You need only a read lock; this enables other clients to continue to query the tables while you are making a copy of the files in the database directory. The FLUSH TABLES statement is needed to ensure that the all active index pages are written to disk before you start the backup. See Section 13.3.5, “LOCK TABLES and UNLOCK TABLES Syntax”, and Section 13.7.6.3, “FLUSH Syntax”.

You can also create a binary backup simply by copying all table files, as long as the server isn’t updating anything. The mysqlhotcopy script uses this method. (But note that table file copying methods do not work if your database contains InnoDB tables. mysqlhotcopy does not work for InnoDB tables because InnoDB does not necessarily store table contents in database directories. Also, even if the server is not actively updating data, InnoDB may still have modified data cached in memory and not flushed to disk.)

Making Delimited-Text File Backups

To create a text file containing a table’s data, you can use SELECT * INTO OUTFILE ‘file_name’ FROM tbl_name. The file is created on the MySQL server host, not the client host. For this statement, the output file cannot already exist because permitting files to be overwritten constitutes a security risk. See Section 13.2.8, “SELECT Syntax”. This method works for any kind of data file, but saves only table data, not the table structure.

Another way to create text data files (along with files containing CREATE TABLE statements for the backed up tables) is to use mysqldump with the --tab option. See Section 7.4.3, “Dumping Data in Delimited-Text Format with mysqldump”.

To reload a delimited-text data file, use LOAD DATA INFILE or mysqlimport.
Making Incremental Backups by Enabling the Binary Log

MySQL supports incremental backups: You must start the server with the `--log-bin` option to enable binary logging; see Section 5.4.4, “The Binary Log”. The binary log files provide you with the information you need to replicate changes to the database that are made subsequent to the point at which you performed a backup. At the moment you want to make an incremental backup (containing all changes that happened since the last full or incremental backup), you should rotate the binary log by using `FLUSH LOGS`. This done, you need to copy to the backup location all binary logs which range from the one of the moment of the last full or incremental backup to the last but one. These binary logs are the incremental backup; at restore time, you apply them as explained in Section 7.5, “Point-in-Time (Incremental) Recovery Using the Binary Log”. The next time you do a full backup, you should also rotate the binary log using `FLUSH LOGS`, `mysqldump --flush-logs`, or `mysqlhotcopy --flushlog`. See Section 4.5.4, “mysqldump — A Database Backup Program”, and Section 4.6.9, “mysqlhotcopy — A Database Backup Program”.

Making Backups Using Replication Slaves

If you have performance problems with your master server while making backups, one strategy that can help is to set up replication and perform backups on the slave rather than on the master. See Section 16.3.1, “Using Replication for Backups”.

If you are backing up a slave replication server, you should back up its `master.info` and `relay-log.info` files when you back up the slave’s databases, regardless of the backup method you choose. These information files are always needed to resume replication after you restore the slave’s data. If your slave is replicating `LOAD DATA INFILE` statements, you should also back up any `SQL_LOAD-*` files that exist in the directory that the slave uses for this purpose. The slave needs these files to resume replication of any interrupted `LOAD DATA INFILE` operations. The location of this directory is the value of the `--slave-load-tmpdir` option. If the server was not started with that option, the directory location is the value of the `tmpdir` system variable.

Recovering Corrupt Tables

If you have to restore MyISAM tables that have become corrupt, try to recover them using `REPAIR TABLE` or `myisamchk -r` first. That should work in 99.9% of all cases. If `myisamchk` fails, see Section 7.6, “MyISAM Table Maintenance and Crash Recovery”.

Making Backups Using a File System Snapshot

If you are using a Veritas file system, you can make a backup like this:

1. From a client program, execute `FLUSH TABLES WITH READ LOCK`.
2. From another shell, execute `mount vxfs snapshot`.
3. From the first client, execute `UNLOCK TABLES`.
4. Copy files from the snapshot.
5. Unmount the snapshot.

Similar snapshot capabilities may be available in other file systems, such as LVM or ZFS.

7.3 Example Backup and Recovery Strategy

This section discusses a procedure for performing backups that enables you to recover data after several types of crashes:

- Operating system crash
Establishing a Backup Policy

- Power failure
- File system crash
- Hardware problem (hard drive, motherboard, and so forth)

The example commands do not include options such as `--user` and `--password` for the `mysqldump` and `mysql` client programs. You should include such options as necessary to enable client programs to connect to the MySQL server.

Assume that data is stored in the InnoDB storage engine, which has support for transactions and automatic crash recovery. Assume also that the MySQL server is under load at the time of the crash. If it were not, no recovery would ever be needed.

For cases of operating system crashes or power failures, we can assume that MySQL’s disk data is available after a restart. The InnoDB data files might not contain consistent data due to the crash, but InnoDB reads its logs and finds in them the list of pending committed and noncommitted transactions that have not been flushed to the data files. InnoDB automatically rolls back those transactions that were not committed, and flushes to its data files those that were committed. Information about this recovery process is conveyed to the user through the MySQL error log. The following is an example log excerpt:

```
InnoDB: Database was not shut down normally.
InnoDB: Starting recovery from log files...
InnoDB: Starting log scan based on checkpoint at
InnoDB: log sequence number 0 13674004
InnoDB: Doing recovery: scanned up to log sequence number 0 13739520
InnoDB: Doing recovery: scanned up to log sequence number 0 13805056
InnoDB: Doing recovery: scanned up to log sequence number 0 13870592
...  
InnoDB: Doing recovery: scanned up to log sequence number 0 20555264
InnoDB: Doing recovery: scanned up to log sequence number 0 20620800
InnoDB: Doing recovery: scanned up to log sequence number 0 20664692
InnoDB: 1 uncommitted transaction(s) which must be rolled back
InnoDB: Starting rollback of uncommitted transactions
InnoDB: Rolling back trx no 16745
InnoDB: Rolling of uncommitted transactions completed
InnoDB: Starting an apply batch of log records to the database...
InnoDB: Apply batch completed
InnoDB: Started
mysqld: ready for connections
```

For the cases of file system crashes or hardware problems, we can assume that the MySQL disk data is not available after a restart. This means that MySQL fails to start successfully because some blocks of disk data are no longer readable. In this case, it is necessary to reformat the disk, install a new one, or otherwise correct the underlying problem. Then it is necessary to recover our MySQL data from backups, which means that backups must already have been made. To make sure that is the case, design and implement a backup policy.

### 7.3.1 Establishing a Backup Policy

To be useful, backups must be scheduled regularly. A full backup (a snapshot of the data at a point in time) can be done in MySQL with several tools. For example, MySQL Enterprise Backup can perform a physical backup of an entire instance, with optimizations to minimize overhead and avoid disruption when backing up InnoDB data files; `mysqldump` provides online logical backup. This discussion uses `mysqldump`.

Assume that we make a full backup of all our InnoDB tables in all databases using the following command on Sunday at 1 p.m., when load is low:
Establishing a Backup Policy

```
shell> mysqldump --single-transaction --all-databases > backup_sunday_1_PM.sql
```

The resulting .sql file produced by mysqldump contains a set of SQL INSERT statements that can be used to reload the dumped tables at a later time.

This backup operation acquires a global read lock on all tables at the beginning of the dump (using FLUSH TABLES WITH READ LOCK). As soon as this lock has been acquired, the binary log coordinates are read and the lock is released. If long updating statements are running when the FLUSH statement is issued, the backup operation may stall until those statements finish. After that, the dump becomes lock-free and does not disturb reads and writes on the tables.

It was assumed earlier that the tables to back up are InnoDB tables, so --single-transaction uses a consistent read and guarantees that data seen by mysqldump does not change. (Changes made by other clients to InnoDB tables are not seen by the mysqldump process.) If the backup operation includes nontransactional tables, consistency requires that they do not change during the backup. For example, for the MyISAM tables in the mysql database, there must be no administrative changes to MySQL accounts during the backup.

Full backups are necessary, but it is not always convenient to create them. They produce large backup files and take time to generate. They are not optimal in the sense that each successive full backup includes all data, even that part that has not changed since the previous full backup. It is more efficient to make an initial full backup, and then to make incremental backups. The incremental backups are smaller and take less time to produce. The tradeoff is that, at recovery time, you cannot restore your data just by reloading the full backup. You must also process the incremental backups to recover the incremental changes.

To make incremental backups, we need to save the incremental changes. In MySQL, these changes are represented in the binary log, so the MySQL server should always be started with the --log-bin option to enable that log. With binary logging enabled, the server writes each data change into a file while it updates data. Looking at the data directory of a MySQL server that was started with the --log-bin option and that has been running for some days, we find these MySQL binary log files:

```
-rw-rw---- 1 guilhem  guilhem   1277324 Nov 10 23:59 gbichot2-bin.000001
-rw-rw---- 1 guilhem  guilhem         4 Nov 10 23:59 gbichot2-bin.000002
-rw-rw---- 1 guilhem  guilhem        79 Nov 11 11:06 gbichot2-bin.000003
-rw-rw---- 1 guilhem  guilhem       508 Nov 11 11:08 gbichot2-bin.000004
-rw-rw---- 1 guilhem  guilhem 220047446 Nov 12 16:47 gbichot2-bin.000005
-rw-rw---- 1 guilhem  guilhem       998412 Nov 14 10:08 gbichot2-bin.000006
-rw-rw---- 1 guilhem  guilhem       361 Nov 14 10:07 gbichot2-bin.index
```

Each time it restarts, the MySQL server creates a new binary log file using the next number in the sequence. While the server is running, you can also tell it to close the current binary log file and begin a new one manually by issuing a FLUSH LOGS SQL statement or with a mysqladmin flush-logs command. mysqldump also has an option to flush the logs. The .index file in the data directory contains the list of all MySQL binary logs in the directory.

The MySQL binary logs are important for recovery because they form the set of incremental backups. If you make sure to flush the logs when you make your full backup, the binary log files created afterward contain all the data changes made since the backup. Let’s modify the previous mysqldump command a bit so that it flushes the MySQL binary logs at the moment of the full backup, and so that the dump file contains the name of the new current binary log:

```
shell> mysqldump --single-transaction --flush-logs --master-data=2 \   --all-databases > backup_sunday_1_PM.sql
```

After executing this command, the data directory contains a new binary log file, gbichot2-bin.000007, because the --flush-logs option causes the server to flush its logs. The --master-data option causes mysqldump to write binary log information to its output, so the resulting .sql dump file includes these lines:

```
shell> mysqldump --single-transaction --flush-logs --master-data=2 \   --all-databases > backup_sunday_1_PM.sql
```

After executing this command, the data directory contains a new binary log file, gbichot2-bin.000007, because the --flush-logs option causes the server to flush its logs. The --master-data option causes mysqldump to write binary log information to its output, so the resulting .sql dump file includes these lines:
-- Position to start replication or point-in-time recovery from
-- CHANGE MASTER TO MASTER_LOG_FILE='gbichot2-bin.000007', MASTER_LOG_POS=4;

Because the `mysqldump` command made a full backup, those lines mean two things:

- The dump file contains all changes made before any changes written to the `gbichot2-bin.000007` binary log file.
- All data changes logged after the backup are not present in the dump file, but are present in the `gbichot2-bin.000007` binary log file.

On Monday at 1 p.m., we can create an incremental backup by flushing the logs to begin a new binary log file. For example, executing a `mysqladmin flush-logs` command creates `gbichot2-bin.000008`. All changes between the Sunday 1 p.m. full backup and Monday 1 p.m. will be in the `gbichot2-bin.000007` file. This incremental backup is important, so it is a good idea to copy it to a safe place. On Tuesday at 1 p.m., execute another `mysqladmin flush-logs` command. All changes between Monday 1 p.m. and Tuesday 1 p.m. will be in the `gbichot2-bin.000008` file (which also should be copied somewhere safe).

The MySQL binary logs take up disk space. To free up space, purge them from time to time. One way to do this is by deleting the binary logs that are no longer needed, such as when we make a full backup:

```
shell> mysqldump --single-transaction --flush-logs --master-data=2 --all-databases --delete-master-logs > backup_sunday_1_PM.sql
```

Note
Deleting the MySQL binary logs with `mysqldump --delete-master-logs` can be dangerous if your server is a replication master server, because slave servers might not yet fully have processed the contents of the binary log. The description for the `PURGE BINARY LOGS` statement explains what should be verified before deleting the MySQL binary logs. See Section 13.4.1.1, “PURGE BINARY LOGS Syntax”.

7.3.2 Using Backups for Recovery

Now, suppose that we have a catastrophic crash on Wednesday at 8 a.m. that requires recovery from backups. To recover, first we restore the last full backup we have (the one from Sunday 1 p.m.). The full backup file is just a set of SQL statements, so restoring it is very easy:

```
shell> mysql < backup_sunday_1_PM.sql
```

At this point, the data is restored to its state as of Sunday 1 p.m.. To restore the changes made since then, we must use the incremental backups; that is, the `gbichot2-bin.000007` and `gbichot2-bin.000008` binary log files. Fetch the files if necessary from where they were backed up, and then process their contents like this:

```
shell> mysqlbinlog gbichot2-bin.000007 gbichot2-bin.000008 | mysql
```

We now have recovered the data to its state as of Tuesday 1 p.m., but still are missing the changes from that date to the date of the crash. To not lose them, we would have needed to have the MySQL server store its MySQL binary logs into a safe location (RAID disks, SAN, ...) different from the place where it stores its data files, so that these logs were not on the destroyed disk. (That is, we can start the server with a `--log-bin` option that specifies a location on a different physical device from the one on which the data directory resides. That way, the logs are safe even if the device containing the directory is lost.) If we had done this, we would have the `gbichot2-bin.000009` file (and any
subsequent files) at hand, and we could apply them using `mysqlbinlog` and `mysql` to restore the most recent data changes with no loss up to the moment of the crash:

```
shell> mysqlbinlog gbichot2-bin.000009 ... | mysql
```

For more information about using `mysqlbinlog` to process binary log files, see Section 7.5, “Point-in-Time (Incremental) Recovery Using the Binary Log”.

### 7.3.3 Backup Strategy Summary

In case of an operating system crash or power failure, InnoDB itself does all the job of recovering data. But to make sure that you can sleep well, observe the following guidelines:

- Always run the MySQL server with the `--log-bin` option, or even `--log-bin=log_name`, where the log file name is located on some safe media different from the drive on which the data directory is located. If you have such safe media, this technique can also be good for disk load balancing (which results in a performance improvement).
- Make periodic full backups, using the `mysqldump` command shown earlier in Section 7.3.1, “Establishing a Backup Policy”, that makes an online, nonblocking backup.
- Make periodic incremental backups by flushing the logs with `FLUSH LOGS` or `mysqladmin flush-logs`.

### 7.4 Using mysqldump for Backups

This section describes how to use `mysqldump` to produce dump files, and how to reload dump files. A dump file can be used in several ways:

- As a backup to enable data recovery in case of data loss.
- As a source of data for setting up replication slaves.
- As a source of data for experimentation:
  - To make a copy of a database that you can use without changing the original data.
  - To test potential upgrade incompatibilities.

`mysqldump` produces two types of output, depending on whether the `--tab` option is given:

- Without `--tab`, `mysqldump` writes SQL statements to the standard output. This output consists of `CREATE` statements to create dumped objects (databases, tables, stored routines, and so forth), and `INSERT` statements to load data into tables. The output can be saved in a file and reloaded later using `mysql` to recreate the dumped objects. Options are available to modify the format of the SQL statements, and to control which objects are dumped.

- With `--tab`, `mysqldump` produces two output files for each dumped table. The server writes one file as tab-delimited text, one line per table row. This file is named `tbl_name.txt` in the output directory. The server also sends a `CREATE TABLE` statement for the table to `mysqldump`, which writes it as a file named `tbl_name.sql` in the output directory.

### 7.4.1 Dumping Data in SQL Format with mysqldump

This section describes how to use `mysqldump` to create SQL-format dump files. For information about reloading such dump files, see Section 7.4.2, “Reloading SQL-Format Backups”.

By default, `mysqldump` writes information as SQL statements to the standard output. You can save the output in a file:
Reloading SQL-Format Backups

shell> mysql dump [arguments] > file_name

To dump all databases, invoke mysql dump with the --all-databases option:

shell> mysql dump --all-databases > dump.sql

To dump only specific databases, name them on the command line and use the --databases option:

shell> mysql dump --databases db1 db2 db3 > dump.sql

The --databases option causes all names on the command line to be treated as database names. Without this option, mysql dump treats the first name as a database name and those following as table names.

With --all-databases or --databases, mysql dump writes CREATE DATABASE and USE statements prior to the dump output for each database. This ensures that when the dump file is reloaded, it creates each database if it does not exist and makes it the default database so database contents are loaded into the same database from which they came. If you want to cause the dump file to force a drop of each database before recreating it, use the --add-drop-database option as well. In this case, mysql dump writes a DROP DATABASE statement preceding each CREATE DATABASE statement.

To dump a single database, name it on the command line:

shell> mysql dump --databases test > dump.sql

In the single-database case, it is permissible to omit the --databases option:

shell> mysql dump test > dump.sql

The difference between the two preceding commands is that without --databases, the dump output contains no CREATE DATABASE or USE statements. This has several implications:

• When you reload the dump file, you must specify a default database name so that the server knows which database to reload.

• For reloading, you can specify a database name different from the original name, which enables you to reload the data into a different database.

• If the database to be reloaded does not exist, you must create it first.

• Because the output will contain no CREATE DATABASE statement, the --add-drop-database option has no effect. If you use it, it produces no DROP DATABASE statement.

To dump only specific tables from a database, name them on the command line following the database name:

shell> mysql dump test t1 t3 t7 > dump.sql

7.4.2 Reloading SQL-Format Backups

To reload a dump file written by mysql dump that consists of SQL statements, use it as input to the mysql client. If the dump file was created by mysql dump with the --all-databases or --databases option, it contains CREATE DATABASE and USE statements and it is not necessary to specify a default database into which to load the data:

shell> mysql < dump.sql
Alternatively, from within `mysql`, use a `source` command:

```sql
class
source dump.sql
```

If the file is a single-database dump not containing `CREATE DATABASE` and `USE` statements, create the database first (if necessary):

```sql
class
mysqladmin create db1
```

Then specify the database name when you load the dump file:

```sql
class
mysql db1 < dump.sql
```

Alternatively, from within `mysql`, create the database, select it as the default database, and load the dump file:

```sql
mysql> CREATE DATABASE IF NOT EXISTS db1;
n
mysql> USE db1;
n
mysql> source dump.sql
```

### 7.4.3 Dumping Data in Delimited-Text Format with `mysqldump`

This section describes how to use `mysqldump` to create delimited-text dump files. For information about reloading such dump files, see Section 7.4.4, “Reloading Delimited-Text Format Backups”.

If you invoke `mysqldump` with the `--tab=dir_name` option, it uses `dir_name` as the output directory and dumps tables individually in that directory using two files for each table. The table name is the base name for these files. For a table named `t1`, the files are named `t1.sql` and `t1.txt`. The `.sql` file contains a `CREATE TABLE` statement for the table. The `.txt` file contains the table data, one line per table row.

The following command dumps the contents of the `db1` database to files in the `/tmp` database:

```sql
class
shell> mysqldump --tab=/tmp db1
```

The `.txt` files containing table data are written by the server, so they are owned by the system account used for running the server. The server uses `SELECT ... INTO OUTFILE` to write the files, so you must have the `FILE` privilege to perform this operation, and an error occurs if a given `.txt` file already exists.

The server sends the `CREATE` definitions for dumped tables to `mysqldump`, which writes them to `.sql` files. These files therefore are owned by the user who executes `mysqldump`.

It is best that `--tab` be used only for dumping a local server. If you use it with a remote server, the `--tab` directory must exist on both the local and remote hosts, and the `.txt` files will be written by the server in the remote directory (on the server host), whereas the `.sql` files will be written by `mysqldump` in the local directory (on the client host).

For `mysqldump --tab`, the server by default writes table data to `.txt` files one line per row with tabs between column values, no quotation marks around column values, and newline as the line terminator. (These are the same defaults as for `SELECT ... INTO OUTFILE`.)

To enable data files to be written using a different format, `mysqldump` supports these options:

- `--fields-terminated-by=string`

  The string for separating column values (default: tab).

- `--fields-enclosed-by=char`
The character within which to enclose column values (default: no character).

- `--fields-optionally-enclosed-by=char`

The character within which to enclose non-numeric column values (default: no character).

- `--fields-escaped-by=char`

The character for escaping special characters (default: no escaping).

- `--lines-terminated-by=str`

The line-termination string (default: newline).

Depending on the value you specify for any of these options, it might be necessary on the command line to quote or escape the value appropriately for your command interpreter. Alternatively, specify the value using hex notation. Suppose that you want `mysqldump` to quote column values within double quotation marks. To do so, specify double quote as the value for the `--fields-enclosed-by` option. But this character is often special to command interpreters and must be treated specially. For example, on Unix, you can quote the double quote like this:

```
--fields-enclosed-by='"'
```

On any platform, you can specify the value in hex:

```
--fields-enclosed-by=0x22
```

It is common to use several of the data-formatting options together. For example, to dump tables in comma-separated values format with lines terminated by carriage-return/newline pairs (\r\n), use this command (enter it on a single line):

```
shell> mysqldump --tab=/tmp --fields-terminated-by=, --fields-enclosed-by='"' --lines-terminated-by=0x0d0a db1
```

Should you use any of the data-formatting options to dump table data, you will need to specify the same format when you reload data files later, to ensure proper interpretation of the file contents.

### 7.4.4 Reloading Delimited-Text Format Backups

For backups produced with `mysqldump --tab`, each table is represented in the output directory by an .sql file containing the `CREATE TABLE` statement for the table, and a .txt file containing the table data. To reload a table, first change location into the output directory. Then process the .sql file with `mysql` to create an empty table and process the .txt file to load the data into the table:

```
shell> mysql db1 < t1.sql
shell> mysqlimport db1 t1.txt
```

An alternative to using `mysqlimport` to load the data file is to use the `LOAD DATA INFILE` statement from within the `mysql` client:

```
mysql> USE db1;
mysql> LOAD DATA INFILE 't1.txt' INTO TABLE t1;
```

If you used any data-formatting options with `mysqldump` when you initially dumped the table, you must use the same options with `mysqlimport` or `LOAD DATA INFILE` to ensure proper interpretation of the data file contents:
MySQL Tips

7.4.5 mysqldump Tips

This section surveys techniques that enable you to use `mysqldump` to solve specific problems:

- How to make a copy a database
- How to copy a database from one server to another
- How to dump stored programs (stored procedures and functions, triggers, and events)
- How to dump definitions and data separately

### 7.4.5.1 Making a Copy of a Database

```shell
mysqldump db1 > dump.sql
mysqldump db1 > dump.sql
mysqldump db1 > dump.sql

Do not use `--databases` on the `mysqldump` command line because that causes `USE db1` to be included in the dump file, which overrides the effect of naming `db2` on the `mysql` command line.
```

### 7.4.5.2 Copy a Database from one Server to Another

On Server 1:

```shell
mysqldump --databases db1 > dump.sql

Copy the dump file from Server 1 to Server 2.
```

On Server 2:

```shell
mysql < dump.sql

Use of `--databases` with the `mysqldump` command line causes the dump file to include CREATE DATABASE and USE statements that create the database if it does exist and make it the default database for the reloaded data.

Alternatively, you can omit `--databases` from the `mysqldump` command. Then you will need to create the database on Server 2 (if necessary) and specify it as the default database when you reload the dump file.

On Server 1:

```shell
mysqldump db1 > dump.sql

On Server 2:

```shell
mysqladmin create db1
mysqldump Tips

shell> mysql db1 < dump.sql

You can specify a different database name in this case, so omitting --databases from the mysqldump command enables you to dump data from one database and load it into another.

7.4.5.3 Dumping Stored Programs

Several options control how mysqldump handles stored programs (stored procedures and functions, triggers, and events):

• --events: Dump Event Scheduler events
• --routines: Dump stored procedures and functions
• --triggers: Dump triggers for tables

The --triggers option is enabled by default so that when tables are dumped, they are accompanied by any triggers they have. The other options are disabled by default and must be specified explicitly to dump the corresponding objects. To disable any of these options explicitly, use its skip form: --skip-events, --skip-routines, or --skip-triggers.

7.4.5.4 Dumping Table Definitions and Content Separately

The --no-data option tells mysqldump not to dump table data, resulting in the dump file containing only statements to create the tables. Conversely, the --no-create-info option tells mysqldump to suppress CREATE statements from the output, so that the dump file contains only table data.

For example, to dump table definitions and data separately for the test database, use these commands:

shell> mysqldump --no-data test > dump-defs.sql
shell> mysqldump --no-create-info test > dump-data.sql

For a definition-only dump, add the --routines and --events options to also include stored routine and event definitions:

shell> mysqldump --no-data --routines --events test > dump-defs.sql

7.4.5.5 Using mysqldump to Test for Upgrade Incompatibilities

When contemplating a MySQL upgrade, it is prudent to install the newer version separately from your current production version. Then you can dump the database and database object definitions from the production server and load them into the new server to verify that they are handled properly. (This is also useful for testing downgrades.)

On the production server:

shell> mysqldump --all-databases --no-data --routines --events > dump-defs.sql

On the upgraded server:

shell> mysql < dump-defs.sql

Because the dump file does not contain table data, it can be processed quickly. This enables you to spot potential incompatibilities without waiting for lengthy data-loading operations. Look for warnings or errors while the dump file is being processed.

After you have verified that the definitions are handled properly, dump the data and try to load it into the upgraded server.
On the production server:

```
shell> mysqldump --all-databases --no-create-info > dump-data.sql
```

On the upgraded server:

```
shell> mysql < dump-data.sql
```

Now check the table contents and run some test queries.

# 7.5 Point-in-Time (Incremental) Recovery Using the Binary Log

Point-in-time recovery refers to recovery of data changes made since a given point in time. Typically, this type of recovery is performed after restoring a full backup that brings the server to its state as of the time the backup was made. (The full backup can be made in several ways, such as those listed in Section 7.2, “Database Backup Methods”.) Point-in-time recovery then brings the server up to date incrementally from the time of the full backup to a more recent time.

Point-in-time recovery is based on these principles:

- The source of information for point-in-time recovery is the set of incremental backups represented by the binary log files generated subsequent to the full backup operation. Therefore, the server must be started with the `--log-bin` option to enable binary logging (see Section 5.4.4, “The Binary Log”).

  To restore data from the binary log, you must know the name and location of the current binary log files. By default, the server creates binary log files in the data directory, but a path name can be specified with the `--log-bin` option to place the files in a different location. Section 5.4.4, “The Binary Log”.

  To see a listing of all binary log files, use this statement:

  ```
  mysql> SHOW BINARY LOGS;
  ```

  To determine the name of the current binary log file, issue the following statement:

  ```
  mysql> SHOW MASTER STATUS;
  ```

- The `mysqlbinlog` utility converts the events in the binary log files from binary format to text so that they can be executed or viewed. `mysqlbinlog` has options for selecting sections of the binary log based on event times or position of events within the log. See Section 4.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”.

- Executing events from the binary log causes the data modifications they represent to be redone. This enables recovery of data changes for a given span of time. To execute events from the binary log, process `mysqlbinlog` output using the `mysql` client:

  ```
  shell> mysqlbinlog binlog_files | mysql -u root -p
  ```

- Viewing log contents can be useful when you need to determine event times or positions to select partial log contents prior to executing events. To view events from the log, send `mysqlbinlog` output into a paging program:

  ```
  shell> mysqlbinlog binlog_files | more
  ```

  Alternatively, save the output in a file and view the file in a text editor:

  ```
  shell> mysqlbinlog binlog_files > tmpfile
  ```
• Saving the output in a file is useful as a preliminary to executing the log contents with certain events removed, such as an accidental DROP DATABASE. You can delete from the file any statements not to be executed before executing its contents. After editing the file, execute the contents as follows:

shell> mysql -u root -p < tmpfile

If you have more than one binary log to execute on the MySQL server, the safe method is to process them all using a single connection to the server. Here is an example that demonstrates what may be unsafe:

shell> mysqlbinlog binlog.000001 | mysql -u root -p # DANGER!!
shell> mysqlbinlog binlog.000002 | mysql -u root -p # DANGER!!

Processing binary logs this way using different connections to the server causes problems if the first log file contains a CREATE TEMPORARY TABLE statement and the second log contains a statement that uses the temporary table. When the first mysql process terminates, the server drops the temporary table. When the second mysql process attempts to use the table, the server reports "unknown table."

To avoid problems like this, use a single connection to execute the contents of all binary logs that you want to process. Here is one way to do so:

shell> mysqlbinlog binlog.000001 binlog.000002 | mysql -u root -p

Another approach is to write all the logs to a single file and then process the file:

shell> mysqlbinlog binlog.000001 > /tmp/statements.sql
shell> mysqlbinlog binlog.000002 >> /tmp/statements.sql
shell> mysql -u root -p -e "source /tmp/statements.sql"

### 7.5.1 Point-in-Time Recovery Using Event Times

To indicate the start and end times for recovery, specify the **--start-datetime** and **--stop-datetime** options for mysqlbinlog, in DATETIME format. As an example, suppose that exactly at 10:00 a.m. on April 20, 2005 an SQL statement was executed that deleted a large table. To restore the table and data, you could restore the previous night's backup, and then execute the following command:

shell> mysqlbinlog --stop-datetime="2005-04-20 9:59:59" \
    /var/log/mysql/bin.123456 | mysql -u root -p

This command recovers all of the data up until the date and time given by the **--stop-datetime** option. If you did not detect the erroneous SQL statement that was entered until hours later, you will probably also want to recover the activity that occurred afterward. Based on this, you could run mysqlbinlog again with a start date and time, like so:

shell> mysqlbinlog --start-datetime="2005-04-20 10:01:00" \
    /var/log/mysql/bin.123456 | mysql -u root -p

In this command, the SQL statements logged from 10:01 a.m. on will be re-executed. The combination of restoring of the previous night's dump file and the two mysqlbinlog commands restores everything up until one second before 10:00 a.m. and everything from 10:01 a.m. on.

To use this method of point-in-time recovery, you should examine the log to be sure of the exact times to specify for the commands. To display the log file contents without executing them, use this command:

```sql
shell> ...
```
Point-in-Time Recovery Using Event Positions

shell> mysqlbinlog /var/log/mysql/bin.123456 > /tmp/mysql_restore.sql

Then open the /tmp/mysql_restore.sql file with a text editor to examine it.

Excluding specific changes by specifying times for mysqlbinlog does not work well if multiple statements executed at the same time as the one to be excluded.

7.5.2 Point-in-Time Recovery Using Event Positions

Instead of specifying dates and times, the --start-position and --stop-position options for mysqlbinlog can be used for specifying log positions. They work the same as the start and stop date options, except that you specify log position numbers rather than dates. Using positions may enable you to be more precise about which part of the log to recover, especially if many transactions occurred around the same time as a damaging SQL statement. To determine the position numbers, run mysqlbinlog for a range of times near the time when the unwanted transaction was executed, but redirect the results to a text file for examination. This can be done like so:

shell> mysqlbinlog --start-datetime="2005-04-20 9:55:00" \  
--stop-datetime="2005-04-20 10:05:00" \ 
/var/log/mysql/bin.123456 > /tmp/mysql_restore.sql

This command creates a small text file in the /tmp directory that contains the SQL statements around the time that the deleterious SQL statement was executed. Open this file with a text editor and look for the statement that you do not want to repeat. Determine the positions in the binary log for stopping and resuming the recovery and make note of them. Positions are labeled as log_pos followed by a number. After restoring the previous backup file, use the position numbers to process the binary log file. For example, you would use commands something like these:

shell> mysqlbinlog --stop-position=368312 /var/log/mysql/bin.123456 \| mysql -u root -p
shell> mysqlbinlog --start-position=368315 /var/log/mysql/bin.123456 \| mysql -u root -p

The first command recovers all the transactions up until the stop position given. The second command recovers all transactions from the starting position given until the end of the binary log. Because the output of mysqlbinlog includes SET TIMESTAMP statements before each SQL statement recorded, the recovered data and related MySQL logs will reflect the original times at which the transactions were executed.

7.6 MyISAM Table Maintenance and Crash Recovery

This section discusses how to use myisamchk to check or repair MyISAM tables (tables that have .MYD and .MYI files for storing data and indexes). For general myisamchk background, see Section 4.6.3, "myisamchk — MyISAM Table-Maintenance Utility". Other table-repair information can be found at Section 2.13.4, "Rebuilding or Repairing Tables or Indexes".

You can use myisamchk to check, repair, or optimize database tables. The following sections describe how to perform these operations and how to set up a table maintenance schedule. For information about using myisamchk to get information about your tables, see Section 4.6.3.5, "Obtaining Table Information with myisamchk".

Even though table repair with myisamchk is quite secure, it is always a good idea to make a backup before doing a repair or any maintenance operation that could make a lot of changes to a table.

myisamchk operations that affect indexes can cause FULLTEXT indexes to be rebuilt with full-text parameters that are incompatible with the values used by the MySQL server. To avoid this problem, follow the guidelines in Section 4.6.3.1, "myisamchk General Options".
MyISAM table maintenance can also be done using the SQL statements that perform operations similar to what myisamchk can do:

- To check MyISAM tables, use `CHECK TABLE`.
- To repair MyISAM tables, use `REPAIR TABLE`.
- To optimize MyISAM tables, use `OPTIMIZE TABLE`.
- To analyze MyISAM tables, use `ANALYZE TABLE`.

For additional information about these statements, see Section 13.7.2, “Table Maintenance Statements”.

These statements can be used directly or by means of the mysqlcheck client program. One advantage of these statements over myisamchk is that the server does all the work. With myisamchk, you must make sure that the server does not use the tables at the same time so that there is no unwanted interaction between myisamchk and the server.

### 7.6.1 Using myisamchk for Crash Recovery

This section describes how to check for and deal with data corruption in MySQL databases. If your tables become corrupted frequently, you should try to find the reason why. See Section B.5.3.3, “What to Do If MySQL Keeps Crashing”.

For an explanation of how MyISAM tables can become corrupted, see Section 14.5.4, “MyISAM Table Problems”.

If you run `mysqld` with external locking disabled (which is the default), you cannot reliably use myisamchk to check a table when `mysqld` is using the same table. If you can be certain that no one will access the tables through `mysqld` while you run myisamchk, you only have to execute `mysqldadmin flush-tables` before you start checking the tables. If you cannot guarantee this, you must stop `mysqld` while you check the tables. If you run myisamchk to check tables that `mysqld` is updating at the same time, you may get a warning that a table is corrupt even when it is not.

If the server is run with external locking enabled, you can use myisamchk to check tables at any time. In this case, if the server tries to update a table that myisamchk is using, the server will wait for myisamchk to finish before it continues.

If you use myisamchk to repair or optimize tables, you must always ensure that the mysqld server is not using the table (this also applies if external locking is disabled). If you do not stop `mysqld`, you should at least do a `mysqldadmin flush-tables` before you run myisamchk. Your tables may become corrupted if the server and myisamchk access the tables simultaneously.

When performing crash recovery, it is important to understand that each MyISAM table `tbl_name` in a database corresponds to the three files in the database directory shown in the following table.

<table>
<thead>
<tr>
<th>File</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>tbl_name.frm</code></td>
<td>Definition (format) file</td>
</tr>
<tr>
<td><code>tbl_name.MYD</code></td>
<td>Data file</td>
</tr>
<tr>
<td><code>tbl_name.MYI</code></td>
<td>Index file</td>
</tr>
</tbody>
</table>

Each of these three file types is subject to corruption in various ways, but problems occur most often in data files and index files.

myisamchk works by creating a copy of the .MYD data file row by row. It ends the repair stage by removing the old .MYD file and renaming the new file to the original file name. If you use `--quick`, myisamchk does not create a temporary .MYD file, but instead assumes that the .MYD file is correct and generates only a new index file without touching the .MYD file. This is safe, because myisamchk automatically detects whether the .MYD file is corrupt and aborts the repair if it is. You can also specify
the --quick option twice to myisamchk. In this case, myisamchk does not abort on some errors (such as duplicate-key errors) but instead tries to resolve them by modifying the .MYD file. Normally the use of two --quick options is useful only if you have too little free disk space to perform a normal repair. In this case, you should at least make a backup of the table before running myisamchk.

7.6.2 How to Check MyISAM Tables for Errors

To check a MyISAM table, use the following commands:

- **myisamchk tbl_name**
  
  This finds 99.99% of all errors. What it cannot find is corruption that involves only the data file (which is very unusual). If you want to check a table, you should normally run myisamchk without options or with the --s (silent) option.

- **myisamchk -m tbl_name**
  
  This finds 99.999% of all errors. It first checks all index entries for errors and then reads through all rows. It calculates a checksum for all key values in the rows and verifies that the checksum matches the checksum for the keys in the index tree.

- **myisamchk -e tbl_name**
  
  This does a complete and thorough check of all data (-e means "extended check"). It does a check-read of every key for each row to verify that they indeed point to the correct row. This may take a long time for a large table that has many indexes. Normally, myisamchk stops after the first error it finds. If you want to obtain more information, you can add the --v (verbose) option. This causes myisamchk to keep going, up through a maximum of 20 errors.

- **myisamchk -e -i tbl_name**
  
  This is like the previous command, but the --i option tells myisamchk to print additional statistical information.

In most cases, a simple myisamchk command with no arguments other than the table name is sufficient to check a table.

7.6.3 How to Repair MyISAM Tables

The discussion in this section describes how to use myisamchk on MyISAM tables (extensions .MYI and .MYD).

You can also use the CHECK TABLE and REPAIR TABLE statements to check and repair MyISAM tables. See Section 13.7.2.3, “CHECK TABLE Syntax”, and Section 13.7.2.6, “REPAIR TABLE Syntax”.

Symptoms of corrupted tables include queries that abort unexpectedly and observable errors such as these:

- **tbl_name.frm** is locked against change
- Can't find file **tbl_name.MYI** (Errcode: **nnn**)
- Unexpected end of file
- Record file is crashed
- Got error **nnn** from table handler

To get more information about the error, run perror **nnn**, where **nnn** is the error number. The following example shows how to use perror to find the meanings for the most common error numbers that indicate a problem with a table:
How to Repair MyISAM Tables

shell> perror 126 127 132 134 135 136 141 144 145
MySQL error code 126 = Index file is crashed
MySQL error code 127 = Record-file is crashed
MySQL error code 132 = Old database file
MySQL error code 134 = Record was already deleted (or record file crashed)
MySQL error code 135 = No more room in record file
MySQL error code 136 = No more room in index file
MySQL error code 141 = Duplicate unique key or constraint on write or update
MySQL error code 144 = Table is crashed and last repair failed
MySQL error code 145 = Table was marked as crashed and should be repaired

Note that error 135 (no more room in record file) and error 136 (no more room in index file) are not errors that can be fixed by a simple repair. In this case, you must use ALTER TABLE to increase the MAX_ROWS and AVG_ROW_LENGTH table option values:

```
ALTER TABLE `tbl_name` MAX_ROWS=`xxx` AVG_ROW_LENGTH=`yyy`
```

If you do not know the current table option values, use SHOW CREATE TABLE.

For the other errors, you must repair your tables. myisamchk can usually detect and fix most problems that occur.

The repair process involves up to four stages, described here. Before you begin, you should change location to the database directory and check the permissions of the table files. On Unix, make sure that they are readable by the user that mysqld runs as (and to you, because you need to access the files you are checking). If it turns out you need to modify files, they must also be writable by you.

This section is for the cases where a table check fails (such as those described in Section 7.6.2, “How to Check MyISAM Tables for Errors”), or you want to use the extended features that myisamchk provides.

The myisamchk options used for table maintenance with are described in Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”. myisamchk also has variables that you can set to control memory allocation that may improve performance. See Section 4.6.3.6, “myisamchk Memory Usage”.

If you are going to repair a table from the command line, you must first stop the mysqld server. Note that when you do mysqladmin shutdown on a remote server, the mysqld server is still available for a while after mysqladmin returns, until all statement-processing has stopped and all index changes have been flushed to disk.

**Stage 1: Checking your tables**

Run myisamchk *.MYI or myisamchk -e *.MYI if you have more time. Use the -s (silent) option to suppress unnecessary information.

If the mysqld server is stopped, you should use the --update-state option to tell myisamchk to mark the table as “checked.”

You have to repair only those tables for which myisamchk announces an error. For such tables, proceed to Stage 2.

If you get unexpected errors when checking (such as out of memory errors), or if myisamchk crashes, go to Stage 3.

**Stage 2: Easy safe repair**

First, try myisamchk -r -q `tbl_name` (-r -q means “quick recovery mode”). This attempts to repair the index file without touching the data file. If the data file contains everything that it should and the delete links point at the correct locations within the data file, this should work, and the table is fixed. Start repairing the next table. Otherwise, use the following procedure:

1. Make a backup of the data file before continuing.
2. Use `myisamchk -r tbl_name` (`-r` means “recovery mode”). This removes incorrect rows and deleted rows from the data file and reconstructs the index file.

3. If the preceding step fails, use `myisamchk --safe-recover tbl_name`. Safe recovery mode uses an old recovery method that handles a few cases that regular recovery mode does not (but is slower).

   **Note**
   
   If you want a repair operation to go much faster, you should set the values of the `sort_buffer_size` and `key_buffer_size` variables each to about 25% of your available memory when running `myisamchk`.

If you get unexpected errors when repairing (such as `out of memory` errors), or if `myisamchk` crashes, go to Stage 3.

**Stage 3: Difficult repair**

You should reach this stage only if the first 16KB block in the index file is destroyed or contains incorrect information, or if the index file is missing. In this case, it is necessary to create a new index file. Do so as follows:

1. Move the data file to a safe place.
2. Use the table description file to create new (empty) data and index files:

   ```shell
   mysql> SET autocommit=1;
   mysql> TRUNCATE TABLE tbl_name;
   mysql> quit
   ```

3. Copy the old data file back onto the newly created data file. (Do not just move the old file back onto the new file. You want to retain a copy in case something goes wrong.)

   **Important**
   
   If you are using replication, you should stop it prior to performing the above procedure, since it involves file system operations, and these are not logged by MySQL.

   Go back to Stage 2. `myisamchk -r -q` should work. (This should not be an endless loop.)

   You can also use the `REPAIR TABLE tbl_name USE_FRM` SQL statement, which performs the whole procedure automatically. There is also no possibility of unwanted interaction between a utility and the server, because the server does all the work when you use `REPAIR TABLE`. See Section 13.7.2.6, “REPAIR TABLE Syntax”.

**Stage 4: Very difficult repair**

You should reach this stage only if the `.frm` description file has also crashed. That should never happen, because the description file is not changed after the table is created:

1. Restore the description file from a backup and go back to Stage 3. You can also restore the index file and go back to Stage 2. In the latter case, you should start with `myisamchk -r`.

2. If you do not have a backup but know exactly how the table was created, create a copy of the table in another database. Remove the new data file, and then move the `.frm` description and `.MYI` index files from the other database to your crashed database. This gives you new description and index files, but leaves the `.MYD` data file alone. Go back to Stage 2 and attempt to reconstruct the index file.

**7.6.4 MyISAM Table Optimization**
To coalesce fragmented rows and eliminate wasted space that results from deleting or updating rows, run `myisamchk` in recovery mode:

```shell
myisamchk -r tbl_name
```

You can optimize a table in the same way by using the `OPTIMIZE TABLE` SQL statement. `OPTIMIZE TABLE` does a table repair and a key analysis, and also sorts the index tree so that key lookups are faster. There is also no possibility of unwanted interaction between a utility and the server, because the server does all the work when you use `OPTIMIZE TABLE`. See Section 13.7.2.5, “OPTIMIZE TABLE Syntax”.

`myisamchk` has a number of other options that you can use to improve the performance of a table:

- `--analyze` or `-a`: Perform key distribution analysis. This improves join performance by enabling the join optimizer to better choose the order in which to join the tables and which indexes it should use.
- `--sort-index` or `-S`: Sort the index blocks. This optimizes seeks and makes table scans that use indexes faster.
- `--sort-records=index_num` or `-R index_num`: Sort data rows according to a given index. This makes your data much more localized and may speed up range-based `SELECT` and `ORDER BY` operations that use this index.

For a full description of all available options, see Section 4.6.3, “`myisamchk` — MyISAM Table-Maintenance Utility”.

### 7.6.5 Setting Up a MyISAM Table Maintenance Schedule

It is a good idea to perform table checks on a regular basis rather than waiting for problems to occur. One way to check and repair MyISAM tables is with the `CHECK TABLE` and `REPAIR TABLE` statements. See Section 13.7.2, “Table Maintenance Statements”.

Another way to check tables is to use `myisamchk`. For maintenance purposes, you can use `myisamchk -s`. The `-s` option (short for `--silent`) causes `myisamchk` to run in silent mode, printing messages only when errors occur.

It is also a good idea to enable automatic MyISAM table checking. For example, whenever the machine has done a restart in the middle of an update, you usually need to check each table that could have been affected before it is used further. (These are “expected crashed tables.”) To cause the server to check MyISAM tables automatically, start it with the `--myisam-recover` option. See Section 5.1.3, “Server Command Options”.

You should also check your tables regularly during normal system operation. For example, you can run a `cron` job to check important tables once a week, using a line like this in a `crontab` file:

```
35 0 * * 0 /path/to/myisamchk --fast --silent /path/to/datadir/*/*.MYI
```

This prints out information about crashed tables so that you can examine and repair them as necessary.

To start with, execute `myisamchk -s` each night on all tables that have been updated during the last 24 hours. As you see that problems occur infrequently, you can back off the checking frequency to once a week or so.

Normally, MySQL tables need little maintenance. If you are performing many updates to MyISAM tables with dynamic-sized rows (tables with `VARCHAR`, `BLOB`, or `TEXT` columns) or have tables with many deleted rows you may want to defragment/reclaim space from the tables from time to time. You can do this by using `OPTIMIZE TABLE` on the tables in question. Alternatively, if you can stop the `mysqld`
server for a while, change location into the data directory and use this command while the server is stopped:

```shell
myisamchk -r -s --sort-index --myisam_sort_buffer_size=16M */*.MYI
```

8.1 Optimization Overview

This chapter explains how to optimize MySQL performance and provides examples. Optimization involves configuring, tuning, and measuring performance, at several levels. Depending on your job role (developer, DBA, or a combination of both), you might optimize at the level of individual SQL statements, entire applications, a single database server, or multiple networked database servers. Sometimes you can be proactive and plan in advance for performance, while other times you might troubleshoot a configuration or code issue after a problem occurs. Optimizing CPU and memory usage can also improve scalability, allowing the database to handle more load without slowing down.

8.1.1 Optimization Overview

Database performance depends on several factors at the database level, such as tables, queries, and configuration settings. These software constructs result in CPU and I/O operations at the hardware level, which you must minimize and make as efficient as possible. As you work on database performance, you start by learning the high-level rules and guidelines for the software side, and measuring performance using wall-clock time. As you become an expert, you learn more about what happens internally, and start measuring things such as CPU cycles and I/O operations.

Typical users aim to get the best database performance out of their existing software and hardware configurations. Advanced users look for opportunities to improve the MySQL software itself, or develop their own storage engines and hardware appliances to expand the MySQL ecosystem.

Optimizing at the Database Level

The most important factor in making a database application fast is its basic design:

- Are the tables structured properly? In particular, do the columns have the right data types, and does each table have the appropriate columns for the type of work? For example, applications that perform frequent updates often have many tables with few columns, while applications that analyze large amounts of data often have few tables with many columns.

- Are the right *indexes* in place to make queries efficient?

- Are you using the appropriate storage engine for each table, and taking advantage of the strengths and features of each storage engine you use? In particular, the choice of a nontransactional
storage engine such as MyISAM or a transactional one such as InnoDB can be very important for performance and scalability.

- Does each table use an appropriate row format? This choice also depends on the storage engine used for the table. In particular, compressed tables use less disk space and so require less disk I/O to read and write the data. Compression is available for read-only MyISAM tables, and for all kinds of workloads with InnoDB tables.

- Does the application use an appropriate locking strategy? For example, by allowing shared access when possible so that database operations can run concurrently, and requesting exclusive access when appropriate so that critical operations get top priority. Again, the choice of storage engine is significant. The InnoDB storage engine handles most locking issues without involvement from you, allowing for better concurrency in the database and reducing the amount of experimentation and tuning for your code.

- Are all memory areas used for caching sized correctly? That is, large enough to hold frequently accessed data, but not so large that they overload physical memory and cause paging. The main memory areas to configure are the MyISAM key cache, the InnoDB buffer pool, and the MySQL query cache.

### Optimizing at the Hardware Level

Any database application eventually hits hardware limits as the database becomes more and more busy. A DBA must evaluate whether it is possible to tune the application or reconfigure the server to avoid these bottlenecks, or whether more hardware resources are required. System bottlenecks typically arise from these sources:

- Disk seeks. It takes time for the disk to find a piece of data. With modern disks, the mean time for this is usually lower than 10ms, so we can in theory do about 100 seeks a second. This time improves slowly with new disks and is very hard to optimize for a single table. The way to optimize seek time is to distribute the data onto more than one disk.

- Disk reading and writing. When the disk is at the correct position, we need to read or write the data. With modern disks, one disk delivers at least 10–20MB/s throughput. This is easier to optimize than seeks because you can read in parallel from multiple disks.

- CPU cycles. When the data is in main memory, we must process it to get our result. Having large tables compared to the amount of memory is the most common limiting factor. But with small tables, speed is usually not the problem.

- Memory bandwidth. When the CPU needs more data than can fit in the CPU cache, main memory bandwidth becomes a bottleneck. This is an uncommon bottleneck for most systems, but one to be aware of.

### Balancing Portability and Performance

Because all SQL servers implement different parts of standard SQL, it takes work to write portable database applications. It is very easy to achieve portability for very simple selects and inserts, but becomes more difficult the more capabilities you require. If you want an application that is fast with many database systems, it becomes even more difficult.

All database systems have some weak points. That is, they have different design compromises that lead to different behavior.

To make a complex application portable, you need to determine which SQL servers it must work with, and then determine what features those servers support. You can use the MySQL crash-me program to find functions, types, and limits that you can use with a selection of database servers. crash-me does not check for every possible feature, but it is still reasonably comprehensive, performing about 450 tests. An example of the type of information crash-me can provide is that you should not use column names that are longer than 18 characters if you want to be able to use Informix or DB2.
The crash-me program and the MySQL benchmarks are all very database independent. By taking a look at how they are written, you can get a feeling for what you must do to make your own applications database independent. The programs can be found in the sql-bench directory of MySQL source distributions. They are written in Perl and use the DBI database interface. Use of DBI in itself solves part of the portability problem because it provides database-independent access methods. See Section 8.13.2, “The MySQL Benchmark Suite”.

If you strive for database independence, you need to get a good feeling for each SQL server’s bottlenecks. For example, MySQL is very fast in retrieving and updating rows for MyISAM tables, but has a problem in mixing slow readers and writers on the same table. Transactional database systems in general are not very good at generating summary tables from log tables, because in this case row locking is almost useless.

To make your application really database independent, you should define an easily extendable interface through which you manipulate your data. For example, C++ is available on most systems, so it makes sense to use a C++ class-based interface to the databases.

If you use some feature that is specific to a given database system (such as the REPLACE statement, which is specific to MySQL), you should implement the same feature for other SQL servers by coding an alternative method. Although the alternative might be slower, it enables the other servers to perform the same tasks.

To use performance-oriented SQL extensions in a portable MySQL program, you can wrap MySQL-specific keywords in a statement within /*! */ comment delimiters. Other SQL servers ignore the commented keywords. For information about writing comments, see Section 9.6, “Comment Syntax”.

If high performance is more important than exactness, as for some Web applications, it is possible to create an application layer that caches all results to give you even higher performance. By letting old results expire after a while, you can keep the cache reasonably fresh. This provides a method to handle high load spikes, in which case you can dynamically increase the cache size and set the expiration timeout higher until things get back to normal.

In this case, the table creation information should contain information about the initial cache size and how often the table should normally be refreshed.

An attractive alternative to implementing an application cache is to use the MySQL query cache. By enabling the query cache, the server handles the details of determining whether a query result can be reused. This simplifies your application. See Section 8.10.3, “The MySQL Query Cache”.

### 8.2 Optimizing SQL Statements

The core logic of a database application is performed through SQL statements, whether issued directly through an interpreter or submitted behind the scenes through an API. The tuning guidelines in this section help to speed up all kinds of MySQL applications. The guidelines cover SQL operations that read and write data, the behind-the-scenes overhead for SQL operations in general, and operations used in specific scenarios such as database monitoring.

#### 8.2.1 Optimizing SELECT Statements

Queries, in the form of SELECT statements, perform all the lookup operations in the database. Tuning these statements is a top priority, whether to achieve sub-second response times for dynamic web pages, or to chop hours off the time to generate huge overnight reports.

Besides SELECT statements, the tuning techniques for queries also apply to constructs such as CREATE TABLE...AS SELECT, INSERT INTO...SELECT, and WHERE clauses in DELETE statements. Those statements have additional performance considerations because they combine write operations with the read-oriented query operations.

In MySQL Cluster NDB 7.2 and later, the NDB storage engine supports a join pushdown optimization whereby a qualifying join is sent in its entirety to MySQL Cluster data nodes, where it can be distributed
among them and executed in parallel. For more information about this optimization, see Conditions for NDB pushdown joins.

### 8.2.1.1 Speed of SELECT Statements

The main considerations for optimizing queries are:

- To make a slow `SELECT ... WHERE` query faster, the first thing to check is whether you can add an index. Set up indexes on columns used in the `WHERE` clause, to speed up evaluation, filtering, and the final retrieval of results. To avoid wasted disk space, construct a small set of indexes that speed up many related queries used in your application.

  Indexes are especially important for queries that reference different tables, using features such as joins and foreign keys. You can use the `EXPLAIN` statement to determine which indexes are used for a `SELECT`. See Section 8.3.1, “How MySQL Uses Indexes” and Section 8.8.1, “Optimizing Queries with EXPLAIN”.

- Isolate and tune any part of the query, such as a function call, that takes excessive time. Depending on how the query is structured, a function could be called once for every row in the result set, or even once for every row in the table, greatly magnifying any inefficiency.

- Minimize the number of full table scans in your queries, particularly for big tables.

- Keep table statistics up to date by using the `ANALYZE TABLE` statement periodically, so the optimizer has the information needed to construct an efficient execution plan.

- Learn the tuning techniques, indexing techniques, and configuration parameters that are specific to the storage engine for each table. Both InnoDB and MyISAM have sets of guidelines for enabling and sustaining high performance in queries. For details, see Section 8.6.5, “Optimizing InnoDB Queries” and Section 8.5.1, “Optimizing MyISAM Queries”.

- Avoid transforming the query in ways that make it hard to understand, especially if the optimizer does some of the same transformations automatically.

- If a performance issue is not easily solved by one of the basic guidelines, investigate the internal details of the specific query by reading the `EXPLAIN` plan and adjusting your indexes, `WHERE` clauses, join clauses, and so on. (When you reach a certain level of expertise, reading the `EXPLAIN` plan might be your first step for every query.)

- Adjust the size and properties of the memory areas that MySQL uses for caching. With efficient use of the MyISAM key cache, InnoDB buffer pool, and the MySQL query cache, repeated queries run faster because the results are retrieved from memory the second and subsequent times.

- Even for a query that runs fast using the cache memory areas, you might still optimize further so that they require less cache memory, making your application more scalable. Scalability means that your application can handle more simultaneous users, larger requests, and so on without experiencing a big drop in performance.

- Deal with locking issues, where the speed of your query might be affected by other sessions accessing the tables at the same time.

### 8.2.1.2 How MySQL Optimizes WHERE Clauses

This section discusses optimizations that can be made for processing `WHERE` clauses. The examples use `SELECT` statements, but the same optimizations apply for `WHERE` clauses in `DELETE` and `UPDATE` statements.

Work on the MySQL optimizer is ongoing, so this section is incomplete. MySQL performs a great many optimizations, not all of which are documented here.

Some of the optimizations performed by MySQL follow:
Optimizing SELECT Statements

- Removal of unnecessary parentheses:

```sql
((a AND b) AND c OR (((a AND b) AND (c AND d))))
-> (a AND b AND c) OR (a AND b AND c AND d)
```

- Constant folding:

```sql
(a<b AND b=c) AND a=5
-> b>5 AND b=c AND a=5
```

- Constant condition removal (needed because of constant folding):

```sql
(B>=5 AND B=5) OR (B=6 AND 5=5) OR (B=7 AND 5=6)
-> B=5 OR B=6
```

- Constant expressions used by indexes are evaluated only once.

- `COUNT(*)` on a single table without a `WHERE` is retrieved directly from the table information for `MyISAM` and `MEMORY` tables. This is also done for any `NOT NULL` expression when used with only one table.

- Early detection of invalid constant expressions. MySQL quickly detects that some `SELECT` statements are impossible and returns no rows.

- `HAVING` is merged with `WHERE` if you do not use `GROUP BY` or aggregate functions (`COUNT()`, `MIN()`, and so on).

- For each table in a join, a simpler `WHERE` is constructed to get a fast `WHERE` evaluation for the table and also to skip rows as soon as possible.

- All constant tables are read first before any other tables in the query. A constant table is any of the following:
  - An empty table or a table with one row.
  - A table that is used with a `WHERE` clause on a `PRIMARY KEY` or a `UNIQUE` index, where all index parts are compared to constant expressions and are defined as `NOT NULL`.

All of the following tables are used as constant tables:

```sql
SELECT * FROM t WHERE primary_key=1;
SELECT * FROM t1,t2
  WHERE t1.primary_key=1 AND t2.primary_key=t1.id;
```

- The best join combination for joining the tables is found by trying all possibilities. If all columns in `ORDER BY` and `GROUP BY` clauses come from the same table, that table is preferred first when joining.

- If there is an `ORDER BY` clause and a different `GROUP BY` clause, or if the `ORDER BY` or `GROUP BY` contains columns from tables other than the first table in the join queue, a temporary table is created.

- If you use the `SQL_SMALL_RESULT` option, MySQL uses an in-memory temporary table.

- Each table index is queried, and the best index is used unless the optimizer believes that it is more efficient to use a table scan. At one time, a scan was used based on whether the best index spanned more than 30% of the table, but a fixed percentage no longer determines the choice between using an index or a scan. The optimizer now is more complex and bases its estimate on additional factors such as table size, number of rows, and I/O block size.

- MySQL can sometimes produce query results using data from the index, without consulting the table data. If all columns used from the index are numeric, only the index data is used to resolve the query.
Optimizing SELECT Statements

- Before each row is output, those that do not match the **HAVING** clause are skipped.

Some examples of queries that are very fast:

```sql
SELECT COUNT(*) FROM tbl_name;
SELECT MIN(key_part1), MAX(key_part1) FROM tbl_name;
SELECT MAX(key_part2) FROM tbl_name
WHERE key_part1 = constant;
SELECT ... FROM tbl_name
ORDER BY key_part1, key_part2, ... LIMIT 10;
SELECT ... FROM tbl_name
ORDER BY key_part1 DESC, key_part2 DESC, ... LIMIT 10;
```

MySQL resolves the following queries using only the index tree, assuming that the indexed columns are numeric:

```sql
SELECT key_part1, key_part2 FROM tbl_name WHERE key_part1 = val;
SELECT COUNT(*) FROM tbl_name
WHERE key_part1 = val1 AND key_part2 = val2;
SELECT key_part2 FROM tbl_name GROUP BY key_part1;
```

The following queries use indexing to retrieve the rows in sorted order without a separate sorting pass:

```sql
SELECT ... FROM tbl_name
ORDER BY key_part1, key_part2, ... ;
SELECT ... FROM tbl_name
ORDER BY key_part1 DESC, key_part2 DESC, ... ;
```

### 8.2.1.3 Range Optimization

The range access method uses a single index to retrieve a subset of table rows that are contained within one or several index value intervals. It can be used for a single-part or multiple-part index. The following sections give a detailed description of how intervals are extracted from the **WHERE** clause.

#### The Range Access Method for Single-Part Indexes

For a single-part index, index value intervals can be conveniently represented by corresponding conditions in the **WHERE** clause, denoted as **range conditions** rather than “intervals.”

The definition of a range condition for a single-part index is as follows:

- For both **BTREE** and **HASH** indexes, comparison of a key part with a constant value is a range condition when using the `=`, `<=`, `IN()`, `IS NULL`, or `IS NOT NULL` operators.

- Additionally, for **BTREE** indexes, comparison of a key part with a constant value is a range condition when using the `>`, `<`, `>=`, `<=`, `BETWEEN`, `!=`, or `<>` operators, or **LIKE** comparisons if the argument to **LIKE** is a constant string that does not start with a wildcard character.

- For all index types, multiple range conditions combined with **OR** or **AND** form a range condition.

“Constant value” in the preceding descriptions means one of the following:

- A constant from the query string
- A column of a **const** or **system** table from the same join
Optimizing SELECT Statements

- The result of an uncorrelated subquery
- Any expression composed entirely from subexpressions of the preceding types

Here are some examples of queries with range conditions in the `WHERE` clause:

```
SELECT * FROM t1
WHERE key_col > 1
AND key_col < 10;

SELECT * FROM t1
WHERE key_col = 1
OR key_col IN (15, 18, 20);

SELECT * FROM t1
WHERE key_col LIKE 'ab%'
OR key_col BETWEEN 'bar' AND 'foo';
```

Some nonconstant values may be converted to constants during the optimizer constant propagation phase.

MySQL tries to extract range conditions from the `WHERE` clause for each of the possible indexes. During the extraction process, conditions that cannot be used for constructing the range condition are dropped, conditions that produce overlapping ranges are combined, and conditions that produce empty ranges are removed.

Consider the following statement, where `key1` is an indexed column and `nonkey` is not indexed:

```
SELECT * FROM t1 WHERE
(key1 < 'abc' AND (key1 LIKE 'abcde%' OR key1 LIKE '%b')) OR
(key1 < 'bar' AND nonkey = 4) OR
(key1 < 'uux' AND key1 > 'z');
```

The extraction process for key `key1` is as follows:

1. Start with original `WHERE` clause:

```
(key1 < 'abc' AND (key1 LIKE 'abcde%' OR key1 LIKE '%b')) OR
(key1 < 'bar' AND nonkey = 4) OR
(key1 < 'uux' AND key1 > 'z');
```

2. Remove `nonkey = 4` and `key1 LIKE '%b'` because they cannot be used for a range scan. The correct way to remove them is to replace them with `TRUE`, so that we do not miss any matching rows when doing the range scan. Having replaced them with `TRUE`, we get:

```
(key1 < 'abc' AND (key1 LIKE 'abcde%' OR TRUE)) OR
(key1 < 'bar' AND TRUE) OR
(key1 < 'uux' AND key1 > 'z');
```

3. Collapse conditions that are always true or false:

- `(key1 LIKE 'abcde%' OR TRUE)` is always true
- `(key1 < 'uux' AND key1 > 'z')` is always false

Replacing these conditions with constants, we get:

```
(key1 < 'abc' AND TRUE) OR (key1 < 'bar' AND TRUE) OR (FALSE)
```

Removing unnecessary `TRUE` and `FALSE` constants, we obtain:
4. Combining overlapping intervals into one yields the final condition to be used for the range scan:

\[(\text{key1} < \text{'abc'}) \text{ OR } (\text{key1} < \text{'bar'})\]

In general (and as demonstrated by the preceding example), the condition used for a range scan is less restrictive than the \text{WHERE} clause. MySQL performs an additional check to filter out rows that satisfy the range condition but not the full \text{WHERE} clause.

The range condition extraction algorithm can handle nested AND/OR constructs of arbitrary depth, and its output does not depend on the order in which conditions appear in \text{WHERE} clause.

MySQL does not support merging multiple ranges for the \text{range} access method for spatial indexes. To work around this limitation, you can use a \texttt{UNION} with identical \texttt{SELECT} statements, except that you put each spatial predicate in a different \texttt{SELECT}.

The Range Access Method for Multiple-Part Indexes

Range conditions on a multiple-part index are an extension of range conditions for a single-part index. A range condition on a multiple-part index restricts index rows to lie within one or several key tuple intervals. Key tuple intervals are defined over a set of key tuples, using ordering from the index.

For example, consider a multiple-part index defined as \texttt{key1(key_part1, key_part2, key_part3)}, and the following set of key tuples listed in key order:

<table>
<thead>
<tr>
<th>key_part1</th>
<th>key_part2</th>
<th>key_part3</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL</td>
<td>1</td>
<td>'abc'</td>
</tr>
<tr>
<td>NULL</td>
<td>1</td>
<td>'xyz'</td>
</tr>
<tr>
<td>NULL</td>
<td>2</td>
<td>'foo'</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>'abc'</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>'xyz'</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>'abc'</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>'aaa'</td>
</tr>
</tbody>
</table>

The condition \texttt{key_part1 = 1} defines this interval:

\[(1,-\infty,-\infty) <= (\text{key_part1, key_part2, key_part3}) < (1,+\infty,+\infty)\]

The interval covers the 4th, 5th, and 6th tuples in the preceding data set and can be used by the range access method.

By contrast, the condition \texttt{key_part3 = 'abc'} does not define a single interval and cannot be used by the range access method.

The following descriptions indicate how range conditions work for multiple-part indexes in greater detail.

• For \texttt{HASH} indexes, each interval containing identical values can be used. This means that the interval can be produced only for conditions in the following form:

\[
\begin{align*}
\text{key_part1 cmp const1} \\
\text{AND key_part2 cmp const2} \\
\text{AND ...} \\
\text{AND key_partN cmp constN}
\end{align*}
\]

Here, \texttt{const1, const2, ...} are constants, \texttt{cmp} is one of the \texttt{=, <=, or IS NULL} comparison operators, and the conditions cover all index parts. (That is, there are \(N\) conditions, one for each part of an \(N\)-part index.) For example, the following is a range condition for a three-part \texttt{HASH} index:
Optimizing SELECT Statements

key_part1 = 1 AND key_part2 IS NULL AND key_part3 = 'foo'

For the definition of what is considered to be a constant, see The Range Access Method for Single-Part Indexes.

- For a BTREE index, an interval might be usable for conditions combined with AND, where each condition compares a key part with a constant value using =, <=>, IS NULL, >, >=, <=, !=, <>, BETWEEN, or LIKE 'pattern' (where 'pattern' does not start with a wildcard). An interval can be used as long as it is possible to determine a single key tuple containing all rows that match the condition (or two intervals if <> or != is used).

  The optimizer attempts to use additional key parts to determine the interval as long as the comparison operator is =, <=>, IS NULL. If the operator is >, >=, <=, !=, <>, BETWEEN, or LIKE, the optimizer uses it but considers no more key parts. For the following expression, the optimizer uses = from the first comparison. It also uses >= from the second comparison but considers no further key parts and does not use the third comparison for interval construction:

    key_part1 = 'foo' AND key_part2 >= 10 AND key_part3 > 10

  The single interval is:

    ('foo',10,-inf) < (key_part1,key_part2,key_part3) < ('foo',+inf,+inf)

  It is possible that the created interval contains more rows than the initial condition. For example, the preceding interval includes the value ('foo', 11, 0), which does not satisfy the original condition.

  - If conditions that cover sets of rows contained within intervals are combined with OR, they form a condition that covers a set of rows contained within the union of their intervals. If the conditions are combined with AND, they form a condition that covers a set of rows contained within the intersection of their intervals. For example, for this condition on a two-part index:

    \((key_part1 = 1 \text{ AND } key_part2 < 2) \text{ OR } (key_part1 > 5)\)

  The intervals are:

    (1,-inf) < (key_part1,key_part2) < (1,2)
    (5,-inf) < (key_part1,key_part2)

  In this example, the interval on the first line uses one key part for the left bound and two key parts for the right bound. The interval on the second line uses only one key part. The key_len column in the EXPLAIN output indicates the maximum length of the key prefix used.

  In some cases, key_len may indicate that a key part was used, but that might be not what you would expect. Suppose that key_part1 and key_part2 can be NULL. Then the key_len column displays two key part lengths for the following condition:

    key_part1 >= 1 AND key_part2 < 2

  But, in fact, the condition is converted to this:

    key_part1 >= 1 AND key_part2 IS NOT NULL

  The Range Access Method for Single-Part Indexes, describes how optimizations are performed to combine or eliminate intervals for range conditions on a single-part index. Analogous steps are performed for range conditions on multiple-part indexes.

8.2.1.4 Index Merge Optimization
The **Index Merge** method is used to retrieve rows with several range scans and to merge their results into one. The merge can produce unions, intersections, or unions-of-intersections of its underlying scans. This access method merges index scans from a single table; it does not merge scans across multiple tables.

In **EXPLAIN** output, the Index Merge method appears as `index_merge` in the `type` column. In this case, the `key` column contains a list of indexes used, and `key_len` contains a list of the longest key parts for those indexes.

**Examples:**

```sql
SELECT * FROM tbl_name WHERE key1 = 10 OR key2 = 20;
SELECT * FROM tbl_name WHERE (key1 = 10 OR key2 = 20) AND non_key=30;
SELECT * FROM t1, t2 WHERE (t1.key1 IN (1,2) OR t1.key2 LIKE 'value%') AND t2.key1=t1.some_col;
SELECT * FROM t1, t2 WHERE t1.key1=1 AND (t2.key1=t1.some_col OR t2.key2=t1.some_col2);
```

The Index Merge method has several access algorithms (seen in the **Extra** field of **EXPLAIN** output):

- Using `intersect(...)`
- Using `union(...)`
- Using `sort_union(...)`

The following sections describe these methods in greater detail.

---

**Note**

The Index Merge optimization algorithm has the following known deficiencies:

- If your query has a complex `WHERE` clause with deep `AND/OR` nesting and MySQL does not choose the optimal plan, try distributing terms using the following identity laws:

```sql
(x AND y) OR z = (x OR z) AND (y OR z)
(x OR y) AND z = (x AND z) OR (y AND z)
```

- Index Merge is not applicable to full-text indexes. We plan to extend it to cover these in a future MySQL release.

- If a range scan is possible on some key, the optimizer will not consider using Index Merge Union or Index Merge Sort-Union algorithms. For example, consider this query:

```sql
SELECT * FROM t1 WHERE (goodkey1 < 10 OR goodkey2 < 20) AND badkey < 30;
```

For this query, two plans are possible:

- An Index Merge scan using the `(goodkey1 < 10 OR goodkey2 < 20)` condition.
- A range scan using the `badkey < 30` condition.
However, the optimizer considers only the second plan.

The choice between different possible variants of the Index Merge access method and other access methods is based on cost estimates of various available options.

**The Index Merge Intersection Access Algorithm**

This access algorithm can be employed when a *WHERE* clause was converted to several range conditions on different keys combined with *AND*, and each condition is one of the following:

- In this form, where the index has exactly *N* parts (that is, all index parts are covered):

  $\text{key}_1 = \text{const}_1 \text{ AND } \text{key}_2 = \text{const}_2 \ldots \text{ AND } \text{key}_N = \text{const}_N$

- Any range condition over a primary key of an InnoDB table.

Examples:

```sql
SELECT * FROM innodb_table WHERE primary_key < 10 AND key_coll = 20;
SELECT * FROM tbl_name
WHERE (key1_part1 = 1 AND key1_part2 = 2) AND key2 = 2;
```

The Index Merge intersection algorithm performs simultaneous scans on all used indexes and produces the intersection of row sequences that it receives from the merged index scans.

If all columns used in the query are covered by the used indexes, full table rows are not retrieved *(EXPLAIN output contains *Using index* in *Extra* field in this case). Here is an example of such a query:

```sql
SELECT COUNT(*) FROM t1 WHERE key1 = 1 AND key2 = 1;
```

If the used indexes do not cover all columns used in the query, full rows are retrieved only when the range conditions for all used keys are satisfied.

If one of the merged conditions is a condition over a primary key of an InnoDB table, it is not used for row retrieval, but is used to filter out rows retrieved using other conditions.

**The Index Merge Union Access Algorithm**

The applicability criteria for this algorithm are similar to those for the Index Merge method intersection algorithm. The algorithm can be employed when the table's *WHERE* clause was converted to several range conditions on different keys combined with *OR*, and each condition is one of the following:

- In this form, where the index has exactly *N* parts (that is, all index parts are covered):

  $\text{key}_1 = \text{const}_1 \text{ AND } \text{key}_2 = \text{const}_2 \ldots \text{ AND } \text{key}_N = \text{const}_N$

- Any range condition over a primary key of an InnoDB table.

- A condition for which the Index Merge method intersection algorithm is applicable.

Examples:

```sql
SELECT * FROM t1 WHERE key1 = 1 OR key2 = 2 OR key3 = 3;
SELECT * FROM innodb_table WHERE (key1 = 1 AND key2 = 2) OR (key3 = 'foo' AND key4 = 'bar') AND key5 = 5;
```
The Index Merge Sort-Union Access Algorithm

This access algorithm is employed when the WHERE clause was converted to several range conditions combined by OR, but for which the Index Merge method union algorithm is not applicable.

Examples:

```
SELECT * FROM tbl_name WHERE key_col1 < 10 OR key_col2 < 20;
SELECT * FROM tbl_name
    WHERE (key_col1 > 10 OR key_col2 = 20) AND nonkey_col=30;
```

The difference between the sort-union algorithm and the union algorithm is that the sort-union algorithm must first fetch row IDs for all rows and sort them before returning any rows.

8.2.1.5 Engine Condition Pushdown Optimization

This optimization improves the efficiency of direct comparisons between a nonindexed column and a constant. In such cases, the condition is “pushed down” to the storage engine for evaluation. This optimization can be used only by the NDB storage engine.

For MySQL Cluster, this optimization can eliminate the need to send nonmatching rows over the network between the cluster's data nodes and the MySQL Server that issued the query, and can speed up queries where it is used by a factor of 5 to 10 times over cases where condition pushdown could be but is not used.

Suppose that a MySQL Cluster table is defined as follows:

```
CREATE TABLE t1 (
    a INT,
    b INT,
    KEY(a)
) ENGINE=NDB;
```

Condition pushdown can be used with queries such as the one shown here, which includes a comparison between a nonindexed column and a constant:

```
SELECT a, b FROM t1 WHERE b = 10;
```

The use of condition pushdown can be seen in the output of EXPLAIN:

```
mysql> EXPLAIN SELECT a,b FROM t1 WHERE b = 10\G
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: t1
type: ALL
possible_keys: NULL
key: NULL
key_len: NULL
ref: NULL
rows: 10
Extra: Using where with pushed condition
```

However, condition pushdown cannot be used with either of these two queries:

```
SELECT a,b FROM t1 WHERE a = 10;
SELECT a,b FROM t1 WHERE b + l = 10;
```

Condition pushdown is not applicable to the first query because an index exists on column a. (An index access method would be more efficient and so would be chosen in preference to condition pushdown.)
Condition pushdown cannot be employed for the second query because the comparison involving the nonindexed column \( b \) is indirect. (However, condition pushdown could be applied if you were to reduce \( b + 1 = 10 \) to \( b = 9 \) in the \textbf{WHERE} clause.)

Condition pushdown may also be employed when an indexed column is compared with a constant using a \( > \) or \( < \) operator:

```sql
mysql> EXPLAIN SELECT a, b FROM t1 WHERE a < 2
```

```
*************************** 1. row ***************************
id: 1
 select_type: SIMPLE
table: t1
type: range
possible_keys: a
  key: a
  key_len: 5
  ref: NULL
  rows: 2
Extra: Using where with pushed condition
```

Other supported comparisons for condition pushdown include the following:

- \( \text{column} \ [\text{NOT}] \ \text{LIKE} \ \text{pattern} \)

  \textit{pattern} must be a string literal containing the pattern to be matched; for syntax, see Section 12.5.1, “String Comparison Functions”.

- \( \text{column} \ \text{IS} \ [\text{NOT}] \ \text{NULL} \)

- \( \text{column IN (value_list)} \)

  Each item in the \textit{value_list} must be a constant, literal value.

- \( \text{column BETWEEN constant1 AND constant2} \)

  \textit{constant1} and \textit{constant2} must each be a constant, literal value.

In all of the cases in the preceding list, it is possible for the condition to be converted into the form of one or more direct comparisons between a column and a constant.

Engine condition pushdown is enabled by default. To disable it at server startup, set the \texttt{engine_condition_pushdown} system variable. For example, in a \texttt{my.cnf} file, use these lines:

```ini
[mysqld]
engine_condition_pushdown=0
```

At runtime, disable condition pushdown with either of the following statements:

```sql
SET engine_condition_pushdown=OFF;
SET engine_condition_pushdown=0;
```

**Limitations.** Engine condition pushdown is subject to the following limitations:

- Condition pushdown is supported only by the \texttt{NDB} storage engine.

- Columns may be compared with constants only; however, this includes expressions which evaluate to constant values.

- Columns used in comparisons cannot be of any of the \texttt{BLOB} or \texttt{TEXT} types.

- A string value to be compared with a column must use the same collation as the column.
• Joins are not directly supported; conditions involving multiple tables are pushed separately where possible. Use EXPLAIN EXTENDED to determine which conditions are actually pushed down.

8.2.1.6 IS NULL Optimization

MySQL can perform the same optimization on col_name IS NULL that it can use for col_name = constant_value. For example, MySQL can use indexes and ranges to search for NULL with IS NULL.

Examples:

```sql
SELECT * FROM tbl_name WHERE key_col IS NULL;
SELECT * FROM tbl_name WHERE key_col <=> NULL;
SELECT * FROM tbl_name
    WHERE key_col=const1 OR key_col=const2 OR key_col IS NULL;
```

If a WHERE clause includes a col_name IS NULL condition for a column that is declared as NOT NULL, that expression is optimized away. This optimization does not occur in cases when the column might produce NULL anyway; for example, if it comes from a table on the right side of a LEFT JOIN.

MySQL can also optimize the combination col_name = expr OR col_name IS NULL, a form that is common in resolved subqueries. EXPLAIN shows ref_or_null when this optimization is used.

This optimization can handle one IS NULL for any key part.

Some examples of queries that are optimized, assuming that there is an index on columns a and b of table t2:

```sql
SELECT * FROM t1 WHERE t1.a=expr OR t1.a IS NULL;
SELECT * FROM t1, t2 WHERE t1.a=t2.a OR t2.a IS NULL;
SELECT * FROM t1, t2
    WHERE (t1.a=t2.a OR t2.a IS NULL) AND t2.b=t1.b;
SELECT * FROM t1, t2
    WHERE t1.a=t2.a AND (t2.b=t1.b OR t2.b IS NULL);
SELECT * FROM t1, t2
    WHERE (t1.a=t2.a AND t2.a IS NULL AND ...)
OR (t1.a=t2.a AND t2.a IS NULL AND ...);
```

ref_or_null works by first doing a read on the reference key, and then a separate search for rows with a NULL key value.

The optimization can handle only one IS NULL level. In the following query, MySQL uses key lookups only on the expression (t1.a=t2.a AND t2.a IS NULL) and is not able to use the key part on b:

```sql
SELECT * FROM t1, t2
    WHERE (t1.a=t2.a AND t2.a IS NULL)
OR (t1.b=t2.b AND t2.b IS NULL);
```

8.2.1.7 LEFT JOIN and RIGHT JOIN Optimization

MySQL implements an A LEFT JOIN B join_condition as follows:

• Table B is set to depend on table A and all tables on which A depends.

• Table A is set to depend on all tables (except B) that are used in the LEFT JOIN condition.
Optimizing SELECT Statements

- The **LEFT JOIN** condition is used to decide how to retrieve rows from table \( B \). (In other words, any condition in the **WHERE** clause is not used.)

- All standard join optimizations are performed, with the exception that a table is always read after all tables on which it depends. If there is a circular dependence, MySQL issues an error.

- All standard **WHERE** optimizations are performed.

- If there is a row in \( A \) that matches the **WHERE** clause, but there is no row in \( B \) that matches the **ON** condition, an extra \( B \) row is generated with all columns set to **NULL**.

- If you use **LEFT JOIN** to find rows that do not exist in some table and you have the following test: `col_name IS NULL` in the **WHERE** part, where `col_name` is a column that is declared as **NOT NULL**, MySQL stops searching for more rows (for a particular key combination) after it has found one row that matches the **LEFT JOIN** condition.

The implementation of **RIGHT JOIN** is analogous to that of **LEFT JOIN** with the roles of the tables reversed.

The join optimizer calculates the order in which tables should be joined. The table read order forced by **LEFT JOIN** or **STRAIGHT_JOIN** helps the join optimizer do its work much more quickly, because there are fewer table permutations to check. Note that this means that if you do a query of the following type, MySQL does a full scan on \( b \) because the **LEFT JOIN** forces it to be read before \( d \):

```sql
SELECT *
FROM a JOIN b LEFT JOIN c ON (c.key=a.key)
LEFT JOIN d ON (d.key=a.key)
WHERE b.key=d.key;
```

The fix in this case is reverse the order in which \( a \) and \( b \) are listed in the **FROM** clause:

```sql
SELECT *
FROM b JOIN a LEFT JOIN c ON (c.key=a.key)
LEFT JOIN d ON (d.key=a.key)
WHERE b.key=d.key;
```

For a **LEFT JOIN**, if the **WHERE** condition is always false for the generated **NULL** row, the **LEFT JOIN** is changed to a normal join. For example, the **WHERE** clause would be false in the following query if \( t2.column1 \) were **NULL**:

```sql
SELECT * FROM t1 LEFT JOIN t2 ON (column1) WHERE t2.column2=5;
```

Therefore, it is safe to convert the query to a normal join:

```sql
SELECT * FROM t1, t2 WHERE t2.column2=5 AND t1.column1=t2.column1;
```

This can be made faster because MySQL can use table \( t2 \) before table \( t1 \) if doing so would result in a better query plan. To provide a hint about the table join order, use **STRAIGHT_JOIN**. (See Section 13.2.8, "SELECT Syntax").

### 8.2.1.8 Nested-Loop Join Algorithms

MySQL executes joins between tables using a nested-loop algorithm or variations on it.

**Nested-Loop Join Algorithm**

A simple nested-loop join (NLJ) algorithm reads rows from the first table in a loop one at a time, passing each row to a nested loop that processes the next table in the join. This process is repeated as many times as there remain tables to be joined.
Assume that a join between three tables $t_1$, $t_2$, and $t_3$ is to be executed using the following join types:

<table>
<thead>
<tr>
<th>Table</th>
<th>Join Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>$t_1$</td>
<td>range</td>
</tr>
<tr>
<td>$t_2$</td>
<td>ref</td>
</tr>
<tr>
<td>$t_3$</td>
<td>ALL</td>
</tr>
</tbody>
</table>

If a simple NLJ algorithm is used, the join is processed like this:

```sql
for each row in t1 matching range {
    for each row in t2 matching reference key {
        for each row in t3 {
            if row satisfies join conditions,
                send to client
        }
    }
}
```

Because the NLJ algorithm passes rows one at a time from outer loops to inner loops, it typically reads tables processed in the inner loops many times.

**Block Nested-Loop Join Algorithm**

A Block Nested-Loop (BNL) join algorithm uses buffering of rows read in outer loops to reduce the number of times that tables in inner loops must be read. For example, if 10 rows are read into a buffer and the buffer is passed to the next inner loop, each row read in the inner loop can be compared against all 10 rows in the buffer. The reduces the number of times the inner table must be read by an order of magnitude.

MySQL uses join buffering under these conditions:

- The `join_buffer_size` system variable determines the size of each join buffer.
- Join buffering can be used when the join is of type `ALL` or `index` (in other words, when no possible keys can be used, and a full scan is done, of either the data or index rows, respectively), or `range`.
- One buffer is allocated for each join that can be buffered, so a given query might be processed using multiple join buffers.
- A join buffer is never allocated for the first nonconst table, even if it would be of type `ALL` or `index`.
- A join buffer is allocated prior to executing the join and freed after the query is done.
- Only columns of interest to the join are stored in the join buffer, not whole rows.

For the example join described previously for the NLJ algorithm (without buffering), the join is done as follow using join buffering:

```sql
for each row in t1 matching range {
    for each row in t2 matching reference key {
        store used columns from t1, t2 in join buffer
        if buffer is full {
            for each row in t3 {
                for each t1, t2 combination in join buffer {
                    if row satisfies join conditions,
                        send to client
                }
            }
        }
        empty buffer
    }
}
```
if buffer is not empty {
    for each row in t3 {
        for each t1, t2 combination in join buffer {
            if row satisfies join conditions,
                send to client
        }
    }
}

If \( S \) is the size of each stored \( t_1, t_2 \) combination is the join buffer and \( C \) is the number of combinations in the buffer, the number of times table \( t_3 \) is scanned is:

\[
\frac{(S \times C)}{\text{join_buffer_size}} + 1
\]

The number of \( t_3 \) scans decreases as the value of \( \text{join_buffer_size} \) increases, up to the point when \( \text{join_buffer_size} \) is large enough to hold all previous row combinations. At that point, there is no speed to be gained by making it larger.

### 8.2.1.9 Nested Join Optimization

The syntax for expressing joins permits nested joins. The following discussion refers to the join syntax described in Section 13.2.8.2, "JOIN Syntax".

The syntax of \( \text{table_factor} \) is extended in comparison with the SQL Standard. The latter accepts only \( \text{table_reference} \), not a list of them inside a pair of parentheses. This is a conservative extension if we consider each comma in a list of \( \text{table_reference} \) items as equivalent to an inner join. For example:

```sql
SELECT * FROM t1 LEFT JOIN (t2, t3, t4)
ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

is equivalent to:

```sql
SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4)
ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

In MySQL, \( \text{CROSS JOIN} \) is a syntactic equivalent to \( \text{INNER JOIN} \) (they can replace each other). In standard SQL, they are not equivalent. \( \text{INNER JOIN} \) is used with an \( \text{ON} \) clause; \( \text{CROSS JOIN} \) is used otherwise.

In general, parentheses can be ignored in join expressions containing only inner join operations. After removing parentheses and grouping operations to the left, the join expression:

```sql
\( t_1 \) LEFT JOIN (\( t_2 \) LEFT JOIN \( t_3 \) ON \( t_2.b=t_3.b \) OR \( t_2.b \) IS NULL)
ON \( t_1.a=t_2.a \)
```

transforms into the expression:

```sql
(t1 LEFT JOIN t2 ON t1.a=t2.a) LEFT JOIN t3
ON t2.b=t3.b OR t2.b IS NULL
```

Yet, the two expressions are not equivalent. To see this, suppose that the tables \( t_1, t_2, \) and \( t_3 \) have the following state:

- Table \( t_1 \) contains rows \((1), (2)\)
- Table \( t_2 \) contains row \((1,101)\)
- Table \( t_3 \) contains row \((101)\)
In this case, the first expression returns a result set including the rows \((1,1,101,101), (2,\text{NULL}, \text{NULL}, \text{NULL})\), whereas the second expression returns the rows \((1,1,101,101), (2,\text{NULL}, \text{NULL}, 101)\):

```
mysql> SELECT *
    -> FROM t1
    -> LEFT JOIN
    -> (t2 LEFT JOIN t3 ON t2.b=t3.b OR t2.b IS NULL)
    -> ON t1.a=t2.a;
+------+------+------+------+
| a    | a    | b    | b    |
+------+------+------+------+
|    1 |    1 |  101 |  101 |
|    2 | \text{NULL} | \text{NULL} | \text{NULL} |
+------+------+------+------+
```

```
mysql> SELECT *
    -> FROM (t1 LEFT JOIN t2 ON t1.a=t2.a)
    -> LEFT JOIN t3
    -> ON t2.b=t3.b OR t2.b IS NULL;
+------+------+------+------+
| a    | a    | b    | b    |
+------+------+------+------+
|    1 |    1 |  101 |  101 |
|    2 | \text{NULL} | \text{NULL} |  101 |
+------+------+------+------+
```

In the following example, an outer join operation is used together with an inner join operation:

```
t1 LEFT JOIN (t2, t3) ON t1.a=t2.a
```

That expression cannot be transformed into the following expression:

```
t1 LEFT JOIN t2 ON t1.a=t2.a, t3.
```

For the given table states, the two expressions return different sets of rows:

```
mysql> SELECT *
    -> FROM t1 LEFT JOIN (t2, t3) ON t1.a=t2.a;
+------+------+------+------+
| a    | a    | b    | b    |
+------+------+------+------+
|    1 |    1 |  101 |  101 |
|    2 | \text{NULL} | \text{NULL} | \text{NULL} |
+------+------+------+------+
```

```
mysql> SELECT *
    -> FROM t1 LEFT JOIN t2 ON t1.a=t2.a, t3;
+------+------+------+------+
| a    | a    | b    | b    |
+------+------+------+------+
|    1 |    1 |  101 |  101 |
|    2 | \text{NULL} | \text{NULL} |  101 |
+------+------+------+------+
```

Therefore, if we omit parentheses in a join expression with outer join operators, we might change the result set for the original expression.

More exactly, we cannot ignore parentheses in the right operand of the left outer join operation and in the left operand of a right join operation. In other words, we cannot ignore parentheses for the inner table expressions of outer join operations. Parentheses for the other operand (operand for the outer table) can be ignored.

The following expression:
Optimizing SELECT Statements

\[(t_1, t_2) \text{ LEFT JOIN } t_3 \text{ ON } P(t_2.b, t_3.b)\]

is equivalent to this expression:

\[t_1, t_2 \text{ LEFT JOIN } t_3 \text{ ON } P(t_2.b, t_3.b)\]

for any tables \(t_1, t_2, t_3\) and any condition \(P\) over attributes \(t_2.b\) and \(t_3.b\).

Whenever the order of execution of the join operations in a join expression (\(join\_table\)) is not from left to right, we talk about nested joins. Consider the following queries:

\[
\begin{align*}
\text{SELECT} & \ast \text{ FROM } t_1 \text{ LEFT JOIN (} t_2 \text{ LEFT JOIN } t_3 \text{ ON } t_2.b=t_3.b \text{) ON } t_1.a=t_2.a \\
& \text{WHERE } t_1.a > 1
\end{align*}
\]

\[
\begin{align*}
\text{SELECT} & \ast \text{ FROM } t_1 \text{ LEFT JOIN (} t_2, t_3 \text{) ON } t_1.a=t_2.a \\
& \text{WHERE } (t_2.b=t_3.b \text{ OR } t_2.b \text{ IS NULL}) \text{ AND } t_1.a > 1
\end{align*}
\]

Those queries are considered to contain these nested joins:

\[
\begin{align*}
t_2 \text{ LEFT JOIN } t_3 \text{ ON } t_2.b=t_3.b \\
t_2, t_3
\end{align*}
\]

The nested join is formed in the first query with a left join operation, whereas in the second query it is formed with an inner join operation.

In the first query, the parentheses can be omitted: The grammatical structure of the join expression will dictate the same order of execution for join operations. For the second query, the parentheses cannot be omitted, although the join expression here can be interpreted unambiguously without them. (In our extended syntax the parentheses in \((t_2, t_3)\) of the second query are required, although theoretically the query could be parsed without them: We still would have unambiguous syntactical structure for the query because \(\text{LEFT JOIN}\) and \(\text{ON}\) would play the role of the left and right delimiters for the expression \((t_2, t_3)\).)

The preceding examples demonstrate these points:

- For join expressions involving only inner joins (and not outer joins), parentheses can be removed. You can remove parentheses and evaluate left to right (or, in fact, you can evaluate the tables in any order).
- The same is not true, in general, for outer joins or for outer joins mixed with inner joins. Removal of parentheses may change the result.

Queries with nested outer joins are executed in the same pipeline manner as queries with inner joins. More exactly, a variation of the nested-loop join algorithm is exploited. Recall by what algorithmic schema the nested-loop join executes a query. Suppose that we have a join query over 3 tables \(T_1, T_2, T_3\) of the form:

\[
\begin{align*}
\text{SELECT} & \ast \text{ FROM } T_1 \text{ INNER JOIN } T_2 \text{ ON } P(T_1, T_2) \\
& \text{INNER JOIN } T_3 \text{ ON } P(T_2, T_3) \\
& \text{WHERE } P(T_1, T_2, T_3).
\end{align*}
\]

Here, \(P_1(T_1, T_2)\) and \(P_2(T_3, T_3)\) are some join conditions (on expressions), whereas \(P(T_1, T_2, T_3)\) is a condition over columns of tables \(T_1, T_2, T_3\).

The nested-loop join algorithm would execute this query in the following manner:

\[
\begin{align*}
& \text{FOR each row } t_1 \text{ in } T_1 \{ \\
& \quad \text{FOR each row } t_2 \text{ in } T_2 \text{ such that } P_1(t_1, t_2) \{ \\
& \quad \quad \text{FOR each row } t_3 \text{ in } T_3 \text{ such that } P_2(t_2, t_3) \{
\end{align*}
\]
Optimizing SELECT Statements

```
IF P(t1,t2,t3) {
  t:=t1||t2||t3; OUTPUT t;
}
```

The notation \( t_1 || t_2 || t_3 \) means “a row constructed by concatenating the columns of rows \( t_1 \), \( t_2 \), and \( t_3 \).” In some of the following examples, NULL where a row name appears means that NULL is used for each column of that row. For example, \( t_1 || t_2 || \text{NULL} \) means “a row constructed by concatenating the columns of rows \( t_1 \) and \( t_2 \), and NULL for each column of \( t_3 \).”

Now let’s consider a query with nested outer joins:

```
SELECT * FROM T1 LEFT JOIN
  (T2 LEFT JOIN T3 ON P2(T2,T3))
ON P1(T1,T2)
WHERE P(T1,T2,T3).
```

For this query, we modify the nested-loop pattern to get:

```
FOR each row t1 in T1 {
  BOOL f1:=FALSE;
  FOR each row t2 in T2 such that P1(t1,t2) {
    BOOL f2:=FALSE;
    FOR each row t3 in T3 such that P2(t2,t3) {
      IF P(t1,t2,t3) {
        t:=t1||t2||t3; OUTPUT t;
      }
      f2=TRUE;
      f1=TRUE;
    }
    IF (!f2) {
      IF P(t1,t2,NULL) {
        t:=t1||t2||NULL; OUTPUT t;
      }
      f1=TRUE;
    }
  }
  IF (!f1) {
    IF P(t1,NULL,NULL) {
      t:=t1||NULL||NULL; OUTPUT t;
    }
  }
}
```

In general, for any nested loop for the first inner table in an outer join operation, a flag is introduced that is turned off before the loop and is checked after the loop. The flag is turned on when for the current row from the outer table a match from the table representing the inner operand is found. If at the end of the loop cycle the flag is still off, no match has been found for the current row of the outer table. In this case, the row is complemented by NULL values for the columns of the inner tables. The result row is passed to the final check for the output or into the next nested loop, but only if the row satisfies the join condition of all embedded outer joins.

In our example, the outer join table expressed by the following expression is embedded:

```
(T2 LEFT JOIN T3 ON P2(T2,T3))
```

For the query with inner joins, the optimizer could choose a different order of nested loops, such as this one:

```
FOR each row t3 in T3 {
  FOR each row t2 in T2 such that P2(t2,t3) {
    FOR each row t1 in T1 such that P1(t1,t2) {
      ...
    }
  }
}
```
Optimizing SELECT Statements

IF P(t1,t2,t3) {
    t:=t1||t2||t3; OUTPUT t;
}
}

For the queries with outer joins, the optimizer can choose only such an order where loops for outer tables precede loops for inner tables. Thus, for our query with outer joins, only one nesting order is possible. For the following query, the optimizer will evaluate two different nestings:

SELECT * T1 LEFT JOIN (T2,T3) ON P1(T1,T2) AND P2(T1,T3)
WHERE P(T1,T2,T3)

The nestings are these:

FOR each row t1 in T1 {
    BOOL f1:=FALSE;
    FOR each row t2 in T2 such that P1(t1,t2) {
        FOR each row t3 in T3 such that P2(t1,t3) {
            IF P(t1,t2,t3) {
                t:=t1||t2||t3; OUTPUT t;
            }
            f1:=TRUE
        }
        IF (!f1) {
            IF P(t1,NULL,NULL) {
                t:=t1||NULL||NULL; OUTPUT t;
            }
        }
    }
}

and:

FOR each row t1 in T1 {
    BOOL f1:=FALSE;
    FOR each row t3 in T3 such that P2(t1,t3) {
        FOR each row t2 in T2 such that P1(t1,t2) {
            IF P(t1,t2,t3) {
                t:=t1||t2||t3; OUTPUT t;
            }
            f1:=TRUE
        }
        IF (!f1) {
            IF P(t1,NULL,NULL) {
                t:=t1||NULL||NULL; OUTPUT t;
            }
        }
    }
}

In both nestings, T1 must be processed in the outer loop because it is used in an outer join. T2 and T3 are used in an inner join, so that join must be processed in the inner loop. However, because the join is an inner join, T2 and T3 can be processed in either order.

When discussing the nested-loop algorithm for inner joins, we omitted some details whose impact on the performance of query execution may be huge. We did not mention so-called “pushed-down” conditions. Suppose that our WHERE condition P(T1,T2,T3) can be represented by a conjunctive formula:

P(T1,T2,T3) = C1(T1) AND C2(T2) AND C3(T3).

In this case, MySQL actually uses the following nested-loop schema for the execution of the query with inner joins:
FOR each row t1 in T1 such that C1(t1) {
    FOR each row t2 in T2 such that P1(t1,t2) AND C2(t2) {
        FOR each row t3 in T3 such that P2(t2,t3) AND C3(t3) {
            IF P(t1,t2,t3) {
                t:=t1||t2||t3; OUTPUT t;
            }
        }
    }
}

You see that each of the conjuncts \( C_1(T_1), C_2(T_2), C_3(T_3) \) are pushed out of the most inner loop to the most outer loop where it can be evaluated. If \( C_1(T_1) \) is a very restrictive condition, this condition pushdown may greatly reduce the number of rows from table \( T_1 \) passed to the inner loops. As a result, the execution time for the query may improve immensely.

For a query with outer joins, the \textit{WHERE} condition is to be checked only after it has been found that the current row from the outer table has a match in the inner tables. Thus, the optimization of pushing conditions out of the inner nested loops cannot be applied directly to queries with outer joins. Here we have to introduce conditional pushed-down predicates guarded by the flags that are turned on when a match has been encountered.

For our example with outer joins with:

\[
P(T1,T2,T3)=C1(T1) \text{ AND } C(T2) \text{ AND } C3(T3)
\]

the nested-loop schema using guarded pushed-down conditions looks like this:

\[
\text{FOR each row } t1 \text{ in } T1 \text{ such that } C1(t1) \{
    \text{BOOL } f1:=FALSE;
    \text{FOR each row } t2 \text{ in } T2
    \text{ such that } P1(t1,t2) \text{ AND } (f1\&\&C2(t2):TRUE) \{
        \text{BOOL } f2:=FALSE;
        \text{FOR each row } t3 \text{ in } T3
        \text{ such that } P2(t2,t3) \text{ AND } (f1\&\&f2\&\&C3(t3):TRUE) \{
            \text{IF } (f1\&\&f2?TRUE:(C2(t2) \text{ AND } C3(t3))) \{
                t:=t1||t2||t3; OUTPUT t;
            }
        }
    }
    \text{IF } (!f2) {
        \text{IF } (f1?TRUE:C2(t2) \&\& P(t1,t2,NULL)) {
            t:=t1||t2||NULL; OUTPUT t;
        }
    }
    \text{f1=TRUE;}
    \}
\text{IF } (!f1 \&\& P(t1,NULL,NULL)) {
    t:=t1||NULL||NULL; OUTPUT t;
}
\]

In general, pushed-down predicates can be extracted from join conditions such as \( P_1(T_1,T_2) \) and \( P(T_2,T_3) \). In this case, a pushed-down predicate is guarded also by a flag that prevents checking the predicate for the \textit{NULL}-complemented row generated by the corresponding outer join operation.

Access by key from one inner table to another in the same nested join is prohibited if it is induced by a predicate from the \textit{WHERE} condition. (We could use conditional key access in this case, but this technique is not employed yet in MySQL 5.1.)

\section*{8.2.1.10 Outer Join Simplification}

Table expressions in the \textit{FROM} clause of a query are simplified in many cases.
At the parser stage, queries with right outer joins operations are converted to equivalent queries containing only left join operations. In the general case, the conversion is performed according to the following rule:

\[(T_1, \ldots) \text{ RIGHT JOIN } (T_2, \ldots) \text{ ON } P(T_1, \ldots, T_2, \ldots) = (T_2, \ldots) \text{ LEFT JOIN } (T_1, \ldots) \text{ ON } P(T_1, \ldots, T_2, \ldots)\]

All inner join expressions of the form \(T_1 \text{ INNER JOIN } T_2 \text{ ON } P(T_1, T_2)\) are replaced by the list \(T_1, T_2, P(T_1, T_2)\) being joined as a conjunct to the \textsc{where} condition (or to the join condition of the embedding join, if there is any).

When the optimizer evaluates plans for join queries with outer join operation, it takes into consideration only the plans where, for each such operation, the outer tables are accessed before the inner tables. The optimizer options are limited because only such plans enables us to execute queries with outer joins operations by the nested loop schema.

Suppose that we have a query of the form:

\[
\begin{align*}
\text{SELECT } \ast & \ T_1 \text{ LEFT JOIN } T_2 \text{ ON } P_1(T_1, T_2) \\
& \text{WHERE } P(T_1, T_2) \text{ AND } R(T_2)
\end{align*}
\]

with \(R(T_2)\) narrowing greatly the number of matching rows from table \(T_2\). If we executed the query as it is, the optimizer would have no other choice besides to access table \(T_1\) before table \(T_2\) that may lead to a very inefficient execution plan.

Fortunately, MySQL converts such a query into a query without an outer join operation if the \textsc{where} condition is null-rejected. A condition is called null-rejected for an outer join operation if it evaluates to \texttt{FALSE} or to \texttt{UNKNOWN} for any \texttt{NULL}-complemented row built for the operation.

Thus, for this outer join:

\[
T_1 \text{ LEFT JOIN } T_2 \text{ ON } T_1.A = T_2.A
\]

Conditions such as these are null-rejected:

- \(T_2.B \text{ IS NOT NULL,}\)
- \(T_2.B > 3,\)
- \(T_2.C <= T_1.C,\)
- \(T_2.B < 2 \text{ OR } T_2.C > 1\)

Conditions such as these are not null-rejected:

- \(T_2.B \text{ IS NULL,}\)
- \(T_1.B < 3 \text{ OR } T_2.B \text{ IS NOT NULL,}\)
- \(T_1.B < 3 \text{ OR } T_2.B > 3\)

The general rules for checking whether a condition is null-rejected for an outer join operation are simple. A condition is null-rejected in the following cases:

- If it is of the form \(A \text{ IS NOT NULL,}\) where \(A\) is an attribute of any of the inner tables
- If it is a predicate containing a reference to an inner table that evaluates to \texttt{UNKNOWN} when one of its arguments is \texttt{NULL}
- If it is a conjunction containing a null-rejected condition as a conjunct
- If it is a disjunction of null-rejected conditions

A condition can be null-rejected for one outer join operation in a query and not null-rejected for another. In the query:
Optimizing SELECT Statements

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
    LEFT JOIN T3 ON T3.B=T1.B
WHERE T3.C > 0
```

the **WHERE** condition is null-rejected for the second outer join operation but is not null-rejected for the first one.

If the **WHERE** condition is null-rejected for an outer join operation in a query, the outer join operation is replaced by an inner join operation.

For example, the preceding query is replaced with the query:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
    INNER JOIN T3 ON T3.B=T1.B
WHERE T3.C > 0
```

For the original query, the optimizer would evaluate plans compatible with only one access order \( T1, T2, T3 \). For the replacing query, it additionally considers the access sequence \( T3, T1, T2 \).

A conversion of one outer join operation may trigger a conversion of another. Thus, the query:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
    LEFT JOIN T3 ON T3.B=T2.B
WHERE T3.C > 0
```

will be first converted to the query:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
    INNER JOIN T3 ON T3.B=T2.B
WHERE T3.C > 0
```

which is equivalent to the query:

```
SELECT * FROM (T1 LEFT JOIN T2 ON T2.A=T1.A), T3
WHERE T3.C > 0 AND T3.B=T2.B
```

Now the remaining outer join operation can be replaced by an inner join, too, because the condition \( T3.B=T2.B \) is null-rejected and we get a query without outer joins at all:

```
SELECT * FROM (T1 INNER JOIN T2 ON T2.A=T1.A), T3
WHERE T3.C > 0 AND T3.B=T2.B
```

Sometimes we succeed in replacing an embedded outer join operation, but cannot convert the embedding outer join. The following query:

```
SELECT * FROM T1 LEFT JOIN
    (T2 LEFT JOIN T3 ON T3.B=T2.B)
ON T2.A=T1.A
WHERE T3.C > 0
```

is converted to:

```
SELECT * FROM T1 LEFT JOIN
    (T2 INNER JOIN T3 ON T3.B=T2.B)
ON T2.A=T1.A
WHERE T3.C > 0,
```

That can be rewritten only to the form still containing the embedding outer join operation:
### Optimizing SELECT Statements

**When trying to convert an embedded outer join operation in a query, we must take into account the join condition for the embedding outer join together with the `WHERE` condition.**

In the query:

```sql
```

the `WHERE` condition is not null-rejected for the embedded outer join, but the join condition of the embedding outer join `T2.A=T1.A AND T3.C=T1.C` is null-rejected. So the query can be converted to:

```sql
```

### 8.2.1.11 ORDER BY Optimization

In some cases, MySQL can use an index to satisfy an `ORDER BY` clause without doing extra sorting.

The index can also be used even if the `ORDER BY` does not match the index exactly, as long as all unused portions of the index and all extra `ORDER BY` columns are constants in the `WHERE` clause. The following queries use the index to resolve the `ORDER BY` part:

```sql
SELECT * FROM t1
ORDER BY key_part1, key_part2, ... ;
```

```sql
SELECT * FROM t1
WHERE key_part1 = constant
ORDER BY key_part2;
```

```sql
SELECT * FROM t1
ORDER BY key_part1 DESC, key_part2 DESC;
```

```sql
SELECT * FROM t1
WHERE key_part1 = 1
ORDER BY key_part1 DESC, key_part2 DESC;
```

```sql
SELECT * FROM t1
WHERE key_part1 > constant
ORDER BY key_part1 ASC;
```

```sql
SELECT * FROM t1
WHERE key_part1 < constant
ORDER BY key_part1 DESC;
```

```sql
SELECT * FROM t1
WHERE key_part1 = constant1 AND key_part2 > constant2
ORDER BY key_part2;
```

In some cases, MySQL cannot use indexes to resolve the `ORDER BY`, although it still uses indexes to find the rows that match the `WHERE` clause. These cases include the following:

- **The query uses `ORDER BY` on different indexes:**
  ```sql
  SELECT * FROM t1 ORDER BY key1, key2;
  ```

- **The query uses `ORDER BY` on nonconsecutive parts of an index:**
  ```sql
  SELECT * FROM t1 WHERE key_part1 ORDER BY key_part1 DESC;
  ```
Optimizing SELECT Statements

SELECT * FROM t1 WHERE key2=constant ORDER BY key_part2;

- The query mixes **ASC** and **DESC**:

SELECT * FROM t1 ORDER BY key_part1 DESC, key_part2 ASC;

- The index used to fetch the rows differs from the one used in the **ORDER BY**:

SELECT * FROM t1 WHERE key2=constant ORDER BY key1;

- The query uses **ORDER BY** with an expression that includes terms other than the index column name:

SELECT * FROM t1 ORDER BY ABS(key);
SELECT * FROM t1 ORDER BY -key;

- The query joins many tables, and the columns in the **ORDER BY** are not all from the first nonconstant table that is used to retrieve rows. (This is the first table in the **EXPLAIN** output that does not have a **const** join type.)

- The query has different **ORDER BY** and **GROUP BY** expressions.

- There is an index on only a prefix of a column named in the **ORDER BY** clause. In this case, the index cannot be used to fully resolve the sort order. For example, if only the first 10 bytes of a **CHAR(20)** column are indexed, the index cannot distinguish values past the 10th byte and a **filesort** will be needed.

- The index does not store rows in order. For example, this is true for a **HASH** index in a **MEMORY** table.

Availability of an index for sorting may be affected by the use of column aliases. Suppose that the column **t1.a** is indexed. In this statement, the name of the column in the select list is **a**. It refers to **t1.a**, so for the reference to **a** in the **ORDER BY**, the index can be used:

SELECT a FROM t1 ORDER BY a;

In this statement, the name of the column in the select list is also **a**, but it is the alias name. It refers to **ABS(a)**, so for the reference to **a** in the **ORDER BY**, the index cannot be used:

SELECT ABS(a) AS a FROM t1 ORDER BY a;

In the following statement, the **ORDER BY** refers to a name that is not the name of a column in the select list. But there is a column in **t1** named **a**, so the **ORDER BY** uses that and the index can be used. (The resulting sort order may be completely different from the order for **ABS(a)**, of course.)

SELECT ABS(a) AS b FROM t1 ORDER BY a;

By default, MySQL sorts all **GROUP BY col1, col2, ...** queries as if you specified **ORDER BY col1, col2, ...** in the query as well. If you include an explicit **ORDER BY** clause that contains the same column list, MySQL optimizes it away without any speed penalty, although the sorting still occurs.

If a query includes **GROUP BY** but you want to avoid the overhead of sorting the result, you can suppress sorting by specifying **ORDER BY NULL**. For example:

```
INSERT INTO foo
SELECT a, COUNT(*) FROM bar GROUP BY a ORDER BY NULL;
```
Optimizing SELECT Statements

The optimizer may still choose to use sorting to implement grouping operations. ORDER BY NULL suppresses sorting of the result, not prior sorting done by grouping operations to determine the result.

With EXPLAIN SELECT ... ORDER BY, you can check whether MySQL can use indexes to resolve the query. It cannot if you see Using filesort in the Extra column. See Section 8.8.1, “Optimizing Queries with EXPLAIN”. Filesort uses a fixed-length row-storage format similar to that used by the MEMORY storage engine. Variable-length types such as VARCHAR are stored using a fixed length.

MySQL has two filesort algorithms for sorting and retrieving results. The original method uses only the ORDER BY columns. The modified method uses not just the ORDER BY columns, but all the columns referenced by the query.

The optimizer selects which filesort algorithm to use. It normally uses the modified algorithm except when BLOB or TEXT columns are involved, in which case it uses the original algorithm. For both algorithms, the sort buffer size is the sort_buffer_size system variable value.

The original filesort algorithm works as follows:

1. Read all rows according to key or by table scanning. Skip rows that do not match the WHERE clause.
2. For each row, store in the sort buffer a tuple consisting of a pair of values (the sort key value and the row ID).
3. If all pairs fit into the sort buffer, no temporary file is created. Otherwise, when the sort buffer becomes full, run a qsort (quicksort) on it in memory and write it to a temporary file. Save a pointer to the sorted block.
4. Repeat the preceding steps until all rows have been read.
5. Do a multi-merge of up to MERGEBUFF (7) regions to one block in another temporary file. Repeat until all blocks from the first file are in the second file.
6. Repeat the following until there are fewer than MERGEBUFF2 (15) blocks left.
7. On the last multi-merge, only the row ID (the last part of the value pair) is written to a result file.
8. Read the rows in sorted order using the row IDs in the result file. To optimize this, read in a large block of row IDs, sort them, and use them to read the rows in sorted order into a row buffer. The row buffer size is the read_rnd_buffer_size system variable value. The code for this step is in the sql/records.cc source file.

One problem with this approach is that it reads rows twice: One time during WHERE clause evaluation, and again after sorting the value pairs. And even if the rows were accessed successively the first time (for example, if a table scan is done), the second time they are accessed randomly. (The sort keys are ordered, but the row positions are not.)

The modified filesort algorithm incorporates an optimization to avoid reading the rows twice: It records the sort key value, but instead of the row ID, it records the columns referenced by the query. The modified filesort algorithm works like this:

1. Read the rows that match the WHERE clause.
2. For each row, store in the sort buffer a tuple consisting of the sort key value and the columns referenced by the query.
3. When the sort buffer becomes full, sort the tuples by sort key value in memory and write it to a temporary file.
4. After merge-sorting the temporary file, retrieve the rows in sorted order, but read the columns required by the query directly from the sorted tuples rather than by accessing the table a second time.
The tuples used by the modified `filesort` algorithm are longer than the pairs used by the original algorithm, and fewer of them fit in the sort buffer. As a result, it is possible for the extra I/O to make the modified approach slower, not faster. To avoid a slowdown, the optimizer uses the modified algorithm only if the total size of the extra columns in the sort tuple does not exceed the value of the `max_length_for_sort_data` system variable. (A symptom of setting the value of this variable too high is a combination of high disk activity and low CPU activity.)

If a `filesort` is done, `EXPLAIN` output includes `Using filesort` in the `Extra` column.

Suppose that a table `t1` has four `VARCHAR` columns `a`, `b`, `c`, and `d` and that the optimizer uses `filesort` for this query:

```
SELECT * FROM t1 ORDER BY a, b;
```

The query sorts by `a` and `b`, but returns all columns, so the columns referenced by the query are `a`, `b`, `c`, and `d`. Depending on which `filesort` algorithm the optimizer chooses, the query executes as follows:

For the original algorithm, sort buffer tuples have these contents:

```
(fixed size a value, fixed size b value, row ID into t1)
```

The optimizer sorts on the fixed size values. After sorting, the optimizer reads the tuples in order and uses the row ID in each tuple to read rows from `t1` to obtain the select list column values.

For the modified algorithm, sort buffer tuples have these contents:

```
(fixed size a value, fixed size b value, a value, b value, c value, d value)
```

The optimizer sorts on the fixed size values. After sorting, the optimizer reads the tuples in order and uses the values for `a`, `b`, `c`, and `d` to obtain the select list column values without reading `t1` again.

For slow queries for which `filesort` is not used, try lowering `max_length_for_sort_data` to a value that is appropriate to trigger a `filesort`.

To increase `ORDER BY` speed, check whether you can get MySQL to use indexes rather than an extra sorting phase. If this is not possible, you can try the following strategies:

- Increase the `sort_buffer_size` variable value.
- Increase the `read_rnd_buffer_size` variable value.
- Use less RAM per row by declaring columns only as large as they need to be to hold the values stored in them. For example, `CHAR(16)` is better than `CHAR(200)` if values never exceed 16 characters.
- Change the `tmpdir` system variable to point to a dedicated file system with large amounts of free space. The variable value can list several paths that are used in round-robin fashion; you can use this feature to spread the load across several directories. Paths should be separated by colon characters (";") on Unix and semicolon characters (";") on Windows, NetWare, and OS/2. The paths should name directories in file systems located on different physical disks, not different partitions on the same disk.

### 8.2.1.12 GROUP BY Optimization

The most general way to satisfy a `GROUP BY` clause is to scan the whole table and create a new temporary table where all rows from each group are consecutive, and then use this temporary table.
to discover groups and apply aggregate functions (if any). In some cases, MySQL is able to do much better than that and to avoid creation of temporary tables by using index access.

The most important preconditions for using indexes for GROUP BY are that all GROUP BY columns reference attributes from the same index, and that the index stores its keys in order (for example, this is a BTREE index and not a HASH index). Whether use of temporary tables can be replaced by index access also depends on which parts of an index are used in a query, the conditions specified for these parts, and the selected aggregate functions.

There are two ways to execute a GROUP BY query through index access, as detailed in the following sections. In the first method, the grouping operation is applied together with all range predicates (if any). The second method first performs a range scan, and then groups the resulting tuples.

In MySQL, GROUP BY is used for sorting, so the server may also apply ORDER BY optimizations to grouping. See Section 8.2.1.11, "ORDER BY Optimization".

Loose Index Scan

The most efficient way to process GROUP BY is when an index is used to directly retrieve the grouping columns. With this access method, MySQL uses the property of some index types that the keys are ordered (for example, BTREE). This property enables use of lookup groups in an index without having to consider all keys in the index that satisfy all WHERE conditions. This access method considers only a fraction of the keys in an index, so it is called a loose index scan. When there is no WHERE clause, a loose index scan reads as many keys as the number of groups, which may be a much smaller number than that of all keys. If the WHERE clause contains range predicates (see the discussion of the range join type in Section 8.8.1, “Optimizing Queries with EXPLAIN”), a loose index scan looks up the first key of each group that satisfies the range conditions, and again reads the least possible number of keys. This is possible under the following conditions:

- The query is over a single table.
- The GROUP BY names only columns that form a leftmost prefix of the index and no other columns. (If, instead of GROUP BY, the query has a DISTINCT clause, all distinct attributes refer to columns that form a leftmost prefix of the index.) For example, if a table t1 has an index on (c1,c2,c3), loose index scan is applicable if the query has GROUP BY c1, c2,. It is not applicable if the query has GROUP BY c2, c3 (the columns are not a leftmost prefix) or GROUP BY c1, c2, c4 (c4 is not in the index).
- The only aggregate functions used in the select list (if any) are MIN() and MAX(), and all of them refer to the same column. The column must be in the index and must immediately follow the columns in the GROUP BY.
- Any other parts of the index than those from the GROUP BY referenced in the query must be constants (that is, they must be referenced in equalities with constants), except for the argument of MIN() or MAX() functions.
- For columns in the index, full column values must be indexed, not just a prefix. For example, with c1 VARCHAR(20), INDEX (c1(10)), the index cannot be used for loose index scan.

If loose index scan is applicable to a query, the EXPLAIN output shows Using index for group-by in the Extra column.

Assume that there is an index idx(c1,c2,c3) on table t1(c1,c2,c3,c4). The loose index scan access method can be used for the following queries:

```
SELECT c1, c2 FROM t1 GROUP BY c1, c2;
SELECT DISTINCT c1, c2 FROM t1;
SELECT c1, MIN(c2) FROM t1 GROUP BY c1;
SELECT c1, c2 FROM t1 WHERE c1 < const GROUP BY c1, c2;
SELECT MAX(c3), MIN(c3), c1, c2 FROM t1 WHERE c2 > const GROUP BY c1, c2;
SELECT c2 FROM t1 WHERE c1 < const GROUP BY c1, c2;
```
SELECT c1, c2 FROM t1 WHERE c3 = const GROUP BY c1, c2;

The following queries cannot be executed with this quick select method, for the reasons given:

- There are aggregate functions other than `MIN()` or `MAX()`:

  SELECT c1, SUM(c2) FROM t1 GROUP BY c1;

- The columns in the `GROUP BY` clause do not form a leftmost prefix of the index:

  SELECT c1, c2 FROM t1 GROUP BY c2, c3;

- The query refers to a part of a key that comes after the `GROUP BY` part, and for which there is no equality with a constant:

  SELECT c1, c3 FROM t1 GROUP BY c1, c2;

  Were the query to include `WHERE c3 = const`, loose index scan could be used.

**Tight Index Scan**

A tight index scan may be either a full index scan or a range index scan, depending on the query conditions.

When the conditions for a loose index scan are not met, it still may be possible to avoid creation of temporary tables for `GROUP BY` queries. If there are range conditions in the `WHERE` clause, this method reads only the keys that satisfy these conditions. Otherwise, it performs an index scan. Because this method reads all keys in each range defined by the `WHERE` clause, or scans the whole index if there are no range conditions, we term it a *tight index scan*. With a tight index scan, the grouping operation is performed only after all keys that satisfy the range conditions have been found.

For this method to work, it is sufficient that there is a constant equality condition for all columns in a query referring to parts of the key coming before or in between parts of the `GROUP BY` key. The constants from the equality conditions fill in any “gaps” in the search keys so that it is possible to form complete prefixes of the index. These index prefixes then can be used for index lookups. If we require sorting of the `GROUP BY` result, and it is possible to form search keys that are prefixes of the index, MySQL also avoids extra sorting operations because searching with prefixes in an ordered index already retrieves all the keys in order.

Assume that there is an index `idx(c1,c2,c3)` on table `t1(c1,c2,c3,c4)`. The following queries do not work with the loose index scan access method described earlier, but still work with the tight index scan access method.

- There is a gap in the `GROUP BY`, but it is covered by the condition `c2 = 'a'`:

  SELECT c1, c2, c3 FROM t1 WHERE c2 = 'a' GROUP BY c1, c3;

- The `GROUP BY` does not begin with the first part of the key, but there is a condition that provides a constant for that part:

  SELECT c1, c2, c3 FROM t1 WHERE c1 = 'a' GROUP BY c2, c3;

**8.2.1.13 DISTINCT Optimization**

`DISTINCT` combined with `ORDER BY` needs a temporary table in many cases.

Because `DISTINCT` may use `GROUP BY`, learn how MySQL works with columns in `ORDER BY` or `HAVING` clauses that are not part of the selected columns. See Section 12.17.3, “MySQL Handling of `GROUP BY`.”
In most cases, a `DISTINCT` clause can be considered as a special case of `GROUP BY`. For example, the following two queries are equivalent:

```sql
SELECT DISTINCT c1, c2, c3 FROM t1
WHERE c1 > const;

SELECT c1, c2, c3 FROM t1
WHERE c1 > const GROUP BY c1, c2, c3;
```

Due to this equivalence, the optimizations applicable to `GROUP BY` queries can be also applied to queries with a `DISTINCT` clause. Thus, for more details on the optimization possibilities for `DISTINCT` queries, see Section 8.2.1.12, “GROUP BY Optimization”.

When combining `LIMIT row_count` with `DISTINCT`, MySQL stops as soon as it finds `row_count` unique rows.

If you do not use columns from all tables named in a query, MySQL stops scanning any unused tables as soon as it finds the first match. In the following case, assuming that `t1` is used before `t2` (which you can check with `EXPLAIN`), MySQL stops reading from `t2` (for any particular row in `t1`) when it finds the first row in `t2`:

```sql
SELECT DISTINCT t1.a FROM t1, t2 where t1.a=t2.a;
```

### 8.2.1.14 Optimizing Subqueries with EXISTS Strategy

Certain optimizations are applicable to comparisons that use the `IN` operator to test subquery results (or that use `=ANY`, which is equivalent). This section discusses these optimizations, particularly with regard to the challenges that `NULL` values present. The last part of the discussion includes suggestions on what you can do to help the optimizer.

Consider the following subquery comparison:

```
outer_expr IN (SELECT inner_expr FROM ... WHERE subquery_where)
```

MySQL evaluates queries “from outside to inside.” That is, it first obtains the value of the outer expression `outer_expr`, and then runs the subquery and captures the rows that it produces.

A very useful optimization is to “inform” the subquery that the only rows of interest are those where the inner expression `inner_expr` is equal to `outer_expr`. This is done by pushing down an appropriate equality into the subquery’s `WHERE` clause. That is, the comparison is converted to this:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where AND outer_expr=inner_expr)
```

After the conversion, MySQL can use the pushed-down equality to limit the number of rows that it must examine when evaluating the subquery.

More generally, a comparison of `N` values to a subquery that returns `N`-value rows is subject to the same conversion. If `oe_i` and `ie_i` represent corresponding outer and inner expression values, this subquery comparison:

```
(oe_1, ..., oe_N) IN
  (SELECT ie_1, ..., ie_N FROM ... WHERE subquery_where)
```

Becomes:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where
       AND oe_1 = ie_1
       AND ...)
```
The following discussion assumes a single pair of outer and inner expression values for simplicity. The conversion just described has its limitations. It is valid only if we ignore possible NULL values. That is, the “pushdown” strategy works as long as both of these two conditions are true:

- `outer_expr` and `inner_expr` cannot be NULL.
- You do not need to distinguish NULL from FALSE subquery results. (If the subquery is a part of an OR or AND expression in the WHERE clause, MySQL assumes that you do not care.)

When either or both of those conditions do not hold, optimization is more complex.

Suppose that `outer_expr` is known to be a non-NULL value but the subquery does not produce a row such that `outer_expr = inner_expr`. Then `outer_expr IN (SELECT ...)` evaluates as follows:

- NULL, if the SELECT produces any row where `inner_expr` is NULL
- FALSE, if the SELECT produces only non-NULL values or produces nothing

In this situation, the approach of looking for rows with `outer_expr = inner_expr` is no longer valid. It is necessary to look for such rows, but if none are found, also look for rows where `inner_expr` is NULL. Roughly speaking, the subquery can be converted to:

```sql
EXISTS (SELECT 1 FROM ... WHERE subquery_where AND
         (outer_expr = inner_expr OR inner_expr IS NULL))
```

The need to evaluate the extra IS NULL condition is why MySQL has the `ref_or_null` access method:

```sql
mysql> EXPLAIN
    -> SELECT outer_expr IN (SELECT t2.maybe_null_key
    -> FROM t2, t3 WHERE ...)
    -> FROM t1;
```

```plaintext
<table>
<thead>
<tr>
<th>id</th>
<th>select_type: PRIMARY</th>
<th>table: t1</th>
<th>...</th>
</tr>
</thead>
</table>
```

```sql
mysql> EXPLAIN EXTENDED
    --> SELECT outer_expr IN (SELECT maybe_null_key FROM t2) FROM t1\G
```

```plaintext
<table>
<thead>
<tr>
<th>id</th>
<th>select_type: PRIMARY</th>
<th>table: t1</th>
<th>...</th>
</tr>
</thead>
</table>
```

The `unique_subquery` and `index_subquery` subquery-specific access methods also have “or NULL” variants. However, they are not visible in EXPLAIN output, so you must use EXPLAIN EXTENDED followed by SHOW WARNINGS (note the checking NULL in the warning message):

```sql
mysql> EXPLAIN EXTENDED
    --> SELECT outer_expr IN (SELECT maybe_null_key FROM t2) FROM t1\G
```

```plaintext
<table>
<thead>
<tr>
<th>id</th>
<th>select_type: PRIMARY</th>
<th>table: t1</th>
<th>...</th>
</tr>
</thead>
</table>
The additional `OR ... IS NULL` condition makes query execution slightly more complicated (and some optimizations within the subquery become inapplicable), but generally this is tolerable.

The situation is much worse when `outer_expr` can be `NULL`. According to the SQL interpretation of `NULL` as “unknown value,” `NULL IN (SELECT inner_expr ...)` should evaluate to:

- **NULL**, if the `SELECT` produces any rows
- **FALSE**, if the `SELECT` produces no rows

For proper evaluation, it is necessary to be able to check whether the `SELECT` has produced any rows at all, so `outer_expr = inner_expr` cannot be pushed down into the subquery. This is a problem, because many real world subqueries become very slow unless the equality can be pushed down.

Essentially, there must be different ways to execute the subquery depending on the value of `outer_expr`. In MySQL 5.1 before 5.1.16, the optimizer chose speed over distinguishing a `NULL` from `FALSE` result, so for some queries, you might get a `FALSE` result rather than `NULL`.

As of MySQL 5.1.16, the optimizer chooses SQL compliance over speed, so it accounts for the possibility that `outer_expr` might be `NULL`.

If `outer_expr` is `NULL`, to evaluate the following expression, it is necessary to run the `SELECT` to determine whether it produces any rows:

```sql
NULL IN (SELECT inner_expr FROM ... WHERE subquery_where)
```

It is necessary to run the original `SELECT` here, without any pushed-down equalities of the kind mentioned earlier.

On the other hand, when `outer_expr` is not `NULL`, it is absolutely essential that this comparison:

```sql
outer_expr IN (SELECT inner_expr FROM ... WHERE subquery_where)
```

be converted to this expression that uses a pushed-down condition:

```sql
EXISTS (SELECT 1 FROM ... WHERE subquery_where AND outer_expr=inner_expr)
```

Without this conversion, subqueries will be slow. To solve the dilemma of whether to push down or not push down conditions into the subquery, the conditions are wrapped in “trigger” functions. Thus, an expression of the following form:
Optimizing SELECT Statements

```sql
outer_expr IN (SELECT inner_expr FROM ... WHERE subquery_where)
```

is converted into:

```sql
EXISTS (SELECT 1 FROM ... WHERE subquery_where AND trigcond(outer_expr=inner_expr))
```

More generally, if the subquery comparison is based on several pairs of outer and inner expressions, the conversion takes this comparison:

```sql
(oe_1, ..., oe_N) IN (SELECT ie_1, ..., ie_N FROM ... WHERE subquery_where)
```

and converts it to this expression:

```sql
EXISTS (SELECT 1 FROM ... WHERE subquery_where AND trigcond(oe_1=ie_1)
       AND ...
       AND trigcond(oe_N=ie_N)
)
```

Each `trigcond(X)` is a special function that evaluates to the following values:

- **X** when the “linked” outer expression `oe_i` is not **NULL**
- **TRUE** when the “linked” outer expression `oe_i` is **NULL**

**Note**

Trigger functions are not triggers of the kind that you create with `CREATE TRIGGER`.

Equalities that are wrapped into `trigcond()` functions are not first class predicates for the query optimizer. Most optimizations cannot deal with predicates that may be turned on and off at query execution time, so they assume any `trigcond(X)` to be an unknown function and ignore it. At the moment, triggered equalities can be used by those optimizations:

- **Reference optimizations:** `trigcond(X=Y [OR Y IS NULL])` can be used to construct `ref`, `eq_ref`, or `ref_or_null` table accesses.
- **Index lookup-based subquery execution engines:** `trigcond(X=Y)` can be used to construct `unique_subquery` or `index_subquery` accesses.
- **Table-condition generator:** If the subquery is a join of several tables, the triggered condition will be checked as soon as possible.

When the optimizer uses a triggered condition to create some kind of index lookup-based access (as for the first two items of the preceding list), it must have a fallback strategy for the case when the condition is turned off. This fallback strategy is always the same: Do a full table scan. In `EXPLAIN` output, the fallback shows up as **Full scan on NULL key** in the **Extra** column:

```sql
mysql> EXPLAIN SELECT t1.col1,
->    -> t1.col1 IN (SELECT t2.key1 FROM t2 WHERE t2.col2=t1.col2) FROM t1
G
```

```
Parent table: t1
Subquery table: t2
Full scan on NULL key in the Extra column:
```

```sql
id: 2
select_type: DEPENDENT SUBQUERY
```
If you run `EXPLAIN EXTENDED` followed by `SHOW WARNINGS`, you can see the triggered condition:

```
*************************** 1. row ***************************
Level: Note
Code: 1003
Message: select `test`.`t1`.`col1` AS `col1`,
<in_optimizer>(`test`.`t1`.`col1`,
<exists>(<index_lookup>({<cache>(`test`.`t1`.`col1`) in t2
on key1 checking NULL
where ('test'.'t2'.'col2' = 'test'.'t1'.'col2') having
trigcond(<is_not_null_test>(`test'.'t2'.'key1'))) AS
't1.col1 IN (select t2.key1 from t2 where t2.col2=t1.col2)'
from `test'.'t1`
```

The use of triggered conditions has some performance implications. A `NULL IN (SELECT ...)` expression now may cause a full table scan (which is slow) when it previously did not. This is the price paid for correct results (the goal of the trigger-condition strategy was to improve compliance and not speed).

For multiple-table subqueries, execution of `NULL IN (SELECT ...)` will be particularly slow because the join optimizer does not optimize for the case where the outer expression is `NULL`. It assumes that subquery evaluations with `NULL` on the left side are very rare, even if there are statistics that indicate otherwise. On the other hand, if the outer expression might be `NULL` but never actually is, there is no performance penalty.

To help the query optimizer better execute your queries, use these tips:

- Declare a column as `NOT NULL` if it really is. (This also helps other aspects of the optimizer by simplifying condition testing for the column.)

- If you do not need to distinguish a `NULL` from `FALSE` subquery result, you can easily avoid the slow execution path. Replace a comparison that looks like this:

```
outer_expr IN (SELECT inner_expr FROM ...)
```

with this expression:

```
(outer_expr IS NOT NULL) AND (outer_expr IN (SELECT inner_expr FROM ...))
```

Then `NULL IN (SELECT ...) will never be evaluated because MySQL stops evaluating AND parts as soon as the expression result is clear.

### 8.2.1.15 LIMIT Query Optimization

In some cases, MySQL handles a query differently when you are using `LIMIT row_count` and not using `HAVING`:

- If you select only a few rows with `LIMIT`, MySQL uses indexes in some cases when normally it would prefer to do a full table scan.

- If you combine `LIMIT row_count` with `ORDER BY`, MySQL ends the sorting as soon as it has found the first `row_count` rows of the sorted result, rather than sorting the entire result. If ordering is done by using an index, this is very fast. If a filesort must be done, all rows that match the query without the `LIMIT` clause must be selected, and most or all of them must be sorted, before it can be
ascertained that the first \texttt{row\_count} rows have been found. In either case, after the initial rows have been found, there is no need to sort any remainder of the result set, and MySQL does not do so.

- If you combine \texttt{LIMIT row\_count} with \texttt{DISTINCT}, MySQL stops as soon as it finds \texttt{row\_count} unique rows.

- In some cases, a \texttt{GROUP BY} can be resolved by reading the index in order (or doing a sort on the index) and then calculating summaries until the index value changes. In this case, \texttt{LIMIT row\_count} does not calculate any unnecessary \texttt{GROUP BY} values.

- As soon as MySQL has sent the required number of rows to the client, it aborts the query unless you are using \texttt{SQL\_CALC\_FOUND\_ROWS}. The number of rows can then be retrieved with \texttt{SELECT FOUND\_ROWS()}. See Section 12.14, “Information Functions”.

- \texttt{LIMIT 0} quickly returns an empty set. This can be useful for checking the validity of a query. It can also be employed to obtain the types of the result columns if you are using a MySQL API that makes result set metadata available. With the \texttt{mysql} client program, you can use the \texttt{--column-type-info} option to display result column types.

- If the server uses temporary tables to resolve the query, it uses the \texttt{LIMIT row\_count} clause to calculate how much space is required.

### 8.2.1.16 Row Constructor Expression Optimization

Row constructors permit simultaneous comparisons of multiple values. For example, these two statements are semantically equivalent:

```sql
SELECT * FROM t1 WHERE (column1,column2) = (1,1);
SELECT * FROM t1 WHERE column1 = 1 AND column2 = 1;
```

In addition, the optimizer handles both expressions the same way.

The optimizer is less likely to use available indexes if the row constructor columns do not cover the prefix of an index. Consider the following table, which has a primary key on \texttt{(c1, c2, c3)}:

```sql
CREATE TABLE t1 (
    c1 INT, c2 INT, c3 INT, c4 CHAR(100),
    PRIMARY KEY(c1,c2,c3)
);
```

In this query, the \texttt{WHERE} clause uses all columns in the index. However, the row constructor itself does not cover an index prefix, with the result that the optimizer uses only \texttt{c1} (\texttt{key\_len}=4, the size of \texttt{c1}):

```sql
mysql> EXPLAIN SELECT * FROM t1
    -> WHERE c1=1 AND (c2,c3) > (1,1)
```

```plaintext
id: 1
select_type: SIMPLE
table: t1
partitions: NULL
type: ref
possible_keys: PRIMARY
key: PRIMARY
key_len: 4
ref: const
rows: 3
Extra: Using where
```

In such cases, rewriting the row constructor expression using an equivalent nonconstructor expression may result in more complete index use. For the given query, the row constructor and equivalent nonconstructor expressions are:
Rewriting the query to use the nonconstructor expression results in the optimizer using all three columns in the index (key_len=12):

MySQL> EXPLAIN SELECT * FROM t1
    -> WHERE c1 = 1 AND (c2 > 1 OR ((c2 = 1) AND (c3 > 1)))

Thus, for better results, avoid mixing row constructors with AND/OR expressions. Use one or the other.

### 8.2.1.17 How to Avoid Full Table Scans

The output from `EXPLAIN` shows **ALL** in the `type` column when MySQL uses a table scan to resolve a query. This usually happens under the following conditions:

- The table is so small that it is faster to perform a table scan than to bother with a key lookup. This is common for tables with fewer than 10 rows and a short row length.

- There are no usable restrictions in the ON or WHERE clause for indexed columns.

- You are comparing indexed columns with constant values and MySQL has calculated (based on the index tree) that the constants cover too large a part of the table and that a table scan would be faster. See Section 8.2.1.2, “How MySQL Optimizes WHERE Clauses”.

- You are using a key with low cardinality (many rows match the key value) through another column. In this case, MySQL assumes that by using the key it probably will do many key lookups and that a table scan would be faster.

For small tables, a table scan often is appropriate and the performance impact is negligible. For large tables, try the following techniques to avoid having the optimizer incorrectly choose a table scan:

- Use `ANALYZE TABLE tbl_name` to update the key distributions for the scanned table. See Section 13.7.2.1, “ANALYZE TABLE Syntax”.

- Use `FORCE INDEX` for the scanned table to tell MySQL that table scans are very expensive compared to using the given index:

  ```sql
  SELECT * FROM t1, t2 FORCE INDEX (index_for_column)
  WHERE t1.col_name=t2.col_name;
  ```

  See Section 8.9.3, “Index Hints”.

- Start `mysql`d with the `--max-seeks-for-key=1000` option or use `SET max_seeks_for_key=1000` to tell the optimizer to assume that no key scan causes more than 1,000 key seeks. See Section 5.1.4, “Server System Variables”.

### 8.2.2 Optimizing Data Change Statements

This section explains how to speed up data change statements: **INSERT**, **UPDATE**, and **DELETE**. Traditional OLTP applications and modern web applications typically do many small data change
operations, where concurrency is vital. Data analysis and reporting applications typically run data change operations that affect many rows at once, where the main considerations is the I/O to write large amounts of data and keep indexes up-to-date. For inserting and updating large volumes of data (known in the industry as ETL, for “extract-transform-load”), sometimes you use other SQL statements or external commands, that mimic the effects of \texttt{INSERT}, \texttt{UPDATE}, and \texttt{DELETE} statements.

\subsection*{8.2.2.1 Speed of INSERT Statements}

To optimize insert speed, combine many small operations into a single large operation. Ideally, you make a single connection, send the data for many new rows at once, and delay all index updates and consistency checking until the very end.

The time required for inserting a row is determined by the following factors, where the numbers indicate approximate proportions:

• Connecting: (3)
• Sending query to server: (2)
• Parsing query: (2)
• Inserting row: \(1 \times \text{size of row}\)
• Inserting indexes: \(1 \times \text{number of indexes}\)
• Closing: (1)

This does not take into consideration the initial overhead to open tables, which is done once for each concurrently running query.

The size of the table slows down the insertion of indexes by \(\log N\), assuming B-tree indexes.

You can use the following methods to speed up inserts:

• If you are inserting many rows from the same client at the same time, use \texttt{INSERT} statements with multiple \texttt{VALUES} lists to insert several rows at a time. This is considerably faster (many times faster in some cases) than using separate single-row \texttt{INSERT} statements. If you are adding data to a nonempty table, you can tune the \texttt{bulk_insert_buffer_size} variable to make data insertion even faster. See Section 5.1.4, “Server System Variables”.

• When loading a table from a text file, use \texttt{LOAD DATA INFILE}. This is usually 20 times faster than using \texttt{INSERT} statements. See Section 13.2.6, “LOAD DATA INFILE Syntax”.

• Take advantage of the fact that columns have default values. Insert values explicitly only when the value to be inserted differs from the default. This reduces the parsing that MySQL must do and improves the insert speed.

• See Section 8.5.2, “Bulk Data Loading for MyISAM Tables” for tips specific to MyISAM tables.

\subsection*{8.2.2.2 Speed of UPDATE Statements}

An update statement is optimized like a \texttt{SELECT} query with the additional overhead of a write. The speed of the write depends on the amount of data being updated and the number of indexes that are updated. Indexes that are not changed do not get updated.

Another way to get fast updates is to delay updates and then do many updates in a row later. Performing multiple updates together is much quicker than doing one at a time if you lock the table.

For a MyISAM table that uses dynamic row format, updating a row to a longer total length may split the row. If you do this often, it is very important to use \texttt{OPTIMIZE TABLE} occasionally. See Section 13.7.2.5, “OPTIMIZE TABLE Syntax”.
8.2.2.3 Speed of DELETE Statements

The time required to delete individual rows is exactly proportional to the number of indexes. To delete rows more quickly, you can increase the size of the key cache by increasing the `key_buffer_size` system variable. See Section 8.12.2, “Tuning Server Parameters”.

To delete all rows from a table, `TRUNCATE TABLE tbl_name` is faster than `DELETE FROM tbl_name`. Truncate operations are not transaction-safe; an error occurs when attempting one in the course of an active transaction or active table lock. See Section 13.1.34, “TRUNCATE TABLE Syntax”.

8.2.3 Optimizing Database Privileges

The more complex your privilege setup, the more overhead applies to all SQL statements. Simplifying the privileges established by `GRANT` statements enables MySQL to reduce permission-checking overhead when clients execute statements. For example, if you do not grant any table-level or column-level privileges, the server need not ever check the contents of the `tables_priv` and `columns_priv` tables. Similarly, if you place no resource limits on any accounts, the server does not have to perform resource counting. If you have a very high statement-processing load, consider using a simplified grant structure to reduce permission-checking overhead.

8.2.4 INFORMATION_SCHEMA Optimization

As of MySQL 5.1.21, the implementation of `INFORMATION_SCHEMA` is such that certain types of queries for `INFORMATION_SCHEMA` tables can be optimized to execute more quickly. This section provides guidelines on writing queries that take advantage of these optimizations. In general, the strategies outlined here minimize the need for the server to access the file system to obtain the information that makes up the contents of `INFORMATION_SCHEMA` tables. By writing queries that enable the server to avoid directory scans or opening table files, you will obtain better performance. These optimizations do have an effect on how collations are used for searches in `INFORMATION_SCHEMA` tables. For more information, see Section 10.1.7.9, “Collation and INFORMATION_SCHEMA Searches”.

1) Try to use constant lookup values for database and table names in the `WHERE` clause

You can take advantage of this principle as follows:

- To look up databases or tables, use expressions that evaluate to a constant, such as literal values, functions that return a constant, or scalar subqueries.

- Avoid queries that use a nonconstant database name lookup value (or no lookup value) because they require a scan of the data directory to find matching database directory names.

- Within a database, avoid queries that use a nonconstant table name lookup value (or no lookup value) because they require a scan of the database directory to find matching table files.

This principle applies to the `INFORMATION_SCHEMA` tables shown in the following table, which shows the columns for which a constant lookup value enables the server to avoid a directory scan. For example, if you are selecting from `TABLES`, using a constant lookup value for `TABLE_SCHEMA` in the `WHERE` clause enables a data directory scan to be avoided.

<table>
<thead>
<tr>
<th>Table</th>
<th>Column to specify to avoid data directory scan</th>
<th>Column to specify to avoid database directory scan</th>
</tr>
</thead>
<tbody>
<tr>
<td>COLUMNS</td>
<td>TABLE_SCHEMA</td>
<td>TABLE_NAME</td>
</tr>
<tr>
<td>KEY_COLUMN_USAGE</td>
<td>TABLE_SCHEMA</td>
<td>TABLE_NAME</td>
</tr>
<tr>
<td>PARTITIONS</td>
<td>TABLE_SCHEMA</td>
<td>TABLE_NAME</td>
</tr>
<tr>
<td>REFERENTIAL_CONSTRAINTS</td>
<td>CONSTRAINT_SCHEMA</td>
<td>TABLE_NAME</td>
</tr>
</tbody>
</table>
The benefit of a query that is limited to a specific constant database name is that checks need be made only for the named database directory. Example:

```sql
SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'test';
```

Use of the literal database name `test` enables the server to check only the `test` database directory, regardless of how many databases there might be. By contrast, the following query is less efficient because it requires a scan of the data directory to determine which database names match the pattern 'test%':

```sql
SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA LIKE 'test%';
```

For a query that is limited to a specific constant table name, checks need be made only for the named table within the corresponding database directory. Example:

```sql
SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME = 't1';
```

Use of the literal table name `t1` enables the server to check only the files for the `t1` table, regardless of how many tables there might be in the `test` database. By contrast, the following query requires a scan of the `test` database directory to determine which table names match the pattern 't%':

```sql
SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME LIKE 't%';
```

The following query requires a scan of the database directory to determine matching database names for the pattern 'test%', and for each matching database, it requires a scan of the database directory to determine matching table names for the pattern 't%':

```sql
SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME LIKE 't%';
```

### 2) Write queries that minimize the number of table files that must be opened

For queries that refer to certain `INFORMATION_SCHEMA` table columns, several optimizations are available that minimize the number of table files that must be opened. Example:

```sql
SELECT TABLE_NAME, ENGINE FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'test';
```

In this case, after the server has scanned the database directory to determine the names of the tables in the database, those names become available with no further file system lookups. Thus, `TABLE_NAME` requires no files to be opened. The `ENGINE` (storage engine) value can be determined by opening the table's `.frm` file, without touching other table files such as the `.MYD` or `.MYI` file.

Some values, such as `INDEX_LENGTH` for `MyISAM` tables, require opening the `.MYD` or `.MYI` file as well.

The file-opening optimization types are denoted thus:
• **SKIP_OPEN_TABLE**: Table files do not need to be opened. The information has already become available within the query by scanning the database directory.

• **OPEN_FRM_ONLY**: Only the table’s `.frm` file need be opened.

• **OPEN_TRIGGER_ONLY**: Only the table’s `.TRG` file need be opened.

• **OPEN_FULL_TABLE**: The unoptimized information lookup. The `.frm`, `.MYD`, and `.MYI` files must be opened.

The following list indicates how the preceding optimization types apply to `INFORMATION_SCHEMA` table columns. For tables and columns not named, none of the optimizations apply.

• **COLUMNS**: **OPEN_FRM_ONLY** applies to all columns

• **KEY_COLUMN_USAGE**: **OPEN_FULL_TABLE** applies to all columns

• **PARTITIONS**: **OPEN_FULL_TABLE** applies to all columns

• **REFERENTIAL_CONSTRAINTS**: **OPEN_FULL_TABLE** applies to all columns

• **STATISTICS**:

<table>
<thead>
<tr>

</tbody>
</table>

3) Use **EXPLAIN** to determine whether the server can use **INFORMATION_SCHEMA** optimizations for a query

This applies particularly for **INFORMATION_SCHEMA** queries that search for information from more than one database, which might take a long time and impact performance. The **Extra** value in **EXPLAIN** output indicates which, if any, of the optimizations described earlier the server can use to evaluate **INFORMATION_SCHEMA** queries. The following examples demonstrate the kinds of information you can expect to see in the **Extra** value.

```
mysql> EXPLAIN SELECT TABLE_NAME FROM INFORMATION_SCHEMA.VIEWS WHERE table_schema = 'test' AND TABLE_NAME = 'v1'
ERROR 1146 (01000): Table 'test.v1' doesn't exist
```
Use of constant database and table lookup values enables the server to avoid directory scans. For references to `VIEWS.TABLE_NAME`, only the `.frm` file need be opened.

```sql
mysql> EXPLAIN SELECT TABLE_NAME, ROW_FORMAT FROM INFORMATION_SCHEMA.TABLES
```
```
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: TABLES
type: ALL
possible_keys: NULL
key: NULL
key_len: NULL
ref: NULL
rows: NULL
Extra: Open_full_table; Scanned all databases
```

No lookup values are provided (there is no `WHERE` clause), so the server must scan the data directory and each database directory. For each table thus identified, the table name and row format are selected. `TABLE_NAME` requires no further table files to be opened (the `SKIP_OPEN_TABLE` optimization applies). `ROW_FORMAT` requires all table files to be opened (`OPEN_FULL_TABLE` applies). `EXPLAIN` reports `OPEN_FULL_TABLE` because it is more expensive than `SKIP_OPEN_TABLE`.

```sql
mysql> EXPLAIN SELECT TABLE_NAME, TABLE_TYPE FROM INFORMATION_SCHEMA.TABLES
```
```
 *************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: TABLES
type: ALL
possible_keys: NULL
key: TABLE_SCHEMA
key_len: NULL
ref: NULL
rows: NULL
Extra: Using where; Open_frm_only; Scanned 1 database
```

No table name lookup value is provided, so the server must scan the `test` database directory. For the `TABLE_NAME` and `TABLE_TYPE` columns, the `SKIP_OPEN_TABLE` and `OPEN_FRM_ONLY` optimizations apply, respectively. `EXPLAIN` reports `OPEN_FRM_ONLY` because it is more expensive.

```sql
mysql> EXPLAIN SELECT B.TABLE_NAME
```
```
  FROM INFORMATION_SCHEMA.TABLES AS A, INFORMATION_SCHEMA.COLUMNS AS B
WHERE A.TABLE_SCHEMA = 'test'
AND A.TABLE_NAME = 't1'
AND B.TABLE_NAME = A.TABLE_NAME
```
```
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: A
type: ALL
possible_keys: NULL
key: TABLE_SCHEMA,TABLE_NAME
key_len: NULL
ref: NULL
rows: NULL
Extra: Using where; Skip_open_table; Scanned 0 databases
```

No lookup values are provided, so the server must scan each table file in the `test` database. For the `TABLE_NAME` column, the `OPEN_FRM_ONLY` optimization applies. `EXPLAIN` reports `OPEN_FRM_ONLY` because it is more expensive.
Extra: Using where; Open_frm_only; Scanned all databases; Using join buffer

For the first `EXPLAIN` output row: Constant database and table lookup values enable the server to avoid directory scans for `TABLES` values. References to `TABLES.TABLE_NAME` require no further table files.

For the second `EXPLAIN` output row: All `COLUMNS` table values are `OPEN_FRM_ONLY` lookups, so `COLUMNS.TABLE_NAME` requires the `.frm` file to be opened.

```sql
mysql> EXPLAIN SELECT * FROM INFORMATION_SCHEMA.COLLATIONS
+-------------------+-------+-------------------+-------------------+-------+-------+-------------------+
| id                | select_type | table             | type              | possible_keys | key | ref | rows | Extra |
+-------------------+-------+-------------------+-------------------+-------+-------+-------------------+
| 1                 | SIMPLE    | COLLATIONS        | ALL               | NULL          | NULL | NULL | NULL |      |
```  

In this case, no optimizations apply because `COLLATIONS` is not one of the `INFORMATION_SCHEMA` tables for which optimizations are available.

### 8.2.5 Other Optimization Tips

This section lists a number of miscellaneous tips for improving query processing speed:

- If your application makes several database requests to perform related updates, combining the statements into a stored routine can help performance. Similarly, if your application computes a single result based on several column values or large volumes of data, combining the computation into a UDF (user-defined function) can help performance. The resulting fast database operations are then available to be reused by other queries, applications, and even code written in different programming languages. See Section 19.2, “Using Stored Routines (Procedures and Functions)” and Section 22.3, “Adding New Functions to MySQL” for more information.

- To fix any compression issues that occur with `ARCHIVE` tables, use `OPTIMIZE TABLE`. See Section 14.12, “The ARCHIVE Storage Engine”.

- If possible, classify reports as “live” or as “statistical”, where data needed for statistical reports is created only from summary tables that are generated periodically from the live data.

- If you have data that does not conform well to a rows-and-columns table structure, you can pack and store data into a `BLOB` column. In this case, you must provide code in your application to pack and unpack information, but this might save I/O operations to read and write the sets of related values.

- With Web servers, store images and other binary assets as files, with the path name stored in the database rather than the file itself. Most Web servers are better at caching files than database contents, so using files is generally faster. (Although you must handle backups and storage issues yourself in this case.)

- If you need really high speed, look at the low-level MySQL interfaces. For example, by accessing the MySQL `InnoDB` or `MyISAM` storage engine directly, you could get a substantial speed increase compared to using the SQL interface.

- Replication can provide a performance benefit for some operations. You can distribute client retrievals among replication servers to split up the load. To avoid slowing down the master while making backups, you can make backups using a slave server. See Chapter 16, Replication.

### 8.3 Optimization and Indexes
The best way to improve the performance of `SELECT` operations is to create indexes on one or more of the columns that are tested in the query. The index entries act like pointers to the table rows, allowing the query to quickly determine which rows match a condition in the `WHERE` clause, and retrieve the other column values for those rows. All MySQL data types can be indexed.

Although it can be tempting to create indexes for every possible column used in a query, unnecessary indexes waste space and waste time for MySQL to determine which indexes to use. Indexes also add to the cost of inserts, updates, and deletes because each index must be updated. You must find the right balance to achieve fast queries using the optimal set of indexes.

### 8.3.1 How MySQL Uses Indexes

Indexes are used to find rows with specific column values quickly. Without an index, MySQL must begin with the first row and then read through the entire table to find the relevant rows. The larger the table, the more this costs. If the table has an index for the columns in question, MySQL can quickly determine the position to seek to in the middle of the data file without having to look at all the data. This is much faster than reading every row sequentially.

Most MySQL indexes (`PRIMARY KEY`, `UNIQUE`, `INDEX`, and `FULLTEXT`) are stored in B-trees. Exceptions are that indexes on spatial data types use R-trees, and that `MEMORY` tables also support hash indexes.

Strings are automatically prefix- and end-space compressed. See Section 13.1.13, “CREATE INDEX Syntax”.

In general, indexes are used as described in the following discussion. Characteristics specific to hash indexes (as used in `MEMORY` tables) are described in Section 8.3.8, “Comparison of B-Tree and Hash Indexes”.

MySQL uses indexes for these operations:

- To find the rows matching a `WHERE` clause quickly.
- To eliminate rows from consideration. If there is a choice between multiple indexes, MySQL normally uses the index that finds the smallest number of rows.
- If the table has a multiple-column index, any leftmost prefix of the index can be used by the optimizer to look up rows. For example, if you have a three-column index on `(col1, col2, col3)`, you have indexed search capabilities on `(col1)`, `(col1, col2)`, and `(col1, col2, col3)`. For more information, see Section 8.3.5, “Multiple-Column Indexes”.
- To retrieve rows from other tables when performing joins. MySQL can use indexes on columns more efficiently if they are declared as the same type and size. In this context, `VARCHAR` and `CHAR` are considered the same if they are declared as the same size. For example, `VARCHAR(10)` and `CHAR(10)` are the same size, but `VARCHAR(10)` and `CHAR(15)` are not.

For comparisons between nonbinary string columns, both columns should use the same character set. For example, comparing a `utf8` column with a `latin1` column precludes use of an index.

Comparison of dissimilar columns (comparing a string column to a temporal or numeric column, for example) may prevent use of indexes if values cannot be compared directly without conversion. For a given value such as `1` in the numeric column, it might compare equal to any number of values in the string column such as `'1'`, `'1'`, `'00001'`, or `'01.e1'`. This rules out use of any indexes for the string column.

- To find the `MIN()` or `MAX()` value for a specific indexed column `key_col`. This is optimized by a preprocessor that checks whether you are using `WHERE key_part_N = constant` on all key parts that occur before `key_col` in the index. In this case, MySQL does a single key lookup for each `MIN()` or `MAX()` expression and replaces it with a constant. If all expressions are replaced with constants, the query returns at once. For example:
### 8.3.2 Using Primary Keys

The primary key for a table represents the column or set of columns that you use in your most vital queries. It has an associated index, for fast query performance. Query performance benefits from the **NOT NULL** optimization, because it cannot include any **NULL** values. With the **InnoDB** storage engine, the table data is physically organized to do ultra-fast lookups and sorts based on the primary key column or columns.

If your table is big and important, but does not have an obvious column or set of columns to use as a primary key, you might create a separate column with auto-increment values to use as the primary key. These unique IDs can serve as pointers to corresponding rows in other tables when you join tables using foreign keys.

### 8.3.3 Using Foreign Keys

If a table has many columns, and you query many different combinations of columns, it might be efficient to split the less-frequently used data into separate tables with a few columns each, and relate them back to the main table by duplicating the numeric ID column from the main table. That way, each small table can have a primary key for fast lookups of its data, and you can query just the set of columns that you need using a join operation. Depending on how the data is distributed, the queries might perform less I/O and take up less cache memory because the relevant columns are packed together on disk. (To maximize performance, queries try to read as few data blocks as possible from disk; tables with only a few columns can fit more rows in each data block.)

### 8.3.4 Column Indexes

All MySQL data types can be indexed. Use of indexes on the relevant columns is the best way to improve the performance of **SELECT** operations.

The maximum number of indexes per table and the maximum index length is defined per storage engine. See Chapter 14, **Storage Engines**. All storage engines support at least 16 indexes per table and a total index length of at least 256 bytes. Most storage engines have higher limits.

For additional information about column indexes, see Section 13.1.13, “CREATE INDEX Syntax”.

---

**Prefix Indexes**

- To sort or group a table if the sorting or grouping is done on a leftmost prefix of a usable index (for example, **ORDER BY key_part1, key_part2**). If all key parts are followed by **DESC**, the key is read in reverse order. See Section 8.2.1.11, “**ORDER BY Optimization**”, and Section 8.2.1.12, “**GROUP BY Optimization**”.

- In some cases, a query can be optimized to retrieve values without consulting the data rows. If a query uses from a table only columns that are included in some index, the selected values can be be retrieved from the index tree for greater speed:
Multiple-Column Indexes

With \texttt{col\_name}(N) syntax in an index specification for a string column, you can create an index that uses only the first \(N\) characters of the column. Indexing only a prefix of column values in this way can make the index file much smaller. When you index a \texttt{BLOB} or \texttt{TEXT} column, you \textit{must} specify a prefix length for the index. For example:

```sql
CREATE TABLE test (blob_col BLOB, INDEX(blob_col(10)));
```

Prefixes can be up to 1000 bytes long (767 bytes for \textit{InnoDB} tables).

\begin{itemize}
\item \textbf{Note}
  Prefix limits are measured in bytes, whereas the prefix length in \texttt{CREATE TABLE}, \texttt{ALTER TABLE}, and \texttt{CREATE INDEX} statements is interpreted as number of characters for nonbinary string types (\texttt{CHAR}, \texttt{VARCHAR}, \texttt{TEXT}) and number of bytes for binary string types (\texttt{BINARY}, \texttt{VARBINARY}, \texttt{BLOB}). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.
\end{itemize}

For additional information about index prefixes, see Section 13.1.13, "CREATE INDEX Syntax".

\textbf{FULLTEXT Indexes}

\texttt{FULLTEXT} indexes are used for full-text searches. Only the \texttt{MyISAM} storage engine supports \texttt{FULLTEXT} indexes and only for \texttt{CHAR}, \texttt{VARCHAR}, and \texttt{TEXT} columns. Indexing always takes place over the entire column and column prefix indexing is not supported. For details, see Section 12.9, "Full-Text Search Functions".

\textbf{Spatial Indexes}

You can create indexes on spatial data types. Only \texttt{MyISAM} supports R-tree indexes on spatial types. Other storage engines use B-trees for indexing spatial types (except for \texttt{ARCHIVE} and \texttt{NDB}, which do not support spatial type indexing).

\textbf{Indexes in the MEMORY Storage Engine}

The \texttt{MEMORY} storage engine uses \texttt{HASH} indexes by default, but also supports \texttt{BTREE} indexes.

\textbf{8.3.5 Multiple-Column Indexes}

MySQL can create composite indexes (that is, indexes on multiple columns). An index may consist of up to 16 columns. For certain data types, you can index a prefix of the column (see Section 8.3.4, “Column Indexes”).

MySQL can use multiple-column indexes for queries that test all the columns in the index, or queries that test just the first column, the first two columns, the first three columns, and so on. If you specify the columns in the right order in the index definition, a single composite index can speed up several kinds of queries on the same table.

A multiple-column index can be considered a sorted array, the rows of which contain values that are created by concatenating the values of the indexed columns.

\begin{itemize}
\item \textbf{Note}
  As an alternative to a composite index, you can introduce a column that is "hashed" based on information from other columns. If this column is short, reasonably unique, and indexed, it might be faster than a "wide" index on many columns. In MySQL, it is very easy to use this extra column:
\end{itemize}
SELECT * FROM `tbl_name` WHERE `hash_col` = MD5(CONCAT(`val1`, `val2`)) AND `col1` = `val1` AND `col2` = `val2`;

Suppose that a table has the following specification:

```sql
CREATE TABLE test (  
id INT NOT NULL,  
last_name CHAR(30) NOT NULL,  
first_name CHAR(30) NOT NULL,  
PRIMARY KEY (id),  
INDEX name (last_name,first_name)
);
```

The name index is an index over the last_name and first_name columns. The index can be used for lookups in queries that specify values in a known range for combinations of last_name and first_name values. It can also be used for queries that specify just a last_name value because that column is a leftmost prefix of the index (as described later in this section). Therefore, the name index is used for lookups in the following queries:

```sql
SELECT * FROM test WHERE last_name='Widenius';
SELECT * FROM test WHERE last_name='Widenius' AND first_name='Michael';
SELECT * FROM test WHERE last_name='Widenius' AND (first_name='Michael' OR first_name='Monty');
SELECT * FROM test WHERE last_name='Widenius' AND first_name >='M' AND first_name < 'N';
```

However, the name index is not used for lookups in the following queries:

```sql
SELECT * FROM test WHERE first_name='Michael';
SELECT * FROM test WHERE last_name='Widenius' OR first_name='Michael';
```

Suppose that you issue the following SELECT statement:

```sql
SELECT * FROM `tbl_name` WHERE `col1` = `val1` AND `col2` = `val2`;
```

If a multiple-column index exists on col1 and col2, the appropriate rows can be fetched directly. If separate single-column indexes exist on col1 and col2, the optimizer attempts to use the Index Merge optimization (see Section 8.2.1.4, "Index Merge Optimization"), or attempts to find the most restrictive index by deciding which index excludes more rows and using that index to fetch the rows.

If the table has a multiple-column index, any leftmost prefix of the index can be used by the optimizer to look up rows. For example, if you have a three-column index on (col1, col2, col3), you have indexed search capabilities on (col1), (col1, col2), and (col1, col2, col3).

MySQL cannot use the index to perform lookups if the columns do not form a leftmost prefix of the index. Suppose that you have the SELECT statements shown here:

```sql
SELECT * FROM `tbl_table` WHERE `col1` = `val1`;
SELECT * FROM `tbl_table` WHERE `col1` = `val1` AND `col2` = `val2`;
SELECT * FROM `tbl_table` WHERE `col2` = `val2`;
SELECT * FROM `tbl_table` WHERE `col2` = `val2` AND `col3` = `val3`;
```
If an index exists on \((col1, col2, col3)\), only the first two queries use the index. The third and fourth queries do involve indexed columns, but \((col2)\) and \((col2, col3)\) are not leftmost prefixes of \((col1, col2, col3)\).

### 8.3.6 Verifying Index Usage

Always check whether all your queries really use the indexes that you have created in the tables. Use the `EXPLAIN` statement, as described in Section 8.8.1, “Optimizing Queries with EXPLAIN”.

### 8.3.7 InnoDB and MyISAM Index Statistics Collection

Storage engines collect statistics about tables for use by the optimizer. Table statistics are based on value groups, where a value group is a set of rows with the same key prefix value. For optimizer purposes, an important statistic is the average value group size.

MySQL uses the average value group size in the following ways:

- To estimate how many rows must be read for each ref access
- To estimate how many row a partial join will produce; that is, the number of rows that an operation of this form will produce:

\[ (...) \text{JOIN tbl_name ON tbl_name.key = expr} \]

As the average value group size for an index increases, the index is less useful for those two purposes because the average number of rows per lookup increases: For the index to be good for optimization purposes, it is best that each index value target a small number of rows in the table. When a given index value yields a large number of rows, the index is less useful and MySQL is less likely to use it.

The average value group size is related to table cardinality, which is the number of value groups. The `SHOW INDEX` statement displays a cardinality value based on \(N/S\), where \(N\) is the number of rows in the table and \(S\) is the average value group size. That ratio yields an approximate number of value groups in the table.

For a join based on the \(<=\) comparison operator, NULL is not treated differently from any other value: \(NULL <= NULL\), just as \(N <= N\) for any other \(N\).

However, for a join based on the \(=\) operator, NULL is different from non-NULL values: \(expr1 = expr2\) is not true when \(expr1\) or \(expr2\) (or both) are NULL. This affects ref accesses for comparisons of the form \(tbl_name.key = expr\): MySQL will not access the table if the current value of \(expr\) is NULL, because the comparison cannot be true.

For = comparisons, it does not matter how many NULL values are in the table. For optimization purposes, the relevant value is the average size of the non-NULL value groups. However, MySQL does not currently enable that average size to be collected or used.

For InnoDB and MyISAM tables, you have some control over collection of table statistics by means of the `innodb_stats_method` and `myisam_stats_method` system variables, respectively. These variables have three possible values, which differ as follows:

- When the variable is set to `nulls_equal`, all NULL values are treated as identical (that is, they all form a single value group).

  If the NULL value group size is much higher than the average non-NULL value group size, this method skews the average value group size upward. This makes index appear to the optimizer to be less useful than it really is for joins that look for non-NULL values. Consequently, the `nulls_equal` method may cause the optimizer not to use the index for ref accesses when it should.

- When the variable is set to `nulls_unequal`, NULL values are not considered the same. Instead, each NULL value forms a separate value group of size 1.
If you have many NULL values, this method skews the average value group size downward. If the average non-NULL value group size is large, counting NULL values each as a group of size 1 causes the optimizer to overestimate the value of the index for joins that look for non-NULL values. Consequently, the nulls_unequal method may cause the optimizer to use this index for ref lookups when other methods may be better.

- When the variable is set to nulls_ignored, NULL values are ignored.
- If you tend to use many joins that use <=> rather than =, NULL values are not special in comparisons and one NULL is equal to another. In this case, nulls_equal is the appropriate statistics method.

The innodb_stats_method system variable has a global value; the myisam_stats_method system variable has both global and session values. Setting the global value affects statistics collection for tables from the corresponding storage engine. Setting the session value affects statistics collection only for the current client connection. This means that you can force a table’s statistics to be regenerated with a given method without affecting other clients by setting the session value of myisam_stats_method.

To regenerate MyISAM table statistics, you can use any of the following methods:

- Execute myisamchk --stats_method=method_name --analyze
- Change the table to cause its statistics to go out of date (for example, insert a row and then delete it), and then set myisam_stats_method and issue an ANALYZE TABLE statement

Some caveats regarding the use of innodb_stats_method and myisam_stats_method:

- You can force table statistics to be collected explicitly, as just described. However, MySQL may also collect statistics automatically. For example, if during the course of executing statements for a table, some of those statements modify the table, MySQL may collect statistics. (This may occur for bulk inserts or deletes, or some ALTER TABLE statements, for example.) If this happens, the statistics are collected using whatever value innodb_stats_method or myisam_stats_method has at the time. Thus, if you collect statistics using one method, but the system variable is set to the other method when a table’s statistics are collected automatically later, the other method will be used.
- There is no way to tell which method was used to generate statistics for a given table.
- These variables apply only to InnoDB and MyISAM tables. Other storage engines have only one method for collecting table statistics. Usually it is closer to the nulls_equal method.

### 8.3.8 Comparison of B-Tree and Hash Indexes

Understanding the B-tree and hash data structures can help predict how different queries perform on different storage engines that use these data structures in their indexes, particularly for the MEMORY storage engine that lets you choose B-tree or hash indexes.

#### B-Tree Index Characteristics

A B-tree index can be used for column comparisons in expressions that use the =, >, >=, <, <=, or BETWEEN operators. The index also can be used for LIKE comparisons if the argument to LIKE is a constant string that does not start with a wildcard character. For example, the following SELECT statements use indexes:

```sql
SELECT * FROM tbl_name WHERE key_col LIKE 'Patrick%';
SELECT * FROM tbl_name WHERE key_col LIKE 'Pat%_ck%';
```

In the first statement, only rows with 'Patrick' <= key_col < 'Patrick' are considered. In the second statement, only rows with 'Pat' <= key_col < 'Pau' are considered.

The following SELECT statements do not use indexes:
Comparison of B-Tree and Hash Indexes

SELECT * FROM tbl_name WHERE key_col LIKE '%Patrick%';
SELECT * FROM tbl_name WHERE key_col LIKE other_col;

In the first statement, the `LIKE` value begins with a wildcard character. In the second statement, the `LIKE` value is not a constant.

If you use `... LIKE '%string%'` and `string` is longer than three characters, MySQL uses the Turbo Boyer-Moore algorithm to initialize the pattern for the string and then uses this pattern to perform the search more quickly.

A search using `col_name IS NULL` employs indexes if `col_name` is indexed.

Any index that does not span all `AND` levels in the `WHERE` clause is not used to optimize the query. In other words, to be able to use an index, a prefix of the index must be used in every `AND` group.

The following `WHERE` clauses use indexes:

```
... WHERE index_part1=1 AND index_part2=2 AND other_column=3
   /* index = 1 OR index = 2 */
   ... WHERE index=1 OR A=10 AND index=2
   /* optimized like "index_part1='hello'" */
   ... WHERE index_part1='hello' AND index_part3=5
   /* Can use index on index1 but not on index2 or index3 */
   ... WHERE index1=1 AND index2=2 OR index1=3 AND index3=3;
```

These `WHERE` clauses do not use indexes:

```
   /* index_part1 is not used */
   ... WHERE index_part2=1 AND index_part3=2
   /* Index is not used in both parts of the WHERE clause */
   ... WHERE index=1 OR A=10
   /* No index spans all rows */
   ... WHERE index_part1=1 OR index_part2=10
```

Sometimes MySQL does not use an index, even if one is available. One circumstance under which this occurs is when the optimizer estimates that using the index would require MySQL to access a very large percentage of the rows in the table. (In this case, a table scan is likely to be much faster because it requires fewer seeks.) However, if such a query uses `LIMIT` to retrieve only some of the rows, MySQL uses an index anyway, because it can much more quickly find the few rows to return in the result.

