.

- **--configinfo**

The `--configinfo` option, added in MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.6, causes `ndb_config` to dump a list of each MySQL Cluster configuration parameter supported by the MySQL Cluster distribution of which `ndb_config` is a part, including the following information:

- A brief description of each parameter's purpose, effects, and usage
- The section of the `config.ini` file where the parameter may be used
- The parameter's data type or unit of measurement
- Where applicable, the parameter's default, minimum, and maximum values
- MySQL Cluster release version and build information

By default, this output is in text format. Part of this output is shown here:

```shell
shell> ndb_config --configinfo

***** SYSTEM *****

Name (String)
Name of system (NDB Cluster)
MANDATORY

PrimaryMGMNode (Non-negative Integer)
Node id of Primary ndb_mgmd(MGM) node
Default: 0 (Min: 0, Max: 4294967039)

ConfigGenerationNumber (Non-negative Integer)
Configuration generation number
Default: 0 (Min: 0, Max: 4294967039)

***** DB *****

MaxNoOfSubscriptions (Non-negative Integer)
Max no of subscriptions (default 0 == MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)

MaxNoOfSubscribers (Non-negative Integer)
Max no of subscribers (default 0 == 2 * MaxNoOfTables)
Default: 0 (Min: 0, Max: 4294967039)
```

- **--configinfo --xml**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.34-ndb-7.0.6</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--configinfo --xml</code></td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type</td>
</tr>
<tr>
<td></td>
<td>Default</td>
</tr>
</tbody>
</table>
You can obtain the output of `ndb_config --configinfo` as XML by adding the `--xml` option (like the `--configinfo` option, available beginning with MySQL Cluster NDB 6.3.25 and MySQL Cluster NDB 7.0.6). A portion of the resulting output is shown in this example:

```plaintext
shell> ndb_config --configinfo --xml

<configvariables protocolversion="1" ndbversionstring="5.1.77-ndb-7.1.37"
  ndbversion="458758" ndbversionmajor="7" ndbversionminor="0"
  ndbversionbuild="6">
  <section name="SYSTEM">
    <param name="Name" comment="Name of system (NDB Cluster)" type="string"
      mandatory="true"/>
    <param name="PrimaryMGMNode" comment="Node id of Primary ndb_mgmd (MGM) node"
      type="unsigned" default="0" min="0" max="4294967039"/>
    <param name="ConfigGenerationNumber" comment="Configuration generation number"
      type="unsigned" default="0" min="0" max="4294967039"/>
  </section>
  <section name="NDBD">
    <param name="MaxNoOfSubscriptions"
      comment="Max no of subscriptions (default 0 == MaxNoOfTables)"
      type="unsigned" default="0" min="0" max="4294967039"/>
    <param name="MaxNoOfSubscribers"
      comment="Max no of subscribers (default 0 == 2 * MaxNoOfTables)"
      type="unsigned" default="0" min="0" max="4294967039"/>
  </section>
  ...
</configvariables>

Note

Normally, the XML output produced by `ndb_config --configinfo --xml` is formatted using one line per element; we have added extra whitespace in the previous example, as well as the next one, for reasons of legibility. This should not make any difference to applications using this output, since most XML processors either ignore nonessential whitespace as a matter of course, or can be instructed to do so.

Beginning with MySQL Cluster NDB 6.3.29 and MySQL Cluster NDB 7.0.10, the XML output also indicates when changing a given parameter requires that data nodes be restarted using the `--initial` option. This is shown by the presence of an `initial="true"` attribute in the corresponding `<param>` element. In addition (also beginning with MySQL Cluster NDB 6.3.29 and MySQL Cluster NDB 7.0.10), the restart type (`system` or `node`) is also shown; if a given parameter requires a system restart, this is indicated by the presence of a `restart="system"` attribute in the corresponding `<param>` element. For example, changing the value set for the `Diskless` parameter requires a system initial restart, as shown here (with the `restart` and `initial` attributes highlighted for visibility):

```plaintext
<param name="Diskless" comment="Run wo/ disk" type="bool" default="false"
  restart="system" initial="true"/>
```

Currently, no `initial` attribute is included in the XML output for `<param>` elements corresponding to parameters which do not require initial restarts; in other words, `initial="false"` is the default, and the value `false` should be assumed if the attribute is not present. Similarly, the default restart type is `node` (that is, an online or “rolling” restart of the cluster), but the `restart` attribute is included only if the restart type is `system` (meaning that all cluster nodes must be shut down at the same time, then restarted).
Important

The `--xml` option can be used only with the `--configinfo` option. Using `--xml` without `--configinfo` fails with an error.

Unlike the options used with this program to obtain current configuration data, `--configinfo` and `--xml` use information obtained from the MySQL Cluster sources when `ndb_config` was compiled. For this reason, no connection to a running MySQL Cluster or access to a `config.ini` or `my.cnf` file is required for these two options.

Combining other `ndb_config` options (such as `--query` or `--type`) with `--configinfo` or `--xml` is not supported. Currently, if you attempt to do so, the usual result is that all other options besides `--configinfo` or `--xml` are simply ignored. However, this behavior is not guaranteed and is subject to change at any time. In addition, since `ndb_config`, when used with the `--configinfo` option, does not access the MySQL Cluster or read any files, trying to specify additional options such as `--ndb-connectstring` or `--config-file` with `--configinfo` serves no purpose.

Examples

1. To obtain the node ID and type of each node in the cluster:

   ```
   shell> ./ndb_config --query=id,type --fields=':' --rows='\n'
   1:ndbd
   2:ndbd
   3:ndbd
   4:ndbd
   5:ndb_mgmd
   6:mysqld
   7:mysqld
   8:mysqld
   9:mysqld
   ```

   In this example, we used the `--fields` options to separate the ID and type of each node with a colon character (:`), and the `--rows` options to place the values for each node on a new line in the output.

2. To produce a connection string that can be used by data, SQL, and API nodes to connect to the management server:

   ```
   shell> ./ndb_config --config-file=usr/local/mysql/cluster-data/config.ini \\n   --query=hostname,portnumber --fields=: --rows=, --type=ndb_mgmd
   192.168.0.179:1186
   ```

3. This invocation of `ndb_config` checks only data nodes (using the `--type` option), and shows the values for each node's ID and host name, as well as the values set for its `DataMemory`, `IndexMemory`, and `DataDir` parameters:

   ```
   shell> ./ndb_config --type=ndbd --query=id,host,datamemory,indexmemory,datadir -f ' : ' -r '\n'
   ```

   In this example, we used the short options `-f` and `-r` for setting the field delimiter and row separator, respectively.

4. To exclude results from any host except one in particular, use the `--host` option:

   ```
   shell> ./ndb_config --host=192.168.0.176 -f : -r '\n' -q id,type
   3:ndbd
   ```
In this example, we also used the short form `-q` to determine the attributes to be queried.

Similarly, you can limit results to a node with a specific ID using the `--id` or `--nodeid` option.

### 17.4.8 ndb_cpcd — Automate Testing for NDB Development

This utility is found in the `libexec` directory. It is part of an internal automated test framework used in testing and debugging MySQL Cluster. Because it can control processes on remote systems, it is not advisable to use `ndb_cpcd` in a production cluster.

The source files for `ndb_cpcd` may be found in the directory `storage/ndb/src/cw/cpcd`, in the MySQL Cluster source tree.

**Deprecated feature.** As of MySQL Cluster NDB 7.0, this program is deprecated and no longer actively maintained. It is subject to removal in a future MySQL Cluster version.

### 17.4.9 ndb_delete_all — Delete All Rows from an NDB Table

`ndb_delete_all` deletes all rows from the given NDB table. In some cases, this can be much faster than `DELETE` or even `TRUNCATE TABLE`.

**Usage**

```
ndb_delete_all -c connection_string tbl_name -d db_name
```

This deletes all rows from the table named `tbl_name` in the database named `db_name`. It is exactly equivalent to executing `TRUNCATE db_name.tbl_name` in MySQL.

The following table includes options that are specific to `ndb_delete_all`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndb_delete_all`), see Section 17.4.26, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”.

**Table 17.75** This table describes command-line options for the `ndb_delete_all` program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--database=dbname</code>, -d</td>
<td>Name of the database in which the table is found</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td><code>--transactional</code>, -t</td>
<td>Perform the delete in a single transaction (may run out of operations)</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td><code>--tupscan</code></td>
<td>Run tup scan</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td><code>--diskscan</code></td>
<td>Run disk scan</td>
<td>All MySQL 5.1 based releases</td>
</tr>
</tbody>
</table>

- `--transactional`, -t

  Use of this option causes the delete operation to be performed as a single transaction.

**Warning**

With very large tables, using this option may cause the number of operations available to the cluster to be exceeded.

### 17.4.10 ndb_desc — Describe NDB Tables

`ndb_desc` provides a detailed description of one or more NDB tables.
**ndb_desc — Describe NDB Tables**

**Usage**

```
ndb_desc -c connection_string tbl_name -d db_name [options]
```

*(MySQL Cluster NDB 7.0.36 and later; MySQL Cluster NDB 7.1.25 and later:)*

```
ndb_desc -c connection_string index_name -d db_name -t tbl_name
```

Additional options that can be used with `ndb_desc` are listed later in this section.

**Sample Output**

MySQL table creation and population statements:

```
USE test;

CREATE TABLE fish (
   id INT(11) NOT NULL AUTO_INCREMENT,
   name VARCHAR(20) NOT NULL,
   length_mm INT(11) NOT NULL,
   weight_gm INT(11) NOT NULL,
   PRIMARY KEY pk (id),
   UNIQUE KEY uk (name)
) ENGINE=NDB;

INSERT INTO fish VALUES
('','guppy', 35, 2), ('','tuna', 2500, 150000),
('','shark', 3000, 110000), ('','manta ray', 1500, 50000),
('','grouper', 900, 125000), ('','puffer', 250, 250);
```

Output from `ndb_desc`:

```
shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 2
Fragment type: 9
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 4
Number of primary keys: 1
Length of frm data: 311
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
FragmentCount: 2
TableStatus: Retrieved
-- Attributes --
id Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCREMENT
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
length_mm Int NOT NULL AT=FIXED ST=MEMORY
weight_gm Int NOT NULL AT=FIXED ST=MEMORY
-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex
uk$unique(name) - UniqueHashIndex
uk(name) - OrderedIndex
-- Per partition info --
Partition Row count Commit count Frag fixed memory ...
0 2 2 32768 ...
1 4 4 32768 ...
```
Information about multiple tables can be obtained in a single invocation of `ndb_desc` by using their names, separated by spaces. All of the tables must be in the same database.

Beginning with MySQL Cluster NDB 7.0.36 and MySQL Cluster NDB 7.1.25, it is possible to obtain additional information about a specific index using the `--table` (short form: `-t`) option introduced in these versions and supplying the name of the index as the first argument to `ndb_desc`, as shown here:

```
shell> ./ndb_desc uk -d test -t fish
-- uk --
Version: 3
Base table: fish
Number of attributes: 1
Logging: 0
Index type: OrderedIndex
Index status: Retrieved
-- Attributes --
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
-- IndexTable 10/uk --
Version: 3
Fragment type: FragUndefined
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: yes
Number of attributes: 2
Number of primary keys: 1
Length of frm data: 0
Row Checksum: 1
Row GCI: 1
SingleUserMode: 2
ForceVarPart: 0
FragmentCount: 4
ExtraRowGciBits: 0
ExtraRowAuthorBits: 0
TableStatus: Retrieved
-- Attributes --
name Varchar(20;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
NDB$TNODE Unsigned [64] PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY
-- Indexes --
PRIMARY KEY(NDB$TNODE) - UniqueHashIndex
NDBT_ProgramExit: 0 - OK
```

When an index is specified in this way, the `--extra-partition-info` and `--extra-node-info` options have no effect.

The `Version` column in the output contains the table's schema object version. For information about interpreting this value, see `NDB Schema Object Versions`.

The `Extent_space` and `Free extent_space` columns were added in MySQL Cluster NDB 6.3.27 and MySQL Cluster NDB 7.0.8. They are applicable only to `NDB` tables having columns on disk; for tables having only in-memory columns, these columns always contain the value 0.

To illustrate their use, we modify the previous example. First, we must create the necessary Disk Data objects, as shown here:

```
CREATE LOGFILE GROUP lg_1
  ADD UNDOFILE 'undo_1.log'
  INITIAL_SIZE 16M
  UNDO_BUFFER_SIZE 2M
ENGINE NDB;
```
ALTER LOGFILE GROUP lg_1
ADD UNDOFILE 'undo_2.log'
INITIAL_SIZE 12M
ENGINE NDB;

CREATE TABLESPACE ts_1
ADD DATAFILE 'data_1.dat'
USE LOGFILE GROUP lg_1
INITIAL_SIZE 32M
ENGINE NDB;

ALTER TABLESPACE ts_1
ADD DATAFILE 'data_2.dat'
INITIAL_SIZE 48M
ENGINE NDB;

(For more information on the statements just shown and the objects created by them, see Section 17.5.12.1, "MySQL Cluster Disk Data Objects", as well as Section 13.1.14, "CREATE LOGFILE GROUP Syntax", and Section 13.1.18, "CREATE TABLESPACE Syntax".)

Now we can create and populate a version of the fish table that stores 2 of its columns on disk (deleting the previous version of the table first, if it already exists):

CREATE TABLE fish (
  id INT(11) NOT NULL AUTO_INCREMENT,
  name VARCHAR(20) NOT NULL,
  length_mm INT(11) NOT NULL,
  weight_gm INT(11) NOT NULL,
  PRIMARY KEY pk (id),
  UNIQUE KEY uk (name)
) TABLESPACE ts_1 STORAGE DISK
ENGINE=NDB;

INSERT INTO fish VALUES
('','guppy', 35, 2), ('','tuna', 2500, 150000),
('','shark', 3000, 110000), ('','manta ray', 1500, 50000),
('','grouper', 900, 125000), ('','puffer', 250, 250);

When run against this version of the table, ndb_desc displays the following output:

shell> ./ndb_desc -c localhost fish -d test -p
-- fish --
Version: 3
Fragment type: 9
K Value: 6
Min load factor: 78
Max load factor: 80
Temporary table: no
Number of attributes: 4
Number of primary keys: 1
Length of frm data: 321
Row Checksum: 1
Row GCI: 1
SingleUserMode: 0
ForceVarPart: 1
FragmentCount: 2
TableStatus: Retrieved
-- Attributes --
id Int PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
name Varchar(20;latin1_swedish_ci) NOT NULL AT=MEMORY AUTO_INCR
length_mm Int NOT NULL AT=DISK
weight_gm Int NOT NULL AT=DISK
-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex
uk$unique(name) - UniqueHashIndex
This means that 1048576 bytes are allocated from the tablespace for this table on each partition, of which 1044440 bytes remain free for additional storage. In other words, 1048576 - 1044440 = 4136 bytes per partition is currently being used to store the data from this table’s disk-based columns. The number of bytes shown as `Free extent_space` is available for storing on-disk column data from the `fish` table only; for this reason, it is not visible when selecting from the `INFORMATION_SCHEMA.FILES` table.

The following table includes options that are specific to `ndb_desc`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndb_desc`), see Section 17.4.26, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”.

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--blob-info, -b</code></td>
<td>Include partition information for BLOB tables in output. Requires the -p option also be used</td>
<td>ADDED: NDB 6.3.32, NDB 7.0.13, NDB 7.1.2</td>
</tr>
<tr>
<td><code>--database=dbname, -d</code></td>
<td>Name of database containing table</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td><code>--extra-node-info, -n</code></td>
<td>Include partition-to-data-node mappings in output. Requires the -p option also be used</td>
<td>ADDED: NDB 6.2.19, NDB 6.3.33, NDB 7.0.14, NDB 7.1.2</td>
</tr>
<tr>
<td><code>--extra-partition-info, -p</code></td>
<td>Display information about partitions</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td><code>--retries=#, -r</code></td>
<td>Number of times to retry the connection (once per second)</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td><code>--table=tbl_name, -t</code></td>
<td>Specify the table in which to find an index. When this option is used, -p and -n have no effect and are ignored.</td>
<td>ADDED: NDB 7.0.36, NDB 7.1.25</td>
</tr>
<tr>
<td><code>--unqualified, -u</code></td>
<td>Use unqualified table names</td>
<td>All MySQL 5.1 based releases</td>
</tr>
</tbody>
</table>

- `--blob-info, -b`  
Include information about subordinate BLOB and TEXT columns.

Use of this option also requires the use of the `--extra-partition-info (-p)` option.

This option was added in MySQL Cluster NDB 6.3.32, MySQL Cluster NDB 7.0.13, and MySQL Cluster NDB 7.1.2.

- `--database=db_name, -d`
Specify the database in which the table should be found.

- **--extra-node-info**, **-n**
  Include information about the mappings between table partitions and the data nodes upon which they reside. This information can be useful for verifying distribution awareness mechanisms and supporting more efficient application access to the data stored in MySQL Cluster.

Use of this option also requires the use of the **--extra-partition-info** (**-p**) option.

This option was added in MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.33, MySQL Cluster NDB 7.0.14, and MySQL Cluster NDB 7.1.2.

- **--extra-partition-info**, **-p**
  Print additional information about the table's partitions.

- **--retries=#**, **-r**
  Try to connect this many times before giving up. One connect attempt is made per second.

- **--table=tbl_name**, **-t**
  Specify the table in which to look for an index.

This option was added in MySQL Cluster NDB 7.0.36 and MySQL Cluster NDB 7.1.25.

- **--unqualified**, **-u**
  Use unqualified table names.

### 17.4.11 ndb_drop_index — Drop Index from an NDB Table

**ndb_drop_index** drops the specified index from an **NDB** table. *It is recommended that you use this utility only as an example for writing NDB API applications*—see the Warning later in this section for details.

**Usage**