Hash Index Characteristics

Hash indexes have somewhat different characteristics from those just discussed:

- They are used only for equality comparisons that use the `=` or `<>` operators (but are very fast). They are not used for comparison operators such as `<` that find a range of values. Systems that rely on this type of single-value lookup are known as “key-value stores”; to use MySQL for such applications, use hash indexes wherever possible.
- The optimizer cannot use a hash index to speed up `ORDER BY` operations. (This type of index cannot be used to search for the next entry in order.)
- MySQL cannot determine approximately how many rows there are between two values (this is used by the range optimizer to decide which index to use). This may affect some queries if you change a `MyISAM` or `InnoDB` table to a hash-indexed `MEMORY` table.
8.4 Optimizing Database Structure

In your role as a database designer, look for the most efficient way to organize your schemas, tables, and columns. As when tuning application code, you minimize I/O, keep related items together, and plan ahead so that performance stays high as the data volume increases. Starting with an efficient database design makes it easier for team members to write high-performing application code, and makes the database likely to endure as applications evolve and are rewritten.

8.4.1 Optimizing Data Size

Design your tables to minimize their space on the disk. This can result in huge improvements by reducing the amount of data written to and read from disk. Smaller tables normally require less main memory while their contents are being actively processed during query execution. Any space reduction for table data also results in smaller indexes that can be processed faster.

MySQL supports many different storage engines (table types) and row formats. For each table, you can decide which storage and indexing method to use. Choosing the proper table format for your application can give you a big performance gain. See Chapter 14, Storage Engines.

You can get better performance for a table and minimize storage space by using the techniques listed here:

**Table Columns**

- Use the most efficient (smallest) data types possible. MySQL has many specialized types that save disk space and memory. For example, use the smaller integer types if possible to get smaller tables. **MEDIUMINT** is often a better choice than **INT** because a **MEDIUMINT** column uses 25% less space.
- Declare columns to be **NOT NULL** if possible. It makes SQL operations faster, by enabling better use of indexes and eliminating overhead for testing whether each value is **NULL**. You also save some storage space, one bit per column. If you really need **NULL** values in your tables, use them. Just avoid the default setting that allows **NULL** values in every column.

**Row Format**

- For **MyISAM** tables, if you do not have any variable-length columns (**VARCHAR**, **TEXT**, or **BLOB** columns), a fixed-size row format is used. This is faster but may waste some space. See Section 14.5.3, “MyISAM Table Storage Formats”. You can hint that you want to have fixed length rows even if you have **VARCHAR** columns with the **CREATE TABLE** option **ROW_FORMAT=FIXED**.
- **InnoDB** tables use a compact storage format. By default, tables are created in the compact format (**ROW_FORMAT=COMPACT**). If you wish to downgrade to older versions of MySQL, you can request the old format with **ROW_FORMAT=REDUNDANT**.

The presence of the compact row format decreases row storage space by about 20% at the cost of increasing CPU use for some operations. If your workload is a typical one that is limited by cache hit rates and disk speed it is likely to be faster. If it is a rare case that is limited by CPU speed, it might be slower.

The compact **InnoDB** format also changes how **CHAR** columns containing UTF-8 data are stored. With **ROW_FORMAT=REDUNDANT**, a UTF-8 **CHAR(N)** occupies $3 \times N$ bytes, given that the maximum length of a UTF-8 encoded character is three bytes. Many languages can be written primarily using single-byte UTF-8 characters, so a fixed storage length often wastes space. With **ROW_FORMAT=COMPACT** format, **InnoDB** allocates a variable amount of storage in the range from $N$ to $3 \times N$ bytes for these columns by stripping trailing spaces if necessary. The minimum storage length is kept as $N$ bytes to facilitate in-place updates in typical cases.
Indexes

- The primary index of a table should be as short as possible. This makes identification of each row easy and efficient.

- Create only the indexes that you need to improve query performance. Indexes are good for retrieval, but slow down insert and update operations. If you access a table mostly by searching on a combination of columns, create a single composite index on them rather than a separate index for each column. The first part of the index should be the column most used. If you always use many columns when selecting from the table, the first column in the index should be the one with the most duplicates, to obtain better compression of the index.

- If it is very likely that a string column has a unique prefix on the first number of characters, it is better to index only this prefix, using MySQL's support for creating an index on the leftmost part of the column (see Section 13.1.13, “CREATE INDEX Syntax”). Shorter indexes are faster, not only because they require less disk space, but because they also give you more hits in the index cache, and thus fewer disk seeks. See Section 8.12.2, “Tuning Server Parameters”.

Joins

- In some circumstances, it can be beneficial to split into two a table that is scanned very often. This is especially true if it is a dynamic-format table and it is possible to use a smaller static format table that can be used to find the relevant rows when scanning the table.

- Declare columns with identical information in different tables with identical data types, to speed up joins based on the corresponding columns.

- Keep column names simple, so that you can use the same name across different tables and simplify join queries. For example, in a table named `customer`, use a column name of `name` instead of `customer_name`. To make your names portable to other SQL servers, consider keeping them shorter than 18 characters.

Normalization

- Normally, try to keep all data nonredundant (observing what is referred to in database theory as third normal form). Instead of repeating lengthy values such as names and addresses, assign them unique IDs, repeat these IDs as needed across multiple smaller tables, and join the tables in queries by referencing the IDs in the join clause.

- If speed is more important than disk space and the maintenance costs of keeping multiple copies of data, for example in a business intelligence scenario where you analyze all the data from large tables, you can relax the normalization rules, duplicating information or creating summary tables to gain more speed.

8.4.2 Optimizing MySQL Data Types

8.4.2.1 Optimizing for Numeric Data

- For unique IDs or other values that can be represented as either strings or numbers, prefer numeric columns to string columns. Since large numeric values can be stored in fewer bytes than the corresponding strings, it is faster and takes less memory to transfer and compare them.

- If you are using numeric data, it is faster in many cases to access information from a database (using a live connection) than to access a text file. Information in the database is likely to be stored in a more compact format than in the text file, so accessing it involves fewer disk accesses. You also save code in your application because you can avoid parsing the text file to find line and column boundaries.

8.4.2.2 Optimizing for Character and String Types

For character and string columns, follow these guidelines:
• Use binary collation order for fast comparison and sort operations, when you do not need language-specific collation features. You can use the BINARY operator to use binary collation within a particular query.

• When comparing values from different columns, declare those columns with the same character set and collation wherever possible, to avoid string conversions while running the query.

• For column values less than 8KB in size, use binary VARCHAR instead of BLOB. The GROUP BY and ORDER BY clauses can generate temporary tables, and these temporary tables can use the MEMORY storage engine if the original table does not contain any BLOB columns.

• If a table contains string columns such as name and address, but many queries do not retrieve those columns, consider splitting the string columns into a separate table and using join queries with a foreign key when necessary. When MySQL retrieves any value from a row, it reads a data block containing all the columns of that row (and possibly other adjacent rows). Keeping each row small, with only the most frequently used columns, allows more rows to fit in each data block. Such compact tables reduce disk I/O and memory usage for common queries.

• When you use a randomly generated value as a primary key in an InnoDB table, prefix it with an ascending value such as the current date and time if possible. When consecutive primary values are physically stored near each other, InnoDB can insert and retrieve them faster.

• See Section 8.4.2.1, “Optimizing for Numeric Data” for reasons why a numeric column is usually preferable to an equivalent string column.

8.4.2.3 Optimizing for BLOB Types

• When storing a large blob containing textual data, consider compressing it first. Do not use this technique when the entire table is compressed by InnoDB or MyISAM.

• For a table with several columns, to reduce memory requirements for queries that do not use the BLOB column, consider splitting the BLOB column into a separate table and referencing it with a join query when needed.

• Since the performance requirements to retrieve and display a BLOB value might be very different from other data types, you could put the BLOB-specific table on a different storage device or even a separate database instance. For example, to retrieve a BLOB might require a large sequential disk read that is better suited to a traditional hard drive than to an SSD device.

• See Section 8.4.2.2, “Optimizing for Character and String Types” for reasons why a binary VARCHAR column is sometimes preferable to an equivalent BLOB column.

• Rather than testing for equality against a very long text string, you can store a hash of the column value in a separate column, index that column, and test the hashed value in queries. (Use the MD5() or CRC32() function to produce the hash value.) Since hash functions can produce duplicate results for different inputs, you still include a clause AND blob_column = long_string_value in the query to guard against false matches; the performance benefit comes from the smaller, easily scanned index for the hashed values.

8.4.2.4 Using PROCEDURE ANALYSE

ANALYSE([max_elements[,max_memory]])

ANALYSE() examines the result from a query and returns an analysis of the results that suggests optimal data types for each column that may help reduce table sizes. To obtain this analysis, append PROCEDURE ANALYSE to the end of a SELECT statement:

SELECT ... FROM ... WHERE ... PROCEDURE ANALYSE([max_elements,[max_memory]])

For example:
The results show some statistics for the values returned by the query, and propose an optimal data type for the columns. This can be helpful for checking your existing tables, or after importing new data. You may need to try different settings for the arguments so that `PROCEDURE ANALYSE()` does not suggest the `ENUM` data type when it is not appropriate.

The arguments are optional and are used as follows:

- `max_elements` (default 256) is the maximum number of distinct values that `ANALYSE()` notices per column. This is used by `ANALYSE()` to check whether the optimal data type should be of type `ENUM`; if there are more than `max_elements` distinct values, then `ENUM` is not a suggested type.

- `max_memory` (default 8192) is the maximum amount of memory that `ANALYSE()` should allocate per column while trying to find all distinct values.

A `PROCEDURE` clause is not permitted in a `UNION` statement.

### 8.4.3 Optimizing for Many Tables

Some techniques for keeping individual queries fast involve splitting data across many tables. When the number of tables runs into the thousands or even millions, the overhead of dealing with all these tables becomes a new performance consideration.

#### 8.4.3.1 How MySQL Opens and Closes Tables

When you execute a `mysqladmin status` command, you should see something like this:

```
Uptime: 426 Running threads: 1 Questions: 11082
Reloads: 1 Open tables: 12
```

The `Open tables` value of 12 can be somewhat puzzling if you have only six tables.

MySQL is multi-threaded, so there may be many clients issuing queries for a given table simultaneously. To minimize the problem with multiple client sessions having different states on the same table, the table is opened independently by each concurrent session. This uses additional memory but normally increases performance. With `MyISAM` tables, one extra file descriptor is required for the data file for each client that has the table open. (By contrast, the index file descriptor is shared between all sessions.)

![Note]

`table_open_cache` was known as `table_cache` in MySQL 5.1.2 and earlier.

The `table_open_cache` and `max_connections` system variables affect the maximum number of files the server keeps open. If you increase one or both of these values, you may run up against a limit imposed by your operating system on the per-process number of open file descriptors. Many operating systems permit you to increase the open-files limit, although the method varies widely from system to system. Consult your operating system documentation to determine whether it is possible to increase the limit and how to do so.

`table_open_cache` is related to `max_connections`. For example, for 200 concurrent running connections, you should have a table cache size of at least $200 \times N$, where $N$ is the maximum number of tables per join in any of the queries which you execute. You must also reserve some extra file descriptors for temporary tables and files.

Make sure that your operating system can handle the number of open file descriptors implied by the `table_open_cache` setting. If `table_open_cache` is set too high, MySQL may run out of file descriptors and refuse connections, fail to perform queries, and be very unreliable.
You should also take into account the fact that the MyISAM storage engine needs two file descriptors for each unique open table. For a partitioned MyISAM table, two file descriptors are required for each partition of the opened table. (Note further that when MyISAM opens a partitioned table, it opens every partition of this table, whether or not a given partition is actually used. See MyISAM and partition file descriptor usage.) You can increase the number of file descriptors available to MySQL using the --open-files-limit startup option to mysqld. See Section B.5.2.18, “File Not Found and Similar Errors”.

The cache of open tables is kept at a level of table_open_cache entries. The default value is 64; this can be changed with the --table_open_cache option to mysqld. Note that MySQL may temporarily open more tables than this to execute queries.

MySQL closes an unused table and removes it from the table cache under the following circumstances:

- When the cache is full and a thread tries to open a table that is not in the cache.
- When the cache contains more than table_open_cache entries and a table in the cache is no longer being used by any threads.
- When a table flushing operation occurs. This happens when someone issues a `FLUSH TABLES` statement or executes a `mysqladmin flush-tables` or `mysqladmin refresh` command.

When the table cache fills up, the server uses the following procedure to locate a cache entry to use:

- Tables that are not currently in use are released, beginning with the table least recently used.
- If a new table needs to be opened, but the cache is full and no tables can be released, the cache is temporarily extended as necessary. When the cache is in a temporarily extended state and a table goes from a used to unused state, the table is closed and released from the cache.

A MyISAM table is opened for each concurrent access. This means the table needs to be opened twice if two threads access the same table or if a thread accesses the table twice in the same query (for example, by joining the table to itself). Each concurrent open requires an entry in the table cache. The first open of any MyISAM table takes two file descriptors: one for the data file and one for the index file. Each additional use of the table takes only one file descriptor for the data file. The index file descriptor is shared among all threads.

If you are opening a table with the `HANDLER tbl_name OPEN` statement, a dedicated table object is allocated for the thread. This table object is not shared by other threads and is not closed until the thread calls `HANDLER tbl_name CLOSE` or the thread terminates. When this happens, the table is put back in the table cache (if the cache is not full). See Section 13.2.4, “HANDLER Syntax”.

You can determine whether your table cache is too small by checking the `mysqld` status variable `Opened_tables`, which indicates the number of table-opening operations since the server started:

```
mysql> SHOW GLOBAL STATUS LIKE 'Opened_tables';
+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| Opened_tables | 2741  |
```

If the value is very large or increases rapidly, even when you have not issued many `FLUSH TABLES` statements, you should increase the table cache size. See Section 5.1.4, “Server System Variables”, and Section 5.1.6, “Server Status Variables”.

8.4.3.2 Disadvantages of Creating Many Tables in the Same Database

If you have many MyISAM tables in the same database directory, open, close, and create operations are slow. If you execute `SELECT` statements on many different tables, there is a little overhead when the table cache is full, because for every table that has to be opened, another must be closed. You can reduce this overhead by increasing the number of entries permitted in the table cache.
8.4.4 Internal Temporary Table Use in MySQL

In some cases, the server creates internal temporary tables while processing statements. Users have no direct control over when this occurs.

The server creates temporary tables under conditions such as these:

- Evaluation of **UNION** statements.
- Evaluation of some views, such those that use the **TEMPTABLE** algorithm, **UNION**, or aggregation.
- Evaluation of statements that contain an **ORDER BY** clause and a different **GROUP BY** clause, or for which the **ORDER BY** or **GROUP BY** contains columns from tables other than the first table in the join queue.
- Evaluation of **DISTINCT** combined with **ORDER BY** may require a temporary table.
- For queries that use the **SQL_SMALL_RESULT** option, MySQL uses an in-memory temporary table, unless the query also contains elements (described later) that require on-disk storage.
- Evaluation of multiple-table **UPDATE** statements.
- Evaluation of **GROUP_CONCAT()** or **COUNT(DISTINCT)** expressions.

To determine whether a statement requires a temporary table, use **EXPLAIN** and check the **Extra** column to see whether it says **Using temporary** (see Section 8.8.1, “Optimizing Queries with **EXPLAIN**”).

When the server creates an internal temporary table (either in memory or on disk), it increments the **Created_tmp_tables** status variable. If the server creates the table on disk (either initially or by converting an in-memory table) it increments the **Created_tmp_disk_tables** status variable.

Some query conditions prevent the use of an in-memory temporary table, in which case the server uses an on-disk table instead:

- Presence of a **BLOB** or **TEXT** column in the table
- Presence of any string column in a **GROUP BY** or **DISTINCT** clause larger than 512 bytes
- Presence of any string column with a maximum length larger than 512 (bytes for binary strings, characters for nonbinary strings) in the **SELECT** list, if **UNION** or **UNION ALL** is used
- The **SHOW COLUMNS** and **DESCRIBE** statements use **BLOB** as the type for some columns, thus the temporary table used for the results is an on-disk table.

Storage Engines Used for Temporary Tables

An internal temporary table can be held in memory and processed by the **MEMORY** storage engine, or stored on disk and processed by the **MyISAM** storage engine.

If an internal temporary table is created as an in-memory table but becomes too large, MySQL automatically converts it to an on-disk table. The maximum size for in-memory temporary tables is the minimum of the **tmp_table_size** and **max_heap_table_size** values. This differs from **MEMORY** tables explicitly created with **CREATE TABLE**: For such tables, only the **max_heap_table_size** system variable determines how large the table is permitted to grow and there is no conversion to on-disk format.

Temporary Table Storage Format

Internal temporary tables are stored using fixed-length row format, whether managed by the **MEMORY** or **MyISAM** storage engine.

8.5 Optimizing for MyISAM Tables
The **MyISAM** storage engine performs best with read-mostly data or with low-concurrency operations, because table locks limit the ability to perform simultaneous updates.

### 8.5.1 Optimizing MyISAM Queries

Some general tips for speeding up queries on **MyISAM** tables:

- To help MySQL better optimize queries, use `ANALYZE TABLE` or run `myisamchk --analyze` on a table after it has been loaded with data. This updates a value for each index part that indicates the average number of rows that have the same value. (For unique indexes, this is always 1.) MySQL uses this to decide which index to choose when you join two tables based on a nonconstant expression. You can check the result from the table analysis by using `SHOW INDEX FROM tbl_name` and examining the `Cardinality` value. `myisamchk --description --verbose` shows index distribution information.

- To sort an index and data according to an index, use `myisamchk --sort-index --sort-records=1` (assuming that you want to sort on index 1). This is a good way to make queries faster if you have a unique index from which you want to read all rows in order according to the index. The first time you sort a large table this way, it may take a long time.

- Try to avoid complex `SELECT` queries on **MyISAM** tables that are updated frequently, to avoid problems with table locking that occur due to contention between readers and writers.

- **MyISAM** supports concurrent inserts: If a table has no free blocks in the middle of the data file, you can `INSERT` new rows into it at the same time that other threads are reading from the table. If it is important to be able to do this, consider using the table in ways that avoid deleting rows. Another possibility is to run `OPTIMIZE TABLE` to defragment the table after you have deleted a lot of rows from it. This behavior is altered by setting the `concurrent_insert` variable. You can force new rows to be appended (and therefore permit concurrent inserts), even in tables that have deleted rows. See Section 8.11.3, “Concurrent Inserts”.

- For **MyISAM** tables that change frequently, try to avoid all variable-length columns (`VARCHAR`, `BLOB`, and `TEXT`). The table uses dynamic row format if it includes even a single variable-length column. See Chapter 14, *Storage Engines*.

- It is normally not useful to split a table into different tables just because the rows become large. In accessing a row, the biggest performance hit is the disk seek needed to find the first byte of the row. After finding the data, most modern disks can read the entire row fast enough for most applications. The only cases where splitting up a table makes an appreciable difference is if it is a **MyISAM** table using dynamic row format that you can change to a fixed row size, or if you very often need to scan the table but do not need most of the columns. See Chapter 14, *Storage Engines*.

- Use `ALTER TABLE ... ORDER BY expr1, expr2, ...` if you usually retrieve rows in `expr1, expr2, ...` order. By using this option after extensive changes to the table, you may be able to get higher performance.

- If you often need to calculate results such as counts based on information from a lot of rows, it may be preferable to introduce a new table and update the counter in real time. An update of the following form is very fast:

  ```sql
  UPDATE tbl_name SET count_col=count_col+1 WHERE key_col=constant;
  ```

  This is very important when you use a MySQL storage engine such as **MyISAM** that has only table-level locking (multiple readers with single writers). This also gives better performance with most database systems, because the row locking manager in this case has less to do.

- Use `INSERT DELAYED` when you do not need to know when your data is written. This reduces the overall insertion impact because many rows can be written with a single disk write.

- Use `INSERT LOW_PRIORITY` when you want to give `SELECT` statements higher priority than your inserts.
Bulk Data Loading for MyISAM Tables

Use `SELECT HIGH_PRIORITY` to get retrievals that jump the queue. That is, the `SELECT` is executed even if there is another client waiting to do a write.

`LOW_PRIORITY` and `HIGH_PRIORITY` have an effect only for storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

- Use `OPTIMIZE TABLE` periodically to avoid fragmentation with dynamic-format `MyISAM` tables. See Section 14.5.3, “MyISAM Table Storage Formats”.

- Declaring a `MyISAM` table with the `DELAY_KEY_WRITE=1` table option makes index updates faster because they are not flushed to disk until the table is closed. The downside is that if something kills the server while such a table is open, you must ensure that the table is okay by running the server with the `--myisam-recover` option, or by running `myisamchk` before restarting the server. (However, even in this case, you should not lose anything by using `DELAY_KEY_WRITE`, because the key information can always be generated from the data rows.)

- Strings are automatically prefix- and end-space compressed in `MyISAM` indexes. See Section 13.1.13, “CREATE INDEX Syntax”.

- You can increase performance by caching queries or answers in your application and then executing many inserts or updates together. Locking the table during this operation ensures that the index cache is only flushed once after all updates. You can also take advantage of MySQL’s query cache to achieve similar results; see Section 8.10.3, “The MySQL Query Cache”.

8.5.2 Bulk Data Loading for MyISAM Tables

These performance tips supplement the general guidelines for fast inserts in Section 8.2.2.1, “Speed of `INSERT` Statements”.

- To improve performance when multiple clients insert a lot of rows, use the `INSERT DELAYED` statement. See Section 13.2.5.2, “INSERT DELAYED Syntax”. This technique works for `MyISAM` and some other storage engines, but not `InnoDB`.

- For a `MyISAM` table, you can use concurrent inserts to add rows at the same time that `SELECT` statements are running, if there are no deleted rows in middle of the data file. See Section 8.11.3, “Concurrent Inserts”.

- With some extra work, it is possible to make `LOAD DATA INFILE` run even faster for a `MyISAM` table when the table has many indexes. Use the following procedure:
  1. Execute a `FLUSH TABLES` statement or a `mysqladmin flush-tables` command.
  2. Use `myisamchk --keys-used=0 -rq /path/to/db/tbl_name` to remove all use of indexes for the table.
  3. Insert data into the table with `LOAD DATA INFILE`. This does not update any indexes and therefore is very fast.
  4. If you intend only to read from the table in the future, use `myisampack` to compress it. See Section 14.5.3.3, “Compressed Table Characteristics”.
  5. Re-create the indexes with `myisamchk -rq /path/to/db/tbl_name`. This creates the index tree in memory before writing it to disk, which is much faster than updating the index during `LOAD DATA INFILE` because it avoids lots of disk seeks. The resulting index tree is also perfectly balanced.
  6. Execute a `FLUSH TABLES` statement or a `mysqladmin flush-tables` command.

`LOAD DATA INFILE` performs the preceding optimization automatically if the `MyISAM` table into which you insert data is empty. The main difference between automatic optimization and using the
procedure explicitly is that you can let myisamchk allocate much more temporary memory for the index creation than you might want the server to allocate for index re-creation when it executes the LOAD DATA INFILE statement.

You can also disable or enable the nonunique indexes for a MyISAM table by using the following statements rather than myisamchk. If you use these statements, you can skip the FLUSH TABLE operations:

```sql
ALTER TABLE tbl_name DISABLE KEYS;
ALTER TABLE tbl_name ENABLE KEYS;
```

• To speed up INSERT operations that are performed with multiple statements for nontransactional tables, lock your tables:

```sql
LOCK TABLES a WRITE;
INSERT INTO a VALUES (1,23),(2,34),(4,33);
INSERT INTO a VALUES (8,26),(6,29);
...
UNLOCK TABLES;
```

This benefits performance because the index buffer is flushed to disk only once, after all INSERT statements have completed. Normally, there would be as many index buffer flushes as there are INSERT statements. Explicit locking statements are not needed if you can insert all rows with a single INSERT.

Locking also lowers the total time for multiple-connection tests, although the maximum wait time for individual connections might go up because they wait for locks. Suppose that five clients attempt to perform inserts simultaneously as follows:

• Connection 1 does 1000 inserts
• Connections 2, 3, and 4 do 1 insert
• Connection 5 does 1000 inserts

If you do not use locking, connections 2, 3, and 4 finish before 1 and 5. If you use locking, connections 2, 3, and 4 probably do not finish before 1 or 5, but the total time should be about 40% faster.

INSERT, UPDATE, and DELETE operations are very fast in MySQL, but you can obtain better overall performance by adding locks around everything that does more than about five successive inserts or updates. If you do very many successive inserts, you could do a LOCK TABLES followed by an UNLOCK TABLES once in a while (each 1,000 rows or so) to permit other threads to access table. This would still result in a nice performance gain.

INSERT is still much slower for loading data than LOAD DATA INFILE, even when using the strategies just outlined.

• To increase performance for MyISAM tables, for both LOAD DATA INFILE and INSERT, enlarge the key cache by increasing the key_buffer_size system variable. See Section 8.12.2, “Tuning Server Parameters”.

### 8.5.3 Speed of REPAIR TABLE Statements

REPAIR TABLE for MyISAM tables is similar to using myisamchk for repair operations, and some of the same performance optimizations apply:

• myisamchk has variables that control memory allocation. You may be able to its improve performance by setting these variables, as described in Section 4.6.3.6, “myisamchk Memory Usage”.

793
• For `REPAIR TABLE`, the same principle applies, but because the repair is done by the server, you set server system variables instead of `myisamchk` variables. Also, in addition to setting memory-allocation variables, increasing the `myisam_max_sort_file_size` system variable increases the likelihood that the repair will use the faster filesort method and avoid the slower repair by key cache method. Set the variable to the maximum file size for your system, after checking to be sure that there is enough free space to hold a copy of the table files. The free space must be available in the file system containing the original table files.

Suppose that a `myisamchk` table-repair operation is done using the following options to set its memory-allocation variables:

```bash
--key_buffer_size=128M --myisam_sort_buffer_size=256M
--read_buffer_size=64M --write_buffer_size=64M
```

Some of those `myisamchk` variables correspond to server system variables:

<table>
<thead>
<tr>
<th><code>myisamchk</code> Variable</th>
<th>System Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>key_buffer_size</code></td>
<td><code>key_buffer_size</code></td>
</tr>
<tr>
<td><code>myisam_sort_buffer_size</code></td>
<td><code>myisam_sort_buffer_size</code></td>
</tr>
<tr>
<td><code>read_buffer_size</code></td>
<td><code>read_buffer_size</code></td>
</tr>
<tr>
<td><code>write_buffer_size</code></td>
<td>None</td>
</tr>
</tbody>
</table>

Each of the server system variables can be set at runtime, and some of them (`myisam_sort_buffer_size`, `read_buffer_size`) have a session value in addition to a global value. Setting a session value limits the effect of the change to your current session and does not affect other users. Changing a global-only variable (`key_buffer_size`, `myisam_max_sort_file_size`) affects other users as well. For `key_buffer_size`, you must take into account that the buffer is shared with those users. For example, if you set the `myisamchk key_buffer_size` variable to 128MB, you could set the corresponding `key_buffer_size` system variable larger than that (if it is not already set larger), to permit key buffer use by activity in other sessions. However, changing the global key buffer size invalidates the buffer, causing increased disk I/O and slowdown for other sessions. An alternative that avoids this problem is to use a separate key cache, assign to it the indexes from the table to be repaired, and deallocate it when the repair is complete. See Section 8.10.1.2, “Multiple Key Caches”.

Based on the preceding remarks, a `REPAIR TABLE` operation can be done as follows to use settings similar to the `myisamchk` command. Here a separate 128MB key buffer is allocated and the file system is assumed to permit a file size of at least 100GB.

```sql
SET SESSION myisam_sort_buffer_size = 256*1024*1024;
SET SESSION read_buffer_size = 64*1024*1024;
SET GLOBAL repair_cache.key_buffer_size = 128*1024*1024;
CACHE INDEX tbl_name IN repair_cache;
LOAD INDEX INTO CACHE tbl_name;
REPAIR TABLE tbl_name;
SET GLOBAL repair_cache.key_buffer_size = 0;
```

If you intend to change a global variable but want to do so only for the duration of a `REPAIR TABLE` operation to minimally affect other users, save its value in a user variable and restore it afterward. For example:

```sql
SET @old_myisam_sort_buffer_size = @@global.myisam_max_sort_file_size;
SET GLOBAL myisam_max_sort_file_size = 100*1024*1024*1024;
REPAIR TABLE tbl_name;
SET GLOBAL myisam_max_sort_file_size = @old_myisam_max_sort_file_size;
```

The system variables that affect `REPAIR TABLE` can be set globally at server startup if you want the values to be in effect by default. For example, add these lines to the server `my.cnf` file:
8.6 Optimizing for InnoDB Tables

This section explains how to optimize database operations for InnoDB tables.

8.6.1 Optimizing Storage Layout for InnoDB Tables

- Once your data reaches a stable size, or a growing table has increased by tens or some hundreds of megabytes, consider using the `OPTIMIZE TABLE` statement to reorganize the table and compact any wasted space. The reorganized tables require less disk I/O to perform full table scans. This is a straightforward technique that can improve performance when other techniques such as improving index usage or tuning application code are not practical.

  `OPTIMIZE TABLE` copies the data part of the table and rebuilds the indexes. The benefits come from improved packing of data within indexes, and reduced fragmentation within the tablespaces and on disk. The benefits vary depending on the data in each table. You may find that there are significant gains for some and not for others, or that the gains decrease over time until you next optimize the table. This operation can be slow if the table is large or if the indexes being rebuilt do not fit into the buffer pool. The first run after adding a lot of data to a table is often much slower than later runs.

- In InnoDB, having a long PRIMARY KEY (either a single column with a lengthy value, or several columns that form a long composite value) wastes a lot of disk space. The primary key value for a row is duplicated in all the secondary index records that point to the same row. (See Section 14.6.3.2, “InnoDB Table and Index Structures”.) Create an AUTO_INCREMENT column as the primary key if your primary key is long, or index a prefix of a long VARCHAR column instead of the entire column.

- Use the VARCHAR data type instead of CHAR to store variable-length strings or for columns with many NULL values. A CHAR(N) column always takes N characters to store data, even if the string is shorter or its value is NULL. Smaller tables fit better in the buffer pool and reduce disk I/O.

  When using COMPACT row format (the default InnoDB format) and variable-length character sets, such as utf8 or sjis, CHAR(N) columns occupy a variable amount of space, but still at least N bytes.

- For tables that are big, or contain lots of repetitive text or numeric data, consider using COMPRESSED row format. Less disk I/O is required to bring data into the buffer pool, or to perform full table scans. Before making a permanent decision, measure the amount of compression you can achieve by using COMPRESSED versus COMPACT row format.

8.6.2 Optimizing InnoDB Transaction Management

To optimize InnoDB transaction processing, find the ideal balance between the performance overhead of transactional features and the workload of your server. For example, an application might encounter performance issues if it commits thousands of times per second, and different performance issues if it commits only every 2-3 hours.

- The default MySQL setting `AUTOCOMMIT=1` can impose performance limitations on a busy database server. Where practical, wrap several related data change operations into a single transaction,
by issuing `SET AUTOCOMMIT=0` or a `START TRANSACTION` statement, followed by a `COMMIT` statement after making all the changes.

InnoDB must flush the log to disk at each transaction commit if that transaction made modifications to the database. When each change is followed by a commit (as with the default autocommit setting), the I/O throughput of the storage device puts a cap on the number of potential operations per second.

- Avoid performing rollbacks after inserting, updating, or deleting huge numbers of rows. If a big transaction is slowing down server performance, rolling it back can make the problem worse, potentially taking several times as long to perform as the original data change operations. Killing the database process does not help, because the rollback starts again on server startup.

To minimize the chance of this issue occurring:

- Increase the size of the buffer pool so that all the data change changes can be cached rather than immediately written to disk.

- Set `innodb_change_buffering=all` so that update and delete operations are buffered in addition to inserts.

- Consider issuing `COMMIT` statements periodically during the big data change operation, possibly breaking a single delete or update into multiple statements that operate on smaller numbers of rows.

To get rid of a runaway rollback once it occurs, increase the buffer pool so that the rollback becomes CPU-bound and runs fast, or kill the server and restart with `innodb_force_recovery=3`, as explained in Section 14.6.10.1, “The InnoDB Recovery Process”.

- If you can afford the loss of some of the latest committed transactions if a crash occurs, you can set the `innodb_flush_log_at_trx_commit` parameter to 0. InnoDB tries to flush the log once per second anyway, although the flush is not guaranteed.

- When rows are modified or deleted, the rows and associated undo logs are not physically removed immediately, or even immediately after the transaction commits. The old data is preserved until transactions that started earlier or concurrently are finished, so that those transactions can access the previous state of modified or deleted rows. Thus, a long-running transaction can prevent InnoDB from purging data that was changed by a different transaction.

- When rows are modified or deleted within a long-running transaction, other transactions using the `READ COMMITTED` and `REPEATABLE READ` isolation levels have to do more work to reconstruct the older data if they read those same rows.

- When a long-running transaction modifies a table, queries against that table from other transactions do not make use of the covering index technique. Queries that normally could retrieve all the result columns from a secondary index, instead look up the appropriate values from the table data.

8.6.3 Optimizing InnoDB Redo Logging

Consider the following guidelines for optimizing redo logging:

- Make your redo log files big, even as big as the buffer pool. When InnoDB has written the redo log files full, it must write the modified contents of the buffer pool to disk in a checkpoint. Small redo log files cause many unnecessary disk writes. Although historically big redo log files caused lengthy recovery times, recovery is now much faster and you can confidently use large redo log files.

The size and number of redo log files are configured using the `innodb_log_file_size` and `innodb_log_files_in_group` configuration options. For information about modifying an existing redo log file configuration, see Section 14.6.5.2, “Changing the Number or Size of InnoDB Redo Log Files”.

796
Bulk Data Loading for InnoDB Tables

- Consider increasing the size of the log_buffer. A large log buffer enables large transactions to run without a need to write the log to disk before the transactions commit. Thus, if you have transactions that update, insert, or delete many rows, making the log buffer larger saves disk I/O. Log buffer size is configured using the innodb_log_buffer_size configuration option.

8.6.4 Bulk Data Loading for InnoDB Tables

These performance tips supplement the general guidelines for fast inserts in Section 8.2.2.1, "Speed of INSERT Statements".

- When importing data into InnoDB, turn off autocommit mode, because it performs a log flush to disk for every insert. To disable autocommit during your import operation, surround it with SET autocommit and COMMIT statements:

```sql
SET autocommit=0;
... SQL import statements ...
COMMIT;
```

The mysqldump option --opt creates dump files that are fast to import into an InnoDB table, even without wrapping them with the SET autocommit and COMMIT statements.

- If you have UNIQUE constraints on secondary keys, you can speed up table imports by temporarily turning off the uniqueness checks during the import session:

```sql
SET unique_checks=0;
... SQL import statements ...
SET unique_checks=1;
```

For big tables, this saves a lot of disk I/O because InnoDB can use its change buffer to write secondary index records in a batch. Be certain that the data contains no duplicate keys.

- If you have FOREIGN KEY constraints in your tables, you can speed up table imports by turning off the foreign key checks for the duration of the import session:

```sql
SET foreign_key_checks=0;
... SQL import statements ...
SET foreign_key_checks=1;
```

For big tables, this can save a lot of disk I/O.

- Use the multiple-row INSERT syntax to reduce communication overhead between the client and the server if you need to insert many rows:

```sql
INSERT INTO yourtable VALUES (1,2), (5,5), ...;
```

This tip is valid for inserts into any table, not just InnoDB tables.

- When doing bulk inserts into tables with auto-increment columns, set innodb_autoinc_lock_mode to 2 instead of the default value 1. See Section 14.6.6.5, "AUTO_INCREMENT Handling in InnoDB" for details.

8.6.5 Optimizing InnoDB Queries

To tune queries for InnoDB tables, create an appropriate set of indexes on each table. See Section 8.3.1, "How MySQL Uses Indexes" for details. Follow these guidelines for InnoDB indexes:

- Because each InnoDB table has a primary key (whether you request one or not), specify a set of primary key columns for each table, columns that are used in the most important and time-critical queries.
• Do not specify too many or too long columns in the primary key, because these column values are duplicated in each secondary index. When an index contains unnecessary data, the I/O to read this data and memory to cache it reduce the performance and scalability of the server.

• Do not create a separate secondary index for each column, because each query can only make use of one index. Indexes on rarely tested columns or columns with only a few different values might not be helpful for any queries. If you have many queries for the same table, testing different combinations of columns, try to create a small number of concatenated indexes rather than a large number of single-column indexes. If an index contains all the columns needed for the result set (known as a covering index), the query might be able to avoid reading the table data at all.

• If an indexed column cannot contain any NULL values, declare it as NOT NULL when you create the table. The optimizer can better determine which index is most effective to use for a query, when it knows whether each column contains NULL values.

• If you often have recurring queries for tables that are not updated frequently, enable the query cache:

```sql
[mysqld]
query_cache_type = 1
query_cache_size = 10M
```

8.6.6 Optimizing InnoDB DDL Operations

• “Fast index creation” makes it faster in some cases to drop an index before loading data into a table, then re-create the index after loading the data.

• Use TRUNCATE TABLE to empty a table, not DELETE FROM tbl_name. Foreign key constraints can make a TRUNCATE statement work like a regular DELETE statement, in which case a sequence of commands like DROP TABLE and CREATE TABLE might be fastest.

• Because the primary key is integral to the storage layout of each InnoDB table, and changing the definition of the primary key involves reorganizing the whole table, always set up the primary key as part of the CREATE TABLE statement, and plan ahead so that you do not need to ALTER or DROP the primary key afterward.

8.6.7 Optimizing InnoDB Disk I/O

If you follow the best practices for database design and the tuning techniques for SQL operations, but your database is still slowed by heavy disk I/O activity, explore these low-level techniques related to disk I/O. If the Unix top tool or the Windows Task Manager shows that the CPU usage percentage with your workload is less than 70%, your workload is probably disk-bound.

• When table data is cached in the InnoDB buffer pool, it can be accessed repeatedly by queries without requiring any disk I/O. Specify the size of the buffer pool with the innodb_buffer_pool_size option. This memory area is important enough that busy databases often specify a size approximately 80% of the amount of physical memory. For more information, see Section 8.10.2, “The InnoDB Buffer Pool”.

• In some versions of GNU/Linux and Unix, flushing files to disk with the Unix fsync() call (which InnoDB uses by default) and similar methods is surprisingly slow. If database write performance is an issue, conduct benchmarks with the innodb_flush_method parameter set to O_DSYNC.

• When using the InnoDB storage engine on Solaris 10 for x86_64 architecture (AMD Opteron), use direct I/O for InnoDB-related files, to avoid degradation of InnoDB performance. To use direct I/O for an entire UFS file system used for storing InnoDB-related files, mount it with the forcedirectio option; see mount_ufs(1M). (The default on Solaris 10/x86_64 is not to use this option.) Alternatively, as of MySQL 5.1.18, to apply direct I/O only to InnoDB file operations rather than the whole file system, set innodb_flush_method = O_DIRECT. With this setting, InnoDB calls directio() instead of fcntl() for I/O to data files (not for I/O to log files).
• When using the InnoDB storage engine with a large innodb_buffer_pool_size value on any release of Solaris 2.6 and up and any platform (sparc/x86/x64/amd64), conduct benchmarks with InnoDB data files and log files on raw devices or on a separate direct I/O UFS file system, using the forcedirectio mount option as described earlier. (It is necessary to use the mount option rather than setting innodb_flush_method if you want direct I/O for the log files.) Users of the Veritas file system VxFS should use the convosync=direct mount option.

Do not place other MySQL data files, such as those for MyISAM tables, on a direct I/O file system. Executables or libraries must not be placed on a direct I/O file system.

• If you have additional storage devices available to set up a RAID configuration or symbolic links to different disks, Section 8.12.3, "Optimizing Disk I/O" for additional low-level I/O tips.

• If throughput drops periodically because of InnoDB checkpoint operations, consider increasing the value of the innodb_io_capacity configuration option. Higher values cause more frequent flushing, avoiding the backlog of work that can cause dips in throughput.

• If the system is not falling behind with InnoDB flushing operations, consider lowering the value of the innodb_io_capacity configuration option. Typically, you keep this option value as low as practical, but not so low that it causes periodic drops in throughput as mentioned in the preceding bullet. In a typical scenario where you could lower the option value, you might see a combination like this in the output from SHOW ENGINE INNODB STATUS:

  • History list length low, below a few thousand.
  • Insert buffer merges close to rows inserted.
  • Modified pages in buffer pool consistently well below innodb_max_dirty_pages_pct of the buffer pool. (Measure at a time when the server is not doing bulk inserts; it is normal during bulk inserts for the modified pages percentage to rise significantly.)
  • Log sequence number – Last checkpoint is at less than 7/8 or ideally less than 6/8 of the total size of the InnoDB log files.

• Other InnoDB configuration options to consider when tuning I/O-bound workloads include innodb_adaptive_flushing, innodb_change_buffering, innodb_log_buffer_size, innodb_log_file_size, innodb_max_dirty_pages_pct, innodb_max_purge_lag, innodb_open_files, innodb_random_read_ahead, innodb_read_ahead_threshold, innodb_read_io_threads, innodb_write_io_threads, and sync_binlog.

8.6.8 Optimizing InnoDB for Systems with Many Tables

• InnoDB computes index cardinality values for a table the first time that table is accessed after startup, instead of storing such values in the table. This step can take significant time on systems that partition the data into many tables. Since this overhead only applies to the initial table open operation, to "warm up" a table for later use, access it immediately after startup by issuing a statement such as SELECT 1 FROM tbl_name LIMIT 1.

8.7 Optimizing for MEMORY Tables

Consider using MEMORY tables for noncritical data that is accessed often, and is read-only or rarely updated. Benchmark your application against equivalent InnoDB or MyISAM tables under a realistic workload, to confirm that any additional performance is worth the risk of losing data, or the overhead of copying data from a disk-based table at application start.

For best performance with MEMORY tables, examine the kinds of queries against each table, and specify the type to use for each associated index, either a B-tree index or a hash index. On the CREATE INDEX statement, use the clause USING BTREE or USING HASH. B-tree indexes are fast for queries that do greater-than or less-than comparisons through operators such as > or BETWEEN. Hash indexes are only fast for queries that look up single values through the = operator, or a restricted set of values.
through the **IN** operator. For why **USING BTREE** is often a better choice than the default **USING HASH**, see Section 8.2.1.17, “How to Avoid Full Table Scans”. For implementation details of the different types of **MEMORY** indexes, see Section 8.3.8, “Comparison of B-Tree and Hash Indexes”.

### 8.8 Understanding the Query Execution Plan

Depending on the details of your tables, columns, indexes, and the conditions in your **WHERE** clause, the MySQL optimizer considers many techniques to efficiently perform the lookups involved in an SQL query. A query on a huge table can be performed without reading all the rows; a join involving several tables can be performed without comparing every combination of rows. The set of operations that the optimizer chooses to perform the most efficient query is called the “query execution plan”, also known as the **EXPLAIN** plan. Your goals are to recognize the aspects of the **EXPLAIN** plan that indicate a query is optimized well, and to learn the SQL syntax and indexing techniques to improve the plan if you see some inefficient operations.

#### 8.8.1 Optimizing Queries with EXPLAIN

The **EXPLAIN** statement can be used to obtain information about how MySQL executes a statement:

- When you precede a **SELECT** statement with the keyword **EXPLAIN**, MySQL displays information from the optimizer about the statement execution plan. That is, MySQL explains how it would process the statement, including information about how tables are joined and in which order. For information about using **EXPLAIN** to obtain execution plan information, see Section 8.8.2, “EXPLAIN Output Format”.

- **EXPLAIN EXTENDED** can be used to obtain additional execution plan information. See Section 8.8.3, “EXPLAIN EXTENDED Output Format”.

- As of MySQL 5.1.5, **EXPLAIN PARTITIONS** is useful for examining queries involving partitioned tables. See Section 18.3.4, “Obtaining Information About Partitions”.

With the help of **EXPLAIN**, you can see where you should add indexes to tables so that the statement executes faster by using indexes to find rows. You can also use **EXPLAIN** to check whether the optimizer joins the tables in an optimal order. To give a hint to the optimizer to use a join order corresponding to the order in which the tables are named in a **SELECT** statement, begin the statement with **SELECT STRAIGHT_JOIN** rather than just **SELECT**. (See Section 13.2.8, “SELECT Syntax”.)

If you have a problem with indexes not being used when you believe that they should be, run **ANALYZE TABLE** to update table statistics, such as cardinality of keys, that can affect the choices the optimizer makes. See Section 13.7.2.1, “ANALYZE TABLE Syntax”.

**Note**

**EXPLAIN** can also be used to obtain information about the columns in a table. **EXPLAIN tbl_name** is synonymous with **DESCRIBE tbl_name** and **SHOW COLUMNS FROM tbl_name**. For more information, see Section 13.8.1, “DESCRIBE Syntax”, and Section 13.7.5.6, “SHOW COLUMNS Syntax”.

#### 8.8.2 EXPLAIN Output Format

The **EXPLAIN** statement provides information about the execution plan for a **SELECT** statement.

**EXPLAIN** returns a row of information for each table used in the **SELECT** statement. It lists the tables in the output in the order that MySQL would read them while processing the statement. MySQL resolves all joins using a nested-loop join method. This means that MySQL reads a row from the first table, and then finds a matching row in the second table, the third table, and so on. When all tables are processed, MySQL outputs the selected columns and backtracks through the table list until a table is found for which there are more matching rows. The next row is read from this table and the process continues with the next table.
When the `EXTENDED` keyword is used, `EXPLAIN` produces extra information that can be viewed by issuing a `SHOW WARNINGS` statement following the `EXPLAIN` statement. `EXPLAIN EXTENDED` also displays the `filtered` column as of MySQL 5.1.12. See Section 8.8.3, “EXPLAIN EXTENDED Output Format”.

**Note**
You cannot use the `EXTENDED` and `PARTITIONS` keywords together in the same `EXPLAIN` statement.

- **EXPLAIN Output Columns**
- **EXPLAIN Join Types**
- **EXPLAIN Extra Information**
- **EXPLAIN Output Interpretation**

### EXPLAIN Output Columns

This section describes the output columns produced by `EXPLAIN`. Later sections provide additional information about the `type` and `Extra` columns.

Each output row from `EXPLAIN` provides information about one table. Each row contains the values summarized in Table 8.1, “EXPLAIN Output Columns”, and described in more detail following the table.

#### Table 8.1 EXPLAIN Output Columns

<table>
<thead>
<tr>
<th>Column</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>The <code>SELECT</code> identifier</td>
</tr>
<tr>
<td><code>select_type</code></td>
<td>The <code>SELECT</code> type</td>
</tr>
<tr>
<td><code>table</code></td>
<td>The table for the output row</td>
</tr>
<tr>
<td><code>partitions</code></td>
<td>The matching partitions</td>
</tr>
<tr>
<td><code>type</code></td>
<td>The join type</td>
</tr>
<tr>
<td><code>possible_keys</code></td>
<td>The possible indexes to choose</td>
</tr>
<tr>
<td><code>key</code></td>
<td>The index actually chosen</td>
</tr>
<tr>
<td><code>key_len</code></td>
<td>The length of the chosen key</td>
</tr>
<tr>
<td><code>ref</code></td>
<td>The columns compared to the index</td>
</tr>
<tr>
<td><code>rows</code></td>
<td>Estimate of rows to be examined</td>
</tr>
<tr>
<td><code>filtered</code></td>
<td>Percentage of rows filtered by table condition</td>
</tr>
<tr>
<td><code>Extra</code></td>
<td>Additional information</td>
</tr>
</tbody>
</table>

- **id**
  The `SELECT` identifier. This is the sequential number of the `SELECT` within the query. The value can be `NULL` if the row refers to the union result of other rows. In this case, the `table` column shows a value like `<union M, N>` to indicate that the row refers to the union of the rows with `id` values of `M` and `N`.

- **select_type**
  The type of `SELECT`, which can be any of those shown in the following table.

<table>
<thead>
<tr>
<th><code>select_type</code> Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIMPLE</td>
<td>Simple <code>SELECT</code> (not using <code>UNION</code> or subqueries)</td>
</tr>
</tbody>
</table>
### EXPLAIN Output Format

<table>
<thead>
<tr>
<th>select_type</th>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>PRIMARY</td>
<td>Outermost SELECT</td>
<td></td>
</tr>
<tr>
<td>UNION</td>
<td>Second or later SELECT statement in a UNION</td>
<td></td>
</tr>
<tr>
<td>DEPENDENT UNION</td>
<td>Second or later SELECT statement in a UNION, dependent on outer query</td>
<td></td>
</tr>
<tr>
<td>UNION RESULT</td>
<td>Result of a UNION.</td>
<td></td>
</tr>
<tr>
<td>SUBQUERY</td>
<td>First SELECT in subquery</td>
<td></td>
</tr>
<tr>
<td>DEPENDENT SUBQUERY</td>
<td>First SELECT in subquery, dependent on outer query</td>
<td></td>
</tr>
<tr>
<td>DERIVED SUBQUERY</td>
<td>Derived table SELECT (subquery in FROM clause)</td>
<td></td>
</tr>
<tr>
<td>UNCACHEABLE SUBQUERY</td>
<td>A subquery for which the result cannot be cached and must be re-evaluated for each row of the outer query</td>
<td></td>
</tr>
<tr>
<td>UNCACHEABLE UNION</td>
<td>The second or later select in a UNION that belongs to an uncacheable subquery (see UNCACHEABLE SUBQUERY)</td>
<td></td>
</tr>
</tbody>
</table>

DEPENDENT typically signifies the use of a correlated subquery. See Section 13.2.9.7, “Correlated Subqueries”.

DEPENDENT SUBQUERY evaluation differs from UNCACHEABLE SUBQUERY evaluation. For DEPENDENT SUBQUERY, the subquery is re-evaluated only once for each set of different values of the variables from its outer context. For UNCACHEABLE SUBQUERY, the subquery is re-evaluated for each row of the outer context.

Cacheability of subqueries differs from caching of query results in the query cache (which is described in Section 8.10.3.1, “How the Query Cache Operates”). Subquery caching occurs during query execution, whereas the query cache is used to store results only after query execution finishes.

• **table**
  The name of the table to which the row of output refers. This can also be one of the following values:
  • `<unionM, N>`: The row refers to the union of the rows with id values of M and N.
  • `<derivedN>`: The row refers to the derived table result for the row with an id value of N. A derived table may result, for example, from a subquery in the FROM clause.

• **partitions**
  The partitions from which records would be matched by the query. This column is displayed only if the PARTITIONS keyword is used. The value is NULL for nonpartitioned tables. See Section 18.3.4, “Obtaining Information About Partitions”.

• **type**
  The join type. For descriptions of the different types, see EXPLAIN Join Types.

• **possible_keys**
  The possible_keys column indicates which indexes MySQL can choose from use to find the rows in this table. Note that this column is totally independent of the order of the tables as displayed in the output from EXPLAIN. That means that some of the keys in possible_keys might not be usable in practice with the generated table order.

  If this column is NULL, there are no relevant indexes. In this case, you may be able to improve the performance of your query by examining the WHERE clause to check whether it refers to some column or columns that would be suitable for indexing. If so, create an appropriate index and check the query with EXPLAIN again. See Section 13.1.7, “ALTER TABLE Syntax”.

---

802
To see what indexes a table has, use `SHOW INDEX FROM tbl_name`.

- **key**
  
  The `key` column indicates the key (index) that MySQL actually decided to use. If MySQL decides to use one of the `possible_keys` indexes to look up rows, that index is listed as the key value.

  It is possible that `key` will name an index that is not present in the `possible_keys` value. This can happen if none of the `possible_keys` indexes are suitable for looking up rows, but all the columns selected by the query are columns of some other index. That is, the named index covers the selected columns, so although it is not used to determine which rows to retrieve, an index scan is more efficient than a data row scan.

  For **InnoDB**, a secondary index might cover the selected columns even if the query also selects the primary key because **InnoDB** stores the primary key value with each secondary index. If `key` is `NULL`, MySQL found no index to use for executing the query more efficiently.

  To force MySQL to use or ignore an index listed in the `possible_keys` column, use `FORCE INDEX`, `USE INDEX`, or `IGNORE INDEX` in your query. See Section 8.9.3, “Index Hints”.

  For **MyISAM** and **NDB** tables, running `ANALYZE TABLE` helps the optimizer choose better indexes. For **MyISAM** tables, `myisamchk --analyze` does the same as `ANALYZE TABLE`. See Section 7.6, “**MyISAM** Table Maintenance and Crash Recovery”.

- **key_len**
  
  The `key_len` column indicates the length of the key that MySQL decided to use. The length is `NULL` if the `key` column says `NULL`. Note that the value of `key_len` enables you to determine how many parts of a multiple-part key MySQL actually uses.

- **ref**
  
  The `ref` column shows which columns or constants are compared to the index named in the `key` column to select rows from the table.

- **rows**
  
  The `rows` column indicates the number of rows MySQL believes it must examine to execute the query.

  For **InnoDB** tables, this number is an estimate, and may not always be exact.

- **filtered**
  
  The `filtered` column indicates an estimated percentage of table rows that will be filtered by the table condition. That is, `rows` shows the estimated number of rows examined and `rows × filtered / 100` shows the number of rows that will be joined with previous tables. This column is displayed if you use `EXPLAIN EXTENDED`. (New in MySQL 5.1.12)

- **Extra**
  
  This column contains additional information about how MySQL resolves the query. For descriptions of the different values, see `EXPLAIN Extra Information`.

**EXPLAIN Join Types**

The `type` column of `EXPLAIN` output describes how tables are joined. The following list describes the join types, ordered from the best type to the worst:

- **system**
  
  The table has only one row (= system table). This is a special case of the `const` join type.
• **const**

The table has at most one matching row, which is read at the start of the query. Because there is only one row, values from the column in this row can be regarded as constants by the rest of the optimizer. **const** tables are very fast because they are read only once.

**const** is used when you compare all parts of a **PRIMARY KEY** or **UNIQUE** index to constant values. In the following queries, `tbl_name` can be used as a **const** table:

```sql
SELECT * FROM tbl_name WHERE primary_key=1;
SELECT * FROM tbl_name
  WHERE primary_key_part1=1 AND primary_key_part2=2;
```

• **eq_ref**

One row is read from this table for each combination of rows from the previous tables. Other than the **system** and **const** types, this is the best possible join type. It is used when all parts of an index are used by the join and the index is a **PRIMARY KEY** or **UNIQUE NOT NULL** index.

**eq_ref** can be used for indexed columns that are compared using the `=` operator. The comparison value can be a constant or an expression that uses columns from tables that are read before this table. In the following examples, MySQL can use an **eq_ref** join to process `ref_table`:

```sql
SELECT * FROM ref_table,other_table
  WHERE ref_table.key_column=other_table.column;
SELECT * FROM ref_table,other_table
  WHERE ref_table.key_column_part1=other_table.column
  AND ref_table.key_column_part2=1;
```

• **ref**

All rows with matching index values are read from this table for each combination of rows from the previous tables. **ref** is used if the join uses only a leftmost prefix of the key or if the key is not a **PRIMARY KEY** or **UNIQUE** index (in other words, if the join cannot select a single row based on the key value). If the key that is used matches only a few rows, this is a good join type.

**ref** can be used for indexed columns that are compared using the `=` or `<>` operator. In the following examples, MySQL can use a **ref** join to process `ref_table`:

```sql
SELECT * FROM ref_table WHERE key_column=expr;
SELECT * FROM ref_table,other_table
  WHERE ref_table.key_column=other_table.column;
SELECT * FROM ref_table,other_table
  WHERE ref_table.key_column_part1=other_table.column
  AND ref_table.key_column_part2=1;
```

• **fulltext**

The join is performed using a **FULLTEXT** index.

• **ref_or_null**

This join type is like **ref**, but with the addition that MySQL does an extra search for rows that contain **NULL** values. This join type optimization is used most often in resolving subqueries. In the following examples, MySQL can use a **ref_or_null** join to process `ref_table`:

```sql
SELECT * FROM ref_table
  WHERE key_column=expr OR key_column IS NULL;
```
See Section 8.2.1.6, “IS NULL Optimization”.

- **index_merge**
  This join type indicates that the Index Merge optimization is used. In this case, the key column in the output row contains a list of indexes used, and key_len contains a list of the longest key parts for the indexes used. For more information, see Section 8.2.1.4, “Index Merge Optimization”.

- **unique_subquery**
  This type replaces `eq_ref` for some `IN` subqueries of the following form:

  ```sql
  value IN (SELECT primary_key FROM single_table WHERE some_expr)
  ```

  `unique_subquery` is just an index lookup function that replaces the subquery completely for better efficiency.

- **index_subquery**
  This join type is similar to `unique_subquery`. It replaces `IN` subqueries, but it works for nonunique indexes in subqueries of the following form:

  ```sql
  value IN (SELECT key_column FROM single_table WHERE some_expr)
  ```

- **range**
  Only rows that are in a given range are retrieved, using an index to select the rows. The key column in the output row indicates which index is used. The key_len contains the longest key part that was used. The ref column is NULL for this type.

  ```sql
  range can be used when a key column is compared to a constant using any of the =, <>, >, >=, <, <=, IS NULL, <=>, BETWEEN, or IN() operators:
  ```

  ```sql
  SELECT * FROM tbl_name
  WHERE key_column = 10;

  SELECT * FROM tbl_name
  WHERE key_column BETWEEN 10 and 20;

  SELECT * FROM tbl_name
  WHERE key_column IN (10,20,30);

  SELECT * FROM tbl_name
  WHERE key_part1 IN (10,20,30) AND key_part2 IN (10,20,30);
  ```

- **index**
  The index join type is the same as `ALL`, except that the index tree is scanned. This occurs two ways:

  - If the index is a covering index for the queries and can be used to satisfy all data required from the table, only the index tree is scanned. In this case, the Extra column says Using index. An index-only scan usually is faster than `ALL` because the size of the index usually is smaller than the table data.

  - A full table scan is performed using reads from the index to look up data rows in index order. Uses index does not appear in the Extra column.

  MySQL can use this join type when the query uses only columns that are part of a single index.

- **ALL**
A full table scan is done for each combination of rows from the previous tables. This is normally not good if the table is the first table not marked `const`, and usually very bad in all other cases. Normally, you can avoid `ALL` by adding indexes that enable row retrieval from the table based on constant values or column values from earlier tables.

**EXPLAIN Extra Information**

The `Extra` column of `EXPLAIN` output contains additional information about how MySQL resolves the query. The following list explains the values that can appear in this column. If you want to make your queries as fast as possible, look out for `Extra` values of `Using filesort` and `Using temporary`.

- **Child of 'table' pushed join**
  
  This table is referenced as the child of `table` in a join that can be pushed down to the NDB kernel. Applies only in MySQL Cluster NDB 7.2.0 and later, when pushed-down joins are enabled. See the description of the `ndb_join_pushdown` server system variable for more information and examples.

- **const row not found**
  
  For a query such as `SELECT ... FROM tbl_name`, the table was empty.

- **Distinct**
  
  MySQL is looking for distinct values, so it stops searching for more rows for the current row combination after it has found the first matching row.

- **Full scan on NULL key**
  
  This occurs for subquery optimization as a fallback strategy when the optimizer cannot use an index-lookup access method.

- **Impossible HAVING**
  
  The `HAVING` clause is always false and cannot select any rows.

- **Impossible WHERE**
  
  The `WHERE` clause is always false and cannot select any rows.

- **Impossible WHERE noticed after reading const tables**
  
  MySQL has read all `const` (and `system`) tables and notice that the `WHERE` clause is always false.

- **No matching min/max row**
  
  No row satisfies the condition for a query such as `SELECT MIN(...) FROM ... WHERE condition`.

- **no matching row in const table**
  
  For a query with a join, there was an empty table or a table with no rows satisfying a unique index condition.

- **No tables used**
  
  The query has no `FROM` clause, or has a `FROM DUAL` clause.

- **Not exists**
  
  MySQL was able to do a `LEFT JOIN` optimization on the query and does not examine more rows in this table for the previous row combination after it finds one row that matches the `LEFT JOIN` criteria. Here is an example of the type of query that can be optimized this way:
SELECT * FROM t1 LEFT JOIN t2 ON t1.id=t2.id  
WHERE t2.id IS NULL;

Assume that \texttt{t2.id} is defined as \texttt{NOT NULL}. In this case, MySQL scans \texttt{t1} and looks up the rows in \texttt{t2} using the values of \texttt{t1.id}. If MySQL finds a matching row in \texttt{t2}, it knows that \texttt{t2.id} can never be \texttt{NULL}, and does not scan through the rest of the rows in \texttt{t2} that have the same \texttt{id} value. In other words, for each row in \texttt{t1}, MySQL needs to do only a single lookup in \texttt{t2}, regardless of how many rows actually match in \texttt{t2}.

- **Parent of \(N\) pushed join@1**

  This table is referenced as the parent of the table in row \(N\) of the current \texttt{EXPLAIN} output in a join that can be pushed down to the NDB kernel. Applies only in MySQL Cluster NDB 7.2.0 and later when pushed-down joins are enabled. See the description of the \texttt{ndb_join_pushdown} server system variable for more information and examples.

- **Range checked for each record (index map: \(N\))**

  MySQL found no good index to use, but found that some of indexes might be used after column values from preceding tables are known. For each row combination in the preceding tables, MySQL checks whether it is possible to use a \texttt{range} or \texttt{index_merge} access method to retrieve rows. This is not very fast, but is faster than performing a join with no index at all. The applicability criteria are as described in Section 8.2.1.3, “Range Optimization”, and Section 8.2.1.4, “Index Merge Optimization”, with the exception that all column values for the preceding table are known and considered to be constants.

  Indexes are numbered beginning with 1, in the same order as shown by \texttt{SHOW INDEX} for the table. The index map value \(N\) is a bitmask value that indicates which indexes are candidates. For example, a value of \texttt{0x19} (binary 11001) means that indexes 1, 4, and 5 will be considered.

- **Scanned \(N\) databases**

  This indicates how many directory scans the server performs when processing a query for \texttt{INFORMATION_SCHEMA} tables, as described in Section 8.2.4, “\texttt{INFORMATION_SCHEMA} Optimization”. The value of \(N\) can be 0, 1, or \texttt{all}.

- **Select tables optimized away**

  The optimizer determined 1) that at most one row should be returned, and 2) that to produce this row, a deterministic set of rows must be read. When the rows to be read can be read during the optimization phase (for example, by reading index rows), there is no need to read any tables during query execution.

  The first condition is fulfilled when the query is implicitly grouped (contains an aggregate function but no \texttt{GROUP BY} clause). The second condition is fulfilled when one row lookup is performed per index used. The number of indexes read determines the number of rows to read.

  Consider the following implicitly grouped query:

  \[
  \texttt{SELECT MIN(c1), MIN(c2) FROM t1;}
  \]

  Suppose that \texttt{MIN(c1)} can be retrieved by reading one index row and \texttt{MIN(c2)} can be retrieved by reading one row from a different index. That is, for each column \texttt{c1} and \texttt{c2}, there exists an index where the column is the first column of the index. In this case, one row is returned, produced by reading two deterministic rows.

  This \texttt{Extra} value does not occur if the rows to read are not deterministic. Consider this query:

  \[
  \texttt{SELECT MIN(c2) FROM t1 WHERE c1 <= 10;}
  \]
Suppose that \((c_1, c_2)\) is a covering index. Using this index, all rows with \(c_1 \leq 10\) must be scanned to find the minimum \(c_2\) value. By contrast, consider this query:

```sql
SELECT MIN(c2) FROM t1 WHERE c1 = 10;
```

In this case, the first index row with \(c_1 = 10\) contains the minimum \(c_2\) value. Only one row must be read to produce the returned row.

For storage engines that maintain an exact row count per table (such as MyISAM, but not InnoDB), this \textit{Extra} value can occur for \texttt{COUNT(*)} queries for which the \texttt{WHERE} clause is missing or always true and there is no \texttt{GROUP BY} clause. (This is an instance of an implicitly grouped query where the storage engine influences whether a deterministic number of rows can be read.)

- \textit{Skip_open_table}, \textit{Open_frm_only}, \textit{Open_trigger_only}, \textit{Open_full_table}

  These values indicate file-opening optimizations that apply to queries for \texttt{INFORMATION_SCHEMA} tables, as described in Section 8.2.4, “\texttt{INFORMATION_SCHEMA} Optimization”.

- \textit{Skip_open_table}: Table files do not need to be opened. The information has already become available within the query by scanning the database directory.

- \textit{Open_frm_only}: Only the table's \texttt{.frm} file need be opened.

- \textit{Open_trigger_only}: Only the table's \texttt{.TRG} file need be opened.

- \textit{Open_full_table}: The unoptimized information lookup. The \texttt{.frm}, \texttt{.MYD}, and \texttt{.MYI} files must be opened.

- \textit{unique row not found}

  For a query such as \texttt{SELECT ... FROM tbl_name}, no rows satisfy the condition for a \texttt{UNIQUE} index or \texttt{PRIMARY KEY} on the table.

- \textit{Using filesort}

  MySQL must do an extra pass to find out how to retrieve the rows in sorted order. The sort is done by going through all rows according to the join type and storing the sort key and pointer to the row for all rows that match the \texttt{WHERE} clause. The keys then are sorted and the rows are retrieved in sorted order. See Section 8.2.1.11, “\texttt{ORDER BY} Optimization”.

- \textit{Using index}

  The column information is retrieved from the table using only information in the index tree without having to do an additional seek to read the actual row. This strategy can be used when the query uses only columns that are part of a single index.

  For InnoDB tables that have a user-defined clustered index, that index can be used even when \textit{Using index} is absent from the \textit{Extra} column. This is the case if \texttt{type} is \texttt{index} and \texttt{key} is \texttt{PRIMARY}.

- \textit{Using index for group-by}

  Similar to the \textit{Using index} table access method, \textit{Using index for group-by} indicates that MySQL found an index that can be used to retrieve all columns of a \texttt{GROUP BY} or \texttt{DISTINCT} query without any extra disk access to the actual table. Additionally, the index is used in the most efficient way so that for each group, only a few index entries are read. For details, see Section 8.2.1.12, “\texttt{GROUP BY} Optimization”.

- \textit{Using join buffer}
Tables from earlier joins are read in portions into the join buffer, and then their rows are used from the buffer to perform the join with the current table.

• Using sort_union(...), Using union(...), Using intersect(...)  

These indicate how index scans are merged for the index_merge join type. See Section 8.2.1.4, “Index Merge Optimization”.

• Using temporary

To resolve the query, MySQL needs to create a temporary table to hold the result. This typically happens if the query contains GROUP BY and ORDER BY clauses that list columns differently.

• Using where

A WHERE clause is used to restrict which rows to match against the next table or send to the client. Unless you specifically intend to fetch or examine all rows from the table, you may have something wrong in your query if the Extra value is not Using where and the table join type is ALL or index. Even if you are using an index for all parts of a WHERE clause, you may see Using where if the column can be NULL.

• Using where with pushed condition

This item applies to NDB tables only. It means that MySQL Cluster is using the Condition Pushdown optimization to improve the efficiency of a direct comparison between a nonindexed column and a constant. In such cases, the condition is “pushed down” to the cluster's data nodes and is evaluated on all data nodes simultaneously. This eliminates the need to send nonmatching rows over the network, and can speed up such queries by a factor of 5 to 10 times over cases where Condition Pushdown could be but is not used. For more information, see Section 8.2.1.5, “Engine Condition Pushdown Optimization”.

EXPLAIN Output Interpretation

You can get a good indication of how good a join is by taking the product of the values in the rows column of the EXPLAIN output. This should tell you roughly how many rows MySQL must examine to execute the query. If you restrict queries with the max_join_size system variable, this row product also is used to determine which multiple-table SELECT statements to execute and which to abort. See Section 8.12.2, “Tuning Server Parameters”.

The following example shows how a multiple-table join can be optimized progressively based on the information provided by EXPLAIN.

Suppose that you have the SELECT statement shown here and that you plan to examine it using EXPLAIN:

```sql
```

For this example, make the following assumptions:

• The columns being compared have been declared as follows.
The tables have the following indexes.

<table>
<thead>
<tr>
<th>Table</th>
<th>Index</th>
</tr>
</thead>
<tbody>
<tr>
<td>tt</td>
<td>ActualPC</td>
</tr>
<tr>
<td>tt</td>
<td>AssignedPC</td>
</tr>
<tr>
<td>tt</td>
<td>ClientID</td>
</tr>
<tr>
<td>et</td>
<td>EMPLOYID (primary key)</td>
</tr>
<tr>
<td>do</td>
<td>CUSTNMBR (primary key)</td>
</tr>
</tbody>
</table>

The `tt.ActualPC` values are not evenly distributed.

Initially, before any optimizations have been performed, the `EXPLAIN` statement produces the following information:

```
+----------+-------------+--------------+--------------+---------+----------+-----------+-------+---------+-------+
<table>
<thead>
<tr>
<th>table</th>
<th>type</th>
<th>possible_keys</th>
<th>key</th>
<th>key_len</th>
<th>ref</th>
<th>rows</th>
<th>Extra</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>et</td>
<td>ALL</td>
<td>PRIMARY</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>74</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>do</td>
<td>ALL</td>
<td>PRIMARY</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>2135</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>et_1</td>
<td>ALL</td>
<td>PRIMARY</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>74</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>tt</td>
<td>ALL</td>
<td>AssignedPC,</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>3872</td>
<td></td>
<td>Using</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>ClientID,</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>where</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>ActualPC</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Range checked for each record (index map: 0x23)</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

Because `type` is `ALL` for each table, this output indicates that MySQL is generating a Cartesian product of all the tables; that is, every combination of rows. This takes quite a long time, because the product of the number of rows in each table must be examined. For the case at hand, this product is $74 \times 2135 \times 74 \times 3872 = 45,268,556,720$ rows. If the tables were bigger, you can only imagine how long it would take.

One problem here is that MySQL can use indexes on columns more efficiently if they are declared as the same type and size. In this context, `VARCHAR` and `CHAR` are considered the same if they are declared as the same size. `tt.ActualPC` is declared as `CHAR(10)` and `et.EMPLOYID` is `CHAR(15)`, so there is a length mismatch.

To fix this disparity between column lengths, use `ALTER TABLE` to lengthen `ActualPC` from 10 characters to 15 characters:

```sql
mysql> ALTER TABLE tt MODIFY ActualPC VARCHAR(15);
```

Now `tt.ActualPC` and `et.EMPLOYID` are both `VARCHAR(15)`. Executing the `EXPLAIN` statement again produces this result:

```
+----------+-------------+--------------+--------------+---------+----------+-----------+-------+---------+-------+
<table>
<thead>
<tr>
<th>table</th>
<th>type</th>
<th>possible_keys</th>
<th>key</th>
<th>key_len</th>
<th>ref</th>
<th>rows</th>
<th>Extra</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>tt</td>
<td>ALL</td>
<td>AssignedPC,</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>3872</td>
<td></td>
<td>Using</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>ClientID,</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>where</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>ActualPC</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Range checked for each record (index map: 0x1)</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>do</td>
<td>ALL</td>
<td>PRIMARY</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>2135</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>et_1</td>
<td>ALL</td>
<td>PRIMARY</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>74</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

810
This is not perfect, but is much better: The product of the `rows` values is less by a factor of 74. This version executes in a couple of seconds.

A second alteration can be made to eliminate the column length mismatches for the `tt.AssignedPC = et_1.EMPLOYID` and `tt.ClientID = do.CUSTNMBR` comparisons:

```
mysql> ALTER TABLE tt MODIFY AssignedPC VARCHAR(15),
      -> MODIFY ClientID VARCHAR(15);
```

After that modification, `EXPLAIN` produces the output shown here:

```
table  type    possible_keys     key    key_len ref   rows Extra
et     ALL      PRIMARY       NULL   NULL   NULL    74
tt   ref       AssignedPC,   ActualPC 15      et.EMPLOYID   52   Using
       ClientID, ActualPC
et_1 eq_ref PRIMARY       PRIMARY 15      tt.AssignedPC 1
do   eq_ref PRIMARY       PRIMARY 15      tt.ClientID   1
```

At this point, the query is optimized almost as well as possible. The remaining problem is that, by default, MySQL assumes that values in the `tt.ActualPC` column are evenly distributed, and that is not the case for the `tt` table. Fortunately, it is easy to tell MySQL to analyze the key distribution:

```
mysql> ANALYZE TABLE tt;
```

With the additional index information, the join is perfect and `EXPLAIN` produces this result:

```
table  type    possible_keys     key    key_len ref   rows Extra
tt   ALL      AssignedPC       NULL   NULL   NULL   3872 Using
       ClientID, ActualPC
et   eq_ref PRIMARY       PRIMARY 15      tt.ActualPC 1
et_1 eq_ref PRIMARY       PRIMARY 15      tt.AssignedPC 1
do   eq_ref PRIMARY       PRIMARY 15      tt.ClientID   1
```

The `rows` column in the output from `EXPLAIN` is an educated guess from the MySQL join optimizer. You should check whether the numbers are even close to the truth by comparing the `rows` product with the actual number of rows that the query returns. If the numbers are quite different, you might get better performance by using `STRAIGHT_JOIN` in your `SELECT` statement and trying to list the tables in a different order in the `FROM` clause.

It is possible in some cases to execute statements that modify data when `EXPLAIN SELECT` is used with a subquery; for more information, see Section 13.2.9.8, “Subqueries in the FROM Clause”.

### 8.8.3 EXPLAIN EXTENDED Output Format

When `EXPLAIN` is used with the `EXTENDED` keyword, the output includes a `filtered` column not otherwise displayed. This column indicates the estimated percentage of table rows that will be filtered by the table condition. In addition, the statement produces extra information that can be viewed by issuing a `SHOW WARNINGS` statement following the `EXPLAIN` statement. The `Message` value in `SHOW WARNINGS` output displays how the optimizer qualifies table and column names in the `SELECT` statement, what the `SELECT` looks like after the application of rewriting and optimization rules, and possibly other notes about the optimization process.

Here is an example of extended output:

```
mysql> EXPLAIN EXTENDED
```
The statement displayed by \texttt{SHOW WARNINGS} may contain special markers to provide information about query rewriting or optimizer actions. The statement is not necessarily valid SQL and is not intended to be executed. The output may also include rows with \texttt{Message} values that provide additional non-SQL explanatory notes about actions taken by the optimizer.

The following list describes special markers that can appear in \texttt{EXTENDED} output displayed by \texttt{SHOW WARNINGS}:

- \texttt{<cache>(expr)}

  The expression (such as a scalar subquery) is executed once and the resulting value is saved in memory for later use.

- \texttt{<exists>(query fragment)}

  The subquery predicate is converted to an \texttt{EXISTS} predicate and the subquery is transformed so that it can be used together with the \texttt{EXISTS} predicate.

- \texttt{<in_optimizer>(query fragment)}

  This is an internal optimizer object with no user significance.

- \texttt{<index_lookup>(query fragment)}

  The query fragment is processed using an index lookup to find qualifying rows.

- \texttt{<is_not_null_test>(expr)}

  A test to verify that the expression does not evaluate to \texttt{NULL}.
8.8.4 Estimating Query Performance

In most cases, you can estimate query performance by counting disk seeks. For small tables, you can usually find a row in one disk seek (because the index is probably cached). For bigger tables, you can estimate that, using B-tree indexes, you need this many seeks to find a row:
\[ \log(\text{row count}) / \log(\text{index block length} / 3 \times 2 / (\text{index length} + \text{data pointer length})) + 1 \].

In MySQL, an index block is usually 1,024 bytes and the data pointer is usually four bytes. For a 500,000-row table with a key value length of three bytes (the size of MEDIUMINT), the formula indicates \( \log(500,000) / \log(1024/3*2/(3+4)) + 1 = 4 \) seeks.

This index would require storage of about 500,000 * 7 * 3/2 = 5.2MB (assuming a typical index buffer fill ratio of 2/3), so you probably have much of the index in memory and so need only one or two calls to read data to find the row.

For writes, however, you need four seek requests to find where to place a new index value and normally two seeks to update the index and write the row.

The preceding discussion does not mean that your application performance slowly degenerates by \( \log N \). As long as everything is cached by the OS or the MySQL server, things become only marginally slower as the table gets bigger. After the data gets too big to be cached, things start to go much slower until your applications are bound only by disk seeks (which increase by \( \log N \)). To avoid this, increase the key cache size as the data grows. For MyISAM tables, the key cache size is controlled by the \texttt{key_buffer_size} system variable. See Section 8.12.2, “Tuning Server Parameters”.

8.9 Controlling the Query Optimizer

MySQL provides optimizer control through system variables that affect how query plans are evaluated, switchable optimizations, and index hints.

8.9.1 Controlling Query Plan Evaluation

The task of the query optimizer is to find an optimal plan for executing an SQL query. Because the difference in performance between “good” and “bad” plans can be orders of magnitude (that is, seconds versus hours or even days), most query optimizers, including that of MySQL, perform a more or less exhaustive search for an optimal plan among all possible query evaluation plans. For join queries, the number of possible plans investigated by the MySQL optimizer grows exponentially with the number of tables referenced in a query. For small numbers of tables (typically less than 7 to 10) this is not a problem. However, when larger queries are submitted, the time spent in query optimization may easily become the major bottleneck in the server's performance.

A more flexible method for query optimization enables the user to control how exhaustive the optimizer is in its search for an optimal query evaluation plan. The general idea is that the fewer plans that are investigated by the optimizer, the less time it spends in compiling a query. On the other hand, because the optimizer skips some plans, it may miss finding an optimal plan.

The behavior of the optimizer with respect to the number of plans it evaluates can be controlled using two system variables:
• The `optimizer_prune_level` variable tells the optimizer to skip certain plans based on estimates of the number of rows accessed for each table. Our experience shows that this kind of “educated guess” rarely misses optimal plans, and may dramatically reduce query compilation times. That is why this option is on (`optimizer_prune_level=1`) by default. However, if you believe that the optimizer missed a better query plan, this option can be switched off (`optimizer_prune_level=0`) with the risk that query compilation may take much longer. Note that, even with the use of this heuristic, the optimizer still explores a roughly exponential number of plans.

• The `optimizer_search_depth` variable tells how far into the “future” of each incomplete plan the optimizer should look to evaluate whether it should be expanded further. Smaller values of `optimizer_search_depth` may result in orders of magnitude smaller query compilation times. For example, queries with 12, 13, or more tables may easily require hours and even days to compile if `optimizer_search_depth` is close to the number of tables in the query. At the same time, if compiled with `optimizer_search_depth` equal to 3 or 4, the optimizer may compile in less than a minute for the same query. If you are unsure of what a reasonable value is for `optimizer_search_depth`, this variable can be set to 0 to tell the optimizer to determine the value automatically.

### 8.9.2 Controlling Switchable Optimizations

The `optimizer_switch` system variable enables control over optimizer behavior. Its value is a set of flags, each of which has a value of `on` or `off` to indicate whether the corresponding optimizer behavior is enabled or disabled. This variable has global and session values and can be changed at runtime. The global default can be set at server startup.

To see the current set of optimizer flags, select the variable value:

```sql
mysql> SELECT @@optimizer_switch
+-----------------------------+-----------------------------+
| @optimizer_switch            | index_merge=on,index_merge_union=on, |
| index_merge_sort_union=on,   | index_merge_intersection=on |
+-----------------------------+-----------------------------+
```

To change the value of `optimizer_switch`, assign a value consisting of a comma-separated list of one or more commands:

```
SET [GLOBAL|SESSION] optimizer_switch='command[,command]...';
```

Each `command` value should have one of the forms shown in the following table.

<table>
<thead>
<tr>
<th>Command Syntax</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>default</code></td>
<td>Reset every optimization to its default value</td>
</tr>
<tr>
<td><code>opt_name=default</code></td>
<td>Set the named optimization to its default value</td>
</tr>
<tr>
<td><code>opt_name=off</code></td>
<td>Disable the named optimization</td>
</tr>
<tr>
<td><code>opt_name=on</code></td>
<td>Enable the named optimization</td>
</tr>
</tbody>
</table>

The order of the commands in the value does not matter, although the `default` command is executed first if present. Setting an `opt_name` flag to `default` sets it to whichever of `on` or `off` is its default value. Specifying any given `opt_name` more than once in the value is not permitted and causes an error. Any errors in the value cause the assignment to fail with an error, leaving the value of `optimizer_switch` unchanged.

The following table lists the permissible `opt_name` flag names.

<table>
<thead>
<tr>
<th>Flag Name</th>
<th>Meaning</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>index_merge</code></td>
<td>Controls all Index Merge optimizations</td>
<td>ON</td>
</tr>
</tbody>
</table>
# Index Hints

<table>
<thead>
<tr>
<th>Flag Name</th>
<th>Meaning</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>index_merge_intersection</code></td>
<td>Controls the Index Merge Intersection Access optimization</td>
<td>ON</td>
</tr>
<tr>
<td><code>index_merge_sort_union</code></td>
<td>Controls the Index Merge Sort-Union Access optimization</td>
<td>ON</td>
</tr>
<tr>
<td><code>index_merge_union</code></td>
<td>Controls the Index Merge Union Access optimization</td>
<td>ON</td>
</tr>
</tbody>
</table>

For information about Index Merge, see [Section 8.2.1.4, “Index Merge Optimization”](#).

When you assign a value to `optimizer_switch`, flags that are not mentioned keep their current values. This makes it possible to enable or disable specific optimizer behaviors in a single statement without affecting other behaviors. The statement does not depend on what other optimizer flags exist and what their values are. Suppose that all Index Merge optimizations are enabled:

```sql
mysql> SELECT @@optimizer_switch
+--------------------+---------------------+---------------------+
| optimizer_switch    |---------------------|---------------------+
| index_merge=on,     | index_merge_union=on |
| index_merge_sort_union=on,  | index_merge_intersection=on |
+--------------------+---------------------+---------------------+
```

If the server is using the Index Merge Union or Index Merge Sort-Union access methods for certain queries and you want to check whether the optimizer will perform better without them, set the variable value like this:

```sql
mysql> SET optimizer_switch='index_merge_union=off,index_merge_sort_union=off';
```

```sql
mysql> SELECT @@optimizer_switch
+--------------------+---------------------+---------------------+
| optimizer_switch    |---------------------|---------------------+
| index_merge=on,     | index_merge_union=off |
| index_merge_sort_union=off,  | index_merge_intersection=on |
+--------------------+---------------------+---------------------+
```

## 8.9.3 Index Hints

Index hints give the optimizer information about how to choose indexes during query processing. Index hints are specified following a table name. (For the general syntax for specifying tables in a `SELECT` statement, see [Section 13.2.8.2, “JOIN Syntax”](#).) The syntax for referring to an individual table, including index hints, looks like this:

```sql
tbl_name [[AS] alias] [index_hint_list]

index_hint_list:

  index_hint [, index_hint] ...

index_hint:

  USE {INDEX|KEY} [FOR {JOIN|ORDER BY|GROUP BY}] ([index_list])
  | IGNORE {INDEX|KEY} [FOR {JOIN|ORDER BY|GROUP BY}] ([index_list])
  | FORCE {INDEX|KEY} [FOR {JOIN|ORDER BY|GROUP BY}] ([index_list])

index_list:

  index_name [, index_name] ...
```

The `USE INDEX (index_list)` hint tells MySQL to use only one of the named indexes to find rows in the table. The alternative syntax `IGNORE INDEX (index_list)` tells MySQL to not use some particular index or indexes. These hints are useful if `EXPLAIN` shows that MySQL is using the wrong index from the list of possible indexes.
Index Hints

The **FORCE INDEX** hint acts like **USE INDEX (index_list)**, with the addition that a table scan is assumed to be very expensive. In other words, a table scan is used only if there is no way to use one of the named indexes to find rows in the table.

Each hint requires the names of indexes, not the names of columns. To refer to a primary key, use the name **PRIMARY**. To see the index names for a table, use **SHOW INDEX**.

An **index_name** value need not be a full index name. It can be an unambiguous prefix of an index name. If a prefix is ambiguous, an error occurs.

Prior to MySQL 5.1.17, **USE INDEX**, **IGNORE INDEX**, and **FORCE INDEX** affect only which indexes are used when MySQL decides how to find rows in the table and how to process joins. They do not affect whether an index is used when resolving an **ORDER BY** or **GROUP BY** clause.

Examples:

```sql
SELECT * FROM table1 USE INDEX (col1_index,col2_index)
  WHERE col1=1 AND col2=2 AND col3=3;

SELECT * FROM table1 IGNORE INDEX (col3_index)
  WHERE col1=1 AND col2=2 AND col3=3;
```

As of MySQL 5.1.17, the syntax for index hints is extended in the following ways:

- It is syntactically valid to omit **index_list** for **USE INDEX**, which means “use no indexes.” Omitting **index_list** for **FORCE INDEX** or **IGNORE INDEX** is a syntax error.

- You can specify the scope of an index hint by adding a **FOR** clause to the hint. This provides more fine-grained control over the optimizer's selection of an execution plan for various phases of query processing. To affect only the indexes used when MySQL decides how to find rows in the table and how to process joins, use **FOR JOIN**. To influence index usage for sorting or grouping rows, use **FOR ORDER BY** or **FOR GROUP BY**.

- You can specify multiple index hints:

```sql
SELECT * FROM t1 USE INDEX (i1) IGNORE INDEX FOR ORDER BY (i2) ORDER BY a;
```

It is not an error to name the same index in several hints (even within the same hint):

```sql
SELECT * FROM t1 USE INDEX (i1) USE INDEX (i1,i1);
```

However, it is an error to mix **USE INDEX** and **FORCE INDEX** for the same table:

```sql
SELECT * FROM t1 USE INDEX FOR JOIN (i1) FORCE INDEX FOR JOIN (i2);
```

The default scope of index hints also is changed as of MySQL 5.1.17. Formerly, index hints applied only to how indexes are used for retrieval of records and not during resolution of **ORDER BY** or **GROUP BY** clauses. As of 5.1.17, if an index hint includes no **FOR** clause, the hint by default applies to all parts of the statement. For example, this hint:

```sql
IGNORE INDEX (i1)
```

is equivalent to this combination of hints:

```sql
IGNORE INDEX FOR JOIN (i1)
IGNORE INDEX FOR ORDER BY (i1)
IGNORE INDEX FOR GROUP BY (i1)
```

To cause the server to use the older behavior for hint scope when no **FOR** clause is present (so that hints apply only to row retrieval), enable the **old** system variable at server startup. Take care about
enabling this variable in a replication setup. With statement-based binary logging, having different modes for the master and slaves might lead to replication errors.

When index hints are processed, they are collected in a single list by type (USE, FORCE, IGNORE) and by scope (FOR JOIN, FOR ORDER BY, FOR GROUP BY). For example:

```
SELECT * FROM t1
  USE INDEX () IGNORE INDEX (i2) USE INDEX (i1) USE INDEX (i2);
```

is equivalent to:

```
SELECT * FROM t1
  USE INDEX (i1,i2) IGNORE INDEX (i2);
```

The index hints then are applied for each scope in the following order:

1. {USE|FORCE} INDEX is applied if present. (If not, the optimizer-determined set of indexes is used.)

2. IGNORE INDEX is applied over the result of the previous step. For example, the following two queries are equivalent:

```
SELECT * FROM t1 USE INDEX (i1) IGNORE INDEX (i2) USE INDEX (i2);
SELECT * FROM t1 USE INDEX (i1);
```

For FULLTEXT searches, index hints do not work before MySQL 5.1.31. As of 5.1.31, index hints work as follows:

- For natural language mode searches, index hints are silently ignored. For example, IGNORE INDEX(i1) is ignored with no warning and the index is still used.

- For boolean mode searches, index hints with FOR ORDER BY or FOR GROUP BY are silently ignored. Index hints with FOR JOIN or no FOR modifier are honored. In contrast to how hints apply for non-FULLTEXT searches, the hint is used for all phases of query execution (finding rows and retrieval, grouping, and ordering). This is true even if the hint is given for a non-FULLTEXT index.

For example, the following two queries are equivalent:

```
SELECT * FROM t
  USE INDEX (index1)
  IGNORE INDEX (index1) FOR ORDER BY
  IGNORE INDEX (index1) FOR GROUP BY
  WHERE ... IN BOOLEAN MODE ... ;

SELECT * FROM t
  USE INDEX (index1)
  WHERE ... IN BOOLEAN MODE ... ;
```

### 8.10 Buffering and Caching

MySQL uses several strategies that cache information in memory buffers to increase performance.

#### 8.10.1 The MyISAM Key Cache

To minimize disk I/O, the MyISAM storage engine exploits a strategy that is used by many database management systems. It employs a cache mechanism to keep the most frequently accessed table blocks in memory:

- For index blocks, a special structure called the key cache (or key buffer) is maintained. The structure contains a number of block buffers where the most-used index blocks are placed.
• For data blocks, MySQL uses no special cache. Instead it relies on the native operating system file system cache.

This section first describes the basic operation of the MyISAM key cache. Then it discusses features that improve key cache performance and that enable you to better control cache operation:

• Multiple sessions can access the cache concurrently.

• You can set up multiple key caches and assign table indexes to specific caches.

To control the size of the key cache, use the `key_buffer_size` system variable. If this variable is set equal to zero, no key cache is used. The key cache also is not used if the `key_buffer_size` value is too small to allocate the minimal number of block buffers (8).

When the key cache is not operational, index files are accessed using only the native file system buffering provided by the operating system. (In other words, table index blocks are accessed using the same strategy as that employed for table data blocks.)

An index block is a contiguous unit of access to the MyISAM index files. Usually the size of an index block is equal to the size of nodes of the index B-tree. (Indexes are represented on disk using a B-tree data structure. Nodes at the bottom of the tree are leaf nodes. Nodes above the leaf nodes are nonleaf nodes.)

All block buffers in a key cache structure are the same size. This size can be equal to, greater than, or less than the size of a table index block. Usually one these two values is a multiple of the other.

When data from any table index block must be accessed, the server first checks whether it is available in some block buffer of the key cache. If it is, the server accesses data in the key cache rather than on disk. That is, it reads from the cache or writes into it rather than reading from or writing to disk. Otherwise, the server chooses a cache block buffer containing a different table index block (or blocks) and replaces the data there by a copy of required table index block. As soon as the new index block is in the cache, the index data can be accessed.

If it happens that a block selected for replacement has been modified, the block is considered “dirty.” In this case, prior to being replaced, its contents are flushed to the table index from which it came.

Usually the server follows an LRU (Least Recently Used) strategy: When choosing a block for replacement, it selects the least recently used index block. To make this choice easier, the key cache module maintains all used blocks in a special list (LRU chain) ordered by time of use. When a block is accessed, it is the most recently used and is placed at the end of the list. When blocks need to be replaced, blocks at the beginning of the list are the least recently used and become the first candidates for eviction.

The InnoDB storage engine also uses an LRU algorithm, to manage its buffer pool. See Section 8.10.2, “The InnoDB Buffer Pool”.

### 8.10.1.1 Shared Key Cache Access

Threads can access key cache buffers simultaneously, subject to the following conditions:

• A buffer that is not being updated can be accessed by multiple sessions.

• A buffer that is being updated causes sessions that need to use it to wait until the update is complete.

• Multiple sessions can initiate requests that result in cache block replacements, as long as they do not interfere with each other (that is, as long as they need different index blocks, and thus cause different cache blocks to be replaced).

Shared access to the key cache enables the server to improve throughput significantly.
8.10.1.2 Multiple Key Caches

Shared access to the key cache improves performance but does not eliminate contention among sessions entirely. They still compete for control structures that manage access to the key cache buffers. To reduce key cache access contention further, MySQL also provides multiple key caches. This feature enables you to assign different table indexes to different key caches.

Where there are multiple key caches, the server must know which cache to use when processing queries for a given MyISAM table. By default, all MyISAM table indexes are cached in the default key cache. To assign table indexes to a specific key cache, use the CACHE INDEX statement (see Section 13.7.6.2, “CACHE INDEX Syntax”). For example, the following statement assigns indexes from the tables t1, t2, and t3 to the key cache named hot_cache:

```
mysql> CACHE INDEX t1, t2, t3 IN hot_cache;
```

The key cache referred to in a CACHE INDEX statement can be created by setting its size with a SET GLOBAL parameter setting statement or by using server startup options. For example:

```
mysql> SET GLOBAL keycache1.key_buffer_size=128*1024;
```

To destroy a key cache, set its size to zero:

```
mysql> SET GLOBAL keycache1.key_buffer_size=0;
```

You cannot destroy the default key cache. Any attempt to do this is ignored:

```
mysql> SET GLOBAL key_buffer_size = 0;
```

```
mysql> SHOW VARIABLES LIKE 'key_buffer_size';
```

Key cache variables are structured system variables that have a name and components. For keycache1.key_buffer_size, keycache1 is the cache variable name and key_buffer_size is the cache component. See Section 5.1.5.1, “Structured System Variables”, for a description of the syntax used for referring to structured key cache system variables.

By default, table indexes are assigned to the main (default) key cache created at the server startup. When a key cache is destroyed, all indexes assigned to it are reassigned to the default key cache.

For a busy server, you can use a strategy that involves three key caches:

- A “hot” key cache that takes up 20% of the space allocated for all key caches. Use this for tables that are heavily used for searches but that are not updated.
- A “cold” key cache that takes up 20% of the space allocated for all key caches. Use this cache for medium-sized, intensively modified tables, such as temporary tables.
- A “warm” key cache that takes up 60% of the key cache space. Employ this as the default key cache, to be used by default for all other tables.
One reason the use of three key caches is beneficial is that access to one key cache structure does not block access to the others. Statements that access tables assigned to one cache do not compete with statements that access tables assigned to another cache. Performance gains occur for other reasons as well:

- The hot cache is used only for retrieval queries, so its contents are never modified. Consequently, whenever an index block needs to be pulled in from disk, the contents of the cache block chosen for replacement need not be flushed first.

- For an index assigned to the hot cache, if there are no queries requiring an index scan, there is a high probability that the index blocks corresponding to nonleaf nodes of the index B-tree remain in the cache.

- An update operation most frequently executed for temporary tables is performed much faster when the updated node is in the cache and need not be read in from disk first. If the size of the indexes of the temporary tables are comparable with the size of cold key cache, the probability is very high that the updated node is in the cache.

The **CACHE INDEX** statement sets up an association between a table and a key cache, but the association is lost each time the server restarts. If you want the association to take effect each time the server starts, one way to accomplish this is to use an option file: Include variable settings that configure your key caches, and an **init-file** option that names a file containing **CACHE INDEX** statements to be executed. For example:

```sql
key_buffer_size = 4G
hot_cache.key_buffer_size = 2G
cold_cache.key_buffer_size = 2G
init_file=/path/to/data-directory/mysqld_init.sql
```

The statements in `mysqld_init.sql` are executed each time the server starts. The file should contain one SQL statement per line. The following example assigns several tables each to `hot_cache` and `cold_cache`:

```sql
CACHE INDEX db1.t1, db1.t2, db2.t3 IN hot_cache
CACHE INDEX db1.t4, db2.t5, db2.t6 IN cold_cache
```

### 8.10.1.3 Midpoint Insertion Strategy

By default, the key cache management system uses a simple LRU strategy for choosing key cache blocks to be evicted, but it also supports a more sophisticated method called the **midpoint insertion strategy**.

When using the midpoint insertion strategy, the LRU chain is divided into two parts: a hot sublist and a warm sublist. The division point between two parts is not fixed, but the key cache management system takes care that the warm part is not "too short," always containing at least $\text{key_cache_division_limit}$ percent of the key cache blocks. $\text{key_cache_division_limit}$ is a component of structured key cache variables, so its value is a parameter that can be set per cache.

When an index block is read from a table into the key cache, it is placed at the end of the warm sublist. After a certain number of hits (accesses of the block), it is promoted to the hot sublist. At present, the number of hits required to promote a block (3) is the same for all index blocks.

A block promoted into the hot sublist is placed at the end of the list. The block then circulates within this sublist. If the block stays at the beginning of the sublist for a long enough time, it is demoted to the warm sublist. This time is determined by the value of the $\text{key_cache_age_threshold}$ component of the key cache.

The threshold value prescribes that, for a key cache containing $N$ blocks, the block at the beginning of the hot sublist not accessed within the last $N \times \text{key_cache_age_threshold} / 100$ hits is to be
moved to the beginning of the warm sublist. It then becomes the first candidate for eviction, because blocks for replacement always are taken from the beginning of the warm sublist.

The midpoint insertion strategy enables you to keep more-valued blocks always in the cache. If you prefer to use the plain LRU strategy, leave the `key_cache_division_limit` value set to its default of 100.

The midpoint insertion strategy helps to improve performance when execution of a query that requires an index scan effectively pushes out of the cache all the index blocks corresponding to valuable high-level B-tree nodes. To avoid this, you must use a midpoint insertion strategy with the `key_cache_division_limit` set to much less than 100. Then valuable frequently hit nodes are preserved in the hot sublist during an index scan operation as well.

### 8.10.1.4 Index Preloading

If there are enough blocks in a key cache to hold blocks of an entire index, or at least the blocks corresponding to its nonleaf nodes, it makes sense to preload the key cache with index blocks before starting to use it. Preloading enables you to put the table index blocks into a key cache buffer in the most efficient way: by reading the index blocks from disk sequentially.

Without preloading, the blocks are still placed into the key cache as needed by queries. Although the blocks will stay in the cache, because there are enough buffers for all of them, they are fetched from disk in random order, and not sequentially.

To preload an index into a cache, use the `LOAD INDEX INTO CACHE` statement. For example, the following statement preloads nodes (index blocks) of indexes of the tables `t1` and `t2`:

```sql
mysql> LOAD INDEX INTO CACHE t1, t2 IGNORE LEAVES;
```

<table>
<thead>
<tr>
<th>Table</th>
<th>Op</th>
<th>Msg_type</th>
<th>Msg_text</th>
</tr>
</thead>
<tbody>
<tr>
<td>test.t1</td>
<td>preload_keys</td>
<td>status</td>
<td>OK</td>
</tr>
<tr>
<td>test.t2</td>
<td>preload_keys</td>
<td>status</td>
<td>OK</td>
</tr>
</tbody>
</table>

The `IGNORE LEAVES` modifier causes only blocks for the nonleaf nodes of the index to be preloaded. Thus, the statement shown preloads all index blocks from `t1`, but only blocks for the nonleaf nodes from `t2`.

If an index has been assigned to a key cache using a `CACHE INDEX` statement, preloading places index blocks into that cache. Otherwise, the index is loaded into the default key cache.

### 8.10.1.5 Key Cache Block Size

It is possible to specify the size of the block buffers for an individual key cache using the `key_cache_block_size` variable. This permits tuning of the performance of I/O operations for index files.

The best performance for I/O operations is achieved when the size of read buffers is equal to the size of the native operating system I/O buffers. But setting the size of key nodes equal to the size of the I/O buffer does not always ensure the best overall performance. When reading the big leaf nodes, the server pulls in a lot of unnecessary data, effectively preventing reading other leaf nodes.

To control the size of blocks in the `.MYI` index file of MyISAM tables, use the `--myisam-block-size` option at server startup.

### 8.10.1.6 Restructuring a Key Cache

A key cache can be restructured at any time by updating its parameter values. For example:
If you assign to either the `key_buffer_size` or `key_cache_block_size` key cache component a value that differs from the component's current value, the server destroys the cache's old structure and creates a new one based on the new values. If the cache contains any dirty blocks, the server saves them to disk before destroying and re-creating the cache. Restructuring does not occur if you change other key cache parameters.

When restructuring a key cache, the server first flushes the contents of any dirty buffers to disk. After that, the cache contents become unavailable. However, restructuring does not block queries that need to use indexes assigned to the cache. Instead, the server directly accesses the table indexes using native file system caching. File system caching is not as efficient as using a key cache, so although queries execute, a slowdown can be anticipated. After the cache has been restructured, it becomes available again for caching indexes assigned to it, and the use of file system caching for the indexes ceases.

### 8.10.2 The InnoDB Buffer Pool

InnoDB maintains a buffer pool for caching data and indexes in memory. InnoDB manages the pool as a list, using a least recently used (LRU) algorithm incorporating a midpoint insertion strategy. When room is needed to add a new block to the pool, InnoDB evicts the least recently used block and adds the new block to the middle of the list. The midpoint insertion strategy in effect causes the list to be treated as two sublists:

- At the head, a sublist of “new” (or “young”) blocks that have been recently used.
- At the tail, a sublist of “old” blocks that are less recently used.

As a result of the algorithm, the new sublist contains blocks that are heavily used by queries. The old sublist contains less-used blocks, and candidates for eviction are taken from this sublist.

The LRU algorithm operates as follows by default:

- 3/8 of the buffer pool is devoted to the old sublist.
- The midpoint of the list is the boundary where the tail of the new sublist meets the head of the old sublist.
- When InnoDB reads a block into the buffer pool, it initially inserts it at the midpoint (the head of the old sublist). A block can be read in as a result of two types of read requests: Because it is required (for example, to satisfy query execution), or as part of read-ahead performed in anticipation that it will be required.
- The first access to a block in the old sublist makes it “young”, causing it to move to the head of the buffer pool (the head of the new sublist). If the block was read in because it was required, the first access occurs immediately and the block is made young. If the block was read in due to read-ahead, the first access does not occur immediately (and might not occur at all before the block is evicted).
- As long as no accesses occur for a block in the pool, it “ages” by moving toward the tail of the list. Blocks in both the new and old sublists age as other blocks are made new. Blocks in the old sublist also age as blocks are inserted at the midpoint. Eventually, a block that remains unused for long enough reaches the tail of the old sublist and is evicted.

In the default operation of the buffer pool, a block when read in is loaded at the midpoint and then moved immediately to the head of the new sublist as soon as an access occurs. In the case of a table scan (such as performed for a `mysqldump` operation), each block read by the scan ends up moving to the head of the new sublist because multiple rows are accessed from each block. This occurs even for a one-time scan, where the blocks are not otherwise used by other queries. Blocks may also be loaded by the read-ahead background thread and then moved to the head of the new sublist by a single access. These effects can be disadvantageous because they push blocks that are in heavy use by other queries out of the new sublist to the old sublist where they become subject to eviction.
Several InnoDB system variables control the size of the buffer pool and let you tune the LRU algorithm:

- **innodb_buffer_pool_size**

  Specifies the size of the buffer pool. If your buffer pool is small and you have sufficient memory, making the pool larger can improve performance by reducing the amount of disk I/O needed as queries access InnoDB tables.

- **innodb_old_blocks_pct**

  Specifies the approximate percentage of the buffer pool that InnoDB uses for the old block sublist. The range of values is 5 to 95. The default value is 37 (that is, 3/8 of the pool).

- **innodb_old_blocks_time**

  Specifies how long in milliseconds (ms) a block inserted into the old sublist must stay there after its first access before it can be moved to the new sublist. The default value is 0: A block inserted into the old sublist moves to the new sublist when InnoDB has evicted 1/4 of the inserted block's pages from the buffer pool, no matter how soon after insertion the access occurs. If the value is greater than 0, blocks remain in the old sublist until an access occurs at least that many ms after the first access. For example, a value of 1000 causes blocks to stay in the old sublist for 1 second after the first access before they become eligible to move to the new sublist.

  `innodb_old_blocks_pct` and `innodb_old_blocks_time` are available as of MySQL 5.1.41, but only for InnoDB Plugin, not the built-in version of InnoDB.

  By setting `innodb_old_blocks_time` greater than 0, you can prevent one-time table scans from flooding the new sublist with blocks used only for the scan. Rows in a block read in for a scan are accessed rapidly many times in succession, but the block is unused after that. If `innodb_old_blocks_time` is set to a value greater than the block scan time, the block is not moved to the new sublist during the table scan. Instead, it remains in the old sublist and ages to the tail of the list to be evicted quickly. This way, blocks used only for a one-time scan do not act to the detriment of heavily used blocks in the new sublist.

  `innodb_old_blocks_time` can be set at runtime, so you can change it temporarily while performing operations such as table scans and dumps to prevent them from flooding the new sublist:

  ```sql
  SET GLOBAL innodb_old_blocks_time = 1000;
  ... perform queries that scan tables ... 
  SET GLOBAL innodb_old_blocks_time = 0;
  ```

  This strategy does not apply if your intent is to fill the buffer pool with a table's content. For example, you might perform a table or index scan at server startup or during benchmarking or testing specifically to “warm up” the buffer pool. In this case, leaving `innodb_old_blocks_time` set to 0 accomplishes the goal of loading the scanned blocks into the new sublist.

  The output from the InnoDB Standard Monitor contains several fields in the BUFFER POOL AND MEMORY section that pertain to operation of the buffer pool LRU algorithm:

  - **Old database pages:** The number of pages in the old sublist of the buffer pool.

  - **Pages made young, not young:** The number of old pages that were moved to the head of the buffer pool (the new sublist), and the number of pages that have remained in the old sublist without being made new.

  - **youngs/s non-youngs/s:** The number of accesses to old pages that have resulted in making them young or not. This metric differs from that of the previous item in two ways. First, it relates only to old pages. Second, it is based on number of accesses to pages and not the number of pages. (There can be multiple accesses to a given page, all of which are counted.)
The MySQL Query Cache

- **young-making rate**: Hits that cause blocks to move to the head of the buffer pool.
- **not**: Hits that do not cause blocks to move to the head of the buffer pool (due to the delay not being met).

The young-making rate and not rate will not normally add up to the overall buffer pool hit rate. Hits for blocks in the old sublist cause them to move to the new sublist, but hits to blocks in the new sublist cause them to move to the head of the list only if they are a certain distance from the head.

The preceding information from the Monitor can help you make LRU tuning decisions:

- If you see very low youngs/s values when you do not have large scans going on, that indicates that you might need to either reduce the delay time, or increase the percentage of the buffer pool used for the old sublist. Increasing the percentage makes the old sublist larger, so blocks in that sublist take longer to move to the tail and be evicted. This increases the likelihood that they will be accessed again and be made young.

- If you do not see a lot of non-youngs/s when you are doing large table scans (and lots of youngs/s), you will want to tune your delay value to be larger.

For more information about InnoDB Monitors, see Section 14.6.9, “InnoDB Monitors”.

The **MyISAM** storage engine also uses an LRU algorithm, to manage its key cache. See Section 8.10.1, “The MyISAM Key Cache”.

### 8.10.3 The MySQL Query Cache

The query cache stores the text of a `SELECT` statement together with the corresponding result that was sent to the client. If an identical statement is received later, the server retrieves the results from the query cache rather than parsing and executing the statement again. The query cache is shared among sessions, so a result set generated by one client can be sent in response to the same query issued by another client.

The query cache can be useful in an environment where you have tables that do not change very often and for which the server receives many identical queries. This is a typical situation for many Web servers that generate many dynamic pages based on database content.

The query cache does not return stale data. When tables are modified, any relevant entries in the query cache are flushed.

**Note**
The query cache does not work in an environment where you have multiple `mysqld` servers updating the same MyISAM tables.

**Note**
As of MySQL 5.1.17, the query cache is used for prepared statements under the conditions described in Section 8.10.3.1, “How the Query Cache Operates”. Before 5.1.17, the query cache is not used for prepared statements.

**Note**
As of MySQL 5.1.63, the query cache is not supported for partitioned tables, and is automatically disabled for queries involving partitioned tables. The query cache cannot be enabled for such queries. (Bug #53775)

Some performance data for the query cache follows. These results were generated by running the MySQL benchmark suite on a Linux Alpha 2×500MHz system with 2GB RAM and a 64MB query cache.
• If all the queries you are performing are simple (such as selecting a row from a table with one row), but still differ so that the queries cannot be cached, the overhead for having the query cache active is 13%. This could be regarded as the worst case scenario. In real life, queries tend to be much more complicated, so the overhead normally is significantly lower.

• Searches for a single row in a single-row table are 238% faster with the query cache than without it. This can be regarded as close to the minimum speedup to be expected for a query that is cached.

To disable the query cache at server startup, set the `query_cache_size` system variable to 0. By disabling the query cache code, there is no noticeable overhead. If you build MySQL from source, query cache capabilities can be excluded from the server entirely by invoking `configure` with the `--without-query-cache` option.

The query cache offers the potential for substantial performance improvement, but you should not assume that it will do so under all circumstances. With some query cache configurations or server workloads, you might actually see a performance decrease:

• Be cautious about sizing the query cache excessively large, which increases the overhead required to maintain the cache, possibly beyond the benefit of enabling it. Sizes in tens of megabytes are usually beneficial. Sizes in the hundreds of megabytes might not be.

• Server workload has a significant effect on query cache efficiency. A query mix consisting almost entirely of a fixed set of `SELECT` statements is much more likely to benefit from enabling the cache than a mix in which frequent `INSERT` statements cause continual invalidation of results in the cache. In some cases, a workaround is to use the `SQL_NO_CACHE` option to prevent results from even entering the cache for `SELECT` statements that use frequently modified tables. (See Section 8.10.3.2, “Query Cache SELECT Options”.)

To verify that enabling the query cache is beneficial, test the operation of your MySQL server with the cache enabled and disabled. Then retest periodically because query cache efficiency may change as server workload changes.

### 8.10.3.1 How the Query Cache Operates

This section describes how the query cache works when it is operational. Section 8.10.3.3, “Query Cache Configuration”, describes how to control whether it is operational.

Incoming queries are compared to those in the query cache before parsing, so the following two queries are regarded as different by the query cache:

```
SELECT * FROM tbl_name
Select * from tbl_name
```

Queries must be exactly the same (byte for byte) to be seen as identical. In addition, query strings that are identical may be treated as different for other reasons. Queries that use different databases, different protocol versions, or different default character sets are considered different queries and are cached separately.

The cache is not used for queries of the following types:

• Queries that are a subquery of an outer query

• Queries executed within the body of a stored function, trigger, or event

Before a query result is fetched from the query cache, MySQL checks whether the user has `SELECT` privilege for all databases and tables involved. If this is not the case, the cached result is not used.

If a query result is returned from query cache, the server increments the `Qcache_hits` status variable, not `Com_select`. See Section 8.10.3.4, “Query Cache Status and Maintenance”. 
If a table changes, all cached queries that use the table become invalid and are removed from the cache. This includes queries that use MERGE tables that map to the changed table. A table can be changed by many types of statements, such as INSERT, UPDATE, DELETE, TRUNCATE TABLE, ALTER TABLE, DROP TABLE, or DROP DATABASE.

The query cache also works within transactions when using InnoDB tables.

The result from a SELECT query on a view is cached.

The query cache works for SELECT SQL_CALC_FOUND_ROWS ... queries and stores a value that is returned by a following SELECT FOUND_ROWS() query. FOUND_ROWS() returns the correct value even if the preceding query was fetched from the cache because the number of found rows is also stored in the cache. The SELECT FOUND_ROWS() query itself cannot be cached.

Before MySQL 5.1.17, prepared statements do not use the query cache. Beginning with 5.1.17, prepared statements use the query cache under certain conditions, which differ depending on the preparation method:

• Statements that are issued using the binary protocol using mysql_stmt_prepare() and mysql_stmt_execute(). See Section 21.8.8, "C API Prepared Statements".

For a prepared statement executed using the binary protocol, comparison with statements in the query cache is based on the text of the statement after expansion of ? parameter markers. The statement is compared only with other cached statements that were executed using the binary protocol. That is, for query cache purposes, statements issued using the binary protocol are distinct from statements issued using the text protocol.

• Statements that are issued using the text (nonbinary) protocol using PREPARE and EXECUTE. See Section 13.5, "SQL Syntax for Prepared Statements". These are denoted SQL PS statements here.

Before MySQL 5.1.21, for a prepared statement executed using PREPARE and EXECUTE, it is not cached if it contains any ? parameter markers. In that case, the statement after parameter expansion contains references to user variables, which prevents caching, even for nonprepared statements. If the statement contains no parameter markers, the statement is compared with statements in the query cache that were executed using the text protocol (that is, it is compared with other SQL PS statements and nonprepared statements). As of MySQL 5.1.21, this limitation is lifted and prepared statements that contain parameter markers can be cached because expansion directly substitutes the user variable values.

A query cannot be cached if it contains any of the functions shown in the following table.

<table>
<thead>
<tr>
<th>Function</th>
<th>Function</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>BENCHMARK()</td>
<td>CONNECTION_ID()</td>
<td>CONVERT_TZ()</td>
</tr>
<tr>
<td>CURDATE()</td>
<td>CURRENT_DATE()</td>
<td>CURRENT_TIME()</td>
</tr>
<tr>
<td>CURRENT_TIMESTAMP()</td>
<td>CURRENT_USER()</td>
<td>CURTIME()</td>
</tr>
<tr>
<td>DATABASE()</td>
<td>ENCRYPT() with one parameter</td>
<td>FOUND_ROWS()</td>
</tr>
<tr>
<td>GET_LOCK()</td>
<td>IS_FREE_LOCK()</td>
<td>IS_USED_LOCK()</td>
</tr>
<tr>
<td>LAST_INSERT_ID()</td>
<td>LOAD_FILE()</td>
<td>MASTER_POS_WAIT()</td>
</tr>
<tr>
<td>NOW()</td>
<td>RAND()</td>
<td>RELEASE_ALL_LOCKS()</td>
</tr>
<tr>
<td>RELEASE_LOCK()</td>
<td>SLEEP()</td>
<td>SYSDATE()</td>
</tr>
<tr>
<td>UNIX_TIMESTAMP() with no</td>
<td>USER()</td>
<td>UUID()</td>
</tr>
<tr>
<td>parameters</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

A query also is not cached under these conditions:

• It refers to user-defined functions (UDFs) or stored functions.
The MySQL Query Cache

- It refers to user variables or local stored program variables.
- It refers to tables in the **mysql** or **INFORMATION_SCHEMA** system database.
- *(MySQL 5.1.63 and later)* It refers to any partitioned tables.
- It is of any of the following forms:
  
  ```
  SELECT ... LOCK IN SHARE MODE
  SELECT ... FOR UPDATE
  SELECT ... INTO OUTFILE ...
  SELECT ... INTO DUMPFILE ...
  SELECT * FROM ... WHERE autoincrement_col IS NULL
  ```

  The last form is not cached because it is used as the ODBC workaround for obtaining the last insert ID value. See the Connector/ODBC section of Chapter 21, Connectors and APIs.

  Statements within transactions that use **SERIALIZABLE** isolation level also cannot be cached because they use **LOCK IN SHARE MODE** locking.

- It uses **TEMPORARY** tables.
- It does not use any tables.
- It generates warnings.
- The user has a column-level privilege for any of the involved tables.

### 8.10.3.2 Query Cache SELECT Options

Two query cache-related options may be specified in **SELECT** statements:

- **SQL_CACHE**

  The query result is cached if it is cacheable and the value of the **query_cache_type** system variable is **ON** or **DEMAND**.

- **SQL_NO_CACHE**

  The server does not use the query cache. It neither checks the query cache to see whether the result is already cached, nor does it cache the query result. (Due to a limitation in the parser, a space character must precede and follow the **SQL_NO_CACHE** keyword; a nonspace such as a newline causes the server to check the query cache to see whether the result is already cached.)

Examples:

```sql
SELECT SQL_CACHE id, name FROM customer;
SELECT SQL_NO_CACHE id, name FROM customer;
```

### 8.10.3.3 Query Cache Configuration

The **have_query_cache** server system variable indicates whether the query cache is available:

```sql
mysql> SHOW VARIABLES LIKE 'have_query_cache';
+------------------+-------+
| Variable_name     | Value |
+------------------+-------+
| have_query_cache  | YES   |
+------------------+-------+
```

When using a standard MySQL binary, this value is always **YES**, even if query caching is disabled.
Several other system variables control query cache operation. These can be set in an option file or on the command line when starting `mysqld`. The query cache system variables all have names that begin with `query_cache_`. They are described briefly in Section 5.1.4, “Server System Variables”, with additional configuration information given here.

To set the size of the query cache, set the `query_cache_size` system variable. Setting it to 0 disables the query cache. The default size is 0, so the query cache is disabled by default.

Be careful not to set the size of the cache too large. Due to the need for threads to lock the cache during updates, you may see lock contention issues with a very large cache.

Note

When using the Windows Configuration Wizard to install or configure MySQL, the default value for `query_cache_size` will be configured automatically for you based on the different configuration types available. When using the Windows Configuration Wizard, the query cache may be enabled (that is, set to a nonzero value) due to the selected configuration. The query cache is also controlled by the setting of the `query_cache_type` variable. You should check the values of these variables as set in your `my.ini` file after configuration has taken place.

When you set `query_cache_size` to a nonzero value, keep in mind that the query cache needs a minimum size of about 40KB to allocate its structures. (The exact size depends on system architecture.) If you set the value too small, you'll get a warning, as in this example:

```
mysql> SET GLOBAL query_cache_size = 40000;
Query OK, 0 rows affected, 1 warning (0.00 sec)
mysql> SHOW WARNINGS
+------------------+-----------------------------+
| Level            | Code | Message                        |
+------------------+-----------------------------+
| Warning          | 1282 | Query cache failed to set size 39936; new query cache size is 0 |
mysql> SET GLOBAL query_cache_size = 41984;
Query OK, 0 rows affected (0.00 sec)
mysql> SHOW VARIABLES LIKE 'query_cache_size';
+------------------+--------+
| Variable_name    | Value  |
+------------------+--------+
| query_cache_size | 41984  |
+------------------+--------+
```

For the query cache to actually be able to hold any query results, its size must be set larger:

```
mysql> SET GLOBAL query_cache_size = 1000000;
Query OK, 0 rows affected (0.04 sec)
mysql> SHOW VARIABLES LIKE 'query_cache_size';
+------------------+--------+
| Variable_name    | Value  |
+------------------+--------+
| query_cache_size | 999424 |
+------------------+--------+
```

The `query_cache_size` value is aligned to the nearest 1024 byte block. The value reported may therefore be different from the value that you assign.

If the query cache size is greater than 0, the `query_cache_type` variable influences how it works. This variable can be set to the following values:
• A value of 0 or OFF prevents caching or retrieval of cached results.

• A value of 1 or ON enables caching except of those statements that begin with SELECT SQL_NO_CACHE.

• A value of 2 or DEMAND causes caching of only those statements that begin with SELECT SQL_CACHE.

Setting the GLOBAL query_cache_type value determines query cache behavior for all clients that connect after the change is made. Individual clients can control cache behavior for their own connection by setting the SESSION query_cache_type value. For example, a client can disable use of the query cache for its own queries like this:

mysql> SET SESSION query_cache_type = OFF;

If you set query_cache_type at server startup (rather than at runtime with a SET statement), only the numeric values are permitted.

To control the maximum size of individual query results that can be cached, set the query_cache_limit system variable. The default value is 1MB.

Note

You can set the maximum size that can be specified for the query cache at runtime with the SET statement by using the --maximum-query_cache_size=32M option on the command line or in the configuration file.

When a query is to be cached, its result (the data sent to the client) is stored in the query cache during result retrieval. Therefore the data usually is not handled in one big chunk. The query cache allocates blocks for storing this data on demand, so when one block is filled, a new block is allocated. Because memory allocation operation is costly (timewise), the query cache allocates blocks with a minimum size given by the query_cache_min_res_unit system variable. When a query is executed, the last result block is trimmed to the actual data size so that unused memory is freed. Depending on the types of queries your server executes, you might find it helpful to tune the value of query_cache_min_res_unit:

• The default value of query_cache_min_res_unit is 4KB. This should be adequate for most cases.

• If you have a lot of queries with small results, the default block size may lead to memory fragmentation, as indicated by a large number of free blocks. Fragmentation can force the query cache to prune (delete) queries from the cache due to lack of memory. In this case, you should decrease the value of query_cache_min_res_unit. The number of free blocks and queries removed due to pruning are given by the values of the Qcache_free_blocks and Qcache_lowmem_prunes status variables.

• If most of your queries have large results (check the Qcache_total_blocks and Qcache_queries_in_cache status variables), you can increase performance by increasing query_cache_min_res_unit. However, be careful to not make it too large (see the previous item).

8.10.3.4 Query Cache Status and Maintenance

To check whether the query cache is present in your MySQL server, use the following statement:

mysql> SHOW VARIABLES LIKE 'have_query_cache';
You can defragment the query cache to better utilize its memory with the `FLUSH QUERY CACHE` statement. The statement does not remove any queries from the cache.

The `RESET QUERY CACHE` statement removes all query results from the query cache. The `FLUSH TABLES` statement also does this.

To monitor query cache performance, use `SHOW STATUS` to view the cache status variables:

```
mysql> SHOW STATUS LIKE 'Qcache%';
+-------------------------+--------+
| Variable_name           | Value  |
+-------------------------+--------+
| Qcache_free_blocks      | 36     |
| Qcache_free_memory      | 138488 |
| Qcache_hits             | 79570  |
| Qcache_inserts          | 27087  |
| Qcache_lowmem_prunes    | 3114   |
| Qcache_not_cached       | 22989  |
| Qcache_queries_in_cache | 415    |
| Qcache_total_blocks     | 912    |
+-------------------------+--------+
```

Descriptions of each of these variables are given in Section 5.1.6, “Server Status Variables”. Some uses for them are described here.

The total number of `SELECT` queries is given by this formula:

\[
\text{Com_select} = \text{Qcache_hits} + \text{queries with errors found by parser}
\]

The `Com_select` value is given by this formula:

\[
\text{Qcache_inserts} + \text{Qcache_not_cached} + \text{queries with errors found during the column-privileges check}
\]

The query cache uses variable-length blocks, so `Qcache_total_blocks` and `Qcache_free_blocks` may indicate query cache memory fragmentation. After `FLUSH QUERY CACHE`, only a single free block remains.

Every cached query requires a minimum of two blocks (one for the query text and one or more for the query results). Also, every table that is used by a query requires one block. However, if two or more queries use the same table, only one table block needs to be allocated.

The information provided by the `Qcache_lowmem_prunes` status variable can help you tune the query cache size. It counts the number of queries that have been removed from the cache to free up memory for caching new queries. The query cache uses a least recently used (LRU) strategy to decide which queries to remove from the cache. Tuning information is given in Section 8.10.3.3, “Query Cache Configuration”.

### 8.11 Optimizing Locking Operations

When your database is busy with multiple sessions reading and writing data, the mechanism that controls access to data files and memory areas can become a consideration for performance tuning. Otherwise, sessions can spend time waiting for access to resources when they could be running concurrently.
MySQL manages contention for table contents using locking:

- Internal locking is performed within the MySQL server itself to manage contention for table contents by multiple threads. This type of locking is internal because it is performed entirely by the server and involves no other programs. See Section 8.11.1, “Internal Locking Methods”.

- External locking occurs when the server and other programs lock MyISAM table files to coordinate among themselves which program can access the tables at which time. See Section 8.11.4, “External Locking”.

### 8.11.1 Internal Locking Methods

This section discusses internal locking; that is, locking performed within the MySQL server itself to manage contention for table contents by multiple sessions. This type of locking is internal because it is performed entirely by the server and involves no other programs. External locking occurs when the server and other programs lock MyISAM table files to coordinate among themselves which program can access the tables at which time. See Section 8.11.4, “External Locking”.

MySQL uses row-level locking for InnoDB tables to support simultaneous write access by multiple sessions, making them suitable for multi-user, highly concurrent, and OLTP applications. MySQL uses table-level locking for MyISAM, MEMORY, and MERGE tables, permitting only one session to update those tables at a time. This locking level makes these storage engines more suitable for read-only, read-mostly, or single-user applications.

**Considerations for Table Locking**

Table locking in MySQL is deadlock-free for storage engines that use table-level locking. Deadlock avoidance is managed by always requesting all needed locks at once at the beginning of a query and always locking the tables in the same order.

MySQL grants table write locks as follows:

1. If there are no locks on the table, put a write lock on it.
2. Otherwise, put the lock request in the write lock queue.

MySQL grants table read locks as follows:

1. If there are no write locks on the table, put a read lock on it.
2. Otherwise, put the lock request in the read lock queue.

Table updates are given higher priority than table retrievals. Therefore, when a lock is released, the lock is made available to the requests in the write lock queue and then to the requests in the read lock queue. This ensures that updates to a table are not “starved” even when there is heavy SELECT activity for the table. However, if there are many updates for a table, SELECT statements wait until there are no more updates.

For information on altering the priority of reads and writes, see Section 8.11.2, “Table Locking Issues”.

You can analyze the table lock contention on your system by checking the `Table_locks_immediate` and `Table_locks_waited` status variables, which indicate the number of times that requests for table locks could be granted immediately and the number that had to wait, respectively:

```sql
mysql> SHOW STATUS LIKE 'Table%';
+-----------------------+---------+
| Variable_name         | Value   |
+-----------------------+---------+
| Table_locks_immediate | 1151552 |
| Table_locks_waited    | 15324   |
+-----------------------+---------+
```
The **MyISAM** storage engine supports concurrent inserts to reduce contention between readers and writers for a given table: If a **MyISAM** table has no free blocks in the middle of the data file, rows are always inserted at the end of the data file. In this case, you can freely mix concurrent **INSERT** and **SELECT** statements for a **MyISAM** table without locks. That is, you can insert rows into a **MyISAM** table at the same time other clients are reading from it. Holes can result from rows having been deleted from or updated in the middle of the table. If there are holes, concurrent inserts are disabled but are enabled again automatically when all holes have been filled with new data. This behavior is altered by the `concurrent_insert` system variable. See Section 8.11.3, “Concurrent Inserts”.

If you acquire a table lock explicitly with **LOCK TABLES**, you can request a **READ LOCAL** lock rather than a **READ** lock to enable other sessions to perform concurrent inserts while you have the table locked.

To perform many **INSERT** and **SELECT** operations on a table `t1` when concurrent inserts are not possible, you can insert rows into a temporary table `temp_t1` and update the real table with the rows from the temporary table:

```sql
mysql> LOCK TABLES t1 WRITE, temp_t1 WRITE;
mysql> INSERT INTO t1 SELECT * FROM temp_t1;
mysql> DELETE FROM temp_t1;
mysql> UNLOCK TABLES;
```

**InnoDB** uses row locks. Deadlocks are possible for **InnoDB** because it automatically acquires locks during the processing of SQL statements, not at the start of the transaction.

### Considerations for Row Locking

**Advantages of row-level locking:**

- Fewer lock conflicts when different sessions access different rows
- Fewer changes for rollbacks
- Possible to lock a single row for a long time

**Disadvantages of row-level locking:**

- Requires more memory than table-level locks
- Slower than table-level locks when used on a large part of the table because you must acquire many more locks
- Slower than other locks if you often do **GROUP BY** operations on a large part of the data or if you must scan the entire table frequently

### Choosing the Type of Locking

Generally, table locks are superior to row-level locks in the following cases:

- Most statements for the table are reads
- Statements for the table are a mix of reads and writes, where writes are updates or deletes for a single row that can be fetched with one key read:
  ```sql
  UPDATE tbl_name SET column=value WHERE unique_key_col=key_value;
  DELETE FROM tbl_name WHERE unique_key_col=key_value;
  ```
- **SELECT** combined with concurrent **INSERT** statements, and very few **UPDATE** or **DELETE** statements
- Many scans or **GROUP BY** operations on the entire table without any writers
With higher-level locks, you can more easily tune applications by supporting locks of different types, because the lock overhead is less than for row-level locks.

Options other than row-level locking:

- Versioning (such as that used in MySQL for concurrent inserts) where it is possible to have one writer at the same time as many readers. This means that the database or table supports different views for the data depending on when access begins. Other common terms for this are “time travel,” “copy on write,” or “copy on demand.”

- Copy on demand is in many cases superior to row-level locking. However, in the worst case, it can use much more memory than using normal locks.

- Instead of using row-level locks, you can employ application-level locks, such as those provided by `GET_LOCK()` and `RELEASE_LOCK()` in MySQL. These are advisory locks, so they work only with applications that cooperate with each other. See Section 12.16, “Miscellaneous Functions”.

### 8.11.2 Table Locking Issues

To achieve a very high lock speed, MySQL uses table locking (instead of page, row, or column locking) for all storage engines except InnoDB and NDB.

For InnoDB tables, MySQL uses table locking only if you explicitly lock the table with `LOCK TABLES`. For this storage engine, avoid using `LOCK TABLES` at all, because InnoDB uses automatic row-level locking to ensure transaction isolation.

For large tables, table locking is often better than row locking, but there are some disadvantages:

- Table locking enables many sessions to read from a table at the same time, but if a session wants to write to a table, it must first get exclusive access. During the update, all other sessions that want to access this particular table must wait until the update is done.

- Table locking causes problems in cases such as when a session is waiting because the disk is full and free space needs to become available before the session can proceed. In this case, all sessions that want to access the problem table are also put in a waiting state until more disk space is made available.

Table locking is also disadvantageous under the following scenario:

- A session issues a `SELECT` that takes a long time to run.

- Another session then issues an `UPDATE` on the same table. This session waits until the `SELECT` is finished.

- Another session issues another `SELECT` statement on the same table. Because `UPDATE` has higher priority than `SELECT`, this `SELECT` waits for the `UPDATE` to finish, after waiting for the first `SELECT` to finish.

The following items describe some ways to avoid or reduce contention caused by table locking:

- Try to get the `SELECT` statements to run faster so that they lock tables for a shorter time. You might have to create some summary tables to do this.

- Start `mysqld` with `--low-priority-updates`. For storage engines that use only table-level locking (such as MyISAM, MEMORY, and MERGE), this gives all statements that update (modify) a table lower priority than `SELECT` statements. In this case, the second `SELECT` statement in the preceding scenario would execute before the `UPDATE` statement, and would not need to wait for the first `SELECT` to finish.

- To specify that all updates issued in a specific connection should be done with low priority, set the `low_priority_updates` server system variable equal to 1.
• To give a specific **INSERT**, **UPDATE**, or **DELETE** statement lower priority, use the **LOW_PRIORITY** attribute.

• To give a specific **SELECT** statement higher priority, use the **HIGH_PRIORITY** attribute. See Section 13.2.8, “**SELECT Syntax**”.

• Start `mysqld` with a low value for the **max_write_lock_count** system variable to temporarily elevate the priority of all **SELECT** statements that are waiting for a table after a specific number of inserts to the table occur. This permits **READ** locks after a certain number of **WRITE** locks.

• If you have problems with **INSERT** combined with **SELECT**, consider switching to **MyISAM** tables, which support concurrent **SELECT** and **INSERT** statements. (See Section 8.11.3, “Concurrent Inserts”.)

• If you mix inserts and deletes on the same table, **INSERT DELAYED** may be of great help. See Section 13.2.5.2, “**INSERT DELAYED Syntax**”.

• If you have problems with mixed **SELECT** and **DELETE** statements, the **LIMIT** option to **DELETE** may help. See Section 13.2.2, “**DELETE Syntax**”.

• Using **SQL_BUFFER_RESULT** with **SELECT** statements can help to make the duration of table locks shorter. See Section 13.2.8, “**SELECT Syntax**”.

• You could change the locking code in `mysys/thr_lock.c` to use a single queue. In this case, write locks and read locks would have the same priority, which might help some applications.

Here are some tips concerning table locks in MySQL:

• Concurrent users are not a problem if you do not mix updates with selects that need to examine many rows in the same table.

• You can use **LOCK TABLES** to increase speed, because many updates within a single lock is much faster than updating without locks. Splitting table contents into separate tables may also help.

• If you encounter speed problems with table locks in MySQL, you may be able to improve performance by converting some of your tables to **InnoDB**. See Section 14.6, “**The InnoDB Storage Engine**”.

### 8.11.3 Concurrent Inserts

The **MyISAM** storage engine supports concurrent inserts to reduce contention between readers and writers for a given table: If a **MyISAM** table has no holes in the data file (deleted rows in the middle), an **INSERT** statement can be executed to add rows to the end of the table at the same time that **SELECT** statements are reading rows from the table. If there are multiple **INSERT** statements, they are queued and performed in sequence, concurrently with the **SELECT** statements. The results of a concurrent **INSERT** may not be visible immediately.

The **concurrent_insert** system variable can be set to modify the concurrent-insert processing. By default, the variable is set to 1 and concurrent inserts are handled as just described. If **concurrent_insert** is set to 0, concurrent inserts are disabled. If the variable is set to 2, concurrent inserts at the end of the table are permitted even for tables that have deleted rows. See also the description of the **concurrent_insert** system variable.

Under circumstances where concurrent inserts can be used, there is seldom any need to use the **DELAYED** modifier for **INSERT** statements. See Section 13.2.5.2, “**INSERT DELAYED Syntax**”.

If you are using the binary log, concurrent inserts are converted to normal inserts for **CREATE ... SELECT** or **INSERT ... SELECT** statements. This is done to ensure that you can re-create an exact copy of your tables by applying the log during a backup operation. See Section 5.4.4, “**The Binary Log**”. In addition, for those statements a read lock is placed on the selected-from table such that inserts into that table are blocked. The effect is that concurrent inserts for that table must wait as well.
With **LOAD DATA INFILE**, if you specify **CONCURRENT** with a **MyISAM** table that satisfies the condition for concurrent inserts (that is, it contains no free blocks in the middle), other sessions can retrieve data from the table while **LOAD DATA** is executing. Use of the **CONCURRENT** option affects the performance of **LOAD DATA** a bit, even if no other session is using the table at the same time.

If you specify **HIGH_PRIORITY**, it overrides the effect of the **--low-priority-updates** option if the server was started with that option. It also causes concurrent inserts not to be used.

For **LOCK TABLE**, the difference between **READ LOCAL** and **READ** is that **READ LOCAL** permits nonconflicting **INSERT** statements (concurrent inserts) to execute while the lock is held. However, this cannot be used if you are going to manipulate the database using processes external to the server while you hold the lock.

**8.11.4 External Locking**

External locking is the use of file system locking to manage contention for **MyISAM** database tables by multiple processes. External locking is used in situations where a single process such as the MySQL server cannot be assumed to be the only process that requires access to tables. Here are some examples:

- If you run multiple servers that use the same database directory (not recommended), each server must have external locking enabled.

- If you use **myisamchk** to perform table maintenance operations on **MyISAM** tables, you must either ensure that the server is not running, or that the server has external locking enabled so that it locks table files as necessary to coordinate with **myisamchk** for access to the tables. The same is true for use of **myisampack** to pack **MyISAM** tables.

If the server is run with external locking enabled, you can use **myisamchk** at any time for read operations such as checking tables. In this case, if the server tries to update a table that **myisamchk** is using, the server will wait for **myisamchk** to finish before it continues.

If you use **myisamchk** for write operations such as repairing or optimizing tables, or if you use **myisampack** to pack tables, you **must** always ensure that the **mysqld** server is not using the table. If you do not stop **mysqld**, you should at least do a **mysqladmin flush-tables** before you run **myisamchk**. Your tables **may become corrupted** if the server and **myisamchk** access the tables simultaneously.

With external locking in effect, each process that requires access to a table acquires a file system lock for the table files before proceeding to access the table. If all necessary locks cannot be acquired, the process is blocked from accessing the table until the locks can be obtained (after the process that currently holds the locks releases them).

External locking affects server performance because the server must sometimes wait for other processes before it can access tables.

External locking is unnecessary if you run a single server to access a given data directory (which is the usual case) and if no other programs such as **myisamchk** need to modify tables while the server is running. If you only **read** tables with other programs, external locking is not required, although **myisamchk** might report warnings if the server changes tables while **myisamchk** is reading them.

With external locking disabled, to use **myisamchk**, you must either stop the server while **myisamchk** executes or else lock and flush the tables before running **myisamchk**. (See Section 8.12.1, “System Factors and Startup Parameter Tuning”.) To avoid this requirement, use the **CHECK TABLE** and **REPAIR TABLE** statements to check and repair **MyISAM** tables.

For **mysqld**, external locking is controlled by the value of the **skip_external_locking** system variable. When this variable is enabled, external locking is disabled, and vice versa. External locking is disabled by default.
Use of external locking can be controlled at server startup by using the `--external-locking` or `--skip-external-locking` option.

If you do use external locking option to enable updates to MyISAM tables from many MySQL processes, you must ensure that the following conditions are satisfied:

- You should not use the query cache for queries that use tables that are updated by another process.
- You should not start the server with the `--delay-key-write=ALL` option or use the `DELAY_KEY_WRITE=1` table option for any shared tables. Otherwise, index corruption can occur.

The easiest way to satisfy these conditions is to always use `--external-locking` together with `--delay-key-write=OFF` and `--query-cache-size=0`. (This is not done by default because in many setups it is useful to have a mixture of the preceding options.)

### 8.12 Optimizing the MySQL Server

#### 8.12.1 System Factors and Startup Parameter Tuning

We start with system-level factors, because some of these decisions must be made very early to achieve large performance gains. In other cases, a quick look at this section may suffice. However, it is always nice to have a sense of how much can be gained by changing factors that apply at this level.

Before using MySQL in production, we advise you to test it on your intended platform.

Other tips:

- If you have enough RAM, you could remove all swap devices. Some operating systems use a swap device in some contexts even if you have free memory.

- Avoid external locking for MyISAM tables. The default is for external locking to be disabled. The `--external-locking` and `--skip-external-locking` options explicitly enable and disable external locking.

Disabling external locking does not affect MySQL's functionality as long as you run only one server. Just remember to take down the server (or lock and flush the relevant tables) before you run `myisamchk`. On some systems it is mandatory to disable external locking because it does not work, anyway.

The only case in which you cannot disable external locking is when you run multiple MySQL servers (not clients) on the same data, or if you run `myisamchk` to check (not repair) a table without telling the server to flush and lock the tables first. Note that using multiple MySQL servers to access the same data concurrently is generally not recommended, except when using MySQL Cluster.

The `LOCK TABLES` and `UNLOCK TABLES` statements use internal locking, so you can use them even if external locking is disabled.

#### 8.12.2 Tuning Server Parameters

You can determine the default buffer sizes used by the `mysqld` server using this command:

```
shell> mysqld --verbose --help
```

This command produces a list of all `mysqld` options and configurable system variables. The output includes the default variable values and looks something like this:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>abort-slave-event-count</td>
<td>0</td>
</tr>
<tr>
<td>allow-suspicious-udfs</td>
<td>FALSE</td>
</tr>
</tbody>
</table>
Tuning Server Parameters

<table>
<thead>
<tr>
<th>Variable</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>auto_increment_increments</td>

For a `mysqld` server that is currently running, you can see the current values of its system variables by connecting to it and issuing this statement:

```
mysql> SHOW VARIABLES;
```

You can also see some statistical and status indicators for a running server by issuing this statement:

```
mysql> SHOW STATUS;
```

System variable and status information also can be obtained using `mysqladmin`:

```
shell> mysqladmin variables
shell> mysqladmin extended-status
```

For a full description of all system and status variables, see Section 5.1.4, “Server System Variables”, and Section 5.1.6, “Server Status Variables”.

MySQL uses algorithms that are very scalable, so you can usually run with very little memory. However, normally better performance results from giving MySQL more memory.

When tuning a MySQL server, the two most important variables to configure are `key_buffer_size` and `table_open_cache`. You should first feel confident that you have these set appropriately before trying to change any other variables.

The following examples indicate some typical variable values for different runtime configurations.

- If you have at least 1-2GB of memory and many tables and want maximum performance with a moderate number of clients, use something like this:

```
shell> mysqld_safe --key_buffer_size=384M --table_cache=4000 \
    --sort_buffer_size=4M --read_buffer_size=1M &
```

- If you have only 256MB of memory and only a few tables, but you still do a lot of sorting, you can use something like this:

```
shell> mysqld_safe --key_buffer_size=64M --sort_buffer_size=1M
```

If there are very many simultaneous connections, swapping problems may occur unless `mysqld` has been configured to use very little memory for each connection. `mysqld` performs better if you have enough memory for all connections.

- With little memory and lots of connections, use something like this:

```
shell> mysqld_safe --key_buffer_size=512K --sort_buffer_size=100K \
    --read_buffer_size=100K &
```
Or even this:

```
shell> mysqld_safe --key_buffer_size=512K --sort_buffer_size=16K \\
    --table_open_cache=32 --read_buffer_size=8K \\
    --net_buffer_length=1K &
```

If you are performing GROUP BY or ORDER BY operations on tables that are much larger than your available memory, increase the value of read_rnd_buffer_size to speed up the reading of rows following sorting operations.

You can make use of the example option files included with your MySQL distribution; see Section 5.1.2, "Server Configuration Defaults".

If you specify an option on the command line for mysqld or mysqld_safe, it remains in effect only for that invocation of the server. To use the option every time the server runs, put it in an option file.

To see the effects of a parameter change, do something like this:

```
shell> mysqld --key_buffer_size=128M --verbose --help
```

The variable values are listed near the end of the output. Make sure that the --verbose and --help options are last. Otherwise, the effect of any options listed after them on the command line are not reflected in the output.

For information on tuning the InnoDB storage engine, see Section 8.6, "Optimizing for InnoDB Tables".

### 8.12.3 Optimizing Disk I/O

This section describes ways to configure storage devices when you can devote more and faster storage hardware to the database server.

- Disk seeks are a huge performance bottleneck. This problem becomes more apparent when the amount of data starts to grow so large that effective caching becomes impossible. For large databases where you access data more or less randomly, you can be sure that you need at least one disk seek to read and a couple of disk seeks to write things. To minimize this problem, use disks with low seek times.

- Increase the number of available disk spindles (and thereby reduce the seek overhead) by either symlinking files to different disks or striping the disks:
  - Using symbolic links
    This means that, for MyISAM tables, you symlink the index file and data files from their usual location in the data directory to another disk (that may also be striped). This makes both the seek and read times better, assuming that the disk is not used for other purposes as well. See Section 8.12.4, "Using Symbolic Links".
  - Striping
    Striping means that you have many disks and put the first block on the first disk, the second block on the second disk, and the $N$-th block on the $(N \mod \text{number of disks})$ disk, and so on. This means if your normal data size is less than the stripe size (or perfectly aligned), you get much better performance. Striping is very dependent on the operating system and the stripe size, so benchmark your application with different stripe sizes. See Section 8.13.3, "Using Your Own Benchmarks".

The speed difference for striping is very dependent on the parameters. Depending on how you set the striping parameters and number of disks, you may get differences measured in orders of magnitude. You have to choose to optimize for random or sequential access.
For reliability, you may want to use RAID 0+1 (striping plus mirroring), but in this case, you need $2 \times N$ drives to hold $N$ drives of data. This is probably the best option if you have the money for it. However, you may also have to invest in some volume-management software to handle it efficiently.

A good option is to vary the RAID level according to how critical a type of data is. For example, store semi-important data that can be regenerated on a RAID 0 disk, but store really important data such as host information and logs on a RAID 0+1 or RAID $N$ disk. RAID $N$ can be a problem if you have many writes, due to the time required to update the parity bits.

On Linux, you can get much better performance by using `hdparm` to configure your disk's interface. (Up to 100% under load is not uncommon.) The following `hdparm` options should be quite good for MySQL, and probably for many other applications:

```
hdparm -m 16 -d 1
```

Performance and reliability when using this command depend on your hardware, so we strongly suggest that you test your system thoroughly after using `hdparm`. Please consult the `hdparm` manual page for more information. If `hdparm` is not used wisely, file system corruption may result, so back up everything before experimenting!

You can also set the parameters for the file system that the database uses:

If you do not need to know when files were last accessed (which is not really useful on a database server), you can mount your file systems with the `-o noatime` option. That skips updates to the last access time in inodes on the file system, which avoids some disk seeks.

On many operating systems, you can set a file system to be updated asynchronously by mounting it with the `-o async` option. If your computer is reasonably stable, this should give you better performance without sacrificing too much reliability. (This flag is on by default on Linux.)

### 8.12.4 Using Symbolic Links

You can move databases or tables from the database directory to other locations and replace them with symbolic links to the new locations. You might want to do this, for example, to move a database to a file system with more free space or increase the speed of your system by spreading your tables to different disks.

The recommended way to do this is to symlink entire database directories to a different disk. Symlink `MyISAM` tables only as a last resort.

To determine the location of your data directory, use this statement:

```
SHOW VARIABLES LIKE 'datadir';
```

### 8.12.4.1 Using Symbolic Links for Databases on Unix

On Unix, the way to symlink a database is first to create a directory on some disk where you have free space and then to create a soft link to it from the MySQL data directory.

```
shell> mkdir /dr1/databases/test
shell> ln -s /dr1/databases/test /path/to/datadir
```

MySQL does not support linking one directory to multiple databases. Replacing a database directory with a symbolic link works as long as you do not make a symbolic link between databases. Suppose that you have a database `db1` under the MySQL data directory, and then make a symlink `db2` that points to `db1`:

```
shell> cd /path/to/datadir
shell> ln -s db1 db2
```
The result is that, or any table `tbl_a` in `db1`, there also appears to be a table `tbl_a` in `db2`. If one client updates `db1.tbl_a` and another client updates `db2.tbl_a`, problems are likely to occur.

### 8.12.4.2 Using Symbolic Links for MyISAM Tables on Unix

Symlinks are fully supported only for MyISAM tables. For files used by tables for other storage engines, you may get strange problems if you try to use symbolic links.

Do not symlink tables on systems that do not have a fully operational `realpath()` call. (Linux and Solaris support `realpath()`). To determine whether your system supports symbolic links, check the value of the `have_symlink` system variable using this statement:

```
SHOW VARIABLES LIKE 'have_symlink';
```

The handling of symbolic links for MyISAM tables works as follows:

- In the data directory, you always have the table format (`.frm`) file, the data (`.MYD`) file, and the index (`.MYI`) file. The data file and index file can be moved elsewhere and replaced in the data directory by symlinks. The format file cannot.

- You can symlink the data file and the index file independently to different directories.

- To instruct a running MySQL server to perform the symlinking, use the `DATA DIRECTORY` and `INDEX DIRECTORY` options to `CREATE TABLE`. See Section 13.1.17, "CREATE TABLE Syntax". Alternatively, if `mysqld` is not running, symlinking can be accomplished manually using `ln -s` from the command line.

**Note**

Beginning with MySQL 5.1.24, the path used with either or both of the `DATA DIRECTORY` and `INDEX DIRECTORY` options may not include the MySQL data directory. (Bug #32167)

- `myisamchk` does not replace a symlink with the data file or index file. It works directly on the file to which the symlink points. Any temporary files are created in the directory where the data file or index file is located. The same is true for the `ALTER TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements.

**Note**

When you drop a table that is using symlinks, both the symlink and the file to which the symlink points are dropped. This is an extremely good reason not to run `mysqld` as the system root or permit system users to have write access to MySQL database directories.

- If you rename a table with `ALTER TABLE ... RENAME` or `RENAME TABLE` and you do not move the table to another database, the symlinks in the database directory are renamed to the new names and the data file and index file are renamed accordingly.

- If you use `ALTER TABLE ... RENAME` or `RENAME TABLE` to move a table to another database, the table is moved to the other database directory. If the table name changed, the symlinks in the new database directory are renamed to the new names and the data file and index file are renamed accordingly.

- If you are not using symlinks, start `mysqld` with the `--skip-symbolic-links` option to ensure that no one can use `mysqld` to drop or rename a file outside of the data directory.

These table symlink operations are not supported:

- `ALTER TABLE` ignores the `DATA DIRECTORY` and `INDEX DIRECTORY` table options.
Using Symbolic Links

- **BACKUP TABLE** and **RESTORE TABLE** do not respect symbolic links.

- As indicated previously, only the data and index files can be symbolic links. The .frm file must *never* be a symbolic link. Attempting to do this (for example, to make one table name a synonym for another) produces incorrect results. Suppose that you have a database `db1` under the MySQL data directory, a table `tbl1` in this database, and in the `db1` directory you make a symlink `tbl2` that points to `tbl1`:

```shell
shell> cd /path/to/datadir/db1
shell> ln -s tbl1.frm tbl2.frm
shell> ln -s tbl1.MYD tbl2.MYD
shell> ln -s tbl1.MYI tbl2.MYI
```

Problems result if one thread reads `db1.tbl1` and another thread updates `db1.tbl2`:

- The query cache is “fooled” (it has no way of knowing that `tbl1` has not been updated, so it returns outdated results).
- **ALTER** statements on `tbl2` fail.

### 8.12.4.3 Using Symbolic Links for Databases on Windows

On Windows, symbolic links can be used for database directories. This enables you to put a database directory at a different location (for example, on a different disk) by setting up a symbolic link to it. Use of database symlinks on Windows is similar to their use on Unix, although the procedure for setting up the link differs.

Suppose that you want to place the database directory for a database named `mydb` at `D:\data\mydb`. To do this, create a symbolic link in the MySQL data directory that points to `D:\data\mydb`. However, before creating the symbolic link, make sure that the `D:\data\mydb` directory exists by creating it if necessary. If you already have a database directory named `mydb` in the data directory, move it to `D:\data`. Otherwise, the symbolic link will be ineffective. To avoid problems, make sure that the server is not running when you move the database directory.

On Windows, create a symbolic link to a MySQL database by creating a `.sym` file in the data directory that contains the path to the destination directory. The file should be named `db_name.sym`, where `db_name` is the database name.

Support for database symbolic links on Windows using `.sym` files is enabled by default. If you do not need `.sym` file symbolic links, you can disable support for them by starting `mysqld` with the `--skip-symbolic-links` option. To determine whether your system supports `.sym` file symbolic links, check the value of the `have_symlink` system variable using this statement:

```
SHOW VARIABLES LIKE 'have_symlink';
```

To create a `.sym` file symlink, use this procedure:

1. Change location into the data directory:

   ```shell
   C:\> cd \path\to\datadir
   ```

2. In the data directory, create a text file named `mydb.sym` that contains this path name: `D:\data\mydb`.

   ![Note]
   The path name to the new database and tables should be absolute. If you specify a relative path, the location will be relative to the `mydb.sym` file.

After this, all tables created in the database `mydb` are created in `D:\data\mydb.`
The following limitations apply to the use of .sym files for database symbolic linking on Windows:

- The symbolic link is not used if a directory with the same name as the database exists in the MySQL data directory.
- The --innodb_file_per_table option cannot be used.
- If you run mysqld as a service, you cannot use a mapped drive to a remote server as the destination of the symbolic link. As a workaround, you can use the full path (\servername\path\).

### 8.12.5 Optimizing Memory Use

#### 8.12.5.1 How MySQL Uses Memory

MySQL allocates buffers and caches to improve performance of database operations. You can improve MySQL performance by increasing the values of certain cache and buffer-related system variables. You can also modify these variables to run MySQL on systems with limited memory.

The following list describes some of the ways that MySQL uses memory. Where applicable, relevant system variables are referenced. Some items are storage engine specific.

- The InnoDB buffer pool is a memory area that holds cached InnoDB data for tables, indexes, and other auxiliary buffers. For efficiency of high-volume read operations, the buffer pool is divided into pages that can potentially hold multiple rows. For efficiency of cache management, the buffer pool is implemented as a linked list of pages; data that is rarely used is aged out of the cache, using a variation of the LRU algorithm. For more information, see Section 8.10.2, “The InnoDB Buffer Pool”.

The size of the buffer pool is important for system performance.

- Typically, it is recommended that innodb_buffer_pool_size is configured to 50 to 75 percent of system memory.

- InnoDB allocates memory for the entire buffer pool at server startup. Memory allocation is performed by malloc() operations. Buffer pool size is defined by the innodb_buffer_pool_size configuration option.

- A buffer pool that is too small may cause excessive churning as pages are flushed from the buffer pool only to be required again a short time later.

- A buffer pool that is too large may cause swapping due to competition for memory.

- All threads share the MyISAM key buffer; its size is determined by the key_buffer_size variable. Other buffers used by the server are allocated as needed. See Section 8.12.2, “Tuning Server Parameters”.

For each MyISAM table that is opened, the index file is opened once; the data file is opened once for each concurrently running thread. For each concurrent thread, a table structure, column structures for each column, and a buffer of size $3 \times N$ are allocated (where $N$ is the maximum row length, not counting BLOB columns). A BLOB column requires five to eight bytes plus the length of the BLOB data. The MyISAM storage engine maintains one extra row buffer for internal use.

- Each thread that is used to manage client connections uses some thread-specific space. The following list indicates these and which variables control their size:
  
  - A stack (variable thread_stack)
  - A connection buffer (variable net_buffer_length)
  - A result buffer (variable net_buffer_length)

The connection buffer and result buffer each begin with a size equal to net_buffer_length bytes, but are dynamically enlarged up to max_allowed_packet bytes as needed. The result buffer
shrinks to `net_buffer_length` bytes after each SQL statement. While a statement is running, a copy of the current statement string is also allocated.

- All threads share the same base memory.
- When a thread is no longer needed, the memory allocated to it is released and returned to the system unless the thread goes back into the thread cache. In that case, the memory remains allocated.
- Before MySQL 5.1.4, only compressed MyISAM tables are memory mapped. As of MySQL 5.1.4, the `myisam_use_mmap` system variable can be set to 1 to enable memory-mapping for all MyISAM tables.
- Each request that performs a sequential scan of a table allocates a read buffer (variable `read_buffer_size`).
- When reading rows in an arbitrary sequence (for example, following a sort), a random-read buffer (variable `read_rnd_buffer_size`) may be allocated to avoid disk seeks.
- All joins are executed in a single pass, and most joins can be done without even using a temporary table. Most temporary tables are memory-based hash tables. Temporary tables with a large row length (calculated as the sum of all column lengths) or that contain BLOB columns are stored on disk.

If an internal in-memory temporary table becomes too large, MySQL handles this automatically by changing the table from in-memory to on-disk format, to be handled by the MyISAM storage engine. You can increase the permissible temporary table size as described in Section 8.4.4, “Internal Temporary Table Use in MySQL”.

- Most requests that perform a sort allocate a sort buffer and zero to two temporary files depending on the result set size. See Section 8.5.3.5, “Where MySQL Stores Temporary Files”.
- Almost all parsing and calculating is done in thread-local and reusable memory pools. No memory overhead is needed for small items, so the normal slow memory allocation and freeing is avoided. Memory is allocated only for unexpectedly large strings.
- For each table having BLOB columns, a buffer is enlarged dynamically to read in larger BLOB values. If you scan a table, a buffer as large as the largest BLOB value is allocated.

MySQL requires memory and descriptors for the table cache. Handler structures for all in-use tables are saved in the table cache and managed as “First In, First Out” (FIFO). The initial table cache size is defined by the `table_open_cache` system variable; see Section 8.4.3.1, “How MySQL Opens and Closes Tables”.

MySQL also requires memory for the table definition cache. The `table_definition_cache` system variable defines the number of table definitions (from `.frm` files) that can be stored in the table definition cache. If you use a large number of tables, you can create a large table definition cache to speed up the opening of tables. The table definition cache takes less space and does not use file descriptors, unlike the table cache.

- A `FLUSH TABLES` statement or `mysqladmin flush-tables` command closes all tables that are not in use at once and marks all in-use tables to be closed when the currently executing thread finishes. This effectively frees most in-use memory. `FLUSH TABLES` does not return until all tables have been closed.
- The server caches information in memory as a result of GRANT, CREATE USER, CREATE SERVER, and INSTALL PLUGIN statements. This memory is not released by the corresponding REVOKE, DROP USER, DROP SERVER, and UNINSTALL PLUGIN statements, so for a server that executes many instances of the statements that cause caching, there will be an increase in memory use. This cached memory can be freed with `FLUSH PRIVILEGES`.

ps and other system status programs may report that `mysqld` uses a lot of memory. This may be caused by thread stacks on different memory addresses. For example, the Solaris version of ps counts
the unused memory between stacks as used memory. To verify this, check available swap with `swap -s`. We test `mysqld` with several memory-leakage detectors (both commercial and Open Source), so there should be no memory leaks.

### 8.12.5.2 Enabling Large Page Support

Some hardware/operating system architectures support memory pages greater than the default (usually 4KB). The actual implementation of this support depends on the underlying hardware and operating system. Applications that perform a lot of memory accesses may obtain performance improvements by using large pages due to reduced Translation Lookaside Buffer (TLB) misses.

In MySQL, large pages can be used by InnoDB, to allocate memory for its buffer pool and additional memory pool.

MySQL supports only the Linux implementation of large page support (which is called HugeTLB in Linux).

Before large pages can be used on Linux, the kernel must be enabled to support them and it is necessary to configure the HugeTLB memory pool. For reference, the HugeTBL API is documented in the `Documentation/vm/hugetlbpage.txt` file of your Linux sources.

The kernel for some recent systems such as Red Hat Enterprise Linux appear to have the large pages feature enabled by default. To check whether this is true for your kernel, use the following command and look for output lines containing “huge”:

```
shell> cat /proc/meminfo | grep -i huge
HugePages_Total:       0
HugePages_Free:        0
HugePages_Rsvd:        0
HugePages_Surp:        0
Hugepagesize:       4096 kB
```

The nonempty command output indicates that large page support is present, but the zero values indicate that no pages are configured for use.

If your kernel needs to be reconfigured to support large pages, consult the `hugetlbpage.txt` file for instructions.

Assuming that your Linux kernel has large page support enabled, configure it for use by MySQL using the following commands. Normally, you put these in an `rc` file or equivalent startup file that is executed during the system boot sequence, so that the commands execute each time the system starts. The commands should execute early in the boot sequence, before the MySQL server starts. Be sure to change the allocation numbers and the group number as appropriate for your system.

```
# Set the number of pages to be used.
# Each page is normally 2MB, so a value of 20 = 40MB.
# This command actually allocates memory, so this much memory must be available.
echo 20 > /proc/sys/vm/nr_hugepages

# Set the group number that is permitted to access this memory (102 in this case). The mysql user must be a member of this group.
echo 102 > /proc/sys/vm/hugetlb_shm_group

# Increase the amount of shmem permitted per segment (12G in this case).
echo 1560281088 > /proc/sys/kernel/shmmax

# Increase total amount of shared memory. The value is the number of pages. At 4KB/page, 4194304 = 16GB.
echo 4194304 > /proc/sys/kernel/shmall
```

For MySQL usage, you normally want the value of `shmmax` to be close to the value of `shmall`. 
To verify the large page configuration, check `/proc/meminfo` again as described previously. Now you should see some nonzero values:

```bash
shell> cat /proc/meminfo | grep -i huge
HugePages_Total:      20
HugePages_Free:       20
HugePages_Rsvd:        0
HugePages_Surp:        0
Hugepagesize:       4096 kB
```

The final step to make use of the `hugetlb_shm_group` is to give the `mysql` user an "unlimited" value for the memlock limit. This can be done either by editing `/etc/security/limits.conf` or by adding the following command to your `mysqld_safe` script:

```bash
ulimit -l unlimited
```

Adding the `ulimit` command to `mysqld_safe` causes the `root` user to set the memlock limit to `unlimited` before switching to the `mysql` user. (This assumes that `mysqld_safe` is started by `root`.)

Large page support in MySQL is disabled by default. To enable it, start the server with the `--large-pages` option. For example, you can use the following lines in your server's `my.cnf` file:

```
[mysqld]
large-pages
```

With this option, InnoDB uses large pages automatically for its buffer pool and additional memory pool. If InnoDB cannot do this, it falls back to use of traditional memory and writes a warning to the error log:

```
Warning: Using conventional memory pool
```

To verify that large pages are being used, check `/proc/meminfo` again:

```bash
shell> cat /proc/meminfo | grep -i huge
HugePages_Total:      20
HugePages_Free:       20
HugePages_Rsvd:        2
HugePages_Surp:        0
Hugepagesize:       4096 kB
```

### 8.12.6 Optimizing Network Use

#### 8.12.6.1 How MySQL Uses Threads for Client Connections

Connection manager threads handle client connection requests on the network interfaces that the server listens to. On all platforms, one manager thread handles TCP/IP connection requests. On Unix, this manager thread also handles Unix socket file connection requests. On Windows, a manager thread handles shared-memory connection requests, and another handles named-pipe connection requests. The server does not create threads to handle interfaces that it does not listen to. For example, a Windows server that does not have support for named-pipe connections enabled does not create a thread to handle them.

Connection manager threads associate each client connection with a thread dedicated to it that handles authentication and request processing for that connection. Manager threads create a new thread when necessary but try to avoid doing so by consulting the thread cache first to see whether it contains a thread that can be used for the connection. When a connection ends, its thread is returned to the thread cache if the cache is not full.

In this connection thread model, there are as many threads as there are clients currently connected, which has some disadvantages when server workload must scale to handle large numbers of connections. For example, thread creation and disposal becomes expensive. Also, each thread
requires server and kernel resources, such as stack space. To accommodate a large number of simultaneous connections, the stack size per thread must be kept small, leading to a situation where it is either too small or the server consumes large amounts of memory. Exhaustion of other resources can occur as well, and scheduling overhead can become significant.

To control and monitor how the server manages threads that handle client connections, several system and status variables are relevant. (See Section 5.1.4, “Server System Variables”, and Section 5.1.6, “Server Status Variables”.)

The thread cache has a size determined by the `thread_cache_size` system variable. The default value is 0 (no caching), which causes a thread to be set up for each new connection and disposed of when the connection terminates. Set `thread_cache_size` to \( N \) to enable \( N \) inactive connection threads to be cached. `thread_cache_size` can be set at server startup or changed while the server runs. A connection thread becomes inactive when the client connection with which it was associated terminates.

To monitor the number of threads in the cache and how many threads have been created because a thread could not be taken from the cache, monitor the `Threads_cached` and `Threads_created` status variables.

You can set `max_connections` at server startup or at runtime to control the maximum number of clients that can connect simultaneously.

When the thread stack is too small, this limits the complexity of the SQL statements which the server can handle, the recursion depth of stored procedures, and other memory-consuming actions. To set a stack size of \( N \) bytes for each thread, start the server with `--thread_stack=N`.

### 8.12.6.2 DNS Lookup Optimization and the Host Cache

The MySQL server maintains a host cache in memory that contains information about clients: IP address, host name, and error information. The server uses this cache for nonlocal TCP connections. It does not use the cache for TCP connections established using the loopback interface address (127.0.0.1), or for connections established using a Unix socket file, named pipe, or shared memory.

For each new client connection, the server uses the client IP address to check whether the client host name is in the host cache. If not, the server attempts to resolve the host name. First, it resolves the IP address to a host name and resolves that host name back to an IP address. Then it compares the result to the original IP address to ensure that they are the same. The server stores information about the result of this operation in the host cache. If the cache is full, the least recently used entry is discarded.

The server performs host name resolution using the thread-safe `gethostbyaddr_r()` and `gethostbyname_r()` calls if the operating system supports them. Otherwise, the thread performing the lookup locks a mutex and calls `gethostbyaddr()` and `gethostbyname()` instead. In this case, no other thread can resolve host names that are not in the host cache until the thread holding the mutex lock releases it.

The server uses the host cache for several purposes:

- By caching the results of IP-to-host name lookups, the server avoids doing a DNS lookup for each client connection. Instead, for a given host, it needs to perform a lookup only for the first connection from that host.

- The cache contains information about errors that occur during the connection process. Some errors are considered “blocking.” If too many of these occur successively from a given host without a successful connection, the server blocks further connections from that host. The `max_connect_errors` system variable determines the number of permitted errors before blocking occurs. See Section B.5.2.6, “Host ‘host_name’ is blocked”.

To unblock blocked hosts, flush the host cache by issuing a `FLUSH HOSTS` statement or executing a `mysqladmin flush-hosts` command.
It is possible for a blocked host to become unblocked even without \texttt{FLUSH HOSTS} if activity from other hosts has occurred since the last connection attempt from the blocked host. This can occur because the server discards the least recently used cache entry to make room for a new entry if the cache is full when a connection arrives from a client IP not in the cache. If the discarded entry is for a blocked host, that host becomes unblocked.

The host cache is enabled by default. To disable it, start the server with the \texttt{--skip-host-cache} option.

To disable DNS host name lookups, start the server with the \texttt{--skip-name-resolve} option. In this case, the server uses only IP addresses and not host names to match connecting hosts to rows in the MySQL grant tables. Only accounts specified in those tables using IP addresses can be used. (Be sure that an account exists that specifies an IP address or you may not be able to connect.)

If you have a very slow DNS and many hosts, you might be able to improve performance either by disabling DNS lookups with \texttt{--skip-name-resolve} or by increasing the \texttt{HOST_CACHE_SIZE} define (default value: 128) and recompiling the server.

To disallow TCP/IP connections entirely, start the server with the \texttt{--skip-networking} option.

Some connection errors are not associated with TCP connections, occur very early in the connection process (even before an IP address is known), or are not specific to any particular IP address (such as out-of-memory conditions).

### 8.13 Measuring Performance (Benchmarking)

To measure performance, consider the following factors:

- Whether you are measuring the speed of a single operation on a quiet system, or how a set of operations (a "workload") works over a period of time. With simple tests, you usually test how changing one aspect (a configuration setting, the set of indexes on a table, the SQL clauses in a query) affects performance. Benchmarks are typically long-running and elaborate performance tests, where the results could dictate high-level choices such as hardware and storage configuration, or how soon to upgrade to a new MySQL version.

- For benchmarking, sometimes you must simulate a heavy database workload to get an accurate picture.

- Performance can vary depending on so many different factors that a difference of a few percentage points might not be a decisive victory. The results might shift the opposite way when you test in a different environment.

- Certain MySQL features help or do not help performance depending on the workload. For completeness, always test performance with those features turned on and turned off. The two most important features to try with each workload are the MySQL query cache, and the adaptive hash index for InnoDB tables.

This section progresses from simple and direct measurement techniques that a single developer can do, to more complicated ones that require additional expertise to perform and interpret the results.

### 8.13.1 Measuring the Speed of Expressions and Functions

To measure the speed of a specific MySQL expression or function, invoke the \texttt{BENCHMARK()} function using the \texttt{mysql} client program. Its syntax is \texttt{BENCHMARK(loop_count, expression)}. The return value is always zero, but \texttt{mysql} prints a line displaying approximately how long the statement took to execute. For example:

```
mysql> SELECT BENCHMARK(1000000, 1+1);
+------------------------+
| BENCHMARK(1000000, 1+1) |
+------------------------+
```
This result was obtained on a Pentium II 400MHz system. It shows that MySQL can execute 1,000,000 simple addition expressions in 0.32 seconds on that system.

The built-in MySQL functions are typically highly optimized, but there may be some exceptions. `BENCHMARK()` is an excellent tool for finding out if some function is a problem for your queries.

### 8.13.2 The MySQL Benchmark Suite

This benchmark suite is meant to tell any user what operations a given SQL implementation performs well or poorly. You can get a good idea for how the benchmarks work by looking at the code and results in the `sql-bench` directory in any MySQL source distribution.

To use the benchmark suite, the following requirements must be satisfied:

- The benchmark suite is provided with MySQL source distributions. You can either download a released distribution from http://dev.mysql.com/downloads/, or use the current development source tree. (See Section 2.11.3, “Installing MySQL Using a Development Source Tree”.)

- The benchmark scripts are written in Perl and use the Perl DBI module to access database servers, so DBI must be installed. You also need the server-specific DBD drivers for each of the servers you want to test. For example, to test MySQL, PostgreSQL, and DB2, you must have the `DBD::mysql`, `DBD::Pg`, and `DBD::DB2` modules installed. See Section 2.15, “Perl Installation Notes”.

After you obtain a MySQL source distribution, you can find the benchmark suite located in its `sql-bench` directory. To run the benchmark tests, build MySQL, and then change location into the `sql-bench` directory and execute the `run-all-tests` script:

```bash
shell> cd sql-bench
shell> perl run-all-tests --server=server_name
```

`server_name` should be the name of one of the supported servers. To get a list of all options and supported servers, invoke this command:

```bash
shell> perl run-all-tests --help
```

The `crash-me` script also is located in the `sql-bench` directory. `crash-me` tries to determine what features a database system supports and what its capabilities and limitations are by actually running queries. For example, it determines:

- What data types are supported
- How many indexes are supported
- What functions are supported
- How big a query can be
- How big a `VARCHAR` column can be

For more information about benchmark results, visit http://www.mysql.com/why-mysql/benchmarks/.

### 8.13.3 Using Your Own Benchmarks

Benchmark your application and database to find out where the bottlenecks are. After fixing one bottleneck (or by replacing it with a “dummy” module), you can proceed to identify the next bottleneck.
Even if the overall performance for your application currently is acceptable, you should at least make a plan for each bottleneck and decide how to solve it if someday you really need the extra performance.

For examples of portable benchmark programs, look at those in the MySQL benchmark suite. See Section 8.13.2, “The MySQL Benchmark Suite”. You can take any program from this suite and modify it for your own needs. By doing this, you can try different solutions to your problem and test which really is fastest for you.

It is very common for a problem to occur only when the system is very heavily loaded. We have had many customers who contact us when they have a (tested) system in production and have encountered load problems. In most cases, performance problems turn out to be due to issues of basic database design (for example, table scans are not good under high load) or problems with the operating system or libraries. Most of the time, these problems would be much easier to fix if the systems were not already in production.

To avoid problems like this, benchmark your whole application under the worst possible load:

- The mysqlslap program can be helpful for simulating a high load produced by multiple clients issuing queries simultaneously. See Section 4.5.7, “mysqlslap — Load Emulation Client”.

- You can also try benchmarking packages such as SysBench and DBT2, available at https://launchpad.net/sysbench, and http://osdldbt.sourceforge.net/#dbt2.

These programs or packages can bring a system to its knees, so be sure to use them only on your development systems.

### 8.14 Examining Thread Information

When you are attempting to ascertain what your MySQL server is doing, it can be helpful to examine the process list, which is the set of threads currently executing within the server. Process list information is available from these sources:

- The SHOW [FULL] PROCESSLIST statement: Section 13.7.5.31, “SHOW PROCESSLIST Syntax”

- The SHOW PROFILE statement: Section 13.7.5.33, “SHOW PROFILES Syntax”

- The INFORMATION_SCHEMA PROCESSLIST table: Section 20.13, “The INFORMATION_SCHEMA PROCESSLIST Table”

- The mysqladmin processlist command: Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”

You can always view information about your own threads. To view information about threads being executed for other accounts, you must have the PROCESS privilege.