```
ndb_drop_index -c connection_string table_name index -d db_name
```

The statement shown above drops the index named **index** from the **table** in the **database**.

The following table includes options that are specific to **ndb_drop_index**. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including **ndb_drop_index**), see Section 17.4.26, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”.

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>--database=dbname</strong>, <strong>-d</strong></td>
<td>Name of the database in which the table is found</td>
<td>All MySQL 5.1 based releases</td>
</tr>
</tbody>
</table>

**Warning**

*Operations performed on Cluster table indexes using the NDB API are not visible to MySQL and make the table unusable by a MySQL server. If you use this program to drop an index, then try to access the table from an SQL node, an error results, as shown here:*
shell> ./ndb_drop_index -c localhost dogs ix -d ctest1
Dropping index dogs/idx...OK

NDBT_ProgramExit: 0 - OK

shell> ./mysql -u jon -p ctest1
Enter password: *******
Reading table information for completion of table and column names
You can turn off this feature to get a quicker startup with -A

Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 7 to server version: 5.1.77-ndb-7.1.37

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>

SHOW TABLES;
+------------------+
| Tables_in_ctest1 |
+------------------+
| a                |
| bt1              |
| bt2              |
| dogs             |
| employees        |
| fish             |
+------------------+
6 rows in set (0.00 sec)

mysql> SELECT * FROM dogs;
ERROR 1296 (HY000): Got error 4243 'Index not found' from NDBCLUSTER

In such a case, your only option for making the table available to MySQL again is to drop the table and re-create it. You can use either the SQL statement `DROP TABLE` or the `ndb_drop_table` utility (see Section 17.4.12, “ndb_drop_table — Drop an NDB Table”) to drop the table.

17.4.12 `ndb_drop_table` — Drop an NDB Table

`ndb_drop_table` drops the specified NDB table. (If you try to use this on a table created with a storage engine other than NDB, the attempt fails with the error 723: No such table exists.) This operation is extremely fast; in some cases, it can be an order of magnitude faster than using a MySQL `DROP TABLE` statement on an NDB table.

Usage

```
ndb_drop_table -c connection_string tbl_name -d db_name
```

The following table includes options that are specific to `ndb_drop_table`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndb_drop_table`), see Section 17.4.26, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”.

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--database=dbname, -d</td>
<td>Name of the database in which the table is found</td>
<td>All MySQL 5.1 based releases</td>
</tr>
</tbody>
</table>

17.4.13 `ndb_error_reporter` — NDB Error-Reporting Utility

`ndb_error_reporter` creates an archive from data node and management node log files that can be used to help diagnose bugs or other problems with a cluster. It is highly recommended that you make use of this utility when filing reports of bugs in MySQL Cluster.
The following table includes command options specific to the MySQL Cluster program `ndb_error_reporter`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndb_error_reporter`), see Section 17.4.26, "Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs".

`ndb_error_reporter` did not support the `--help` option prior to MySQL Cluster NDB 6.3.52, MySQL Cluster NDB 7.0.40, and MySQL Cluster NDB 7.1.29 (Bug #11756666, Bug #48606). The `--connection-timeout --dry-scp`, and `--skip-nodegroup` options were also added in these releases (Bug #16602002).

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--connection-timeout=timeout</code></td>
<td>Number of seconds to wait when connecting to nodes before timing out.</td>
<td>ADDED: NDB 6.3.52, NDB 7.0.40, NDB 7.1.29</td>
</tr>
<tr>
<td><code>--dry-scp</code></td>
<td>Disable scp with remote hosts; used only for testing.</td>
<td>ADDED: NDB 6.3.52, NDB 7.0.40, NDB 7.1.29</td>
</tr>
<tr>
<td><code>--fs</code></td>
<td>Include file system data in error report; can use a large amount of disk space</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td><code>--skip-nodegroup=nodegroup_id</code></td>
<td>Skip all nodes in the node group having this ID.</td>
<td>ADDED: NDB 6.3.52, NDB 7.0.40, NDB 7.1.29</td>
</tr>
</tbody>
</table>

**Usage**

```
ndb_error_reporter path/to/config-file [username] [options]
```

This utility is intended for use on a management node host, and requires the path to the management host configuration file (usually named `config.ini`). Optionally, you can supply the name of a user that is able to access the cluster's data nodes using SSH, to copy the data node log files. `ndb_error_reporter` then includes all of these files in archive that is created in the same directory in which it is run. The archive is named `ndb_error_report_YYYYMMDDHHMMSS.tar.bz2`, where `YYYYMMDDHHMMSS` is a datetime string.

`ndb_error_reporter` also accepts the options listed here:

• **--connection-timeout=timeout**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.72-ndb-7.1.29</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--connection-timeout=timeout</code></td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type <code>integer</code></td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
</tbody>
</table>

  Wait this many seconds when trying to connect to nodes before timing out.

• **--dry-scp**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.72-ndb-7.1.29</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--dry-scp</code></td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type <code>boolean</code></td>
</tr>
<tr>
<td>Default</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

  Run `ndb_error_reporter` without using scp from remote hosts. Used for testing only.

• **--fs**
ndb_index_stat — NDB Index Statistics Utility

Command-Line Format: **--fs**

Permitted Values:
- Type: boolean
- Default: FALSE

Copy the data node file systems to the management host and include them in the archive.

Because data node file systems can be extremely large, even after being compressed, we ask that you please do **not** send archives created using this option to Oracle unless you are specifically requested to do so.

- **--skip-nodegroup=nodegroup_id**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>Command-Line Format</th>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.1.72-ndb-7.1.29</td>
<td><strong>--connection-timeout=timeout</strong></td>
<td>Type: integer, Default: 0</td>
</tr>
</tbody>
</table>

Skip all nodes belong to the node group having the supplied node group ID.

17.4.14 ndb_index_stat — NDB Index Statistics Utility

ndb_index_stat provides per-fragment statistical information about indexes on NDB tables. This includes cache version and age, number of index entries per partition, and memory consumption by indexes.

Usage

To obtain basic index statistics about a given NDB table, invoke ndb_index_stat as shown here, with the name of the table as the first argument and the name of the database containing this table specified immediately following it, using the **--database (-d)** option:

```bash
ndb_index_stat -d database table
```

In this example, we use ndb_index_stat to obtain such information about an NDB table named `mytable` in the `test` database:

```shell
shell> ndb_index_stat -d test mytable
table:City index:PRIMARY fragCount:2
  query cache: valid:1 sampleCount:1994 totalBytes:27916
times in ms: save: 7.133 sort: 1.974 sort per sample: 0.000
NDBT_ProgramExit: 0 - OK
```

**sampleVersion** is the version number of the cache from which the statistics data is taken. Running ndb_index_stat with the **--update** option causes sampleVersion to be incremented.

**loadTime** shows when the cache was last updated. This is expressed as seconds since the Unix Epoch.

**sampleCount** is the number of index entries found per partition. You can estimate the total number of entries by multiplying this by the number of fragments (shown as **fragCount**).

**sampleCount** can be compared with the cardinality of SHOW INDEX or INFORMATION_SCHEMA.STATISTICS, although the latter two provide a view of the table as a whole, while ndb_index_stat provides a per-fragment average.
keyBytes is the number of bytes used by the index. In this example, the primary key is an integer, which requires four bytes for each index, so keyBytes can be calculated in this case as shown here:

| keyBytes = sampleCount * (4 bytes per index) = 1994 * 4 = 7976 |

This information can also be obtained using the corresponding column definitions from INFORMATION_SCHEMA.COLUMNS (this requires a MySQL Server and a MySQL client application).

totalBytes is the total memory consumed by all indexes on the table, in bytes.

Timings shown in the preceding examples are specific to each invocation of ndb_index_stat.

The --verbose option provides some additional output, as shown here:

```
sHELL> ndb_index_stat -d test mytable --verbose
random seed 1337010518
connected
loop 1 of 1
table:mytable index:PRIMARY fragCount:4
sampleVersion:2 loadTime:1336751773 sampleCount:0 keyBytes:0
read stats
query cache created
query cache: valid:1 sampleCount:0 totalBytes:0
times in ms: save: 20.766 sort: 0.001
 disconnected
```

Options

The following table includes options that are specific to the MySQL Cluster ndb_index_stat utility. Additional descriptions are listed following the table. For options common to most MySQL Cluster programs (including ndb_index_stat), see Section 17.4.26, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”.

Table 17.80 This table describes command-line options for the ndb_index_stat program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--database=name, -d</td>
<td>Name of the database containing the table.</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--delete</td>
<td>Delete index statistics for the given table, stopping any auto-update previously configured.</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--update</td>
<td>Update index statistics for the given table, restarting any auto-update previously configured.</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--dump</td>
<td>Print the query cache.</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--query=#</td>
<td>Perform a number of random range queries on first key attr (must be int unsigned).</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--sys-drop</td>
<td>Drop any statistics tables and events in NDB kernel (all statistics are lost)</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--sys-create</td>
<td>Create all statistics tables and events in NDB kernel, if none of them already exist</td>
<td>All MySQL 5.1 based releases</td>
</tr>
</tbody>
</table>
### ndb_index_stat statistics options

The following options are used to generate index statistics. They work with a given table and database. They cannot be mixed with system options (see `ndb_index_stat system options`).

- `--database=name, -d name`
  - **Command-Line Format**
    - `--database=name`
  - **Permitted Values**
    - **Type**: string
    - **Default**: [none]
    - **Min Value**: [none]
    - **Max Value**: [none]

  The name of the database that contains the table being queried.

- `--delete`
  - **Command-Line Format**
    - `--delete`
  - **Permitted Values**
    - **Type**: boolean
    - **Default**: false
    - **Min Value**: false
    - **Max Value**: false

  Delete the index statistics for the given table, stopping any auto-update that was previously configured.

- `--update`
  - **Command-Line Format**
    - `--update`
**ndb_index_stat** — NDB Index Statistics Utility

<table>
<thead>
<tr>
<th>Permitted Values</th>
<th>Type</th>
<th>Default</th>
<th>Min Value</th>
<th>Max Value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>boolean</td>
<td>false</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**ndb_index_stat system options.** The following options are used to generate and update the statistics tables in the NDB kernel. None of these options can be mixed with statistics options (see ndb_index_stat statistics options).

- **--sys-drop**

  **Command-Line Format**
  ```
  --sys-drop
  ```

  **Permitted Values**
  ```
  Type    boolean
  Default false
  Min Value
  Max Value
  ```

  Drop all statistics tables and events in the NDB kernel. *This causes all statistics to be lost.*

- **--sys-create**

  **Command-Line Format**
  ```
  --sys-create
  ```

**Update the index statistics for the given table, and restart any auto-update that was previously configured.**

- **--dump**

  **Command-Line Format**
  ```
  --dump
  ```

  **Permitted Values**
  ```
  Type    boolean
  Default false
  Min Value
  Max Value
  ```

  Dump the contents of the query cache.

- **--query=#**

  **Command-Line Format**
  ```
  --query=#
  ```

  **Permitted Values**
  ```
  Type    numeric
  Default 0
  Min Value 0
  Max Value MAX_INT
  ```

  Perform random range queries on first key attribute (must be int unsigned).
Create all statistics tables and events in the NDB kernel. This works only if none of them exist previously.

- **sys-create-if-not-exist**

Command-Line Format: `--sys-create-if-not-exist`

<table>
<thead>
<tr>
<th>Permitted Values</th>
<th>Type</th>
<th>Default</th>
<th>Min Value</th>
<th>Max Value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>boolean</td>
<td>false</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Create any NDB system statistics tables or events (or both) that do not already exist when the program is invoked.

- **--sys-create-if-not-valid**

Command-Line Format: `--sys-create-if-not-valid`

<table>
<thead>
<tr>
<th>Permitted Values</th>
<th>Type</th>
<th>Default</th>
<th>Min Value</th>
<th>Max Value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>boolean</td>
<td>false</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Create any NDB system statistics tables or events that do not already exist, after dropping any that are invalid.

- **--sys-check**

Command-Line Format: `--sys-check`

<table>
<thead>
<tr>
<th>Permitted Values</th>
<th>Type</th>
<th>Default</th>
<th>Min Value</th>
<th>Max Value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>boolean</td>
<td>false</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Verify that all required system statistics tables and events exist in the NDB kernel.

- **--sys-skip-tables**

Command-Line Format: `--sys-skip-tables`

<table>
<thead>
<tr>
<th>Permitted Values</th>
<th>Type</th>
<th>Default</th>
<th>Min Value</th>
<th>Max Value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>boolean</td>
<td>false</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
ndb_print_backup_file — Print NDB Backup File Contents

Default false
Min Value
Max Value

Do not apply any --sys-* options to any statistics tables.

- --sys-skip-events

Command-Line Format --sys-skip-events
Permitted Values
Type boolean
Default false
Min Value
Max Value

Do not apply any --sys-* options to any events.

- --verbose

Command-Line Format --verbose
Permitted Values
Type boolean
Default false
Min Value
Max Value

Turn on verbose output.

- --loops=#

Command-Line Format --loops=#
Permitted Values
Type numeric
Default 0
Min Value
Max Value MAX_INT

Repeat commands this number of times (for use in testing).

17.4.15 ndb_print_backup_file — Print NDB Backup File Contents

ndb_print_backup_file obtains diagnostic information from a cluster backup file.

Usage

ndb_print_backup_file file_name

file_name is the name of a cluster backup file. This can be any of the files (.Data, .ctl, or .log file) found in a cluster backup directory. These files are found in the data node's backup directory under
the subdirectory BACKUP-#, where # is the sequence number for the backup. For more information about cluster backup files and their contents, see Section 17.5.3.1, “MySQL Cluster Backup Concepts”.

Like ndb_print_schema_file and ndb_print_sys_file (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) ndb_print_backup_file must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options

None.

17.4.16 ndb_print_file — Print NDB Disk Data File Contents

ndb_print_file obtains information from a MySQL Cluster Disk Data file.

Usage

```
ndb_print_file [-v] [-q] file_name+
```

`file_name` is the name of a MySQL Cluster Disk Data file. Multiple filenames are accepted, separated by spaces.

Like ndb_print_schema_file and ndb_print_sys_file (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) ndb_print_file must be run on a MySQL Cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

Additional Options

ndb_print_file supports the following options:

- `-v`: Make output verbose.
- `-q`: Suppress output (quiet mode).
- `--help`, `-h`, `?-`: Print help message.

This option did not work correctly prior to MySQL Cluster NDB 7.1.33. (Bug #17069285)

For more information, see Section 17.5.12, “MySQL Cluster Disk Data Tables”.

17.4.17 ndb_print_schema_file — Print NDB Schema File Contents

ndb_print_schema_file obtains diagnostic information from a cluster schema file.

Usage

```
ndb_print_schema_file file_name
```

`file_name` is the name of a cluster schema file. For more information about cluster schema files, see MySQL Cluster Data Node File System Directory Files.

Like ndb_print_backup_file and ndb_print_sys_file (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) ndb_print_schema_file must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be
used when the management server is not running, and even when the cluster has been completely shut down.

**Additional Options**

None.

### 17.4.18 ndb_print_sys_file — Print NDB System File Contents

*ndb_print_sys_file* obtains diagnostic information from a MySQL Cluster system file.

**Usage**