Each process list entry contains several pieces of information:

- **Id** is the connection identifier for the client associated with the thread.

- **User** and **Host** indicate the account associated with the thread.

- **db** is the default database for the thread, or **NULL** if none is selected.

- **Command** and **State** indicate what the thread is doing.

Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that needs to be investigated.

- **Time** indicates how long the thread has been in its current state. The thread's notion of the current time may be altered in some cases: The thread can change the time with `SET TIMESTAMP =`
value. For a thread running on a slave that is processing events from the master, the thread time is set to the time found in the events and thus reflects current time on the master and not the slave.

- **Info** contains the text of the statement being executed by the thread, or **NULL** if it is not executing one. By default, this value contains only the first 100 characters of the statement. To see the complete statements, use **SHOW FULL PROCESSLIST**.

The following sections list the possible **Command** values, and **State** values grouped by category. The meaning for some of these values is self-evident. For others, additional description is provided.

### 8.14.1 Thread Command Values

A thread can have any of the following **Command** values:

- **Binlog Dump**
  
  This is a thread on a master server for sending binary log contents to a slave server.

- **Change user**
  
  The thread is executing a change-user operation.

- **Close stmt**
  
  The thread is closing a prepared statement.

- **Connect**
  
  A replication slave is connected to its master.

- **Connect Out**
  
  A replication slave is connecting to its master.

- **Create DB**
  
  The thread is executing a create-database operation.

- **Daemon**
  
  This thread is internal to the server, not a thread that services a client connection.

- **Debug**
  
  The thread is generating debugging information.

- **Delayed insert**
  
  The thread is a delayed-insert handler.

- **Drop DB**
  
  The thread is executing a drop-database operation.

- **Error**
  
- **Execute**
  
  The thread is executing a prepared statement.

- **Fetch**
  
  The thread is fetching the results from executing a prepared statement.
Thread Command Values

- **Field List**
  The thread is retrieving information for table columns.

- **Init DB**
  The thread is selecting a default database.

- **Kill**
  The thread is killing another thread.

- **Long Data**
  The thread is retrieving long data in the result of executing a prepared statement.

- **Ping**
  The thread is handling a server-ping request.

- **Prepare**
  The thread is preparing a prepared statement.

- **Processlist**
  The thread is producing information about server threads.

- **Query**
  The thread is executing a statement.

- **Quit**
  The thread is terminating.

- **Refresh**
  The thread is flushing table, logs, or caches, or resetting status variable or replication server information.

- **Register Slave**
  The thread is registering a slave server.

- **Reset stmt**
  The thread is resetting a prepared statement.

- **Set option**
  The thread is setting or resetting a client statement-execution option.

- **Shutdown**
  The thread is shutting down the server.

- **Sleep**
  The thread is waiting for the client to send a new statement to it.

- **Statistics**
  The thread is producing server-status information.
• **Table Dump**
  The thread is sending table contents to a slave server.

• **Time**
  Unused.

### 8.14.2 General Thread States

The following list describes thread *State* values that are associated with general query processing and not more specialized activities such as replication. Many of these are useful only for finding bugs in the server.

• **After create**
  This occurs when the thread creates a table (including internal temporary tables), at the end of the function that creates the table. This state is used even if the table could not be created due to some error.

• **Analyzing**
  The thread is calculating a MyISAM table key distributions (for example, for `ANALYZE TABLE`).

• **checking permissions**
  The thread is checking whether the server has the required privileges to execute the statement.

• **Checking table**
  The thread is performing a table check operation.

• **cleaning up**
  The thread has processed one command and is preparing to free memory and reset certain state variables.

• **closing tables**
  The thread is flushing the changed table data to disk and closing the used tables. This should be a fast operation. If not, you should verify that you do not have a full disk and that the disk is not in very heavy use.

• **converting HEAP to MyISAM**
  The thread is converting an internal temporary table from a MEMORY table to an on-disk MyISAM table.

• **copy to tmp table**
  The thread is processing an `ALTER TABLE` statement. This state occurs after the table with the new structure has been created but before rows are copied into it.

• **Copying to group table**
  If a statement has different `ORDER BY` and `GROUP BY` criteria, the rows are sorted by group and copied to a temporary table.

• **Copying to tmp table**
  The server is copying to a temporary table in memory.

• **Copying to tmp table on disk**
The server is copying to a temporary table on disk. The temporary result set has become too large (see Section 8.4.4, “Internal Temporary Table Use in MySQL”). Consequently, the thread is changing the temporary table from in-memory to disk-based format to save memory.

- **Creating index**
  The thread is processing `ALTER TABLE ... ENABLE KEYS` for a MyISAM table.

- **Creating sort index**
  The thread is processing a `SELECT` that is resolved using an internal temporary table.

- **creating table**
  The thread is creating a table. This includes creation of temporary tables.

- **Creating tmp table**
  The thread is creating a temporary table in memory or on disk. If the table is created in memory but later is converted to an on-disk table, the state during that operation will be **Copying to tmp table on disk**.

- **deleting from main table**
  The server is executing the first part of a multiple-table delete. It is deleting only from the first table, and saving columns and offsets to be used for deleting from the other (reference) tables.

- **deleting from reference tables**
  The server is executing the second part of a multiple-table delete and deleting the matched rows from the other tables.

- **discard_or_import_tablespace**
  The thread is processing an `ALTER TABLE ... DISCARD TABLESPACE` or `ALTER TABLE ... IMPORT TABLESPACE` statement.

- **end**
  This occurs at the end but before the cleanup of `ALTER TABLE`, `CREATE VIEW`, `DELETE`, `INSERT`, `SELECT`, or `UPDATE` statements.

- **executing**
  The thread has begun executing a statement.

- **Execution of init_command**
  The thread is executing statements in the value of the `init_command` system variable.

- **freeing items**
  The thread has executed a command. Some freeing of items done during this state involves the query cache. This state is usually followed by **cleaning up**.

- **Flushing tables**
  The thread is executing `FLUSH TABLES` and is waiting for all threads to close their tables.

- **FULLTEXT initialization**
  The server is preparing to perform a natural-language full-text search.
General Thread States

- **init**
  
  This occurs before the initialization of `ALTER_TABLE`, `DELETE`, `INSERT`, `SELECT`, or `UPDATE` statements. Actions taken by the server in this state include flushing the binary log, the InnoDB log, and some query cache cleanup operations.

For the **end** state, the following operations could be happening:

- Removing query cache entries after data in a table is changed
- Writing an event to the binary log
- Freeing memory buffers, including for blobs

- **Killed**
  
  Someone has sent a `KILL` statement to the thread and it should abort next time it checks the kill flag. The flag is checked in each major loop in MySQL, but in some cases it might still take a short time for the thread to die. If the thread is locked by some other thread, the kill takes effect as soon as the other thread releases its lock.

- **Locked**
  
  The query is locked by another query.

- **logging slow query**
  
  The thread is writing a statement to the slow-query log.

- **login**
  
  The initial state for a connection thread until the client has been authenticated successfully.

- **manage keys**
  
  The server is enabling or disabling a table index.

- **NULL**
  
  This state is used for the `SHOW PROCESSLIST` state.

- **Opening tables, Opening table**
  
  The thread is trying to open a table. This is should be very fast procedure, unless something prevents opening. For example, an `ALTER_TABLE` or a `LOCK_TABLE` statement can prevent opening a table until the statement is finished. It is also worth checking that your `table_open_cache` value is large enough.

- **optimizing**
  
  The server is performing initial optimizations for a query.

- **preparing**
  
  This state occurs during query optimization.

- **Purging old relay logs**
  
  The thread is removing unneeded relay log files.

- **query end**
  
  This state occurs after processing a query but before the **freeing items** state.
• **Reading from net**
  The server is reading a packet from the network.

• **Removing duplicates**
  The query was using `SELECT DISTINCT` in such a way that MySQL could not optimize away the distinct operation at an early stage. Because of this, MySQL requires an extra stage to remove all duplicated rows before sending the result to the client.

• **removing tmp table**
  The thread is removing an internal temporary table after processing a `SELECT` statement. This state is not used if no temporary table was created.

• **rename**
  The thread is renaming a table.

• **rename result table**
  The thread is processing an `ALTER TABLE` statement, has created the new table, and is renaming it to replace the original table.

• **Reopen tables**
  The thread got a lock for the table, but noticed after getting the lock that the underlying table structure changed. It has freed the lock, closed the table, and is trying to reopen it.

• **Repair by sorting**
  The repair code is using a sort to create indexes.

• **Repair done**
  The thread has completed a multi-threaded repair for a MyISAM table.

• **Repair with keycache**
  The repair code is using creating keys one by one through the key cache. This is much slower than Repair by sorting.

• **Rolling back**
  The thread is rolling back a transaction.

• **Saving state**
  For MyISAM table operations such as repair or analysis, the thread is saving the new table state to the .MYI file header. State includes information such as number of rows, the AUTO_INCREMENT counter, and key distributions.

• **Searching rows for update**
  The thread is doing a first phase to find all matching rows before updating them. This has to be done if the UPDATE is changing the index that is used to find the involved rows.

• **Sending data**
  The thread is reading and processing rows for a `SELECT` statement, and sending data to the client. Because operations occurring during this state tend to perform large amounts of disk access (reads), it is often the longest-running state over the lifetime of a given query.
The thread is beginning an \texttt{ALTER TABLE} operation.

- \textbf{Sorting for group}
  The thread is doing a sort to satisfy a \texttt{GROUP BY}.

- \textbf{Sorting for order}
  The thread is doing a sort to satisfy an \texttt{ORDER BY}.

- \textbf{Sorting index}
  The thread is sorting index pages for more efficient access during a \texttt{MyISAM} table optimization operation.

- \textbf{Sorting result}
  For a \texttt{SELECT} statement, this is similar to \texttt{Creating sort index}, but for nontemporary tables.

- \textbf{statistics}
  The server is calculating statistics to develop a query execution plan. If a thread is in this state for a long time, the server is probably disk-bound performing other work.

- \textbf{System lock}
  The thread is going to request or is waiting for an internal or external system lock for the table. For example, this can occur when \texttt{InnoDB} waits for a table-level lock during execution of \texttt{LOCK TABLES}. If this state is being caused by requests for external locks and you are not using multiple \texttt{mysqld} servers that are accessing the same \texttt{MyISAM} tables, you can disable external system locks with the \texttt{--skip-external-locking} option. However, external locking is disabled by default, so it is likely that this option will have no effect.

- \textbf{Table lock}
  The next thread state after \texttt{System lock}. After acquiring a system lock, the thread is going to request an internal table lock (a \texttt{THR_LOCK} lock).

  For more information about table lock indicators, see \texttt{Section 8.11.1, “Internal Locking Methods”}.

- \textbf{update}
  The thread is getting ready to start updating the table.

  - \textbf{Updating}
    The thread is searching for rows to update and is updating them.

  - \textbf{updating main table}
    The server is executing the first part of a multiple-table update. It is updating only the first table, and saving columns and offsets to be used for updating the other (reference) tables.

  - \textbf{updating reference tables}
    The server is executing the second part of a multiple-table update and updating the matched rows from the other tables.

- \textbf{User lock}
  The thread is going to request or is waiting for an advisory lock requested with a \texttt{GET_LOCK()} call. For \texttt{SHOW PROFILE}, this state means the thread is requesting the lock (not waiting for it).
Delayed-Insert Thread States

- **User sleep**
  The thread has invoked a `SLEEP()` call.

- **Waiting for release of readlock**
  The thread is waiting for a global read lock obtained by another thread (with `FLUSH TABLES WITH READ LOCK`) to be released.

- **Waiting for tables, Waiting for table**
  The thread got a notification that the underlying structure for a table has changed and it needs to reopen the table to get the new structure. However, to reopen the table, it must wait until all other threads have closed the table in question.

  This notification takes place if another thread has used `FLUSH TABLES` or one of the following statements on the table in question: `FLUSH TABLES tbl_name`, `ALTER TABLE`, `RENAME TABLE`, `REPAIR TABLE`, `ANALYZE TABLE`, or `OPTIMIZE TABLE`.

- **Waiting on cond**
  A generic state in which the thread is waiting for a condition to become true. No specific state information is available.

- **Waiting to get readlock**
  The thread has issued a `FLUSH TABLES WITH READ LOCK` statement to obtain a global read lock and is waiting to obtain the lock.

- **Writing to net**
  The server is writing a packet to the network.

### 8.14.3 Delayed-Insert Thread States

These thread states are associated with processing for `DELAYED` inserts (see Section 13.2.5.2, “INSERT DELAYED Syntax”). Some states are associated with connection threads that process `INSERT DELAYED` statements from clients. Other states are associated with delayed-insert handler threads that insert the rows. There is a delayed-insert handler thread for each table for which `INSERT DELAYED` statements are issued.

States associated with a connection thread that processes an `INSERT DELAYED` statement from the client:

- **allocating local table**
  The thread is preparing to feed rows to the delayed-insert handler thread.

- **Creating delayed handler**
  The thread is creating a handler for `DELAYED` inserts.

- **got handler lock**
  This occurs before the `allocating local table` state and after the `waiting for handler lock` state, when the connection thread gets access to the delayed-insert handler thread.

- **got old table**
  This occurs after the `waiting for handler open` state. The delayed-insert handler thread has signaled that it has ended its initialization phase, which includes opening the table for delayed inserts.
Query Cache Thread States

- **storing row into queue**
  The thread is adding a new row to the list of rows that the delayed-insert handler thread must insert.

- **waiting for delay_list**
  This occurs during the initialization phase when the thread is trying to find the delayed-insert handler thread for the table, and before attempting to gain access to the list of delayed-insert threads.

- **waiting for handler insert**
  An `INSERT DELAYED` handler has processed all pending inserts and is waiting for new ones.

- **waiting for handler lock**
  This occurs before the allocating local table state when the connection thread waits for access to the delayed-insert handler thread.

- **waiting for handler open**
  This occurs after the creating delayed handler state and before the got old table state. The delayed-insert handler thread has just been started, and the connection thread is waiting for it to initialize.

States associated with a delayed-insert handler thread that inserts the rows:

- **insert**
  The state that occurs just before inserting rows into the table.

- **reschedule**
  After inserting a number of rows, the delayed-insert thread sleeps to let other threads do work.

- **upgrading lock**
  A delayed-insert handler is trying to get a lock for the table to insert rows.

- **Waiting for INSERT**
  A delayed-insert handler is waiting for a connection thread to add rows to the queue (see storing row into queue).

### 8.14.4 Query Cache Thread States

These thread states are associated with the query cache (see Section 8.10.3, “The MySQL Query Cache”).

- **checking privileges on cached query**
  The server is checking whether the user has privileges to access a cached query result.

- **checking query cache for query**
  The server is checking whether the current query is present in the query cache.

- **invalidating query cache entries**
  Query cache entries are being marked invalid because the underlying tables have changed.

- **sending cached result to client**
  The server is taking the result of a query from the query cache and sending it to the client.
• storing result in query cache

The server is storing the result of a query in the query cache.

8.14.5 Replication Master Thread States

The following list shows the most common states you may see in the State column for the master’s Binlog Dump thread. If you see no Binlog Dump threads on a master server, this means that replication is not running—that is, that no slaves are currently connected.

• Sending binlog event to slave

Binary logs consist of events, where an event is usually an update plus some other information. The thread has read an event from the binary log and is now sending it to the slave.

• Finished reading one binlog; switching to next binlog

The thread has finished reading a binary log file and is opening the next one to send to the slave.

• Has sent all binlog to slave; waiting for binlog to be updated

The thread has read all outstanding updates from the binary logs and sent them to the slave. The thread is now idle, waiting for new events to appear in the binary log resulting from new updates occurring on the master.

• Waiting to finalize termination

A very brief state that occurs as the thread is stopping.

8.14.6 Replication Slave I/O Thread States

The following list shows the most common states you see in the State column for a slave server I/O thread. This state also appears in the Slave_IO_State column displayed by SHOW SLAVE STATUS, so you can get a good view of what is happening by using that statement.

• Waiting for master update

The initial state before Connecting to master.

• Connecting to master

The thread is attempting to connect to the master.

• Checking master version

A state that occurs very briefly, after the connection to the master is established.

• Registering slave on master

A state that occurs very briefly after the connection to the master is established.

• Requesting binlog dump

A state that occurs very briefly, after the connection to the master is established. The thread sends to the master a request for the contents of its binary logs, starting from the requested binary log file name and position.

• Waiting to reconnect after a failed binlog dump request

If the binary log dump request failed (due to disconnection), the thread goes into this state while it sleeps, then tries to reconnect periodically. The interval between retries can be specified using the CHANGE MASTER TO statement or the --master-connect-retry option.
Replication Slave SQL Thread States

- **Reconnecting after a failed binlog dump request**
  The thread is trying to reconnect to the master.

- **Waiting for master to send event**
  The thread has connected to the master and is waiting for binary log events to arrive. This can last for a long time if the master is idle. If the wait lasts for `slave_net_timeout` seconds, a timeout occurs. At that point, the thread considers the connection to be broken and makes an attempt to reconnect.

- **Queueing master event to the relay log**
  The thread has read an event and is copying it to the relay log so that the SQL thread can process it.

- **Waiting to reconnect after a failed master event read**
  An error occurred while reading (due to disconnection). The thread is sleeping for the number of seconds set by the `CHANGE MASTER TO` statement or `--master-connect-retry` option (default 60) before attempting to reconnect.

- **Reconnecting after a failed master event read**
  The thread is trying to reconnect to the master. When connection is established again, the state becomes **Waiting for master to send event**.

- **Waiting for the slave SQL thread to free enough relay log space**
  You are using a nonzero `relay_log_space_limit` value, and the relay logs have grown large enough that their combined size exceeds this value. The I/O thread is waiting until the SQL thread frees enough space by processing relay log contents so that it can delete some relay log files.

- **Waiting for slave mutex on exit**
  A state that occurs briefly as the thread is stopping.

**8.14.7 Replication Slave SQL Thread States**

The following list shows the most common states you may see in the **State** column for a slave server SQL thread:

- **Waiting for the next event in relay log**
  The initial state before **Reading event from the relay log**.

- **Reading event from the relay log**
  The thread has read an event from the relay log so that the event can be processed.

- **Has read all relay log; waiting for the slave I/O thread to update it**
  The thread has processed all events in the relay log files, and is now waiting for the I/O thread to write new events to the relay log.

- **Making temp file**
  The thread is executing a `LOAD DATA INFILE` statement and is creating a temporary file containing the data from which the slave will read rows.

- **Waiting for slave mutex on exit**
  A very brief state that occurs as the thread is stopping.
The State column for the I/O thread may also show the text of a statement. This indicates that the thread has read an event from the relay log, extracted the statement from it, and is executing it.

**8.14.8 Replication Slave Connection Thread States**

These thread states occur on a replication slave but are associated with connection threads, not with the I/O or SQL threads.

- **Changing master**
  The thread is processing a `CHANGE MASTER TO` statement.

- **Creating table from master dump**
  The slave is creating a table using the `CREATE TABLE` statement contained in the dump from the master. Used for `LOAD TABLE FROM MASTER` and `LOAD DATA FROM MASTER`.

- **Killing slave**
  The thread is processing a `STOP SLAVE` statement.

- **Opening master dump table**
  This state occurs after `Creating table from master dump`.

- **Reading master dump table data**
  This state occurs after `Opening master dump table`.

- **Rebuilding the index on master dump table**
  This state occurs after `Reading master dump table data`.

- **starting slave**
  The thread is starting the slave threads after processing a successful `LOAD DATA FROM MASTER` load operation.

**8.14.9 MySQL Cluster Thread States**

- **Committing events to binlog**

- **Opening mysql.ndb_apply_status**

- **Processing events**
  The thread is processing events for binary logging.

- **Processing events from schema table**
  The thread is doing the work of schema replication.

- **Shutting down**

- **Syncing ndb table schema operation and binlog**
  This is used to have a correct binary log of schema operations for NDB.

- **Waiting for event from ndbcluster**
  The server is acting as an SQL node in a MySQL Cluster, and is connected to a cluster management node.
8.14.10 Event Scheduler Thread States

These states occur for the Event Scheduler thread, threads that are created to execute scheduled events, or threads that terminate the scheduler.

- **Clearing**
  
The scheduler thread or a thread that was executing an event is terminating and is about to end.

- **Initialized**
  
The scheduler thread or a thread that will execute an event has been initialized.

- **Waiting for next activation**
  
The scheduler has a nonempty event queue but the next activation is in the future.

- **Waiting for scheduler to stop**
  
The thread issued `SET GLOBAL event_scheduler=OFF` and is waiting for the scheduler to stop.

- **Waiting on empty queue**
  
The scheduler's event queue is empty and it is sleeping.

This chapter discusses the rules for writing the following elements of SQL statements when using MySQL:

- Literal values such as strings and numbers
- Identifiers such as database, table, and column names
- Keywords and reserved words
- User-defined and system variables
- Comments

9.1 Literal Values

This section describes how to write literal values in MySQL. These include strings, numbers, hexadecimal values, boolean values, and NULL. The section also covers the various nuances and "gotchas" that you may run into when dealing with these basic types in MySQL.

9.1.1 String Literals

A string is a sequence of bytes or characters, enclosed within either single quote ("'") or double quote (""") characters. Examples:

'a string'

"another string"

Quoted strings placed next to each other are concatenated to a single string. The following lines are equivalent:

'a string'

'a' ' ' 'string'

If the ANSI_QUOTES SQL mode is enabled, string literals can be quoted only within single quotation marks because a string quoted within double quotation marks is interpreted as an identifier.
A *binary string* is a string of bytes that has no character set or collation. A *nonbinary string* is a string of characters that has a character set and collation. For both types of strings, comparisons are based on the numeric values of the string unit. For binary strings, the unit is the byte. For nonbinary strings the unit is the character and some character sets support multibyte characters. Character value ordering is a function of the string collation.

String literals may have an optional character set introducer and **COLLATE** clause:

```
[charset_name] 'string' [COLLATE collation_name]
```

Examples:

```
SELECT _latin1'string';
SELECT _latin1'string' COLLATE latin1_danish_ci;
```

You can use *N'literal'* (or *n'literal'* ) to create a string in the national character set. These statements are equivalent:

```
SELECT N'some text';
SELECT n'some text';
SELECT _utf8'some text';
```

For more information about these forms of string syntax, see Section 10.1.3.5, “Character String Literal Character Set and Collation”, and Section 10.1.3.6, “National Character Set”.

Within a string, certain sequences have special meaning unless the **NO_BACKSLASH_ESCAPES** SQL mode is enabled. Each of these sequences begins with a backslash ( \ ), known as the *escape character*. MySQL recognizes the escape sequences shown in Table 9.1, “Special Character Escape Sequences”. For all other escape sequences, backslash is ignored. That is, the escaped character is interpreted as if it was not escaped. For example, \x is just x. These sequences are case sensitive. For example, \b is interpreted as a backspace, but \B is interpreted as B. Escape processing is done according to the character set indicated by the **character_set_connection** system variable. This is true even for strings that are preceded by an introducer that indicates a different character set, as discussed in Section 10.1.3.5, “Character String Literal Character Set and Collation”.

**Table 9.1 Special Character Escape Sequences**

<table>
<thead>
<tr>
<th>Escape Sequence</th>
<th>Character Represented by Sequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>\0</td>
<td>An ASCII NUL (X'00') character</td>
</tr>
<tr>
<td>'</td>
<td>A single quote (’’) character</td>
</tr>
<tr>
<td>&quot;</td>
<td>A double quote (“”) character</td>
</tr>
<tr>
<td>\b</td>
<td>A backspace character</td>
</tr>
<tr>
<td>\n</td>
<td>A newline (linefeed) character</td>
</tr>
<tr>
<td>\r</td>
<td>A carriage return character</td>
</tr>
<tr>
<td>\t</td>
<td>A tab character</td>
</tr>
<tr>
<td>\Z</td>
<td>ASCII 26 (Control+Z); see note following the table</td>
</tr>
<tr>
<td>\</td>
<td>A backslash (\”) character</td>
</tr>
<tr>
<td>%</td>
<td>A “%” character; see note following the table</td>
</tr>
<tr>
<td>_</td>
<td>A “_” character; see note following the table</td>
</tr>
</tbody>
</table>

The ASCII 26 character can be encoded as “\Z” to enable you to work around the problem that ASCII 26 stands for END-OF-FILE on Windows. ASCII 26 within a file causes problems if you try to use *mysql db_name < file_name*.
The "\%" and "\_" sequences are used to search for literal instances of "%" and "_" in pattern-matching contexts where they would otherwise be interpreted as wildcard characters. See the description of the LIKE operator in Section 12.5.1, "String Comparison Functions". If you use "\%" or "\_" outside of pattern-matching contexts, they evaluate to the strings "\%" and "\_", not to "%" and "_".

There are several ways to include quote characters within a string:

- A "'" inside a string quoted with "'" may be written as "''.
- A "" inside a string quoted with "" may be written as """".
- Precede the quote character by an escape character ("\").
- A "'" inside a string quoted with "" needs no special treatment and need not be doubled or escaped. In the same way, "" inside a string quoted with "" needs no special treatment.

The following SELECT statements demonstrate how quoting and escaping work:

```sql
mysql> SELECT 'hello', "hello", ""hello"", 'hel\'lo', '\hello';
+-------+---------+-----------+--------+--------+
| hello | "hello" | ""hello"" | hel'lo | 'hello |
+-------+---------+-----------+--------+--------+
mysql> SELECT 'hello', "'hello'", "''hello''", "hel"lo", "\hello";
+-------+---------+-----------+--------+--------+
| hello | 'hello' | ''hello'' | hel"lo | "hello |
+-------+---------+-----------+--------+--------+
mysql> SELECT 'This\nIs\nFour\nLines';
+---------------------+
| This
Is
Four
Lines | 
+---------------------+
mysql> SELECT 'disappearing\ backslash';
+-----------------------+
| disappearing backslash |
+-----------------------+
```

If you want to insert binary data into a string column (such as a BLOB column), you should represent certain characters by escape sequences. Backslash ("\") and the quote character used to quote the string must be escaped. In certain client environments, it may also be necessary to escape NUL or Control-Z. The mysql client truncates quoted strings containing NUL characters if they are not escaped, and Control-Z may be taken for END-OF-FILE on Windows if not escaped. For the escape sequences that represent each of these characters, see Table 9.1, "Special Character Escape Sequences".

When writing application programs, any string that might contain any of these special characters must be properly escaped before the string is used as a data value in an SQL statement that is sent to the MySQL server. You can do this in two ways:

- Process the string with a function that escapes the special characters. In a C program, you can use the mysql_real_escape_string() C API function to escape characters. See Section 21.8.7.53, "mysql_real_escape_string()". Within SQL statements that construct other SQL statements, you can use the QUOTE() function. The Perl DBI interface provides a quote method to convert special characters to the proper escape sequences. See Section 21.10, "MySQL Perl API". Other language interfaces may provide a similar capability.
- As an alternative to explicitly escaping special characters, many MySQL APIs provide a placeholder capability that enables you to insert special markers into a statement string, and then bind data values to them when you issue the statement. In this case, the API takes care of escaping special characters in the values for you.
9.1.2 Number Literals

Number literals include exact-value (integer and DECIMAL) literals and approximate-value (floating-point) literals.

Integers are represented as a sequence of digits. Numbers may include “.” as a decimal separator. Numbers may be preceded by “-” or “+” to indicate a negative or positive value, respectively. Numbers represented in scientific notation with a mantissa and exponent are approximate-value numbers.

Exact-value numeric literals have an integer part or fractional part, or both. They may be signed. Examples: 1, .2, 3.4, -5, -6.78, +9.10.

Approximate-value numeric literals are represented in scientific notation with a mantissa and exponent. Either or both parts may be signed. Examples: 1.2E3, 1.2E-3, -1.2E3, -1.2E-3.

Two numbers that look similar may be treated differently. For example, 2.34 is an exact-value (fixed-point) number, whereas 2.34E0 is an approximate-value (floating-point) number.

The DECIMAL data type is a fixed-point type and calculations are exact. In MySQL, the DECIMAL type has several synonyms: NUMERIC, DEC, FIXED. The integer types also are exact-value types. For more information about exact-value calculations, see Section 12.18, “Precision Math”.

The FLOAT and DOUBLE data types are floating-point types and calculations are approximate. In MySQL, types that are synonymous with FLOAT or DOUBLE are DOUBLE PRECISION and REAL.

An integer may be used in a floating-point context; it is interpreted as the equivalent floating-point number.

9.1.3 Date and Time Literals

Date and time values can be represented in several formats, such as quoted strings or as numbers, depending on the exact type of the value and other factors. For example, in contexts where MySQL expects a date, it interprets any of '2015-07-21', '20150721', and 20150721 as a date.

This section describes the acceptable formats for date and time literals. For more information about the temporal data types, such as the range of permitted values, consult these sections:

• Section 11.1.2, “Date and Time Type Overview”
• Section 11.3, “Date and Time Types”

Standard SQL and ODBC Date and Time Literals. Standard SQL permits temporal literals to be specified using a type keyword and a string. The space between the keyword and string is optional.

```
DATE 'str'
TIME 'str'
TIMESTAMP 'str'
```

MySQL recognizes those constructions and also the corresponding ODBC syntax:

```
{ d 'str' }
{ t 'str' }
{ ts 'str' }
```

However, MySQL ignores the type keyword and each of the preceding constructions produces the string value 'str', with a type of VARCHAR.

String and Numeric Literals in Date and Time Context. MySQL recognizes DATE values in these formats:

• As a string in either 'YYYY-MM-DD' or 'YY-MM-DD' format. A “relaxed” syntax is permitted: any punctuation character may be used as the delimiter between date parts. For example, '2012-12-31', '2012/12/31', '2012^12^31', and '2012@12@31' are equivalent.
• As a string with no delimiters in either 'YYYYMMDD' or 'YYMMDD' format, provided that the string makes sense as a date. For example, '20070523' and '070523' are interpreted as '2007-05-23', but '071332' is illegal (it has nonsensical month and day parts) and becomes '0000-00-00'.

• As a number in either YYYYMMDD or YYMMDD format, provided that the number makes sense as a date. For example, 19830905 and 830905 are interpreted as '1983-09-05'.

MySQL recognizes DATETIME and TIMESTAMP values in these formats:

• As a string in either 'YYYY-MM-DD HH:MM:SS' or 'YY-MM-DD HH:MM:SS' format. A "relaxed" syntax is permitted here, too: Any punctuation character may be used as the delimiter between date parts or time parts. For example, '2012-12-31 11:30:45', '2012^12^31 11+30+45', '2012/12/31 11*30*45', and '2012@12@31 11^30^45' are equivalent.

The date and time parts can be separated by T rather than a space. For example, '2012-12-31 11:30:45' '2012-12-31T11:30:45' are equivalent.

• As a string with no delimiters in either 'YYYYMMDDHHMMSS' or 'YYMMDDHHMMSS' format, provided that the string makes sense as a date. For example, '20070523091528' and '070523091528' are interpreted as '2007-05-23 09:15:28', but '071122129015' is illegal (it has a nonsensical minute part) and becomes '0000-00-00 00:00:00'.

• As a number in either YYYYMMDDHHMMSS or YYMMDDHHMMSS format, provided that the number makes sense as a date. For example, 19830905132800 and 830905132800 are interpreted as '1983-09-05 13:28:00'.

A DATETIME or TIMESTAMP value can include a trailing fractional seconds part in up to microseconds (6 digits) precision. Although this fractional part is recognized, it is discarded from values stored into DATETIME or TIMESTAMP columns. For information about fractional seconds support in MySQL, see Section 11.3.6, "Fractional Seconds in Time Values".

Dates containing two-digit year values are ambiguous because the century is unknown. MySQL interprets two-digit year values using these rules:

• Year values in the range 70–99 are converted to 1970–1999.

• Year values in the range 00–69 are converted to 2000–2069.

See also Section 11.3.8, “Two-Digit Years in Dates".

For values specified as strings that include date part delimiters, it is unnecessary to specify two digits for month or day values that are less than 10. '2015-6-9' is the same as '2015-06-09'. Similarly, for values specified as strings that include time part delimiters, it is unnecessary to specify two digits for hour, minute, or second values that are less than 10. '2015-10-30 1:2:3' is the same as '2015-10-30 01:02:03'.

Values specified as numbers should be 6, 8, 12, or 14 digits long. If a number is 8 or 14 digits long, it is assumed to be in YYYYMMDD or YYYYMMDDHHMMSS format and that the year is given by the first 4 digits. If the number is 6 or 12 digits long, it is assumed to be in YYMMDD or YYMMDDHHMMSS format and that the year is given by the first 2 digits. Numbers that are not one of these lengths are interpreted as though padded with leading zeros to the closest length.

Values specified as nondelimited strings are interpreted according their length. For a string 8 or 14 characters long, the year is assumed to be given by the first 4 characters. Otherwise, the year is assumed to be given by the first 2 characters. The string is interpreted from left to right to find year, month, day, hour, minute, and second values, for as many parts as are present in the string. This means you should not use strings that have fewer than 6 characters. For example, if you specify '9903', thinking that represents March, 1999, MySQL converts it to the "zero" date value. This occurs because the year and month values are 99 and 03, but the day part is completely missing. However, you can explicitly specify a value of zero to represent missing month or day parts. For example, to insert the value '1999-03-00', use '990300'.
MySQL recognizes `TIME` values in these formats:

- As a string in 'D HH:MM:SS' format. You can also use one of the following “relaxed” syntaxes:
  - 'HH:MM:SS', 'HH:MM', 'D HH:MM', 'D HH', or 'SS'. Here D represents days and can have a value from 0 to 34.
  - As a string with no delimiters in 'HHMMSS' format, provided that it makes sense as a time. For example, '10:11:12' is understood as '10:11:12', but '109712' is illegal (it has a nonsensical minute part) and becomes '00:00:00'.
  - As a number in HHMMSS format, provided that it makes sense as a time. For example, 101112 is understood as '10:11:12'. The following alternative formats are also understood: SS, MMSS, or HHMMSS.

A trailing fractional seconds part is recognized in the 'D HH:MM:SS.fraction', 'HH:MM:SS.fraction', 'HHMMSS.fraction', and HHMMSS.fraction time formats, where fraction is the fractional part in up to microseconds (6 digits) precision. Although this fractional part is recognized, it is discarded from values stored into `TIME` columns. For information about fractional seconds support in MySQL, see Section 11.3.6, “Fractional Seconds in Time Values”.

For `TIME` values specified as strings that include a time part delimiter, it is unnecessary to specify two digits for hours, minutes, or seconds values that are less than 10. '8:3:2' is the same as '08:03:02'.

### 9.1.4 Hexadecimal Literals

MySQL supports hexadecimal values, written using `X'val'`, `x'val'`, or `0xval` format, where `val` contains hexadecimal digits (0..9, A..F). Lettercase of the digits does not matter. For values written using `X'val'` or `x'val'` format, `val` must contain an even number of digits. For values written using `0xval` syntax, values that contain an odd number of digits are treated as having an extra leading 0. For example, `0x0a` and `0xaa` are interpreted as `0x00a` and `0x0aaa`.

In numeric contexts, hexadecimal values act like integers (64-bit precision). In string contexts, they act like binary strings, where each pair of hex digits is converted to a character:

```sql
mysql> SELECT X'4D7953514C';
-> 'MySQL'
mysql> SELECT x'0a'+0;
-> 10
mysql> SELECT 0x5061756c;
-> 'Paul'
```

The default type of a hexadecimal value is a string. If you want to ensure that the value is treated as a number, you can use `CAST(... AS UNSIGNED)`:

```sql
mysql> SELECT X'41', CAST(X'41' AS UNSIGNED);
-> 'A', 65
```

The `X'hexstring'` and `x'val'` syntaxes are based on standard SQL. The `0x` syntax is based on ODBC. Hexadecimal strings are often used by ODBC to supply values for `BLOB` columns.

To convert a string or a number to a string in hexadecimal format, use the `HEX()` function:

```sql
mysql> SELECT HEX('cat');
-> '636174'
mysql> SELECT X'636174';
-> 'cat'
```

### 9.1.5 Boolean Literals

The constants `TRUE` and `FALSE` evaluate to 1 and 0, respectively. The constant names can be written in any lettercase.
9.1.6 Bit-Field Literals

Bit-field values can be written using \texttt{b'value'} or \texttt{0bvalue} notation. \texttt{value} is a binary value written using zeros and ones.

Bit-field notation is convenient for specifying values to be assigned to \texttt{BIT} columns:

\begin{verbatim}
mysql> CREATE TABLE t (b BIT(8));
mysql> INSERT INTO t SET b = b'11111111';
mysql> INSERT INTO t SET b = b'1010';
mysql> INSERT INTO t SET b = b'0101';
\end{verbatim}

Bit values are returned as binary values. To display them in printable form, add 0 or use a conversion function such as \texttt{BIN()}. High-order 0 bits are not displayed in the converted value.

\begin{verbatim}
mysql> SELECT b+0, BIN(b+0), OCT(b+0), HEX(b+0) FROM t;
\end{verbatim}

\begin{verbatim}
+------+----------+----------+----------+
| b+0  | BIN(b+0) | OCT(b+0) | HEX(b+0) |
| 255  | 11111111 | 377      | FF       |
| 10   | 1010     | 12       | A        |
| 5    | 101      | 5        | 5        |
+------+----------+----------+----------+
\end{verbatim}

Bit values assigned to user variables are treated as binary strings. To assign a bit value as a number to a user variable, use \texttt{CAST()} or \texttt{+0}:

\begin{verbatim}
mysql> SET @v1 = 0b1000001;
mysql> SET @v2 = CAST(0b1000001 AS UNSIGNED), @v3 = 0b1000001+0;
mysql> SELECT @v1, @v2, @v3;
\end{verbatim}

\begin{verbatim}
+------+------+------+
| @v1  | @v2  | @v3  |
| A    | 65   | 65   |
+------+------+------+
\end{verbatim}

9.1.7 NULL Values

The \texttt{NULL} value means “no data.” \texttt{NULL} can be written in any lettercase. A synonym is \texttt{\N} (case sensitive).

For text file import or export operations performed with \texttt{LOAD DATA INFILE} or \texttt{SELECT ... INTO OUTFILE}, \texttt{NULL} is represented by the \texttt{\N} sequence. See Section 13.2.6, “LOAD DATA INFILE Syntax”.

Be aware that the \texttt{NULL} value is different from values such as 0 for numeric types or the empty string for string types. For more information, see Section B.5.4.3, “Problems with NULL Values”.

9.2 Schema Object Names

Certain objects within MySQL, including database, table, index, column, alias, view, stored procedure, partition, tablespace, and other object names are known as identifiers. This section describes the permissible syntax for identifiers in MySQL. Section 9.2.2, “Identifier Case Sensitivity”, describes which types of identifiers are case sensitive and under what conditions.

An identifier may be quoted or unquoted. If an identifier contains special characters or is a reserved word, you \textit{must} quote it whenever you refer to it. (Exception: A reserved word that follows a period
in a qualified name must be an identifier, so it need not be quoted.) Reserved words are listed at Section 9.3, “Keywords and Reserved Words”.

Identifiers are converted to Unicode internally. They may contain these characters:

- Permitted characters in unquoted identifiers:
  - ASCII: [0-9,a-z,A-Z$_] (basic Latin letters, digits 0-9, dollar, underscore)
  - Extended: U+0080 .. U+FFFF

- Permitted characters in quoted identifiers include the full Unicode Basic Multilingual Plane (BMP), except U+0000:
  - ASCII: U+0001 .. U+007F
  - Extended: U+0080 .. U+FFFF

- ASCII NUL (U+0000) and supplementary characters (U+10000 and higher) are not permitted in quoted or unquoted identifiers.

- Identifiers may begin with a digit but unless quoted may not consist solely of digits.

- Database, table, and column names cannot end with space characters.

- Before MySQL 5.1.6, database and table names cannot contain “/”, “\”, “.”, or characters that are not permitted in file names.

The identifier quote character is the backtick (``):

```
mysql> SELECT * FROM `select` WHERE `select`.id > 100;
```

If the ANSI_QUOTES SQL mode is enabled, it is also permissible to quote identifiers within double quotation marks:

```
mysql> CREATE TABLE "test" (col INT);
ERROR 1064: You have an error in your SQL syntax...
```

The ANSI_QUOTES mode causes the server to interpret double-quoted strings as identifiers. Consequently, when this mode is enabled, string literals must be enclosed within single quotation marks. They cannot be enclosed within double quotation marks. The server SQL mode is controlled as described in Section 5.1.7, “Server SQL Modes”.

Identifier quote characters can be included within an identifier if you quote the identifier. If the character to be included within the identifier is the same as that used to quote the identifier itself, then you need to double the character. The following statement creates a table named a`b that contains a column named c"d:

```
mysql> CREATE TABLE `a``b` (`c"d` INT);
```

In the select list of a query, a quoted column alias can be specified using identifier or string quoting characters:

```
mysql> SELECT 1 AS `one`, 2 AS 'two';
```

<table>
<thead>
<tr>
<th>one</th>
<th>two</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
</tr>
</tbody>
</table>
Elsewhere in the statement, quoted references to the alias must use identifier quoting or the reference is treated as a string literal.

It is recommended that you do not use names that begin with \texttt{Me} or \texttt{MeN}, where \texttt{M} and \texttt{N} are integers. For example, avoid using \texttt{1e} as an identifier, because an expression such as \texttt{1e+3} is ambiguous. Depending on context, it might be interpreted as the expression \texttt{1e + 3} or as the number \texttt{1e+3}.

Be careful when using \texttt{MD5()} to produce table names because it can produce names in illegal or ambiguous formats such as those just described.

A user variable cannot be used directly in an SQL statement as an identifier or as part of an identifier. See Section 9.4, “User-Defined Variables”, for more information and examples of workarounds.

As of MySQL 5.1.6, special characters in database and table names are encoded in the corresponding file system names as described in Section 9.2.3, “Mapping of Identifiers to File Names”. If you have databases or tables from an older version of MySQL that contain special characters and for which the underlying directory names or file names have not been updated to use the new encoding, the server displays their names with a prefix of \texttt{#mysql50#}. For information about referring to such names or converting them to the newer encoding, see that section.

The following table describes the maximum length for each type of identifier.

<table>
<thead>
<tr>
<th>Identifier</th>
<th>Maximum Length (characters)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>64 (NDB storage engine: 63)</td>
</tr>
<tr>
<td>Table</td>
<td>64 (NDB storage engine: 63)</td>
</tr>
<tr>
<td>Column</td>
<td>64</td>
</tr>
<tr>
<td>Index</td>
<td>64</td>
</tr>
<tr>
<td>Constraint</td>
<td>64</td>
</tr>
<tr>
<td>Stored Program</td>
<td>64</td>
</tr>
<tr>
<td>View</td>
<td>64</td>
</tr>
<tr>
<td>Tablespace</td>
<td>64</td>
</tr>
<tr>
<td>Server</td>
<td>64</td>
</tr>
<tr>
<td>Log File Group</td>
<td>64</td>
</tr>
<tr>
<td>Alias</td>
<td>256 (see exception following table)</td>
</tr>
<tr>
<td>Compound Statement Label</td>
<td>16</td>
</tr>
</tbody>
</table>

As of MySQL 5.1.23, aliases for column names in \texttt{CREATE VIEW} statements are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters).

Identifiers are stored using Unicode (UTF-8). This applies to identifiers in table definitions that are stored in \texttt{.frm} files and to identifiers stored in the grant tables in the \texttt{mysql} database. The sizes of the identifier string columns in the grant tables are measured in characters. You can use multibyte characters without reducing the number of characters permitted for values stored in these columns. As indicated earlier, the permissible Unicode characters are those in the Basic Multilingual Plane (BMP). Supplementary characters are not permitted.

MySQL Cluster imposes a maximum length of 63 characters for names of databases and tables. See Section 17.1.6.5, “Limits Associated with Database Objects in MySQL Cluster”.

### 9.2.1 Identifier Qualifiers

MySQL permits names that consist of a single identifier or multiple identifiers. The components of a multiple-part name must be separated by period (\texttt{.}) characters. The initial parts of a multiple-part name act as qualifiers that affect the context within which the final identifier is interpreted.

In MySQL, you can refer to a table column using any of the following forms.
### Identifier Case Sensitivity

<table>
<thead>
<tr>
<th>Column Reference</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>col_name</code></td>
<td>The column <code>col_name</code> from whichever table used in the statement contains a column of that name.</td>
</tr>
<tr>
<td><code>tbl_name.col_name</code></td>
<td>The column <code>col_name</code> from table <code>tbl_name</code> of the default database.</td>
</tr>
<tr>
<td><code>db_name.tbl_name.col_name</code></td>
<td>The column <code>col_name</code> from table <code>tbl_name</code> of the database <code>db_name</code>.</td>
</tr>
</tbody>
</table>

The qualifier character is a separate token and need not be contiguous with the associated identifiers. For example, `tbl_name.col_name` and `tbl_name . col_name` are equivalent.

If any components of a multiple-part name require quoting, quote them individually rather than quoting the name as a whole. For example, write `"my-table"."my-column"`, not `"my-table.my-column"`.

A reserved word that follows a period in a qualified name must be an identifier, so in that context it need not be quoted.

You need not specify a `tbl_name` or `db_name.tbl_name` prefix for a column reference in a statement unless the reference would be ambiguous. Suppose that tables `t1` and `t2` each contain a column `c`, and you retrieve `c` in a `SELECT` statement that uses both `t1` and `t2`. In this case, `c` is ambiguous because it is not unique among the tables used in the statement. You must qualify it with a table name as `t1.c` or `t2.c` to indicate which table you mean. Similarly, to retrieve from a table `t` in database `db1` and from a table `t` in database `db2` in the same statement, you must refer to columns in those tables as `db1.t.col_name` and `db2.t.col_name`.

The syntax `.tbl_name` means the table `tbl_name` in the default database. This syntax is accepted for ODBC compatibility because some ODBC programs prefix table names with a `"."` character.

#### 9.2.2 Identifier Case Sensitivity

In MySQL, databases correspond to directories within the data directory. Each table within a database corresponds to at least one file within the database directory (and possibly more, depending on the storage engine). Triggers also correspond to files. Consequently, the case sensitivity of the underlying operating system plays a part in the case sensitivity of database, table, and trigger names. This means such names are not case sensitive in Windows, but are case sensitive in most varieties of Unix. One notable exception is OS X, which is Unix-based but uses a default file system type (HFS+) that is not case sensitive. However, OS X also supports UFS volumes, which are case sensitive just as on any Unix. See Section 1.8.1, "MySQL Extensions to Standard SQL". The `lower_case_table_names` system variable also affects how the server handles identifier case sensitivity, as described later in this section.

**Note**

Although database, table, and trigger names are not case sensitive on some platforms, you should not refer to one of these using different cases within the same statement. The following statement would not work because it refers to a table both as `my_table` and as `MY_TABLE`:

```
mysql> SELECT * FROM my_table WHERE MY_TABLE.col=1;
```

Column, index, stored routine, and event names are not case sensitive on any platform, nor are column aliases.

However, names of logfile groups are case sensitive. This differs from standard SQL.

By default, table aliases are case sensitive on Unix, but not so on Windows or OS X. The following statement would not work on Unix, because it refers to the alias both as `a` and as `A`:

```
mysql> SELECT col_name FROM tbl_name AS a
```
However, this same statement is permitted on Windows. To avoid problems caused by such differences, it is best to adopt a consistent convention, such as always creating and referring to databases and tables using lowercase names. This convention is recommended for maximum portability and ease of use.

How table and database names are stored on disk and used in MySQL is affected by the `lower_case_table_names` system variable, which you can set when starting `mysqld`. `lower_case_table_names` can take the values shown in the following table. This variable does not affect case sensitivity of trigger identifiers. On Unix, the default value of `lower_case_table_names` is 0. On Windows, the default value is 1. On OS X, the default value is 2.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Table and database names are stored on disk using the lettercase specified in the <code>CREATE TABLE</code> or <code>CREATE DATABASE</code> statement. Name comparisons are case sensitive. You should <em>not</em> set this variable to 0 if you are running MySQL on a system that has case-insensitive file names (such as Windows or OS X). If you force this variable to 0 with <code>--lower-case-table-names=0</code> on a case-insensitive file system and access MyISAM tablenames using different lettercases, index corruption may result.</td>
</tr>
<tr>
<td>1</td>
<td>Table names are stored in lowercase on disk and name comparisons are not case sensitive. MySQL converts all table names to lowercase on storage and lookup. This behavior also applies to database names and table aliases.</td>
</tr>
<tr>
<td>2</td>
<td>Table and database names are stored on disk using the lettercase specified in the <code>CREATE TABLE</code> or <code>CREATE DATABASE</code> statement, but MySQL converts them to lowercase on lookup. Name comparisons are not case sensitive. This works <em>only</em> on file systems that are not case sensitive! InnoDB table names are stored in lowercase, as for <code>lower_case_table_names=1</code>.</td>
</tr>
</tbody>
</table>

If you are using MySQL on only one platform, you do not normally have to change the `lower_case_table_names` variable from its default value. However, you may encounter difficulties if you want to transfer tables between platforms that differ in file system case sensitivity. For example, on Unix, you can have two different tables named `my_table` and `MY_TABLE`, but on Windows these two names are considered identical. To avoid data transfer problems arising from lettercase of database or table names, you have two options:

- **Use** `lower_case_table_names=1` on all systems. The main disadvantage with this is that when you use `SHOW TABLES` or `SHOW DATABASES`, you do not see the names in their original lettercase.

- **Use** `lower_case_table_names=0` on Unix and `lower_case_table_names=2` on Windows. This preserves the lettercase of database and table names. The disadvantage of this is that you must ensure that your statements always refer to your database and table names with the correct lettercase on Windows. If you transfer your statements to Unix, where lettercase is significant, they do not work if the lettercase is incorrect. **Exception:** If you are using InnoDB tables and you are trying to avoid these data transfer problems, you should set `lower_case_table_names` to 1 on all platforms to force names to be converted to lowercase.

If you plan to set the `lower_case_table_names` system variable to 1 on Unix, you must first convert your old database and table names to lowercase before stopping `mysqld` and restarting it with the new variable setting. To do this for an individual table, use `RENAME TABLE`:

```sql
RENAME TABLE T1 TO t1;
```

To convert one or more entire databases, dump them before setting `lower_case_table_names`, then drop the databases, and reload them after setting `lower_case_table_names`:

1. Use `mysqldump` to dump each database:
Do this for each database that must be recreated.

2. Use `DROP DATABASE` to drop each database.

3. Stop the server, set `lower_case_table_names`, and restart the server.

4. Reload the dump file for each database. Because `lower_case_table_names` is set, each database and table name will be converted to lowercase as it is recreated:

   ```
   mysql < db1.sql
   mysql < db2.sql
   ...
   ```

Object names may be considered duplicates if their uppercase forms are equal according to a binary collation. That is true for names of cursors, conditions, procedures, functions, savepoints, stored routine parameters, stored program local variables, and plugins. It is not true for names of columns, constraints, databases, partitions, statements prepared with `PREPARE`, tables, triggers, users, and user-defined variables.

File system case sensitivity can affect searches in string columns of `INFORMATION_SCHEMA` tables. For more information, see Section 10.1.7.9, "Collation and INFORMATION_SCHEMA Searches".

### 9.2.3 Mapping of Identifiers to File Names

There is a correspondence between database and table identifiers and names in the file system. For the basic structure, MySQL represents each database as a directory in the data directory, and each table by one or more files in the appropriate database directory. For the table format files (`.FRM`), the data is always stored in this structure and location.

For the data and index files, the exact representation on disk is storage engine specific. These files may be stored in the same location as the `.FRM` files, or the information may be stored in a separate file. InnoDB data is stored in the InnoDB data files. If you are using tablespaces with InnoDB, then the specific tablespace files you create are used instead.

Before MySQL 5.1.6, there are some limitations on the characters that can be used in identifiers for database objects that correspond to file system objects. For example, path name separator characters are not permitted, and "." is not permitted because it begins the extension for table files.

As of MySQL 5.1.6, any character is legal in database or table identifiers except ASCII NUL (0x00). MySQL encodes any characters that are problematic in the corresponding file system objects when it creates database directories or table files:

- Basic Latin letters (a..zA..Z), digits (0..9) and underscore (_) are encoded as is. Consequently, their case sensitivity directly depends on file system features.

- All other national letters from alphabets that have uppercase/lowercase mapping are encoded as shown in the following table. Values in the Code Range column are UCS-2 values.

<table>

</tr>
</tbody>
</table>

One of the bytes in the sequence encodes lettercase. For example: LATIN CAPITAL LETTER A WITH GRAVE is encoded as @0G, whereas LATIN SMALL LETTER A WITH GRAVE is encoded as @0g. Here the third byte (G or g) indicates lettercase. (On a case-insensitive file system, both letters will be treated as the same.)

For some blocks, such as Cyrillic, the second byte determines lettercase. For other blocks, such as Latin1 Supplement, the third byte determines lettercase. If two bytes in the sequence are letters (as in Greek Extended), the leftmost letter character stands for lettercase. All other letter bytes must be in lowercase.

- All nonletter characters except underscore (_), as well as letters from alphabets that do not have uppercase/lowercase mapping (such as Hebrew) are encoded using hexadecimal representation using lowercase letters for hex digits a..f:

- 0x003F -> @003f
- 0xFFFF -> @ffff

The hexadecimal values correspond to character values in the ucs2 double-byte character set.

On Windows, some names such as nul, prn, and aux cannot be used as file names because they are reserved as device names. As of MySQL 5.1.10, these are permissible names in MySQL. They are encoded by appending @@ to the name when the server creates the corresponding file or directory. This occurs on all platforms for portability of the corresponding database object between platforms.

If you have databases or tables from a version of MySQL older than 5.1.6 that contain special characters and for which the underlying directory names or file names have not been updated to use the new encoding, the server displays their names with a prefix of `#mysql50#` in the output from INFORMATION_SCHEMA tables or SHOW statements. For example, if you have a table named a@b and its name encoding has not been updated, SHOW TABLES displays it like this:

```
mysql> SHOW TABLES;
+----------------+
| Tables_in_test |
+----------------+
| #mysql50#a@b   |
+----------------+```

To refer to such a name for which the encoding has not been updated, you must supply the `#mysql50#` prefix:

```
mysql> SHOW COLUMNS FROM `a@b`;
ERROR 1146 (42S02): Table 'test.a@b' doesn't exist
```

```
mysql> SHOW COLUMNS FROM `#mysql50#a@b`;```
To update old names to eliminate the need to use the special prefix to refer to them, re-encode them with `mysqlcheck`. The following command updates all names to the new encoding:

```
shell> mysqlcheck --check-upgrade --fix-db-names --fix-table-names --all-databases
```

To check only specific databases or tables, omit `--all-databases` and provide the appropriate database or table arguments. For information about `mysqlcheck` invocation syntax, see Section 4.5.3, "mysqlcheck — A Table Maintenance Program".

**Note**
The `#mysql50#` prefix is intended only to be used internally by the server. You should not create databases or tables with names that use this prefix.

Also, `mysqlcheck` cannot fix names that contain literal instances of the `@` character that is used for encoding special characters. If you have databases or tables that contain this character, use `mysqldump` to dump them before upgrading to MySQL 5.1.6 or later, and then reload the dump file after upgrading.

### 9.2.4 Function Name Parsing and Resolution

MySQL 5.1 supports built-in (native) functions, user-defined functions (UDFs), and stored functions. This section describes how the server recognizes whether the name of a built-in function is used as a function call or as an identifier, and how the server determines which function to use in cases when functions of different types exist with a given name.

**Built-In Function Name Parsing**

The parser uses default rules for parsing names of built-in functions. These rules can be changed by enabling the `IGNORE_SPACE` SQL mode.

When the parser encounters a word that is the name of a built-in function, it must determine whether the name signifies a function call or is instead a nonexpression reference to an identifier such as a table or column name. For example, in the following statements, the first reference to `count` is a function call, whereas the second reference is a table name:

```
SELECT COUNT(*) FROM mytable;
CREATE TABLE count (i INT);
```

The parser should recognize the name of a built-in function as indicating a function call only when parsing what is expected to be an expression. That is, in nonexpression context, function names are permitted as identifiers.

However, some built-in functions have special parsing or implementation considerations, so the parser uses the following rules by default to distinguish whether their names are being used as function calls or as identifiers in nonexpression context:

- To use the name as a function call in an expression, there must be no whitespace between the name and the following "(`" parenthesis character.

- Conversely, to use the function name as an identifier, it must not be followed immediately by a parenthesis.

The requirement that function calls be written with no whitespace between the name and the parenthesis applies only to the built-in functions that have special considerations. `COUNT` is one such
name. The sql_functions[] array in the sql/lex.h source file lists the names of these special functions for which following whitespace determines their interpretation. Before MySQL 5.1, these are rather numerous (about 200). In MySQL 5.1, parser improvements reduce to about 30 the number of affected function names. You may find it easiest to treat the no-whitespace requirement as applying to all function calls.

The following table names the functions that are affected by the IGNORE_SPACE setting and listed as special in the sql/lex.h source file. For versions older than MySQL 5.1.13, the list is much longer; check the sql_functions[] array in the sql/lex.h source file.

<table>
<thead>
<tr>
<th>Function</th>
<th>Function</th>
<th>Function</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADDDATE</td>
<td>BIT_AND</td>
<td>BIT_OR</td>
<td>BIT_XOR</td>
</tr>
<tr>
<td>CAST</td>
<td>COUNT</td>
<td>CURDATE</td>
<td>CURTIME</td>
</tr>
<tr>
<td>DATE_ADD</td>
<td>DATE_SUB</td>
<td>EXTRACT</td>
<td>GROUP_CONCAT</td>
</tr>
<tr>
<td>MAX</td>
<td>MID</td>
<td>MIN</td>
<td>NOW</td>
</tr>
<tr>
<td>POSITION</td>
<td>SESSION_USER</td>
<td>STD</td>
<td>STDDEV</td>
</tr>
<tr>
<td>STDDEV_POP</td>
<td>STDDEV_SAMP</td>
<td>SUBDATE</td>
<td>SUBSTR</td>
</tr>
<tr>
<td>SUBSTRING</td>
<td>SUM</td>
<td>SYSDATE</td>
<td>SYSTEM_USER</td>
</tr>
<tr>
<td>TRIM</td>
<td>VARIANCE</td>
<td>VAR_POP</td>
<td>VAR_SAMP</td>
</tr>
</tbody>
</table>

For functions not listed as special in sql/lex.h, whitespace does not matter. They are interpreted as function calls only when used in expression context and may be used freely as identifiers otherwise. ASCII is one such name. However, for these nonaffected function names, interpretation may vary in expression context: func_name() is interpreted as a built-in function if there is one with the given name; if not, func_name() is interpreted as a user-defined function or stored function if one exists with that name.

The IGNORE_SPACE SQL mode can be used to modify how the parser treats function names that are whitespace-sensitive:

- With IGNORE_SPACE disabled, the parser interprets the name as a function call when there is no whitespace between the name and the following parenthesis. This occurs even when the function name is used in nonexpression context:

```sql
mysql> CREATE TABLE count (i INT);
ERROR 1064 (42000): You have an error in your SQL syntax ...
near 'count(i INT)'
```

To eliminate the error and cause the name to be treated as an identifier, either use whitespace following the name or write it as a quoted identifier (or both):

```sql
CREATE TABLE count (i INT);
CREATE TABLE 'count'(i INT);
CREATE TABLE 'count' (i INT);
```

- With IGNORE_SPACE enabled, the parser loosens the requirement that there be no whitespace between the function name and the following parenthesis. This provides more flexibility in writing function calls. For example, either of the following function calls are legal:

```sql
SELECT COUNT(*) FROM mytable;
SELECT COUNT (*) FROM mytable;
```

However, enabling IGNORE_SPACE also has the side effect that the parser treats the affected function names as reserved words (see Section 9.3, “Keywords and Reserved Words”). This means that a space following the name no longer signifies its use as an identifier. The name can be used in function calls with or without following whitespace, but causes a syntax error in nonexpression context unless it is quoted. For example, with IGNORE_SPACE enabled, both of the following statements fail with a syntax error because the parser interprets count as a reserved word:
CREATE TABLE count(i INT);
CREATE TABLE count(i INT);

To use the function name in nonexpression context, write it as a quoted identifier:

CREATE TABLE `count`(i INT);
CREATE TABLE `count`(i INT);

To enable the IGNORE_SPACE SQL mode, use this statement:

SET sql_mode = 'IGNORE_SPACE';

IGNORE_SPACE is also enabled by certain other composite modes such as ANSI that include it in their value:

SET sql_mode = 'ANSI';

Check Section 5.1.7, “Server SQL Modes”, to see which composite modes enable IGNORE_SPACE.

To minimize the dependency of SQL code on the IGNORE_SPACE setting, use these guidelines:

- Avoid creating UDFs or stored functions that have the same name as a built-in function.
- Avoid using function names in nonexpression context. For example, these statements use count (one of the affected function names affected by IGNORE_SPACE), so they fail with or without whitespace following the name if IGNORE_SPACE is enabled:

CREATE TABLE count(i INT);
CREATE TABLE count(i INT);

If you must use a function name in nonexpression context, write it as a quoted identifier:

CREATE TABLE `count`(i INT);
CREATE TABLE `count`(i INT);

Incompatibility warning: The change in MySQL 5.1.13 that reduces the number of function names affected by IGNORE_SPACE improves the consistency of parser operation. However, it also introduces the possibility of incompatibility for old SQL code that relies on the following conditions:

- IGNORE_SPACE is disabled.
- The presence or absence of whitespace following a function name is used to distinguish between a built-in function and stored function that have the same name, such as PI() versus PI().

For functions that are no longer affected by IGNORE_SPACE as of MySQL 5.1.13, that strategy no longer works. Either of the following approaches can be used if you have code that is subject to the preceding incompatibility:

- If a stored function has a name that conflicts with a built-in function, refer to the stored function with a schema name qualifier, regardless of whether whitespace is present. For example, write schema_name.PI() or schema_name.PI().
- Alternatively, rename the stored function to use a nonconflicting name and change invocations of the function to use the new name.

Function Name Resolution

The following rules describe how the server resolves references to function names for function creation and invocation:
• Built-in functions and user-defined functions

As of MySQL 5.1.14, an error occurs if you try to create a UDF with the same name as a built-in function. Before 5.1.14, a UDF can be created with the same name as a built-in function but the UDF cannot be invoked because the parser resolves invocations of the function to refer to the built-in function. For example, if you create a UDF named ABS, references to ABS() invoke the built-in function.

• Built-in functions and stored functions

It is possible to create a stored function with the same name as a built-in function, but to invoke the stored function it is necessary to qualify it with a schema name. For example, if you create a stored function named PI in the test schema, you invoke it as test.PI() because the server resolves PI() as a reference to the built-in function. As of 5.1.14, the server creates a warning if the stored function name collides with a built-in function name. The warning can be displayed with SHOW WARNINGS.

• User-defined functions and stored functions

User-defined functions and stored functions share the same namespace, so you cannot create a UDF and a stored function with the same name.

The preceding function name resolution rules have implications for upgrading to versions of MySQL that implement new built-in functions:

• If you have already created a user-defined function with a given name and upgrade MySQL to a version that implements a new built-in function with the same name, the UDF becomes inaccessible. To correct this, use DROP FUNCTION to drop the UDF and CREATE FUNCTION to re-create the UDF with a different nonconflicting name. Then modify any affected code to use the new name.

• If a new version of MySQL implements a built-in function with the same name as an existing stored function, you have two choices: Rename the stored function to use a nonconflicting name, or change calls to the function so that they use a schema qualifier (that is, use schema_name.func_name() syntax). In either case, modify any affected code accordingly.

9.3 Keywords and Reserved Words

Keywords are words that have significance in SQL. Certain keywords, such as SELECT, DELETE, or BIGINT, are reserved and require special treatment for use as identifiers such as table and column names. This may also be true for the names of built-in functions.

Nonreserved keywords are permitted as identifiers without quoting. Reserved words are permitted as identifiers if they quote them as described in Section 9.2, “Schema Object Names”:

mysql> CREATE TABLE interval (begin INT, end INT);
ERROR 1064 (42000): You have an error in your SQL syntax ...
BEGIN and END are keywords but not reserved, so their use as identifiers does not require quoting.
INTERVAL is a reserved keyword and must be quoted to be used as an identifier:

mysql> CREATE TABLE `interval` (begin INT, end INT);
Query OK, 0 rows affected (0.01 sec)

Exception: A word that follows a period in a qualified name must be an identifier, so it need not be quoted even if it is reserved:

mysql> CREATE TABLE mydb.interval (begin INT, end INT);
Query OK, 0 rows affected (0.01 sec)
Keywords and Reserved Words

Names of built-in functions are permitted as identifiers but may require care to be used as such. For example, `COUNT` is acceptable as a column name. However, by default, no whitespace is permitted in function invocations between the function name and the following `(` character. This requirement enables the parser to distinguish whether the name is used in a function call or in nonfunction context. For further details on recognition of function names, see Section 9.2.4, “Function Name Parsing and Resolution”.

The following table shows the keywords and reserved words in MySQL 5.1, along with changes to individual words from version to version. Reserved keywords are marked with (R). In addition, `_FILENAME` is reserved.

At some point, you might upgrade to a higher version, so it is a good idea to have a look at future reserved words, too. You can find these in the manuals that cover higher versions of MySQL. Most of the reserved words in the table are forbidden by standard SQL as column or table names (for example, `GROUP`). A few are reserved because MySQL needs them and uses a yacc parser.

### 9.4 User-Defined Variables

You can store a value in a user-defined variable in one statement and then refer to it later in another statement. This enables you to pass values from one statement to another.

User variables are written as `@var_name`, where the variable name `var_name` consists of alphanumeric characters, `.`, `_`, and `$`. A user variable name can contain other characters if you quote it as a string or identifier (for example, `@'my-var'`, `@"my-var"`, or `@`my-var`).

**User-defined variables are session-specific.** That is, a user variable defined by one client cannot be seen or used by other clients. All variables for a given client session are automatically freed when that client exits.

User variable names are not case sensitive in MySQL 5.0 and up.

One way to set a user-defined variable is by issuing a **SET** statement:

```sql
SET @var_name = expr [, @var_name = expr] ...
```

For **SET**, either `=` or `:=` can be used as the assignment operator.

You can also assign a value to a user variable in statements other than **SET**. In this case, the assignment operator must be `:=` and not `=` because the latter is treated as the comparison operator `=` in non-**SET** statements:
User variables can be assigned a value from a limited set of data types: integer, decimal, floating-point, binary or nonbinary string, or NULL value. Assignment of decimal and real values does not preserve the precision or scale of the value. A value of a type other than one of the permissible types is converted to a permissible type. For example, a value having a temporal or spatial data type is converted to a binary string.

If a user variable is assigned a nonbinary (character) string value, it has the same character set and collation as the string. The coercibility of user variables is implicit. (This is the same coercibility as for table column values.)

Bit values assigned to user variables are treated as binary strings. To assign a bit value as a number to a user variable, use CAST() or +0:

User variables may be used in most contexts where expressions are permitted. This does not currently include contexts that explicitly require a literal value, such as in the LIMIT clause of a SELECT statement, or the IGNORE N LINES clause of a LOAD DATA statement.

As a general rule, other than in SET statements, you should never assign a value to a user variable and read the value within the same statement. For example, to increment a variable, this is okay:

For other statements, such as SELECT, you might get the results you expect, but this is not guaranteed. In the following statement, you might think that MySQL will evaluate @a first and then do an assignment second:

However, the order of evaluation for expressions involving user variables is undefined.

Another issue with assigning a value to a variable and reading the value within the same non-SET statement is that the default result type of a variable is based on its type at the start of the statement. The following example illustrates this:

For this SELECT statement, MySQL reports to the client that column one is a string and converts all accesses of @a to strings, even though @a is set to a number for the second row. After the SELECT statement executes, @a is regarded as a number for the next statement.
To avoid problems with this behavior, either do not assign a value to and read the value of the same variable within a single statement, or else set the variable to 0, 0.0, or '' to define its type before you use it.

In a SELECT statement, each select expression is evaluated only when sent to the client. This means that in a HAVING, GROUP BY, or ORDER BY clause, referring to a variable that is assigned a value in the select expression list does not work as expected:

```sql
mysql> SELECT (@aa:=id) AS a, (@aa+3) AS b FROM tbl_name HAVING b=5;
```

The reference to b in the HAVING clause refers to an alias for an expression in the select list that uses @aa. This does not work as expected: @aa contains the value of id from the previous selected row, not from the current row.

User variables are intended to provide data values. They cannot be used directly in an SQL statement as an identifier or as part of an identifier, such as in contexts where a table or database name is expected, or as a reserved word such as SELECT. This is true even if the variable is quoted, as shown in the following example:

```sql
mysql> SELECT c1 FROM t;
+----+
| c1 |
|  0 |
|  1 |
+----+
2 rows in set (0.00 sec)
mysql> SET @col = "c1";
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT @col FROM t;
+------+
| @col |
| c1   |
+------+
1 row in set (0.00 sec)
mysql> SELECT `@col` FROM t;
ERROR 1054 (42S22): Unknown column '@col' in 'field list'
```

An exception to this principle that user variables cannot be used to provide identifiers, is when you are constructing a string for use as a prepared statement to execute later. In this case, user variables can be used to provide any part of the statement. The following example illustrates how this can be done:

```sql
mysql> SET @c = "c1";
Query OK, 0 rows affected (0.00 sec)
mysql> SET @s = CONCAT("SELECT ", @c, " FROM t");
Query OK, 0 rows affected (0.00 sec)
mysql> PREPARE stmt FROM @s;
Query OK, 0 rows affected (0.04 sec)
```
Statement prepared

mysql> EXECUTE stmt;
+----+
| c1 |
+----+
| 0  |
+----+
| 1  |
+----+
2 rows in set (0.00 sec)

mysql> DEALLOCATE PREPARE stmt;
Query OK, 0 rows affected (0.00 sec)

A similar technique can be used in application programs to construct SQL statements using program variables, as shown here using PHP 5:

```php
<?php
    $mysqli = new mysqli("localhost", "user", "pass", "test");
    if( mysqli_connect_errno() )
        die("Connection failed: %s\n", mysqli_connect_error());
    $col = "c1";
    $query = "SELECT $col FROM t";
    $result = $mysqli->query($query);
    while($row = $result->fetch_assoc())
    {
        echo "<p>" . $row[$col] . "</p>\n";
    }
    $result->close();
    $mysqli->close();
?>
```

Assembling an SQL statement in this fashion is sometimes known as “Dynamic SQL”.

### 9.5 Expression Syntax

The following rules define expression syntax in MySQL. The grammar shown here is based on that given in the `sql/sql_yacc.yy` file of MySQL source distributions. See the notes after the grammar for additional information about some of the terms.

```
expr:
    expr OR expr
    | expr | expr
    | expr XOR expr
    | expr AND expr
    | expr && expr
    | NOT expr
    | ! expr
    | boolean_primary IS [NOT] {TRUE | FALSE | UNKNOWN}
    | boolean_primary

boolean_primary:
    boolean_primary IS [NOT] NULL
    | boolean_primary <=> predicate
    | boolean_primary comparison_operator predicate
    | boolean_primary comparison_operator {ALL | ANY} (subquery)
    | predicate
```
### Expression Syntax

#### Comparison Operators

- `=`
- `>=`
- `>`
- `<=`
- `<`
- `<>`
- `!=`

#### Predicate

- `bit_expr [NOT] IN (subquery)`
- `bit_expr [NOT] IN (expr [, expr] ...)`
- `bit_expr [NOT] BETWEEN bit_expr AND predicate`
- `bit_expr SOUNDS LIKE bit_expr`
- `bit_expr [NOT] LIKE simple_expr [ESCAPE simple_expr]`
- `bit_expr [NOT] REGEXP bit_expr`

#### Bit Expressions

- `bit_expr | bit_expr`
- `bit_expr & bit_expr`
- `bit_expr << bit_expr`
- `bit_expr >> bit_expr`
- `bit_expr + bit_expr`
- `bit_expr - bit_expr`
- `bit_expr / bit_expr`
- `bit_expr DIV bit_expr`
- `bit_expr MOD bit_expr`
- `bit_expr % bit_expr`
- `bit_expr ^ bit_expr`
- `bit_expr + interval_expr`
- `bit_expr - interval_expr`

#### Simple Expressions

- `literal`
- `identifier`
- `function_call`
- `simple_expr COLLATE collation_name`
- `param_marker`
- `variable`
- `simple_expr | simple_expr`
- `+ simple_expr`
- `- simple_expr`
- `! simple_expr`
- `BINARY simple_expr`
- `{expr [, expr] ...}
- `ROW (expr, expr [, expr] ...)`
- `(subquery)`
- `EXISTS (subquery)`
- `[identifier expr]`
- `match_expr`
- `case_expr`
- `interval_expr`

### Notes:

For operator precedence, see in Section 12.3.1, “Operator Precedence”.

For literal value syntax, see Section 9.1, “Literal Values”.

For identifier syntax, see Section 9.2, “Schema Object Names”.

Variables can be user variables, system variables, or stored program local variables or parameters:

- **User variables**: Section 9.4, “User-Defined Variables”
- **System variables**: Section 5.1.5, “Using System Variables”
- **Local variables**: Section 13.6.4.1, “Local Variable DECLARE Syntax”
- **Parameters**: Section 13.1.15, “CREATE PROCEDURE and CREATE FUNCTION Syntax”

`param_marker` is `?` as used in prepared statements for placeholders. See Section 13.5.1, “PREPARE Syntax”.

890
Comment Syntax

(subquery) indicates a subquery that returns a single value; that is, a scalar subquery. See Section 13.2.9.1, “The Subquery as Scalar Operand”.

(identifier expr) is ODBC escape syntax and is accepted for ODBC compatibility. The value is expr. The curly braces in the syntax should be written literally; they are not metasyntax as used elsewhere in syntax descriptions.

match_expr indicates a MATCH expression. See Section 12.9, “Full-Text Search Functions”.

case_expr indicates a CASE expression. See Section 12.4, “Control Flow Functions”.

interval_expr represents a time interval. The syntax is INTERVAL expr unit, where unit is a specifier such as HOUR, DAY, or WEEK. For the full list of unit specifiers, see the description of the DATE_ADD() function in Section 12.7, “Date and Time Functions”.

The meaning of some operators depends on the SQL mode:

- By default, || is a logical OR operator. With PIPES_AS_CONCAT enabled, || is string concatenation, with a precedence between ^ and the unary operators.
- By default, ! has a higher precedence than NOT. With HIGH_NOT_PRECEDENCE enabled, ! and NOT have the same precedence.

See Section 5.1.7, “Server SQL Modes”.

9.6 Comment Syntax

MySQL Server supports three comment styles:

- From a "#" character to the end of the line.
- From a "-- " sequence to the end of the line. In MySQL, the "-- " (double-dash) comment style requires the second dash to be followed by at least one whitespace or control character (such as a space, tab, newline, and so on). This syntax differs slightly from standard SQL comment syntax, as discussed in Section 1.8.2.5, “-- as the Start of a Comment”.
- From a /* sequence to the following */ sequence, as in the C programming language. This syntax enables a comment to extend over multiple lines because the beginning and closing sequences need not be on the same line.

The following example demonstrates all three comment styles:

```sql
mysql> SELECT 1+1;     # This comment continues to the end of line
mysql> SELECT 1+1;     -- This comment continues to the end of line
mysql> SELECT 1 /* this is an in-line comment */ + 1;
mysql> SELECT 1+/
        this is a
        multiple-line comment
    */
    1;
```

Nested comments are not supported. (Under some conditions, nested comments might be permitted, but usually are not, and users should avoid them.)

MySQL Server supports some variants of C-style comments. These enable you to write code that includes MySQL extensions, but is still portable, by using comments of the following form:

```sql
/*!
MySQL-specific code */
```

In this case, MySQL Server parses and executes the code within the comment as it would any other SQL statement, but other SQL servers will ignore the extensions. For example, MySQL Server recognizes the STRAIGHTJOIN keyword in the following statement, but other servers will not:
If you add a version number after the "!" character, the syntax within the comment is executed only if the MySQL version is greater than or equal to the specified version number. The `TEMPORARY` keyword in the following comment is executed only by servers from MySQL 3.23.02 or higher:

```sql
CREATE /*!32302 TEMPORARY */ TABLE t (a INT);
```

The comment syntax just described applies to how the `mysqld` server parses SQL statements. The `mysql` client program also performs some parsing of statements before sending them to the server. (It does this to determine statement boundaries within a multiple-statement input line.)

Comments in this format, `/*!12345 ... */`, are not stored on the server. If this format is used to comment stored routines, the comments will not be retained on the server.

The use of short-form `mysql` commands such as `\C` within multiple-line `/* ... */` comments is not supported.

10.7 MySQL Server Locale Support ........................................................................................ 952

This chapter covers issues of globalization, which includes internationalization (MySQL's capabilities for adapting to local use) and localization (selecting particular local conventions):

- MySQL support for character sets in SQL statements.
- How to configure the server to support different character sets.
- Selecting the language for error messages.
- How to set the server's time zone and enable per-connection time zone support.
- Selecting the locale for day and month names.

10.1 Character Set Support

MySQL includes character set support that enables you to store data using a variety of character sets and perform comparisons according to a variety of collations. You can specify character sets at the server, database, table, and column level. MySQL supports the use of character sets for the MyISAM, MEMORY, NDBCLUSTER, and InnoDB storage engines.

This chapter discusses the following topics:

- What are character sets and collations?
Character Sets and Collations in General

- The multiple-level default system for character set assignment.
- Syntax for specifying character sets and collations.
- Affected functions and operations.
- Unicode support.
- The character sets and collations that are available, with notes.

Character set issues affect not only data storage, but also communication between client programs and the MySQL server. If you want the client program to communicate with the server using a character set different from the default, you'll need to indicate which one. For example, to use the utf8 Unicode character set, issue this statement after connecting to the server:

```
SET NAMES 'utf8';
```

For more information about configuring character sets for application use and character set-related issues in client/server communication, see Section 10.1.5, “Configuring the Character Set and Collation for Applications”, and Section 10.1.4, “Connection Character Sets and Collations”.

### 10.1.1 Character Sets and Collations in General

A **character set** is a set of symbols and encodings. A **collation** is a set of rules for comparing characters in a character set. Let's make the distinction clear with an example of an imaginary character set.

Suppose that we have an alphabet with four letters: "A", "B", "a", "b". We give each letter a number: "A" = 0, "B" = 1, "a" = 2, "b" = 3. The letter "A" is a symbol, the number 0 is the **encoding** for "A", and the combination of all four letters and their encodings is a **character set**.

Suppose that we want to compare two string values, "A" and "B". The simplest way to do this is to look at the encodings: 0 for "A" and 1 for "B". Because 0 is less than 1, we say "A" is less than "B". What we've just done is apply a collation to our character set. The collation is a set of rules (only one rule in this case): “compare the encodings.” We call this simplest of all possible collations a **binary** collation.

But what if we want to say that the lowercase and uppercase letters are equivalent? Then we would have at least two rules: (1) treat the lowercase letters "a" and "b" as equivalent to "A" and "B"; (2) then compare the encodings. We call this a **case-insensitive** collation. It is a little more complex than a binary collation.

In real life, most character sets have many characters: not just "A" and "B" but whole alphabets, sometimes multiple alphabets or eastern writing systems with thousands of characters, along with many special symbols and punctuation marks. Also in real life, most collations have many rules, not just for whether to distinguish lettercase, but also for whether to distinguish accents (an “accent” is a mark attached to a character as in German “Ö”), and for multiple-character mappings (such as the rule that “Ö” = “OE” in one of the two German collations).

MySQL can do these things for you:

- Store strings using a variety of character sets.
- Compare strings using a variety of collations.
- Mix strings with different character sets or collations in the same server, the same database, or even the same table.
- Enable specification of character set and collation at any level.

In these respects, MySQL is far ahead of most other database management systems. However, to use these features effectively, you need to know what character sets and collations are available, how to change the defaults, and how they affect the behavior of string operators and functions.
10.1.2 Character Sets and Collations in MySQL

The MySQL server supports multiple character sets. To list the available character sets, use the SHOW CHARACTER SET statement. A partial listing follows. For more complete information, see Section 10.1.13, “Character Sets and Collations That MySQL Supports”.

```
mysql> SHOW CHARACTER SET;
+----------+-----------------------------+---------------------+--------+
| Charset  | Description                 | Default collation   | Maxlen |
+----------+-----------------------------+---------------------+--------+
| big5     | Big5 Traditional Chinese    | big5_chinese_ci     |      2 |
| dec8     | DEC West European           | dec8_swedish_ci     |      1 |
| cp850    | DOS West European           | cp850_general_ci    |      1 |
| hp8      | HP West European            | hp8_english_ci      |      1 |
| koi8r    | KOI8-R Relcom Russian       | koi8r_general_ci    |      1 |
| latin1   | cp1252 West European        | latin1_swedish_ci   |      1 |
| latin2   | ISO 8859-2 Central European | latin2_general_ci   |      1 |
| swe7     | 7bit Swedish                | swe7_swedish_ci     |      1 |
| ascii    | US ASCII                    | ascii_general_ci    |      1 |
| ujis     | EUC-JP Japanese             | ujis_japanese_ci    |      2 |
| sjis     | Shift-JIS Japanese          | sjis_japanese_ci    |      2 |
| hebrew   | ISO 8859-8 Hebrew           | hebrew_general_ci   |      1 |
| tis620   | TIS620 Thai                  | tis620_thai_ci      |      1 |
| euckr    | EUC-KR Korean               | euckr_korean_ci     |      2 |
| koi8u    | KOI8-U Ukrainian            | koi8u_general_ci    |      1 |
| gb2312   | GB2312 Simplified Chinese   | gb2312_chinese_ci   |      2 |
| greek    | ISO 8859-7 Greek            | greek_general_ci    |      1 |
| cp1250   | Windows Central European    | cp1250_general_ci   |      1 |
| gbk      | GBK Simplified Chinese      | gbk_chinese_ci      |      2 |
| latin5   | ISO 8859-9 Turkish          | latin5_turkish_ci   |      1 |
+----------+-----------------------------+---------------------+--------+
```

Any given character set always has at least one collation. It may have several collations. To list the collations for a character set, use the SHOW COLLATION statement. For example, to see the collations for the latin1 (cp1252 West European) character set, use this statement to find those collation names that begin with latin1:

```
mysql> SHOW COLLATION LIKE 'latin1%';
+---------------------+---------+----+---------+----------+---------+
| Collation           | Charset | Id | Default | Compiled | Sortlen |
+---------------------+---------+----+---------+----------+---------+
| latin1_german1_ci   | latin1  |  5 |         |          |       0 |
| latin1_swedish_ci   | latin1  |  8 |         | Yes      |       1 |
| latin1_danish_ci    | latin1  | 15 |         | Yes      |       2 |
| latin1_german2_ci   | latin1  | 31 |         |         |       0 |
| latin1_bin          | latin1  | 47 |         | Yes      |       1 |
| latin1_general_ci   | latin1  | 48 |         |          |       0 |
| latin1_general_cs   | latin1  | 49 |         |          |       0 |
| latin1_spanish_ci   | latin1  | 94 |         |          |       0 |
+---------------------+---------+----+---------+----------+---------+
```

The latin1 collations have the following meanings.

<table>
<thead>
<tr>
<th>Collation</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>latin1_german1_ci</td>
<td>German DIN-1</td>
</tr>
<tr>
<td>latin1_swedish_ci</td>
<td>Swedish/Finnish</td>
</tr>
<tr>
<td>latin1_danish_ci</td>
<td>Danish/Norwegian</td>
</tr>
<tr>
<td>latin1_german2_ci</td>
<td>German DIN-2</td>
</tr>
<tr>
<td>latin1_bin</td>
<td>Binary according to latin1 encoding</td>
</tr>
<tr>
<td>latin1_general_ci</td>
<td>Multilingual (Western European)</td>
</tr>
<tr>
<td>latin1_general_cs</td>
<td>Multilingual (ISO Western European), case sensitive</td>
</tr>
</tbody>
</table>
Collation have these general characteristics:

- Two different character sets cannot have the same collation.
- Each character set has one collation that is the default collation. For example, the default collation for `latin1` is `latin1_swedish_ci`. The output for `SHOW CHARACTER SET` indicates which collation is the default for each displayed character set.
- There is a convention for collation names: They start with the name of the character set with which they are associated, they usually include a language name, and they end with `_ci` (case insensitive), `_cs` (case sensitive), or `_bin` (binary).

In cases where a character set has multiple collations, it might not be clear which collation is most suitable for a given application. To avoid choosing the wrong collation, it can be helpful to perform some comparisons with representative data values to make sure that a given collation sorts values the way you expect.

Collation-Charts.Org is a useful site for information that shows how one collation compares to another.

### 10.1.3 Specifying Character Sets and Collations

There are default settings for character sets and collations at four levels: server, database, table, and column. The description in the following sections may appear complex, but it has been found in practice that multiple-level defaulting leads to natural and obvious results.

**CHARACTER SET** is used in clauses that specify a character set. **CHARSET** can be used as a synonym for **CHARACTER SET**.

Character set issues affect not only data storage, but also communication between client programs and the MySQL server. If you want the client program to communicate with the server using a character set different from the default, you'll need to indicate which one. For example, to use the `utf8` Unicode character set, issue this statement after connecting to the server:

```
SET NAMES 'utf8';
```

For more information about character set-related issues in client/server communication, see Section 10.1.4, “Connection Character Sets and Collations”.

### 10.1.3.1 Server Character Set and Collation

MySQL Server has a server character set and a server collation. These can be set at server startup on the command line or in an option file and changed at runtime.

Initially, the server character set and collation depend on the options that you use when you start `mysqld`. You can use `--character-set-server` for the character set. Along with it, you can add `--collation-server` for the collation. If you don't specify a character set, that is the same as saying `--character-set-server=latin1`. If you specify only a character set (for example, `latin1`) but not a collation, that is the same as saying `--character-set-server=latin1 --collation-server=latin1_swedish_ci` because `latin1_swedish_ci` is the default collation for `latin1`. Therefore, the following three commands all have the same effect:

```sh
shell> mysqld
shell> mysqld --character-set-server=latin1
shell> mysqld --character-set-server=latin1 \n--collation-server=latin1_swedish_ci
```
One way to change the settings is by recompiling. If you want to change the default server character set and collation when building from sources, use: `--with-charset` and `--with-collation` as arguments for `configure`. For example:

```
shell> ./configure --with-charset=latin1
```

Or:

```
shell> ./configure --with-charset=latin1 \
 --with-collation=latin1_german1_ci
```

Both `mysqld` and `configure` verify that the character set/collation combination is valid. If not, each program displays an error message and terminates.

The server character set and collation are used as default values if the database character set and collation are not specified in `CREATE DATABASE` statements. They have no other purpose.

The current server character set and collation can be determined from the values of the `character_set_server` and `collation_server` system variables. These variables can be changed at runtime.

### 10.1.3.2 Database Character Set and Collation

Every database has a database character set and a database collation. The `CREATE DATABASE` and `ALTER DATABASE` statements have optional clauses for specifying the database character set and collation:

```
CREATE DATABASE db_name
  [DEFAULT] CHARACTER SET charset_name
  [DEFAULT] COLLATE collation_name

ALTER DATABASE db_name
  [DEFAULT] CHARACTER SET charset_name
  [DEFAULT] COLLATE collation_name
```

The keyword `SCHEMA` can be used instead of `DATABASE`.

All database options are stored in a text file named `db.opt` that can be found in the database directory.

The `CHARACTER SET` and `COLLATE` clauses make it possible to create databases with different character sets and collations on the same MySQL server.

Example:

```
CREATE DATABASE db_name CHARACTER SET latin1 COLLATE latin1_swedish_ci;
```

MySQL chooses the database character set and database collation in the following manner:

- If both `CHARACTER SET` X and `COLLATE` Y are specified, character set X and collation Y are used.
- If `CHARACTER SET` X is specified without `COLLATE`, character set X and its default collation are used. To see the default collation for each character set, use the `SHOW COLLATION` statement.
- If `COLLATE` Y is specified without `CHARACTER SET`, the character set associated with Y and collation Y are used.
- Otherwise, the server character set and server collation are used.

The character set and collation for the default database can be determined from the values of the `character_set_database` and `collation_database` system variables. The server sets these...
variables whenever the default database changes. If there is no default database, the variables have the same value as the corresponding server-level system variables, `character_set_server` and `collation_server`.

To see the default character set and collation for a given database, use these statements:

```
USE db_name;
SELECT @@character_set_database, @@collation_database;
```

Alternatively, to display the values without changing the default database:

```
SELECT DEFAULT_CHARACTER_SET_NAME, DEFAULT_COLLATION_NAME
FROM INFORMATION_SCHEMA.SCHEMATA WHERE SCHEMA_NAME = 'db_name';
```

The database character set and collation affect these aspects of server operation:

- For `CREATE TABLE` statements, the database character set and collation are used as default values for table definitions if the table character set and collation are not specified. To override this, provide explicit `CHARACTER SET` and `COLLATE` table options.

- For `LOAD DATA` statements that include no `CHARACTER SET` clause, the server uses the character set indicated by the `character_set_database` system variable to interpret the information in the file. To override this, provide an explicit `CHARACTER SET` clause.

- For stored routines (procedures and functions), the database character set and collation in effect at routine creation time are used as the character set and collation of character data parameters for which the declaration includes no `CHARACTER SET` or `COLLATE` attribute. To override this, provide explicit `CHARACTER SET` and `COLLATE` attributes.

### 10.1.3.3 Table Character Set and Collation

Every table has a table character set and a table collation. The `CREATE TABLE` and `ALTER TABLE` statements have optional clauses for specifying the table character set and collation:

```
CREATE TABLE tbl_name (column_list)
[[DEFAULT] CHARACTER SET charset_name]
[COLLATE collation_name]]

ALTER TABLE tbl_name
[[DEFAULT] CHARACTER SET charset_name]
[COLLATE collation_name]
```

Example:

```
CREATE TABLE t1 ( ... )
CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

MySQL chooses the table character set and collation in the following manner:

- If both `CHARACTER SET X` and `COLLATE Y` are specified, character set `X` and collation `Y` are used.

- If `CHARACTER SET X` is specified without `COLLATE`, character set `X` and its default collation are used. To see the default collation for each character set, use the `SHOW COLLATION` statement.

- If `COLLATE Y` is specified without `CHARACTER SET`, the character set associated with `Y` and collation `Y` are used.

- Otherwise, the database character set and collation are used.

The table character set and collation are used as default values for column definitions if the column character set and collation are not specified in individual column definitions. The table character set and collation are MySQL extensions; there are no such things in standard SQL.
10.1.3.4 Column Character Set and Collation

Every “character” column (that is, a column of type \texttt{CHAR}, \texttt{VARCHAR}, or \texttt{TEXT}) has a column character set and a column collation. Column definition syntax for \texttt{CREATE TABLE} and \texttt{ALTER TABLE} has optional clauses for specifying the column character set and collation:

\begin{verbatim}
col_name \{CHAR | VARCHAR | TEXT\} (col_length)
  [CHARACTER SET charset_name]
  [COLLATE collation_name]
\end{verbatim}

These clauses can also be used for \texttt{ENUM} and \texttt{SET} columns:

\begin{verbatim}
col_name \{ENUM | SET\} (val_list)
  [CHARACTER SET charset_name]
  [COLLATE collation_name]
\end{verbatim}

Examples:

```sql
CREATE TABLE t1
  (
    col1 VARCHAR(5) CHARACTER SET latin1
    COLLATE latin1_german1_ci
  );
```

ALTER TABLE t1 MODIFY
  col1 VARCHAR(5)
  CHARACTER SET latin1
  COLLATE latin1_swedish_ci;

MySQL chooses the column character set and collation in the following manner:

- If both \texttt{CHARACTER SET} \texttt{X} and \texttt{COLLATE} \texttt{Y} are specified, character set \texttt{X} and collation \texttt{Y} are used.

CREATE TABLE t1
  (
    col1 CHAR(10) CHARACTER SET utf8 COLLATE utf8_unicode_ci
  ) CHARACTER SET latin1 COLLATE latin1_bin;

The character set and collation are specified for the column, so they are used. The column has character set \texttt{utf8} and collation \texttt{utf8_unicode_ci}.

- If \texttt{CHARACTER SET} \texttt{X} is specified without \texttt{COLLATE}, character set \texttt{X} and its default collation are used.

CREATE TABLE t1
  (
    col1 CHAR(10) CHARACTER SET utf8
  ) CHARACTER SET latin1 COLLATE latin1_bin;

The character set is specified for the column, but the collation is not. The column has character set \texttt{utf8} and the default collation for \texttt{utf8}, which is \texttt{utf8_general_ci}. To see the default collation for each character set, use the \texttt{SHOW COLLATION} statement.

- If \texttt{COLLATE} \texttt{Y} is specified without \texttt{CHARACTER SET}, the character set associated with \texttt{Y} and collation \texttt{Y} are used.

CREATE TABLE t1
  (
    col1 CHAR(10) COLLATE utf8_polish_ci
  ) CHARACTER SET latin1 COLLATE latin1_bin;
The collation is specified for the column, but the character set is not. The column has collation `utf8_polish_ci` and the character set is the one associated with the collation, which is `utf8`.

- Otherwise, the table character set and collation are used.

```sql
CREATE TABLE t1
(
  col1 CHAR(10) CHARACTER SET latin1 COLLATE latin1_bin;
)
```

Neither the character set nor collation are specified for the column, so the table defaults are used. The column has character set `latin1` and collation `latin1_bin`.

The `CHARACTER SET` and `COLLATE` clauses are standard SQL.

If you use `ALTER TABLE` to convert a column from one character set to another, MySQL attempts to map the data values, but if the character sets are incompatible, there may be data loss.

### 10.1.3.5 Character String Literal Character Set and Collation

Every character string literal has a character set and a collation.

A character string literal may have an optional character set introducer and `COLLATE` clause:

```sql
[_[_charset_name]'string' [COLLATE _collation_name]]
```

Examples:

```sql
SELECT 'string';
SELECT _latin1'string';
SELECT _latin1'string' COLLATE latin1_danish_ci;
```

For the simple statement `SELECT 'string'`, the string has the character set and collation defined by the `character_set_connection` and `collation_connection` system variables.

The `_charset_name` expression is formally called an `introducer`. It tells the parser, “the string that is about to follow uses character set X.” Because this has confused people in the past, we emphasize that an introducer does not change the string to the introducer character set like `CONVERT()` would do. It does not change the string's value, although padding may occur. The introducer is just a signal. An introducer is also legal before standard hex literal and numeric hex literal notation (`x'literal'` and `0xnnnn`), or before bit-field literal notation (`b'literal'` and `0bnnnn`).

Examples:

```sql
SELECT _latin1 x'AABBCC';
SELECT _latin1 0xAABBCC;
SELECT _latin1 b'1100011';
SELECT _latin1 0b1100011;
```

MySQL determines a literal's character set and collation in the following manner:

- If both `_X` and `COLLATE Y` are specified, character set `X` and collation `Y` are used.

- If `_X` is specified but `COLLATE` is not specified, character set `X` and its default collation are used. To see the default collation for each character set, use the `SHOW COLLATION` statement.

- Otherwise, the character set and collation given by the `character_set_connection` and `collation_connection` system variables are used.

Examples:
Specifying Character Sets and Collations

- A string with latin1 character set and latin1_german1_ci collation:

  ```
  SELECT _latin1'Müller' COLLATE latin1_german1_ci;
  ```

- A string with latin1 character set and its default collation (that is, latin1_swedish_ci):

  ```
  SELECT _latin1'Müller';
  ```

- A string with the connection default character set and collation:

  ```
  SELECT 'Müller';
  ```

Character set introducers and the `COLLATE` clause are implemented according to standard SQL specifications.

An introducer indicates the character set for the following string, but does not change now how the parser performs escape processing within the string. Escapes are always interpreted by the parser according to the character set given by `character_set_connection`.

The following examples show that escape processing occurs using `character_set_connection` even in the presence of an introducer. The examples use `SET NAMES` (which changes `character_set_connection`, as discussed in Section 10.1.4, “Connection Character Sets and Collations”), and display the resulting strings using the `HEX()` function so that the exact string contents can be seen.

**Example 1:**

```
mysql> SET NAMES latin1;
Query OK, 0 rows affected (0.01 sec)

mysql> SELECT HEX('à
'), HEX(_sjis'à
');
```

| HEX('à
') | HEX(_sjis'à
') |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>E00A</td>
<td>E00A</td>
</tr>
</tbody>
</table>

1 row in set (0.00 sec)

Here, “à” (hex value E0) is followed by “\n”, the escape sequence for newline. The escape sequence is interpreted using the `character_set_connection` value of latin1 to produce a literal newline (hex value 0A). This happens even for the second string. That is, the introducer of _sjis does not affect the parser’s escape processing.

**Example 2:**

```
mysql> SET NAMES sjis;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT HEX('à
'), HEX(_latin1'à
');
```

| HEX('à
') | HEX(_latin1'à
') |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>E05C6E</td>
<td>E05C6E</td>
</tr>
</tbody>
</table>

1 row in set (0.04 sec)

Here, `character_set_connection` is sjis, a character set in which the sequence of “à” followed by “\n” (hex values 05 and 5C) is a valid multibyte character. Hence, the first two bytes of the string are interpreted as a single sjis character, and the “\n” is not interpreted as an escape character. The following “n” (hex value 6E) is not interpreted as part of an escape sequence. This is true even for the second string; the introducer of _latin1 does not affect escape processing.
10.1.3.6 National Character Set

Standard SQL defines `NCHAR` or `NATIONAL CHAR` as a way to indicate that a `CHAR` column should use some predefined character set. MySQL uses `utf8` as this predefined character set. For example, these data type declarations are equivalent:

```
CHAR(10) CHARACTER SET utf8
NATIONAL CHARACTER(10)
NCHAR(10)
```

As are these:

```
VARCHAR(10) CHARACTER SET utf8
NATIONAL VARCHAR(10)
NVARCHAR(10)
NCHAR VARCHAR(10)
NATIONAL CHARACTER VARYING(10)
NATIONAL CHAR VARYING(10)
```

You can use `N'literal'` (or `n'literal'`) to create a string in the national character set. These statements are equivalent:

```
SELECT N'some text';
SELECT n'some text';
SELECT _utf8'some text';
```

For information on upgrading character sets to MySQL 5.1 from versions prior to 4.1, see the MySQL 3.23, 4.0, 4.1 Reference Manual.

10.1.3.7 Examples of Character Set and Collation Assignment

The following examples show how MySQL determines default character set and collation values.

**Example 1: Table and Column Definition**

```
CREATE TABLE t1
(
  c1 CHAR(10) CHARACTER SET latin1 COLLATE latin1_german1_ci
) DEFAULT CHARACTER SET latin2 COLLATE latin2_bin;
```

Here we have a column with a `latin1` character set and a `latin1_german1_ci` collation. The definition is explicit, so that is straightforward. Notice that there is no problem with storing a `latin1` column in a `latin2` table.

**Example 2: Table and Column Definition**

```
CREATE TABLE t1
(
  c1 CHAR(10) CHARACTER SET latin1
) DEFAULT CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

This time we have a column with a `latin1` character set and a default collation. Although it might seem natural, the default collation is not taken from the table level. Instead, because the default collation for `latin1` is always `latin1_swedish_ci`, column `c1` has a collation of `latin1_swedish_ci` (not `latin1_danish_ci`).

**Example 3: Table and Column Definition**

```
CREATE TABLE t1
(
```

902
We have a column with a default character set and a default collation. In this circumstance, MySQL checks the table level to determine the column character set and collation. Consequently, the character set for column `c1` is `latin1` and its collation is `latin1_danish_ci`.

Example 4: Database, Table, and Column Definition

```
CREATE DATABASE d1
  DEFAULT CHARACTER SET latin2 COLLATE latin2_czech_ci;
USE d1;
CREATE TABLE t1
  (c1 CHAR(10));
```

We create a column without specifying its character set and collation. We're also not specifying a character set and a collation at the table level. In this circumstance, MySQL checks the database level to determine the table settings, which thereafter become the column settings.) Consequently, the character set for column `c1` is `latin2` and its collation is `latin2_czech_ci`.

10.1.3.8 Compatibility with Other DBMSs

For MaxDB compatibility these two statements are the same:

```
CREATE TABLE t1 (f1 CHAR(N) UNICODE);
CREATE TABLE t1 (f1 CHAR(N) CHARACTER SET ucs2);
```

10.1.4 Connection Character Sets and Collations

Several character set and collation system variables relate to a client's interaction with the server. Some of these have been mentioned in earlier sections:

- The server character set and collation are the values of the `character_set_server` and `collation_server` system variables.

- The character set and collation of the default database are the values of the `character_set_database` and `collation_database` system variables.

Additional character set and collation system variables are involved in handling traffic for the connection between a client and the server. Every client has connection-related character set and collation system variables.

A “connection” is what you make when you connect to the server. The client sends SQL statements, such as queries, over the connection to the server. The server sends responses, such as result sets or error messages, over the connection back to the client. This leads to several questions about character set and collation handling for client connections, each of which can be answered in terms of system variables:

- What character set is the statement in when it leaves the client?

  The server takes the `character_set_client` system variable to be the character set in which statements are sent by the client.

- What character set should the server translate a statement to after receiving it?

  For this, the server uses the `character_set_connection` and `collation_connection` system variables. It converts statements sent by the client from `character_set_client` to `character_set_connection` (except for string literals that have an introducer such as `_latin1` or `_utf8`). `collation_connection` is important for comparisons of literal strings. For
comparisons of strings with column values, `collation_connection` does not matter because columns have their own collation, which has a higher collation precedence.

- What character set should the server translate to before shipping result sets back to the client?

The `character_set_results` system variable indicates the character set in which the server returns query results to the client. This includes result data such as column values, and result metadata such as column names.

Clients can fine-tune the settings for these variables, or depend on the defaults (in which case, you can skip the rest of this section). If you do not use the defaults, you must change the character settings for each connection to the server.

Two statements affect the connection-related character set variables as a group:

- `SET NAMES 'charset_name' [COLLATE 'collation_name']`

`SET NAMES` indicates what character set the client will use to send SQL statements to the server. Thus, `SET NAMES 'cp1251'` tells the server, “future incoming messages from this client are in character set cp1251.” It also specifies the character set that the server should use for sending results back to the client. (For example, it indicates what character set to use for column values if you use a `SELECT` statement.)

A `SET NAMES 'charset_name'` statement is equivalent to these three statements:

```sql
SET character_set_client = charset_name;
SET character_set_results = charset_name;
SET character_set_connection = charset_name;
```

Setting `character_set_connection` to `charset_name` also implicitly sets `collation_connection` to the default collation for `charset_name`. It is unnecessary to set that collation explicitly. To specify a particular collation, use the optional `COLLATE` clause:

```sql
SET NAMES 'charset_name' COLLATE 'collation_name'
```

- `SET CHARACTER SET charset_name`

`SET CHARACTER SET` is similar to `SET NAMES` but sets `character_set_connection` and `collation_connection` to `character_set_database` and `collation_database`. A `SET CHARACTER SET charset_name` statement is equivalent to these three statements:

```sql
SET character_set_client = charset_name;
SET character_set_results = charset_name;
SET collection_connection = @@collation_database;
```

Setting `collation_connection` also implicitly sets `character_set_connection` to the character set associated with the collation (equivalent to executing `SET character_set_connection = @@character_set_database`). It is unnecessary to set `character_set_connection` explicitly.

**Note**

`ucs2` cannot be used as a client character set, which means that it does not work for `SET NAMES` or `SET CHARACTER SET`.

The MySQL client programs `mysql`, `mysqladmin`, `mysqlcheck`, `mysqldump`, and `mysqlshow` determine the default character set to use as follows:

- In the absence of other information, the programs use the compiled-in default character set, usually `latin1`.

904
The programs support a `--default-character-set` option, which enables users to specify the character set explicitly to override whatever default the client otherwise determines.

When a client connects to the server, it sends the name of the character set that it wants to use. The server uses the name to set the `character_set_client`, `character_set_results`, and `character_set_connection` system variables. In effect, the server performs a `SET NAMES` operation using the character set name.

With the MySQL client, to use a character set different from the default, you could explicitly execute `SET NAMES` every time you start up. To accomplish the same result more easily, add the `--default-character-set` option setting to your MySQL command line or in your option file. For example, the following option file setting changes the three connection-related character set variables set to `koi8r` each time you invoke `mysql`:

```
[mysql]
default-character-set=koi8r
```

If you are using the MySQL client with auto-reconnect enabled (which is not recommended), it is preferable to use the `charset` command rather than `SET NAMES`. For example:

```
mysql> charset utf8
Charset changed
```

The `charset` command issues a `SET NAMES` statement, and also changes the default character set that MySQL uses when it reconnects after the connection has dropped.

Example: Suppose that `column1` is defined as `CHAR(5) CHARACTER SET latin2`. If you do not say `SET NAMES` or `SET CHARACTER SET`, then for `SELECT column1 FROM t`, the server sends back all the values for `column1` using the character set that the client specified when it connected. On the other hand, if you say `SET NAMES 'latin1'` or `SET CHARACTER SET latin1` before issuing the `SELECT` statement, the server converts the `latin2` values to `latin1` just before sending results back. Conversion may be lossy if there are characters that are not in both character sets.

If you want the server to perform no conversion of result sets or error messages, set `character_set_results` to `NULL` or `binary`:

```
SET character_set_results = NULL;
```

To see the values of the character set and collation system variables that apply to your connection, use these statements:

```
SHOW VARIABLES LIKE 'character_set%';
SHOW VARIABLES LIKE 'collation%';
```

You must also consider the environment within which your MySQL applications execute. See Section 10.1.5, “Configuring the Character Set and Collation for Applications”.

For more information about character sets and error messages, see Section 10.1.6, “Character Set for Error Messages”.

10.1.5 Configuring the Character Set and Collation for Applications

For applications that store data using the default MySQL character set and collation (`latin1`, `latin1_swedish_ci`), no special configuration should be needed. If applications require data storage using a different character set or collation, you can configure character set information several ways:

- Specify character settings per database. For example, applications that use one database might require `utf8`, whereas applications that use another database might require `sjis`.  

905
• Specify character settings at server startup. This causes the server to use the given settings for all applications that do not make other arrangements.

• Specify character settings at configuration time, if you build MySQL from source. This causes the server to use the given settings for all applications, without having to specify them at server startup.

When different applications require different character settings, the per-database technique provides a good deal of flexibility. If most or all applications use the same character set, specifying character settings at server startup or configuration time may be most convenient.

For the per-database or server-startup techniques, the settings control the character set for data storage. Applications must also tell the server which character set to use for client/server communications, as described in the following instructions.

The examples shown here assume use of the utf8 character set and utf8_general_ci collation.

Specify character settings per database. To create a database such that its tables will use a given default character set and collation for data storage, use a CREATE DATABASE statement like this:

CREATE DATABASE mydb
DEFAULT CHARACTER SET utf8
DEFAULT COLLATE utf8_general_ci;

Tables created in the database will use utf8 and utf8_general_ci by default for any character columns.

Applications that use the database should also configure their connection to the server each time they connect. This can be done by executing a SET NAMES 'utf8' statement after connecting. The statement can be used regardless of connection method: The mysql client, PHP scripts, and so forth.

In some cases, it may be possible to configure the connection to use the desired character set some other way. For example, for connections made using mysql, you can specify the --default-character-set=utf8 command-line option to achieve the same effect as SET NAMES 'utf8'.

For more information about configuring client connections, see Section 10.1.4, “Connection Character Sets and Collations”.

If you change the default character set or collation for a database, stored routines that use the database defaults must be dropped and recreated so that they use the new defaults. (In a stored routine, variables with character data types use the database defaults if the character set or collation are not specified explicitly. See Section 13.1.15, “CREATE PROCEDURE and CREATE FUNCTION Syntax”.)

Specify character settings at server startup. To select a character set and collation at server startup, use the --character-set-server and --collation-server options. For example, to specify the options in an option file, include these lines:

[mysqld]
character-set-server=utf8
collation-server=utf8_general_ci

These settings apply server-wide and apply as the defaults for databases created by any application, and for tables created in those databases.

It is still necessary for applications to configure their connection using SET NAMES or equivalent after they connect, as described previously. You might be tempted to start the server with the --init_connect="SET NAMES 'utf8'" option to cause SET NAMES to be executed automatically for each client that connects. However, this will yield inconsistent results because the init_connect value is not executed for users who have the SUPER privilege.
Specify character settings at MySQL configuration time. To select a character set and collation when you configure and build MySQL from source, use the --with-charset and --with-collation options:

```
sHELL> ./configure --with-charset=utf8 --with-collation=utf8_general_ci
```

The resulting server uses utf8 and utf8_general_ci as the default for databases and tables and for client connections. It is unnecessary to use --character-set-server and --collation-server to specify those defaults at server startup. It is also unnecessary for applications to configure their connection using SET NAMES or equivalent after they connect to the server.

Regardless of how you configure the MySQL character set for application use, you must also consider the environment within which those applications execute. If you will send statements using UTF-8 text taken from a file that you create in an editor, you should edit the file with the locale of your environment set to UTF-8 so that the file encoding is correct and so that the operating system handles it correctly. If you use the mysql client from within a terminal window, the window must be configured to use UTF-8 or characters may not display properly. For a script that executes in a Web environment, the script must handle character encoding properly for its interaction with the MySQL server, and it must generate pages that correctly indicate the encoding so that browsers know how to display the content of the pages. For example, you can include this `meta` tag within your `<head>` element:

```
<meta http-equiv="Content-Type" content="text/html; charset=utf-8" />
```

### 10.1.6 Character Set for Error Messages

This section describes how the server uses character sets for constructing error messages and returning them to clients. For information about the language of error messages (rather than the character set), see Section 10.2, “Setting the Error Message Language”.

In MySQL, the server constructs error messages and returns them to clients as follows:

- The message template has the character set associated with the error message language. For example, English, Korean, and Russian messages use latin1, euckr, and koi8r, respectively.

- Parameters in the message template are replaced with values that apply to a specific error occurrence. These parameters use their own character set. Identifiers such as table or column names use UTF-8. Data values retain their character set. For example, in the following duplicate-key message, 'xxx' has the character set of the table column associated with key 1:

```
Duplicate entry 'xxx' for key1
```

The preceding method of error-message construction can result in messages that contain a mix of character sets unless all items involved contain only ASCII characters. This issue is resolved in MySQL 5.5, in which error messages are constructed internally within the server using UTF-8 and returned to the client in the character set specified by the `character_set_results` system variable.

### 10.1.7 Collation Issues

The following sections discuss various aspects of character set collations.

#### 10.1.7.1 Collation Naming Conventions

MySQL collation names follow these conventions:

- A name ending in `_ci` indicates a case-insensitive collation.
- A name ending in `_cs` indicates a case-sensitive collation.
• A name ending in \_bin indicates a binary collation. Character comparisons are based on character binary code values.

10.1.7.2 Using COLLATE in SQL Statements

With the **COLLATE** clause, you can override whatever the default collation is for a comparison. **COLLATE** may be used in various parts of SQL statements. Here are some examples:

• With **ORDER BY**:

  ```sql
  SELECT k
  FROM t1
  ORDER BY k COLLATE latin1_german2_ci;
  ```

• With **AS**:

  ```sql
  SELECT k COLLATE latin1_german2_ci AS k1
  FROM t1
  ORDER BY k1;
  ```

• With **GROUP BY**:

  ```sql
  SELECT k
  FROM t1
  GROUP BY k COLLATE latin1_german2_ci;
  ```

• With aggregate functions:

  ```sql
  SELECT MAX(k COLLATE latin1_german2_ci)
  FROM t1;
  ```

• With **DISTINCT**:

  ```sql
  SELECT DISTINCT k COLLATE latin1_german2_ci
  FROM t1;
  ```

• With **WHERE**:

  ```sql
  SELECT *
  FROM t1
  WHERE _latin1 'Müller' COLLATE latin1_german2_ci = k;
  ```

  ```sql
  SELECT *
  FROM t1
  WHERE k LIKE _latin1 'Müller' COLLATE latin1_german2_ci;
  ```

• With **HAVING**:

  ```sql
  SELECT k
  FROM t1
  GROUP BY k
  HAVING k = _latin1 'Müller' COLLATE latin1_german2_ci;
  ```

10.1.7.3 COLLATE Clause Precedence

The **COLLATE** clause has high precedence (higher than `|`), so the following two expressions are equivalent:

```sql
x || y COLLATE z
```
10.1.7.4 Collations Must Be for the Right Character Set

Each character set has one or more collations, but each collation is associated with one and only one character set. Therefore, the following statement causes an error message because the `latin2_bin` collation is not legal with the `latin1` character set:

```sql
mysql> SELECT _latin1 'x' COLLATE latin2_bin;
ERROR 1253 (42000): COLLATION 'latin2_bin' is not valid for CHARACTER SET 'latin1'
```

10.1.7.5 Collation of Expressions

In the great majority of statements, it is obvious what collation MySQL uses to resolve a comparison operation. For example, in the following cases, it should be clear that the collation is the collation of column `charset_name`:

```sql
SELECT x FROM T ORDER BY x;
SELECT x FROM T WHERE x = x;
SELECT DISTINCT x FROM T;
```

However, with multiple operands, there can be ambiguity. For example:

```sql
SELECT x FROM T WHERE x = 'Y';
```

Should the comparison use the collation of the column `x`, or of the string literal `'Y'`? Both `x` and `'Y'` have collations, so which collation takes precedence?

Standard SQL resolves such questions using what used to be called “coercibility” rules. MySQL assigns coercibility values as follows:

- An explicit `COLLATE` clause has a coercibility of 0. (Not coercible at all.)
- The concatenation of two strings with different collations has a coercibility of 1.
- The collation of a column or a stored routine parameter or local variable has a coercibility of 2.
- A “system constant” (the string returned by functions such as `USER()` or `VERSION()`) has a coercibility of 3.
- The collation of a literal has a coercibility of 4.
- `NULL` or an expression that is derived from `NULL` has a coercibility of 5.

MySQL uses coercibility values with the following rules to resolve ambiguities:

- Use the collation with the lowest coercibility value.
- If both sides have the same coercibility, then:
  - If both sides are Unicode, or both sides are not Unicode, it is an error.
  - If one of the sides has a Unicode character set, and another side has a non-Unicode character set, the side with Unicode character set wins, and automatic character set conversion is applied to the non-Unicode side. For example, the following statement does not return an error:
    ```sql
    SELECT CONCAT(utf8_column, latin1_column) FROM t1;
    ```
    It returns a result that has a character set of `utf8` and the same collation as `utf8_column`. Values of `latin1_column` are automatically converted to `utf8` before concatenating.
• For an operation with operands from the same character set but that mix a _bin collation and a _ci or _cs collation, the _bin collation is used. This is similar to how operations that mix nonbinary and binary strings evaluate the operands as binary strings, except that it is for collations rather than data types.

Although automatic conversion is not in the SQL standard, the SQL standard document does say that every character set is (in terms of supported characters) a “subset” of Unicode. Because it is a well-known principle that “what applies to a superset can apply to a subset,” we believe that a collation for Unicode can apply for comparisons with non-Unicode strings.

Examples:

<table>
<thead>
<tr>
<th>Comparison</th>
<th>Collation Used</th>
</tr>
</thead>
<tbody>
<tr>
<td>column1 = 'A'</td>
<td>Use collation of column1</td>
</tr>
<tr>
<td>column1 = 'A' COLLATE x</td>
<td>Use collation of 'A' COLLATE x</td>
</tr>
<tr>
<td>column1 COLLATE x = 'A' COLLATE y</td>
<td>Error</td>
</tr>
</tbody>
</table>

The COERCIBILITY() function can be used to determine the coercibility of a string expression:

```sql
mysql> SELECT COERCIBILITY('A' COLLATE latin1_swedish_ci);
-> 0
mysql> SELECT COERCIBILITY(VERSION());
-> 3
mysql> SELECT COERCIBILITY('A');
-> 4
```

See Section 12.14, “Information Functions”.

For implicit conversion of a numeric or temporal value to a string, such as occurs for the argument 1 in the expression CONCAT(1, 'abc'), the result is a binary string for which the character set and collation are binary. See Section 12.2, “Type Conversion in Expression Evaluation”.

10.1.7.6 The _bin and binary Collations

This section describes how _bin collations for nonbinary strings differ from the binary “collation” for binary strings.

Nonbinary strings (as stored in the CHAR, VARCHAR, and TEXT data types) have a character set and collation. A given character set can have several collations, each of which defines a particular sorting and comparison order for the characters in the set. One of these is the binary collation for the character set, indicated by a _bin suffix in the collation name. For example, latin1 and utf8 have binary collations named latin1_bin and utf8_bin.

Binary strings (as stored in the BINARY, VARBINARY, and BLOB data types) have no character set or collation in the sense that nonbinary strings do. (Applied to a binary string, the CHARSET() and COLLATION() functions both return a value of binary.) Binary strings are sequences of bytes and the numeric values of those bytes determine sort order.

The _bin collations differ from the binary collation in several respects.

The unit for sorting and comparison. Binary strings are sequences of bytes. Sorting and comparison is always based on numeric byte values. Nonbinary strings are sequences of characters, which might be multibyte. Collations for nonbinary strings define an ordering of the character values for sorting and comparison. For the _bin collation, this ordering is based solely on binary code values of the characters (which is similar to ordering for binary strings except that a _bin collation must take into account that a character might contain multiple bytes). For other collations, character ordering might take additional factors such as lettercase into account.
Character set conversion. A nonbinary string has a character set and is converted to another character set in many cases, even when the string has a \texttt{_bin} collation:

- When assigning column values from another column that has a different character set:

  \begin{verbatim}
  UPDATE t1 SET utf8_bin_column=latin1_column;
  INSERT INTO t1 (latin1_column) SELECT utf8_bin_column FROM t2;
  \end{verbatim}

- When assigning column values for \texttt{INSERT} or \texttt{UPDATE} using a string literal:

  \begin{verbatim}
  SET NAMES latin1;
  INSERT INTO t1 (utf8_bin_column) VALUES ('string-in-latin1');
  \end{verbatim}

- When sending results from the server to a client:

  \begin{verbatim}
  SET NAMES latin1;
  SELECT utf8_bin_column FROM t2;
  \end{verbatim}

For binary string columns, no conversion occurs. For the preceding cases, the string value is copied byte-wise.

Lettercase conversion. Collations provide information about lettercase of characters, so characters in a nonbinary string can be converted from one lettercase to another, even for \texttt{_bin} collations that ignore lettercase for ordering:

\begin{verbatim}
mysql> SET NAMES latin1 COLLATE latin1_bin;
Query OK, 0 rows affected (0.02 sec)
mysql> SELECT LOWER('aA'), UPPER('zZ');
+-------------+-------------+
| LOWER('aA') | UPPER('zZ') |
| aa          | ZZ          |
+-------------+-------------+
1 row in set (0.13 sec)
\end{verbatim}

The concept of lettercase does not apply to bytes in a binary string. To perform lettercase conversion, the string must be converted to a nonbinary string:

\begin{verbatim}
mysql> SET NAMES binary;
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT LOWER('aA'), LOWER(CONVERT('aA' USING latin1));
  +-------------+------------------+
  | LOWER('aA') | LOWER(CONVERT('aA' USING latin1)) |
  | aA          | aa               |
  +-------------+------------------+
1 row in set (0.00 sec)
\end{verbatim}

Trailing space handling in comparisons. Nonbinary strings have \texttt{PADSPACE} behavior for all collations, including \texttt{_bin} collations. Trailing spaces are insignificant in comparisons:

\begin{verbatim}
mysql> SET NAMES utf8 COLLATE utf8_bin;
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT 'a ' = 'a';
  +------------+
  | 'a ' = 'a' |
  |          1  |
  +------------+
\end{verbatim}
For binary strings, all characters are significant in comparisons, including trailing spaces:

```sql
mysql> SET NAMES binary;
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT 'a ' = 'a';
+------------+
| 'a ' = 'a' |
+------------+
|          0  |
+------------+
1 row in set (0.00 sec)
```

### Trailing space handling for inserts and retrievals.

**CHAR (N)** columns store nonbinary strings. Values shorter than \( N \) characters are extended with spaces on insertion. For retrieval, trailing spaces are removed.

**BINARY (N)** columns store binary strings. Values shorter than \( N \) bytes are extended with \( 0x00 \) bytes on insertion. For retrieval, nothing is removed; a value of the declared length is always returned.

```sql
mysql> CREATE TABLE t1 (  
  > a CHAR(10) CHARACTER SET utf8 COLLATE utf8_bin,  
  > b BINARY(10)  
  > );
Query OK, 0 rows affected (0.09 sec)
mysql> INSERT INTO t1 VALUES ('a','a');
Query OK, 1 row affected (0.01 sec)
mysql> SELECT HEX(a), HEX(b) FROM t1;
+--------+----------------------+
| HEX(a) | HEX(b)               |
+--------+----------------------+
| 61     | 61000000000000000000 |
+--------+----------------------+
1 row in set (0.04 sec)
```

### 10.1.7.7 The BINARY Operator

The **BINARY** operator casts the string following it to a binary string. This is an easy way to force a comparison to be done byte by byte rather than character by character. **BINARY** also causes trailing spaces to be significant.

```sql
mysql> SELECT 'a' = 'A';
    -> 1
mysql> SELECT BINARY 'a' = 'A';
    -> 0
mysql> SELECT 'a' = 'a ';
    -> 1
mysql> SELECT BINARY 'a' = 'a ';
    -> 0
```

**BINARY str** is shorthand for **CAST(str AS BINARY)**.

The **BINARY** attribute in character column definitions has a different effect. A character column defined with the **BINARY** attribute is assigned the binary collation of the column character set. Every character set has a binary collation. For example, the binary collation for the **latin1** character set is **latin1_bin**, so if the table default character set is **latin1**, these two column definitions are equivalent:

```sql
CHAR(10) BINARY
CHAR(10) CHARACTER SET latin1 COLLATE latin1_bin
```
The use of `CHARACTER SET binary` in the definition of a `CHAR`, `VARCHAR`, or `TEXT` column causes the column to be treated as a binary data type. For example, the following pairs of definitions are equivalent:

<table>
<thead>
<tr>
<th>Definition</th>
<th>Equivalent Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>CHAR(10) CHARACTER SET binary</code></td>
<td></td>
</tr>
<tr>
<td><code>BINARY(10)</code></td>
<td></td>
</tr>
<tr>
<td><code>VARCHAR(10) CHARACTER SET binary</code></td>
<td></td>
</tr>
<tr>
<td><code>VARBINARY(10)</code></td>
<td></td>
</tr>
<tr>
<td><code>TEXT CHARACTER SET binary</code></td>
<td></td>
</tr>
<tr>
<td><code>BLOB</code></td>
<td></td>
</tr>
</tbody>
</table>

### 10.1.7.8 Examples of the Effect of Collation

#### Example 1: Sorting German Umlauts

Suppose that column `x` in table `T` has these `latin1` column values:

<table>
<thead>
<tr>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Muffler</td>
</tr>
<tr>
<td>Müller</td>
</tr>
<tr>
<td>MX Systems</td>
</tr>
<tr>
<td>MySQL</td>
</tr>
</tbody>
</table>

Suppose also that the column values are retrieved using the following statement:

```sql
SELECT X FROM T ORDER BY X COLLATE `collation_name`;
```

The following table shows the resulting order of the values if we use `ORDER BY` with different collations.

<table>
<thead>
<tr>
<th><code>latin1_swedish_ci</code></th>
<th><code>latin1_german1_ci</code></th>
<th><code>latin1_german2_ci</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Muffler</td>
<td>Muffler</td>
<td>Müller</td>
</tr>
<tr>
<td>MX Systems</td>
<td>Müller</td>
<td>Muffler</td>
</tr>
<tr>
<td>Müller</td>
<td>MX Systems</td>
<td>MX Systems</td>
</tr>
<tr>
<td>MySQL</td>
<td>MySQL</td>
<td>MySQL</td>
</tr>
</tbody>
</table>

The character that causes the different sort orders in this example is the U with two dots over it (ü), which the Germans call “U-umlaut.”

- The first column shows the result of the `SELECT` using the Swedish/Finnish collating rule, which says that U-umlaut sorts with Y.
- The second column shows the result of the `SELECT` using the German DIN-1 rule, which says that U-umlaut sorts with U.
- The third column shows the result of the `SELECT` using the German DIN-2 rule, which says that U-umlaut sorts with UE.

#### Example 2: Searching for German Umlauts

Suppose that you have three tables that differ only by the character set and collation used:

```sql
mysql> SET NAMES utf8;
mysql> CREATE TABLE german1 (c CHAR(10)) CHARACTER SET latin1 COLLATE latin1_german1_ci;
mysql> CREATE TABLE german2 (c CHAR(10)) CHARACTER SET latin1 COLLATE latin1_german2_ci;
mysql> CREATE TABLE germanutf8 (c CHAR(10)) CHARACTER SET utf8;
```
Each table contains two records:

```sql
mysql> SELECT * FROM german1 WHERE c = 'Bär';
+------+
| c    |
+------+
| Bar  |
| Bär  |
+------+

mysql> SELECT * FROM german2 WHERE c = 'Bär';
+------+
| c    |
+------+
| Bär  |
+------+

mysql> SELECT * FROM germanutf8 WHERE c = 'Bär';
+------+
| c    |
+------+
| Bar  |
| Bär  |
+------+
```

This is not a bug but rather a consequence of the sorting properties of `latin1_german1_ci` and `utf8_unicode_ci` (the sorting shown is done according to the German DIN 5007 standard).

### 10.1.7.9 Collation and INFORMATION_SCHEMA Searches

String columns in `INFORMATION_SCHEMA` tables have a collation of `utf8_general_ci`, which is case insensitive. However, searches in `INFORMATION_SCHEMA` string columns are also affected by file system case sensitivity. For values that correspond to objects that are represented in the file system, such as names of databases and tables, searches may be case sensitive if the file system is case sensitive. This section describes how to work around this issue if necessary; see also Bug #34921.

Suppose that a query searches the `SCHEMATA.SCHEMA_NAME` column for the `test` database. On Linux, file systems are case sensitive, so comparisons of `SCHEMATA.SCHEMA_NAME` with `'test'` match, but comparisons with `'TEST'` do not:

```sql
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
    -> WHERE SCHEMA_NAME = 'test';
+---------------+
| SCHEMA_NAME   |
+---------------+
| test          |
+---------------+
1 row in set (0.01 sec)

mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
    -> WHERE SCHEMA_NAME = 'TEST';
Empty set (0.00 sec)
```

On Windows or OS X where file systems are not case sensitive, comparisons match both `'test'` and `'TEST'`:

```sql
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
```
Collation Issues

```sql
-> WHERE SCHEMA_NAME = 'test';
+-------------+
| SCHEMA_NAME |
+-------------+
| test        |
+-------------+
1 row in set (0.00 sec)
```

```sql
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
    -> WHERE SCHEMA_NAME = 'TEST';
+-------------+
| SCHEMA_NAME |
+-------------+
| TEST        |
+-------------+
1 row in set (0.00 sec)
```

The value of the `lower_case_table_names` system variable makes no difference in this context.

This behavior occurs because the `utf8_general_ci` collation is not used for `INFORMATION_SCHEMA` queries when searching the file system for database objects. It is a result of optimizations implemented for `INFORMATION_SCHEMA` searches in MySQL 5.1.21 and thus does not occur prior to 5.1.21. For information about these optimizations, see Section 8.2.4, “INFORMATION_SCHEMA Optimization”.

Searches in `INFORMATION_SCHEMA` string columns for values that refer to `INFORMATION_SCHEMA` itself do use the `utf8_general_ci` collation because `INFORMATION_SCHEMA` is a “virtual” database and is not represented in the file system. For example, comparisons with `SCHEMATA.SCHEMA_NAME` match 'information_schema' or 'INFORMATION_SCHEMA' regardless of platform:

```sql
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
    -> WHERE SCHEMA_NAME = 'information_schema';
+--------------------+
| SCHEMA_NAME         |
+--------------------+
| information_schema  |
+--------------------+
1 row in set (0.00 sec)
```

```sql
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
    -> WHERE SCHEMA_NAME = 'INFORMATION_SCHEMA';
+--------------------+
| SCHEMA_NAME         |
+--------------------+
| information_schema  |
+--------------------+
1 row in set (0.00 sec)
```

If the result of a string operation on an `INFORMATION_SCHEMA` column differs from expectations, a workaround is to use an explicit `COLLATE` clause to force a suitable collation (Section 10.1.7.2, “Using COLLATE in SQL Statements”). For example, to perform a case-insensitive search, use `COLLATE` with the `INFORMATION_SCHEMA` column name:

```sql
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
    -> WHERE SCHEMA_NAME COLLATE utf8_general_ci = 'test';
+-------------+
| SCHEMA_NAME |
+-------------+
| test        |
+-------------+
1 row in set (0.00 sec)
```

```sql
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
    -> WHERE SCHEMA_NAME COLLATE utf8_general_ci = 'TEST';
+-------------+
| SCHEMA_NAME |
+-------------+
| test        |
+-------------+
1 row in set (0.00 sec)
```
You can also use the `UPPER()` or `LOWER()` function:

```
WHERE UPPER(SCHEMA_NAME) = 'TEST'
WHERE LOWER(SCHEMA_NAME) = 'test'
```

Although a case-insensitive comparison can be performed even on platforms with case-sensitive file systems, as just shown, it is not necessarily always the right thing to do. On such platforms, it is possible to have multiple objects with names that differ only in lettercase. For example, tables named `city`, `CITY`, and `City` can all exist simultaneously. Consider whether a search should match all such names or just one and write queries accordingly:

```
WHERE TABLE_NAME COLLATE utf8_bin = 'City'
WHERE TABLE_NAME COLLATE utf8_general_ci = 'city'
WHERE UPPER(TABLE_NAME) = 'CITY'
WHERE LOWER(TABLE_NAME) = 'city'
```

The first of those comparisons (with `utf8_bin`) is case sensitive; the others are not.

### 10.1.8 String Repertoire

The *repertoire* of a character set is the collection of characters in the set.

As of MySQL 5.1.21, string expressions have a repertoire attribute, which can have two values:

- **ASCII**: The expression can contain only characters in the Unicode range `U+0000` to `U+007F`.
- **UNICODE**: The expression can contain characters in the Unicode range `U+0000` to `U+FFFF`.

The ASCII range is a subset of UNICODE range, so a string with ASCII repertoire can be converted safely without loss of information to the character set of any string with UNICODE repertoire or to a character set that is a superset of ASCII. (All MySQL character sets are supersets of ASCII with the exception of swe7, which reuses some punctuation characters for Swedish accented characters.) The use of repertoire enables character set conversion in expressions for many cases where MySQL would otherwise return an "illegal mix of collations" error.

The following discussion provides examples of expressions and their repertoires, and describes how the use of repertoire changes string expression evaluation:

- The repertoire for string constants depends on string content:

  ```
  SET NAMES utf8; SELECT 'abc';
  SELECT _utf8'def';
  SELECT N'MySQL';
  ```

  Although the character set is utf8 in each of the preceding cases, the strings do not actually contain any characters outside the ASCII range, so their repertoire is **ASCII** rather than **UNICODE**.

- Columns having the ascii character set have **ASCII** repertoire because of their character set. In the following table, `c1` has **ASCII** repertoire:

  ```
  CREATE TABLE t1 (c1 CHAR(1) CHARACTER SET ascii);
  ```

  The following example illustrates how repertoire enables a result to be determined in a case where an error occurs without repertoire:

  ```
  CREATE TABLE t1 {
      c1 CHAR(1) CHARACTER SET latin1,
      c2 CHAR(1) CHARACTER SET ascii
  }
  ```
Without repertoire, this error occurs:

```
ERROR 1267 (HY000): Illegal mix of collations (latin1_swedish_ci,IMPLICIT)
and (ascii_general_ci,IMPLICIT) for operation 'concat'
```

Using repertoire, subset to superset (ascii to latin1) conversion can occur and a result is returned:

```
+---------------+
| CONCAT(c1,c2) |
+---------------+
| ab            |
```

• Functions with one string argument inherit the repertoire of their argument. The result of `UPPER(_utf8'abc')` has ASCII repertoire, because its argument has ASCII repertoire.

• For functions that return a string but do not have string arguments and use `character_set_connection` as the result character set, the result repertoire is ASCII if `character_set_connection` is ascii, and UNICODE otherwise:

```
FORMAT(numeric_column, 4);
```

Use of repertoire changes how MySQL evaluates the following example:

```
SET NAMES ascii;
CREATE TABLE t1 (a INT, b VARCHAR(10) CHARACTER SET latin1);
INSERT INTO t1 VALUES (1,'b');
SELECT CONCAT(FORMAT(a, 4), b) FROM t1;
```

Without repertoire, this error occurs:

```
ERROR 1267 (HY000): Illegal mix of collations (ascii_general_ci,COERCIBLE)
and (latin1_swedish_ci,IMPLICIT) for operation 'concat'
```

With repertoire, a result is returned:

```
+-------------------------+
| CONCAT(FORMAT(a, 4), b) |
+-------------------------+
| 1.0000b                 |
```

• Functions with two or more string arguments use the “widest” argument repertoire for the result repertoire (UNICODE is wider than ASCII). Consider the following `CONCAT()` calls:

```
CONCAT(_ucs2 X'0041', _ucs2 X'00C2')
CONCAT(_ucs2 X'0041', _ucs2 X'00C2')
```

For the first call, the repertoire is ASCII because both arguments are within the range of the ascii character set. For the second call, the repertoire is UNICODE because the second argument is outside the ascii character set range.

• The repertoire for function return values is determined based only on the repertoire of the arguments that affect the result's character set and collation.
IF(column1 < column2, 'smaller', 'greater')

The result repertoire is ASCII because the two string arguments (the second argument and the third argument) both have ASCII repertoire. The first argument does not matter for the result repertoire, even if the expression uses string values.

10.1.9 Operations Affected by Character Set Support

This section describes operations that take character set information into account.

10.1.9.1 Result Strings

MySQL has many operators and functions that return a string. This section answers the question: What is the character set and collation of such a string?

For simple functions that take string input and return a string result as output, the output's character set and collation are the same as those of the principal input value. For example, UPPER(x) returns a string whose character string and collation are the same as that of x. The same applies for INSTR(), LCASE(), LOWER(), LTRIM(), MID(), REPEAT(), REPLACE(), REVERSE(), RIGHT(), RPAD(), RTRIM(), SOUNDEX(), SUBSTRING(), TRIM(), UCASE(), and UPPER.

Note: The REPLACE() function, unlike all other functions, always ignores the collation of the string input and performs a case-sensitive comparison.

If a string input or function result is a binary string, the string has no character set or collation. This can be checked by using the CHARSET() and COLLATION() functions, both of which return binary to indicate that their argument is a binary string:

```
mysql> SELECT CHARSET(BINARY 'a'), COLLATION(BINARY 'a');
+---------------------+-----------------------+
| CHARSET(BINARY 'a') | COLLATION(BINARY 'a') |
|---------------------+-----------------------+
| binary              | binary                |
```

For operations that combine multiple string inputs and return a single string output, the “aggregation rules” of standard SQL apply for determining the collation of the result:

- If an explicit COLLATE X occurs, use X.
- If explicit COLLATE X and COLLATE Y occur, raise an error.
- Otherwise, if all collations are X, use X.
- Otherwise, the result has no collation.

For example, with CASE ... WHEN a THEN b WHEN b THEN c COLLATE X END, the resulting collation is X. The same applies for UNION, ||, CONCAT(), ELT(), GREATEST(), IF(), and LEAST.

For operations that convert to character data, the character set and collation of the strings that result from the operations are defined by the character_set_connection and collation_connection system variables. This applies only to CAST(), CONV(), FORMAT(), HEX(), and SPACE.

If you are uncertain about the character set or collation of the result returned by a string function, you can use the CHARSET() or COLLATION() function to find out:

```
mysql> SELECT USER(), CHARSET(USER()), COLLATION(USER());
+--------------------+------------------+
<table>
<thead>
<tr>
<th>USER()</th>
<th>CHARSET(USER)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>binary</td>
</tr>
</tbody>
</table>
```

```
10.1.9.2 CONVERT() and CAST()

**CONVERT()** provides a way to convert data between different character sets. The syntax is:

```sql
CONVERT(expr USING transcoding_name)
```

In MySQL, transcoding names are the same as the corresponding character set names.

Examples:

```sql
SELECT CONVERT(_latin1'Müller' USING utf8);
INSERT INTO utf8table (utf8column)
    SELECT CONVERT(latin1field USING utf8) FROM latin1table;
```

**CONVERT(... USING ...)** is implemented according to the standard SQL specification.

You may also use **CAST()** to convert a string to a different character set. The syntax is:

```sql
CAST(character_string AS character_data_type CHARACTER SET charset_name)
```

Example:

```sql
SELECT CAST(_latin1'test' AS CHAR CHARACTER SET utf8);
```

If you use **CAST()** without specifying **CHARACTER SET**, the resulting character set and collation are defined by the **character_set_connection** and **collation_connection** system variables.

If you use **CAST()** with **CHARACTER SET X**, the resulting character set and collation are **X** and the default collation of **X**.

You may not use a **COLLATE** clause inside a **CONVERT()** or **CAST()** call, but you may use it outside. For example, **CAST(... COLLATE ...)** is illegal, but **CAST(...) COLLATE ...** is legal:

```sql
SELECT CAST(_latin1'test' AS CHAR CHARACTER SET utf8) COLLATE utf8_bin;
```

10.1.9.3 SHOW Statements and INFORMATION_SCHEMA

Several **SHOW** statements provide additional character set information. These include **SHOW CHARACTER SET**, **SHOW COLLATION**, **SHOW CREATE DATABASE**, **SHOW CREATE TABLE** and **SHOW COLUMNS**. These statements are described here briefly. For more information, see Section 13.7.5, "SHOW Syntax".

**INFORMATION_SCHEMA** has several tables that contain information similar to that displayed by the **SHOW** statements. For example, the **CHARACTER SETS** and **COLLATIONS** tables contain the information displayed by **SHOW CHARACTER SET** and **SHOW COLLATION**. See Chapter 20, **INFORMATION_SCHEMA Tables**.

The **SHOW CHARACTER SET** statement shows all available character sets. It takes an optional **LIKE** clause that indicates which character set names to match. For example:

```sql
mysql> SHOW CHARACTER SET LIKE 'latin%';
+---------+-----------------------------+-------------------+--------+
| Charset | Description                 | Default collation | Maxlen |
+---------+-----------------------------+-------------------+--------+
```
| latin1 | cp1252 West European | latin1_swedish_ci | 1 |
| latin2 | ISO 8859-2 Central European | latin2_general_ci | 1 |
| latin5 | ISO 8859-9 Turkish | latin5_turkish_ci | 1 |
| latin7 | ISO 8859-13 Baltic | latin7_general_ci | 1 |

The output from `SHOW COLLATION` includes all available character sets. It takes an optional `LIKE` clause that indicates which collation names to match. For example:

```sql
mysql> SHOW COLLATION LIKE 'latin1%';

+-------------------+---------+----+---------+----------+---------+
| Collation          | Charset | Id | Default | Compiled | Sortlen |
|-------------------+---------+----+---------+----------+---------+
| latin1_german1_ci | latin1  | 5  |         |          |       0 |
| latin1_swedish_ci | latin1  | 8  | Yes     | Yes      |       0 |
| latin1_danish_ci  | latin1  | 15 |         |          |       0 |
| latin1_german2_ci | latin1  | 31 |         | Yes      |       2 |
| latin1_bin        | latin1  | 47 |         | Yes      |       0 |
| latin1_general_ci | latin1  | 48 |         |          |       0 |
| latin1_general_cs | latin1  | 49 |         |          |       0 |
| latin1_spanish_ci | latin1  | 94 |         |          |       0 |
+-------------------+---------+----+---------+----------+---------+
```

`SHOW CREATE DATABASE` displays the `CREATE DATABASE` statement that creates a given database:

```sql
mysql> SHOW CREATE DATABASE test;

+----------+-----------------------------------------------------------------+
| Database | Create Database                                                   |
|----------+-----------------------------------------------------------------+
| test     | CREATE DATABASE `test` /*!40100 DEFAULT CHARACTER SET latin1 */ |
+----------+-----------------------------------------------------------------+
```

If no `COLLATE` clause is shown, the default collation for the character set applies.

`SHOW CREATE TABLE` is similar, but displays the `CREATE TABLE` statement to create a given table. The column definitions indicate any character set specifications, and the table options include character set information.

The `SHOW COLUMNS` statement displays the collations of a table's columns when invoked as `SHOW FULL COLUMNS`. Columns with `CHAR`, `VARCHAR`, or `TEXT` data types have collations. Numeric and other noncharacter types have no collation (indicated by `NULL` as the `Collation` value). For example:

```sql
mysql> SHOW FULL COLUMNS FROM person\G

<table>
<thead>
<tr>
<th>Field: id</th>
<th>Type: smallint(5) unsigned</th>
</tr>
</thead>
<tbody>
<tr>
<td>Collation: NULL</td>
<td></td>
</tr>
<tr>
<td>Null: NO</td>
<td></td>
</tr>
<tr>
<td>Key: PRI</td>
<td></td>
</tr>
<tr>
<td>Default: NULL</td>
<td></td>
</tr>
<tr>
<td>Extra: auto_increment</td>
<td></td>
</tr>
<tr>
<td>Privileges: select,insert,update,references</td>
<td></td>
</tr>
<tr>
<td>Comment:</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Field: name</th>
<th>Type: char(60)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Collation: latin1_swedish_ci</td>
<td></td>
</tr>
<tr>
<td>Null: NO</td>
<td></td>
</tr>
<tr>
<td>Key:</td>
<td></td>
</tr>
<tr>
<td>Default:</td>
<td></td>
</tr>
<tr>
<td>Extra:</td>
<td></td>
</tr>
<tr>
<td>Privileges: select,insert,update,references</td>
<td></td>
</tr>
<tr>
<td>Comment:</td>
<td></td>
</tr>
</tbody>
</table>
```

The character set is not part of the display but is implied by the collation name.
10.1.10 Unicode Support

MySQL supports two character sets for storing Unicode data:

• **ucs2**, the UCS-2 encoding of the Unicode character set using 16 bits per character.
• **utf8**, a UTF-8 encoding of the Unicode character set using one to three bytes per character.

These two character sets support the characters from the Basic Multilingual Plane (BMP) of Unicode Version 3.0. BMP characters have these characteristics:

• Their code values are between 0 and 65535 (or \U0000 .. \UFFFF).
• They can be encoded with a fixed 16-bit word, as in **ucs2**.
• They can be encoded with 8, 16, or 24 bits, as in **utf8**.
• They are sufficient for almost all characters in major languages.

The **ucs2** and **utf8** character sets do not support supplementary characters that lie outside the BMP. Characters outside the BMP compare as REPLACEMENT CHARACTER and convert to '?' when converted to a Unicode character set.

A similar set of collations is available for each Unicode character set. For example, each has a Danish collation, the names of which are **ucs2_danish_ci** and **utf8_danish_ci**. All Unicode collations are listed at Section 10.1.13.1, “Unicode Character Sets”.

The MySQL implementation of UCS-2 stores characters in big-endian byte order and does not use a byte order mark (BOM) at the beginning of values. Other database systems might use little-endian byte order or a BOM. In such cases, conversion of values will need to be performed when transferring data between those systems and MySQL.

MySQL uses no BOM for UTF-8 values.

Client applications that need to communicate with the server using Unicode should set the client character set accordingly; for example, by issuing a SET NAMES ‘utf8’ statement. **ucs2** cannot be used as a client character set, which means that it does not work for SET NAMES or SET CHARACTER SET. (See Section 10.1.4, “Connection Character Sets and Collations”.)

The following sections provide additional detail on the Unicode character sets in MySQL.

10.1.10.1 The ucs2 Character Set (UCS-2 Unicode Encoding)

In UCS-2, every character is represented by a 2-byte Unicode code with the most significant byte first. For example: **LATIN CAPITAL LETTER A** has the code 0x0041 and it is stored as a 2-byte sequence: 0x00 0x41. **CYRILLIC SMALL LETTER YERU** (Unicode 0x044B) is stored as a 2-byte sequence: 0x04 0x4B. For Unicode characters and their codes, please refer to the Unicode Home Page.

In MySQL, the **ucs2** character set is a fixed-length 16-bit encoding for Unicode BMP characters.

10.1.10.2 The utf8 Character Set (3-Byte UTF-8 Unicode Encoding)

UTF-8 (Unicode Transformation Format with 8-bit units) is an alternative way to store Unicode data. It is implemented according to RFC 3629, which describes encoding sequences that take from one to four bytes. MySQL support for UTF-8 does not include 4-byte sequences. (An older standard for UTF-8 encoding, RFC 2279, describes UTF-8 sequences that take from one to six bytes. RFC 3629 renders RFC 2279 obsolete; for this reason, sequences with five and six bytes are no longer used.)

The idea of UTF-8 is that various Unicode characters are encoded using byte sequences of different lengths:
• Basic Latin letters, digits, and punctuation signs use one byte.

• Most European and Middle East script letters fit into a 2-byte sequence: extended Latin letters (with tilde, macron, acute, grave and other accents), Cyrillic, Greek, Armenian, Hebrew, Arabic, Syriac, and others.

• Korean, Chinese, and Japanese ideographs use 3-byte sequences.

Tip: To save space with UTF-8, use `VARCHAR` instead of `CHAR`. Otherwise, MySQL must reserve three bytes for each character in a `CHAR CHARACTER SET utf8` column because that is the maximum possible length. For example, MySQL must reserve 30 bytes for a `CHAR(10) CHARACTER SET utf8` column.

For additional information about data type storage, see Section 11.7, “Data Type Storage Requirements”. For information about InnoDB physical row storage, including how InnoDB tables that use COMPACT row format handle UTF-8 `CHAR(N)` columns internally, see Physical Row Structure.

10.1.11 UTF-8 for Metadata

Metadata is “the data about the data.” Anything that describes the database—as opposed to being the contents of the database—is metadata. Thus column names, database names, user names, version names, and most of the string results from `SHOW` are metadata. This is also true of the contents of tables in INFORMATION_SCHEMA because those tables by definition contain information about database objects.

Representation of metadata must satisfy these requirements:

• All metadata must be in the same character set. Otherwise, neither the `SHOW` statements nor `SELECT` statements for tables in INFORMATION_SCHEMA would work properly because different rows in the same column of the results of these operations would be in different character sets.

• Metadata must include all characters in all languages. Otherwise, users would not be able to name columns and tables using their own languages.

To satisfy both requirements, MySQL stores metadata in a Unicode character set, namely UTF-8. This does not cause any disruption if you never use accented or non-Latin characters. But if you do, you should be aware that metadata is in UTF-8.

The metadata requirements mean that the return values of the `USER()`, `CURRENT_USER()`, `SESSION_USER()`, `SYSTEM_USER()`, `DATABASE()`, and `VERSION()` functions have the UTF-8 character set by default.

The server sets the `character_set_system` system variable to the name of the metadata character set:

```
mysql> SHOW VARIABLES LIKE 'character_set_system';
+----------------------+-------+
<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>character_set_system</td>
<td>utf8</td>
</tr>
</tbody>
</table>
+----------------------+-------+
```

Storage of metadata using Unicode does *not* mean that the server returns headers of columns and the results of `DESCRIBE` functions in the `character_set_system` character set by default. When you use `SELECT column1 FROM t`, the name `column1` itself is returned from the server to the client in the character set determined by the value of the `character_set_results` system variable, which has a default value of `latin1`. If you want the server to pass metadata results back in a different character set, use the `SET NAMES` statement to force the server to perform character set conversion. `SET NAMES` sets the `character_set_results` and other related system variables.

(See Section 10.1.4, “Connection Character Sets and Collations”.) Alternatively, a client program can
perform the conversion after receiving the result from the server. It is more efficient for the client to perform the conversion, but this option is not always available for all clients.

If `character_set_results` is set to `NULL`, no conversion is performed and the server returns metadata using its original character set (the set indicated by `character_set_system`).

Error messages returned from the server to the client are converted to the client character set automatically, as with metadata.

If you are using (for example) the `USER()` function for comparison or assignment within a single statement, don’t worry. MySQL performs some automatic conversion for you.

```sql
SELECT * FROM t1 WHERE USER() = latin1_column;
```

This works because the contents of `latin1_column` are automatically converted to UTF-8 before the comparison.

```sql
INSERT INTO t1 (latin1_column) SELECT USER();
```

This works because the contents of `USER()` are automatically converted to `latin1` before the assignment.

Although automatic conversion is not in the SQL standard, the SQL standard document does say that every character set is (in terms of supported characters) a “subset” of Unicode. Because it is a well-known principle that “what applies to a superset can apply to a subset,” we believe that a collation for Unicode can apply for comparisons with non-Unicode strings. For more information about coercion of strings, see Section 10.1.7.5, “Collation of Expressions”.

### 10.1.12 Column Character Set Conversion

To convert a binary or nonbinary string column to use a particular character set, use `ALTER TABLE`.

For successful conversion to occur, one of the following conditions must apply:

- If the column has a binary data type (`BINARY`, `VARBINARY`, `BLOB`), all the values that it contains must be encoded using a single character set (the character set you’re converting the column to). If you use a binary column to store information in multiple character sets, MySQL has no way to know which values use which character set and cannot convert the data properly.

- If the column has a nonbinary data type (`CHAR`, `VARCHAR`, `TEXT`), its contents should be encoded in the column character set, not some other character set. If the contents are encoded in a different character set, you can convert the column to use a binary data type first, and then to a nonbinary column with the desired character set.

Suppose that a table `t` has a binary column named `col1` defined as `VARBINARY(50)`. Assuming that the information in the column is encoded using a single character set, you can convert it to a nonbinary column that has that character set. For example, if `col1` contains binary data representing characters in the `greek` character set, you can convert it as follows:

```sql
ALTER TABLE t MODIFY col1 VARCHAR(50) CHARACTER SET greek;
```

If your original column has a type of `BINARY(50)`, you could convert it to `CHAR(50)`, but the resulting values will be padded with `0x00` bytes at the end, which may be undesirable. To remove these bytes, use the `TRIM()` function:

```sql
UPDATE t SET col1 = TRIM(TRAILING 0x00 FROM col1);
```

Suppose that table `t` has a nonbinary column named `col1` defined as `CHAR(50) CHARACTER SET latin1` but you want to convert it to use `utf8` so that you can store values from many languages. The following statement accomplishes this:
ALTER TABLE t MODIFY col1 CHAR(50) CHARACTER SET utf8;

Conversion may be lossy if the column contains characters that are not in both character sets.

A special case occurs if you have old tables from before MySQL 4.1 where a nonbinary column contains values that actually are encoded in a character set different from the server’s default character set. For example, an application might have stored sjis values in a column, even though MySQL’s default character set was latin1. It is possible to convert the column to use the proper character set but an additional step is required. Suppose that the server’s default character set was latin1 and col1 is defined as CHAR(50) but its contents are sjis values. The first step is to convert the column to a binary data type, which removes the existing character set information without performing any character conversion:

```
ALTER TABLE t MODIFY col1 BLOB;
```

The next step is to convert the column to a nonbinary data type with the proper character set:

```
ALTER TABLE t MODIFY col1 CHAR(50) CHARACTER SET sjis;
```

This procedure requires that the table not have been modified already with statements such as INSERT or UPDATE after an upgrade to MySQL 4.1 or later. In that case, MySQL would store new values in the column using latin1, and the column will contain a mix of sjis and latin1 values and cannot be converted properly.

If you specified attributes when creating a column initially, you should also specify them when altering the table with ALTER TABLE. For example, if you specified NOT NULL and an explicit DEFAULT value, you should also provide them in the ALTER TABLE statement. Otherwise, the resulting column definition will not include those attributes.

To convert all character columns in a table, the ALTER TABLE ... CONVERT TO CHARACTER SET charset statement may be useful. See Section 13.1.7, “ALTER TABLE Syntax”.

### 10.1.13 Character Sets and Collations That MySQL Supports

This section indicates which character sets MySQL supports. There is one subsection for each group of related character sets. For each character set, the permissible collations are listed.

To list the available character sets and their default collations, use the SHOW CHARACTER SET statement or query the INFORMATION_SCHEMA.CHARACTER_SETS table. For example:

```sql
mysql> SHOW CHARACTER SET;
```

<table>
<thead>
<tr>

</tbody>
</table>

In cases where a character set has multiple collations, it might not be clear which collation is most suitable for a given application. To avoid choosing the wrong collation, it can be helpful to perform some comparisons with representative data values to make sure that a given collation sorts values the way you expect.

Collation-Charts.Org is a useful site for information that shows how one collation compares to another.

### 10.1.13.1 Unicode Character Sets

MySQL has two Unicode character sets:

- **ucs2**, the UCS-2 encoding of the Unicode character set using 16 bits per character.
- **utf8**, a UTF-8 encoding of the Unicode character set using one to three bytes per character.

You can store text in about 650 languages using these character sets. This section lists the collations available for each Unicode character set and describes their differentiating properties. For general information about the character sets, see Section 10.1.10, “Unicode Support”.

A similar set of collations is available for each Unicode character set. These are shown in the following list, where `xxx` represents the character set name. For example, `xxx_danish_ci` represents the Danish collations, the specific names of which are `ucs2_danish_ci` and `utf8_danish_ci`.

- `xxx_bin`
- `xxx_czech_ci`
- `xxx_danish_ci`
- `xxx_esperanto_ci`
- `xxx_estonian_ci`
- `xxx_general_ci` (default)
- `xxx_general_mysql500_ci`
- `xxx_hungarian_ci`
- `xxx_icelandic_ci`
- `xxx_latvian_ci`
- `xxx_lithuanian_ci`
- `xxx_persian_ci`
• \_polish_ci  
• \_roman_ci  
• \_romanian_ci  
• \_slovak_ci  
• \_slovenian_ci  
• \_spanish_ci  
• \_spanish2_ci  
• \_swedish_ci  
• \_turkish_ci  
• \_unicode_ci  

The \_hungarian_ci collations were added in MySQL 5.1.5.

MySQL implements the \_unicode_ci collations according to the Unicode Collation Algorithm (UCA) described at http://www.unicode.org/reports/tr10/. The collation uses the version-4.0.0 UCA weight keys: http://www.unicode.org/Public/UCA/4.0.0/allkeys-4.0.0.txt. The \_unicode_ci collations have only partial support for the Unicode Collation Algorithm. Some characters are not supported yet. Also, combining marks are not fully supported. This affects primarily Vietnamese, Yoruba, and some smaller languages such as Navajo. A combined character will be considered different from the same character written with a single unicode character in string comparisons, and the two characters are considered to have a different length (for example, as returned by the CHAR_LENGTH() function or in result set metadata).

MySQL implements language-specific Unicode collations only if the ordering with \_unicode_ci does not work well for a language. Language-specific collations are UCA-based. They are derived from \_unicode_ci with additional language tailoring rules.

For any Unicode character set, operations performed using the \_general_ci collation are faster than those for the \_unicode_ci collation. For example, comparisons for the utf8_general_ci collation are faster, but slightly less correct, than comparisons for utf8_unicode_ci. The reason for this is that utf8_unicode_ci supports mappings such as expansions; that is, when one character compares as equal to combinations of other characters. For example, in German and some other languages “ß” is equal to “ss”. utf8_unicode_ci also supports contractions and ignorable characters. utf8_general_ci is a legacy collation that does not support expansions, contractions, or ignorable characters. It can make only one-to-one comparisons between characters.

To further illustrate, the following equalities hold in both utf8_general_ci and utf8_unicode_ci (for the effect this has in comparisons or when doing searches, see Section 10.1.7.8, “Examples of the Effect of Collation”):

<table>
<thead>
<tr>
<th>Ä</th>
<th>A</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ö</td>
<td>O</td>
</tr>
<tr>
<td>Ù</td>
<td>U</td>
</tr>
</tbody>
</table>

A difference between the collations is that this is true for utf8_general_ci:

| ß | s |

Whereas this is true for utf8_unicode_ci, which supports the German DIN-1 ordering (also known as dictionary order):

| ß | ss |
MySQL implements language-specific collations for the utf8 character set only if the ordering with utf8_unicode_ci does not work well for a language. For example, utf8_unicode_ci works fine for German dictionary order and French, so there is no need to create special utf8 collations.

utf8_general_ci also is satisfactory for both German and French, except that “ß” is equal to “s”, and not to “ss”. If this is acceptable for your application, you should use utf8_general_ci because it is faster. Otherwise, use utf8_unicode_ci because it is more accurate.

xxx_swedish_ci includes Swedish rules. For example, in Swedish, the following relationship holds, which is not something expected by a German or French speaker:

\[
\ddot{a} = \gamma < \ddot{o}
\]

The xxx_spanish_ci and xxx_spanish2_ci collations correspond to modern Spanish and traditional Spanish, respectively. In both collations, “ñ” (n-tilde) is a separate letter between “n” and “o”. In addition, for traditional Spanish, “ch” is a separate letter between “c” and “d”, and “ll” is a separate letter between “l” and “n”.

The xxx_spanish2_ci collations may also be used for Asturian and Galician.

The xxx_danish_ci collations may also be used for Norwegian.

In the xxx_roman_ci collations, I and J compare as equal, and U and V compare as equal.

The xxx_general_mysql500_ci collations were added in MySQL 5.1.62. They preserve the pre-5.1.24 ordering of the original xxx_general_ci collations and permit upgrades for tables created before MySQL 5.1.24. For more information, see Section 2.13.3, “Checking Whether Tables or Indexes Must Be Rebuilt”, and Section 2.13.4, “Rebuilding or Repairing Tables or Indexes”.

For additional information about Unicode collations in MySQL, see Collation-Charts.Org (utf8).

### 10.1.13.2 West European Character Sets

Western European character sets cover most West European languages, such as French, Spanish, Catalan, Basque, Portuguese, Italian, Albanian, Dutch, German, Danish, Swedish, Norwegian, Finnish, Faroese, Icelandic, Irish, Scottish, and English.

- ascii (US ASCII) collations:
  - ascii_bin
  - ascii_general_ci (default)
- cp850 (DOS West European) collations:
  - cp850_bin
  - cp850_general_ci (default)
- dec8 (DEC Western European) collations:
  - dec8_bin
  - dec8_swedish_ci (default)
- hp8 (HP Western European) collations:
  - hp8_bin
  - hp8_english_ci (default)
- latin1 (cp1252 West European) collations:
Character Sets and Collations That MySQL Supports

- latin1_bin
- latin1_danish_ci
- latin1_general_ci
- latin1_general_cs
- latin1_german1_ci
- latin1_german2_ci
- latin1_spanish_ci
- latin1_swedish_ci (default)

latin1 is the default character set. MySQL’s latin1 is the same as the Windows cp1252 character set. This means it is the same as the official ISO 8859-1 or IANA (Internet Assigned Numbers Authority) latin1, except that IANA latin1 treats the code points between 0x80 and 0x9f as “undefined,” whereas cp1252, and therefore MySQL’s latin1, assign characters for those positions. For example, 0x80 is the Euro sign. For the “undefined” entries in cp1252, MySQL translates 0x81 to Unicode 0x0081, 0x8d to 0x008d, 0x8f to 0x008f, 0x90 to 0x0090, and 0x9d to 0x009d.

The latin1_swedish_ci collation is the default that probably is used by the majority of MySQL customers. Although it is frequently said that it is based on the Swedish/Finnish collation rules, there are Swedes and Finns who disagree with this statement.

The latin1_german1_ci and latin1_german2_ci collations are based on the DIN-1 and DIN-2 standards, where DIN stands for Deutsches Institut für Normung (the German equivalent of ANSI). DIN-1 is called the “dictionary collation” and DIN-2 is called the “phone book collation.” For an example of the effect this has in comparisons or when doing searches, see Section 10.1.7.8, “Examples of the Effect of Collation”.

- latin1_german1_ci (dictionary) rules:

  | Ä | a |
  | Ö | o |
  | Ü | u |
  | ß | s |

- latin1_german2_ci (phone-book) rules:

  | Ä | AE |
  | Ö | OE |
  | Ü | UE |
  | ß | ss |

In the latin1_spanish_ci collation, “ñ” (n-tilde) is a separate letter between “n” and “o”.

- macroman (Mac West European) collations:
  - macroman_bin
  - macroman_general_ci (default)

- swe7 (7bit Swedish) collations:
  - swe7_bin
  - swe7_swedish_ci (default)
For additional information about Western European collations in MySQL, see Collation-Charts.Org (ascii, cp850, dec8, hp8, latin1, macroman, swe7).

### 10.1.13.3 Central European Character Sets

MySQL provides some support for character sets used in the Czech Republic, Slovakia, Hungary, Romania, Slovenia, Croatia, Poland, and Serbia (Latin).

- **cp1250** (Windows Central European) collations:
  - cp1250_bin
  - cp1250_croatian_ci
  - cp1250_czech_cs
  - cp1250_general_ci (default)
  - cp1250_polish_ci
- **cp852** (DOS Central European) collations:
  - cp852_bin
  - cp852_general_ci (default)
- **keybcs2** (DOS Kamenicky Czech-Slovak) collations:
  - keybcs2_bin
  - keybcs2_general_ci (default)
- **latin2** (ISO 8859-2 Central European) collations:
  - latin2_bin
  - latin2_croatian_ci
  - latin2_czech_cs
  - latin2_general_ci (default)
  - latin2_hungarian_ci
- **macce** (Mac Central European) collations:
  - macce_bin
  - macce_general_ci (default)

For additional information about Central European collations in MySQL, see Collation-Charts.Org (cp1250, cp852, keybcs2, latin2, macce).

### 10.1.13.4 South European and Middle East Character Sets

South European and Middle Eastern character sets supported by MySQL include Armenian, Arabic, Georgian, Greek, Hebrew, and Turkish.

- **armscii8** (ARMSCEII-8 Armenian) collations:
  - armscii8_bin
  - armscii8_general_ci (default)
• cp1256 (Windows Arabic) collations:
  • cp1256_bin
  • cp1256_general_ci (default)

• geostd8 (GEOSTD8 Georgian) collations:
  • geostd8_bin
  • geostd8_general_ci (default)

• greek (ISO 8859-7 Greek) collations:
  • greek_bin
  • greek_general_ci (default)

• hebrew (ISO 8859-8 Hebrew) collations:
  • hebrew_bin
  • hebrew_general_ci (default)

• latin5 (ISO 8859-9 Turkish) collations:
  • latin5_bin
  • latin5_turkish_ci (default)

For additional information about South European and Middle Eastern collations in MySQL, see Collation-Charts.Org (armsci8, cp1256, geostd8, greek, hebrew, latin5).

10.1.13.5 Baltic Character Sets

The Baltic character sets cover Estonian, Latvian, and Lithuanian languages.

• cp1257 (Windows Baltic) collations:
  • cp1257_bin
  • cp1257_general_ci (default)
  • cp1257_lithuanian_ci

• latin7 (ISO 8859-13 Baltic) collations:
  • latin7_bin
  • latin7_estonian_cs
  • latin7_general_ci (default)
  • latin7_general_cs

For additional information about Baltic collations in MySQL, see Collation-Charts.Org (cp1257, latin7).

10.1.13.6 Cyrillic Character Sets

The Cyrillic character sets and collations are for use with Belarusian, Bulgarian, Russian, Ukrainian, and Serbian (Cyrillic) languages.

• cp1251 (Windows Cyrillic) collations:
• cp1251_bin
• cp1251_bulgarian_ci
• cp1251_general_ci (default)
• cp1251_general_cs
• cp1251_ukrainian_ci
• cp866 (DOS Russian) collations:
  • cp866_bin
  • cp866_general_ci (default)
• koi8r (KOI8-R Relcom Russian) collations:
  • koi8r_bin
  • koi8r_general_ci (default)
• koi8u (KOI8-U Ukrainian) collations:
  • koi8u_bin
  • koi8u_general_ci (default)

For additional information about Cyrillic collations in MySQL, see Collation-Charts.Org (cp1251, cp866, koi8r, koi8u).

10.1.13.7 Asian Character Sets

The Asian character sets that we support include Chinese, Japanese, Korean, and Thai. These can be complicated. For example, the Chinese sets must allow for thousands of different characters. See The cp932 Character Set, for additional information about the cp932 and sjis character sets.

For answers to some common questions and problems relating support for Asian character sets in MySQL, see Section A.11, “MySQL 5.1 FAQ: MySQL Chinese, Japanese, and Korean Character Sets”.

• big5 (Big5 Traditional Chinese) collations:
  • big5_bin
  • big5_chinese_ci (default)
• cp932 (SJIS for Windows Japanese) collations:
  • cp932_bin
  • cp932_japanese_ci (default)
• eucjpms (UJIS for Windows Japanese) collations:
  • eucjpms_bin
  • eucjpms_japanese_ci (default)
• euckr (EUC-KR Korean) collations:
  • euckr_bin
  • euckr_korean_ci (default)
• \text{gb2312} (GB2312 Simplified Chinese) collations:
  • \text{gb2312\_bin}
  • \text{gb2312\_chinese\_ci} (default)
• \text{gbk} (GBK Simplified Chinese) collations:
  • \text{gbk\_bin}
  • \text{gbk\_chinese\_ci} (default)
• \text{sjis} (Shift-JIS Japanese) collations:
  • \text{sjis\_bin}
  • \text{sjis\_japanese\_ci} (default)
• \text{tis620} (TIS620 Thai) collations:
  • \text{tis620\_bin}
  • \text{tis620\_thai\_ci} (default)
• \text{ujis} (EUC-JP Japanese) collations:
  • \text{ujis\_bin}
  • \text{ujis\_japanese\_ci} (default)

The \text{big5\_chinese\_ci} collation sorts on number of strokes.

For additional information about Asian collations in MySQL, see Collation-Charts.Org (big5, cp932, eucjpmx, euckr, gb2312, gbk, sjis, tis620, ujis).

The \text{cp932} Character Set

Why is \text{cp932} needed?

In MySQL, the \text{sjis} character set corresponds to the \text{Shift\_JIS} character set defined by IANA, which supports JIS X0201 and JIS X0208 characters. (See \url{http://www.iana.org/assignments/character-sets}.)

However, the meaning of “SHIFT JIS” as a descriptive term has become very vague and it often includes the extensions to \text{Shift\_JIS} that are defined by various vendors.

For example, “SHIFT JIS” used in Japanese Windows environments is a Microsoft extension of \text{Shift\_JIS} and its exact name is \text{Microsoft Windows Codepage : 932} or \text{cp932}. In addition to the characters supported by \text{Shift\_JIS}, \text{cp932} supports extension characters such as NEC special characters, NEC selected—IBM extended characters, and IBM selected characters.

Many Japanese users have experienced problems using these extension characters. These problems stem from the following factors:

• MySQL automatically converts character sets.

• Character sets are converted using Unicode (\text{ucs2}).

• The \text{sjis} character set does not support the conversion of these extension characters.

• There are several conversion rules from so-called “SHIFT JIS” to Unicode, and some characters are converted to Unicode differently depending on the conversion rule. MySQL supports only one of these rules (described later).
The MySQL `cp932` character set is designed to solve these problems.

Because MySQL supports character set conversion, it is important to separate IANA `Shift_JIS` and `cp932` into two different character sets because they provide different conversion rules.

**How does `cp932` differ from `sjis`?**

The `cp932` character set differs from `sjis` in the following ways:

- `cp932` supports NEC special characters, NEC selected—IBM extended characters, and IBM selected characters.

- Some `cp932` characters have two different code points, both of which convert to the same Unicode code point. When converting from Unicode back to `cp932`, one of the code points must be selected. For this “round trip conversion,” the rule recommended by Microsoft is used. (See [http://support.microsoft.com/kb/170559/EN-US/](http://support.microsoft.com/kb/170559/EN-US/).

  The conversion rule works like this:

  - If the character is in both JIS X 0208 and NEC special characters, use the code point of JIS X 0208.

  - If the character is in both NEC special characters and IBM selected characters, use the code point of NEC special characters.

  - If the character is in both IBM selected characters and NEC selected—IBM extended characters, use the code point of IBM extended characters.

The table shown at [https://msdn.microsoft.com/en-us/goglobal/cc305152.aspx](https://msdn.microsoft.com/en-us/goglobal/cc305152.aspx) provides information about the Unicode values of `cp932` characters. For `cp932` table entries with characters under which a four-digit number appears, the number represents the corresponding Unicode (ucs2) encoding. For table entries with an underlined two-digit value appears, there is a range of `cp932` character values that begin with those two digits. Clicking such a table entry takes you to a page that displays the Unicode value for each of the `cp932` characters that begin with those digits.

The following links are of special interest. They correspond to the encodings for the following sets of characters:

- NEC special characters (lead byte `0x87`):

- NEC selected—IBM extended characters (lead byte `0xED` and `0xEE`):

- IBM selected characters (lead byte `0xFA`, `0xFB`, `0xFC`):

- `cp932` supports conversion of user-defined characters in combination with eucjpms, and solves the problems with sjis/ujis conversion. For details, please refer to [http://www.sljfaq.org/afaq/encodings.html](http://www.sljfaq.org/afaq/encodings.html).

For some characters, conversion to and from ucs2 is different for sjis and cp932. The following tables illustrate these differences.

**Conversion to ucs2:**
10.2 Setting the Error Message Language

By default, `mysqld` produces error messages in English, but they can also be displayed in any of several other languages: Czech, Danish, Dutch, Estonian, French, German, Greek, Hungarian, Italian, Japanese, Korean, Norwegian, Norwegian-ny, Polish, Portuguese, Romanian, Russian, Slovak, Spanish, or Swedish.

You can select which language the server uses for error messages using the instructions in this section.

To start `mysqld` with a particular language for error messages, use the `--language` or `-L` option. The option value can be a language name or the full path to the error message file. For example:

```
 mysqld --language=ja
```

Users of any Japanese character sets should be aware that using `--character-set-client-handshake` (or `--skip-character-set-client-handshake`) has an important effect. See Section 5.1.3, “Server Command Options”.
Adding a Character Set

shell> mysql --language=swedish

Or:

shell> mysql --language=/usr/local/share/swedish

The language name should be specified in lowercase.

By default, the language files are located in the share/mysql/LANGUAGE directory under the MySQL base directory.

For information about changing the character set for error messages (rather than the language), see Section 10.1.6, “Character Set for Error Messages”.

You can change the content of the error messages produced by the server using the instructions in the MySQL Internals manual, available at MySQL Internals: Error Messages. If you do change the content of error messages, remember to repeat your changes after each upgrade to a newer version of MySQL.

10.3 Adding a Character Set

This section discusses the procedure for adding a character set to MySQL. The proper procedure depends on whether the character set is simple or complex:

- If the character set does not need special string collating routines for sorting and does not need multibyte character support, it is simple.
- If the character set needs either of those features, it is complex.

For example, greek and swe7 are simple character sets, whereas big5 and czech are complex character sets.

To use the following instructions, you must have a MySQL source distribution. In the instructions, MYSET represents the name of the character set that you want to add.

1. Add a <charset> element for MYSET to the sql/share/charsets/Index.xml file. Use the existing contents in the file as a guide to adding new contents. A partial listing for the latin1 <charset> element follows:

   <charset name="latin1">
     <family>Western</family>
     <description>cp1252 West European</description>
     ...
     <collation name="latin1_swedish_ci" id="8" order="Finnish, Swedish">
       <flag>primary</flag>
       <flag>compiled</flag>
     </collation>
     <collation name="latin1_danish_ci" id="15" order="Danish"/>
     ...
     <collation name="latin1_bin" id="47" order="Binary">
       <flag>binary</flag>
       <flag>compiled</flag>
     </collation>
     ...
   </charset>

   The <charset> element must list all the collations for the character set. These must include at least a binary collation and a default (primary) collation. The default collation is often named using a suffix of general_ci (general, case insensitive). It is possible for the binary collation to be the default collation, but usually they are different. The default collation should have a primary flag. The binary collation should have a binary flag.
You must assign a unique ID number to each collation, chosen from the range 1 to 254. To find the maximum of the currently used collation IDs, use this query:

```
SELECT MAX(ID) FROM INFORMATION_SCHEMA.COLLATIONS;
```

2. This step depends on whether you are adding a simple or complex character set. A simple character set requires only a configuration file, whereas a complex character set requires C source file that defines collation functions, multibyte functions, or both.

For a simple character set, create a configuration file, `MYSET.xml`, that describes the character set properties. Create this file in the `sql/share/charsets` directory. You can use a copy of `latin1.xml` as the basis for this file. The syntax for the file is very simple:

- Comments are written as ordinary XML comments (`<!-- text -->`).
- Words within `<map>` array elements are separated by arbitrary amounts of whitespace.
- Each word within `<map>` array elements must be a number in hexadecimal format.
- The `<map>` array element for the `<ctype>` element has 257 words. The other `<map>` array elements after that have 256 words. See Section 10.3.1, “Character Definition Arrays”.
- For each collation listed in the `<charset>` element for the character set in `Index.xml`, `MYSET.xml` must contain a `<collation>` element that defines the character ordering.

For a complex character set, create a C source file that describes the character set properties and defines the support routines necessary to properly perform operations on the character set:

- Create the file `ctype-MYSET.c` in the `strings` directory. Look at one of the existing `ctype-*` files (such as `ctype-big5.c`) to see what needs to be defined. The arrays in your file must have names like `ctype_MYSET`, `to_lower_MYSET`, and so on. These correspond to the arrays for a simple character set. See Section 10.3.1, “Character Definition Arrays”.
- For each `<collation>` element listed in the `<charset>` element for the character set in `Index.xml`, the `ctype-MYSET.c` file must provide an implementation of the collation.
- If the character set requires string collating functions, see Section 10.3.2, “String Collating Support for Complex Character Sets”.
- If the character set requires multibyte character support, see Section 10.3.3, “Multi-Byte Character Support for Complex Character Sets”.

3. Modify the configuration information. Use the existing configuration information as a guide to adding information for `MYSYS`. The example here assumes that the character set has default and binary collations, but more lines are needed if `MYSET` has additional collations.

a. Edit `mysys/charset-def.c`, and “register” the collations for the new character set.

Add these lines to the “declaration” section:

```
#ifdef HAVE_CHARSET_MYSET
extern CHARSET_INFO my_charset_MYSET_general_ci;
extern CHARSET_INFO my_charset_MYSET_bin;
#endif
```

Add these lines to the “registration” section:

```
#ifdef HAVE_CHARSET_MYSET
add_compiled_collation(&my_charset_MYSET_general_ci);
add_compiled_collation(&my_charset_MYSET_bin);
#endif
```
Character Definition Arrays

b. If the character set uses `ctype-MYSET.c`, edit `strings/Makefile.am` and add `ctype-MYSET.c` to each definition of the `CSRCS` variable, and to the `EXTRA_DIST` variable.

c. If the character set uses `ctype-MYSET.c`, edit `libmysql/Makefile.shared` and add `ctype-MYSET.lo` to the `mystringsobjects` definition.

d. Edit `config/ac-macros/character_sets.m4`:
   
   i. Add `MYSET` to one of the `define(CHARSETS_AVAILABLE...)` lines in alphabetic order.
   
   ii. Add `MYSET` to `CHARSETS_COMPLEX`. This is needed even for simple character sets, or `configure` will not recognize `--with-charset=MYSET`.
   
   iii. Add `MYSET` to the first `case` control structure. Omit the `USE_MB` and `USE_MB_IDENT` lines for 8-bit character sets.

   ```
   MYSET
   AC_DEFINE(HAVE_CHARSET_MYSET, 1, [Define to enable charset MYSET])
   AC_DEFINE([USE_MB], 1, [Use multi-byte character routines])
   AC_DEFINE(USE_MB_IDENT, 1)
   ;;
   ```

   iv. Add `MYSET` to the second `case` control structure:

   ```
   MYSET
   default_charset_default_collation="MYSET_general_ci"
   default_charset_collations="MYSET_general_ci MYSET_bin"
   ;;
   ```

4. Reconfigure, recompile, and test.

10.3.1 Character Definition Arrays

Each simple character set has a configuration file located in the `sql/share/charsets` directory. For a character set named `MYSYS`, the file is named `MYSET.xml`. It uses `<map>` array elements to list character set properties. `<map>` elements appear within these elements:

- `<ctype>` defines attributes for each character.
- `<lower>` and `<upper>` list the lowercase and uppercase characters.
- `<unicode>` maps 8-bit character values to Unicode values.
- `<collation>` elements indicate character ordering for comparisons and sorts, one element per collation. Binary collations need no `<map>` element because the character codes themselves provide the ordering.

For a complex character set as implemented in a `ctype-MYSET.c` file in the `strings` directory, there are corresponding arrays: `ctype_MYSET[]`, `to_lower_MYSET[]`, and so forth. Not every complex character set has all of the arrays. See also the existing `ctype-* .c` files for examples. See the `CHARSET_INFO.txt` file in the `strings` directory for additional information.

Most of the arrays are indexed by character value and have 256 elements. The `<ctype>` array is indexed by character value + 1 and has 257 elements. This is a legacy convention for handling `EOF`.

`<ctype>` array elements are bit values. Each element describes the attributes of a single character in the character set. Each attribute is associated with a bitmask, as defined in `include/m_cctype.h`:

```
#define _MY_U 01 /* Upper case */
```
The `<ctype>` value for a given character should be the union of the applicable bitmask values that describe the character. For example, 'A' is an uppercase character (_MY_U) as well as a hexadecimal digit (_MY_X), so its `ctype` value should be defined like this:

```
ctype['A'+1] = _MY_U | _MY_X = 01 | 0200 = 0201
```

The bitmask values in `m_ctype.h` are octal values, but the elements of the `<ctype>` array in `MYSET.xml` should be written as hexadecimal values.

The `<lower>` and `<upper>` arrays hold the lowercase and uppercase characters corresponding to each member of the character set. For example:

```
lower['A'] should contain 'a'
upper['a'] should contain 'A'
```

Each `<collation>` array indicates how characters should be ordered for comparison and sorting purposes. MySQL sorts characters based on the values of this information. In some cases, this is the same as the `<upper>` array, which means that sorting is case-insensitive. For more complicated sorting rules (for complex character sets), see the discussion of string collating in Section 10.3.2, "String Collating Support for Complex Character Sets".

### 10.3.2 String Collating Support for Complex Character Sets

For a simple character set named `MYSET`, sorting rules are specified in the `MYSET.xml` configuration file using `<map>` array elements within `<collation>` elements. If the sorting rules for your language are too complex to be handled with simple arrays, you must define string collating functions in the `ctype-MYSET.c` source file in the `strings` directory.

The existing character sets provide the best documentation and examples to show how these functions are implemented. Look at the `ctype-*.c` files in the `strings` directory, such as the files for the big5, czech, gbk, sjis, and tis160 character sets. Take a look at the `MY_COLLATION_HANDLER` structures to see how they are used. See also the `CHARSET_INFO.txt` file in the `strings` directory for additional information.

### 10.3.3 Multi-Byte Character Support for Complex Character Sets

If you want to add support for a new character set named `MYSET` that includes multibyte characters, you must use multibyte character functions in the `ctype-MYSET.c` source file in the `strings` directory.

The existing character sets provide the best documentation and examples to show how these functions are implemented. Look at the `ctype-*.c` files in the `strings` directory, such as the files for the euc_kr, gb2312, gbk, sjis, and ujis character sets. Take a look at the `MY_CHARSET_HANDLER` structures to see how they are used. See also the `CHARSET_INFO.txt` file in the `strings` directory for additional information.

### 10.4 Adding a Collation to a Character Set

A collation is a set of rules that defines how to compare and sort character strings. Each collation in MySQL belongs to a single character set. Every character set has at least one collation, and most have two or more collations.
A collation orders characters based on weights. Each character in a character set maps to a weight. Characters with equal weights compare as equal, and characters with unequal weights compare according to the relative magnitude of their weights.

MySQL supports several collation implementations, as discussed in Section 10.4.1, “Collation Implementation Types”. Some of these can be added to MySQL without recompiling:

- Simple collations for 8-bit character sets.
- UCA-based collations for Unicode character sets.
- Binary (**xxx_bin**) collations.

The following sections describe how to add collations of the first two types to existing character sets. All existing character sets already have a binary collation, so there is no need here to describe how to add one.

Summary of the procedure for adding a new collation:

1. Choose a collation ID.
2. Add configuration information that names the collation and describes the character-ordering rules.
3. Restart the server.
4. Verify that the collation is present.

The instructions here cover only collations that can be added without recompiling MySQL. To add a collation that does require recompiling (as implemented by means of functions in a C source file), use the instructions in Section 10.3, “Adding a Character Set”. However, instead of adding all the information required for a complete character set, just modify the appropriate files for an existing character set. That is, based on what is already present for the character set’s current collations, add data structures, functions, and configuration information for the new collation.

**Note**

If you modify an existing collation, that may affect the ordering of rows for indexes on columns that use the collation. In this case, rebuild any such indexes to avoid problems such as incorrect query results. For further information, see Section 2.13.3, “Checking Whether Tables or Indexes Must Be Rebuilt”.

**Additional Resources**

- The Unicode Collation Algorithm (UCA) specification: [http://www.unicode.org/reports/tr10/](http://www.unicode.org/reports/tr10/)
- The Locale Data Markup Language (LDML) specification: [http://www.unicode.org/reports/tr35/](http://www.unicode.org/reports/tr35/)

**10.4.1 Collation Implementation Types**

MySQL implements several types of collations:

**Simple collations for 8-bit character sets**

This kind of collation is implemented using an array of 256 weights that defines a one-to-one mapping from character codes to weights. **latin1_swedish_ci** is an example. It is a case-insensitive collation, so the uppercase and lowercase versions of a character have the same weights and they compare as equal.

```sql
mysql> SET NAMES 'latin1' COLLATE 'latin1_swedish_ci';
Query OK, 0 rows affected (0.00 sec)
```
Collation Implementation Types

mysql> SELECT 'a' = 'A';
+-----------+
| 'a' = 'A' |
+-----------+
|         1 |
+-----------+
1 row in set (0.00 sec)

For implementation instructions, see Section 10.4.3, “Adding a Simple Collation to an 8-Bit Character Set”.

Complex collations for 8-bit character sets

This kind of collation is implemented using functions in a C source file that define how to order characters, as described in Section 10.3, “Adding a Character Set”.

Collations for non-Unicode multibyte character sets

For this type of collation, 8-bit (single-byte) and multibyte characters are handled differently. For 8-bit characters, character codes map to weights in case-insensitive fashion. (For example, the single-byte characters 'a' and 'A' both have a weight of 0x41.) For multibyte characters, there are two types of relationship between character codes and weights:

• Weights equal character codes. sjis_japanese_ci is an example of this kind of collation. The multibyte character 'ぢ' has a character code of 0x82C0, and the weight is also 0x82C0.

• Character codes map one-to-one to weights, but a code is not necessarily equal to the weight. gbk_chinese_ci is an example of this kind of collation. The multibyte character '膰' has a character code of 0x81B0 but a weight of 0xC286.

For implementation instructions, see Section 10.3, “Adding a Character Set”.

Collations for Unicode multibyte character sets

Some of these collations are based on the Unicode Collation Algorithm (UCA), others are not.

Non-UCA collations have a one-to-one mapping from character code to weight. In MySQL, such collations are case insensitive and accent insensitive. utf8_general_ci is an example: 'a', 'A', 'À', and 'á' each have different character codes but all have a weight of 0x0041 and compare as equal.

mysql> SET NAMES 'utf8' COLLATE 'utf8_general_ci';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT 'a' = 'A', 'a' = 'À', 'a' = 'á';
+-----------+-----------+-----------+
| 'a' = 'A' | 'a' = 'À' | 'a' = 'á' |
+-----------+-----------+-----------+
|         1 |         1 |         1 |
+-----------+-----------+-----------+
1 row in set (0.06 sec)

UCA-based collations in MySQL have these properties:

• If a character has weights, each weight uses 2 bytes (16 bits).

• A character may have zero weights (or an empty weight). In this case, the character is ignorable. Example: "U+0000 NULL" does not have a weight and is ignorable.

• A character may have one weight. Example: 'a' has a weight of 0x0E33.

• A character may have many weights. This is an expansion. Example: The German letter 'ß' (SZ ligature, or SHARP S) has a weight of 0x0FEA0FEA.
• Many characters may have one weight. This is a contraction. Example: ‘ch’ is a single letter in Czech and has a weight of 0x0EE2.

A many-characters-to-many-weights mapping is also possible (this is contraction with expansion), but is not supported by MySQL.

For implementation instructions, for a non-UCA collation, see Section 10.3, “Adding a Character Set”. For a UCA collation, see Section 10.4.4, “Adding a UCA Collation to a Unicode Character Set”.

Miscellaneous collations

There are also a few collations that do not fall into any of the previous categories.

10.4.2 Choosing a Collation ID

Each collation must have a unique ID. To add a collation, you must choose an ID value that is not currently used. The value must be in the range from 1 to 254. The collation ID that you choose will appear in these contexts:

• The ID column of the INFORMATION_SCHEMA.COLLATIONS table.

• The Id column of SHOW COLLATION output.

• The charsetnr member of the MYSQL_FIELD C API data structure.

• The number member of the MY_CHARSET_INFO data structure returned by the mysql_get_character_set_info() C API function.

To determine the largest currently used ID, issue the following statement:

```
mysql> SELECT MAX(ID) FROM INFORMATION_SCHEMA.COLLATIONS;
```

<table>
<thead>
<tr>
<th>MAX(ID)</th>
</tr>
</thead>
<tbody>
<tr>
<td>210</td>
</tr>
</tbody>
</table>

For the output just shown, you could choose an ID higher than 210 for the new collation.

To display a list of all currently used IDs, issue this statement:

```
mysql> SELECT ID FROM INFORMATION_SCHEMA.COLLATIONS ORDER BY ID;
```

<table>
<thead>
<tr>
<th>ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>...</td>
</tr>
<tr>
<td>52</td>
</tr>
<tr>
<td>53</td>
</tr>
<tr>
<td>57</td>
</tr>
<tr>
<td>58</td>
</tr>
<tr>
<td>...</td>
</tr>
<tr>
<td>98</td>
</tr>
<tr>
<td>99</td>
</tr>
<tr>
<td>128</td>
</tr>
<tr>
<td>129</td>
</tr>
<tr>
<td>...</td>
</tr>
<tr>
<td>210</td>
</tr>
</tbody>
</table>

In this case, you can either choose an unused ID from within the current range of IDs, or choose an ID that is higher than the current maximum ID. For example, in the output just shown, there are unused IDs between 53 and 57, and between 99 and 128. Or you could choose an ID higher than 210.
Adding a Simple Collation to an 8-Bit Character Set

Warning
If you upgrade MySQL, you may find that the collation ID you choose has been assigned to a collation included in the new MySQL distribution. In this case, you will need to choose a new value for your own collation.

In addition, before upgrading, you should save the configuration files that you change. If you upgrade in place, the process will replace the your modified files.

10.4.3 Adding a Simple Collation to an 8-Bit Character Set

This section describes how to add a simple collation for an 8-bit character set by writing the <collation> elements associated with a <charset> character set description in the MySQL Index.xml file. The procedure described here does not require recompiling MySQL. The example adds a collation named latin1_test_ci to the latin1 character set.

1. Choose a collation ID, as shown in Section 10.4.2, “Choosing a Collation ID”. The following steps use an ID of 56.

2. Modify the Index.xml and latin1.xml configuration files. These files will be located in the directory named by the character_sets_dir system variable. You can check the variable value as follows, although the path name might be different on your system:

```sql
mysql> SHOW VARIABLES LIKE 'character_sets_dir';
```

+--------------------+-----------------------------------------+
| Variable_name      | Value                                   |
|--------------------+-----------------------------------------|
| character_sets_dir | /user/local/mysql/share/mysql/charsets/ |
+--------------------+-----------------------------------------+

3. Choose a name for the collation and list it in the Index.xml file. Find the <charset> element for the character set to which the collation is being added, and add a <collation> element that indicates the collation name and ID, to associate the name with the ID. For example:

```xml
<charset name="latin1">
...
<collation name="latin1_test_ci" id="56"/>
...
</charset>
```

4. In the latin1.xml configuration file, add a <collation> element that names the collation and that contains a <map> element that defines a character code-to-weight mapping table for character codes 0 to 255. Each value within the <map> element must be a number in hexadecimal format.

```xml
<collation name="latin1_test_ci">
<map>
00 01 02 03 04 05 06 07 08 09 0A 0B 0C 0D 0E 0F
10 11 12 13 14 15 16 17 18 19 1A 1B 1C 1D 1E 1F
20 21 22 23 24 25 26 27 28 29 2A 2B 2C 2D 2E 2F
30 31 32 33 34 35 36 37 38 39 3A 3B 3C 3D 3E 3F
40 41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F
50 51 52 53 54 55 56 57 58 59 5A 5B 5C 5D 5E 5F
60 61 62 63 64 65 66 67 68 69 6A 6B 6C 6D 6E 6F
70 71 72 73 74 75 76 77 78 79 7A 7B 7C 7D 7E 7F
80 81 82 83 84 85 86 87 88 89 8A 8B 8C 8D 8E 8F
90 91 92 93 94 95 96 97 98 99 9A 9B 9C 9D 9E 9F
A0 A1 A2 A3 A4 A5 A6 A7 A8 A9 AA AB AC AD AE AF
B0 B1 B2 B3 B4 B5 B6 B7 B8 B9 BA BB BC BD BE BF
C0 C1 C2 C3 C4 C5 C6 C7 C8 C9 CA CB CC CD CE CF
D0 D1 D2 D3 D4 D5 D6 D7 D8 D9 DA DB DC DD DE DF
E0 E1 E2 E3 E4 E5 E6 E7 E8 E9 EA EB EC ED EE EF
F0 F1 F2 F3 F4 F5 F6 F7 F8 F9 FA FB FC FD FE FF
</map>
</collation>
```
5. Restart the server and use this statement to verify that the collation is present:

```sql
mysql> SHOW COLLATION LIKE 'latin1_test_ci';
| Collation      | Charset | Id | Default | Compiled | Sortlen |
|----------------+---------+----+---------+----------+---------|
| latin1_test_ci | latin1  | 56 |         |          |       1 |
```

### 10.4.4 Adding a UCA Collation to a Unicode Character Set

This section describes how to add a UCA collation for a Unicode character set by writing the `<collation>` element within a `<charset>` character set description in the MySQL `Index.xml` file. The procedure described here does not require recompiling MySQL. It uses a subset of the Locale Data Markup Language (LDML) specification, which is available at [http://www.unicode.org/reports/tr35/](http://www.unicode.org/reports/tr35/). In 5.1, this method of adding collations is supported as of MySQL 5.1.20. With this method, you need not define the entire collation. Instead, you begin with an existing “base” collation and describe the new collation in terms of how it differs from the base collation. The following table lists the base collations of the Unicode character sets for which UCA collations can be defined.

<table>
<thead>
<tr>
<th>Character Set</th>
<th>Base Collation</th>
</tr>
</thead>
<tbody>
<tr>
<td>utf8</td>
<td>utf8_unicode_ci</td>
</tr>
<tr>
<td>ucs2</td>
<td>ucs2_unicode_ci</td>
</tr>
</tbody>
</table>

The following sections show how to add a collation that is defined using LDML syntax, and provide a summary of LDML rules supported in MySQL.

#### 10.4.4.1 Defining a UCA Collation Using LDML Syntax

To add a UCA collation for a Unicode character set without recompiling MySQL, use the following procedure. If you are unfamiliar with the LDML rules used to describe the collation's sort characteristics, see Section 10.4.4.2, “LDML Syntax Supported in MySQL”.

The example adds a collation named `utf8_phone_ci` to the `utf8` character set. The collation is designed for a scenario involving a Web application for which users post their names and phone numbers. Phone numbers can be given in very different formats:

```
+7-12345-67
+7-12-345-67
+7 12 345 67
+7 (12) 345 67
+71234567
```

The problem raised by dealing with these kinds of values is that the varying permissible formats make searching for a specific phone number very difficult. The solution is to define a new collation that reorders punctuation characters, making them ignorable.

1. Choose a collation ID, as shown in Section 10.4.2, “Choosing a Collation ID”. The following steps use an ID of 252.

2. To modify the `Index.xml` configuration file. This file will be located in the directory named by the `character_sets_dir` system variable. You can check the variable value as follows, although the path name might be different on your system:

```sql
mysql> SHOW VARIABLES LIKE 'character_sets_dir';
```
Adding a UCA Collation to a Unicode Character Set

<table>
<thead>
<tr>
<th>Variable name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>character_sets_dir</td>
<td>/user/local/mysql/share/mysql/charsets/</td>
</tr>
</tbody>
</table>

3. Choose a name for the collation and list it in the `Index.xml` file. In addition, you'll need to provide the collation ordering rules. Find the `<charset>` element for the character set to which the collation is being added, and add a `<collation>` element that indicates the collation name and ID, to associate the name with the ID. Within the `<collation>` element, provide a `<rules>` element containing the ordering rules:

```xml
<charset name="utf8">
  ...
  <collation name="utf8_phone_ci" id="252">
    <rules>
      <reset>\u0000</reset>
      <s>\u0020</s> <!-- space -->
      <s>\u0028</s> <!-- left parenthesis -->
      <s>\u0029</s> <!-- right parenthesis -->
      <s>\u002b</s> <!-- plus -->
      <s>\u002d</s> <!-- hyphen -->
    </rules>
  </collation>
  ...
</charset>
```

4. If you want a similar collation for other Unicode character sets, add other `<collation>` elements. For example, to define `ucs2_phone_ci`, add a `<collation>` element to the `<charset name="ucs2">` element. Remember that each collation must have its own unique ID.

5. Restart the server and use this statement to verify that the collation is present:

   ```
   mysql> SHOW COLLATION LIKE 'utf8_phone_ci';
   +---------------+---------+-----+---------+----------+---------+
   | Collation     | Charset | Id  | Default | Compiled | Sortlen |
   +---------------+---------+-----+---------+----------+---------+
   | utf8_phone_ci | utf8    | 252 |         |          |       8 |
   +---------------+---------+-----+---------+----------+---------+
   ```

Now test the collation to make sure that it has the desired properties.

Create a table containing some sample phone numbers using the new collation:

```sql
mysql> CREATE TABLE phonebook (  
    >   name VARCHAR(64),  
    >   phone VARCHAR(64) CHARACTER SET utf8 COLLATE utf8_phone_ci  
    > );
Query OK, 0 rows affected (0.09 sec)

mysql> INSERT INTO phonebook VALUES ('Svoj','+7 912 800 80 02');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Hf','+7 (912) 800 80 04');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Bar','+7-912-800-80-01');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Ramil','(7912) 800 80 03');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Sanja','+380 (912) 8008005');
Query OK, 1 row affected (0.00 sec)
```

Run some queries to see whether the ignored punctuation characters are in fact ignored for sorting and comparisons:
Adding a UCA Collation to a Unicode Character Set

10.4.4.2 LDML Syntax Supported in MySQL

This section describes the LDML syntax that MySQL recognizes. This is a subset of the syntax described in the LDML specification available at http://www.unicode.org/reports/tr35/, which should be consulted for further information. The rules described here are all supported except that character sorting occurs only at the primary level. Rules that specify differences at secondary or higher sort levels are recognized (and thus can be included in collation definitions) but are treated as equality at the primary level.

Character Representation

Characters named in LDML rules can be written in \unnnn format, where nnnn is the hexadecimal Unicode code point value. Within hexadecimal values, the digits A through F are not case sensitive; \u00E1 and \u00e1 are equivalent. Basic Latin letters A-Z and a-z can also be written literally (this is a MySQL limitation; the LDML specification permits literal non-Latin1 characters in the rules). Only characters in the Basic Multilingual Plane can be specified. This notation does not apply to characters outside the BMP range of 0000 to FFFF.

The Index.xml file itself should be written using ASCII encoding.

Syntax Rules

LDML has reset rules and shift rules to specify character ordering. Orderings are given as a set of rules that begin with a reset rule that establishes an anchor point, followed by shift rules that indicate how characters sort relative to the anchor point.

- A <reset> rule does not specify any ordering in and of itself. Instead, it “resets” the ordering for subsequent shift rules to cause them to be taken in relation to a given character. Either of the following rules resets subsequent shift rules to be taken in relation to the letter ‘A’:

```sql
mysql> SELECT * FROM phonebook ORDER BY phone;
+-------+--------------------+
| name  | phone              |
+-------+--------------------+
| Sanja | +380 (912) 8008005 |
| Bar   | +7-912-800-80-01   |
| Svoj  | +7 912 800 80 02   |
| Ramil | (7912) 800 80 03   |
| Hf    | +7 (912) 800 80 04 |
+-------+--------------------+
5 rows in set (0.00 sec)
```

```sql
mysql> SELECT * FROM phonebook WHERE phone='+7(912)800-80-01';
+-------+--------------------+
| name  | phone              |
+-------+--------------------+
| Bar   | +7-912-800-80-01   |
+-------+--------------------+
1 row in set (0.00 sec)
```

```sql
mysql> SELECT * FROM phonebook WHERE phone='79128008001';
+-------+--------------------+
| name  | phone              |
+-------+--------------------+
| Bar   | +7-912-800-80-01   |
+-------+--------------------+
1 row in set (0.00 sec)
```

```sql
mysql> SELECT * FROM phonebook WHERE phone='7 9 1 2 8 0 8 0 0 1';
+-------+--------------------+
| name  | phone              |
+-------+--------------------+
| Bar   | +7-912-800-80-01   |
+-------+--------------------+
1 row in set (0.00 sec)
```
• The `<p>`, `<s>`, and `<t>` shift rules define primary, secondary, and tertiary differences of a character from another character:
  
  • Use primary differences to distinguish separate letters.
  • Use secondary differences to distinguish accent variations.
  • Use tertiary differences to distinguish lettercase variations.

Either of these rules specifies a primary shift rule for the `'G'` character:

```
<p>G</p>
<p>G</p>
```

### 10.5 Character Set Configuration

You can change the default server character set and collation with the `--character-set-server` and `--collation-server` options when you start the server. The collation must be a legal collation for the default character set. (Use the `SHOW COLLATION` statement to determine which collations are available for each character set.) See Section 5.1.3, “Server Command Options”.

If you try to use a character set that is not compiled into your binary, you might run into the following problems:

• Your program uses an incorrect path to determine where the character sets are stored (which is typically the `share/mysql/charsets` or `share/charsets` directory under the MySQL installation directory). This can be fixed by using the `--character-sets-dir` option when you run the program in question. For example, to specify a directory to be used by MySQL client programs, list it in the `[client]` group of your option file. The examples given here show what the setting might look like for Unix or Windows, respectively:

```
[client]
character-sets-dir=/usr/local/mysql/share/mysql/charsets

[client]
character-sets-dir="C:/Program Files/MySQL/MySQL Server 5.1/share/charsets"
```

• The character set is a complex character set that cannot be loaded dynamically. In this case, you must recompile the program with support for the character set.

For Unicode character sets, you can define collations without recompiling by using LDML notation. See Section 10.4.4, “Adding a UCA Collation to a Unicode Character Set”.

• The character set is a dynamic character set, but you do not have a configuration file for it. In this case, you should install the configuration file for the character set from a new MySQL distribution.

• If your character set index file does not contain the name for the character set, your program displays an error message. The file is named `Index.xml` and the message is:

```
Character set 'charset_name' is not a compiled character set and is not specified in the '/usr/share/mysql/charsets/Index.xml' file
```

To solve this problem, you should either get a new index file or manually add the name of any missing character sets to the current file.
You can force client programs to use specific character set as follows:

```
[client]
default-character-set=charset_name
```

This is normally unnecessary. However, when `character_set_system` differs from `character_set_server` or `character_set_client`, and you input characters manually (as database object identifiers, column values, or both), these may be displayed incorrectly in output from the client or the output itself may be formatted incorrectly. In such cases, starting the mysql client with `--default-character-set=sys_character_set`—that is, setting the client character set to match the system character set—should fix the problem.

For MyISAM tables, you can check the character set name and number for a table with `myisamchk -dvv tbl_name`.

### 10.6 MySQL Server Time Zone Support

The MySQL server maintains several time zone settings:

- The system time zone. When the server starts, it attempts to determine the time zone of the host machine and uses it to set the `system_time_zone` variable. The value does not change thereafter.

  You can set the system time zone for MySQL Server at startup with the `--timezone=timezone_name` option to `mysqld_safe`. You can also set it by setting the `TZ` environment variable before you start `mysqld`. The permissible values for `--timezone` or `TZ` are system dependent. Consult your operating system documentation to see what values are acceptable.

- The server's current time zone. The global `time_zone` variable indicates the time zone the server currently is operating in. The initial value for `time_zone` is `'SYSTEM'`, which indicates that the server time zone is the same as the system time zone.

  The initial global server time zone value can be specified explicitly at startup with the `--default-time-zone=timezone` option on the command line, or you can use the following line in an option file:

  ```
  default-time-zone='timezone'
  ```

  If you have the `SUPER` privilege, you can set the global server time zone value at runtime with this statement:

  ```
  mysql> SET GLOBAL time_zone = timezone;
  ```

- Per-connection time zones. Each client that connects has its own time zone setting, given by the session `time_zone` variable. Initially, the session variable takes its value from the global `time_zone` variable, but the client can change its own time zone with this statement:

  ```
  mysql> SET time_zone = timezone;
  ```

  The current session time zone setting affects display and storage of time values that are zone-sensitive. This includes the values displayed by functions such as `NOW()` or `CURTIME()`, and values stored in and retrieved from `TIMESTAMP` columns. Values for `TIMESTAMP` columns are converted from the current time zone to UTC for storage, and from UTC to the current time zone for retrieval.

  The current time zone setting does not affect values displayed by functions such as `UTC_TIMESTAMP()` or values in `DATE`, `TIME`, or `DATETIME` columns. Nor are values in those data types stored in UTC; the time zone applies for them only when converting from `TIMESTAMP` values.
you want locale-specific arithmetic for `DATE`, `TIME`, or `DATETIME` values, convert them to UTC, perform the arithmetic, and then convert back.

The current values of the global and client-specific time zones can be retrieved like this:

```
mysql> SELECT @@global.time_zone, @@session.time_zone;
```

timezone values can be given in several formats, none of which are case sensitive:

- The value `'SYSTEM'` indicates that the time zone should be the same as the system time zone.
- The value can be given as a string indicating an offset from UTC, such as `'+10:00'` or `'-6:00'`.
- The value can be given as a named time zone, such as `'Europe/Helsinki'`, `'US/Eastern'`, or `'MET'`. Named time zones can be used only if the time zone information tables in the `mysql` database have been created and populated.

## Populating the Time Zone Tables

Several tables in the `mysql` system database exist to maintain time zone information (see Section 5.3, “The mysql System Database”). The MySQL installation procedure creates the time zone tables, but does not load them. You must do so manually using the following instructions.

### Note

Loading the time zone information is not necessarily a one-time operation because the information changes occasionally. When such changes occur, applications that use the old rules become out of date and you may find it necessary to reload the time zone tables to keep the information used by your MySQL server current. See the notes at the end of this section.

If your system has its own `zoneinfo` database (the set of files describing time zones), you should use the `mysql_tzinfo_to_sql` program for filling the time zone tables. Examples of such systems are Linux, FreeBSD, Solaris, and OS X. One likely location for these files is the `/usr/share/zoneinfo` directory. If your system does not have a zoneinfo database, you can use the downloadable package described later in this section.

The `mysql_tzinfo_to_sql` program is used to load the time zone tables. On the command line, pass the zoneinfo directory path name to `mysql_tzinfo_to_sql` and send the output into the `mysql` program. For example:

```
shell> mysql_tzinfo_to_sql /usr/share/zoneinfo | mysql -u root mysql
```

`mysql_tzinfo_to_sql` reads your system's time zone files and generates SQL statements from them. `mysql` processes those statements to load the time zone tables.

`mysql_tzinfo_to_sql` also can be used to load a single time zone file or to generate leap second information:

- To load a single time zone file `tz_file` that corresponds to a time zone name `tz_name`, invoke `mysql_tzinfo_to_sql` like this:

```
shell> mysql_tzinfo_to_sql tz_file tz_name | mysql -u root mysql
```

With this approach, you must execute a separate command to load the time zone file for each named zone that the server needs to know about.

- If your time zone needs to account for leap seconds, initialize the leap second information like this, where `tz_file` is the name of your time zone file:
Staying Current with Time Zone Changes

```shell>
mysql_tzinfo_to_sql --leap tz_file | mysql -u root mysql
```

- After running `mysql_tzinfo_to_sql`, it is best to restart the server so that it does not continue to use any previously cached time zone data.

If your system is one that has no zoneinfo database (for example, Windows or HP-UX), you can use a package that is available for download at the MySQL Developer Zone:

You can use either a package that contains SQL statements to populate your existing time zone tables, or a package that contains pre-built MyISAM time zone tables to replace your existing tables:

- To use a time zone package that contains SQL statements, download and unpack it, then load the package file contents into your existing time zone tables:

```shell>
mysql -u root mysql < file_name
```

Then restart the server.

- To use a time zone package that contains .frm, .MYD, and .MYI files for the MyISAM time zone tables, download and unpack it. These table files are part of the `mysql` database, so you should place the files in the `mysql` subdirectory of your MySQL server's data directory. Stop the server before doing this and restart it afterward.

**Warning**

Do not use a downloadable package if your system has a zoneinfo database. Use the `mysql_tzinfo_to_sql` utility instead. Otherwise, you may cause a difference in datetime handling between MySQL and other applications on your system.

For information about time zone settings in replication setup, please see Section 16.4.1, “Replication Features and Issues”.

### 10.6.1 Staying Current with Time Zone Changes

When time zone rules change, applications that use the old rules become out of date. To stay current, it is necessary to make sure that your system uses current time zone information is used. For MySQL, there are two factors to consider in staying current:

- The operating system time affects the value that the MySQL server uses for times if its time zone is set to `SYSTEM`. Make sure that your operating system is using the latest time zone information. For most operating systems, the latest update or service pack prepares your system for the time changes. Check the Web site for your operating system vendor for an update that addresses the time changes.

- If you replace the system's `/etc/localtime` timezone file with a version that uses rules differing from those in effect at `mysqld` startup, you should restart `mysqld` so that it uses the updated rules. Otherwise, `mysqld` might not notice when the system changes its time.

- If you use named time zones with MySQL, make sure that the time zone tables in the `mysql` database are up to date. If your system has its own zoneinfo database, you should reload the MySQL time zone tables whenever the zoneinfo database is updated. For systems that do not have their own zoneinfo database, check the MySQL Developer Zone for updates. When a new update is available, download it and use it to replace the content of your current time zone tables. For instructions for both methods, see Populating the Time Zone Tables. `mysqld` caches time zone
information that it looks up, so after updating the time zone tables, you should restart `mysqld` to make sure that it does not continue to serve outdated time zone data.

If you are uncertain whether named time zones are available, for use either as the server's time zone setting or by clients that set their own time zone, check whether your time zone tables are empty. The following query determines whether the table that contains time zone names has any rows:

```
mysql> SELECT COUNT(*) FROM mysql.time_zone_name;
```

```
+----------+
| COUNT(*) |
+----------+
|        0 |
+----------+
```

A count of zero indicates that the table is empty. In this case, no one can be using named time zones, and you don't need to update the tables. A count greater than zero indicates that the table is not empty and that its contents are available to be used for named time zone support. In this case, you should be sure to reload your time zone tables so that anyone who uses named time zones will get correct query results.

To check whether your MySQL installation is updated properly for a change in Daylight Saving Time rules, use a test like the one following. The example uses values that are appropriate for the 2007 DST 1-hour change that occurs in the United States on March 11 at 2 a.m.

The test uses these two queries:

```
SELECT CONVERT_TZ('2007-03-11 2:00:00', 'US/Eastern', 'US/Central');
SELECT CONVERT_TZ('2007-03-11 3:00:00', 'US/Eastern', 'US/Central');
```

The two time values indicate the times at which the DST change occurs, and the use of named time zones requires that the time zone tables be used. The desired result is that both queries return the same result (the input time, converted to the equivalent value in the 'US/Central' time zone).

Before updating the time zone tables, you would see an incorrect result like this:

```
mysql> SELECT CONVERT_TZ('2007-03-11 2:00:00', 'US/Eastern', 'US/Central');
+------------------------------------------------------------+
| CONVERT_TZ('2007-03-11 2:00:00', 'US/Eastern', 'US/Central') |
| 2007-03-11 01:00:00                                          |
+------------------------------------------------------------+
mysql> SELECT CONVERT_TZ('2007-03-11 3:00:00', 'US/Eastern', 'US/Central');
+------------------------------------------------------------+
| CONVERT_TZ('2007-03-11 3:00:00', 'US/Eastern', 'US/Central') |
| 2007-03-11 02:00:00                                          |
+------------------------------------------------------------+
```

After updating the tables, you should see the correct result:

```
mysql> SELECT CONVERT_TZ('2007-03-11 2:00:00', 'US/Eastern', 'US/Central');
+------------------------------------------------------------+
| CONVERT_TZ('2007-03-11 2:00:00', 'US/Eastern', 'US/Central') |
| 2007-03-11 01:00:00                                          |
+------------------------------------------------------------+
mysql> SELECT CONVERT_TZ('2007-03-11 3:00:00', 'US/Eastern', 'US/Central');
+------------------------------------------------------------+
| CONVERT_TZ('2007-03-11 3:00:00', 'US/Eastern', 'US/Central') |
| 2007-03-11 01:00:00                                          |
+------------------------------------------------------------+
10.6.2 Time Zone Leap Second Support

Before MySQL 5.1.31, if the operating system is configured to return leap seconds from OS time calls or if the MySQL server uses a time zone definition that has leap seconds, functions such as `NOW()` could return a value having a time part that ends with `:59:60` or `:59:61`. If such values are inserted into a table, they would be dumped as is by `mysqldump` but considered invalid when reloaded, leading to backup/restore problems.

As of MySQL 5.1.31, leap second values are returned with a time part that ends with `:59:59`. This means that a function such as `NOW()` can return the same value for two or three consecutive seconds during the leap second. It remains true that literal temporal values having a time part that ends with `:59:60` or `:59:61` are considered invalid.

If it is necessary to search for `TIMESTAMP` values one second before the leap second, anomalous results may be obtained if you use a comparison with `'YYYY-MM-DD hh:mm:ss'` values. The following example demonstrates this. It changes the local time zone to UTC so there is no difference between internal values (which are in UTC) and displayed values (which have time zone correction applied).

```
mysql> CREATE TABLE t1 (
    -> a INT,
    -> ts TIMESTAMP DEFAULT NOW(),
    -> PRIMARY KEY (ts)
    -> );
Query OK, 0 rows affected (0.01 sec)
mysql> -- change to UTC
mysql> SET time_zone = '+00:00';
Query OK, 0 rows affected (0.00 sec)
mysql> -- Simulate NOW() = '2008-12-31 23:59:59'
mysql> SET timestamp = 1230767999;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO t1 (a) VALUES (1);
Query OK, 1 row affected (0.00 sec)
mysql> -- Simulate NOW() = '2008-12-31 23:59:60'
mysql> SET timestamp = 1230768000;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO t1 (a) VALUES (2);
Query OK, 1 row affected (0.00 sec)
mysql> -- values differ internally but display the same
mysql> SELECT a, ts, UNIX_TIMESTAMP(ts) FROM t1;
+------ | --------------------- | --------------------+
<table>
<thead>
<tr>
<th>a</th>
<th>ts</th>
<th>UNIX_TIMESTAMP(ts)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2008-12-31 23:59:59</td>
<td>1230767999</td>
</tr>
<tr>
<td>2</td>
<td>2008-12-31 23:59:59</td>
<td>1230768000</td>
</tr>
</tbody>
</table>
+------ |-----------------------|---------------------+
2 rows in set (0.00 sec)
mysql> -- only the non-leap value matches
mysql> SELECT * FROM t1 WHERE ts = '2008-12-31 23:59:59';
+---- |--------------+
| a   | ts           |
| 1   | 2008-12-31 23:59:59 |
+---- |--------------+
1 row in set (0.00 sec)
mysql> -- the leap value with seconds=60 is invalid
mysql> SELECT * FROM t1 WHERE ts = '2008-12-31 23:59:60';
```
To work around this, you can use a comparison based on the UTC value actually stored in column, which has the leap second correction applied:

```sql
mysql> -- selecting using UNIX_TIMESTAMP value return leap value
mysql> SELECT * FROM t1 WHERE UNIX_TIMESTAMP(ts) = 1230768000;
+------+---------------------+
| a    | ts                  |
| 2    | 2008-12-31 23:59:59  |
+------+---------------------+
1 row in set (0.00 sec)
```

10.7 MySQL Server Locale Support

Beginning with MySQL 5.1.12, the locale indicated by the `lc_time_names` system variable controls the language used to display day and month names and abbreviations. This variable affects the output from the `DATE_FORMAT()`, `DAYNAME()`, and `MONTHNAME()` functions.

`lc_time_names` does not affect the `STR_TO_DATE()` or `GET_FORMAT()` function.

Locale names have language and region subtags listed by IANA (http://www.iana.org/assignments/language-subtag-registry) such as 'ja_JP' or 'pt_BR'. The default value is 'en_US' regardless of your system's locale setting, but you can set the value at server startup or set the `GLOBAL` value if you have the `SUPER` privilege. Any client can examine the value of `lc_time_names` or set its `SESSION` value to affect the locale for its own connection.

```sql
mysql> SET NAMES 'utf8';
Query OK, 0 rows affected (0.09 sec)
```

```sql
mysql> SELECT @lc_time_names;
+-----------------+
| @lc_time_names  |
| en_US           |
+-----------------+
1 row in set (0.00 sec)
```

```sql
mysql> SELECT DAYNAME('2010-01-01'), MONTHNAME('2010-01-01');
+-----------------------+-------------------------+
| DAYNAME('2010-01-01') | MONTHNAME('2010-01-01') |
| Friday                | January                 |
+-----------------------+-------------------------+
1 row in set (0.00 sec)
```

```sql
mysql> SELECT DATE_FORMAT('2010-01-01','%W %a %M %b');
+-----------------------------------------+
| DATE_FORMAT('2010-01-01','%W %a %M %b') |
| Friday Fri January Jan                  |
+-----------------------------------------+
1 row in set (0.00 sec)
```

```sql
mysql> SET lc_time_names = 'es_MX';
Query OK, 0 rows affected (0.00 sec)
```

```sql
mysql> SELECT @lc_time_names;
+-----------------+
| @lc_time_names  |
| es_MX           |
+-----------------+
1 row in set (0.00 sec)
```

```sql
mysql> SELECT DAYNAME('2010-01-01'), MONTHNAME('2010-01-01');
```
The day or month name for each of the affected functions is converted from `utf8` to the character set indicated by the `character_set_connection` system variable.

`lc_time_names` may be set to any of the following locale values.

- **ar_AE**: Arabic - United Arab Emirates
- **ar_BH**: Arabic - Bahrain
- **ar_DZ**: Arabic - Algeria

11.8 Choosing the Right Type for a Column ............................................................................ 1006
11.9 Using Data Types from Other Database Engines .......................................................... 1006

MySQL supports a number of SQL data types in several categories: numeric types, date and time types, string (character and byte) types, and spatial types. This chapter provides an overview of these data types, a more detailed description of the properties of the types in each category, and a summary of the data type storage requirements. The initial overview is intentionally brief. The more detailed descriptions later in the chapter should be consulted for additional information about particular data types, such as the permissible formats in which you can specify values.

Data type descriptions use these conventions:

- $M$ indicates the maximum display width for integer types. For floating-point and fixed-point types, $M$ is the total number of digits that can be stored (the precision). For string types, $M$ is the maximum length. The maximum permissible value of $M$ depends on the data type.

- $D$ applies to floating-point and fixed-point types and indicates the number of digits following the decimal point (the scale). The maximum possible value is 30, but should be no greater than $M–2$.

- Square brackets (“[ ” and “]”) indicate optional parts of type definitions.
11.1 Data Type Overview

11.1.1 Numeric Type Overview

A summary of the numeric data types follows. For additional information about properties and storage requirements of the numeric types, see Section 11.2, “Numeric Types”, and Section 11.7, “Data Type Storage Requirements”.

$M$ indicates the maximum display width for integer types. The maximum display width is 255. Display width is unrelated to the range of values a type can contain, as described in Section 11.2, “Numeric Types”. For floating-point and fixed-point types, $M$ is the total number of digits that can be stored.

If you specify ZEROFILL for a numeric column, MySQL automatically adds the UNSIGNED attribute to the column.

Numeric data types that permit the UNSIGNED attribute also permit SIGNED. However, these data types are signed by default, so the SIGNED attribute has no effect.

SERIAL is an alias for BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE.

SERIAL DEFAULT VALUE in the definition of an integer column is an alias for NOT NULL AUTO_INCREMENT UNIQUE.

**Warning**

When you use subtraction between integer values where one is of type UNSIGNED, the result is unsigned unless the NO_UNSIGNED_SUBTRACTION SQL mode is enabled. See Section 12.10, “Cast Functions and Operators”.

- **BIT [ (M) ]**

  A bit-field type. $M$ indicates the number of bits per value, from 1 to 64. The default is 1 if $M$ is omitted.

- **TINYINT [ (M) ] [UNSIGNED] [ZEROFILL]**

  A very small integer. The signed range is $-128$ to $127$. The unsigned range is 0 to 255.

- **BOOL, BOOLEAN**

  These types are synonyms for TINYINT (1). A value of zero is considered false. Nonzero values are considered true:

  ```sql
  mysql> SELECT IF(0, 'true', 'false');
  +------------------------+
  | IF(0, 'true', 'false') |
  | false                  |
  +------------------------+
  mysql> SELECT IF(1, 'true', 'false');
  +------------------------+
  | IF(1, 'true', 'false') |
  | true                   |
  +------------------------+
  mysql> SELECT IF(2, 'true', 'false');
  +------------------------+
  | IF(2, 'true', 'false') |
  | true                   |
  +------------------------+
  ```
However, the values **TRUE** and **FALSE** are merely aliases for 1 and 0, respectively, as shown here:

| mysql> SELECT IF(0 = FALSE, 'true', 'false'); | +--------------------------------+ |
| | IF(0 = FALSE, 'true', 'false') | |
| | true | |
| mysql> SELECT IF(1 = TRUE, 'true', 'false'); | +-------------------------------+ |
| | IF(1 = TRUE, 'true', 'false') | |
| | true | |
| mysql> SELECT IF(2 = TRUE, 'true', 'false'); | +-------------------------------+ |
| | IF(2 = TRUE, 'true', 'false') | |
| | false | |
| mysql> SELECT IF(2 = FALSE, 'true', 'false'); | +--------------------------------+ |
| | IF(2 = FALSE, 'true', 'false') | |
| | false | |

The last two statements display the results shown because 2 is equal to neither 1 nor 0.

- **SMALLINT**(M) [UNSIGNED] [ZEROFILL]
  
  A small integer. The signed range is **−32768** to **32767**. The unsigned range is **0 to 65535**.

- **MEDIUMINT**(M) [UNSIGNED] [ZEROFILL]
  
  A medium-sized integer. The signed range is **−8388608** to **8388607**. The unsigned range is **0 to 16777215**.

- **INT**(M) [UNSIGNED] [ZEROFILL]
  
  A normal-size integer. The signed range is **−2147483648** to **2147483647**. The unsigned range is **0 to 4294967295**.

- **INTEGER**(M) [UNSIGNED] [ZEROFILL]
  
  This type is a synonym for **INT**.

- **BIGINT**(M) [UNSIGNED] [ZEROFILL]
  
  A large integer. The signed range is **−9223372036854775808** to **9223372036854775807**. The unsigned range is **0 to 18446744073709551615**.

**SERIAL** is an alias for **BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE**.

Some things you should be aware of with respect to **BIGINT** columns:

- All arithmetic is done using signed **BIGINT** or **DOUBLE** values, so you should not use unsigned big integers larger than **9223372036854775807** (63 bits) except with bit functions! If you do that, some of the last digits in the result may be wrong because of rounding errors when converting a **BIGINT** value to a **DOUBLE**.

MySQL can handle **BIGINT** in the following cases:
Numeric Type Overview

- When using integers to store large unsigned values in a **BIGINT** column.
- In **MIN(col_name)** or **MAX(col_name)**, where **col_name** refers to a **BIGINT** column.
- When using operators (+, -, *, and so on) where both operands are integers.
- You can always store an exact integer value in a **BIGINT** column by storing it using a string. In this case, MySQL performs a string-to-number conversion that involves no intermediate double-precision representation.
- The -, +, and * operators use **BIGINT** arithmetic when both operands are integer values. This means that if you multiply two big integers (or results from functions that return integers), you may get unexpected results when the result is larger than 9223372036854775807.

**DECIMAL[(M[,D])] [UNSIGNED] [ZEROFILL]**

A packed “exact” fixed-point number. **M** is the total number of digits (the precision) and **D** is the number of digits after the decimal point (the scale). The decimal point and (for negative numbers) the “−” sign are not counted in **M**. If **D** is 0, values have no decimal point or fractional part. The maximum number of digits (**M**) for **DECIMAL** is 65. The maximum number of supported decimals (**D**) is 30. If **D** is omitted, the default is 0. If **M** is omitted, the default is 10.

**UNSIGNED**, if specified, disallows negative values.

All basic calculations (+, −, *, /) with **DECIMAL** columns are done with a precision of 65 digits.

**DEC[(M,D)] [UNSIGNED] [ZEROFILL], NUMERIC[(M,D)] [UNSIGNED] [ZEROFILL], FIXED[(M,D)] [UNSIGNED] [ZEROFILL]**

These types are synonyms for **DECIMAL**. The **FIXED** synonym is available for compatibility with other database systems.

**FLOAT[(M,D)] [UNSIGNED] [ZEROFILL]**

A small (single-precision) floating-point number. Permissible values are −3.402823466E+38 to −1.175494351E-38, 0, and 1.175494351E-38 to 3.402823466E+38. These are the theoretical limits, based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.

**M** is the total number of digits and **D** is the number of digits following the decimal point. If **M** and **D** are omitted, values are stored to the limits permitted by the hardware. A single-precision floating-point number is accurate to approximately 7 decimal places.

**UNSIGNED**, if specified, disallows negative values.

Using **FLOAT** might give you some unexpected problems because all calculations in MySQL are done with double precision. See Section B.5.4.7, “Solving Problems with No Matching Rows”.

**DOUBLE[(M,D)] [UNSIGNED] [ZEROFILL]**

A normal-size (double-precision) floating-point number. Permissible values are −1.7976931348623157E+308 to −2.2250738585072014E−308, 0, and 2.2250738585072014E−308 to 1.7976931348623157E+308. These are the theoretical limits, based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.

**M** is the total number of digits and **D** is the number of digits following the decimal point. If **M** and **D** are omitted, values are stored to the limits permitted by the hardware. A double-precision floating-point number is accurate to approximately 15 decimal places.

**UNSIGNED**, if specified, disallows negative values.
11.1.2 Date and Time Type Overview

A summary of the temporal data types follows. For additional information about properties and storage requirements of the temporal types, see Section 11.3, "Date and Time Types", and Section 11.7, "Data Type Storage Requirements". For descriptions of functions that operate on temporal values, see Section 12.7, "Date and Time Functions".

For the DATE and DATETIME range descriptions, “supported” means that although earlier values might work, there is no guarantee.

**DATE**

A date. The supported range is '1000-01-01' to '9999-12-31'. MySQL displays DATE values in 'YYYY-MM-DD' format, but permits assignment of values to DATE columns using either strings or numbers.

**DATETIME**

A date and time combination. The supported range is '1000-01-01 00:00:00' to '9999-12-31 23:59:59'. MySQL displays DATETIME values in 'YYYY-MM-DD HH:MM:SS' format, but permits assignment of values to DATETIME columns using either strings or numbers.

**TIMESTAMP**

A timestamp. The range is '1970-01-01 00:00:01' UTC to '2038-01-19 03:14:07' UTC. TIMESTAMP values are stored as the number of seconds since the epoch ('1970-01-01 00:00:00' UTC). A TIMESTAMP cannot represent the value '1970-01-01 00:00:00' because that is equivalent to 0 seconds from the epoch and the value 0 is reserved for representing '0000-00-00 00:00:00', the "zero" TIMESTAMP value.

Unless specified otherwise, the first TIMESTAMP column in a table is defined to be automatically set to the date and time of the most recent modification if not explicitly assigned a value. This makes TIMESTAMP useful for recording the timestamp of an INSERT or UPDATE operation. You can also set any TIMESTAMP column to the current date and time by assigning it a NULL value, unless it has been defined with the NULL attribute to permit NULL values. The automatic initialization and updating to the current date and time can be specified using DEFAULT CURRENT_TIMESTAMP and ON UPDATE CURRENT_TIMESTAMP clauses, as described in Section 11.3.5, "Automatic Initialization and Updating for TIMESTAMP".

Note

The TIMESTAMP format that was used prior to MySQL 4.1 is not supported in MySQL 5.1; see MySQL 3.23, 4.0, 4.1 Reference Manual for information regarding the old format.
• **TIME**

A time. The range is `-838:59:59` to `838:59:59`. MySQL displays **TIME** values in `'HH:MM:SS'` format, but permits assignment of values to **TIME** columns using either strings or numbers.

• **YEAR[(2|4)]**

A year in two-digit or four-digit format. The default is four-digit format. **YEAR(2)** or **YEAR(4)** differ in display format, but have the same range of values. In four-digit format, values display as `1901` to `2155`, and `0000`. In two-digit format, values display as `70` to `69`, representing years from 1970 to 2069. MySQL displays **YEAR** values in **YYYY** or **YY** format, but permits assignment of values to **YEAR** columns using either strings or numbers.

**Note**

The **YEAR(2)** data type has certain issues that you should consider before choosing to use it. As of MySQL 5.1.65, **YEAR(2)** is deprecated. For more information, see Section 11.3.4, “YEAR(2) Limitations and Migrating to YEAR(4)”.

For additional information about **YEAR** display format and interpretation of input values, see Section 11.3.3, “The YEAR Type”.

The **SUM**() and **AVG**() aggregate functions do not work with temporal values. (They convert the values to numbers, losing everything after the first nonnumeric character.) To work around this problem, convert to numeric units, perform the aggregate operation, and convert back to a temporal value. Examples:

```sql
SELECT SEC_TO_TIME(SUM(TIME_TO_SEC(time_col))) FROM tbl_name;
SELECT FROM_DAYS(SUM(TO_DAYS(date_col))) FROM tbl_name;
```

**Note**

The MySQL server can be run with the **MAXDB** SQL mode enabled. In this case, **TIMESTAMP** is identical with **DATETIME**. If this mode is enabled at the time that a table is created, **TIMESTAMP** columns are created as **DATETIME** columns. As a result, such columns use **DATETIME** display format, have the same range of values, and there is no automatic initialization or updating to the current date and time. See Section 5.1.7, “Server SQL Modes”.

### 11.1.3 String Type Overview

A summary of the string data types follows. For additional information about properties and storage requirements of the string types, see Section 11.4, “String Types”, and Section 11.7, “Data Type Storage Requirements”.

In some cases, MySQL may change a string column to a type different from that given in a **CREATE TABLE** or **ALTER TABLE** statement. See Section 13.1.17.4, “Silent Column Specification Changes”.

MySQL interprets length specifications in character column definitions in character units. This applies to **CHAR**, **VARCHAR**, and the **TEXT** types.

Column definitions for many string data types can include attributes that specify the character set or collation of the column. These attributes apply to the **CHAR**, **VARCHAR**, the **TEXT** types, **ENUM**, and **SET** data types:

- The **CHARACTER_SET** attribute specifies the character set, and the **COLLATE** attribute specifies a collation for the character set. For example:
CREATE TABLE t
(
    c1 VARCHAR(20) CHARACTER SET utf8,
    c2 TEXT CHARACTER SET latin1 COLLATE latin1_general_cs
);

This table definition creates a column named \texttt{c1} that has a character set of \texttt{utf8} with the default collation for that character set, and a column named \texttt{c2} that has a character set of \texttt{latin1} and a case-sensitive collation.

The rules for assigning the character set and collation when either or both of the \texttt{CHARACTER SET} and \texttt{COLLATE} attributes are missing are described in Section 10.1.3.4, “Column Character Set and Collation”.

\texttt{CHARSET} is a synonym for \texttt{CHARACTER SET}.

- Specifying the \texttt{CHARACTER SET binary} attribute for a character data type causes the column to be created as the corresponding binary data type: \texttt{CHAR} becomes \texttt{BINARY}, \texttt{VARCHAR} becomes \texttt{VARBINARY}, and \texttt{TEXT} becomes \texttt{BLOB}. For the \texttt{ENUM} and \texttt{SET} data types, this does not occur; they are created as declared. Suppose that you specify a table using this definition:

```
CREATE TABLE t
(
    c1 VARCHAR(10) CHARACTER SET binary,
    c2 TEXT CHARACTER SET binary,
    c3 ENUM('a','b','c') CHARACTER SET binary
);
```

The resulting table has this definition:

```
CREATE TABLE t
(
    c1 VARBINARY(10),
    c2 BLOB,
    c3 ENUM('a','b','c') CHARACTER SET binary
);
```

- The \texttt{ASCII} attribute is shorthand for \texttt{CHARACTER SET latin1}.
- The \texttt{UNICODE} attribute is shorthand for \texttt{CHARACTER SET ucs2}.
- The \texttt{BINARY} attribute is shorthand for specifying the binary collation of the column character set. In this case, sorting and comparison are based on numeric character values.

Character column sorting and comparison are based on the character set assigned to the column. For the \texttt{CHAR}, \texttt{VARCHAR}, \texttt{TEXT}, \texttt{ENUM}, and \texttt{SET} data types, you can declare a column with a binary collation or the \texttt{BINARY} attribute to cause sorting and comparison to use the underlying character code values rather than a lexical ordering.

Section 10.1, “Character Set Support”, provides additional information about use of character sets in MySQL.

- \texttt{[NATIONAL] CHAR[(M)] [CHARACTER SET charset_name] [COLLATE collation_name]}

A fixed-length string that is always right-padded with spaces to the specified length when stored. \texttt{M} represents the column length in characters. The range of \texttt{M} is 0 to 255. If \texttt{M} is omitted, the length is 1.

\textbf{Note}

Trailing spaces are removed when \texttt{CHAR} values are retrieved unless the \texttt{PAD_CHAR_TO_FULL_LENGTH} SQL mode is enabled.
**String Type Overview**

**CHAR** is shorthand for **CHARACTER, NATIONAL CHAR** (or its equivalent short form, **NCHAR**) is the standard SQL way to define that a **CHAR** column should use some predefined character set. MySQL uses **utf8** as this predefined character set. **Section 10.1.3.6, “National Character Set”**.

The **CHAR BYTE** data type is an alias for the **BINARY** data type. This is a compatibility feature.

MySQL permits you to create a column of type **CHAR(0)**. This is useful primarily when you have to be compliant with old applications that depend on the existence of a column but that do not actually use its value. **CHAR(0)** is also quite nice when you need a column that can take only two values: A column that is defined as **CHAR(0) NULL** occupies only one bit and can take only the values **NULL** and ‘’ (the empty string).

- **[NATIONAL] VARCHAR(M) [CHARACTER SET charset_name] [COLLATE collation_name]**

  A variable-length string. **M** represents the maximum column length in characters. The range of **M** is 0 to 65,535. The effective maximum length of a **VARCHAR** is subject to the maximum row size (65,535 bytes, which is shared among all columns) and the character set used. For example, **utf8** characters can require up to three bytes per character, so a **VARCHAR** column that uses the **utf8** character set can be declared to be a maximum of 21,844 characters. See **Section C.7.4, “Limits on Table Column Count and Row Size”**.

MySQL stores **VARCHAR** values as a 1-byte or 2-byte length prefix plus data. The length prefix indicates the number of bytes in the value. A **VARCHAR** column uses one length byte if values require no more than 255 bytes, two length bytes if values may require more than 255 bytes.

- **BINARY(M)**

  The **BINARY** type is similar to the **CHAR** type, but stores binary byte strings rather than nonbinary character strings. **M** represents the column length in bytes.

- **VARBINARY(M)**

  The **VARBINARY** type is similar to the **VARCHAR** type, but stores binary byte strings rather than nonbinary character strings. **M** represents the maximum column length in bytes.

- **TINYBLOB**

  A **BLOB** column with a maximum length of 255 ($2^8 - 1$) bytes. Each **TINYBLOB** value is stored using a 1-byte length prefix that indicates the number of bytes in the value.

- **TINYTEXT [CHARACTER SET charset_name] [COLLATE collation_name]**

  A **TEXT** column with a maximum length of 255 ($2^8 - 1$) characters. The effective maximum length is less if the value contains multibyte characters. Each **TINYTEXT** value is stored using a 1-byte length prefix that indicates the number of bytes in the value.

- **BLOB[(M)]**

  A **BLOB** column with a maximum length of 65,535 ($2^{16} - 1$) bytes. Each **BLOB** value is stored using a 2-byte length prefix that indicates the number of bytes in the value.

---

**Note**

MySQL follows the standard SQL specification, and does not remove trailing spaces from **VARCHAR** values.

**VARCHAR** is shorthand for **CHARACTER VARYING, NATIONAL VARCHAR** is the standard SQL way to define that a **VARCHAR** column should use some predefined character set. MySQL uses **utf8** as this predefined character set. **Section 10.1.3.6, “National Character Set”**. **NVARCHAR** is shorthand for **NATIONAL VARCHAR**.
An optional length \( M \) can be given for this type. If this is done, MySQL creates the column as the smallest \texttt{BLOB} type large enough to hold values \( M \) bytes long.

- \texttt{TEXT[\( (M) \)] [CHARACTER SET charset_name] [COLLATE collation_name]}

  A \texttt{TEXT} column with a maximum length of 65,535 \( (2^{16} - 1) \) characters. The effective maximum length is less if the value contains multibyte characters. Each \texttt{TEXT} value is stored using a 2-byte length prefix that indicates the number of bytes in the value.

  An optional length \( M \) can be given for this type. If this is done, MySQL creates the column as the smallest \texttt{TEXT} type large enough to hold values \( M \) characters long.

- \texttt{MEDIUMBLOB}

  A \texttt{BLOB} column with a maximum length of 16,777,215 \( (2^{24} - 1) \) bytes. Each \texttt{MEDIUMBLOB} value is stored using a 3-byte length prefix that indicates the number of bytes in the value.

- \texttt{MEDIUMTEXT [CHARACTER SET charset_name] [COLLATE collation_name]}

  A \texttt{TEXT} column with a maximum length of 16,777,215 \( (2^{24} - 1) \) characters. The effective maximum length is less if the value contains multibyte characters. Each \texttt{MEDIUMTEXT} value is stored using a 3-byte length prefix that indicates the number of bytes in the value.

- \texttt{LONGBLOB}

  A \texttt{BLOB} column with a maximum length of 4,294,967,295 or 4GB \( (2^{32} - 1) \) bytes. The effective maximum length of \texttt{LONGBLOB} columns depends on the configured maximum packet size in the client/server protocol and available memory. Each \texttt{LONGBLOB} value is stored using a 4-byte length prefix that indicates the number of bytes in the value.

- \texttt{LONGTEXT [CHARACTER SET charset_name] [COLLATE collation_name]}

  A \texttt{TEXT} column with a maximum length of 4,294,967,295 or 4GB \( (2^{32} - 1) \) characters. The effective maximum length is less if the value contains multibyte characters. The effective maximum length of \texttt{LONGTEXT} columns also depends on the configured maximum packet size in the client/server protocol and available memory. Each \texttt{LONGTEXT} value is stored using a 4-byte length prefix that indicates the number of bytes in the value.

- \texttt{ENUM('value1','value2',...)} [CHARACTER SET charset_name] [COLLATE collation_name]

  An enumeration. A string object that can have only one value, chosen from the list of values 'value1', 'value2', ..., NULL or the special '' error value. \texttt{ENUM} values are represented internally as integers.

  An \texttt{ENUM} column can have a maximum of 65,535 distinct elements. (The practical limit is less than 3000.) A table can have no more than 255 unique element list definitions among its \texttt{ENUM} and \texttt{SET} columns considered as a group. For more information on these limits, see Section C.7.5, “Limits Imposed by .frm File Structure”.

- \texttt{SET('value1','value2',...)} [CHARACTER SET charset_name] [COLLATE collation_name]

  A set. A string object that can have zero or more values, each of which must be chosen from the list of values 'value1', 'value2', ... \texttt{SET} values are represented internally as integers.

  A \texttt{SET} column can have a maximum of 64 distinct members. A table can have no more than 255 unique element list definitions among its \texttt{ENUM} and \texttt{SET} columns considered as a group. For more information on this limit, see Section C.7.5, “Limits Imposed by .frm File Structure”.

\section*{11.2 Numeric Types}
MySQL supports all standard SQL numeric data types. These types include the exact numeric data types (INTEGER, SMALLINT, DECIMAL, and NUMERIC), as well as the approximate numeric data types (FLOAT, REAL, and DOUBLE PRECISION). The keyword INT is a synonym for INTEGER, and the keywords DEC and FIXED are synonyms for DECIMAL. MySQL treats DOUBLE as a synonym for DOUBLE PRECISION (a nonstandard extension). MySQL also treats REAL as a synonym for DOUBLE PRECISION (a nonstandard variation), unless the REAL_AS_FLOAT SQL mode is enabled.

The BIT data type stores bit-field values and is supported for MyISAM, MEMORY, InnoDB, and NDBCLUSTER tables.

For information about how MySQL handles assignment of out-of-range values to columns and overflow during expression evaluation, see Section 11.2.6, "Out-of-Range and Overflow Handling".

For information about numeric type storage requirements, see Section 11.7, "Data Type Storage Requirements".

The data type used for the result of a calculation on numeric operands depends on the types of the operands and the operations performed on them. For more information, see Section 12.6.1, "Arithmetic Operators".

### 11.2.1 Integer Types (Exact Value) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT

MySQL supports the SQL standard integer types INTEGER (or INT) and SMALLINT. As an extension to the standard, MySQL also supports the integer types TINYINT, MEDIUMINT, and BIGINT. The following table shows the required storage and range for each integer type.

<table>
<thead>
<tr>
<th>Type</th>

</tbody>
</table>

### 11.2.2 Fixed-Point Types (Exact Value) - DECIMAL, NUMERIC

The DECIMAL and NUMERIC types store exact numeric data values. These types are used when it is important to preserve exact precision, for example with monetary data. In MySQL, NUMERIC is implemented as DECIMAL, so the following remarks about DECIMAL apply equally to NUMERIC.

MySQL stores DECIMAL values in binary format. See Section 12.18, "Precision Math".

In a DECIMAL column declaration, the precision and scale can be (and usually is) specified; for example:
salary DECIMAL(5,2)

In this example, 5 is the precision and 2 is the scale. The precision represents the number of significant digits that are stored for values, and the scale represents the number of digits that can be stored following the decimal point.

Standard SQL requires that DECIMAL(5,2) be able to store any value with five digits and two decimals, so values that can be stored in the salary column range from -999.99 to 999.99.

In standard SQL, the syntax DECIMAL(M) is equivalent to DECIMAL(M,0). Similarly, the syntax DECIMAL is equivalent to DECIMAL(M,0), where the implementation is permitted to decide the value of M. MySQL supports both of these variant forms of DECIMAL syntax. The default value of M is 10.

If the scale is 0, DECIMAL values contain no decimal point or fractional part.

The maximum number of digits for DECIMAL is 65, but the actual range for a given DECIMAL column can be constrained by the precision or scale for a given column. When such a column is assigned a value with more digits following the decimal point than are permitted by the specified scale, the value is converted to that scale. (The precise behavior is operating system-specific, but generally the effect is truncation to the permissible number of digits.)

### 11.2.3 Floating-Point Types (Approximate Value) - FLOAT, DOUBLE

The FLOAT and DOUBLE types represent approximate numeric data values. MySQL uses four bytes for single-precision values and eight bytes for double-precision values.

For FLOAT, the SQL standard permits an optional specification of the precision (but not the range of the exponent) in bits following the keyword FLOAT in parentheses. MySQL also supports this optional precision specification, but the precision value is used only to determine storage size. A precision from 0 to 23 results in a 4-byte single-precision FLOAT column. A precision from 24 to 53 results in an 8-byte double-precision DOUBLE column.

MySQL permits a nonstandard syntax: FLOAT(M, D) or REAL(M, D) or DOUBLE PRECISION(M, D). Here, "(M, D)" means than values can be stored with up to M digits in total, of which D digits may be after the decimal point. For example, a column defined as FLOAT(7,4) will look like -999.9999 when displayed. MySQL performs rounding when storing values, so if you insert 999.00009 into a FLOAT(7,4) column, the approximate result is 999.0001.

Because floating-point values are approximate and not stored as exact values, attempts to treat them as exact in comparisons may lead to problems. They are also subject to platform or implementation dependencies. For more information, see Section B.5.4.8, “Problems with Floating-Point Values”

For maximum portability, code requiring storage of approximate numeric data values should use FLOAT or DOUBLE PRECISION with no specification of precision or number of digits.

### 11.2.4 Bit-Value Type - BIT

The BIT data type is used to store bit-field values. A type of BIT(M) enables storage of M-bit values. M can range from 1 to 64.

To specify bit values, b'value' notation can be used. value is a binary value written using zeros and ones. For example, b'111' and b'10000000' represent 7 and 128, respectively. See Section 9.1.6, “Bit-Field Literals”.

If you assign a value to a BIT(M) column that is less than M bits long, the value is padded on the left with zeros. For example, assigning a value of b'101' to a BIT(6) column is, in effect, the same as assigning b'000101'.

MySQL Cluster. The maximum combined size of all BIT columns used in a given NDB table must not exceed 4096 bits.
11.2.5 Numeric Type Attributes

MySQL supports an extension for optionally specifying the display width of integer data types in parentheses following the base keyword for the type. For example, **INT (4)** specifies an **INT** with a display width of four digits. This optional display width may be used by applications to display integer values having a width less than the width specified for the column by left-padding them with spaces. (That is, this width is present in the metadata returned with result sets. Whether it is used or not is up to the application.)

The display width does not constrain the range of values that can be stored in the column. Nor does it prevent values wider than the column display width from being displayed correctly. For example, a column specified as **SMALLINT (3)** has the usual **SMALLINT** range of -32768 to 32767, and values outside the range permitted by three digits are displayed in full using more than three digits.

When used in conjunction with the optional (nonstandard) attribute **ZEROFILL**, the default padding of spaces is replaced with zeros. For example, for a column declared as **INT(4) ZEROFILL**, a value of 5 is retrieved as **0005**.

**Note**

The **ZEROFILL** attribute is ignored when a column is involved in expressions or **UNION** queries.

If you store values larger than the display width in an integer column that has the **ZEROFILL** attribute, you may experience problems when MySQL generates temporary tables for some complicated joins. In these cases, MySQL assumes that the data values fit within the column display width.

All integer types can have an optional (nonstandard) attribute **UNSIGNED**. Unsigned type can be used to permit only nonnegative numbers in a column or when you need a larger upper numeric range for the column. For example, if an **INT** column is **UNSIGNED**, the size of the column’s range is the same but its endpoints shift from -2147483648 and 2147483647 up to 0 and 4294967295.

Floating-point and fixed-point types also can be **UNSIGNED**. As with integer types, this attribute prevents negative values from being stored in the column. Unlike the integer types, the upper range of column values remains the same.

If you specify **ZEROFILL** for a numeric column, MySQL automatically adds the **UNSIGNED** attribute to the column.

Integer or floating-point data types can have the additional attribute **AUTO_INCREMENT**. When you insert a value of **NULL** (recommended) or 0 into an indexed **AUTO_INCREMENT** column, the column is set to the next sequence value. Typically this is **value+1**, where **value** is the largest value for the column currently in the table. **AUTO_INCREMENT** sequences begin with 1. (Inserting **NULL** to generate **AUTO_INCREMENT** values requires that the column be declared **NOT NULL**. If the column is declared **NULL**, inserting **NULL** stores a **NULL**.) When you insert any other value into an **AUTO_INCREMENT** column, the column is set to that value and the sequence is reset so that the next automatically generated value follows sequentially from the inserted value.

As of MySQL 5.1.67, negative values for **AUTO_INCREMENT** columns are not supported.

11.2.6 Out-of-Range and Overflow Handling

When MySQL stores a value in a numeric column that is outside the permissible range of the column data type, the result depends on the SQL mode in effect at the time:

- If strict SQL mode is enabled, MySQL rejects the out-of-range value with an error, and the insert fails, in accordance with the SQL standard.
- If no restrictive modes are enabled, MySQL clips the value to the appropriate endpoint of the range and stores the resulting value instead.
When an out-of-range value is assigned to an integer column, MySQL stores the value representing the corresponding endpoint of the column data type range. If you store 256 into a `TINYINT` or `TINYINT UNSIGNED` column, MySQL stores 127 or 255, respectively.

When a floating-point or fixed-point column is assigned a value that exceeds the range implied by the specified (or default) precision and scale, MySQL stores the value representing the corresponding endpoint of that range.

Column-assignment conversions that occur due to clipping when MySQL is not operating in strict mode are reported as warnings for `ALTER TABLE`, `LOAD DATA INFILE`, `UPDATE`, and `multiple-row INSERT` statements. In strict mode, these statements fail, and some or all the values will not be inserted or changed, depending on whether the table is a transactional table and other factors. For details, see Section 5.1.7, “Server SQL Modes”.

Overflow handling during numeric expression evaluation depends on the types of the operands:

- Integer overflow results in silent wraparound.
- `DECIMAL` overflow results in a truncated result and a warning.
- Floating-point overflow produces a `NULL` result. Before MySQL 5.1.24, overflow for some operations results in `+INF`, `-INF`, or `NaN`.

For example, the largest signed `BIGINT` value is 922372036854775807, so the following expression wraps around to the minimum `BIGINT` value:

```sql
mysql> SELECT 9223372036854775807 + 1;
+-------------------------+
| 9223372036854775807 + 1 |
| -9223372036854775808   |
+-------------------------+
```

To enable the operation to succeed in this case, convert the value to unsigned:

```sql
mysql> SELECT CAST(9223372036854775807 AS UNSIGNED) + 1;
+-------------------------------------------+
| CAST(9223372036854775807 AS UNSIGNED) + 1 |
| 9223372036854775808                     |
+-------------------------------------------+
```

Whether overflow occurs depends on the range of the operands, so another way to handle the preceding expression is to use exact-value arithmetic because `DECIMAL` values have a larger range than integers:

```sql
mysql> SELECT 9223372036854775807.0 + 1;
+---------------------------+
| 9223372036854775807.0 + 1 |
| 9223372036854775808       |
+---------------------------+
```

Subtraction between integer values, where one is of type `UNSIGNED`, produces an unsigned result by default. If the result would otherwise have been negative, it becomes the maximum integer value. If the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled, the result is negative.

```sql
mysql> SET sql_mode = '';
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
+-------------------------+
| CAST(0 AS UNSIGNED) - 1 |
| -9223372036854775808   |
+-------------------------+
```
If the result of such an operation is used to update an `UNSIGNED` integer column, the result is clipped to the maximum value for the column type, or clipped to 0 if `NO_UNSIGNED_SUBTRACTION` is enabled. If strict SQL mode is enabled, an error occurs and the column remains unchanged.

### 11.3 Date and Time Types

The date and time types for representing temporal values are `DATE`, `TIME`, `DATETIME`, `TIMESTAMP`, and `YEAR`. Each temporal type has a range of valid values, as well as a “zero” value that may be used when you specify an invalid value that MySQL cannot represent. The `TIMESTAMP` type has special automatic updating behavior, described later. For temporal type storage requirements, see Section 11.7, “Data Type Storage Requirements”.

Keep in mind these general considerations when working with date and time types:

- MySQL retrieves values for a given date or time type in a standard output format, but it attempts to interpret a variety of formats for input values that you supply (for example, when you specify a value to be assigned to or compared to a date or time type). For a description of the permitted formats for date and time types, see Section 9.1.3, “Date and Time Literals”. It is expected that you supply valid values. Unpredictable results may occur if you use values in other formats.

- Although MySQL tries to interpret values in several formats, date parts must always be given in year-month-day order (for example, `'98-09-04'`), rather than in the month-day-year or day-month-year orders commonly used elsewhere (for example, `'09-04-98'`, `'04-09-98'`).

- Dates containing two-digit year values are ambiguous because the century is unknown. MySQL interprets two-digit year values using these rules:
  
  - Year values in the range `70–99` are converted to `1970–1999`.
  
  - Year values in the range `00–69` are converted to `2000–2069`.

  See also Section 11.3.8, “Two-Digit Years in Dates”.

- Conversion of values from one temporal type to another occurs according to the rules in Section 11.3.7, “Conversion Between Date and Time Types”.

- MySQL automatically converts a date or time value to a number if the value is used in a numeric context and vice versa.

- By default, when MySQL encounters a value for a date or time type that is out of range or otherwise invalid for the type, it converts the value to the “zero” value for that type. The exception is that out-of-range `TIME` values are clipped to the appropriate endpoint of the `TIME` range.

- By setting the SQL mode to the appropriate value, you can specify more exactly what kind of dates you want MySQL to support. (See Section 5.1.7, “Server SQL Modes”.) You can get MySQL to accept certain dates, such as `'2009-11-31'`, by enabling the `ALLOW_INVALID_DATES` SQL mode. This is useful when you want to store a “possibly wrong” value which the user has specified (for example, in a web form) in the database for future processing. Under this mode, MySQL verifies only that the month is in the range from 1 to 12 and that the day is in the range from 1 to 31.
MySQL permits you to store dates where the day or month and day are zero in a DATE or DATETIME column. This is useful for applications that need to store birthdates for which you may not know the exact date. In this case, you simply store the date as '2009-00-00' or '2009-01-00'. If you store dates such as these, you should not expect to get correct results for functions such as DATE_SUB() or DATE_ADD() that require complete dates. To disallow zero month or day parts in dates, enable the NO_ZERO_IN_DATE SQL mode.

MySQL permits you to store a “zero” value of '0000-00-00' as a “dummy date.” This is in some cases more convenient than using NULL values, and uses less data and index space. To disallow '0000-00-00', enable the NO_ZERO_DATE SQL mode.

“Zero” date or time values used through Connector/ODBC are converted automatically to NULL because ODBC cannot handle such values.

The following table shows the format of the “zero” value for each type. The “zero” values are special, but you can store or refer to them explicitly using the values shown in the table. You can also do this using the values '0' or 0, which are easier to write. For temporal types that include a date part (DATE, DATETIME, and TIMESTAMP), use of these values produces warnings if the NO_ZERO_DATE SQL mode is enabled.

<table>

### 11.3.1 The DATE, DATETIME, and TIMESTAMP Types

The DATE, DATETIME, and TIMESTAMP types are related. This section describes their characteristics, how they are similar, and how they differ. MySQL recognizes DATE, DATETIME, and TIMESTAMP values in several formats, described in Section 9.1.3, “Date and Time Literals”. For the DATE and DATETIME range descriptions, “supported” means that although earlier values might work, there is no guarantee.

The DATE type is used for values with a date part but no time part. MySQL retrieves and displays DATE values in 'YYYY-MM-DD' format. The supported range is '1000-01-01' to '9999-12-31'.

The DATETIME type is used for values that contain both date and time parts. MySQL retrieves and displays DATETIME values in 'YYYY-MM-DD HH:MM:SS' format. The supported range is '1000-01-01 00:00:00' to '9999-12-31 23:59:59'.

The TIMESTAMP data type is used for values that contain both date and time parts. TIMESTAMP has a range of '1970-01-01 00:00:00' UTC to '2038-01-19 03:14:07' UTC.

MySQL converts TIMESTAMP values from the current time zone to UTC for storage, and back from UTC to the current time zone for retrieval. (This does not occur for other types such as DATETIME.) By default, the current time zone for each connection is the server's time. The time zone can be set on a per-connection basis. As long as the time zone setting remains constant, you get back the same value you store. If you store a TIMESTAMP value, and then change the time zone and retrieve the value, the retrieved value is different from the value you stored. This occurs because the same time zone was not used for conversion in both directions. The current time zone is available as the value of the time_zone system variable. For more information, see Section 10.6, “MySQL Server Time Zone Support”.

The TIMESTAMP data type offers automatic initialization and updating to the current date and time. For more information, see Section 11.3.5, “Automatic Initialization and Updating for TIMESTAMP”.

969
The TIME Type

A DATETIME or TIMESTAMP value can include a trailing fractional seconds part in up to microseconds (6 digits) precision. Although this fractional part is recognized, it is discarded from values stored into DATETIME or TIMESTAMP columns. For information about fractional seconds support in MySQL, see Section 11.3.6, “Fractional Seconds in Time Values”.

Invalid DATE, DATETIME, or TIMESTAMP values are converted to the “zero” value of the appropriate type (‘0000-00-00’ or ‘0000-00-00 00:00:00’).

Be aware of certain properties of date value interpretation in MySQL:

- MySQL permits a “relaxed” format for values specified as strings, in which any punctuation character may be used as the delimiter between date parts or time parts. In some cases, this syntax can be deceiving. For example, a value such as '10:11:12' might look like a time value because of the “:” delimiter, but is interpreted as the year '2010-11-12' if used in a date context. The value '10:45:15' is converted to '0000-00-00' because '45' is not a valid month.

- The server requires that month and day values be valid, and not merely in the range 1 to 12 and 1 to 31, respectively. With strict mode disabled, invalid dates such as '2004-04-31' are converted to '0000-00-00' and a warning is generated. With strict mode enabled, invalid dates generate an error. To permit such dates, enable ALLOW_INVALID_DATES. See Section 5.1.7, “Server SQL Modes”, for more information.

- MySQL does not accept TIMESTAMP values that include a zero in the day or month column or values that are not a valid date. The sole exception to this rule is the special “zero” value '0000-00-00 00:00:00'.

- CAST() treats a TIMESTAMP value as a string when not selecting from a table. (This is true even if you specify FROM DUAL.) See Section 12.10, “Cast Functions and Operators”.

- Dates containing two-digit year values are ambiguous because the century is unknown. MySQL interprets two-digit year values using these rules:
  - Year values in the range 00–69 are converted to 2000–2069.
  - Year values in the range 70–99 are converted to 1970–1999.

See also Section 11.3.8, “Two-Digit Years in Dates”.

Note

The MySQL server can be run with the MAXDB SQL mode enabled. In this case, TIMESTAMP is identical with DATETIME. If this mode is enabled at the time that a table is created, TIMESTAMP columns are created as DATETIME columns. As a result, such columns use DATETIME display format, have the same range of values, and there is no automatic initialization or updating to the current date and time. See Section 5.1.7, “Server SQL Modes”.

11.3.2 The TIME Type

MySQL retrieves and displays TIME values in 'HH:MM:SS' format (or 'HHH:MM:SS' format for large hours values). TIME values may range from '-838:59:59' to '838:59:59'. The hours part may be so large because the TIME type can be used not only to represent a time of day (which must be less than 24 hours), but also elapsed time or a time interval between two events (which may be much greater than 24 hours, or even negative).

MySQL recognizes TIME values in several formats, described in Section 9.1.3, “Date and Time Literals”. Some of these formats can include a trailing fractional seconds part in up to microseconds (6 digits) precision. Although this fractional part is recognized, it is discarded from values stored into TIME columns. For information about fractional seconds support in MySQL, see Section 11.3.6, “Fractional Seconds in Time Values”.

970
Be careful about assigning abbreviated values to a `TIME` column. MySQL interprets abbreviated `TIME` values with colons as time of the day. That is, '11:12' means '11:12:00', not '00:11:12'. MySQL interprets abbreviated values without colons using the assumption that the two rightmost digits represent seconds (that is, as elapsed time rather than as time of day). For example, you might think of '1112' and 1112 as meaning '11:12:00' (12 minutes after 11 o'clock), but MySQL interprets them as '00:11:12' (11 minutes, 12 seconds). Similarly, '12' and 12 are interpreted as '00:00:12'.

By default, values that lie outside the `TIME` range but are otherwise valid are clipped to the closest endpoint of the range. For example, '-850:00:00' and '850:00:00' are converted to '-838:59:59' and '838:59:59'. Invalid `TIME` values are converted to '00:00:00'. Note that because '00:00:00' is itself a valid `TIME` value, there is no way to tell, from a value of '00:00:00' stored in a table, whether the original value was specified as '00:00:00' or whether it was invalid.

For more restrictive treatment of invalid `TIME` values, enable strict SQL mode to cause errors to occur. See Section 5.1.7, “Server SQL Modes”.

### 11.3.3 The YEAR Type

The `YEAR` type is a 1-byte type used to represent year values. It can be declared as `YEAR(4)` or `YEAR(2)` to specify a display width of four or two characters. The default is four characters if no width is given.

**Note**

The `YEAR(2)` data type has certain issues that you should consider before choosing to use it. As of MySQL 5.1.65, `YEAR(2)` is deprecated. For more information, see Section 11.3.4, “YEAR(2) Limitations and Migrating to YEAR(4)”.

`YEAR(4)` and `YEAR(2)` differ in display format, but have the same range of values. For 4-digit format, MySQL displays `YEAR` values in `YYYY` format, with a range of 1901 to 2155, or 0000. For 2-digit format, MySQL displays only the last two (least significant) digits; for example, 70 (1970 or 2070) or 69 (2069).

You can specify input `YEAR` values in a variety of formats:

- As a 4-digit number in the range 1901 to 2155.
- As a 4-digit string in the range '1901' to '2155'.
- As a 1- or 2-digit number in the range 1 to 99. MySQL converts values in the ranges 1 to 69 and 70 to 99 to `YEAR` values in the ranges 2001 to 2069 and 1970 to 1999.
- As a 1- or 2-digit string in the range '0' to '99'. MySQL converts values in the ranges '0' to '69' and '70' to '99' to `YEAR` values in the ranges 2000 to 2069 and 1970 to 1999.
- Inserting a numeric 0 has a different effect for `YEAR(2)` and `YEAR(4)`. For `YEAR(2)`, the result has a display value of 00 and an internal value of 2000. For `YEAR(4)`, the result has a display value of 0000 and an internal value of 0000. To specify zero for `YEAR(4)` and have it be interpreted as 2000, specify it as a string '0' or '00'.
- As the result of a function that returns a value that is acceptable in a `YEAR` context, such as `NOW()`.

MySQL converts invalid `YEAR` values to 0000.

See also Section 11.3.8, “Two-Digit Years in Dates”.

### 11.3.4 YEAR(2) Limitations and Migrating to YEAR(4)

This section describes problems that can occur when using `YEAR(2)` and provides information about converting existing `YEAR(2)` columns to `YEAR(4)`.
Although the internal range of values for \texttt{YEAR(4)} and \texttt{YEAR(2)} is the same (1901 to 2155, and 0000), the display width for \texttt{YEAR(2)} makes that type inherently ambiguous because displayed values indicate only the last two digits of the internal values and omit the century digits. The result can be a loss of information under certain circumstances. For this reason, consider avoiding \texttt{YEAR(2)} throughout your applications and using \texttt{YEAR(4)} wherever you need a \texttt{YEAR} data type. Note that conversion will become necessary at some point because support for \texttt{YEAR} data types with display values other than 4, most notably \texttt{YEAR(2)}, is reduced as of MySQL 5.6.6 and will be removed entirely in a future release.

\textbf{YEAR(2) Limitations}

Issues with the \texttt{YEAR(2)} data type include ambiguity of displayed values, and possible loss of information when values are dumped and reloaded or converted to strings.

- Displayed \texttt{YEAR(2)} values can be ambiguous. It is possible for up to three \texttt{YEAR(2)} values that have different internal values to have the same displayed value, as the following example demonstrates:

\begin{verbatim}
mysql> CREATE TABLE t (y2 YEAR(2), y4 YEAR(4));
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t (y2) VALUES(1912),(2012),(2112);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> UPDATE t SET y4 = y2;
Query OK, 3 rows affected (0.00 sec)
Rows matched: 3 Changed: 3 Warnings: 0

mysql> SELECT * FROM t;
+------+------+
| y2   | y4   |
+------+------+
|   12 | 1912 |
|   12 | 2012 |
|   12 | 2112 |
+------+------+
3 rows in set (0.00 sec)
\end{verbatim}

- If you use \texttt{mysqldump} to dump the table created in the preceding item, the dump file represents all \texttt{y2} values using the same 2-digit representation (12). If you reload the table from the dump file, all resulting rows have internal value 2012 and display value 12, thus losing the distinctions among them.

- Conversion of a \texttt{YEAR(2)} or \texttt{YEAR(4)} data value to string form uses the display width of the \texttt{YEAR} type. Suppose that \texttt{YEAR(2)} and \texttt{YEAR(4)} columns both contain the value 1970. Assigning each column to a string results in a value of '70' or '1970', respectively. That is, loss of information occurs for conversion from \texttt{YEAR(2)} to string.

- Values outside the range from 1970 to 2069 are stored incorrectly when inserted into a \texttt{YEAR(2)} column in a \texttt{CSV} table. For example, inserting 2111 results in a display value of 11 but an internal value of 2011.

To avoid these problems, use \texttt{YEAR(4)} rather than \texttt{YEAR(2)}. Suggestions regarding migration strategies appear later in this section.

\textbf{Migrating from YEAR(2) to YEAR(4)}

To convert \texttt{YEAR(2)} columns to \texttt{YEAR(4)}, use \texttt{ALTER TABLE}. Suppose that a table \texttt{t1} has this definition:

\begin{verbatim}
CREATE TABLE t1 {ycol YEAR(2) NOT NULL DEFAULT '70'};
\end{verbatim}
Modify the column using `ALTER TABLE` as follows. Remember to include any column attributes such as `NOT NULL` or `DEFAULT`:

```sql
ALTER TABLE t1 MODIFY ycol YEAR(4) NOT NULL DEFAULT '1970';
```

The `ALTER TABLE` statement converts the table without changing `YEAR(2)` values. If the server is a replication master, the `ALTER TABLE` statement replicates to slaves and makes the corresponding table change on each one.

One migration method should be avoided: Do not dump your data with `mysqldump` and reload the dump file after upgrading. This has the potential to change `YEAR(2)` values, as described previously.

A migration from `YEAR(2)` to `YEAR(4)` should also involve examining application code for the possibility of changed behavior under conditions such as these:

- Code that expects selecting a `YEAR` column to produce exactly two digits.
- Code that does not account for different handling for inserts of numeric `0`: Inserting `0` into `YEAR(2)` or `YEAR(4)` results in an internal value of `2000` or `0000`, respectively.

### 11.3.5 Automatic Initialization and Updating for TIMESTAMP

**Note**

In older versions of MySQL (prior to 4.1), the properties of the `TIMESTAMP` data type differed significantly in several ways from what is described in this section (see the MySQL 3.23, 4.0, 4.1 Reference Manual for details); these include syntax extensions which are deprecated in MySQL 5.1, and no longer supported in MySQL 5.5. This has implications for performing a dump and restore or replicating between MySQL Server versions. If you are using columns that are defined using the old `TIMESTAMP (N)` syntax, see Section 2.13.1.1, “Changes Affecting Upgrades to 5.1”, prior to upgrading to MySQL 5.1 or later.

The `TIMESTAMP` data type offers automatic initialization and updating to the current date and time (that is, the current timestamp). You can choose whether to use these properties and which column should have them:

- One `TIMESTAMP` column in a table can have the current timestamp as the default value for initializing the column, as the auto-update value, or both. It is not possible to have the current timestamp be the default value for one column and the auto-update value for another column.
- If the column is auto-initialized, it is set to the current timestamp for inserted rows that specify no value for the column.
- If the column is auto-updated, it is automatically updated to the current timestamp when the value of any other column in the row is changed from its current value. The column remains unchanged if all other columns are set to their current values. To prevent the column from updating when other columns change, explicitly set it to its current value. To update the column even when other columns do not change, explicitly set it to the value it should have (for example, set it to `CURRENT_TIMESTAMP`).
- In addition, you can initialize or update any `TIMESTAMP` column to the current date and time by assigning it a `NULL` value, unless it has been defined with the `NULL` attribute to permit `NULL` values.

To specify automatic properties, use the `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` clauses. The order of the clauses does not matter. If both are present in a column definition, either can occur first. Any of the synonyms for `CURRENT_TIMESTAMP` have the same meaning as `CURRENT_TIMESTAMP`. These are `CURRENT_TIMESTAMP()`, `NOW()`, `LOCALTIME`, `LOCALTIME()`, `LOCALTIMESTAMP`, and `LOCALTIMESTAMP()`.
Use of `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` is specific to `TIMESTAMP`. The `DEFAULT` clause also can be used to specify a constant (nonautomatic) default value; for example, `DEFAULT 0` or `DEFAULT '2000-01-01 00:00:00'`.

**Note**

The following examples use `DEFAULT 0`, a default that can produce warnings or errors depending on whether strict SQL mode or the `NO_ZERO_DATE` SQL mode is enabled. Be aware that the `TRADITIONAL` SQL mode includes strict mode and `NO_ZERO_DATE`. See Section 5.1.7, "Server SQL Modes".

The following rules describe the possibilities for defining the first `TIMESTAMP` column in a table with the current timestamp for both the default and auto-update values, for one but not the other, or for neither:

- **With both `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP`, the column has the current timestamp for its default value and is automatically updated to the current timestamp.**

```
CREATE TABLE t1 (  
  ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP  
);
```

- **With neither `DEFAULT CURRENT_TIMESTAMP` nor `ON UPDATE CURRENT_TIMESTAMP`, it is the same as specifying both `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP`.**

```
CREATE TABLE t1 (  
  ts TIMESTAMP  
);
```

- **With a `DEFAULT` clause but no `ON UPDATE CURRENT_TIMESTAMP` clause, the column has the given default value and is not automatically updated to the current timestamp.**

  The default depends on whether the `DEFAULT` clause specifies `CURRENT_TIMESTAMP` or a constant value. With `CURRENT_TIMESTAMP`, the default is the current timestamp.

```
CREATE TABLE t1 (  
  ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP  
);
```

  With a constant, the default is the given value. In this case, the column has no automatic properties at all.

```
CREATE TABLE t1 (  
  ts TIMESTAMP DEFAULT 0  
);
```

- **With an `ON UPDATE CURRENT_TIMESTAMP` clause and a constant `DEFAULT` clause, the column is automatically updated to the current timestamp and has the given constant default value.**

```
CREATE TABLE t1 (  
  ts TIMESTAMP DEFAULT 0 ON UPDATE CURRENT_TIMESTAMP  
);
```

- **With an `ON UPDATE CURRENT_TIMESTAMP` clause but no `DEFAULT` clause, the column is automatically updated to the current timestamp. The default is 0 unless the column is defined with the `NULL` attribute, in which case the default is `NULL`.**

```
CREATE TABLE t1 (  
  ts TIMESTAMP ON UPDATE CURRENT_TIMESTAMP  -- default 0  
);
CREATE TABLE t2 (  
```
It need not be the first TIMESTAMP column in a table that is automatically initialized or updated to the current timestamp. However, to specify automatic initialization or updating for a different TIMESTAMP column, you must suppress the automatic properties for the first one. Then, for the other TIMESTAMP column, the rules for the DEFAULT and ON UPDATE clauses are the same as for the first TIMESTAMP column, except that if you omit both clauses, no automatic initialization or updating occurs.

To suppress automatic properties for the first TIMESTAMP column, do either of the following:

- Define the column with a DEFAULT clause that specifies a constant default value.
- Specify the NULL attribute. This also causes the column to permit NULL values, which means that you cannot assign the current timestamp by setting the column to NULL. Assigning NULL sets the column to NULL.

Consider these table definitions:

```sql
CREATE TABLE t1 (  
  ts1 TIMESTAMP DEFAULT 0,  
  ts2 TIMESTAMP DEFAULT CURRENT_TIMESTAMP  
) ON UPDATE CURRENT_TIMESTAMP;
CREATE TABLE t2 (  
  ts1 TIMESTAMP NULL,  
  ts2 TIMESTAMP DEFAULT CURRENT_TIMESTAMP  
) ON UPDATE CURRENT_TIMESTAMP;
CREATE TABLE t3 (  
  ts1 TIMESTAMP NULL DEFAULT 0,  
  ts2 TIMESTAMP DEFAULT CURRENT_TIMESTAMP  
) ON UPDATE CURRENT_TIMESTAMP;
```

The tables have these properties:

- In each table definition, the first TIMESTAMP column has no automatic initialization or updating.
- The tables differ in how the ts1 column handles NULL values. For t1, ts1 is NOT NULL and assigning it a value of NULL sets it to the current timestamp. For t2 and t3, ts1 permits NULL and assigning it a value of NULL sets it to NULL.
- t2 and t3 differ in the default value for ts1. For t2, ts1 is defined to permit NULL, so the default is also NULL in the absence of an explicit DEFAULT clause. For t3, ts1 permits NULL but has an explicit default of 0.

**TIMESTAMP Initialization and the NULL Attribute**

By default, TIMESTAMP columns are NOT NULL, cannot contain NULL values, and assigning NULL assigns the current timestamp. To permit a TIMESTAMP column to contain NULL, explicitly declare it with the NULL attribute. In this case, the default value also becomes NULL unless overridden with a DEFAULT clause that specifies a different default value. DEFAULT NULL can be used to explicitly specify NULL as the default value. (For a TIMESTAMP column not declared with the NULL attribute, DEFAULT NULL is invalid.) If a TIMESTAMP column permits NULL values, assigning NULL sets it to NULL, not to the current timestamp.

The following table contains several TIMESTAMP columns that permit NULL values:

```sql
CREATE TABLE t (  
  ts1 TIMESTAMP NULL DEFAULT NULL,  
  ts2 TIMESTAMP NULL DEFAULT 0,  
  ts3 TIMESTAMP NULL DEFAULT CURRENT_TIMESTAMP  
);
```
A `TIMESTAMP` column that permits `NULL` values does not take on the current timestamp at insert time except under one of the following conditions:

- Its default value is defined as `CURRENT_TIMESTAMP` and no value is specified for the column
- `CURRENT_TIMESTAMP` or any of its synonyms such as `NOW()` is explicitly inserted into the column

In other words, a `TIMESTAMP` column defined to permit `NULL` values auto-initializes only if its definition includes `DEFAULT CURRENT_TIMESTAMP`:

```
CREATE TABLE t (ts TIMESTAMP NULL DEFAULT CURRENT_TIMESTAMP);
```

If the `TIMESTAMP` column permits `NULL` values but its definition does not include `DEFAULT CURRENT_TIMESTAMP`, you must explicitly insert a value corresponding to the current date and time. Suppose that tables `t1` and `t2` have these definitions:

```
CREATE TABLE t1 (ts TIMESTAMP NULL DEFAULT '0000-00-00 00:00:00');
CREATE TABLE t2 (ts TIMESTAMP NULL DEFAULT NULL);
```

To set the `TIMESTAMP` column in either table to the current timestamp at insert time, explicitly assign it that value. For example:

```
INSERT INTO t1 VALUES (NOW());
INSERT INTO t2 VALUES (CURRENT_TIMESTAMP);
```

### 11.3.6 Fractional Seconds in Time Values

A trailing fractional seconds part is permissible for temporal values in contexts such as literal values, and in the arguments to or return values from some temporal functions. Example:

```
mysql> SELECT MICROSECOND('2010-12-10 14:12:09.019473');
+-------------------------------------------+
| MICROSECOND('2010-12-10 14:12:09.019473') |
+-------------------------------------------+
|                                     19473 |
+-------------------------------------------+
```

However, when MySQL stores a value into a column of any temporal data type, it discards any fractional part and does not store it.

### 11.3.7 Conversion Between Date and Time Types

To some extent, you can convert a value from one temporal type to another. However, there may be some alteration of the value or loss of information. In all cases, conversion between temporal types is subject to the range of valid values for the resulting type. For example, although `DATE`, `DATETIME`, and `TIMESTAMP` values all can be specified using the same set of formats, the types do not all have the same range of values. `TIMESTAMP` values cannot be earlier than 1970 UTC or later than '2038-01-19 03:14:07' UTC. This means that a date such as '1968-01-01', while valid as a `DATE` or `DATETIME` value, is not valid as a `TIMESTAMP` value and is converted to 0.

Conversion of `DATE` values:

- Conversion to a `DATETIME` or `TIMESTAMP` value adds a time part of '00:00:00' because the `DATE` value contains no time information.
- Conversion to a `TIME` value is not useful; the result is '00:00:00'.

Conversion of `DATETIME` and `TIMESTAMP` values:

- Conversion to a `DATE` value discards the time part because the `DATE` type contains no time information.
Conversion of TIME values:

MySQL converts a time value to a date or date-and-time value by parsing the string value of the time as a date or date-and-time. This is unlikely to be useful. For example, '23:12:31' interpreted as a date becomes '2023-12-31'. Time values not valid as dates become '0000-00-00' or NULL.

Prior to MySQL 5.1.18, when DATE values are compared with DATETIME values, the time portion of the DATETIME value is ignored, or the comparison could be performed as a string compare. Starting from MySQL 5.1.18, a DATE value is coerced to the DATETIME type by adding the time portion as '00:00:00'. To mimic the old behavior, use the CAST() function to cause the comparison operands to be treated as previously. For example:

```
date_col = CAST(datetime_col AS DATE)
```

Conversion of TIME or DATETIME values to numeric form (for example, by adding +0) results in a double-precision value with a microseconds part of .000000:

```
mysql> SELECT CURTIME(), CURTIME()+0;
+-----------+---------------+
| CURTIME() | CURTIME()+0   |
+-----------+---------------+
| 10:41:36  | 104136.000000 |
+-----------+---------------+

mysql> SELECT NOW(), NOW()+0;
+---------------------+-----------------------+
| NOW()               | NOW()+0               |
+---------------------+-----------------------+
| 2007-11-30 10:41:47 | 20071130104147.000000 |
+---------------------+-----------------------+
```

11.3.8 Two-Digit Years in Dates

Date values with two-digit years are ambiguous because the century is unknown. Such values must be interpreted into four-digit form because MySQL stores years internally using four digits.

For DATETIME, DATE, and TIMESTAMP types, MySQL interprets dates specified with ambiguous year values using these rules:

- Year values in the range 00-69 are converted to 2000-2069.
- Year values in the range 70-99 are converted to 1970-1999.

For YEAR, the rules are the same, with this exception: A numeric 00 inserted into YEAR(4) results in 0000 rather than 2000. To specify zero for YEAR(4) and have it be interpreted as 2000, specify it as a string '0' or '00'.

Remember that these rules are only heuristics that provide reasonable guesses as to what your data values mean. If the rules used by MySQL do not produce the values you require, you must provide unambiguous input containing four-digit year values.

ORDER BY properly sorts YEAR values that have two-digit years.

Some functions like MIN() and MAX() convert a YEAR to a number. This means that a value with a two-digit year does not work properly with these functions. The fix in this case is to convert the YEAR to four-digit year format.

11.4 String Types
The string types are `CHAR`, `VARCHAR`, `BINARY`, `VARBINARY`, `BLOB`, `TEXT`, `ENUM`, and `SET`. This section describes how these types work and how to use them in your queries. For string type storage requirements, see Section 11.7, “Data Type Storage Requirements”.

### 11.4.1 The CHAR and VARCHAR Types

The `CHAR` and `VARCHAR` types are similar, but differ in the way they are stored and retrieved. They also differ in maximum length and in whether trailing spaces are retained.

The `CHAR` and `VARCHAR` types are declared with a length that indicates the maximum number of characters you want to store. For example, `CHAR(30)` can hold up to 30 characters.

The length of a `CHAR` column is fixed to the length that you declare when you create the table. The length can be any value from 0 to 255. When `CHAR` values are stored, they are right-padded with spaces to the specified length. When `CHAR` values are retrieved, trailing spaces are removed unless the `PAD_CHAR_TO_FULL_LENGTH` SQL mode is enabled.

Values in `VARCHAR` columns are variable-length strings. The length can be specified as a value from 0 to 65,535. The effective maximum length of a `VARCHAR` is subject to the maximum row size (65,535 bytes, which is shared among all columns) and the character set used. See Section C.7.4, “Limits on Table Column Count and Row Size”.

In contrast to `CHAR`, `VARCHAR` values are stored as a 1-byte or 2-byte length prefix plus data. The length prefix indicates the number of bytes in the value. A column uses one length byte if values require no more than 255 bytes, two length bytes if values may require more than 255 bytes.

If strict SQL mode is not enabled and you assign a value to a `CHAR` or `VARCHAR` column that exceeds the column's maximum length, the value is truncated to fit and a warning is generated. For truncation of non-space characters, you can cause an error to occur (rather than a warning) and suppress insertion of the value by using strict SQL mode. See Section 5.1.7, “Server SQL Modes”.

For `VARCHAR` columns, trailing spaces in excess of the column length are truncated prior to insertion and a warning is generated, regardless of the SQL mode in use. For `CHAR` columns, truncation of excess trailing spaces from inserted values is performed silently regardless of the SQL mode.

`VARCHAR` values are not padded when they are stored. Trailing spaces are retained when values are stored and retrieved, in conformance with standard SQL.

The following table illustrates the differences between `CHAR` and `VARCHAR` by showing the result of storing various string values into `CHAR(4)` and `VARCHAR(4)` columns (assuming that the column uses a single-byte character set such as `latin1`).

<table>
<thead>
<tr>
<th>Value</th>
<th><code>CHAR(4)</code></th>
<th>Storage Required</th>
<th><code>VARCHAR(4)</code></th>
<th>Storage Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>''</td>
<td>''</td>
<td>4 bytes</td>
<td>''</td>
<td>1 byte</td>
</tr>
<tr>
<td>'ab'</td>
<td>'ab'</td>
<td>4 bytes</td>
<td>'ab'</td>
<td>3 bytes</td>
</tr>
<tr>
<td>'abcd'</td>
<td>'abcd'</td>
<td>4 bytes</td>
<td>'abcd'</td>
<td>5 bytes</td>
</tr>
<tr>
<td>'abcdefg'</td>
<td>'abcd'</td>
<td>4 bytes</td>
<td>'abcd'</td>
<td>5 bytes</td>
</tr>
</tbody>
</table>

The values shown as stored in the last row of the table apply only when not using strict mode; if MySQL is running in strict mode, values that exceed the column length are not stored, and an error results.

If a given value is stored into the `CHAR(4)` and `VARCHAR(4)` columns, the values retrieved from the columns are not always the same because trailing spaces are removed from `CHAR` columns upon retrieval. The following example illustrates this difference:

```sql
mysql> CREATE TABLE vc (v VARCHAR(4), c CHAR(4));
```
The BINARY and VARBINARY Types

Values in CHAR and VARCHAR columns are sorted and compared according to the character set collation assigned to the column.

All MySQL collations are of type PADSPACE. This means that all CHAR, VARCHAR, and TEXT values in MySQL are compared without regard to any trailing spaces. “Comparison” in this context does not include the LIKE pattern-matching operator, for which trailing spaces are significant. For example:

```
mysql> CREATE TABLE names (myname CHAR(10));
Query OK, 0 rows affected (0.03 sec)
mysql> INSERT INTO names VALUES ('Monty');
Query OK, 1 row affected (0.00 sec)
mysql> SELECT myname = 'Monty', myname = 'Monty  ' FROM names;
+------------------+--------------------+
| myname = 'Monty' | myname = 'Monty  ' |
|                  |                  1 |
|                  |                  1 |
+------------------+--------------------+
1 row in set (0.00 sec)
mysql> SELECT myname LIKE 'Monty', myname LIKE 'Monty  ' FROM names;
+---------------------+-----------------------+
| myname LIKE 'Monty' | myname LIKE 'Monty  ' |
|                   1 |                     0 |
+---------------------+-----------------------+
1 row in set (0.00 sec)
```

This is true for all MySQL versions, and is not affected by the server SQL mode.

**Note**

For more information about MySQL character sets and collations, see Section 10.1, “Character Set Support”. For additional information about storage requirements, see Section 11.7, “Data Type Storage Requirements”.

For those cases where trailing pad characters are stripped or comparisons ignore them, if a column has an index that requires unique values, inserting into the column values that differ only in number of trailing pad characters will result in a duplicate-key error. For example, if a table contains 'a', an attempt to store 'a ' causes a duplicate-key error.

**11.4.2 The BINARY and VARBINARY Types**

The BINARY and VARBINARY types are similar to CHAR and VARCHAR, except that they contain binary strings rather than nonbinary strings. That is, they contain byte strings rather than character strings. This means that they have no character set, and sorting and comparison are based on the numeric values of the bytes in the values.

The permissible maximum length is the same for BINARY and VARBINARY as it is for CHAR and VARCHAR, except that the length for BINARY and VARBINARY is a length in bytes rather than in characters.
The `BINARY` and `VARBINARY` data types are distinct from the `CHAR BINARY` and `VARCHAR BINARY` data types. For the latter types, the `BINARY` attribute does not cause the column to be treated as a binary string column. Instead, it causes the binary collation for the column character set to be used, and the column itself contains nonbinary character strings rather than binary byte strings. For example, `CHAR(5) BINARY` is treated as `CHAR(5) CHARACTER SET latin1 COLLATE latin1_bin`, assuming that the default character set is `latin1`. This differs from `BINARY(5)`, which stores 5-byte binary strings that have no character set or collation. For information about differences between nonbinary string binary collations and binary strings, see Section 10.1.7.6, “The _bin and binary Collations”.

If strict SQL mode is not enabled and you assign a value to a `BINARY` or `VARBINARY` column that exceeds the column's maximum length, the value is truncated to fit and a warning is generated. For cases of truncation, you can cause an error to occur (rather than a warning) and suppress insertion of the value by using strict SQL mode. See Section 5.1.7, “Server SQL Modes”.

When `BINARY` values are stored, they are right-padded with the pad value to the specified length. The pad value is `0x00` (the zero byte). Values are right-padded with `0x00` on insert, and no trailing bytes are removed on select. All bytes are significant in comparisons, including `ORDER BY` and `DISTINCT` operations. `0x00` bytes and spaces are different in comparisons, with `0x00 < space`.

Example: For a `BINARY(3)` column, `'a '` becomes `'a \0'` when inserted. `'a\0'` becomes `'a \0\0'` when inserted. Both inserted values remain unchanged when selected.

For `VARBINARY`, there is no padding on insert and no bytes are stripped on select. All bytes are significant in comparisons, including `ORDER BY` and `DISTINCT` operations. `0x00` bytes and spaces are different in comparisons, with `0x00 < space`.

For those cases where trailing pad bytes are stripped or comparisons ignore them, if a column has an index that requires unique values, inserting into the column values that differ only in number of trailing pad bytes will result in a duplicate-key error. For example, if a table contains `'a'`, an attempt to store `'a\0'` causes a duplicate-key error.

You should consider the preceding padding and stripping characteristics carefully if you plan to use the `BINARY` data type for storing binary data and you require that the value retrieved be exactly the same as the value stored. The following example illustrates how `0x00`-padding of `BINARY` values affects column value comparisons:

```
mysql> CREATE TABLE t (c BINARY(3));
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t SET c = 'a';
Query OK, 1 row affected (0.01 sec)

mysql> SELECT HEX(c), c = 'a', c = 'a\0\0' from t;
+--------+---------+-------------+
| HEX(c) | c = 'a' | c = 'a\0\0' |
|--------+---------+-------------+
| 610000 |       0 |           1 |
+--------+---------+-------------+
1 row in set (0.09 sec)
```

If the value retrieved must be the same as the value specified for storage with no padding, it might be preferable to use `VARBINARY` or one of the `BLOB` data types instead.

### 11.4.3 The BLOB and TEXT Types

A `BLOB` is a binary large object that can hold a variable amount of data. The four `BLOB` types are `TINYBLOB`, `BLOB`, `MEDIUMBLOB`, and `LONGBLOB`. These differ only in the maximum length of the values they can hold. The four `TEXT` types are `TINYTEXT`, `TEXT`, `MEDIUMTEXT`, and `LONGTEXT`. These correspond to the four `BLOB` types and have the same maximum lengths and storage requirements. See Section 11.7, “Data Type Storage Requirements”.

980
BLOB values are treated as binary strings (byte strings). They have no character set, and sorting and comparison are based on the numeric values of the bytes in column values. TEXT values are treated as nonbinary strings (character strings). They have a character set, and values are sorted and compared based on the collation of the character set.

If strict SQL mode is not enabled and you assign a value to a BLOB or TEXT column that exceeds the column’s maximum length, the value is truncated to fit and a warning is generated. For truncation of nonspace characters, you can cause an error to occur (rather than a warning) and suppress insertion of the value by using strict SQL mode. See Section 5.1.7, “Server SQL Modes”.

Beginning with MySQL 5.1.24, truncation of excess trailing spaces from values to be inserted into TEXT columns always generates a warning, regardless of the SQL mode.

For TEXT and BLOB columns, there is no padding on insert and no bytes are stripped on select.

If a TEXT column is indexed, index entry comparisons are space-padded at the end. This means that, if the index requires unique values, duplicate-key errors will occur for values that differ only in the number of trailing spaces. For example, if a table contains 'a ', an attempt to store 'a ' causes a duplicate-key error. This is not true for BLOB columns.

In most respects, you can regard a BLOB column as a VARBINARY column that can be as large as you like. Similarly, you can regard a TEXT column as a VARCHAR column. BLOB and TEXT differ from VARBINARY and VARCHAR in the following ways:

- For indexes on BLOB and TEXT columns, you must specify an index prefix length. For CHAR and VARCHAR, a prefix length is optional. See Section 8.3.4, “Column Indexes”.

- BLOB and TEXT columns cannot have DEFAULT values.

If you use the BINARY attribute with a TEXT data type, the column is assigned the binary collation of the column character set.

LONG and LONG VARCHAR map to the MEDIUMTEXT data type. This is a compatibility feature.

MySQL Connector/ODBC defines BLOB values as LONGVARBINARY and TEXT values as LONGVARCHAR.

Because BLOB and TEXT values can be extremely long, you might encounter some constraints in using them:

- Only the first max_sort_length bytes of the column are used when sorting. The default value of max_sort_length is 1024. You can make more bytes significant in sorting or grouping by increasing the value of max_sort_length at server startup or runtime. Any client can change the value of its session max_sort_length variable:

```
mysql> SET max_sort_length = 2000;
mysql> SELECT id, comment FROM t
     ORDER BY comment;
```

- Instances of BLOB or TEXT columns in the result of a query that is processed using a temporary table causes the server to use a table on disk rather than in memory because the MEMORY storage engine does not support those data types (see Section 8.4.4, “Internal Temporary Table Use in MySQL”). Use of disk incurs a performance penalty, so include BLOB or TEXT columns in the query result only if they are really needed. For example, avoid using SELECT * , which selects all columns.

- The maximum size of a BLOB or TEXT object is determined by its type, but the largest value you actually can transmit between the client and server is determined by the amount of available memory and the size of the communications buffers. You can change the message buffer size by changing the value of the max_allowed_packet variable, but you must do so for both the server and your client program. For example, both mysql and mysqldump enable you to change the client-side max_allowed_packet value. See Section 8.12.2, “Tuning Server Parameters”, Section 4.5.1,
Each BLOB or TEXT value is represented internally by a separately allocated object. This is in contrast to all other data types, for which storage is allocated once per column when the table is opened.

In some cases, it may be desirable to store binary data such as media files in BLOB or TEXT columns. You may find MySQL's string handling functions useful for working with such data. See Section 12.5, "String Functions". For security and other reasons, it is usually preferable to do so using application code rather than giving application users the FILE privilege. You can discuss specifics for various languages and platforms in the MySQL Forums (http://forums.mysql.com/).

11.4.4 The ENUM Type

An ENUM is a string object with a value chosen from a list of permitted values that are enumerated explicitly in the column specification at table creation time. It has these advantages:

- Compact data storage in situations where a column has a limited set of possible values. The strings you specify as input values are automatically encoded as numbers. See Section 11.7, "Data Type Storage Requirements" for the storage requirements for ENUM types.

- Readable queries and output. The numbers are translated back to the corresponding strings in query results.

and these potential issues to consider:

- If you make enumeration values that look like numbers, it is easy to mix up the literal values with their internal index numbers, as explained in Enumeration Limitations.

- Using ENUM columns in ORDER BY clauses requires extra care, as explained in Enumeration Sorting.

Creating and Using ENUM Columns

An enumeration value must be a quoted string literal. For example, you can create a table with an ENUM column like this:

```
CREATE TABLE shirts (
    name VARCHAR(40),
    size ENUM('x-small', 'small', 'medium', 'large', 'x-large')
);
```

`INSERT INTO shirts (name, size) VALUES ('dress shirt','large'), ('t-shirt','medium'), ('polo shirt','small');`

`SELECT name, size FROM shirts WHERE size = 'medium';`

```
+---------+--------+
<table>
<thead>
<tr>
<th>name</th>
<th>size</th>
</tr>
</thead>
<tbody>
<tr>
<td>t-shirt</td>
<td>medium</td>
</tr>
</tbody>
</table>
```

`UPDATE shirts SET size = 'small' WHERE size = 'large';`

COMMIT;

Inserting 1 million rows into this table with a value of 'medium' would require 1 million bytes of storage, as opposed to 6 million bytes if you stored the actual string 'medium' in a VARCHAR column.

Index Values for Enumeration Literals

Each enumeration value has an index:

- The elements listed in the column specification are assigned index numbers, beginning with 1.

- The index value of the empty string error value is 0. This means that you can use the following SELECT statement to find rows into which invalid ENUM values were assigned:
The ENUM Type

mysql> SELECT * FROM tbl_name WHERE enum_col=0;

• The index of the NULL value is NULL.

• The term “index” here refers to a position within the list of enumeration values. It has nothing to do with table indexes.

For example, a column specified as ENUM('Mercury', 'Venus', 'Earth') can have any of the values shown here. The index of each value is also shown.

<table>
<thead>
<tr>
<th>Value</th>
<th>Index</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL</td>
<td>NULL</td>
</tr>
<tr>
<td>''</td>
<td>0</td>
</tr>
<tr>
<td>'Mercury'</td>
<td>1</td>
</tr>
<tr>
<td>'Venus'</td>
<td>2</td>
</tr>
<tr>
<td>'Earth'</td>
<td>3</td>
</tr>
</tbody>
</table>

An ENUM column can have a maximum of 65,535 distinct elements. (The practical limit is less than 3000.) A table can have no more than 255 unique element list definitions among its ENUM and SET columns considered as a group. For more information on these limits, see Section C.7.5, “Limits Imposed by .frm File Structure”.

If you retrieve an ENUM value in a numeric context, the column value’s index is returned. For example, you can retrieve numeric values from an ENUM column like this:

mysql> SELECT enum_col + 0 FROM tbl_name;

Functions such as SUM() or AVG() that expect a numeric argument cast the argument to a number if necessary. For ENUM values, the index number is used in the calculation.

Handling of Enumeration Literals

Trailing spaces are automatically deleted from ENUM member values in the table definition when a table is created.

When retrieved, values stored into an ENUM column are displayed using the lettercase that was used in the column definition. Note that ENUM columns can be assigned a character set and collation. For binary or case-sensitive collations, lettercase is taken into account when assigning values to the column.

If you store a number into an ENUM column, the number is treated as the index into the possible values, and the value stored is the enumeration member with that index. (However, this does not work with LOAD DATA, which treats all input as strings.) If the numeric value is quoted, it is still interpreted as an index if there is no matching string in the list of enumeration values. For these reasons, it is not advisable to define an ENUM column with enumeration values that look like numbers, because this can easily become confusing. For example, the following column has enumeration members with string values of '0', '1', and '2', but numeric index values of 1, 2, and 3:

| numbers ENUM('0','1','2') |

If you store 2, it is interpreted as an index value, and becomes '1' (the value with index 2). If you store '2', it matches an enumeration value, so it is stored as '2'. If you store '3', it does not match any enumeration value, so it is treated as an index and becomes '2' (the value with index 3).

mysql> INSERT INTO t (numbers) VALUES(2),('2'),('3');
mysql> SELECT * FROM t;
To determine all possible values for an **ENUM** column, use `SHOW COLUMNS FROM tbl_name LIKE 'enum_col'` and parse the **ENUM** definition in the **Type** column of the output.

In the C API, **ENUM** values are returned as strings. For information about using result set metadata to distinguish them from other strings, see Section 21.8.5, "C API Data Structures".

**Empty or NULL Enumeration Values**

An enumeration value can also be the empty string ("") or **NULL** under certain circumstances:

- If you insert an invalid value into an **ENUM** (that is, a string not present in the list of permitted values), the empty string is inserted instead as a special error value. This string can be distinguished from a "normal" empty string by the fact that this string has the numeric value 0. See [Index Values for Enumeration Literals](#) for details about the numeric indexes for the enumeration values.

  If strict SQL mode is enabled, attempts to insert invalid **ENUM** values result in an error.

- If an **ENUM** column is declared to permit **NULL**, the **NULL** value is a valid value for the column, and the default value is **NULL**. If an **ENUM** column is declared **NOT NULL**, its default value is the first element of the list of permitted values.

**Enumeration Sorting**

**ENUM** values are sorted based on their index numbers, which depend on the order in which the enumeration members were listed in the column specification. For example, "b" sorts before "a" for `ENUM('b', 'a')`. The empty string sorts before nonempty strings, and **NULL** values sort before all other enumeration values.

To prevent unexpected results when using the `ORDER BY` clause on an **ENUM** column, use one of these techniques:

- Specify the **ENUM** list in alphabetic order.

- Make sure that the column is sorted lexically rather than by index number by coding `ORDER BY CAST(col AS CHAR)` or `ORDER BY CONCAT(col)`.

**Enumeration Limitations**

An enumeration value cannot be an expression, even one that evaluates to a string value.

For example, this `CREATE TABLE` statement does not work because the `CONCAT` function cannot be used to construct an enumeration value:

```sql
CREATE TABLE sizes (  
  size ENUM('small', CONCAT('med','ium'), 'large')
);  
```

You also cannot employ a user variable as an enumeration value. This pair of statements do not work:

```sql
SET @mysize = 'medium';
CREATE TABLE sizes (  
  size ENUM('small', @mysize, 'large')
);  
```
The SET Type

We strongly recommend that you do not use numbers as enumeration values, because it does not save on storage over the appropriate TINYINT or SMALLINT type, and it is easy to mix up the strings and the underlying number values (which might not be the same) if you quote the ENUM values incorrectly. If you do use a number as an enumeration value, always enclose it in quotation marks. If the quotation marks are omitted, the number is regarded as an index. See Handling of Enumeration Literals to see how even a quoted number could be mistakenly used as a numeric index value.

Duplicate values in the definition cause a warning, or an error if strict SQL mode is enabled.

11.4.5 The SET Type

A SET is a string object that can have zero or more values, each of which must be chosen from a list of permitted values specified when the table is created. SET column values that consist of multiple set members are specified with members separated by commas (","). A consequence of this is that SET member values should not themselves contain commas.

For example, a column specified as SET('one', 'two') NOT NULL can have any of these values:

- ''
- 'one'
- 'two'
- 'one,two'

A SET column can have a maximum of 64 distinct members. A table can have no more than 255 unique element list definitions among its ENUM and SET columns considered as a group. For more information on this limit, see Section C.7.5, "Limits Imposed by .frm File Structure".

Duplicate values in the definition cause a warning, or an error if strict SQL mode is enabled.

Trailing spaces are automatically deleted from SET member values in the table definition when a table is created.

When retrieved, values stored in a SET column are displayed using the lettercase that was used in the column definition. Note that SET columns can be assigned a character set and collation. For binary or case-sensitive collations, lettercase is taken into account when assigning values to the column.

MySQL stores SET values numerically, with the low-order bit of the stored value corresponding to the first set member. If you retrieve a SET value in a numeric context, the value retrieved has bits set corresponding to the set members that make up the column value. For example, you can retrieve numeric values from a SET column like this:

```
mysql> SELECT set_col+0 FROM tbl_name;
```

If a number is stored into a SET column, the bits that are set in the binary representation of the number determine the set members in the column value. For a column specified as SET('a','b','c','d'), the members have the following decimal and binary values.

<table>
<thead>
<tr>
<th>SET Member</th>
<th>Decimal Value</th>
<th>Binary Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'a'</td>
<td>1</td>
<td>0001</td>
</tr>
<tr>
<td>'b'</td>
<td>2</td>
<td>0010</td>
</tr>
<tr>
<td>'c'</td>
<td>4</td>
<td>0100</td>
</tr>
<tr>
<td>'d'</td>
<td>8</td>
<td>1000</td>
</tr>
</tbody>
</table>

If you assign a value of 9 to this column, that is 1001 in binary, so the first and fourth SET value members 'a' and 'd' are selected and the resulting value is 'a,d'.

For a value containing more than one SET element, it does not matter what order the elements are listed in when you insert the value. It also does not matter how many times a given element is listed in
the value. When the value is retrieved later, each element in the value appears once, with elements listed according to the order in which they were specified at table creation time. For example, suppose that a column is specified as `SET('a','b','c','d')`:

```sql
mysql> CREATE TABLE myset (col SET('a', 'b', 'c', 'd'));
```

If you insert the values 'a,d', 'd,a', 'a,d,d', 'a,d,a', and 'd,a,d':

```sql
mysql> INSERT INTO myset (col) VALUES
    +-----------+----------+----------------+
    | 'a,d'     | 'd,a'    | 'a,d,d'        |
    +-----------+----------+----------------+
    | 'a,d,a'   | 'd,a,d'  |                |
    +-----------+----------+----------------+
```

Query OK, 5 rows affected (0.01 sec)
Records: 5 Duplicates: 0 Warnings: 0

Then all these values appear as 'a,d' when retrieved:

```sql
mysql> SELECT col FROM myset;
+------+
| col  |
+------+
| a,d  |
| a,d  |
| a,d  |
| a,d  |
| a,d  |
+------+
5 rows in set (0.04 sec)
```

If you set a `SET` column to an unsupported value, the value is ignored and a warning is issued:

```sql
mysql> INSERT INTO myset (col) VALUES ('a,d,d,s');
Query OK, 1 row affected, 1 warning (0.03 sec)
```

```sql
mysql> SHOW WARNINGS;
+---------+------+------------------------------------------+
| Level   | Code | Message                                  |
+---------+------+------------------------------------------+
| Warning | 1265 | Data truncated for column 'col' at row 1 |
+---------+------+------------------------------------------+
1 row in set (0.04 sec)
```

```sql
mysql> SELECT col FROM myset;
+------+
| col  |
+------+
| a,d  |
| a,d  |
| a,d  |
| a,d  |
| a,d  |
| a,d  |
+------+
6 rows in set (0.01 sec)
```

If strict SQL mode is enabled, attempts to insert invalid `SET` values result in an error.

`SET` values are sorted numerically. `NULL` values sort before non-`NULL` `SET` values.

Functions such as `SUM()` or `AVG()` that expect a numeric argument cast the argument to a number if necessary. For `SET` values, the cast operation causes the numeric value to be used.

Normally, you search for `SET` values using the `FIND_IN_SET()` function or the `LIKE` operator:

```sql
mysql> SELECT * FROM tbl_name WHERE FIND_IN_SET('value', set_col)>0;
mysql> SELECT * FROM tbl_name WHERE set_col LIKE '%value%';
```
The first statement finds rows where `set_col` contains the `value` set member. The second is similar, but not the same: It finds rows where `set_col` contains `value` anywhere, even as a substring of another set member.

The following statements also are permitted:

```
mysql> SELECT * FROM tbl_name WHERE set_col & 1;
mysql> SELECT * FROM tbl_name WHERE set_col = 'val1,val2';
```

The first of these statements looks for values containing the first set member. The second looks for an exact match. Be careful with comparisons of the second type. Comparing set values to 'val1,val2' returns different results than comparing values to 'val2,val1'. You should specify the values in the same order they are listed in the column definition.

To determine all possible values for a SET column, use `SHOW COLUMNS FROM tbl_name LIKE set_col` and parse the SET definition in the `Type` column of the output.

In the C API, SET values are returned as strings. For information about using result set metadata to distinguish them from other strings, see Section 21.8.5, “C API Data Structures”.

### 11.5 Extensions for Spatial Data

The Open Geospatial Consortium (OGC) is an international consortium of more than 250 companies, agencies, and universities participating in the development of publicly available conceptual solutions that can be useful with all kinds of applications that manage spatial data.

The Open Geospatial Consortium publishes the *OpenGIS® Implementation Standard for Geographic information - Simple feature access - Part 2: SQL option*, a document that proposes several conceptual ways for extending an SQL RDBMS to support spatial data. This specification is available from the OGC Web site at [http://www.opengeospatial.org/standards/sfs](http://www.opengeospatial.org/standards/sfs).

Following the OGC specification, MySQL implements spatial extensions as a subset of the [SQL with Geometry Types](http://www.opengeospatial.org/standards/sfs) environment. This term refers to an SQL environment that has been extended with a set of geometry types. A geometry-valued SQL column is implemented as a column that has a geometry type. The specification describes a set of SQL geometry types, as well as functions on those types to create and analyze geometry values.

MySQL spatial extensions enable the generation, storage, and analysis of geographic features:

- Data types for representing spatial values
- Functions for manipulating spatial values
- Spatial indexing for improved access times to spatial columns

The data types and functions are available for MyISAM, InnoDB, NDB, and ARCHIVE tables. For indexing spatial columns, MyISAM supports both SPATIAL and non-SPATIAL indexes. The other storage engines support non-SPATIAL indexes, as described in Section 13.1.13, “CREATE INDEX Syntax”.

A geographic feature is anything in the world that has a location. A feature can be:

- An entity. For example, a mountain, a pond, a city.
- A space. For example, town district, the tropics.
- A definable location. For example, a crossroad, as a particular place where two streets intersect.

Some documents use the term geospatial feature to refer to geographic features.
Geometry is another word that denotes a geographic feature. Originally the word geometry meant measurement of the earth. Another meaning comes from cartography, referring to the geometric features that cartographers use to map the world.

The discussion here considers these terms synonymous: geographic feature, geospatial feature, feature, or geometry. The term most commonly used is geometry, defined as a point or an aggregate of points representing anything in the world that has a location.

The following material covers these topics:

- The spatial data types implemented in MySQL model
- The basis of the spatial extensions in the OpenGIS geometry model
- Data formats for representing spatial data
- How to use spatial data in MySQL
- Use of indexing for spatial data
- MySQL differences from the OpenGIS specification

For information about functions that operate on spatial data, see Section 12.15, “Spatial Analysis Functions”.

MySQL GIS Conformance and Compatibility

MySQL does not implement the following GIS features:

- Additional Metadata Views

  OpenGIS specifications propose several additional metadata views. For example, a system view named GEOMETRY_COLUMNS contains a description of geometry columns, one row for each geometry column in the database.

- The OpenGIS function Length() on LineString and MultiLineString should be called in MySQL as GLength()

  The problem is that there is an existing SQL function Length() that calculates the length of string values, and sometimes it is not possible to distinguish whether the function is called in a textual or spatial context.

Additional Resources

- The Open Geospatial Consortium publishes the OpenGIS® Implementation Standard for Geographic information - Simple feature access - Part 2: SQL option, a document that proposes several conceptual ways for extending an SQL RDBMS to support spatial data. The Open Geospatial Consortium (OGC) maintains a Web site at http://www.opengeospatial.org/. The specification is available there at http://www.opengeospatial.org/standards/sfs. It contains additional information relevant to the material here.

- If you have questions or concerns about the use of the spatial extensions to MySQL, you can discuss them in the GIS forum: http://forums.mysql.com/list.php?23.

11.5.1 Spatial Data Types

MySQL has data types that correspond to OpenGIS classes. Some of these types hold single geometry values:

- GEOMETRY
- POINT
The OpenGIS Geometry Model

- **LINESTRING**
- **POLYGON**

**GEOMETRY** can store geometry values of any type. The other single-value types (**POINT, LINESTRING, and POLYGON**) restrict their values to a particular geometry type.

The other data types hold collections of values:

- **MULTIPOINT**
- **MULTILINESTRING**
- **MULTIPOLYGON**
- **GEOMETRYCOLLECTION**

**GEOMETRYCOLLECTION** can store a collection of objects of any type. The other collection types (**MULTIPOINT, MULTILINESTRING, MULTIPOLYGON, and GEOMETRYCOLLECTION**) restrict collection members to those having a particular geometry type.

MySQL spatial data types have their basis in the OpenGIS geometry model, described in Section 11.5.2, “The OpenGIS Geometry Model”. For examples showing how to use spatial data types in MySQL, see Section 11.5.3, “Using Spatial Data”.

### 11.5.2 The OpenGIS Geometry Model

The set of geometry types proposed by OGC's **SQL with Geometry Types** environment is based on the **OpenGIS Geometry Model**. In this model, each geometric object has the following general properties:

- It is associated with a Spatial Reference System, which describes the coordinate space in which the object is defined.
- It belongs to some geometry class.

#### 11.5.2.1 The Geometry Class Hierarchy

The geometry classes define a hierarchy as follows:

- **Geometry** (noninstantiable)
  - **Point** (instantiable)
  - **Curve** (noninstantiable)
    - **LineString** (instantiable)
      - **Line**
      - **LinearRing**
  - **Surface** (noninstantiable)
    - **Polygon** (instantiable)
    - **GeometryCollection** (instantiable)
      - **MultiPoint** (instantiable)
      - **MultiCurve** (noninstantiable)
      - **MultiLineString** (instantiable)
• **MultiSurface** (noninstantiable)

• **MultiPolygon** (instantiable)

It is not possible to create objects in noninstantiable classes. It is possible to create objects in instantiable classes. All classes have properties, and instantiable classes may also have assertions (rules that define valid class instances).

**Geometry** is the base class. It is an abstract class. The instantiable subclasses of Geometry are restricted to zero-, one-, and two-dimensional geometric objects that exist in two-dimensional coordinate space. All instantiable geometry classes are defined so that valid instances of a geometry class are topologically closed (that is, all defined geometries include their boundary).

The base **Geometry** class has subclasses for **Point**, **Curve**, **Surface**, and **GeometryCollection**:

• **Point** represents zero-dimensional objects.

• **Curve** represents one-dimensional objects, and has subclass **LineString**, with sub-subclasses **Line** and **LinearRing**.

• **Surface** is designed for two-dimensional objects and has subclass **Polygon**.

• **GeometryCollection** has specialized zero-, one-, and two-dimensional collection classes named **MultiPoint**, **MultiLineString**, and **MultiPolygon** for modeling geometries corresponding to collections of **Points**, **LineStrings**, and **Polygons**, respectively. **MultiCurve** and **MultiSurface** are introduced as abstract superclasses that generalize the collection interfaces to handle **Curves** and **Surfaces**.

**Geometry**, **Curve**, **Surface**, **MultiCurve**, and **MultiSurface** are defined as noninstantiable classes. They define a common set of methods for their subclasses and are included for extensibility.

**Point**, **LineString**, **Polygon**, **GeometryCollection**, **MultiPoint**, **MultiLineString**, and **MultiPolygon** are instantiable classes.

### 11.5.2.2 Geometry Class

**Geometry** is the root class of the hierarchy. It is a noninstantiable class but has a number of properties, described in the following list, that are common to all geometry values created from any of the **Geometry** subclasses. Particular subclasses have their own specific properties, described later.

**Geometry Properties**

A geometry value has the following properties:

• Its **type**. Each geometry belongs to one of the instantiable classes in the hierarchy.

• Its **SRID**, or Spatial Reference Identifier. This value identifies the geometry's associated Spatial Reference System that describes the coordinate space in which the geometry object is defined.

  In MySQL, the SRID value is an integer associated with the geometry value. All calculations are done assuming Euclidean (planar) geometry. The maximum usable SRID value is $2^{32} - 1$. If a larger value is given, only the lower 32 bits are used.

• Its **coordinates** in its Spatial Reference System, represented as double-precision (8-byte) numbers. All nonempty geometries include at least one pair of $(X,Y)$ coordinates. Empty geometries contain no coordinates.

  Coordinates are related to the SRID. For example, in different coordinate systems, the distance between two objects may differ even when objects have the same coordinates, because the distance on the **planar** coordinate system and the distance on the **geodetic** system (coordinates on the Earth's surface) are different things.
• Its interior, boundary, and exterior.

Every geometry occupies some position in space. The exterior of a geometry is all space not occupied by the geometry. The interior is the space occupied by the geometry. The boundary is the interface between the geometry’s interior and exterior.

• Its MBR (minimum bounding rectangle), or envelope. This is the bounding geometry, formed by the minimum and maximum (X,Y) coordinates:

\[
(\text{MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY})
\]

• Whether the value is simple or nonsimple. Geometry values of types (LineString, MultiPoint, MultiLineString) are either simple or nonsimple. Each type determines its own assertions for being simple or nonsimple.

• Whether the value is closed or not closed. Geometry values of types (LineString, MultiString) are either closed or not closed. Each type determines its own assertions for being closed or not closed.

• Whether the value is empty or nonempty. A geometry is empty if it does not have any points. Exterior, interior, and boundary of an empty geometry are not defined (that is, they are represented by a NULL value). An empty geometry is defined to be always simple and has an area of 0.

• Its dimension. A geometry can have a dimension of −1, 0, 1, or 2:
  • −1 for an empty geometry.
  • 0 for a geometry with no length and no area.
  • 1 for a geometry with nonzero length and zero area.
  • 2 for a geometry with nonzero area.

  **Point** objects have a dimension of zero. **LineString** objects have a dimension of 1. **Polygon** objects have a dimension of 2. The dimensions of **MultiPoint**, **MultiLineString**, and **MultiPolygon** objects are the same as the dimensions of the elements they consist of.

### 11.5.2.3 Point Class

A **Point** is a geometry that represents a single location in coordinate space.

**Point** Examples

• Imagine a large-scale map of the world with many cities. A **Point** object could represent each city.

• On a city map, a **Point** object could represent a bus stop.

**Point** Properties

• X-coordinate value.

• Y-coordinate value.

**Point** is defined as a zero-dimensional geometry.

• The boundary of a **Point** is the empty set.

### 11.5.2.4 Curve Class

A **Curve** is a one-dimensional geometry, usually represented by a sequence of points. Particular subclasses of **Curve** define the type of interpolation between points. **Curve** is a noninstantiable class.
**Curve Properties**

- A *Curve* has the coordinates of its points.
- A *Curve* is defined as a one-dimensional geometry.
- A *Curve* is simple if it does not pass through the same point twice, with the exception that a curve can still be simple if the start and end points are the same.
- A *Curve* is closed if its start point is equal to its endpoint.
- The boundary of a closed *Curve* is empty.
- The boundary of a nonclosed *Curve* consists of its two endpoints.
- A *Curve* that is simple and closed is a *LinearRing*.

**11.5.2.5 LineString Class**

A *LineString* is a *Curve* with linear interpolation between points.

**LineString Examples**

- On a world map, *LineString* objects could represent rivers.
- In a city map, *LineString* objects could represent streets.

**LineString Properties**

- A *LineString* has coordinates of segments, defined by each consecutive pair of points.
- A *LineString* is a *Line* if it consists of exactly two points.
- A *LineString* is a *LinearRing* if it is both closed and simple.

**11.5.2.6 Surface Class**

A *Surface* is a two-dimensional geometry. It is a noninstantiable class. Its only instantiable subclass is *Polygon*.

**Surface Properties**

- A *Surface* is defined as a two-dimensional geometry.
- The OpenGIS specification defines a simple *Surface* as a geometry that consists of a single “patch” that is associated with a single exterior boundary and zero or more interior boundaries.
- The boundary of a simple *Surface* is the set of closed curves corresponding to its exterior and interior boundaries.

**11.5.2.7 Polygon Class**

A *Polygon* is a planar *Surface* representing a multisided geometry. It is defined by a single exterior boundary and zero or more interior boundaries, where each interior boundary defines a hole in the *Polygon*.

**Polygon Examples**

- On a region map, *Polygon* objects could represent forests, districts, and so on.

**Polygon Assertions**

- The boundary of a *Polygon* consists of a set of *LinearRing* objects (that is, *LineString* objects that are both simple and closed) that make up its exterior and interior boundaries.
• A **Polygon** has no rings that cross. The rings in the boundary of a **Polygon** may intersect at a **Point**, but only as a tangent.

• A **Polygon** has no lines, spikes, or punctures.

• A **Polygon** has an interior that is a connected point set.

• A **Polygon** may have holes. The exterior of a **Polygon** with holes is not connected. Each hole defines a connected component of the exterior.

The preceding assertions make a **Polygon** a simple geometry.

### 11.5.2.8 GeometryCollection Class

A **GeometryCollection** is a geometry that is a collection of one or more geometries of any class. All the elements in a **GeometryCollection** must be in the same Spatial Reference System (that is, in the same coordinate system). There are no other constraints on the elements of a **GeometryCollection**, although the subclasses of **GeometryCollection** described in the following sections may restrict membership. Restrictions may be based on:

• Element type (for example, a **MultiPoint** may contain only **Point** elements)

• Dimension

• Constraints on the degree of spatial overlap between elements

### 11.5.2.9 MultiPoint Class

A **MultiPoint** is a geometry collection composed of **Point** elements. The points are not connected or ordered in any way.

**MultiPoint** Examples

• On a world map, a **MultiPoint** could represent a chain of small islands.

• On a city map, a **MultiPoint** could represent the outlets for a ticket office.

**MultiPoint** Properties

• A **MultiPoint** is a zero-dimensional geometry.

• A **MultiPoint** is simple if no two of its **Point** values are equal (have identical coordinate values).

• The boundary of a **MultiPoint** is the empty set.

### 11.5.2.10 MultiCurve Class

A **MultiCurve** is a geometry collection composed of **Curve** elements. **MultiCurve** is a noninstantiable class.

**MultiCurve** Properties

• A **MultiCurve** is a one-dimensional geometry.

• A **MultiCurve** is simple if and only if all of its elements are simple; the only intersections between any two elements occur at points that are on the boundaries of both elements.

• A **MultiCurve** boundary is obtained by applying the “mod 2 union rule” (also known as the “odd-even rule”): A point is in the boundary of a **MultiCurve** if it is in the boundaries of an odd number of **Curve** elements.

• A **MultiCurve** is closed if all of its elements are closed.
• The boundary of a closed MultiCurve is always empty.

11.5.2.11 MultiLineString Class

A MultiLineString is a MultiCurve geometry collection composed of LineString elements.

MultiLineString Examples

• On a region map, a MultiLineString could represent a river system or a highway system.

11.5.2.12 MultiSurface Class

A MultiSurface is a geometry collection composed of surface elements. MultiSurface is a noninstantiable class. Its only instantiable subclass is MultiPolygon.

MultiSurface Assertions

• Surfaces within a MultiSurface have no interiors that intersect.
• Surfaces within a MultiSurface have boundaries that intersect at most at a finite number of points.

11.5.2.13 MultiPolygon Class

A MultiPolygon is a MultiSurface object composed of Polygon elements.

MultiPolygon Examples

• On a region map, a MultiPolygon could represent a system of lakes.

MultiPolygon Assertions

• A MultiPolygon has no two Polygon elements with interiors that intersect.
• A MultiPolygon has no two Polygon elements that cross (crossing is also forbidden by the previous assertion), or that touch at an infinite number of points.
• A MultiPolygon may not have cut lines, spikes, or punctures. A MultiPolygon is a regular, closed point set.
• A MultiPolygon that has more than one Polygon has an interior that is not connected. The number of connected components of the interior of a MultiPolygon is equal to the number of Polygon values in the MultiPolygon.

MultiPolygon Properties

• A MultiPolygon is a two-dimensional geometry.
• A MultiPolygon boundary is a set of closed curves (LineString values) corresponding to the boundaries of its Polygon elements.
• Each Curve in the boundary of the MultiPolygon is in the boundary of exactly one Polygon element.
• Every Curve in the boundary of an Polygon element is in the boundary of the MultiPolygon.

11.5.3 Using Spatial Data

This section describes how to create tables that include spatial data type columns, and how to manipulate spatial information.

11.5.3.1 Supported Spatial Data Formats

Two standard spatial data formats are used to represent geometry objects in queries:
• Well-Known Text (WKT) format

• Well-Known Binary (WKB) format

Internally, MySQL stores geometry values in a format that is not identical to either WKT or WKB format. There are functions available to convert between different data formats; see Section 12.15.6, “Geometry Format Conversion Functions”.

Well-Known Text (WKT) Format

The Well-Known Text (WKT) representation of geometry values is designed for exchanging geometry data in ASCII form. The OpenGIS specification provides a Backus-Naur grammar that specifies the formal production rules for writing WKT values (see Section 11.5, “Extensions for Spatial Data”).

Examples of WKT representations of geometry objects:

• A Point:

\[
\text{POINT}(15 \ 20)
\]

The point coordinates are specified with no separating comma. This differs from the syntax for the SQL \texttt{Point()} function, which requires a comma between the coordinates. Take care to use the syntax appropriate to the context of a given spatial operation. For example, the following statements both extract the X-coordinate from a \texttt{Point} object. The first produces the object directly using the \texttt{Point()} function. The second uses a WKT representation converted to a \texttt{Point} with \texttt{GeomFromText()}.

```sql
mysql> SELECT X(Point(15, 20));
+------------------+
| X(POINT(15, 20)) |
+------------------+
|    15            |
+------------------+

mysql> SELECT X(GeomFromText('POINT(15 20)'));
+---------------------------------+
| X(GeomFromText('POINT(15 20)')) |
+---------------------------------+
|        15                      |
+---------------------------------+
```

• A LineString with four points:

\[
\text{LINESTRING}(0 \ 0, 10 \ 10, 20 \ 25, 50 \ 60)
\]

The point coordinate pairs are separated by commas.

• A Polygon with one exterior ring and one interior ring:

\[
\text{POLYGON}((0 \ 0,10 \ 0,10 \ 0,0 \ 10,0 \ 0),(5 \ 5,5 \ 7,7 \ 5, 5 \ 5))
\]

• A MultiPoint with three Point values:

\[
\text{MULTIPOINT}(0 \ 0, 20 \ 20, 60 \ 60)
\]

• A MultiLineString with two LineString values:

\[
\text{MULTILINESTRING}((10 \ 10, 20 \ 20), (15 \ 15, 30 \ 15))
\]

• A MultiPolygon with two Polygon values:
MULTIPOLYGON(((0 0,10 0,10 10,0 10,0 0)),((5 5,7 5,7 7,5 7, 5 5)))

- A GeometryCollection consisting of two Point values and one LineString:

GEOMETRYCOLLECTION(POINT(10 10), POINT(30 30), LINESTRING(15 15, 20 20))

Well-Known Binary (WKB) Format

The Well-Known Binary (WKB) representation of geometric values is used for exchanging geometry data as binary streams represented by BLOB values containing geometric WKB information. This format is defined by the OpenGIS specification (see Section 11.5, “Extensions for Spatial Data”). It is also defined in the ISO SQL/MM Part 3: Spatial standard.

WKB uses 1-byte unsigned integers, 4-byte unsigned integers, and 8-byte double-precision numbers (IEEE 754 format). A byte is eight bits.

For example, a WKB value that corresponds to POINT(1 1) consists of this sequence of 21 bytes, each represented by two hex digits:

0101000000000000000000F03F00000000000F03F

The sequence consists of these components:

- The byte order is either 1 or 0 to indicate little-endian or big-endian storage. The little-endian and big-endian byte orders are also known as Network Data Representation (NDR) and External Data Representation (XDR), respectively.

- The WKB type is a code that indicates the geometry type. Values from 1 through 7 indicate Point, LineString, Polygon, MultiPoint, MultiLineString, MultiPolygon, and GeometryCollection.

- A Point value has X and Y coordinates, each represented as a double-precision value.

WKB values for more complex geometry values have more complex data structures, as detailed in the OpenGIS specification.

11.5.3.2 Creating Spatial Columns

MySQL provides a standard way of creating spatial columns for geometry types, for example, with CREATE TABLE or ALTER TABLE. Spatial columns are supported for MyISAM, InnoDB, NDB, and ARCHIVE tables. See also the notes about spatial indexes under Section 11.5.3.6, “Creating Spatial Indexes”.

- Use the CREATE TABLE statement to create a table with a spatial column:

CREATE TABLE geom (g GEOMETRY);

- Use the ALTER TABLE statement to add or drop a spatial column to or from an existing table:

ALTER TABLE geom ADD pt POINT;
ALTER TABLE geom DROP pt;
11.5.3.3 Populating Spatial Columns

After you have created spatial columns, you can populate them with spatial data. Values should be stored in internal geometry format, but you can convert them to that format from either Well-Known Text (WKT) or Well-Known Binary (WKB) format. The following examples demonstrate how to insert geometry values into a table by converting WKT values to internal geometry format:

- Perform the conversion directly in the `INSERT` statement:

  ```sql
  INSERT INTO geom VALUES (GeomFromText('POINT(1 1)'));
  SET @g = 'POINT(1 1)';
  INSERT INTO geom VALUES (GeomFromText(@g));
  ```

- Perform the conversion prior to the `INSERT`:

  ```sql
  SET @g = GeomFromText('POINT(1 1)');
  INSERT INTO geom VALUES (@g);
  ```

The following examples insert more complex geometries into the table:

```sql
SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (GeomFromText(@g));

SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7,5 5))';
INSERT INTO geom VALUES (GeomFromText(@g));

SET @g = 'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0 0,1 1,2 2,3 3,4 4))';
INSERT INTO geom VALUES (GeomFromText(@g));
```

The preceding examples use `GeomFromText()` to create geometry values. You can also use type-specific functions:

```sql
SET @g = 'POINT(1 1)';
INSERT INTO geom VALUES (PointFromText(@g));

SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (LineStringFromText(@g));

SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7,5 5))';
INSERT INTO geom VALUES (PolygonFromText(@g));

SET @g = 'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0,1,2,3,4))';
INSERT INTO geom VALUES (GeomCollFromText(@g));
```

A client application program that wants to use WKB representations of geometry values is responsible for sending correctly formed WKB in queries to the server. There are several ways to satisfy this requirement. For example:

- Inserting a `POINT(1 1)` value with hex literal syntax:

  ```sql
  mysql> INSERT INTO geom VALUES
  -> (GeomFromWKB(0x0101000000000000000000F03F00000000000F03F));
  ```

- An ODBC application can send a WKB representation, binding it to a placeholder using an argument of `BLOB` type:

  ```sql
  INSERT INTO geom VALUES (GeomFromWKB(?))
  ```
Other programming interfaces may support a similar placeholder mechanism.

- In a C program, you can escape a binary value using `mysql_real_escape_string()` and include the result in a query string that is sent to the server. See Section 21.8.7.53, “mysql_real_escape_string()”.

### 11.5.3.4 Fetching Spatial Data

Geometry values stored in a table can be fetched in internal format. You can also convert them to WKT or WKB format.

- **Fetching spatial data in internal format:**

  Fetching geometry values using internal format can be useful in table-to-table transfers:

  ```sql
  CREATE TABLE geom2 (g GEOMETRY) SELECT g FROM geom;
  ```

- **Fetching spatial data in WKT format:**

  The `AsText()` function converts a geometry from internal format to a WKT string.

  ```sql
  SELECT AsText(g) FROM geom;
  ```

- **Fetching spatial data in WKB format:**

  The `AsBinary()` function converts a geometry from internal format to a `BLOB` containing the WKB value.

  ```sql
  SELECT AsBinary(g) FROM geom;
  ```

### 11.5.3.5 Optimizing Spatial Analysis

For `MyISAM` tables, search operations in columns containing spatial data can be optimized using `SPATIAL` indexes. The most typical operations are:

- Point queries that search for all objects that contain a given point
- Region queries that search for all objects that overlap a given region

MySQL uses **R-Trees with quadratic splitting** for `SPATIAL` indexes on spatial columns. A `SPATIAL` index is built using the minimum bounding rectangle (MBR) of a geometry. For most geometries, the MBR is a minimum rectangle that surrounds the geometries. For a horizontal or a vertical linestring, the MBR is a rectangle degenerated into the linestring. For a point, the MBR is a rectangle degenerated into the point.

It is also possible to create normal indexes on spatial columns. In a non-`SPATIAL` index, you must declare a prefix for any spatial column except for `POINT` columns.

`MyISAM` supports both `SPATIAL` and non-`SPATIAL` indexes. Other storage engines support non-`SPATIAL` indexes, as described in Section 13.1.13, “CREATE INDEX Syntax”.

### 11.5.3.6 Creating Spatial Indexes

For `MyISAM` tables, MySQL can create spatial indexes using syntax similar to that for creating regular indexes, but using the `SPATIAL` keyword. Columns in spatial indexes must be declared `NOT NULL`.

The following examples demonstrate how to create spatial indexes:

- **With CREATE TABLE:**
CREATE TABLE geom (g GEOMETRY NOT NULL, SPATIAL INDEX(g) ENGINE=MyISAM);

- With **ALTER TABLE**:
  
  ALTER TABLE geom ADD SPATIAL INDEX(g);

- With **CREATE INDEX**:
  
  CREATE SPATIAL INDEX sp_index ON geom (g);

**SPATIAL INDEX** creates an R-tree index. For storage engines that support nonspatial indexing of spatial columns, the engine creates a B-tree index. A B-tree index on spatial values is useful for exact-value lookups, but not for range scans.

For more information on indexing spatial columns, see Section 13.1.13, “CREATE INDEX Syntax”.

To drop spatial indexes, use **ALTER TABLE** or **DROP INDEX**:

- With **ALTER TABLE**:
  
  ALTER TABLE geom DROP INDEX g;

- With **DROP INDEX**:
  
  DROP INDEX sp_index ON geom;

Example: Suppose that a table `geom` contains more than 32,000 geometries, which are stored in the column `g` of type `GEOMETRY`. The table also has an `AUTO_INCREMENT` column `fid` for storing object ID values.

```
mysql> DESCRIBE geom;
+-------+----------+------+-----+---------+----------------+
| Field | Type     | Null | Key | Default | Extra          |
+-------+----------+------+-----+---------+----------------+
| fid   | int(11)  |      | PRI | NULL    | auto_increment |
| g     | geometry |      |     |         |                |
+-------+----------+------+-----+---------+----------------+
2 rows in set (0.00 sec)
```

```
mysql> SELECT COUNT(*) FROM geom;
+----------+
| count(*) |
+----------+
|    32376 |
+----------+
1 row in set (0.00 sec)
```

To add a spatial index on the column `g`, use this statement:

```
mysql> ALTER TABLE geom ADD SPATIAL INDEX(g) ENGINE=MyISAM;
Query OK, 32376 rows affected (4.05 sec)
Records: 32376  Duplicates: 0  Warnings: 0
```

### 11.5.3.7 Using Spatial Indexes

The optimizer investigates whether available spatial indexes can be involved in the search for queries that use a function such as `MBRContains()` or `MBRWithin()` in the **WHERE** clause. The following query finds all objects that are in the given rectangle:

```
mysql> SET @poly =
    -> 'Polygon((30000 15000,
```
Using Spatial Data

```sql
mysql> SET @poly = 'Polygon((30000 15000, 31000 15000, 31000 16000, 30000 16000, 30000 15000))';

mysql> SELECT fid, AsText(geom) FROM geom WHERE MBRContains(GeomFromText(@poly), geom);

+----+---------------------------------------------------------------+
| fid | AsText(geom)                                                     |
+----+---------------------------------------------------------------+
|   1 | LINESTRING(30250.4 15129.2, 30248.8 15138.4, 30238.2 15136, ... |
|   2 | LINESTRING(30220.2 15122.8, 30217.2 15137.8, 30207.6 15136, ... |
|   3 | LINESTRING(30179 15114.4, 30176.6 15129.4, 30167 15128, 3016 ... |
|   4 | LINESTRING(30155 15121.4, 30140.4 15118.6, 30142 15109.3, 301 ... |
|   5 | LINESTRING(30192 15085, 30177.6 15082.2, 30179.2 15072.4, 301 ... |
|   6 | LINESTRING(30244 15087, 30229 15086.2, 30229.4 15076.4, 3022 ... |
|   7 | LINESTRING(30200 15059.4, 30185.6 15058.6, 30186 15048.8, 301 ... |
|  10 | LINESTRING(30179.6 15017.8, 30181 15020.8, 30190.8 15030.6, 301 ... |
|  11 | LINESTRING(30154.2 15000.4, 30168.6 15004.8, 30166 15014.2, 301 ... |
|  13 | LINESTRING(30105 15065.8, 30108.4 15050.8, 30118 15053.3, 301 ... |
|  154 | LINESTRING(30276.2 15143.8, 30261.4 15141, 30263 15131.4, 301 ... |
|  155 | LINESTRING(30269.8 15084, 30269.4 15093.4, 30258.6 15093, 301 ... |
|  157 | LINESTRING(30128.2 15011, 30113.2 15010.2, 30113.6 15000.4, 300 ... |
+----+---------------------------------------------------------------+
20 rows in set (0.00 sec)

Use `EXPLAIN` to check the way this query is executed:

```sql
mysql> SET @poly = 'Polygon((30000 15000, 31000 15000, 31000 16000, 30000 16000, 30000 15000))';

mysql> EXPLAIN SELECT fid, AsText(geom) FROM geom WHERE MBRContains(GeomFromText(@poly), geom)

*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: geom
type: range
possible_keys: g
key: g
key_len: 32
ref: NULL
rows: 50
Extra: Using where
1 row in set (0.00 sec)

Check what would happen without a spatial index:

```sql
mysql> SET @poly = 'Polygon((30000 15000, 31000 15000, 31000 16000, 30000 16000, 30000 15000))';

mysql> EXPLAIN SELECT fid, AsText(geom) FROM geom WHERE MBRContains(GeomFromText(@poly), geom) IGNORE INDEX (g)

*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: geom
type: ALL
```
11.6 Data Type Default Values

The `DEFAULT value` clause in a data type specification indicates a default value for a column. With one exception, the default value must be a constant; it cannot be a function or an expression. This means, for example, that you cannot set the default for a date column to be the value of a function such as `NOW()` or `CURRENT_DATE`. The exception is that you can specify `CURRENT_TIMESTAMP` as the default for a `TIMESTAMP` column. See Section 11.3.5, "Automatic Initialization and Updating for TIMESTAMP".

`BLOB` and `TEXT` columns cannot be assigned a default value.

If a column definition includes no explicit `DEFAULT` value, MySQL determines the default value as follows:

If the column can take `NULL` as a value, the column is defined with an explicit `DEFAULT NULL` clause.

If the column cannot take `NULL` as the value, MySQL defines the column with no explicit `DEFAULT` clause. Exception: If the column is defined as part of a `PRIMARY KEY` but not explicitly as `NOT NULL`, MySQL creates it as a `NOT NULL` column (because `PRIMARY KEY` columns must be `NOT NULL`), but also assigns it a `DEFAULT` clause using the implicit default value. To prevent this, include an explicit `NOT NULL` in the definition of any `PRIMARY KEY` column.
For data entry into a `NOT NULL` column that has no explicit `DEFAULT` clause, if an `INSERT` or `REPLACE` statement includes no value for the column, or an `UPDATE` statement sets the column to `NULL`, MySQL handles the column according to the SQL mode in effect at the time:

- If strict SQL mode is enabled, an error occurs for transactional tables and the statement is rolled back. For nontransactional tables, an error occurs, but if this happens for the second or subsequent row of a multiple-row statement, the preceding rows will have been inserted.

- If strict mode is not enabled, MySQL sets the column to the implicit default value for the column data type.

Suppose that a table `t` is defined as follows:

```sql
CREATE TABLE t (i INT NOT NULL);
```

In this case, `i` has no explicit default, so in strict mode each of the following statements produce an error and no row is inserted. When not using strict mode, only the third statement produces an error; the implicit default is inserted for the first two statements, but the third fails because `DEFAULT(i)` cannot produce a value:

```sql
INSERT INTO t VALUES();
INSERT INTO t VALUES(DEFAULT);
INSERT INTO t VALUES(DEFAULT(i));
```

See Section 5.1.7, “Server SQL Modes”.

For a given table, you can use the `SHOW CREATE TABLE` statement to see which columns have an explicit `DEFAULT` clause.

Implicit defaults are defined as follows:

- For numeric types, the default is `0`, with the exception that for integer or floating-point types declared with the `AUTO_INCREMENT` attribute, the default is the next value in the sequence.

- For date and time types other than `TIMESTAMP`, the default is the appropriate “zero” value for the type. For the first `TIMESTAMP` column in a table, the default value is the current date and time. See Section 11.3, “Date and Time Types”.

- For string types other than `ENUM`, the default value is the empty string. For `ENUM`, the default is the first enumeration value.

`SERIAL DEFAULT VALUE` in the definition of an integer column is an alias for `NOT NULL AUTO_INCREMENT UNIQUE`.

### 11.7 Data Type Storage Requirements

The storage requirements for data vary, according to the storage engine being used for the table in question. Different storage engines use different methods for recording the raw data and different data types. In addition, some engines may compress the information in a given row, either on a column or entire row basis, making calculation of the storage requirements for a given table or column structure.

However, all storage engines must communicate and exchange information on a given row within a table using the same structure, and this information is consistent, irrespective of the storage engine used to write the information to disk.

This sections includes some guidelines and information for the storage requirements for each data type supported by MySQL, including details for the internal format and the sizes used by storage engines that used a fixed size representation for different types. Information is listed by category or storage engine.
The internal representation of a table has a maximum row size of 65,535 bytes, even if the storage engine is capable of supporting larger rows. This figure excludes BLOB or TEXT columns, which contribute only 9 to 12 bytes toward this size. For BLOB and TEXT data, the information is stored internally in a different area of memory than the row buffer. Different storage engines handle the allocation and storage of this data in different ways, according to the method they use for handling the corresponding types. For more information, see Chapter 14, Storage Engines, and Section C.7.4, “Limits on Table Column Count and Row Size”.

Storage Requirements for InnoDB Tables

See Physical Row Structure for information about storage requirements for InnoDB tables.

Storage Requirements for NDBCLUSTER Tables

Important

For tables using the NDBCLUSTER storage engine, there is the factor of 4-byte alignment to be taken into account when calculating storage requirements. This means that all NDB data storage is done in multiples of 4 bytes. Thus, a column value that would take 15 bytes in a table using a storage engine other than NDB requires 16 bytes in an NDB table. This requirement applies in addition to any other considerations that are discussed in this section. For example, in NDBCLUSTER tables, the TINYINT, SMALLINT, MEDIUMINT, and INTEGER (INT) column types each require 4 bytes storage per record due to the alignment factor.

An exception to this rule is the BIT type, which is not 4-byte aligned. In MySQL Cluster tables, a BIT(M) column takes M bits of storage space. However, if a table definition contains 1 or more BIT columns (up to 32 BIT columns), then NDBCLUSTER reserves 4 bytes (32 bits) per row for these. If a table definition contains more than 32 BIT columns (up to 64 such columns), then NDBCLUSTER reserves 8 bytes (that is, 64 bits) per row.

In addition, while a NULL itself does not require any storage space, NDBCLUSTER reserves 4 bytes per row if the table definition contains any columns defined as NULL, up to 32 NULL columns. (If a MySQL Cluster table is defined with more than 32 NULL columns up to 64 NULL columns, then 8 bytes per row is reserved.)

When calculating storage requirements for MySQL Cluster tables, you must also remember that every table using the NDBCLUSTER storage engine requires a primary key; if no primary key is defined by the user, then a “hidden” primary key will be created by NDB. This hidden primary key consumes 31-35 bytes per table record.

You may find the ndb_size.pl utility to be useful for estimating NDB storage requirements. This Perl script connects to a current MySQL (non-Cluster) database and creates a report on how much space that database would require if it used the NDBCLUSTER storage engine. See Section 17.4.24, “ndb_size.pl — NDBCLUSTER Size Requirement Estimator”, for more information.

Storage Requirements for Numeric Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Storage Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>TINYINT</td>
<td>1 byte</td>
</tr>
<tr>
<td>SMALLINT</td>
<td>2 bytes</td>
</tr>
<tr>
<td>MEDIUMINT</td>
<td>3 bytes</td>
</tr>
<tr>
<td>INT, INTEGER</td>
<td>4 bytes</td>
</tr>
</tbody>
</table>
### Storage Requirements for Date and Time Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Storage Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIGINT</td>
<td>8 bytes</td>
</tr>
<tr>
<td>FLOAT ((p))</td>
<td>4 bytes if 0 &lt;= (p) &lt;= 24, 8 bytes if 25 &lt;= (p) &lt;= 53</td>
</tr>
<tr>
<td>FLOAT</td>
<td>4 bytes</td>
</tr>
<tr>
<td>DOUBLE ([\text{PRECISION}], \text{REAL})</td>
<td>8 bytes</td>
</tr>
<tr>
<td>DECIMAL ((M, D)), NUMERIC ((M, D))</td>
<td>Varies; see following discussion</td>
</tr>
<tr>
<td>BIT ((M))</td>
<td>approximately ((M+7)/8) bytes</td>
</tr>
</tbody>
</table>

Values for DECIMAL (and NUMERIC) columns are represented using a binary format that packs nine decimal (base 10) digits into four bytes. Storage for the integer and fractional parts of each value are determined separately. Each multiple of nine digits requires four bytes, and the “leftover” digits require some fraction of four bytes. The storage required for excess digits is given by the following table.

<table>
<thead>
<tr>
<th>Leftover Digits</th>
<th>Number of Bytes</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
</tr>
<tr>
<td>4</td>
<td>2</td>
</tr>
<tr>
<td>5</td>
<td>3</td>
</tr>
<tr>
<td>6</td>
<td>3</td>
</tr>
<tr>
<td>7</td>
<td>4</td>
</tr>
<tr>
<td>8</td>
<td>4</td>
</tr>
</tbody>
</table>

### Storage Requirements for String Types

In the following table, \(M\) represents the declared column length in characters for nonbinary string types and bytes for binary string types. \(L\) represents the actual length in bytes of a given string value.