```
ndb_print_sys_file file_name
```

*file_name* is the name of a cluster system file (sysfile). Cluster system files are located in a data node's data directory (*DataDir*); the path under this directory to system files matches the pattern `ndb_#_fs/D/#/DBDIH/P/#.sysfile`. In each case, the # represents a number (not necessarily the same number). For more information, see MySQL Cluster Data Node File System Directory Files.

Like *ndb_print_backup_file* and *ndb_print_schema_file* (and unlike most of the other NDB utilities that are intended to be run on a management server host or to connect to a management server) *ndb_print_backup_file* must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

**Additional Options**

None.

### 17.4.19 ndbd_redo_log_reader — Check and Print Content of Cluster Redo Log

Reads a redo log file, checking it for errors, printing its contents in a human-readable format, or both. *ndbd_redo_log_reader* is intended for use primarily by MySQL Cluster developers and Support personnel in debugging and diagnosing problems.

This utility was made available as part of default builds beginning with MySQL Cluster NDB 6.1.3. It remains under development, and its syntax and behavior are subject to change in future releases. For this reason, it should be considered experimental at this time.

The C++ source files for *ndbd_redo_log_reader* can be found in the directory `/storage/ndb/src/kernel/blocks/dblqh/redoLogReader`.

The following table includes options that are specific to the MySQL Cluster program *ndbd_redo_log_reader*. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including *ndbd_redo_log_reader*), see Section 17.4.26, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”.

**Table 17.81** This table describes command-line options for the *ndbd_redo_log_reader* program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>-noprint</td>
<td>Do not print records</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>-nocheck</td>
<td>Do not check records for errors</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--help</td>
<td>Print usage information</td>
<td>ADDED: NDB 6.3.53, NDB 7.0.41, NDB 7.1.30</td>
</tr>
</tbody>
</table>

**Usage**
**ndbd_redo_log_reader**  
*file_name* is the name of a cluster redo log file. redo log files are located in the numbered directories under the data node’s data directory (*DataDir*); the path under this directory to the redo log files matches the pattern *ndb_* #_fs/D#/*LCP/*#T/#F#.*Data*. In each case, the *#* represents a number (not necessarily the same number). For more information, see MySQL Cluster Data Node File System Directory Files.

The name of the file to be read may be followed by one or more of the options listed here:

- **Command-Line Format**  
  - `--noprint`

  **Permitted Values**  
  - **Type**: boolean
  - **Default**: FALSE

  **--noprint**: Do not print the contents of the log file.

- **Command-Line Format**  
  - `--nocheck`

  **Permitted Values**  
  - **Type**: boolean
  - **Default**: FALSE

  **--nocheck**: Do not check the log file for errors.

- **Introduced**  
  - 5.1.73-ndb-7.1.30

  **Command-Line Format**  
  - `--help`

  **--help**: Print usage information.

  Added in MySQL Cluster NDB 6.3.53, MySQL Cluster NDB 7.0.41, and MySQL Cluster NDB 7.1.30. (Bug #11749591, Bug #36805)

Like **ndb_print_backup_file** and **ndb_print_schema_file** (and unlike most of the NDB utilities that are intended to be run on a management server host or to connect to a management server)** ndbd_redo_log_reader** must be run on a cluster data node, since it accesses the data node file system directly. Because it does not make use of the management server, this utility can be used when the management server is not running, and even when the cluster has been completely shut down.

### 17.4.20 ndb_restore — Restore a MySQL Cluster Backup

The cluster restoration program is implemented as a separate command-line utility **ndb_restore**, which can normally be found in the MySQL *bin* directory. This program reads the files created as a result of the backup and inserts the stored information into the database.

**ndb_restore** must be executed once for each of the backup files that were created by the **START BACKUP** command used to create the backup (see Section 17.5.3.2, "Using The MySQL Cluster Management Client to Create a Backup"). This is equal to the number of data nodes in the cluster at the time that the backup was created.

**Note**

Before using **ndb_restore**, it is recommended that the cluster be running in single user mode, unless you are restoring multiple data nodes in parallel. See Section 17.5.8, "MySQL Cluster Single User Mode", for more information.

The following table includes options that are specific to the MySQL Cluster native backup restoration program **ndb_restore**. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including **ndb_restore**), see Section 17.4.26, "Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs".

---

**ndb_restore** — Restore a MySQL Cluster Backup
### Table 17.82
This table describes command-line options for the ndb_restore program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--connect, -c</td>
<td>Alias for --connectstring.</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--nodeid=#, -n</td>
<td>Restore backup files to node with this ID</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--backupid=#, -b</td>
<td>Restore from the backup with the given ID</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--restore_data, -r</td>
<td>Restore table data and logs into NDB Cluster using the NDB API</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--restore_meta, -m</td>
<td>Restore metadata to NDB Cluster using the NDB API</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--no-upgrade, -u</td>
<td>Do not upgrade array type for varsize attributes which do not already resize VAR data, and do not change column attributes</td>
<td>ADDED: 5.1.19</td>
</tr>
<tr>
<td>--promote-attributes, -A</td>
<td>Allow attributes to be promoted when restoring data from backup</td>
<td>ADDED: NDB 6.3.8</td>
</tr>
<tr>
<td>--preserve-trailing-spaces, -P</td>
<td>Allow preservation of trailing spaces (including padding) when promoting fixed-width string types to variable-width types</td>
<td>ADDED: NDB 6.3.8</td>
</tr>
<tr>
<td>--no-restore-disk-objects, -d</td>
<td>Do not restore objects relating to Disk Data</td>
<td>ADDED: 5.1.6</td>
</tr>
<tr>
<td>--restore_epoch, -e</td>
<td>Restore epoch info into the status table. Convenient on a MySQL Cluster replication slave for starting replication. The row in mysql.ndb_apply_status with id 0 will be updated/inserted.</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--skip-table-check, -s</td>
<td>Skip table structure check during restoring of data</td>
<td>ADDED: 5.1.17</td>
</tr>
<tr>
<td>--parallelism=#, -p</td>
<td>Number of parallel transactions to use while restoring data</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--print</td>
<td>Print metadata, data and log to stdout (equivalent to --print_meta --print_data --print_log)</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--print_meta</td>
<td>Print metadata to stdout</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--print_data</td>
<td>Print data to stdout</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--print_log</td>
<td>Print to stdout</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--backup_path=dir_name</td>
<td>Path to backup files directory</td>
<td>ADDED: 5.1.17, NDB 6.1.5</td>
</tr>
<tr>
<td>Format</td>
<td>Description</td>
<td>Added or Removed</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
<td>------------------</td>
</tr>
<tr>
<td>--dont_ignore_systab_0, -f</td>
<td>Do not ignore system table during restore. Experimental only; not for production use</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--ndb-nodegroup-map=map, -z</td>
<td>Nodegroup map for NDBCLUSTER storage engine. Syntax: list of (source_nodegroup, destination_nodegroup)</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--fields-enclosed-by=char</td>
<td>Fields are enclosed with the indicated character</td>

<tr>
<td>--fields-terminated-by=char</td>
<td>Fields are terminated by the indicated character</td>
<td>ADDED: 5.1.18</td>
</tr>
<tr>
<td>--fields-optionally-enclosed-by</td>
<td>Fields are optionally enclosed with the indicated character</td>
<td>ADDED: 5.1.18</td>
</tr>
<tr>
<td>--lines-terminated-by=char</td>
<td>Lines are terminated by the indicated character</td>
<td>ADDED: 5.1.18</td>
</tr>
<tr>
<td>--hex</td>
<td>Print binary types in hexadecimal format</td>
<td>ADDED: 5.1.18</td>
</tr>
<tr>
<td>--tab=dir_name, -T dir_name</td>
<td>Creates a tab-separated .txt file for each table in the given path</td>
<td>ADDED: 5.1.18</td>
</tr>
<tr>
<td>--append</td>
<td>Append data to a tab-delimited file</td>
<td>ADDED: 5.1.18</td>
</tr>
<tr>
<td>--progress-frequency=#</td>
<td>Print status of restoration each given number of seconds</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--no-binlog</td>
<td>If a mysqld is connected and using binary logging, do not log the restored data</td>
<td>ADDED: NDB 6.2.16, NDB 6.3.16</td>
</tr>
<tr>
<td>--verbose=#</td>
<td>Level of verbosity in output</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--include-databases=db-list</td>
<td>List of one or more databases to restore (excludes those not named)</td>
<td>ADDED: NDB 6.3.22, NDB 6.4.3</td>
</tr>
<tr>
<td>--exclude-databases=db-list</td>
<td>List of one or more databases to exclude (includes those not named)</td>
<td>ADDED: NDB 6.3.22, NDB 6.4.3</td>
</tr>
<tr>
<td>--include-tables=table-list</td>
<td>List of one or more tables to restore (excludes those in same database that are not named); each table reference must include the database name</td>
<td>ADDED: NDB 6.3.22, NDB 6.4.3</td>
</tr>
<tr>
<td>--exclude-tables=table-list</td>
<td>List of one or more tables to exclude (includes those in the same database that are not named); each table reference must include the database name</td>
<td>ADDED: NDB 6.3.22, NDB 6.4.3</td>
</tr>
<tr>
<td>--exclude-missing-columns</td>
<td>Causes columns from the backup version of a table that are missing from the version of the table in the database to be ignored.</td>

<td>FALSE]</td>
<td>If TRUE (the default), do not restore any intermediate tables (having names prefixed with '#sql-') that were left over from copying ALTER TABLE operations.</td>
</tr>
</tbody>
</table>

Typical options for this utility are shown here:

```
ndb_restore [-c connection_string] -n node_id -b backup_id \
    [-m] -r --backup_path=/path/to/backup/files
```

Normally, when restoring from a MySQL Cluster backup, `ndb_restore` requires at a minimum the `--nodeid` (short form: `-n`), `--backupid` (short form: `-b`), and `--backup_path` options.

The `-c` option is used to specify a connection string which tells `ndb_restore` where to locate the cluster management server. (See Section 17.3.3.3, “MySQL Cluster Connection Strings”, for information on connection strings.) If this option is not used, then `ndb_restore` attempts to connect to a management server on `localhost:1186`. This utility acts as a cluster API node, and so requires a free connection “slot” to connect to the cluster management server. This means that there must be at least one [api] or [mysqld] section that can be used by it in the cluster `config.ini` file. It is a good idea to keep at least one empty [api] or [mysqld] section in `config.ini` that is not being used for a MySQL server or other application for this reason (see Section 17.3.3.7, “Defining SQL and Other API Nodes in a MySQL Cluster”).
You can verify that `ndb_restore` is connected to the cluster by using the `SHOW` command in the `ndb_mgm` management client. You can also accomplish this from a system shell, as shown here:

```
shell> ndb_mgm -e "SHOW"
```

The `--nodeid` or `-n` is used to specify the node ID of the data node on which the backup should be restored.

The first time you run the `ndb_restore` restoration program, you also need to restore the metadata. In other words, you must re-create the database tables—which can be done by running it with the `--restore_meta` (``-m``) option. Restoring the metadata need be done only on a single data node; this is sufficient to restore it to the entire cluster. Note that the cluster should have an empty database when starting to restore a backup. (In other words, you should start `ndbd` with `--initial` prior to performing the restore.)

It is possible to restore data without restoring table metadata. Prior to MySQL 5.1.17, `ndb_restore` did not perform any checks of table schemas; if a table was altered between the time the backup was taken and when `ndb_restore` was run, `ndb_restore` would still attempt to restore the data to the altered table.

Beginning with MySQL 5.1.17, the default behavior is for `ndb_restore` to fail with an error if table data do not match the table schema; this can be overridden using the `--skip-table-check` or `-s` option. Prior to MySQL 5.1.21, if this option is used, then `ndb_restore` attempts to fit data into the existing table schema, but the result of restoring a backup to a table schema that does not match the original is unspecified.

Beginning with MySQL Cluster NDB 6.3.35, MySQL Cluster NDB 7.0.16, and MySQL Cluster NDB 7.1.5, some of the restrictions on mismatches in column definitions when restoring data using `ndb_restore` are relaxed; when one of these types of mismatches is encountered, `ndb_restore` does not stop with an error as it did previously, but rather accepts the data and inserts it into the target table while issuing a warning to the user that this is being done. This behavior occurs whether or not either of the options `--skip-table-check` or `--promote-attributes` is in use. These differences in column definitions are of the following types:

- Different `COLUMN_FORMAT` settings (`FIXED`, `DYNAMIC`, `DEFAULT`)
- Different `STORAGE` settings (`MEMORY`, `DISK`)
- Different default values
- Different distribution key settings

Beginning with MySQL Cluster NDB 6.3.8, `ndb_restore` supports limited `attribute promotion` in much the same way that it is supported by MySQL replication; that is, data backed up from a column of a given type can generally be restored to a column using a “larger, similar” type. For example, data from a `CHAR(20)` column can be restored to a column declared as `VARCHAR(20)`, `VARCHAR(30)`, or `CHAR(30)`; data from a `MEDIUMINT` column can be restored to a column of type `INT` or `BIGINT`. See `Replication of Columns Having Different Data Types`, for a table of type conversions currently supported by attribute promotion.

Attribute promotion by `ndb_restore` must be enabled explicitly, as follows:

1. Prepare the table to which the backup is to be restored. `ndb_restore` cannot be used to re-create the table with a different definition from the original; this means that you must either create the table manually, or alter the columns which you wish to promote using `ALTER TABLE` after restoring the table metadata but before restoring the data.

2. Invoke `ndb_restore` with the `--promote-attributes` option (short form `-A`) when restoring the table data. Attribute promotion does not occur if this option is not used; instead, the restore operation fails with an error.
Prior to MySQL Cluster NDB 7.0.40 and MySQL Cluster NDB 7.1.29, conversions between character data types and TEXT or BLOB were not handled correctly (Bug #17325051).

Prior to MySQL Cluster NDB 7.1.32, demotion of TEXT to TINYTEXT was not handled correctly (Bug #18875137).

When converting between character data types and TEXT or BLOB, only conversions between character types (CHAR and VARCHAR) and binary types (BINARY and VARBINARY) can be performed at the same time. For example, you cannot promote an INT column to BIGINT while promoting a VARCHAR column to TEXT in the same invocation of ndb_restore.

Converting between TEXT columns using different character sets is not supported. Beginning with MySQL Cluster NDB 7.1.32, it is expressly disallowed (Bug #18875137).

When performing conversions of character or binary types to TEXT or BLOB with ndb_restore, you may notice that it creates and uses one or more staging tables named table_name$STnode_id. These tables are not needed afterwards, and are normally deleted by ndb_restore following a successful restoration.

```
--lossy-conversions, -L
```

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.51-ndb-7.1.11</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--lossy-conversions</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type  boolean</td>
</tr>
<tr>
<td></td>
<td>Default  FALSE</td>
</tr>
</tbody>
</table>

This option is intended to complement the --promote-attributes option. Using --lossy-conversions allows lossy conversions of column values (type demotions or changes in sign) when restoring data from backup. With some exceptions, the rules governing demotion are the same as for MySQL replication; see Replication of Columns Having Different Data Types, for information about specific type conversions currently supported by attribute demotion.

ndb_restore reports any truncation of data that it performs during lossy conversions once per attribute and column.

This option was added in MySQL Cluster NDB 7.1.11.

The --preserve-trailing-spaces option is also available beginning with MySQL Cluster NDB 6.3.8. This option (short form -R) causes trailing spaces to be preserved when promoting a fixed-width character data type to its variable-width equivalent—that is, when promoting a CHAR column value to VARCHAR or a BINARY column value to VARBINARY. Otherwise, any trailing spaces are dropped from such column values when they are inserted into the new columns.

**Note**

Although you can promote CHAR columns to VARCHAR and BINARY columns to VARBINARY, you cannot promote VARCHAR columns to CHAR or VARBINARY columns to BINARY.

The -b option is used to specify the ID or sequence number of the backup, and is the same number shown by the management client in the Backup backup_id completed message displayed upon completion of a backup. (See Section 17.5.3.2, “Using The MySQL Cluster Management Client to Create a Backup”.)

**Important**

When restoring cluster backups, you must be sure to restore all data nodes from backups having the same backup ID. Using files from different backups will at best result in restoring the cluster to an inconsistent state, and may fail altogether.
--restore_epoch (short form: -e) adds (or restores) epoch information to the cluster replication status table. This is useful for starting replication on a MySQL Cluster replication slave. When this option is used, the row in the mysql.ndb_apply_status having 0 in the id column is updated if it already exists; such a row is inserted if it does not already exist. (See Section 17.6.9, “MySQL Cluster Backups With MySQL Cluster Replication”.)

--restore_data

This option causes ndb_restore to output NDB table data and logs.

--restore_meta

This option causes ndb_restore to print NDB table metadata. Generally, you need only use this option when restoring the first data node of a cluster; additional data nodes can obtain the metadata from the first one.

--restore-privilege-tables

ndb_restore does not by default restore distributed MySQL privilege tables (MySQL Cluster NDB 7.2.0 and later). This option causes ndb_restore to restore the privilege tables. This works only if the privilege tables were converted to NDB before the backup was taken. For more information, see Section 17.5.14, “Distributed MySQL Privileges for MySQL Cluster”.

--backup_path

The path to the backup directory is required; this is supplied to ndb_restore using the --backup_path option, and must include the subdirectory corresponding to the ID backup of the backup to be restored. For example, if the data node’s DataDir is /var/lib/mysql-cluster, then the backup directory is /var/lib/mysql-cluster/BACKUP, and the backup files for the backup with the ID 3 can be found in /var/lib/mysql-cluster/BACKUP/BACKUP-3. The path may be absolute or relative to the directory in which the ndb_restore executable is located, and may be optionally prefixed with backup_path=.

Note

Previous to MySQL 5.1.17 and MySQL Cluster NDB 6.1.5, the path to the backup directory was specified as shown here, with backup_path= being optional:

[backup_path=]/path/to/backup/files

Beginning with MySQL 5.1.17 and MySQL Cluster NDB 6.1.5, this syntax changed to --backup_path=path/to/backup/files, to conform more closely with options used by other MySQL programs; --backupid is required, and there is no short form for this option.

It is possible to restore a backup to a database with a different configuration than it was created from. For example, suppose that a backup with backup ID 12, created in a cluster with two database nodes having the node IDs 2 and 3, is to be restored to a cluster with four nodes. Then ndb_restore must be run twice—once for each database node in the cluster where the backup was taken. However, ndb_restore cannot always restore backups made from a cluster running one version of MySQL to a cluster running a different MySQL version. See Section 17.2.7, “Upgrading and Downgrading MySQL Cluster”, for more information.

Important

It is not possible to restore a backup made from a newer version of MySQL Cluster using an older version of ndb_restore. You can restore a backup
made from a newer version of MySQL to an older cluster, but you must use a copy of `ndb_restore` from the newer MySQL Cluster version to do so.

For example, to restore a cluster backup taken from a cluster running MySQL Cluster NDB 7.1.8 to a cluster running MySQL Cluster NDB 7.0.16, you must use the `ndb_restore` that comes with the MySQL Cluster NDB 7.1.8 distribution.

For more rapid restoration, the data may be restored in parallel, provided that there is a sufficient number of cluster connections available. That is, when restoring to multiple nodes in parallel, you must have an `[api]` or `[mysqld]` section in the cluster `config.ini` file available for each concurrent `ndb_restore` process. However, the data files must always be applied before the logs.

`--no-upgrade`

Formerly, when using `ndb_restore` to restore a backup made from a MySQL 5.0 cluster to a 5.1 cluster, `VARCHAR` columns were not resized and were recreated using the 5.0 fixed format. Beginning with MySQL 5.1.19, `ndb_restore` recreates such `VARCHAR` columns using MySQL Cluster 5.1’s variable-width format. Also beginning with MySQL 5.1.19, this behavior can be overridden using the `--no-upgrade` option (short form: `-u`) when running `ndb_restore`.

`--print_data`

The `--print_data` option causes `ndb_restore` to direct its output to `stdout`.

`TEXT` and `BLOB` column values are always truncated to the first 256 bytes in the output; this cannot currently be overridden when using `--print_data`.

Beginning with MySQL 5.1.18, several additional options are available for use with the `--print_data` option in generating data dumps, either to `stdout`, or to a file. These are similar to some of the options used with `mysqldump`, and are shown in the following list:

- `--tab, -T`

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.18</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--tab=dir_name</code></td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type directory name</td>
</tr>
</tbody>
</table>

This option causes `--print_data` to create dump files, one per table, each named `tbl_name.txt`. It requires as its argument the path to the directory where the files should be saved; use `.` for the current directory.

- `--fields-enclosed-by=string`

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.18</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--fields-enclosed-by=char</code></td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type string</td>
</tr>
<tr>
<td>Default</td>
<td></td>
</tr>
</tbody>
</table>

Each column values are enclosed by the string passed to this option (regardless of data type; see next item).

- `--fields-optionally-enclosed-by=string`

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.18</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--fields-optionally-enclosed-by</code></td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type string</td>
</tr>
</tbody>
</table>
The string passed to this option is used to enclose column values containing character data (such as CHAR, VARCHAR, BINARY, TEXT, or ENUM).

- **--fields-terminated-by=string**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.18</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--fields-terminated-by=char</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type string</td>
</tr>
<tr>
<td></td>
<td>Default \t (tab)</td>
</tr>
</tbody>
</table>

The string passed to this option is used to separate column values. The default value is a tab character (\t).

- **--hex**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.18</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--hex</td>
</tr>
</tbody>
</table>

If this option is used, all binary values are output in hexadecimal format.

- **--fields-terminated-by=string**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.18</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--fields-terminated-by=char</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type string</td>
</tr>
<tr>
<td></td>
<td>Default \t (tab)</td>
</tr>
</tbody>
</table>

This option specifies the string used to end each line of output. The default is a linefeed character (\n).

- **--append**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.18</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--append</td>
</tr>
</tbody>
</table>

When used with the --tab and --print_data options, this causes the data to be appended to any existing files having the same names.

---

**Note**

If a table has no explicit primary key, then the output generated when using the --print_data option includes the table’s hidden primary key.

--print_meta

This option causes ndb_restore to print all metadata to stdout.

--print_log

The --print_log option causes ndb_restore to output its log to stdout.

--print

Causes ndb_restore to print all data, metadata, and logs to stdout. Equivalent to using the --print_data, --print_meta, and --print_log options together.
**ndb_restore** — Restore a MySQL Cluster Backup

**Note**
Use of `--print` or any of the `--print_*` options is in effect performing a dry run. Including one or more of these options causes any output to be redirected to `stdout`; in such cases, `ndb_restore` makes no attempt to restore data or metadata to a MySQL Cluster.

`--dont_ignore_systab_0`

Normally, when restoring table data and metadata, `ndb_restore` ignores the copy of the NDB system table that is present in the backup. `--dont_ignore_systab_0` causes the system table to be restored. This option is intended for experimental and development use only, and is not recommended in a production environment.

`--ndb-nodegroup-map, -z`

This option can be used to restore a backup taken from one node group to a different node group. Its argument is a list of the form `source_node_group, target_node_group`.

`--no-binlog`

This option prevents any connected SQL nodes from writing data restored by `ndb_restore` to their binary logs. Available beginning with MySQL Cluster NDB 6.2.16 and MySQL Cluster NDB 6.3.16.

`--no-restore-disk-objects, -d`

This option stops `ndb_restore` from restoring any MySQL Cluster Disk Data objects, such as tablespaces and log file groups; see Section 17.5.12, “MySQL Cluster Disk Data Tables”, for more information about these. Added in MySQL 5.1.6.

`--parallelism=#, -p`

`ndb_restore` uses single-row transactions to apply many rows concurrently. This parameter determines the number of parallel transactions (concurrent rows) that an instance of `ndb_restore` tries to use. By default, this is 128; the minimum is 1, and the maximum is 1024.

The work of performing the inserts is parallelized across the threads in the data nodes involved. This mechanism is employed for restoring bulk data from the `.Data` file—that is, the fuzzy snapshot of the data; it is not used for building or rebuilding indexes. The change log is applied serially; index drops and builds are DDL operations and handled separately. There is no thread-level parallelism on the client side of the restore.

`--progress-frequency=N`

Print a status report each `N` seconds while the backup is in progress. 0 (the default) causes no status reports to be printed. The maximum is 65535.

`--verbose= #`

Sets the level for the verbosity of the output. The minimum is 0; the maximum is 255. The default value is 1.

Beginning with MySQL 5.1.18, it is possible to restore only selected databases, or selected tables from a single database, using the syntax shown here:

```
ndb_restore other_options db_name[, db_name][,...] | tbl_name[, tbl_name][, ...]
```

In other words, you can specify either of the following to be restored:

- All tables from one or more databases
- One or more tables from a single database

`--include-databases=db_name[, db_name][,...]`
**ndb_restore — Restore a MySQL Cluster Backup**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.32-ndb-6.4.3</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>--include-databases=db-list</td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td>Type string</td>
</tr>
<tr>
<td>Default</td>
<td>--include-databases=db-list</td>
</tr>
</tbody>
</table>

```
--include-tables=\\db_name.\\tbl_name,\\db_name.\\tbl_name,\ldots
```

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.32-ndb-6.4.3</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td>--include-tables=table-list</td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td>Type string</td>
</tr>
<tr>
<td>Default</td>
<td>--include-tables=table-list</td>
</tr>
</tbody>
</table>

Beginning with MySQL Cluster NDB 6.3.22 and MySQL Cluster NDB 6.4.3, you can (and should) use instead the `--include-databases` option or the `--include-tables` option for restoring only specific databases or tables, respectively. `--include-databases` takes a comma-delimited list of databases to be restored. `--include-tables` takes a comma-delimited list of tables (in `database.table` format) to be restored.

When `--include-databases` or `--include-tables` is used, only those databases or tables named by the option are restored; all other databases and tables are excluded by `ndb_restore`, and are not restored.

The following table shows several invocations of `ndb_restore` using `--include-*` options (other options possibly required have been omitted for clarity), and the effects these have on restoring from a MySQL Cluster backup:

<table>
<thead>
<tr>
<th>Option Used</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--include-databases=db1</code></td>
<td>Only tables in database <code>db1</code> are restored; all tables in all other databases are ignored</td>
</tr>
<tr>
<td><code>--include-databases=db1,db2</code> or <code>--include-databases=db1 --include-databases=db2</code></td>
<td>Only tables in databases <code>db1</code> and <code>db2</code> are restored; all tables in all other databases are ignored</td>
</tr>
<tr>
<td><code>--include-tables=db1.t1</code></td>
<td>Only table <code>t1</code> in database <code>db1</code> is restored; no other tables in <code>db1</code> or in any other database are restored</td>
</tr>
<tr>
<td><code>--include-tables=db1.t2,db2.t1</code> or <code>--include-tables=db1.t2 --include-tables=db2.t1</code></td>
<td>Only the table <code>t2</code> in database <code>db1</code> and the table <code>t1</code> in database <code>db2</code> are restored; no other tables in <code>db1,db2</code>, or any other database are restored</td>
</tr>
</tbody>
</table>

Beginning with MySQL Cluster NDB 6.3.29 and MySQL Cluster NDB 7.0.10, you can use these two options together. For example, the following causes all tables in databases `db1` and `db2`, together with the tables `t1` and `t2` in database `db3`, to be restored (and no other databases or tables):

```
shell> ndb_restore [...] --include-databases=db1,db2 --include-tables=db3.t1,db3.t2
```

(Again we have omitted other, possibly required, options in the example just shown.)

**Note**

Prior to MySQL Cluster NDB 6.3.29 and MySQL Cluster NDB 7.0.10, multiple `--include-*` options were not handled correctly, and the result of the options shown in the previous example was that only the tables `db3.t1` and `db3.t2` were actually restored. (Bug #48907)

```
--exclude-databases=db_name[,db_name][,...]
```

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.32-ndb-6.4.3</th>
</tr>
</thead>
</table>
### — Restore a MySQL Cluster Backup

**Command-Line Format**

`--exclude-databases=db-list`  
**Permitted Values**  
**Type**: string  
**Default**

```
--exclude-tables=db_name.tbl_name[,db_name.tbl_name][,...]
```

**Introduced**  
5.1.32-ndb-6.4.3  
**Command-Line Format**  
`--exclude-tables=table-list`  
**Permitted Values**  
**Type**: string  
**Default**

Beginning with MySQL Cluster NDB 6.3.22 and MySQL Cluster NDB 6.4.3, it is possible to prevent one or more databases or tables from being restored using the `ndb_restore` options `--exclude-databases` and `--exclude-tables`. `--exclude-databases` takes a comma-delimited list of one or more databases which should not be restored. `--exclude-tables` takes a comma-delimited list of one or more tables (using `database.table` format) which should not be restored.

When `--exclude-databases` or `--exclude-tables` is used, only those databases or tables named by the option are excluded; all other databases and tables are restored by `ndb_restore`.

This table shows several invocations of `ndb_restore` using `--exclude-*` options (other options possibly required have been omitted for clarity), and the effects these options have on restoring from a MySQL Cluster backup:

<table>
<thead>
<tr>
<th>Option Used</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--exclude-databases=db1</code></td>
<td>All tables in all databases except <code>db1</code> are restored; no tables in <code>db1</code> are restored</td>
</tr>
<tr>
<td><code>--exclude-databases=db1,db2</code> (or <code>--exclude-databases=db1 --exclude-databases=db2</code>)</td>
<td>All tables in all databases except <code>db1</code> and <code>db2</code> are restored; no tables in <code>db1</code> or <code>db2</code> are restored</td>
</tr>
<tr>
<td><code>--exclude-tables=db1.t1</code></td>
<td>All tables except <code>t1</code> in database <code>db1</code> are restored; all other tables in <code>db1</code> are restored; all tables in all other databases are restored</td>
</tr>
<tr>
<td><code>--exclude-tables=db1.t2,db2.t1</code> (or <code>--exclude-tables=db1.t2 --exclude-tables=db2.t1</code>)</td>
<td>All tables in database <code>db1</code> except for <code>t2</code> and all tables in database <code>db2</code> except for table <code>t1</code> are restored; no other tables in <code>db1</code> or <code>db2</code> are restored; all tables in all other databases are restored</td>
</tr>
</tbody>
</table>

Beginning with MySQL Cluster NDB 6.3.29 and MySQL Cluster NDB 7.0.10, you can use these two options together. For example, the following causes all tables in all databases except for databases `db1` and `db2`, and tables `t1` and `t2` in database `db3`, to be restored:

```
shell> ndb_restore [...] --exclude-databases=db1,db2 --exclude-tables=db3.t1,db3.t2
```

(Again, we have omitted other possibly necessary options in the interest of clarity and brevity from the example just shown.)

**Note**

Prior to MySQL Cluster NDB 6.3.29 and MySQL Cluster NDB 7.0.10, multiple `--exclude-*` options were not handled correctly, with the result that the options shown in the previous example caused `ndb_restore` to exclude only the tables `db3.t1` and `db3.t2`. (Bug #48907)

Beginning with MySQL Cluster NDB 6.3.29 and MySQL Cluster NDB 7.0.10, you can use `--include-*` and `--exclude-*` options together, subject to the following rules:
• The actions of all `--include-*` and `--exclude-*` options are cumulative.

• All `--include-*` and `--exclude-*` options are evaluated in the order passed to ndb_restore, from right to left.

• In the event of conflicting options, the first (rightmost) option takes precedence. In other words, the first option (going from right to left) that matches against a given database or table “wins”.

For example, the following set of options causes `ndb_restore` to restore all tables from database `db1` except `db1.t1`, while restoring no other tables from any other databases:

```
--include-databases=db1 --exclude-tables=db1.t1
```

However, reversing the order of the options just given simply causes all tables from database `db1` to be restored (including `db1.t1`, but no tables from any other database), because the `--include-databases` option, being farthest to the right, is the first match against database `db1` and thus takes precedence over any other option that matches `db1` or any tables in `db1`:

```
--exclude-tables=db1.t1 --include-databases=db1
```

**Note**

Prior to MySQL Cluster NDB 6.3.29 and MySQL Cluster NDB 7.0.10, it was not possible to use `--include-databases` or `--include-tables` together with `--exclude-databases` or `--exclude-tables`, as these combinations were evaluated inconsistently. (Bug #48907)

`--exclude-missing-columns`

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.35-ndb-7.0.7</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--exclude-missing-columns</code></td>
</tr>
</tbody>
</table>

Beginning with MySQL Cluster NDB 6.3.26 and MySQL Cluster NDB 7.0.7, it is also possible to restore only selected table columns using the `--exclude-missing-columns` option. When this option is used, `ndb_restore` ignores any columns missing from tables being restored as compared to the versions of those tables found in the backup. This option applies to all tables being restored. If you wish to apply this option only to selected tables or databases, you can use it in combination with one or more of the options described in the previous paragraph to do so, then restore data to the remaining tables using a complementary set of these options.

`--exclude-missing-tables`

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.73-ndb-7.1.33</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--exclude-missing-tables</code></td>
</tr>
</tbody>
</table>

Beginning with MySQL Cluster NDB 7.1.33, it is also possible to restore only selected tables columns using this option, which causes `ndb_restore` to ignore any tables from the backup that are not found in the target database.

`--disable-indexes`

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.41-ndb-7.1.2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--disable-indexes</code></td>
</tr>
</tbody>
</table>

Beginning with MySQL Cluster NDB 6.3.31, MySQL Cluster NDB 7.0.11, and MySQL Cluster NDB 7.1.2, you can use this option with `ndb_restore` to disable restoration of indexes during restoration of the data from a native NDB backup. Afterwards, you can restore indexes for all tables at once with multi-threaded building of indexes using `--rebuild-indexes`, which should be faster than rebuilding indexes concurrently for very large tables.
### --rebuild-indexes

**Introduced** 5.1.41-ndb-7.1.2

**Command-Line Format**

```
--rebuild-indexes
```

Beginning with MySQL Cluster NDB 6.3.31, MySQL Cluster NDB 7.0.11, and MySQL Cluster NDB 7.1.2, you can use this option with `ndb_restore` to cause multi-threaded rebuilding of the ordered indexes while restoring a native NDB backup. The number of threads used for building ordered indexes by `ndb_restore` with this option is controlled by the `BuildIndexThreads` data node configuration parameter.

It is necessary to use this option only for the first run of `ndb_restore`; this causes all ordered indexes to be rebuilt without using `--rebuild-indexes` again when restoring subsequent nodes. You should use this option prior to inserting new rows into the database; otherwise, it is possible for a row to be inserted that later causes a unique constraint violation when trying to rebuild the indexes.

Building of ordered indices is parallelized with the number of LDMs by default. Offline index builds performed during node and system restarts can be made faster using the `BuildIndexThreads` data node configuration parameter; this parameter has no effect on dropping and rebuilding of indexes by `ndb_restore`, which is performed online.

Rebuilding of unique indexes uses disk write bandwidth for redo logging and local checkpointing. An insufficient amount of this bandwidth can lead to redo buffer overload or log overload errors. In such cases you can run `ndb_restore --rebuild-indexes` again; the process resumes at the point where the error occurred. You can also do this when you have encountered temporary errors. You can repeat execution of `ndb_restore --rebuild-indexes` indefinitely; you may be able to stop such errors by reducing the value of `DiskCheckpointSpeed` to provide additional disk bandwidth to redo logging, or reducing the `--parallelism`. If the problem is insufficient space, you can increase the size of the redo log (`FragmentLogFileSize` node configuration parameter), or you can increase the speed at which LCPs are performed (`DiskCheckpointSpeed`), in order to free space more quickly.

---

### --skip-broken-objects

**Introduced** 5.1.51-ndb-7.1.10

**Command-Line Format**

```
--skip-broken-objects
```

This option causes `ndb_restore` to ignore corrupt tables while reading a native NDB backup, and to continue restoring any remaining tables (that are not also corrupted). Currently, the `--skip-broken-objects` option works only in the case of missing blob parts tables.

This option was added in MySQL Cluster NDB 6.3.40, MySQL Cluster NDB 7.0.21, and MySQL Cluster NDB 7.1.10.

---

### --skip-unknown-objects

**Introduced** 5.1.44-ndb-7.1.4

**Command-Line Format**

```
--skip-unknown-objects
```

This option causes `ndb_restore` to ignore any schema objects it does not recognize while reading a native NDB backup. This can be used for restoring a backup made from a cluster running MySQL Cluster NDB 7.0 to a cluster running MySQL Cluster NDB 6.3.

This option was added in MySQL Cluster NDB 6.3.34, MySQL Cluster NDB 7.0.15, and MySQL Cluster NDB 7.1.4.

---

### --rewrite-database=old_dbname,new_dbname

**Introduced** 5.1.51-ndb-7.1.11

**Command-Line Format**

```
--rewrite-database=old_dbname,new_dbname
```

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
</tr>
</tbody>
</table>
This option makes it possible to restore to a database having a different name from that used in the backup. For example, if a backup is made of a database named `products`, you can restore the data it contains to a database named `inventory`, use this option as shown here (omitting any other options that might be required):

```
shell> ndb_restore --rewrite-database=product,inventory
```

The option can be employed multiple times in a single invocation of `ndb_restore`. Thus it is possible to restore simultaneously from a database named `db1` to a database named `db2` and from a database named `db3` to one named `db4` using `--rewrite-database=db1,db2 --rewrite-database=db3,db4`. Other `ndb_restore` options may be used between multiple occurrences of `--rewrite-database`.

In the event of conflicts between multiple `--rewrite-database` options, the last `--rewrite-database` option used, reading from left to right, is the one that takes effect. For example, if `--rewrite-database=db1,db2 --rewrite-database=db1,db3` is used, only `--rewrite-database=db1,db3` is honored, and `--rewrite-database=db1,db2` is ignored. It is also possible to restore from multiple databases to a single database, so that `--rewrite-database=db1,db3 --rewrite-database=db2,db3` restores all tables and data from databases `db1` and `db2` into database `db3`.

**Important**

When restoring from multiple backup databases into a single target database using `--rewrite-database`, no check is made for collisions between table or other object names, and the order in which rows are restored is not guaranteed. This means that it is possible in such cases for rows to be overwritten and updates to be lost.

This option was added in MySQL Cluster NDB 6.3.41, MySQL Cluster NDB 7.0.22, and MySQL Cluster NDB 7.1.11.