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Storage Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR ((M))</td>
<td>(M \times w) bytes, 0 &lt;= (M) &lt;= 255, where (w) is the number of bytes required for the maximum-length character in the character set. See Physical Row Structure for information about CHAR data type storage requirements for InnoDB tables.</td>
</tr>
<tr>
<td>BINARY ((M))</td>
<td>(M) bytes, 0 &lt;= (M) &lt;= 255</td>
</tr>
<tr>
<td>VARCHAR ((M)), VARBINARY ((M))</td>
<td>(L + 1) bytes if column values require 0 – 255 bytes, (L + 2) bytes if values may require more than 255 bytes</td>
</tr>
</tbody>
</table>
### Storage Requirements for String Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Storage Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>TINYBLOB, TINYTEXT</td>
<td>( L + 1 \text{ bytes, where } L &lt; 2^8 )</td>
</tr>
<tr>
<td>BLOB, TEXT</td>
<td>( L + 2 \text{ bytes, where } L &lt; 2^{16} )</td>
</tr>
<tr>
<td>MEDIUMBLOB, MEDIUMTEXT</td>
<td>( L + 3 \text{ bytes, where } L &lt; 2^{24} )</td>
</tr>
<tr>
<td>LONGBLOB, LONGTEXT</td>
<td>( L + 4 \text{ bytes, where } L &lt; 2^{32} )</td>
</tr>
<tr>
<td>ENUM('value1', 'value2',...)</td>
<td>1 or 2 bytes, depending on the number of enumeration values (65,535 values maximum)</td>
</tr>
<tr>
<td>SET('value1', 'value2',...)</td>
<td>1, 2, 3, 4, or 8 bytes, depending on the number of set members (64 members maximum)</td>
</tr>
</tbody>
</table>

Variable-length string types are stored using a length prefix plus data. The length prefix requires from one to four bytes depending on the data type, and the value of the prefix is \( L \) (the byte length of the string). For example, storage for a MEDIUMTEXT value requires \( L \) bytes to store the value plus three bytes to store the length of the value.

To calculate the number of bytes used to store a particular CHAR, VARCHAR, or TEXT column value, you must take into account the character set used for that column and whether the value contains multibyte characters. In particular, when using the utf8 Unicode character set, you must keep in mind that not all characters use the same number of bytes and can require up to three bytes per character. For a breakdown of the storage used for different categories of utf8 characters, see Section 10.1.10, “Unicode Support”.

VARCHAR, VARBINARY, and the BLOB and TEXT types are variable-length types. For each, the storage requirements depend on these factors:

- The actual length of the column value
- The column’s maximum possible length
- The character set used for the column, because some character sets contain multibyte characters

For example, a VARCHAR(255) column can hold a string with a maximum length of 255 characters. Assuming that the column uses the latin1 character set (one byte per character), the actual storage required is the length of the string (\( L \)), plus one byte to record the length of the string. For the string ‘abcd’, \( L \) is 4 and the storage requirement is five bytes. If the same column is instead declared to use the ucs2 double-byte character set, the storage requirement is 10 bytes: The length of ‘abcd’ is eight bytes and the column requires two bytes to store lengths because the maximum length is greater than 255 (up to 510 bytes).

The effective maximum number of bytes that can be stored in a VARCHAR or VARBINARY column is subject to the maximum row size of 65,535 bytes, which is shared among all columns. For a VARCHAR column that stores multibyte characters, the effective maximum number of characters is less. For example, utf8 characters can require up to three bytes per character, so a VARCHAR column that uses the utf8 character set can be declared to be a maximum of 21,844 characters. See Section C.7.4, “Limits on Table Column Count and Row Size”.

The NDBCLUSTER storage engine in MySQL 5.1 supports variable-width columns. This means that a VARCHAR column in a MySQL Cluster table requires the same amount of storage as it would using any other storage engine, with the exception that such values are 4-byte aligned. Thus, the string ‘abcd’ stored in a VARCHAR(50) column using the latin1 character set requires 8 bytes (rather than 5 bytes for the same column value in a MyISAM table). This represents a change in behavior from earlier versions of NDBCLUSTER, where a VARCHAR(50) column would require 52 bytes storage per record regardless of the length of the string being stored.

TEXT and BLOB columns are implemented differently in the NDB Cluster storage engine, wherein each row in a TEXT column is made up of two separate parts. One of these is of fixed size (256 bytes), and is actually stored in the original table. The other consists of any data in excess of 256 bytes, which
Choosing the Right Type for a Column

1006

is stored in a hidden table. The rows in this second table are always 2,000 bytes long. This means that the size of a TEXT column is 256 if \( \text{size} \leq 256 \) (where \( \text{size} \) represents the size of the row); otherwise, the size is 256 + \( \text{size} + (2000 \mod (\text{size} - 256)) \).

The size of an ENUM object is determined by the number of different enumeration values. One byte is used for enumerations with up to 255 possible values. Two bytes are used for enumerations having between 256 and 65,535 possible values. See Section 11.4.4, “The ENUM Type”.

The size of a SET object is determined by the number of different set members. If the set size is \( N \), the object occupies \( \frac{(N+7)}{8} \) bytes, rounded up to 1, 2, 3, 4, or 8 bytes. A SET can have a maximum of 64 members. See Section 11.4.5, “The SET Type”.

11.8 Choosing the Right Type for a Column

For optimum storage, you should try to use the most precise type in all cases. For example, if an integer column is used for values in the range from 1 to 99999, MEDIUMINT UNSIGNED is the best type. Of the types that represent all the required values, this type uses the least amount of storage.

All basic calculations (\(+\), \(-\), \(*\), and \(/\)) with DECIMAL columns are done with precision of 65 decimal (base 10) digits. See Section 11.1.1, “Numeric Type Overview”.

If accuracy is not too important or if speed is the highest priority, the DOUBLE type may be good enough. For high precision, you can always convert to a fixed-point type stored in a BIGINT. This enables you to do all calculations with 64-bit integers and then convert results back to floating-point values as necessary.

PROCEDURE ANALYSE can be used to obtain suggestions for optimal column data types. For more information, see Section 8.4.2.4, “Using PROCEDURE ANALYSE”.

11.9 Using Data Types from Other Database Engines

To facilitate the use of code written for SQL implementations from other vendors, MySQL maps data types as shown in the following table. These mappings make it easier to import table definitions from other database systems into MySQL.

<table>
<thead>
<tr>
<th>Other Vendor Type</th>
<th>MySQL Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOOL</td>
<td>TINYINT</td>
</tr>
<tr>
<td>BOOLEAN</td>
<td>TINYINT</td>
</tr>
<tr>
<td>CHARACTER VARYING(M)</td>
<td>VARCHAR(M)</td>
</tr>
<tr>
<td>FIXED</td>
<td>DECIMAL</td>
</tr>
<tr>
<td>FLOAT4</td>
<td>FLOAT</td>
</tr>
<tr>
<td>FLOAT8</td>
<td>DOUBLE</td>
</tr>
<tr>
<td>INT1</td>
<td>TINYINT</td>
</tr>
<tr>
<td>INT2</td>
<td>SMALLINT</td>
</tr>
<tr>
<td>INT3</td>
<td>MEDIUMINT</td>
</tr>
<tr>
<td>INT4</td>
<td>INT</td>
</tr>
<tr>
<td>INT8</td>
<td>BIGINT</td>
</tr>
<tr>
<td>LONG VARBINARY</td>
<td>MEDIUMBLOB</td>
</tr>
<tr>
<td>LONG VARCHAR</td>
<td>MEDIUMTEXT</td>
</tr>
<tr>
<td>LONG</td>
<td>MEDIUMTEXT</td>
</tr>
<tr>
<td>MIDDLEINT</td>
<td>MEDIUMINT</td>
</tr>
<tr>
<td>NUMERIC</td>
<td>DECIMAL</td>
</tr>
</tbody>
</table>
Data type mapping occurs at table creation time, after which the original type specifications are discarded. If you create a table with types used by other vendors and then issue a `DESCRIBE tbl_name` statement, MySQL reports the table structure using the equivalent MySQL types. For example:

```sql
mysql> CREATE TABLE t (a BOOL, b FLOAT8, c LONG VARCHAR, d NUMERIC);
Query OK, 0 rows affected (0.00 sec)

mysql> DESCRIBE t;
+-------+---------------+------+-----+---------+-------+
| Field | Type          | Null | Key | Default | Extra |
+-------+---------------+------+-----+---------+-------+
| a     | tinyint(1)    | YES  |     | NULL    |       |
| b     | double        | YES  |     | NULL    |       |
| c     | mediumtext    | YES  |     | NULL    |       |
| d     | decimal(10,0) | YES  |     | NULL    |       |
+-------+---------------+------+-----+---------+-------+
4 rows in set (0.01 sec)
```
## Chapter 12 Functions and Operators

### Table of Contents

12.1 Function and Operator Reference ........................................ 1010

   12.18.4 Rounding Behavior ............................................. 1161
   12.18.5 Precision Math Examples ....................................... 1162
Expressions can be used at several points in SQL statements, such as in the ORDER BY or HAVING clauses of SELECT statements, in the WHERE clause of a SELECT, DELETE, or UPDATE statement, or in SET statements. Expressions can be written using literal values, column values, NULL, built-in functions, stored functions, user-defined functions, and operators. This chapter describes the functions and operators that are permitted for writing expressions in MySQL. Instructions for writing stored functions and user-defined functions are given in Section 19.2, “Using Stored Routines (Procedures and Functions)”, and Section 22.3, “Adding New Functions to MySQL”. See Section 9.2.4, “Function Name Parsing and Resolution”, for the rules describing how the server interprets references to different kinds of functions.

An expression that contains NULL always produces a NULL value unless otherwise indicated in the documentation for a particular function or operator.

Note

By default, there must be no whitespace between a function name and the parenthesis following it. This helps the MySQL parser distinguish between function calls and references to tables or columns that happen to have the same name as a function. However, spaces around function arguments are permitted.

You can tell the MySQL server to accept spaces after function names by starting it with the --sql-mode=IGNORE_SPACE option. (See Section 5.1.7, “Server SQL Modes”.) Individual client programs can request this behavior by using the CLIENT_IGNORE_SPACE option for mysql_real_connect(). In either case, all function names become reserved words.

For the sake of brevity, most examples in this chapter display the output from the mysql program in abbreviated form. Rather than showing examples in this format:

```sql
mysql> SELECT MOD(29,9);
+-----------+
<table>
<thead>
<tr>
<th>mod(29,9)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
</tr>
</tbody>
</table>
+-----------+
1 row in set (0.00 sec)
```

This format is used instead:

```sql
mysql> SELECT MOD(29,9);
-> 2
```

### 12.1 Function and Operator Reference

#### Table 12.1 Functions/Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABS()</td>
<td>Return the absolute value</td>
</tr>
<tr>
<td>ACOS()</td>
<td>Return the arc cosine</td>
</tr>

<tr>
<td>CONNECTION_ID()</td>
<td>Return the connection ID (thread ID) for the connection</td>
</tr>
<tr>
<td>Contains()</td>
<td>Whether MBR of one geometry contains MBR of another</td>
</tr>
<tr>
<td>CONV()</td>
<td>Convert numbers between different number bases</td>
</tr>
<tr>
<td>CONVERT()</td>
<td>Cast a value as a certain type</td>
</tr>
<tr>
<td>CONVERT_TZ()</td>
<td>Convert from one timezone to another</td>
</tr>
<tr>
<td>COS()</td>
<td>Return the cosine</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>-------------------------------------------------------</td>
</tr>
<tr>
<td>COT()</td>
<td>Return the cotangent</td>
</tr>
<tr>
<td>COUNT()</td>
<td>Return a count of the number of rows returned</td>
</tr>
<tr>
<td>COUNT(DISTINCT)</td>
<td>Return the count of a number of different values</td>
</tr>
<tr>
<td>CRC32()</td>
<td>Compute a cyclic redundancy check value</td>
</tr>
<tr>
<td>Crosses()</td>
<td>Whether one geometry crosses another</td>
</tr>
<tr>
<td>CURDATE()</td>
<td>Return the current date</td>
</tr>
<tr>
<td>CURRENT_DATE(), CURRENT_DATE</td>
<td>Synonyms for CURDATE()</td>
</tr>
<tr>
<td>CURRENT_TIME(), CURRENT_TIME</td>
<td>Synonyms for CURTIME()</td>
</tr>
<tr>
<td>CURRENT_TIMESTAMP(), CURRENT_TIMESTAMP</td>
<td>Synonyms for NOW()</td>
</tr>
<tr>
<td>CURRENT_USER(), CURRENT_USER</td>
<td>The authenticated user name and host name</td>
</tr>
<tr>
<td>CURTIME()</td>
<td>Return the current time</td>
</tr>
<tr>
<td>DATABASE()</td>
<td>Return the default (current) database name</td>
</tr>
<tr>
<td>DATE()</td>
<td>Extract the date part of a date or datetime expression</td>
</tr>
<tr>
<td>DATE_ADD()</td>
<td>Add time values (intervals) to a date value</td>
</tr>
<tr>
<td>DATE_FORMAT()</td>
<td>Format date as specified</td>
</tr>
<tr>
<td>DATE_SUB()</td>
<td>Subtract a time value (interval) from a date</td>
</tr>
<tr>
<td>DATEDIFF()</td>
<td>Subtract two dates</td>
</tr>
<tr>
<td>DAY()</td>
<td>Synonym for DAYOFMONTH()</td>
</tr>
<tr>
<td>DAYNAME()</td>
<td>Return the name of the weekday</td>
</tr>
<tr>
<td>DAYOFMONTH()</td>
<td>Return the day of the month (0-31)</td>
</tr>
<tr>
<td>DAYOFWEEK()</td>
<td>Return the weekday index of the argument</td>
</tr>
<tr>
<td>DAYOFYEAR()</td>
<td>Return the day of the year (1-366)</td>
</tr>
<tr>
<td>DECODE()</td>
<td>Decodes a string encrypted using ENCODE()</td>
</tr>
<tr>
<td>DEFAULT()</td>
<td>Return the default value for a table column</td>
</tr>
<tr>
<td>DEGREES()</td>
<td>Convert radians to degrees</td>
</tr>
<tr>
<td>DES_DECRYPT()</td>
<td>Decrypt a string</td>
</tr>
<tr>
<td>DES_ENCRYPT()</td>
<td>Encrypt a string</td>
</tr>
<tr>
<td>Dimension()</td>
<td>Dimension of geometry</td>
</tr>
<tr>
<td>Disjoint()</td>
<td>Whether MBRs of two geometries are disjoint</td>
</tr>
<tr>
<td>DIV</td>
<td>Integer division</td>
</tr>
<tr>
<td>/</td>
<td>Division operator</td>
</tr>
<tr>
<td>ELT()</td>
<td>Return string at index number</td>
</tr>
<tr>
<td>ENCODE()</td>
<td>Encode a string</td>
</tr>
<tr>
<td>ENCRYPT()</td>
<td>Encrypt a string</td>
</tr>
<tr>
<td>EndPoint()</td>
<td>End Point of LineString</td>
</tr>
<tr>
<td>Envelope()</td>
<td>Return MBR of geometry</td>
</tr>
<tr>
<td>=</td>
<td>Equal operator</td>
</tr>
<tr>
<td>&lt;==&gt;</td>
<td>NULL-safe equal to operator</td>
</tr>
<tr>
<td>Equals()</td>
<td>Whether MBRs of two geometries are equal</td>
</tr>
<tr>
<td>EXP()</td>
<td>Raise to the power of</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>EXPORT_SET()</td>
<td>Return a string such that for every bit set in the value bits, you get an on string and for every unset bit, you get an off string</td>
</tr>
<tr>
<td>ExteriorRing()</td>
<td>Return exterior ring of Polygon</td>
</tr>
<tr>
<td>EXTRACT()</td>
<td>Extract part of a date</td>
</tr>
<tr>
<td>ExtractValue()</td>
<td>Extracts a value from an XML string using XPath notation</td>
</tr>
<tr>
<td>FIELD()</td>
<td>Return the index (position) of the first argument in the subsequent arguments</td>
</tr>
<tr>
<td>FIND_IN_SET()</td>
<td>Return the index position of the first argument within the second argument</td>
</tr>
<tr>
<td>FLOOR()</td>
<td>Return the largest integer value not greater than the argument</td>
</tr>
<tr>
<td>FORMAT()</td>
<td>Return a number formatted to specified number of decimal places</td>
</tr>
<tr>
<td>FOUND_ROWS()</td>
<td>For a SELECT with a LIMIT clause, the number of rows that would be returned were there no LIMIT clause</td>
</tr>
<tr>
<td>FROM_DAYS()</td>
<td>Convert a day number to a date</td>
</tr>
<tr>
<td>FROM_UNIXTIME()</td>
<td>Format UNIX timestamp as a date</td>
</tr>
<tr>
<td>GeomCollFromText(),</td>
<td>Return geometry collection from WKT</td>
</tr>
<tr>
<td>GeometryCollectionFromText()</td>
<td></td>
</tr>
<tr>
<td>GeomCollFromWKB(),</td>
<td>Return geometry collection from WKB</td>
</tr>
<tr>
<td>GeometryCollectionFromWKB()</td>
<td></td>
</tr>
<tr>
<td>GeometryCollection()</td>
<td>Construct geometry collection from geometries</td>
</tr>
<tr>
<td>GeometryN()</td>
<td>Return N-th geometry from geometry collection</td>
</tr>
<tr>
<td>GeometryType()</td>
<td>Return name of geometry type</td>
</tr>
<tr>
<td>GeomFromText(),</td>
<td>Return geometry from WKT</td>
</tr>
<tr>
<td>GeometryFromText()</td>
<td></td>
</tr>
<tr>
<td>GeomFromWKB(),</td>
<td>Return geometry from WKB</td>
</tr>
<tr>
<td>GeometryFromWKB()</td>
<td></td>
</tr>
<tr>
<td>GET_FORMAT()</td>
<td>Return a date format string</td>
</tr>
<tr>
<td>GET_LOCK()</td>
<td>Get a named lock</td>
</tr>
<tr>
<td>GLength()</td>
<td>Return length of LineString</td>
</tr>
<tr>
<td>&gt;</td>
<td>Greater than operator</td>
</tr>
<tr>
<td>&gt;=</td>
<td>Greater than or equal operator</td>
</tr>
<tr>
<td>GREATEST()</td>
<td>Return the largest argument</td>
</tr>
<tr>
<td>GROUP_CONCAT()</td>
<td>Return a concatenated string</td>
</tr>
<tr>
<td>HEX()</td>
<td>Return a hexadecimal representation of a decimal or string value</td>
</tr>
<tr>
<td>HOUR()</td>
<td>Extract the hour</td>
</tr>
<tr>
<td>IF()</td>
<td>If/else construct</td>
</tr>
<tr>
<td>IFNULL()</td>
<td>Null if/else construct</td>
</tr>
<tr>
<td>IN()</td>
<td>Check whether a value is within a set of values</td>
</tr>
<tr>
<td>INET_ATON()</td>
<td>Return the numeric value of an IP address</td>
</tr>
<tr>
<td>INET_NTOA()</td>
<td>Return the IP address from a numeric value</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>INSERT()</td>
<td>Insert a substring at the specified position up to the specified number of characters</td>
</tr>
<tr>
<td>INSTR()</td>
<td>Return the index of the first occurrence of substring</td>
</tr>
<tr>
<td>InteriorRingN()</td>
<td>Return N-th interior ring of Polygon</td>
</tr>
<tr>
<td>Intersects()</td>
<td>Whether MBRs of two geometries intersect</td>
</tr>
<tr>
<td>INTERVAL()</td>
<td>Return the index of the argument that is less than the first argument</td>
</tr>
<tr>
<td>IS</td>
<td>Test a value against a boolean</td>
</tr>
<tr>
<td>IS_FREE_LOCK()</td>
<td>Whether the named lock is free</td>
</tr>
<tr>
<td>IS NOT</td>
<td>Test a value against a boolean</td>
</tr>
<tr>
<td>IS NOT NULL</td>
<td>NOT NULL value test</td>
</tr>
<tr>
<td>IS NULL</td>
<td>NULL value test</td>
</tr>
<tr>
<td>IS_USED_LOCK()</td>
<td>Whether the named lock is in use; return connection identifier if true</td>
</tr>
<tr>
<td>IsClosed()</td>
<td>Whether a geometry is closed and simple</td>
</tr>
<tr>
<td>IsEmpty()</td>
<td>Placeholder function</td>
</tr>
<tr>
<td>ISNULL()</td>
<td>Test whether the argument is NULL</td>
</tr>
<tr>
<td>IsSimple()</td>
<td>Whether a geometry is simple</td>
</tr>
<tr>
<td>LAST_DAY</td>
<td>Return the last day of the month for the argument</td>
</tr>
<tr>
<td>LAST_INSERT_ID()</td>
<td>Value of the AUTOINCREMENT column for the last INSERT</td>
</tr>
<tr>
<td>LCASE()</td>
<td>Synonym for LOWER()</td>
</tr>
<tr>
<td>LEAST()</td>
<td>Return the smallest argument</td>
</tr>
<tr>
<td>LEFT()</td>
<td>Return the leftmost number of characters as specified</td>
</tr>
<tr>
<td>&lt;&lt;</td>
<td>Left shift</td>
</tr>
<tr>
<td>LENGTH()</td>
<td>Return the length of a string in bytes</td>
</tr>
<tr>
<td>&lt;</td>
<td>Less than operator</td>
</tr>
<tr>
<td>&lt;=</td>
<td>Less than or equal operator</td>
</tr>
<tr>
<td>LIKE</td>
<td>Simple pattern matching</td>
</tr>
<tr>
<td>LineFromText(),</td>
<td>Construct LineString from WKT</td>
</tr>
<tr>
<td>LineStringFromText()</td>
<td></td>
</tr>
<tr>
<td>LineFromWKB(),</td>
<td>Construct LineString from WKB</td>
</tr>
<tr>
<td>LineStringFromWKB()</td>
<td></td>
</tr>
<tr>
<td>LineString()</td>
<td>Construct LineString from Point values</td>
</tr>
<tr>
<td>LN()</td>
<td>Return the natural logarithm of the argument</td>
</tr>
<tr>
<td>LOAD_FILE()</td>
<td>Load the named file</td>
</tr>
<tr>
<td>LOCALTIME(),</td>
<td>Synonym for NOW()</td>
</tr>
<tr>
<td>LOCALTIMESTAMP</td>
<td>Synonym for NOW()</td>
</tr>
<tr>
<td>LOCATE()</td>
<td>Return the position of the first occurrence of substring</td>
</tr>
<tr>
<td>LOG()</td>
<td>Return the natural logarithm of the first argument</td>
</tr>
<tr>
<td>LOG10()</td>
<td>Return the base-10 logarithm of the argument</td>
</tr>
<tr>
<td>LOG2()</td>
<td>Return the base-2 logarithm of the argument</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td>LOWER()</td>
<td>Return the argument in lowercase</td>
</tr>
<tr>
<td>LPAD()</td>
<td>Return the string argument, left-padded with the specified string</td>
</tr>
<tr>
<td>LTRIM()</td>
<td>Remove leading spaces</td>
</tr>
<tr>
<td>MAKE_SET()</td>
<td>Return a set of comma-separated strings that have the corresponding bit in bits set</td>
</tr>
<tr>
<td>MAKEDATE()</td>
<td>Create a date from the year and day of year</td>
</tr>
<tr>
<td>MAKETIME()</td>
<td>Create time from hour, minute, second</td>
</tr>
<tr>
<td>MASTER_POS_WAIT()</td>
<td>Block until the slave has read and applied all updates up to the specified position</td>
</tr>
<tr>
<td>MATCH</td>
<td>Perform full-text search</td>
</tr>
<tr>
<td>MAX()</td>
<td>Return the maximum value</td>
</tr>
<tr>
<td>MBRContains()</td>
<td>Whether MBR of one geometry contains MBR of another</td>
</tr>
<tr>
<td>MBRDisjoint()</td>
<td>Whether MBRs of two geometries are disjoint</td>
</tr>
<tr>
<td>MBREqual()</td>
<td>Whether MBRs of two geometries are equal</td>
</tr>
<tr>
<td>MBRIntersects()</td>
<td>Whether MBRs of two geometries intersect</td>
</tr>
<tr>
<td>MBROverlaps()</td>
<td>Whether MBRs of two geometries overlap</td>
</tr>
<tr>
<td>MBRTouches()</td>
<td>Whether MBRs of two geometries touch</td>
</tr>
<tr>
<td>MBRWithin()</td>
<td>Whether MBR of one geometry is within MBR of another</td>
</tr>
<tr>
<td>MD5()</td>
<td>Calculate MD5 checksum</td>
</tr>
<tr>
<td>MICROSECOND()</td>
<td>Return the microseconds from argument</td>
</tr>
<tr>
<td>MID()</td>
<td>Return a substring starting from the specified position</td>
</tr>
<tr>
<td>MIN()</td>
<td>Return the minimum value</td>
</tr>
<tr>
<td>-</td>
<td>Minus operator</td>
</tr>
<tr>
<td>MINUTE()</td>
<td>Return the minute from the argument</td>
</tr>
<tr>
<td>MLineFromText(), MultiLineStringFromText()</td>
<td>Construct MultiLineString from WKT</td>
</tr>
<tr>
<td>MLineFromWKB(), MultiLineStringFromWKB()</td>
<td>Construct MultiLineString from WKB</td>
</tr>
<tr>
<td>MOD()</td>
<td>Return the remainder</td>
</tr>
<tr>
<td>%, MOD</td>
<td>Modulo operator</td>
</tr>
<tr>
<td>MONTH()</td>
<td>Return the month from the date passed</td>
</tr>
<tr>
<td>MONTHNAME()</td>
<td>Return the name of the month</td>
</tr>
<tr>
<td>MPointFromText(), MultiPointFromText()</td>
<td>Construct MultiPoint from WKT</td>
</tr>
<tr>
<td>MPointFromWKB(), MultiPointFromWKB()</td>
<td>Construct MultiPoint from WKB</td>
</tr>
<tr>
<td>MPolyFromText(), MultiPolygonFromText()</td>
<td>Construct MultiPolygon from WKT</td>
</tr>
<tr>
<td>MPolyFromWKB(), MultiPolygonFromWKB()</td>
<td>Construct MultiPolygon from WKB</td>
</tr>
<tr>
<td>MultiLineString()</td>
<td>Construct MultiLineString from LineString values</td>
</tr>
<tr>
<td>MultiPoint()</td>
<td>Construct MultiPoint from Point values</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>MultiPolygon()</td>
<td>Construct MultiPolygon from Polygon values</td>
</tr>
<tr>
<td>NAME_CONST()</td>
<td>Causes the column to have the given name</td>
</tr>
<tr>
<td>NOT, !</td>
<td>Negates value</td>
</tr>
<tr>
<td>NOT BETWEEN ... AND</td>
<td>Check whether a value is not within a range of values</td>
</tr>
<tr>
<td>!=, &lt;&gt;,</td>
<td>Not equal operator</td>
</tr>
<tr>
<td>NOT IN()</td>
<td>Check whether a value is not within a set of values</td>
</tr>
<tr>
<td>NOT LIKE</td>
<td>Negation of simple pattern matching</td>
</tr>
<tr>
<td>NOT REGEXP</td>
<td>Negation of REGEXP</td>
</tr>
<tr>
<td>NOW()</td>
<td>Return the current date and time</td>
</tr>
<tr>
<td>NULLIF()</td>
<td>Return NULL if expr1 = expr2</td>
</tr>
<tr>
<td>NumGeometries()</td>
<td>Return number of geometries in geometry collection</td>
</tr>
<tr>
<td>NumInteriorRings()</td>
<td>Return number of interior rings in Polygon</td>
</tr>
<tr>
<td>NumPoints()</td>
<td>Return number of points in LineString</td>
</tr>
<tr>
<td>OCT()</td>
<td>Return a string containing octal representation of a number</td>
</tr>
<tr>
<td>OCTET_LENGTH()</td>
<td>Synonym for LENGTH()</td>
</tr>
<tr>
<td>OLD_PASSWORD()</td>
<td>Return the value of the pre-4.1 implementation of PASSWORD</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>ORD()</td>
<td>Return character code for leftmost character of the argument</td>
</tr>
<tr>
<td>Overlaps()</td>
<td>Whether MBRs of two geometries overlap</td>
</tr>
<tr>
<td>PASSWORD()</td>
<td>Calculate and return a password string</td>
</tr>
<tr>
<td>PERIOD_ADD()</td>
<td>Add a period to a year-month</td>
</tr>
<tr>
<td>PERIOD_DIFF()</td>
<td>Return the number of months between periods</td>
</tr>
<tr>
<td>PI()</td>
<td>Return the value of pi</td>
</tr>
<tr>
<td>+</td>
<td>Addition operator</td>
</tr>
<tr>
<td>Point()</td>
<td>Construct Point from coordinates</td>
</tr>
<tr>
<td>PointFromText()</td>
<td>Construct Point from WKT</td>
</tr>
<tr>
<td>PointFromWKB()</td>
<td>Construct Point from WKB</td>
</tr>
<tr>
<td>PointN()</td>
<td>Return N-th point from LineString</td>
</tr>
<tr>
<td>PolyFromText(),</td>
<td>Construct Polygon from WKT</td>
</tr>
<tr>
<td>PolygonFromText()</td>
<td></td>
</tr>
<tr>
<td>PolyFromWKB(),</td>
<td>Construct Polygon from WKB</td>
</tr>
<tr>
<td>PolygonFromWKB()</td>
<td></td>
</tr>
<tr>
<td>Poly()</td>
<td>Construct Polygon from LineString arguments</td>
</tr>
<tr>
<td>POSITION()</td>
<td>Synonym for LOCATE()</td>
</tr>
<tr>
<td>POW()</td>
<td>Return the argument raised to the specified power</td>
</tr>
<tr>
<td>POWER()</td>
<td>Return the argument raised to the specified power</td>
</tr>
<tr>
<td>PROCEDURE ANALYSE()</td>
<td>Analyze the results of a query</td>
</tr>
<tr>
<td>QUARTER()</td>
<td>Return the quarter from a date argument</td>
</tr>
<tr>
<td>QUOTE()</td>
<td>Escape the argument for use in an SQL statement</td>
</tr>
<tr>
<td>RADIANS()</td>
<td>Return argument converted to radians</td>
</tr>
<tr>
<td>RAND()</td>
<td>Return a random floating-point value</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>---------------------------------------------------------------</td>
</tr>
<tr>
<td>REGEXP</td>
<td>Pattern matching using regular expressions</td>
</tr>
<tr>
<td>RELEASE_LOCK()</td>
<td>Releases the named lock</td>
</tr>
<tr>
<td>REPEAT()</td>
<td>Repeat a string the specified number of times</td>
</tr>
<tr>
<td>REPLACE()</td>
<td>Replace occurrences of a specified string</td>
</tr>
<tr>
<td>REVERSE()</td>
<td>Reverse the characters in a string</td>
</tr>
<tr>
<td>RIGHT()</td>
<td>Return the specified rightmost number of characters</td>
</tr>
<tr>
<td>&gt;&gt;</td>
<td>Right shift</td>
</tr>
<tr>
<td>RLIKE</td>
<td>Synonym for REGEXP</td>
</tr>
<tr>
<td>ROUND()</td>
<td>Round the argument</td>
</tr>
<tr>
<td>ROW_COUNT()</td>
<td>The number of rows updated</td>
</tr>
<tr>
<td>RPAD()</td>
<td>Append string the specified number of times</td>
</tr>
<tr>
<td>RTRIM()</td>
<td>Remove trailing spaces</td>
</tr>
<tr>
<td>SCHEMA()</td>
<td>Synonym for DATABASE()</td>
</tr>
<tr>
<td>SEC_TO_TIME()</td>
<td>Converts seconds to 'HH:MM:SS' format</td>
</tr>
<tr>
<td>SECOND()</td>
<td>Return the second (0-59)</td>
</tr>
<tr>
<td>SESSION_USER()</td>
<td>Synonym for USER()</td>
</tr>
<tr>
<td>SHA1(), SHA()</td>
<td>Calculate an SHA-1 160-bit checksum</td>
</tr>
<tr>
<td>SIGN()</td>
<td>Return the sign of the argument</td>
</tr>
<tr>
<td>SIN()</td>
<td>Return the sine of the argument</td>
</tr>
<tr>
<td>SLEEP()</td>
<td>Sleep for a number of seconds</td>
</tr>
<tr>
<td>SOUNDEX()</td>
<td>Return a soundex string</td>
</tr>
<tr>
<td>SOUNDS LIKE</td>
<td>Compare sounds</td>
</tr>
<tr>
<td>SPACE()</td>
<td>Return a string of the specified number of spaces</td>
</tr>
<tr>
<td>SQRT()</td>
<td>Return the square root of the argument</td>
</tr>
<tr>
<td>SRID()</td>
<td>Return spatial reference system ID for geometry</td>
</tr>
<tr>
<td>StartPoint()</td>
<td>Start Point of LineString</td>
</tr>
<tr>
<td>STD()</td>
<td>Return the population standard deviation</td>
</tr>
<tr>
<td>STDERR()</td>
<td>Return the population standard deviation</td>
</tr>
<tr>
<td>STDDEV_POP()</td>
<td>Return the population standard deviation</td>
</tr>
<tr>
<td>STDDEV_SAMP()</td>
<td>Return the sample standard deviation</td>
</tr>
<tr>
<td>STR_TO_DATE()</td>
<td>Convert a string to a date</td>
</tr>
<tr>
<td>STRCMP()</td>
<td>Compare two strings</td>
</tr>
<tr>
<td>SUBDATE()</td>
<td>Synonym for DATE_SUB() when invoked with three arguments</td>
</tr>
<tr>
<td>SUBSTR()</td>
<td>Return the substring as specified</td>
</tr>
<tr>
<td>SUBSTRING()</td>
<td>Return the substring as specified</td>
</tr>
<tr>
<td>SUBSTRING_INDEX()</td>
<td>Return a substring from a string before the specified number of occurrences of the delimiter</td>
</tr>
<tr>
<td>SUBTIME()</td>
<td>Subtract times</td>
</tr>
<tr>
<td>SUM()</td>
<td>Return the sum</td>
</tr>
<tr>
<td>SYSDATE()</td>
<td>Return the time at which the function executes</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SYSTEM_USER()</td>
<td>Synonym for USER()</td>
</tr>
<tr>
<td>TAN()</td>
<td>Return the tangent of the argument</td>
</tr>
<tr>
<td>TIME()</td>
<td>Extract the time portion of the expression passed</td>
</tr>
<tr>
<td>TIME_FORMAT()</td>
<td>Format as time</td>
</tr>
<tr>
<td>TIME_TO_SEC()</td>
<td>Return the argument converted to seconds</td>
</tr>
<tr>
<td>TIMEDIFF()</td>
<td>Subtract time</td>
</tr>
<tr>
<td>*</td>
<td>Multiplication operator</td>
</tr>
<tr>
<td>TIMESTAMP()</td>
<td>With a single argument, this function returns the date or datetime expression; with two arguments, the sum of the arguments</td>
</tr>
<tr>
<td>TIMESTAMPADD()</td>
<td>Add an interval to a datetime expression</td>
</tr>
<tr>
<td>TIMESTAMPDIFF()</td>
<td>Subtract an interval from a datetime expression</td>
</tr>
<tr>
<td>TO_DAYS()</td>
<td>Return the date argument converted to days</td>
</tr>
<tr>
<td>Touches()</td>
<td>Whether one geometry touches another</td>
</tr>
<tr>
<td>TRIM()</td>
<td>Remove leading and trailing spaces</td>
</tr>
<tr>
<td>TRUNCATE()</td>
<td>Truncate to specified number of decimal places</td>
</tr>
<tr>
<td>UCASE()</td>
<td>Synonym for UPPER()</td>
</tr>
<tr>
<td>-</td>
<td>Change the sign of the argument</td>
</tr>
<tr>
<td>UNCOMPRESS()</td>
<td>Uncompress a string compressed</td>
</tr>
<tr>
<td>UNCOMPRESSED_LENGTH()</td>
<td>Return the length of a string before compression</td>
</tr>
<tr>
<td>UNHEX()</td>
<td>Return a string containing hex representation of a number</td>
</tr>
<tr>
<td>UNIX_TIMESTAMP()</td>
<td>Return a UNIX timestamp</td>
</tr>
<tr>
<td>UpdateXML()</td>
<td>Return replaced XML fragment</td>
</tr>
<tr>
<td>UPPER()</td>
<td>Convert to uppercase</td>
</tr>
<tr>
<td>USER()</td>
<td>The user name and host name provided by the client</td>
</tr>
<tr>
<td>UTC_DATE()</td>
<td>Return the current UTC date</td>
</tr>
<tr>
<td>UTC_TIME()</td>
<td>Return the current UTC time</td>
</tr>
<tr>
<td>UTC_TIMESTAMP()</td>
<td>Return the current UTC date and time</td>
</tr>
<tr>
<td>UUID()</td>
<td>Return a Universal Unique Identifier (UUID)</td>
</tr>
<tr>
<td>UUID_SHORT()</td>
<td>Return an integer-valued universal identifier</td>
</tr>
<tr>
<td>VALUES()</td>
<td>Defines the values to be used during an INSERT</td>
</tr>
<tr>
<td>VAR_POP()</td>
<td>Return the population standard variance</td>
</tr>
<tr>
<td>VAR_SAMP()</td>
<td>Return the sample variance</td>
</tr>
<tr>
<td>VARIANCE()</td>
<td>Return the population standard variance</td>
</tr>
<tr>
<td>VERSION()</td>
<td>Return a string that indicates the MySQL server version</td>
</tr>
<tr>
<td>WEEK()</td>
<td>Return the week number</td>
</tr>
<tr>
<td>WEEKDAY()</td>
<td>Return the weekday index</td>
</tr>
<tr>
<td>WEEKOFYEAR()</td>
<td>Return the calendar week of the date (1-53)</td>
</tr>
<tr>
<td>Within()</td>
<td>Whether MBR of one geometry is within MBR of another</td>
</tr>
<tr>
<td>X()</td>
<td>Return X coordinate of Point</td>
</tr>
<tr>
<td>XOR</td>
<td>Logical XOR</td>
</tr>
</tbody>
</table>
12.2 Type Conversion in Expression Evaluation

When an operator is used with operands of different types, type conversion occurs to make the operands compatible. Some conversions occur implicitly. For example, MySQL automatically converts numbers to strings as necessary, and vice versa.

It is also possible to convert a number to a string explicitly using the \texttt{CAST()} function. Conversion occurs implicitly with the \texttt{CONCAT()} function because it expects string arguments.

See later in this section for information about the character set of implicit number-to-string conversions, and for modified rules that apply to \texttt{CREATE TABLE ... SELECT} statements.

The following rules describe how conversion occurs for comparison operations:

- If one or both arguments are \texttt{NULL}, the result of the comparison is \texttt{NULL}, except for the \texttt{NULL}-safe $\leftrightarrow$ equality comparison operator. For \texttt{NULL $\leftrightarrow$ NULL}, the result is true. No conversion is needed.

- If both arguments in a comparison operation are strings, they are compared as strings.

- If both arguments are integers, they are compared as integers.

- Hexadecimal values are treated as binary strings if not compared to a number.

- If one of the arguments is a \texttt{TIMESTAMP} or \texttt{DATETIME} column and the other argument is a constant, the constant is converted to a timestamp before the comparison is performed. This is done to be more ODBC-friendly. Note that this is not done for the arguments to \texttt{IN()}! To be safe, always use complete datetime, date, or time strings when doing comparisons. For example, to achieve best results when using \texttt{BETWEEN} with date or time values, use \texttt{CAST()} to explicitly convert the values to the desired data type.

- If one of the arguments is a decimal value, comparison depends on the other argument. The arguments are compared as decimal values if the other argument is a decimal or integer value, or as floating-point values if the other argument is a floating-point value.

- In all other cases, the arguments are compared as floating-point (real) numbers.

For information about conversion of values from one temporal type to another, see Section 11.3.7, “Conversion Between Date and Time Types”.

The following examples illustrate conversion of strings to numbers for comparison operations:
For comparisons of a string column with a number, MySQL cannot use an index on the column to look up the value quickly. If `str_col` is an indexed string column, the index cannot be used when performing the lookup in the following statement:

```sql
SELECT * FROM tbl_name WHERE str_col=1;
```

The reason for this is that there are many different strings that may convert to the value 1, such as '1', ' 1', or '1a'.

Comparisons that use floating-point numbers (or values that are converted to floating-point numbers) are approximate because such numbers are inexact. This might lead to results that appear inconsistent:

```sql
mysql> SELECT '18015376320243458' = 18015376320243458;
-> 1
mysql> SELECT '18015376320243459' = 18015376320243459;
-> 0
```

Such results can occur because the values are converted to floating-point numbers, which have only 53 bits of precision and are subject to rounding:

```sql
mysql> SELECT '18015376320243459' + 0.0;
-> 1.8015376320243e+16
```

Furthermore, the conversion from string to floating-point and from integer to floating-point do not necessarily occur the same way. The integer may be converted to floating-point by the CPU, whereas the string is converted digit by digit in an operation that involves floating-point multiplications.

The results shown will vary on different systems, and can be affected by factors such as computer architecture or the compiler version or optimization level. One way to avoid such problems is to use `CAST()` so that a value is not converted implicitly to a float-point number:

```sql
mysql> SELECT CAST('18015376320243459' AS UNSIGNED) = 18015376320243459;
-> 1
```

For more information about floating-point comparisons, see Section B.5.4.8, "Problems with Floating-Point Values".

Implicit conversion of a numeric or temporal value to a string produces a binary string (a `BINARY`, `VARBINARY`, or `BLOB` value). Such implicit conversions to string typically occur for functions that are passed numeric or temporal values when string values are more usual, and thus can have effects beyond the type of the converted value. Consider the expression `CONCAT(1, 'abc')`. The numeric argument 1 is converted to the binary string '1' and the concatenation of that value with the nonbinary string 'abc' produces the binary string '1abc'.

For integer expressions, the preceding remarks about expression `evaluation` apply somewhat differently for expression `assignment`; for example, in a statement such as this:

```sql
CREATE TABLE t SELECT integer_expr;
```

In this case, the table in the column resulting from the expression has type `INT` or `BIGINT` depending on the length of the integer expression. If the maximum length of the expression does not fit in an `INT`,
**BIGINT** is used instead. The length is taken from the `max_length` value of the `SELECT` result set metadata (see Section 21.8.5, “C API Data Structures”). This means that you can force a **BIGINT** rather than **INT** by use of a sufficiently long expression:

```sql
CREATE TABLE t SELECT 000000000000000000000;
```

### 12.3 Operators

### 12.3.1 Operator Precedence

Operator precedences are shown in the following list, from highest precedence to the lowest. Operators that are shown together on a line have the same precedence. The precedence of `=` depends on whether it is used as a comparison operator (\(\approx\)) or as an assignment operator (\(=\)). When used as a comparison operator, it has the same precedence as `\(\leq\)`, `\(\geq\)`, `\(<\)` and `\(\leq\)`, `\(<\)` and `\(!=\)`, `IS`, `LIKE`, `REGEXP` and `IN`. When used as an assignment operator, it has the same precedence as `\(=\)`. Section 13.7.4.1, “SET Syntax for Variable Assignment”, and Section 9.4, “User-Defined Variables”, explain how MySQL determines which interpretation of `=` should apply.

For operators that occur at the same precedence level within an expression, evaluation proceeds left to right, with the exception that assignments evaluate right to left.

The meaning of some operators depends on the SQL mode:

- By default, `||` is a logical `OR` operator. With `PIPES_AS_CONCAT` enabled, `||` is string concatenation, with a precedence between `^` and the unary operators.

- By default, `!` has a higher precedence than `NOT`. With `HIGH_NOT_PRECEDENCE` enabled, `!` and `NOT` have the same precedence.

See Section 5.1.7, “Server SQL Modes”.

The precedence of operators determines the order of evaluation of terms in an expression. To override this order and group terms explicitly, use parentheses. For example:

```sql
mysql> SELECT 1+2*3;
-> 7
mysql> SELECT (1+2)*3;
-> 9
```
12.3.2 Comparison Functions and Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>

<td>Check whether a value is not within a range of values</td>
</tr>
<tr>
<td>!=,&lt;&gt;</td>
<td>Not equal operator</td>
</tr>
<tr>
<td>NOT IN()</td>
<td>Check whether a value is not within a set of values</td>
</tr>
<tr>
<td>NOT LIKE</td>
<td>Negation of simple pattern matching</td>
</tr>
<tr>
<td>STRCMP()</td>
<td>Compare two strings</td>
</tr>
</tbody>
</table>

Comparison operations result in a value of `1 (TRUE)`, `0 (FALSE)`, or `NULL`. These operations work for both numbers and strings. Strings are automatically converted to numbers and numbers to strings as necessary.

The following relational comparison operators can be used to compare not only scalar operands, but row operands:

`=  >  <  >=  <=  <>  !=`

The descriptions for those operators later in this section detail how they work with row operands. For additional examples of row comparisons in the context of row subqueries, see Section 13.2.9.5, "Row Subqueries".

Some of the functions in this section return values other than `1 (TRUE)`, `0 (FALSE)`, or `NULL`. For example, `LEAST()` and `GREATEST()`. However, the value they return is based on comparison operations performed according to the rules described in Section 12.2, "Type Conversion in Expression Evaluation".
To convert a value to a specific type for comparison purposes, you can use the \texttt{CAST()} function. String values can be converted to a different character set using \texttt{CONVERT()}. See Section 12.10, “Cast Functions and Operators”.

By default, string comparisons are not case sensitive and use the current character set. The default is \texttt{latin1} (cp1252 West European), which also works well for English.

- \texttt{=}

\begin{verbatim}
mysql> SELECT 1 = 0;
-> 0
mysql> SELECT '0' = 0;
-> 1
mysql> SELECT '0.0' = 0;
-> 1
mysql> SELECT '0.01' = 0;
-> 0
mysql> SELECT '.01' = 0.01;
-> 1
\end{verbatim}

For row comparisons, \texttt{(a, b) = (x, y)} is equivalent to:

\begin{verbatim}
(a = x) AND (b = y)
\end{verbatim}

- \texttt{<>}

\texttt{NULL}-safe equal. This operator performs an equality comparison like the \texttt{=} operator, but returns 1 rather than \texttt{NULL} if both operands are \texttt{NULL}, and 0 rather than \texttt{NULL} if one operand is \texttt{NULL}.

The \texttt{<>} operator is equivalent to the standard SQL \texttt{IS NOT DISTINCT FROM} operator.

\begin{verbatim}
mysql> SELECT 1 <=> 1, NULL <=> NULL, 1 <=> NULL;
-> 1, 1, 0
mysql> SELECT 1 = 1, NULL = NULL, 1 = NULL;
-> 1, NULL, NULL
\end{verbatim}

For row comparisons, \texttt{(a, b) <=> (x, y)} is equivalent to:

\begin{verbatim}
(a <=> x) AND (b <=> y)
\end{verbatim}

- \texttt{!,<>

Not equal:

\begin{verbatim}
mysql> SELECT '.01' <> '0.01';
-> 1
mysql> SELECT .01 <> '0.01';
-> 0
mysql> SELECT 'zapp' <> 'zappp';
-> 1
\end{verbatim}

For row comparisons, \texttt{(a, b) <> (x, y)} and \texttt{(a, b) != (x, y)} are equivalent to:

\begin{verbatim}
(a <> x) OR (b <> y)
\end{verbatim}

- \texttt{<=}

Less than or equal:
Comparison Functions and Operators

mysql> SELECT 0.1 <= 2;
   
   -> 1

For row comparisons, \((a, b) \leq (x, y)\) is equivalent to:

\[(a < x) \lor ((a = x) \land (b \leq y))\]

• <

Less than:

mysql> SELECT 2 < 2;
   
   -> 0

For row comparisons, \((a, b) < (x, y)\) is equivalent to:

\[(a < x) \lor ((a = x) \land (b < y))\]

• >=

Greater than or equal:

mysql> SELECT 2 >= 2;
   
   -> 1

For row comparisons, \((a, b) \geq (x, y)\) is equivalent to:

\[(a > x) \lor ((a = x) \land (b \geq y))\]

• >

Greater than:

mysql> SELECT 2 > 2;
   
   -> 0

For row comparisons, \((a, b) > (x, y)\) is equivalent to:

\[(a > x) \lor ((a = x) \land (b > y))\]

• IS boolean_value

Tests a value against a boolean value, where \(boolean_value\) can be TRUE, FALSE, or UNKNOWN.

mysql> SELECT 1 IS TRUE, 0 IS FALSE, NULL IS UNKNOWN;
   
   -> 1, 1, 1

• IS NOT boolean_value

Tests a value against a boolean value, where \(boolean_value\) can be TRUE, FALSE, or UNKNOWN.

mysql> SELECT 1 IS NOT UNKNOWN, 0 IS NOT UNKNOWN, NULL IS NOT UNKNOWN;
   
   -> 1, 1, 0

• IS NULL

Tests whether a value is NULL.
Comparison Functions and Operators

mysql> SELECT 1 IS NULL, 0 IS NULL, NULL IS NULL;
-> 0, 0, 1

To work well with ODBC programs, MySQL supports the following extra features when using IS NULL:

- If `sql_auto_is_null` variable is set to 1 (the default), then after a statement that successfully inserts an automatically generated `AUTO_INCREMENT` value, you can find that value by issuing a statement of the following form:

  ```sql
  SELECT * FROM tbl_name WHERE auto_col IS NULL
  ```

  If the statement returns a row, the value returned is the same as if you invoked the `LAST_INSERT_ID()` function. For details, including the return value after a multiple-row insert, see Section 12.14, “Information Functions”. If no `AUTO_INCREMENT` value was successfully inserted, the `SELECT` statement returns no row.

  The behavior of retrieving an `AUTO_INCREMENT` value by using an `IS NULL` comparison can be disabled by setting `sql_auto_is_null = 0`. See Section 5.1.4, “Server System Variables”.

- For `DATE` and `DATETIME` columns that are declared as `NOT NULL`, you can find the special date `'0000-00-00'` by using a statement like this:

  ```sql
  SELECT * FROM tbl_name WHERE date_column IS NULL
  ```

  This is needed to get some ODBC applications to work because ODBC does not support a `'0000-00-00'` date value.

  See Obtaining Auto-Increment Values, and the description for the `FLAG_AUTO_IS_NULL` option at Connector/ODBC Connection Parameters.

- **IS NOT NULL**

  Tests whether a value is not NULL.

  ```sql
  mysql> SELECT 1 IS NOT NULL, 0 IS NOT NULL, NULL IS NOT NULL;
  -> 1, 1, 0
  ```

- **expr BETWEEN min AND max**

  If `expr` is greater than or equal to `min` and `expr` is less than or equal to `max`, `BETWEEN` returns 1, otherwise it returns 0. This is equivalent to the expression `(min <= expr AND expr <= max)` if all the arguments are of the same type. Otherwise type conversion takes place according to the rules described in Section 12.2, “Type Conversion in Expression Evaluation”, but applied to all the three arguments.

  ```sql
  mysql> SELECT 2 BETWEEN 1 AND 3, 2 BETWEEN 3 and 1;
  -> 1, 0
  mysql> SELECT 1 BETWEEN 2 AND 3;
  -> 0
  mysql> SELECT 'b' BETWEEN 'a' AND 'c';
  -> 1
  mysql> SELECT 2 BETWEEN 2 AND '3';
  -> 1
  mysql> SELECT 2 BETWEEN 2 AND 'x-3';
  -> 0
  ```

  For best results when using `BETWEEN` with date or time values, use `CAST()` to explicitly convert the values to the desired data type. Examples: If you compare a `DATETIME` to two `DATE` values, convert the `DATE` values to `DATETIME` values. If you use a string constant such as `'2001-1-1'` in a comparison to a `DATE`, cast the string to a `DATE`. 

1026
Comparison Functions and Operators

- **expr NOT BETWEEN min AND max**
  
  This is the same as NOT (expr BETWEEN min AND max).

- **COALESCE(value,...)**
  
  Returns the first non-NULL value in the list, or NULL if there are no non-NULL values.

  ```sql
  mysql> SELECT COALESCE(NULL,1);
  -> 1
  mysql> SELECT COALESCE(NULL,NULL,NULL);
  -> NULL
  ```

- **GREATEST(value1,value2,...)**
  
  With two or more arguments, returns the largest (maximum-valued) argument. The arguments are compared using the same rules as for LEAST().

  ```sql
  mysql> SELECT GREATEST(2,0);
  -> 2
  mysql> SELECT GREATEST(34.0,3.0,5.0,767.0);
  -> 767.0
  mysql> SELECT GREATEST('B','A','C');
  -> 'C'
  ```

  **GREATEST()** returns NULL if any argument is NULL.

- **expr IN (value,...)**
  
  Returns 1 if expr is equal to any of the values in the IN list, else returns 0. If all values are constants, they are evaluated according to the type of expr and sorted. The search for the item then is done using a binary search. This means IN is very quick if the IN value list consists entirely of constants. Otherwise, type conversion takes place according to the rules described in Section 12.2, “Type Conversion in Expression Evaluation”, but applied to all the arguments.

  ```sql
  mysql> SELECT 2 IN (0,3,5,7);
  -> 0
  mysql> SELECT 'wefwfy' IN ('wee','wefwfy','weg');
  -> 1
  ```

  **IN** can be used to compare row constructors:

  ```sql
  mysql> SELECT (3,4) IN ((1,2), (3,4));
  -> 1
  mysql> SELECT (3,4) IN ((1,2), (3,5));
  -> 0
  ```

  You should never mix quoted and unquoted values in an **IN** list because the comparison rules for quoted values (such as strings) and unquoted values (such as numbers) differ. Mixing types may therefore lead to inconsistent results. For example, do not write an IN expression like this:

  ```sql
  SELECT val1 FROM tbl1 WHERE val1 IN (1,2,'a');
  ```

  Instead, write it like this:

  ```sql
  SELECT val1 FROM tbl1 WHERE val1 IN ('1','2','a');
  ```

  The number of values in the **IN** list is only limited by the max_allowed_packet value.

  To comply with the SQL standard, **IN** returns NULL not only if the expression on the left hand side is **NULL**, but also if no match is found in the list and one of the expressions in the list is **NULL**.
IN() syntax can also be used to write certain types of subqueries. See Section 13.2.9.3, "Subqueries with ANY, IN, or SOME".

- `expr NOT IN (value,...)`

  This is the same as `NOT (expr IN (value,...))`.

- `ISNULL(expr)`

  If `expr` is NULL, `ISNULL()` returns 1, otherwise it returns 0.

  ```
  mysql> SELECT ISNULL(1+1);
  -> 0
  mysql> SELECT ISNULL(1/0);
  -> 1
  ```

  `ISNULL()` can be used instead of `=` to test whether a value is NULL. (Comparing a value to NULL using `=` always yields false.)

  The `ISNULL()` function shares some special behaviors with the `IS NULL` comparison operator. See the description of `IS NULL`.

- `INTERVAL(N, N1, N2, N3,...)`

  Returns 0 if `N < N1`, 1 if `N < N2` and so on or -1 if `N` is NULL. All arguments are treated as integers. It is required that `N1 < N2 < N3 < ... < Nn` for this function to work correctly. This is because a binary search is used (very fast).

  ```
  mysql> SELECT INTERVAL(23, 1, 15, 17, 30, 44, 200);
  -> 3
  mysql> SELECT INTERVAL(10, 1, 10, 100, 1000);
  -> 2
  mysql> SELECT INTERVAL(22, 23, 30, 44, 200);
  -> 0
  ```

- `LEAST(value1,value2,...)`

  With two or more arguments, returns the smallest (minimum-valued) argument. The arguments are compared using the following rules:

  - If any argument is NULL, the result is NULL. No comparison is needed.
  - If the return value is used in an INTEGER context or all arguments are integer-valued, they are compared as integers.
  - If the return value is used in a REAL context or all arguments are real-valued, they are compared as reals.
  - If the arguments comprise a mix of numbers and strings, they are compared as numbers.
  - If any argument is a nonbinary (character) string, the arguments are compared as nonbinary strings.
  - In all other cases, the arguments are compared as binary strings.

  ```
  mysql> SELECT LEAST(2,0);
  -> 0
  mysql> SELECT LEAST(34.0,3.0,5.0,767.0);
  -> 3.0
  mysql> SELECT LEAST('B','A','C');
  -> 'A'
  ```
Logical Operators

Note that the preceding conversion rules can produce strange results in some borderline cases:

```sql
mysql> SELECT CAST(LEAST(3600, 9223372036854775808.0) AS SIGNED);
-> -9223372036854775808
```

This happens because MySQL reads `9223372036854775808.0` in an integer context. The integer representation is not good enough to hold the value, so it wraps to a signed integer.

### 12.3.3 Logical Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AND, &amp;&amp;</td>
<td>Logical AND</td>
</tr>
<tr>
<td>NOT, !</td>
<td>Negates value</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>XOR</td>
<td>Logical XOR</td>
</tr>
</tbody>
</table>

In SQL, all logical operators evaluate to `TRUE`, `FALSE`, or `NULL` (`UNKNOWN`). In MySQL, these are implemented as `1` (`TRUE`), `0` (`FALSE`), and `NULL`. Most of this is common to different SQL database servers, although some servers may return any nonzero value for `TRUE`.

MySQL evaluates any nonzero, non-`NULL` value to `TRUE`. For example, the following statements all assess to `TRUE`:

```sql
mysql> SELECT 10 IS TRUE;
-> 1
mysql> SELECT -10 IS TRUE;
-> 1
mysql> SELECT 'string' IS NOT NULL;
-> 1
```

- **NOT, !**

  Logical NOT. Evaluates to `1` if the operand is `0`, to `0` if the operand is nonzero, and `NOT NULL` returns `NULL`.

  ```sql
  mysql> SELECT NOT 10;
  -> 0
  mysql> SELECT NOT 0;
  -> 1
  mysql> SELECT NOT NULL;
  -> NULL
  mysql> SELECT ! (1+1);
  -> 0
  mysql> SELECT ! 1+1;
  -> 1
  ```
  
  The last example produces `1` because the expression evaluates the same way as `(1+1)!`.

- **AND, &&**

  Logical AND. Evaluates to `1` if all operands are nonzero and not `NULL`, to `0` if one or more operands are `0`, otherwise `NULL` is returned.

  ```sql
  mysql> SELECT 1 AND 1;
  -> 1
  mysql> SELECT 1 AND 0;
  -> 0
  mysql> SELECT 1 AND NULL;
  ```
Assignment Operators

- NULL

mysql> SELECT 0 AND NULL;
   -> 0

mysql> SELECT NULL AND 0;
   -> 0

- OR, ||

Logical OR. When both operands are non-NULL, the result is 1 if any operand is nonzero, and 0 otherwise. With a NULL operand, the result is 1 if the other operand is nonzero, and NULL otherwise. If both operands are NULL, the result is NULL.

mysql> SELECT 1 OR 1;
   -> 1

mysql> SELECT 1 OR 0;
   -> 1

mysql> SELECT 0 OR 0;
   -> 0

mysql> SELECT 0 OR NULL;
   -> NULL

mysql> SELECT 1 OR NULL;
   -> 1

- XOR

Logical XOR. Returns NULL if either operand is NULL. For non-NULL operands, evaluates to 1 if an odd number of operands is nonzero, otherwise 0 is returned.

mysql> SELECT 1 XOR 1;
   -> 0

mysql> SELECT 1 XOR 0;
   -> 1

mysql> SELECT 1 XOR NULL;
   -> NULL

mysql> SELECT 1 XOR 1 XOR 1;
   -> 1

\[ a \ XOR \ b \ \text{is mathematically equal to} \ (a \ AND \ (NOT \ b)) \ OR \ ((NOT \ a) \ AND \ b). \]

12.3.4 Assignment Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>=</td>
<td>Assign a value (as part of a <code>SET</code> statement, or as part of the <code>SET</code> clause in an <code>UPDATE</code> statement)</td>
</tr>
<tr>
<td>:=</td>
<td>Assign a value</td>
</tr>
</tbody>
</table>

- :=

Assignment operator. Causes the user variable on the left hand side of the operator to take on the value to its right. The value on the right hand side may be a literal value, another variable storing a value, or any legal expression that yields a scalar value, including the result of a query (provided that this value is a scalar value). You can perform multiple assignments in the same `SET` statement. You can perform multiple assignments in the same statement.

Unlike =, the := operator is never interpreted as a comparison operator. This means you can use := in any valid SQL statement (not just in `SET` statements) to assign a value to a variable.

mysql> SELECT @var1, @var2;
   -> NULL, NULL

mysql> SELECT @var1 := 1, @var2;
   -> 1, NULL
Assignment Operators

You can make value assignments using := in other statements besides SELECT, such as UPDATE, as shown here:

```sql
mysql> SELECT @var1, @var2;
   -> 1, NULL
mysql> SELECT @var1, @var2 := @var1;
   -> 1, 1
mysql> SELECT @var1, @var2;
   -> 1, 1

mysql> SELECT @var1:=COUNT(*) FROM t1;
   -> 4
mysql> SELECT @var1;
   -> 4
```

While it is also possible both to set and to read the value of the same variable in a single SQL statement using the := operator, this is not recommended. Section 9.4, “User-Defined Variables”, explains why you should avoid doing this.

The operator := is used to perform value assignments in two cases, described in the next two paragraphs.

Within a SET statement, := is treated as an assignment operator that causes the user variable on the left hand side of the operator to take on the value to its right. (In other words, when used in a SET statement, := is treated identically to :=.) The value on the right hand side may be a literal value, another variable storing a value, or any legal expression that yields a scalar value, including the result of a query (provided that this value is a scalar value). You can perform multiple assignments in the same SET statement.

In the SET clause of an UPDATE statement, := also acts as an assignment operator; in this case, however, it causes the column named on the left hand side of the operator to assume the value given to the right, provided any WHERE conditions that are part of the UPDATE are met. You can make multiple assignments in the same SET clause of an UPDATE statement.

In any other context, := is treated as a comparison operator.

For more information, see Section 13.7.4.1, “SET Syntax for Variable Assignment”, Section 13.2.10, “UPDATE Syntax”, and Section 13.2.9, “Subquery Syntax”.
12.4 Control Flow Functions

Table 12.6 Flow Control Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CASE</td>
<td>Case operator</td>
</tr>
<tr>
<td>IF()</td>
<td>If/else construct</td>
</tr>
<tr>
<td>IFNULL()</td>
<td>Null if/else construct</td>
</tr>
<tr>
<td>NULLIF()</td>
<td>Return NULL if expr1 = expr2</td>
</tr>
</tbody>
</table>

- CASE value WHEN [compare_value] THEN result [WHEN [compare_value] THEN result ...] [ELSE result] END
- CASE WHEN [condition] THEN result [WHEN [condition] THEN result ...] [ELSE result] END

The first version returns the result where value=compare_value. The second version returns the result for the first condition that is true. If there was no matching result value, the result after ELSE is returned, or NULL if there is no ELSE part.

```sql
mysql> SELECT CASE 1 WHEN 1 THEN 'one'
             ->    WHEN 2 THEN 'two' ELSE 'more' END;
-> 'one'
mysql> SELECT CASE WHEN 1>0 THEN 'true' ELSE 'false' END;
-> 'true'
mysql> SELECT CASE BINARY 'B'
             -> WHEN 'a' THEN 1 WHEN 'b' THEN 2 END;
-> NULL
```

The return type of a CASE expression is the compatible aggregated type of all return values, but also depends on the context in which it is used. If used in a string context, the result is returned as a string. If used in a numeric context, the result is returned as a decimal, real, or integer value.

**Note**
The syntax of the CASE expression shown here differs slightly from that of the SQL CASE statement described in Section 13.6.5.1, “CASE Syntax”, for use inside stored programs. The CASE statement cannot have an ELSE NULL clause, and it is terminated with END CASE instead of END.

- IF(expr1, expr2, expr3)

If expr1 is TRUE (expr1 <> 0 and expr1 <> NULL) then IF() returns expr2; otherwise it returns expr3. IF() returns a numeric or string value, depending on the context in which it is used.

```sql
mysql> SELECT IF(1>2,2,3);
-> 3
mysql> SELECT IF(1<2,'yes','no');
-> 'yes'
mysql> SELECT IF(STRCMP('test','test1'),'no','yes');
-> 'no'
```

If only one of expr2 or expr3 is explicitly NULL, the result type of the IF() function is the type of the non-NULL expression.

The default return type of IF() (which may matter when it is stored into a temporary table) is calculated as follows.
### Expression

<table>
<thead>
<tr>
<th>Expression</th>
<th>Return Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>expr2</code> or <code>expr3</code> returns a string</td>
<td>string</td>
</tr>
<tr>
<td><code>expr2</code> or <code>expr3</code> returns a floating-point value</td>
<td>floating-point</td>
</tr>
<tr>
<td><code>expr2</code> or <code>expr3</code> returns an integer</td>
<td>integer</td>
</tr>
</tbody>
</table>

If `expr2` and `expr3` are both strings, the result is case sensitive if either string is case sensitive.

---

**Note**

There is also an `IF` statement, which differs from the `IF()` function described here. See Section 13.6.5.2, "IF Syntax".

- **`IFNULL(expr1, expr2)`**

  If `expr1` is not NULL, `IFNULL()` returns `expr1`; otherwise it returns `expr2`. `IFNULL()` returns a numeric or string value, depending on the context in which it is used.

  ```sql
  mysql> SELECT IFNULL(1,0);
  -> 1
  mysql> SELECT IFNULL(NULL,10);
  -> 10
  mysql> SELECT IFNULL(1/0,10);
  -> 10
  mysql> SELECT IFNULL(1/0,'yes');
  -> 'yes'
  ```

  The default result value of `IFNULL(expr1, expr2)` is the more “general” of the two expressions, in the order `STRING`, `REAL`, or `INTEGER`. Consider the case of a table based on expressions or where MySQL must internally store a value returned by `IFNULL()` in a temporary table:

  ```sql
  mysql> CREATE TABLE tmp SELECT IFNULL(1,'test') AS test;
  mysql> DESCRIBE tmp;
  +-------+--------------+------+-----+---------+-------+
  | Field | Type         | Null | Key | Default | Extra |
  +-------+--------------+------+-----+---------+-------+
  | test  | varbinary(4) | NO   |     |         |       |
  +-------+--------------+------+-----+---------+-------+
  ```

  In this example, the type of the `test` column is `VARBINARY(4)`.

- **`NULLIF(expr1, expr2)`**

  Returns `NULL` if `expr1 = expr2` is true, otherwise returns `expr1`. This is the same as `CASE WHEN expr1 = expr2 THEN NULL ELSE expr1 END`.

  ```sql
  mysql> SELECT NULLIF(1,1);
  -> NULL
  mysql> SELECT NULLIF(1,2);
  -> 1
  ```

  Note that MySQL evaluates `expr1` twice if the arguments are not equal.

### 12.5 String Functions

#### Table 12.7 String Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASCII()</td>
<td>Return numeric value of left-most character</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>BIN()</td>
<td>Return a string containing binary representation of a number</td>
</tr>
<tr>
<td>BIT_LENGTH()</td>
<td>Return length of argument in bits</td>
</tr>
<tr>
<td>CHAR()</td>
<td>Return the character for each integer passed</td>
</tr>
<tr>
<td>CHAR_LENGTH()</td>
<td>Return number of characters in argument</td>
</tr>
<tr>
<td>CHARACTER_LENGTH()</td>
<td>Synonym for CHAR_LENGTH()</td>
</tr>
<tr>
<td>CONCAT()</td>
<td>Return concatenated string</td>
</tr>
<tr>
<td>CONCAT_WS()</td>
<td>Return concatenate with separator</td>
</tr>
<tr>
<td>ELT()</td>
<td>Return string at index number</td>
</tr>
<tr>
<td>EXPORT_SET()</td>
<td>Return a string such that for every bit set in the value bits, you get an on string and for every unset bit, you get an off string</td>
</tr>
<tr>
<td>FIELD()</td>
<td>Return the index (position) of the first argument in the subsequent arguments</td>
</tr>
<tr>
<td>FIND_IN_SET()</td>
<td>Return the index position of the first argument within the second argument</td>
</tr>
<tr>
<td>FORMAT()</td>
<td>Return a number formatted to specified number of decimal places</td>
</tr>
<tr>
<td>HEX()</td>
<td>Return a hexadecimal representation of a decimal or string value</td>
</tr>
<tr>
<td>INSERT()</td>
<td>Insert a substring at the specified position up to the specified number of characters</td>
</tr>
<tr>
<td>INSTR()</td>
<td>Return the index of the first occurrence of substring</td>
</tr>
<tr>
<td>LCASE()</td>
<td>Synonym for LOWER()</td>
</tr>
<tr>
<td>LEFT()</td>
<td>Return the leftmost number of characters as specified</td>
</tr>
<tr>
<td>LENGTH()</td>
<td>Return the length of a string in bytes</td>
</tr>
<tr>
<td>LIKE</td>
<td>Simple pattern matching</td>
</tr>
<tr>
<td>LOAD_FILE()</td>
<td>Load the named file</td>
</tr>
<tr>
<td>LOCATE()</td>
<td>Return the position of the first occurrence of substring</td>
</tr>
<tr>
<td>LOWER()</td>
<td>Return the argument in lowercase</td>
</tr>
<tr>
<td>LPAD()</td>
<td>Return the string argument, left-padded with the specified string</td>
</tr>
<tr>
<td>LTRIM()</td>
<td>Remove leading spaces</td>
</tr>
<tr>
<td>MAKE_SET()</td>
<td>Return a set of comma-separated strings that have the corresponding bit in bits set</td>
</tr>
<tr>
<td>MATCH</td>
<td>Perform full-text search</td>
</tr>
<tr>
<td>MID()</td>
<td>Return a substring starting from the specified position</td>
</tr>
<tr>
<td>NOT LIKE</td>
<td>Negation of simple pattern matching</td>
</tr>
<tr>
<td>NOT REGEXP</td>
<td>Negation of REGEXP</td>
</tr>
<tr>
<td>OCT()</td>
<td>Return a string containing octal representation of a number</td>
</tr>
<tr>
<td>OCTET_LENGTH()</td>
<td>Synonym for LENGTH()</td>
</tr>
<tr>
<td>ORD()</td>
<td>Return character code for leftmost character of the argument</td>
</tr>
<tr>
<td>POSITION()</td>
<td>Synonym for LOCATE()</td>
</tr>
<tr>
<td>QUOTE()</td>
<td>Escape the argument for use in an SQL statement</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------------------------------------------</td>
</tr>
<tr>
<td>REGEXP</td>
<td>Pattern matching using regular expressions</td>
</tr>
<tr>
<td>REPEAT()</td>
<td>Repeat a string the specified number of times</td>
</tr>
<tr>
<td>REPLACE()</td>
<td>Replace occurrences of a specified string</td>
</tr>
<tr>
<td>REVERSE()</td>
<td>Reverse the characters in a string</td>
</tr>
<tr>
<td>RIGHT()</td>
<td>Return the specified rightmost number of characters</td>
</tr>
<tr>
<td>RLIKE</td>
<td>Synonym for REGEXP</td>
</tr>
<tr>
<td>RPAD()</td>
<td>Append string the specified number of times</td>
</tr>
<tr>
<td>RTRIM()</td>
<td>Remove trailing spaces</td>
</tr>
<tr>
<td>SOURNDEX()</td>
<td>Return a soundex string</td>
</tr>
<tr>
<td>SOURNDEX LIKE</td>
<td>Compare sounds</td>
</tr>
<tr>
<td>SPACE()</td>
<td>Return a string of the specified number of spaces</td>
</tr>
<tr>
<td>STRCMP()</td>
<td>Compare two strings</td>
</tr>
<tr>
<td>SUBSTR()</td>
<td>Return the substring as specified</td>
</tr>
<tr>
<td>SUBSTRING()</td>
<td>Return the substring as specified</td>
</tr>
<tr>
<td>SUBSTRING_INDEX()</td>
<td>Return a substring from a string before the specified number of occurrences of the delimiter</td>
</tr>
<tr>
<td>TRIM()</td>
<td>Remove leading and trailing spaces</td>
</tr>
<tr>
<td>UCASE()</td>
<td>Synonym for UPPER()</td>
</tr>
<tr>
<td>UNHEX()</td>
<td>Return a string containing hex representation of a number</td>
</tr>
<tr>
<td>UPPER()</td>
<td>Convert to uppercase</td>
</tr>
</tbody>
</table>

String-valued functions return **NULL** if the length of the result would be greater than the value of the `max_allowed_packet` system variable. See Section 8.12.2, “Tuning Server Parameters”.

For functions that operate on string positions, the first position is numbered 1.

For functions that take length arguments, noninteger arguments are rounded to the nearest integer.

- **ASCII(str)**

  Returns the numeric value of the leftmost character of the string `str`. Returns 0 if `str` is the empty string. Returns **NULL** if `str` is **NULL**. `ASCII()` works for 8-bit characters.

  ```
  mysql> SELECT ASCII('2');
  -> 50
  mysql> SELECT ASCII(2);
  -> 50
  mysql> SELECT ASCII('dx');
  -> 100
  ```

  See also the **ORD()** function.

- **BIN(N)**

  Returns a string representation of the binary value of `N`, where `N` is a longlong (BIGINT) number. This is equivalent to `CONV(N,10,2)`. Returns **NULL** if `N` is **NULL**.

  ```
  mysql> SELECT BIN(12);
  -> '1100'
  ```

- **BIT_LENGTH(str)**
Returns the length of the string \textit{str} in bits.

```
mysql> SELECT BIT_LENGTH('text');
-> 32
```

- \texttt{CHAR(N, \ldots \ [USING\ charset\_name])}

\textit{CHAR()} interprets each argument \textit{N} as an integer and returns a string consisting of the characters given by the code values of those integers. \texttt{NULL} values are skipped.

```
mysql> SELECT CHAR(77,121,83,81,'76');
-> 'MySQL'
```

\textit{CHAR()} arguments larger than 255 are converted into multiple result bytes. For example, \texttt{CHAR(256)} is equivalent to \texttt{CHAR(1,0)}, and \texttt{CHAR(256*256)} is equivalent to \texttt{CHAR(1,0,0)}:

```
mysql> SELECT HEX(CHAR(1,0)), HEX(CHAR(256));
+----------------+----------------+
| HEX(CHAR(1,0)) | HEX(CHAR(256)) |
+----------------+----------------+
| 0100           | 0100           |
+----------------+----------------+
mysql> SELECT HEX(CHAR(1,0,0)), HEX(CHAR(256*256));
+------------------+--------------------+
| HEX(CHAR(1,0,0)) | HEX(CHAR(256*256)) |
| 010000           | 010000             |
+------------------+--------------------+
```

By default, \textit{CHAR()} returns a binary string. To produce a string in a given character set, use the optional \texttt{USING} clause:

```
mysql> SELECT CHARSET(CHAR(X'65')), CHARSET(CHAR(X'65' USING utf8));
+----------------------+---------------------------------+
| CHARSET(CHAR(X'65')) | CHARSET(CHAR(X'65' USING utf8)) |
+----------------------+---------------------------------+
| binary               | utf8                            |
+----------------------+---------------------------------+
```

If \texttt{USING} is given and the result string is illegal for the given character set, a warning is issued. Also, if strict SQL mode is enabled, the result from \textit{CHAR()} becomes \texttt{NULL}.

- \texttt{CHAR\_LENGTH(str)}

Returns the length of the string \textit{str}, measured in characters. A multibyte character counts as a single character. This means that for a string containing five 2-byte characters, \texttt{LENGTH()} returns \texttt{10}, whereas \texttt{CHAR\_LENGTH()} returns \texttt{5}.

- \texttt{CHARACTER\_LENGTH(str)}

\texttt{CHARACTER\_LENGTH()} is a synonym for \texttt{CHAR\_LENGTH()}.

- \texttt{CONCAT(str1,str2,\ldots)}

Returns the string that results from concatenating the arguments. May have one or more arguments. If all arguments are nonbinary strings, the result is a nonbinary string. If the arguments include any binary strings, the result is a binary string. A numeric argument is converted to its equivalent binary string form; if you want to avoid that, you can use an explicit type cast, as in this example:
### String Functions

```sql
SELECT CONCAT(CAST(int_col AS CHAR), char_col);
```

**CONCAT()** returns NULL if any argument is NULL.

```sql
mysql> SELECT CONCAT('My', 'S', 'QL');
-> 'MySQL'
mysql> SELECT CONCAT('My', NULL, 'QL');
-> NULL
mysql> SELECT CONCAT(14.3);
-> '14.3'
```

For quoted strings, concatenation can be performed by placing the strings next to each other:

```sql
mysql> SELECT 'My' 'S' 'QL';
-> 'MySQL'
```

**CONCAT_WS()**

**CONCAT_WS()** stands for Concatenate With Separator and is a special form of **CONCAT()**. The first argument is the separator for the rest of the arguments. The separator is added between the strings to be concatenated. The separator can be a string, as can the rest of the arguments. If the separator is NULL, the result is NULL.

```sql
mysql> SELECT CONCAT_WS(',', 'First name', 'Second name', 'Last Name');
-> 'First name,Second name,Last Name'
mysql> SELECT CONCAT_WS(',', 'First name', NULL, 'Last Name');
-> 'First name,Last Name'
```

**CONCAT_WS()** does not skip empty strings. However, it does skip any NULL values after the separator argument.

**ELT()**

**ELT()** returns the \( N \)th element of the list of strings: \( str1 \) if \( N = 1 \), \( str2 \) if \( N = 2 \), and so on. Returns NULL if \( N \) is less than 1 or greater than the number of arguments. **ELT()** is the complement of **FIELD()**.

```sql
mysql> SELECT ELT(1, 'ej', 'Heja', 'hej', 'foo');
-> 'ej'
mysql> SELECT ELT(4, 'ej', 'Heja', 'hej', 'foo');
-> 'foo'
```

**EXPORT_SET()**

**EXPORT_SET()** returns a string such that for every bit set in the value \( bits \), you get an \( on \) string and for every bit not set in the value, you get an \( off \) string. Bits in \( bits \) are examined from right to left (from low-order to high-order bits). Strings are added to the result from left to right, separated by the separator string (the default being the comma character ","). The number of bits examined is given by \( number_of_bits \), which has a default of 64 if not specified. \( number_of_bits \) is silently clipped to 64 if larger than 64. It is treated as an unsigned integer, so a value of -1 is effectively the same as 64.

```sql
mysql> SELECT EXPORT_SET(5, 'Y', 'N', ',', 4);  
-> 'Y,N,Y,N'
mysql> SELECT EXPORT_SET(6, '1', '0', ',', 10); 
-> '0,1,1,0,0,0,0,0,0,0'
```

**FIELD()**

**FIELD()** returns the index (position) of \( str \) in the \( str1, str2, str3, \ldots \) list. Returns 0 if \( str \) is not found.
If all arguments to `FIELD()` are strings, all arguments are compared as strings. If all arguments are numbers, they are compared as numbers. Otherwise, the arguments are compared as double.

If `str` is NULL, the return value is 0 because NULL fails equality comparison with any value. `FIELD()` is the complement of `ELT()`.

```sql
mysql> SELECT FIELD('ej', 'Hej', 'ej', 'Heja', 'hej', 'foo');
-> 2
```

```sql
mysql> SELECT FIELD('fo', 'Hej', 'ej', 'Heja', 'hej', 'foo');
-> 0
```

• **FIND_IN_SET(str,strlist)**

Returns a value in the range of 1 to `N` if the string `str` is in the string list `strlist` consisting of `N` substrings. A string list is a string composed of substrings separated by `,` characters. If the first argument is a constant string and the second is a column of type `SET`, the `FIND_IN_SET()` function is optimized to use bit arithmetic. Returns 0 if `str` is not in `strlist` or if `strlist` is the empty string. Returns NULL if either argument is NULL. This function does not work properly if the first argument contains a comma (`,`) character.

```sql
mysql> SELECT FIND_IN_SET('b','a,b,c,d');
-> 2
```

• **FORMAT(X,D)**

Formats the number `X` to a format like '#,###,###.##', rounded to `D` decimal places, and returns the result as a string. If `D` is 0, the result has no decimal point or fractional part.

```sql
mysql> SELECT FORMAT(12332.123456, 4);
-> '12,332.1235'
```

```sql
mysql> SELECT FORMAT(12332.1,4);
-> '12,332.1000'
```

```sql
mysql> SELECT FORMAT(12332.2,0);
-> '12,332'
```

• **HEX(str), HEX(N)**

For a string argument `str`, `HEX()` returns a hexadecimal string representation of `str` where each byte of each character in `str` is converted to two hexadecimal digits. (Multibyte characters therefore become more than two digits.) The inverse of this operation is performed by the `UNHEX()` function.

For a numeric argument `N`, `HEX()` returns a hexadecimal string representation of the value of `N` treated as a longlong (`BIGINT`) number. This is equivalent to `CONV(N,10,16)`. The inverse of this operation is performed by `CONV(HEX(N),16,10)`.

```sql
mysql> SELECT X'616263', HEX('abc'), UNHEX(HEX('abc'));
-> 'abc', 616263, 'abc'
```

```sql
mysql> SELECT HEX(255), CONV(HEX(255),16,10);
-> 'FF', 255
```

• **INSERT(str,pos,len,newstr)**

Returns the string `str`, with the substring beginning at position `pos` and `len` characters long replaced by the string `newstr`. Returns the original string if `pos` is not within the length of the string. Replaces the rest of the string from position `pos` if `len` is not within the length of the rest of the string. Returns NULL if any argument is NULL.

```sql
mysql> SELECT INSERT('Quadratic', 3, 4, 'What');
-> 'QuWhattic'
```

```sql
mysql> SELECT INSERT('Quadratic', -1, 4, 'What');
```

1038
-> 'Quadratic'

mysql> SELECT INSERT('Quadratic', 3, 100, 'What');
-> 'QuWhat'

This function is multibyte safe.

• \texttt{INSTR(str, substr)}

Returns the position of the first occurrence of substring \texttt{substr} in string \texttt{str}. This is the same as the two-argument form of \texttt{LOCATE()}, except that the order of the arguments is reversed.

mysql> SELECT INSTR('foobabbar', 'bar');
-> 4
mysql> SELECT INSTR('xbar', 'foobabbar');
-> 0

This function is multibyte safe, and is case sensitive only if at least one argument is a binary string.

• \texttt{LCASE(str)}

\texttt{LCASE()} is a synonym for \texttt{LOWER()}.

• \texttt{LEFT(str, len)}

Returns the leftmost \texttt{len} characters from the string \texttt{str}, or \texttt{NULL} if any argument is \texttt{NULL}.

mysql> SELECT LEFT('foobabbar', 5);
-> 'fooba'

This function is multibyte safe.

• \texttt{LENGTH(str)}

Returns the length of the string \texttt{str}, measured in bytes. A multibyte character counts as multiple bytes. This means that for a string containing five 2-byte characters, \texttt{LENGTH()} returns 10, whereas \texttt{CHAR_LENGTH()} returns 5.

mysql> SELECT LENGTH('text');
-> 4

\textbf{Note}

The \texttt{Length()} OpenGIS spatial function is named \texttt{GLength()} in MySQL.

• \texttt{LOAD_FILE(file_name)}

Reads the file and returns the file contents as a string. To use this function, the file must be located on the server host, you must specify the full path name to the file, and you must have the \texttt{FILE} privilege. The file must be readable by all and its size less than \texttt{max_allowed_packet} bytes. If the \texttt{secure_file_priv} system variable is set to a nonempty directory name, the file to be loaded must be located in that directory.

If the file does not exist or cannot be read because one of the preceding conditions is not satisfied, the function returns \texttt{NULL}.

As of MySQL 5.1.6, the \texttt{character_set_filesystem} system variable controls interpretation of file names that are given as literal strings.

mysql> UPDATE t
    SET blob_col=LOAD_FILE('/tmp/picture')
    WHERE id=1;
• **LOCATE(substr, str), LOCATE(substr, str, pos)**

The first syntax returns the position of the first occurrence of substring `substr` in string `str`. The second syntax returns the position of the first occurrence of substring `substr` in string `str`, starting at position `pos`. Returns 0 if `substr` is not in `str`.

```sql
mysql> SELECT LOCATE('bar', 'foobobar');
-> 4
mysql> SELECT LOCATE('xbar', 'foobob');
-> 0
mysql> SELECT LOCATE('bar', 'foobobbar', 5);
-> 7
```

This function is multibyte safe, and is case-sensitive only if at least one argument is a binary string.

• **LOWER(str)**

Returns the string `str` with all characters changed to lowercase according to the current character set mapping. The default is `latin1` (cp1252 West European).

```sql
mysql> SELECT LOWER('QUADRATICALLY');
-> 'quadratically'
```

`LOWER()` (and `UPPER()`) are ineffective when applied to binary strings (BINARY, VARBINARY, BLOB). To perform lettercase conversion, convert the string to a nonbinary string:

```sql
mysql> SET @str = BINARY 'New York';
mysql> SELECT LOWER(@str), LOWER(CONVERT(@str USING latin1));
+-------------+-----------------------------------+
| LOWER(@str) | LOWER(CONVERT(@str USING latin1)) |
+-------------+-----------------------------------+
| New York    | new york                          |
+-------------+-----------------------------------+
```

This function is multibyte safe.

• **LPAD(str, len, padstr)**

Returns the string `str`, left-padded with the string `padstr` to a length of `len` characters. If `str` is longer than `len`, the return value is shortened to `len` characters.

```sql
mysql> SELECT LPAD('hi',4,'??');
-> '??hi'
mysql> SELECT LPAD('hi',1,'??');
-> 'h'
```

• **LTRIM(str)**

Returns the string `str` with leading space characters removed.

```sql
mysql> SELECT LTRIM('  barbar');
-> 'barbar'
```

This function is multibyte safe.

• **MAKE_SET(bits, str1, str2,...)**

Returns a set value (a string containing substrings separated by ”,” characters) consisting of the strings that have the corresponding bit in `bits` set. `str1` corresponds to bit 0, `str2` to bit 1, and so on. NULL values in `str1, str2,...` are not appended to the result.
String Functions

- **MID** (str, pos, len)

  `MID(str, pos, len)` is a synonym for `SUBSTRING(str, pos, len)`.

- **OCT** (N)

  Returns a string representation of the octal value of `N`, where `N` is a longlong (`BIGINT`) number. This is equivalent to `CONV(N, 10, 8)`. Returns `NULL` if `N` is `NULL`.

  ```
  mysql> SELECT OCT(12);
  -> '14'
  ```

- **OCTET_LENGTH** (str)

  `OCTET_LENGTH(str)` is a synonym for `LENGTH()`.

- **ORD** (str)

  If the leftmost character of the string `str` is a multibyte character, returns the code for that character, calculated from the numeric values of its constituent bytes using this formula:

  ```
  1st byte code + (2nd byte code * 256) + (3rd byte code * 256^2) ...
  ```

  If the leftmost character is not a multibyte character, `ORD()` returns the same value as the `ASCII()` function.

  ```
  mysql> SELECT ORD('2');
  -> 50
  ```

- **POSITION** (substr IN str)

  `POSITION(substr IN str)` is a synonym for `LOCATE(substr, str)`.

- **QUOTE** (str)

  Quotes a string to produce a result that can be used as a properly escaped data value in an SQL statement. The string is returned enclosed by single quotation marks and with each instance of backslash ("\\"), single quote ("\'"), ASCII NUL, and Control+Z preceded by a backslash. If the argument is `NULL`, the return value is the word "NULL" without enclosing single quotation marks.

  ```
  mysql> SELECT QUOTE('Don\'t!');
  -> 'Don\'t!'
  mysql> SELECT QUOTE(NULL);
  -> NULL
  ```

  For comparison, see the quoting rules for literal strings and within the C API in Section 9.1.1, “String Literals”, and Section 21.8.7.53, “mysql_real_escape_string()”.

- **REPEAT** (str, count)
Returns a string consisting of the string `str` repeated `count` times. If `count` is less than 1, returns an empty string. Returns `NULL` if `str` or `count` are `NULL`.

```sql
mysql> SELECT REPEAT('MySQL', 3);
-> 'MySQLMySQLMySQL'
```

- **REPLACE**(str, from_str, to_str)

Returns the string `str` with all occurrences of the string `from_str` replaced by the string `to_str`. `REPLACE()` performs a case-sensitive match when searching for `from_str`.

```sql
mysql> SELECT REPLACE('www.mysql.com', 'w', 'Ww');
-> 'WwWwWw.mysql.com'
```

This function is multibyte safe.

- **REVERSE**(str)

Returns the string `str` with the order of the characters reversed.

```sql
mysql> SELECT REVERSE('abc');
-> 'cba'
```

This function is multibyte safe.

- **RIGHT**(str, len)

Returns the rightmost `len` characters from the string `str`, or `NULL` if any argument is `NULL`.

```sql
mysql> SELECT RIGHT('foobarbar', 4);  
-> 'rbar'
```

This function is multibyte safe.

- **RPAD**(str, len, padstr)

Returns the string `str`, right-padded with the string `padstr` to a length of `len` characters. If `str` is longer than `len`, the return value is shortened to `len` characters.

```sql
mysql> SELECT RPAD('hi',5,'?');    
-> 'hi???'  
mysql> SELECT RPAD('hi',1,'?');    
-> 'h'
```

This function is multibyte safe.

- **RTRIM**(str)

Returns the string `str` with trailing space characters removed.

```sql
mysql> SELECT RTRIM('barbar   '); 
-> 'barbar'
```

This function is multibyte safe.

- **SOUNDEX**(str)

Returns a soundex string from `str`. Two strings that sound almost the same should have identical soundex strings. A standard soundex string is four characters long, but the `SOUNDEX()` function returns an arbitrarily long string. You can use `SUBSTRING()` on the result to get a standard soundex
string. All nonalphabetic characters in \texttt{str} are ignored. All international alphabetic characters outside the A-Z range are treated as vowels.

\begin{itemize}
\item \textbf{Important}
\end{itemize}

When using \texttt{SOUNDEX()}, you should be aware of the following limitations:

\begin{itemize}
\item This function, as currently implemented, is intended to work well with strings that are in the English language only. Strings in other languages may not produce reliable results.
\item This function is not guaranteed to provide consistent results with strings that use multibyte character sets, including \texttt{utf-8}.
\end{itemize}

We hope to remove these limitations in a future release. See Bug \#22638 for more information.

\begin{verbatim}
mysql> SELECT SOUNDEX('Hello');
-> 'H400'
mysql> SELECT SOUNDEX('Quadratically');
-> 'Q36324'
\end{verbatim}

\begin{itemize}
\item \textbf{Note}
\end{itemize}

This function implements the original Soundex algorithm, not the more popular enhanced version (also described by D. Knuth). The difference is that original version discards vowels first and duplicates second, whereas the enhanced version discards duplicates first and vowels second.

\begin{itemize}
\item \texttt{expr1} \texttt{SOUNDS LIKE} \texttt{expr2}
\end{itemize}

This is the same as \texttt{SOUNDEX(expr1) = SOUNDEX(expr2)}.

\begin{itemize}
\item \texttt{SPACE(N)}
\end{itemize}

Returns a string consisting of \texttt{N} space characters.

\begin{verbatim}
mysql> SELECT SPACE(6);
-> '      ';
\end{verbatim}

\begin{itemize}
\item \texttt{SUBSTR(str,pos)}, \texttt{SUBSTR(str FROM pos)}, \texttt{SUBSTR(str,pos,len)}, \texttt{SUBSTR(str FROM pos FOR len)}
\end{itemize}

\texttt{SUBSTR()} is a synonym for \texttt{SUBSTRING()}.

\begin{itemize}
\item \texttt{SUBSTRING(str,pos)}, \texttt{SUBSTRING(str FROM pos)}, \texttt{SUBSTRING(str,pos,len)}, \texttt{SUBSTRING(str FROM pos FOR len)}
\end{itemize}

The forms without a \texttt{len} argument return a substring from string \texttt{str} starting at position \texttt{pos}. The forms with a \texttt{len} argument return a substring \texttt{len} characters long from string \texttt{str}, starting at position \texttt{pos}. The forms that use \texttt{FROM} are standard SQL syntax. It is also possible to use a negative value for \texttt{pos}. In this case, the beginning of the substring is \texttt{pos} characters from the end of the string, rather than the beginning. A negative value may be used for \texttt{pos} in any of the forms of this function.

For all forms of \texttt{SUBSTRING()}, the position of the first character in the string from which the substring is to be extracted is reckoned as \texttt{1}.

\begin{verbatim}
mysql> SELECT SUBSTRING('Quadratically',5);
-> 'ratically'
mysql> SELECT SUBSTRING('foobarbar' FROM 4);
-> 'barbar'
mysql> SELECT SUBSTRING('Quadratically',5,6);
\end{verbatim}
This function is multibyte safe.

If \texttt{len} is less than 1, the result is the empty string.

\begin{itemize}
  \item \texttt{SUBSTRING\_INDEX(str, delim, count)}
  \end{itemize}

Returns the substring from string \texttt{str} before \texttt{count} occurrences of the delimiter \texttt{delim}. If \texttt{count} is positive, everything to the left of the final delimiter (counting from the left) is returned. If \texttt{count} is negative, everything to the right of the final delimiter (counting from the right) is returned. \texttt{SUBSTRING\_INDEX()} performs a case-sensitive match when searching for \texttt{delim}.

This function is multibyte safe.

\begin{itemize}
  \item \texttt{TRIM([{BOTH | LEADING | TRAILING} [remstr] FROM] str),TRIM([remstr FROM] str)}
  \end{itemize}

Returns the string \texttt{str} with all \texttt{remstr} prefixes or suffixes removed. If none of the specifiers \texttt{BOTH}, \texttt{LEADING}, or \texttt{TRAILING} is given, \texttt{BOTH} is assumed. \texttt{remstr} is optional and, if not specified, spaces are removed.

This function is multibyte safe.

\begin{itemize}
  \item \texttt{UCASE(str)}
  \end{itemize}

\texttt{UCASE()} is a synonym for \texttt{UPPER()}. 

\begin{itemize}
  \item \texttt{UNHEX(str)}
  \end{itemize}

For a string argument \texttt{str}, \texttt{UNHEX(str)} interprets each pair of characters in the argument as a hexadecimal number and converts it to the byte represented by the number. The return value is a binary string.
String Comparison Functions

The characters in the argument string must be legal hexadecimal digits: '0'.. '9', 'A'.. 'F', 'a'.. 'f'. If the argument contains any nonhexadecimal digits, the result is NULL:

```sql
mysql> SELECT UNHEX('GG');
+-------------------+
| UNHEX('GG')       |
+-------------------+
| NULL              |
+-------------------+
```

A NULL result can occur if the argument to UNHEX() is a BINARY column, because values are padded with 0x00 bytes when stored but those bytes are not stripped on retrieval. For example, '41' is stored into a CHAR(3) column as '41 ' and retrieved as '41' (with the trailing pad space stripped), so UNHEX() for the column value returns 'A'. By contrast '41' is stored into a BINARY(3) column as '41\0' and retrieved as '41\0' (with the trailing pad 0x00 byte not stripped). '\0' is not a legal hexadecimal digit, so UNHEX() for the column value returns NULL.

For a numeric argument N, the inverse of HEX(N) is not performed by UNHEX(). Use CONV(HEX(N),16,10) instead. See the description of HEX().

- **UPPER(str)**

Returns the string str with all characters changed to uppercase according to the current character set mapping. The default is latin1 (cp1252 West European).

```sql
mysql> SELECT UPPER('Hej');
-> 'HEJ'
```

See the description of LOWER() for information that also applies to UPPER(), such as information about how to perform lettercase conversion of binary strings (BINARY, VARBINARY, BLOB) for which these functions are ineffective.

This function is multibyte safe.

### 12.5.1 String Comparison Functions

**Table 12.8 String Comparison Operators**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LIKE</td>
<td>Simple pattern matching</td>
</tr>
<tr>
<td>NOT LIKE</td>
<td>Negation of simple pattern matching</td>
</tr>
<tr>
<td>STRCMP()</td>
<td>Compare two strings</td>
</tr>
</tbody>
</table>

If a string function is given a binary string as an argument, the resulting string is also a binary string. A number converted to a string is treated as a binary string. This affects only comparisons.

Normally, if any expression in a string comparison is case sensitive, the comparison is performed in case-sensitive fashion.

- **expr LIKE pat [ESCAPE 'escape_char']**

Pattern matching using an SQL pattern. Returns 1 (TRUE) or 0 (FALSE). If either expr or pat is NULL, the result is NULL.

The pattern need not be a literal string. For example, it can be specified as a string expression or table column.

Per the SQL standard, LIKE performs matching on a per-character basis, thus it can produce results different from the = comparison operator:
In particular, trailing spaces are significant, which is not true for \texttt{CHAR} or \texttt{VARCHAR} comparisons performed with the = operator:

\begin{verbatim}
mysql> SELECT 'a' = 'a ', 'a' LIKE 'a ';  
<table>
<thead>
<tr>
<th>'a' = 'a '</th>
<th>'a' LIKE 'a '</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

1 row in set (0.00 sec)
\end{verbatim}

With \texttt{LIKE} you can use the following two wildcard characters in the pattern:

- \texttt{%} matches any number of characters, even zero characters.
- \texttt{\_} matches exactly one character.

\begin{verbatim}
mysql> SELECT 'David!' LIKE 'David_';  
-> 1
mysql> SELECT 'David!' LIKE '%D%v%';  
-> 1
\end{verbatim}

To test for literal instances of a wildcard character, precede it by the escape character. If you do not specify the \texttt{ESCAPE} character, \texttt{	extasciitilde} is assumed.

- \texttt{	extasciitilde} matches one \texttt{%} character.
- \texttt{\_} matches one \texttt{\_} character.

\begin{verbatim}
mysql> SELECT 'David!' LIKE 'David\_';  
-> 0
mysql> SELECT 'David_' LIKE 'David\_';  
-> 1
\end{verbatim}

To specify a different escape character, use the \texttt{ESCAPE} clause:

\begin{verbatim}
mysql> SELECT 'David_' LIKE 'David|_' ESCAPE '|';  
-> 1
\end{verbatim}

The escape sequence should be empty or one character long. The expression must evaluate as a constant at execution time. As of MySQL 5.1.2, if the \texttt{NO_BACKSLASH_ESCAPES} SQL mode is enabled, the sequence cannot be empty.

The following two statements illustrate that string comparisons are not case sensitive unless one of the operands is a case sensitive (uses a case-sensitive collation or is a binary string):

\begin{verbatim}
mysql> SELECT 'abc' LIKE 'ABC';  
-> 1
\end{verbatim}
As an extension to standard SQL, MySQL permits `LIKE` on numeric expressions.

```sql
mysql> SELECT 10 LIKE '1%';
-> 1
```

**Note**

Because MySQL uses C escape syntax in strings (for example, "\n" to represent a newline character), you must double any "\" that you use in `LIKE` strings. For example, to search for "\n", specify it as "\\n". To search for "\", specify it as "\\\"; this is because the backslashes are stripped once by the parser and again when the pattern match is made, leaving a single backslash to be matched against.

**Exception:** At the end of the pattern string, backslash can be specified as "\". At the end of the string, backslash stands for itself because there is nothing following to escape. Suppose that a table contains the following values:

```sql
mysql> SELECT filename FROM t1;
+-------------+
| filename    |
+-------------+
| C:          |
| C:\         |
| C:\Programs |
| C:\Programs\ |
+-------------+
```

To test for values that end with backslash, you can match the values using either of the following patterns:

```sql
mysql> SELECT filename, filename LIKE '%\' FROM t1;
+--------------+---------------------+
| filename     | filename LIKE '%\'  |
+--------------+---------------------+
| C:           |                    0 |
| C:\          |                    1 |
| C:\Programs  |                    0 |
| C:\Programs\ |                    1 |
+--------------+---------------------+
```

```sql
mysql> SELECT filename, filename LIKE '%\\' FROM t1;
+--------------+-----------------------+
| filename     | filename LIKE '%\\' |
+--------------+-----------------------+
| C:           |                     0 |
| C:\          |                     1 |
| C:\Programs  |                     0 |
| C:\Programs\ |                     1 |
+--------------+-----------------------+
```

- `expr NOT LIKE pat [ESCAPE 'escape_char']`

  This is the same as `NOT (expr LIKE pat [ESCAPE 'escape_char'])`. 

Note

Aggregate queries involving NOT LIKE comparisons with columns containing NULL may yield unexpected results. For example, consider the following table and data:

```
CREATE TABLE foo (bar VARCHAR(10));
INSERT INTO foo VALUES (NULL), (NULL);
```

The query `SELECT COUNT(*) FROM foo WHERE bar LIKE '%baz%'` returns 0. You might assume that `SELECT COUNT(*) FROM foo WHERE bar NOT LIKE '%baz%'` would return 2. However, this is not the case: The second query returns 0. This is because NULL NOT LIKE expr always returns NULL, regardless of the value of expr. The same is true for aggregate queries involving NULL and comparisons using NOT RLIKE or NOT REGEXP. In such cases, you must test explicitly for NOT NULL using OR (and not AND), as shown here:

```
SELECT COUNT(*) FROM foo WHERE bar NOT LIKE '%baz%' OR bar IS NULL;
```

- `STRCMP (expr1, expr2)`

`STRCMP()` returns 0 if the strings are the same, -1 if the first argument is smaller than the second according to the current sort order, and 1 otherwise.

```
mysql> SELECT STRCMP('text', 'text2');
-> -1

mysql> SELECT STRCMP('text2', 'text');
-> 1

mysql> SELECT STRCMP('text', 'text');
-> 0
```

`STRCMP()` performs the comparison using the collation of the arguments.

```
mysql> SET @s1 = _latin1 'x' COLLATE latin1_general_ci;
mysql> SET @s2 = _latin1 'X' COLLATE latin1_general_ci;
mysql> SET @s3 = _latin1 'x' COLLATE latin1_general_cs;
mysql> SET @s4 = _latin1 'X' COLLATE latin1_general_cs;
mysql> SELECT STRCMP(@s1, @s2), STRCMP(@s3, @s4);
```

```
+------------------++------------------+
| STRCMP(@s1, @s2) | STRCMP(@s3, @s4) |
+------------------++------------------+
|                  0 |                  1 |
```

If the collations are incompatible, one of the arguments must be converted to be compatible with the other. See Section 10.1.7.5, “Collation of Expressions”.

```
mysql> SELECT STRCMP(@s1, @s3);  
ERROR 1267 (HY000): Illegal mix of collations (latin1_general_ci,IMPlicit) and (latin1_general_cs,IMPlicit) for operation 'strcmp'
```

```
mysql> SELECT STRCMP(@s1, @s3 COLLATE latin1_general_ci);
```

```
+------------------+
| STRCMP(@s1, @s3 COLLATE latin1_general_ci) |
|                  0 |
```

12.5.2 Regular Expressions
Regular Expressions

Table 12.9 String Regular Expression Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NOT REGEXP</td>
<td>Negation of REGEXP</td>
</tr>
<tr>
<td>REGEXP</td>
<td>Pattern matching using regular expressions</td>
</tr>
<tr>
<td>RLIKE</td>
<td>Synonym for REGEXP</td>
</tr>
</tbody>
</table>

A regular expression is a powerful way of specifying a pattern for a complex search.

MySQL uses Henry Spencer's implementation of regular expressions, which is aimed at conformance with POSIX 1003.2. MySQL uses the extended version to support pattern-matching operations performed with the `REGEXP` operator in SQL statements.

This section summarizes, with examples, the special characters and constructs that can be used in MySQL for `REGEXP` operations. It does not contain all the details that can be found in Henry Spencer's `regex(7)` manual page. That manual page is included in MySQL source distributions, in the `regex.7` file under the `regex` directory. See also Section 3.3.4.7, "Pattern Matching".

### Regular Expression Operators

- `expr NOT REGEXP pat, expr NOT RLIKE pat`
  
  This is the same as `NOT (expr REGEXP pat)`.  

- `expr REGEXP pat, expr RLIKE pat`
  
  Performs a pattern match of a string expression `expr` against a pattern `pat`. The pattern can be an extended regular expression, the syntax for which is discussed later in this section. Returns 1 if `expr` matches `pat`; otherwise it returns 0. If either `expr` or `pat` is NULL, the result is NULL. RLIKE is a synonym for REGEXP, provided for mSQL compatibility.

The pattern need not be a literal string. For example, it can be specified as a string expression or table column.

#### Note

Because MySQL uses the C escape syntax in strings (for example, “\n” to represent the newline character), you must double any “\" that you use in your REGEXP strings.

**REGEXP** is not case sensitive, except when used with binary strings.

```sql
mysql> SELECT 'Monty!' REGEXP '.*';
-> 1
mysql> SELECT 'new\n*line' REGEXP 'new\*.\*line';
-> 1
mysql> SELECT 'a' REGEXP 'A', 'a' REGEXP BINARY 'A';
-> 1  0
mysql> SELECT 'a' REGEXP '^[a-d]';
-> 1
```

**REGEXP** and **RLIKE** use the character set and collations of the arguments when deciding the type of a character and performing the comparison. If the arguments have different character sets or collations, coercibility rules apply as described in Section 10.1.7.5, "Collation of Expressions".

#### Warning

The **REGEXP** and **RLIKE** operators work in byte-wise fashion, so they are not multibyte safe and may produce unexpected results with multibyte character
sets. In addition, these operators compare characters by their byte values and accented characters may not compare as equal even if a given collation treats them as equal.

Syntax of Regular Expressions

A regular expression describes a set of strings. The simplest regular expression is one that has no special characters in it. For example, the regular expression `hello` matches `hello` and nothing else.

Nontrivial regular expressions use certain special constructs so that they can match more than one string. For example, the regular expression `hello|word` matches either the string `hello` or the string `word`.

As a more complex example, the regular expression `B[an]*s` matches any of the strings `Bananas`, `Baaaaas`, `Bs`, and any other string starting with a `B`, ending with an `s`, and containing any number of `a` or `n` characters in between.

A regular expression for the `REGEXP` operator may use any of the following special characters and constructs:

- `^`
  
  Match the beginning of a string.

  ```
  mysql> SELECT 'fo\nfo' REGEXP '^fo$'; -> 0
  mysql> SELECT 'fofo' REGEXP '^fo$'; -> 1
  ```

- `$`
  
  Match the end of a string.

  ```
  mysql> SELECT 'fo\no' REGEXP '^fo\no$'; -> 1
  mysql> SELECT 'fo\no' REGEXP '^fo$'; -> 0
  ```

- `.`
  
  Match any character (including carriage return and newline).

  ```
  mysql> SELECT 'fofo' REGEXP '^f.*$'; -> 1
  mysql> SELECT 'fo\r\nfo' REGEXP '^f.*$'; -> 1
  ```

- `a*`
  
  Match any sequence of zero or more `a` characters.

  ```
  mysql> SELECT 'Ban' REGEXP '^Ba*n'; -> 1
  mysql> SELECT 'Baaan' REGEXP '^Ba*n'; -> 1
  mysql> SELECT 'Bn' REGEXP '^Ba*n'; -> 1
  ```

- `a+`
  
  Match any sequence of one or more `a` characters.

  ```
  mysql> SELECT 'Ban' REGEXP '^Ba+n'; -> 1
  mysql> SELECT 'Bn' REGEXP '^Ba+n'; -> 1
  ```

- `a?`
  
  Match either zero or one `a` character.

  ```
  mysql> SELECT 'Ban' REGEXP '^Ba+n'; -> 1
  mysql> SELECT 'Bn' REGEXP '^Ba+n'; -> 0
  ```
**Regular Expressions**

- **de|abc**
  
  Match either of the sequences de or abc.

- **(abc)***
  
  Match zero or more instances of the sequence abc.

- **{1, (2, 3)}**

  The \( n \) or \( (m, n) \) notation provides a more general way of writing regular expressions that match many occurrences of the previous atom (or “piece”) of the pattern. \( m \) and \( n \) are integers.

  - **a**
    
    Can be written as \( a\{0,\} \).

  - **a+**
    
    Can be written as \( a\{1,\} \).

  - **a?**
    
    Can be written as \( a\{0,1\} \).

    To be more precise, \( a\{n\} \) matches exactly \( n \) instances of \( a \). \( a\{n,\} \) matches \( n \) or more instances of \( a \). \( a\{m,n\} \) matches \( m \) through \( n \) instances of \( a \), inclusive.

    \( m \) and \( n \) must be in the range from 0 to RE_DUP_MAX (default 255), inclusive. If both \( m \) and \( n \) are given, \( m \) must be less than or equal to \( n \).

- **[a-dX], [^a-dX]**

  Matches any character that is (or is not, if ^ is used) either a, b, c, d or X. A – character between two other characters forms a range that matches all characters from the first character to the second.

  For example, \([0-9]\) matches any decimal digit. To include a literal – character, it must immediately follow the opening bracket [. To include a literal – character, it must be written first or last. Any character that does not have a defined special meaning inside a \([\]) pair matches only itself.
• [.characters.]

Within a bracket expression (written using [ and ]), matches the sequence of characters of that collating element. characters is either a single character or a character name like newline. The following table lists the permissible character names.

The following table shows the permissible character names and the characters that they match. For characters given as numeric values, the values are represented in octal.

<table>

</table>
Within a bracket expression (written using [ and ]), \[=character_class=\] represents an equivalence class. It matches all characters with the same collation value, including itself. For example, if \o\ and \(+\) are the members of an equivalence class, \[[=o=]\], \[[=(+)=]\], and \[o(+)\] are all synonymous. An equivalence class may not be used as an endpoint of a range.

Within a bracket expression (written using [ and ]), \[:character_class:\] represents a character class that matches all characters belonging to that class. The following table lists the standard class names. These names stand for the character classes defined in the ctype(3) manual page. A particular locale may provide other class names. A character class may not be used as an endpoint of a range.

### Numeric Functions and Operators

#### Character Class Name

<table>
<thead>
<tr>
<th>Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>print</code></td>
<td>Graphic or space characters</td>
</tr>
<tr>
<td><code>punct</code></td>
<td>Punctuation characters</td>
</tr>
<tr>
<td><code>space</code></td>
<td>Space, tab, newline, and carriage return</td>
</tr>
<tr>
<td><code>upper</code></td>
<td>Uppercase alphabetic characters</td>
</tr>
<tr>
<td><code>xdigit</code></td>
<td>Hexadecimal digit characters</td>
</tr>
</tbody>
</table>

```sql
mysql> SELECT 'justalnums' REGEXP '[:alnum:]+'; -- 1
mysql> SELECT '!!' REGEXP '[:alnum:]+'; -- 0
```

- `[:<:][:>:]`

These markers stand for word boundaries. They match the beginning and end of words, respectively. A word is a sequence of word characters that is not preceded by or followed by word characters. A word character is an alphanumeric character in the `alnum` class or an underscore `_`

```sql
mysql> SELECT 'a word a' REGEXP '[:<:]word[:>:]'; -- 1
mysql> SELECT 'a xword a' REGEXP '[:<:]word[:>:]'; -- 0
```

To use a literal instance of a special character in a regular expression, precede it by two backslash (`\`) characters. The MySQL parser interprets one of the backslashes, and the regular expression library interprets the other. For example, to match the string `1+2` that contains the special `+` character, only the last of the following regular expressions is the correct one:

```sql
mysql> SELECT '1+2' REGEXP '1+2'; -- 0
mysql> SELECT '1\+2' REGEXP '1\+2'; -- 0
mysql> SELECT '1\+2' REGEXP '1\+2'; -- 1
```

### 12.6 Numeric Functions and Operators

<table>

<td>Return the remainder</td>
</tr>
<tr>
<td>%, MOD</td>
<td>Modulo operator</td>
</tr>
<tr>
<td>PI()</td>
<td>Return the value of pi</td>
</tr>
<tr>
<td>+</td>
<td>Addition operator</td>
</tr>
<tr>
<td>POW()</td>
<td>Return the argument raised to the specified power</td>
</tr>
<tr>
<td>POWER()</td>
<td>Return the argument raised to the specified power</td>
</tr>
<tr>
<td>RADIANS()</td>
<td>Return argument converted to radians</td>
</tr>
<tr>
<td>RAND()</td>
<td>Return a random floating-point value</td>
</tr>
<tr>
<td>ROUND()</td>
<td>Round the argument</td>
</tr>
<tr>
<td>SIGN()</td>
<td>Return the sign of the argument</td>
</tr>
<tr>
<td>SIN()</td>
<td>Return the sine of the argument</td>
</tr>
<tr>
<td>SQRT()</td>
<td>Return the square root of the argument</td>
</tr>
<tr>
<td>TAN()</td>
<td>Return the tangent of the argument</td>
</tr>
<tr>
<td>*</td>
<td>Multiplication operator</td>
</tr>
<tr>
<td>TRUNCATE()</td>
<td>Truncate to specified number of decimal places</td>
</tr>
<tr>
<td>-</td>
<td>Change the sign of the argument</td>
</tr>
</tbody>
</table>

The usual arithmetic operators are available. The result is determined according to the following rules:

- In the case of −, +, and *, the result is calculated with BIGINT (64-bit) precision if both operands are integers.

- If both operands are integers and any of them are unsigned, the result is an unsigned integer. For subtraction, if the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled, the result is signed even if any operand is unsigned.

- If any of the operands of a +, −, /, *, % is a real or string value, the precision of the result is the precision of the operand with the maximum precision.
Arithmetic Operators

- In division performed with `/`, the scale of the result when using two exact-value operands is the scale of the first operand plus the value of the `div_precision_increment` system variable (which is 4 by default). For example, the result of the expression `5.05 / 0.014` has a scale of six decimal places (`360.714286`).

These rules are applied for each operation, such that nested calculations imply the precision of each component. Hence, `(14620 / 9432456) / (24250 / 9432456)`, resolves first to `(0.0014) / (0.0026)`, with the final result having 8 decimal places (`0.60288653`).

Because of these rules and the way they are applied, care should be taken to ensure that components and subcomponents of a calculation use the appropriate level of precision. See Section 12.10, "Cast Functions and Operators".

For information about handling of overflow in numeric expression evaluation, see Section 11.2.6, "Out-of-Range and Overflow Handling".

Arithmetic operators apply to numbers. For other types of values, alternative operations may be available. For example, to add date values, use `DATE_ADD();` see Section 12.7, "Date and Time Functions".

- `+`

  Addition:

  ```
  mysql> SELECT 3+5;
  -> 8
  ```

- `-`

  Subtraction:

  ```
  mysql> SELECT 3-5;
  -> -2
  ```

- `-`

  Unary minus. This operator changes the sign of the operand.

  ```
  mysql> SELECT -2;
  -> -2
  ```

  **Note**

  If this operator is used with a `BIGINT`, the return value is also a `BIGINT`. This means that you should avoid using `–` on integers that may have the value of `−2^63`.

- `*`

  Multiplication:

  ```
  mysql> SELECT 3*5;
  -> 15
  ```

  ```
  mysql> SELECT 18014398509481984*18014398509481984.0;
  -> 324518553658426726783156020576256.0
  ```

- `/`

  Division:
Division by zero produces a **NULL** result:

```sql
mysql> SELECT 3/5;
-> 0.60
```

A division is calculated with **BIGINT** arithmetic only if performed in a context where its result is converted to an integer.

- **DIV**

  Integer division. Discards from the division result any fractional part to the right of the decimal point. Incorrect results may occur for noninteger operands that exceed **BIGINT** range.

```sql
mysql> SELECT 5 DIV 2, -5 DIV 2, 5 DIV -2, -5 DIV -2;
-> 2, -2, -2, 2
```

- **N % M, N MOD M**

  Modulo operation. Returns the remainder of **N** divided by **M**. For more information, see the description for the **MOD()** function in **Section 12.6.2, “Mathematical Functions”**.

### 12.6.2 Mathematical Functions

**Table 12.12 Mathematical Functions**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>

<tr>
<td>TRUNCATE()</td>
<td>Truncate to specified number of decimal places</td>
</tr>
</tbody>
</table>

All mathematical functions return NULL in the event of an error.

- **ABS**(X)
  Returns the absolute value of \( X \).

  ```
  mysql> SELECT ABS(2);
  -> 2
  mysql> SELECT ABS(-32);
  -> 32
  ``

  This function is safe to use with BIGINT values.

- **ACOS**(X)
  Returns the arc cosine of \( X \), that is, the value whose cosine is \( X \). Returns NULL if \( X \) is not in the range \(-1\) to \(1\).

  ```
  mysql> SELECT ACOS(1);
  -> 0
  mysql> SELECT ACOS(1.0001);
  -> NULL
  mysql> SELECT ACOS(0);
  -> 1.5707963267949
  ```

- **ASIN**(X)
  Returns the arc sine of \( X \), that is, the value whose sine is \( X \). Returns NULL if \( X \) is not in the range \(-1\) to \(1\).

  ```
  mysql> SELECT ASIN(0.2);
  -> 0.20135792079033
  mysql> SELECT ASIN('foo');
  +-------------+
  | ASIN('foo') |
  +-------------+
  |           0 |
  +-------------+
  1 row in set, 1 warning (0.00 sec)
  ```

  ```
  mysql> SHOW WARNINGS;
  +---------+------+-----------------------------------------+
  | Level   | Code | Message                                 |
  +---------+------+-----------------------------------------+
  | Warning | 1292 | Truncated incorrect DOUBLE value: 'foo' |
  +---------+------+-----------------------------------------+
  ```

- **ATAN**(X)
Returns the arc tangent of $x$, that is, the value whose tangent is $x$.

```sql
mysql> SELECT ATAN(2);
-> 1.1071487177941
mysql> SELECT ATAN(-2);
-> -1.1071487177941
```

- **ATAN($y, x$)**
  Returns the arc tangent of the two variables $x$ and $y$. It is similar to calculating the arc tangent of $y / x$, except that the signs of both arguments are used to determine the quadrant of the result.

  ```sql
  mysql> SELECT ATAN(-2,2);
  -> -0.78539816339745
  mysql> SELECT ATAN2(PI(),0);
  -> 1.5707963267949
  ```

- **CEIL($x$)**
  `CEIL()` is a synonym for `CEILING()`.

- **CEILING($x$)**
  Returns the smallest integer value not less than $x$.

  ```sql
  mysql> SELECT CEILING(1.23);
  -> 2
  mysql> SELECT CEILING(-1.23);
  -> -1
  ```

  For exact-value numeric arguments, the return value has an exact-value numeric type. For string or floating-point arguments, the return value has a floating-point type.

- **CONV($n$, $from_base$, $to_base$)**
  Converts numbers between different number bases. Returns a string representation of the number $n$, converted from base $from_base$ to base $to_base$. Returns NULL if any argument is NULL. The argument $n$ is interpreted as an integer, but may be specified as an integer or a string. The minimum base is 2 and the maximum base is 36. If $from_base$ is a negative number, $n$ is regarded as a signed number. Otherwise, $n$ is treated as unsigned. `CONV()` works with 64-bit precision.

  ```sql
  mysql> SELECT CONV('a',16,2);
  -> '1010'
  mysql> SELECT CONV('6E',18,8);
  -> '172'
  mysql> SELECT CONV(-17,10,-18);
  -> '-H'
  mysql> SELECT CONV(10+'10'+X'0a',10,10);
  -> '40'
  ```

- **COS($x$)**
  Returns the cosine of $x$, where $x$ is given in radians.

  ```sql
  mysql> SELECT COS(PI());
  -> -1
  ```

- **COT($x$)**
  Returns the cotangent of $x$. 
**Mathematical Functions**

```sql
dJudging, SELECT COT(12); -- -1.5726734063977
dJudging, SELECT COT(0); -- NULL
```

- **CRC32(expr)**

  Computes a cyclic redundancy check value and returns a 32-bit unsigned value. The result is `NULL` if the argument is `NULL`. The argument is expected to be a string and (if possible) is treated as one if it is not.

```sql
dJudging, SELECT CRC32('MySQL'); -- 3259397556
dJudging, SELECT CRC32('mysql'); -- 2501908538
```

- **DEGREES(X)**

  Returns the argument `X`, converted from radians to degrees.

```sql
dJudging, SELECT DEGREES(PI()); -- 180
dJudging, SELECT DEGREES(PI() / 2); -- 90
```

- **EXP(X)**

  Returns the value of $e$ (the base of natural logarithms) raised to the power of `X`. The inverse of this function is `LOG()` (using a single argument only) or `LN()`.

```sql
dJudging, SELECT EXP(2); -- 7.3890560989307
dJudging, SELECT EXP(-2); -- 0.13533528323661
dJudging, SELECT EXP(0); -- 1
```

- **FLOOR(X)**

  Returns the largest integer value not greater than `X`.

```sql
dJudging, SELECT FLOOR(1.23), FLOOR(-1.23); -- 1, -2
```

For exact-value numeric arguments, the return value has an exact-value numeric type. For string or floating-point arguments, the return value has a floating-point type.

- **FORMAT(X, D)**

  Formats the number `X` to a format like `'#,###,###.##'`, rounded to `D` decimal places, and returns the result as a string. For details, see Section 12.5, “String Functions”.

- **HEX(N_or_S)**

  This function can be used to obtain a hexadecimal representation of a decimal number or a string; the manner in which it does so varies according to the argument's type. See this function's description in Section 12.5, “String Functions”, for details.

- **LN(X)**

  Returns the natural logarithm of `X`; that is, the base-$e$ logarithm of `X`. If `X` is less than or equal to 0, then `NULL` is returned.
This function is synonymous with \( \log(x) \). The inverse of this function is the \( \exp() \) function.

- \( \log(x) \), \( \log(b, x) \)

If called with one parameter, this function returns the natural logarithm of \( x \). If \( x \) is less than or equal to 0, then \( \text{NULL} \) is returned.

The inverse of this function (when called with a single argument) is the \( \exp() \) function.

- \( \log_2(x) \)

Returns the base-2 logarithm of \( x \).

- \( \log_{10}(x) \)

Returns the base-10 logarithm of \( x \).

- \( \text{mod}(n, m), n \% m, n \ modulo \ m \)

Modulo operation. Returns the remainder of \( n \) divided by \( m \).
This function is safe to use with BIGINT values.

MOD() also works on values that have a fractional part and returns the exact remainder after division:

```
mysql> SELECT MOD(34.5,3);
-> 1.5
```

MOD(N, 0) returns NULL.

- **PI()**
  Returns the value of π (pi). The default number of decimal places displayed is seven, but MySQL uses the full double-precision value internally.

```
mysql> SELECT PI();
-> 3.141593
```

```
mysql> SELECT PI()+0.000000000000000000;
-> 3.141592653589793116
```

- **POW(X, Y)**
  Returns the value of X raised to the power of Y.

```
mysql> SELECT POW(2,2);
-> 4
```

```
mysql> SELECT POW(2,-2);
-> 0.25
```

- **POWER(X, Y)**
  This is a synonym for POW().

- **RADIANS(X)**
  Returns the argument X, converted from degrees to radians. (Note that π radians equals 180 degrees.)

```
mysql> SELECT RADIANS(90);
-> 1.5707963267949
```

- **RAND(), RAND(N)**
  Returns a random floating-point value v in the range 0 <= v < 1.0. If a constant integer argument N is specified, it is used as the seed value, which produces a repeatable sequence of column values. In the following example, note that the sequences of values produced by RAND(3) is the same both places where it occurs.

```
mysql> CREATE TABLE t (i INT);
Query OK, 0 rows affected (0.42 sec)

mysql> INSERT INTO t VALUES(1),(2),(3);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0
```
With a constant initializer, the seed is initialized once when the statement is compiled, prior to execution. As of MySQL 5.1.16, if a nonconstant initializer (such as a column name) is used as the argument, the seed is initialized with the value for each invocation of \texttt{RAND()}. (One implication of this is that for equal argument values, \texttt{RAND()} will return the same value each time.) From MySQL 5.1.3 to 5.1.15, nonconstant arguments are not permitted. Before that, the effect of using a nonconstant argument is undefined.

To obtain a random integer \( R \) in the range \( i \leq R < j \), use the expression \( \text{FLOOR}(i + \text{RAND()} \times (j - i)) \). For example, to obtain a random integer in the range \( 7 \leq R < 12 \), you could use the following statement:

\[
\text{SELECT FLOOR}(7 + (\text{RAND()} \times 5));
\]

\texttt{RAND()} in a \texttt{WHERE} clause is re-evaluated every time the \texttt{WHERE} is executed.

Use of a column with \texttt{RAND()} values in an \texttt{ORDER BY} or \texttt{GROUP BY} clause may yield unexpected results because for either clause a \texttt{RAND()} expression can be evaluated multiple times for the same row, each time returning a different result. However, you can retrieve rows in random order like this:

\[
\text{SELECT * FROM tbl_name ORDER BY RAND();}
\]

\texttt{ORDER BY RAND()} combined with \texttt{LIMIT} is useful for selecting a random sample from a set of rows:
**Mathematical Functions**

```sql
mysql> SELECT * FROM table1, table2 WHERE a=b AND c<d ORDER BY RAND() LIMIT 1000;
```

**RAND()** is not meant to be a perfect random generator. It is a fast way to generate random numbers on demand that is portable between platforms for the same MySQL version.

Beginning with MySQL 5.1.43, this function is flagged as unsafe for statement-based replication; use of this function causes a warning when using statement-based replication, and the statement is logged using the binary format when `binlog_format` is `MIXED`. (Bug #49222)

- **ROUND**(X), **ROUND**(X, D)

Rounds the argument X to D decimal places. The rounding algorithm depends on the data type of X. D defaults to 0 if not specified. D can be negative to cause D digits left of the decimal point of the value X to become zero.

```
mysql> SELECT ROUND(-1.23);
-> -1
mysql> SELECT ROUND(-1.58);
-> -2
mysql> SELECT ROUND(1.58);
-> 2
mysql> SELECT ROUND(1.298, 1);
-> 1.3
mysql> SELECT ROUND(1.298, 0);
-> 1
mysql> SELECT ROUND(23.298, -1);
-> 20
```

The return type is the same type as that of the first argument (assuming that it is integer, double, or decimal). This means that for an integer argument, the result is an integer (no decimal places):

```
mysql> SELECT ROUND(150.000,2), ROUND(150,2);
+------------------+--------------+
| ROUND(150.000,2) | ROUND(150,2) |
+------------------+--------------+
|           150.00 |          150 |
+------------------+--------------+
```

**ROUND()** uses the following rules depending on the type of the first argument:

- For exact-value numbers, **ROUND()** uses the "round half away from zero" or "round toward nearest" rule: A value with a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negative. (In other words, it is rounded away from zero.) A value with a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative.

- For approximate-value numbers, the result depends on the C library. On many systems, this means that **ROUND()** uses the "round to nearest even" rule: A value with any fractional part is rounded to the nearest even integer.

The following example shows how rounding differs for exact and approximate values:

```
mysql> SELECT ROUND(2.5), ROUND(25E-1);
+-----------+-----------+
| ROUND(2.5) | ROUND(25E-1) |
| 3         | 2          |
+-----------+-----------+
```

For more information, see [Section 12.18, “Precision Math”](#).

This function is unsafe for statement-based replication. Beginning with MySQL 5.1.43, a warning is logged if you use this function when `binlog_format` is set to `STATEMENT`. (Bug #49222)
Date and Time Functions

- **SIGN\((X)\)**
  Returns the sign of the argument as \(-1\), \(0\), or \(1\), depending on whether \(X\) is negative, zero, or positive.

  ```
  mysql> SELECT SIGN(-32);  
  -> -1  
  mysql> SELECT SIGN(0);  
  -> 0  
  mysql> SELECT SIGN(234);  
  -> 1
  ```

- **SIN\((X)\)**
  Returns the sine of \(X\), where \(X\) is given in radians.

  ```
  mysql> SELECT SIN(PI());  
  -> 1.2246063538224e-16  
  mysql> SELECT ROUND(SIN(PI()));  
  -> 0
  ```

- **SQRT\((X)\)**
  Returns the square root of a nonnegative number \(X\).

  ```
  mysql> SELECT SQRT(4);  
  -> 2  
  mysql> SELECT SQRT(20);  
  -> 4.4721359549996  
  mysql> SELECT SQRT(-16);  
  -> NULL
  ```

- **TAN\((X)\)**
  Returns the tangent of \(X\), where \(X\) is given in radians.

  ```
  mysql> SELECT TAN(PI());  
  -> -1.2246063538224e-16  
  mysql> SELECT TAN(PI()+1);  
  -> 1.5574077246549
  ```

- **TRUNCATE\((X, D)\)**
  Returns the number \(X\), truncated to \(D\) decimal places. If \(D\) is \(0\), the result has no decimal point or fractional part. \(D\) can be negative to cause \(D\) digits left of the decimal point of the value \(X\) to become zero.

  ```
  mysql> SELECT TRUNCATE(1.223,1);  
  -> 1.2  
  mysql> SELECT TRUNCATE(1.999,1);  
  -> 1.9  
  mysql> SELECT TRUNCATE(1.999,0);  
  -> 1  
  mysql> SELECT TRUNCATE(-1.999,1);  
  -> -1.9  
  mysql> SELECT TRUNCATE(122,-2);  
  -> 100  
  mysql> SELECT TRUNCATE(10.28*100,0);  
  -> 1028
  ```

  All numbers are rounded toward zero.

**12.7 Date and Time Functions**
This section describes the functions that can be used to manipulate temporal values. See Section 11.3, “Date and Time Types”, for a description of the range of values each date and time type has and the valid formats in which values may be specified.

### Table 12.13 Date/Time Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADDDATE()</td>
<td>Add time values (intervals) to a date value</td>
</tr>
<tr>
<td>ADDTIME()</td>
<td>Add time</td>
</tr>
<tr>
<td>CONVERT_TZ()</td>
<td>Convert from one timezone to another</td>
</tr>
<tr>
<td>CURDATE()</td>
<td>Return the current date</td>
</tr>
<tr>
<td>CURRENT_DATE(), CURRENT_DATE</td>
<td>Synonyms for CURDATE()</td>
</tr>
<tr>
<td>CURRENT_TIME(), CURRENT_TIME</td>
<td>Synonyms for CURTIME()</td>
</tr>
<tr>
<td>CURRENT_TIMESTAMP(), CURRENT_TIMESTAMP</td>
<td>Synonyms for NOW()</td>
</tr>
<tr>
<td>CURTIME()</td>
<td>Return the current time</td>
</tr>
<tr>
<td>DATE()</td>
<td>Extract the date part of a date or datetime expression</td>
</tr>
<tr>
<td>DATE_ADD()</td>
<td>Add time values (intervals) to a date value</td>
</tr>
<tr>
<td>DATE_FORMAT()</td>
<td>Format date as specified</td>
</tr>
<tr>
<td>DATE_SUB()</td>
<td>Subtract a time value (interval) from a date</td>
</tr>
<tr>
<td>DATEDIFF()</td>
<td>Subtract two dates</td>
</tr>
<tr>
<td>DAY()</td>
<td>Synonym for DAYOFMONTH()</td>
</tr>
<tr>
<td>DAYNAME()</td>
<td>Return the name of the weekday</td>
</tr>
<tr>
<td>DAYOFMONTH()</td>
<td>Return the day of the month (0-31)</td>
</tr>
<tr>
<td>DAYOFWEEK()</td>
<td>Return the weekday index of the argument</td>
</tr>
<tr>
<td>DAYOFYEAR()</td>
<td>Return the day of the year (1-366)</td>
</tr>
<tr>
<td>EXTRACT()</td>
<td>Extract part of a date</td>
</tr>
<tr>
<td>FROM_DAYS()</td>
<td>Convert a day number to a date</td>
</tr>
<tr>
<td>FROM_UNIXTIME()</td>
<td>Format UNIX timestamp as a date</td>
</tr>
<tr>
<td>GET_FORMAT()</td>
<td>Return a date format string</td>
</tr>
<tr>
<td>HOUR()</td>
<td>Extract the hour</td>
</tr>
<tr>
<td>LAST_DAY</td>
<td>Return the last day of the month for the argument</td>
</tr>
<tr>
<td>LOCALTIME(), LOCALTIME</td>
<td>Synonym for NOW()</td>
</tr>
<tr>
<td>LOCALTIMESTAMP, LOCALTIMESTAMP</td>
<td>Synonym for NOW()</td>
</tr>
<tr>
<td>MAKEDATE()</td>
<td>Create a date from the year and day of year</td>
</tr>
<tr>
<td>MAKETIME()</td>
<td>Create time from hour, minute, second</td>
</tr>
<tr>
<td>MICROSECOND()</td>
<td>Return the microseconds from argument</td>
</tr>
<tr>
<td>MINUTE()</td>
<td>Return the minute from the argument</td>
</tr>
<tr>
<td>MONTH()</td>
<td>Return the month from the date passed</td>
</tr>
<tr>
<td>MONTHNAME()</td>
<td>Return the name of the month</td>
</tr>
<tr>
<td>NOW()</td>
<td>Return the current date and time</td>
</tr>
<tr>
<td>PERIOD_ADD()</td>
<td>Add a period to a year-month</td>
</tr>
<tr>
<td>PERIOD_DIFF()</td>
<td>Return the number of months between periods</td>
</tr>
</tbody>
</table>
## Date and Time Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>QUARTER()</td>
<td>Return the quarter from a date argument</td>
</tr>
<tr>
<td>SEC_TO_TIME()</td>
<td>Converts seconds to 'HH:MM:SS' format</td>
</tr>
<tr>
<td>SECOND()</td>
<td>Return the second (0-59)</td>
</tr>
<tr>
<td>STR_TO_DATE()</td>
<td>Convert a string to a date</td>
</tr>
<tr>
<td>SUBDATE()</td>
<td>Synonym for DATE_SUB() when invoked with three arguments</td>
</tr>
<tr>
<td>SUBTIME()</td>
<td>Subtract times</td>
</tr>
<tr>
<td>SYSDATE()</td>
<td>Return the time at which the function executes</td>
</tr>
<tr>
<td>TIME()</td>
<td>Extract the time portion of the expression passed</td>
</tr>
<tr>
<td>TIME_FORMAT()</td>
<td>Format as time</td>
</tr>
<tr>
<td>TIME_TO_SEC()</td>
<td>Return the argument converted to seconds</td>
</tr>
<tr>
<td>TIMEDIFF()</td>
<td>Subtract time</td>
</tr>
<tr>
<td>TIMESTAMP()</td>
<td>With a single argument, this function returns the date or datetime expression; with two arguments, the sum of the arguments</td>
</tr>
<tr>
<td>TIMEDIFFADD()</td>
<td>Add an interval to a datetime expression</td>
</tr>
<tr>
<td>TIMEDIFFDIFF()</td>
<td>Subtract an interval from a datetime expression</td>
</tr>
<tr>
<td>TO_DAYS()</td>
<td>Return the date argument converted to days</td>
</tr>
<tr>
<td>UNIX_TIMESTAMP()</td>
<td>Return a UNIX timestamp</td>
</tr>
<tr>
<td>UTC_DATE()</td>
<td>Return the current UTC date</td>
</tr>
<tr>
<td>UTC_TIME()</td>
<td>Return the current UTC time</td>
</tr>
<tr>
<td>UTC_TIMESTAMP()</td>
<td>Return the current UTC date and time</td>
</tr>
<tr>
<td>WEEK()</td>
<td>Return the week number</td>
</tr>
<tr>
<td>WEEKDAY()</td>
<td>Return the weekday index</td>
</tr>
<tr>
<td>WEEKOFYEAR()</td>
<td>Return the calendar week of the date (1-53)</td>
</tr>
<tr>
<td>YEAR()</td>
<td>Return the year</td>
</tr>
<tr>
<td>YEARWEEK()</td>
<td>Return the year and week</td>
</tr>
</tbody>
</table>

Here is an example that uses date functions. The following query selects all rows with a `date_col` value from within the last 30 days:

```sql
mysql> SELECT something FROM tbl_name
       -> WHERE DATE_SUB(CURDATE(), INTERVAL 30 DAY) <= date_col;
```

The query also selects rows with dates that lie in the future.

Functions that expect date values usually accept datetime values and ignore the time part. Functions that expect time values usually accept datetime values and ignore the date part.

Functions that return the current date or time each are evaluated only once per query at the start of query execution. This means that multiple references to a function such as `NOW()` within a single query always produce the same result. (For our purposes, a single query also includes a call to a stored program (stored routine, trigger, or event) and all subprograms called by that program.) This principle also applies to `CURDATE()`, `CURTIME()`, `UTC_DATE()`, `UTC_TIME()`, `UTC_TIMESTAMP()`, and to any of their synonyms.

The `CURRENT_TIMESTAMP()`, `CURRENT_TIME()`, `CURRENT_DATE()`, and `FROM_UNIXTIME()` functions return values in the connection’s current time zone, which is available as the value of the
time_zone system variable. In addition, UNIX_TIMESTAMP() assumes that its argument is a
datetime value in the current time zone. See Section 10.6, “MySQL Server Time Zone Support”.

Some date functions can be used with “zero” dates or incomplete dates such as '2001-11-00',
whereas others cannot. Functions that extract parts of dates typically work with incomplete dates
and thus can return 0 when you might otherwise expect a nonzero value. For example:

mysql> SELECT DAYOFMONTH('2001-11-00'), MONTH('2005-00-00');
-> 0, 0

Other functions expect complete dates and return NULL for incomplete dates. These include functions
that perform date arithmetic or that map parts of dates to names. For example:

mysql> SELECT DATE_ADD('2006-05-00',INTERVAL 1 DAY);
-> NULL
mysql> SELECT DAYNAME('2006-05-00');
-> NULL

Note
From MySQL 5.1.59 to 5.1.61, a change in handling of a date-related assertion
caused several functions to become more strict when passed a DATE() function value as their argument and reject incomplete dates with a day
part of zero. These functions are affected: CONVERT_TZ(), DATE_ADD(),
DATE_SUB(), DAYOFYEAR(), LAST_DAY(), TIMESTAMPDIFF(), TO_DAYS(),
WEEK(), WEEKDAY(), WEEKOFYEAR(), YEARWEEK(). Because this changes
date-handling behavior in General Availability-status series MySQL 5.1, the
change was reverted in 5.1.62.

• ADDDATE(date,INTERVAL expr unit), ADDDATE(expr,days)

When invoked with the INTERVAL form of the second argument, ADDDATE() is a synonym for
DATE_ADD(). The related function SUBDATE() is a synonym for DATE_SUB(). For information on
the INTERVAL unit argument, see the discussion for DATE_ADD().

mysql> SELECT DATE_ADD('2008-01-02', INTERVAL 31 DAY);
-> '2008-02-02'
mysql> SELECT ADDDATE('2008-01-02', INTERVAL 31 DAY);
-> '2008-02-02'

When invoked with the days form of the second argument, MySQL treats it as an integer number of
days to be added to expr.

mysql> SELECT ADDDATE('2008-01-02', 31);
-> '2008-02-02'

• ADDTIME(expr1,expr2)

ADDTIME() adds expr2 to expr1 and returns the result. expr1 is a time or datetime expression,
and expr2 is a time expression.

mysql> SELECT ADDTIME('2007-12-31 23:59:59.999999', '1 1:1:1.000002');
-> '2008-01-02 01:00:01.000001'

mysql> SELECT ADDTIME('01:00:00.999999', '02:00:00.999998');
-> '03:00:01.999997'

• CONVERT_TZ(dt, from_tz, to_tz)

CONVERT_TZ() converts a datetime value dt from the time zone given by from_tz to the time
zone given by to_tz and returns the resulting value. Time zones are specified as described in
**Section 10.6, “MySQL Server Time Zone Support”.** This function returns **NULL** if the arguments are invalid.

If the value falls out of the supported range of the **TIMESTAMP** type when converted from `from_tz` to UTC, no conversion occurs. The **TIMESTAMP** range is described in Section 11.1.2, "Date and Time Type Overview".

```sql
mysql> SELECT CONVERT_TZ('2004-01-01 12:00:00','GMT','MET');
-> '2004-01-01 13:00:00'
```

```sql
mysql> SELECT CONVERT_TZ('2004-01-01 12:00:00','+00:00','+10:00');
-> '2004-01-01 22:00:00'
```

**Note**

To use named time zones such as 'MET' or 'Europe/Moscow', the time zone tables must be properly set up. See Section 10.6, “MySQL Server Time Zone Support”, for instructions.

Before MySQL 5.1.17, if you intend to use `CONVERT_TZ()` while other tables are locked with `LOCK TABLES`, you must also lock the `mysql.time_zone_name` table. See Section 13.3.5, “LOCK TABLES and UNLOCK TABLES Syntax”.

- **CURDATE()**

  Returns the current date as a value in 'YYYY-MM-DD' or YYYYMMDD format, depending on whether the function is used in a string or numeric context.

```sql
mysql> SELECT CURDATE();
-> '2008-06-13'
```

```sql
mysql> SELECT CURDATE() + 0;
-> 20080613
```

- **CURRENT_DATE, CURRENT_DATE()**

  `CURRENT_DATE` and `CURRENT_DATE()` are synonyms for `CURDATE()`.

- **CURRENT_TIME, CURRENT_TIME()**

  `CURRENT_TIME` and `CURRENT_TIME()` are synonyms for `CURTIME()`.

- **CURRENT_TIMESTAMP, CURRENT_TIMESTAMP()**

  `CURRENT_TIMESTAMP` and `CURRENT_TIMESTAMP()` are synonyms for `NOW()`.

- **CURTIME()**

  Returns the current time as a value in 'HH:MM:SS' or HHMMSS.uuuuuu format, depending on whether the function is used in a string or numeric context. The value is expressed in the current time zone.

```sql
mysql> SELECT CURTIME();
-> '23:50:26'
```

```sql
mysql> SELECT CURTIME() + 0;
-> 235026.000000
```

- **DATE(expr)**

  Extracts the date part of the date or datetime expression `expr`.

```sql
mysql> SELECT DATE('2003-12-31 01:02:03');
-> '2003-12-31'
```
• **DATEDIFF(expr1, expr2)**

DATEDIFF() returns \( expr1 - expr2 \) expressed as a value in days from one date to the other. \( expr1 \) and \( expr2 \) are date or date-and-time expressions. Only the date parts of the values are used in the calculation.

```sql
mysql> SELECT DATEDIFF('2007-12-31 23:59:59', '2007-12-30');
-> 1
mysql> SELECT DATEDIFF('2010-11-30 23:59:59', '2010-12-31');
-> -31
```

• **DATE_ADD(date, INTERVAL expr unit), DATE_SUB(date, INTERVAL expr unit)**

These functions perform date arithmetic. The \( date \) argument specifies the starting date or datetime value. \( expr \) is an expression specifying the interval value to be added or subtracted from the starting date. \( expr \) is a string; it may start with a “-” for negative intervals. \( unit \) is a keyword indicating the units in which the expression should be interpreted.

The **INTERVAL** keyword and the \( unit \) specifier are not case sensitive.

The following table shows the expected form of the \( expr \) argument for each \( unit \) value.

<table>
<thead>
<tr>
<th><strong>unit</strong> Value</th>
<th><strong>Expected expr Format</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>MICROSECOND</td>
<td>MICROSECONDS</td>
</tr>
<tr>
<td>SECOND</td>
<td>SECONDS</td>
</tr>
<tr>
<td>MINUTE</td>
<td>MINUTES</td>
</tr>
<tr>
<td>HOUR</td>
<td>HOURS</td>
</tr>
<tr>
<td>DAY</td>
<td>DAYS</td>
</tr>
<tr>
<td>WEEK</td>
<td>WEEKS</td>
</tr>
<tr>
<td>MONTH</td>
<td>MONTHS</td>
</tr>
<tr>
<td>QUARTER</td>
<td>QUARTERS</td>
</tr>
<tr>
<td>YEAR</td>
<td>YEARS</td>
</tr>
<tr>
<td>SECOND_MICROSECOND</td>
<td>'SECONDS.MICROSECONDS'</td>
</tr>
<tr>
<td>MINUTE_MICROSECOND</td>
<td>'MINUTES:SECONDS.MICROSECONDS'</td>
</tr>
<tr>
<td>MINUTE_SECOND</td>
<td>'MINUTES:SECONDS'</td>
</tr>
<tr>
<td>HOUR_MICROSECOND</td>
<td>'HOURS:MINUTES:SECONDS.MICROSECONDS'</td>
</tr>
<tr>
<td>HOUR_SECOND</td>
<td>'HOURS:MINUTES:SECONDS'</td>
</tr>
<tr>
<td>HOUR_MINUTE</td>
<td>'HOURS:MINUTES'</td>
</tr>
<tr>
<td>DAY_MICROSECOND</td>
<td>'DAYS HOURS:MINUTES:SECONDS.MICROSECONDS'</td>
</tr>
<tr>
<td>DAY_SECOND</td>
<td>'DAYS HOURS:MINUTES:SECONDS'</td>
</tr>
<tr>
<td>DAY_MINUTE</td>
<td>'DAYS HOURS:MINUTES'</td>
</tr>
<tr>
<td>DAY_HOUR</td>
<td>'DAYS HOURS'</td>
</tr>
<tr>
<td>YEAR_MONTH</td>
<td>'YEARS-MONTHS'</td>
</tr>
</tbody>
</table>

The return value depends on the arguments:

- **DATETIME** if the first argument is a DATETIME (or TIMESTAMP) value, or if the first argument is a DATE and the **unit** value uses HOURS, MINUTES, or SECONDS.
- String otherwise.
To ensure that the result is `DATETIME`, you can use `CAST()` to convert the first argument to `DATETIME`.

MySQL permits any punctuation delimiter in the `expr` format. Those shown in the table are the suggested delimiters. If the `date` argument is a `DATE` value and your calculations involve only `YEAR`, `MONTH`, and `DAY` parts (that is, no time parts), the result is a `DATE` value. Otherwise, the result is a `DATETIME` value.

Date arithmetic also can be performed using `INTERVAL` together with the `+` or `−` operator:

\[
\text{date} + \text{INTERVAL} \ expr \ \text{unit} \\
\text{date} - \text{INTERVAL} \ expr \ \text{unit}
\]

`INTERVAL \ expr \ unit` is permitted on either side of the `+` operator if the expression on the other side is a date or datetime value. For the `−` operator, `INTERVAL \ expr \ unit` is permitted only on the right side, because it makes no sense to subtract a date or datetime value from an interval.

If you specify an interval value that is too short (does not include all the interval parts that would be expected from the `unit` keyword), MySQL assumes that you have left out the leftmost parts of the interval value. For example, if you specify a `unit` of `DAY_SECOND`, the value of `expr` is expected to have days, hours, minutes, and seconds parts. If you specify a value like `'1:10'`, MySQL assumes that the days and hours parts are missing and the value represents minutes and seconds. In other words, `'1:10' \ DAY_SECOND` is interpreted in such a way that it is equivalent to `'1:10' \ MINUTE_SECOND`. This is analogous to the way that MySQL interprets `TIME` values as representing elapsed time rather than as a time of day.

Because `expr` is treated as a string, be careful if you specify a nonstring value with `INTERVAL`. For example, with an interval specifier of `HOUR_MINUTE`, `6/4` evaluates to `1.5000` and is treated as `1` hour, `5000` minutes:

<table>
<thead>
<tr>
<th>mysql&gt;</th>
<th>SELECT '2008-12-31 23:59:59' + INTERVAL 1 SECOND;</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql&gt;</td>
<td>SELECT INTERVAL 1 DAY + '2008-12-31';</td>
</tr>
<tr>
<td>mysql&gt;</td>
<td>SELECT '2005-01-01' − INTERVAL 1 SECOND;</td>
</tr>
<tr>
<td>mysql&gt;</td>
<td>SELECT DATE_ADD('2000-12-31 23:59:59', INTERVAL 1 SECOND);</td>
</tr>
<tr>
<td>mysql&gt;</td>
<td>SELECT DATE_ADD('2010-12-31 23:59:59', INTERVAL 1 DAY);</td>
</tr>
<tr>
<td>mysql&gt;</td>
<td>SELECT DATE_ADD('2100-12-31 23:59:59', INTERVAL '1:1' MINUTE_SECOND);</td>
</tr>
<tr>
<td>mysql&gt;</td>
<td>SELECT DATE_ADD('1900-01-01 00:00:00', INTERVAL '-1 10' DAY_HOUR);</td>
</tr>
<tr>
<td>mysql&gt;</td>
<td>SELECT DATE_SUB('1998-01-02', INTERVAL 31 DAY);</td>
</tr>
<tr>
<td>mysql&gt;</td>
<td>SELECT DATE_ADD('1992-12-31 23:59:59.000002', INTERVAL '1.999999' SECOND_MICROSECOND);</td>
</tr>
</tbody>
</table>

Because `expr` is treated as a string, be careful if you specify a nonstring value with `INTERVAL`. For example, with an interval specifier of `HOUR_MINUTE`, `6/4` evaluates to `1.5000` and is treated as `1` hour, `5000` minutes:

| mysql> | SELECT 6/4; |
| mysql> | SELECT DATE_ADD('2009-01-01', INTERVAL 6/4 HOUR_MINUTE); |
To ensure interpretation of the interval value as you expect, a CAST() operation may be used. To treat 6/4 as 1 hour, 5 minutes, cast it to a DECIMAL value with a single fractional digit:

```sql
mysql> SELECT CAST(6/4 AS DECIMAL(3,1));
-> 1.5
mysql> SELECT DATE_ADD('1970-01-01 12:00:00', INTERVAL CAST(6/4 AS DECIMAL(3,1)) HOUR_MINUTE);
-> '1970-01-01 13:05:00'
```

If you add to or subtract from a date value something that contains a time part, the result is automatically converted to a datetime value:

```sql
mysql> SELECT DATE_ADD('2013-01-01', INTERVAL 1 DAY);
-> '2013-01-02'
mysql> SELECT DATE_ADD('2013-01-01', INTERVAL 1 HOUR);
-> '2013-01-01 01:00:00'
```

If you add MONTH, YEAR_MONTH, or YEAR and the resulting date has a day that is larger than the maximum day for the new month, the day is adjusted to the maximum days in the new month:

```sql
mysql> SELECT DATE_ADD('2009-01-30', INTERVAL 1 MONTH);
-> '2009-02-28'
```

Date arithmetic operations require complete dates and do not work with incomplete dates such as '2006-07-00' or badly malformed dates:

```sql
mysql> SELECT DATE_ADD('2006-07-00', INTERVAL 1 DAY);
-> NULL
mysql> SELECT '2005-03-32' + INTERVAL 1 MONTH;
-> NULL
```

- **DATE_FORMAT(date, format)**

  Formats the date value according to the format string.

  The following specifiers may be used in the format string. The "%" character is required before format specifier characters.

<table>
<thead>
<tr>
<th>Specifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>%a</td>
<td>Abbreviated weekday name (Sun..Sat)</td>
</tr>
<tr>
<td>%b</td>
<td>Abbreviated month name (Jan..Dec)</td>
</tr>
<tr>
<td>%c</td>
<td>Month, numeric (0..12)</td>
</tr>
<tr>
<td>%D</td>
<td>Day of the month with English suffix (0th, 1st, 2nd, 3rd, ...)</td>
</tr>
<tr>
<td>%d</td>
<td>Day of the month, numeric (00..31)</td>
</tr>
<tr>
<td>%e</td>
<td>Day of the month, numeric (0..31)</td>
</tr>
<tr>
<td>%f</td>
<td>Microseconds (000000..999999)</td>
</tr>
<tr>
<td>%H</td>
<td>Hour (00..23)</td>
</tr>
<tr>
<td>%h</td>
<td>Hour (01..12)</td>
</tr>
<tr>
<td>%I</td>
<td>Hour (01..12)</td>
</tr>
<tr>
<td>%i</td>
<td>Minutes, numeric (00..59)</td>
</tr>
<tr>
<td>%j</td>
<td>Day of year (001..369)</td>
</tr>
<tr>
<td>%k</td>
<td>Hour (00..23)</td>
</tr>
<tr>
<td>%l</td>
<td>Hour (1..12)</td>
</tr>
<tr>
<td>Specifier</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>%M</td>
<td>Month name (January..December)</td>
</tr>
<tr>
<td>%m</td>
<td>Month, numeric (00..12)</td>
</tr>
<tr>
<td>%p</td>
<td>AM or PM</td>
</tr>
<tr>
<td>%r</td>
<td>Time, 12-hour (hh:mm:ss followed by AM or PM)</td>
</tr>
<tr>
<td>%S</td>
<td>Seconds (00..59)</td>
</tr>
<tr>
<td>%s</td>
<td>Seconds (00..59)</td>
</tr>
<tr>
<td>%T</td>
<td>Time, 24-hour (hh:mm:ss)</td>
</tr>
<tr>
<td>%U</td>
<td>Week (00..53), where Sunday is the first day of the week; WEEK() mode 0</td>
</tr>
<tr>
<td>%u</td>
<td>Week (00..53), where Monday is the first day of the week; WEEK() mode 1</td>
</tr>
<tr>
<td>%V</td>
<td>Week (01..53), where Sunday is the first day of the week; WEEK() mode 2; used with %X</td>
</tr>
<tr>
<td>%v</td>
<td>Week (01..53), where Monday is the first day of the week; WEEK() mode 3; used with %x</td>
</tr>
<tr>
<td>%W</td>
<td>Weekday name (Sunday..Saturday)</td>
</tr>
<tr>
<td>%w</td>
<td>Day of the week (0=Sunday..6=Saturday)</td>
</tr>
<tr>
<td>%x</td>
<td>Year for the week where Sunday is the first day of the week, numeric, four digits; used with %V</td>
</tr>
<tr>
<td>%y</td>
<td>Year, numeric, four digits</td>
</tr>
<tr>
<td>%y</td>
<td>Year, numeric (two digits)</td>
</tr>
<tr>
<td>%%</td>
<td>A literal “%” character</td>
</tr>
<tr>
<td>%x</td>
<td>x, for any “x” not listed above</td>
</tr>
</tbody>
</table>

Ranges for the month and day specifiers begin with zero due to the fact that MySQL permits the storing of incomplete dates such as '2014-00-00'.

As of MySQL 5.1.12, the language used for day and month names and abbreviations is controlled by the value of the `lc_time_names` system variable (Section 10.7, ‘MySQL Server Locale Support’).

For the %U, %u, %V, and %v specifiers, see the description of the WEEK() function for information about the mode values. The mode affects how week numbering occurs.

As of MySQL 5.1.15, DATE_FORMAT() returns a string with a character set and collation given by character_set_connection and collation_connection so that it can return month and weekday names containing non-ASCII characters. Before 5.1.15, the return value is a binary string.

```
mysql> SELECT DATE_FORMAT('2009-10-04 22:23:00', '%W %M %Y');
-> 'Sunday October 2009'
mysql> SELECT DATE_FORMAT('2007-10-04 22:23:00', '%H:%i:%s');
-> '22:23:00'
mysql> SELECT DATE_FORMAT('1900-10-04 22:23:00', '%D %y %a %d %m %b %j');
-> '4th 00 Thu 04 10 Oct 277'
mysql> SELECT DATE_FORMAT('1997-10-04 22:23:00', '%H %l %i %r %T %S %w');
-> '22 22 10 23:00 PM 22:23:00 00 6'
mysql> SELECT DATE_FORMAT('1999-01-01', '%X %V');
-> '1998 52'
mysql> SELECT DATE_FORMAT('2006-06-00', '%d');
-> '00'
```
Date and Time Functions

• **DATE_SUB**(date,INTERVAL expr unit)

  See the description for **DATE_ADD()**.

• **DAY**(date)

  **DAY()** is a synonym for **DAYOFMONTH()**.

• **DAYNAME**(date)

  Returns the name of the weekday for **date**. As of MySQL 5.1.12, the language used for the name is controlled by the value of the `lc_time_names` system variable (Section 10.7, "MySQL Server Locale Support").

  mysql> SELECT DAYNAME('2007-02-03');
  -> 'Saturday'

• **DAYOFMONTH**(date)

  Returns the day of the month for **date**, in the range 1 to 31, or 0 for dates such as '0000-00-00' or '2008-00-00' that have a zero day part.

  mysql> SELECT DAYOFMONTH('2007-02-03');
  -> 3

• **DAYOFWEEK**(date)

  Returns the weekday index for **date** (1 = Sunday, 2 = Monday, …, 7 = Saturday). These index values correspond to the ODBC standard.

  mysql> SELECT DAYOFWEEK('2007-02-03');
  -> 7

• **DAYOFYEAR**(date)

  Returns the day of the year for **date**, in the range 1 to 366.

  mysql> SELECT DAYOFYEAR('2007-02-03');
  -> 34

• **EXTRACT**(unit FROM date)

  The **EXTRACT()** function uses the same kinds of unit specifiers as **DATE_ADD()** or **DATE_SUB()**, but extracts parts from the date rather than performing date arithmetic.

  mysql> SELECT EXTRACT(YEAR FROM '2009-07-02');
  -> 2009
  mysql> SELECT EXTRACT(YEAR_MONTH FROM '2009-07-02 01:02:03');
  -> 200907
  mysql> SELECT EXTRACT(DAY_MINUTE FROM '2009-07-02 01:02:03');
  -> 20102
  mysql> SELECT EXTRACT(MICROSECOND FROM '2003-01-02 10:30:00.000123');
  -> 123

• **FROM_DAYS**(N)

  Given a day number **N**, returns a **DATE** value.

  mysql> SELECT FROM_DAYS(730669);
  -> '2007-07-03'
Use `FROM_DAYS()` with caution on old dates. It is not intended for use with values that precede the advent of the Gregorian calendar (1582). See Section 12.8, “What Calendar Is Used By MySQL?”.

- `FROM_UNIXTIME(unix_timestamp), FROM_UNIXTIME(unix_timestamp, format)`

Returns a representation of the `unix_timestamp` argument as a value in 'YYYY-MM-DD HH:MM:SS' or YYYYMMDDHHMMSS.uuuuuu format, depending on whether the function is used in a string or numeric context. The value is expressed in the current time zone. `unix_timestamp` is an internal timestamp value such as is produced by the `UNIX_TIMESTAMP()` function.

If `format` is given, the result is formatted according to the `format` string, which is used the same way as listed in the entry for the `DATE_FORMAT()` function.

```sql
mysql> SELECT FROM_UNIXTIME(1447430881);
-> '2015-11-13 10:08:01'
mysql> SELECT FROM_UNIXTIME(1447430881) + 0;
-> 20151113100801
mysql> SELECT FROM_UNIXTIME(UNIX_TIMESTAMP(),
-> '%Y %D %M %h:%i:%s %x');
-> '2015 13th November 10:08:01 2015'
```

Note: If you use `UNIX_TIMESTAMP()` and `FROM_UNIXTIME()` to convert between `TIMESTAMP` values and Unix timestamp values, the conversion is lossy because the mapping is not one-to-one in both directions. For details, see the description of the `UNIX_TIMESTAMP()` function.

- `GET_FORMAT({DATE|TIME|DATETIME}, {'EUR'|'USA'|'JIS'|'ISO'|'INTERNAL'})`

Returns a format string. This function is useful in combination with the `DATE_FORMAT()` and the `STR_TO_DATE()` functions.

The possible values for the first and second arguments result in several possible format strings (for the specifiers used, see the table in the `DATE_FORMAT()` function description). ISO format refers to ISO 9075, not ISO 8601.

<table>
<thead>
<tr>
<th>Function Call</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET_FORMAT(DATE,'USA')</td>
<td>'%m.%d.%Y'</td>
</tr>
<tr>
<td>GET_FORMAT(DATE,'JIS')</td>
<td>'%Y-%m-%d'</td>
</tr>
<tr>
<td>GET_FORMAT(DATE,'ISO')</td>
<td>'%Y-%m-%d'</td>
</tr>
<tr>
<td>GET_FORMAT(DATE,'EUR')</td>
<td>'%d.%m.%Y'</td>
</tr>
<tr>
<td>GET_FORMAT(DATE,'INTERNAL')</td>
<td>'%Y%m%d'</td>
</tr>
<tr>
<td>GET_FORMAT(DATETIME,'USA')</td>
<td>'%Y-%m-%d %H.%i.%s'</td>
</tr>
<tr>
<td>GET_FORMAT(DATETIME,'JIS')</td>
<td>'%Y-%m-%d %H:%i:%s'</td>
</tr>
<tr>
<td>GET_FORMAT(DATETIME,'ISO')</td>
<td>'%Y-%m-%d %H:%i:%s'</td>
</tr>
<tr>
<td>GET_FORMAT(DATETIME,'EUR')</td>
<td>'%Y-%m-%d %H:%i:%s'</td>
</tr>
<tr>
<td>GET_FORMAT(DATETIME,'INTERNAL')</td>
<td>'%Y%m%d%H%i%s'</td>
</tr>
<tr>
<td>GET_FORMAT(TIME,'USA')</td>
<td>'%h:%i:%s %p'</td>
</tr>
<tr>
<td>GET_FORMAT(TIME,'JIS')</td>
<td>'%H:%i:%s'</td>
</tr>
<tr>
<td>GET_FORMAT(TIME,'ISO')</td>
<td>'%H:%i:%s'</td>
</tr>
<tr>
<td>GET_FORMAT(TIME,'EUR')</td>
<td>'%H:%i:%s'</td>
</tr>
<tr>
<td>GET_FORMAT(TIME,'INTERNAL')</td>
<td>'%H%i%s'</td>
</tr>
</tbody>
</table>

`TIMESTAMP` can also be used as the first argument to `GET_FORMAT()`, in which case the function returns the same values as for `DATETIME`.  

1075
Date and Time Functions

```sql
mysql> SELECT DATE_FORMAT('2003-10-03', GET_FORMAT(DATE, 'EUR'));
-> '03.10.2003'
mysql> SELECT STR_TO_DATE('10.31.2003', GET_FORMAT(DATE, 'USA'));
-> '2003-10-31'
```

- **HOUR(time)**

  Returns the hour for `time`. The range of the return value is 0 to 23 for time-of-day values. However, the range of `TIME` values actually is much larger, so `HOUR` can return values greater than 23.

```sql
mysql> SELECT HOUR('10:05:03');
-> 10
mysql> SELECT HOUR('272:59:59');
-> 272
```

- **LAST_DAY(date)**

  Takes a date or datetime value and returns the corresponding value for the last day of the month. Returns `NULL` if the argument is invalid.

```sql
mysql> SELECT LAST_DAY('2003-02-05');
-> '2003-02-28'
mysql> SELECT LAST_DAY('2004-02-05');
-> '2004-02-29'
mysql> SELECT LAST_DAY('2004-01-01 01:01:01');
-> '2004-01-31'
mysql> SELECT LAST_DAY('2003-03-32');
-> NULL
```

- **LOCALTIME, LOCALTIME()**

  `LOCALTIME` and `LOCALTIME()` are synonyms for `NOW()`.

- **LOCALTIMESTAMP, LOCALTIMESTAMP()**

  `LOCALTIMESTAMP` and `LOCALTIMESTAMP()` are synonyms for `NOW()`.

- **MAKEDATE(year, dayofyear)**

  Returns a date, given year and day-of-year values. `dayofyear` must be greater than 0 or the result is `NULL`.

```sql
mysql> SELECT MAKEDATE(2011,31), MAKEDATE(2011,32);
-> '2011-01-31', '2011-02-01'
mysql> SELECT MAKEDATE(2011,365), MAKEDATE(2014,365);
-> '2011-12-31', '2014-12-31'
mysql> SELECT MAKEDATE(2011,0);  
-> NULL
```

- **MAKETIME(hour, minute, second)**

  Returns a time value calculated from the `hour`, `minute`, and `second` arguments.

```sql
mysql> SELECT MAKETIME(12,15,30);
-> '12:15:30'
```

- **MICROSECOND(expr)**

  Returns the microseconds from the time or datetime expression `expr` as a number in the range from 0 to 999999.
Date and Time Functions

• `MINUTE(time)`

Returns the minute for `time`, in the range 0 to 59.

```sql
mysql> SELECT MINUTE('2008-02-03 10:05:03');
-> 5
```

• `MONTH(date)`

Returns the month for `date`, in the range 1 to 12 for January to December, or 0 for dates such as '0000-00-00' or '2008-00-00' that have a zero month part.

```sql
mysql> SELECT MONTH('2008-02-03');
-> 2
```

• `MONTHNAME(date)`

Returns the full name of the month for `date`. As of MySQL 5.1.12, the language used for the name is controlled by the value of the `lc_time_names` system variable (Section 10.7, "MySQL Server Locale Support").

```sql
mysql> SELECT MONTHNAME('2008-02-03');
-> 'February'
```

• `NOW()`

Returns the current date and time as a value in 'YYYY-MM-DD HH:MM:SS' or YYYYMMDDHHMMSS.uuuuuu format, depending on whether the function is used in a string or numeric context. The value is expressed in the current time zone.

```sql
mysql> SELECT NOW();
-> '2007-12-15 23:50:26'
mysql> SELECT NOW() + 0;
-> 20071215235026.000000
```

`NOW()` returns a constant time that indicates the time at which the statement began to execute. (Within a stored function or trigger, `NOW()` returns the time at which the function or triggering statement began to execute.) This differs from the behavior for `SYSDATE()`, which returns the exact time at which it executes.

```sql
mysql> SELECT NOW(), SLEEP(2), NOW();
+---------------------+----------+---------------------+
| NOW()               | SLEEP(2) | NOW()               |
+---------------------+----------+---------------------+
```

```sql
mysql> SELECT SYSDATE(), SLEEP(2), SYSDATE();
+---------------------+----------+---------------------+
| SYSDATE()           | SLEEP(2) | SYSDATE()           |
+---------------------+----------+---------------------+
```

In addition, the `SET TIMESTAMP` statement affects the value returned by `NOW()` but not by `SYSDATE()`. This means that timestamp settings in the binary log have no effect on invocations of `SYSDATE()`. Setting the timestamp to a nonzero value causes each subsequent invocation of
**Date and Time Functions**

`NOW()` to return that value. Setting the timestamp to zero cancels this effect so that `NOW()` once again returns the current date and time.

See the description for `SYSDATE()` for additional information about the differences between the two functions.

- **PERIOD_ADD(\(P, N\))**
  Adds \(N\) months to period \(P\) (in the format `YYMM` or `YYYYMM`). Returns a value in the format `YYYYMM`. Note that the period argument \(P\) is not a date value.

  ```sql
  mysql> SELECT PERIOD_ADD(200801,2);
  -> 200803
  ```

- **PERIOD_DIFF(\(P1, P2\))**
  Returns the number of months between periods \(P1\) and \(P2\). \(P1\) and \(P2\) should be in the format `YYMM` or `YYYYMM`. Note that the period arguments \(P1\) and \(P2\) are not date values.

  ```sql
  mysql> SELECT PERIOD_DIFF(200802,200703);
  -> 11
  ```

- **QUARTER(date)**
  Returns the quarter of the year for `date`, in the range 1 to 4.

  ```sql
  mysql> SELECT QUARTER('2008-04-01');
  -> 2
  ```

- **SECOND(time)**
  Returns the second for `time`, in the range 0 to 59.

  ```sql
  mysql> SELECT SECOND('10:05:03');
  -> 3
  ```

- **SEC_TO_TIME(seconds)**
  Returns the `seconds` argument, converted to hours, minutes, and seconds, as a `TIME` value. The range of the result is constrained to that of the `TIME` data type. A warning occurs if the argument corresponds to a value outside that range.

  ```sql
  mysql> SELECT SEC_TO_TIME(2378);  
  -> '00:39:38'
  mysql> SELECT SEC_TO_TIME(2378) + 0;  
  -> 3938
  ```

- **STR_TO_DATE(str, format)**
  This is the inverse of the `DATE_FORMAT()` function. It takes a string `str` and a format string `format`. `STR_TO_DATE()` returns a `DATETIME` value if the format string contains both date and time parts, or a `DATE` or `TIME` value if the string contains only date or time parts. If the date, time, or datetime value extracted from `str` is illegal, `STR_TO_DATE()` returns `NULL` and produces a warning.

  The server scans `str` attempting to match `format` to it. The format string can contain literal characters and format specifiers beginning with `%`. Literal characters in `format` must match literally in `str`. Format specifiers in `format` must match a date or time part in `str`. For the specifiers that can be used in `format`, see the `DATE_FORMAT()` function description.
### Date and Time Functions

#### mysql>
```
SELECT STR_TO_DATE('01, 5, 2013', '%d, %m, %Y');
-> '2013-05-01'
SELECT STR_TO_DATE('May 1, 2013', '%M %d, %Y');
-> '2013-05-01'
```

Scanning starts at the beginning of `str` and fails if `format` is found not to match. Extra characters at the end of `str` are ignored.

```
SELECT STR_TO_DATE('a09:30:17', 'a%h:%i:%s');
-> '09:30:17'
SELECT STR_TO_DATE('a09:30:17', '%h:%i:%s');
-> NULL
SELECT STR_TO_DATE('09:30:17a', '%h:%i:%s');
-> '09:30:17'
```

Unspecified date or time parts have a value of 0, so incompletely specified values in `str` produce a result with some or all parts set to 0:

```
SELECT STR_TO_DATE('abc', 'abc');
-> '0000-00-00'
SELECT STR_TO_DATE('9', '%m');
-> '0000-09-00'
SELECT STR_TO_DATE('9', '%s');
-> '00:00:09'
```

Range checking on the parts of date values is as described in Section 11.3.1, “The DATE, DATETIME, and TIMESTAMP Types”. This means, for example, that “zero” dates or dates with part values of 0 are permitted unless the SQL mode is set to disallow such values.

```
SELECT STR_TO_DATE('00/00/0000', '%m/%d/%Y');
-> '0000-00-00'
SELECT STR_TO_DATE('04/31/2004', '%m/%d/%Y');
-> '2004-04-31'
```

---

#### Note

You cannot use format "%X%V" to convert a year-week string to a date because the combination of a year and week does not uniquely identify a year and month if the week crosses a month boundary. To convert a year-week to a date, you should also specify the weekday:

```
SELECT STR_TO_DATE('200442 Monday', '%X%V %W');
-> '2004-10-18'
```

---

#### `SUBDATE(date, INTERVAL expr unit)`

When invoked with the `INTERVAL` form of the second argument, `SUBDATE()` is a synonym for `DATE_SUB()`. For information on the `INTERVAL unit` argument, see the discussion for `DATE_ADD()`.

```
SELECT DATE_SUB('2008-01-02', INTERVAL 31 DAY);
-> '2007-12-02'
SELECT SUBDATE('2008-01-02', INTERVAL 31 DAY);
-> '2007-12-02'
```

The second form enables the use of an integer value for `days`. In such cases, it is interpreted as the number of days to be subtracted from the date or datetime expression `expr`.

```
SELECT SUBDATE('2008-01-02 12:00:00', 31);
-> '2007-12-02 12:00:00'
```
Date and Time Functions

- **SUBTIME(expr1, expr2)**

  `SUBTIME()` returns `expr1 - expr2` expressed as a value in the same format as `expr1`. `expr1` is a time or datetime expression, and `expr2` is a time expression.

  ```sql
  mysql> SELECT SUBTIME('2007-12-31 23:59:59.999999','1 1:1:1.000002');
  -> '2007-12-30 22:58:58.999997'
  mysql> SELECT SUBTIME('01:00:00.999999', '02:00:00.999998');
  -> '-00:59:59.999999'
  ```

- **SYSDATE()**

  Returns the current date and time as a value in 'YYYY-MM-DD HH:MM:SS' or YYYYMMDDHHMMSS.uuuuuu format, depending on whether the function is used in a string or numeric context.

  `SYSDATE()` returns the time at which it executes. This differs from the behavior for `NOW()`, which returns a constant time that indicates the time at which the statement began to execute. (Within a stored function or trigger, `NOW()` returns the time at which the function or triggering statement began to execute.)

  ```sql
  mysql> SELECT NOW(), SLEEP(2), NOW();
  +---------------------+----------+---------------------+
  | NOW()               | SLEEP(2) | NOW()               |
  +---------------------+----------+---------------------+
  +---------------------+----------+---------------------+
  mysql> SELECT SYSDATE(), SLEEP(2), SYSDATE();
  +---------------------+----------+---------------------+
  | SYSDATE()           | SLEEP(2) | SYSDATE()           |
  +---------------------+----------+---------------------+
  +---------------------+----------+---------------------+
  ```

  In addition, the `SET TIMESTAMP` statement affects the value returned by `NOW()` but not by `SYSDATE()`. This means that timestamp settings in the binary log have no effect on invocations of `SYSDATE()`.

  Because `SYSDATE()` can return different values even within the same statement, and is not affected by `SET TIMESTAMP`, it is nondeterministic and therefore unsafe for replication if statement-based binary logging is used. If that is a problem, you can use row-based logging.

  Alternatively, you can use the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`. This works if the option is used on both the master and the slave.

  The nondeterministic nature of `SYSDATE()` also means that indexes cannot be used for evaluating expressions that refer to it.

  Beginning with MySQL 5.1.42, a warning is logged if you use this function when `binlog_format` is set to `STATEMENT`. (Bug #47995)

- **TIME(expr)**

  Extracts the time part of the time or datetime expression `expr` and returns it as a string.

  This function is unsafe for statement-based replication. Beginning with MySQL 5.1.42, a warning is logged if you use this function when `binlog_format` is set to `STATEMENT`. (Bug #47995)
Date and Time Functions

- **TIMEDIFF(expr1, expr2)**

  The `TIMEDIFF()` function returns `expr1 - expr2` expressed as a time value. `expr1` and `expr2` are time or date-and-time expressions, but both must be of the same type.

  The result returned by `TIMEDIFF()` is limited to the range allowed for `TIME` values. Alternatively, you can use either of the functions `TIMESTAMPDIFF()` and `UNIX_TIMESTAMP()`, both of which return integers.

  ```sql
  mysql> SELECT TIMEDIFF('2000:01:01 00:00:00', '2000:01:01 00:00:00.000001');
  -> '-00:00:00.000001'
  mysql> SELECT TIMEDIFF('2008-12-31 23:59:59.000001', '2008-12-30 01:01:01.000002');
  -> '46:58:57.999999'
  ```

- **TIMESTAMP(expr)**, **TIMESTAMP(expr1, expr2)**

  With a single argument, this function returns the date or datetime expression `expr` as a datetime value. With two arguments, it adds the time expression `expr2` to the date or datetime expression `expr1` and returns the result as a datetime value.

  ```sql
  mysql> SELECT TIMESTAMP('2003-12-31');
  -> '2003-12-31 00:00:00'
  mysql> SELECT TIMESTAMP('2003-12-31 12:00:00','12:00:00');
  -> '2004-01-01 00:00:00'
  ```

- **TIMESTAMPADD(unit, interval, datetime_expr)**

  Adds the integer expression `interval` to the date or datetime expression `datetime_expr`. The unit for `interval` is given by the `unit` argument, which should be one of the following values: `FRAC_SECOND` (microseconds), `SECOND`, `MINUTE`, `HOUR`, `DAY`, `WEEK`, `MONTH`, `QUARTER`, or `YEAR`.

  Beginning with MySQL 5.1.24, it is possible to use `MICROSECOND` in place of `FRAC_SECOND` with this function, and `FRAC_SECOND` is deprecated. `FRAC_SECOND` is removed in MySQL 5.5.

  The `unit` value may be specified using one of keywords as shown, or with a prefix of `SQL_TSI_`. For example, `DAY` and `SQL_TSI_DAY` both are legal.

  ```sql
  mysql> SELECT TIMESTAMPADD(MINUTE,1,'2003-01-02');
  -> '2003-01-02 00:01:00'
  mysql> SELECT TIMESTAMPADD(WEEK,1,'2003-01-02');
  -> '2003-01-09'
  ```

- **TIMESTAMPDIFF(unit, datetime_expr1, datetime_expr2)**

  Returns `datetime_expr2 - datetime_expr1`, where `datetime_expr1` and `datetime_expr2` are date or datetime expressions. One expression may be a date and the other a datetime; a date value is treated as a datetime having the time part '00:00:00' where necessary. The unit for the result (an integer) is given by the `unit` argument. The legal values for `unit` are the same as those listed in the description of the `TIMESTAMPADD()` function.

  ```sql
  mysql> SELECT TIMESTAMPDIFF(MONTH, '2003-02-01', '2003-05-01');
  -> 3
  mysql> SELECT TIMESTAMPDIFF(YEAR, '2002-05-01', '2001-01-01');
  -> -1
  mysql> SELECT TIMESTAMPDIFF(MINUTE, '2003-02-01', '2003-05-01 12:05:55');
  -> 128885
  ```
Note

The order of the date or datetime arguments for this function is the opposite of that used with the `TIMESTAMP()` function when invoked with 2 arguments.

- `TIME_FORMAT(time, format)`

This is used like the `DATE_FORMAT()` function, but the `format` string may contain format specifiers only for hours, minutes, seconds, and microseconds. Other specifiers produce a `NULL` value or `0`.

If the `time` value contains an hour part that is greater than `23`, the `%H` and `%k` hour format specifiers produce a value larger than the usual range of `0..23`. The other hour format specifiers produce the hour value modulo `12`.

```sql
mysql> SELECT TIME_FORMAT('100:00:00', '%H %k %h %I %l');
-> '100 100 04 04 4'
```

- `TIME_TO_SEC(time)`

Returns the `time` argument, converted to seconds.

```sql
mysql> SELECT TIME_TO_SEC('22:23:00');
-> 80580
mysql> SELECT TIME_TO_SEC('00:39:38');
-> 2378
```

- `TO_DAYS(date)`

Given a date `date`, returns a day number (the number of days since year `0`).

```sql
mysql> SELECT TO_DAYS(950501);  
-> 728779
mysql> SELECT TO_DAYS('2007-10-07');  
-> 733321
```

`TO_DAYS()` is not intended for use with values that precede the advent of the Gregorian calendar (1582), because it does not take into account the days that were lost when the calendar was changed. For dates before 1582 (and possibly a later year in other locales), results from this function are not reliable. See Section 12.8, “What Calendar Is Used By MySQL?”, for details.

Remember that MySQL converts two-digit year values in dates to four-digit form using the rules in Section 11.3, “Date and Time Types”. For example, `'2008-10-07'` and `'08-10-07'` are seen as identical dates:

```sql
mysql> SELECT TO_DAYS('2008-10-07'), TO_DAYS('08-10-07');  
-> 733687, 733687
```

In MySQL, the zero date is defined as `'0000-00-00'`, even though this date is itself considered invalid. This means that, for `'0000-00-00'` and `'0000-01-01'`, `TO_DAYS()` returns the values shown here:

```sql
mysql> SELECT TO_DAYS('0000-00-00');  
+-----------------------+  
| to_days('0000-00-00') |  
+-----------------------+  
| NULL                  |  
+-----------------------+  
1 row in set, 1 warning (0.00 sec)
mysql> SHOW WARNINGS;
```
### Date and Time Functions

<table>
<thead>
<tr>
<th>Level</th>
<th>Code</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>Warning</td>
<td>1292</td>
<td>Incorrect datetime value: '0000-00-00'</td>
</tr>
</tbody>
</table>

1 row in set (0.00 sec)

mysql> SELECT TO_DAYS('0000-01-01');
+-----------------------+
<table>
<thead>
<tr>
<th>to_days('0000-01-01')</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>
+-----------------------+

1 row in set (0.00 sec)

This is true whether or not the `ALLOW_INVALID_DATES` SQL server mode is enabled.

- **UNIX_TIMESTAMP(), UNIX_TIMESTAMP(date)**

  If called with no argument, returns a Unix timestamp (seconds since '1970-01-01 00:00:00' UTC) as an unsigned integer. If `UNIX_TIMESTAMP()` is called with a `date` argument, it returns the value of the argument as seconds since '1970-01-01 00:00:00' UTC. `date` may be a `DATE` string, a `DATETIME` string, a `TIMESTAMP`, or a number in the format `YYMMDD` or `YYYYMMDD`. The server interprets `date` as a value in the current time zone and converts it to an internal value in UTC. Clients can set their time zone as described in Section 10.6, “MySQL Server Time Zone Support”.

  mysql> SELECT UNIX_TIMESTAMP();
  -> 1447431666
  mysql> SELECT UNIX_TIMESTAMP('2015-11-13 10:20:19');
  -> 1447431619

  When `UNIX_TIMESTAMP()` is used on a `TIMESTAMP` column, the function returns the internal timestamp value directly, with no implicit “string-to-Unix-timestamp” conversion. If you pass an out-of-range date to `UNIX_TIMESTAMP()`, it returns 0.

  **Note:** If you use `UNIX_TIMESTAMP()` and `FROM_UNIXTIME()` to convert between `TIMESTAMP` values and Unix timestamp values, the conversion is lossy because the mapping is not one-to-one in both directions. For example, due to conventions for local time zone changes, it is possible for two `UNIX_TIMESTAMP()` to map two `TIMESTAMP` values to the same Unix timestamp value. `FROM_UNIXTIME()` will map that value back to only one of the original `TIMESTAMP` values. Here is an example, using `TIMESTAMP` values in the CET time zone:

    mysql> SELECT UNIX_TIMESTAMP('2005-03-27 03:00:00');
    +---------------------------------------+
    | UNIX_TIMESTAMP('2005-03-27 03:00:00') |
    |---------------------------------------|
    | 1111885200                             |
    +---------------------------------------+

    mysql> SELECT UNIX_TIMESTAMP('2005-03-27 02:00:00');
    +---------------------------------------+
    | UNIX_TIMESTAMP('2005-03-27 02:00:00') |
    |---------------------------------------|
    | 1111885200                             |
    +---------------------------------------+

    mysql> SELECT FROM_UNIXTIME(1111885200);
    +---------------------------+
    | FROM_UNIXTIME(1111885200)  |
    |---------------------------|
    | 2005-03-27 03:00:00       |
    +---------------------------+

  If you want to subtract `UNIX_TIMESTAMP()` columns, you might want to cast the result to signed integers. See Section 12.10, “Cast Functions and Operators”.

  1083
• **UTC_DATE, UTC_DATE()**

Returns the current UTC date as a value in 'YYYY-MM-DD' or YYYYMMDD format, depending on whether the function is used in a string or numeric context.

```sql
mysql> SELECT UTC_DATE(), UTC_DATE() + 0;
-> '2003-08-14', 20030814
```

• **UTC_TIME, UTC_TIME()**

Returns the current UTC time as a value in 'HH:MM:SS' or HHMMSS.uuuuuu format, depending on whether the function is used in a string or numeric context.

```sql
mysql> SELECT UTC_TIME(), UTC_TIME() + 0;
-> '18:07:53', 180753.000000
```

• **UTC_TIMESTAMP, UTC_TIMESTAMP()**

Returns the current UTC date and time as a value in 'YYYY-MM-DD HH:MM:SS' or YYYYMMDDHHMMSS.uuuuuu format, depending on whether the function is used in a string or numeric context.

```sql
mysql> SELECT UTC_TIMESTAMP(), UTC_TIMESTAMP() + 0;
-> '2003-08-14 18:08:04', 20030814180804.000000
```

• **WEEK(date[, mode])**

This function returns the week number for `date`. The two-argument form of `WEEK()` enables you to specify whether the week starts on Sunday or Monday and whether the return value should be in the range from 0 to 53 or from 1 to 53. If the `mode` argument is omitted, the value of the `default_week_format` system variable is used. See Section 5.1.4, "Server System Variables".

The following table describes how the `mode` argument works.

<table>
<thead>
<tr>
<th>Mode</th>
<th>First day of week</th>
<th>Range</th>
<th>Week 1 is the first week ...</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Sunday</td>
<td>0-53</td>
<td>with a Sunday in this year</td>
</tr>
<tr>
<td>1</td>
<td>Monday</td>
<td>0-53</td>
<td>with 4 or more days this year</td>
</tr>
<tr>
<td>2</td>
<td>Sunday</td>
<td>1-53</td>
<td>with a Sunday in this year</td>
</tr>
<tr>
<td>3</td>
<td>Monday</td>
<td>1-53</td>
<td>with 4 or more days this year</td>
</tr>
<tr>
<td>4</td>
<td>Sunday</td>
<td>0-53</td>
<td>with 4 or more days this year</td>
</tr>
<tr>
<td>5</td>
<td>Monday</td>
<td>0-53</td>
<td>with a Monday in this year</td>
</tr>
<tr>
<td>6</td>
<td>Sunday</td>
<td>1-53</td>
<td>with 4 or more days this year</td>
</tr>
<tr>
<td>7</td>
<td>Monday</td>
<td>1-53</td>
<td>with a Monday in this year</td>
</tr>
</tbody>
</table>

For `mode` values with a meaning of “with 4 or more days this year,” weeks are numbered according to ISO 8601:1988:

- If the week containing January 1 has 4 or more days in the new year, it is week 1.
- Otherwise, it is the last week of the previous year, and the next week is week 1.

```sql
mysql> SELECT WEEK('2008-02-20');
-> 7
mysql> SELECT WEEK('2008-02-20',0);
-> 7
mysql> SELECT WEEK('2008-02-20',1);
-> 8
```
Date and Time Functions

mysql> SELECT WEEK('2008-12-31',1);
-> 53

Note that if a date falls in the last week of the previous year, MySQL returns 0 if you do not use 2, 3, 6, or 7 as the optional mode argument:

mysql> SELECT YEAR('2000-01-01'), WEEK('2000-01-01',0);
-> 2000, 0

One might argue that WEEK() should return 52 because the given date actually occurs in the 52nd week of 1999. WEEK() returns 0 instead so that the return value is "the week number in the given year." This makes use of the WEEK() function reliable when combined with other functions that extract a date part from a date.

If you prefer a result evaluated with respect to the year that contains the first day of the week for the given date, use 0, 2, 5, or 7 as the optional mode argument.

mysql> SELECT WEEK('2000-01-01',2);
-> 52

Alternatively, use the YEARWEEK() function:

mysql> SELECT YEARWEEK('2000-01-01');
-> 199952
mysql> SELECT MID(YEARWEEK('2000-01-01'),5,2);
-> '52'

- WEEKDAY(date)

Returns the weekday index for date (0 = Monday, 1 = Tuesday, ... 6 = Sunday).

mysql> SELECT WEEKDAY('2008-02-03 22:23:00');
-> 6
mysql> SELECT WEEKDAY('2007-11-06');
-> 1

- WEEKOFYEAR(date)

Returns the calendar week of the date as a number in the range from 1 to 53. WEEKOFYEAR() is a compatibility function that is equivalent to WEEK(date,3).

mysql> SELECT WEEKOFYEAR('2008-02-20');
-> 8

- YEAR(date)

Returns the year for date, in the range 1000 to 9999, or 0 for the "zero" date.

mysql> SELECT YEAR('1987-01-01');
-> 1987

- YEARWEEK(date), YEARWEEK(date,mode)

Returns year and week for a date. The year in the result may be different from the year in the date argument for the first and the last week of the year.

The mode argument works exactly like the mode argument to WEEK(). For the single-argument syntax, a mode value of 0 is used. Unlike WEEK(), the value of default_week_format does not influence YEARWEEK().
What Calendar Is Used By MySQL?

MySQL uses what is known as a proleptic Gregorian calendar.

Every country that has switched from the Julian to the Gregorian calendar has had to discard at least ten days during the switch. To see how this works, consider the month of October 1582, when the first Julian-to-Gregorian switch occurred.

<table>
<thead>
<tr>
<th>Monday</th>
<th>Tuesday</th>
<th>Wednesday</th>
<th>Thursday</th>
<th>Friday</th>
<th>Saturday</th>
<th>Sunday</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>3</td>

</table>

There are no dates between October 4 and October 15. This discontinuity is called the cutover. Any dates before the cutover are Julian, and any dates following the cutover are Gregorian. Dates during a cutover are nonexistent.

A calendar applied to dates when it was not actually in use is called proleptic. Thus, if we assume there was never a cutover and Gregorian rules always rule, we have a proleptic Gregorian calendar. This is what is used by MySQL, as is required by standard SQL. For this reason, dates prior to the cutover stored as MySQL DATE or DATETIME values must be adjusted to compensate for the difference. It is important to realize that the cutover did not occur at the same time in all countries, and that the later it happened, the more days were lost. For example, in Great Britain, it took place in 1752, when Wednesday September 2 was followed by Thursday September 14. Russia remained on the Julian calendar until 1918, losing 13 days in the process, and what is popularly referred to as its “October Revolution” occurred in November according to the Gregorian calendar.

12.9 Full-Text Search Functions

MATCH (col1, col2, ...) AGAINST (expr [search_modifer])

search_modifer:

| IN NATURAL LANGUAGE MODE | IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION | IN BOOLEAN MODE | WITH QUERY EXPANSION |

MySQL has support for full-text indexing and searching:

- A full-text index in MySQL is an index of type FULLTEXT.
- Full-text indexes can be used only with MyISAM tables. (In MySQL 5.6 and up, they can also be used with InnoDB tables.) Full-text indexes can be created only for CHAR, VARCHAR, or TEXT columns.
- A FULLTEXT index definition can be given in the CREATE TABLE statement when a table is created, or added later using ALTER TABLE or CREATE INDEX.
- For large data sets, it is much faster to load your data into a table that has no FULLTEXT index and then create the index after that, than to load data into a table that has an existing FULLTEXT index.
Full-text searching is performed using MATCH() ... AGAINST syntax. MATCH() takes a comma-separated list that names the columns to be searched. AGAINST takes a string to search for, and an optional modifier that indicates what type of search to perform. The search string must be a string value that is constant during query evaluation. This rules out, for example, a table column because that can differ for each row.

There are three types of full-text searches:

- A natural language search interprets the search string as a phrase in natural human language (a phrase in free text). There are no special operators. The stopword list applies. In addition, words that are present in 50% or more of the rows are considered common and do not match.

  Full-text searches are natural language searches if the IN NATURAL LANGUAGE MODE modifier is given or if no modifier is given. For more information, see Section 12.9.1, “Natural Language Full-Text Searches”.

- A boolean search interprets the search string using the rules of a special query language. The string contains the words to search for. It can also contain operators that specify requirements such that a word must be present or absent in matching rows, or that it should be weighted higher or lower than usual. Common words such as “some” or “then” are stopwords and do not match if present in the search string. The IN BOOLEAN MODE modifier specifies a boolean search. For more information, see Section 12.9.2, “Boolean Full-Text Searches”.

- A query expansion search is a modification of a natural language search. The search string is used to perform a natural language search. Then words from the most relevant rows returned by the search are added to the search string and the search is done again. The query returns the rows from the second search. The IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION or WITH QUERY EXPANSION modifier specifies a query expansion search. For more information, see Section 12.9.3, “Full-Text Searches with Query Expansion”.

The IN NATURAL LANGUAGE MODE and IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION modifiers were added in MySQL 5.1.7.

Constraints on full-text searching are listed in Section 12.9.5, “Full-Text Restrictions”.

The myisam_ftdump utility can be used to dump the contents of a full-text index. This may be helpful for debugging full-text queries. See Section 4.6.2, “myisam_ftdump — Display Full-Text Index information”.

### 12.9.1 Natural Language Full-Text Searches

By default or with the IN NATURAL LANGUAGE MODE modifier, the MATCH() function performs a natural language search for a string against a text collection. A collection is a set of one or more columns included in a FULLTEXT index. The search string is given as the argument to AGAINST(). For each row in the table, MATCH() returns a relevance value; that is, a similarity measure between the search string and the text in that row in the columns named in the MATCH() list.

```
mysql> CREATE TABLE articles (  
>    id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,  
>    title VARCHAR(200),  
>    body TEXT,  
>    MATCH (title, body)  
> ) ENGINE=MyISAM;  
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> INSERT INTO articles (title, body) VALUES  
>    ('MySQL Tutorial', 'DBMS stands for DataBase ...'),  
>    ('How To Use MySQL Well', 'After you went through a ...'),  
>    ('Optimizing MySQL', 'In this tutorial we will show ...'),  
>    ('1001 MySQL Tricks', '1. Never run mysqld as root. 2. ...'),  
>    ('MySQL vs. YourSQL', 'In the following database comparison ...'),  
```
By default, the search is performed in case-insensitive fashion. However, you can perform a case-
sensitive full-text search by using a binary collation for the indexed columns. For example, a column
that uses the latin1 character set of can be assigned a collation of latin1_bin to make it case
sensitive for full-text searches.

When MATCH() is used in a WHERE clause, as in the example shown earlier, the rows returned are
automatically sorted with the highest relevance first. Relevance values are nonnegative floating-point
numbers. Zero relevance means no similarity. Relevance is computed based on the number of words
in the row, the number of unique words in that row, the total number of words in the collection, and the
number of documents (rows) that contain a particular word.

To simply count matches, you could use a query like this:

```sql
mysql> SELECT COUNT(*) FROM articles
       -> WHERE MATCH (title, body)
       -> AGAINST ('database' IN NATURAL LANGUAGE MODE);
```

However, you might find it quicker to rewrite the query as follows:

```sql
mysql> SELECT
       -> COUNT(IF(MATCH (title, body) AGAINST ('database' IN NATURAL LANGUAGE MODE), 1, NULL))
       -> AS count
       -> FROM articles;
```

The first query sorts the results by relevance whereas the second does not. However, the second
query performs a full table scan and the first does not. The first may be faster if the search matches few
rows; otherwise, the second may be faster because it would read many rows anyway.

For natural-language full-text searches, it is a requirement that the columns named in the MATCH()
function be the same columns included in some FULLTEXT index in your table. For the preceding
query, note that the columns named in the MATCH() function (title and body) are the same as those
named in the definition of the article table's FULLTEXT index. If you wanted to search the title or
body separately, you would need to create separate FULLTEXT indexes for each column.

It is also possible to perform a boolean search or a search with query expansion. These search types
are described in Section 12.9.2, "Boolean Full-Text Searches", and Section 12.9.3, "Full-Text Searches
with Query Expansion".
A full-text search that uses an index can name columns only from a single table in the `MATCH()` clause because an index cannot span multiple tables. A boolean search can be done in the absence of an index (albeit more slowly), in which case it is possible to name columns from multiple tables.

The preceding example is a basic illustration that shows how to use the `MATCH()` function where rows are returned in order of decreasing relevance. The next example shows how to retrieve the relevance values explicitly. Returned rows are not ordered because the `SELECT` statement includes neither `WHERE` nor `ORDER BY` clauses:

```sql
mysql> SELECT id, MATCH (title,body) -> AGAINST ('Tutorial' IN NATURAL LANGUAGE MODE) AS score -> FROM articles;
+----+------------------+
| id | score            |
+----+------------------+
|  1 | 0.6554833110809 |
|  3 | 0.66266459226608 |
|  4 | 0                |
|  5 | 0                |
|  6 | 0                |
+----+------------------+
6 rows in set (0.00 sec)
```

The following example is more complex. The query returns the relevance values and it also sorts the rows in order of decreasing relevance. To achieve this result, specify `MATCH()` twice: once in the `SELECT` list and once in the `WHERE` clause. This causes no additional overhead, because the MySQL optimizer notices that the two `MATCH()` calls are identical and invokes the full-text search code only once.

```sql
mysql> SELECT id, body, MATCH (title,body) AGAINST -> ('Security implications of running MySQL as root' -> IN NATURAL LANGUAGE MODE) AS score -> FROM articles WHERE MATCH (title,body) AGAINST -> ('Security implications of running MySQL as root' -> IN NATURAL LANGUAGE MODE);  
+----+-------------------------------------+-----------------+
| id | body                                | score           |
|  4 | 1. Never run mysqld as root. 2. ... | 1.5219271183014 |
|  6 | When configured properly, MySQL ... | 1.3114095926285 |
+----+-------------------------------------+-----------------+
2 rows in set (0.00 sec)
```

The MySQL `FULLTEXT` implementation regards any sequence of true word characters (letters, digits, and underscores) as a word. That sequence may also contain apostrophes ("'"), but not more than one in a row. This means that `aaa''bbb` is regarded as one word, but `aaa''bbb` is regarded as two words. Apostrophes at the beginning or the end of a word are stripped by the `FULLTEXT` parser; `aaa''bbb` would be parsed as `aaa'bbb`.

The `FULLTEXT` parser determines where words start and end by looking for certain delimiter characters; for example, `" "` (space), `","` (comma), and `"."` (period). If words are not separated by delimiters (as in, for example, Chinese), the `FULLTEXT` parser cannot determine where a word begins or ends. To be able to add words or other indexed terms in such languages to a `FULLTEXT` index, you must preprocess them so that they are separated by some arbitrary delimiter such as `""`.

It is possible to write a plugin that replaces the built-in full-text parser. For details, see Section 22.2, "The MySQL Plugin API". For example parser plugin source code, see the `plugin/fulltext` directory of a MySQL source distribution.

Some words are ignored in full-text searches:

- Any word that is too short is ignored. The default minimum length of words that are found by full-text searches is four characters.
Boolean Full-Text Searches

• Words in the stopword list are ignored. A stopword is a word such as “the” or “some” that is so common that it is considered to have zero semantic value. There is a built-in stopword list, but it can be overwritten by a user-defined list.

The default stopword list is given in Section 12.9.4, “Full-Text Stopwords”. The default minimum word length and stopword list can be changed as described in Section 12.9.6, “Fine-Tuning MySQL Full-Text Search”.

Every correct word in the collection and in the query is weighted according to its significance in the collection or query. Consequently, a word that is present in many documents has a lower weight (and may even have a zero weight), because it has lower semantic value in this particular collection. Conversely, if the word is rare, it receives a higher weight. The weights of the words are combined to compute the relevance of the row.

Such a technique works best with large collections (in fact, it was carefully tuned this way). For very small tables, word distribution does not adequately reflect their semantic value, and this model may sometimes produce bizarre results. For example, although the word “MySQL” is present in every row of the articles table shown earlier, a search for the word produces no results:

```
mysql> SELECT * FROM articles
    -> WHERE MATCH (title,body)
    -> AGAINST ('MySQL' IN NATURAL LANGUAGE MODE);
Empty set (0.00 sec)
```

The search result is empty because the word “MySQL” is present in at least 50% of the rows. As such, it is effectively treated as a stopword. For large data sets, this is the most desirable behavior: A natural language query should not return every second row from a 1GB table. For small data sets, it may be less desirable.

A word that matches half of the rows in a table is less likely to locate relevant documents. In fact, it most likely finds plenty of irrelevant documents. We all know this happens far too often when we are trying to find something on the Internet with a search engine. It is with this reasoning that rows containing the word are assigned a low semantic value for the particular data set in which they occur. A given word may reach the 50% threshold in one data set but not another.

The 50% threshold has a significant implication when you first try full-text searching to see how it works: If you create a table and insert only one or two rows of text into it, every word in the text occurs in at least 50% of the rows. As a result, no search returns any results. Be sure to insert at least three rows, and preferably many more. Users who need to bypass the 50% limitation can use the boolean search mode; see Section 12.9.2, “Boolean Full-Text Searches”.

12.9.2 Boolean Full-Text Searches

MySQL can perform boolean full-text searches using the IN BOOLEAN MODE modifier. With this modifier, certain characters have special meaning at the beginning or end of words in the search string. In the following query, the + and − operators indicate that a word is required to be present or absent, respectively, for a match to occur. Thus, the query retrieves all the rows that contain the word “MySQL” but that do not contain the word “YourSQL”:

```
mysql> SELECT * FROM articles WHERE MATCH (title,body)
    -> AGAINST ('+MySQL -YourSQL' IN BOOLEAN MODE);
```

```
+----+-----------------------+-------------------------------------+
| id | title                 | body                                |
+----+-----------------------+-------------------------------------+
|  1 | MySQL Tutorial        | DBMS stands for DataBase ...        |
|  2 | How To Use MySQL Well | After you went through a ...         |
|  3 | Optimizing MySQL      | In this tutorial we will show ...    |
|  4 | 1001 MySQL Tricks     | 1. Never run mysqld as root. 2. ... |
|  6 | MySQL Security        | When configured properly, MySQL ...  |
```

1090
Note

In implementing this feature, MySQL uses what is sometimes referred to as *implied Boolean logic*, in which

- + stands for **AND**
- - stands for **NOT**
- [no operator] implies **OR**

Boolean full-text searches have these characteristics:

- They do not use the 50% threshold.
- They do not automatically sort rows in order of decreasing relevance. You can see this from the preceding query result: The row with the highest relevance is the one that contains “MySQL” twice, but it is listed last, not first.
- They can work even without a **FULLTEXT** index, although a search executed in this fashion would be quite slow.
- The minimum and maximum word length full-text parameters apply.
- The stopword list applies.

The boolean full-text search capability supports the following operators:

- +

  A leading plus sign indicates that this word **must** be present in each row that is returned.

- -

  A leading minus sign indicates that this word **must not** be present in any of the rows that are returned.

  **Note:** The - operator acts only to exclude rows that are otherwise matched by other search terms. Thus, a boolean-mode search that contains only terms preceded by - returns an empty result. It does not return “all rows except those containing any of the excluded terms.”

- (no operator)

  By default (when neither + nor - is specified) the word is optional, but the rows that contain it are rated higher. This mimics the behavior of **MATCH() . . . AGAINST()** without the **IN BOOLEAN MODE** modifier.

- > <

  These two operators are used to change a word's contribution to the relevance value that is assigned to a row. The > operator increases the contribution and the < operator decreases it. See the example following this list.

- ( )

  Parentheses group words into subexpressions. Parenthesized groups can be nested.

- ~

  A leading tilde acts as a negation operator, causing the word's contribution to the row's relevance to be negative. This is useful for marking “noise” words. A row containing such a word is rated lower than others, but is not excluded altogether, as it would be with the - operator.
Boolean Full-Text Searches

- *
  The asterisk serves as the truncation (or wildcard) operator. Unlike the other operators, it should be appended to the word to be affected. Words match if they begin with the word preceding the * operator.

  If a word is specified with the truncation operator, it is not stripped from a boolean query, even if it is too short (as determined from the \texttt{ft\_min\_word\_len} setting) or a stopword. This occurs because the word is not seen as too short or a stopword, but as a prefix that must be present in the document in the form of a word that begins with the prefix. Suppose that \texttt{ft\_min\_word\_len}=4. Then a search for \\texttt{'+word \+the*'} will likely return fewer rows than a search for \\texttt{'+word \+the'}:
  
  - The former query remains as is and requires both \texttt{word} and \texttt{the} (a word starting with \texttt{the}) to be present in the document.
  
  - The latter query is transformed to \texttt{+word} (requiring only \texttt{word} to be present). \texttt{the} is both too short and a stopword, and either condition is enough to cause it to be ignored.

- "
  A phrase that is enclosed within double quote (""") characters matches only rows that contain the phrase literally, as it was typed. The full-text engine splits the phrase into words and performs a search in the \texttt{FULLTEXT} index for the words. Nonword characters need not be matched exactly: Phrase searching requires only that matches contain exactly the same words as the phrase and in the same order. For example, "\texttt{test phrase}" matches "\texttt{test, phrase}".

  If the phrase contains no words that are in the index, the result is empty. For example, if all words are either stopwords or shorter than the minimum length of indexed words, the result is empty.

The following examples demonstrate some search strings that use boolean full-text operators:

- 'apple banana'
  Find rows that contain at least one of the two words.

- '+apple +juice'
  Find rows that contain both words.

- '+apple macintosh'
  Find rows that contain the word “apple”, but rank rows higher if they also contain “macintosh”.

- '+apple ~macintosh'
  Find rows that contain the word “apple” but not “macintosh”.

- '+apple ~macintosh'
  Find rows that contain the word “apple”, but if the row also contains the word “macintosh”, rate it lower than if row does not. This is “softer” than a search for \texttt{'+apple -macintosh'}, for which the presence of “macintosh” causes the row not to be returned at all.

- '+apple +(>turnover <strudel)'
  Find rows that contain the words “apple” and “turnover”, or “apple” and “strudel” (in any order), but rank “apple turnover” higher than “apple strudel”.

- 'apple*'
  Find rows that contain words such as “apple”, “apples”, “applesauce”, or “applet”.

- "some words"
Find rows that contain the exact phrase “some words” (for example, rows that contain “some words of wisdom” but not “some noise words”). Note that the “” characters that enclose the phrase are operator characters that delimit the phrase. They are not the quotation marks that enclose the search string itself.

### 12.9.3 Full-Text Searches with Query Expansion

Full-text search supports query expansion (and in particular, its variant “blind query expansion”). This is generally useful when a search phrase is too short, which often means that the user is relying on implied knowledge that the full-text search engine lacks. For example, a user searching for “database” may really mean that “MySQL”, “Oracle”, “DB2”, and “RDBMS” all are phrases that should match “databases” and should be returned, too. This is implied knowledge.

Blind query expansion (also known as automatic relevance feedback) is enabled by adding WITH QUERY EXPANSION or IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION following the search phrase. It works by performing the search twice, where the search phrase for the second search is the original search phrase concatenated with the few most highly relevant documents from the first search. Thus, if one of these documents contains the word “databases” and the word “MySQL”, the second search finds the documents that contain the word “MySQL” even if they do not contain the word “database”. The following example shows this difference:

```sql
mysql> SELECT * FROM articles
    -> WHERE MATCH (title,body)
    -> AGAINST ('database' IN NATURAL LANGUAGE MODE);
+----+-------------------+------------------------------------------+
<table>
<thead>
<tr>
<th>id</th>
<th>title</th>
<th>body</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>MySQL vs. YourSQL</td>
<td>In the following database comparison ...</td>
</tr>
<tr>
<td>1</td>
<td>MySQL Tutorial</td>
<td>DBMS stands for Database ...</td>
</tr>
</tbody>
</table>
+----+-------------------+------------------------------------------+
2 rows in set (0.00 sec)

mysql> SELECT * FROM articles
    -> WHERE MATCH (title,body)
    -> AGAINST ('database' WITH QUERY EXPANSION);
+----+-------------------+------------------------------------------+
<table>
<thead>
<tr>
<th>id</th>
<th>title</th>
<th>body</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>MySQL vs. YourSQL</td>
<td>In the following database comparison ...</td>
</tr>
<tr>
<td>1</td>
<td>MySQL Tutorial</td>
<td>DBMS stands for Database ...</td>
</tr>
<tr>
<td>3</td>
<td>Optimizing MySQL</td>
<td>In this tutorial we will show ...</td>
</tr>
</tbody>
</table>
+----+-------------------+------------------------------------------+
3 rows in set (0.00 sec)
```

Another example could be searching for books by Georges Simenon about Maigret, when a user is not sure how to spell “Maigret”. A search for “Megre and the reluctant witnesses” finds only “Maigret and the Reluctant Witnesses” without query expansion. A search with query expansion finds all books with the word “Maigret” on the second pass.

Note
---
Because blind query expansion tends to increase noise significantly by returning nonrelevant documents, it is meaningful to use only when a search phrase is rather short.

### 12.9.4 Full-Text Stopwords

The stopword list is loaded and searched for full-text queries using the server character set and collation (the values of the character_set_server and collation_server system variables). False hits or misses may occur for stopword lookups if the stopword file or columns used for full-text indexing or searches have a character set or collation different from character_set_server or collation_server.
Case sensitivity of stopword lookups depends on the server collation. For example, lookups are case insensitive if the collation is `latin1_swedish_ci`, whereas lookups are case sensitive if the collation is `latin1_general_cs` or `latin1_bin`.

The following table shows the default list of full-text stopwords. In a MySQL source distribution, you can find this list in the `storage/myisam/ft_static.c` file.

<table>
<thead>

12.9.5 Full-Text Restrictions

- Full-text searches are supported for MyISAM tables only. (In MySQL 5.6 and up, they can also be used with InnoDB tables.)

- Full-text searches are not supported for partitioned tables. See Section 18.5, “Restrictions and Limitations on Partitioning”.

- Full-text searches can be used with most multibyte character sets. The exception is that for Unicode, the utf8 character set can be used, but not the ucs2 character set. However, although FULLTEXT indexes on ucs2 columns cannot be used, you can perform IN BOOLEAN MODE searches on a ucs2 column that has no such index.

- Ideographic languages such as Chinese and Japanese do not have word delimiters. Therefore, the FULLTEXT parser cannot determine where words begin and end in these and other such languages. The implications of this and some workarounds for the problem are described in Section 12.9, “Full-Text Search Functions”.

1096
Fine-Tuning MySQL Full-Text Search

Although the use of multiple character sets within a single table is supported, all columns in a `FULLTEXT` index must use the same character set and collation.

The `MATCH()` column list must match exactly the column list in some `FULLTEXT` index definition for the table, unless this `MATCH()` is in BOOLEAN MODE. Boolean-mode searches can be done on nonindexed columns, although they are likely to be slow.

The argument to `AGAINST()` must be a string value that is constant during query evaluation. This rules out, for example, a table column because that can differ for each row.

Index hints are more limited for `FULLTEXT` searches than for non-`FULLTEXT` searches. See Section 8.9.3, “Index Hints”.

The ‘%’ character is not a supported wildcard character for full-text searches.

12.9.6 Fine-Tuning MySQL Full-Text Search

MySQL’s full-text search capability has few user-tunable parameters. You can exert more control over full-text searching behavior if you have a MySQL source distribution because some changes require source code modifications. See Section 2.11, “Installing MySQL from Source”.

Full-text search is carefully tuned for the most effectiveness. Modifying the default behavior in most cases can actually decrease effectiveness. Do not alter the MySQL sources unless you know what you are doing.

Most full-text variables described in this section must be set at server startup time. A server restart is required to change them; they cannot be modified while the server is running.

Some variable changes require that you rebuild the `FULLTEXT` indexes in your tables. Instructions for doing so are given later in this section.

• The minimum and maximum lengths of words to be indexed are defined by the `ft_min_word_len` and `ft_max_word_len` system variables. (See Section 5.1.4, “Server System Variables”.) The default minimum value is four characters; the default maximum is version dependent. If you change either value, you must rebuild your `FULLTEXT` indexes. For example, if you want three-character words to be searchable, you can set the `ft_min_word_len` variable by putting the following lines in an option file:

```
[mysqld]
ft_min_word_len=3
```

Then restart the server and rebuild your `FULLTEXT` indexes. Note particularly the remarks regarding `myisamchk` in the instructions following this list.

• To override the default stopword list, set the `ft_stopword_file` system variable. (See Section 5.1.4, “Server System Variables”.) The variable value should be the path name of the file containing the stopword list, or the empty string to disable stopword filtering. The server looks for the file in the data directory unless an absolute path name is given to specify a different directory. After changing the value of this variable or the contents of the stopword file, restart the server and rebuild your `FULLTEXT` indexes.

The stopword list is free-form. That is, you may use any nonalphanumeric character such as newline, space, or comma to separate stopwords. Exceptions are the underscore character (“_”) and a single apostrophe (“’”) which are treated as part of a word. The character set of the stopword list is the server’s default character set; see Section 10.1.3.1, “Server Character Set and Collation”.

• The 50% threshold for natural language searches is determined by the particular weighting scheme chosen. To disable it, look for the following line in `storage/myisam/ftdefs.h`:

```
#define GWS_IN_USE GWS_PROB
```
Change that line to this:

```c
#define GWS_IN_USE GWS_FREQ
```

Then recompile MySQL. There is no need to rebuild the indexes in this case.

**Note**

By making this change, you severely decrease MySQL's ability to provide adequate relevance values for the `MATCH()` function. If you really need to search for such common words, it would be better to search using `IN BOOLEAN MODE` instead, which does not observe the 50% threshold.

- To change the operators used for boolean full-text searches, set the `ft_boolean_syntax` system variable. This variable can be changed while the server is running, but you must have the `SUPER` privilege to do so. No rebuilding of indexes is necessary in this case. See Section 5.1.4, "Server System Variables", which describes the rules governing how to set this variable.

- If you want to change the set of characters that are considered word characters, you can do so in several ways, as described in the following list. After making the modification, you must rebuild the indexes for each table that contains any `FULLTEXT` indexes. Suppose that you want to treat the hyphen character (\'-\') as a word character. Use one of these methods:
  
  - Modify the MySQL source: In `storage/myisam/ftdefs.h`, see the `true_word_char()` and `misc_word_char()` macros. Add `'- '` to one of those macros and recompile MySQL.
  
  - Modify a character set file: This requires no recompilation. The `true_word_char()` macro uses a "character type" table to distinguish letters and numbers from other characters. You can edit the contents of the `<ctype><map>` array in one of the character set XML files to specify that `'- '` is a "letter." Then use the given character set for your `FULLTEXT` indexes. For information about the `<ctype><map>` array format, see Section 10.3.1, "Character Definition Arrays".

  - Add a new collation for the character set used by the indexed columns, and alter the columns to use that collation. For general information about adding collations, see Section 10.4, “Adding a Collation to a Character Set”. For an example specific to full-text indexing, see Section 12.9.7, “Adding a Collation for Full-Text Indexing”.

If you modify full-text variables that affect indexing (`ft_min_word_len`, `ft_max_word_len`, or `ft_stopword_file`), or if you change the stopword file itself, you must rebuild your `FULLTEXT` indexes after making the changes and restarting the server. To rebuild the indexes in this case, it is sufficient to do a `QUICK` repair operation:

```
mysql> REPAIR TABLE tbl_name QUICK;
```

Alternatively, use `ALTER TABLE` with the `DROP_INDEX` and `ADD_INDEX` options to drop and re-create each `FULLTEXT` index. In some cases, this may be faster than a repair operation.

Each table that contains any `FULLTEXT` index must be repaired as just shown. Otherwise, queries for the table may yield incorrect results, and modifications to the table will cause the server to see the table as corrupt and in need of repair.

If you use `myisamchk` to perform an operation that modifies table indexes (such as repair or analyze), the `FULLTEXT` indexes are rebuilt using the default full-text parameter values for minimum word length, maximum word length, and stopword file unless you specify otherwise. This can result in queries failing.

The problem occurs because these parameters are known only by the server. They are not stored in MyISAM index files. To avoid the problem if you have modified the minimum or maximum word length or stopword file values used by the server, specify the same `ft_min_word_len`, `ft_max_word_len`, etc., in your `myisamchk` command.
and ft_stopword_file values for myisamchk that you use for mysqld. For example, if you have set the minimum word length to 3, you can repair a table with myisamchk like this:

```
shell> myisamchk --recover --ft_min_word_len=3 tbl_name.MYI
```

To ensure that myisamchk and the server use the same values for full-text parameters, place each one in both the [mysqld] and [myisamchk] sections of an option file:

```
[mysqld]
ft_min_word_len=3

[myisamchk]
ft_min_word_len=3
```

An alternative to using myisamchk for index modification is to use the REPAIR TABLE, ANALYZE TABLE, OPTIMIZE TABLE, or ALTER TABLE statements. These statements are performed by the server, which knows the proper full-text parameter values to use.

### 12.9.7 Adding a Collation for Full-Text Indexing

This section describes how to add a new collation for full-text searches. The sample collation is like latin1_swedish_ci but treats the '‐' character as a letter rather than as a punctuation character so that it can be indexed as a word character. General information about adding collations is given in Section 10.4, “Adding a Collation to a Character Set”; it is assumed that you have read it and are familiar with the files involved.

To add a collation for full-text indexing, use this procedure:

1. Add a collation to the Index.xml file. The collation ID must be unused, so choose a value different from 62 if that ID is already taken on your system.

   ```xml
   <charset name="latin1">
   ...
   <collation name="latin1_fulltext_ci" id="62"/>
   </charset>
   ```

2. Declare the sort order for the collation in the latin1.xml file. In this case, the order can be copied from latin1_swedish_ci:

   ```xml
   <collation name="latin1_fulltext_ci">
   <map>
   00 01 02 03 04 05 06 07 08 09 0A 0B 0C 0D 0E 0F
   10 11 12 13 14 15 16 17 18 19 1A 1B 1C 1D 1E 1F
   20 21 22 23 24 25 26 27 28 29 2A 2B 2C 2D 2E 2F
   30 31 32 33 34 35 36 37 38 39 3A 3B 3C 3D 3E 3F
   40 41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F
   50 51 52 53 54 55 56 57 58 59 5A 5B 5C 5D 5E 5F
   60 61 62 63 64 65 66 67 68 69 6A 6B 6C 6D 6E 6F
   70 71 72 73 74 75 76 77 78 79 7A 7B 7C 7D 7E 7F
   80 81 82 83 84 85 86 87 88 89 8A 8B 8C 8D 8E 8F
   90 91 92 93 94 95 96 97 98 99 9A 9B 9C 9D 9E 9F
   A0 A1 A2 A3 A4 A5 A6 A7 A8 A9 AA AB AC AD AE AF
   B0 B1 B2 B3 B4 B5 B6 B7 B8 B9 BA BB BC BD BE BF
   C1 C2 C3 C4 C5 C6 C7 C8 C9 CA CB CC CD CE CF
   D1 D2 D3 D4 D5 D6 D7 D8 D9 DA DB DC DD DE DF
   E1 E2 E3 E4 E5 E6 E7 E8 E9 EA EB EC ED EE EF
   F0 F1 F2 F3 F4 F5 F6 F7 F8 F9 FA FB FC FD FE FF
   </map>
   </collation>
   ```

3. Modify the ctype array in latin1.xml. Change the value corresponding to 0x2D (which is the code for the '‐' character) from 10 (punctuation) to 01 (small letter). In the following array, this is the element in the fourth row down, third value from the end.
4. Restart the server.

5. To employ the new collation, include it in the definition of columns that are to use it:

```sql
mysql> DROP TABLE IF EXISTS t1;
Query OK, 0 rows affected (0.13 sec)

mysql> CREATE TABLE t1 (
  -> a TEXT CHARACTER SET latin1 COLLATE latin1_fulltext_ci,
  -> FULLTEXT INDEX(a)
  -> ) ENGINE=MyISAM;
Query OK, 0 rows affected (0.47 sec)
```

6. Test the collation to verify that hyphen is considered as a word character:

```sql
mysql> INSERT INTO t1 VALUES ('----'),('....'),('abcd');
Query OK, 3 rows affected (0.22 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM t1 WHERE MATCH a AGAINST ('----' IN BOOLEAN MODE);
+------+
| a    |
+------+
| ---- |
1 row in set (0.00 sec)
```

### 12.10 Cast Functions and Operators

#### Table 12.14 Cast Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BINARY</td>
<td>Cast a string to a binary string</td>
</tr>
<tr>
<td>CAST()</td>
<td>Cast a value as a certain type</td>
</tr>
<tr>
<td>CONVERT()</td>
<td>Cast a value as a certain type</td>
</tr>
</tbody>
</table>

- **BINARY**

The **BINARY** operator casts the string following it to a binary string. This is an easy way to force a column comparison to be done byte by byte rather than character by character. This causes the
comparison to be case sensitive even if the column is not defined as \texttt{BINARY} or \texttt{BLOB}. \texttt{BINARY} also causes trailing spaces to be significant.

\begin{verbatim}
mysql> SELECT 'a' = 'A';
-> 1
mysql> SELECT BINARY 'a' = 'A';
-> 0
mysql> SELECT 'a' = 'a ';
-> 1
mysql> SELECT BINARY 'a' = 'a ';
-> 0
\end{verbatim}

In a comparison, \texttt{BINARY} affects the entire operation; it can be given before either operand with the same result.

\texttt{BINARY str} is shorthand for \texttt{CAST(str AS BINARY)}.

Note that in some contexts, if you cast an indexed column to \texttt{BINARY}, MySQL is not able to use the index efficiently.

- \texttt{CAST(expr AS type)}

  The \texttt{CAST()} function takes an expression of any type and produces a result value of a specified type, similar to \texttt{CONVERT()}. See the description of \texttt{CONVERT()} for more information.

- \texttt{CONVERT(expr,type), CONVERT(expr USING transcoding_name)}

  The \texttt{CONVERT()} and \texttt{CAST()} functions take an expression of any type and produce a result value of a specified type.

\texttt{CAST()} and \texttt{CONVERT(... USING ...)} are standard SQL syntax. The non-\texttt{USING} form of \texttt{CONVERT()} is ODBC syntax.

\texttt{CONVERT()} with \texttt{USING} converts data between different character sets. In MySQL, transcoding names are the same as the corresponding character set names. For example, this statement converts the string \texttt{'abc'} in the default character set to the corresponding string in the \texttt{utf8} character set:

\begin{verbatim}
SELECT CONVERT('abc' USING utf8);
\end{verbatim}

The \texttt{type} for the result can be one of the following values:

- \texttt{BINARY(\texttt{\texttt{\texttt{\texttt{\texttt{\texttt{(N)}}}}}%)}}
- \texttt{CHAR(\texttt{\texttt{\texttt{\texttt{\texttt{\texttt{(N)}}}}}%)}}
- \texttt{DATE}
- \texttt{DATETIME}
- \texttt{DECIMAL(\texttt{\texttt{\texttt{\texttt{\texttt{(M[,D]})}}}%)}}
- \texttt{SIGNED [INTEGER]}
- \texttt{TIME}
- \texttt{UNSIGNED [INTEGER]}

\texttt{BINARY} produces a string with the \texttt{BINARY} data type. See Section 11.4.2, “The BINARY and VARBINARY Types” for a description of how this affects comparisons. If the optional length \texttt{N} is given, \texttt{BINARY(\texttt{\texttt{\texttt{\texttt{\texttt{\texttt{\texttt{(N)}}}}}%)}}} causes the cast to use no more than \texttt{N} bytes of the argument. Values shorter than \texttt{N} bytes are padded with \texttt{0x00} bytes to a length of \texttt{N}.  

1101
CHAR \((N)\) causes the cast to use no more than \(N\) characters of the argument.

Normally, you cannot compare a BLOB value or other binary string in case-insensitive fashion because binary strings have no character set, and thus no concept of lettercase. To perform a case-insensitive comparison, use the CONVERT() function to convert the value to a nonbinary string. Comparisons of the result use the string collation. For example, if the character set of the result has a case-insensitive collation, a LIKE operation is not case sensitive:

```
SELECT 'A' LIKE CONVERT(blob_col USING latin1) FROM tbl_name;
```

To use a different character set, substitute its name for \(\text{latin1}\) in the preceding statement. To specify a particular collation for the converted string, use a COLLATE clause following the CONVERT() call, as described in Section 10.1.9.2, “CONVERT() and CAST()”. For example, to use \(\text{latin1\_german1\_ci}\):

```
SELECT 'A' LIKE CONVERT(blob_col USING latin1) COLLATE latin1_german1_ci
FROM tbl_name;
```

CONVERT() can be used more generally for comparing strings that are represented in different character sets.

LOWER() (and UPPER()) are ineffective when applied to binary strings (BINARY, VARBINARY, BLOB). To perform lettercase conversion, convert the string to a nonbinary string:

```
mysql> SET @str = BINARY 'New York';
mysql> SELECT LOWER(@str), LOWER(CONVERT(@str USING latin1));
+-------------+-----------------------------------+
<table>
<thead>
<tr>
<th>LOWER(@str)</th>
<th>LOWER(CONVERT(@str USING latin1))</th>
</tr>
</thead>
<tbody>
<tr>
<td>New York</td>
<td>new york</td>
</tr>
</tbody>
</table>
+-------------+-----------------------------------+
```

The cast functions are useful when you want to create a column with a specific type in a CREATE TABLE ... SELECT statement:

```
CREATE TABLE new_table SELECT CAST('2000-01-01' AS DATE);
```

The functions also can be useful for sorting ENUM columns in lexical order. Normally, sorting of ENUM columns occurs using the internal numeric values. Casting the values to CHAR results in a lexical sort:

```
SELECT enum_col FROM tbl_name ORDER BY CAST(enum_col AS CHAR);
```

CAST(str AS BINARY) is the same thing as BINARY str. CAST(expr AS CHAR) treats the expression as a string with the default character set.

CAST() also changes the result if you use it as part of a more complex expression such as CONCAT('Date: ', CAST(NOW() AS DATE)).

You should not use CAST() to extract data in different formats but instead use string functions like LEFT() or EXTRACT(). See Section 12.7, “Date and Time Functions”.

To cast a string to a numeric value in numeric context, you normally do not have to do anything other than to use the string value as though it were a number:

```
mysql> SELECT 1+'1';
-> 2
```

If you use a string in an arithmetic operation, it is converted to a floating-point number during expression evaluation.

If you use a number in string context, the number automatically is converted to a string:
Cast Functions and Operators

mysql> SELECT CONCAT('hello you ',2);  
-> 'hello you 2'

For information about implicit conversion of numbers to strings, see Section 12.2, “Type Conversion in Expression Evaluation”.

When using an explicit `CAST()` on a `TIMESTAMP` value in a statement that does not select from any tables, the value is treated by MySQL as a string prior to performing any conversion. This results in the value being truncated when casting to a numeric type, as shown here:

```
mysql> SELECT CAST(TIMESTAMP '2014-09-08 18:07:54' AS SIGNED);
+-------------------------------------------------+  
| CAST(TIMESTAMP '2014-09-08 18:07:54' AS SIGNED) |  
+-------------------------------------------------+  
|                                            2014 |  
+-------------------------------------------------+  
1 row in set, 1 warning (0.00 sec)
```

```
mysql> SHOW WARNINGS;
+---------+------+----------------------------------------------------------+  
| Level   | Code | Message                                                  |  
+---------+------+----------------------------------------------------------+  
| Warning | 1292 | Truncated incorrect INTEGER value: '2014-09-08 18:07:54' |  
+---------+------+----------------------------------------------------------+  
1 row in set (0.00 sec)
```

This does not apply when selecting rows from a table, as shown here:

```
mysql> USE test;  
Database changed
mysql> CREATE TABLE c_test (col TIMESTAMP);
Query OK, 0 rows affected (0.07 sec)
mysql> INSERT INTO c_test VALUES ('2014-09-08 18:07:54');
Query OK, 1 row affected (0.05 sec)
mysql> SELECT col, CAST(col AS UNSIGNED) AS c_col FROM c_test;
+---------------------+----------------+
<table>
<thead>
<tr>
<th>col</th>
<th>c_col</th>
</tr>
</thead>
<tbody>
<tr>
<td>2014-09-08 18:07:54</td>
<td>20140908180754</td>
</tr>
</tbody>
</table>
+---------------------+----------------+
1 row in set (0.00 sec)
```

This is a known issue which is resolved in MySQL 5.6.

MySQL supports arithmetic with both signed and unsigned 64-bit values. If you are using numeric operators (such as `+` or `=`) and one of the operands is an unsigned integer, the result is unsigned by default (see Section 12.6.1, “Arithmetic Operators”). You can override this by using the `SIGNED` or `UNSIGNED` cast operator to cast a value to a signed or unsigned 64-bit integer, respectively.

```
mysql> SELECT CAST(1-2 AS UNSIGNED);
-> 18446744073709551615
mysql> SELECT CAST(1-2 AS UNSIGNED) AS SIGNED;
-> -1
```

If either operand is a floating-point value, the result is a floating-point value and is not affected by the preceding rule. (In this context, `DECIMAL` column values are regarded as floating-point values.)

```
mysql> SELECT CAST(1 AS UNSIGNED) - 2.0;
-> -1.0
```

The SQL mode affects the result of conversion operations. Examples:
• If you convert a “zero” date string to a date, `CONVERT()` and `CAST()` return `NULL` and produce a warning when the `NO_ZERO_DATE` SQL mode is enabled.

• For integer subtraction, if the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled, the subtraction result is signed even if any operand is unsigned.

For more information, see Section 5.1.7, “Server SQL Modes”.

### 12.11 XML Functions

**Table 12.15 XML Functions**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ExtractValue()</code></td>
<td>Extracts a value from an XML string using XPath notation</td>
</tr>
<tr>
<td><code>UpdateXML()</code></td>
<td>Return replaced XML fragment</td>
</tr>
</tbody>
</table>

This section discusses XML and related functionality in MySQL.

**Note**

It is possible to obtain XML-formatted output from MySQL in the `mysql` and `mysqldump` clients by invoking them with the `--xml` option. See Section 4.5.1, “mysql — The MySQL Command-Line Tool”, and Section 4.5.4, “mysqldump — A Database Backup Program”.

Beginning with MySQL 5.1.5, two functions providing basic XPath 1.0 (XML Path Language, version 1.0) capabilities are available. Some basic information about XPath syntax and usage is provided later in this section; however, an in-depth discussion of these topics is beyond the scope of this Manual, and you should refer to the XML Path Language (XPath) 1.0 standard for definitive information. A useful resource for those new to XPath or who desire a refresher in the basics is the Zvon.org XPath Tutorial, which is available in several languages.

**Note**

These functions remain under development. We continue to improve these and other aspects of XML and XPath functionality in MySQL 5.1 and onwards. You may discuss these, ask questions about them, and obtain help from other users with them in the MySQL XML User Forum.

Beginning with MySQL 5.1.20, XPath expressions used with these functions support user variables and local stored program variables. User variables are weakly checked; variables local to stored programs are strongly checked (see also Bug #26518):

• **User variables (weak checking).** Variables using the syntax `$@variable_name` (that is, user variables) are not checked. No warnings or errors are issued by the server if a variable has the wrong type or has previously not been assigned a value. This also means the user is fully responsible for any typographical errors, since no warnings will be given if (for example) `$@myvariable` is used where `$@myvariable` was intended.

**Example:**

```sql
mysql> SET @xml = '<a><b>X</b><b>Y</b></a>';  
Query OK, 0 rows affected (0.00 sec)

mysql> SET @i = 1, @j = 2;  
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @i, ExtractValue(@xml, '//b[$@i]');  
+------|----------------------------------+
| @i   | ExtractValue(@xml, '//b[$@i]')  |
| +------|----------------------------------+
| 1     | X                                |
```
Variables in stored programs (strong checking). Variables using the syntax $variable_name can be declared and used with these functions when they are called inside stored programs. Such variables are local to the stored program in which they are defined, and are strongly checked for type and value.

Example:

```sql
mysql> DELIMITER |

mysql> CREATE PROCEDURE myproc ()
-> BEGIN
-> DECLARE i INT DEFAULT 1;
-> DECLARE xml VARCHAR(25) DEFAULT '<a>X</a><a>Y</a><a>Z</a>';
-> WHILE i < 4 DO
-> SELECT xml, i, ExtractValue(xml, '//a[$i]');
-> SET i = i+1;
-> END WHILE;
-> END |

Query OK, 0 rows affected (0.01 sec)

mysql> DELIMITER ;

mysql> CALL myproc();

| xml                      | i | ExtractValue(xml, '//a[$i]') |
|--------------------------+---+------------------------------|
| <a>X</a><a>Y</a><a>Z</a> | 1 | X                            |
| <a>X</a><a>Y</a><a>Z</a> | 2 | Y                            |
| <a>X</a><a>Y</a><a>Z</a> | 3 | Z                            |
```

Parameters. Variables used in XPath expressions inside stored routines that are passed in as parameters are also subject to strong checking.

Expressions containing user variables or variables local to stored programs must otherwise (except for notation) conform to the rules for XPath expressions containing variables as given in the XPath 1.0 specification.
Note

A user variable used to store an XPath expression is treated as an empty string. Because of this, it is not possible to store an XPath expression as a user variable. (Bug #32911)

- **ExtractValue(xml_frag, xpath_expr)**

`ExtractValue()` takes two string arguments, a fragment of XML markup `xml_frag` and an XPath expression `xpath_expr` (also known as a locator); it returns the text (CDATA) of the first text node which is a child of the elements or elements matched by the XPath expression. In MySQL 5.1, the XPath expression can contain at most 127 characters. (This limitation is lifted in MySQL 5.6.)

Using this function is the equivalent of performing a match using the `xpath_expr` after appending `/text()`. In other words, `ExtractValue('<a><b>Sakila</b></a>', '/a/b')` and `ExtractValue('<a><b>Sakila</b></a>', '/a/b/text()')` produce the same result.

If multiple matches are found, the content of the first child text node of each matching element is returned (in the order matched) as a single, space-delimited string.

If no matching text node is found for the expression (including the implicit `/text()`)—for whatever reason, as long as `xpath_expr` is valid, and `xml_frag` consists of elements which are properly nested and closed—an empty string is returned. No distinction is made between a match on an empty element and no match at all. This is by design.

If you need to determine whether no matching element was found in `xml_frag` or such an element was found but contained no child text nodes, you should test the result of an expression that uses the XPath `count()` function. For example, both of these statements return an empty string, as shown here:

```sql
mysql> SELECT ExtractValue('<a><b/></a>', '/a/b');
+-------------------------------------+
| ExtractValue('<a><b/></a>', '/a/b') |
+-------------------------------------+
|                                     |
+-------------------------------------+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a><c/></a>', '/a/b');
+-------------------------------------+
| ExtractValue('<a><c/></a>', '/a/b') |
+-------------------------------------+
|                                     |
+-------------------------------------+
1 row in set (0.00 sec)
```

However, you can determine whether there was actually a matching element using the following:

```sql
mysql> SELECT ExtractValue('<a><b/></a>', 'count(/a/b)');
+-------------------------------------+
| ExtractValue('<a><b/></a>', 'count(/a/b)') |
+-------------------------------------+
| 1                                   |
+-------------------------------------+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a><c/></a>', 'count(/a/b)');
+-------------------------------------+
| ExtractValue('<a><c/></a>', 'count(/a/b)') |
+-------------------------------------+
| 0                                   |
+-------------------------------------+
1 row in set (0.01 sec)
```
XML Functions

Important

ExtractValue() returns only CDATA, and does not return any tags that might be contained within a matching tag, nor any of their content (see the result returned as val1 in the following example).

```
mysql> SELECT
  -> ExtractValue('<a>ccc</a><b>ddd</b></a>', '/a') AS val1,
  -> ExtractValue('<a>ccc</a><b>ddd</b></a>', '/a/b') AS val2,
  -> ExtractValue('<a>ccc</a><b>ddd</b></a>', '//b') AS val3,
  -> ExtractValue('<a>ccc</a><b>ddd</b></a>', '/b') AS val4,
  -> ExtractValue('<a>ccc</a><b>ddd</b><b>eee</b></a>', '//b') AS val5;

+------+------+------+------+---------+
| val1 | val2 | val3 | val4 | val5    |
+------+------+------+------+---------+
| ccc  | ddd  | ddd  |      | ddd eee |
+------+------+------+------+---------+
```

Beginning with MySQL 5.1.8, this function uses the current SQL collation for making comparisons with contains(), performing the same collation aggregation as other string functions (such as CONCAT()), in taking into account the collation coercibility of their arguments; see Section 10.1.7.5, "Collation of Expressions", for an explanation of the rules governing this behavior.

(Previously, binary—that is, case-sensitive—comparison was always used.)

Beginning with MySQL 5.1.12, NULL is returned if xml_frag contains elements which are not properly nested or closed, and a warning is generated, as shown in this example:

```
mysql> SELECT ExtractValue('<a>c</a><b>', '//a');
+-----------------------------------+
| ExtractValue('<a>c</a><b>', '//a') |
+-----------------------------------+
| NULL                              |
+-----------------------------------+
1 row in set, 1 warning (0.00 sec)
```

```
mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Warning
Code: 1525
Message: Incorrect XML value: 'parse error at line 1 pos 11: END-OF-INPUT unexpected ('>' wanted)'
1 row in set (0.00 sec)
```

```
mysql> SELECT ExtractValue('<a>c</a><b/>', '//a');
+-------------------------------------+
| ExtractValue('<a>c</a><b/>', '//a') |
+-------------------------------------+
| c                                   |
+-------------------------------------+
1 row in set (0.00 sec)
```

Prior to MySQL 5.1.12, an empty string was returned in such cases. (Bug #18201)

• UpdateXML(xml_target, xpath_expr, new_xml)

This function replaces a single portion of a given fragment of XML markup xml_target with a new XML fragment new_xml, and then returns the changed XML. The portion of xml_target that is replaced matches an XPath expression xpath_expr supplied by the user. In MySQL 5.1, the XPath expression can contain at most 127 characters. (This limitation is lifted in MySQL 5.6.)

If no expression matching xpath_expr is found, or if multiple matches are found, the function returns the original xml_target XML fragment. All three arguments should be strings.
xml> SELECT
    -> UpdateXML('<a><b>ccc</b><d></d></a>', '/a', '<e>fff</e>') AS val1,
    -> UpdateXML('<a><b>ccc</b><d></d></a>', '/b', '<e>fff</e>') AS val2,
    -> UpdateXML('<a><b>ccc</b><d></d></a>', '//b', '<e>fff</e>') AS val3,
    -> UpdateXML('<a><b>ccc</b><d></d></a>', '/a/d', '<e>fff</e>') AS val4,
    -> UpdateXML('<a><d></d><b>ccc</b><d></d></a>', '/a/d', '<e>fff</e>') AS val5
G

*************************** 1. row ***************************
val1: <e>fff</e>
val2: <a><b>ccc</b><d></d></a>
val3: <a><e>fff</e><d></d></a>
val4: <a><b>ccc</b><e>fff</e></a>
val5: <a><d></d><b>ccc</b><d></d></a>

Note
A discussion in depth of XPath syntax and usage are beyond the scope of this Manual. Please see the XML Path Language (XPath) 1.0 specification for definitive information. A useful resource for those new to XPath or who are wishing a refresher in the basics is the Zvon.org XPath Tutorial, which is available in several languages.

Descriptions and examples of some basic XPath expressions follow:

• /tag

Matches <tag/> if and only if <tag/> is the root element.

Example: /a has a match in <a><b/></a> because it matches the outermost (root) tag. It does not match the inner a element in <a><b/></a> because in this instance it is the child of another element.

• /tag1/tag2

Matches <tag2/> if and only if it is a child of <tag1/> , and <tag1/> is the root element.

Example: /a/b matches the b element in the XML fragment <a><b/></a> because it is a child of the root element a. It does not have a match in <b><a/></b> because in this case, b is the root element (and hence the child of no other element). Nor does the XPath expression have a match in <a><b><c/></b></a>; here, b is a descendant of a, but not actually a child of a.

This construct is extendable to three or more elements. For example, the XPath expression /a/b/c matches the c element in the fragment <a><b><c/></b></a>.

• //tag

Matches any instance of <tag>.

Example: //a matches the a element in any of the following: <a><b><c/></b></a>; <c><a><b/></a>;</c><b><a/</b></c>.

// can be combined with / . For example, //a/b matches the b element in either of the fragments <a><b/></a> or <a><b><c/></b></a>.

Note
//tag is the equivalent of /descendant-or-self::*//tag. A common error is to confuse this with /descendant-or-self::*tag, although the latter expression can actually lead to very different results, as can be seen here:
XML Functions

```sql
mysql> SET @xml = '<a><b>c</b><w></c><b>x</b><d>y</d>z</b></a>;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @xml;
+-----------------------------------------+
| @xml                                    |
+-----------------------------------------+
| <a><b>c</b><w></c><b>x</b><d>y</d>z</b></a> |
+-----------------------------------------+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue(@xml, '//b[1]');
+------------------------------+
| ExtractValue(@xml, '//b[1]') |
| x z                          |
+------------------------------+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue(@xml, '//b[2]');
+------------------------------+
| ExtractValue(@xml, '//b[2]') |
|                              |
+------------------------------+
1 row in set (0.01 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::*//b[1]');
+---------------------------------------------------+
| ExtractValue(@xml, '/descendant-or-self::*//b[1]') |
| x z                                               |
+---------------------------------------------------+
1 row in set (0.06 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::*//b[2]');
+---------------------------------------------------+
| ExtractValue(@xml, '/descendant-or-self::*//b[2]') |
|                                                   |
+---------------------------------------------------+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::b[1]');
+-------------------------------------------------+
| ExtractValue(@xml, '/descendant-or-self::b[1]') |
| z                                               |
+-------------------------------------------------+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::b[2]');
+-------------------------------------------------+
| ExtractValue(@xml, '/descendant-or-self::b[2]') |
| x                                               |
+-------------------------------------------------+
1 row in set (0.00 sec)
```

- The * operator acts as a “wildcard” that matches any element. For example, the expression `/*//b` matches the `b` element in either of the XML fragments `<a><b/></a>` or `<c><b/></c>`. However, the expression does not produce a match in the fragment `<b><a/></b>` because `b` must be a child of some other element. The wildcard may be used in any position: The expression `/*/b/*` will match any child of a `b` element that is itself not the root element.

- You can match any of several locators using the `|` (`UNION`) operator. For example, the expression `//b|//c` matches all `b` and `c` elements in the XML target.
It is also possible to match an element based on the value of one or more of its attributes. This done using the syntax `tag[@attribute="value"]`. For example, the expression `//b[@id="idB"]` matches the second `b` element in the fragment `<a><b id="idA"/>/<c/>/<b id="idB"/></a>`. To match against any element having attribute="value", use the XPath expression `//*[attribute="value"]`.

To filter multiple attribute values, simply use multiple attribute-comparison clauses in succession. For example, the expression `//b[@c="x"][@d="y"]` matches the element `<b c="x" d="y"/>` occurring anywhere in a given XML fragment.

To find elements for which the same attribute matches any of several values, you can use multiple locators joined by the `|` operator. For example, to match all `b` elements whose `c` attributes have either of the values 23 or 17, use the expression `//b[@c="23"]|//b[@c="17"]'). You can also use the logical or operator for this purpose: `//b[@c="23" or @c="17"]`.

**Note**
The difference between or and `|` is that or joins conditions, while `|` joins result sets.

**XPath Limitations.** The XPath syntax supported by these functions is currently subject to the following limitations:

- Nodeset-to-nodeset comparison (such as `'/a/b[@c=@d]'`) is not supported.
- Prior to MySQL 5.1.14, equality and inequality (`=` and `!=`) were the only supported comparison operators. Beginning with MySQL 5.1.14, all of the standard XPath comparison operators are supported. (Bug #22823)
- Relative locator expressions are resolved in the context of the root node. For example, consider the following query and result:

```sql
mysql> SELECT ExtractValue(-> '<a><b c="1">X</b><b c="2">Y</b></a>', -> 'a/b' -> ) AS result;
```

```
+----------+
| result   |
+----------+
| X Y      |
+----------+
1 row in set (0.03 sec)
```

In this case, the locator `a/b` resolves to `/a/b`.

Relative locators are also supported within predicates. In the following example, `d[../@c="1"]` is resolved as `/a/b[@c="1"]/d:`

```sql
mysql> SELECT ExtractValue(-> '<a> -> '<b c="1">X</b><b c="2">X</b></a>', -> '<b c="1">X</b><b c="2">X</b></a>' -> ) AS result;
```

```
+----------+
| result   |
+----------+
| X        |
+----------+
1 row in set (0.00 sec)
```
• Locators prefixed with expressions that evaluate as scalar values—including variable references, literals, numbers, and scalar function calls—are not supported. Beginning with MySQL 5.1.32, they are not permitted, and their use results in an error. (Bug #42495)

• The `::` operator is not supported in combination with node types such as the following:
  • `axis::comment()`
  • `axis::text()`
  • `axis::processing-instructions()`
  • `axis::node()`

However, name tests (such as `axis::name` and `axis::*`) are supported, as shown in these examples:

```sql
mysql> SELECT ExtractValue('<a><b>x</b><c>y</c></a>','/a/child::b');
+-------------------------------------------------------+
| ExtractValue('<a><b>x</b><c>y</c></a>','/a/child::b') |
+-------------------------------------------------------+
| x                                                     |
+-------------------------------------------------------+
1 row in set (0.02 sec)
```

```sql
mysql> SELECT ExtractValue('<a><b>x</b><c>y</c></a>','/a/child::*');
+-------------------------------------------------------+
| ExtractValue('<a><b>x</b><c>y</c></a>','/a/child::*') |
+-------------------------------------------------------+
| x y                                                   |
+-------------------------------------------------------+
1 row in set (0.01 sec)
```

• “Up-and-down” navigation is not supported in cases where the path would lead “above” the root element. That is, you cannot use expressions which match on descendants of ancestors of a given element, where one or more of the ancestors of the current element is also an ancestor of the root element (see Bug #16321).

• The following XPath functions are not supported, or have known issues as indicated:
  • Prior to MySQL 5.1.24, the `boolean()` function did not produce correct results for some string and nodeset values, including the `NULL` string (see Bug #26051).
  • `id()`
  • `lang()`
  • Prior to MySQL 5.1.8, the `last()` function was not supported (see Bug #16318).
  • `local-name()`
  • `name()`
  • `namespace-uri()`
  • `normalize-space()`
  • `starts-with()`
  • `string()`
  • `substring-after()`
  • `substring-before()`
• translate()

• The following axes are not supported:
  • following-sibling
  • following
  • preceding-sibling
  • preceding

Beginning with MySQL 5.1.10, XPath expressions passed as arguments to ExtractValue() and UpdateXML() may contain the colon character (":") in element selectors, which enables their use with markup employing XML namespaces notation. For example:

```
mysql> SET @xml = '<a>111<b:c>222<d>333</d><e:f>444</e:f></b:c></a>,'
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT ExtractValue(@xml, '//e:f');
  | ExtractValue(@xml, '//e:f')  |
  | 444                          |
+-----------------------------+
1 row in set (0.00 sec)

mysql> SELECT UpdateXML(@xml, '//b:c', '<g:h>555</g:h>');
  | UpdateXML(@xml, '//b:c', '<g:h>555</g:h>')  |
  | <a>111<g:h>555</g:h></a>                   |
+--------------------------------------------+
1 row in set (0.00 sec)
```

This is similar in some respects to what is permitted by Apache Xalan and some other parsers, and is much simpler than requiring namespace declarations or the use of the namespace-uri() and local-name() functions.

**Error handling.** For both ExtractValue() and UpdateXML(), the XPath locator used must be valid and the XML to be searched must consist of elements which are properly nested and closed. If the locator is invalid, an error is generated:

```
mysql> SELECT ExtractValue('<a>c</a><b/>', '/&a');
ERROR 1105 (HY000): XPATH syntax error: '&a'
```

If xml_frag does not consist of elements which are properly nested and closed, NULL is returned and a warning is generated, as shown in this example:

```
mysql> SELECT ExtractValue('<a>c</a><b>', '//a');
+-----------------------------+
  | ExtractValue('<a>c</a><b>', '//a')  |
  | NULL                          |
+-----------------------------+
1 row in set, 1 warning (0.00 sec)
```

```
SHOW WARNINGS
*************************** 1. row ***************************
Level: Warning
Code: 1525
Message: Incorrect XML value: 'parse error at line 1 pos 11: END-OF-INPUT unexpected ('>' wanted)'
```
Prior to MySQL 5.1.12, an empty string was returned in such cases. (Bug #18201)

Important

The replacement XML used as the third argument to \texttt{UpdateXML()} \textit{is not} checked to determine whether it consists solely of elements which are properly nested and closed.

\textbf{XPath Injection.} \textit{Code injection} occurs when malicious code is introduced into the system to gain unauthorized access to privileges and data. It is based on exploiting assumptions made by developers about the type and content of data input from users. XPath is no exception in this regard.

A common scenario in which this can happen is the case of application which handles authorization by matching the combination of a login name and password with those found in an XML file, using an XPath expression like this one:

\begin{verbatim}
//user[login/text()='neapolitan' and password/text()='1c3cr34m']/attribute::id
\end{verbatim}

This is the XPath equivalent of an SQL statement like this one:

\begin{verbatim}
SELECT id FROM users WHERE login='neapolitan' AND password='1c3cr34m';
\end{verbatim}

A PHP application employing XPath might handle the login process like this:

\begin{verbatim}
<?php
    $file     =   "users.xml";
    $login    =   $POST["login"];    
    $password =   $POST["password"];    
    $xpath = "//user[login/text()=$login and password/text()=$password]/attribute::id";
    if( file_exists($file) )
    |
    |   $xml = simplexml_load_file($file);
    |   if($result = $xml->xpath($xpath))
    |     echo "You are now logged in as user $result[0].";
    |   else
    |     echo "Invalid login name or password.";
    |}
    else
    |   exit("Failed to open $file.");
?>
\end{verbatim}

No checks are performed on the input. This means that a malevolent user can “short-circuit” the test by entering ' or 1=1 for both the login name and password, resulting in \texttt{$xpath$} being evaluated as shown here:

\begin{verbatim}
//user[login/text()='' or 1=1 and password/text()='' or 1=1]/attribute::id
\end{verbatim}
Since the expression inside the square brackets always evaluates as true, it is effectively the same as this one, which matches the id attribute of every user element in the XML document:

\[//\text{user/attribute::id}\]

One way in which this particular attack can be circumvented is simply by quoting the variable names to be interpolated in the definition of \$xpath, forcing the values passed from a Web form to be converted to strings:

\$xpath = \\
"//\text{user[login/text()='') or 1=1 and password/text()='') or 1=1]/attribute::id}";

This is the same strategy that is often recommended for preventing SQL injection attacks. In general, the practices you should follow for preventing XPath injection attacks are the same as for preventing SQL injection:

- Never accepted untested data from users in your application.
- Check all user-submitted data for type; reject or convert data that is of the wrong type.
- Test numeric data for out of range values; truncate, round, or reject values that are out of range. Test strings for illegal characters and either strip them out or reject input containing them.
- Do not output explicit error messages that might provide an unauthorized user with clues that could be used to compromise the system; log these to a file or database table instead.

Just as SQL injection attacks can be used to obtain information about database schemas, so can XPath injection be used to traverse XML files to uncover their structure, as discussed in Amit Klein’s paper Blind XPath Injection (PDF file, 46KB).

It is also important to check the output being sent back to the client. Consider what can happen when we use the MySQL \texttt{ExtractValue()} function:

```sql
mysql> SELECT ExtractValue(
  -> LOAD_FILE('users.xml'),
  -> '//\text{user[login/text()='') or 1=1 and password/text()='') or 1=1]/attribute::id'
  -> AS id);
+-------------------------------+
| id                            |
| 00327 13579 02403 42354 28570 |
+-------------------------------+
1 row in set (0.01 sec)
```

Because \texttt{ExtractValue()} returns multiple matches as a single space-delimited string, this injection attack provides every valid ID contained within users.xml to the user as a single row of output. As an extra safeguard, you should also test output before returning it to the user. Here is a simple example:

```sql
mysql> SELECT @id = ExtractValue(
  -> LOAD_FILE('users.xml'),
  -> '//\text{user[login/text()='') or 1=1 and password/text()='') or 1=1]/attribute::id'
  -> )
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT IF(
  -> INSTR(@id, ' ') = 0,
  -> @id,
  -> 'Unable to retrieve user ID')
AS singleID;
+-------------------------------+
| singleID                   |
| Unable to retrieve user ID |
+-------------------------------+
```

Because \texttt{ExtractValue()} returns multiple matches as a single space-delimited string, this injection attack provides every valid ID contained within users.xml to the user as a single row of output. As an extra safeguard, you should also test output before returning it to the user. Here is a simple example:
In general, the guidelines for returning data to users securely are the same as for accepting user input. These can be summed up as:

- Always test outgoing data for type and permissible values.
- Never permit unauthorized users to view error messages that might provide information about the application that could be used to exploit it.

## 12.12 Bit Functions and Operators

Table 12.16 Bit Functions and Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIT_COUNT()</td>
<td>Return the number of bits that are set</td>
</tr>
<tr>
<td>&amp;</td>
<td>Bitwise AND</td>
</tr>
<tr>
<td>~</td>
<td>Bitwise inversion</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>^</td>
<td>Bitwise XOR</td>
</tr>
<tr>
<td>&lt;&lt;</td>
<td>Left shift</td>
</tr>
<tr>
<td>&gt;&gt;</td>
<td>Right shift</td>
</tr>
</tbody>
</table>

Bit functions and operators comprise `BIT_COUNT()`, `BIT_AND()`, `BIT_OR()`, `BIT_XOR()`, `&`, `|`, `^`, `~`, `<<`, and `>>`. (`BIT_AND()`, `BIT_OR()`, and `BIT_XOR()` are aggregate functions described at Section 12.17.1, “Aggregate (GROUP BY) Function Descriptions”.) Bit functions and operators require BIGINT (64-bit integer) arguments and return BIGINT values, so they have a maximum range of 64 bits. Arguments of other types (such as the BINARY and VARBINARY binary string types) are converted to BIGINT and truncation might occur.

The following list describes available bit functions and operators:

- **|**

  | Bitwise OR:
  
  mysql> `SELECT 29 | 15;`
  
  -> 31

  The result is an unsigned 64-bit integer.

- **&**

  | Bitwise AND:
  
  mysql> `SELECT 29 & 15;`
  
  -> 13

  The result is an unsigned 64-bit integer.

- **^**

  | Bitwise XOR:
  
  mysql> `SELECT 1 ^ 1;`
  
  -> 0
  
  mysql> `SELECT 1 ^ 0;`
The result is an unsigned 64-bit integer.

• $\ll$

Shifts a longlong (BIGINT) number to the left.

```sql
mysql> SELECT 1 << 2;
-> 4
```

The result is an unsigned 64-bit integer. The value is truncated to 64 bits. In particular, if the shift count is greater or equal to the width of an unsigned 64-bit number, the result is zero.

• $\gg$

Shifts a longlong (BIGINT) number to the right.

```sql
mysql> SELECT 4 >> 2;
-> 1
```

The result is an unsigned 64-bit integer. The value is truncated to 64 bits. In particular, if the shift count is greater or equal to the width of an unsigned 64-bit number, the result is zero.

• $\sim$

Invert all bits.

```sql
mysql> SELECT 5 & ~1;
-> 4
```

The result is an unsigned 64-bit integer.

• `BIT_COUNT(N)`

Returns the number of bits that are set in the argument $N$.

```sql
mysql> SELECT BIT_COUNT(29), BIT_COUNT(b'101010');
-> 4, 3
```

12.13 Encryption and Compression Functions

### Table 12.17 Encryption Functions

<table>

<td>Calculate an SHA-1 160-bit checksum</td>
</tr>
<tr>
<td>UNCOMPRESS()</td>
<td>Uncompress a string compressed</td>
</tr>
<tr>
<td>UNCOMPRESSED_LENGTH()</td>
<td>Return the length of a string before compression</td>
</tr>
</tbody>
</table>

Many encryption and compression functions return strings for which the result might contain arbitrary byte values. If you want to store these results, use a column with a `VARBINARY` or `BLOB` binary string data type. This will avoid potential problems with trailing space removal or character set conversion that would change data values, such as may occur if you use a nonbinary string data type (`CHAR`, `VARCHAR`, `TEXT`).

For functions such as `MD5()` or `SHA1()` that return a string of hex digits, the return value cannot be converted to uppercase or compared in case-insensitive fashion as is. You must convert the value to a nonbinary string. See the discussion of binary string conversion in Section 12.10, “Cast Functions and Operators”.

If an application stores values from a function such as `MD5()` or `SHA1()` that returns a string of hex digits, more efficient storage and comparisons can be obtained by converting the hex representation to binary using `UNHEX()` and storing the result in a `BINARY(N)` column. Each pair of hex digits requires one byte in binary form, so the value of `N` depends on the length of the hex string. `N` is 16 for an `MD5()` value and 20 for a `SHA1()` value.

The size penalty for storing the hex string in a `CHAR` column is at least two times, up to six times if the value is stored in a column that uses the `utf8` character set (where each character uses 3 bytes). Storing the string also results in slower comparisons because of the larger values and the need to take character set collation rules into account.

Suppose that an application stores `MD5()` string values in a `CHAR(32)` column:

```sql
CREATE TABLE md5_tbl (md5_val CHAR(32), ...);
INSERT INTO md5_tbl (md5_val, ...) VALUES(MD5('abcdef'), ...);
```

To convert hex strings to more compact form, modify the application to use `UNHEX()` and `BINARY(16)` instead as follows:

```sql
CREATE TABLE md5_tbl (md5_val BINARY(16), ...);
INSERT INTO md5_tbl (md5_val, ...) VALUES(UNHEX(MD5('abcdef')), ...);
```

Applications should be prepared to handle the very rare case that a hashing function produces the same value for two different input values. One way to make collisions detectable is to make the hash column a primary key.

### Note
Exploits for the MD5 and SHA-1 algorithms have become known. You may wish to consider using one of the other encryption functions described in this section instead.

### Caution
Passwords or other sensitive values supplied as arguments to encryption functions are sent in cleartext to the MySQL server unless an SSL connection is used. Also, such values will appear in any MySQL logs to which they are written. To avoid these types of exposure, applications can encrypt sensitive...
values on the client side before sending them to the server. The same considerations apply to encryption keys. To avoid exposing these, applications can use stored procedures to encrypt and decrypt values on the server side.

- **AES_DECRYPT**(crypt_str, key_str)**

This function decrypts data using the official AES (Advanced Encryption Standard) algorithm. For more information, see the description of **AES_ENCRYPT()**.

- **AES_ENCRYPT**(str, key_str)**

**AES_ENCRYPT()** and **AES_DECRYPT()** implement encryption and decryption of data using the official AES (Advanced Encryption Standard) algorithm, previously known as “Rijndael.” The AES standard permits various key lengths. These functions implement AES with a 128-bit key length, but you can extend them to 256 bits by modifying the source. The key length is a trade off between performance and security.

**AES_ENCRYPT()** encrypts the string **str** using the key string **key_str** and returns a binary string containing the encrypted output. **AES_DECRYPT()** decrypts the encrypted string **crypt_str** using the key string **key_str** and returns the original cleartext string. If either function argument is **NULL**, the function returns **NULL**.

The **str** and **crypt_str** arguments can be any length, and padding is automatically added to **str** so it is a multiple of a block as required by block-based algorithms such as AES. This padding is automatically removed by the **AES_DECRYPT()** function. The length of **crypt_str** can be calculated using this formula:

\[ 16 \times (\text{trunc}(\text{string}\_\text{length} / 16) + 1) \]

For a key length of 128 bits, the most secure way to pass a key to the **key_str** argument is to create a truly random 128-bit value and pass it as a binary value. For example:

```
INSERT INTO t
VALUES (1,AES_ENCRYPT('text',UNHEX('F3229A0B371ED2D9441B830D21A390C3')));
```

A passphrase can be used to generate an AES key by hashing the passphrase. For example:

```
INSERT INTO t
VALUES (1,AES_ENCRYPT('text', SHA1('My secret passphrase')));
```

Do not pass a password or passphrase directly to **crypt_str**, hash it first. Previous versions of this documentation suggested the former approach, but it is no longer recommended as the examples shown here are more secure.

If **AES_DECRYPT()** detects invalid data or incorrect padding, it returns **NULL**. However, it is possible for **AES_DECRYPT()** to return a non-**NULL** value (possibly garbage) if the input data or the key is invalid.

- **COMPRESS**(string_to_compress)**

Compresses a string and returns the result as a binary string. This function requires MySQL to have been compiled with a compression library such as **zlib**. Otherwise, the return value is always **NULL**. The compressed string can be uncompressed with **UNCOMPRESS()**.

```
mysql> SELECT LENGTH(COMPRESS(REPEAT('a',1000)));
-> 21
mysql> SELECT LENGTH(COMPRESS(''));
-> 0
mysql> SELECT LENGTH(COMPRESS('a'));
-> 13
mysql> SELECT LENGTH(COMPRESS(REPEAT('a',16)));
```
The compressed string contents are stored the following way:

- Empty strings are stored as empty strings.
- Nonempty strings are stored as a 4-byte length of the uncompressed string (low byte first), followed by the compressed string. If the string ends with space, an extra "\." character is added to avoid problems with endspace trimming should the result be stored in a CHAR or VARCHAR column. (However, use of nonbinary string data types such as CHAR or VARCHAR to store compressed strings is not recommended anyway because character set conversion may occur. Use a VARBINARY or BLOB binary string column instead.)

- \texttt{DECODE(crypt\_str, pass\_str)}

Decrypts the encrypted string \texttt{crypt\_str} using \texttt{pass\_str} as the password. \texttt{crypt\_str} should be a string returned from \texttt{ENCODE()}.

- \texttt{DES\_DECRYPT(crypt\_str[, key\_str])}

Decrypts a string encrypted with \texttt{DES\_ENCRYPT()}. If an error occurs, this function returns NULL.

This function works only if MySQL has been configured with SSL support. See Section 6.4, "Using Secure Connections".

If no \texttt{key\_str} argument is given, \texttt{DES\_DECRYPT()} examines the first byte of the encrypted string to determine the DES key number that was used to encrypt the original string, and then reads the key from the DES key file to decrypt the message. For this to work, the user must have the \texttt{SUPER} privilege. The key file can be specified with the \texttt{--des\_key\_file} server option.

If you pass this function a \texttt{key\_str} argument, that string is used as the key for decrypting the message.

If the \texttt{crypt\_str} argument does not appear to be an encrypted string, MySQL returns the given \texttt{crypt\_str}.

- \texttt{DES\_ENCRYPT(str[,\{key\_num|key\_str\}])}

Encrypts the string with the given key using the Triple-DES algorithm.

This function works only if MySQL has been configured with SSL support. See Section 6.4, "Using Secure Connections".

The encryption key to use is chosen based on the second argument to \texttt{DES\_ENCRYPT()}, if one was given. With no argument, the first key from the DES key file is used. With a \texttt{key\_num} argument, the given key number (0 to 9) from the DES key file is used. With a \texttt{key\_str} argument, the given key string is used to encrypt \texttt{str}.

The key file can be specified with the \texttt{--des\_key\_file} server option.

The return string is a binary string where the first character is \texttt{CHAR(128 | key\_num)}. If an error occurs, \texttt{DES\_ENCRYPT()} returns NULL.

The 128 is added to make it easier to recognize an encrypted key. If you use a string key, \texttt{key\_num} is 127.

The string length for the result is given by this formula:

\[
\text{new\_len} = \text{orig\_len} + (8 - (\text{orig\_len} \% 8)) + 1
\]

Each line in the DES key file has the following format:
key_num des_key_str

Each key_num value must be a number in the range from 0 to 9. Lines in the file may be in any order. des_key_str is the string that is used to encrypt the message. There should be at least one space between the number and the key. The first key is the default key that is used if you do not specify any key argument to DES_ENCRYPT().

You can tell MySQL to read new key values from the key file with the FLUSH DES_KEY_FILE statement. This requires the RELOAD privilege.

One benefit of having a set of default keys is that it gives applications a way to check for the existence of encrypted column values, without giving the end user the right to decrypt those values.

mysql> SELECT customer_address FROM customer_table
    > WHERE crypted_credit_card = DES_ENCRYPT('credit_card_number');

• ENCODE(str, pass_str)

Encrypt str using pass_str as the password. The result is a binary string of the same length as str. To decrypt the result, use DECODE().

The ENCODE() function should no longer be used. If you still need to use ENCODE(), a salt value must be used with it to reduce risk. For example:

ENCODE('cleartext', CONCAT('my_random_salt','my_secret_password'))

A new random salt value must be used whenever a password is updated.

• ENCRYPT(str[, salt])

Encrypts str using the Unix crypt() system call and returns a binary string. The salt argument must be a string with at least two characters or the result will be NULL. If no salt argument is given, a random value is used.

mysql> SELECT ENCRYPT('hello');
-> 'VxuFAJXVARROc'

ENCRYPT() ignores all but the first eight characters of str, at least on some systems. This behavior is determined by the implementation of the underlying crypt() system call.

The use of ENCRYPT() with the ucs2 multibyte character set is not recommended because the system call expects a string terminated by a zero byte.

If crypt() is not available on your system (as is the case with Windows), ENCRYPT() always returns NULL.

• MD5(str)

Calculates an MD5 128-bit checksum for the string. The value is returned as a binary string of 32 hex digits, or NULL if the argument was NULL. The return value can, for example, be used as a hash key. See the notes at the beginning of this section about storing hash values efficiently.

mysql> SELECT MD5('testing');
-> 'ae2bf1ca515949e5d54fb22b8ed95575'

This is the “RSA Data Security, Inc. MD5 Message-Digest Algorithm.”

See the note regarding the MD5 algorithm at the beginning this section.
Encryption and Compression Functions

- **OLD_PASSWORD**(str)

  `OLD_PASSWORD()` was added when the implementation of `PASSWORD()` was changed in MySQL 4.1 to improve security. `OLD_PASSWORD()` returns the value of the pre-4.1 implementation of `PASSWORD()` as a binary string, and is intended to permit you to reset passwords for any pre-4.1 clients that need to connect to your version MySQL 5.1 server without locking them out. See Section 6.1.2.4, “Password Hashing in MySQL”.

- **PASSWORD**(str)

  Returns a hashed password string calculated from the cleartext password `str`. The return value is a binary string, or `NULL` if the argument is `NULL`. This function is the SQL interface to the algorithm used by the server to encrypt MySQL passwords for storage in the `mysql.user` grant table.

  The `old_passwords` system variable controls the password hashing method used by the `PASSWORD()` function. It also influences password hashing performed by `CREATE USER` and `GRANT` statements that specify a password using an `IDENTIFIED BY` clause.

  The value determines whether or not to use “old” native MySQL password hashing. A value of 0 (or `OFF`) causes passwords to be encrypted using the format available from MySQL 4.1 on. A value of 1 (or `ON`) causes password encryption to use the older pre-4.1 format.

  If `old_passwords=1`, `PASSWORD(str)` returns the same value as `OLD_PASSWORD(str)`. The latter function is not affected by the value of `old_passwords`.

  ```
  mysql> SET old_passwords = 0;
  mysql> SELECT PASSWORD('mypass'), OLD_PASSWORD('mypass');
  +-------------------------------------------+------------------------+
  | PASSWORD('mypass')                        | OLD_PASSWORD('mypass') |
  +-------------------------------------------+------------------------+
  | *6C898936EAF75B670AD8EA7A7FC1176A95CEF4 | 6f8c114b58f2ce9e       |
  +-------------------------------------------+------------------------+
  mysql> SET old_passwords = 1;
  mysql> SELECT PASSWORD('mypass'), OLD_PASSWORD('mypass');
  +--------------------+------------------------+
  | PASSWORD('mypass') | OLD_PASSWORD('mypass') |
  +--------------------+------------------------+
  | 6f8c114b58f2ce9e   | 6f8c114b58f2ce9e       |
  +--------------------+------------------------+
  ```

  Encryption performed by `PASSWORD()` is one-way (not reversible). It is not the same type of encryption as used for Unix passwords; for that, use `ENCRYPT()`.

  **Note**

  `PASSWORD()` is used by the authentication system in MySQL Server; you should not use it in your own applications. For that purpose, consider `MD5()` or `SHA1()` instead. Also see RFC 2195, section 2 (Challenge-Response Authentication Mechanism (CRAM)), for more information about handling passwords and authentication securely in your applications.

  **Caution**

  Statements that invoke `PASSWORD()` may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about password logging in the server logs, see Section 6.1.2.3, “Passwords and Logging”. For similar information about client-side logging, see Section 4.5.1.3, “mysql Logging”.

- **SHA1**(str)**, SHA**(str)**
Calculates an SHA-1 160-bit checksum for the string, as described in RFC 3174 (Secure Hash Algorithm). The value is returned as a binary string of 40 hex digits, or NULL if the argument was NULL. One of the possible uses for this function is as a hash key. See the notes at the beginning of this section about storing hash values efficiently. You can also use SHA1() as a cryptographic function for storing passwords. SHA() is synonymous with SHA1().

```
mysql> SELECT SHA1('abc');
-> 'a9993e364706816aba3e25717850c26c9c9d0d89d'
```

SHA1() can be considered a cryptographically more secure equivalent of MD5(). However, see the note regarding the MD5 and SHA-1 algorithms at the beginning this section.

- **UNCOMPRESS(string_to_uncompress)**

  Uncompresses a string compressed by the COMPRESS() function. If the argument is not a compressed value, the result is NULL. This function requires MySQL to have been compiled with a compression library such as zlib. Otherwise, the return value is always NULL.

```
mysql> SELECT UNCOMPRESS(COMPRESS('any string'));
-> 'any string'

mysql> SELECT UNCOMPRESS('any string');
-> NULL
```

- **UNCOMPRESSED_LENGTH(compressed_string)**

  Returns the length that the compressed string had before being compressed.

```
mysql> SELECT UNCOMPRESSED_LENGTH(COMPRESS(REPEAT('a',30)));
-> 30
```

### 12.14 Information Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BENCHMARK()</td>
<td>Repeatedly execute an expression</td>
</tr>
<tr>
<td>CHARSET()</td>

<td>Synonym for USER()</td>
</tr>
<tr>
<td>SYSTEM_USER()</td>
<td>Synonym for USER()</td>
</tr>
<tr>
<td>USER()</td>
<td>The user name and host name provided by the client</td>
</tr>
<tr>
<td>VERSION()</td>
<td>Return a string that indicates the MySQL server version</td>
</tr>
</tbody>
</table>
The **BENCHMARK()** function executes the expression `expr` repeatedly `count` times. It may be used to time how quickly MySQL processes the expression. The result value is always `0`. The intended use is from within the `mysql` client, which reports query execution times:

```sql
mysql> SELECT BENCHMARK(1000000, ENCODE('hello','goodbye'));
+---------------------------------------------------+
| BENCHMARK(1000000, ENCODE('hello','goodbye'))    |
| 0                                                 |
+---------------------------------------------------+
1 row in set (4.74 sec)
```

The time reported is elapsed time on the client end, not CPU time on the server end. It is advisable to execute **BENCHMARK()** several times, and to interpret the result with regard to how heavily loaded the server machine is.

**BENCHMARK()** is intended for measuring the runtime performance of scalar expressions, which has some significant implications for the way that you use it and interpret the results:

- Only scalar expressions can be used. Although the expression can be a subquery, it must return a single column and at most a single row. For example, `BENCHMARK(10, (SELECT * FROM t))` will fail if the table `t` has more than one column or more than one row.

- Executing a `SELECT expr` statement `N` times differs from executing `SELECT BENCHMARK(N, expr)` in terms of the amount of overhead involved. The two have very different execution profiles and you should not expect them to take the same amount of time. The former involves the parser, optimizer, table locking, and runtime evaluation `N` times each. The latter involves only runtime evaluation `N` times, and all the other components just once. Memory structures already allocated are reused, and runtime optimizations such as local caching of results already evaluated for aggregate functions can alter the results. Use of **BENCHMARK()** thus measures performance of the runtime component by giving more weight to that component and removing the “noise” introduced by the network, parser, optimizer, and so forth.

- **CHARSET(str)**

  Returns the character set of the string argument.

  ```sql
  mysql> SELECT CHARSET('abc');
  +-------------------+
  | 'latin1'          |
  +-------------------+
  mysql> SELECT CHARSET(CONVERT('abc' USING utf8));
  +-------------------+
  | 'utf8'            |
  +-------------------+
  mysql> SELECT CHARSET(USER());
  +-------------------+
  | 'utf8'            |
  +-------------------+
  ``

  The return values have the meanings shown in the following table. Lower values have higher precedence.

- **COERCIBILITY(str)**

  Returns the collation coercibility value of the string argument.

  ```sql
  mysql> SELECT COERCIBILITY('abc' COLLATE latin1_swedish_ci);
  +-------------------+
  | 0                 |
  +-------------------+
  mysql> SELECT COERCIBILITY(USER());
  +-------------------+
  | 3                 |
  +-------------------+
  mysql> SELECT COERCIBILITY('abc');
  +-------------------+
  | 4                 |
  +-------------------+
  ```
### Information Functions

<table>
<thead>
<tr>
<th>Coercibility</th>
<th>Meaning</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Explicit collation</td>
<td>Value with <code>COLLATE</code> clause</td>
</tr>
<tr>
<td>1</td>
<td>No collation</td>
<td>Concatenation of strings with different collations</td>
</tr>
<tr>
<td>2</td>
<td>Implicit collation</td>
<td>Column value, stored routine parameter or local variable</td>
</tr>
<tr>
<td>3</td>
<td>System constant</td>
<td><code>USER()</code> return value</td>
</tr>
<tr>
<td>4</td>
<td>Coercible</td>
<td>Literal string</td>
</tr>
<tr>
<td>5</td>
<td>Ignorable</td>
<td><code>NULL</code> or an expression derived from <code>NULL</code></td>
</tr>
</tbody>
</table>

- **`COLLATION(str)`**

  Returns the collation of the string argument.

  ```sql
  mysql> SELECT COLLATION('abc');
  -> 'latin1_swedish_ci'
  mysql> SELECT COLLATION(_utf8'abc');
  -> 'utf8_general_ci'
  ```

- **`CONNECTION_ID()`**

  Returns the connection ID (thread ID) for the connection. Every connection has an ID that is unique among the set of currently connected clients.

  The value returned by `CONNECTION_ID()` is the same type of value as displayed in the `ID` column of the `INFORMATION_SCHEMA.PROCESSLIST` table and the `Id` column of `SHOW PROCESSLIST` output.

  ```sql
  mysql> SELECT CONNECTION_ID();
  -> 23786
  ```

- **`CURRENT_USER, CURRENT_USER()`**

  Returns the user name and host name combination for the MySQL account that the server used to authenticate the current client. This account determines your access privileges. The return value is a string in the `utf8` character set.

  The value of `CURRENT_USER()` can differ from the value of `USER()`.

  ```sql
  mysql> SELECT CURRENT_USER();
  -> '@localhost'
  mysql> SELECT USER();
  -> 'davida@localhost'
  ```

  The example illustrates that although the client specified a user name of `davida` (as indicated by the value of the `USER()` function), the server authenticated the client using an anonymous user account (as seen by the empty user name part of the `CURRENT_USER()` value). One way this might occur is that there is no account listed in the grant tables for `davida`.

  Within a stored program or view, `CURRENT_USER()` returns the account for the user who defined the object (as given by its `DEFINER` value) unless defined with the `SQL SECURITY INVOKER` characteristic. In the latter case, `CURRENT_USER()` returns the object’s invoker.
Triggers and events have no option to define the SQL SECURITY characteristic, so for these objects, CURRENT_USER() returns the account for the user who defined the object. To return the invoker, use USER() or SESSION_USER().

The following statements support use of the CURRENT_USER() function to take the place of the name of (and, possibly, a host for) an affected user or a definer; in such cases, CURRENT_USER() is expanded where and as needed:

- DROP USER
- RENAME USER
- GRANT
- REVOKE
- CREATE FUNCTION
- CREATE PROCEDURE
- CREATE TRIGGER
- CREATE EVENT
- CREATE VIEW
- ALTER EVENT
- ALTER VIEW
- SET PASSWORD

For information about the implications that this expansion of CURRENT_USER() has for replication in different releases of MySQL 5.1, see Section 16.4.1.7, “Replication of CURRENT_USER()”.

- DATABASE()

Returns the default (current) database name as a string in the utf8 character set. If there is no default database, DATABASE() returns NULL. Within a stored routine, the default database is the database that the routine is associated with, which is not necessarily the same as the database that is the default in the calling context.

```sql
mysql> SELECT DATABASE();
-> 'test'
```

If there is no default database, DATABASE() returns NULL.

- FOUND_ROWS()

A SELECT statement may include a LIMIT clause to restrict the number of rows the server returns to the client. In some cases, it is desirable to know how many rows the statement would have returned without the LIMIT, but without running the statement again. To obtain this row count, include a SQL_CALC_FOUND_ROWS option in the SELECT statement, and then invoke FOUND_ROWS() afterward:

```sql
mysql> SELECT SQL_CALC_FOUND_ROWS * FROM tbl_name
    -> WHERE id > 100 LIMIT 10;
mysql> SELECT FOUND_ROWS();
```
The second `SELECT` returns a number indicating how many rows the first `SELECT` would have returned had it been written without the `LIMIT` clause.

In the absence of the `SQL_CALC_FOUND_ROWS` option in the most recent successful `SELECT` statement, `FOUND_ROWS()` returns the number of rows in the result set returned by that statement. If the statement includes a `LIMIT` clause, `FOUND_ROWS()` returns the number of rows up to the limit. For example, `FOUND_ROWS()` returns 10 or 60, respectively, if the statement includes `LIMIT 10` or `LIMIT 50`, 10.

The row count available through `FOUND_ROWS()` is transient and not intended to be available past the statement following the `SELECT SQL_CALC_FOUND_ROWS` statement. If you need to refer to the value later, save it:

```sql
mysql> SELECT SQL_CALC_FOUND_ROWS * FROM ... ;
mysql> SET @rows = FOUND_ROWS();
```

If you are using `SELECT SQL_CALC_FOUND_ROWS`, MySQL must calculate how many rows are in the full result set. However, this is faster than running the query again without `LIMIT`, because the result set need not be sent to the client.

`SQL_CALC_FOUND_ROWS` and `FOUND_ROWS()` can be useful in situations when you want to restrict the number of rows that a query returns, but also determine the number of rows in the full result set without running the query again. An example is a Web script that presents a paged display containing links to the pages that show other sections of a search result. Using `FOUND_ROWS()` enables you to determine how many other pages are needed for the rest of the result.

The use of `SQL_CALC_FOUND_ROWS` and `FOUND_ROWS()` is more complex for `UNION` statements than for simple `SELECT` statements, because `LIMIT` may occur at multiple places in a `UNION`. It may be applied to individual `SELECT` statements in the `UNION`, or global to the `UNION` result as a whole.

The intent of `SQL_CALC_FOUND_ROWS` for `UNION` is that it should return the row count that would be returned without a global `LIMIT`. The conditions for use of `SQL_CALC_FOUND_ROWS` with `UNION` are:

- The `SQL_CALC_FOUND_ROWS` keyword must appear in the first `SELECT` of the `UNION`.
- The value of `FOUND_ROWS()` is exact only if `UNION ALL` is used. If `UNION` without `ALL` is used, duplicate removal occurs and the value of `FOUND_ROWS()` is only approximate.
- If no `LIMIT` is present in the `UNION`, `SQL_CALC_FOUND_ROWS` is ignored and returns the number of rows in the temporary table that is created to process the `UNION`.

Beyond the cases described here, the behavior of `FOUND_ROWS()` is undefined (for example, its value following a `SELECT` statement that fails with an error).

**Important**

`FOUND_ROWS()` is not replicated reliably using statement-based replication. Starting with MySQL 5.1.23, this function is automatically replicated using row-based replication.

- `LAST_INSERT_ID()`, `LAST_INSERT_ID(expr)`

For MySQL 5.1.12 and later, with no argument, `LAST_INSERT_ID()` returns a 64-bit value representing the first automatically generated value successfully inserted for an `AUTO_INCREMENT` column as a result of the most recently executed `INSERT` statement. The value has a type of `BIGINT UNSIGNED` as of MySQL 5.1.67, `BIGINT` (signed) before that. The value of `LAST_INSERT_ID()` remains unchanged if no rows are successfully inserted.
With an argument, `LAST_INSERT_ID()` returns an unsigned integer as of MySQL 5.1.67, a signed integer before that.

For example, after inserting a row that generates an `AUTO_INCREMENT` value, you can get the value like this:

```
mysql> SELECT LAST_INSERT_ID();
-> 195
```

In MySQL 5.1.11 and earlier, `LAST_INSERT_ID()` (with no argument) returns the first automatically generated value if any rows were successfully inserted or updated. This means that the returned value could be a value that was not successfully inserted into the table. If no rows were successfully inserted, `LAST_INSERT_ID()` returns 0.

The value of `LAST_INSERT_ID()` will be consistent across all MySQL versions if all rows in the `INSERT` or `UPDATE` statement were successful.

If a table contains an `AUTO_INCREMENT` column and `INSERT ... ON DUPLICATE KEY UPDATE` updates (rather than inserts) a row, the value of `LAST_INSERT_ID()` is not meaningful prior to MySQL 5.1.12. For a workaround, see Section 13.2.5.3, “INSERT ... ON DUPLICATE KEY UPDATE Syntax”.

The currently executing statement does not affect the value of `LAST_INSERT_ID()`. Suppose that you generate an `AUTO_INCREMENT` value with one statement, and then refer to `LAST_INSERT_ID()` in a multiple-row `INSERT` statement that inserts rows into a table with its own `AUTO_INCREMENT` column. The value of `LAST_INSERT_ID()` will remain stable in the second statement; its value for the second and later rows is not affected by the earlier row insertions. (However, if you mix references to `LAST_INSERT_ID()` and `LAST_INSERT_ID(expr)`, the effect is undefined.)

If the previous statement returned an error, the value of `LAST_INSERT_ID()` is undefined. For transactional tables, if the statement is rolled back due to an error, the value of `LAST_INSERT_ID()` is left undefined. For manual `ROLLBACK`, the value of `LAST_INSERT_ID()` is not restored to that before the transaction; it remains as it was at the point of the `ROLLBACK`.

Prior to MySQL 5.1.73, this function was not replicated correctly if replication filtering rules were in use. (Bug #17234370, Bug #69861)

Within the body of a stored routine (procedure or function) or a trigger, the value of `LAST_INSERT_ID()` changes the same way as for statements executed outside the body of these kinds of objects. The effect of a stored routine or trigger upon the value of `LAST_INSERT_ID()` that is seen by following statements depends on the kind of routine:

- If a stored procedure executes statements that change the value of `LAST_INSERT_ID()`, the changed value is seen by statements that follow the procedure call.
- For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so following statements will not see a changed value.

The ID that was generated is maintained in the server on a per-connection basis. This means that the value returned by the function to a given client is the first `AUTO_INCREMENT` value generated for most recent statement affecting an `AUTO_INCREMENT` column by that client. This value cannot be affected by other clients, even if they generate `AUTO_INCREMENT` values of their own. This behavior ensures that each client can retrieve its own ID without concern for the activity of other clients, and without the need for locks or transactions.

The value of `LAST_INSERT_ID()` is not changed if you set the `AUTO_INCREMENT` column of a row to a non-“magic” value (that is, a value that is not `NULL` and not `0`).
Important

If you insert multiple rows using a single `INSERT` statement, `LAST_INSERT_ID()` returns the value generated for the *first* inserted row only. The reason for this is to make it possible to reproduce easily the same `INSERT` statement against some other server.

For example:

```sql
mysql> USE test;
Database changed
mysql> CREATE TABLE t (  
    -> id INT AUTO_INCREMENT NOT NULL PRIMARY KEY,
    -> name VARCHAR(10) NOT NULL
    -> );
Query OK, 0 rows affected (0.09 sec)

mysql> INSERT INTO t VALUES (NULL, 'Bob');
Query OK, 1 row affected (0.01 sec)

mysql> SELECT * FROM t;
+----+------+
| id | name |
+----+------+
|  1 | Bob  |
+----+------+
1 row in set (0.01 sec)

mysql> SELECT LAST_INSERT_ID();
+------------------+
| LAST_INSERT_ID() |
+------------------+
|                1 |
+------------------+
1 row in set (0.00 sec)

mysql> INSERT INTO t VALUES (NULL, 'Mary'), (NULL, 'Jane'), (NULL, 'Lisa');
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM t;
+----+------+
<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Bob</td>
</tr>
<tr>
<td>2</td>
<td>Mary</td>
</tr>
<tr>
<td>3</td>
<td>Jane</td>
</tr>
<tr>
<td>4</td>
<td>Lisa</td>
</tr>
</tbody>
</table>
+----+------+
4 rows in set (0.01 sec)

mysql> SELECT LAST_INSERT_ID();
+------------------+
| LAST_INSERT_ID() |
+------------------+
|                2 |
+------------------+
1 row in set (0.00 sec)
```

Although the second `INSERT` statement inserted three new rows into `t`, the ID generated for the first of these rows was 2, and it is this value that is returned by `LAST_INSERT_ID()` for the following `SELECT` statement.

If you use `INSERT IGNORE` and the row is ignored, the `LAST_INSERT_ID()` remains unchanged from the current value (or 0 is returned if the connection has not yet performed a successful `INSERT`) and, for non-transactional tables, the `AUTO_INCREMENT` counter is not incremented. For InnoDB
tables, the **AUTO_INCREMENT** counter is incremented if `innodb_autoinc_lock_mode` is set to 1 or 2, as demonstrated in the following example:

```sql
mysql> USE test;
Database changed

mysql> SELECT @@innodb_autoinc_lock_mode;
+---------------------------------+
| @@innodb_autoinc_lock_mode      |
+---------------------------------+
|                          1        |
+---------------------------------+
1 row in set (0.00 sec)

mysql> CREATE TABLE `t` (  
`id` INT(11) NOT NULL AUTO_INCREMENT,  
`val` INT(11) DEFAULT NULL,
PRIMARY KEY (`id`),  
UNIQUE KEY `i1` (`val`)  
) ENGINE=InnoDB DEFAULT CHARSET=latin1;
Query OK, 0 rows affected (0.02 sec)

-- Insert two rows
mysql> INSERT INTO t (val) VALUES (1),(2);
Query OK, 2 rows affected (0.00 sec)
Records: 2  Duplicates: 0  Warnings: 0

-- With auto_increment_offset=1, the inserted rows  
-- result in an AUTO_INCREMENT value of 3
mysql> SHOW CREATE TABLE t\G
*************************** 1. row ***************************
Table: t
Create Table: CREATE TABLE `t` (  
`id` int(11) NOT NULL AUTO_INCREMENT,  
`val` int(11) DEFAULT NULL,
PRIMARY KEY (`id`),  
UNIQUE KEY `i1` (`val`)  
) ENGINE=MyISAM AUTO_INCREMENT=3 DEFAULT CHARSET=latin1
1 row in set (0.00 sec)

-- LAST_INSERT_ID() returns the first automatically generated  
-- value that is successfully inserted for the AUTO_INCREMENT column
mysql> SELECT LAST_INSERT_ID();
+------------------+
| LAST_INSERT_ID() |
+------------------+
|                1 |
+------------------+
1 row in set (0.00 sec)

-- The attempted insertion of duplicate rows fail but errors are ignored
mysql> INSERT IGNORE INTO t (val) VALUES (1),(2);
Query OK, 0 rows affected (0.00 sec)
Records: 2  Duplicates: 2  Warnings: 0

-- With innodb_autoinc_lock_mode=1, the AUTO_INCREMENT counter  
-- is incremented for the ignored rows
mysql> SHOW CREATE TABLE t\G
*************************** 1. row ***************************
Table: t
Create Table: CREATE TABLE `t` (  
`id` int(11) NOT NULL AUTO_INCREMENT,  
`val` int(11) DEFAULT NULL,
PRIMARY KEY (`id`),  
UNIQUE KEY `i1` (`val`)  
) ENGINE=MyISAM AUTO_INCREMENT=5 DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```
-- The LAST_INSERT_ID is unchanged because the previous insert was unsuccessful

```sql
mysql> SELECT LAST_INSERT_ID();
+------------------+
| LAST_INSERT_ID() |
+------------------+
|                1 |
+------------------+
1 row in set (0.00 sec)
```

See Section 14.6.6.5, “AUTO_INCREMENT Handling in InnoDB” for more information.

If `expr` is given as an argument to `LAST_INSERT_ID()`, the value of the argument is returned by the function and is remembered as the next value to be returned by `LAST_INSERT_ID()`. This can be used to simulate sequences:

1. Create a table to hold the sequence counter and initialize it:

   ```sql
   mysql> CREATE TABLE sequence (id INT NOT NULL);
   mysql> INSERT INTO sequence VALUES (0);
   ```

2. Use the table to generate sequence numbers like this:

   ```sql
   mysql> UPDATE sequence SET id=LAST_INSERT_ID(id+1);
   mysql> SELECT LAST_INSERT_ID();
   ```

   The `UPDATE` statement increments the sequence counter and causes the next call to `LAST_INSERT_ID()` to return the updated value. The `SELECT` statement retrieves that value. The `mysql_insert_id()` C API function can also be used to get the value. See Section 21.8.7.37, “mysql_insert_id()”.

You can generate sequences without calling `LAST_INSERT_ID()`, but the utility of using the function this way is that the ID value is maintained in the server as the last automatically generated value. It is multi-user safe because multiple clients can issue the `UPDATE` statement and get their own sequence value with the `SELECT` statement (or `mysql_insert_id()`), without affecting or being affected by other clients that generate their own sequence values.

Note that `mysql_insert_id()` is only updated after `INSERT` and `UPDATE` statements, so you cannot use the C API function to retrieve the value for `LAST_INSERT_ID(expr)` after executing other SQL statements like `SELECT` or `SET`.

- **ROW_COUNT()**

  `ROW_COUNT()` returns the number of rows changed, deleted, or inserted by the last statement if it was an `UPDATE`, `DELETE`, or `INSERT`. For other statements, the value may not be meaningful.

  For `UPDATE` statements, the affected-rows value by default is the number of rows actually changed. If you specify the `CLIENT_FOUND_ROWS` flag to `mysql_real_connect()` when connecting to `mysqld`, the affected-rows value is the number of rows “found”; that is, matched by the `WHERE` clause.

  For `REPLACE` statements, the affected-rows value is 2 if the new row replaced an old row, because in this case, one row was inserted after the duplicate was deleted.

  For `INSERT ... ON DUPLICATE KEY UPDATE` statements, the affected-rows value is 1 if the row is inserted as a new row and 2 if an existing row is updated.

  The `ROW_COUNT()` value is similar to the value from the `mysql_affected_rows()` C API function and the row count that the `mysql` client displays following statement execution.
Information Functions

mysql> INSERT INTO t VALUES(1),(2),(3);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT ROW_COUNT();
+-------------+
| ROW_COUNT() |
+-------------+
| 3           |
+-------------+
1 row in set (0.00 sec)

mysql> DELETE FROM t WHERE i IN(1,2);
Query OK, 2 rows affected (0.00 sec)

mysql> SELECT ROW_COUNT();
+-------------+
| ROW_COUNT() |
+-------------+
| 2           |
+-------------+
1 row in set (0.00 sec)

Important

ROW_COUNT() is not replicated reliably using statement-based replication. Beginning with MySQL 5.1.23, this function is automatically replicated using row-based replication. (Bug #30244)

• SCHEMA()

This function is a synonym for DATABASE().

• SESSION_USER()

SESSION_USER() is a synonym for USER().

• SYSTEM_USER()

SYSTEM_USER() is a synonym for USER().

• USER()

Returns the current MySQL user name and host name as a string in the utf8 character set.

mysql> SELECT USER();
-> 'davida@localhost'

The value indicates the user name you specified when connecting to the server, and the client host from which you connected. The value can be different from that of CURRENT_USER().

• VERSION()

Returns a string that indicates the MySQL server version. The string uses the utf8 character set. The value might have a suffix in addition to the version number. See the description of the version system variable in Section 5.1.4, “Server System Variables”.

This function is unsafe for statement-based replication. Beginning with MySQL 5.1.42, a warning is logged if you use this function when binlog_format is set to STATEMENT. (Bug #47995)

mysql> SELECT VERSION();
-> '5.1.73-standard'
12.15 Spatial Analysis Functions

MySQL provides functions to perform various operations on spatial data. These functions can be grouped into several major categories according to the type of operation they perform:

- Functions that create geometries in various formats (WKT, WKB, internal)
- Functions that convert geometries between formats
- Functions that access qualitative or quantitative properties of a geometry
- Functions that describe relations between two geometries
- Functions that create new geometries from existing ones

For general background about MySQL support for using spatial data, see Section 11.5, “Extensions for Spatial Data”.

12.15.1 Spatial Function Reference

The following table lists each spatial function and provides a short description of each one.

Table 12.19 Spatial Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Area()</td>
<td>Return Polygon or MultiPolygon area</td>
</tr>
<tr>
<td>AsBinary(), AsWKB()</td>
<td>Convert from internal geometry format to WKB</td>
</tr>
<tr>
<td>AsText(), AsWKT()</td>
<td>Convert from internal geometry format to WKT</td>
</tr>
<tr>
<td>Centroid()</td>
<td>Return centroid as a point</td>
</tr>
<tr>
<td>Contains()</td>
<td>Whether MBR of one geometry contains MBR of another</td>
</tr>
<tr>
<td>Crosses()</td>
<td>Whether one geometry crosses another</td>
</tr>
<tr>
<td>Dimension()</td>
<td>Dimension of geometry</td>
</tr>
<tr>
<td>Disjoint()</td>
<td>Whether MBRs of two geometries are disjoint</td>
</tr>
<tr>
<td>EndPoint()</td>
<td>End Point of LineString</td>
</tr>
<tr>
<td>Envelope()</td>
<td>Return MBR of geometry</td>
</tr>
<tr>
<td>Equals()</td>
<td>Whether MBRs of two geometries are equal</td>
</tr>
<tr>
<td>ExteriorRing()</td>
<td>Return exterior ring of Polygon</td>
</tr>
<tr>
<td>GeomCollFromText(),</td>
<td>Return geometry collection from WKT</td>
</tr>
<tr>
<td>GeometryCollectionFromText()</td>
<td></td>
</tr>
<tr>
<td>GeomCollFromWKB(),</td>
<td>Return geometry collection from WKB</td>
</tr>
<tr>
<td>GeometryCollectionFromWKB()</td>
<td></td>
</tr>
<tr>
<td>GeometryCollection()</td>
<td>Construct geometry collection from geometries</td>
</tr>
<tr>
<td>GeometryN()</td>
<td>Return N-th geometry from geometry collection</td>
</tr>
<tr>
<td>GeometryType()</td>
<td>Return name of geometry type</td>
</tr>
<tr>
<td>GeomFromText(),</td>
<td>Return geometry from WKT</td>
</tr>
<tr>
<td>GeometryFromText()</td>
<td></td>
</tr>
<tr>
<td>GeomFromWKB(),</td>
<td>Return geometry from WKB</td>
</tr>
<tr>
<td>GeometryFromWKB()</td>
<td></td>
</tr>
<tr>
<td>QLength()</td>
<td>Return length of LineString</td>
</tr>
<tr>
<td>InteriorRingN()</td>
<td>Return N-th interior ring of Polygon</td>
</tr>
<tr>
<td>Intersects()</td>
<td>Whether MBRs of two geometries intersect</td>
</tr>
<tr>
<td>IsClosed()</td>
<td>Whether a geometry is closed and simple</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>IsEmpty()</td>
<td>Placeholder function</td>
</tr>
<tr>
<td>IsSimple()</td>
<td>Whether a geometry is simple</td>
</tr>
<tr>
<td>LineFromText(), LineStringFromText()</td>
<td>Construct LineString from WKT</td>
</tr>
<tr>
<td>LineFromWKB(), LineStringFromWKB()</td>
<td>Construct LineString from WKB</td>
</tr>
<tr>
<td>LineString()</td>
<td>Construct LineString from Point values</td>
</tr>
<tr>
<td>MBRContains()</td>
<td>Whether MBR of one geometry contains MBR of another</td>
</tr>
<tr>
<td>MBRDisjoint()</td>
<td>Whether MBRs of two geometries are disjoint</td>
</tr>
<tr>
<td>MBREqual()</td>
<td>Whether MBRs of two geometries are equal</td>
</tr>
<tr>
<td>MBRIntersects()</td>
<td>Whether MBRs of two geometries intersect</td>
</tr>
<tr>
<td>MBROverlaps()</td>
<td>Whether MBRs of two geometries overlap</td>
</tr>
<tr>
<td>MBRTouches()</td>
<td>Whether MBRs of two geometries touch</td>
</tr>
<tr>
<td>MBRWithin()</td>
<td>Whether MBR of one geometry is within MBR of another</td>
</tr>
<tr>
<td>MLineFromText(), MultiLineStringFromText()</td>
<td>Construct MultiLineString from WKT</td>
</tr>
<tr>
<td>MLineFromWKB(), MultiLineStringFromWKB()</td>
<td>Construct MultiLineString from WKB</td>
</tr>
<tr>
<td>MPointFromText(), MultiPointFromText()</td>
<td>Construct MultiPoint from WKT</td>
</tr>
<tr>
<td>MPointFromWKB(), MultiPointFromWKB()</td>
<td>Construct MultiPoint from WKB</td>
</tr>
<tr>
<td>MPolyFromText(), MultiPolygonFromText()</td>
<td>Construct MultiPolygon from WKT</td>
</tr>
<tr>
<td>MPolyFromWKB(), MultiPolygonFromWKB()</td>
<td>Construct MultiPolygon from WKB</td>
</tr>
<tr>
<td>MultiLineString()</td>
<td>Construct MultiLineString from LineString values</td>
</tr>
<tr>
<td>MultiPoint()</td>
<td>Construct MultiPoint from Point values</td>
</tr>
<tr>
<td>MultiPolygon()</td>
<td>Construct MultiPolygon from Polygon values</td>
</tr>
<tr>
<td>NumGeometries()</td>
<td>Return number of geometries in geometry collection</td>
</tr>
<tr>
<td>NumInteriorRings()</td>
<td>Return number of interior rings in Polygon</td>
</tr>
<tr>
<td>NumPoints()</td>
<td>Return number of points in LineString</td>
</tr>
<tr>
<td>Overlaps()</td>
<td>Whether MBRs of two geometries overlap</td>
</tr>
<tr>
<td>Point()</td>
<td>Construct Point from coordinates</td>
</tr>
<tr>
<td>PointFromText()</td>
<td>Construct Point from WKT</td>
</tr>
<tr>
<td>PointFromWKB()</td>
<td>Construct Point from WKB</td>
</tr>
<tr>
<td>PointN()</td>
<td>Return N-th point from LineString</td>
</tr>
<tr>
<td>PolyFromText(), PolygonFromText()</td>
<td>Construct Polygon from WKT</td>
</tr>
<tr>
<td>PolyFromWKB(), PolygonFromWKB()</td>
<td>Construct Polygon from WKB</td>
</tr>
<tr>
<td>Polygon()</td>
<td>Construct Polygon from LineString arguments</td>
</tr>
<tr>
<td>SRID()</td>
<td>Return spatial reference system ID for geometry</td>
</tr>
<tr>
<td>StartPoint()</td>
<td>Start Point of LineString</td>
</tr>
</tbody>
</table>
Spatial values, or geometries, have the properties described at Section 11.5.2.2, “Geometry Class”. The following discussion lists general spatial function argument-handling characteristics. Specific functions or groups of functions may have additional argument-handling characteristics, as discussed in the sections where those function descriptions occur.

Spatial functions are defined only for valid geometry values. If an invalid geometry is passed to a spatial function, the result is undefined.

The Spatial Reference Identifier (SRID) of a geometry identifies the coordinate space in which the geometry is defined. In MySQL, the SRID value is an integer associated with the geometry value. However, all calculations are done assuming SRID 0, representing cartesian (planar) coordinates, regardless of the actual SRID value. In the future, calculations may use the specified SRID values. To ensure SRID 0 behavior, create geometries using SRID 0. SRID 0 is the default for new geometries if no SRID is specified.

The maximum usable SRID value is \( 2^{32} - 1 \). If a larger value is given, only the lower 32 bits are used.

Geometry values produced by any spatial function inherit the SRID of the geometry arguments.

### 12.15.3 Functions That Create Geometry Values from WKT Values

These functions take as arguments a Well-Known Text (WKT) representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry.

- **GeomFromText()** accepts a WKT value of any geometry type as its first argument. Other functions provide type-specific construction functions for construction of geometry values of each geometry type.

For a description of WKT format, see Well-Known Text (WKT) Format.

- **GeomCollFromText(wkt[, srid])**

  Constructs a GeometryCollection value using its WKT representation and SRID.

- **GeomFromText(wkt[, srid])**

  Constructs a geometry value of any type using its WKT representation and SRID.

- **LineFromText(wkt[, srid])**, **LineStringFromText(wkt[, srid])**

  Constructs a LineString value using its WKT representation and SRID.

- **MLineFromText(wkt[, srid])**, **MultiLineStringFromText(wkt[, srid])**

  Constructs a MultiLineString value using its WKT representation and SRID.

- **MPointFromText(wkt[, srid])**, **MultiPointFromText(wkt[, srid])**

  Constructs a MultiPoint value using its WKT representation and SRID.

- **MPolyFromText(wkt[, srid])**, **MultiPolygonFromText(wkt[, srid])**

  Constructs a MultiPolygon value using its WKT representation and SRID.
Functions That Create Geometry Values from WKB Values

Constructs a MultiPolygon value using its WKT representation and SRID.

- **PointFromText**(wkt[, srid]) Constructs a Point value using its WKT representation and SRID.
- **PolyFromText**(wkt[, srid]), **PolygonFromText**(wkt[, srid]) Constructs a Polygon value using its WKT representation and SRID.

### 12.15.4 Functions That Create Geometry Values from WKB Values

These functions take as arguments a BLOB containing a Well-Known Binary (WKB) representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry.

As of MySQL 5.1.35, these functions also accept geometry objects for compatibility with the changes made in MySQL 5.1.35 to the return value of the functions in Section 12.15.5, "MySQL-Specific Functions That Create Geometry Values". Thus, those functions may continue to be used to provide the first argument to the functions in this section.

**GeomFromWKB()** accepts a WKB value of any geometry type as its first argument. Other functions provide type-specific construction functions for construction of geometry values of each geometry type.

For a description of WKB format, see Well-Known Binary (WKB) Format.

- **GeomCollFromWKB**(wkb[, srid]), **GeometryCollectionFromWKB**(wkb[, srid]) Constructs a GeometryCollection value using its WKB representation and SRID.
- **GeomFromWKB**(wkb[, srid]), **GeometryFromWKB**(wkb[, srid]) Constructs a geometry value of any type using its WKB representation and SRID.
- **LineFromWKB**(wkb[, srid]), **LineStringFromWKB**(wkb[, srid]) Constructs a LineString value using its WKB representation and SRID.
- **MLineFromWKB**(wkb[, srid]), **MultiLineStringFromWKB**(wkb[, srid]) Constructs a MultiLineString value using its WKB representation and SRID.
- **MPointFromWKB**(wkb[, srid]), **MultiPointFromWKB**(wkb[, srid]) Constructs a MultiPoint value using its WKB representation and SRID.
- **MPolyFromWKB**(wkb[, srid]), **MultiPolygonFromWKB**(wkb[, srid]) Constructs a MultiPolygon value using its WKB representation and SRID.
- **PointFromWKB**(wkb[, srid]) Constructs a Point value using its WKB representation and SRID.
- **PolyFromWKB**(wkb[, srid]), **PolygonFromWKB**(wkb[, srid]) Constructs a Polygon value using its WKB representation and SRID.

### 12.15.5 MySQL-Specific Functions That Create Geometry Values

MySQL provides a set of useful nonstandard functions for creating geometry values. The functions described in this section are MySQL extensions to the OpenGIS specification.
As of MySQL 5.1.35, these functions produce geometry objects from either WKB values or geometry objects as arguments. If any argument is not a proper WKB or geometry representation of the proper object type, the return value is NULL.

Before MySQL 5.1.35, these functions produce BLOB values containing WKB representations of geometry values with no SRID from WKB arguments. The WKB value returned from these functions can be converted to geometry arguments by using them as the first argument to functions in the GeomFromWKB() function family.

For example, as of MySQL 5.1.35, you can insert the geometry return value from Point() directly into a POINT column:

```sql
INSERT INTO t1 (pt_col) VALUES(Point(1,2));
```

Prior to MySQL 5.1.35, convert the WKB return value to a Point before inserting it:

```sql
INSERT INTO t1 (pt_col) VALUES(GeomFromWKB(Point(1,2)));
```

- **GeometryCollection**(g1, g2,...)
  Constructs a GeometryCollection.
  If the argument contains a nonsupported geometry, the return value is NULL.

- **LineString**(pt1, pt2,...)
  Constructs a LineString value from a number of Point or WKB Point arguments. If the number of arguments is less than two, the return value is NULL.

- **MultiLineString**(ls1, ls2,...)
  Constructs a MultiLineString value using LineString or WKB LineString arguments.

- **MultiPoint**(pt1, pt2,...)
  Constructs a MultiPoint value using Point or WKB Point arguments.

- **MultiPolygon**(poly1, poly2,...)
  Constructs a MultiPolygon value from a set of Polygon or WKB Polygon arguments.

- **Point**(x, y)
  Constructs a Point using its coordinates.

- **Polygon**(ls1, ls2,...)
  Constructs a Polygon value from a number of LineString or WKB LineString arguments. If any argument does not represent a LinearRing (that is, not a closed and simple LineString), the return value is NULL.

### 12.15.6 Geometry Format Conversion Functions

MySQL supports the functions listed in this section for converting geometry values from internal geometry format to WKT or WKB format.

In addition, there are functions to convert a string from WKT or WKB format to internal geometry format. See Section 12.15.3, “Functions That Create Geometry Values from WKT Values”, and Section 12.15.4, “Functions That Create Geometry Values from WKB Values”.

- **AsBinary**(g), **AsWKB**(g)
  Converts a value in internal geometry format to its WKB representation and returns the binary result.
SELECT AsBinary(g) FROM geom;

- AsText(g), AsWKT(g)

Converts a value in internal geometry format to its WKT representation and returns the string result.

```sql
mysql> SET @g = 'LineString(1 1,2 2,3 3)';
mysql> SELECT AsText(GeomFromText(@g));
+--------------------------+
| AsText(GeomFromText(@g)) |
| LINESTRING(1 1,2 2,3 3)  |
+--------------------------+
```

### 12.15.7 Geometry Property Functions

Each function that belongs to this group takes a geometry value as its argument and returns some quantitative or qualitative property of the geometry. Some functions restrict their argument type. Such functions return NULL if the argument is of an incorrect geometry type. For example, the `Area()` polygon function returns NULL if the object type is neither `Polygon` nor `MultiPolygon`.

#### 12.15.7.1 General Geometry Property Functions

The functions listed in this section do not restrict their argument and accept a geometry value of any type.

- **Dimension(g)**

  Returns the inherent dimension of the geometry value g. The result can be −1, 0, 1, or 2. The meaning of these values is given in Section 11.5.2.2, “Geometry Class”.

```sql
mysql> SELECT Dimension(GeomFromText('LineString(1 1,2 2)'));
+------------------------------------------------+
| Dimension(GeomFromText('LineString(1 1,2 2)')) |
| 1                                              |
+------------------------------------------------+
```

- **Envelope(g)**

  Returns the minimum bounding rectangle (MBR) for the geometry value g. The result is returned as a `Polygon` value that is defined by the corner points of the bounding box: `POLYGON((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))`

```sql
mysql> SELECT AsText(Envelope(GeomFromText('LineString(1 1,2 2)')));
+-------------------------------------------------------+
| AsText(Envelope(GeomFromText('LineString(1 1,2 2)'))) |
| POLYGON((1 1,2 1,2 2,1 2,1 1))                        |
+-------------------------------------------------------+
```

- **GeometryType(g)**

  Returns a binary string indicating the name of the geometry type of which the geometry instance g is a member. The name corresponds to one of the instantiable `Geometry` subclasses.

```sql
mysql> SELECT GeometryType(GeomFromText('POINT(1 1)'));
+------------------------------------------+
| GeometryType(GeomFromText('POINT(1 1)')) |
+------------------------------------------+
```
### Geometry Property Functions

<table>
<thead>
<tr>
<th>POINT</th>
</tr>
</thead>
</table>

- **IsEmpty\(g\)**
  
  This function is a placeholder that returns 0 for any valid geometry value, 1 for any invalid geometry value or \(NULL\).

  MySQL does not support GIS EMPTY values such as \(POINT\ \text{EMPTY}\).

- **IsSimple\(g\)**
  
  In MySQL 5.1, this function is a placeholder that always returns 0.

  The description of each instantiable geometric class given earlier in the chapter includes the specific conditions that cause an instance of that class to be classified as not simple. (See Section 11.5.2.1, “The Geometry Class Hierarchy”.)

- **SRID\(g\)**
  
  Returns an integer indicating the Spatial Reference System ID for the geometry value \(g\).

  In MySQL, the SRID value is just an integer associated with the geometry value. All calculations are done assuming Euclidean (planar) geometry.

  ```
  mysql> SELECT SRID(GeomFromText('LineString(1 1,2 2)',101));
  +-----------------------------------------------+
  | SRID(GeomFromText('LineString(1 1,2 2)',101)) |
  +-----------------------------------------------+
  |                                           101 |
  +-----------------------------------------------+
  ```

#### 12.15.7.2 Point Property Functions

A **Point** consists of X and Y coordinates, which may be obtained using the following functions:

- **X\(p\)**
  
  Returns the X-coordinate value for the **Point** object \(p\) as a double-precision number.

  ```
  mysql> SELECT X(POINT(56.7, 53.34));
  +-----------------------+
  | X(POINT(56.7, 53.34)) |
  +-----------------------+
  |                  56.7 |
  +-----------------------+
  ```

- **Y\(p\)**
  
  Returns the Y-coordinate value for the **Point** object \(p\) as a double-precision number.

  ```
  mysql> SELECT Y(POINT(56.7, 53.34));
  +-----------------------+
  | Y(POINT(56.7, 53.34)) |
  +-----------------------+
  |                 53.34 |
  +-----------------------+
  ```

#### 12.15.7.3 LineString and MultiLineString Property Functions

A **LineString** consists of **Point** values. You can extract particular points of a **LineString**, count the number of points that it contains, or obtain its length.

```
Some functions in this section also work for `MultiLineString` values.

- **EndPoint(ls)**

  Returns the `Point` that is the endpoint of the `LineString` value `ls`.

  ```sql
  mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
  mysql> SELECT AsText(EndPoint(GeomFromText(@ls)));
  +----------------------------------------------------+
  | AsText(EndPoint(GeomFromText(@ls)))                |
  +----------------------------------------------------+
  | POINT(3 3)                                         |
  +----------------------------------------------------+
  ```

- **GLength(ls)**

  Returns a double-precision number indicating the length of the `LineString` or `MultiLineString` value `ls` in its associated spatial reference. The length of a `MultiLineString` value is equal to the sum of the lengths of its elements.

  ```sql
  mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
  mysql> SELECT GLength(GeomFromText(@ls));
  +------------------------+
  | GLength(GeomFromText(@ls)) |
  +------------------------+
  | 2.8284271247461903      |
  +------------------------+
  mysql> SET @mls = 'MultiLineString((1 1,2 2,3 3),(4 4,5 5))';
  mysql> SELECT GLength(GeomFromText(@mls));
  +-----------------------------+
  | GLength(GeomFromText(@mls)) |
  +-----------------------------+
  | 4.242640687119286           |
  +-----------------------------+
  ```

  `GLength()` is a nonstandard name. It corresponds to the OpenGIS `Length()` function. (There is an existing SQL function `Length()` that calculates the length of string values.)

- **IsClosed(ls)**

  For a `LineString` value `ls`, `IsClosed()` returns 1 if `ls` is closed (that is, its `StartPoint()` and `EndPoint()` values are the same).

  For a `MultiLineString` value `ls`, `IsClosed()` returns 1 if `ls` is closed (that is, the `StartPoint()` and `EndPoint()` values are the same for each `LineString` in `ls`).

  `IsClosed()` returns 0 if `ls` is not closed, and NULL if `ls` is NULL.
Geometry Property Functions

12.15.7.4 Polygon and MultiPolygon Property Functions

These functions return properties of Polygon or MultiPolygon values.

• **Area(poly)**

Returns a double-precision number indicating the area of the argument, as measured in its spatial reference system. For arguments of dimension 0 or 1, the result is 0.

```sql
mysql> SET @poly = 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 1,1 1))';
mysql> SELECT Area(GeomFromText(@poly));
+---------------------------+
<table>
<thead>
<tr>
<th>Area(GeomFromText(@poly))</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
</tr>
</tbody>
</table>
+---------------------------+
```

```sql
mysql> SET @mpoly = 'MultiPolygon(((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 1,1 1)))';
mysql> SELECT Area(GeomFromText(@mpoly));
```
Geometry Property Functions

<table>
<thead>
<tr>
<th>Area(GeomFromText(@mpoly))</th>
<th>8</th>
</tr>
</thead>
</table>

- **Centroid(mpoly)**

  Returns the mathematical centroid for the MultiPolygon value `mpoly` as a Point. The result is not guaranteed to be on the MultiPolygon.

  ```sql
  mysql> SET @poly = GeomFromText('POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7,5 5))');
  mysql> SELECT GeometryType(@poly),AsText(Centroid(@poly));
  +---------------------+--------------------------------------------+
  | GeometryType(@poly) | AsText(Centroid(@poly))                    |
  +---------------------+--------------------------------------------+
  | POLYGON             | POINT(4.958333333333333 4.958333333333333) |
  +---------------------+--------------------------------------------+
  
- **ExteriorRing(poly)**

  Returns the exterior ring of the Polygon value `poly` as a LineString.

  ```sql
  mysql> SET @poly = 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
  mysql> SELECT AsText(ExteriorRing(GeomFromText(@poly)));
  +-------------------------------------------+
  | AsText(ExteriorRing(GeomFromText(@poly))) |
  +-------------------------------------------+
  | LINESTRING(0 0,0 3,3 3,3 0,0 0)           |
  +-------------------------------------------+
  
- **InteriorRingN(poly, N)**

  Returns the N-th interior ring for the Polygon value `poly` as a LineString. Rings are numbered beginning with 1.

  ```sql
  mysql> SET @poly = 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
  mysql> SELECT AsText(InteriorRingN(GeomFromText(@poly),1));
  +----------------------------------------------+
  | AsText(InteriorRingN(GeomFromText(@poly),1)) |
  +----------------------------------------------+
  | LINESTRING(1 1,1 2,2 2,2 1,1 1)              |
  +----------------------------------------------+
  
- **NumInteriorRings(poly)**

  Returns the number of interior rings in the Polygon value `poly`.

  ```sql
  mysql> SET @poly = 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
  mysql> SELECT NumInteriorRings(GeomFromText(@poly));
  +---------------------------------------+
  | NumInteriorRings(GeomFromText(@poly)) | |
  +---------------------------------------+
  |                                     1 | |
  +---------------------------------------+
  
12.15.7.5 GeometryCollection Property Functions

These functions return properties of GeometryCollection values.

- **GeometryN(gc, N)**
Returns the $N$-th geometry in the `GeometryCollection` value $gc$. Geometries are numbered beginning with 1.

```sql
mysql> SET @gc = 'GeometryCollection(Point(1 1), LineString(2 2, 3 3))';

mysql> SELECT AsText(GeometryN(GeomFromText(@gc), 1));
+----------------------------------------+
| AsText(GeometryN(GeomFromText(@gc), 1)) |
+----------------------------------------+
| POINT(1 1)                             |
+----------------------------------------+
```

- `NumGeometries(gc)`

Returns the number of geometries in the `GeometryCollection` value $gc$.

```sql
mysql> SET @gc = 'GeometryCollection(Point(1 1), LineString(2 2, 3 3))';

mysql> SELECT NumGeometries(GeomFromText(@gc));
+----------------------------------+
| NumGeometries(GeomFromText(@gc)) |
|                                2 |
+----------------------------------+
```

### 12.15.8 Spatial Operator Functions

Section 12.15.7, “Geometry Property Functions”, discusses several functions that construct new geometries from existing ones. See that section for descriptions of these functions:

- `Envelope(g)`
- `StartPoint(ls)`
- `EndPoint(ls)`
- `PointN(ls, N)`
- `ExteriorRing(poly)`
- `InteriorRingN(poly, N)`
- `GeometryN(gc, N)`

### 12.15.9 Functions That Test Spatial Relations Between Geometry Objects

The functions described in this section take two geometries as arguments and return a qualitative or quantitative relation between them.

MySQL implements two sets of functions using function names defined by the OpenGIS specification. One set tests the relationship between two geometry values using precise object shapes, the other set uses object minimum bounding rectangles (MBRs).

There is also a MySQL-specific set of MBR-based functions available to test the relationship between two geometry values.

#### 12.15.9.1 Spatial Relation Functions That Use Object Shapes

The OpenGIS specification defines the following functions. They test the relationship between two geometry values $g_1$ and $g_2$, using precise object shapes. The return values 1 and 0 indicate true and false, respectively.

- `Crosses(g1, g2)`
Functions That Test Spatial Relations Between Geometry Objects

Returns 1 if \( g_1 \) spatially crosses \( g_2 \). Returns NULL if \( g_1 \) is a Polygon or a MultiPolygon, or if \( g_2 \) is a Point or a MultiPoint. Otherwise, returns 0.

The term *spatially crosses* denotes a spatial relation between two given geometries that has the following properties:

- The two geometries intersect
- Their intersection results in a geometry that has a dimension that is one less than the maximum dimension of the two given geometries
- Their intersection is not equal to either of the two given geometries
- \( \text{Touches}(g_1, g_2) \)

Returns 1 or 0 to indicate whether \( g_1 \) spatially touches \( g_2 \). Two geometries *spatially touch* if the interiors of the geometries do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

12.15.9.2 Spatial Relation Functions That Use Minimum Bounding Rectangles (MBRs)

The OpenGIS specification defines the following functions that test the relationship between two geometry values \( g_1 \) and \( g_2 \). The MySQL implementation uses minimum bounding rectangles, so these functions return the same result as the corresponding MBR-based functions. The return values 1 and 0 indicate true and false, respectively.

- \( \text{Contains}(g_1, g_2) \)

Returns 1 or 0 to indicate whether \( g_1 \) completely contains \( g_2 \). This tests the opposite relationship as \( \text{Within}() \).

- \( \text{Disjoint}(g_1, g_2) \)

Returns 1 or 0 to indicate whether \( g_1 \) is spatially disjoint from (does not intersect) \( g_2 \).

- \( \text{Equals}(g_1, g_2) \)

Returns 1 or 0 to indicate whether \( g_1 \) is spatially equal to \( g_2 \).

- \( \text{Intersects}(g_1, g_2) \)

Returns 1 or 0 to indicate whether \( g_1 \) spatially intersects \( g_2 \).

- \( \text{Overlaps}(g_1, g_2) \)

Returns 1 or 0 to indicate whether \( g_1 \) spatially overlaps \( g_2 \). The term *spatially overlaps* is used if two geometries intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

- \( \text{Within}(g_1, g_2) \)

Returns 1 or 0 to indicate whether \( g_1 \) is spatially within \( g_2 \). This tests the opposite relationship as \( \text{Contains}() \).

12.15.9.3 MySQL-Specific Spatial Relation Functions That Use Minimum Bounding Rectangles (MBRs)

MySQL provides several MySQL-specific functions that test relations between minimum bounding rectangles of two geometries \( g_1 \) and \( g_2 \). The return values 1 and 0 indicate true and false, respectively.

- \( \text{MBRContains}(g_1, g_2) \)
Returns 1 or 0 to indicate whether the minimum bounding rectangle of \( g1 \) contains the minimum bounding rectangle of \( g2 \). This tests the opposite relationship as \( \text{MBRWithin()} \).

\[
\begin{align*}
\text{mysql} & \text{> SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');} \\
\text{mysql} & \text{> SET @g2 = GeomFromText('Point(1 1)');} \\
\text{mysql} & \text{> SELECT MBRContains(@g1,@g2), MBRWithin(@g2,@g1);}
\end{align*}
\]

<table>
<thead>
<tr>
<th>MBRContains(@g1,@g2)</th>
<th>MBRWithin(@g2,@g1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

- **MBRDisjoint\((g1,g2)\)**

Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries \( g1 \) and \( g2 \) are disjoint (do not intersect).

- **MBREqual\((g1,g2)\)**

Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries \( g1 \) and \( g2 \) are the same.

- **MBRIntersects\((g1,g2)\)**

Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries \( g1 \) and \( g2 \) intersect.

- **MBROverlaps\((g1,g2)\)**

Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries \( g1 \) and \( g2 \) overlap. The term **spatially overlaps** is used if two geometries intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

- **MBRTouches\((g1,g2)\)**

Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries \( g1 \) and \( g2 \) touch. Two geometries **spatially touch** if the interiors of the geometries do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

- **MBRWithin\((g1,g2)\)**

Returns 1 or 0 to indicate whether the minimum bounding rectangle of \( g1 \) is within the minimum bounding rectangle of \( g2 \). This tests the opposite relationship as \( \text{MBRContains()} \).

\[
\begin{align*}
\text{mysql} & \text{> SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');} \\
\text{mysql} & \text{> SET @g2 = GeomFromText('Polygon((0 0,0 5,5 5,5 0,0 0))');} \\
\text{mysql} & \text{> SELECT MBRWithin(@g1,@g2), MBRWithin(@g2,@g1);}
\end{align*}
\]

<table>
<thead>
<tr>
<th>MBRWithin(@g1,@g2)</th>
<th>MBRWithin(@g2,@g1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

### 12.16 Miscellaneous Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFAULT()</td>
<td>Return the default value for a table column</td>
</tr>
<tr>
<td>GET_LOCK()</td>
<td>Get a named lock</td>
</tr>
<tr>
<td>INET_ATON()</td>
<td>Return the numeric value of an IP address</td>
</tr>
</tbody>
</table>
### Miscellaneous Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INET_NTOA()</td>
<td>Return the IP address from a numeric value</td>
</tr>
<tr>
<td>IS_FREE_LOCK()</td>
<td>Whether the named lock is free</td>
</tr>
<tr>
<td>IS_USED_LOCK()</td>
<td>Whether the named lock is in use; return connection identifier if true</td>
</tr>
<tr>
<td>MASTER_POS_WAIT()</td>
<td>Block until the slave has read and applied all updates up to the specified position</td>
</tr>
<tr>
<td>NAME_CONST()</td>
<td>Causes the column to have the given name</td>
</tr>
<tr>
<td>RAND()</td>
<td>Return a random floating-point value</td>
</tr>
<tr>
<td>RELEASE_LOCK()</td>
<td>Releases the named lock</td>
</tr>
<tr>
<td>SLEEP()</td>
<td>Sleep for a number of seconds</td>
</tr>
<tr>
<td>UUID()</td>
<td>Return a Universal Unique Identifier (UUID)</td>
</tr>
<tr>
<td>UUID_SHORT()</td>
<td>Return an integer-valued universal identifier</td>
</tr>
<tr>
<td>VALUES()</td>
<td>Defines the values to be used during an INSERT</td>
</tr>
</tbody>
</table>

- **DEFAULT(col_name)**

  Returns the default value for a table column. An error results if the column has no default value.

  ```sql
  mysql> UPDATE t SET i = DEFAULT(i)+1 WHERE id < 100;
  ```

- **FORMAT(X,D)**

  Formats the number $X$ to a format like '#,###,###.##', rounded to $D$ decimal places, and returns the result as a string. For details, see Section 12.5, “String Functions”.

- **GET_LOCK(str,timeout)**

  Tries to obtain a lock with a name given by the string $str$, using a timeout of $timeout$ seconds. Returns 1 if the lock was obtained successfully, 0 if the attempt timed out (for example, because another client has previously locked the name), or NULL if an error occurred (such as running out of memory or the thread was killed with `mysqladmin kill`).

  A lock obtained with `GET_LOCK()` is released explicitly by executing `RELEASE_LOCK()` or a new `GET_LOCK()`, or implicitly when your session terminates (either normally or abnormally).

  Locks obtained with `GET_LOCK()` are not released when transactions commit or roll back.

  `GET_LOCK()` can be used to implement application locks or to simulate record locks. Names are locked on a server-wide basis. If a name has been locked within one session, `GET_LOCK()` blocks any request by another session for a lock with the same name. This enables clients that agree on a given lock name to use the name to perform cooperative advisory locking. But be aware that it also enables a client that is not among the set of cooperating clients to lock a name, either inadvertently or deliberately, and thus prevent any of the cooperating clients from locking that name. One way to reduce the likelihood of this is to use lock names that are database-specific or application-specific. For example, use lock names of the form `db_name.str` or `app_name.str`.

  ```sql
  mysql> SELECT GET_LOCK('lock1',10);
  -> 1
  mysql> SELECT IS_FREE_LOCK('lock2');
  -> 1
  mysql> SELECT GET_LOCK('lock2',10);
  -> 1
  mysql> SELECT RELEASE_LOCK('lock2');
  -> 1
  mysql> SELECT RELEASE_LOCK('lock1');
  ```
The second `RELEASE_LOCK()` call returns `NULL` because the lock 'lock1' was automatically released by the second `GET_LOCK()` call.

If multiple clients are waiting for a lock, the order in which they will acquire it is undefined. Applications should not assume that clients will acquire the lock in the same order that they issued the lock requests.

**Note**

If a client attempts to acquire a lock that is already held by another client, it blocks according to the `timeout` argument. If the blocked client terminates, its thread does not die until the lock request times out. This is a known bug (fixed in MySQL 5.5).

This function is unsafe for statement-based replication. Beginning with MySQL 5.1.42, a warning is logged if you use this function when `binlog_format` is set to `STATEMENT`. (Bug #47995)

• **INET_ATON(expr)**

   Given the dotted-quad representation of an IPv4 network address as a string, returns an integer that represents the numeric value of the address in network byte order (big endian). `INET_ATON()` returns `NULL` if it does not understand its argument.

   ```
   mysql> SELECT INET_ATON('10.0.5.9');
   --> 167773449
   ```

   For this example, the return value is calculated as $10 \times 256^3 + 0 \times 256^2 + 5 \times 256 + 9$.

   `INET_ATON()` may or may not return a non-`NULL` result for short-form IP addresses (such as '127.1' as a representation of '127.0.0.1'). Because of this, `INET_ATON()` a should not be used for such addresses.

   **Note**

   To store values generated by `INET_ATON()`, use an `INT UNSIGNED` column rather than `INT`, which is signed. If you use a signed column, values corresponding to IP addresses for which the first octet is greater than 127 cannot be stored correctly. See Section 11.2.6, "Out-of-Range and Overflow Handling".

• **INET_NTOA(expr)**

   Given a numeric IPv4 network address in network byte order, returns the dotted-quad representation of the address as a binary string. `INET_NTOA()` returns `NULL` if it does not understand its argument.

   ```
   mysql> SELECT INET_NTOA(167773449);
   --> '10.0.5.9'
   ```

• **IS_FREE_LOCK(str)**

   Checks whether the lock named `str` is free to use (that is, not locked). Returns 1 if the lock is free (no one is using the lock), 0 if the lock is in use, and `NULL` if an error occurs (such as an incorrect argument).

   This function is unsafe for statement-based replication. Beginning with MySQL 5.1.42, a warning is logged if you use this function when `binlog_format` is set to `STATEMENT`. (Bug #47995)

• **IS_USED_LOCK(str)**
Checks whether the lock named str is in use (that is, locked). If so, it returns the connection identifier of the client session that holds the lock. Otherwise, it returns NULL.

This function is unsafe for statement-based replication. Beginning with MySQL 5.1.42, a warning is logged if you use this function when binlog_format is set to STATEMENT. (Bug #47995)

- **MASTER_POS_WAIT(log_name, log_pos[, timeout])**

This function is useful for control of master/slave synchronization. It blocks until the slave has read and applied all updates up to the specified position in the master log. The return value is the number of log events the slave had to wait for to advance to the specified position. The function returns NULL if the slave SQL thread is not started, the slave’s master information is not initialized, the arguments are incorrect, or an error occurs. It returns -1 if the timeout has been exceeded. If the slave SQL thread stops while MASTER_POS_WAIT() is waiting, the function returns NULL. If the slave is past the specified position, the function returns immediately.

If a timeout value is specified, MASTER_POS_WAIT() stops waiting when timeout seconds have elapsed. timeout must be greater than 0; a zero or negative timeout means no timeout. The lock is exclusive. While held by one session, other sessions cannot obtain a lock of the same name.

This function is unsafe for statement-based replication. Beginning with MySQL 5.1.42, a warning is logged if you use this function when binlog_format is set to STATEMENT. (Bug #47995)

- **NAME_CONST(name, value)**

Returns the given value. When used to produce a result set column, NAME_CONST() causes the column to have the given name. The arguments should be constants.

```
mysql> SELECT NAME_CONST('myname', 14);
+--------+
| myname |
| 14     |
+--------+
```

This function is for internal use only. The server uses it when writing statements from stored programs that contain references to local program variables, as described in Section 19.7, “Binary Logging of Stored Programs”. You might see this function in the output from mysqlbinlog.

For your applications, you can obtain exactly the same result as in the example just shown by using simple aliasing, like this:

```
mysql> SELECT 14 AS myname;
+--------+
| myname |
| 14     |
+--------+
```

1 row in set (0.00 sec)

See Section 13.2.8, “SELECT Syntax”, for more information about column aliases.

- **RELEASE_LOCK(str)**

Releases the lock named by the string str that was obtained with GET_LOCK(). Returns 1 if the lock was released, 0 if the lock was not established by this thread (in which case the lock is not released), and NULL if the named lock did not exist. The lock does not exist if it was never obtained by a call to GET_LOCK() or if it has previously been released.

The **DO** statement is convenient to use with RELEASE_LOCK(). See Section 13.2.3, “DO Syntax”. 
This function is unsafe for statement-based replication. Beginning with MySQL 5.1.42, a warning is logged if you use this function when `binlog_format` is set to `STATEMENT`. (Bug #47995)

- **SLEEP**(duration)

Sleeps (pauses) for the number of seconds given by the `duration` argument, then returns 0. If `SLEEP()` is interrupted, it returns 1. The duration may have a fractional part.

When sleep returns normally (without interruption), it returns 0:

```
mysql> SELECT SLEEP(1000);
+-------------+
<table>
<thead>
<tr>
<th>SLEEP(1000)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
</tbody>
</table>
+-------------+
```

When `SLEEP()` is the only thing invoked by a query that is interrupted, it returns 1 and the query itself returns no error. This statement is interrupted using `KILL QUERY` from another session:

```
mysql> SELECT SLEEP(1000);
+-------------+
<table>
<thead>
<tr>
<th>SLEEP(1000)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
</tbody>
</table>
+-------------+
```

When `SLEEP()` is only part of a query that is interrupted, the query returns an error. This statement is interrupted using `KILL QUERY` from another session:

```
mysql> SELECT 1 FROM t1 WHERE SLEEP(1000);
ERROR 1317 (70100): Query execution was interrupted
```

This function is unsafe for statement-based replication. Beginning with MySQL 5.1.42, a warning is logged if you use this function when `binlog_format` is set to `STATEMENT`. (Bug #47995)

- **UUID()**

Returns a Universal Unique Identifier (UUID) generated according to RFC 4122, “A Universally Unique IDentifier (UUID) URN Namespace” (http://www.ietf.org/rfc/rfc4122.txt).

A UUID is designed as a number that is globally unique in space and time. Two calls to `UUID()` are expected to generate two different values, even if these calls are performed on two separate devices not connected to each other.

**Warning**

Although `UUID()` values are intended to be unique, they are not necessarily unguessable or unpredictable. If unpredictability is required, UUID values should be generated some other way.

`UUID()` returns a value that conforms to UUID version 1 as described in RFC 4122. The value is a 128-bit number represented as a `utf8` string of five hexadecimal numbers in `aaaaaaaa-bbbb-cccc-dddd-eeeee` format:

- The first three numbers are generated from the low, middle, and high parts of a timestamp. The high part also includes the UUID version number.

- The fourth number preserves temporal uniqueness in case the timestamp value loses monotonicity (for example, due to daylight saving time).
• The fifth number is an IEEE 802 node number that provides spatial uniqueness. A random number is substituted if the latter is not available (for example, because the host device has no Ethernet card, or it is unknown how to find the hardware address of an interface on the host operating system). In this case, spatial uniqueness cannot be guaranteed. Nevertheless, a collision should have very low probability.

The MAC address of an interface is taken into account only on FreeBSD and Linux. On other operating systems, MySQL uses a randomly generated 48-bit number.

```sql
mysql> SELECT UUID();
-> '6ccd780c-baba-1026-9564-0040f4311e29'
```

**Note**

`UUID()` does not work with statement-based replication.

• `UUID_SHORT()`

Returns a "short" universal identifier as a 64-bit unsigned integer. Values returned by `UUID_SHORT()` differ from the string-format 128-bit identifiers returned by the `UUID()` function and have different uniqueness properties. The value of `UUID_SHORT()` is guaranteed to be unique if the following conditions hold:

• The `server_id` value of the current server is between 0 and 255 and is unique among your set of master and slave servers

• You do not set back the system time for your server host between `mysqld` restarts

• You invoke `UUID_SHORT()` on average fewer than 16 million times per second between `mysqld` restarts

The `UUID_SHORT()` return value is constructed this way:

```sql
(server_id & 255) << 56
+ (server_startup_time_in_seconds << 24)
+ incremented_variable++;
```

```sql
mysql> SELECT UUID_SHORT();
-> 92395783831158784
```

**Note**

`UUID_SHORT()` does not work with statement-based replication.

This function was added in MySQL 5.1.20.

• `VALUES(col_name)`

In an `INSERT ... ON DUPLICATE KEY UPDATE` statement, you can use the `VALUES(col_name)` function in the `UPDATE` clause to refer to column values from the `INSERT` portion of the statement. In other words, `VALUES(col_name)` in the `UPDATE` clause refers to the value of `col_name` that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The `VALUES()` function is meaningful only in the `ON DUPLICATE KEY UPDATE` clause of `INSERT` statements and returns `NULL` otherwise. See Section 13.2.5.3, "INSERT ... ON DUPLICATE KEY UPDATE Syntax".

```sql
mysql> INSERT INTO table (a,b,c) VALUES (1,2,3),(4,5,6)
    ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```
12.17 Aggregate (GROUP BY) Functions

12.17.1 Aggregate (GROUP BY) Function Descriptions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AVG()</td>
<td>Return the average value of the argument</td>
</tr>
<tr>
<td>BIT_AND()</td>
<td>Return bitwise AND</td>
</tr>
<tr>

</tr>
<tr>
<td>VARIANCE()</td>
<td>Return the population standard variance</td>
</tr>
</tbody>
</table>

This section describes group (aggregate) functions that operate on sets of values. Unless otherwise stated, group functions ignore NULL values.

If you use a group function in a statement containing no GROUP BY clause, it is equivalent to grouping on all rows. For more information, see Section 12.17.3, “MySQL Handling of GROUP BY”.

For numeric arguments, the variance and standard deviation functions return a DOUBLE value. The SUM() and AVG() functions return a DECIMAL value for exact-value arguments (integer or DECIMAL), and a DOUBLE value for approximate-value arguments (FLOAT or DOUBLE).

The SUM() and AVG() aggregate functions do not work with temporal values. (They convert the values to numbers, losing everything after the first nonnumeric character.) To work around this problem, convert to numeric units, perform the aggregate operation, and convert back to a temporal value. Examples:

```sql
SELECT SEC_TO_TIME(SUM(TIME_TO_SEC(time_col))) FROM tbl_name;
SELECT FROM_DAYS(SUM(TO_DAYS(date_col))) FROM tbl_name;
```

Functions such as SUM() or AVG() that expect a numeric argument cast the argument to a number if necessary. For SET or ENUM values, the cast operation causes the underlying numeric value to be used.

The BIT_AND(), BIT_OR(), and BIT_XOR() aggregate functions perform bit operations. They require BIGINT (64-bit integer) arguments and return BIGINT values. Arguments of other types are converted to BIGINT and truncation might occur.

- AVG([DISTINCT] expr)
Returns the average value of `expr`. The **DISTINCT** option can be used to return the average of the distinct values of `expr`.

**AVG()** returns NULL if there were no matching rows.

```sql
mysql> SELECT student_name, AVG(test_score) -> FROM student -> GROUP BY student_name;
```

- **BIT_AND(expr)**
  Returns the bitwise **AND** of all bits in `expr`. The calculation is performed with 64-bit (**BIGINT**) precision.
  **BIT_AND()** returns 18446744073709551615 if there were no matching rows. (This is the value of an unsigned **BIGINT** value with all bits set to 1.)

- **BIT_OR(expr)**
  Returns the bitwise **OR** of all bits in `expr`. The calculation is performed with 64-bit (**BIGINT**) precision.
  **BIT_OR()** returns 0 if there were no matching rows.

- **BIT_XOR(expr)**
  Returns the bitwise **XOR** of all bits in `expr`. The calculation is performed with 64-bit (**BIGINT**) precision.
  **BIT_XOR()** returns 0 if there were no matching rows.

- **COUNT(expr)**
  Returns a count of the number of non-NULL values of `expr` in the rows retrieved by a **SELECT** statement. The result is a **BIGINT** value.
  **COUNT()** returns 0 if there were no matching rows.