```
--exclude-intermediate-sql-tables[=TRUE|FALSE]
```

**Introduced** 5.1.73-ndb-7.1.31

**Command-Line Format**

```
--exclude-intermediate-sql-tables[=TRUE|FALSE]
```

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
</tr>
</tbody>
</table>

**Default** TRUE

When performing copying `ALTER TABLE` operations, `mysqld` creates intermediate tables (whose names are prefixed with `#sql-`). When TRUE, the `--exclude-intermediate-sql-tables` option keeps `ndb_restore` from restoring such tables that may have been left over from such operations. This option is TRUE by default.

The `--exclude-intermediate-sql-tables` option was introduced in MySQL Cluster NDB 7.1.31. (Bug #17882305)

**Error reporting.**

`ndb_restore` reports both temporary and permanent errors. In the case of temporary errors, it may be able to recover from them. Beginning with MySQL 5.1.12, it reports

```
Restore successful, but encountered temporary error, please look at configuration in such cases.
```

**Important**

After using `ndb_restore` to initialize a MySQL Cluster for use in circular replication, binary logs on the SQL node acting as the replication slave are not automatically created, and you must cause them to be created manually.
To cause the binary logs to be created, issue a `SHOW TABLES` statement on that SQL node before running `START SLAVE`. This is a known issue in MySQL Cluster.

### 17.4.21 ndb_select_all — Print Rows from an NDB Table

`ndb_select_all` prints all rows from an NDB table to stdout.

**Usage**

```
ndb_select_all -c connection_string tbl_name -d db_name [> file_name]
```

The following table includes options that are specific to the MySQL Cluster native backup restoration program `ndb_select_all`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndb_select_all`), see Section 17.4.26, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”.

**Table 17.83 This table describes command-line options for the ndb_select_all program**

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>

<td></td>
<td></td>
</tr>
<tr>
<td><code>--disk</code></td>
<td>Print disk references (useful only for Disk Data tables having nonindexed columns)</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td><code>--rowid</code></td>
<td>Print rowid</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td><code>--gci</code></td>
<td>Include GCI in output</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td><code>--gci64</code></td>
<td>Include GCI and row epoch in output</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td><code>--tupscan</code>,</td>
<td>Scan in tup order</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td><code>-t</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>--nodata</code></td>
<td>Do not print table column data</td>
<td>All MySQL 5.1 based releases</td>
</tr>
</tbody>
</table>
--database=dbname, -d dbname
Name of the database in which the table is found. The default value is TEST_DB.

parallelism=#, -p #
Specifies the degree of parallelism.

--lock=lock_type, -l lock_type
Employs a lock when reading the table. Possible values for lock_type are:
• 0: Read lock
• 1: Read lock with hold
• 2: Exclusive read lock
There is no default value for this option.

--order=index_name, -o index_name
Orders the output according to the index named index_name.

Note
This is the name of an index, not of a column; the index must have been explicitly named when created.

--descending, -z
Sorts the output in descending order. This option can be used only in conjunction with the -o (--order) option.

--header=FALSE
Excludes column headers from the output.

--useHexFormat -x
Causes all numeric values to be displayed in hexadecimal format. This does not affect the output of numerals contained in strings or datetime values.

--delimiter=character, -D character
Causes the character to be used as a column delimiter. Only table data columns are separated by this delimiter.
The default delimiter is the tab character.

--disk
Adds a disk reference column to the output. The column is nonempty only for Disk Data tables having nonindexed columns.

--rowid
Adds a ROWID column providing information about the fragments in which rows are stored.

--gci
Adds a GCI column to the output showing the global checkpoint at which each row was last updated. See Section 17.1, “MySQL Cluster Overview”, and Section 17.5.6.2, “MySQL Cluster Log Events”, for more information about checkpoints.
---

**ndb_select_all** — Print Rows from an NDB Table

- **--gci64**
  
  Adds a `ROW$GCI64` column to the output showing the global checkpoint at which each row was last updated, as well as the number of the epoch in which this update occurred.

- **--tupscan, -t**
  
  Scan the table in the order of the tuples.

- **--nodata**
  
  Causes any table data to be omitted.

**Sample Output**

Output from a MySQL **SELECT** statement:

```sql
mysql> SELECT * FROM ctest1.fish;
+----+-----------+
| id | name      |
+----+-----------+
|  3 | shark     |
|  6 | puffer    |
|  2 | tuna      |
|  4 | manta ray |
|  5 | grouper   |
|  1 | guppy     |
+----+-----------+
6 rows in set (0.04 sec)
```

Output from the equivalent invocation of **ndb_select_all**:

```shell
shell> ./ndb_select_all -c localhost fish -d ctest1
id      name
3       [shark]
6       [puffer]
2       [tuna]
4       [manta ray]
5       [grouper]
1       [guppy]
6 rows returned
```

All string values are enclosed by square brackets (“[...]”) in the output of **ndb_select_all**. For another example, consider the table created and populated as shown here:

```sql
CREATE TABLE dogs ( 
  id INT(11) NOT NULL AUTO_INCREMENT, 
  name VARCHAR(25) NOT NULL, 
  breed VARCHAR(50) NOT NULL, 
  PRIMARY KEY pk (id), 
  KEY ix (name) 
) 
TABLESPACE ts STORAGE DISK 
ENGINE=NDBCLUSTER; 
INSERT INTO dogs VALUES 
('', 'Lassie', 'collie'), 
('', 'Scooby-Doo', 'Great Dane'), 
('', 'Rin-Tin-Tin', 'Alsatian'), 
('', 'Rosscoe', 'Mutt'); 
```

This demonstrates the use of several additional **ndb_select_all** options:
17.4.22 ndb_select_count — Print Row Counts for NDB Tables

ndb_select_count prints the number of rows in one or more NDB tables. With a single table, the result is equivalent to that obtained by using the MySQL statement `SELECT COUNT(*) FROM tbl_name`.

Usage

```
ndb_select_count [-c connection_string] -d database_name tbl_name, tbl_name2[, ...]
```

The following table includes options that are specific to the MySQL Cluster native backup restoration program ndb_select_count. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including ndb_select_count), see Section 17.4.26, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”.

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--database=dbname,</td>
<td>Name of the database in which the table is found</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>-d</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--parallelism=#,</td>
<td>Degree of parallelism</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>-p</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--lock=#,</td>
<td>Lock type</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>-l</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

You can obtain row counts from multiple tables in the same database by listing the table names separated by spaces when invoking this command, as shown under Sample Output.

Sample Output

```
shell> ./ndb_select_count -c localhost -d ctest1 fish dogs
6 records in table fish
4 records in table dogs
NDBT_ProgramExit: 0 - OK
```

17.4.23 ndb_show_tables — Display List of NDB Tables

ndb_show_tables displays a list of all NDB database objects in the cluster. By default, this includes not only both user-created tables and NDB system tables, but NDB-specific indexes, internal triggers, and MySQL Cluster Disk Data objects as well.
The following table includes options that are specific to the MySQL Cluster native backup restoration program `ndb_show_tables`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndb_show_tables`), see Section 17.4.26, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”.

**Table 17.85** This table describes command-line options for the `ndb_show_tables` program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--database=string, -d</code></td>
<td>Specifies the database in which the table is found</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td><code>--loops=#, -l</code></td>
<td>Number of times to repeat output</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td><code>--type=#, -t</code></td>
<td>Limit output to objects of this type</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td><code>--unqualified, -u</code></td>
<td>Do not qualify table names</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td><code>--parsable, -p</code></td>
<td>Return output suitable for MySQL LOAD DATA INFILE statement</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td><code>--show-temp-status</code></td>
<td>Show table temporary flag</td>
<td>All MySQL 5.1 based releases</td>
</tr>
</tbody>
</table>

**Usage**

`ndb_show_tables [-c connection_string]`

- `--database, -d`
  Specifies the name of the database in which the tables are found.

- `--loops, -l`
  Specifies the number of times the utility should execute. This is 1 when this option is not specified, but if you do use the option, you must supply an integer argument for it.

- `--parsable, -p`
  Using this option causes the output to be in a format suitable for use with `LOAD DATA INFILE`.

- `--show-temp-status`
  If specified, this causes temporary tables to be displayed.

- `--type, -t`
  Can be used to restrict the output to one type of object, specified by an integer type code as shown here:
  - **1**: System table
  - **2**: User-created table
  - **3**: Unique hash index
  Any other value causes all NDB database objects to be listed (the default).

- `--unqualified, -u`
If specified, this causes unqualified object names to be displayed.

Note
Only user-created MySQL Cluster tables may be accessed from MySQL; system tables such as SYSTAB_0 are not visible to mysqld. However, you can examine the contents of system tables using NDB API applications such as ndb_select_all (see Section 17.4.21, "ndb_select_all — Print Rows from an NDB Table").

17.4.24 ndb_size.pl — NDBCLUSTER Size Requirement Estimator

This is a Perl script that can be used to estimate the amount of space that would be required by a MySQL database if it were converted to use the NDBCLUSTER storage engine. Unlike the other utilities discussed in this section, it does not require access to a MySQL Cluster (in fact, there is no reason for it to do so). However, it does need to access the MySQL server on which the database to be tested resides.

Requirements

- A running MySQL server. The server instance does not have to provide support for MySQL Cluster.
- A working installation of Perl.
- The DBI module, which can be obtained from CPAN if it is not already part of your Perl installation. (Many Linux and other operating system distributions provide their own packages for this library.)
- Previous to MySQL 5.1.18, ndb_size.pl also required the HTML::Template module and an associated template file share/mysql/ndb_size.tmpl. Beginning with MySQL 5.1.18, ndb_size.tmpl is no longer needed (or included).
- A MySQL user account having the necessary privileges. If you do not wish to use an existing account, then creating one using GRANT USAGE ON db_name.*—where db_name is the name of the database to be examined—is sufficient for this purpose.

ndb_size.pl can also be found in the MySQL sources in storage/ndb/tools.

The following table includes options that are specific to the MySQL Cluster program ndb_size.pl. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including ndb_size.pl), see Section 17.4.26, "Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs".

Table 17.86 This table describes command-line options for the ndb_size.pl program

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--database=dbname</td>
<td>The database or databases to examine; accepts a comma-delimited list; the default is ALL (use all databases found on the server)</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--hostname[:port]</td>
<td>Specify host and optional port as host[:port]</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--socket=file_name</td>
<td>Specify a socket to connect to host[:port]</td>
<td>ADDED: NDB 6.2.5</td>
</tr>
<tr>
<td>--user=string</td>
<td>Specify a MySQL user name</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--password=string</td>
<td>Specify a MySQL user password</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--format=string</td>
<td>Set output format (text or HTML)</td>
<td>All MySQL 5.1 based releases</td>
</tr>
</tbody>
</table>
### ndb_size.pl — NDBCLUSTER Size Requirement Estimator

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--excludetables=tbl_list</td>
<td>Skip any tables in a comma-separated list of tables</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--excludedbs=db_list</td>
<td>Skip any databases in a comma-separated list of databases</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--savequeries=file</td>
<td>Saves all queries to the database into the file specified</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--loadqueries=file</td>
<td>Loads all queries from the file specified; does not connect to a database</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--real_table_name=table</td>
<td>Designates a table to handle unique index size calculations</td>
<td>ADDED: NDB 6.2.5</td>
</tr>
</tbody>
</table>

#### Usage

```perl
perl ndb_size.pl [--database={db_name|ALL}] [--hostname=host[:port]] [--socket=socket] \ [--user=user] [--password=password] \ [--help|-h] [--format={html|text}] \ [--loadqueries=file_name] [--savequeries=file_name]
```

By default, this utility attempts to analyze all databases on the server. You can specify a single database using the `--database` option; the default behavior can be made explicit by using `ALL` for the name of the database. You can also exclude one or more databases by using the `--excludedbs` option with a comma-separated list of the names of the databases to be skipped. Similarly, you can cause specific tables to be skipped by listing their names, separated by commas, following the optional `--excludetables` option. A host name (and possibly a port as well) can be specified using `--hostname`; the default is `localhost`. Beginning with MySQL Cluster NDB 6.3.49, MySQL Cluster NDB 7.0.32, and MySQL Cluster NDB 7.1.21, you can specify a port in addition to the host using `host:port` format for the value of `--hostname`. The default port number is 3306. If necessary, you can also specify a socket; the default is `/var/lib/mysql.sock` a MySQL user name and password can be specified the corresponding options shown. It also possible to control the format of the output using the `--format` option; this can take either of the values `html` or `text`, with `text` being the default. An example of the text output is shown here:

```
shell> ndb_size.pl --database=test --socket=/tmp/mysql.sock
ndb_size.pl report for database: 'test' (1 tables)
--------------------------------------------------
Connected to: DBI:mysql:host=localhost;mysql_socket=/tmp/mysql.sock
Including information for versions: 4.1, 5.0, 5.1
test.t1
-------
DataMemory for Columns (* means varsized DataMemory):
  Column Name        Type  Varsized   Key  4.1  5.0   5.1
HIDDEN_NDB_PKEY     bigint             PRI    8    8     8
                    c2     varchar(50)         Y         52   52    4*
c1         int(11)                    4    4     4
  --   --    --
Fixed Size Columns DM/Row                              64   64    12
Varsize Columns DM/Row
DataMemory for Indexes:
  Index Name        Type  4.1  5.0   5.1

Parameter Minimum Requirements
----------------------------------
* indicates greater than default

For debugging purposes, the Perl arrays containing the queries run by this script can be read from the file specified using the `--savequeries` option; a file containing such arrays to be read in during script execution can be specified using the `--loadqueries` option. Neither of these options has a default value.

To produce output in HTML format, use the `--format` option and redirect the output to a file, as shown here:

```
shell> ndb_size.pl --database=test --socket=/tmp/mysql.sock --format=html > ndb_size.html
```

(Wihtout the redirection, the output is sent to `stdout`.)

The output from this script includes the following information:

- Minimum values for the `DataMemory`, `IndexMemory`, `MaxNoOfTables`, `MaxNoOfAttributes`, `MaxNoOfOrderedIndexes`, `MaxNoOfUniqueHashIndexes`, and `MaxNoOfTriggers` configuration parameters required to accommodate the tables analyzed.

- Memory requirements for all of the tables, attributes, ordered indexes, and unique hash indexes defined in the database.

- The `IndexMemory` and `DataMemory` required per table and table row.

**Note**

Prior to MySQL 5.1.23, MySQL Cluster NDB 6.2.5, and MySQL Cluster NDB 6.3.7, `ndb_size.pl` was invoked as shown here:
perl ndb_size.pl db_name hostname username password > file_name.html

For more information about this change, see Bug #28683 and Bug #28253.

**17.4.25 ndb_waiter — Wait for MySQL Cluster to Reach a Given Status**

`ndb_waiter` repeatedly (each 100 milliseconds) prints out the status of all cluster data nodes until either the cluster reaches a given status or the `--timeout` limit is exceeded, then exits. By default, it waits for the cluster to achieve `STARTED` status, in which all nodes have started and connected to the cluster. This can be overridden using the `--no-contact` and `--not-started` options.

The node states reported by this utility are as follows:

- **NO_CONTACT**: The node cannot be contacted.
- **UNKNOWN**: The node can be contacted, but its status is not yet known. Usually, this means that the node has received a `START` or `RESTART` command from the management server, but has not yet acted on it.
- **NOT_STARTED**: The node has stopped, but remains in contact with the cluster. This is seen when restarting the node using the management client's `RESTART` command.
- **STARTING**: The node's `ndbd` process has started, but the node has not yet joined the cluster.
- **STARTED**: The node is operational, and has joined the cluster.
- **SHUTTING_DOWN**: The node is shutting down.
- **SINGLE USER MODE**: This is shown for all cluster data nodes when the cluster is in single user mode.

The following table includes options that are specific to the MySQL Cluster native backup restoration program `ndb_waiter`. Additional descriptions follow the table. For options common to most MySQL Cluster programs (including `ndb_waiter`), see Section 17.4.26, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”.

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--no-contact</code>, <code>-n</code></td>
<td>Wait for cluster to reach NO CONTACT state</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td><code>--not-started</code></td>
<td>Wait for cluster to reach NOT STARTED state</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td><code>--single-user</code></td>
<td>Wait for cluster to enter single user mode</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td><code>--timeout=#</code>, <code>-t</code></td>
<td>Wait this many seconds, then exit whether or not cluster has reached desired state; default is 2 minutes (120 seconds)</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td><code>--nowait-nodes=list</code></td>
<td>List of nodes not to be waited for.</td>
<td>ADDED: NDB 6.2.1</td>
</tr>
<tr>
<td><code>--wait-nodes=list</code>, <code>-w</code></td>
<td>List of nodes to be waited for.</td>
<td>ADDED: NDB 6.3.34, NDB 7.0.15, NDB 7.1.4</td>
</tr>
</tbody>
</table>

**Usage**

```
ndb_waiter [-c connection_string]
```
ndb_waiter — Wait for MySQL Cluster to Reach a Given Status

Additional Options

- **--no-contact, -n**
  Instead of waiting for the **STARTED** state, `ndb_waiter` continues running until the cluster reaches **NO>Contact** status before exiting.

- **--not-started**
  Instead of waiting for the **STARTED** state, `ndb_waiter` continues running until the cluster reaches **NOT>Started** status before exiting.

- **--timeout=seconds, -t seconds**
  Time to wait. The program exits if the desired state is not achieved within this number of seconds. The default is 120 seconds (1200 reporting cycles).

- **--single-user**
  The program waits for the cluster to enter single user mode.

- **--nowait-nodes=list**
  When this option is used, `ndb_waiter` does not wait for the nodes whose IDs are listed. The list is comma-delimited; ranges can be indicated by dashes, as shown here:

```shell
shell> ndb_waiter --nowait-nodes=1,3,7-9
```

**Important**
Do *not* use this option together with the **--wait-nodes** option.

This option was added in MySQL Cluster NDB 6.2.1.

- **--wait-nodes=list, -w list**
  When this option is used, `ndb_waiter` waits only for the nodes whose IDs are listed. The list is comma-delimited; ranges can be indicated by dashes, as shown here:

```shell
shell> ndb_waiter --wait-nodes=2,4-6,10
```

**Important**
Do *not* use this option together with the **--nowait-nodes** option.

This option was added in MySQL Cluster NDB 6.3.34, 7.0.15, and 7.1.4.

**Sample Output.** Shown here is the output from `ndb_waiter` when run against a 4-node cluster in which two nodes have been shut down and then started again manually. Duplicate reports (indicated by “...”) are omitted.

```shell
shell> ./ndb_waiter -c localhost
Connecting to mgmsrv at (localhost)
State node 1 STARTED
State node 2 NO_CONTACT
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED
...
```
State node 1 STARTED
State node 2 UNKNOWN
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED
...
State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 NO_CONTACT
Waiting for cluster enter state STARTED
...
State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 UNKNOWN
Waiting for cluster enter state STARTED
...
State node 1 STARTED
State node 2 STARTING
State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED
...
State node 1 STARTED
State node 2 STARTED
State node 3 STARTED
State node 4 STARTING
Waiting for cluster enter state STARTED
...
State node 1 STARTED
State node 2 STARTED
State node 3 STARTED
State node 4 STARTED
Waiting for cluster enter state STARTED
NDBT_ProgramExit: 0 - OK

Note
If no connection string is specified, then ndb_waiter tries to connect to a management on localhost, and reports Connecting to mgmsrv at (null).

17.4.26 Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs

All MySQL Cluster programs accept the options described in this section, with the following exceptions:

- `mysqld`
- `ndb_print_backup_file`
- `ndb_print_schema_file`
- `ndb_print_sys_file`

Users of earlier MySQL Cluster versions should note that some of these options have been changed to make them consistent with one another as well as with `mysqld`. You can use the `--help`
option with any MySQL Cluster program—with the exception of ndb_print_backup_file, ndb_print_schema_file, and ndb_print_sys_file—to view a list of the options which the program supports.

The options in the following table are common to all MySQL Cluster executables (except those noted previously in this section).

Table 17.88 This table describes command-line options common to all MySQL Cluster programs

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Added or Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--help,</td>
<td>Display help message and exit</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--usage,</td>
<td></td>
<td></td>
</tr>
<tr>
<td>-?</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--character-sets-dir=dir_name</td>
<td>Directory where character sets are installed</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--core-file</td>
<td>Write core on errors (defaults to TRUE in debug builds)</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--debug=options</td>
<td>Enable output from debug calls. Can be used only for versions compiled with debugging enabled</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--ndb-connectstring=connectstring</td>
<td>Set connection string for connecting to ndb_mgmd. Syntax: [nodeid=&lt;id&gt;];[host=]&lt;hostname&gt;[:&lt;port&gt;]. Overrides entries specified in NDB_CONNECTSTRING or my.cnf.</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--connect-string=connectstring, -c</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--ndb-mgmd-host=host[:port]</td>
<td>Set the host (and port, if desired) for connecting to management server</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--ndb-nodeid=#</td>
<td>Set node id for this node</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--ndb-optimized-node-selection</td>
<td>Select nodes for transactions in a more optimal way</td>
<td>All MySQL 5.1 based releases</td>
</tr>
<tr>
<td>--ndb-shm</td>
<td>Allow for optimization using shared memory connections where available (was EXPERIMENTAL, later REMOVED)</td>
<td>REMOVED: NDB 7.0.16, NDB 7.1.5</td>
</tr>
<tr>
<td>--version, -v</td>
<td>Output version information and exit</td>
<td>All MySQL 5.1 based releases</td>
</tr>
</tbody>
</table>

For options specific to individual MySQL Cluster programs, see Section 17.4, “MySQL Cluster Programs”.

See MySQL Server Options for MySQL Cluster, for mysqld options relating to MySQL Cluster.

* --help, --usage, -?
Prints a short list with descriptions of the available command options.

- **--character-sets-dir=name**

  **Command-Line Format**  
  ```plaintext```
  --character-sets-dir=dir_name
  ```plaintext```

  **Permitted Values**
  - **Type**: directory name
  - **Default**

  Tells the program where to find character set information.

- **--ndb-connectstring=connection_string, --connect-string=connection_string, -c connection_string**

  **Command-Line Format**
  ```plaintext```
  --ndb-connectstring=connectstring
  --connect-string=connectstring
  ```plaintext```

  **Permitted Values**
  - **Type**: string
  - **Default**: localhost:1186

  This option takes a MySQL Cluster connection string that specifies the management server for the application to connect to, as shown here:

  ```plaintext```
  shell> ndbd --ndb-connectstring="nodeid=2;host=ndb_mgmd.mysql.com:1186"
  ```plaintext```

  For more information, see Section 17.3.3.3, “MySQL Cluster Connection Strings”.

- **--core-file**

  **Command-Line Format**
  ```plaintext```
  --core-file
  ```plaintext```

  **Permitted Values**
  - **Type**: boolean
  - **Default**: FALSE

  Write a core file if the program dies. The name and location of the core file are system-dependent. (For MySQL Cluster programs nodes running on Linux, the default location is the program’s working directory—for a data node, this is the node’s DataDir.) For some systems, there may be restrictions or limitations; for example, it might be necessary to execute `ulimit -c unlimited` before starting the server. Consult your system documentation for detailed information.

  If MySQL Cluster was built using the `--debug` option for `configure`, then `--core-file` is enabled by default. For regular builds, `--core-file` is disabled by default.

- **--debug[=options]**

  **Command-Line Format**
  ```plaintext```
  --debug=options
  ```plaintext```

  **Permitted Values**
  - **Type**: string
  - **Default**: d:t:O,/tmp/ndb_restore.trace

  This option can be used only for versions compiled with debugging enabled. It is used to enable output from debug calls in the same manner as for the `mysqld` process.

- **--ndb-mgmd-host=host[[:port]]**

  **Command-Line Format**
  ```plaintext```
  --ndb-mgmd-host=host[:port]
  ```plaintext```

  **Permitted Values**
  - **Type**: string
  - **Default**: localhost:1186
Can be used to set the host and port number of a single management server for the program to connect to. If the program requires node IDs or references to multiple management servers (or both) in its connection information, use the `--ndb-connectstring` option instead.

- `--ndb-nodeid=size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--ndb-nodeid=size</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>Type numeric</td>
</tr>
<tr>
<td></td>
<td>Default 0</td>
</tr>
</tbody>
</table>

Sets this node's MySQL Cluster node ID. The range of permitted values depends on the node's type (data, management, or API) and the MySQL Cluster software version. See Section 17.1.6.2, “Limits and Differences of MySQL Cluster from Standard MySQL Limits”, for more information.

- `--ndb-optimized-node-selection`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--ndb-optimized-node-selection</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td>Type boolean</td>
</tr>
<tr>
<td></td>
<td>Default TRUE</td>
</tr>
</tbody>
</table>

Optimize selection of nodes for transactions. Enabled by default.

- `--version, -V`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--version</code></th>
</tr>
</thead>
</table>

Prints the MySQL Cluster version number of the executable. The version number is relevant because not all versions can be used together, and the MySQL Cluster startup process verifies that the versions of the binaries being used can co-exist in the same cluster. This is also important when performing an online (rolling) software upgrade or downgrade of MySQL Cluster.

See Section 17.5.5, “Performing a Rolling Restart of a MySQL Cluster”), for more information.

- `--ndb-shm`

<table>
<thead>
<tr>
<th>Removed</th>
<th>5.1.47-ndb-7.1.5</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ndb-shm</code></td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type boolean</td>
</tr>
<tr>
<td></td>
<td>Default FALSE</td>
</tr>
</tbody>
</table>

In older versions of MySQL Cluster, this experimental option allowed the application to use shared memory for optimization when available. `--ndb-shm` was removed from all MySQL Cluster programs beginning with MySQL Cluster NDB 7.0.16 and MySQL Cluster 7.1.5.

## 17.5 Management of MySQL Cluster

Managing a MySQL Cluster involves a number of tasks, the first of which is to configure and start MySQL Cluster. This is covered in Section 17.3, “Configuration of MySQL Cluster NDB 6.1-7.1”, and Section 17.4, “MySQL Cluster Programs”.

The next few sections cover the management of a running MySQL Cluster.

For information about security issues relating to management and deployment of a MySQL Cluster, see Section 17.5.11, “MySQL Cluster Security Issues”.

There are essentially two methods of actively managing a running MySQL Cluster. The first of these is through the use of commands entered into the management client whereby cluster status can be...
checked, log levels changed, backups started and stopped, and nodes stopped and started. The second method involves studying the contents of the cluster log ndb_node_id_cluster.log; this is usually found in the management server's DataDir directory, but this location can be overridden using the LogDestination option. (Recall that node_id represents the unique identifier of the node whose activity is being logged.) The cluster log contains event reports generated by ndbd. It is also possible to send cluster log entries to a Unix system log.

Some aspects of the cluster's operation can also be monitored from an SQL node using the SHOW ENGINE NDB STATUS statement.

In MySQL Cluster NDB 7.1.1 and later, detailed information about cluster operations is available in real time through an SQL interface using the ndbinfo database. For more information, see Section 17.5.10, "The ndbinfo MySQL Cluster Information Database".

Beginning with MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11, NDB statistics counters provide improved monitoring using the mysql client. These counters, implemented in the NDB kernel, relate to operations performed by or affecting Ndb objects, such as starting, closing, and aborting transactions; primary key and unique key operations; table, range, and pruned scans; blocked threads waiting for various operations to complete; and data and events sent and received by MySQL Cluster. The counters are incremented by the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes.

mysql exposes the NDB API statistics counters as system status variables, which can be identified from the prefix common to all of their names (Ndb_api__). The values of these variables can be read in the mysql client from the output of a SHOW STATUS statement, or by querying either the SESSION_STATUS table or the GLOBAL_STATUS table (in the INFORMATION_SCHEMA database). By comparing the values of the status variables before and after the execution of an SQL statement that acts on NDB tables, you can observe the actions taken on the NDB API level that correspond to this statement, which can be beneficial for monitoring and performance tuning of MySQL Cluster.

MySQL Cluster Manager provides an advanced command-line interface that simplifies many otherwise complex MySQL Cluster management tasks, such as starting, stopping, or restarting a MySQL Cluster with a large number of nodes. The MySQL Cluster Manager client also supports commands for getting and setting the values of most node configuration parameters as well as mysql server options and variables relating to MySQL Cluster. See MySQL™ Cluster Manager 1.3.6 User Manual, for more information.

### 17.5.1 Summary of MySQL Cluster Start Phases

This section provides a simplified outline of the steps involved when MySQL Cluster data nodes are started. More complete information can be found in MySQL Cluster Start Phases, in the NDB Internals Guide.

These phases are the same as those reported in the output from the node_id STATUS command in the management client (see Section 17.5.2, "Commands in the MySQL Cluster Management Client"). In MySQL Cluster NDB 7.1.1 and later, these start phases are also reported in the start_phase column of the ndbinfo.nodes table.

#### Start types.

There are several different startup types and modes, as shown in the following list:

- **Initial start.** The cluster starts with a clean file system on all data nodes. This occurs either when the cluster started for the very first time, or when all data nodes are restarted using the --initial option.

  ![Note](image)

  Disk Data files are not removed when restarting a node using --initial.

- **System restart.** The cluster starts and reads data stored in the data nodes. This occurs when the cluster has been shut down after having been in use, when it is desired for the cluster to resume operations from the point where it left off.
Summary of MySQL Cluster Start Phases

• **Node restart.** This is the online restart of a cluster node while the cluster itself is running.

• **Initial node restart.** This is the same as a node restart, except that the node is reinitialized and started with a clean file system.

**Setup and initialization (phase -1).** Prior to startup, each data node (ndbd process) must be initialized. Initialization consists of the following steps:

1. Obtain a node ID
2. Fetch configuration data
3. Allocate ports to be used for inter-node communications
4. Allocate memory according to settings obtained from the configuration file

When a data node or SQL node first connects to the management node, it reserves a cluster node ID. To make sure that no other node allocates the same node ID, this ID is retained until the node has managed to connect to the cluster and at least one ndbd reports that this node is connected. This retention of the node ID is guarded by the connection between the node in question and ndb_mgmd.

**Freeing unused node IDs.** Normally, in the event of a problem with the node, the node disconnects from the management server, the socket used for the connection is closed, and the reserved node ID is freed. However, if a node is disconnected abruptly—for example, due to a hardware failure in one of the cluster hosts, or because of network issues—the normal closing of the socket by the operating system may not take place. In this case, the node ID continues to be reserved and not released until a TCP timeout occurs 10 or so minutes later.

To take care of this problem, you can use `PURGE STALE SESSIONS`. Running this statement forces all reserved node IDs to be checked; any that are not being used by nodes actually connected to the cluster are then freed.

Beginning with MySQL 5.1.11, timeout handling of node ID assignments is implemented. This performs the ID usage checks automatically after approximately 20 seconds, so that `PURGE STALE SESSIONS` should no longer be necessary in a normal Cluster start.

After each data node has been initialized, the cluster startup process can proceed. The stages which the cluster goes through during this process are listed here:

• **Phase 0.** The NDBFS and NDBCNTR blocks start (see NDB Kernel Blocks). Data node file systems are cleared on those data nodes that were started with --initial option.

• **Phase 1.** In this stage, all remaining NDB kernel blocks are started. MySQL Cluster connections are set up, inter-block communications are established, and heartbeats are started. In the case of a node restart, API node connections are also checked.

  **Note**
  
  When one or more nodes hang in Phase 1 while the remaining node or nodes hang in Phase 2, this often indicates network problems. One possible cause of such issues is one or more cluster hosts having multiple network interfaces. Another common source of problems causing this condition is the blocking of TCP/IP ports needed for communications between cluster nodes. In the latter case, this is often due to a misconfigured firewall.

• **Phase 2.** The NDBCNTR kernel block checks the states of all existing nodes. The master node is chosen, and the cluster schema file is initialized.

• **Phase 3.** The DBLQH and DBTC kernel blocks set up communications between them. The startup type is determined; if this is a restart, the DBDIH block obtains permission to perform the restart.

• **Phase 4.** For an initial start or initial node restart, the redo log files are created. The number of these files is equal to NoOffFragmentLogFiles.
For a system restart:
• Read schema or schemas.
• Read data from the local checkpoint.
• Apply all redo information until the latest restorable global checkpoint has been reached.

For a node restart, find the tail of the redo log.

• **Phase 5.** Most of the database-related portion of a data node start is performed during this phase. For an initial start or system restart, a local checkpoint is executed, followed by a global checkpoint. Periodic checks of memory usage begin during this phase, and any required node takeovers are performed.

• **Phase 6.** In this phase, node groups are defined and set up.

• **Phase 7.** The arbitrator node is selected and begins to function. The next backup ID is set, as is the backup disk write speed. Nodes reaching this start phase are marked as **Started**. It is now possible for API nodes (including SQL nodes) to connect to the cluster.

• **Phase 8.** If this is a system restart, all indexes are rebuilt (by **DBDIH**).

• **Phase 9.** The node internal startup variables are reset.

• **Phase 100 (OBSOLETE).** Formerly, it was at this point during a node restart or initial node restart that API nodes could connect to the node and begin to receive events. Currently, this phase is empty.

• **Phase 101.** At this point in a node restart or initial node restart, event delivery is handed over to the node joining the cluster. The newly-joined node takes over responsibility for delivering its primary data to subscribers. This phase is also referred to as **SUMA handover phase**.

After this process is completed for an initial start or system restart, transaction handling is enabled. For a node restart or initial node restart, completion of the startup process means that the node may now act as a transaction coordinator.

### 17.5.2 Commands in the MySQL Cluster Management Client

In addition to the central configuration file, a cluster may also be controlled through a command-line interface available through the management client **ndb_mgm**. This is the primary administrative interface to a running cluster.

Commands for the event logs are given in Section 17.5.6, “Event Reports Generated in MySQL Cluster”; commands for creating backups and restoring from them are provided in Section 17.5.3, “Online Backup of MySQL Cluster”.

**Using ndb_mgm with MySQL Cluster Manager.** MySQL Cluster Manager handles starting and stopping processes and tracks their states internally, so it is not necessary to use **ndb_mgm** for these tasks for a MySQL Cluster that is under MySQL Cluster Manager control. It is recommended not to use the **ndb_mgm** command-line client that comes with the MySQL Cluster distribution to perform operations that involve starting or stopping nodes. These include but are not limited to the **START**, **STOP**, **RESTART**, and **SHUTDOWN** commands. For more information, see MySQL Cluster Manager Process Commands.

The management client has the following basic commands. In the listing that follows, **node_id** denotes either a database node ID or the keyword **ALL**, which indicates that the command should be applied to all of the cluster's data nodes.

• **HELP**
Displays information on all available commands.

- **CONNECT connection-string**

  Connects to the management server indicated by the connection string. If the client is already connected to this server, the client reconnects.

- **SHOW**

  Displays information on the cluster's status. Possible node status values include **UNKNOWN**, **NO_CONTACT**, **NOT_STARTED**, **STARTING**, **STARTED**, **SHUTTING_DOWN**, and **RESTARTING**.

  Beginning with MySQL Cluster NDB 6.2.8 and MySQL Cluster NDB 6.3.6, the output from this command indicates when the cluster is in single user mode (status **SINGLE_USER_MODE**).

  Prior to MySQL Cluster NDB 7.0.26 and MySQL Cluster NDB 7.1.5, in a cluster having multiple management nodes, this command displayed information only for data nodes that were actually connected to the current management server; in addition, management servers could not find each other until all nodes had been started. Beginning with these versions, such issues are fixed (see Bug #12352191), and management nodes can be additionally be reported with status **RESUME** or **CONNECTED**.

- **node_id START**

  Brings online the data node identified by **node_id** (or all data nodes).

  **ALL START** works on all data nodes only, and does not affect management nodes.

  **Important**

  To use this command to bring a data node online, the data node must have been started using **--nostart** or **-n**.

- **node_id STOP [-a] [-f]**

  Stops the data or management node identified by **node_id**.

  **Note**

  **ALL STOP** works to stop all data nodes only, and does not affect management nodes.

  A node affected by this command disconnects from the cluster, and its associated **ndbd** or **ndb_mgmd** process terminates.

  The **-a** option causes the node to be stopped immediately, without waiting for the completion of any pending transactions.

  Normally, **STOP** fails if the result would cause an incomplete cluster. The **-f** option, added in MySQL Cluster NDB 7.0.19 and MySQL Cluster NDB 7.1.8, forces the node to shut down without checking for this. If this option is used and the result is an incomplete cluster, the cluster immediately shuts down.

  **Warning**

  Use of the **-a** option also disables the safety check otherwise performed when **STOP** is invoked to insure that stopping the node does not cause an incomplete cluster. In other words, you should exercise extreme care when using the **-a** option with the **STOP** command, due to the fact that this option makes it possible for the cluster to undergo a forced shutdown because it no longer has a complete copy of all data stored in **NDB**.
• **node_id** RESTART [-n] [-i] [-a] [-f]

Restarts the data node identified by **node_id** (or all data nodes).

Using the **-i** option with **RESTART** causes the data node to perform an initial restart; that is, the node’s file system is deleted and recreated. The effect is the same as that obtained from stopping the data node process and then starting it again using `ndbd --initial` from the system shell.

**Note**
Backup files and Disk Data files are not removed when this option is used.

Using the **-n** option causes the data node process to be restarted, but the data node is not actually brought online until the appropriate **START** command is issued. The effect of this option is the same as that obtained from stopping the data node and then starting it again using `ndbd --nostart` or `ndbd -n` from the system shell.

Using the **-a** causes all current transactions relying on this node to be aborted. No GCP check is done when the node rejoins the cluster.

Normally, **RESTART** fails if taking the node offline would result in an incomplete cluster. The **-f** option, added in MySQL Cluster NDB 7.0.19 and MySQL Cluster NDB 7.1.8, forces the node to restart without checking for this. If this option is used and the result is an incomplete cluster, the entire cluster is restarted.

• **node_id** STATUS

Displays status information for the data node identified by **node_id** (or for all data nodes).

Beginning with MySQL Cluster NDB 6.2.8 and MySQL Cluster NDB 6.3.6, the output from this command indicates when the cluster is in single user mode.

• **node_id** REPORT report-type

Displays a report of type **report-type** for the data node identified by **node_id**, or for all data nodes using **ALL**.

Currently, there are three accepted values for **report-type**:

• **BackupStatus** provides a status report on a cluster backup in progress

• **MemoryUsage** displays how much data memory and index memory is being used by each data node as shown in this example:

```
ndb_mgm> ALL REPORT MEMORY
Node 1: Data usage is 5%(177 32K pages of total 3200)
Node 1: Index usage is 0%(108 8K pages of total 12832)
Node 2: Data usage is 5%(177 32K pages of total 3200)
Node 2: Index usage is 0%(108 8K pages of total 12832)
```

In MySQL Cluster NDB 7.1.1 and later, this information is also available from the `ndbinfo.memoryusage` table.

• **EventLog** reports events from the event log buffers of one or more data nodes.