```sql
mysql> SELECT student.student_name,COUNT(*) -> FROM student,course -> WHERE student.student_id=course.student_id -> GROUP BY student_name;
```

**COUNT(*)** is somewhat different in that it returns a count of the number of rows retrieved, whether or not they contain NULL values.

**COUNT(*)** is optimized to return very quickly if the **SELECT** retrieves from one table, no other columns are retrieved, and there is no **WHERE** clause. For example:

```sql
mysql> SELECT COUNT(*) FROM student;
```

This optimization applies only to **MyISAM** tables only, because an exact row count is stored for this storage engine and can be accessed very quickly. For transactional storage engines such as **InnoDB**, storing an exact row count is more problematic because multiple transactions may be occurring, each of which may affect the count.

- **COUNT(DISTINCT expr,[expr...])**
  Returns a count of the number of rows with different non-NULL `expr` values.
  **COUNT(DISTINCT)** returns 0 if there were no matching rows.
In MySQL, you can obtain the number of distinct expression combinations that do not contain NULL by giving a list of expressions. In standard SQL, you would have to do a concatenation of all expressions inside COUNT(DISTINCT ...).

- **GROUP_CONCAT(expr)**

  This function returns a string result with the concatenated non-NULL values from a group. It returns NULL if there are no non-NULL values. The full syntax is as follows:

  ```sql
  GROUP_CONCAT([DISTINCT] expr [, expr ...] [ORDER BY {unsigned_integer | col_name | expr} [ASC | DESC] [, col_name ...]] [SEPARATOR str_val])
  ```

  ```sql
  mysql> SELECT student_name, 
                   GROUP_CONCAT(test_score) 
                   FROM student 
                   GROUP BY student_name;
  Or:
  ```
  ```sql
  mysql> SELECT student_name, 
                   GROUP_CONCAT(DISTINCT test_score 
                                ORDER BY test_score DESC SEPARATOR ' ') 
                   FROM student 
                   GROUP BY student_name;
  ```

  In MySQL, you can get the concatenated values of expression combinations. To eliminate duplicate values, use the DISTINCT clause. To sort values in the result, use the ORDER BY clause. To sort in reverse order, add the DESC (descending) keyword to the name of the column you are sorting by in the ORDER BY clause. The default is ascending order; this may be specified explicitly using the ASC keyword. The default separator between values in a group is comma (","). To specify a separator explicitly, use SEPARATOR followed by the string literal value that should be inserted between group values. To eliminate the separator altogether, specify SEPARATOR '"'.

  The result is truncated to the maximum length that is given by the group_concat_max_len system variable, which has a default value of 1024. The value can be set higher, although the effective maximum length of the return value is constrained by the value of max_allowed_packet. The syntax to change the value of group_concat_max_len at runtime is as follows, where `val` is an unsigned integer:

  ```sql
  SET [GLOBAL | SESSION] group_concat_max_len = val;
  ```

  The return value is a nonbinary or binary string, depending on whether the arguments are nonbinary or binary strings. The result type is TEXT or BLOB unless group_concat_max_len is less than or equal to 512, in which case the result type is VARCHAR or VARBINARY.

  See also CONCAT() and CONCAT_WS(): Section 12.5, “String Functions”.

- **MAX([DISTINCT] expr)**

  Returns the maximum value of expr. MAX() may take a string argument; in such cases, it returns the maximum string value. See Section 8.3.1, “How MySQL Uses Indexes”. The DISTINCT keyword can be used to find the maximum of the distinct values of expr, however, this produces the same result as omitting DISTINCT.

  MAX() returns NULL if there were no matching rows.
For **MAX()**, MySQL currently compares **ENUM** and **SET** columns by their string value rather than by the string's relative position in the set. This differs from how **ORDER BY** compares them. This is expected to be rectified in a future MySQL release.

- **MIN([DISTINCT] expr)**

  Returns the minimum value of **expr**. **MIN()** may take a string argument; in such cases, it returns the minimum string value. See Section 8.3.1, “How MySQL Uses Indexes”. The **DISTINCT** keyword can be used to find the minimum of the distinct values of **expr**, however, this produces the same result as omitting **DISTINCT**.

  **MIN()** returns **NULL** if there were no matching rows.

- **STD(expr)**

  Returns the population standard deviation of **expr**. This is an extension to standard SQL. The standard SQL function **STDDEV_POP()** can be used instead.

  **STD()** returns **NULL** if there were no matching rows.

- **STDDEV(expr)**

  Returns the population standard deviation of **expr**. This function is provided for compatibility with Oracle. The standard SQL function **STDDEV_POP()** can be used instead.

  **STDDEV()** returns **NULL** if there were no matching rows.

- **STDDEV_POP(expr)**

  Returns the population standard deviation of **expr** (the square root of **VAR_POP()**). You can also use **STD()** or **STDDEV()**, which are equivalent but not standard SQL.

  **STDDEV_POP()** returns **NULL** if there were no matching rows.

- **STDDEV_SAMP(expr)**

  Returns the sample standard deviation of **expr** (the square root of **VAR_SAMP()**).

  **STDDEV_SAMP()** returns **NULL** if there were no matching rows.

- **SUM([DISTINCT] expr)**

  Returns the sum of **expr**. If the return set has no rows, **SUM()** returns **NULL**. The **DISTINCT** keyword can be used to sum only the distinct values of **expr**.

  **SUM()** returns **NULL** if there were no matching rows.

- **VAR_POP(expr)**

  Returns the population variance of **expr**. The standard SQL function **VAR_POP()** can be used instead.

  **VAR_POP()** returns **NULL** if there were no matching rows.
Returns the population standard variance of \( expr \). It considers rows as the whole population, not as a sample, so it has the number of rows as the denominator. You can also use \( \text{VARIANCE()} \), which is equivalent but is not standard SQL.

\[ \text{VAR\_POP}(expr) \]

returns \( \text{NULL} \) if there were no matching rows.

* **VAR\_SAMP(expr)**

Returns the sample variance of \( expr \). That is, the denominator is the number of rows minus one.

\[ \text{VAR\_SAMP}(expr) \]

returns \( \text{NULL} \) if there were no matching rows.

* **VARIANCE(expr)**

Returns the population standard variance of \( expr \). This is an extension to standard SQL. The standard SQL function \( \text{VAR\_POP}(expr) \) can be used instead.

\[ \text{VARIANCE}(expr) \]

returns \( \text{NULL} \) if there were no matching rows.

### 12.17.2 GROUP BY Modifiers

The **GROUP BY** clause permits a **WITH ROLLUP** modifier that causes extra rows to be added to the summary output. These rows represent higher-level (or super-aggregate) summary operations. **ROLLUP** thus enables you to answer questions at multiple levels of analysis with a single query. It can be used, for example, to provide support for OLAP (Online Analytical Processing) operations.

Suppose that a table named **sales** has **year**, **country**, **product**, and **profit** columns for recording sales profitability:

```sql
CREATE TABLE sales
(
  year INT NOT NULL,
  country VARCHAR(20) NOT NULL,
  product VARCHAR(32) NOT NULL,
  profit INT
);
```

The table’s contents can be summarized per year with a simple **GROUP BY** like this:

```sql
mysql> SELECT year, SUM(profit) FROM sales GROUP BY year;
```

<table>
<thead>
<tr>
<th>year</th>
<th>SUM(profit)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>4525</td>
</tr>
<tr>
<td>2001</td>
<td>3010</td>
</tr>
</tbody>
</table>

This output shows the total profit for each year, but if you also want to determine the total profit summed over all years, you must add up the individual values yourself or run an additional query.

Or you can use **ROLLUP**, which provides both levels of analysis with a single query. Adding a **WITH ROLLUP** modifier to the **GROUP BY** clause causes the query to produce another row that shows the grand total over all year values:

```sql
mysql> SELECT year, SUM(profit) FROM sales GROUP BY year WITH ROLLUP;
```

<table>
<thead>
<tr>
<th>year</th>
<th>SUM(profit)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>4525</td>
</tr>
<tr>
<td>2001</td>
<td>3010</td>
</tr>
<tr>
<td>NULL</td>
<td>7535</td>
</tr>
</tbody>
</table>
The grand total super-aggregate line is identified by the value `NULL` in the `year` column.

`ROLLUP` has a more complex effect when there are multiple `GROUP BY` columns. In this case, each time there is a “break” (change in value) in any but the last grouping column, the query produces an extra super-aggregate summary row.

For example, without `ROLLUP`, a summary on the `sales` table based on `year`, `country`, and `product` might look like this:

```sql
mysql> SELECT year, country, product, SUM(profit) -> FROM sales -> GROUP BY year, country, product;
```

<table>
<thead>
<tr>
<th>year</th>
<th>country</th>
<th>product</th>
<th>SUM(profit)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>Finland</td>
<td>Computer</td>
<td>1500</td>
</tr>
<tr>
<td>2000</td>
<td>Finland</td>
<td>Phone</td>
<td>100</td>
</tr>
<tr>
<td>2000</td>
<td>India</td>
<td>Calculator</td>
<td>150</td>
</tr>
<tr>
<td>2000</td>
<td>India</td>
<td>Computer</td>
<td>1200</td>
</tr>
<tr>
<td>2000</td>
<td>USA</td>
<td>Calculator</td>
<td>75</td>
</tr>
<tr>
<td>2000</td>
<td>USA</td>
<td>Computer</td>
<td>1500</td>
</tr>
<tr>
<td>2001</td>
<td>Finland</td>
<td>Phone</td>
<td>10</td>
</tr>
<tr>
<td>2001</td>
<td>USA</td>
<td>Calculator</td>
<td>50</td>
</tr>
<tr>
<td>2001</td>
<td>USA</td>
<td>Computer</td>
<td>2700</td>
</tr>
<tr>
<td>2001</td>
<td>USA</td>
<td>NULL</td>
<td>250</td>
</tr>
</tbody>
</table>

The output indicates summary values only at the year/country/product level of analysis. When `ROLLUP` is added, the query produces several extra rows:

```sql
mysql> SELECT year, country, product, SUM(profit) -> FROM sales -> GROUP BY year, country, product WITH ROLLUP;
```

<table>
<thead>
<tr>
<th>year</th>
<th>country</th>
<th>product</th>
<th>SUM(profit)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>Finland</td>
<td>Computer</td>
<td>1500</td>
</tr>
<tr>
<td>2000</td>
<td>Finland</td>
<td>Phone</td>
<td>100</td>
</tr>
<tr>
<td>2000</td>
<td>Finland</td>
<td>NULL</td>
<td>1600</td>
</tr>
<tr>
<td>2000</td>
<td>India</td>
<td>Calculator</td>
<td>150</td>
</tr>
<tr>
<td>2000</td>
<td>India</td>
<td>Computer</td>
<td>1200</td>
</tr>
<tr>
<td>2000</td>
<td>India</td>
<td>NULL</td>
<td>1350</td>
</tr>
<tr>
<td>2000</td>
<td>USA</td>
<td>Calculator</td>
<td>75</td>
</tr>
<tr>
<td>2000</td>
<td>USA</td>
<td>Computer</td>
<td>1500</td>
</tr>
<tr>
<td>2000</td>
<td>USA</td>
<td>NULL</td>
<td>1575</td>
</tr>
<tr>
<td>2000</td>
<td>NULL</td>
<td>NULL</td>
<td>4525</td>
</tr>
<tr>
<td>2001</td>
<td>Finland</td>
<td>Phone</td>
<td>10</td>
</tr>
<tr>
<td>2001</td>
<td>Finland</td>
<td>NULL</td>
<td>10</td>
</tr>
<tr>
<td>2001</td>
<td>USA</td>
<td>Calculator</td>
<td>50</td>
</tr>
<tr>
<td>2001</td>
<td>USA</td>
<td>Computer</td>
<td>2700</td>
</tr>
<tr>
<td>2001</td>
<td>USA</td>
<td>TV</td>
<td>250</td>
</tr>
<tr>
<td>2001</td>
<td>USA</td>
<td>NULL</td>
<td>3000</td>
</tr>
<tr>
<td>2001</td>
<td>NULL</td>
<td>NULL</td>
<td>3010</td>
</tr>
<tr>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>7535</td>
</tr>
</tbody>
</table>

For this query, adding `ROLLUP` causes the output to include summary information at four levels of analysis, not just one. Here is how to interpret the `ROLLUP` output:

- Following each set of product rows for a given year and country, an extra summary row is produced showing the total for all products. These rows have the `product` column set to `NULL`.
- Following each set of rows for a given year, an extra summary row is produced showing the total for all countries and products. These rows have the `country` and `products` columns set to `NULL`. 
• Finally, following all other rows, an extra summary row is produced showing the grand total for all years, countries, and products. This row has the `year`, `country`, and `products` columns set to `NULL`.

**Other Considerations When using ROLLUP**

The following items list some behaviors specific to the MySQL implementation of `ROLLUP`.

When you use `ROLLUP`, you cannot also use an `ORDER BY` clause to sort the results. In other words, `ROLLUP` and `ORDER BY` are mutually exclusive. However, you still have some control over sort order. `GROUP BY` in MySQL sorts results, and you can use explicit `ASC` and `DESC` keywords with columns named in the `GROUP BY` list to specify sort order for individual columns. (The higher-level summary rows added by `ROLLUP` still appear after the rows from which they are calculated, regardless of the sort order.)

`LIMIT` can be used to restrict the number of rows returned to the client. `LIMIT` is applied after `ROLLUP`, so the limit applies against the extra rows added by `ROLLUP`. For example:

```sql
mysql> SELECT year, country, product, SUM(profit)
  -> FROM sales
  -> GROUP BY year, country, product WITH ROLLUP
  -> LIMIT 5;
+-----+---------+-----------+------------+
<table>
<thead>
<tr>
<th>year</th>
<th>country</th>
<th>product</th>
<th>SUM(profit)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>Finland</td>
<td>Computer</td>
<td>1500</td>
</tr>
<tr>
<td>2000</td>
<td>Finland</td>
<td>Phone</td>
<td>100</td>
</tr>
<tr>
<td>2000</td>
<td>Finland</td>
<td>NULL</td>
<td>1600</td>
</tr>
<tr>
<td>2000</td>
<td>India</td>
<td>Calculator</td>
<td>150</td>
</tr>
<tr>
<td>2000</td>
<td>India</td>
<td>Computer</td>
<td>1200</td>
</tr>
</tbody>
</table>
```

Using `LIMIT` with `ROLLUP` may produce results that are more difficult to interpret, because you have less context for understanding the super-aggregate rows.

The `NULL` indicators in each super-aggregate row are produced when the row is sent to the client. The server looks at the columns named in the `GROUP BY` clause following the leftmost one that has changed value. For any column in the result set with a name that is a lexical match to any of those names, its value is set to `NULL`. (If you specify grouping columns by column number, the server identifies which columns to set to `NULL` by number.)

Because the `NULL` values in the super-aggregate rows are placed into the result set at such a late stage in query processing, you cannot test them as `NULL` values within the query itself. For example, you cannot add `HAVING product IS NULL` to the query to eliminate from the output all but the super-aggregate rows.

On the other hand, the `NULL` values do appear as `NULL` on the client side and can be tested as such using any MySQL client programming interface.

MySQL permits a column that does not appear in the `GROUP BY` list to be named in the select list. In this case, the server is free to choose any value from this nonaggregated column in summary rows, and this includes the extra rows added by `WITH ROLLUP`. For example, in the following query, `country` is a nonaggregated column that does not appear in the `GROUP BY` list and values chosen for this column are indeterminate:

```sql
mysql> SELECT year, country, SUM(profit)
  -> FROM sales GROUP BY year WITH ROLLUP;
+-----+-----------+------------+
<table>
<thead>
<tr>
<th>year</th>
<th>country</th>
<th>SUM(profit)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>India</td>
<td>4525</td>
</tr>
<tr>
<td>2001</td>
<td>USA</td>
<td>3010</td>
</tr>
</tbody>
</table>
```
This behavior occurs if the `ONLY_FULL_GROUP_BY` SQL mode is not enabled. If that mode is enabled, the server rejects the query as illegal because `country` is not listed in the `GROUP BY` clause. For more information about nonaggregated columns and `GROUP BY`, see Section 12.17.3, "MySQL Handling of GROUP BY".

### 12.17.3 MySQL Handling of GROUP BY

In standard SQL, a query that includes a `GROUP BY` clause cannot refer to nonaggregated columns in the select list that are not named in the `GROUP BY` clause. For example, this query is illegal in standard SQL because the nonaggregated `name` column in the select list does not appear in the `GROUP BY`:

```
SELECT o.custid, c.name, MAX(o.payment)
FROM orders AS o, customers AS c
WHERE o.custid = c.custid
GROUP BY o.custid;
```

For the query to be legal, the `name` column must be omitted from the select list or named in the `GROUP BY` clause.

MySQL extends the standard SQL use of `GROUP BY` so that the select list can refer to nonaggregated columns not named in the `GROUP BY` clause. This means that the preceding query is legal in MySQL. You can use this feature to get better performance by avoiding unnecessary column sorting and grouping. However, this is useful primarily when all values in each nonaggregated column not named in the `GROUP BY` are the same for each group. The server is free to choose any value from each group, so unless they are the same, the values chosen are indeterminate. Furthermore, the selection of values from each group cannot be influenced by adding an `ORDER BY` clause. Result set sorting occurs after values have been chosen, and `ORDER BY` does not affect which values within each group the server chooses.

A similar MySQL extension applies to the `HAVING` clause. In standard SQL, a query cannot refer to nonaggregated columns in the `HAVING` clause that are not named in the `GROUP BY` clause. To simplify calculations, a MySQL extension permits references to such columns. This extension assumes that the nongrouped columns have the same group-wise values. Otherwise, the result is indeterminate.

To disable the MySQL `GROUP BY` extension and enable standard SQL behavior, enable the `ONLY_FULL_GROUP_BY` SQL mode. In this case, columns not named in the `GROUP BY` clause cannot be used in the select list or `HAVING` clause unless enclosed in an aggregate function.

The select list extension also applies to `ORDER BY`. That is, you can refer to nonaggregated columns in the `ORDER BY` clause that do not appear in the `GROUP BY` clause. (However, as mentioned previously, `ORDER BY` does not affect which values are chosen from nonaggregated columns; it only sorts them after they have been chosen.) This extension does not apply if the `ONLY_FULL_GROUP_BY` SQL mode is enabled.

If a query has aggregate functions and no `GROUP BY` clause, it cannot have nonaggregated columns in the select list, `HAVING` condition, or `ORDER BY` list with `ONLY_FULL_GROUP_BY` enabled:

```
mysql> SELECT name, MAX(age) FROM t;
ERROR 1140 (42000): Mixing of GROUP columns (MIN(),MAX(),COUNT(),...) with no GROUP columns is illegal if there is no GROUP BY clause
```

Without `GROUP BY`, there is a single group and it is indeterminate which `name` value to choose for the group.

Another MySQL extension to standard SQL permits references in the `HAVING` clause to aliased expressions in the select list. Enabling `ONLY_FULL_GROUP_BY` prevents this. For example, the
following query returns name values that occur only once in table orders; the query is accepted regardless of whether ONLY_FULL_GROUP_BY is enabled:

```sql
SELECT name, COUNT(name) FROM orders
GROUP BY name
HAVING COUNT(name) = 1;
```

The following query is accepted only if ONLY_FULL_GROUP_BY is disabled.

```sql
SELECT name, COUNT(name) AS c FROM orders
GROUP BY name
HAVING c = 1;
```

If you are trying to follow standard SQL, you cannot use expressions in GROUP BY clauses. As a workaround, use an alias for the expression:

```sql
SELECT id, FLOOR(value/100) AS val
FROM tbl_name
GROUP BY id, val;
```

MySQL permits expressions in GROUP BY clauses, so the alias is unnecessary:

```sql
SELECT id, FLOOR(value/100)
FROM tbl_name
GROUP BY id, FLOOR(value/100);
```

### 12.18 Precision Math

MySQL 5.1 provides support for precision math: numeric value handling that results in extremely accurate results and a high degree control over invalid values. Precision math is based on these two features:

- SQL modes that control how strict the server is about accepting or rejecting invalid data.
- The MySQL library for fixed-point arithmetic.

These features have several implications for numeric operations and provide a high degree of compliance with standard SQL:

- **Precise calculations**: For exact-value numbers, calculations do not introduce floating-point errors. Instead, exact precision is used. For example, MySQL treats a number such as `.0001` as an exact value rather than as an approximation, and summing it 10,000 times produces a result of exactly `1`, not a value that is merely “close” to `1`.

- **Well-defined rounding behavior**: For exact-value numbers, the result of `ROUND()` depends on its argument, not on environmental factors such as how the underlying C library works.

- **Platform independence**: Operations on exact numeric values are the same across different platforms such as Windows and Unix.

- **Control over handling of invalid values**: Overflow and division by zero are detectable and can be treated as errors. For example, you can treat a value that is too large for a column as an error rather than having the value truncated to lie within the range of the column's data type. Similarly, you can treat division by zero as an error rather than as an operation that produces a result of `NULL`. The choice of which approach to take is determined by the setting of the server SQL mode.

The following discussion covers several aspects of how precision math works, including possible incompatibilities with older applications. At the end, some examples are given that demonstrate how MySQL handles numeric operations precisely. For information about controlling the SQL mode, see Section 5.1.7, “Server SQL Modes”.

1158
12.18.1 Types of Numeric Values

The scope of precision math for exact-value operations includes the exact-value data types (integer and DECIMAL types) and exact-value numeric literals. Approximate-value data types and numeric literals are handled as floating-point numbers.

Exact-value numeric literals have an integer part or fractional part, or both. They may be signed. Examples: 1, .2, 3.4, −5, −6.78, +9.10.

Approximate-value numeric literals are represented in scientific notation with a mantissa and exponent. Either or both parts may be signed. Examples: 1.2E3, 1.2E−3, −1.2E3, −1.2E−3.

Two numbers that look similar may be treated differently. For example, 2.34 is an exact-value (fixed-point) number, whereas 2.34E0 is an approximate-value (floating-point) number.

The DECIMAL data type is a fixed-point type and calculations are exact. In MySQL, the DECIMAL type has several synonyms: NUMERIC, DEC, FIXED. The integer types also are exact-value types.

12.18.2 DECIMAL Data Type Characteristics

This section discusses the characteristics of the DECIMAL data type (and its synonyms) in MySQL 5.1, with particular regard to the following topics:

- Maximum number of digits
- Storage format
- Storage requirements
- The nonstandard MySQL extension to the upper range of DECIMAL columns

Possible incompatibilities with applications that are written for older versions of MySQL (prior to 5.0.3) are noted throughout this section.

The declaration syntax for a DECIMAL column is DECIMAL(M, D). The ranges of values for the arguments in MySQL 5.1 are as follows:

- M is the maximum number of digits (the precision). It has a range of 1 to 65. (Older versions of MySQL permitted a range of 1 to 254.)
- D is the number of digits to the right of the decimal point (the scale). It has a range of 0 to 30 and must be no larger than M.

The maximum value of 65 for M means that calculations on DECIMAL values are accurate up to 65 digits. This limit of 65 digits of precision also applies to exact-value numeric literals, so the maximum range of such literals differs from before. (In older versions of MySQL, decimal values could have up to 254 digits. However, calculations were done using floating-point and thus were approximate, not exact.)

Values for DECIMAL columns in MySQL 5.1 are stored using a binary format that packs nine decimal digits into 4 bytes. The storage requirements for the integer and fractional parts of each value are determined separately. Each multiple of nine digits requires 4 bytes, and any remaining digits left over require some fraction of 4 bytes. The storage required for remaining digits is given by the following table.

<table>
<thead>
<tr>
<th>Leftover Digits</th>
<th>Number of Bytes</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

1159
Leftover Digits | Number of Bytes
---|---
1–2 | 1
3–4 | 2
5–6 | 3
7–9 | 4

For example, a `DECIMAL(18,9)` column has nine digits on either side of the decimal point, so the integer part and the fractional part each require 4 bytes. A `DECIMAL(20,6)` column has fourteen integer digits and six fractional digits. The integer digits require four bytes for nine of the digits and 3 bytes for the remaining five digits. The six fractional digits require 3 bytes.

Unlike some older versions of MySQL, `DECIMAL` columns in MySQL 5.1 do not store a leading `+` character or `–` character or leading 0 digits. If you insert `+0003.1` into a `DECIMAL(5,1)` column, it is stored as `3.1`. For negative numbers, a literal `–` character is not stored. Applications that rely on the older behavior must be modified to account for this change.

`DECIMAL` columns in MySQL 5.1 do not permit values larger than the range implied by the column definition. For example, a `DECIMAL(3,0)` column supports a range of −999 to 999. A `DECIMAL(M,D)` column permits at most `M-D` digits to the left of the decimal point. This is not compatible with applications relying on older versions of MySQL that permitted storing an extra digit in lieu of a `+` sign.

The SQL standard requires that the precision of `NUMERIC(M,D)` be exactly `M` digits. For `DECIMAL(M,D)`, the standard requires a precision of at least `M` digits but permits more. In MySQL, `DECIMAL(M,D)` and `NUMERIC(M,D)` are the same, and both have a precision of exactly `M` digits.

For more detailed information about porting applications that rely on the old treatment of the `DECIMAL` data type, see the MySQL 5.0 Reference Manual.

### 12.18.3 Expression Handling

With precision math, exact-value numbers are used as given whenever possible. For example, numbers in comparisons are used exactly as given without a change in value. In strict SQL mode, for `INSERT` into a column with an exact data type (`DECIMAL` or integer), a number is inserted with its exact value if it is within the column range. When retrieved, the value should be the same as what was inserted. (If strict SQL mode is not enabled, truncation for `INSERT` is permissible.)

Handling of a numeric expression depends on what kind of values the expression contains:

- If any approximate values are present, the expression is approximate and is evaluated using floating-point arithmetic.
- If no approximate values are present, the expression contains only exact values. If any exact value contains a fractional part (a value following the decimal point), the expression is evaluated using `DECIMAL` exact arithmetic and has a precision of 65 digits. The term “exact” is subject to the limits of what can be represented in binary. For example, `1.0/3.0` can be approximated in decimal notation as `.333...`, but not written as an exact number, so `(1.0/3.0)*3.0` does not evaluate to exactly `1.0`.
- Otherwise, the expression contains only integer values. The expression is exact and is evaluated using integer arithmetic and has a precision the same as `BIGINT` (64 bits).

If a numeric expression contains any strings, they are converted to double-precision floating-point values and the expression is approximate.

Inserts into numeric columns are affected by the SQL mode, which is controlled by the `sql_mode` system variable. (See Section 5.1.7, “Server SQL Modes”) The following discussion mentions strict mode (selected by the `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` mode values) and `ERROR_FOR_DIVISION_BY_ZERO`. To turn on all restrictions, you can simply use `TRADITIONAL` mode, which includes both strict mode values and `ERROR_FOR_DIVISION_BY_ZERO`.
If a number is inserted into an exact type column (DECIMAL or integer), it is inserted with its exact value if it is within the column range.

If the value has too many digits in the fractional part, rounding occurs and a warning is generated. Rounding is done as described in Section 12.18.4, “Rounding Behavior”.

If the value has too many digits in the integer part, it is too large and is handled as follows:

- If strict mode is not enabled, the value is truncated to the nearest legal value and a warning is generated.
- If strict mode is enabled, an overflow error occurs.

Underflow is not detected, so underflow handling is undefined.

For inserts of strings into numeric columns, conversion from string to number is handled as follows if the string has nonnumeric contents:

- A string that does not begin with a number cannot be used as a number and produces an error in strict mode, or a warning otherwise. This includes the empty string.
- A string that begins with a number can be converted, but the trailing nonnumeric portion is truncated. If the truncated portion contains anything other than spaces, this produces an error in strict mode, or a warning otherwise.

By default, division by zero produces a result of NULL and no warning. By setting the SQL mode appropriately, division by zero can be restricted.

With the ERROR_FOR_DIVISION_BY_ZERO SQL mode enabled, MySQL handles division by zero differently:

- If strict mode is not enabled, a warning occurs.
- If strict mode is enabled, inserts and updates involving division by zero are prohibited, and an error occurs.

In other words, inserts and updates involving expressions that perform division by zero can be treated as errors, but this requires ERROR_FOR_DIVISION_BY_ZERO in addition to strict mode.

Suppose that we have this statement:

```
INSERT INTO t SET i = 1/0;
```

This is what happens for combinations of strict and ERROR_FOR_DIVISION_BY_ZERO modes.

<table>
<thead>
<tr>
<th>sql_mode</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>' ' (Default)</td>
<td>No warning, no error; i is set to NULL.</td>
</tr>
<tr>
<td>strict</td>
<td>No warning, no error; i is set to NULL.</td>
</tr>
<tr>
<td>ERROR_FOR_DIVISION_BY_ZERO</td>
<td>Warning, no error; i is set to NULL.</td>
</tr>
<tr>
<td>strict,ERROR_FOR_DIVISION_BY_ZERO</td>
<td>Error condition; no row is inserted.</td>
</tr>
</tbody>
</table>

### 12.18.4 Rounding Behavior

This section discusses precision math rounding for the \texttt{ROUND()} function and for inserts into columns with exact-value types (DECIMAL and integer).

The \texttt{ROUND()} function rounds differently depending on whether its argument is exact or approximate:
• For exact-value numbers, \texttt{ROUND()} uses the “round half up” rule: A value with a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negative. (In other words, it is rounded away from zero.) A value with a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative.

• For approximate-value numbers, the result depends on the C library. On many systems, this means that \texttt{ROUND()} uses the “round to nearest even” rule: A value with any fractional part is rounded to the nearest even integer.

The following example shows how rounding differs for exact and approximate values:

```
mysql> SELECT ROUND(2.5), ROUND(25E-1);
+------------+--------------+
| ROUND(2.5) | ROUND(25E-1) |
+------------+--------------+
| 3          | 2            |
```

For inserts into a \texttt{DECIMAL} or integer column, the target is an exact data type, so rounding uses “round half away from zero,” regardless of whether the value to be inserted is exact or approximate:

```
mysql> CREATE TABLE t (d DECIMAL(10,0));
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO t VALUES(2.5),(2.5E0);
Query OK, 2 rows affected, 2 warnings (0.00 sec)
Records: 2  Duplicates: 0  Warnings: 2
mysql> SELECT d FROM t;
+------+
| d    |
+------+
| 3    |
| 3    |
```

### 12.18.5 Precision Math Examples

This section provides some examples that show precision math query results in MySQL 5.1. These examples demonstrate the principles described in Section 12.18.3, “Expression Handling”, and Section 12.18.4, “Rounding Behavior”.

**Example 1.** Numbers are used with their exact value as given when possible:

```
mysql> SELECT (.1 + .2) = .3;
+----------------+
| (.1 + .2) = .3 |
+----------------+
| 1              |
```

For floating-point values, results are inexact:

```
mysql> SELECT (.1E0 + .2E0) = .3E0;
+----------------------+
| (.1E0 + .2E0) = .3E0 |
+----------------------+
|                    0 |
```

Another way to see the difference in exact and approximate value handling is to add a small number to a sum many times. Consider the following stored procedure, which adds \texttt{.0001} to a variable 1,000 times.
CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 0;
  DECLARE d DECIMAL(10,4) DEFAULT 0;
  DECLARE f FLOAT DEFAULT 0;
  WHILE i < 10000 DO
    SET d = d + .0001;
    SET f = f + .0001E0;
    SET i = i + 1;
  END WHILE;
  SELECT d, f;
END;

The sum for both \textit{d} and \textit{f} logically should be 1, but that is true only for the decimal calculation. The floating-point calculation introduces small errors:

\begin{verbatim}
| d     | f                    |
|--------+---------------------|
| 1.0000 | 0.99999999999991    |
\end{verbatim}

\textbf{Example 2.} Multiplication is performed with the scale required by standard SQL. That is, for two numbers \textit{X1} and \textit{X2} that have scale \textit{S1} and \textit{S2}, the scale of the result is \textit{S1} + \textit{S2}:

```
mysql> SELECT .01 * .01;
<table>
<thead>
<tr>
<th>.01 * .01</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.0001</td>
</tr>
</tbody>
</table>
```

\textbf{Example 3.} Rounding behavior for exact-value numbers is well-defined:

Rounding behavior (for example, with the \texttt{ROUND()} function) is independent of the implementation of the underlying C library, which means that results are consistent from platform to platform.

- Rounding for exact-value columns (\texttt{DECIMAL} and integer) and exact-valued numbers uses the “round half away from zero” rule. Values with a fractional part of .5 or greater are rounded away from zero to the nearest integer, as shown here:

```
mysql> SELECT ROUND(2.5), ROUND(-2.5);
<table>
<thead>
<tr>
<th>ROUND(2.5)</th>
<th>ROUND(-2.5)</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>-3</td>
</tr>
</tbody>
</table>
```

- Rounding for floating-point values uses the C library, which on many systems uses the “round to nearest even” rule. Values with any fractional part on such systems are rounded to the nearest even integer:

```
mysql> SELECT ROUND(2.5E0), ROUND(-2.5E0);
<table>
<thead>
<tr>
<th>ROUND(2.5E0)</th>
<th>ROUND(-2.5E0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>-2</td>
</tr>
</tbody>
</table>
```

\textbf{Example 4.} In strict mode, inserting a value that is out of range for a column causes an error, rather than truncation to a legal value.

When MySQL is not running in strict mode, truncation to a legal value occurs:
Example 5: In strict mode and with `ERROR_FOR_DIVISION_BY_ZERO` set, division by zero causes an error, not a result of `NULL`.

In nonstrict mode, division by zero has a result of `NULL`:

However, division by zero is an error if the proper SQL modes are in effect:
Example 6. Exact-value literals are evaluated as exact values.

Prior to MySQL 5.0.3, exact-value and approximate-value literals both are evaluated as double-precision floating-point values:

```sql
mysql> SELECT VERSION();
+------------+
| VERSION()  |
+------------+
| 4.1.18-log |
+------------+
1 row in set (0.01 sec)

mysql> CREATE TABLE t SELECT 2.5 AS a, 25E-1 AS b;
Query OK, 1 row affected (0.07 sec)
Records: 1  Duplicates: 0  Warnings: 0

mysql> DESCRIBE t;
+-------+-------------+------+-----+---------+-------+
| Field | Type        | Null | Key | Default | Extra |
|-------+-------------+------+-----+---------+-------|
| a     | double(3,1) |      |     | 0.0     |       |
| b     | double      |      |     | 0       |       |
+-------+-------------+------+-----+---------+-------+
2 rows in set (0.04 sec)
```

As of MySQL 5.0.3, the approximate-value literal is evaluated using floating point, but the exact-value literal is handled as DECIMAL:

```sql
mysql> SELECT VERSION();
+-----------------+
| VERSION()       |
+-----------------+
| 5.1.6-alpha-log |
+-----------------+
1 row in set (0.11 sec)

mysql> CREATE TABLE t SELECT 2.5 AS a, 25E-1 AS b;
Query OK, 1 row affected (0.01 sec)
Records: 1  Duplicates: 0  Warnings: 0

mysql> DESCRIBE t;
+-------+-----------------------+------+-----+---------+-------+
| Field  | Type                  | Null | Key | Default | Extra |
|--------+-----------------------+------+-----+---------+-------|
| a      | decimal(2,1) unsigned | NO   |     | 0.0     |       |
| b      | double                | NO   |     | 0       |       |
+-------+-----------------------+------+-----+---------+-------+
2 rows in set (0.01 sec)
```

Example 7. If the argument to an aggregate function is an exact numeric type, the result is also an exact numeric type, with a scale at least that of the argument.

Consider these statements:

```sql
mysql> CREATE TABLE t (i INT, d DECIMAL, f FLOAT);
mysql> INSERT INTO t VALUES(1,1,1);
mysql> CREATE TABLE y SELECT AVG(i), AVG(d), AVG(f) FROM t;

Before MySQL 5.0.3, the result is a double no matter the argument type:

```sql
mysql> DESCRIBE y;
+--------+--------------+------+-----+---------+-------+
| Field  | Type         | Null | Key | Default | Extra |
|--------+--------------+-------|-----+---------+-------|
| AVG(i) | double(17,4) | YES   | NULL | NULL    |       |
```
As of MySQL 5.0.3, the result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type:

```
mysql> DESCRIBE y;
+--------+---------------+------+-----+---------+-------+
| Field  | Type          | Null | Key | Default | Extra |
+--------+---------------+------+-----+---------+-------+
| AVG(i) | decimal(14,4) | YES  |     | NULL    |       |
| AVG(d) | decimal(14,4) | YES  |     | NULL    |       |
| AVG(f) | double        | YES  |     | NULL    |       |
+--------+---------------+------+-----+---------+-------+
```

The result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type.

This chapter describes the syntax for the SQL statements supported by MySQL.

### 13.1 Data Definition Statements

#### 13.1.1 ALTER DATABASE Syntax

```sql
ALTER (DATABASE | SCHEMA) [db_name]
    alter_specification ...

ALTER (DATABASE | SCHEMA) db_name
    UPGRADE DATA DIRECTORY NAME
```

**ALTER DATABASE** enables you to change the overall characteristics of a database. These characteristics are stored in the `db.opt` file in the database directory. To use **ALTER DATABASE**, you need the **ALTER** privilege on the database. **ALTER SCHEMA** is a synonym for **ALTER DATABASE**.

The database name can be omitted from the first syntax, in which case the statement applies to the default database.

**National Language Characteristics**

The **CHARACTER SET** clause changes the default database character set. The **COLLATE** clause changes the default database collation. Section 10.1, "Character Set Support", discusses character set and collation names.
You can see what character sets and collations are available using, respectively, the `SHOW CHARACTER SET` and `SHOW COLLATION` statements. See Section 13.7.5.4, “SHOW CHARACTER SET Syntax”, and Section 13.7.5.5, “SHOW COLLATION Syntax”, for more information.

If you change the default character set or collation for a database, stored routines that use the database defaults must be dropped and recreated so that they use the new defaults. (In a stored routine, variables with character data types use the database defaults if the character set or collation are not specified explicitly. See Section 13.1.15, “CREATE PROCEDURE and CREATE FUNCTION Syntax”.)

**Upgrading from Versions Older than MySQL 5.1**

The syntax that includes the `UPGRADE DATA DIRECTORY NAME` clause was added in MySQL 5.1.23. It updates the name of the directory associated with the database to use the encoding implemented in MySQL 5.1 for mapping database names to database directory names (see Section 9.2.3, “Mapping of Identifiers to File Names”). This clause is for use under these conditions:

- It is intended when upgrading MySQL to 5.1 or later from older versions.
- It is intended to update a database directory name to the current encoding format if the name contains special characters that need encoding.
- The statement is used by `mysqlcheck` (as invoked by `mysql_upgrade`).

For example, if a database in MySQL 5.0 has the name `a-b-c`, the name contains instances of the – (dash) character. In MySQL 5.0, the database directory is also named `a-b-c`, which is not necessarily safe for all file systems. In MySQL 5.1 and later, the same database name is encoded as `a@002db@002dc` to produce a file system-neutral directory name.

When a MySQL installation is upgraded to MySQL 5.1 or later from an older version, the server displays a name such as `a-b-c` (which is in the old format) as `#mysql50#a-b-c`, and you must refer to the name using the `#mysql50#` prefix. Use `UPGRADE DATA DIRECTORY NAME` in this case to explicitly tell the server to re-encode the database directory name to the current encoding format:

```sql
ALTER DATABASE `#mysql50#a-b-c` UPGRADE DATA DIRECTORY NAME;
```

After executing this statement, you can refer to the database as `a-b-c` without the special `#mysql50#` prefix.

### 13.1.2 ALTER EVENT Syntax

```sql
ALTER
  [DEFINER = { user | CURRENT_USER }]
  EVENT event_name
  [ON SCHEDULE schedule]
  [ON COMPLETION (NOT) PRESERVE]
  [RENAME TO new_event_name]
  [ENABLE | DISABLE | DISABLE ON SLAVE]
  [COMMENT 'comment']
  [DO event_body]
```

The `ALTER EVENT` statement changes one or more of the characteristics of an existing event without the need to drop and recreate it. The syntax for each of the `DEFINER`, `ON SCHEDULE`, `ON COMPLETION`, `COMMENT`, `ENABLE / DISABLE`, and `DO` clauses is exactly the same as when used with `CREATE EVENT`. (See Section 13.1.11, “CREATE EVENT Syntax”.)

Support for the `DEFINER` clause was added in MySQL 5.1.17.

Beginning with MySQL 5.1.12, this statement requires the `EVENT` privilege. When a user executes a successful `ALTER EVENT` statement, that user becomes the definer for the affected event.

(In MySQL 5.1.11 and earlier, an event could be altered only by its definer, or by a user having the `SUPER` privilege.)
**ALTER EVENT** works only with an existing event:

```sql
mysql> ALTER EVENT no_such_event
    > ON SCHEDULE
    > EVERY '2:3' DAY_HOUR;
ERROR 1517 (HY000): Unknown event 'no_such_event'
```

In each of the following examples, assume that the event named `myevent` is defined as shown here:

```sql
CREATE EVENT myevent
    ON SCHEDULE
    EVERY 6 HOUR
    COMMENT 'A sample comment.'
    DO
    UPDATE myschema.mytable SET mycol = mycol + 1;
```

The following statement changes the schedule for `myevent` from once every six hours starting immediately to once every twelve hours, starting four hours from the time the statement is run:

```sql
ALTER EVENT myevent
    ON SCHEDULE
    EVERY 12 HOUR
    STARTS CURRENT_TIMESTAMP + INTERVAL 4 HOUR;
```

It is possible to change multiple characteristics of an event in a single statement. This example changes the SQL statement executed by `myevent` to one that deletes all records from `mytable`; it also changes the schedule for the event such that it executes once, one day after this `ALTER EVENT` statement is run.

```sql
ALTER EVENT myevent
    ON SCHEDULE
    AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
    DO
    TRUNCATE TABLE myschema.mytable;
```

Specify the options in an `ALTER EVENT` statement only for those characteristics that you want to change; omitted options keep their existing values. This includes any default values for `CREATE EVENT` such as `ENABLE`.

To disable `myevent`, use this `ALTER EVENT` statement:

```sql
ALTER EVENT myevent
    DISABLE;
```

The `ON SCHEDULE` clause may use expressions involving built-in MySQL functions and user variables to obtain any of the `timestamp` or `interval` values which it contains. You cannot use stored routines or user-defined functions in such expressions, and you cannot use any table references; however, you can use `SELECT FROM DUAL`. This is true for both `ALTER EVENT` and `CREATE EVENT` statements.

Beginning with MySQL 5.1.13, references to stored routines, user-defined functions, and tables in such cases are specifically not permitted, and fail with an error (see Bug #22830).

Although an `ALTER EVENT` statement that contains another `ALTER EVENT` statement in its `DO` clause appears to succeed, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

To rename an event, use the `ALTER EVENT` statement's `RENAME TO` clause. This statement renames the event `myevent` to `yourevent`:

```sql
ALTER EVENT myevent
    RENAME TO yourevent;
```
You can also move an event to a different database using `ALTER EVENT ... RENAME TO ...` and `db_name.event_name` notation, as shown here:

```
ALTER EVENT olddb.myevent
    RENAME TO newdb.myevent;
```

To execute the previous statement, the user executing it must have the `EVENT` privilege on both the `olddb` and `newdb` databases.

**Note**

There is no `RENAME EVENT` statement.

Beginning with MySQL 5.1.18, a third value may also appear in place of `ENABLE` or `DISABLE`; `DISABLE ON SLAVE` is used on a replication slave to indicate an event which was created on the master and replicated to the slave, but which is not executed on the slave. Normally, `DISABLE ON SLAVE` is set automatically as required; however, there are some circumstances under which you may want or need to change it manually. See Section 16.4.1.12, “Replication of Invoked Features”, for more information.

### 13.1.3 ALTER LOGFILE GROUP Syntax

```
ALTER LOGFILE GROUP logfile_group
    ADD UNDOFILE 'file_name'
    [INITIAL_SIZE [=] size]
    [WAIT]
    [ENGINE [=] engine_name]
```

This statement adds an `UNDO` file named `file_name` to an existing log file group `logfile_group`. An `ALTER LOGFILE GROUP` statement has one and only one `ADD UNDOFILE` clause. No `DROP UNDOFILE` clause is currently supported.

**Note**

All MySQL Cluster Disk Data objects share the same namespace. This means that each Disk Data object must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and an undo log file with the same name, or an undo log file and a data file with the same name.

Prior to MySQL Cluster NDB 6.2.17, 6.3.23, and 6.4.3, path and file names for undo log files could not be longer than 128 characters. (Bug #31769)

The optional `INITIAL_SIZE` parameter sets the `UNDO` file's initial size in bytes; if not specified, the initial size default to `128M` (128 megabytes). You may optionally follow `size` with a one-letter abbreviation for an order of magnitude, similar to those used in `my.cnf`. Generally, this is one of the letters `M` (for megabytes) or `G` (for gigabytes).

On 32-bit systems, the maximum supported value for `INITIAL_SIZE` is `4G`. (Bug #29186)

Beginning with MySQL Cluster NDB 6.2.18, 6.3.24, and 7.0.4, the minimum permitted value for `INITIAL_SIZE` is `1M`. (Bug #29574)

**Note**

`WAIT` is parsed but otherwise ignored. This keyword has no effect in MySQL 5.1, MySQL Cluster NDB 6.x, or MySQL Cluster NDB 7.x, and is intended for future expansion.

The `ENGINE` parameter (required) determines the storage engine which is used by this log file group, with `engine_name` being the name of the storage engine. In MySQL 5.1, MySQL Cluster NDB 6.x,
and MySQL Cluster NDB 7.x, the only accepted values for \textit{engine\_name} are “NDCLUSTER” and “NDB”. The two values are equivalent.

Here is an example, which assumes that the log file group \texttt{lg\_3} has already been created using \texttt{CREATE LOGFILE GROUP} (see Section 13.1.14, “CREATE LOGFILE GROUP Syntax”):

\begin{verbatim}
ALTER LOGFILE GROUP lg_3
    ADD UNDOFILE 'undo_10.dat'
    INITIAL\_SIZE=32M
    ENGINE=NDCLUSTER;
\end{verbatim}

When \texttt{ALTER LOGFILE GROUP} is used with \texttt{ENGINE = NDCLUSTER} (alternatively, \texttt{ENGINE = NDB}), an \texttt{UNDO} log file is created on each MySQL Cluster data node. You can verify that the \texttt{UNDO} files were created and obtain information about them by querying the \texttt{INFORMATION\_SCHEMA\_FILES} table. For example:

\begin{verbatim}
mysql> SELECT FILE\_NAME, LOGFILE\_GROUP\_NUMBER, EXTRA
               -> FROM INFORMATION\_SCHEMA\_FILES
               -> WHERE LOGFILE\_GROUP\_NAME = 'lg\_3';
+-------------+----------------------+----------------+
<table>
<thead>
<tr>
<th>FILE_NAME</th>
<th>LOGFILE_GROUP_NUMBER</th>
<th>EXTRA</th>
</tr>
</thead>
<tbody>
<tr>
<td>newdata.dat</td>
<td>0</td>
<td>CLUSTER_NODE=3</td>
</tr>
<tr>
<td>newdata.dat</td>
<td>0</td>
<td>CLUSTER_NODE=4</td>
</tr>
<tr>
<td>undo_10.dat</td>
<td>11</td>
<td>CLUSTER_NODE=3</td>
</tr>
<tr>
<td>undo_10.dat</td>
<td>11</td>
<td>CLUSTER_NODE=4</td>
</tr>
</tbody>
</table>
+-------------+-----------------------+----------------+
4 rows in set (0.01 sec)
\end{verbatim}

(See Section 20.26.1, “The INFORMATION\_SCHEMA\_FILES Table”.)

Memory used for \texttt{UNDO\_BUFFER\_SIZE} comes from the global pool whose size is determined by the value of the \texttt{SharedGlobalMemory} data node configuration parameter. This includes any default value implied for this option by the setting of the \texttt{InitialLogFileGroup} data node configuration parameter.

\texttt{ALTER LOGFILE GROUP} was added in MySQL 5.1.6. It is useful only with Disk Data storage for MySQL Cluster. For more information, see Section 17.5.12, “MySQL Cluster Disk Data Tables”.

\subsection*{13.1.4 ALTER FUNCTION Syntax}

\begin{verbatim}
ALTER FUNCTION func\_name [characteristic \ldots]
\end{verbatim}

This statement can be used to change the characteristics of a stored function. More than one change may be specified in an \texttt{ALTER FUNCTION} statement. However, you cannot change the parameters or body of a stored function using this statement; to make such changes, you must drop and re-create the function using \texttt{DROP FUNCTION} and \texttt{CREATE FUNCTION}.

You must have the \texttt{ALTER ROUTINE} privilege for the function. (That privilege is granted automatically to the function creator.) If binary logging is enabled, the \texttt{ALTER FUNCTION} statement might also require the \texttt{SUPER} privilege, as described in Section 19.7, “Binary Logging of Stored Programs”.

\subsection*{13.1.5 ALTER PROCEDURE Syntax}

\begin{verbatim}
ALTER PROCEDURE proc\_name [characteristic \ldots]
\end{verbatim}

This statement can be used to change the characteristics of a stored procedure. More than one change may be specified in an \texttt{ALTER PROCEDURE} statement. However, you cannot change the parameters or body of a stored procedure using this statement; to make such changes, you must drop and re-create the procedure using \texttt{DROP PROCEDURE} and \texttt{CREATE PROCEDURE}.
This statement can be used to change the characteristics of a stored procedure. More than one change may be specified in an `ALTER PROCEDURE` statement. However, you cannot change the parameters or body of a stored procedure using this statement; to make such changes, you must drop and re-create the procedure using `DROP PROCEDURE` and `CREATE PROCEDURE`.

You must have the `ALTER ROUTINE` privilege for the procedure. By default, that privilege is granted automatically to the procedure creator. This behavior can be changed by disabling the `automatic_sp_privileges` system variable. See Section 19.2.2, “Stored Routines and MySQL Privileges”.

### 13.1.6 ALTER SERVER Syntax

```sql
ALTER SERVER  server_name
  OPTIONS (option [, option] ...)
```

Alters the server information for `server_name`, adjusting any of the options permitted in the `CREATE SERVER` statement. The corresponding fields in the `mysql.servers` table are updated accordingly. This statement requires the `SUPER` privilege.

For example, to update the `USER` option:

```sql
ALTER SERVER s OPTIONS (USER 'sally');
```

`ALTER SERVER` does not cause an automatic commit.

In MySQL 5.1, `ALTER SERVER` is written to the binary log only when using row-based logging. It is not logged when `binlog_format` is equal to `STATEMENT` or `MIXED`.

`ALTER SERVER` was added in MySQL 5.1.15.

### 13.1.7 ALTER TABLE Syntax

```sql
ALTER [ONLINE | OFFLINE] [IGNORE] TABLE tbl_name
  [alter_specification [, alter_specification] ...]
  [partition_options]
alter_specification:
table_options
  | ADD [COLUMN] col_name column_definition
  | [FIRST | AFTER col_name ]
  | ADD [COLUMN] (col_name column_definition,...)
  | ADD [INDEX] [index_name]
  | [index_type] (index_col_name,...) [index_option] ...  
  | ADD [CONSTRAINT [symbol]] PRIMARY KEY
  | [index_type] (index_col_name,...) [index_option] ...
  | ADD [CONSTRAINT [symbol]]
  | UNIQUE [INDEX] [index_name]
  | [index_type] (index_col_name,...) [index_option] ...  
  | ADD FULLTEXT [INDEX][KEY] [index_name]
  | (index_col_name,...) [index_option] ...
  | ADD SPATIAL [INDEX][KEY] [index_name]
  | (index_col_name,...) [index_option] ...
  | ADD [CONSTRAINT [symbol]]
  | FOREIGN KEY [index_name] (index_col_name,...)
  | reference_definition
  | ALTER [COLUMN] col_name [SET DEFAULT literal | DROP DEFAULT]
  | CHANGE [COLUMN] old_col_name new_col_name column_definition
  | [FIRST] [AFTER col_name]
  | MODIFY [COLUMN] col_name column_definition
  | [FIRST | AFTER col_name]
  | DROP [COLUMN] col_name
```

1173
ALTER TABLE Syntax

```
DROP PRIMARY KEY
DROP {INDEX|KEY} index_name
DROP FOREIGN KEY fk_symbol
DISABLE KEYS
ENABLE KEYS
RENAME [TO|AS] new_tbl_name
ORDER BY col_name [, col_name] ...
CONVERT TO CHARACTER SET charset_name [COLLATE collation_name]
[DEFAULT] CHARACTER SET [=] charset_name [COLLATE [=] collation_name]
DISCARD TABLESPACE
IMPORT TABLESPACE
ADD PARTITION (partition_definition)
DROP PARTITION partition_names
COALESCE PARTITION number
REORGANIZE PARTITION [partition_names INTO (partition_definitions)]
ANALYZE PARTITION {partition_names | ALL}
CHECK PARTITION {partition_names | ALL}
OPTIMIZE PARTITION {partition_names | ALL}
REBUILD PARTITION {partition_names | ALL}
REPAIR PARTITION {partition_names | ALL}
PARTITION BY partitioning_expression
REMOVE PARTITIONING

index_col_name:
    col_name [(length)] [ASC | DESC]

index_type:
    USING {BTREE | HASH}

index_option:
    KEY_BLOCK_SIZE [=] value
    | index_type
    | WITH PARSER parser_name

table_options:
    table_option [ , ] table_option ... (see CREATE TABLE options)

partition_options:
    (see CREATE TABLE options)
```

**ALTER TABLE** changes the structure of a table. For example, you can add or delete columns, create or destroy indexes, change the type of existing columns, or rename columns or the table itself. You can also change characteristics such as the storage engine used for the table or the table comment.

Following the table name, specify the alterations to be made. If none are given, **ALTER TABLE** does nothing.

The syntax for many of the permissible alterations is similar to clauses of the **CREATE TABLE** statement. See Section 13.1.17, “CREATE TABLE Syntax”, for more information.

**table_options** signifies table options of the kind that can be used in the **CREATE TABLE** statement, such as **ENGINE**, **AUTO_INCREMENT**, **AVG_ROW_LENGTH**, **MAX_ROWS**, or **ROW_FORMAT**. For a list of all table options and a description of each, see Section 13.1.17, “CREATE TABLE Syntax”. However, **ALTER TABLE** ignores the **DATA DIRECTORY** and **INDEX DIRECTORY** table options.

**partition_options** signifies options that can be used with partitioned tables. A number of partitioning-related extensions to **ALTER TABLE** were added in MySQL 5.1.5. These can be used with partitioned tables for repartitioning, for adding, dropping, merging, and splitting partitions, and for performing partitioning maintenance. It is possible for an **ALTER TABLE** statement to contain a **PARTITION BY** or **REMOVE PARTITIONING** clause in an addition to other alter specifications, but the **PARTITION BY** or **REMOVE PARTITIONING** clause must be specified last after any other specifications. The **ADD PARTITION**, **DROP PARTITION**, **COALESCE PARTITION**, **REORGANIZE PARTITION**, **ANALYZE PARTITION**, **CHECK PARTITION**, and **REPAIR PARTITION** options cannot be combined with other alter specifications in a single **ALTER TABLE**, since the options just listed act on individual partitions. For a list of partition options and a description of each, see Section 13.1.17, “CREATE TABLE Syntax”. For additional information, see Section 13.1.7.1, “ALTER TABLE Partition Operations”.
Some operations may result in warnings if attempted on a table for which the storage engine does not support the operation. These warnings can be displayed with `SHOW WARNINGS`. See Section 13.7.5.42, “SHOW WARNINGS Syntax”.

For information on troubleshooting `ALTER TABLE`, see Section B.5.6.1, “Problems with ALTER TABLE”.

### Storage, Performance, and Concurrency Considerations

In most cases, `ALTER TABLE` makes a temporary copy of the original table. MySQL waits for other operations that are modifying the table, then proceeds. It incorporates the alteration into the copy, deletes the original table, and renames the new one. While `ALTER TABLE` is executing, the original table is readable by other sessions. Updates and writes to the table that begin after the `ALTER TABLE` operation begins are stalled until the new table is ready, then are automatically redirected to the new table without any failed updates. The temporary copy of the original table is created in the database directory of the new table. This can differ from the database directory of the original table for `ALTER TABLE` operations that rename the table to a different database.

For `MyISAM` tables, you can speed up index re-creation (the slowest part of the alteration process) by setting the `myisam_sort_buffer_size` system variable to a high value.

For some operations, an in-place `ALTER TABLE` is possible that does not require a temporary table:

- **For `ALTER TABLE tbl_name RENAME TO new_tbl_name`** without any other options, MySQL simply renames any files that correspond to the table `tbl_name` without making a copy. (You can also use the `RENAME TABLE` statement to rename tables. See Section 13.1.33, “RENAME TABLE Syntax”.) Any privileges granted specifically for the renamed table are not migrated to the new name. They must be changed manually.

- **Alterations that modify only table metadata and not table data are immediate because the server only needs to alter the table `.frm` file, not touch table contents.** The following changes are fast alterations that can be made this way:

  - Renaming a column, except for the InnoDB storage engine.

  - Changing the default value of a column (except for NDB tables; see Limitations of NDBCLUSTER online operations).

  - Changing the definition of an ENUM or SET column by adding new enumeration or set members to the end of the list of valid member values, as long as the storage size of the data type does not change. For example, adding a member to a SET column that has 8 members changes the required storage per value from 1 byte to 2 bytes; this will require a table copy. Adding members in the middle of the list causes renumbering of existing members, which requires a table copy.

- **`ALTER TABLE` with ADD PARTITION, DROP PARTITION, COALESCE PARTITION, REBUILD PARTITION, or REORGANIZE PARTITION does not create any temporary tables (except when used with NDB tables); however, these operations can and do create temporary partition files.**

  ADD or DROP operations for RANGE or LIST partitions are immediate operations or nearly so. ADD or COALESCE operations for HASH or KEY partitions copy data between all partitions, unless LINEAR HASH or LINEAR KEY was used; this is effectively the same as creating a new table, although the ADD or COALESCE operation is performed partition by partition. REORGANIZE operations copy only changed partitions and do not touch unchanged ones.

  - Renaming an index, except for InnoDB.

  - Adding or dropping an index, for InnoDB (if InnoDB Plugin is used) and NDB.

You can force an `ALTER TABLE` operation that would otherwise not require a table copy to use the temporary table method (as supported in MySQL 5.0) by setting the `old_alter_table` system variable to `ON`.

1175
For **NDBCLUSTER** tables, operations that add and drop indexes on variable-width columns occur online, without any table copying and without blocking concurrent DML actions for most of their duration. See Section 13.1.7.2, “ALTER TABLE Online Operations in MySQL Cluster”.

**Usage Notes**

- To use **ALTER TABLE**, you need **ALTER**, **CREATE**, and **INSERT** privileges for the table. Renaming a table requires **ALTER** and **DROP** on the old table, **ALTER**, **CREATE**, and **INSERT** on the new table.

- **IGNORE** is a MySQL extension to standard SQL. It controls how **ALTER TABLE** works if there are duplicates on unique keys in the new table or if warnings occur when strict mode is enabled. If **IGNORE** is not specified, the copy is aborted and rolled back if duplicate-key errors occur. If **IGNORE** is specified, only one row is used of rows with duplicates on a unique key. The other conflicting rows are deleted. Incorrect values are truncated to the closest matching acceptable value.

- Pending **INSERT DELAYED** statements are lost if a table is write locked and **ALTER TABLE** is used to modify the table structure.

- **table_options** signifies table options of the kind that can be used in the **CREATE TABLE** statement, such as **ENGINE**, **AUTO_INCREMENT**, **AVG_ROW_LENGTH**, **MAX_ROWS**, or **ROW_FORMAT**. For a list of all table options and a description of each, see Section 13.1.17, “CREATE TABLE Syntax”. However, **ALTER TABLE** ignores the **DATA DIRECTORY** and **INDEX DIRECTORY** table options.

For example, to convert a table to be an **InnoDB** table, use this statement:

```sql
ALTER TABLE t1 ENGINE = InnoDB;
```

See Section 14.6.6.4, “Converting Tables from MyISAM to InnoDB” for considerations when switching tables to the **InnoDB** storage engine.

When you specify an **ENGINE** clause, **ALTER TABLE** rebuilds the table. This is true even if the table already has the specified storage engine.

The outcome of attempting to change a table’s storage engine is affected by whether the desired storage engine is available and the setting of the **NO_ENGINE_SUBSTITUTION** SQL mode, as described in Section 5.1.7, “Server SQL Modes”.

As of MySQL 5.1.11, to prevent inadvertent loss of data, **ALTER TABLE** cannot be used to change the storage engine of a table to **MERGE** or **BLACKHOLE**.

To change the value of the **AUTO_INCREMENT** counter to be used for new rows, do this:

```sql
ALTER TABLE t2 AUTO_INCREMENT = value;
```

You cannot reset the counter to a value less than or equal to any that have already been used. For **MyISAM**, if the value is less than or equal to the maximum value currently in the **AUTO_INCREMENT** column, the value is reset to the current maximum plus one. For **InnoDB**, if the value is less than the current maximum value in the column, no error occurs and the current sequence value is not changed.

- You can issue multiple **ADD**, **ALTER**, **DROP**, and **CHANGE** clauses in a single **ALTER TABLE** statement, separated by commas. This is a MySQL extension to standard SQL, which permits only one of each clause per **ALTER TABLE** statement. For example, to drop multiple columns in a single statement, do this:

  ```sql
  ALTER TABLE t2 DROP COLUMN c, DROP COLUMN d;
  ```

- **CHANGE col_name, DROP col_name**, and **DROP INDEX** are MySQL extensions to standard SQL.
• The word COLUMN is optional and can be omitted.

• column_definition clauses use the same syntax for ADD and CHANGE as for CREATE TABLE. See Section 13.1.17, “CREATE TABLE Syntax”.

• You can rename a column using a CHANGE old_col_name new_col_name column_definition clause. To do so, specify the old and new column names and the definition that the column currently has. For example, to rename an INTEGER column from \texttt{a} to \texttt{b}, you can do this:

\begin{verbatim}
ALTER TABLE t1 CHANGE a b INTEGER;
\end{verbatim}

To change a column's type but not the name, CHANGE syntax still requires an old and new column name, even if they are the same. For example:

\begin{verbatim}
ALTER TABLE t1 CHANGE b b BIGINT NOT NULL;
\end{verbatim}

You can also use MODIFY to change a column's type without renaming it:

\begin{verbatim}
ALTER TABLE t1 MODIFY b BIGINT NOT NULL;
\end{verbatim}

MODIFY is an extension to ALTER TABLE for Oracle compatibility.

When you use CHANGE or MODIFY, column_definition must include the data type and all attributes that should apply to the new column, other than index attributes such as PRIMARY KEY or UNIQUE. Attributes present in the original definition but not specified for the new definition are not carried forward. Suppose that a column \texttt{col1} is defined as INT UNSIGNED DEFAULT 1 COMMENT 'my column' and you modify the column as follows:

\begin{verbatim}
ALTER TABLE t1 MODIFY col1 BIGINT;
\end{verbatim}

The resulting column will be defined as BIGINT, but will not include the attributes UNSIGNED DEFAULT 1 COMMENT 'my column'. To retain them, the statement should be:

\begin{verbatim}
ALTER TABLE t1 MODIFY col1 BIGINT UNSIGNED DEFAULT 1 COMMENT 'my column';
\end{verbatim}

• When you change a data type using CHANGE or MODIFY, MySQL tries to convert existing column values to the new type as well as possible.

\begin{center}
\textbf{Warning}
\end{center}

This conversion may result in alteration of data. For example, if you shorten a string column, values may be truncated. To prevent the operation from succeeding if conversions to the new data type would result in loss of data, enable strict SQL mode before using ALTER TABLE (see Section 5.1.7, “Server SQL Modes”).

• To add a column at a specific position within a table row, use FIRST or AFTER col_name. The default is to add the column last. You can also use FIRST and AFTER in CHANGE or MODIFY operations to reorder columns within a table.

• ALTER ... SET DEFAULT or ALTER ... DROP DEFAULT specify a new default value for a column or remove the old default value, respectively. If the old default is removed and the column can be NULL, the new default is NULL. If the column cannot be NULL, MySQL assigns a default value as described in Section 11.6, “Data Type Default Values”.
• **DROP INDEX** removes an index. This is a MySQL extension to standard SQL. See Section 13.1.24, “DROP INDEX Syntax”. If you are unsure of the index name, use `SHOW INDEX FROM tbl_name`.

• If columns are dropped from a table, the columns are also removed from any index of which they are a part. If all columns that make up an index are dropped, the index is dropped as well. If you use `CHANGE` or `MODIFY` to shorten a column for which an index exists on the column, and the resulting column length is less than the index length, MySQL shortens the index automatically.

• If a table contains only one column, the column cannot be dropped. If what you intend is to remove the table, use `DROP TABLE` instead.

• **DROP PRIMARY KEY** drops the primary key. If there is no primary key, an error occurs. For information about the performance characteristics of primary keys, especially for InnoDB tables, see Section 8.3.2, “Using Primary Keys”.

If you add a **UNIQUE INDEX** or **PRIMARY KEY** to a table, MySQL stores it before any nonunique index to permit detection of duplicate keys as early as possible.

• Some storage engines permit you to specify an index type when creating an index. The syntax for the `index_type` specifier is **USING type_name**. For details about **USING**, see Section 13.1.13, “CREATE INDEX Syntax”. Before MySQL 5.1.10, **USING** can be given only before the index column list. As of 5.1.10, the preferred position is after the column list. Support for use of the option before the column list will be removed in a future MySQL release.

  `index_option` values specify additional options for an index. **USING** is one such option. For details about permissible `index_option` values, see Section 13.1.13, “CREATE INDEX Syntax”.

• After an **ALTER TABLE** statement, it may be necessary to run **ANALYZE TABLE** to update index cardinality information. See Section 13.7.5.23, “SHOW INDEX Syntax”.

• **ORDER BY** enables you to create the new table with the rows in a specific order. This option is useful primarily when you know that you are mostly to query the rows in a certain order most of the time. By using this option after major changes to the table, you might be able to get higher performance. In some cases, it might make sorting easier for MySQL if the table is in order by the column that you want to order it by later.

  **Note**
  The table does not remain in the specified order after inserts and deletes.

**ORDER BY** syntax permits one or more column names to be specified for sorting, each of which optionally can be followed by **ASC** or **DESC** to indicate ascending or descending sort order, respectively. The default is ascending order. Only column names are permitted as sort criteria; arbitrary expressions are not permitted. This clause should be given last after any other clauses.

**ORDER BY** does not make sense for InnoDB tables because InnoDB always orders table rows according to the clustered index.

  **Note**
  When used on a partitioned table, **ALTER TABLE ... ORDER BY** orders rows within each partition only.

• If you use **ALTER TABLE** on a MyISAM table, all nonunique indexes are created in a separate batch (as for **REPAIR TABLE**). This should make **ALTER TABLE** much faster when you have many indexes.

  For MyISAM tables, key updating can be controlled explicitly. Use **ALTER TABLE ... DISABLE KEYS** to tell MySQL to stop updating nonunique indexes. Then use **ALTER TABLE ... ENABLE KEYS** to re-create missing indexes. MyISAM does this with a special algorithm that is much faster.
than inserting keys one by one, so disabling keys before performing bulk insert operations should give a considerable speedup. Using `ALTER TABLE ... DISABLE KEYS` requires the `INDEX` privilege in addition to the privileges mentioned earlier.

While the nonunique indexes are disabled, they are ignored for statements such as `SELECT` and `EXPLAIN` that otherwise would use them.

`ENABLE KEYS` and `DISABLE KEYS` were not supported for partitioned tables prior to MySQL 5.1.11.

- If `ALTER TABLE` for an InnoDB table results in changes to column values (for example, because a column is truncated), InnoDB’s `FOREIGN KEY` constraint checks do not notice possible violations caused by changing the values.

- The `FOREIGN KEY` and `REFERENCES` clauses are supported by the InnoDB storage engine, which implements `ADD [CONSTRAINT [symbol]] FOREIGN KEY [index_name] (...) REFERENCES ... (...)`. See Section 14.6.6.6, “InnoDB and FOREIGN KEY Constraints”. For other storage engines, the clauses are parsed but ignored. The `CHECK` clause is parsed but ignored by all storage engines. See Section 13.1.17, “CREATE TABLE Syntax”. The reason for accepting but ignoring syntax clauses is for compatibility, to make it easier to port code from other SQL servers, and to run applications that create tables with references. See Section 1.8.2, “MySQL Differences from Standard SQL”.

For `ALTER TABLE`, unlike `CREATE TABLE`, `ADD FOREIGN KEY` ignores `index_name` if given and uses an automatically generated foreign key name. As a workaround, include the `CONSTRAINT` clause to specify the foreign key name:

```
ADD CONSTRAINT name FOREIGN KEY (....) ... 
```

---

**Important**

The inline `REFERENCES` specifications where the references are defined as part of the column specification are silently ignored by InnoDB. InnoDB only accepts `REFERENCES` clauses defined as part of a separate `FOREIGN KEY` specification.

---

**Note**

Partitioned InnoDB tables do not support foreign keys. See Section 18.5.2, “Partitioning Limitations Relating to Storage Engines”, for more information.

- InnoDB supports the use of `ALTER TABLE` to drop foreign keys:

```
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```

For more information, see Section 14.6.6.6, “InnoDB and FOREIGN KEY Constraints”.

- Adding and dropping a foreign key in separate clauses of a single `ALTER TABLE` statement may be problematic in some cases and is therefore unsupported. Use separate statements for each operation.

- For an InnoDB table that is created with its own tablespace in an `.ibd` file, that file can be discarded and imported. To discard the `.ibd` file, use this statement:

```
ALTER TABLE tbl_name DISCARD TABLESPACE;
```

This deletes the current `.ibd` file, so be sure that you have a backup first. Attempting to access the table while the tablespace file is discarded results in an error.

To import the backup `.ibd` file back into the table, copy it into the database directory, and then issue this statement:
ALTER TABLE tbl_name IMPORT TABLESPACE;

The tablespace file must have been created on the server into which it is imported later.

Note

The `ALTER TABLE ... IMPORT TABLESPACE` feature does not enforce foreign key constraints on imported data.

See Section 14.6.5.4, "InnoDB File-Per-Table Tablespaces".

- To change the table default character set and all character columns (CHAR, VARCHAR, TEXT) to a new character set, use a statement like this:

```sql
ALTER TABLE tbl_name CONVERT TO CHARACTER SET charset_name [COLLATE collation_name];
```

The statement also changes the collation of all character columns. If you specify no `COLLATE` clause to indicate which collation to use, the statement uses default collation for the character set. If this collation is inappropriate for the intended table use (for example, if it would change from a case-sensitive collation to a case-insensitive collation), specify a collation explicitly.

For a column that has a data type of VARCHAR or one of the TEXT types, `CONVERT TO CHARACTER SET` will change the data type as necessary to ensure that the new column is long enough to store as many characters as the original column. For example, a TEXT column has two length bytes, which store the byte-length of values in the column, up to a maximum of 65,535. For a latin1 TEXT column, each character requires a single byte, so the column can store up to 65,535 characters. If the column is converted to utf8, each character might require up to three bytes, for a maximum possible length of \(3 \times 65,535 = 196,605\) bytes. That length will not fit in a TEXT column's length bytes, so MySQL will convert the data type to MEDIUMTEXT, which is the smallest string type for which the length bytes can record a value of 196,605. Similarly, a VARCHAR column might be converted to MEDIUMTEXT.

To avoid data type changes of the type just described, do not use `CONVERT TO CHARACTER SET`. Instead, use `MODIFY` to change individual columns. For example:

```sql
ALTER TABLE t MODIFY latin1_text_col TEXT CHARACTER SET utf8;
ALTER TABLE t MODIFY latin1_varchar_col VARCHAR(M) CHARACTER SET utf8;
```

If you specify `CONVERT TO CHARACTER SET binary`, the CHAR, VARCHAR, and TEXT columns are converted to their corresponding binary string types (BINARY, VARBINARY, BLOB). This means that the columns no longer will have a character set and a subsequent `CONVERT TO` operation will not apply to them.

If `charset_name` is DEFAULT, the database character set is used.

Warning

The `CONVERT TO` operation converts column values between the character sets. This is not what you want if you have a column in one character set (like latin1) but the stored values actually use some other, incompatible character set (like utf8). In this case, you have to do the following for each such column:

```sql
ALTER TABLE t1 CHANGE c1 c1 BLOB;
ALTER TABLE t1 CHANGE c1 c1 TEXT CHARACTER SET utf8;
```
The reason this works is that there is no conversion when you convert to or from BLOB columns.

To change only the default character set for a table, use this statement:

```
ALTER TABLE tbl_name DEFAULT CHARACTER SET charset_name;
```

The word DEFAULT is optional. The default character set is the character set that is used if you do not specify the character set for columns that you add to a table later (for example, with `ALTER TABLE ... ADD column`).

When `foreign_key_checks` is enabled, which is the default setting, character set conversion is not permitted on tables that include a character string column used in a foreign key constraint. The workaround is to disable `foreign_key_checks` before performing the character set conversion. You must perform the conversion on both tables involved in the foreign key constraint before re-enabling `foreign_key_checks`. If you re-enable `foreign_key_checks` after converting only one of the tables, an `ON DELETE CASCADE` or `ON UPDATE CASCADE` operation could corrupt data in the referencing table due to implicit conversion that occurs during these operations (Bug #45290, Bug #74816).

With the `mysql_info()` C API function, you can find out how many rows were copied by `ALTER TABLE`, and (when `IGNORE` is used) how many rows were deleted due to duplication of unique key values. See Section 21.8.7.35, “mysql_info()”.

### 13.1.7.1 ALTER TABLE Partition Operations

A number of partitioning-related extensions to `ALTER TABLE` were added in MySQL 5.1.5. These can be used with partitioned tables for repartitioning, for adding, dropping, merging, and splitting partitions, and for performing partitioning maintenance.

It is possible for an `ALTER TABLE` statement to contain a `PARTITION BY` or `REMOVE PARTITIONING` clause in an addition to other alter specifications, but the `PARTITION BY` or `REMOVE PARTITIONING` clause must be specified last after any other specifications. The `ADD PARTITION`, `DROP PARTITION`, `COALESCE PARTITION`, `REORGANIZE PARTITION`, `ANALYZE PARTITION`, `CHECK PARTITION`, and `REPAIR PARTITION` options cannot be combined with other alter specifications in a single `ALTER TABLE`, since the options just listed act on individual partitions.

- Simply using a `partition_options` clause with `ALTER TABLE` on a partitioned table repartitions the table according to the partitioning scheme defined by the `partition_options`. This clause always begins with `PARTITION BY`, and follows the same syntax and other rules as apply to the `partition_options` clause for `CREATE TABLE` (see Section 13.1.17, “CREATE TABLE Syntax”, for more detailed information), and can also be used to partition an existing table that is not already partitioned. For example, consider a (nonpartitioned) table defined as shown here:

  ```
  CREATE TABLE t1 (  
    id INT,  
    year_col INT  
  );
  ```

  This table can be partitioned by `HASH`, using the `id` column as the partitioning key, into 8 partitions by means of this statement:

  ```
  ALTER TABLE t1  
    PARTITION BY HASH(id)  
    PARTITIONS 8;
  ```

  The table that results from using an `ALTER TABLE ... PARTITION BY` statement must follow the same rules as one created using `CREATE TABLE ... PARTITION BY`. This includes the rules
governing the relationship between any unique keys (including any primary key) that the table might have, and the column or columns used in the partitioning expression, as discussed in Section 18.5.1, “Partitioning Keys, Primary Keys, and Unique Keys”. The CREATE TABLE ... PARTITION BY rules for specifying the number of partitions also apply to ALTER TABLE ... PARTITION BY.

ALTER TABLE ... PARTITION BY became available in MySQL 5.1.6.

The partition_definition clause for ALTER TABLE ADD PARTITION supports the same options as the clause of the same name for the CREATE TABLE statement. (See Section 13.1.17, “CREATE TABLE Syntax”, for the syntax and description.) Suppose that you have the partitioned table created as shown here:

```
CREATE TABLE t1 (  
id INT,  
year_col INT  
)  
PARTITION BY RANGE (year_col) (  
    PARTITION p0 VALUES LESS THAN (1991),  
    PARTITION p1 VALUES LESS THAN (1995),  
    PARTITION p2 VALUES LESS THAN (1999)  
);
```

You can add a new partition `p3` to this table for storing values less than 2002 as follows:

```
ALTER TABLE t1 ADD PARTITION (PARTITION p3 VALUES LESS THAN (2002));
```

DROP PARTITION can be used to drop one or more RANGE or LIST partitions. This statement cannot be used with HASH or KEY partitions; instead, use COALESCE PARTITION (see below). Any data that was stored in the dropped partitions named in the partition_names list is discarded. For example, given the table `t1` defined previously, you can drop the partitions named `p0` and `p1` as shown here:

```
ALTER TABLE t1 DROP PARTITION p0, p1;
```

Note

DROP PARTITION does not work with tables that use the NDBCLUSTER storage engine. See Section 18.3.1, “Management of RANGE and LIST Partitions”, and Section 17.1.6, “Known Limitations of MySQL Cluster”.

ADD PARTITION and DROP PARTITION do not currently support IF [NOT] EXISTS.

Renames of partitioned table are supported. You can rename individual partitions indirectly using ALTER TABLE ... REORGANIZE PARTITION; however, this operation makes a copy of the partition's data.

COALESCE PARTITION can be used with a table that is partitioned by HASH or KEY to reduce the number of partitions by number. Suppose that you have created table `t2` using the following definition:

```
CREATE TABLE t2 (  
    name VARCHAR (30),  
    started DATE  
)  
PARTITION BY HASH( YEAR(started) )  
PARTITIONS 6;
```

You can reduce the number of partitions used by `t2` from 6 to 4 using the following statement:

```
ALTER TABLE t2 COALESCE PARTITION 2;
```
The data contained in the last `number` partitions will be merged into the remaining partitions. In this case, partitions 4 and 5 will be merged into the first 4 partitions (the partitions numbered 0, 1, 2, and 3).

To change some but not all the partitions used by a partitioned table, you can use `REORGANIZE PARTITION`. This statement can be used in several ways:

- To merge a set of partitions into a single partition. This can be done by naming several partitions in the `partition_names` list and supplying a single definition for `partition_definition`.
- To split an existing partition into several partitions. You can accomplish this by naming a single partition for `partition_names` and providing multiple `partition_definitions`.
- To change the ranges for a subset of partitions defined using `VALUES LESS THAN` or the value lists for a subset of partitions defined using `VALUES IN`.
- This statement may also be used without the `partition_names INTO (partition_definitions)` option on tables that are automatically partitioned using `HASH` partitioning to force redistribution of data. (Currently, only `NDBCLUSTER` tables are automatically partitioned in this way.) This is useful in MySQL Cluster NDB 7.0 and later where, after you have added new MySQL Cluster data nodes online to an existing MySQL Cluster, you wish to redistribute existing MySQL Cluster table data to the new data nodes. In such cases, you should invoke the statement with the `ONLINE` option; in other words, as shown here:

```
ALTER ONLINE TABLE table REORGANIZE PARTITION;
```

You cannot perform other DDL concurrently with online table reorganization—that is, no other DDL statements can be issued while an `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statement is executing. For more information about adding MySQL Cluster data nodes online, see Section 17.5.13, “Adding MySQL Cluster Data Nodes Online”.

`ALTER ONLINE TABLE ... REORGANIZE PARTITION` does not work with tables which were created using the `MAX_ROWS` option, because it uses the constant `MAX_ROWS` value specified in the original `CREATE TABLE` statement to determine the number of partitions required, so no new partitions are created. Beginning with MySQL Cluster NDB 7.0.32 and MySQL Cluster NDB 7.1.21, you can use `ALTER ONLINE TABLE ... MAX_ROWS=rows` to increase the maximum number of rows for the table; after this, `ALTER ONLINE TABLE ... REORGANIZE PARTITION` can use this new, larger value to increase the number of partitions. The value of `rows` must be greater than the value specified for `MAX_ROWS` in the original `CREATE TABLE` statement for this to work.

Attempting to use `REORGANIZE PARTITION` without the `partition_names INTO (partition_definitions)` option on explicitly partitioned tables results in the error.

**Note**

For partitions that have not been explicitly named, MySQL automatically provides the default names `p0, p1, p2`, and so on. As of MySQL 5.1.7, the same is true with regard to subpartitions.

For more detailed information about and examples of `ALTER TABLE ... REORGANIZE PARTITION` statements, see Section 18.3.1, “Management of RANGE and LIST Partitions”.

- Several additional options were introduced in MySQL 5.1.5 for providing partition maintenance and repair functionality analogous to that implemented for nonpartitioned tables by statements such as `CHECK TABLE` and `REPAIR TABLE` (which are also supported for partitioned tables, beginning with MySQL 5.1.27—see note at the end of this item). These include `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, `REBUILD PARTITION`, and `REPAIR PARTITION`. Each
of these options takes a `partition_names` clause consisting of one or more names of partitions, separated by commas. The partitions must already exist in the table to be altered. You can also use the `ALL` keyword in place of `partition_names`, in which case the statement acts on all partitions in the table. For more information and examples, see Section 18.3.3, “Maintenance of Partitions”.

Prior to MySQL 5.1.68, it was not safe to execute multiple concurrent `REBUILD TABLE` operations on partitioned tables, whether on the same or different tables. (Bug #14589559, Bug #66645)

Some MySQL storage engines, such as InnoDB, do not support per-partition optimization. For a partitioned table using such a storage engine, `ALTER TABLE ... OPTIMIZE PARTITION` rebuilds the entire table. This is a known issue. Beginning with MySQL 5.1.68, running this statement on such a table causes the entire table to be rebuilt and analyzed, and an appropriate warning to be issued. (Bug #11751825, Bug #42822)

To work around this problem, use the statements `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION` instead.

The `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, and `REPAIR PARTITION` options were disabled in MySQL 5.1.24, and re-enabled in MySQL 5.1.27. (Bug #20129) They are not supported for tables which are not partitioned; beginning with MySQL 5.1.31, they are not permitted for such tables.

Beginning with MySQL 5.1.27, you can use the statements `ANALYZE TABLE`, `CHECK TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` on partitioned tables. See Section 13.7.2, “Table Maintenance Statements”, for more information.

• `REMOVE PARTITIONING` was introduced in MySQL 5.1.8 for the purpose of removing a table's partitioning without otherwise affecting the table or its data. (Previously, this was done using the `ENGINE` option.) This option can be combined with other `ALTER TABLE` options such as those used to add, drop, or rename columns or indexes.

• In MySQL 5.1.7 and earlier, using the `ENGINE` option with `ALTER TABLE` caused any partitioning that a table might have had to be removed. Beginning with MySQL 5.1.8, this option merely changes the storage engine used by the table and no longer affects partitioning in any way.

Only a single instance of any one of the following options can be used in a given `ALTER TABLE` statement: `PARTITION BY`, `ADD PARTITION`, `DROP PARTITION`, `TRUNCATE PARTITION`, `REORGANIZE PARTITION`, or `COALESCE PARTITION`, `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, `REBUILD PARTITION`, `REPAIR PARTITION`.

For example, the following two statements are invalid:

```sql
ALTER TABLE t1 ANALYZE PARTITION p1, ANALYZE PARTITION p2;
ALTER TABLE t1 ANALYZE PARTITION p1, CHECK PARTITION p2;
```

In the first case, you can analyze partitions `p1` and `p2` of table `t1` concurrently using a single statement with a single `ANALYZE PARTITION` option that lists both of the partitions to be analyzed, like this:

```sql
ALTER TABLE t1 ANALYZE PARTITION p1, p2;
```

In the second case, it is not possible to perform `ANALYZE` and `CHECK` operations on different partitions of the same table concurrently. Instead, you must issue two separate statements, like this:

```sql
ALTER TABLE t1 ANALYZE PARTITION p1;
ALTER TABLE t1 CHECK PARTITION p2;
```

`ANALYZE`, `CHECK`, `OPTIMIZE`, `REBUILD`, `REPAIR`, and `TRUNCATE` operations are not allowed with subpartitions.
13.1.7.2 ALTER TABLE Online Operations in MySQL Cluster

Beginning with MySQL 5.1.17, operations that add and drop indexes on variable-width columns of NDBCLUSTER tables occur online. Online operations are noncopying; that is, they do not require that indexes be re-created. They do not lock the table being altered from access by other API nodes in a MySQL Cluster (but see Limitations later in this section). Such operations do not require single user mode for NDBCLUSTER table alterations made in a cluster with multiple API nodes; transactions can continue uninterrupted during online DDL operations.

The ONLINE keyword can be used to perform online ADD COLUMN, ADD INDEX (including CREATE INDEX statements), and DROP INDEX operations on NDBCLUSTER tables. Online renaming of NDBCLUSTER tables is also supported.

The ONLINE and OFFLINE keywords are supported only in MySQL Cluster NDB 6.2 (beginning with 6.2.5) and 6.3 (beginning with 6.3.2) or later. For earlier MySQL Cluster releases or standard MySQL 5.1 releases:

- The server determines automatically whether an ADD INDEX or DROP INDEX operation can be (and is) performed online or offline; if the column is of a variable-width data type, the operation is performed online. It is not possible to override the server behavior in this regard.
- Attempting to use the ONLINE or OFFLINE keyword in an ALTER TABLE, CREATE INDEX, or DROP INDEX statement results in an error.

Currently you cannot add disk-based columns to NDBCLUSTER tables online. This means that, if you wish to add an in-memory column to an NDBCLUSTER table that uses a table-level STORAGE DISK option, you must declare the new column as using memory-based storage explicitly. For example—assuming that you have already created tablespace tsl—suppose that you create table t1 as follows:

```sql
mysql> CREATE TABLE t1 (
    >   c1 INT NOT NULL PRIMARY KEY,
    >   c2 VARCHAR(30)
    > )
    > TABLESPACE tsl STORAGE DISK
    > ENGINE NDBCLUSTER;
Query OK, 0 rows affected (1.73 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

You can add a new in-memory column to this table online as shown here:

```sql
mysql> ALTER ONLINE TABLE t1 ADD COLUMN c3 INT COLUMN_FORMAT DYNAMIC STORAGE MEMORY;
Query OK, 0 rows affected (1.25 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

This statement fails if the STORAGE MEMORY option is omitted:

```sql
mysql> ALTER ONLINE TABLE t1 ADD COLUMN c3 INT COLUMN_FORMAT DYNAMIC;
ERROR 1235 (42000): This version of MySQL doesn't yet support 'ALTER ONLINE TABLE t1 ADD COLUMN c3 INT COLUMN_FORMAT DYNAMIC'
```

If you omit the COLUMN_FORMAT DYNAMIC option, the dynamic column format is employed automatically, but a warning is issued, as shown here:

```sql
mysql> ALTER ONLINE TABLE t1 ADD COLUMN c3 INT STORAGE MEMORY;
Query OK, 0 rows affected, 1 warning (1.17 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> SHOW WARNINGS;
+---------+------+---------------------------------------------------------------+
<table>
<thead>
<tr>
<th>Level</th>
<th>Code</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>Warning</td>
<td>1478</td>
<td>Converted FIXED field to DYNAMIC to enable on-line ADD COLUMN</td>
</tr>
</tbody>
</table>
```

1185
Prior to MySQL Cluster NDB 6.2.17, 6.3.23, and 6.4.3, adding in-memory columns to tables that were created using a table-level or column-level `STORAGE DISK` option did not work correctly. (Bug #42549)

Note

The `STORAGE` and `COLUMN_FORMAT` keywords are supported only in MySQL Cluster; in any other version of MySQL, attempting to use either of these keywords in a `CREATE TABLE` or `ALTER TABLE` statement results in an error.

In MySQL Cluster NDB 7.0 and later, it is also possible to use the statement `ALTER ONLINE TABLE ... REORGANIZE PARTITION` option on NDBCLUSTER tables. This can be used to redistribute MySQL Cluster data among new data nodes that have been added to the cluster online. For more information about this statement, see Section 13.1.7.1, “ALTER TABLE Partition Operations” For more information about adding data nodes online to a MySQL Cluster, see Section 17.5.13, “Adding MySQL Cluster Data Nodes Online”.

Prior to MySQL Cluster NDB 6.4.3, `ALTER ONLINE TABLE ... REORGANIZE PARTITION` option did not work correctly with Disk Data tables or with in-memory NDBCLUSTER tables having one or more disk-based columns. (Bug #42549)

Limitations of NDBCLUSTER online operations

Online `DROP_COLUMN` operations are not supported.

Online `ALTER_TABLE`, `CREATE_INDEX`, or `DROP_INDEX` statements that add columns or add or drop indexes are subject to the following limitations:

- A given online `ALTER_TABLE` can use only one of `ADD_COLUMN`, `ADD_INDEX`, or `DROP_INDEX`. One or more columns can be added online in a single statement; only one index may be created or dropped online in a single statement.

- An `ALTER_TABLE` statement that performs a rename while using the `ONLINE` or `OFFLINE` keyword cannot perform any other operations, including but not limited to `ADD_COLUMN`, `ADD_INDEX`, or `DROP_INDEX`. Beginning with MySQL Cluster NDB 6.3.52, MySQL Cluster NDB 7.0.38, and MySQL Cluster NDB 7.1.27, such statements are specifically disallowed, and fail with `ER_NOT_SUPPORTED_YET`. (Bug #16021021)

- The table being altered is not locked with respect to API nodes other than the one on which an online `ALTER_TABLE ADD_COLUMN, ADD_INDEX, or DROP_INDEX` operation (or `CREATE_INDEX` or `DROP_INDEX` statement) is run. However, the table is locked against any other operations originating on the same API node while the online operation is being executed.

- The table to be altered must have an explicit primary key; the hidden primary key created by the NDBCLUSTER storage engine is not sufficient for this purpose.

- The storage engine used by the table cannot be changed online.

- When used with MySQL Cluster Disk Data tables, it is not possible to change the storage type (`DISK` or `MEMORY`) of a column online. This means, that when you add or drop an index in such a way that
the operation would be performed online, and you want the storage type of the column or columns to be changed, you must use the \texttt{OFFLINE} keyword in the statement that adds or drops the index.

Columns to be added online cannot use the \texttt{BLOB} or \texttt{TEXT} type, and must meet the following criteria:

- The columns must be dynamic; that is, it must be possible to create them using \texttt{COLUMN\_FORMAT DYNAMIC}. If you omit the \texttt{COLUMN\_FORMAT DYNAMIC} option, the dynamic column format is employed automatically.

- The columns must permit \texttt{NULL} values and not have any explicit default value other than \texttt{NULL}. Columns added online are automatically created as \texttt{DEFAULT NULL}, as can be seen here:

  ```sql
  mysql> CREATE TABLE t1 (
  > c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY
  > ) ENGINE=NDBCLUSTER;
  Query OK, 0 rows affected (1.44 sec)
  mysql> ALTER ONLINE TABLE t1
  > ADD COLUMN c2 INT,
  > ADD COLUMN c3 INT;
  Query OK, 0 rows affected, 2 warnings (0.93 sec)
  mysql> SHOW CREATE TABLE t1
  *************************** 1. row ***************************
  Table: t1
  Create Table: CREATE TABLE `t1` (
  `c1` int(11) NOT NULL AUTO_INCREMENT,
  `c2` int(11) DEFAULT NULL,
  `c3` int(11) DEFAULT NULL,
  PRIMARY KEY (`c1`)
  ) ENGINE=ndbcluster DEFAULT CHARSET=latin1
  1 row in set (0.00 sec)
  ```

- The columns must be added following any existing columns. If you attempt to add a column online before any existing columns or using the \texttt{FIRST} keyword, the statement fails with an error.

- Existing table columns cannot be reordered online.

For online \texttt{ALTER TABLE} operations on \texttt{NDBCLUSTER} tables, fixed-format columns are converted to dynamic when they are added online, or when indexes are created or dropped online, as shown here:

  ```sql
  mysql> CREATE TABLE t1 (
  > c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY
  > ) ENGINE=NDBCLUSTER;
  Query OK, 0 rows affected (1.44 sec)
  mysql> ALTER ONLINE TABLE t1 ADD COLUMN c2 INT, ADD COLUMN c3 INT;
  Query OK, 0 rows affected, 2 warnings (0.93 sec)
  Records: 0  Duplicates: 0  Warnings: 0
  mysql> SHOW WARNINGS;
  +---------+------+---------------------------------------------------------------+
  | Level   | Code | Message                                                       |
  +---------+------+---------------------------------------------------------------+
  | Warning | 1475 | Converted FIXED field to DYNAMIC to enable on-line ADD COLUMN |
  | Warning | 1475 | Converted FIXED field to DYNAMIC to enable on-line ADD COLUMN |
  +---------+------+---------------------------------------------------------------+
  2 rows in set (0.00 sec)
  ```

\textbf{Note}

Existing columns, including the table's primary key, need not be dynamic; only the column or columns to be added online must be dynamic.

  ```sql
  mysql> CREATE TABLE t2 (
  > c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY COLUMN\_FORMAT FIXED
  > ) ENGINE=NDBCLUSTER;
  Query OK, 0 rows affected (1.44 sec)
  ```
ALTER TABLE Syntax

> ) ENGINE=NDBCluster;
Query OK, 0 rows affected (2.10 sec)

mysql> ALTER ONLINE TABLE t2 ADD COLUMN c2 INT;
Query OK, 0 rows affected, 1 warning (0.78 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> SHOW WARNINGS;
+---------+------+---------------------------------------------------------------+
| Level   | Code | Message                                                       |
+---------+------+---------------------------------------------------------------+
| Warning | 1475 | Converted FIXED field to DYNAMIC to enable on-line ADD COLUMN |
+---------+------+---------------------------------------------------------------+
1 row in set (0.00 sec)

Columns are not converted from FIXED to DYNAMIC column format by renaming operations. For more
information about COLUMN_FORMAT, see Section 13.1.17, “CREATE TABLE Syntax”.

The KEY, CONSTRAINT, and IGNORE keywords are supported in ALTER TABLE statements using the
ONLINE keyword.

13.1.7.3 ALTER TABLE Examples

Begin with a table t1 that is created as shown here:

CREATE TABLE t1 (a INTEGER,b CHAR(10));

To rename the table from t1 to t2:

ALTER TABLE t1 RENAME t2;

To change column a from INTEGER to TINYINT NOT NULL (leaving the name the same), and to
change column b from CHAR(10) to CHAR(20) as well as renaming it from b to c:

ALTER TABLE t2 MODIFY a TINYINT NOT NULL, CHANGE b c CHAR(20);

To add a new TIMESTAMP column named d:

ALTER TABLE t2 ADD d TIMESTAMP;

To add an index on column d and a UNIQUE index on column a:

ALTER TABLE t2 ADD INDEX (d), ADD UNIQUE (a);

To remove column c:

ALTER TABLE t2 DROP COLUMN c;

To add a new AUTO_INCREMENT integer column named c:

ALTER TABLE t2 ADD c INT UNSIGNED NOT NULL AUTO_INCREMENT,
ADD PRIMARY KEY (c);

We indexed c (as a PRIMARY KEY) because AUTO_INCREMENT columns must be indexed, and we
declare c as NOT NULL because primary key columns cannot be NULL.

For NDB tables, it is also possible to change the storage type used for a table or column. For example,
consider an NDB table created as shown here:

mysql> CREATE TABLE t1 (c1 INT) TABLESPACE ts_1 ENGINE NDB;
Query OK, 0 rows affected (1.27 sec)
To convert this table to disk-based storage, you can use the following `ALTER TABLE` statement:

```sql
mysql> ALTER TABLE t1 TABLESPACE ts_1 STORAGE DISK;
Query OK, 0 rows affected (2.99 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

```sql
mysql> SHOW CREATE TABLE t1\G
*************************** 1. row ***************************
Table: t1
Create Table: CREATE TABLE `t1` (  `c1` int(11) DEFAULT NULL ) /*!50100 TABLESPACE ts_1 STORAGE DISK */
ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.01 sec)
```

It is not necessary that the tablespace was referenced when the table was originally created; however, the tablespace must be referenced by the `ALTER TABLE`:

```sql
mysql> CREATE TABLE t2 (c1 INT) TABLESPACE ts_1 ENGINE NDB;
Query OK, 0 rows affected (1.00 sec)
```

```sql
mysql> ALTER TABLE t2 STORAGE DISK;
ERROR 1005 (HY000): Can't create table 'c.#sql-1750_3' (errno: 140)
```

```sql
mysql> ALTER TABLE t2 TABLESPACE ts_1 STORAGE DISK;
Query OK, 0 rows affected (3.42 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

To change the storage type of an individual column, you can use `ALTER TABLE ... MODIFY [COLUMN]`. For example, suppose you create a MySQL Cluster Disk Data table with two columns, using this `CREATE TABLE` statement:

```sql
mysql> CREATE TABLE t3 (c1 INT, c2 INT) TABLESPACE ts_1 STORAGE DISK ENGINE NDB;
Query OK, 0 rows affected (1.34 sec)
```

To change column `c2` from disk-based to in-memory storage, include a `STORAGE MEMORY` clause in the column definition used by the `ALTER TABLE` statement, as shown here:

```sql
mysql> ALTER TABLE t3 MODIFY c2 INT STORAGE MEMORY;
Query OK, 0 rows affected (3.14 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

You can make an in-memory column into a disk-based column by using `STORAGE DISK` in a similar fashion.

Column `c1` uses disk-based storage, since this is the default for the table (determined by the table-level `STORAGE DISK` clause in the `CREATE TABLE` statement). However, column `c2` uses in-memory storage, as can be seen here in the output of `SHOW CREATE TABLE`:

```sql
mysql> SHOW CREATE TABLE t3\G
*************************** 1. row ***************************
Table: t3
Create Table: CREATE TABLE `t3` (  `c1` int(11) DEFAULT NULL,  `c2` int(11) /*!50120 STORAGE MEMORY */ DEFAULT NULL ) /*!50100 TABLESPACE ts_1 STORAGE DISK */
ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.02 sec)
```
When you add an `AUTO_INCREMENT` column, column values are filled in with sequence numbers automatically. For `MyISAM` tables, you can set the first sequence number by executing `SET INSERT_ID=value` before `ALTER TABLE` or by using the `AUTO_INCREMENT=value` table option. See Section 5.1.4, "Server System Variables".

With `MyISAM` tables, if you do not change the `AUTO_INCREMENT` column, the sequence number is not affected. If you drop an `AUTO_INCREMENT` column and then add another `AUTO_INCREMENT` column, the numbers are resequenced beginning with 1.

When replication is used, adding an `AUTO_INCREMENT` column to a table might not produce the same ordering of the rows on the slave and the master. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the master and slave, the rows must be ordered before assigning an `AUTO_INCREMENT` number. Assuming that you want to add an `AUTO_INCREMENT` column to the table `t1`, the following statements produce a new table `t2` identical to `t1` but with an `AUTO_INCREMENT` column:

```sql
CREATE TABLE t2 (id INT AUTO_INCREMENT PRIMARY KEY)
SELECT * FROM t1 ORDER BY col1, col2;
```

This assumes that the table `t1` has columns `col1` and `col2`.

This set of statements will also produce a new table `t2` identical to `t1`, with the addition of an `AUTO_INCREMENT` column:

```sql
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

Important
To guarantee the same ordering on both master and slave, all columns of `t1` must be referenced in the `ORDER BY` clause.

Regardless of the method used to create and populate the copy having the `AUTO_INCREMENT` column, the final step is to drop the original table and then rename the copy:

```sql
DROP TABLE t1;
ALTER TABLE t2 RENAME t1;
```

13.1.8 ALTER TABLESPACE Syntax

```
ALTER TABLESPACE tablespace_name
  [ADD|DROP] DATAFILE 'file_name'
  [INITIAL_SIZE [=] size]
  [WAIT]
  ENGINE [=] engine_name
```

This statement can be used either to add a new data file, or to drop a data file from a tablespace.

The `ADD DATAFILE` variant enables you to specify an initial size using an `INITIAL_SIZE` clause, where `size` is measured in bytes; the default value is `128M` (128 megabytes). You may optionally follow this integer value with a one-letter abbreviation for an order of magnitude, similar to those used in `my.cnf`. Generally, this is one of the letters `M` (for megabytes) or `G` (for gigabytes).

Note
All MySQL Cluster Disk Data objects share the same namespace. This means that each Disk Data object must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and an data file with the same name, or an undo log file and a with the same name.
Prior to MySQL Cluster NDB 6.2.17, 6.3.23, and 6.4.3, path and file names for data files could not be longer than 128 characters. (Bug #31770)

On 32-bit systems, the maximum supported value for `INITIAL_SIZE` is 4G. (Bug #29186)

`INITIAL_SIZE` is rounded as for `CREATE TABLESPACE`. Beginning with MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.32, MySQL Cluster NDB 7.0.13, and MySQL Cluster NDB 7.1.2, this rounding is done explicitly (also as with `CREATE TABLESPACE`).

Once a data file has been created, its size cannot be changed; however, you can add more data files to the tablespace using additional `ALTER TABLESPACE ... ADD DATAFILE` statements.

Using `DROP DATAFILE` with `ALTER TABLESPACE` drops the data file `file_name` from the tablespace. You cannot drop a data file from a tablespace which is in use by any table; in other words, the data file must be empty (no extents used). See Section 17.5.12.1, “MySQL Cluster Disk Data Objects”. In addition, any data file to be dropped must previously have been added to the tablespace with `CREATE TABLESPACE` or `ALTER TABLESPACE`.

Both `ALTER TABLESPACE ... ADD DATAFILE` and `ALTER TABLESPACE ... DROP DATAFILE` require an `ENGINE` clause which specifies the storage engine used by the tablespace. In MySQL 5.1, the only accepted values for `engine_name` are NDB and NDDBCLUSTER.

`WAIT` is parsed but otherwise ignored, and so has no effect in MySQL 5.1. It is intended for future expansion.

When `ALTER TABLESPACE ... ADD DATAFILE` is used with `ENGINE = NDB`, a data file is created on each Cluster data node. You can verify that the data files were created and obtain information about them by querying the `INFORMATION_SCHEMA.FILES` table. For example, the following query shows all data files belonging to the tablespace named `newts`:

```
mysql> SELECT LOGFILE_GROUP_NAME, FILE_NAME, EXTRA
    -> FROM INFORMATION_SCHEMA.FILES
    -> WHERE TABLESPACE_NAME = 'newts' AND FILE_TYPE = 'DATAFILE';
+--------------------+--------------+----------------+
<table>
<thead>
<tr>
<th>LOGFILE_GROUP_NAME</th>
<th>FILE_NAME</th>
<th>EXTRA</th>
</tr>
</thead>
<tbody>
<tr>
<td>lg_3</td>
<td>newdata.dat</td>
<td>CLUSTER_NODE=3</td>
</tr>
<tr>
<td>lg_3</td>
<td>newdata.dat</td>
<td>CLUSTER_NODE=4</td>
</tr>
<tr>
<td>lg_3</td>
<td>newdata2.dat</td>
<td>CLUSTER_NODE=3</td>
</tr>
<tr>
<td>lg_3</td>
<td>newdata2.dat</td>
<td>CLUSTER_NODE=4</td>
</tr>
</tbody>
</table>
+--------------------+--------------+----------------+
2 rows in set (0.03 sec)
```

See Section 20.26.1, “The INFORMATION_SCHEMA FILES Table”.

`ALTER TABLESPACE` was added in MySQL 5.1.6. In MySQL 5.1, it is useful only with Disk Data storage for MySQL Cluster. See Section 17.5.12, “MySQL Cluster Disk Data Tables”.

13.1.9 ALTER VIEW Syntax

This statement changes the definition of a view, which must exist. The syntax is similar to that for `CREATE VIEW` and the effect is the same as for `CREATE OR REPLACE VIEW`. See Section 13.1.20, “CREATE VIEW Syntax”. This statement requires the `CREATE VIEW` and `DROP` privileges for the view, and some privilege for each column referred to in the `SELECT` statement. As of MySQL 5.1.23, `ALTER VIEW` is permitted only to the definer or users with the `SUPER` privilege.
CREATE DATABASE Syntax

13.1.10 CREATE DATABASE Syntax

```
CREATE (DATABASE | SCHEMA) [IF NOT EXISTS] db_name
[create_specification] ...
create_specification:
    [DEFAULT] CHARACTER SET [=] charset_name
    | [DEFAULT] COLLATE [=] collation_name
```

CREATE DATABASE creates a database with the given name. To use this statement, you need the CREATE privilege for the database. CREATE SCHEMA is a synonym for CREATE DATABASE.

An error occurs if the database exists and you did not specify IF NOT EXISTS.

create_specification options specify database characteristics. Database characteristics are stored in the db.opt file in the database directory. The CHARACTER SET clause specifies the default database character set. The COLLATE clause specifies the default database collation. Section 10.1, “Character Set Support”, discusses character set and collation names.

A database in MySQL is implemented as a directory containing files that correspond to tables in the database. Because there are no tables in a database when it is initially created, the CREATE DATABASE statement creates only a directory under the MySQL data directory and the db.opt file. Rules for permissible database names are given in Section 9.2, “Schema Object Names”. If a database name contains special characters, the name for the database directory contains encoded versions of those characters as described in Section 9.2.3, “Mapping of Identifiers to File Names”.

If you manually create a directory under the data directory (for example, with `mkdir`), the server considers it a database directory and it shows up in the output of `SHOW DATABASES`.

You can also use the `mysqladmin` program to create databases. See Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”.

13.1.11 CREATE EVENT Syntax

```
CREATE [DEFINER = { user | CURRENT_USER }] EVENT [IF NOT EXISTS] event_name ON SCHEDULE schedule [ON COMPLETION [NOT] PRESERVE] [ENABLE | DISABLE | DISABLE ON SLAVE] [COMMENT 'comment'] DO event_body;

schedule:
    AT timestamp [+ INTERVAL interval] ...
    | EVERY interval
    | [STARTS timestamp [+ INTERVAL interval] ...]
    [ENDS timestamp [+ INTERVAL interval] ...]

interval:
    quantity (YEAR | QUARTER | MONTH | DAY | HOUR | MINUTE |
    WEEK | SECOND | YEAR_MONTH | DAY_HOUR | DAY_MINUTE |
    DAY_SECOND | HOUR_MINUTE | HOUR_SECOND | MINUTE_SECOND)
```

This statement creates and schedules a new event. The event will not run unless the Event Scheduler is enabled. For information about checking Event Scheduler status and enabling it if necessary, see Section 19.4.2, “Event Scheduler Configuration”.

CREATE EVENT requires the EVENT privilege for the schema in which the event is to be created. It might also require the SUPER privilege, depending on the DEFINER value, as described later in this section.
The minimum requirements for a valid `CREATE EVENT` statement are as follows:

- The keywords `CREATE EVENT` plus an event name, which uniquely identifies the event within a database schema. (Prior to MySQL 5.1.12, the event name needed to be unique only among events created by the same user within a schema.)

- An `ON SCHEDULE` clause, which determines when and how often the event executes.

- A `DO` clause, which contains the SQL statement to be executed by an event.

This is an example of a minimal `CREATE EVENT` statement:

```sql
CREATE EVENT myevent
    ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
    DO
        UPDATE myschema.mytable SET mycol = mycol + 1;
```

The previous statement creates an event named `myevent`. This event executes once—one hour following its creation—by running an SQL statement that increments the value of the `myschema.mytable` table's `mycol` column by 1.

The `event_name` must be a valid MySQL identifier with a maximum length of 64 characters. Event names are not case sensitive, so you cannot have two events named `myevent` and `MyEvent` in the same schema. In general, the rules governing event names are the same as those for names of stored routines. See Section 9.2, “Schema Object Names”.

An event is associated with a schema. If no schema is indicated as part of `event_name`, the default (current) schema is assumed. To create an event in a specific schema, qualify the event name with a schema using `schema_name.event_name` syntax.

The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at event execution time. If a `user` value is given, it should be a MySQL account specified as `'user_name'@'host_name'` (the same format used in the `GRANT` statement), `CURRENT_USER`, or `CURRENT_USER()`.

The default `DEFINER` value is the user who executes the `CREATE EVENT` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

If you specify the `DEFINER` clause, these rules determine the valid `DEFINER` user values:

- If you do not have the `SUPER` privilege, the only permitted `user` value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definier to some other account.

- If you have the `SUPER` privilege, you can specify any syntactically valid account name. If the account does not exist, a warning is generated.

- Although it is possible to create an event with a nonexistent `DEFINER` account, an error occurs at event execution time if the account does not exist.

For more information about event security, see Section 19.6, “Access Control for Stored Programs and Views”.

The `DEFINER` clause was added in MySQL 5.1.17.

Within an event, the `CURRENT_USER()` function returns the account used to check privileges at event execution time, which is the `DEFINER` user. For information about user auditing within events, see Section 6.3.6, “SQL-Based MySQL Account Activity Auditing”.

`IF NOT EXISTS` has the same meaning for `CREATE EVENT` as for `CREATE TABLE`: If an event named `event_name` already exists in the same schema, no action is taken, and no error results. (However, a warning is generated in such cases.)

The `ON SCHEDULE` clause determines when, how often, and for how long the `event_body` defined for the event repeats. This clause takes one of two forms:
CREATE EVENT Syntax

- **AT timestamp** is used for a one-time event. It specifies that the event executes one time only at the date and time given by *timestamp*, which must include both the date and time, or must be an expression that resolves to a datetime value. You may use a value of either the DATETIME or TIMESTAMP type for this purpose. If the date is in the past, a warning occurs, as shown here:

  ```sql
  mysql> SELECT NOW();
  +---------------------+
  | NOW()               |
  +---------------------+
  | 2006-02-10 23:59:01 |
  +---------------------+
  1 row in set (0.04 sec)
  mysql> CREATE EVENT e_totals
          -> ON SCHEDULE AT '2006-02-10 23:59:00'
          -> DO INSERT INTO test.totals VALUES (NOW());
  Query OK, 0 rows affected, 1 warning (0.00 sec)
  mysql> SHOW WARNINGS\G
  *************************** 1. row ***************************
  Level: Note
  Code: 1588
  Message: Event execution time is in the past and ON COMPLETION NOT PRESERVE is set. The event was dropped immediately after creation.
  ```

CREATE EVENT statements which are themselves invalid—for whatever reason—fail with an error.

You may use CURRENT_TIMESTAMP to specify the current date and time. In such a case, the event acts as soon as it is created.

To create an event which occurs at some point in the future relative to the current date and time—such as that expressed by the phrase “three weeks from now”—you can use the optional clause + INTERVAL interval. The *interval* portion consists of two parts, a quantity and a unit of time, and follows the same syntax rules that govern intervals used in the DATE_ADD() function (see Section 12.7, “Date and Time Functions”. The units keywords are also the same, except that you cannot use any units involving microseconds when defining an event. With some interval types, complex time units may be used. For example, “two minutes and ten seconds” can be expressed as + INTERVAL '2:10' MINUTE_SECOND.

You can also combine intervals. For example, AT CURRENT_TIMESTAMP + INTERVAL 3 WEEK + INTERVAL 2 DAY is equivalent to “three weeks and two days from now”. Each portion of such a clause must begin with + INTERVAL.

- To repeat actions at a regular interval, use an EVERY clause. The EVERY keyword is followed by an *interval* as described in the previous discussion of the AT keyword. (+ INTERVAL is not used with EVERY.) For example, EVERY 6 WEEK means “every six weeks”. Although + INTERVAL clauses are not permitted in an EVERY clause, you can use the same complex time units permitted in a + INTERVAL.

An EVERY clause may contain an optional STARTS clause. STARTS is followed by a *timestamp* value that indicates when the action should begin repeating, and may also use + INTERVAL interval to specify an amount of time “from now”. For example, EVERY 3 MONTH STARTS CURRENT_TIMESTAMP + INTERVAL 1 WEEK means “every three months, beginning one week from now”. Similarly, you can express “every two weeks, beginning six hours and fifteen minutes from now” as EVERY 2 WEEK STARTS CURRENT_TIMESTAMP + INTERVAL '6:15' HOUR_MINUTE. Not specifying STARTS is the same as using STARTS CURRENT_TIMESTAMP—that is, the action specified for the event begins repeating immediately upon creation of the event.

An EVERY clause may contain an optional ENDS clause. The ENDS keyword is followed by a *timestamp* value that tells MySQL when the event should stop repeating. You may also use + INTERVAL interval with ENDS; for instance, EVERY 12 HOUR STARTS CURRENT_TIMESTAMP...
CREATE EVENT Syntax

+ INTERVAL 30 MINUTE ENDS CURRENT_TIMESTAMP + INTERVAL 4 WEEK is equivalent to “every twelve hours, beginning thirty minutes from now, and ending four weeks from now”. Not using ENDS means that the event continues executing indefinitely.

ENDS supports the same syntax for complex time units as STARTS does.

You may use STARTS, ENDS, both, or neither in an EVERY clause.

If a repeating event does not terminate within its scheduling interval, the result may be multiple instances of the event executing simultaneously. If this is undesirable, you should institute a mechanism to prevent simultaneous instances. For example, you could use the GET_LOCK() function, or row or table locking.

The ON SCHEDULE clause may use expressions involving built-in MySQL functions and user variables to obtain any of the timestamp or interval values which it contains. You may not use stored functions or user-defined functions in such expressions, nor may you use any table references; however, you may use SELECT FROM DUAL. This is true for both CREATE EVENT and ALTER EVENT statements. Beginning with MySQL 5.1.13, references to stored functions, user-defined functions, and tables in such cases are specifically not permitted, and fail with an error (see Bug #22830).

Times in the ON SCHEDULE clause are interpreted using the current session time_zone value. This becomes the event time zone; that is, the time zone that is used for event scheduling and is in effect within the event as it executes. These times are converted to UTC and stored along with the event time zone in the mysql.event table. This enables event execution to proceed as defined regardless of any subsequent changes to the server time zone or daylight saving time effects. For additional information about representation of event times, see Section 19.4.4, “Event Metadata”. See also Section 13.7.5.19, “SHOW EVENTS Syntax”, and Section 20.7, “The INFORMATION_SCHEMA EVENTS Table”.

Note

Prior to MySQL 5.1.17, the event time zone is not stored. The mysql.event table must be updated before events created in earlier releases can be created, altered, viewed, or used in MySQL 5.1.17 or later. You can use mysql_upgrade for this (see Section 4.4.8, “mysql_upgrade — Check and Upgrade MySQL Tables”).

Normally, once an event has expired, it is immediately dropped. You can override this behavior by specifying ON COMPLETION PRESERVE. Using ON COMPLETION NOT PRESERVE merely makes the default nonpersistent behavior explicit.

You can create an event but prevent it from being active using the DISABLE keyword. Alternatively, you can use ENABLE to make explicit the default status, which is active. This is most useful in conjunction with ALTER EVENT (see Section 13.1.2, “ALTER EVENT Syntax”).

Beginning with MySQL 5.1.18, a third value may also appear in place of ENABLE or DISABLE; DISABLE ON SLAVE is set for the status of an event on a replication slave to indicate that the event was created on the master and replicated to the slave, but is not executed on the slave. See Section 16.4.1.12, “Replication of Invoked Features”.

You may supply a comment for an event using a COMMENT clause. comment may be any string of up to 64 characters that you wish to use for describing the event. The comment text, being a string literal, must be surrounded by quotation marks.

The DO clause specifies an action carried by the event, and consists of an SQL statement. Nearly any valid MySQL statement that can be used in a stored routine can also be used as the action statement for a scheduled event. (See Section C.1, “Restrictions on Stored Programs”.) For example, the following event e_hourly deletes all rows from the sessions table once per hour, where this table is part of the site_activity schema:

```
CREATE EVENT e_hourly
    ON SCHEDULE
```
MySQL stores the `sql_mode` system variable setting in effect when an event is created or altered, and always executes the event with this setting in force, regardless of the current server SQL mode when the event begins executing.

A `CREATE EVENT` statement that contains an `ALTER EVENT` statement in its `DO` clause appears to succeed; however, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

**Note**

Statements such as `SELECT` or `SHOW` that merely return a result set have no effect when used in an event; the output from these is not sent to the MySQL Monitor, nor is it stored anywhere. However, you can use statements such as `SELECT ... INTO` and `INSERT INTO ... SELECT` that store a result. (See the next example in this section for an instance of the latter.)

The schema to which an event belongs is the default schema for table references in the `DO` clause. Any references to tables in other schemas must be qualified with the proper schema name. (In MySQL 5.1.6, all tables referenced in event `DO` clauses had to include a reference to the schema.)

As with stored routines, you can use compound-statement syntax in the `DO` clause by using the `BEGIN` and `END` keywords, as shown here:

```sql
CREATE EVENT e_daily
ON SCHEDULE
EVERY 1 DAY
COMMENT 'Saves total number of sessions then clears the table each day'
DO
BEGIN
    INSERT INTO site_activity.totals (time, total)
    SELECT CURRENT_TIMESTAMP, COUNT(*)
    FROM site_activity.sessions;
    DELETE FROM site_activity.sessions;
END
```

This example uses the `delimiter` command to change the statement delimiter. See Section 19.1, “Defining Stored Programs”.

More complex compound statements, such as those used in stored routines, are possible in an event. This example uses local variables, an error handler, and a flow control construct:

```sql
CREATE EVENT e
ON SCHEDULE
EVERY 5 SECOND
DO
BEGIN
    DECLARE v INTEGER;
    DECLARE CONTINUE HANDLER FOR SQLEXCEPTION BEGIN END;
    SET v = 0;
    WHILE v < 5 DO
        INSERT INTO t1 VALUES (0);
        UPDATE t2 SET s1 = s1 + 1;
        SET v = v + 1;
    END WHILE;
```
There is no way to pass parameters directly to or from events; however, it is possible to invoke a stored routine with parameters within an event:

```sql
CREATE EVENT e_call_myproc
ON SCHEDULE
  AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
DO CALL myproc(5, 27);
```

If an event’s definer has the `SUPER` privilege, the event can read and write global variables. As granting this privilege entails a potential for abuse, extreme care must be taken in doing so.

Generally, any statements that are valid in stored routines may be used for action statements executed by events. For more information about statements permitted within stored routines, see Section 19.2.1, “Stored Routine Syntax”. You can create an event as part of a stored routine, but an event cannot be created by another event.

### 13.1.12 CREATE FUNCTION Syntax

The `CREATE FUNCTION` statement is used to create stored functions and user-defined functions (UDFs):

- For information about creating stored functions, see Section 13.1.15, “CREATE PROCEDURE and CREATE FUNCTION Syntax”.
- For information about creating user-defined functions, see Section 13.7.3.1, “CREATE FUNCTION Syntax for User-Defined Functions”.

### 13.1.13 CREATE INDEX Syntax

```sql
CREATE [ONLINE|OFFLINE] [UNIQUE|FULLTEXT|SPATIAL] INDEX index_name
    [index_type] ON tbl_name (index_col_name,...)
    [index_option] ...
index_col_name:
  col_name [(length)] [ASC | DESC]

index_type:
  USING {BTREE | HASH}

index_option:
  KEY_BLOCK_SIZE [=] value
  | index_type
  | WITH PARSER parser_name
```

`CREATE INDEX` is mapped to an `ALTER TABLE` statement to create indexes. See Section 13.1.7, “ALTER TABLE Syntax”. `CREATE INDEX` cannot be used to create a `PRIMARY KEY`; use `ALTER TABLE` instead. For more information about indexes, see Section 8.3.1, “How MySQL Uses Indexes”.

Normally, you create all indexes on a table at the time the table itself is created with `CREATE TABLE`. See Section 13.1.17, “CREATE TABLE Syntax”. This guideline is especially important for InnoDB tables, where the primary key determines the physical layout of rows in the data file. `CREATE INDEX` enables you to add indexes to existing tables.

A column list of the form `(col1,col2,...)` creates a multiple-column index. Index key values are formed by concatenating the values of the given columns.

For string columns, indexes can be created that use only the leading part of column values, using `col_name(length)` syntax to specify an index prefix length:
CREATE INDEX Syntax

- Prefixes can be specified for `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY` column indexes.
- Prefixes must be specified for `BLOB` and `TEXT` column indexes.
- Prefix limits are measured in bytes, whereas the prefix length in `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements is interpreted as number of characters for nonbinary string types (`CHAR`, `VARCHAR`, `TEXT`) and number of bytes for binary string types (`BINARY`, `VARBINARY`, `BLOB`). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.
- For spatial columns, prefix values cannot be given, as described later in this section.

The statement shown here creates an index using the first 10 characters of the `name` column (assuming that `name` has a nonbinary string type):

```sql
CREATE INDEX part_of_name ON customer (name(10));
```

If names in the column usually differ in the first 10 characters, this index should not be much slower than an index created from the entire `name` column. Also, using column prefixes for indexes can make the index file much smaller, which could save a lot of disk space and might also speed up `INSERT` operations.

Prefix support and lengths of prefixes (where supported) are storage engine dependent. For example, a prefix can be up to 1000 bytes long for `MyISAM` tables, and 767 bytes for `InnoDB` tables. The `NDB` storage engine does not support prefixes (see Section 17.1.6.6, “Unsupported or Missing Features in MySQL Cluster”).

Beginning with MySQL 5.1.17, indexes on variable-width columns of `NDBCLUSTER` tables are created online; that is, without any table copying. The table is not locked against access from other MySQL Cluster API nodes, although it is locked against other operations on the same API node for the duration of the operation. This is done automatically by the server whenever it determines that it is possible to do so; you do not have to use any special SQL syntax or server options to cause it to happen.

In standard MySQL 5.1 releases, it is not possible to override the server when it determines that an index is to be created without table copying. In MySQL Cluster, you can create indexes offline (which causes the table to be locked to all API nodes in the cluster) using the `OFFLINE` keyword. The rules and limitations governing `CREATE OFFLINE INDEX` and `CREATE ONLINE INDEX` are the same as for `ALTER OFFLINE TABLE ... ADD INDEX` and `ALTER ONLINE TABLE ... ADD INDEX`. You cannot cause the noncopying creation of an index that would normally be created offline by using the `ONLINE` keyword: If it is not possible to perform the `CREATE INDEX` operation without table copying, the server ignores the `ONLINE` keyword. For more information, see Section 13.1.7.2, “ALTER TABLE Online Operations in MySQL Cluster”.

Note

The `ONLINE` and `OFFLINE` keywords are available only in MySQL Cluster NDB 6.2.5, 6.3.2, and later MySQL Cluster releases; attempting to use these keywords in earlier MySQL Cluster releases or standard MySQL 5.1 releases results in a syntax error.

A `UNIQUE` index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. For all engines, a `UNIQUE` index permits multiple `NULL` values for columns that can contain `NULL`. If you specify a prefix value for a column in a `UNIQUE` index, the column values must be unique within the prefix.

`FULLTEXT` indexes are supported only for `MyISAM` tables and can include only `CHAR`, `VARCHAR`, and `TEXT` columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See Section 12.9, “Full-Text Search Functions”, for details of operation.

The `MyISAM`, `InnoDB`, `NDB`, and `ARCHIVE` storage engines support spatial columns such as `POINT` and `GEOMETRY`. (Section 11.5, “Extensions for Spatial Data”, describes the spatial data types.)
However, support for spatial column indexing varies among engines. Spatial and nonspatial indexes are available according to the following rules.

Spatial indexes (created using `SPATIAL INDEX`) have these characteristics:

- Available only for `MyISAM` tables. Specifying `SPATIAL INDEX` for other storage engines results in an error.
- Indexed columns must be `NOT NULL`.
- Column prefix lengths are prohibited. The full width of each column is indexed.

Characteristics of nonspatial indexes (created with `INDEX`, `UNIQUE`, or `PRIMARY KEY`):

- Permitted for any storage engine that supports spatial columns except `ARCHIVE`.
- Columns can be `NULL` unless the index is a primary key.
- For each spatial column in a non-`SPATIAL` index except `POINT` columns, a column prefix length must be specified. (This is the same requirement as for indexed `BLOB` columns.) The prefix length is given in bytes.
- The index type for a non-`SPATIAL` index depends on the storage engine. Currently, B-tree is used.
- You can add an index on a column that can have `NULL` values only for `MyISAM`, `InnoDB`, and `MEMORY` tables.

An `index_col_name` specification can end with `ASC` or `DESC`. These keywords are permitted for future extensions for specifying ascending or descending index value storage. Currently, they are parsed but ignored; index values are always stored in ascending order.

As of MySQL 5.1.10, index options can be given following the index column list. An `index_option` value can be any of the following:

- `KEY_BLOCK_SIZE [=] value`
  
  For `MyISAM` tables, `KEY_BLOCK_SIZE` optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A `KEY_BLOCK_SIZE` value specified for an individual index definition overrides a table-level `KEY_BLOCK_SIZE` value.

- `index_type`

  Some storage engines permit you to specify an index type when creating an index. Table 13.1, “Index Types Per Storage Engine” shows the permissible index type values supported by different storage engines. Where multiple index types are listed, the first one is the default when no index type specifier is given. Storage engines not listed in the table do not support an `index_type` clause in index definitions.

### Table 13.1 Index Types Per Storage Engine

<table>
<thead>
<tr>
<th>Storage Engine</th>
<th>Permissible Index Types</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>MyISAM</code></td>
<td><code>BTREE</code></td>
</tr>
<tr>
<td><code>InnoDB</code></td>
<td><code>BTREE</code></td>
</tr>
<tr>
<td><code>MEMORY/HEAP</code></td>
<td><code>HASH, BTREE</code></td>
</tr>
<tr>
<td><code>NDB</code></td>
<td><code>BTREE, HASH</code></td>
</tr>
</tbody>
</table>

Example:
CREATE TABLE lookup (id INT) ENGINE = MEMORY;
CREATE INDEX id_index ON lookup (id) USING BTREE;

The `index_type` clause cannot be used for `FULLTEXT INDEX` or `SPATIAL INDEX` specifications. Full-text index implementation is storage engine dependent. Spatial indexes are implemented as R-tree indexes.

**Note**

For indexes on NDB table columns, the `USING` option can be specified only for a unique index or primary key. `USING HASH` prevents the creation of an ordered index; otherwise, creating a unique index or primary key on an NDB table automatically results in the creation of both an ordered index and a hash index, each of which indexes the same set of columns.

For unique indexes that include one or more `NULL` columns of an NDB table, the hash index can be used only to look up literal values, which means that `IS [NOT] NULL` conditions require a full scan of the table. One workaround is to make sure that a unique index using one or more `NULL` columns on such a table is always created in such a way that it includes the ordered index; that is, avoid employing `USING HASH` when creating the index.

If you specify an index type that is not valid for a given storage engine, but another index type is available that the engine can use without affecting query results, the engine uses the available type. The parser recognizes `RTREE` as a type name, but currently this cannot be specified for any storage engine.

**Note**

Before MySQL 5.1.10, the `index_type` option can be given only before the `ON tbl_name` clause. Use of the option in this position is deprecated as of 5.1.10 and support for it there will be removed in a future MySQL release. If an `index_type` option is given in both the earlier and later positions, the final option applies.

`TYPE type_name` is recognized as a synonym for `USING type_name`. However, `USING` is the preferred form.

- `WITH PARSER parser_name`

This option can be used only with `FULLTEXT` indexes. It associates a parser plugin with the index if full-text indexing and searching operations need special handling. See Section 22.2, “The MySQL Plugin API”, for details on creating plugins.

### 13.1.14 CREATE LOGFILE GROUP Syntax

```sql
CREATE LOGFILE GROUP logfile_group
ADD UNDOFILE 'undo_file'
[INITIAL_SIZE [=] initial_size]
[UNDO_BUFFER_SIZE [=] undo_buffer_size]
[REDO_BUFFER_SIZE [=] redo_buffer_size]
[NODEGROUP [=] nodegroup_id]
[WAIT]
[COMMENT [=] comment_text]
ENGINE [=] engine_name
```

This statement creates a new log file group named `logfile_group` having a single `UNDO` file named `undo_file`. A `CREATE LOGFILE GROUP` statement has one and only one `ADD UNDOFILE` clause. For rules covering the naming of log file groups, see Section 9.2, “Schema Object Names”.

1200
Note

All MySQL Cluster Disk Data objects share the same namespace. This means that each Disk Data object must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group with the same name, or a tablespace and a data file with the same name.

Beginning with MySQL 5.1.8, you can have only one log file group per Cluster at any given time. (See Bug #16386)

Prior to MySQL Cluster NDB 6.2.17, 6.3.23, and 6.4.3, path and file names for undo log files could not be longer than 128 characters. (Bug #31769)

The optional INITIAL_SIZE parameter sets the UNDO file's initial size; if not specified, it defaults to 128M (128 megabytes). The optional UNDO_BUFFER_SIZE parameter sets the size used by the UNDO buffer for the log file group; The default value for UNDO_BUFFER_SIZE is 8M (eight megabytes); this value cannot exceed the amount of system memory available. Both of these parameters are specified in bytes. You may optionally follow either or both of these with a one-letter abbreviation for an order of magnitude, similar to those used in my.cnf. Generally, this is one of the letters M (for megabytes) or G (for gigabytes).

Memory used for UNDO_BUFFER_SIZE comes from the global pool whose size is determined by the value of the SharedGlobalMemory data node configuration parameter. This includes any default value implied for this option by the setting of the InitialLogFileGroup data node configuration parameter.

Beginning with MySQL Cluster NDB 6.2.17, 6.3.23, and 6.4.3, the maximum permitted for UNDO_BUFFER_SIZE is 600M; previously, it was 150M. (Bug #34102)

On 32-bit systems, the maximum supported value for INITIAL_SIZE is 4G. (Bug #29186)

Beginning with MySQL Cluster NDB 2.1.18, 6.3.24, and 7.0.4, the minimum permitted value for INITIAL_SIZE is 1M. (Bug #29574)

The ENGINE option determines the storage engine to be used by this log file group, with engine_name being the name of the storage engine. In MySQL 5.1, this must be NDB (or NDBCLUSTER). If ENGINE is not set, MySQL tries to use the engine specified by the storage_engine server system variable. In any case, if the engine is not specified as NDB or NDBCLUSTER, the CREATE LOGFILE GROUP statement appears to succeed but actually fails to create the log file group, as shown here:

```
mysql> CREATE LOGFILE GROUP lg1
  -> ADD UNDOFILE 'undo.dat' INITIAL_SIZE = 10M;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-------+------+------------------------------------------------------------------------------------------------+
| Level | Code | Message                                                                                        |
+-------+------+------------------------------------------------------------------------------------------------+
| Error | 1478 | Table storage engine 'MyISAM' does not support the create option 'TABLESPACE or LOGFILE GROUP'  |
+-------+------+------------------------------------------------------------------------------------------------+
1 row in set (0.00 sec)

mysql> DROP LOGFILE GROUP lg1 ENGINE = NDB;
ERROR 1529 (HY000): Failed to drop LOGFILE GROUP

mysql> CREATE LOGFILE GROUP lg1
  -> ADD UNDOFILE 'undo.dat' INITIAL_SIZE = 10M
  -> ENGINE = NDB;
Query OK, 0 rows affected (2.97 sec)
```

The fact that the CREATE LOGFILE GROUP statement does not actually return an error when a non-NDB storage engine is named, but rather appears to succeed, is a known issue which we hope to address in a future release of MySQL Cluster.
CREATE PROCEDURE and CREATE FUNCTION Syntax

`REDO_BUFFER_SIZE`, `NODEGROUP`, `WAIT`, and `COMMENT` are parsed but ignored, and so have no effect in MySQL 5.1. These options are intended for future expansion.

When used with `ENGINE [=] NDB`, a log file group and associated `UNDO` log file are created on each Cluster data node. You can verify that the `UNDO` files were created and obtain information about them by querying the `INFORMATION_SCHEMA.FILES` table. For example:

```sql
mysql> SELECT LOGFILE_GROUP_NAME, LOGFILE_GROUP_NUMBER, EXTRA
   -> FROM INFORMATION_SCHEMA.FILES
   -> WHERE FILE_NAME = 'undo_10.dat';
+--------------------+----------------------+----------------+
<table>
<thead>
<tr>
<th>LOGFILE_GROUP_NAME</th>
<th>LOGFILE_GROUP_NUMBER</th>
<th>EXTRA</th>
</tr>
</thead>
<tbody>
<tr>
<td>lg_3</td>
<td>11</td>
<td>CLUSTER_NODE=3</td>
</tr>
<tr>
<td>lg_3</td>
<td>11</td>
<td>CLUSTER_NODE=4</td>
</tr>
</tbody>
</table>
+--------------------+----------------------+----------------+
2 rows in set (0.06 sec)
```

`CREATE LOGFILE GROUP` was added in MySQL 5.1.6. In MySQL 5.1, it is useful only with Disk Data storage for MySQL Cluster. See Section 17.5.12, “MySQL Cluster Disk Data Tables”.

13.1.15 CREATE PROCEDURE and CREATE FUNCTION Syntax

These statements create stored routines. By default, a routine is associated with the default database. To associate the routine explicitly with a given database, specify the name as `db_name.sp_name` when you create it.

The `CREATE FUNCTION` statement is also used in MySQL to support UDFs (user-defined functions). See Section 22.3, “Adding New Functions to MySQL”. A UDF can be regarded as an external stored function. Stored functions share their namespace with UDFs. See Section 9.2.4, “Function Name Parsing and Resolution”, for the rules describing how the server interprets references to different kinds of functions.

To invoke a stored procedure, use the `CALL` statement (see Section 13.2.1, “CALL Syntax”). To invoke a stored function, refer to it in an expression. The function returns a value during expression evaluation.
CREATE PROCEDURE and CREATE FUNCTION require the CREATE ROUTINE privilege. They might also require the SUPER privilege, depending on the DEFINER value, as described later in this section. If binary logging is enabled, CREATE FUNCTION might require the SUPER privilege, as described in Section 19.7, "Binary Logging of Stored Programs".

By default, MySQL automatically grants the ALTER ROUTINE and EXECUTE privileges to the routine creator. This behavior can be changed by disabling the automatic_sp_privileges system variable. See Section 19.2.2, "Stored Routines and MySQL Privileges".

The DEFINER and SQL SECURITY clauses specify the security context to be used when checking access privileges at routine execution time, as described later in this section.

If the routine name is the same as the name of a built-in SQL function, a syntax error occurs unless you use a space between the name and the following parenthesis when defining the routine or invoking it later. For this reason, avoid using the names of existing SQL functions for your own stored routines.

The IGNORE_SPACE SQL mode applies to built-in functions, not to stored routines. It is always permissible to have spaces after a stored routine name, regardless of whether IGNORE_SPACE is enabled.

The parameter list enclosed within parentheses must always be present. If there are no parameters, an empty parameter list of () should be used. Parameter names are not case sensitive.

Each parameter is an IN parameter by default. To specify otherwise for a parameter, use the keyword OUT or INOUT before the parameter name.

Note
Specifying a parameter as IN, OUT, or INOUT is valid only for a PROCEDURE. For a FUNCTION, parameters are always regarded as IN parameters.

An IN parameter passes a value into a procedure. The procedure might modify the value, but the modification is not visible to the caller when the procedure returns. An OUT parameter passes a value from the procedure back to the caller. Its initial value is NULL within the procedure, and its value is visible to the caller when the procedure returns. An INOUT parameter is initialized by the caller, can be modified by the procedure, and any change made by the procedure is visible to the caller when the procedure returns.

For each OUT or INOUT parameter, pass a user-defined variable in the CALL statement that invokes the procedure so that you can obtain its value when the procedure returns. If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an IN or INOUT parameter.

Routine parameters cannot be referenced in statements prepared within the routine; see Section C.1, "Restrictions on Stored Programs".

The following example shows a simple stored procedure that uses an OUT parameter:

```
mymysql> delimiter //
mymysql> CREATE PROCEDURE simpleproc (OUT param1 INT)
    -> BEGIN
    -> SELECT COUNT(*) INTO param1 FROM t;
    -> END //
Query OK, 0 rows affected (0.00 sec)
mymysql> delimiter ;
mymysql> CALL simpleproc(@a);
Query OK, 0 rows affected (0.00 sec)
mymysql> SELECT @a;
+------+
<table>
<thead>
<tr>
<th>@a</th>
</tr>
</thead>
</table>
```
The example uses the mysql client delimiter command to change the statement delimiter from ; to /
// while the procedure is being defined. This enables the , delimiter used in the procedure body to be
passed through to the server rather than being interpreted by mysql itself. See Section 19.1, “Defining
Stored Programs”.

The RETURNS clause may be specified only for a FUNCTION, for which it is mandatory. It indicates
the return type of the function, and the function body must contain a RETURN value statement. If
the RETURN statement returns a value of a different type, the value is coerced to the proper type.
For example, if a function specifies an ENUM or SET value in the RETURNS clause, but the RETURN
statement returns an integer, the value returned from the function is the string for the corresponding
ENUM member of set of SET members.

The following example function takes a parameter, performs an operation using an SQL function, and
returns the result. In this case, it is unnecessary to use delimiter because the function definition
contains no internal ; statement delimiters:

```
mysql> CREATE FUNCTION hello (s CHAR(20))
mysql> RETURNS CHAR(50) DETERMINISTIC
    -> RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT hello('world');
+----------------+
| hello('world') |
+----------------+
| Hello, world!  |
+----------------+
1 row in set (0.00 sec)
```

Parameter types and function return types can be declared to use any valid data type, except that the
COLLATE attribute cannot be used.

The routine_body consists of a valid SQL routine statement. This can be a simple statement
such as SELECT or INSERT, or a compound statement written using BEGIN and END. Compound
statements can contain declarations, loops, and other control structure statements. The syntax for
these statements is described in Section 13.6, “MySQL Compound-Statement Syntax”.

MySQL permits routines to contain DDL statements, such as CREATE and DROP. MySQL also permits
stored procedures (but not stored functions) to contain SQL transaction statements such as COMMIT.
Stored functions may not contain statements that perform explicit or implicit commit or rollback. Support
for these statements is not required by the SQL standard, which states that each DBMS vendor may
decide whether to permit them.

Statements that return a result set can be used within a stored procedure but not within a stored
function. This prohibition includes SELECT statements that do not have an INTO var_list clause
and other statements such as SHOW, EXPLAIN, and CHECK TABLE. For statements that can be
determined at function definition time to return a result set, a Not allowed to return a result
set from a function error occurs (ER_SP_NO_RETSET). For statements that can be determined
only at runtime to return a result set, a PROCEDURE %s can't return a result set in the
given context error occurs (ER_SP_BADSELECT).

USE statements within stored routines are not permitted. When a routine is invoked, an implicit USE
db_name is performed (and undone when the routine terminates). This causes the routine to have the
given default database while it executes. References to objects in databases other than the routine
default database should be qualified with the appropriate database name.

For additional information about statements that are not permitted in stored routines, see Section C.1,
“Restrictions on Stored Programs”.

1204
For information about invoking stored procedures from within programs written in a language that has a MySQL interface, see Section 13.2.1, “CALL Syntax”.

MySQL stores the sql_mode system variable setting in effect when a routine is created or altered, and always executes the routine with this setting in force, regardless of the current server SQL mode when the routine begins executing.

The switch from the SQL mode of the invoker to that of the routine occurs after evaluation of arguments and assignment of the resulting values to routine parameters. If you define a routine in strict SQL mode but invoke it in nonstrict mode, assignment of arguments to routine parameters does not take place in strict mode. If you require that expressions passed to a routine be assigned in strict SQL mode, you should invoke the routine with strict mode in effect.

The COMMENT characteristic is a MySQL extension, and may be used to describe the stored routine. This information is displayed by the SHOW CREATE PROCEDURE and SHOW CREATE FUNCTION statements.

The LANGUAGE characteristic indicates the language in which the routine is written. The server ignores this characteristic; only SQL routines are supported.

A routine is considered “deterministic” if it always produces the same result for the same input parameters, and “not deterministic” otherwise. If neither DETERMINISTIC nor NOT DETERMINISTIC is given in the routine definition, the default is NOT DETERMINISTIC. To declare that a function is deterministic, you must specify DETERMINISTIC explicitly.

Assessment of the nature of a routine is based on the “honesty” of the creator: MySQL does not check that a routine declared DETERMINISTIC is free of statements that produce nondeterministic results. However, misdeclaring a routine might affect results or affect performance. Declaring a nondeterministic routine as DETERMINISTIC might lead to unexpected results by causing the optimizer to make incorrect execution plan choices. Declaring a deterministic routine as NONDETERMINISTIC might diminish performance by causing available optimizations not to be used. Prior to MySQL 5.1.21, the DETERMINISTIC characteristic is accepted, but not used by the optimizer.

If binary logging is enabled, the DETERMINISTIC characteristic affects which routine definitions MySQL accepts. See Section 19.7, “Binary Logging of Stored Programs”.

A routine that contains the NOW() function (or its synonyms) or RAND() is nondeterministic, but it might still be replication-safe. For NOW(), the binary log includes the timestamp and replicates correctly. RAND() also replicates correctly as long as it is called only a single time during the execution of a routine. (You can consider the routine execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

Several characteristics provide information about the nature of data use by the routine. In MySQL, these characteristics are advisory only. The server does not use them to constrain what kinds of statements a routine will be permitted to execute.

- CONTAINS SQL indicates that the routine does not contain statements that read or write data. This is the default if none of these characteristics is given explicitly. Examples of such statements are SET @x = 1 or DO RELEASE_LOCK ('abc'), which execute but neither read nor write data.
- NO SQL indicates that the routine contains no SQL statements.
- READS SQL DATA indicates that the routine contains statements that read data (for example, SELECT), but not statements that write data.
- MODIFIES SQL DATA indicates that the routine contains statements that may write data (for example, INSERT or DELETE).

The SQL SECURITY characteristic can be DEFINER or INVOKER to specify the security context; that is, whether the routine executes using the privileges of the account named in the routine DEFINER clause or the user who invokes it. This account must have permission to access the database with which the routine is associated. The default value is DEFINER. The user who invokes the routine must have...
CREATE PROCEDURE and CREATE FUNCTION Syntax

the `EXECUTE` privilege for it, as must the `DEFINER` account if the routine executes in definer security context.

The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at routine execution time for routines that have the `SQL SECURITY DEFINER` characteristic. The `DEFINER` clause was added in MySQL 5.1.8.

If a `user` value is given for the `DEFINER` clause, it should be a MySQL account specified as `'user_name'@'host_name'` (the same format used in the `GRANT` statement), `CURRENT_USER`, or `CURRENT_USER()`. The default `DEFINER` value is the user who executes the `CREATE PROCEDURE` or `CREATE FUNCTION` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

If you specify the `DEFINER` clause, these rules determine the valid `DEFINER` user values:

• If you do not have the `SUPER` privilege, the only permitted `user` value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.

• If you have the `SUPER` privilege, you can specify any syntactically valid account name. If the account does not exist, a warning is generated.

• Although it is possible to create a routine with a nonexistent `DEFINER` account, an error occurs at routine execution time if the `SQL SECURITY` value is `DEFINER` but the definer account does not exist.

For more information about stored routine security, see Section 19.6, “Access Control for Stored Programs and Views”.

Within a stored routine that is defined with the `SQL SECURITY DEFINER` characteristic, `CURRENT_USER` returns the routine’s `DEFINER` value. For information about user auditing within stored routines, see Section 6.3.6, “SQL-Based MySQL Account Activity Auditing”.

Consider the following procedure, which displays a count of the number of MySQL accounts listed in the `mysql.user` table:

```sql
CREATE DEFINER = 'admin'@'localhost' PROCEDURE account_count()
BEGIN
    SELECT 'Number of accounts:', COUNT(*) FROM mysql.user;
END;
```

The procedure is assigned a `DEFINER` account of `'admin'@'localhost'` no matter which user defines it. It executes with the privileges of that account no matter which user invokes it (because the default security characteristic is `DEFINER`). The procedure succeeds or fails depending on whether invoker has the `EXECUTE` privilege for it and `'admin'@'localhost'` has the `SELECT` privilege for the `mysql.user` table.

Now suppose that the procedure is defined with the `SQL SECURITY INVOKER` characteristic:

```sql
CREATE DEFINER = 'admin'@'localhost' PROCEDURE account_count()
SQL SECURITY INVOKER
BEGIN
    SELECT 'Number of accounts:', COUNT(*) FROM mysql.user;
END;
```

The procedure still has a `DEFINER` of `'admin'@'localhost'`, but in this case, it executes with the privileges of the invoking user. Thus, the procedure succeeds or fails depending on whether the invoker has the `EXECUTE` privilege for it and the `SELECT` privilege for the `mysql.user` table.

The server handles the data type of a routine parameter, local routine variable created with `DECLARE`, or function return value as follows:

• Assignments are checked for data type mismatches and overflow. Conversion and overflow problems result in warnings, or errors in strict SQL mode.
CREATE SERVER Syntax

- Only scalar values can be assigned. For example, a statement such as `SET x = (SELECT 1, 2)` is invalid.

- For character data types, if there is a `CHARACTER SET` attribute in the declaration, the specified character set and its default collation are used. If there is no such attribute, the database character set in effect at routine creation time and its default collation are used. The `COLLATE` attribute is not supported. (This includes use of `BINARY`, which in this context specifies the binary collation of the character set.)

To avoid having the server use the database character set and collation, provide an explicit `CHARACTER SET` attribute for character data parameters.

If you change the database default character set or collation, stored routines that use the database defaults must be dropped and recreated so that they use the new defaults.

The database character set and collation are given by the value of the `character_set_database` and `collation_database` system variables. For more information, see Section 10.1.3.2, “Database Character Set and Collation”.

13.1.16 CREATE SERVER Syntax

```
CREATE SERVER server_name
    FOREIGN DATA WRAPPER wrapper_name
    OPTIONS (option [, option] ...)
```

This statement creates the definition of a server for use with the `FEDERATED` storage engine. The `CREATE SERVER` statement creates a new row in the `servers` table in the `mysql` database. This statement requires the `SUPER` privilege.

The `server_name` should be a unique reference to the server. Server definitions are global within the scope of the server, it is not possible to qualify the server definition to a specific database. `server_name` has a maximum length of 64 characters (names longer than 64 characters are silently truncated), and is case insensitive. You may specify the name as a quoted string.

The `wrapper_name` should be `mysql`, and may be quoted with single quotation marks. Other values for `wrapper_name` are not currently supported.

For each `option` you must specify either a character literal or numeric literal. Character literals are UTF-8, support a maximum length of 64 characters and default to a blank (empty) string. String literals are silently truncated to 64 characters. Numeric literals must be a number between 0 and 9999, default value is 0.

**Note**

The `OWNER` option is currently not applied, and has no effect on the ownership or operation of the server connection that is created.

The `CREATE SERVER` statement creates an entry in the `mysql.servers` table that can later be used with the `CREATE TABLE` statement when creating a `FEDERATED` table. The options that you specify will be used to populate the columns in the `mysql.servers` table. The table columns are `Server_name`, `Host`, `Db`, `Username`, `Password`, `Port` and `Socket`.

For example:
CREATE SERVER s
FOREIGN DATA WRAPPER mysql
OPTIONS (USER 'Remote', HOST '192.168.1.106', DATABASE 'test');

Be sure to specify all options necessary to establish a connection to the server. The user name, host
name, and database name are mandatory. Other options might be required as well, such as password.

The data stored in the table can be used when creating a connection to a FEDERATED table:

CREATE TABLE t (s1 INT) ENGINE=FEDERATED CONNECTION='s';

For more information, see Section 14.11, “The FEDERATED Storage Engine”.

CREATE SERVER causes an implicit commit.

In MySQL 5.1, CREATE SERVER is written to the binary log only when using row-based logging. It is
not logged when binlog_format is equal to STATEMENT or MIXED.

CREATE SERVER was added in MySQL 5.1.15.

13.1.17 CREATE TABLE Syntax

CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name

( Some valid select statement )

CREATE TABLE creates a table with the given name. You must have the CREATE privilege for the table.

Rules for permissible table names are given in Section 9.2, "Schema Object Names". By default, the table is created in the default database. An error occurs if the table exists, if there is no default database, or if the database does not exist.

The table name can be specified as db_name.tbl_name to create the table in a specific database. This works regardless of whether there is a default database, assuming that the database exists. If you use quoted identifiers, quote the database and table names separately. For example, write `mydb`.`mytbl`, not `mydb.mytbl`.

Cloning or Copying a Table

Use CREATE TABLE ... LIKE to create an empty table based on the definition of another table, including any column attributes and indexes defined in the original table:

CREATE TABLE new_tbl LIKE orig_tbl;

For more information, see Section 13.1.17.1, "CREATE TABLE ... LIKE Syntax".
To create one table from another, add a `SELECT` statement at the end of the `CREATE TABLE` statement:

```
CREATE TABLE new_tbl SELECT * FROM orig_tbl;
```

For more information, see Section 13.1.17.2, “CREATE TABLE ... SELECT Syntax”.

**Temporary Tables**

You can use the `TEMPORARY` keyword when creating a table. A `TEMPORARY` table is visible only to the current session, and is dropped automatically when the session is closed. This means that two different sessions can use the same temporary table name without conflicting with each other or with an existing non-`TEMPORARY` table of the same name. (The existing table is hidden until the temporary table is dropped.) To create temporary tables, you must have the `CREATE TEMPORARY TABLES` privilege.

**Note**

`CREATE TABLE` does not automatically commit the current active transaction if you use the `TEMPORARY` keyword.

**Note**

`TEMPORARY` tables have a very loose relationship with databases (schemas). Dropping a database does not automatically drop any `TEMPORARY` tables created within that database. Also, you can create a `TEMPORARY` table in a nonexistent database if you qualify the table name with the database name in the `CREATE TABLE` statement. In this case, all subsequent references to the table must be qualified with the database name.

**Existing Table with Same Name**

The keywords `IF NOT EXISTS` prevent an error from occurring if the table exists. However, there is no verification that the existing table has a structure identical to that indicated by the `CREATE TABLE` statement.

**Physical Representation**

MySQL represents each table by an `.frm` table format (definition) file in the database directory. The storage engine for the table might create other files as well.

For `InnoDB` tables, the file storage is controlled by the `innodb_file_per_table` configuration option. For each `InnoDB` table created when this option is turned on, the table data and all associated indexes are stored in a `.ibd` file located inside the database directory. When this option is turned off, all `InnoDB` tables and indexes are stored in the system tablespace, represented by one or more `ibdata*` files.

For `MyISAM` tables, the storage engine creates data and index files. Thus, for each `MyISAM` table `tbl_name`, there are three disk files.

<table>
<thead>
<tr>
<th>File</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>tbl_name.frm</code></td>
<td>Table format (definition) file</td>
</tr>
<tr>
<td><code>tbl_name.MYD</code></td>
<td>Data file</td>
</tr>
<tr>
<td><code>tbl_name.MYI</code></td>
<td>Index file</td>
</tr>
</tbody>
</table>

Chapter 14, *Storage Engines*, describes what files each storage engine creates to represent tables. If a table name contains special characters, the names for the table files contain encoded versions of those characters as described in Section 9.2.3, “Mapping of Identifiers to File Names”.

1211
Data Types and Attributes for Columns

`data_type` represents the data type in a column definition. `spatial_type` represents a spatial data type. The data type syntax shown is representative only. For a full description of the syntax available for specifying column data types, as well as information about the properties of each type, see Chapter 11, Data Types, and Section 11.5, “Extensions for Spatial Data”.

Some attributes do not apply to all data types. `AUTO_INCREMENT` applies only to integer and floating-point types. `DEFAULT` does not apply to the `BLOB` or `TEXT` types.

- If neither `NULL` nor `NOT NULL` is specified, the column is treated as though `NULL` had been specified.
- An integer or floating-point column can have the additional attribute `AUTO_INCREMENT`. When you insert a value of `NULL` (recommended) or `0` into an indexed `AUTO_INCREMENT` column, the column is set to the next sequence value. Typically this is `value+1`, where `value` is the largest value for the column currently in the table. `AUTO_INCREMENT` sequences begin with `1`.

To retrieve an `AUTO_INCREMENT` value after inserting a row, use the `LAST_INSERT_ID()` SQL function or the `mysql_insert_id()` C API function. See Section 12.14, “Information Functions”, and Section 21.8.7.37, “mysql_insert_id()”.

If the `NO_AUTO_VALUE_ON_ZERO` SQL mode is enabled, you can store `0` in `AUTO_INCREMENT` columns as `0` without generating a new sequence value. See Section 5.1.7, “Server SQL Modes”.

Note

There can be only one `AUTO_INCREMENT` column per table, it must be indexed, and it cannot have a `DEFAULT` value. An `AUTO_INCREMENT` column works properly only if it contains only positive values. Inserting a negative number is regarded as inserting a very large positive number. This is done to avoid precision problems when numbers “wrap” over from positive to negative and also to ensure that you do not accidentally get an `AUTO_INCREMENT` column that contains `0`.

For MyISAM tables, you can specify an `AUTO_INCREMENT` secondary column in a multiple-column key. See Section 3.6.9, “Using AUTO_INCREMENT”.

To make MySQL compatible with some ODBC applications, you can find the `AUTO_INCREMENT` value for the last inserted row with the following query:

```sql
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

This method requires that `sql_auto_is_null` variable is not set to `0`. See Section 5.1.4, “Server System Variables”.

For information about InnoDB and `AUTO_INCREMENT`, see Section 14.6.6.5, “AUTO_INCREMENT Handling in InnoDB”. For information about `AUTO_INCREMENT` and MySQL Replication, see Section 16.4.1.1, “Replication and AUTO_INCREMENT”.

- Character data types (`CHAR`, `VARCHAR`, `TEXT`) can include `CHARACTER_SET` and `COLLATE` attributes to specify the character set and collation for the column. For details, see Section 10.1, “Character Set Support”. `CHARSET` is a synonym for `CHARACTER_SET`. Example:

```sql
CREATE TABLE t (c CHAR(20) CHARACTER SET utf8 COLLATE utf8_bin);
```

MySQL 5.1 interprets length specifications in character column definitions in characters. Lengths for `BINARY` and `VARBINARY` are in bytes.
CREATE TABLE Syntax

- The **DEFAULT** clause specifies a default value for a column. With one exception, the default value must be a constant; it cannot be a function or an expression. This means, for example, that you cannot set the default for a date column to be the value of a function such as `NOW()` or `CURRENT_DATE`. The exception is that you can specify `CURRENT_TIMESTAMP` as the default for a `TIMESTAMP` column. See Section 11.3.5, “Automatic Initialization and Updating for TIMESTAMP”.

  If a column definition includes no explicit **DEFAULT** value, MySQL determines the default value as described in Section 11.6, “Data Type Default Values”.

  **BLOB** and **TEXT** columns cannot be assigned a default value.

  **CREATE TABLE** fails if a date-valued default is not correct according to the **NO_ZERO_IN_DATE** SQL mode, even if strict SQL mode is not enabled. For example, `c1 DATE DEFAULT '2010-00-00'` causes **CREATE TABLE** to fail with **Invalid default value for 'c1'**.

  **Native default value handling in MySQL Cluster NDB 7.0.15, MySQL Cluster NDB 7.1.4, and later.** Starting with MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4, default values for table columns are stored by **NDBCLUSTER**, rather than by the MySQL server as was previously the case. Because less data must be sent from an SQL node to the data nodes, inserts on tables having column value defaults can be performed more efficiently than before.

  Tables created using MySQL Cluster releases previous to the introduction of native default value support can still be used in MySQL Cluster NDB 7.0.15 and later, as well as MySQL Cluster NDB 7.1.4 and later. However, such tables continue to use defaults supplied by the MySQL server until they are upgraded. This upgrade can be done by means of an offline **ALTER TABLE** statement.

  ! Important
  
  You cannot set or change a table column's default value using a noncopying **ALTER TABLE** operation.

  Tables created in versions of MySQL Cluster that support native default values cannot be used with versions of MySQL Cluster that lack this support.

  **NDBCLUSTER** tables supporting native default values are still subject to the restrictions on default values imposed by the MySQL server. For more information, see Section 11.6, “Data Type Default Values”.

- A comment for a column can be specified with the **COMMENT** option, up to 255 characters long. The comment is displayed by the **SHOW CREATE TABLE** and **SHOW FULL COLUMNS** statements.

- In MySQL Cluster—beginning with MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.2—it is also possible to specify a data storage format for individual columns of **NDB** tables using **COLUMN_FORMAT**. Permissible column formats are **FIXED**, **DYNAMIC**, and **DEFAULT**. **FIXED** is used to specify fixed-width storage, **DYNAMIC** permits the column to be variable-width, and **DEFAULT** causes the column to use fixed-width or variable-width storage as determined by the column's data type (possibly overridden by a **ROW_FORMAT** specifier).

  For **NDB** tables, the default value for **COLUMN_FORMAT** is **DEFAULT**.

  **COLUMN_FORMAT** currently has no effect on columns of tables using storage engines other than **NDB**. The **COLUMN_FORMAT** keyword is supported only in the build of **mysqld** that is supplied with MySQL Cluster; it is not recognized in MySQL 5.1, where attempting to use **COLUMN_FORMAT** causes a syntax error.

- For **NDB** tables, beginning with MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.2, it is also possible to specify whether the column is stored on disk or in memory by using a **STORAGE** clause. **STORAGE DISK** causes the column to be stored on disk, and **STORAGE MEMORY** causes in-memory storage to be used. The **CREATE TABLE** statement used must still include a **TABLESPACE** clause:
CREATE TABLE Syntax

mysql> CREATE TABLE t1 {
   -> c1 INT STORAGE DISK,
   -> c2 INT STORAGE MEMORY
   -> ) ENGINE NDB;
ERROR 1005 (HY000): Can't create table 'c.t1' (errno: 140)

mysql> CREATE TABLE t1 {
   -> c1 INT STORAGE DISK,
   -> c2 INT STORAGE MEMORY
   -> ) TABLESPACE ts_1 ENGINE NDB;
Query OK, 0 rows affected (1.06 sec)

For NDB tables, STORAGE DEFAULT is equivalent to STORAGE MEMORY.

The STORAGE clause has no effect on tables using storage engines other than NDB. The STORAGE keyword is supported only in the build of mysql that is supplied with MySQL Cluster; it is not recognized in any other version of MySQL, where any attempt to use the STORAGE keyword causes a syntax error.

- **KEY** is normally a synonym for **INDEX**. The key attribute PRIMARY KEY can also be specified as just **KEY** when given in a column definition. This was implemented for compatibility with other database systems.

- A **UNIQUE** index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. For all engines, a UNIQUE index permits multiple NULL values for columns that can contain NULL.

- A **PRIMARY KEY** is a unique index where all key columns must be defined as NOT NULL. If they are not explicitly declared as NOT NULL, MySQL declares them so implicitly (and silently). A table can have only one PRIMARY KEY. The name of a PRIMARY KEY is always PRIMARY, which thus cannot be used as the name for any other kind of index.

If you do not have a PRIMARY KEY and an application asks for the PRIMARY KEY in your tables, MySQL returns the first UNIQUE index that has no NULL columns as the PRIMARY KEY.

In InnoDB tables, keep the PRIMARY KEY short to minimize storage overhead for secondary indexes. Each secondary index entry contains a copy of the primary key columns for the corresponding row. (See Section 14.6.3.2, “InnoDB Table and Index Structures”.)

- In the created table, a PRIMARY KEY is placed first, followed by all UNIQUE indexes, and then the nonunique indexes. This helps the MySQL optimizer to prioritize which index to use and also more quickly to detect duplicated UNIQUE keys.

- A PRIMARY KEY can be a multiple-column index. However, you cannot create a multiple-column index using the PRIMARY KEY key attribute in a column specification. Doing so only marks that single column as primary. You must use a separate PRIMARY KEY(index_col_name, ...) clause.

- If a PRIMARY KEY or UNIQUE index consists of only one column that has an integer type, you can also refer to the column as _rowid in SELECT statements.

- In MySQL, the name of a PRIMARY KEY is PRIMARY. For other indexes, if you do not assign a name, the index is assigned the same name as the first indexed column, with an optional suffix (_2, _3, ...) to make it unique. You can see index names for a table using SHOW INDEX FROM tbl_name. See Section 13.7.5.23, “SHOW INDEX Syntax”.

- Some storage engines permit you to specify an index type when creating an index. The syntax for the index_type specifier is USING type_name.

Example:

```sql
CREATE TABLE lookup
   (id INT, INDEX USING BTREE (id))
```
CREATE TABLE Syntax

Before MySQL 5.1.10, `USING` can be given only before the index column list. As of 5.1.10, the preferred position is after the column list. Support for use of the option before the column list will be removed in a future MySQL release.

`index_option` values specify additional options for an index. `USING` is one such option. For details about permissible `index_option` values, see Section 13.1.13, “CREATE INDEX Syntax”.

For more information about indexes, see Section 8.3.1, “How MySQL Uses Indexes”.

- In MySQL 5.1, only the InnoDB, MyISAM, and MEMORY storage engines support indexes on columns that can have `NULL` values. In other cases, you must declare indexed columns as `NOT NULL` or an error results.

- For CHAR, VARCHAR, BINARY, and VARBINARY columns, indexes can be created that use only the leading part of column values, using `col_name(length)` syntax to specify an index prefix length. BLOB and TEXT columns also can be indexed, but a prefix length must be given. Prefix lengths are given in characters for nonbinary string types and in bytes for binary string types. That is, index entries consist of the first `length` characters of each column value for CHAR, VARCHAR, and TEXT columns, and the first `length` bytes of each column value for BINARY, VARBINARY, and BLOB columns. Indexing only a prefix of column values like this can make the index file much smaller. For additional information about index prefixes, see Section 13.1.13, “CREATE INDEX Syntax”.

Only the InnoDB and MyISAM storage engines support indexing on BLOB and TEXT columns. For example:

```
CREATE TABLE test (blob_col BLOB, INDEX(blob_col(10)));
```

Prefixes can be up to 1000 bytes long (767 bytes for InnoDB tables).

**Note**

Prefix limits are measured in bytes, whereas the prefix length in CREATE TABLE, ALTER TABLE, and CREATE_INDEX statements is interpreted as number of characters for nonbinary string types (CHAR, VARCHAR, TEXT) and number of bytes for binary string types (BINARY, VARBINARY, BLOB). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

- An `index_col_name` specification can end with ASC or DESC. These keywords are permitted for future extensions for specifying ascending or descending index value storage. Currently, they are parsed but ignored; index values are always stored in ascending order.

- When you use ORDER BY or GROUP BY on a column in a SELECT, the server sorts values using only the initial number of bytes indicated by the `max_sort_length` system variable.

- You can create special FULLTEXT indexes, which are used for full-text searches. Only the MyISAM storage engine supports FULLTEXT indexes. They can be created only from CHAR, VARCHAR, and TEXT columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See Section 12.9, “Full-Text Search Functions”, for details of operation. A WITH PARSER clause can be specified as an `index_option` value to associate a parser plugin with the index if full-text indexing and searching operations need special handling. This clause is valid only for FULLTEXT indexes. See Section 22.2, “The MySQL Plugin API”, for details on creating plugins.

- You can create SPATIAL indexes on spatial data types. Spatial types are supported only for MyISAM tables and indexed columns must be declared as NOT NULL. See Section 11.5, “Extensions for Spatial Data”.
CREATE TABLE Syntax

- **InnoDB** tables support checking of foreign key constraints. The columns of the referenced table must always be explicitly named. Both **ON DELETE** and **ON UPDATE** actions on foreign keys. For more detailed information and examples, see [Section 13.1.17.3, “Using FOREIGN KEY Constraints”](https://dev.mysql.com/doc/refman/8.0/en/create-table-foreign-key.html). For information specific to foreign keys in **InnoDB**, see [Section 14.6.6.6, “InnoDB and FOREIGN KEY Constraints”](https://dev.mysql.com/doc/refman/8.0/en/innodb-foreign-key-constraints.html).

For other storage engines, MySQL Server parses and ignores the **FOREIGN KEY** and **REFERENCES** syntax in **CREATE TABLE** statements. The **CHECK** clause is parsed but ignored by all storage engines. See [Section 1.8.2.4, “Foreign Key Differences”](https://dev.mysql.com/doc/refman/8.0/en/foreign-keys.html).

**Important**

For users familiar with the ANSI/ISO SQL Standard, please note that no storage engine, including **InnoDB**, recognizes or enforces the **MATCH** clause used in referential integrity constraint definitions. Use of an explicit **MATCH** clause will not have the specified effect, and also causes **ON DELETE** and **ON UPDATE** clauses to be ignored. For these reasons, specifying **MATCH** should be avoided.

The **MATCH** clause in the SQL standard controls how **NULL** values in a composite (multiple-column) foreign key are handled when comparing to a primary key. **InnoDB** essentially implements the semantics defined by **MATCH SIMPLE**, which permit a foreign key to be all or partially **NULL**. In that case, the (child table) row containing such a foreign key is permitted to be inserted, and does not match any row in the referenced (parent) table. It is possible to implement other semantics using triggers.

Additionally, MySQL requires that the referenced columns be indexed for performance. However, **InnoDB** does not enforce any requirement that the referenced columns be declared **UNIQUE** or **NOT NULL**. The handling of foreign key references to nonunique keys or keys that contain **NULL** values is not well defined for operations such as **UPDATE** or **DELETE CASCADE**. You are advised to use foreign keys that reference only keys that are both **UNIQUE** (or **PRIMARY**) and **NOT NULL**.

MySQL parses but ignores “inline REFERENCES specifications” (as defined in the SQL standard) where the references are defined as part of the column specification. MySQL accepts REFERENCES clauses only when specified as part of a separate **FOREIGN KEY** specification.

**Note**

- There is a hard limit of 4096 columns per table, but the effective maximum may be less for a given table and depends on the factors discussed in [Section C.7.4, “Limits on Table Column Count and Row Size”](https://dev.mysql.com/doc/refman/8.0/en/limits.html).

The **TABLESPACE** and **STORAGE** table options were both introduced in MySQL 5.1.6. In MySQL 5.1, they are employed only with **NDBCLUSTER** tables. The tablespace named **tablespace_name** must already have been created using **CREATE TABLESPACE**. **STORAGE** determines the type of storage used (disk or memory), and can be one of **DISK**, **MEMORY**, or **DEFAULT**.

**TABLESPACE** ... **STORAGE** **DISK** assigns a table to a MySQL Cluster Disk Data tablespace. See [Section 17.5.12, “MySQL Cluster Disk Data Tables”](https://dev.mysql.com/doc/refman/8.0/en/cluster-disk-data-tables.html), for more information.
CREATE TABLE Syntax

Important
A **STORAGE** clause cannot be used in a **CREATE TABLE** statement without a **TABLESPACE** clause.

The **ENGINE** table option specifies the storage engine for the table.

**Storage Engines**

The **ENGINE** table option specifies the storage engine for the table, using one of the names shown in the following table. The engine name can be unquoted or quoted. The quoted name 'DEFAULT' is equivalent to specifying the default storage engine name.

<table>
<thead>
<tr>
<th>Storage Engine</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARCHIVE</td>
<td>The archiving storage engine. See Section 14.12, &quot;The ARCHIVE Storage Engine&quot;.</td>
</tr>
<tr>
<td>CSV</td>
<td>Tables that store rows in comma-separated values format. See Section 14.13, &quot;The CSV Storage Engine&quot;.</td>
</tr>
<tr>
<td>EXAMPLE</td>
<td>An example engine. See Section 14.10, &quot;The EXAMPLE Storage Engine&quot;.</td>
</tr>
<tr>
<td>FEDERATED</td>
<td>Storage engine that accesses remote tables. See Section 14.11, &quot;The FEDERATED Storage Engine&quot;.</td>
</tr>
<tr>
<td>HEAP</td>
<td>This is a synonym for MEMORY.</td>
</tr>
<tr>
<td>InnoDB</td>
<td>Transaction-safe tables with row locking and foreign keys. See Section 14.6, &quot;The InnoDB Storage Engine&quot;.</td>
</tr>
<tr>
<td>MEMORY</td>
<td>The data for this storage engine is stored only in memory. See Section 14.9, &quot;The MEMORY Storage Engine&quot;.</td>
</tr>
<tr>
<td>MERGE</td>
<td>A collection of <strong>MyISAM</strong> tables used as one table. Also known as <strong>MRG_MyISAM</strong>. See Section 14.8, &quot;The MERGE Storage Engine&quot;.</td>
</tr>
<tr>
<td>MyISAM</td>
<td>The binary portable storage engine that is the default storage engine used by MySQL. See Section 14.5, &quot;The MyISAM Storage Engine&quot;.</td>
</tr>
<tr>
<td>NDBCLUSTER</td>
<td>Clustered, fault-tolerant, memory-based tables. Also known as NDB. See Chapter 17, MySQL Cluster NDB 6.1 - 7.1.</td>
</tr>
</tbody>
</table>

If a storage engine is specified that is not available, MySQL uses the default engine instead. Normally, this is **MyISAM**. For example, if a table definition includes the **ENGINE=INNODB** option but the MySQL server does not support **INNODB** tables, the table is created as a **MyISAM** table. This makes it possible to have a replication setup where you have transactional tables on the master but tables created on the slave are nontransactional (to get more speed). In MySQL 5.1, a warning occurs if the storage engine specification is not honored.

Engine substitution can be controlled by the setting of the **NO_ENGINE_SUBSTITUTION** SQL mode, as described in Section 5.1.7, "Server SQL Modes".

**Note**
The older **TYPE** option was synonymous with **ENGINE**. **TYPE** has been deprecated since MySQL 4.0 but is still supported for backward compatibility in MySQL 5.1 (excepting MySQL 5.1.7). Since MySQL 5.1.8, it produces a warning. It is removed in MySQL 5.5. **You should not use TYPE in any new applications, and you should immediately begin conversion of existing applications to use ENGINE instead.** (See the Release Notes for MySQL 5.1.8.)

**Optimizing Performance**
The other table options are used to optimize the behavior of the table. In most cases, you do not have to specify any of them. These options apply to all storage engines unless otherwise indicated. Options that do not apply to a given storage engine may be accepted and remembered as part of the table...
CREATE TABLE Syntax

Such options then apply if you later use `ALTER TABLE` to convert the table to use a different storage engine.

- **AUTO_INCREMENT**

  The initial `AUTO_INCREMENT` value for the table. In MySQL 5.1, this works for `MyISAM`, `MEMORY`, and `InnoDB` tables. It also works for `ARCHIVE` tables as of MySQL 5.1.6. To set the first auto-increment value for engines that do not support the `AUTO_INCREMENT` table option, insert a "dummy" row with a value one less than the desired value after creating the table, and then delete the dummy row.

  For engines that support the `AUTO_INCREMENT` table option in `CREATE TABLE` statements, you can also use `ALTER TABLE tbl_name AUTO_INCREMENT = N` to reset the `AUTO_INCREMENT` value. The value cannot be set lower than the maximum value currently in the column.

- **AVG_ROW_LENGTH**

  An approximation of the average row length for your table. You need to set this only for large tables with variable-size rows.

  When you create a `MyISAM` table, MySQL uses the product of the `MAX_ROWS` and `AVG_ROW_LENGTH` options to decide how big the resulting table is. If you don't specify either option, the maximum size for `MyISAM` data and index files is 256TB by default. (If your operating system does not support files that large, table sizes are constrained by the file size limit.) If you want to keep down the pointer sizes to make the index smaller and faster and you don't really need big files, you can decrease the default pointer size by setting the `myisam_data_pointer_size` system variable. (See Section 5.1.4, "Server System Variables".) If you want all your tables to be able to grow above the default limit and are willing to have your tables slightly slower and larger than necessary, you can increase the default pointer size by setting this variable. Setting the value to 7 permits table sizes up to 65,536TB.

- **[DEFAULT] CHARACTER SET**

  Specify a default character set for the table. `CHARSET` is a synonym for `CHARACTER SET`. If the character set name is `DEFAULT`, the database character set is used.

- **CHECKSUM**

  Set this to 1 if you want MySQL to maintain a live checksum for all rows (that is, a checksum that MySQL updates automatically as the table changes). This makes the table a little slower to update, but also makes it easier to find corrupted tables. The `CHECKSUM TABLE` statement reports the checksum. (MyISAM only.)

- **[DEFAULT] COLLATE**

  Specify a default collation for the table.

- **COMMENT**

  A comment for the table, up to 60 characters long.

- **CONNECTION**

  The connection string for a `FEDERATED` table.

  **Note**

  Older versions of MySQL used a `COMMENT` option for the connection string.

- **DATA DIRECTORY, INDEX DIRECTORY**
By using `DATA DIRECTORY='directory'` or `INDEX DIRECTORY='directory'` you can specify where the MyISAM storage engine should put a table's data file and index file. The directory must be the full path name to the directory, not a relative path.

**Important**

Beginning with MySQL 5.1.23, table-level `DATA DIRECTORY` and `INDEX DIRECTORY` options are ignored for partitioned tables. (Bug #32091)

These options work only when you are not using the `--skip-symbolic-links` option. Your operating system must also have a working, thread-safe `realpath()` call. See Section 8.12.4.2, “Using Symbolic Links for MyISAM Tables on Unix”, for more complete information.

If a MyISAM table is created with no `DATA DIRECTORY` option, the `.MYD` file is created in the database directory. By default, if MyISAM finds an existing `.MYD` file in this case, it overwrites it. The same applies to `.MYI` files for tables created with no `INDEX DIRECTORY` option. As of MySQL 5.1.23, to suppress this behavior, start the server with the `--keep_files_on_create` option, in which case MyISAM will not overwrite existing files and returns an error instead.

If a MyISAM table is created with a `DATA DIRECTORY` or `INDEX DIRECTORY` option and an existing `.MYD` or `.MYI` file is found, MyISAM always returns an error. It will not overwrite a file in the specified directory.

**Important**

Beginning with MySQL 5.1.24, you cannot use path names that contain the MySQL data directory with `DATA DIRECTORY` or `INDEX DIRECTORY`. This includes partitioned tables and individual table partitions. (See Bug #32167.)

- **DELAY_KEY_WRITE**

  Set this to 1 if you want to delay key updates for the table until the table is closed. See the description of the `delay_key_write` system variable in Section 5.1.4, “Server System Variables”. (MyISAM only.)