**report-type** is case-insensitive and “fuzzy”; for **MemoryUsage**, you can use **MEMORY** (as shown in the prior example), **memory**, or even simply **MEM** (or **mem**). You can abbreviate **BackupStatus** in a similar fashion.
Prior to MySQL Cluster NDB 7.0.37 and MySQL Cluster NDB 7.1.26, ALL REPORT BackupStatus did not work correctly with multi-threaded data nodes. (Bug #15908907)

The REPORT command was introduced in MySQL Cluster NDB 6.2.3 and MySQL Cluster NDB 6.3.0.

• ENTER SINGLE USER MODE node_id

Enters single user mode, whereby only the MySQL server identified by the node ID node_id is permitted to access the database.

Currently, it is not possible for data nodes to join a MySQL Cluster while it is running in single user mode. (Bug #20395)

• EXIT SINGLE USER MODE

Exits single user mode, enabling all SQL nodes (that is, all running mysqld processes) to access the database.

Note

It is possible to use EXIT SINGLE USER MODE even when not in single user mode, although the command has no effect in this case.

• QUIT, EXIT

Terminates the management client.

This command does not affect any nodes connected to the cluster.

• SHUTDOWN

Shuts down all cluster data nodes and management nodes. To exit the management client after this has been done, use EXIT or QUIT.

This command does not shut down any SQL nodes or API nodes that are connected to the cluster.

• CREATE NODEGROUP nodeid[, nodeid, ...]

Creates a new MySQL Cluster node group and causes data nodes to join it.

This command is used after adding new data nodes online to a MySQL Cluster, and causes them to join a new node group and thus to begin participating fully in the cluster. The command takes as its sole parameter a comma-separated list of node IDs—these are the IDs of the nodes just added and started that are to join the new node group. The number of nodes must be the same as the number of nodes in each node group that is already part of the cluster (each MySQL Cluster node group must have the same number of nodes). In other words, if the MySQL Cluster has 2 node groups of 2 data nodes each, then the new node group must also have 2 data nodes.

The node group ID of the new node group created by this command is determined automatically, and always the next highest unused node group ID in the cluster; it is not possible to set it manually.

This command was introduced in MySQL Cluster NDB 6.4.0. For more information, see Section 17.5.13, "Adding MySQL Cluster Data Nodes Online".

• DROP NODEGROUP nodegroup_id

Drops the MySQL Cluster node group with the given nodegroup_id.

This command can be used to drop a node group from a MySQL Cluster. DROP NODEGROUP takes as its sole argument the node group ID of the node group to be dropped.
**DROP NODEGROUP** acts only to remove the data nodes in the effected node group from that node group. It does not stop data nodes, assign them to a different node group, or remove them from the cluster's configuration. A data node that does not belong to a node group is indicated in the output of the management client **SHOW** command with `no nodegroup` in place of the node group ID, like this (indicated using bold text):

```
 id=3  @10.100.2.67  (5.1.77-ndb-7.1.37, no nodegroup)
```

Prior to MySQL Cluster NDB 7.0.4, the **SHOW** output was not updated correctly following **DROP NODEGROUP**. (Bug #43413)

**DROP NODEGROUP** works only when all data nodes in the node group to be dropped are completely empty of any table data and table definitions. Since there is currently no way using **ndb_mgm** or the **mysql** client to remove all data from a specific data node or node group, this means that the command succeeds only in the two following cases:

1. After issuing **CREATE NODEGROUP** in the **ndb_mgm** client, but before issuing any **ALTER ONLINE TABLE ... REORGANIZE PARTITION** statements in the **mysql** client.
2. After dropping all **NDBCLUSTER** tables using **DROP TABLE**.

**TRUNCATE TABLE** does not work for this purpose because this removes only the table data; the data nodes continue to store an **NDBCLUSTER** table's definition until a **DROP TABLE** statement is issued that causes the table metadata to be dropped.

**DROP NODEGROUP** was introduced in MySQL Cluster NDB 6.4.0. For more information, see Section 17.5.13, "Adding MySQL Cluster Data Nodes Online".

### Additional commands.

A number of other commands available in the **ndb_mgm** client are described elsewhere, as shown in the following list:

- **START BACKUP** is used to perform an online backup in the **ndb_mgm** client; the **ABORT BACKUP** command is used to cancel a backup already in progress. For more information, see Section 17.5.3, "Online Backup of MySQL Cluster".

- The **CLUSTERLOG** command is used to perform various logging functions. See Section 17.5.6, "Event Reports Generated in MySQL Cluster", for more information and examples.

- For testing and diagnostics work, the client also supports a **DUMP** command which can be used to execute internal commands on the cluster. It should never be used in a production setting unless directed to do so by MySQL Support. For more information, see MySQL Cluster Internals.

- In older versions of MySQL Cluster (prior to MySQL 5.1.11), it could sometimes be necessary to force the management server to check connections to the data nodes to ensure that dropped connections were not missed. This could be done using the **PURGE STALE SESSIONS** command. Newer versions now perform this check automatically, so that the command is no longer needed. See Section 17.5.1, "Summary of MySQL Cluster Start Phases", for more information.

### 17.5.3 Online Backup of MySQL Cluster

The next few sections describe how to prepare for and then to create a MySQL Cluster backup using the functionality for this purpose found in the **ndb_mgm** management client. To distinguish this type of backup from a backup made using **mysqldump**, we sometimes refer to it as a “native” MySQL Cluster backup. (For information about the creation of backups with **mysqldump**, see Section 4.5.4, "mysqldump — A Database Backup Program"). Restoration of MySQL Cluster backups is done using the **ndb_restore** utility provided with the MySQL Cluster distribution; for information about **ndb_restore** and its use in restoring MySQL Cluster backups, see Section 17.4.20, "ndb_restore — Restore a MySQL Cluster Backup".
17.5.3.1 MySQL Cluster Backup Concepts

A backup is a snapshot of the database at a given time. The backup consists of three main parts:

- **Metadata.** The names and definitions of all database tables
- **Table records.** The data actually stored in the database tables at the time that the backup was made
- **Transaction log.** A sequential record telling how and when data was stored in the database

Each of these parts is saved on all nodes participating in the backup. During backup, each node saves these three parts into three files on disk:

- **BACKUP-backup_id.node_id.ctl**
  A control file containing control information and metadata. Each node saves the same table definitions (for all tables in the cluster) to its own version of this file.

- **BACKUP-backup_id-0.node_id.data**
  A data file containing the table records, which are saved on a per-fragment basis. That is, different nodes save different fragments during the backup. The file saved by each node starts with a header that states the tables to which the records belong. Following the list of records there is a footer containing a checksum for all records.

- **BACKUP-backup_id.node_id.log**
  A log file containing records of committed transactions. Only transactions on tables stored in the backup are stored in the log. Nodes involved in the backup save different records because different nodes host different database fragments.

In the listing above, `backup_id` stands for the backup identifier and `node_id` is the unique identifier for the node creating the file.

17.5.3.2 Using The MySQL Cluster Management Client to Create a Backup

Before starting a backup, make sure that the cluster is properly configured for performing one. (See Section 17.5.3.3, “Configuration for MySQL Cluster Backups”.)

The **START BACKUP** command is used to create a backup:

```
START BACKUP [backup_id] [wait_option] [snapshot_option]
```

- **wait_option:**
  - WAIT {STARTED | COMPLETED} | NOWAIT
- **snapshot_option:**
  - SNAPSHOTSTART | SNAPSHOTEND

Successive backups are automatically identified sequentially, so the `backup_id`, an integer greater than or equal to 1, is optional; if it is omitted, the next available value is used. If an existing `backup_id` value is used, the backup fails with the error `Backup failed: file already exists`. If used, the `backup_id` must follow `START BACKUP` immediately, before any other options are used.

Prior to MySQL Cluster NDB 6.2.17, 6.3.23, and 6.4.3, backup IDs greater than 2147483648 ($2^{31}$) were not supported correctly. (Bug #43042) Beginning with these versions, the maximum possible backup ID is 4294967296 ($2^{32}$).

**Note**

Prior to MySQL Cluster NDB 7.0.5, when starting a backup using `ndb_mgm -e "START BACKUP"`, the `backup_id` was required. (Bug #31754)
The `wait_option` can be used to determine when control is returned to the management client after a `START BACKUP` command is issued, as shown in the following list:

- If `NOWAIT` is specified, the management client displays a prompt immediately, as seen here:

```plaintext
ndb_mgm> START BACKUP NOWAIT
ndb_mgm>
```

In this case, the management client can be used even while it prints progress information from the backup process.

- With `WAIT STARTED` the management client waits until the backup has started before returning control to the user, as shown here:

```plaintext
ndb_mgm> START BACKUP WAIT STARTED
Waiting for started, this may take several minutes
Node 2: Backup 3 started from node 1
ndb_mgm>
```

- `WAIT COMPLETED` causes the management client to wait until the backup process is complete before returning control to the user. `WAIT COMPLETED` is the default.

Beginning with MySQL Cluster NDB 6.4.0, a `snapshot_option` can be used to determine whether the backup matches the state of the cluster when `START BACKUP` was issued, or when it was completed. `SNAPSHOTSTART` causes the backup to match the state of the cluster when the backup began; `SNAPSHOTEND` causes the backup to reflect the state of the cluster when the backup was finished. `SNAPSHOTEND` is the default, and matches the behavior found in previous MySQL Cluster releases.

**Note**

If you use the `SNAPSHOTSTART` option with `START BACKUP`, and the `CompressedBackup` parameter is enabled, only the data and control files are compressed—the log file is not compressed.

If both a `wait_option` and a `snapshot_option` are used, they may be specified in either order. For example, all of the following commands are valid, assuming that there is no existing backup having 4 as its ID:

```
START BACKUP WAIT STARTED SNAPSHOTSTART
START BACKUP SNAPSHOTSTART WAIT STARTED
START BACKUP 4 WAIT COMPLETED SNAPSHOTSTART
START BACKUP SNAPSHOTEND WAIT COMPLETED
START BACKUP 4 NOWAIT SNAPSHOTSTART
```

The procedure for creating a backup consists of the following steps:

1. Start the management client (`ndb_mgm`), if it not running already.
2. Execute the `START BACKUP` command. This produces several lines of output indicating the progress of the backup, as shown here:

```plaintext
ndb_mgm> START BACKUP
Waiting for completed, this may take several minutes
Node 2: Backup 1 started from node 1
Node 2: Backup 1 started from node 1 completed
StartGCP: 177 StopGCP: 180
#Records: 7362 #LogRecords: 0
Data: 453648 bytes Log: 0 bytes
```
3. When the backup has started the management client displays this message:

```
Backup backup_id started from node node_id
```

`backup_id` is the unique identifier for this particular backup. This identifier is saved in the cluster log, if it has not been configured otherwise. `node_id` is the identifier of the management server that is coordinating the backup with the data nodes. At this point in the backup process the cluster has received and processed the backup request. It does not mean that the backup has finished. An example of this statement is shown here:

```
Node 2: Backup 1 started from node 1
```

4. The management client indicates with a message like this one that the backup has started:

```
Backup backup_id started from node node_id completed
```

As is the case for the notification that the backup has started, `backup_id` is the unique identifier for this particular backup, and `node_id` is the node ID of the management server that is coordinating the backup with the data nodes. This output is accompanied by additional information including relevant global checkpoints, the number of records backed up, and the size of the data, as shown here:

```
Node 2: Backup 1 started from node 1 completed
StartGCP: 177 StopGCP: 180
#Records: 7362 #LogRecords: 0
Data: 453648 bytes Log: 0 bytes
```

It is also possible to perform a backup from the system shell by invoking `ndb_mgm` with the `-e` or `--execute` option, as shown in this example:

```
shell> ndb_mgm -e "START BACKUP 6 WAIT COMPLETED SNAPSHOTSTART"
```

When using `START BACKUP` in this way, you must specify the backup ID.

Cluster backups are created by default in the `BACKUP` subdirectory of the `DataDir` on each data node. This can be overridden for one or more data nodes individually, or for all cluster data nodes in the `config.ini` file using the `BackupDataDir` configuration parameter. The backup files created for a backup with a given `backup_id` are stored in a subdirectory named `BACKUP-backup_id` in the backup directory.

**Cancelling backups.** To cancel or abort a backup that is already in progress, perform the following steps:

1. Start the management client.

2. Execute this command:

```
ndb_mgm> ABORT BACKUP backup_id
```

The number `backup_id` is the identifier of the backup that was included in the response of the management client when the backup was started (in the message `Backup backup_id started from node management_node_id`).

3. The management client acknowledges the abort request with `Abort of backup backup_id ordered`. 
At this point, the management client has not yet received a response from the cluster data nodes to this request, and the backup has not yet actually been aborted.

4. After the backup has been aborted, the management client will report this fact in a manner similar to what is shown here:

<table>
<thead>
<tr>
<th>Node</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Backup 3 started from 5 has been aborted.</td>
</tr>
<tr>
<td></td>
<td>Error: 1321 - Backup aborted by user request: Permanent error: User defined error</td>
</tr>
<tr>
<td>2</td>
<td>Backup 3 started from 5 has been aborted.</td>
</tr>
<tr>
<td></td>
<td>Error: 1323 - 1323: Permanent error: Internal error</td>
</tr>
<tr>
<td>3</td>
<td>Backup 3 started from 5 has been aborted.</td>
</tr>
<tr>
<td></td>
<td>Error: 1323 - 1323: Permanent error: Internal error</td>
</tr>
<tr>
<td>4</td>
<td>Backup 3 started from 5 has been aborted.</td>
</tr>
<tr>
<td></td>
<td>Error: 1323 - 1323: Permanent error: Internal error</td>
</tr>
</tbody>
</table>

In this example, we have shown sample output for a cluster with 4 data nodes, where the sequence number of the backup to be aborted is 3, and the management node to which the cluster management client is connected has the node ID 5. The first node to complete its part in aborting the backup reports that the reason for the abort was due to a request by the user. (The remaining nodes report that the backup was aborted due to an unspecified internal error.)

There is no guarantee that the cluster nodes respond to an ABORT BACKUP command in any particular order.

The Backup backup_id started from node management_node_id has been aborted messages mean that the backup has been terminated and that all files relating to this backup have been removed from the cluster file system.

It is also possible to abort a backup in progress from a system shell using this command:

```
shell> ndb_mgm -e "ABORT BACKUP backup_id"
```

If there is no backup having the ID backup_id running when an ABORT BACKUP is issued, the management client makes no response, nor is it indicated in the cluster log that an invalid abort command was sent.

17.5.3.3 Configuration for MySQL Cluster Backups

Five configuration parameters are essential for backup:

- **BackupDataBufferSize**
  
The amount of memory used to buffer data before it is written to disk.

- **BackupLogBufferSize**
  
The amount of memory used to buffer log records before these are written to disk.

- **BackupMemory**
  
The total memory allocated in a data node for backups. This should be the sum of the memory allocated for the backup data buffer and the backup log buffer.

- **BackupWriteSize**
The default size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

- **BackupMaxWriteSize**

  The maximum size of blocks written to disk. This applies for both the backup data buffer and the backup log buffer.

More detailed information about these parameters can be found in [Backup Parameters](#).

### 17.5.3.4 MySQL Cluster Backup Troubleshooting

If an error code is returned when issuing a backup request, the most likely cause is insufficient memory or disk space. You should check that there is enough memory allocated for the backup.

**Important**

If you have set `BackupDataBufferSize` and `BackupLogBufferSize` and their sum is greater than 4MB, then you must also set `BackupMemory` as well.

You should also make sure that there is sufficient space on the hard drive partition of the backup target.

**NDB** does not support repeatable reads, which can cause problems with the restoration process. Although the backup process is “hot”, restoring a MySQL Cluster from backup is not a 100% “hot” process. This is due to the fact that, for the duration of the restore process, running transactions get nonrepeatable reads from the restored data. This means that the state of the data is inconsistent while the restore is in progress.

### 17.5.4 MySQL Server Usage for MySQL Cluster

**mysqlld** is the traditional MySQL server process. To be used with MySQL Cluster, **mysqlld** needs to be built with support for the **NDBCLUSTER** storage engine, as it is in the precompiled binaries available from [http://dev.mysql.com/downloads/](http://dev.mysql.com/downloads/). If you build MySQL from source, you must invoke `configure` with one of the options to enable **NDBCLUSTER** storage engine support:

- `--with-plugins=ndbcluster`
- `--with-plugins=max`
- `--with-plugins=max-no-innodb`

(`--with-ndbcluster` also works to enable **NDBCLUSTER** support, but is deprecated and so produces a `configure` warning as of MySQL 5.1.9.)

For information about other MySQL server options and variables relevant to MySQL Cluster in addition to those discussed in this section, see Section 17.3.3.8, “MySQL Server Options and Variables for MySQL Cluster”.

If the **mysqlld** binary has been built with Cluster support, the **NDBCLUSTER** storage engine is still disabled by default. You can use either of two possible options to enable this engine:

- **Use** `--ndbcluster` as a startup option on the command line when starting **mysqlld**.
- Insert a line containing `ndbcluster` in the `[mysql]` section of your `my.cnf` file.

An easy way to verify that your server is running with the **NDBCLUSTER** storage engine enabled is to issue the `SHOW ENGINES` statement in the MySQL Monitor (mysql). You should see the value **YES** as the **Support** value in the row for **NDBCLUSTER**. If you see **NO** in this row or if there is no such row displayed in the output, you are not running an **NDB**-enabled version of MySQL. If you see **DISABLED** in this row, you need to enable it in either one of the two ways just described.
Performing a Rolling Restart of a MySQL Cluster

To read cluster configuration data, the MySQL server requires at a minimum three pieces of information:

- The MySQL server's own cluster node ID
- The host name or IP address for the management server (MGM node)
- The number of the TCP/IP port on which it can connect to the management server

Node IDs can be allocated dynamically, so it is not strictly necessary to specify them explicitly.

The `mysqld` parameter `ndb-connectstring` is used to specify the connection string either on the command line when starting `mysqld` or in `my.cnf`. The connection string contains the host name or IP address where the management server can be found, as well as the TCP/IP port it uses.

In the following example, `ndb_mgmd.mysql.com` is the host where the management server resides, and the management server listens for cluster messages on port 1186:

```
shell> mysqld --ndbcluster --ndb-connectstring=ndb_mgmd.mysql.com:1186
```

See Section 17.3.3.3, “MySQL Cluster Connection Strings”, for more information on connection strings.

Given this information, the MySQL server will be a full participant in the cluster. (We often refer to a `mysqld` process running in this manner as an SQL node.) It will be fully aware of all cluster data nodes as well as their status, and will establish connections to all data nodes. In this case, it is able to use any data node as a transaction coordinator and to read and update node data.

You can see in the `mysql` client whether a MySQL server is connected to the cluster using `SHOW PROCESSLIST`. If the MySQL server is connected to the cluster, and you have the `PROCESS` privilege, then the first row of the output is as shown here:

```
mysql> SHOW PROCESSLIST \G
*************************** 1. row ***************************
    Id: 1
  User: system user
    Host: 
    Command: Daemon
    Time: 1
  State: Waiting for event from ndbcluster
    Info: NULL
```

Important

To participate in a MySQL Cluster, the `mysqld` process must be started with both the options `--ndbcluster` and `--ndb-connectstring` (or their equivalents in `my.cnf`). If `mysqld` is started with only the `--ndbcluster` option, or if it is unable to contact the cluster, it is not possible to work with NDB tables, nor is it possible to create any new tables regardless of storage engine. The latter restriction is a safety measure intended to prevent the creation of tables having the same names as NDB tables while the SQL node is not connected to the cluster. If you wish to create tables using a different storage engine while the `mysqld` process is not participating in a MySQL Cluster, you must restart the server without the `--ndbcluster` option.

### 17.5.5 Performing a Rolling Restart of a MySQL Cluster

This section discusses how to perform a rolling restart of a MySQL Cluster installation, so called because it involves stopping and starting (or restarting) each node in turn, so that the cluster itself
remains operational. This is often done as part of a rolling upgrade or rolling downgrade, where high availability of the cluster is mandatory and no downtime of the cluster as a whole is permissible. Where we refer to upgrades, the information provided here also generally applies to downgrades as well.

There are a number of reasons why a rolling restart might be desirable. These are described in the next few paragraphs.

Configuration change.
To make a change in the cluster’s configuration, such as adding an SQL node to the cluster, or setting a configuration parameter to a new value.

MySQL Cluster software upgrade or downgrade.
To upgrade the cluster to a newer version of the MySQL Cluster software (or to downgrade it to an older version). This is usually referred to as a “rolling upgrade” (or “rolling downgrade”, when reverting to an older version of MySQL Cluster).

Change on node host.
To make changes in the hardware or operating system on which one or more MySQL Cluster node processes are running.

System reset (cluster reset).
To reset the cluster because it has reached an undesirable state. In such cases it is often desirable to reload the data and metadata of one or more data nodes. This can be done in any of three ways:

- Start each data node process (ndbd, or possibly ndbmtd in MySQL Cluster NDB 7.0 and later) with the --initial option, which forces the data node to clear its file system and to reload all MySQL Cluster data and metadata from the other data nodes.

- Create a backup using the ndb_mgm client BACKUP command prior to performing the restart. Following the upgrade, restore the node or nodes using ndb_restore.

  See Section 17.5.3, “Online Backup of MySQL Cluster”, and Section 17.4.20, “ndb_restore – Restore a MySQL Cluster Backup”, for more information.

- Use mysqldump to create a backup prior to the upgrade; afterward, restore the dump using LOAD DATA INFILE.

Resource Recovery.
To free memory previously allocated to a table by successive INSERT and DELETE operations, for re-use by other MySQL Cluster tables.

The process for performing a rolling restart may be generalized as follows:

1. Stop all cluster management nodes (ndb_mgmd processes), reconfigure them, then restart them.

   (If there are multiple management servers and you are using MySQL Cluster NDB 7.0.8 or later, see Rolling restarts with multiple management servers (MySQL Cluster NDB 7.0.8 and later).)

2. Stop, reconfigure, then restart each cluster data node (ndbd process) in turn.

3. Stop, reconfigure, then restart each cluster SQL node (mysqld process) in turn.

The specifics for implementing a given rolling upgrade depend upon the changes being made. A more detailed view of the process is presented here:
Performing a Rolling Restart of a MySQL Cluster

Figure 17.8 MySQL Cluster Rolling Restarts By Type

In the previous diagram, the **Stop** and **Start** steps indicate that the process must be stopped completely using a shell command (such as `kill` on most Unix systems) or the management client **STOP** command, then started again from a system shell by invoking the `ndbd` or `ndb_mgmd` executable as appropriate. On Windows (MySQL Cluster NDB 7.1.3 and later), you can also use the system **NET START** and **NET STOP** commands or the Windows Service Manager to start and stop nodes which have been installed as Windows services (see Section 17.2.2.4, “Installing MySQL Cluster Processes as Windows Services”).

Restart indicates that the process may be restarted using the `ndb_mgm` management client **RESTART** command (see Section 17.5.2, “Commands in the MySQL Cluster Management Client”).

Prior to MySQL Cluster NDB 6.3.29 and MySQL Cluster NDB 7.0.10. When performing an upgrade or downgrade of the cluster software, you must upgrade or downgrade the management nodes first, then the data nodes, and finally the SQL nodes. Doing so in any other order may leave the cluster in an unusable state.

MySQL Cluster NDB 6.3.29 and later; MySQL Cluster NDB 7.0.10 and later. MySQL Cluster supports a more flexible order for upgrading the cluster nodes. When upgrading a cluster running MySQL Cluster NDB 6.3.29 or later, or a cluster that is running MySQL Cluster NDB 7.0.10 or later, you may upgrade API nodes (including SQL nodes) before upgrading the management nodes, data nodes, or both. In other words, you are permitted to upgrade the API and SQL nodes in any order. This is subject to the following provisions:

- This functionality is intended for use as part of an online upgrade only. A mix of node binaries from different MySQL Cluster releases is neither intended nor supported for constant, long-term use in a production setting.

- All management nodes must be upgraded before any data nodes are upgraded. This remains true regardless of the order in which you upgrade the cluster's API and SQL nodes.
For MySQL Cluster NDB 6.3, the ability to upgrade API nodes in any order relative to upgrading management nodes and data nodes is supported only for MySQL Cluster NDB 6.3.29 and later; for MySQL Cluster NDB 7.0, it supported only for MySQL Cluster NDB 7.0.10 and later. This means that, if you are upgrading from a MySQL Cluster NDB 6.3 release to a MySQL Cluster NDB 7.0 release, the “old” NDB engine version must be 6.3.29 or later, and the “new” NDB engine version must be 7.0.10 or later.

When upgrading the cluster from a MySQL Cluster NDB 6.3 release to a MySQL Cluster NDB 7.0 release: Once you have started upgrading the API nodes, you should not perform DDL operations until all management nodes and data nodes have been upgraded. DML operations should be unaffected, and can continue while the upgrade is in progress.

However, it is possible to perform DDL from an “old” (NDB 6.3 version) API node as long as the master data node is also running the “old” version of MySQL Cluster. You should keep in mind that a data node restart could result in the master node running a “new” (NDB 7.0 version) binary while one or more data nodes are still using the “old” (NDB 6.3) version; in this situation, no DDL can be performed from any API node, because the master data node is no longer using an NDB 6.3 binary, but the cluster still contains nodes which are not yet using NDB 7.0. For this reason, we recommend that you avoid performing DDL at any time while the upgrade is in progress.

Features specific to the “new” version must not be used until all management nodes and data nodes have been upgraded.

This also applies to any MySQL Server version change that may apply, in addition to the NDB engine version change, so do not forget to take this into account when planning the upgrade. (This is true for online upgrades of MySQL Cluster in general.)

See also Bug #48528 and Bug #49163.

Rolling restarts with multiple management servers (MySQL Cluster NDB 7.0.8 and later). A change in MySQL Cluster NDB 7.0.8 in the way in which management nodes obtain configuration data makes it necessary to alter the procedure previously outlined, when performing a rolling restart of a MySQL Cluster with multiple management nodes. (Previously, a management node checked only its own configuration cache, but in MySQL Cluster NDB 7.0.8 and later, ndb_mgmd also checks to see if any other management node is running, and, if so, tries to use that node’s configuration data.) To keep this from occurring, and to force ndb_mgmd to reread its configuration file, perform the following steps:

1. Stop all MySQL Cluster ndb_mgmd processes.
2. Update all config.ini files.
3. Start a single ndb_mgmd with --reload, --initial, or both options as desired.
4. If you started the first ndb_mgmd with the --initial option, you must also start any remaining ndb_mgmd processes using --initial.

Regardless of any other options used when starting the first ndb_mgmd, you should not start any remaining ndb_mgmd processes after the first one using --reload.
5. Complete the rolling restarts of the data nodes and API nodes as normal.

See also Bug #45495 and Bug #46488.

MySQL Cluster NDB 7.0.24 and later; MySQL Cluster NDB 7.1.13 and later. When performing a rolling restart to update the cluster’s configuration, you can use the config_generation column of the ndbinfo.nodes table to keep track of which data nodes have been successfully restarted with the new configuration. See Section 17.5.10.13, “The ndbinfo nodes Table”.

17.5.6 Event Reports Generated in MySQL Cluster

In this section, we discuss the types of event logs provided by MySQL Cluster, and the types of events that are logged.
MySQL Cluster provides two types of event log:

- The **cluster log**, which includes events generated by all cluster nodes. The cluster log is the log recommended for most uses because it provides logging information for an entire cluster in a single location.

  By default, the cluster log is saved to a file named `ndb_node_id_cluster.log` (where `node_id` is the node ID of the management server) in the management server's `DataDir`.

  Cluster logging information can also be sent to `stdout` or a `syslog` facility in addition to or instead of being saved to a file, as determined by the values set for the `DataDir` and `LogDestination` configuration parameters. See Section 17.3.3.5, “Defining a MySQL Cluster Management Server”, for more information about these parameters.

- **Node logs** are local to each node.

  Output generated by node event logging is written to the file `ndb_node_id_out.log` (where `node_id` is the node's node ID) in the node's `DataDir`. Node event logs are generated for both management nodes and data nodes.

  Node logs are intended to be used only during application development, or for debugging application code.

Both types of event logs can be set to log different subsets of events.

Each reportable event can be distinguished according to three different criteria:

- **Category**: This can be any one of the following values: `STARTUP`, `SHUTDOWN`, `STATISTICS`, `CHECKPOINT`, `NODERESTART`, `CONNECTION`, `ERROR`, or `INFO`.

- **Priority**: This is represented by one of the numbers from 0 to 15 inclusive, where 0 indicates “most important” and 15 “least important.”

- **Severity Level**: This can be any one of the following values: `ALERT`, `CRITICAL`, `ERROR`, `WARNING`, `INFO`, or `DEBUG`.

Both the cluster log and the node log can be filtered on these properties.

The format used in the cluster log is as shown here:

Each line in the cluster log contains the following information:
Event Reports Generated in MySQL Cluster

- A timestamp in **YYYY-MM-DD HH:MM:SS** format.
- The type of node which is performing the logging. In the cluster log, this is always [MgmSrvr].
- The severity of the event.
- The ID of the node reporting the event.
- A description of the event. The most common types of events to appear in the log are connections and disconnections between different nodes in the cluster, and when checkpoints occur. In some cases, the description may contain status information.

### 17.5.6.1 MySQL Cluster Logging Management Commands

`ndb_mgm` supports a number of management commands related to the cluster log. In the listing that follows, `node_id` denotes either a database node ID or the keyword **ALL**, which indicates that the command should be applied to all of the cluster’s data nodes.

- **CLUSTERLOG ON**
  - Turns the cluster log on.
- **CLUSTERLOG OFF**
  - Turns the cluster log off.
- **CLUSTERLOG INFO**
  - Provides information about cluster log settings.
- **node_id CLUSTERLOG category=threshold**
  - Logs `category` events with priority less than or equal to `threshold` in the cluster log.
- **CLUSTERLOG FILTER severity_level**
  - Toggles cluster logging of events of the specified `severity_level`.

The following table describes the default setting (for all data nodes) of the cluster log category threshold. If an event has a priority with a value lower than or equal to the priority threshold, it is reported in the cluster log.

Note that events are reported per data node, and that the threshold can be set to different values on different nodes.

<table>
<thead>
<tr>
<th>Category</th>
<th>Default threshold (All data nodes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>STARTUP</td>
<td>7</td>
</tr>
<tr>
<td>SHUTDOWN</td>
<td>7</td>
</tr>
<tr>
<td>STATISTICS</td>
<td>7</td>
</tr>
<tr>
<td>CHECKPOINT</td>
<td>7</td>
</tr>
<tr>
<td>NODERESTART</td>
<td>7</td>
</tr>
<tr>
<td>CONNECTION</td>
<td>7</td>
</tr>
<tr>
<td>ERROR</td>
<td>15</td>
</tr>
<tr>
<td>INFO</td>
<td>7</td>
</tr>
</tbody>
</table>

The **STATISTICS** category can provide a great deal of useful data. See Section 17.5.6.3, “Using CLUSTERLOG STATISTICS in the MySQL Cluster Management Client”, for more information.
Event Reports Generated in MySQL Cluster

Thresholds are used to filter events within each category. For example, a STARTUP event with a priority of 3 is not logged unless the threshold for STARTUP is set to 3 or higher. Only events with priority 3 or lower are sent if the threshold is 3.

The following table shows the event severity levels.

<table>
<thead>
<tr>
<th>Severity Level Value</th>
<th>Severity</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>ALERT</td>
<td>A condition that should be corrected immediately, such as a corrupted system database</td>
</tr>
<tr>
<td>2</td>
<td>CRITICAL</td>
<td>Critical conditions, such as device errors or insufficient resources</td>
</tr>
<tr>
<td>3</td>
<td>ERROR</td>
<td>Conditions that should be corrected, such as configuration errors</td>
</tr>
<tr>
<td>4</td>
<td>WARNING</td>
<td>Conditions that are not errors, but that might require special handling</td>
</tr>
<tr>
<td>5</td>
<td>INFO</td>
<td>Informational messages</td>
</tr>
<tr>
<td>6</td>
<td>DEBUG</td>
<td>Debugging messages used for NDBCLUSTER development</td>
</tr>
</tbody>
</table>

Event severity levels can be turned on or off (using CLUSTERLOG FILTER—see above). If a severity level is turned on, then all events with a priority less than or equal to the category thresholds are logged. If the severity level is turned off then no events belonging to that severity level are logged.

Important

Cluster log levels are set on a per ndb_mgmd, per subscriber basis. This means that, in a MySQL Cluster with multiple management servers, using a CLUSTERLOG command in an instance of ndb_mgm connected to one management server affects only logs generated by that management server but not by any of the others. This also means that, should one of the management servers be restarted, only logs generated by that management server are affected by the resetting of log levels caused by the restart.

17.5.6.2 MySQL Cluster Log Events

An event report reported in the event logs has the following format:

```
datetime [string] severity -- message
```

For example:

```
```

This section discusses all reportable events, ordered by category and severity level within each category.

In the event descriptions, GCP and LCP mean “Global Checkpoint” and “Local Checkpoint”, respectively.

**CONNECTION Events**

These events are associated with connections between Cluster nodes.
**Event Reports Generated in MySQL Cluster**

<table>
<thead>
<tr>
<th>Event</th>
<th>Priority</th>
<th>Severity Level</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connected</td>
<td>8</td>
<td>INFO</td>
<td>Data nodes connected</td>
</tr>
<tr>
<td>Disconnected</td>
<td>8</td>
<td>ALERT</td>
<td>Data nodes disconnected</td>
</tr>
<tr>
<td>CommunicationClosed</td>
<td>8</td>
<td>INFO</td>
<td>SQL node or data node connection closed</td>
</tr>
<tr>
<td>CommunicationOpened</td>
<td>8</td>
<td>INFO</td>
<td>SQL node or data node connection open</td>
</tr>
<tr>
<td>ConnectedApiVersion</td>
<td>8</td>
<td>INFO</td>
<td>Connection using API version</td>
</tr>
</tbody>
</table>

**CHECKPOINT Events**

The logging messages shown here are associated with checkpoints.

<table>
<thead>
<tr>
<th>Event</th>
<th>Priority</th>
<th>Severity Level</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlobalCheckpointStarted</td>
<td>9</td>
<td>INFO</td>
<td>Start of GCP: REDO log is written to disk</td>
</tr>
<tr>
<td>GlobalCheckpointCompleted</td>
<td>10</td>
<td>INFO</td>
<td>GCP finished</td>
</tr>
<tr>
<td>LocalCheckpointStarted</td>
<td>7</td>
<td>INFO</td>
<td>Start of LCP: data written to disk</td>
</tr>
<tr>
<td>LocalCheckpointCompleted</td>
<td>7</td>
<td>INFO</td>
<td>LCP completed normally</td>
</tr>
<tr>
<td>LCPStoppedInCalcKeepGci</td>
<td>0</td>
<td>ALERT</td>
<td>LCP stopped</td>
</tr>
<tr>
<td>LCPFragmentCompleted</td>
<td>11</td>
<td>INFO</td>
<td>LCP on a fragment has been completed</td>
</tr>
<tr>
<td>UndoLogBlocked</td>
<td>7</td>
<td>INFO</td>
<td>UNDO logging blocked; buffer near overflow</td>
</tr>
<tr>
<td>RedoStatus</td>
<td>7</td>
<td>INFO</td>
<td>Redo status</td>
</tr>
</tbody>
</table>

**STARTUP Events**

The following events are generated in response to the startup of a node or of the cluster and of its success or failure. They also provide information relating to the progress of the startup process, including information concerning logging activities.

<table>
<thead>
<tr>
<th>Event</th>
<th>Priority</th>
<th>Severity Level</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDBStartStarted</td>
<td>1</td>
<td>INFO</td>
<td>Data node start phases initiated (all nodes starting)</td>
</tr>
<tr>
<td>NDBStartCompleted</td>
<td>1</td>
<td>INFO</td>
<td>Start phases completed, all data nodes</td>
</tr>
<tr>
<td>SADDRERSRecieved</td>
<td>15</td>
<td>INFO</td>
<td>Blocks received after completion of restart</td>
</tr>
<tr>
<td>StartPhaseCompleted</td>
<td>4</td>
<td>INFO</td>
<td>Data node start phase X completed</td>
</tr>
<tr>
<td>CM_REGCONF</td>
<td>3</td>
<td>INFO</td>
<td>Node has been successfully included into the cluster; shows the node, managing node, and dynamic ID</td>
</tr>
<tr>
<td>CM_REGREF</td>
<td>8</td>
<td>INFO</td>
<td>Node has been refused for inclusion in the cluster; cannot be included in cluster due to misconfiguration, inability to establish communication, or other problem</td>
</tr>
<tr>
<td>FIND_NEIGHBOURS</td>
<td>8</td>
<td>INFO</td>
<td>Shows neighboring data nodes</td>
</tr>
<tr>