- **INSERT_METHOD**

  If you want to insert data into a MERGE table, you must specify with `INSERT_METHOD` the table into which the row should be inserted. `INSERT_METHOD` is an option useful for MERGE tables only. Use a value of `FIRST` or `LAST` to have inserts go to the first or last table, or a value of `NO` to prevent inserts. See Section 14.8, “The MERGE Storage Engine”.

- **KEY_BLOCK_SIZE**

  For MyISAM tables, `KEY_BLOCK_SIZE` optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A `KEY_BLOCK_SIZE` value specified for an individual index definition overrides the table-level `KEY_BLOCK_SIZE` value.

  `KEY_BLOCK_SIZE` was added in MySQL 5.1.10.

- **MAX_ROWS**

  The maximum number of rows you plan to store in the table. This is not a hard limit, but rather a hint to the storage engine that the table must be able to store at least this many rows.

  The NDB storage engine treats this value as a maximum. If you plan to create very large MySQL Cluster tables (containing millions of rows), you should use this option to insure that NDB allocates sufficient number of index slots in the hash table used for storing hashes of the table's primary keys.
by setting `MAX_ROWS = 2 * rows`, where `rows` is the number of rows that you expect to insert into the table.

**Note**
This option was incorrectly ignored by MySQL Cluster NDB 7.0 prior to version 7.0.20 and MySQL Cluster NDB 7.1 prior to version 7.1.9 (see Bug #57360).

The maximum `MAX_ROWS` value is 4294967295; larger values are truncated to this limit.

• **MIN_ROWS**

  The minimum number of rows you plan to store in the table. The `MEMORY` storage engine uses this option as a hint about memory use.

• **PACK_KEYS**

  `PACK_KEYS` takes effect only with `MyISAM` tables. Set this option to 1 if you want to have smaller indexes. This usually makes updates slower and reads faster. Setting the option to 0 disables all packing of keys. Setting it to `DEFAULT` tells the storage engine to pack only long `CHAR`, `VARCHAR`, `BINARY`, or `VARBINARY` columns.

  If you do not use `PACK_KEYS`, the default is to pack strings, but not numbers. If you use `PACK_KEYS=1`, numbers are packed as well.

  When packing binary number keys, MySQL uses prefix compression:

  • Every key needs one extra byte to indicate how many bytes of the previous key are the same for the next key.

  • The pointer to the row is stored in high-byte-first order directly after the key, to improve compression.

  This means that if you have many equal keys on two consecutive rows, all following “same” keys usually only take two bytes (including the pointer to the row). Compare this to the ordinary case where the following keys takes `storage_size_for_key + pointer_size` (where the pointer size is usually 4). Conversely, you get a significant benefit from prefix compression only if you have many numbers that are the same. If all keys are totally different, you use one byte more per key, if the key is not a key that can have `NULL` values. (In this case, the packed key length is stored in the same byte that is used to mark if a key is `NULL`.)

• **PASSWORD**

  This option is unused. If you have a need to scramble your `.frm` files and make them unusable to any other MySQL server, please contact our sales department.

• **ROW_FORMAT**

  Defines the physical format in which the rows are stored. The choices differ depending on the storage engine used for the table.

  For `InnoDB` tables:

  • Rows are stored in compact format (`ROW_FORMAT=COMPACT`) by default.

  • The noncompact format used in older versions of MySQL can still be requested by specifying `ROW_FORMAT=REDUNDANT`.

  • To enable compression for `InnoDB` tables, specify `ROW_FORMAT=COMPRESSED` and follow the procedures in `InnoDB Table Compression`. This feature is available when you use the `InnoDB Plugin` for MySQL 5.1.
For more efficient InnoDB storage of data types, especially BLOB types, specify ROW_FORMAT=DYNAMIC and follow the procedures in DYNAMIC and COMPRESSED Row Formats. This feature is available when you use the InnoDB Plugin for MySQL 5.1. Both the COMPRESSED and DYNAMIC row formats require creating the table with the configuration settings innodb_file_per_table=1 and innodb_file_format=barracuda.

When you specify a non-default ROW_FORMAT clause, consider also enabling the innodb_strict_mode configuration option.

ROW_FORMAT=FIXED is not supported. If ROW_FORMAT=FIXED is specified while innodb_strict_mode is disabled, InnoDB defaults to ROW_FORMAT=COMPACT. If ROW_FORMAT=FIXED is specified while innodb_strict_mode is enabled, InnoDB returns an error.

For MyISAM tables, the option value can be FIXED or DYNAMIC for static or variable-length row format. myisampack sets the type to COMPRESSED. See Section 14.5.3, “MyISAM Table Storage Formats”.

Note

When executing a CREATE TABLE statement, if you specify a row format which is not supported by the storage engine that is used for the table, the table is created using that storage engine's default row format. The information reported in this column in response to SHOW TABLE STATUS is the actual row format used. This may differ from the value in the Create_options column because the original CREATE TABLE definition is retained during creation.

UNION

UNION is used when you want to access a collection of identical MyISAM tables as one. This works only with MERGE tables. See Section 14.8, “The MERGE Storage Engine”.

You must have SELECT, UPDATE, and DELETE privileges for the tables you map to a MERGE table.

Note

Formerly, all tables used had to be in the same database as the MERGE table itself. This restriction no longer applies.

Creating Partitioned Tables

partition_options can be used to control partitioning of the table created with CREATE TABLE.

Important

Not all options shown in the syntax for partition_options at the beginning of this section are available for all partitioning types. Please see the listings for the following individual types for information specific to each type, and see Chapter 18, Partitioning, for more complete information about the workings of and uses for partitioning in MySQL, as well as additional examples of table creation and other statements relating to MySQL partitioning.

If used, a partition_options clause begins with PARTITION BY. This clause contains the function that is used to determine the partition; the function returns an integer value ranging from 1 to num, where num is the number of partitions. (The maximum number of user-defined partitions which a table may contain is 1024; the number of subpartitions—discussed later in this section—is included in this maximum.) The choices that are available for this function in MySQL 5.1 are shown in the following list:
• **HASH(expr):** Hashes one or more columns to create a key for placing and locating rows. `expr` is an expression using one or more table columns. This can be any valid MySQL expression (including MySQL functions) that yields a single integer value. For example, these are both valid `CREATE TABLE` statements using `PARTITION BY HASH`:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5))
    PARTITION BY HASH(col1);
```
```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATETIME)
    PARTITION BY HASH ( YEAR(col3) );
```

You may not use either `VALUES LESS THAN` or `VALUES IN` clauses with `PARTITION BY HASH`.

**PARTITION BY HASH** uses the remainder of `expr` divided by the number of partitions (that is, the modulus). For examples and additional information, see Section 18.2.3, “HASH Partitioning”.

The `LINEAR` keyword entails a somewhat different algorithm. In this case, the number of the partition in which a row is stored is calculated as the result of one or more logical `AND` operations. For discussion and examples of linear hashing, see Section 18.2.3.1, “LINEAR HASH Partitioning”.

• **KEY(column_list):** This is similar to `HASH`, except that MySQL supplies the hashing function so as to guarantee an even data distribution. The `column_list` argument is simply a list of table columns. This example shows a simple table partitioned by key, with 4 partitions:

```
CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)
    PARTITION BY KEY(col3)
    PARTITIONS 4;
```

For tables that are partitioned by key, you can employ linear partitioning by using the `LINEAR` keyword. This has the same effect as with tables that are partitioned by `HASH`. That is, the partition number is found using the `&` operator rather than the modulus (see Section 18.2.3.1, “LINEAR HASH Partitioning”, and Section 18.2.4, “KEY Partitioning”, for details). This example uses linear partitioning by key to distribute data between 5 partitions:

```
CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)
    PARTITION BY LINEAR KEY(col3)
    PARTITIONS 5;
```

You may not use either `VALUES LESS THAN` or `VALUES IN` clauses with `PARTITION BY KEY`.

• **RANGE(expr):** In this case, `expr` shows a range of values using a set of `VALUES LESS THAN` operators. When using range partitioning, you must define at least one partition using `VALUES LESS THAN`. You cannot use `VALUES IN` with range partitioning.

`VALUES LESS THAN` can be used with either a literal value or an expression that evaluates to a single value.

Suppose that you have a table that you wish to partition on a column containing year values, according to the following scheme.

<table>
<thead>
<tr>
<th>Partition Number</th>
<th>Years Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1990 and earlier</td>
</tr>
<tr>
<td>1</td>
<td>1991 to 1994</td>
</tr>
<tr>
<td>2</td>
<td>1995 to 1998</td>
</tr>
<tr>
<td>3</td>
<td>1999 to 2002</td>
</tr>
<tr>
<td>4</td>
<td>2003 to 2005</td>
</tr>
<tr>
<td>5</td>
<td>2006 and later</td>
</tr>
</tbody>
</table>
A table implementing such a partitioning scheme can be realized by the `CREATE TABLE` statement shown here:

```sql
CREATE TABLE t1 (
  year_col  INT,
  some_data INT
)
PARTITION BY RANGE (year_col) (
  PARTITION p0 VALUES LESS THAN (1991),
  PARTITION p1 VALUES LESS THAN (1995),
  PARTITION p2 VALUES LESS THAN (1999),
  PARTITION p3 VALUES LESS THAN (2002),
  PARTITION p4 VALUES LESS THAN (2006),
  PARTITION p5 VALUES LESS THAN MAXVALUE
);
```

`PARTITION ... VALUES LESS THAN ...` statements work in a consecutive fashion. `VALUES LESS THAN MAXVALUE` works to specify “leftover” values that are greater than the maximum value otherwise specified.

`VALUES LESS THAN` clauses work sequentially in a manner similar to that of the `case` portions of a `switch ... case` block (as found in many programming languages such as C, Java, and PHP). That is, the clauses must be arranged in such a way that the upper limit specified in each successive `VALUES LESS THAN` is greater than that of the previous one, with the one referencing `MAXVALUE` coming last of all in the list.

- **LIST(expr):** This is useful when assigning partitions based on a table column with a restricted set of possible values, such as a state or country code. In such a case, all rows pertaining to a certain state or country can be assigned to a single partition, or a partition can be reserved for a certain set of states or countries. It is similar to `RANGE`, except that only `VALUES IN` may be used to specify permissible values for each partition.

`VALUES IN` is used with a list of values to be matched. For instance, you could create a partitioning scheme such as the following:

```sql
CREATE TABLE client_firms (
  id   INT,
  name VARCHAR(35)
)
PARTITION BY LIST (id) (
  PARTITION r0 VALUES IN (1, 5, 9, 13, 17, 21),
  PARTITION r1 VALUES IN (2, 6, 10, 14, 18, 22),
  PARTITION r2 VALUES IN (3, 7, 11, 15, 19, 23),
  PARTITION r3 VALUES IN (4, 8, 12, 16, 20, 24)
);
```

When using list partitioning, you must define at least one partition using `VALUES IN`. You cannot use `VALUES LESS THAN` with `PARTITION BY LIST`.

**Note**

Currently, the value list used with `VALUES IN` must consist of integer values only.

- The number of partitions may optionally be specified with a `PARTITIONS num` clause, where `num` is the number of partitions. If both this clause and any `PARTITION` clauses are used, `num` must be equal to the total number of any partitions that are declared using `PARTITION` clauses.
Whether or not you use a PARTITIONS clause in creating a table that is partitioned by RANGE or LIST, you must still include at least one PARTITION VALUES clause in the table definition (see below).

A partition may optionally be divided into a number of subpartitions. This can be indicated by using the optional SUBPARTITION BY clause. Subpartitioning may be done by HASH or KEY. Either of these may be LINEAR. These work in the same way as previously described for the equivalent partitioning types. (It is not possible to subpartition by LIST or RANGE.)

The number of subpartitions can be indicated using the SUBPARTITIONS keyword followed by an integer value.

MySQL 5.1.12 introduces rigorous checking of the value used in a PARTITIONS or SUBPARTITIONS clause. Beginning with this version, this value must adhere to the following rules:

- The value must be a positive, nonzero integer.
- No leading zeros are permitted.
- The value must be an integer literal, and cannot not be an expression. For example, PARTITIONS 0.2E+01 is not permitted, even though 0.2E+01 evaluates to 2. (Bug #15890)

Each partition may be individually defined using a partition_definition clause. The individual parts making up this clause are as follows:

- PARTITION partition_name: This specifies a logical name for the partition.

- A VALUES clause: For range partitioning, each partition must include a VALUES LESS THAN clause; for list partitioning, you must specify a VALUES IN clause for each partition. This is used to determine which rows are to be stored in this partition. See the discussions of partitioning types in Chapter 18, Partitioning, for syntax examples.

- An optional COMMENT clause may be used to specify a string that describes the partition. Example:

  `COMMENT = 'Data for the years previous to 1999'`

- DATA DIRECTORY and INDEX DIRECTORY may be used to indicate the directory where, respectively, the data and indexes for this partition are to be stored. Both the data_dir and the index_dir must be absolute system path names. Example:

```sql
CREATE TABLE th (id INT, name VARCHAR(30), adate DATE)
PARTITION BY LIST(YEAR(adate))
(
  DATA DIRECTORY = '/var/appdata/95/data',
  INDEX DIRECTORY = '/var/appdata/95/idx',
  DATA DIRECTORY = '/var/appdata/96/data',
  INDEX DIRECTORY = '/var/appdata/96/idx',
  DATA DIRECTORY = '/var/appdata/97/data',
  INDEX DIRECTORY = '/var/appdata/97/idx',
```
CREATE TABLE Syntax

```
DATA DIRECTORY = '/var/appdata/98/data' 
INDEX DIRECTORY = '/var/appdata/98/idx'
```

DATA DIRECTORY and INDEX DIRECTORY behave in the same way as in the CREATE TABLE statement's table_option clause as used for MyISAM tables.

One data directory and one index directory may be specified per partition. If left unspecified, the data and indexes are stored by default in the table's database directory.

On Windows, the DATA DIRECTORY and INDEX DIRECTORY options are not supported for individual partitions or subpartitions. Beginning with MySQL 5.1.24, these options are ignored on Windows, except that a warning is generated. (Bug #30459)

**Note**

Prior to MySQL 5.1.18, DATA DIRECTORY and INDEX DIRECTORY were permitted even if the NO_DIR_IN_CREATE server SQL mode was in effect at the time that a partitioned table was created. Beginning with MySQL 5.1.18, these options are ignored for creating partitioned tables if NO_DIR_IN_CREATE is in effect. (Bug #24633)

- MAX_ROWS and MIN_ROWS may be used to specify, respectively, the maximum and minimum number of rows to be stored in the partition. The values for max_number_of_rows and min_number_of_rows must be positive integers. As with the table-level options with the same names, these act only as “suggestions” to the server and are not hard limits.

- The optional TABLESPACE clause may be used to designate a tablespace for the partition. Used for MySQL Cluster only.

- The partitioning handler accepts a [STORAGE] ENGINE option for both PARTITION and SUBPARTITION. Currently, the only way in which this can be used is to set all partitions or all subpartitions to the same storage engine, and an attempt to set different storage engines for partitions or subpartitions in the same table will give rise to the error ERROR 1469 (HY000): The mix of handlers in the partitions is not permitted in this version of MySQL. We expect to lift this restriction on partitioning in a future MySQL release.

- The NODEGROUP option can be used to make this partition act as part of the node group identified by node_group_id. This option is applicable only to MySQL Cluster.

- The partition definition may optionally contain one or more subpartition_definition clauses. Each of these consists at a minimum of the SUBPARTITION name, where name is an identifier for the subpartition. Except for the replacement of the PARTITION keyword with SUBPARTITION, the syntax for a subpartition definition is identical to that for a partition definition.

Subpartitioning must be done by HASH or KEY, and can be done only on RANGE or LIST partitions. See Section 18.2.5, “Subpartitioning”.

Partitions can be modified, merged, added to tables, and dropped from tables. For basic information about the MySQL statements to accomplish these tasks, see Section 13.1.7, “ALTER TABLE Syntax”. For more detailed descriptions and examples, see Section 18.3, “Partition Management”.

**Important**

The original CREATE TABLE statement, including all specifications and table options are stored by MySQL when the table is created. The information is retained so that if you change storage engines, collations or other settings using an ALTER TABLE statement, the original table options specified are retained. This enables you to change between InnoDB and MyISAM table types even though the row formats supported by the two engines are different.
Because the text of the original statement is retained, but due to the way that certain values and options may be silently reconfigured (such as the ROW_FORMAT), the active table definition (accessible through DESCRIBE or with SHOW TABLE STATUS) and the table creation string (accessible through SHOW CREATE TABLE) will report different values.

### 13.1.17.1 CREATE TABLE ... LIKE Syntax

Use `CREATE TABLE ... LIKE` to create an empty table based on the definition of another table, including any column attributes and indexes defined in the original table:

```sql
CREATE TABLE new_tbl LIKE orig_tbl;
```

The copy is created using the same version of the table storage format as the original table. The `LIKE` privilege is required on the original table.

`LIKE` works only for base tables, not for views.

`CREATE TABLE ... LIKE` does not preserve any `DATA DIRECTORY` or `INDEX DIRECTORY` table options that were specified for the original table, or any foreign key definitions.

If the original table is a `TEMPORARY` table, `CREATE TABLE ... LIKE` does not preserve `TEMPORARY`. To create a `TEMPORARY` destination table, use `CREATE TEMPORARY TABLE ... LIKE`.

In MySQL 5.1, changes to the SQL mode do not affect `CREATE TABLE ... LIKE`. If the current SQL mode is different from the mode in effect when the original table was created, the statement succeeds even if the table definition is invalid for the new mode.

### 13.1.17.2 CREATE TABLE ... SELECT Syntax

You can create one table from another by adding a `SELECT` statement at the end of the `CREATE TABLE` statement:

```sql
CREATE TABLE new_tbl [AS] SELECT * FROM orig_tbl;
```

MySQL creates new columns for all elements in the `SELECT`. For example:

```sql
mysql> CREATE TABLE test (a INT NOT NULL AUTO_INCREMENT,
                                      PRIMARY KEY (a), KEY(b))
                     ENGINE=MyISAM SELECT b,c FROM test2;
```

This creates a `MyISAM` table with three columns, `a`, `b`, and `c`. The `ENGINE` option is part of the `CREATE TABLE` statement, and should not be used following the `SELECT`; this would result in a syntax error. The same is true for other `CREATE TABLE` options such as CHARSET.

Notice that the columns from the `SELECT` statement are appended to the right side of the table, not overlapped onto it. Take the following example:

```sql
mysql> SELECT * FROM foo;
+---+
| n |
+---+
| 1 |
+---+

mysql> CREATE TABLE bar (m INT) SELECT n FROM foo;
Query OK, 1 row affected (0.02 sec)
Records: 1  Duplicates: 0  Warnings: 0
```
CREATE TABLE Syntax

mysql> SELECT * FROM bar;
+------+---+
| m    | n  |
| NULL | 1  |
+------+---+
1 row in set (0.00 sec)

For each row in table foo, a row is inserted in bar with the values from foo and default values for the new columns.

In a table resulting from `CREATE TABLE ... SELECT`, columns named only in the `CREATE TABLE` part come first. Columns named in both parts or only in the `SELECT` part come after that. The data type of `SELECT` columns can be overridden by also specifying the column in the `CREATE TABLE` part.

If any errors occur while copying the data to the table, it is automatically dropped and not created.

You can precede the `SELECT` by `IGNORE` or `REPLACE` to indicate how to handle rows that duplicate unique key values. With `IGNORE`, rows that duplicate an existing row on a unique key value are discarded. With `REPLACE`, new rows replace rows that have the same unique key value. If neither `IGNORE` nor `REPLACE` is specified, duplicate unique key values result in an error.

`CREATE TABLE ... SELECT` does not automatically create any indexes for you. This is done intentionally to make the statement as flexible as possible. If you want to have indexes in the created table, you should specify these before the `SELECT` statement:

```sql
mysql> CREATE TABLE bar (UNIQUE (n)) SELECT n FROM foo;
```

Some conversion of data types might occur. For example, the `AUTO_INCREMENT` attribute is not preserved, and `VARCHAR` columns can become `CHAR` columns. Retained attributes are `NULL` (or `NOT NULL`) and, for those columns that have them, `CHARACTER SET`, `COLLATION`, `COMMENT`, and the `DEFAULT` clause.

When creating a table with `CREATE TABLE ... SELECT`, make sure to alias any function calls or expressions in the query. If you do not, the `CREATE` statement might fail or result in undesirable column names.

```sql
CREATE TABLE artists_and_works
SELECT artist.name, COUNT(work.artist_id) AS number_of_works
FROM artist LEFT JOIN work ON artist.id = work.artist_id
GROUP BY artist.id;
```

You can also explicitly specify the data type for a column in the created table:

```sql
CREATE TABLE foo (a TINYINT NOT NULL) SELECT b+1 AS a FROM bar;
```

For `CREATE TABLE ... SELECT`, if `IF NOT EXISTS` is given and the destination table already exists, the result is version dependent. Before MySQL 5.5.6, MySQL handles the statement as follows:

- The table definition given in the `CREATE TABLE` part is ignored. No error occurs, even if the definition does not match that of the existing table. MySQL attempts to insert the rows from the `SELECT` part anyway.

- If there is a mismatch between the number of columns in the table and the number of columns produced by the `SELECT` part, the selected values are assigned to the rightmost columns. For example, if the table contains \( n \) columns and the `SELECT` produces \( m \) columns, where \( m < n \), the selected values are assigned to the \( m \) rightmost columns in the table. Each of the initial \( n - m \) columns is assigned its default value, either that specified explicitly in the column definition or the implicit column data type default if the definition contains no default. If the `SELECT` part produces too many columns \( (m > n) \), an error occurs.
CREATE TABLE Syntax

• If strict SQL mode is enabled and any of these initial columns do not have an explicit default value, the statement fails with an error.

The following example illustrates IF NOT EXISTS handling:

```
CREATE TABLE t1 (i1 INT DEFAULT 0, i2 INT, i3 INT, i4 INT);
Query OK, 0 rows affected (0.05 sec)
```

```
CREATE TABLE IF NOT EXISTS t1 (c1 CHAR(10)) SELECT 1, 2;
Query OK, 1 row affected, 1 warning (0.01 sec)
Records: 1  Duplicates: 0  Warnings: 0
```

```
SELECT * FROM t1;
+------+------+------+------+
<table>
<thead>
<tr>
<th>i1</th>
<th>i2</th>
<th>i3</th>
<th>i4</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>NULL</td>
<td>1</td>
<td>2</td>
</tr>
</tbody>
</table>
+------+------+------+------+
1 row in set (0.00 sec)
```

As of MySQL 5.5.6, handling of `CREATE TABLE IF NOT EXISTS ... SELECT` statements was changed for the case that the destination table already exists. This change also involves a change in MySQL 5.1 beginning with 5.1.51.

• Previously, for `CREATE TABLE IF NOT EXISTS ... SELECT`, MySQL produced a warning that the table exists, but inserted the rows and wrote the statement to the binary log anyway. By contrast, `CREATE TABLE ... SELECT` (without IF NOT EXISTS) failed with an error, but MySQL inserted no rows and did not write the statement to the binary log.

• MySQL now handles both statements the same way when the destination table exists, in that neither statement inserts rows or is written to the binary log. The difference between them is that MySQL produces a warning when IF NOT EXISTS is present and an error when it is not.

This means that, for the preceding example, the `CREATE TABLE IF NOT EXISTS ... SELECT` statement inserts nothing into the destination table as of MySQL 5.5.6.

This change in handling of IF NOT EXISTS results in an incompatibility for statement-based replication from a MySQL 5.1 master with the original behavior and a MySQL 5.5 slave with the new behavior. Suppose that `CREATE TABLE IF NOT EXISTS ... SELECT` is executed on the master and the destination table exists. The result is that rows are inserted on the master but not on the slave. (Row-based replication does not have this problem.)

To address this issue, statement-based binary logging for `CREATE TABLE IF NOT EXISTS ... SELECT` statement inserts nothing into the destination table as of MySQL 5.5.6.

This change is changed in MySQL 5.1 as of 5.1.51:

• If the destination table does not exist, there is no change: The statement is logged as is.

• If the destination table does exist, the statement is logged as the equivalent pair of `CREATE TABLE IF NOT EXISTS` and `INSERT ... SELECT` statements. (If the `SELECT` in the original statement is preceded by `IGNORE` or `REPLACE`, the `INSERT` becomes `INSERT IGNORE` or `REPLACE`, respectively.)

This change provides forward compatibility for statement-based replication from MySQL 5.1 to 5.5 because when the destination table exists, the rows will be inserted on both the master and slave. To take advantage of this compatibility measure, the 5.1 server must be at least 5.1.51 and the 5.5 server must be at least 5.5.6.

To upgrade an existing 5.1-to-5.5 replication scenario, upgrade the master first to 5.1.51 or higher. Note that this differs from the usual replication upgrade advice of upgrading the slave first.

A workaround for applications that wish to achieve the original effect (rows inserted regardless of whether the destination table exists) is to use `CREATE TABLE IF NOT EXISTS` and `INSERT ... SELECT` statements rather than `CREATE TABLE IF NOT EXISTS ... SELECT` statements.
Along with the change just described, the following related change was made: Previously, if an existing view was named as the destination table for `CREATE TABLE IF NOT EXISTS ... SELECT`, rows were inserted into the underlying base table and the statement was written to the binary log. As of MySQL 5.1.51 and 5.5.6, nothing is inserted or logged.

To ensure that the binary log can be used to re-create the original tables, MySQL does not permit concurrent inserts during `CREATE TABLE ... SELECT`.

### 13.1.17.3 Using FOREIGN KEY Constraints

MySQL supports foreign keys, which let you cross-reference related data across tables, and foreign key constraints, which help keep this spread-out data consistent. The essential syntax for a foreign key constraint definition in a `CREATE TABLE` or `ALTER TABLE` statement looks like this:

```
[CONSTRAINT [symbol]] FOREIGN KEY
  [index_name] (index_col_name, ...)
REFERENCES tbl_name (index_col_name, ...)
[ON DELETE reference_option]
[ON UPDATE reference_option]
```

`index_name` represents a foreign key ID. The `index_name` value is ignored if there is already an explicitly defined index on the child table that can support the foreign key. Otherwise, MySQL implicitly creates a foreign key index that is named according to the following rules:

- If defined, the `CONSTRAINT symbol` value is used. Otherwise, the `FOREIGN KEY index_name` value is used.
- If neither a `CONSTRAINT symbol` or `FOREIGN KEY index_name` is defined, the foreign key index name is generated using the name of the referencing foreign key column.

Foreign keys definitions are subject to the following conditions:

- Foreign key relationships involve a parent table that holds the central data values, and a child table with identical values pointing back to its parent. The `FOREIGN KEY` clause is specified in the child table. The parent and child tables must use the same storage engine. They must not be `TEMPORARY` tables.

- Corresponding columns in the foreign key and the referenced key must have similar data types. The size and sign of integer types must be the same. The length of string types need not be the same. For nonbinary (character) string columns, the character set and collation must be the same.

- When `foreign_key_checks` is enabled, which is the default setting, character set conversion is not permitted on tables that include a character string column used in a foreign key constraint. The workaround is described in Section 13.1.7, “ALTER TABLE Syntax”.

- MySQL requires indexes on foreign keys and referenced keys so that foreign key checks can be fast and not require a table scan. In the referencing table, there must be an index where the foreign key columns are listed as the first columns in the same order. Such an index is created on the referencing table automatically if it does not exist. This index might be silently dropped later, if you create another index that can be used to enforce the foreign key constraint. `index_name`, if given, is used as described previously.

- InnoDB permits a foreign key to reference any index column or group of columns. However, in the referenced table, there must be an index where the referenced columns are listed as the first columns in the same order.

- Index prefixes on foreign key columns are not supported. One consequence of this is that BLOB and TEXT columns cannot be included in a foreign key because indexes on those columns must always include a prefix length.
If the CONSTRAINT symbol clause is given, the symbol value, if used, must be unique in the database. A duplicate symbol will result in an error similar to: "ERROR 1005 (HY000): Can't create table 'test.#sql-211d_3' (errno: 121). If the clause is not given, or a symbol is not included following the CONSTRAINT keyword, a name for the constraint is created automatically.

InnoDB does not currently support foreign keys for tables with user-defined partitioning. This includes both parent and child tables.

Referential Actions

This section describes how foreign keys help guarantee referential integrity.

For storage engines supporting foreign keys, MySQL rejects any INSERT or UPDATE operation that attempts to create a foreign key value in a child table if there is no a matching candidate key value in the parent table.

When an UPDATE or DELETE operation affects a key value in the parent table that has matching rows in the child table, the result depends on the referential action specified using ON UPDATE and ON DELETE subclauses of the FOREIGN KEY clause. MySQL supports five options regarding the action to be taken, listed here:

- **CASCADE**: Delete or update the row from the parent table, and automatically delete or update the matching rows in the child table. Both ON DELETE CASCADE and ON UPDATE CASCADE are supported. Between two tables, do not define several ON UPDATE CASCADE clauses that act on the same column in the parent table or in the child table.

  Note
  Cascaded foreign key actions do not activate triggers.

- **SET NULL**: Delete or update the row from the parent table, and set the foreign key column or columns in the child table to NULL. Both ON DELETE SET NULL and ON UPDATE SET NULL clauses are supported.

  If you specify a SET NULL action, make sure that you have not declared the columns in the child table as NOT NULL.

- **RESTRICT**: Rejects the delete or update operation for the parent table. Specifying RESTRICT (or NO ACTION) is the same as omitting the ON DELETE or ON UPDATE clause.

- **NO ACTION**: A keyword from standard SQL. In MySQL, equivalent to RESTRICT. The MySQL Server rejects the delete or update operation for the parent table if there is a related foreign key value in the referenced table. Some database systems have deferred checks, and NO ACTION is a deferred check. In MySQL, foreign key constraints are checked immediately, so NO ACTION is the same as RESTRICT.

- **SET DEFAULT**: This action is recognized by the MySQL parser, but InnoDB rejects table definitions containing ON DELETE SET DEFAULT or ON UPDATE SET DEFAULT clauses.

  For an ON DELETE or ON UPDATE that is not specified, the default action is always RESTRICT.

MySQL supports foreign key references between one column and another within a table. (A column cannot have a foreign key reference to itself.) In these cases, “child table records” really refers to dependent records within the same table.

Examples of Foreign Key Clauses

Here is a simple example that relates parent and child tables through a single-column foreign key:
### CREATE TABLE Syntax

```sql
CREATE TABLE parent (  
id INT NOT NULL,  
PRIMARY KEY (id)  ) ENGINE=INNODB;

CREATE TABLE child (  
id INT,  
parent_id INT,  
INDEX par_ind (parent_id),  
FOREIGN KEY (parent_id)  
REFERENCES parent(id)  
ON DELETE CASCADE  ) ENGINE=INNODB;
```

A more complex example in which a `product_order` table has foreign keys for two other tables. One foreign key references a two-column index in the `product` table. The other references a single-column index in the `customer` table:

```sql
CREATE TABLE product (  
category INT NOT NULL, id INT NOT NULL,  
price DECIMAL,  
PRIMARY KEY(category, id)  )   ENGINE=INNODB;

CREATE TABLE customer (  
id INT NOT NULL,  
PRIMARY KEY (id)  )   ENGINE=INNODB;

CREATE TABLE product_order (  
o INT NOT NULL AUTO_INCREMENT,  
product_category INT NOT NULL,  
product_id INT NOT NULL,  
customer_id INT NOT NULL,  
PRIMARY KEY(no),  
INDEX (product_category, product_id),  
INDEX (customer_id),  
FOREIGN KEY (product_category, product_id)  
REFERENCES product(category, id)  
ON UPDATE CASCADE ON DELETE RESTRICT,  
FOREIGN KEY (customer_id)  
REFERENCES customer(id)  )   ENGINE=INNODB;
```

### Adding foreign keys

You can add a new foreign key constraint to an existing table by using `ALTER TABLE`. The syntax relating to foreign keys for this statement is shown here:

```sql
ALTER TABLE tbl_name  
ADD [CONSTRAINT [symbol]] FOREIGN KEY  
[index_name] (index_col_name, ...)
REFERENCES tbl_name (index_col_name,...)  
[ON UPDATE reference_option]  
[ON DELETE reference_option]
```

The foreign key can be self referential (referring to the same table). When you add a foreign key constraint to a table using `ALTER TABLE`, **remember to create the required indexes first.**

### Dropping Foreign Keys

You can also use `ALTER TABLE` to drop foreign keys, using the syntax shown here:

```sql
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```
If the `FOREIGN KEY` clause included a `CONSTRAINT` name when you created the foreign key, you can refer to that name to drop the foreign key. Otherwise, the `fk_symbol` value is generated internally when the foreign key is created. To find out the symbol value when you want to drop a foreign key, use a `SHOW CREATE TABLE` statement, as shown here:

```sql
SHOW CREATE TABLE ibtest11c
```

```text
*************************** 1. row ***************************
Table: ibtest11c
Create Table: CREATE TABLE `ibtest11c` (
  `A` int(11) NOT NULL auto_increment,
  `D` int(11) NOT NULL default '0',
  `B` varchar(200) NOT NULL default '',
  `C` varchar(175) default NULL,
  PRIMARY KEY  (`A`,`D`,`B`),
  KEY `B` (`B`,
  KEY `C` (`C`),
  CONSTRAINT `0_38775` FOREIGN KEY (`A`, `D`) REFERENCES `ibtest11a` (`A`, `D`) ON DELETE CASCADE ON UPDATE CASCADE,
  CONSTRAINT `0_38776` FOREIGN KEY (`B`, `C`) REFERENCES `ibtest11a` (`B`, `C`) ON DELETE CASCADE ON UPDATE CASCADE
) ENGINE=INNODB CHARSET=latin1
```

```sql
ALTER TABLE ibtest11c DROP FOREIGN KEY `0_38775`;
```

Adding and dropping a foreign key in separate clauses of a single `ALTER TABLE` statement may be problematic in some cases and is therefore unsupported. Use separate statements for each operation.

If an `ALTER TABLE` statement results in changes to column values (for example, because a column is truncated), MySQL's foreign key constraint checks do not notice possible violations caused by changing the values.

**Foreign Keys and Other MySQL Statements**

Table and column identifiers in a `FOREIGN KEY ... REFERENCES ...` clause can be quoted within backticks (``). Alternatively, double quotation marks ("`) can be used if the `ANSI_QUOTES` SQL mode is enabled. The setting of the `lower_case_table_names` system variable is also taken into account.

You can view a child table's foreign key definitions as part of the output of the `SHOW CREATE TABLE` statement:

```sql
SHOW CREATE TABLE tbl_name;
```

You can also obtain information about foreign keys by querying the `INFORMATION_SCHEMA.KEY_COLUMN_USAGE` table.

`mysqldump` produces correct definitions of tables in the dump file, including the foreign keys for child tables.

To make it easier to reload dump files for tables that have foreign key relationships, `mysqldump` automatically includes a statement in the dump output to set `foreign_key_checks` to 0. This avoids problems with tables having to be reloaded in a particular order when the dump is reloaded. It is also possible to set this variable manually:

```sql
SET foreign_key_checks = 0;
```

```sql
SOURCE dump_file_name;
```

```sql
SET foreign_key_checks = 1;
```

This enables you to import the tables in any order if the dump file contains tables that are not correctly ordered for foreign keys. It also speeds up the import operation. Setting `foreign_key_checks` to 0 can also be useful for ignoring foreign key constraints during `LOAD DATA` and `ALTER TABLE`
CREATE TABLE Syntax

operations. However, even if `foreign_key_checks = 0`, MySQL does not permit the creation of a foreign key constraint where a column references a nonmatching column type. Also, if a table has foreign key constraints, ALTER TABLE cannot be used to alter the table to use another storage engine. To change the storage engine, you must drop any foreign key constraints first.

You cannot issue DROP TABLE for a table that is referenced by a FOREIGN KEY constraint, unless you do SET foreign_key_checks = 0. When you drop a table, any constraints that were defined in the statement used to create that table are also dropped.

If you re-create a table that was dropped, it must have a definition that conforms to the foreign key constraints referencing it. It must have the correct column names and types, and it must have indexes on the referenced keys, as stated earlier. If these are not satisfied, MySQL returns Error 1005 and refers to Error 150 in the error message, which means that a foreign key constraint was not correctly formed. Similarly, if an ALTER TABLE fails due to Error 150, this means that a foreign key definition would be incorrectly formed for the altered table.

For InnoDB tables, you can obtain a detailed explanation of the most recent InnoDB foreign key error in the MySQL Server, by checking the output of SHOW ENGINE INNODB STATUS.

Important

For users familiar with the ANSI/ISO SQL Standard, please note that no storage engine, including InnoDB, recognizes or enforces the MATCH clause used in referential-integrity constraint definitions. Use of an explicit MATCH clause will not have the specified effect, and also causes ON DELETE and ON UPDATE clauses to be ignored. For these reasons, specifying MATCH should be avoided.

The MATCH clause in the SQL standard controls how NULL values in a composite (multiple-column) foreign key are handled when comparing to a primary key. MySQL essentially implements the semantics defined by MATCH SIMPLE, which permit a foreign key to be all or partially NULL. In that case, the (child table) row containing such a foreign key is permitted to be inserted, and does not match any row in the referenced (parent) table. It is possible to implement other semantics using triggers.

Additionally, MySQL requires that the referenced columns be indexed for performance reasons. However, the system does not enforce a requirement that the referenced columns be UNIQUE or be declared NOT NULL. The handling of foreign key references to nonunique keys or keys that contain NULL values is not well defined for operations such as UPDATE or DELETE CASCADE. You are advised to use foreign keys that reference only UNIQUE (including PRIMARY) and NOT NULL keys.

Furthermore, MySQL parses but ignores “inline REFERENCES specifications” (as defined in the SQL standard) where the references are defined as part of the column specification. MySQL accepts REFERENCES clauses only when specified as part of a separate FOREIGN KEY specification. For storage engines that do not support foreign keys (such as MyISAM), MySQL Server parses and ignores foreign key specifications.

13.1.17.4 Silent Column Specification Changes

In some cases, MySQL silently changes column specifications from those given in a CREATE TABLE or ALTER TABLE statement. These might be changes to a data type, to attributes associated with a data type, or to an index specification.

All changes are subject to the internal row-size limit of 65,535 bytes, which may cause some attempts at data type changes to fail. See Section C.7.4, “Limits on Table Column Count and Row Size”.

• TIMESTAMP display sizes are discarded.
Also note that `TIMESTAMP` columns are `NOT NULL` by default.

- Columns that are part of a `PRIMARY KEY` are made `NOT NULL` even if not declared that way.
- Trailing spaces are automatically deleted from `ENUM` and `SET` member values when the table is created.
- MySQL maps certain data types used by other SQL database vendors to MySQL types. See Section 11.9, “Using Data Types from Other Database Engines”.
- If you include a `USING` clause to specify an index type that is not permitted for a given storage engine, but there is another index type available that the engine can use without affecting query results, the engine uses the available type.
- If strict SQL mode is not enabled, a `VARCHAR` column with a length specification greater than 65535 is converted to `TEXT`, and a `VARBINARY` column with a length specification greater than 65535 is converted to `BLOB`. Otherwise, an error occurs in either of these cases.
- Specifying the `CHARACTER SET binary` attribute for a character data type causes the column to be created as the corresponding binary data type: `CHAR` becomes `BINARY`, `VARCHAR` becomes `VARBINARY`, and `TEXT` becomes `BLOB`. For the `ENUM` and `SET` data types, this does not occur; they are created as declared. Suppose that you specify a table using this definition:

```sql
cREATE TABLE t
(
  c1 VARCHAR(10) CHARACTER SET binary,
  c2 TEXT CHARACTER SET binary,
  c3 ENUM('a','b','c') CHARACTER SET binary
);
```

The resulting table has this definition:

```sql
cREATE TABLE t
(
  c1 VARBINARY(10),
  c2 BLOB,
  c3 ENUM('a','b','c') CHARACTER SET binary
);
```

To see whether MySQL used a data type other than the one you specified, issue a `DESCRIBE` or `SHOW CREATE TABLE` statement after creating or altering the table.

Certain other data type changes can occur if you compress a table using `myisampack`. See Section 14.5.3.3, “Compressed Table Characteristics”.

### 13.1.18 CREATE TABLESPACE Syntax

```sql
CREATE TABLESPACE `tablespace_name`
   ADD DATAFILE 'file_name'
   USE LOGFILE GROUP `logfile_group`
   [EXTENT_SIZE [=] `extent_size`]
   [INITIAL_SIZE [=] `initial_size`]
   [AUTOEXTEND_SIZE [=] `autoextend_size`]
   [MAX_SIZE [=] `max_size`]
   [NODEGROUP [=] `nodegroup_id`]
   [WAIT]
   [COMMENT [=] `comment_text`]
   ENGINE [=] `engine_name`
```

This statement is used to create a tablespace, which can contain one or more data files, providing storage space for tables. One data file is created and added to the tablespace using this statement. Additional data files may be added to the tablespace by using the `ALTER TABLESPACE` statement (see
CREATE TABLESPACE Syntax

Section 13.1.8, “ALTER TABLESPACE Syntax”). For rules covering the naming of tablespaces, see Section 9.2, “Schema Object Names”.

Note
All MySQL Cluster Disk Data objects share the same namespace. This means that each Disk Data object must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group with the same name, or a tablespace and a data file with the same name.

Prior to MySQL Cluster NDB 6.2.17, 6.3.23, and 6.4.3, path and file names for data files could not be longer than 128 characters. (Bug #31770)

A log file group of one or more UNDO log files must be assigned to the tablespace to be created with the USE LOGFILE GROUP clause. logfile_group must be an existing log file group created with CREATE LOGFILE GROUP (see Section 13.1.14, “CREATE LOGFILE GROUP Syntax”). Multiple tablespaces may use the same log file group for UNDO logging.

The EXTENT_SIZE sets the size, in bytes, of the extents used by any files belonging to the tablespace. The default value is 1M. The minimum size is 32K, and theoretical maximum is 2G, although the practical maximum size depends on a number of factors. In most cases, changing the extent size does not have any measurable effect on performance, and the default value is recommended for all but the most unusual situations.

An extent is a unit of disk space allocation. One extent is filled with as much data as that extent can contain before another extent is used. In theory, up to 65,535 (64K) extents may used per data file; however, the recommended maximum is 32,768 (32K). The recommended maximum size for a single data file is 32G—that is, 32K extents × 1 MB per extent. In addition, once an extent is allocated to a given partition, it cannot be used to store data from a different partition; an extent cannot store data from more than one partition. This means, for example that a tablespace having a single datafile whose INITIAL_SIZE is 256 MB and whose EXTENT_SIZE is 128M has just two extents, and so can be used to store data from at most two different disk data table partitions.

You can see how many extents remain free in a given data file by querying the INFORMATION_SCHEMA.FILES table, and so derive an estimate for how much space remains free in the file. For further discussion and examples, see Section 20.26.1, “The INFORMATION_SCHEMA FILES Table”.

The INITIAL_SIZE parameter sets the data file’s total size in bytes. Once the file has been created, its size cannot be changed; however, you can add more data files to the tablespace using ALTER TABLESPACE . . . ADD DATAFILE. See Section 13.1.8, “ALTER TABLESPACE Syntax”.

INITIAL_SIZE is optional; its default value is 128M.

On 32-bit systems, the maximum supported value for INITIAL_SIZE is 4G. (Bug #29186)

When setting EXTENT_SIZE or INITIAL_SIZE (either or both), you may optionally follow the number with a one-letter abbreviation for an order of magnitude, similar to those used in my.cnf. Generally, this is one of the letters M (for megabytes) or G (for gigabytes).

INITIAL_SIZE, EXTENT_SIZE, and UNDO_BUFFER_SIZE are subject to rounding as follows:

• EXTENT_SIZE and UNDO_BUFFER_SIZE are each rounded up to the nearest whole multiple of 32K.

• INITIAL_SIZE is rounded down to the nearest whole multiple of 32K.

For data files, INITIAL_SIZE is subject to further rounding; the result just obtained is rounded up to the nearest whole multiple of EXTENT_SIZE (after any rounding).

The rounding just described has always (since Disk Data tablespaces were introduced in MySQL 5.1.6) been performed implicitly, but beginning with MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.32,
MySQL Cluster NDB 7.0.13, and MySQL Cluster NDB 7.1.2, this rounding is done explicitly, and a warning is issued by the MySQL Server when any such rounding is performed. The rounded values are also used by the NDB kernel for calculating INFORMATION_SCHEMA.FILES column values and other purposes. However, to avoid an unexpected result, we suggest that you always use whole multiples of 32K in specifying these options.

AUTOEXTEND_SIZE, MAX_SIZE, NODEGROUP, WAIT, and COMMENT are parsed but ignored, and so currently have no effect. These options are intended for future expansion.

The ENGINE parameter determines the storage engine which uses this tablespace, with engine_name being the name of the storage engine. In MySQL 5.1, engine_name must be one of the values NDB or NDBCLUSTER.

When CREATE TABLESPACE is used with ENGINE = NDB, a tablespace and associated data file are created on each Cluster data node. You can verify that the data files were created and obtain information about them by querying the INFORMATION_SCHEMA.FILES table. For example:

```sql
mysql> SELECT LOGFILE_GROUP_NAME, FILE_NAME, EXTRA
    -> FROM INFORMATION_SCHEMA.FILES
    -> WHERE TABLESPACE_NAME = 'newts' AND FILE_TYPE = 'DATAFILE';
+--------------------+-------------+----------------+
<table>
<thead>
<tr>
<th>LOGFILE_GROUP_NAME</th>
<th>FILE_NAME</th>
<th>EXTRA</th>
</tr>
</thead>
<tbody>
<tr>
<td>lg_3</td>
<td>newdata.dat</td>
<td>CLUSTER_NODE=3</td>
</tr>
<tr>
<td>lg_3</td>
<td>newdata.dat</td>
<td>CLUSTER_NODE=4</td>
</tr>
</tbody>
</table>
+--------------------+-------------+----------------+
2 rows in set (0.01 sec)
```

(See Section 20.26.1, “The INFORMATION_SCHEMA.FILES Table”.)

CREATE TABLESPACE was added in MySQL 5.1.6. In MySQL 5.1, it is useful only with Disk Data storage for MySQL Cluster. See Section 17.5.12, “MySQL Cluster Disk Data Tables”.

13.1.19 CREATE TRIGGER Syntax

This statement creates a new trigger. A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. The trigger becomes associated with the table named tbl_name, which must refer to a permanent table. You cannot associate a trigger with a TEMPORARY table or a view.

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

This section describes CREATE TRIGGER syntax. For additional discussion, see Section 19.3.1, “Trigger Syntax and Examples”.

CREATE TRIGGER requires the TRIGGER privilege for the table associated with the trigger. The statement might also require the SUPER privilege, depending on the DEFINER value, as described later in this section. If binary logging is enabled, CREATE TRIGGER might require the SUPER privilege, as described in Section 19.7, “Binary Logging of Stored Programs”. (Before MySQL 5.1.6, there is no TRIGGER privilege and this statement requires the SUPER privilege in all cases.)
CREATE TRIGGER Syntax

The `DEFINER` clause determines the security context to be used when checking access privileges at trigger activation time, as described later in this section.

`trigger_time` is the trigger action time. It can be `BEFORE` or `AFTER` to indicate that the trigger activates before or after each row to be modified.

`trigger_event` indicates the kind of operation that activates the trigger. These `trigger_event` values are permitted:

- **INSERT**: The trigger activates whenever a new row is inserted into the table; for example, through `INSERT`, `LOAD DATA`, and `REPLACE` statements.
- **UPDATE**: The trigger activates whenever a row is modified; for example, through `UPDATE` statements.
- **DELETE**: The trigger activates whenever a row is deleted from the table; for example, through `DELETE` and `REPLACE` statements. `DROP TABLE` and `TRUNCATE TABLE` statements on the table do not activate this trigger, because they do not use `DELETE`. Dropping a partition does not activate `DELETE` triggers, either.

The `trigger_event` does not represent a literal type of SQL statement that activates the trigger so much as it represents a type of table operation. For example, an `INSERT` trigger activates not only for `INSERT` statements but also `LOAD DATA` statements because both statements insert rows into a table.

A potentially confusing example of this is the `INSERT INTO ... ON DUPLICATE KEY UPDATE ...` syntax: a `BEFORE INSERT` trigger activates for every row, followed by either an `AFTER INSERT` trigger or both the `BEFORE UPDATE` and `AFTER UPDATE` triggers, depending on whether there was a duplicate key for the row.

Note: Cascaded foreign key actions do not activate triggers.

There cannot be multiple triggers for a given table that have the same trigger event and action time. For example, you cannot have two `BEFORE UPDATE` triggers for a table. But you can have a `BEFORE UPDATE` and a `BEFORE INSERT` trigger, or a `BEFORE UPDATE` and an `AFTER UPDATE` trigger.

`trigger_body` is the statement to execute when the trigger activates. To execute multiple statements, use the `BEGIN ... END` compound statement construct. This also enables you to use the same statements that are permissible within stored routines. See Section 13.8.1, “BEGIN ... END Compound-Statement Syntax”. Some statements are not permitted in triggers; see Section C.1, “Restrictions on Stored Programs”.

Within the trigger body, you can refer to columns in the subject table (the table associated with the trigger) by using the aliases `OLD` and `NEW`. `OLD.col_name` refers to a column of an existing row before it is updated or deleted. `NEW.col_name` refers to the column of a new row to be inserted or an existing row after it is updated.

MySQL stores the `sql_mode` system variable setting in effect when a trigger is created, and always executes the trigger body with this setting in force, regardless of the current server SQL mode when the trigger begins executing.

The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at trigger activation time. If a `user` value is given, it should be a MySQL account specified as `'user_name'@'host_name'` (the same format used in the `GRANT` statement), `CURRENT_USER`, or `CURRENT_USER()`. The default `DEFINER` value is the user who executes the `CREATE TRIGGER` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

If you specify the `DEFINER` clause, these rules determine the valid `DEFINER` user values:

- If you do not have the `SUPER` privilege, the only permitted `user` value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.
CREATE VIEW Syntax

- If you have the `SUPER` privilege, you can specify any syntactically valid account name. If the account does not exist, a warning is generated.

- Although it is possible to create a trigger with a nonexistent `DEFINER` account, it is not a good idea for such triggers to be activated until the account actually does exist. Otherwise, the behavior with respect to privilege checking is undefined.

Note: Prior to MySQL 5.1.6, `CREATE TRIGGER` always requires the `SUPER` privilege, so only the second of the preceding rules applies.

MySQL takes the `DEFINER` user into account when checking trigger privileges as follows:

- At `CREATE TRIGGER` time, the user who issues the statement must have the `TRIGGER` privilege. (`SUPER` prior to MySQL 5.1.6.)

- At trigger activation time, privileges are checked against the `DEFINER` user. This user must have these privileges:
  
  - The `TRIGGER` privilege. (`SUPER` prior to MySQL 5.1.6.)
  
  - The `SELECT` privilege for the subject table if references to table columns occur using `OLD.col_name` or `NEW.col_name` in the trigger body.
  
  - The `UPDATE` privilege for the subject table if table columns are targets of `SET NEW.col_name = value` assignments in the trigger body.
  
  - Whatever other privileges normally are required for the statements executed by the trigger.

For more information about trigger security, see Section 19.6, “Access Control for Stored Programs and Views”.

Within a trigger body, the `CURRENT_USER()` function returns the account used to check privileges at trigger activation time. This is the `DEFINER` user, not the user whose actions caused the trigger to be activated. For information about user auditing within triggers, see Section 6.3.6, “SQL-Based MySQL Account Activity Auditing”.

If you use `LOCK TABLES` to lock a table that has triggers, the tables used within the trigger are also locked, as described in Section 13.3.5.2, “LOCK TABLES and Triggers”.

For additional discussion of trigger use, see Section 19.3.1, “Trigger Syntax and Examples”.

13.1.20 CREATE VIEW Syntax

```
CREATE [OR REPLACE]
[ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
[DEFINER = { user | CURRENT_USER }]
[SQL SECURITY { DEFINER | INVOKER }]
VIEW view_name [(column_list)]
AS select_statement [(WITH [CASCADED | LOCAL] CHECK OPTION)]
```

The `CREATE VIEW` statement creates a new view, or replaces an existing view if the `OR REPLACE` clause is given. If the view does not exist, `CREATE OR REPLACE VIEW` is the same as `CREATE VIEW`. If the view does exist, `CREATE OR REPLACE VIEW` is the same as `ALTER VIEW`.

The `select_statement` is a `SELECT` statement that provides the definition of the view. (Selecting from the view selects, in effect, using the `SELECT` statement.) The `select_statement` can select from base tables or other views.

The view definition is “frozen” at creation time and is not affected by subsequent changes to the definitions of the underlying tables. For example, if a view is defined as `SELECT *` on a table, new
columns added to the table later do not become part of the view, and columns dropped from the table will result in an error when selecting from the view.

The `ALGORITHM` clause affects how MySQL processes the view. The `DEFINER` and `SQL SECURITY` clauses specify the security context to be used when checking access privileges at view invocation time. The `WITH CHECK OPTION` clause can be given to constrain inserts or updates to rows in tables referenced by the view. These clauses are described later in this section.

The `CREATE VIEW` statement requires the `CREATE VIEW` privilege for the view, and some privilege for each column selected by the `SELECT` statement. For columns used elsewhere in the `SELECT` statement, you must have the `SELECT` privilege. If the `OR REPLACE` clause is present, you must also have the `DROP` privilege for the view. `CREATE VIEW` might also require the `SUPER` privilege, depending on the `DEFINER` value, as described later in this section.

When a view is referenced, privilege checking occurs as described later in this section.

A view belongs to a database. By default, a new view is created in the default database. To create the view explicitly in a given database, use `db_name.view_name` syntax to qualify the view name with the database name:

```sql
mysql> CREATE VIEW test.v AS SELECT * FROM t;
```

Within a database, base tables and views share the same namespace, so a base table and a view cannot have the same name.

Columns retrieved by the `SELECT` statement can be simple references to table columns, or expressions that use functions, constant values, operators, and so forth.

A view must have unique column names with no duplicates, just like a base table. By default, the names of the columns retrieved by the `SELECT` statement are used for the view column names. To define explicit names for the view columns, the optional `column_list` clause can be given as a list of comma-separated identifiers. The number of names in `column_list` must be the same as the number of columns retrieved by the `SELECT` statement.

**Note**

Prior to MySQL 5.1.29, when you modify an existing view, the server saves a backup of the current view definition under the view database directory, in a subdirectory named `arc`. The backup file for a view `v` is named `v.frm-00001`. If you alter the view again, the next backup is named `v.frm-00002`. The three latest view backup definitions are stored.

Backed up view definitions are not preserved by `mysqldump`, or any other such programs, but you can retain them using a file copy operation. However, they are not needed for anything but to provide you with a backup of your previous view definition.

It is safe to remove these backup definitions, but only while `mysqld` is not running. If you delete the `arc` subdirectory or its files while `mysqld` is running, an error occurs the next time you try to alter the view:

```sql
mysql> ALTER VIEW v AS SELECT * FROM t;
ERROR 6 (HY000): Error on delete of '.\test\arc/v.frm-0004' (Errcode: 2)
```

Unqualified table or view names in the `SELECT` statement are interpreted with respect to the default database. A view can refer to tables or views in other databases by qualifying the table or view name with the appropriate database name.

A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables.
The following example defines a view that selects two columns from another table as well as an expression calculated from those columns:

```sql
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50);
mvsql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mvsql> SELECT * FROM v;
+-----+-----+-----+
<table>
<thead>
<tr>
<th>qty</th>
<th>price</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>50</td>
<td>150</td>
</tr>
</tbody>
</table>
+-----+-----+-----+
```

A view definition is subject to the following restrictions:

- The `SELECT` statement cannot contain a subquery in the `FROM` clause.
- The `SELECT` statement cannot refer to system variables or user-defined variables.
- Within a stored program, the `SELECT` statement cannot refer to program parameters or local variables.
- The `SELECT` statement cannot refer to prepared statement parameters.
- Any table or view referred to in the definition must exist. After the view has been created, it is possible to drop a table or view that the definition refers to. In this case, use of the view results in an error. To check a view definition for problems of this kind, use the `CHECK TABLE` statement.
- The definition cannot refer to a `TEMPORARY` table, and you cannot create a `TEMPORARY` view.
- You cannot associate a trigger with a view.
- As of MySQL 5.1.23, aliases for column names in the `SELECT` statement are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters).

`ORDER BY` is permitted in a view definition, but it is ignored if you select from a view using a statement that has its own `ORDER BY`.

For other options or clauses in the definition, they are added to the options or clauses of the statement that references the view, but the effect is undefined. For example, if a view definition includes a `LIMIT` clause, and you select from the view using a statement that has its own `LIMIT` clause, it is undefined which limit applies. This same principle applies to options such as `ALL`, `DISTINCT`, or `SQL_SMALL_RESULT` that follow the `SELECT` keyword, and to clauses such as `INTO`, `FOR UPDATE`, `LOCK IN SHARE MODE`, and `PROCEDURE`.

If you create a view and then change the query processing environment by changing system variables, that may affect the results you get from the view:

```sql
mysql> CREATE VIEW v (mycol) AS SELECT 'abc';
Query OK, 0 rows affected (0.01 sec)
mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT "mycol" FROM v;
+-----+
| mycol |
+-----+
1 row in set (0.01 sec)
mysql> SET sql_mode = 'ANSI_QUOTES';
Query OK, 0 rows affected (0.00 sec)
```
CREATE VIEW Syntax

mysql> SELECT "mycol" FROM v;
+-------+
| mycol |
+-------+
| abc   |
+-------+
1 row in set (0.00 sec)

The **DEFINER** and **SQL SECURITY** clauses determine which MySQL account to use when checking access privileges for the view when a statement is executed that references the view. These clauses were added in MySQL 5.1.2. The valid **SQL SECURITY** characteristic values are **DEFINER** (the default) and **INVOKER**. These indicate that the required privileges must be held by the user who defined or invoked the view, respectively.

If a **user** value is given for the **DEFINER** clause, it should be a MySQL account specified as `'user_name'@'host_name'` (the same format used in the **GRANT** statement), **CURRENT_USER**, or **CURRENT_USER()**. The default **DEFINER** value is the user who executes the **CREATE VIEW** statement. This is the same as specifying **DEFINER = CURRENT_USER** explicitly.

If you specify the **DEFINER** clause, these rules determine the valid **DEFINER** user values:

- If you do not have the **SUPER** privilege, the only valid **user** value is your own account, either specified literally or by using **CURRENT_USER**. You cannot set the definer to some other account.
- If you have the **SUPER** privilege, you can specify any syntactically valid account name. If the account does not exist, a warning is generated.
- Although it is possible to create a view with a nonexistent **DEFINER** account, an error occurs when the view is referenced if the **SQL SECURITY** value is **DEFINER** but the definer account does not exist.

For more information about view security, see Section 19.6, “Access Control for Stored Programs and Views”.

Within a view definition, **CURRENT_USER** returns the view's **DEFINER** value by default as of MySQL 5.1.12. For older versions, and for views defined with the **SQL SECURITY INVOKER** characteristic, **CURRENT_USER** returns the account for the view's invoker. For information about user auditing within views, see Section 6.3.6, “SQL-Based MySQL Account Activity Auditing”.

Within a stored routine that is defined with the **SQL SECURITY DEFINER** characteristic, **CURRENT_USER** returns the routine's **DEFINER** value. This also affects a view defined within such a routine, if the view definition contains a **DEFINER** value of **CURRENT_USER**.

As of MySQL 5.1.2 (when the **DEFINER** and **SQL SECURITY** clauses were implemented), view privileges are checked like this:

- At view definition time, the view creator must have the privileges needed to use the top-level objects accessed by the view. For example, if the view definition refers to table columns, the creator must have some privilege for each column in the select list of the definition, and the **SELECT** privilege for each column used elsewhere in the definition. If the definition refers to a stored function, only the privileges needed to invoke the function can be checked. The privileges required at function invocation time can be checked only as it executes: For different invocations, different execution paths within the function might be taken.
- The user who references a view must have appropriate privileges to access it (**SELECT** to select from it, **INSERT** to insert into it, and so forth.)
- When a view has been referenced, privileges for objects accessed by the view are checked against the privileges held by the view **DEFINER** account or invoker, depending on whether the **SQL SECURITY** characteristic is **DEFINER** or **INVOKER**, respectively.
- If reference to a view causes execution of a stored function, privilege checking for statements executed within the function depend on whether the function **SQL SECURITY** characteristic is
DEFINER or INVOKER. If the security characteristic is DEFINER, the function runs with the privileges of the DEFINER account. If the characteristic is INVOKER, the function runs with the privileges determined by the view's SQL SECURITY characteristic.

Prior to MySQL 5.1.2 (before the DEFINER and SQL SECURITY clauses were implemented), privileges required for objects used in a view are checked at view creation time.

Example: A view might depend on a stored function, and that function might invoke other stored routines. For example, the following view invokes a stored function f():

```sql
CREATE VIEW v AS SELECT * FROM t WHERE t.id = f(t.name);
```

Suppose that f() contains a statement such as this:

```sql
IF name IS NULL then
  CALL p1();
ELSE
  CALL p2();
END IF;
```

The privileges required for executing statements within f() need to be checked when f() executes. This might mean that privileges are needed for p1() or p2(), depending on the execution path within f(). Those privileges must be checked at runtime, and the user who must possess the privileges is determined by the SQL SECURITY values of the view v and the function f().

The DEFINER and SQL SECURITY clauses for views are extensions to standard SQL. In standard SQL, views are handled using the rules for SQL SECURITY DEFINER. The standard says that the definer of the view, which is the same as the owner of the view's schema, gets applicable privileges on the view (for example, SELECT) and may grant them. MySQL has no concept of a schema “owner”, so MySQL adds a clause to identify the definer. The DEFINER clause is an extension where the intent is to have what the standard has; that is, a permanent record of who defined the view. This is why the default DEFINER value is the account of the view creator.

If you invoke a view that was created before MySQL 5.1.2, it is treated as though it was created with a SQL SECURITY DEFINER characteristic and with a DEFINER value that is the same as your account. However, because the actual definer is unknown, MySQL issues a warning. To eliminate the warning, it is sufficient to re-create the view so that the view definition includes a DEFINER clause.

The optional ALGORITHM clause is a MySQL extension to standard SQL. It affects how MySQL processes the view. ALGORITHM takes three values: MERGE, TEMPTABLE, or UNDEFINED. The default algorithm is UNDEFINED if no ALGORITHM clause is present. For more information, see Section 19.5.2, “View Processing Algorithms”.

Some views are updatable. That is, you can use them in statements such as UPDATE, DELETE, or INSERT to update the contents of the underlying table. For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view nonupdatable.

The WITH CHECK OPTION clause can be given for an updatable view to prevent inserts or updates to rows except those for which the WHERE clause in the select_statement is true.

In a WITH CHECK OPTION clause for an updatable view, the LOCAL and CASCADED keywords determine the scope of check testing when the view is defined in terms of another view. The LOCAL keyword restricts the CHECK OPTION only to the view being defined. CASCADED causes the checks for underlying views to be evaluated as well. When neither keyword is given, the default is CASCADED.

For more information about updatable views and the WITH CHECK OPTION clause, see Section 19.5.3, “Updatable and Insertable Views”, and Section 19.5.4, “The View WITH CHECK OPTION Clause”.

13.1.21 DROP DATABASE Syntax
DROP EVENT Syntax

DROP DATABASE | SCHEMA] [IF EXISTS] db_name

DROP DATABASE drops all tables in the database and deletes the database. Be very careful with this statement! To use DROP DATABASE, you need the DROP privilege on the database. DROP_SCHEMA is a synonym for DROP_DATABASE.

Important

When a database is dropped, user privileges on the database are not automatically dropped. See Section 13.7.1.3, “GRANT Syntax”.

IF EXISTS is used to prevent an error from occurring if the database does not exist.

If the default database is dropped, the default database is unset (the DATABASE() function returns NULL).

If you use DROP DATABASE on a symbolically linked database, both the link and the original database are deleted.

DROP DATABASE returns the number of tables that were removed. This corresponds to the number of .frm files removed.

The DROP DATABASE statement removes from the given database directory those files and directories that MySQL itself may create during normal operation:

• All files with the following extensions.

<table>
<thead>
<tr>
<th>.BAK</th>
<th>.DAT</th>
<th>.HSH</th>
<th>.MRG</th>
</tr>
</thead>
<tbody>
<tr>
<td>.MYD</td>
<td>.MYI</td>
<td>.TRG</td>
<td>.TRN</td>
</tr>
<tr>
<td>.db</td>
<td>.frm</td>
<td>.ibd</td>
<td>.ndb</td>
</tr>
<tr>
<td>.par</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

• The db.opt file, if it exists.

If other files or directories remain in the database directory after MySQL removes those just listed, the database directory cannot be removed. In this case, you must remove any remaining files or directories manually and issue the DROP DATABASE statement again.

Dropping a database does not remove any TEMPORARY tables that were created in that database. TEMPORARY tables are automatically removed when the session that created them ends. See Temporary Tables.

You can also drop databases with mysqladmin. See Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”.

13.1.22 DROP EVENT Syntax

DROP EVENT [IF EXISTS] event_name

This statement drops the event named event_name. The event immediately ceases being active, and is deleted completely from the server.

If the event does not exist, the error ERROR 1517 (HY000): Unknown event 'event_name' results. You can override this and cause the statement to generate a warning for nonexistent events instead using IF EXISTS.

Beginning with MySQL 5.1.12, this statement requires the EVENT privilege for the schema to which the event to be dropped belongs. (In MySQL 5.1.11 and earlier, an event could be dropped only by its definer, or by a user having the SUPER privilege.)
13.1.23 DROP FUNCTION Syntax

The **DROP FUNCTION** statement is used to drop stored functions and user-defined functions (UDFs):

- For information about dropping stored functions, see Section 13.1.26, "DROP PROCEDURE and DROP FUNCTION Syntax".
- For information about dropping user-defined functions, see Section 13.7.3.2, "DROP FUNCTION Syntax".

13.1.24 DROP INDEX Syntax

```sql
DROP [ONLINE|OFFLINE] INDEX index_name ON tbl_name
```

**DROP INDEX** drops the index named **index_name** from the table **tbl_name**. This statement is mapped to an **ALTER TABLE** statement to drop the index. See Section 13.1.7, "ALTER TABLE Syntax".

To drop a primary key, the index name is always **PRIMARY**, which must be specified as a quoted identifier because **PRIMARY** is a reserved word:

```sql
DROP INDEX `PRIMARY` ON t;
```

Beginning with MySQL 5.1.17, indexes on variable-width columns of **NDBCLUSTER** tables are dropped online; that is, without any table copying. The table is not locked against access from other MySQL Cluster API nodes, although it is locked against other operations on the same API node for the duration of the operation. This is done automatically by the server whenever it determines that it is possible to do so; you do not have to use any special SQL syntax or server options to cause it to happen.

In standard MySQL 5.1 releases, it is not possible to override the server when it determines that an index is to be dropped without table copying. In MySQL Cluster, you can drop indexes offline (which causes the table to be locked for all API nodes in the cluster) using the **OFFLINE** keyword. The rules and limitations governing **DROP OFFLINE INDEX** and **DROP ONLINE INDEX** are the same as for **ALTER OFFLINE TABLE ... DROP INDEX** and **ALTER ONLINE TABLE ... DROP INDEX**. You cannot cause the noncopying dropping of an index that would normally be dropped offline by using the **ONLINE** keyword: If it is not possible to perform the **DROP** operation without table copying, the server ignores the **ONLINE** keyword. For more information, see Section 13.1.7.2, "ALTER TABLE Online Operations in MySQL Cluster".

**Note**

The **ONLINE** and **OFFLINE** keywords are available only in MySQL Cluster NDB 6.2.5, 6.3.2, and later MySQL Cluster releases; attempting to use these keywords in earlier MySQL Cluster releases or standard MySQL 5.1 releases results in a syntax error.

13.1.25 DROP LOGFILE GROUP Syntax

```sql
DROP LOGFILE GROUP logfile_group ENGINE [=] engine_name
```

This statement drops the log file group named **logfile_group**. The log file group must already exist or an error results. (For information on creating log file groups, see Section 13.1.14, "CREATE LOGFILE GROUP Syntax".)

**Important**

Before dropping a log file group, you must drop all tablespaces that use that log file group for **UNDO** logging.
The required **ENGINE** clause provides the name of the storage engine used by the log file group to be dropped. In MySQL 5.1, the only permitted values for **engine_name** are **NDB** and **NDBCLUSTER**.

**DROP LOGFILE GROUP** was added in MySQL 5.1.6. In MySQL 5.1, it is useful only with Disk Data storage for MySQL Cluster. See Section 17.5.12, “MySQL Cluster Disk Data Tables”.

### 13.1.26 DROP PROCEDURE and DROP FUNCTION Syntax

```
DROP {PROCEDURE | FUNCTION} [IF EXISTS] sp_name
```

This statement is used to drop a stored procedure or function. That is, the specified routine is removed from the server. You must have the **ALTER ROUTINE** privilege for the routine. (If the **automatic_sp_privileges** system variable is enabled, that privilege and **EXECUTE** are granted automatically to the routine creator when the routine is created and dropped from the creator when the routine is dropped. See Section 19.2.2, “Stored Routines and MySQL Privileges”.)

The **IF EXISTS** clause is a MySQL extension. It prevents an error from occurring if the procedure or function does not exist. A warning is produced that can be viewed with **SHOW WARNINGS**.

**DROP FUNCTION** is also used to drop user-defined functions (see Section 13.7.3.2, “DROP FUNCTION Syntax”).

### 13.1.27 DROP SERVER Syntax

```
DROP SERVER [ IF EXISTS ] server_name
```

Drops the server definition for the server named **server_name**. The corresponding row in the **mysql.servers** table is deleted. This statement requires the **SUPER** privilege.

Dropping a server for a table does not affect any **FEDERATED** tables that used this connection information when they were created. See Section 13.1.16, “CREATE SERVER Syntax”.

**DROP SERVER** does not cause an automatic commit.

In MySQL 5.1, **DROP SERVER** is written to the binary log only when using row-based logging. It is not logged when **binlog_format** is equal to **STATEMENT** or **MIXED**.

**DROP SERVER** was added in MySQL 5.1.15.

### 13.1.28 DROP TABLE Syntax

```
DROP [TEMPORARY] TABLE [IF EXISTS] [RESTRICT | CASCADE] tbl_name [, tbl_name] ...
```

**DROP TABLE** removes one or more tables. You must have the **DROP** privilege for each table. All table data and the table definition are removed, so be careful with this statement! If any of the tables named in the argument list do not exist, MySQL returns an error indicating by name which nonexistent tables it was unable to drop, but it also drops all of the tables in the list that do exist.

**Important**

When a table is dropped, user privileges on the table are **not** automatically dropped. See Section 13.7.1.3, “GRANT Syntax”.

For a partitioned table, **DROP TABLE** permanently removes the table definition, all of its partitions, and all of the data which was stored in those partitions. It also removes the partitioning definition (.par) file associated with the dropped table.

Use **IF EXISTS** to prevent an error from occurring for tables that do not exist. A **NOTE** is generated for each nonexistent table when using **IF EXISTS**. See Section 13.7.5.42, “SHOW WARNINGS Syntax”.
RESTRICT and CASCADE are permitted to make porting easier. In MySQL 5.1, they do nothing.

**Note**

DROP TABLE automatically commits the current active transaction, unless you use the TEMPORARY keyword.

The TEMPORARY keyword has the following effects:

- The statement drops only TEMPORARY tables.
- The statement does not end an ongoing transaction.
- No access rights are checked. (A TEMPORARY table is visible only to the session that created it, so no check is necessary.)

Using TEMPORARY is a good way to ensure that you do not accidentally drop a non-TEMPORARY table.

### 13.1.29 DROP TABLESPACE Syntax

```
DROP TABLESPACE tablespace_name
    ENGINE [=] engine_name
```

This statement drops a tablespace that was previously created using CREATE TABLESPACE (see Section 13.1.18, “CREATE TABLESPACE Syntax”).

**Important**

The tablespace to be dropped must not contain any data files; in other words, before you can drop a tablespace, you must first drop each of its data files using ALTER TABLESPACE ... DROP DATAFILE (see Section 13.1.8, “ALTER TABLESPACE Syntax”).

The ENGINE clause (required) specifies the storage engine used by the tablespace. In MySQL 5.1, the only accepted values for engine_name are NDB and NDBCLUSTER.

DROP TABLESPACE was added in MySQL 5.1.6. In MySQL 5.1, it is useful only with Disk Data storage for MySQL Cluster. See Section 17.5.12, “MySQL Cluster Disk Data Tables”.

### 13.1.30 DROP TRIGGER Syntax

```
DROP TRIGGER [IF EXISTS] [schema_name.]trigger_name
```

This statement drops a trigger. The schema (database) name is optional. If the schema is omitted, the trigger is dropped from the default schema. DROP TRIGGER requires the TRIGGER privilege for the table associated with the trigger. (This statement requires the SUPER privilege prior to MySQL 5.1.6.)

Use IF EXISTS to prevent an error from occurring for a trigger that does not exist. A NOTE is generated for a nonexistent trigger when using IF EXISTS. See Section 13.7.5.42, “SHOW WARNINGS Syntax”. The IF EXISTS clause was added in MySQL 5.1.14.

Triggers for a table are also dropped if you drop the table.

**Note**

When upgrading from a version of MySQL older than MySQL 5.0.10 to 5.0.10 or newer—including all MySQL 5.1 releases—you must drop all triggers and re-create them. Otherwise, DROP TRIGGER does not work for older triggers after the upgrade. See Section 2.13.1.1, “Changes Affecting Upgrades to 5.1”, for a suggested upgrade procedure.
13.1.31 DROP VIEW Syntax

```
DROP VIEW [IF EXISTS]
    view_name [, view_name] ...
[RESTRICT | CASCADE]
```

DROP VIEW removes one or more views. You must have the DROP privilege for each view. If any of the views named in the argument list do not exist, MySQL returns an error indicating by name which nonexisting views it was unable to drop, but it also drops all of the views in the list that do exist.

The IF EXISTS clause prevents an error from occurring for views that don't exist. When this clause is given, a NOTE is generated for each nonexistent view. See Section 13.7.5.42, “SHOW WARNINGS Syntax”.

RESTRICT and CASCADE, if given, are parsed and ignored.

13.1.32 RENAME DATABASE Syntax

```
RENAME {DATABASE | SCHEMA} db_name TO new_db_name;
```

This statement was added in MySQL 5.1.7 but was found to be dangerous and was removed in MySQL 5.1.23. It was intended to enable upgrading pre-5.1 databases to use the encoding implemented in 5.1 for mapping database names to database directory names (see Section 9.2.3, “Mapping of Identifiers to File Names”). However, use of this statement could result in loss of database contents, which is why it was removed. Do not use RENAME DATABASE in earlier versions in which it is present.

To perform the task of upgrading database names with the new encoding, use ALTER DATABASE db_name UPGRADE DATA DIRECTORY NAME instead (see Section 13.1.1, “ALTER DATABASE Syntax”).

13.1.33 RENAME TABLE Syntax

```
RENAME TABLE tbl_name TO new_tbl_name
    [, tbl_name2 TO new_tbl_name2] ...
```

This statement renames one or more tables. The rename operation is done atomically, which means that no other session can access any of the tables while the rename is running.

For example, a table named old_table can be renamed to new_table as shown here:

```
RENAME TABLE old_table TO new_table;
```

This statement is equivalent to the following ALTER TABLE statement:

```
ALTER TABLE old_table RENAME new_table;
```

If the statement renames more than one table, renaming operations are done from left to right. If you want to swap two table names, you can do so like this (assuming that tmp_table does not already exist):

```
RENAME TABLE old_table TO tmp_table,
    new_table TO old_table,
    tmp_table TO new_table;
```

MySQL checks the destination table name before checking whether the source table exists. For example, if new_table already exists and old_table does not, the following statement fails as shown here:
As long as two databases are on the same file system, you can use `RENAME TABLE` to move a table from one database to another:

```
RENAME TABLE current_db.tbl_name TO other_db.tbl_name;
```

You can use this method to move all tables from one database to a different one, in effect renaming the database. (MySQL 5.1.7 through 5.1.23 had a `RENAME DATABASE` statement, but this statement was not always safe to use, and was subsequently removed.)

If there are any triggers associated with a table which is moved to a different database using `RENAME TABLE`, then the statement fails with the error `Trigger in wrong schema`.

Foreign keys that point to the renamed table are not automatically updated. In such cases, you must drop and re-create the foreign keys in order for them to function properly.

`RENAME TABLE` also works for views, as long as you do not try to rename a view into a different database.

Any privileges granted specifically for the renamed table or view are not migrated to the new name. They must be changed manually.

When you execute `RENAME TABLE`, you cannot have any locked tables or active transactions. You must also have the `ALTER` and `DROP` privileges on the original table, and the `CREATE` and `INSERT` privileges on the new table.

If MySQL encounters any errors in a multiple-table rename, it does a reverse rename for all renamed tables to return everything to its original state.

You cannot use `RENAME TABLE` to rename a `TEMPORARY` table. However, you can use `ALTER` `TABLE` with temporary tables.

Like `RENAME TABLE, ALTER TABLE ... RENAME` can also be used to move a table to a different database. Regardless of the statement used to perform the rename, if the rename operation would move the table to a database located on a different file system, the success of the outcome is platform specific and depends on the underlying operating system calls used to move the table files.

### 13.1.34 TRUNCATE TABLE Syntax

```
TRUNCATE [TABLE] tbl_name
```

`TRUNCATE TABLE` empties a table completely. It requires the `DROP` privilege as of MySQL 5.1.16. (Before 5.1.16, it requires the `DELETE` privilege).

Logically, `TRUNCATE TABLE` is equivalent to a `DELETE` statement that deletes all rows, but there are practical differences under some circumstances.

For an InnoDB table:

- If there are no `FOREIGN KEY` constraints, InnoDB performs fast truncation by dropping the original table and creating an empty one with the same definition, which is much faster than deleting rows one by one.
- When you use this fast truncation technique with the `innodb_file_per_table` option enabled, the operating system can reuse the freed disk space. For users of the InnoDB Plugin, the space is reclaimed automatically, as described in Reclaiming Disk Space with TRUNCATE TABLE. If you do not have the InnoDB Plugin installed, issue the OPTIMIZE TABLE statement to free the disk space for the table.

- If there are any FOREIGN KEY constraints that reference the table, InnoDB processes TRUNCATE TABLE by deleting rows one by one, processing the constraints as it proceeds. If the FOREIGN KEY constraint specifies DELETE CASCADE, rows from the child (referenced) table are deleted, and the truncated table becomes empty. If the FOREIGN KEY constraint does not specify CASCADE, the TRUNCATE TABLE statement deletes rows one by one and stops if it encounters a parent row that is referenced by the child, returning this error:

```
ERROR 1451 (23000): Cannot delete or update a parent row: a foreign key constraint fails (`test`.`child`, CONSTRAINT `child_ibfk_1` FOREIGN KEY (`parent_id`) REFERENCES `parent` (`id`))
```

**Note**

In MySQL 5.1 and higher, TRUNCATE TABLE is not allowed for InnoDB tables referenced by foreign keys. For ease of upgrading, rewrite such statements to use DELETE instead.

- The AUTO_INCREMENT counter is reset to zero by TRUNCATE TABLE, regardless of whether there is a FOREIGN KEY constraint.

This is the same as a DELETE statement with no WHERE clause.

The count of rows affected by TRUNCATE TABLE is accurate only when it is mapped to a DELETE statement.

For other storage engines, TRUNCATE TABLE differs from DELETE in the following ways in MySQL 5.1:

- Truncate operations drop and re-create the table, which is much faster than deleting rows one by one, particularly for large tables.
- Truncate operations cause an implicit commit.
- Truncation operations cannot be performed if the session holds an active table lock.
- Truncation operations do not return a meaningful value for the number of deleted rows. The usual result is “0 rows affected,” which should be interpreted as “no information.”
- As long as the table format file `tbl_name.frm` is valid, the table can be re-created as an empty table with TRUNCATE TABLE, even if the data or index files have become corrupted.
- The table handler does not remember the last used AUTO_INCREMENT value, but starts counting from the beginning. This is true even for MyISAM and InnoDB, which normally do not reuse sequence values.
- When used with partitioned tables, TRUNCATE TABLE preserves the partitioning; that is, the data and index files are dropped and re-created, while the partition definitions (.par) file is unaffected.
- Since truncation of a table does not make any use of DELETE, the TRUNCATE TABLE statement does not invoke ON DELETE triggers.

As of MySQL 5.1.39, TRUNCATE TABLE for a table closes all handlers for the table that were opened with HANDLER OPEN.

Beginning with MySQL 5.1.32, TRUNCATE TABLE is treated for purposes of binary logging and replication as DROP TABLE followed by CREATE TABLE—that is, as DDL rather than DML. This is due to the fact that, when using InnoDB and other transactional storage engines where the transaction
isolation level does not permit statement-based logging (READ COMMITTED or READ UNCOMMITTED), the statement was not logged and replicated when using STATEMENT or MIXED logging mode. (Bug #36763) However, it is still applied on replication slaves using InnoDB in the manner described previously.

13.2 Data Manipulation Statements

13.2.1 CALL Syntax

The CALL statement invokes a stored procedure that was defined previously with CREATE PROCEDURE.

As of MySQL 5.1.13, stored procedures that take no arguments can be invoked without parentheses. That is, CALL p() and CALL p are equivalent.

CALL can pass back values to its caller using parameters that are declared as OUT or INOUT parameters. When the procedure returns, a client program can also obtain the number of rows affected for the final statement executed within the routine: At the SQL level, call the ROW_COUNT() function; from the C API, call the mysql_affected_rows() function.

To get back a value from a procedure using an OUT or INOUT parameter, pass the parameter by means of a user variable, and then check the value of the variable after the procedure returns. (If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an IN or INOUT parameter.) For an INOUT parameter, initialize its value before passing it to the procedure. The following procedure has an OUT parameter that the procedure sets to the current server version, and an INOUT value that the procedure increments by one from its current value:

CREATE PROCEDURE p (OUT ver_param VARCHAR(25), INOUT incr_param INT)
BEGIN
    # Set value of OUT parameter
    SELECT VERSION() INTO ver_param;
    # Increment value of INOUT parameter
    SET incr_param = incr_param + 1;
END;

Before calling the procedure, initialize the variable to be passed as the INOUT parameter. After calling the procedure, the values of the two variables will have been set or modified:

```
mysql> SET @increment = 10;
mysql> CALL p(@version, @increment);
mysql> SELECT @version, @increment;
+------------+------------+
<table>
<thead>
<tr>
<th>@version</th>
<th>@increment</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.1.32-log</td>
<td>11</td>
</tr>
</tbody>
</table>
+------------+------------+
```

In prepared CALL statements used with PREPARE and EXECUTE, placeholder support is available in MySQL 5.1 for IN parameters, but not for OUT or INOUT parameters. To work around this limitation for OUT and INOUT parameters, forego the use of placeholders; instead, refer to user variables in the CALL statement itself and do not specify them in the EXECUTE statement:

```
mysql> SET @increment = 10;
mysql> PREPARE s FROM 'CALL p(@version, @increment)';
mysql> EXECUTE s;
mysql> SELECT @version, @increment;
+------------+------------+
<table>
<thead>
<tr>
<th>@version</th>
<th>@increment</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.1.32-log</td>
<td>11</td>
</tr>
</tbody>
</table>
+------------+------------+
```
To write C programs that use the `CALL` SQL statement to execute stored procedures that produce result sets, the `CLIENT_MULTI_RESULTS` flag must be enabled. This is because each `CALL` returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure. `CLIENT_MULTI_RESULTS` must also be enabled if `CALL` is used to execute any stored procedure that contains prepared statements. It cannot be determined when such a procedure is loaded whether those statements will produce result sets, so it is necessary to assume that they will.

`CLIENT_MULTI_RESULTS` can be enabled when you call `mysql_real_connect()`, either explicitly by passing the `CLIENT_MULTI_RESULTS` flag itself, or implicitly by passing `CLIENT_MULTI_STATEMENTS` (which also enables `CLIENT_MULTI_RESULTS`).

To process the result of a `CALL` statement executed using `mysql_query()` or `mysql_real_query()`, use a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see Section 21.8.16, “C API Support for Multiple Statement Execution”.

For programs written in a language that provides a MySQL interface, there is no native method for directly retrieving the results of `OUT` or `INOUT` parameters from `CALL` statements. To get the parameter values, pass user-defined variables to the procedure in the `CALL` statement and then execute a `SELECT` statement to produce a result set containing the variable values. To handle an `INOUT` parameter, execute a statement prior to the `CALL` that sets the corresponding user variable to the value to be passed to the procedure.

The following example illustrates the technique (without error checking) for the stored procedure `p` described earlier that has an `OUT` parameter and an `INOUT` parameter:

```c
mysql_query(mysql, "SET @increment = 10");
mysql_query(mysql, "CALL p(@version, @increment)" );
result = mysql_store_result(mysql);
row = mysql_fetch_row(result);
mysql_free_result(result);
```

After the preceding code executes, `row[0]` and `row[1]` contain the values of `@version` and `@increment`, respectively.

### 13.2.2 DELETE Syntax

**Single-table syntax:**

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE] FROM tbl_name
    [WHERE where_condition]
    [ORDER BY ...]
    [LIMIT row_count]
```

**Multiple-table syntax:**

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
    tbl_name[.\*] [tbl_name[.\*]] ...
    FROM table_references
    [WHERE where_condition]
```

Or:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
    FROM tbl_name[.\*] [tbl_name[.\*]] ...
```
For the single-table syntax, the DELETE statement deletes rows from `tbl_name` and returns a count of the number of deleted rows. This count can be obtained by calling the `ROW_COUNT()` function (see Section 12.14, "Information Functions"). The `WHERE` clause, if given, specifies the conditions that identify which rows to delete. With no `WHERE` clause, all rows are deleted. If the `ORDER BY` clause is specified, the rows are deleted in the order that is specified. The `LIMIT` clause places a limit on the number of rows that can be deleted.

For the multiple-table syntax, DELETE deletes from each `tbl_name` the rows that satisfy the conditions. In this case, `ORDER BY` and `LIMIT` cannot be used.

`where_condition` is an expression that evaluates to true for each row to be deleted. It is specified as described in Section 13.2.8, "SELECT Syntax".

You cannot delete from a table and select from the same table in a subquery.

You need the DELETE privilege on a table to delete rows from it. You need only the SELECT privilege for any columns that are only read, such as those named in the `WHERE` clause.

As stated, a DELETE statement with no WHERE clause deletes all rows. A faster way to do this, when you do not need to know the number of deleted rows, is to use TRUNCATE TABLE. However, within a transaction or if you have a lock on the table, TRUNCATE TABLE cannot be used whereas DELETE can. See Section 13.1.34, "TRUNCATE TABLE Syntax", and Section 13.3.5, "LOCK TABLES and UNLOCK TABLES Syntax".

If you delete the row containing the maximum value for an AUTO_INCREMENT column, the value is not reused for a MyISAM or InnoDB table. If you delete all rows in the table with DELETE FROM `tbl_name` (without a WHERE clause) in autocommit mode, the sequence starts over for all storage engines except InnoDB and MyISAM. There are some exceptions to this behavior for InnoDB tables, as discussed in Section 14.6.6.5, "AUTO_INCREMENT Handling in InnoDB".

For MyISAM tables, you can specify an AUTO_INCREMENT secondary column in a multiple-column key. In this case, reuse of values deleted from the top of the sequence occurs even for MyISAM tables. See Section 3.6.9, "Using AUTO_INCREMENT".

The DELETE statement supports the following modifiers:

- If you specify LOW_PRIORITY, the server delays execution of the DELETE until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as MyISAM, MEMORY, and MERGE).

- For MyISAM tables, if you use the QUICK keyword, the storage engine does not merge index leaves during delete, which may speed up some kinds of delete operations.

- The IGNORE keyword causes MySQL to ignore errors during the process of deleting rows. (Errors encountered during the parsing stage are processed in the usual manner.) Errors that are ignored due to the use of IGNORE are returned as warnings.

The speed of delete operations may also be affected by factors discussed in Section 8.2.2.3, "Speed of DELETE Statements".

In MyISAM tables, deleted rows are maintained in a linked list and subsequent INSERT operations reuse old row positions. To reclaim unused space and reduce file sizes, use the OPTIMIZE TABLE statement or the myisamchk utility to reorganize tables. OPTIMIZE TABLE is easier to use, but myisamchk is faster. See Section 13.7.2.5, "OPTIMIZE TABLE Syntax", and Section 4.6.3, "myisamchk — MyISAM Table-Maintenance Utility".

The QUICK modifier affects whether index leaves are merged for delete operations. DELETE QUICK is most useful for applications where index values for deleted rows are replaced by similar index values from rows inserted later. In this case, the holes left by deleted values are reused.
**DELETE Syntax**

**DELETE QUICK** is not useful when deleted values lead to underfilled index blocks spanning a range of index values for which new inserts occur again. In this case, use of **QUICK** can lead to wasted space in the index that remains unreclaimed. Here is an example of such a scenario:

1. Create a table that contains an indexed **AUTO_INCREMENT** column.
2. Insert many rows into the table. Each insert results in an index value that is added to the high end of the index.
3. Delete a block of rows at the low end of the column range using **DELETE QUICK**.

In this scenario, the index blocks associated with the deleted index values become underfilled but are not merged with other index blocks due to the use of **QUICK**. They remain underfilled when new inserts occur, because new rows do not have index values in the deleted range. Furthermore, they remain underfilled even if you later use **DELETE** without **QUICK**, unless some of the deleted index values happen to lie in index blocks within or adjacent to the underfilled blocks. To reclaim unused index space under these circumstances, use **OPTIMIZE TABLE**.

If you are going to delete many rows from a table, it might be faster to use **DELETE QUICK** followed by **OPTIMIZE TABLE**. This rebuilds the index rather than performing many index block merge operations.

The MySQL-specific **LIMIT row_count** option to **DELETE** tells the server the maximum number of rows to be deleted before control is returned to the client. This can be used to ensure that a given **DELETE** statement does not take too much time. You can simply repeat the **DELETE** statement until the number of affected rows is less than the **LIMIT** value.

If the **DELETE** statement includes an **ORDER BY** clause, rows are deleted in the order specified by the clause. This is useful primarily in conjunction with **LIMIT**. For example, the following statement finds rows matching the **WHERE** clause, sorts them by **timestamp_column**, and deletes the first (oldest) one:

```
DELETE FROM somelog WHERE user = 'jcole'
ORDER BY timestamp_column LIMIT 1;
```

**ORDER BY** may also be useful in some cases to delete rows in an order required to avoid referential integrity violations.

If you are deleting many rows from a large table, you may exceed the lock table size for an **InnoDB** table. To avoid this problem, or simply to minimize the time that the table remains locked, the following strategy (which does not use **DELETE** at all) might be helpful:

1. Select the rows *not* to be deleted into an empty table that has the same structure as the original table:

   ```
   INSERT INTO t_copy SELECT * FROM t WHERE ... ;
   ```

2. Use **RENAME TABLE** to atomically move the original table out of the way and rename the copy to the original name:

   ```
   RENAME TABLE t TO t_old, t_copy TO t;
   ```

3. Drop the original table:

   ```
   DROP TABLE t_old;
   ```

No other sessions can access the tables involved while **RENAME TABLE** executes, so the rename operation is not subject to concurrency problems. See Section 13.1.33, “RENAME TABLE Syntax”.

You can specify multiple tables in a **DELETE** statement to delete rows from one or more tables depending on the particular condition in the **WHERE** clause. However, you cannot use **ORDER BY** or
**DELETE Syntax**

The `DELETE` statement in MySQL has a syntax that allows you to delete records from multiple tables at once. Let's break down the key points:

- **Syntax**: `DELETE t1, t2 FROM t1 INNER JOIN t2 INNER JOIN t3 WHERE t1.id=t2.id AND t2.id=t3.id;`

- **Example**: The above SQL statement deletes matching rows from tables `t1`, `t2`, and `t3` based on the join conditions. It's an example of using INNER JOIN in a multi-table `DELETE` statement.

- **Limitation**: The first multiple-table syntax only deletes matching rows from the tables listed before the `FROM` clause. The second syntax, using `USING` before the `FROM` clause, deletes rows from the tables listed in the `FROM` clause before the `USING` clause.

- **Example Comparison**:
  - First Syntax:
    ```sql
    DELETE t1, t2 FROM t1 INNER JOIN t2 INNER JOIN t3 WHERE t1.id=t2.id AND t2.id=t3.id;
    ```
  - Second Syntax (using `USING`):
    ```sql
    DELETE FROM t1, t2 USING t1 INNER JOIN t2 INNER JOIN t3 WHERE t1.id=t2.id AND t2.id=t3.id;
    ```

- **Compatibility**: The syntax permits `.*` after each `tbl_name` for compatibility with Access.

- **InnoDB Tables**: If you use a multi-table `DELETE` statement involving InnoDB tables with foreign key constraints, the optimizer might process tables in a different order than their parent/child relationship. In this case, you should delete from a single table and rely on the `ON DELETE` capabilities provided by InnoDB.

- **Aliases**: If you declare an alias for a table, you must use the alias when referring to the table:
  ```sql
  DELETE t1 FROM test AS t1, test2 WHERE ...
  ```

- **Table Aliases**: Table aliases in a multi-table `DELETE` should be declared only in the `table_references` part of the statement.

- **Correct Example**:
  ```sql
  DELETE as1, as2 FROM t1 AS as1 INNER JOIN t2 AS as2 WHERE as1.id=as2.id;
  ```

- **Incorrect Example**:
  ```sql
  DELETE t1 AS as1, t2 AS as2 FROM t1 INNER JOIN t2 WHERE as1.id=as2.id;
  ```

This breakdown should help you understand how to use the `DELETE` statement effectively in multi-table scenarios in MySQL.
Declaration of aliases other than in the *table_references* part of the statement should be avoided because that can lead to ambiguous statements that have unexpected results such as deleting rows from the wrong table. This is such a statement:

```
DELETE t1 AS a2 FROM t1 AS a1 INNER JOIN t2 AS a2;
```

As of MySQL 5.1.23, alias declarations outside the *table_references* part of the statement are disallowed for the *USING* variant of multiple-table *DELETE* syntax. (In MySQL 5.5, alias declarations outside *table_references* are disallowed for all multiple-table *DELETE* statements.)

For alias references in the list of tables from which to delete rows in a multiple-table delete, the default database is used unless one is specified explicitly. For example, if the default database is *db1*, the following statement does not work because the unqualified alias reference *a2* is interpreted as having a database of *db1*:

```
DELETE a1, a2 FROM db1.t1 AS a1 INNER JOIN db2.t2 AS a2
WHERE a1.id=a2.id;
```

To correctly match an alias that refers to a table outside the default database, you must explicitly qualify the reference with the name of the proper database:

```
DELETE a1, db2.a2 FROM db1.t1 AS a1 INNER JOIN db2.t2 AS a2
WHERE a1.id=a2.id;
```

### 13.2.3 DO Syntax

```
DO expr [, expr] ...
```

*DO* executes the expressions but does not return any results. In most respects, *DO* is shorthand for *SELECT expr, ...*, but has the advantage that it is slightly faster when you do not care about the result.

*DO* is useful primarily with functions that have side effects, such as *RELEASE_LOCK()*.

Example: This *SELECT* statement pauses, but also produces a result set:

```
mysql> SELECT SLEEP(5);
+----------+
| SLEEP(5) |
+----------+
|        0 |
+----------+
1 row in set (5.02 sec)
```

*DO*, on the other hand, pauses without producing a result set:.

```
mysql> DO SLEEP(5);
Query OK, 0 rows affected (4.99 sec)
```

This could be useful, for example in a stored function or trigger, which prohibit statements that produce result sets.

*DO* only executes expressions. It cannot be used in all cases where *SELECT* can be used. For example, *DO id FROM t1* is invalid because it references a table.

### 13.2.4 HANDLER Syntax

```
HANDLER tbl_name OPEN [ AS alias]
HANDLER tbl_name READ index_name { = | <= | >= | < | > } (value1,value2,...)
```
The HANDLER statement provides direct access to table storage engine interfaces. It is available for InnoDB and MyISAM tables.

The HANDLER ... OPEN statement opens a table, making it accessible using subsequent HANDLER ... READ statements. This table object is not shared by other sessions and is not closed until the session calls HANDLER ... CLOSE or the session terminates.

If you open the table using an alias, further references to the open table with other HANDLER statements must use the alias rather than the table name. If you do not use an alias, but open the table using a table name qualified by the database name, further references must use the unqualified table name. For example, for a table opened using `mydb.mytable`, further references must use `mytable`.

The first HANDLER ... READ syntax fetches a row where the index specified satisfies the given values and the WHERE condition is met. If you have a multiple-column index, specify the index column values as a comma-separated list. Either specify values for all the columns in the index, or specify values for a leftmost prefix of the index columns. Suppose that an index `my_idx` includes three columns named `col_a`, `col_b`, and `col_c`, in that order. The HANDLER statement can specify values for all three columns in the index, or for the columns in a leftmost prefix. For example:

```
HANDLER ... READ my_idx = (col_a_val,col_b_val,col_c_val) ...
HANDLER ... READ my_idx = (col_a_val,col_b_val) ...
HANDLER ... READ my_idx = (col_a_val) ...
```

To employ the HANDLER interface to refer to a table's PRIMARY KEY, use the quoted identifier `PRIMARY`:

```
HANDLER tbl_name READ 'PRIMARY' ...
```

The second HANDLER ... READ syntax fetches a row from the table in index order that matches the WHERE condition.

The third HANDLER ... READ syntax fetches a row from the table in natural row order that matches the WHERE condition. It is faster than HANDLER tbl_name READ index_name when a full table scan is desired. Natural row order is the order in which rows are stored in a MyISAM table data file. This statement works for InnoDB tables as well, but there is no such concept because there is no separate data file.

Without a LIMIT clause, all forms of HANDLER ... READ fetch a single row if one is available. To return a specific number of rows, include a LIMIT clause. It has the same syntax as for the SELECT statement. See Section 13.2.8, “SELECT Syntax”.

HANDLER ... CLOSE closes a table that was opened with HANDLER ... OPEN.

There are several reasons to use the HANDLER interface instead of normal SELECT statements:

- HANDLER is faster than SELECT:
  - A designated storage engine handler object is allocated for the HANDLER ... OPEN. The object is reused for subsequent HANDLER statements for that table; it need not be reinitialized for each one.
  - There is less parsing involved.
  - There is no optimizer or query-checking overhead.
The handler interface does not have to provide a consistent look of the data (for example, dirty reads are permitted), so the storage engine can use optimizations that `SELECT` does not normally permit.

`HANDLER` makes it easier to port to MySQL applications that use a low-level `ISAM`-like interface.

`HANDLER` enables you to traverse a database in a manner that is difficult (or even impossible) to accomplish with `SELECT`. The `HANDLER` interface is a more natural way to look at data when working with applications that provide an interactive user interface to the database.

`HANDLER` is a somewhat low-level statement. For example, it does not provide consistency. That is, `HANDLER ... OPEN` does not take a snapshot of the table, and does not lock the table. This means that after a `HANDLER ... OPEN` statement is issued, table data can be modified (by the current session or other sessions) and these modifications might be only partially visible to `HANDLER ... NEXT` or `HANDLER ... PREV` scans.

An open handler can be closed and marked for reopen, in which case the handler loses its position in the table. This occurs when both of the following circumstances are true:

- Any session executes `FLUSH TABLES` or DDL statements on the handler's table.
- The session in which the handler is open executes non-`HANDLER` statements that use tables.

As of MySQL 5.1.39, `TRUNCATE TABLE` for a table closes all handlers for the table that were opened with `HANDLER OPEN`.

`HANDLER` is not supported with partitioned tables.

### 13.2.5 INSERT Syntax

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
   [INTO] tbl_name [(col_name, ...)]
   {VALUES | VALUE} ({expr | DEFAULT}, ...), (...), ...
   [ ON DUPLICATE KEY UPDATE
      col_name=expr
      [, col_name=expr] ... ]
```

Or:

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
   [INTO] tbl_name
   SET col_name={expr | DEFAULT}, ...
   [ ON DUPLICATE KEY UPDATE
      col_name=expr
      [, col_name=expr] ... ]
```

Or:

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
   [INTO] tbl_name [(col_name, ...)]
   SELECT ...
   [ ON DUPLICATE KEY UPDATE
      col_name=expr
      [, col_name=expr] ... ]
```

`INSERT` inserts new rows into an existing table. The `INSERT ... VALUES` and `INSERT ... SET` forms of the statement insert rows based on explicitly specified values. The `INSERT ... SELECT` form inserts rows selected from another table or tables. `INSERT ... SELECT` is discussed further in Section 13.2.5.1, "INSERT ... SELECT Syntax".

You can use `REPLACE` instead of `INSERT` to overwrite old rows. `REPLACE` is the counterpart to `INSERT IGNORE` in the treatment of new rows that contain unique key values that duplicate old rows: The new
rows are used to replace the old rows rather than being discarded. See Section 13.2.7, “REPLACE Syntax”.

.tbl_name is the table into which rows should be inserted. The columns for which the statement provides values can be specified as follows:

- You can provide a comma-separated list of column names following the table name. In this case, a value for each named column must be provided by the VALUES list or the SELECT statement.

- If you do not specify a list of column names for INSERT ... VALUES or INSERT ... SELECT, values for every column in the table must be provided by the VALUES list or the SELECT statement. If you do not know the order of the columns in the table, use DESCRIBE tbl_name to find out.

- The SET clause indicates the column names explicitly.

Column values can be given in several ways:

- If you are not running in strict SQL mode, any column not explicitly given a value is set to its default (explicit or implicit) value. For example, if you specify a column list that does not name all the columns in the table, unnamed columns are set to their default values. Default value assignment is described in Section 11.6, “Data Type Default Values”. See also Section 1.8.3.3, “Constraints on Invalid Data”.

If you want an INSERT statement to generate an error unless you explicitly specify values for all columns that do not have a default value, you should use strict mode. See Section 5.1.7, “Server SQL Modes”.

- Use the keyword DEFAULT to set a column explicitly to its default value. This makes it easier to write INSERT statements that assign values to all but a few columns, because it enables you to avoid writing an incomplete VALUES list that does not include a value for each column in the table. Otherwise, you would have to write out the list of column names corresponding to each value in the VALUES list.

You can also use DEFAULT(col_name) as a more general form that can be used in expressions to produce a given column's default value.

- If both the column list and the VALUES list are empty, INSERT creates a row with each column set to its default value:

```
INSERT INTO tbl_name () VALUES();
```

In strict mode, an error occurs if any column doesn't have a default value. Otherwise, MySQL uses the implicit default value for any column that does not have an explicitly defined default.

- You can specify an expression expr to provide a column value. This might involve type conversion if the type of the expression does not match the type of the column, and conversion of a given value can result in different inserted values depending on the data type. For example, inserting the string '1999.0e-2' into an INT, FLOAT, DECIMAL(10,6), or YEAR column results in the values 1999, 19.9921, 19.992100, and 1999 being inserted, respectively. The reason the value stored in the INT and YEAR columns is 1999 is that the string-to-integer conversion looks only at as much of the initial part of the string as may be considered a valid integer or year. For the floating-point and fixed-point columns, the string-to-floating-point conversion considers the entire string a valid floating-point value.

An expression expr can refer to any column that was set earlier in a value list. For example, you can do this because the value for col2 refers to col1, which has previously been assigned:

```
INSERT INTO tbl_name (col1,col2) VALUES(15,col1*2);
```

But the following is not legal, because the value for col1 refers to col2, which is assigned after col1:
INSERT INTO `tbl_name` (col1, col2) VALUES(col2*2, 15);

One exception involves columns that contain `AUTO_INCREMENT` values. Because the `AUTO_INCREMENT` value is generated after other value assignments, any reference to an `AUTO_INCREMENT` column in the assignment returns a 0.

INSERT statements that use `VALUES` syntax can insert multiple rows. To do this, include multiple lists of column values, each enclosed within parentheses and separated by commas. Example:

```
INSERT INTO `tbl_name` (a, b, c) VALUES(1, 2, 3), (4, 5, 6), (7, 8, 9);
```

The values list for each row must be enclosed within parentheses. The following statement is illegal because the number of values in the list does not match the number of column names:

```
INSERT INTO `tbl_name` (a, b, c) VALUES(1, 2, 3, 4, 5, 6, 7, 8, 9);
```

`VALUE` is a synonym for `VALUES` in this context. Neither implies anything about the number of values lists, and either may be used whether there is a single values list or multiple lists.

The affected-rows value for an `INSERT` can be obtained using the `ROW_COUNT()` function (see Section 12.14, “Information Functions”), or the `mysql_affected_rows()` C API function (see Section 21.8.7.1, “mysql_affected_rows()”).

If you use an `INSERT ... VALUES` statement with multiple value lists or `INSERT ... SELECT`, the statement returns an information string in this format:

```
Records: 100 Duplicates: 0 Warnings: 0
```

`Records` indicates the number of rows processed by the statement. (This is not necessarily the number of rows actually inserted because `Duplicates` can be nonzero.) `Duplicates` indicates the number of rows that could not be inserted because they would duplicate some existing unique index value. `Warnings` indicates the number of attempts to insert column values that were problematic in some way. Warnings can occur under any of the following conditions:

- Inserting `NULL` into a column that has been declared `NOT NULL`. For multiple-row `INSERT` statements or `INSERT INTO ... SELECT` statements, the column is set to the implicit default value for the column data type. This is 0 for numeric types, the empty string ("") for string types, and the "zero" value for date and time types. `INSERT INTO ... SELECT` statements are handled the same way as multiple-row inserts because the server does not examine the result set from the `SELECT` to see whether it returns a single row. (For a single-row `INSERT`, no warning occurs when `NULL` is inserted into a `NOT NULL` column. Instead, the statement fails with an error.)

- Setting a numeric column to a value that lies outside the column's range. The value is clipped to the closest endpoint of the range.

- Assigning a value such as '10.34 a' to a numeric column. The trailing nonnumeric text is stripped off and the remaining numeric part is inserted. If the string value has no leading numeric part, the column is set to 0.

- Inserting a string into a string column (CHAR, VARCHAR, TEXT, or BLOB) that exceeds the column's maximum length. The value is truncated to the column's maximum length.

- Inserting a value into a date or time column that is illegal for the data type. The column is set to the appropriate zero value for the type.

If you are using the C API, the information string can be obtained by invoking the `mysql_info()` function. See Section 21.8.7.35, “mysql_info()”.
If **INSERT** inserts a row into a table that has an **AUTO_INCREMENT** column, you can find the value used for that column by using the SQL **LAST_INSERT_ID()** function. From within the C API, use the **mysql_insert_id()** function. However, you should note that the two functions do not always behave identically. The behavior of **INSERT** statements with respect to **AUTO_INCREMENT** columns is discussed further in Section 12.14, “Information Functions”, and Section 21.8.7.37, “mysql_insert_id()”.

The **INSERT** statement supports the following modifiers:

- If you use the **DELAYED** keyword, the server puts the row or rows to be inserted into a buffer, and the client issuing the **INSERT DELAYED** statement can then continue immediately. If the table is in use, the server holds the rows. When the table is free, the server begins inserting rows, checking periodically to see whether there are any new read requests for the table. If there are, the delayed row queue is suspended until the table becomes free again. See Section 13.2.5.2, “INSERT DELAYED Syntax”.

**DELAYED** is ignored with **INSERT ... SELECT** or **INSERT ... ON DUPLICATE KEY UPDATE**.

Beginning with MySQL 5.1.19, **DELAYED** is also disregarded for an **INSERT** that uses functions accessing tables or triggers, or that is called from a function or a trigger.

- If you use the **LOW_PRIORITY** keyword, execution of the **INSERT** is delayed until no other clients are reading from the table. This includes other clients that began reading while existing clients are reading, and while the **INSERT LOW_PRIORITY** statement is waiting. It is possible, therefore, for a client that issues an **INSERT LOW_PRIORITY** statement to wait for a very long time (or even forever) in a read-heavy environment. (This is in contrast to **INSERT DELAYED**, which lets the client continue at once.)

Note

**LOW_PRIORITY** should normally not be used with **MyISAM** tables because doing so disables concurrent inserts. See Section 8.11.3, “Concurrent Inserts”.

If you specify **HIGH_PRIORITY**, it overrides the effect of the **--low-priority-updates** option if the server was started with that option. It also causes concurrent inserts not to be used. See Section 8.11.3, “Concurrent Inserts”.

**LOW_PRIORITY** and **HIGH_PRIORITY** affect only storage engines that use only table-level locking (such as **MyISAM**, **MEMORY**, and **MERGE**).

- If you use the **IGNORE** keyword, errors that occur while executing the **INSERT** statement are ignored. For example, without **IGNORE**, a row that duplicates an existing **UNIQUE** index or **PRIMARY KEY** value in the table causes a duplicate-key error and the statement is aborted. With **IGNORE**, the row is discarded and no error occurs. Ignored errors may generate warnings instead, although duplicate-key errors do not.

**IGNORE** has a similar effect on inserts into partitioned tables where no partition matching a given value is found. Without **IGNORE**, such **INSERT** statements are aborted with an error; however, when **INSERT IGNORE** is used, the insert operation fails silently for the row containing the unmatched value, but any rows that are matched are inserted. For an example, see Section 18.2.2, “LIST Partitioning”.

Data conversions that would trigger errors abort the statement if **IGNORE** is not specified. With **IGNORE**, invalid values are adjusted to the closest values and inserted; warnings are produced but the statement does not abort. You can determine with the **mysql_info()** C API function how many rows were actually inserted into the table.

- If you specify **ON DUPLICATE KEY UPDATE**, and a row is inserted that would cause a duplicate value in a **UNIQUE** index or **PRIMARY KEY**, an **UPDATE** of the old row is performed. The affected-rows value per row is 1 if the row is inserted as a new row and 2 if an existing row is updated. See Section 13.2.5.3, “**INSERT ... ON DUPLICATE KEY UPDATE** Syntax”.
Inserting into a table requires the `INSERT` privilege for the table. If the `ON DUPLICATE KEY UPDATE` clause is used and a duplicate key causes an `UPDATE` to be performed instead, the statement requires the `UPDATE` privilege for the columns to be updated. For columns that are read but not modified you need only the `SELECT` privilege (such as for a column referenced only on the right hand side of an `col_name=expr` assignment in an `ON DUPLICATE KEY UPDATE` clause).

An `INSERT` statement that acts on a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks all partitions of the table. This does not occur with tables using storage engines such as `InnoDB` that employ row-level locking. This issue is resolved in MySQL 5.6. See Section 18.5.4, “Partitioning and Table-Level Locking”, for more information.

### 13.2.5.1 INSERT ... SELECT Syntax

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
    [INTO] tbl_name [(col_name,...)]
    SELECT ...
    [ ON DUPLICATE KEY UPDATE col_name=expr, ... ]
```

With `INSERT ... SELECT`, you can quickly insert many rows into a table from one or many tables. For example:

```
INSERT INTO tbl_temp2 (fld_id)
SELECT tbl_temp1.fld_order_id
FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

The following conditions hold for a ` INSERT ... SELECT` statements:

- Specify `IGNORE` to ignore rows that would cause duplicate-key violations.
- `DELAYED` is ignored with `INSERT ... SELECT`.
- The target table of the `INSERT` statement may appear in the `FROM` clause of the `SELECT` part of the query. (This was not possible in some older versions of MySQL.) However, you cannot insert into a table and select from the same table in a subquery.

When selecting from and inserting into a table at the same time, MySQL creates a temporary table to hold the rows from the `SELECT` and then inserts those rows into the target table. However, it remains true that you cannot use `INSERT INTO t ... SELECT ... FROM t` when `t` is a `TEMPORARY` table, because `TEMPORARY` tables cannot be referred to twice in the same statement (see Section B.5.6.2, “TEMPORARY Table Problems”).

- `AUTO_INCREMENT` columns work as usual.
- To ensure that the binary log can be used to re-create the original tables, MySQL does not permit concurrent inserts for `INSERT ... SELECT` statements.
- To avoid ambiguous column reference problems when the `SELECT` and the `INSERT` refer to the same table, provide a unique alias for each table used in the `SELECT` part, and qualify column names in that part with the appropriate alias.

In the values part of `ON DUPLICATE KEY UPDATE`, you can refer to columns in other tables, as long as you do not use `GROUP BY` in the `SELECT` part. One side effect is that you must qualify nonunique column names in the values part.

The order in which rows are returned by a `SELECT` statement with no `ORDER BY` clause is not determined. This means that, when using replication, there is no guarantee that such a `SELECT` returns rows in the same order on the master and the slave; this can lead to inconsistencies between them. To prevent this from occurring, you should always write `INSERT ... SELECT` statements that are to be replicated as `INSERT ... SELECT ... ORDER BY column`. The choice of `column` does not matter as long as the same order for returning the rows is enforced on both the master and the slave. See also Section 16.4.1.16, “Replication and LIMIT”.

1261
An `INSERT ... SELECT` statement that acts on partitioned tables using a storage engine such as `MyISAM` that employs table-level locks locks all partitions of the source and target tables. This does not occur with tables using storage engines such as `InnoDB` that employ row-level locking. This issue is resolved in MySQL 5.6. See Section 18.5.4, "Partitioning and Table-Level Locking", for more information.

### 13.2.5.2 INSERT DELAYED Syntax

The `DELAYED` option for the `INSERT` statement is a MySQL extension to standard SQL that is very useful if you have clients that cannot or need not wait for the `INSERT` to complete. This is a common situation when you use MySQL for logging and you also periodically run `SELECT` and `UPDATE` statements that take a long time to complete.

When a client uses `INSERT DELAYED`, it gets an okay from the server at once, and the row is queued to be inserted when the table is not in use by any other thread.

Another major benefit of using `INSERT DELAYED` is that inserts from many clients are bundled together and written in one block. This is much faster than performing many separate inserts.

Note that `INSERT DELAYED` is slower than a normal `INSERT` if the table is not otherwise in use. There is also the additional overhead for the server to handle a separate thread for each table for which there are delayed rows. This means that you should use `INSERT DELAYED` only when you are really sure that you need it.

The queued rows are held only in memory until they are inserted into the table. This means that if you terminate `mysqld` forcibly (for example, with `kill -9`) or if `mysqld` dies unexpectedly, *any queued rows that have not been written to disk are lost*.

There are some constraints on the use of `DELAYED`:

- `INSERT DELAYED` works only with `MyISAM`, `MEMORY`, `ARCHIVE`, and (as of MySQL 5.1.19) `BLACKHOLE` tables. For engines that do not support `DELAYED`, an error occurs.

- An error occurs for `INSERT DELAYED` if used with a table that has been locked with `LOCK TABLES` because the insert must be handled by a separate thread, not by the session that holds the lock.

- For `MyISAM` tables, if there are no free blocks in the middle of the data file, concurrent `SELECT` and `INSERT` statements are supported. Under these circumstances, you very seldom need to use `INSERT DELAYED` with `MyISAM`.

- `INSERT DELAYED` should be used only for `INSERT` statements that specify value lists. The server ignores `DELAYED` for `INSERT ... SELECT` or `INSERT ... ON DUPLICATE KEY UPDATE` statements.

- Because the `INSERT DELAYED` statement returns immediately, before the rows are inserted, you cannot use `LAST_INSERT_ID()` to get the `AUTO_INCREMENT` value that the statement might generate.

- `DELAYED` rows are not visible to `SELECT` statements until they actually have been inserted.

- `INSERT DELAYED` is treated as a normal `INSERT` if the statement inserts multiple rows and binary logging is enabled and the global logging format is to use statement-based logging (`binlog_format` is set to `STATEMENT`). This restriction does not apply to row-based binary logging.

- `DELAYED` is ignored on slave replication servers, so that `INSERT DELAYED` is treated as a normal `INSERT` on slaves. This is because `DELAYED` could cause the slave to have different data than the master.

- Pending `INSERT DELAYED` statements are lost if a table is write locked and `ALTER TABLE` is used to modify the table structure.
• **INSERT DELAYED** is not supported for views.

• **INSERT DELAYED** is not supported for partitioned tables.

The following describes in detail what happens when you use the **DELAYED** option to **INSERT** or **REPLACE**. In this description, the “thread” is the thread that received an **INSERT DELAYED** statement and “handler” is the thread that handles all **INSERT DELAYED** statements for a particular table.

• When a thread executes a **DELAYED** statement for a table, a handler thread is created to process all **DELAYED** statements for the table, if no such handler already exists.

• The thread checks whether the handler has previously acquired a **DELAYED** lock; if not, it tells the handler thread to do so. The **DELAYED** lock can be obtained even if other threads have a **READ** or **WRITE** lock on the table. However, the handler waits for all **ALTER TABLE** locks or **FLUSH TABLES** statements to finish, to ensure that the table structure is up to date.

• The thread executes the **INSERT** statement, but instead of writing the row to the table, it puts a copy of the final row into a queue that is managed by the handler thread. Any syntax errors are noticed by the thread and reported to the client program.

• The client cannot obtain from the server the number of duplicate rows or the **AUTO_INCREMENT** value for the resulting row, because the **INSERT** returns before the insert operation has been completed. (If you use the C API, the **mysql_info()** function does not return anything meaningful, for the same reason.)

• The binary log is updated by the handler thread when the row is inserted into the table. In case of multiple-row inserts, the binary log is updated when the first row is inserted.

• Each time that **delayed_insert_limit** rows are written, the handler checks whether any **SELECT** statements are still pending. If so, it permits these to execute before continuing.

• When the handler has no more rows in its queue, the table is unlocked. If no new **INSERT DELAYED** statements are received within **delayed_insert_timeout** seconds, the handler terminates.

• If more than **delayed_queue_size** rows are pending in a specific handler queue, the thread requesting **INSERT DELAYED** waits until there is room in the queue. This is done to ensure that **mysqld** does not use all memory for the delayed memory queue.

• The handler thread shows up in the MySQL process list with **delayed_insert** in the Command column. It is killed if you execute a **FLUSH TABLES** statement or kill it with **KILL thread_id**. However, before exiting, it first stores all queued rows into the table. During this time it does not accept any new **INSERT** statements from other threads. If you execute an **INSERT DELAYED** statement after this, a new handler thread is created.

Note that this means that **INSERT DELAYED** statements have higher priority than normal **INSERT** statements if there is an **INSERT DELAYED** handler running. Other update statements have to wait until the **INSERT DELAYED** queue is empty, someone terminates the handler thread (with **KILL thread_id**), or someone executes a **FLUSH TABLES**.

• The following status variables provide information about **INSERT DELAYED** statements.

<table>
<thead>
<tr>
<th>Status Variable</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Delayed_insert_threads</strong></td>
<td>Number of handler threads</td>
</tr>
<tr>
<td><strong>Delayed_writes</strong></td>
<td>Number of rows written with <strong>INSERT DELAYED</strong></td>
</tr>
<tr>
<td><strong>Not_flushed_delayed_rows</strong></td>
<td>Number of rows waiting to be written</td>
</tr>
</tbody>
</table>

You can view these variables by issuing a **SHOW STATUS** statement or by executing a **mysqladmin extended-status** command.
13.2.5.3 INSERT ... ON DUPLICATE KEY UPDATE Syntax

If you specify ON DUPLICATE KEY UPDATE, and a row is inserted that would cause a duplicate value in a UNIQUE index or PRIMARY KEY, MySQL performs an UPDATE of the old row. For example, if column a is declared as UNIQUE and contains the value 1, the following two statements have similar effect:

```
INSERT INTO table (a,b,c) VALUES (1,2,3)
ON DUPLICATE KEY UPDATE c=c+1;
UPDATE table SET c=c+1 WHERE a=1;
```

(The effects are not identical for an InnoDB table where a is an auto-increment column. With an auto-increment column, an INSERT statement increases the auto-increment value but UPDATE does not.)

The ON DUPLICATE KEY UPDATE clause can contain multiple column assignments, separated by commas.

With ON DUPLICATE KEY UPDATE, the affected-rows value per row is 1 if the row is inserted as a new row, and 2 if an existing row is updated.

If column b is also unique, the INSERT is equivalent to this UPDATE statement instead:

```
UPDATE table SET c=c+1 WHERE a=1 OR b=2 LIMIT 1;
```

If a=1 OR b=2 matches several rows, only one row is updated. In general, you should try to avoid using an ON DUPLICATE KEY UPDATE clause on tables with multiple unique indexes.

You can use the `VALUES(col_name)` function in the UPDATE clause to refer to column values from the INSERT portion of the INSERT ... ON DUPLICATE KEY UPDATE statement. In other words, `VALUES(col_name)` in the ON DUPLICATE KEY UPDATE clause refers to the value of col_name that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The `VALUES()` function is meaningful only in INSERT ... UPDATE statements and returns NULL otherwise. Example:

```
INSERT INTO table (a,b,c) VALUES (1,2,3),(4,5,6)
ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

That statement is identical to the following two statements:

```
INSERT INTO table (a,b,c) VALUES (1,2,3)
ON DUPLICATE KEY UPDATE c=3;
INSERT INTO table (a,b,c) VALUES (4,5,6)
ON DUPLICATE KEY UPDATE c=9;
```

If a table contains an AUTO_INCREMENT column and INSERT ... ON DUPLICATE KEY UPDATE inserts or updates a row, the LAST_INSERT_ID() function returns the AUTO_INCREMENT value. Exception: For updates, LAST_INSERT_ID() is not meaningful prior to MySQL 5.1.12. However, you can work around this by using LAST_INSERT_ID(expr). Suppose that id is the AUTO_INCREMENT column. To make LAST_INSERT_ID() meaningful for updates, insert rows as follows:

```
INSERT INTO table (a,b,c) VALUES (1,2,3)
ON DUPLICATE KEY UPDATE id=LAST_INSERT_ID(id), c=3;
```

The DELAYED option is ignored when you use ON DUPLICATE KEY UPDATE.

An INSERT ... ON DUPLICATE KEY UPDATE on a partitioned table using a storage engine such as MyISAM that employs table-level locks locks all partitions of the table. This does not occur with tables using storage engines such as InnoDB that employ row-level locking. This issue is resolved in MySQL 5.6. See Section 18.5.4, “Partitioning and Table-Level Locking”, for more information.
13.2.6 LOAD DATA INFILE Syntax

```sql
LOAD DATA [LOW_PRIORITY | CONCURRENT] [LOCAL] INFILE 'file_name'
[REPLACE | IGNORE]
INTO TABLE tbl_name
[CHARACTER SET charset_name]
[FIELDS | COLUMNS]
[TERMINATED BY 'string']
[[OPTIONALLY] ENCLOSED BY 'char']
[ESCAPED BY 'char']
]
[LINES
[STARTING BY 'string']
[TERMINATED BY 'string']
]
[IGNORE number LINES]
[(col_name_or_user_var,...)]
[SET col_name = expr,...]
```

The `LOAD DATA INFILE` statement reads rows from a text file into a table at a very high speed. `LOAD DATA INFILE` is the complement of `SELECT ... INTO OUTFILE`. (See Section 13.2.8.1, “SELECT ... INTO Syntax.”) To write data from a table to a file, use `SELECT ... INTO OUTFILE`. To read the file back into a table, use `LOAD DATA INFILE`. The syntax of the `FIELDS` and `LINES` clauses is the same for both statements. Both clauses are optional, but `FIELDS` must precede `LINES` if both are specified.

You can also load data files by using the `mysqlimport` utility; it operates by sending a `LOAD DATA INFILE` statement to the server. The `--local` option causes `mysqlimport` to read data files from the client host. You can specify the `--compress` option to get better performance over slow networks if the client and server support the compressed protocol. See Section 4.5.5, “mysqlimport — A Data Import Program”.

For more information about the efficiency of `INSERT` versus `LOAD DATA INFILE` and speeding up `LOAD DATA INFILE`, see Section 8.2.2.1, “Speed of INSERT Statements”.

The file name must be given as a literal string. On Windows, specify backslashes in path names as forward slashes or doubled backslashes. As of MySQL 5.1.6, the `character_set_filesystem` system variable controls the interpretation of the file name.

The server uses the character set indicated by the `character_set_database` system variable to interpret the information in the file. `SET NAMES` and the setting of `character_set_client` do not affect interpretation of input. If the contents of the input file use a character set that differs from the default, it is usually preferable to specify the character set of the file by using the `CHARACTER SET` clause, which is available as of MySQL 5.1.17. A character set of `binary` specifies “no conversion.”

`LOAD DATA INFILE` interprets all fields in the file as having the same character set, regardless of the data types of the columns into which field values are loaded. For proper interpretation of file contents, you must ensure that it was written with the correct character set. For example, if you write a data file with `mysqldump -T` or by issuing a `SELECT ... INTO OUTFILE` statement in `mysql`, be sure to use a `--default-character-set` option so that output is written in the character set to be used when the file is loaded with `LOAD DATA INFILE`.

**Note**

It is not possible to load data files that use the `ucs2` character set.

If you use `LOW_PRIORITY`, execution of the `LOAD DATA` statement is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

If you specify `CONCURRENT` with a `MyISAM` table that satisfies the condition for concurrent inserts (that is, it contains no free blocks in the middle), other threads can retrieve data from the table while `LOAD
DATA is executing. This option affects the performance of LOAD DATA a bit, even if no other thread is using the table at the same time.

With row-based replication, CONCURRENT is replicated regardless of MySQL version. With statement-based replication CONCURRENT is not replicated prior to MySQL 5.1.43 (see Bug #34628). For more information, see Section 16.4.1.17, “Replication and LOAD DATA INFILE”.

Note
Prior to MySQL 5.1.23, LOAD DATA performed very poorly when importing into partitioned tables. The statement now uses buffering to improve performance; however, the buffer uses 130KB memory per partition to achieve this. (Bug #26527)

The LOCAL keyword affects expected location of the file and error handling, as described later. LOCAL works only if your server and your client both have been configured to permit it. For example, if mysqld was started with --local-infile=0, LOCAL does not work. See Section 6.1.6, “Security Issues with LOAD DATA LOCAL”.

The LOCAL keyword affects where the file is expected to be found:

• If LOCAL is specified, the file is read by the client program on the client host and sent to the server. The file can be given as a full path name to specify its exact location. If given as a relative path name, the name is interpreted relative to the directory in which the client program was started.

  When using LOCAL with LOAD DATA, a copy of the file is created in the server’s temporary directory. This is not the directory determined by the value of tmpdir or slave_load_tmpdir, but rather the operating system's temporary directory, and is not configurable in the MySQL Server. (Typically the system temporary directory is /tmp on Linux systems and C:\WINDOWS\TEMP on Windows.) Lack of sufficient space for the copy in this directory can cause the LOAD DATA LOCAL statement to fail.

• If LOCAL is not specified, the file must be located on the server host and is read directly by the server. The server uses the following rules to locate the file:

  • If the file name is an absolute path name, the server uses it as given.
  • If the file name is a relative path name with one or more leading components, the server searches for the file relative to the server’s data directory.
  • If a file name with no leading components is given, the server looks for the file in the database directory of the default database.

In the non-LOCAL case, these rules mean that a file named as ./myfile.txt is read from the server’s data directory, whereas the file named as myfile.txt is read from the database directory of the default database. For example, if db1 is the default database, the following LOAD DATA statement reads the file data.txt from the database directory for db1, even though the statement explicitly loads the file into a table in the db2 database:

```
LOAD DATA INFILE 'data.txt' INTO TABLE db2.my_table;
```

Note
A regression in MySQL 5.1.40 caused the database referenced in a fully qualified table name to be ignored by LOAD DATA when using replication with either STATEMENT or MIXED as the binary logging format; this could lead to problems if the table was not in the current database. As a workaround, you can specify the correct database with the USE statement prior to executing LOAD DATA. If necessary, you can reset the default database with a second USE statement following the LOAD DATA statement.

This issue was fixed in MySQL 5.1.41. (Bug #48297)
For security reasons, when reading text files located on the server, the files must either reside in the database directory or be readable by all. Also, to use \texttt{LOAD DATA INFILE} on server files, you must have the \texttt{FILE} privilege. See Section 6.2.1, “Privileges Provided by MySQL”. For non-\texttt{LOCAL} load operations, if the \texttt{secure_file_priv} system variable is set to a nonempty directory name, the file to be loaded must be located in that directory.

Using \texttt{LOCAL} is a bit slower than letting the server access the files directly, because the contents of the file must be sent over the connection by the client to the server. On the other hand, you do not need the \texttt{FILE} privilege to load local files.

\texttt{LOCAL} also affects error handling:

\begin{itemize}
  \item With \texttt{LOAD DATA INFILE}, data-interpretation and duplicate-key errors terminate the operation.
  \item With \texttt{LOAD DATA LOCAL INFILE}, data-interpretation and duplicate-key errors become warnings and the operation continues because the server has no way to stop transmission of the file in the middle of the operation. For duplicate-key errors, this is the same as if \texttt{IGNORE} is specified. \texttt{IGNORE} is explained further later in this section.
\end{itemize}

The \texttt{REPLACE} and \texttt{IGNORE} keywords control handling of input rows that duplicate existing rows on unique key values:

\begin{itemize}
  \item If you specify \texttt{REPLACE}, input rows replace existing rows. In other words, rows that have the same value for a primary key or unique index as an existing row. See Section 13.2.7, “REPLACE Syntax”.
  \item If you specify \texttt{IGNORE}, rows that duplicate an existing row on a unique key value are discarded.
  \item If you do not specify either option, the behavior depends on whether the \texttt{LOCAL} keyword is specified. Without \texttt{LOCAL}, an error occurs when a duplicate key value is found, and the rest of the text file is ignored. With \texttt{LOCAL}, the default behavior is the same as if \texttt{IGNORE} is specified; this is because the server has no way to stop transmission of the file in the middle of the operation.
\end{itemize}

To ignore foreign key constraints during the load operation, issue a \texttt{SET foreign_key_checks = 0} statement before executing \texttt{LOAD DATA}.

If you use \texttt{LOAD DATA INFILE} on an empty \texttt{MyISAM} table, all nonunique indexes are created in a separate batch (as for \texttt{REPAIR TABLE}). Normally, this makes \texttt{LOAD DATA INFILE} much faster when you have many indexes. In some extreme cases, you can create the indexes even faster by turning them off with \texttt{ALTER TABLE ... DISABLE KEYS} before loading the file into the table and using \texttt{ALTER TABLE ... ENABLE KEYS} to re-create the indexes after loading the file. See Section 8.2.2.1, “Speed of INSERT Statements”.

For both the \texttt{LOAD DATA INFILE} and \texttt{SELECT ... INTO OUTFILE} statements, the syntax of the \texttt{FIELDS} and \texttt{LINES} clauses is the same. Both clauses are optional, but \texttt{FIELDS} must precede \texttt{LINES} if both are specified.

If you specify a \texttt{FIELDS} clause, each of its subclauses (\texttt{TERMINATED BY}, [\texttt{OPTIONALLY} \texttt{ENCLOSED BY}, and \texttt{ESCAPED BY}) is also optional, except that you must specify at least one of them.

If you specify no \texttt{FIELDS} or \texttt{LINES} clause, the defaults are the same as if you had written this:

\begin{verbatim}
FIELDS TERMINATED BY '	' ENCLOSED BY '' ESCAPED BY '\\n'
LINES TERMINATED BY '
' STARTING BY ''
\end{verbatim}

(Backslash is the MySQL escape character within strings in SQL statements, so to specify a literal backslash, you must specify two backslashes for the value to be interpreted as a single backslash. The escape sequences '\t' and '\n' specify tab and newline characters, respectively.)

In other words, the defaults cause \texttt{LOAD DATA INFILE} to act as follows when reading input:

\begin{itemize}
  \item Look for line boundaries at newlines.
  \item Do not skip over any line prefix.
\end{itemize}
LOAD DATA INFILE Syntax

- Break lines into fields at tabs.
- Do not expect fields to be enclosed within any quoting characters.
- Interpret characters preceded by the escape character \" as escape sequences. For example, \t, \n, and \ signify tab, newline, and backslash, respectively. See the discussion of FIELDS ESCAPED BY later for the full list of escape sequences.

Conversely, the defaults cause SELECT ... INTO OUTFILE to act as follows when writing output:

- Write tabs between fields.
- Do not enclose fields within any quoting characters.
- Use \ to escape instances of tab, newline, or \ that occur within field values.
- Write newlines at the ends of lines.

Note

If you have generated the text file on a Windows system, you might have to use LINES TERMINATED BY '\r
' to read the file properly, because Windows programs typically use two characters as a line terminator. Some programs, such as WordPad, might use \r as a line terminator when writing files. To read such files, use LINES TERMINATED BY '\r'.

If all the lines you want to read in have a common prefix that you want to ignore, you can use LINES STARTING BY 'prefix_string' to skip over the prefix, and anything before it. If a line does not include the prefix, the entire line is skipped. Suppose that you issue the following statement:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test
  FIELDS TERMINATED BY ','  LINES STARTING BY 'xxx';
```

If the data file looks like this:

```
xxx"abc",1
something xxx"def",2
"ghi",3
```

The resulting rows will be ("abc",1) and ("def",2). The third row in the file is skipped because it does not contain the prefix.

The IGNORE number LINES option can be used to ignore lines at the start of the file. For example, you can use IGNORE 1 LINES to skip over an initial header line containing column names:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test IGNORE 1 LINES;
```

When you use SELECT ... INTO OUTFILE in tandem with LOAD DATA INFILE to write data from a database into a file and then read the file back into the database later, the field- and line-handling options for both statements must match. Otherwise, LOAD DATA INFILE will not interpret the contents of the file properly. Suppose that you use SELECT ... INTO OUTFILE to write a file with fields delimited by commas:

```
SELECT * INTO OUTFILE 'data.txt'
  FIELDS TERMINATED BY ','
FROM table2;
```

To read the comma-delimited file back in, the correct statement would be:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
  FIELDS TERMINATED BY ',';
```
LOAD DATA INFILE Syntax

If instead you tried to read in the file with the statement shown following, it wouldn't work because it instructs **LOAD DATA INFILE** to look for tabs between fields:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
  FIELDS TERMINATED BY '\t';
```

The likely result is that each input line would be interpreted as a single field.

**LOAD DATA INFILE** can be used to read files obtained from external sources. For example, many programs can export data in comma-separated values (CSV) format, such that lines have fields separated by commas and enclosed within double quotation marks, with an initial line of column names. If the lines in such a file are terminated by carriage return/newline pairs, the statement shown here illustrates the field- and line-handling options you would use to load the file:

```
LOAD DATA INFILE 'data.txt' INTO TABLE tbl_name
  FIELDS TERMINATED BY ',' ENCLOSED BY '"'
  LINES TERMINATED BY '\r\n'
  IGNORE 1 LINES;
```

If the input values are not necessarily enclosed within quotation marks, use **OPTIONALLY** before the **ENCLOSED BY** keywords.

Any of the field- or line-handling options can specify an empty string (''). If not empty, the **FIELDS [OPTIONALLY] ENCLOSED BY** and **FIELDS ESCAPED BY** values must be a single character. The **FIELDS TERMINATED BY**, **LINES STARTING BY**, and **LINES TERMINATED BY** values can be more than one character. For example, to write lines that are terminated by carriage return/linefeed pairs, or to read a file containing such lines, specify a **LINES TERMINATED BY '\r\n'** clause.

To read a file containing jokes that are separated by lines consisting of `%%`, you can do this:

```
CREATE TABLE jokes
  (a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
   joke TEXT NOT NULL);
LOAD DATA INFILE '/tmp/jokes.txt' INTO TABLE jokes
  FIELDS TERMINATED BY ''
  LINES TERMINATED BY '
%%
' (joke);
```

**FIELDS [OPTIONALLY] ENCLOSED BY** controls quoting of fields. For output (**SELECT ... INTO OUTFILE**), if you omit the word **OPTIONALLY**, all fields are enclosed by the **ENCLOSED BY** character. An example of such output (using a comma as the field delimiter) is shown here:

```
"1","a string","100.20"
"2","a string containing a , comma","102.20"
"3","a string containing a \" quote","102.20"
"4","a string containing a ", quote and comma","102.20"
```

If you specify **OPTIONALLY**, the **ENCLOSED BY** character is used only to enclose values from columns that have a string data type (such as **CHAR**, **BINARY**, **TEXT**, or **ENUM**):

```
1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a \" quote",102.20
4,"a string containing a ", quote and comma",102.20
```

Occurrences of the **ENCLOSED BY** character within a field value are escaped by prefixing them with the **ESCAPED BY** character. Also note that if you specify an empty **ESCAPED BY** value, it is possible to inadvertently generate output that cannot be read properly by **LOAD DATA INFILE**. For example, the preceding output just shown would appear as follows if the escape character is empty. Observe that the second field in the fourth line contains a comma following the quote, which (erroneously) appears to terminate the field:
For input, the ENCLOSED BY character, if present, is stripped from the ends of field values. (This is true regardless of whether OPTIONALLY is specified; OPTIONALLY has no effect on input interpretation.) Occurrences of the ENCLOSED BY character preceded by the ESCAPED BY character are interpreted as part of the current field value.

If the field begins with the ENCLOSED BY character, instances of that character are recognized as terminating a field value only if followed by the field or line TERMINATED BY sequence. To avoid ambiguity, occurrences of the ENCLOSED BY character within a field value can be doubled and are interpreted as a single instance of the character. For example, if ENCLOSED BY ‘”’ is specified, quotation marks are handled as shown here:

*The ""BIG"" boss*  ->  The "BIG" boss
The "BIG" boss      ->  The "BIG" boss
The ""BIG"" boss     ->  The ""BIG"" boss

FIELDS ESCAPED BY controls how to read or write special characters:

- For input, if the FIELDS ESCAPED BY character is not empty, occurrences of that character are stripped and the following character is taken literally as part of a field value. Some two-character sequences that are exceptions, where the first character is the escape character. These sequences are shown in the following table (using "\" for the escape character). The rules for NULL handling are described later in this section.

<table>
<thead>
<tr>
<th>Character</th>
<th>Escape Sequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>\0</td>
<td>An ASCII NUL (X'00') character</td>
</tr>
<tr>
<td>\b</td>
<td>A backspace character</td>
</tr>
<tr>
<td>\n</td>
<td>A newline (linefeed) character</td>
</tr>
<tr>
<td>\r</td>
<td>A carriage return character</td>
</tr>
<tr>
<td>\t</td>
<td>A tab character.</td>
</tr>
<tr>
<td>\Z</td>
<td>ASCII 26 (Control+Z)</td>
</tr>
<tr>
<td>\N</td>
<td>NULL</td>
</tr>
</tbody>
</table>

For more information about "\"-escape syntax, see Section 9.1.1, “String Literals”.

If the FIELDS ESCAPED BY character is empty, escape-sequence interpretation does not occur.

- For output, if the FIELDS ESCAPED BY character is not empty, it is used to prefix the following characters on output:
  - The FIELDS ESCAPED BY character
  - The FIELDS [OPTIONALLY] ENCLOSED BY character
  - The first character of the FIELDS TERMINATED BY and LINES TERMINATED BY values
  - ASCII 0 (what is actually written following the escape character is ASCII “0", not a zero-valued byte)

If the FIELDS ESCAPED BY character is empty, no characters are escaped and NULL is output as NULL, not \N. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

In certain cases, field- and line-handling options interact:
• If `LINES TERMINATED BY` is an empty string and `FIELDS TERMINATED BY` is nonempty, lines are also terminated with `FIELDS TERMINATED BY`.

• If the `FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` values are both empty (""), a fixed-row (nondelimited) format is used. With fixed-row format, no delimiters are used between fields (but you can still have a line terminator). Instead, column values are read and written using a field width wide enough to hold all values in the field. For `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT`, and `BIGINT`, the field widths are 4, 6, 8, 11, and 20, respectively, no matter what the declared display width is.

`LINES TERMINATED BY` is still used to separate lines. If a line does not contain all fields, the rest of the columns are set to their default values. If you do not have a line terminator, you should set this to "". In this case, the text file must contain all fields for each row.

Fixed-row format also affects handling of `NULL` values, as described later.

Note

Fixed-size format does not work if you are using a multibyte character set.

Handling of `NULL` values varies according to the `FIELDS` and `LINES` options in use:

• For the default `FIELDS` and `LINES` values, `NULL` is written as a field value of \N for output, and a field value of \N is read as `NULL` for input (assuming that the `ESCAPED BY` character is "\".

• If `FIELDS ENCLOSED BY` is not empty, a field containing the literal word `NULL` as its value is read as a `NULL` value. This differs from the word `NULL` enclosed within `FIELDS ENCLOSED BY` characters, which is read as the string 'NULL'.

• If `FIELDS ESCAPED BY` is empty, `NULL` is written as the word `NULL`.

• With fixed-row format (which is used when `FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` are both empty), `NULL` is written as an empty string. This causes both `NULL` values and empty strings in the table to be indistinguishable when written to the file because both are written as empty strings. If you need to be able to tell the two apart when reading the file back in, you should not use fixed-row format.

An attempt to load `NULL` into a `NOT NULL` column causes assignment of the implicit default value for the column's data type and a warning, or an error in strict SQL mode. Implicit default values are discussed in Section 11.6, "Data Type Default Values".

Some cases are not supported by `LOAD DATA INFILE`:

• Fixed-size rows (`FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` both empty) and `BLOB` or `TEXT` columns.

• If you specify one separator that is the same as or a prefix of another, `LOAD DATA INFILE` cannot interpret the input properly. For example, the following `FIELDS` clause would cause problems:

```
FIELDS TERMINATED BY '"' ENCLOSED BY '"'
```

• If `FIELDS ESCAPED BY` is empty, a field value that contains an occurrence of `FIELDS ENCLOSED BY` or `LINES TERMINATED BY` followed by the `FIELDS TERMINATED BY` value causes `LOAD DATA INFILE` to stop reading a field or line too early. This happens because `LOAD DATA INFILE` cannot properly determine where the field or line value ends.

The following example loads all columns of the `persondata` table:

```
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata;
```
LOAD DATA INFILE Syntax

By default, when no column list is provided at the end of the `LOAD DATA INFILE` statement, input lines are expected to contain a field for each table column. If you want to load only some of a table’s columns, specify a column list:

```
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata (col1, col2, ...);
```

You must also specify a column list if the order of the fields in the input file differs from the order of the columns in the table. Otherwise, MySQL cannot tell how to match input fields with table columns.

The column list can contain either column names or user variables. With user variables, the `SET` clause enables you to perform transformations on their values before assigning the result to columns.

User variables in the `SET` clause can be used in several ways. The following example uses the first input column directly for the value of `t1.column1`, and assigns the second input column to a user variable that is subjected to a division operation before being used for the value of `t1.column2`:

```
LOAD DATA INFILE 'file.txt'
    INTO TABLE t1
    (column1, @var1)
    SET column2 = @var1/100;
```

The `SET` clause can be used to supply values not derived from the input file. The following statement sets `column3` to the current date and time:

```
LOAD DATA INFILE 'file.txt'
    INTO TABLE t1
    (column1, column2)
    SET column3 = CURRENT_TIMESTAMP;
```

You can also discard an input value by assigning it to a user variable and not assigning the variable to a table column:

```
LOAD DATA INFILE 'file.txt'
    INTO TABLE t1
    (column1, @dummy, column2, @dummy, column3);
```

Use of the column/variable list and `SET` clause is subject to the following restrictions:

- Assignments in the `SET` clause should have only column names on the left hand side of assignment operators.

- You can use subqueries in the right hand side of `SET` assignments. A subquery that returns a value to be assigned to a column may be a scalar subquery only. Also, you cannot use a subquery to select from the table that is being loaded.

- Lines ignored by an `IGNORE` clause are not processed for the column/variable list or `SET` clause.

- User variables cannot be used when loading data with fixed-row format because user variables do not have a display width.

When processing an input line, `LOAD DATA` splits it into fields and uses the values according to the column/variable list and the `SET` clause, if they are present. Then the resulting row is inserted into the table. If there are `BEFORE INSERT` or `AFTER INSERT` triggers for the table, they are activated before or after inserting the row, respectively.

If an input line has too many fields, the extra fields are ignored and the number of warnings is incremented.

If an input line has too few fields, the table columns for which input fields are missing are set to their default values. Default value assignment is described in Section 11.6, “Data Type Default Values”.

An empty field value is interpreted different from a missing field:
LOAD DATA INFILE Syntax

• For string types, the column is set to the empty string.

• For numeric types, the column is set to 0.

• For date and time types, the column is set to the appropriate “zero” value for the type. See Section 11.3, “Date and Time Types”.

These are the same values that result if you assign an empty string explicitly to a string, numeric, or date or time type explicitly in an INSERT or UPDATE statement.

Treatment of empty or incorrect field values differs from that just described if the SQL mode is set to a restrictive value. For example, if sql_mode is set to TRADITIONAL, conversion of an empty value or a value such as 'x' for a numeric column results in an error, not conversion to 0. (With LOCAL or IGNORE, warnings occur rather than errors, even with a restrictive sql_mode value, and the row is inserted using the same closest-value behavior used for nonrestrictive SQL modes. This occurs because the server has no way to stop transmission of the file in the middle of the operation.)

TIMESTAMP columns are set to the current date and time only if there is a NULL value for the column (that is, \N) and the column is not declared to permit NULL values, or if the TIMESTAMP column’s default value is the current timestamp and it is omitted from the field list when a field list is specified.

LOAD DATA INFILE regards all input as strings, so you cannot use numeric values for ENUM or SET columns the way you can with INSERT statements. All ENUM and SET values must be specified as strings.

BIT values cannot be loaded using binary notation (for example, b'011010'). To work around this, specify the values as regular integers and use the SET clause to convert them so that MySQL performs a numeric type conversion and loads them into the BIT column properly:

```
shell> cat /tmp/bit_test.txt
2
127
shell> mysql test
mysql> LOAD DATA INFILE '/tmp/bit_test.txt' INTO TABLE bit_test (@var1) SET b = CAST(@var1 AS UNSIGNED);
Query OK, 2 rows affected (0.00 sec)
Records: 2  Deleted: 0  Skipped: 0  Warnings: 0
mysql> SELECT BIN(b+0) FROM bit_test;
+----------+
| bin(b+0) |
+----------+
| 10       |
| 111111    |
+----------+
2 rows in set (0.00 sec)
```

On Unix, if you need LOAD DATA to read from a pipe, you can use the following technique (the example loads a listing of the / directory into the table db1.t1):

```
mkfifo /mysql/data/db1/ls.dat
chmod 666 /mysql/data/db1/ls.dat
find / -ls > /mysql/data/db1/ls.dat &
mysql -e "LOAD DATA INFILE 'ls.dat' INTO TABLE t1" db1
```

Here you must run the command that generates the data to be loaded and the mysql commands either on separate terminals, or run the data generation process in the background (as shown in the preceding example). If you do not do this, the pipe will block until data is read by the mysql process.

When the LOAD DATA INFILE statement finishes, it returns an information string in the following format:

```
Records: 1  Deleted: 0  Skipped: 0  Warnings: 0
```
Warnings occur under the same circumstances as when values are inserted using the `INSERT` statement (see Section 13.2.5, “INSERT Syntax”), except that `LOAD DATA INFILE` also generates warnings when there are too few or too many fields in the input row.

You can use `SHOW WARNINGS` to get a list of the first `max_error_count` warnings as information about what went wrong. See Section 13.7.5.42, “SHOW WARNINGS Syntax”.

If you are using the C API, you can get information about the statement by calling the `mysql_info()` function. See Section 21.8.7.35, “mysql_info()”.

For partitioned tables using storage engines that employ table locks, such as `MyISAM`, any locks caused by `LOAD DATA` perform locks on all partitions of the table. This does not apply to tables using storage engines which employ row-level locking, such as `InnoDB`. For more information, see Section 18.5.4, “Partitioning and Table-Level Locking”.

### 13.2.7 REPLACE Syntax

```
REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name [{(col_name,...)}]
  {VALUES | VALUE} {{expr | DEFAULT},...},(...),...
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name
  SET col_name=expr | DEFAULT, ...
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name [{(col_name,...)}]
  SELECT ...
```

REPLACE works exactly like `INSERT`, except that if an old row in the table has the same value as a new row for a `PRIMARY KEY` or a `UNIQUE` index, the old row is deleted before the new row is inserted. See Section 13.2.5, “INSERT Syntax”.

REPLACE is a MySQL extension to the SQL standard. It either inserts, or deletes and inserts. For another MySQL extension to standard SQL—that either inserts or updates—see Section 13.2.5.3, “INSERT ... ON DUPLICATE KEY UPDATE Syntax”.

**Note**

REPLACE makes sense only if a table has a PRIMARY KEY or UNIQUE index. Otherwise, it becomes equivalent to `INSERT`, because there is no index to be used to determine whether a new row duplicates another.

Values for all columns are taken from the values specified in the REPLACE statement. Any missing columns are set to their default values, just as happens for `INSERT`. You cannot refer to values from the current row and use them in the new row. If you use an assignment such as `SET col_name = col_name + 1`, the reference to the column name on the right hand side is treated as `DEFAULT(col_name)`, so the assignment is equivalent to `SET col_name = DEFAULT(col_name) + 1`.

To use REPLACE, you must have both the INSERT and DELETE privileges for the table.

The REPLACE statement returns a count to indicate the number of rows affected. This is the sum of the rows deleted and inserted. If the count is 1 for a single-row REPLACE, a row was inserted and no rows were deleted. If the count is greater than 1, one or more old rows were deleted before the new row was inserted. It is possible for a single row to replace more than one old row if the table contains multiple unique indexes and the new row duplicates values for different old rows in different unique indexes.
The affected-rows count makes it easy to determine whether \texttt{REPLACE} only added a row or whether it also replaced any rows: Check whether the count is 1 (added) or greater (replaced).

If you are using the C API, the affected-rows count can be obtained using the \texttt{mysql_affected_rows()} function.

You cannot replace into a table and select from the same table in a subquery.

MySQL uses the following algorithm for \texttt{REPLACE} (and \texttt{LOAD DATA ... REPLACE}):

1. Try to insert the new row into the table
2. While the insertion fails because a duplicate-key error occurs for a primary key or unique index:
   a. Delete from the table the conflicting row that has the duplicate key value
   b. Try again to insert the new row into the table

It is possible that in the case of a duplicate-key error, a storage engine may perform the \texttt{REPLACE} as an update rather than a delete plus insert, but the semantics are the same. There are no user-visible effects other than a possible difference in how the storage engine increments \texttt{Handler}}_{xxx} status variables.

When modifying an existing table that is not partitioned to accommodate partitioning, or, when modifying the partitioning of an already partitioned table, you may consider altering the table's primary key (see Section 18.5.1, “Partitioning Keys, Primary Keys, and Unique Keys”). You should be aware that, if you do this, the results of \texttt{REPLACE} statements may be affected, just as they would be if you modified the primary key of a nonpartitioned table. Consider the table created by the following \texttt{CREATE TABLE} statement:

```sql
CREATE TABLE test (  
  id INT UNSIGNED NOT NULL AUTO_INCREMENT,  
  data VARCHAR(64) DEFAULT NULL,  
  ts TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,  
  PRIMARY KEY (id)  
);
```

When we create this table and run the statements shown in the mysql client, the result is as follows:

```sql
mysql> REPLACE INTO test VALUES (1, 'Old', '2014-08-20 18:47:00');  
Query OK, 1 row affected (0.04 sec)
```

```sql
mysql> REPLACE INTO test VALUES (1, 'New', '2014-08-20 18:47:42');  
Query OK, 2 rows affected (0.04 sec)
```

```sql
mysql> SELECT * FROM test;  
<table>
<thead>
<tr>
<th>id</th>
<th>data</th>
<th>ts</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>New</td>
<td>2014-08-20 18:47:42</td>
</tr>
</tbody>
</table>
```

Now we create a second table almost identical to the first, except that the primary key now covers 2 columns, as shown here (emphasized text):

```sql
CREATE TABLE test2 (  
  id INT UNSIGNED NOT NULL AUTO_INCREMENT,  
  data VARCHAR(64) DEFAULT NULL,  
  ts TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,  
  PRIMARY KEY (id, ts)  
);
```
When we run on `test2` the same two `REPLACE` statements as we did on the original `test` table, we obtain a different result:

```
mysql> REPLACE INTO test2 VALUES (1, 'Old', '2014-08-20 18:47:00');
Query OK, 1 row affected (0.05 sec)
mysql> REPLACE INTO test2 VALUES (1, 'New', '2014-08-20 18:47:42');
Query OK, 1 row affected (0.06 sec)
mysql> SELECT * FROM test2;
+----+------+---------------------+
<table>
<thead>
<tr>
<th>id</th>
<th>data</th>
<th>ts</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Old</td>
<td>2014-08-20 18:47:00</td>
</tr>
<tr>
<td>1</td>
<td>New</td>
<td>2014-08-20 18:47:42</td>
</tr>
</tbody>
</table>
+----+------+---------------------+
2 rows in set (0.00 sec)
```

This is due to the fact that, when run on `test2`, both the `id` and `ts` column values must match those of an existing row for the row to be replaced; otherwise, a row is inserted.

A `REPLACE` statement that acts on a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks all partitions of the table. This does not occur with tables using storage engines such as `InnoDB` that employ row-level locking. This issue is resolved in MySQL 5.6. See Section 18.5.4, “Partitioning and Table-Level Locking”, for more information.

### 13.2.8 SELECT Syntax

`SELECT` is used to retrieve rows selected from one or more tables, and can include `UNION` statements and subqueries. See Section 13.2.8.3, “UNION Syntax”, and Section 13.2.9, “Subquery Syntax”.

The most commonly used clauses of `SELECT` statements are these:

- Each `select_expr` indicates a column that you want to retrieve. There must be at least one `select_expr`.

- `table_references` indicates the table or tables from which to retrieve rows. Its syntax is described in Section 13.2.8.2, “JOIN Syntax”.

- The `WHERE` clause, if given, indicates the condition or conditions that rows must satisfy to be selected. `where_condition` is an expression that evaluates to true for each row to be selected. The statement selects all rows if there is no `WHERE` clause.
In the `WHERE` expression, you can use any of the functions and operators that MySQL supports, except for aggregate (summary) functions. See Section 9.5, “Expression Syntax”, and Chapter 12, Functions and Operators.

`SELECT` can also be used to retrieve rows computed without reference to any table. For example:

```sql
mysql> SELECT 1 + 1;
-> 2
```

You are permitted to specify `DUAL` as a dummy table name in situations where no tables are referenced:

```sql
mysql> SELECT 1 + 1 FROM DUAL;
-> 2
```

`DUAL` is purely for the convenience of people who require that all `SELECT` statements should have `FROM` and possibly other clauses. MySQL may ignore the clauses. MySQL does not require `FROM` if no tables are referenced.

In general, clauses used must be given in exactly the order shown in the syntax description. For example, a `HAVING` clause must come after any `GROUP BY` clause and before any `ORDER BY` clause. The exception is that the `INTO` clause can appear either as shown in the syntax description or immediately following the `select_expr` list. For more information about `INTO`, see Section 13.2.8.1, “SELECT ... INTO Syntax”.

The list of `select_expr` terms comprises the select list that indicates which columns to retrieve. Terms specify a column or expression or can use `-shorthand:

- A select list consisting only of a single unqualified `*` can be used as shorthand to select all columns from all tables:

  ```sql
  SELECT * FROM t1 INNER JOIN t2 ...
  ```

- `tbl_name.*` can be used as a qualified shorthand to select all columns from the named table:

  ```sql
  SELECT t1.*, t2.* FROM t1 INNER JOIN t2 ...
  ```

- Use of an unqualified `*` with other items in the select list may produce a parse error. To avoid this problem, use a qualified `tbl_name.*` reference:

  ```sql
  SELECT AVG(score), t1.* FROM t1 ...
  ```

The following list provides additional information about other `SELECT` clauses:

- A `select_expr` can be given an alias using `AS alias_name`. The alias is used as the expression's column name and can be used in `GROUP BY, ORDER BY, or HAVING` clauses. For example:

  ```sql
  SELECT CONCAT(last_name,', ',first_name) AS full_name
  FROM mytable ORDER BY full_name;
  ```

  The `AS` keyword is optional when aliasing a `select_expr` with an identifier. The preceding example could have been written like this:

  ```sql
  SELECT CONCAT(last_name,', ',first_name) full_name
  FROM mytable ORDER BY full_name;
  ```
However, because the AS is optional, a subtle problem can occur if you forget the comma between two select_expr expressions: MySQL interprets the second as an alias name. For example, in the following statement, columnb is treated as an alias name:

```sql
SELECT columna columnb FROM mytable;
```

For this reason, it is good practice to be in the habit of using AS explicitly when specifying column aliases.

It is not permissible to refer to a column alias in a WHERE clause, because the column value might not yet be determined when the WHERE clause is executed. See Section B.5.4.4, “Problems with Column Aliases”.

- The FROM table_references clause indicates the table or tables from which to retrieve rows. If you name more than one table, you are performing a join. For information on join syntax, see Section 13.2.8.2, “JOIN Syntax”. For each table specified, you can optionally specify an alias.

```sql
tbl_name [[AS] alias] [index_hint]
```

The use of index hints provides the optimizer with information about how to choose indexes during query processing. For a description of the syntax for specifying these hints, see Section 8.9.3, “Index Hints”.

You can use SET max_seeks_for_key=value as an alternative way to force MySQL to prefer key scans instead of table scans. See Section 5.1.4, “Server System Variables”.

- You can refer to a table within the default database as tbl_name, or as db_name.tbl_name to specify a database explicitly. You can refer to a column as col_name, tbl_name.col_name, or db_name.tbl_name.col_name. You need not specify a tbl_name or db_name prefix for a column reference unless the reference would be ambiguous. See Section 9.2.1, “Identifier Qualifiers”, for examples of ambiguity that require the more explicit column reference forms.

- A table reference can be aliased using tbl_name AS alias_name or tbl_name alias_name:

```sql
SELECT t1.name, t2.salary FROM employee AS t1, info AS t2
WHERE t1.name = t2.name;
```

- Columns selected for output can be referred to in ORDER BY and GROUP BY clauses using column names, column aliases, or column positions. Column positions are integers and begin with 1:

```sql
SELECT college, region, seed FROM tournament
ORDER BY region, seed;
```

To sort in reverse order, add the DESC (descending) keyword to the name of the column in the ORDER BY clause that you are sorting by. The default is ascending order; this can be specified explicitly using the ASC keyword.

If ORDER BY occurs within a subquery and also is applied in the outer query, the outermost ORDER BY takes precedence. For example, results for the following statement are sorted in descending order, not ascending order:

```sql
SELECT column1 column2 FROM table1
ORDER BY column2 DESC;
```
Use of column positions is deprecated because the syntax has been removed from the SQL standard.

- If you use `GROUP BY`, output rows are sorted according to the `GROUP BY` columns as if you had an `ORDER BY` for the same columns. To avoid the overhead of sorting that `GROUP BY` produces, add `ORDER BY NULL`:

  ```sql
  SELECT a, COUNT(b) FROM test_table GROUP BY a ORDER BY NULL;
  ```

- MySQL extends the `GROUP BY` clause so that you can also specify `ASC` and `DESC` after columns named in the clause:

  ```sql
  SELECT a, COUNT(b) FROM test_table GROUP BY a DESC;
  ```

- MySQL extends the use of `GROUP BY` to permit selecting fields that are not mentioned in the `GROUP BY` clause. If you are not getting the results that you expect from your query, please read the description of `GROUP BY` found in Section 12.17, “Aggregate (GROUP BY) Functions”.

- `GROUP BY` permits a `WITH ROLLUP` modifier. See Section 12.17.2, “GROUP BY Modifiers”.

- The `HAVING` clause is applied nearly last, just before items are sent to the client, with no optimization. (`LIMIT` is applied after `HAVING`.)

  The SQL standard requires that `HAVING` must reference only columns in the `GROUP BY` clause or columns used in aggregate functions. However, MySQL supports an extension to this behavior, and permits `HAVING` to refer to columns in the `SELECT` list and columns in outer subqueries as well.

  If the `HAVING` clause refers to a column that is ambiguous, a warning occurs. In the following statement, `col2` is ambiguous because it is used as both an alias and a column name:

  ```sql
  SELECT COUNT(col1) AS col2 FROM t GROUP BY col2 HAVING col2 = 2;
  ```

  Preference is given to standard SQL behavior, so if a `HAVING` column name is used both in `GROUP BY` and as an aliased column in the output column list, preference is given to the column in the `GROUP BY` column.

- Do not use `HAVING` for items that should be in the `WHERE` clause. For example, do not write the following:

  ```sql
  SELECT col_name FROM tbl_name HAVING col_name > 0;
  ```

  Write this instead:

  ```sql
  SELECT col_name FROM tbl_name WHERE col_name > 0;
  ```

- The `HAVING` clause can refer to aggregate functions, which the `WHERE` clause cannot:

  ```sql
  SELECT user, MAX(salary) FROM users
  GROUP BY user HAVING MAX(salary) > 10;
  ```

  (This did not work in some older versions of MySQL.)

- MySQL permits duplicate column names. That is, there can be more than one `select_expr` with the same name. This is an extension to standard SQL. Because MySQL also permits `GROUP BY` and `HAVING` to refer to `select_expr` values, this can result in an ambiguity:
SELECT 12 AS a, a FROM t GROUP BY a;

In that statement, both columns have the name a. To ensure that the correct column is used for grouping, use different names for each `select_expr`.

- MySQL resolves unqualified column or alias references in `ORDER BY` clauses by searching in the `select_expr` values, then in the columns of the tables in the `FROM` clause. For `GROUP BY` or `HAVING` clauses, it searches the `FROM` clause before searching in the `select_expr` values. (For `GROUP BY` and `HAVING`, this differs from the pre-MySQL 5.0 behavior that used the same rules as for `ORDER BY`.)

- The `LIMIT` clause can be used to constrain the number of rows returned by the `SELECT` statement. `LIMIT` takes one or two numeric arguments, which must both be nonnegative integer constants (except when using prepared statements).

With two arguments, the first argument specifies the offset of the first row to return, and the second specifies the maximum number of rows to return. The offset of the initial row is 0 (not 1):

```
SELECT * FROM tbl LIMIT 5,10;  # Retrieve rows 6-15
```

To retrieve all rows from a certain offset up to the end of the result set, you can use some large number for the second parameter. This statement retrieves all rows from the 96th row to the last:

```
SELECT * FROM tbl LIMIT 95,18446744073709551615;
```

With one argument, the value specifies the number of rows to return from the beginning of the result set:

```
SELECT * FROM tbl LIMIT 5;     # Retrieve first 5 rows
```

In other words, `LIMIT row_count` is equivalent to `LIMIT 0, row_count`.

For prepared statements, you can use placeholders. The following statements will return one row from the `tbl` table:

```
SET @a=1;
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?';
EXECUTE STMT USING @a;
```

The following statements will return the second to sixth row from the `tbl` table:

```
SET @skip=1; SET @numrows=5;
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?, ?';
EXECUTE STMT USING @skip, @numrows;
```

For compatibility with PostgreSQL, MySQL also supports the `LIMIT row_count OFFSET offset` syntax.

If `LIMIT` occurs within a subquery and also is applied in the outer query, the outermost `LIMIT` takes precedence. For example, the following statement produces two rows, not one:

```
(SELECT ... LIMIT 1) LIMIT 2;
```

- A `PROCEDURE` clause names a procedure that should process the data in the result set. For an example, see Section 8.4.2.4, “Using PROCEDURE ANALYSE”, which describes `ANALYSE`, a procedure that can be used to obtain suggestions for optimal column data types that may help reduce table sizes.
A **PROCEDURE** clause is not permitted in a **UNION** statement.

- The **SELECT ... INTO** form of **SELECT** enables the query result to be written to a file or stored in variables. For more information, see Section 13.2.8.1, "SELECT ... INTO Syntax".

- If you use **FOR UPDATE** with a storage engine that uses page or row locks, rows examined by the query are write-locked until the end of the current transaction. Using **LOCK IN SHARE MODE** sets a shared lock that permits other transactions to read the examined rows but not to update or delete them. See Section 14.6.4.5, "SELECT ... FOR UPDATE and SELECT ... LOCK IN SHARE MODE Locking Reads".

Following the **SELECT** keyword, you can use a number of options that affect the operation of the statement. **HIGH_PRIORITY**, **STRAIGHT_JOIN**, and options beginning with **SQL_** are MySQL extensions to standard SQL.

- The **ALL** and **DISTINCT** options specify whether duplicate rows should be returned. **ALL** (the default) specifies that all matching rows should be returned, including duplicates. **DISTINCT** specifies removal of duplicate rows from the result set. It is an error to specify both options. **DISTINCTROW** is a synonym for **DISTINCT**.

- **HIGH_PRIORITY** gives the **SELECT** higher priority than a statement that updates a table. You should use this only for queries that are very fast and must be done at once. A **SELECT** **HIGH_PRIORITY** query that is issued while the table is locked for reading runs even if there is an update statement waiting for the table to be free. This affects only storage engines that use only table-level locking (such as **MyISAM**, **MEMORY**, and **MERGE**). **HIGH_PRIORITY** cannot be used with **SELECT** statements that are part of a **UNION**.

- **STRAIGHT_JOIN** forces the optimizer to join the tables in the order in which they are listed in the **FROM** clause. You can use this to speed up a query if the optimizer joins the tables in nonoptimal order. **STRAIGHT_JOIN** also can be used in the **table_references** list. See Section 13.2.8.2, "JOIN Syntax".

  **STRAIGHT_JOIN** does not apply to any table that the optimizer treats as a **const** or **system** table. Such a table produces a single row, is read during the optimization phase of query execution, and references to its columns are replaced with the appropriate column values before query execution proceeds. These tables will appear first in the query plan displayed by **EXPLAIN**. See Section 8.8.1, "Optimizing Queries with EXPLAIN". This exception may not apply to **const** or **system** tables that are used on the **NULL**-complemented side of an outer join (that is, the right-side table of a **LEFT** **JOIN** or the left-side table of a **RIGHT** **JOIN**).

- **SQL_BIG_RESULT** or **SQL_SMALL_RESULT** can be used with **GROUP BY** or **DISTINCT** to tell the optimizer that the result set has many rows or is small, respectively. For **SQL_BIG_RESULT**, MySQL directly uses disk-based temporary tables if needed, and prefers sorting to using a temporary table with a key on the **GROUP BY** elements. For **SQL_SMALL_RESULT**, MySQL uses fast temporary tables to store the resulting table instead of using sorting. This should not normally be needed.

- **SQL_BUFFER_RESULT** forces the result to be put into a temporary table. This helps MySQL free the table locks early and helps in cases where it takes a long time to send the result set to the client. This option can be used only for top-level **SELECT** statements, not for subqueries or following **UNION**.

- **SQL_CALC_FOUND_ROWS** tells MySQL to calculate how many rows there would be in the result set, disregarding any **LIMIT** clause. The number of rows can then be retrieved with **SELECT FOUND_ROWS()**. See Section 12.14, "Information Functions".

- The **SQL_CACHE** and **SQL_NO_CACHE** options affect caching of query results in the query cache (see Section 8.10.3, "The MySQL Query Cache"). **SQL_CACHE** tells MySQL to store the result in the query cache if it is cacheable and the value of the **query_cache_type** system variable is **2** or **DEMAND**. With **SQL_NO_CACHE**, the server does not use the query cache. It neither checks the
query cache to see whether the result is already cached, nor does it cache the query result. (Due to a limitation in the parser, a space character must precede and follow the SQL_NO_CACHE keyword; a non-space such as a newline causes the server to check the query cache to see whether the result is already cached.)

For a query that uses UNION, subqueries, or views, the following rules apply:

- **SQL_NO_CACHE** applies if it appears in any SELECT in the query.
- For a cacheable query, **SQL_CACHE** applies if it appears in the first SELECT of the query, or in the first SELECT of a view referred to by the query.

A SELECT from a partitioned table using a storage engine such as MyISAM that employs table-level locks locks all partitions of the table. This does not occur with tables using storage engines such as InnoDB that employ row-level locking. This issue is resolved in MySQL 5.6. See Section 18.5.4, "Partitioning and Table-Level Locking", for more information.

### 13.2.8.1 SELECT ... INTO Syntax

The SELECT ... INTO form of SELECT enables a query result to be stored in variables or written to a file:

- **SELECT ... INTO var_list** selects column values and stores them into variables.
- **SELECT ... INTO OUTFILE** writes the selected rows to a file. Column and line terminators can be specified to produce a specific output format.
- **SELECT ... INTO DUMPFILE** writes a single row to a file without any formatting.

The SELECT syntax description (see Section 13.2.8, "SELECT Syntax") shows the INTO clause near the end of the statement. It is also possible to use INTO immediately following the select_expr list.

An INTO clause should not be used in a nested SELECT because such a SELECT must return its result to the outer context.

The INTO clause can name a list of one or more variables, which can be user-defined variables, stored procedure or function parameters, or stored program local variables. (Within a prepared SELECT ... INTO OUTFILE statement, only user-defined variables are permitted; see Section 13.6.4.2, "Local Variable Scope and Resolution").

The selected values are assigned to the variables. The number of variables must match the number of columns. The query should return a single row. If the query returns no rows, a warning with error code 1329 occurs (No data), and the variable values remain unchanged. If the query returns multiple rows, error 1172 occurs (Result consisted of more than one row). If it is possible that the statement may retrieve multiple rows, you can use LIMIT 1 to limit the result set to a single row.

```sql
SELECT id, data INTO @x, @y FROM test.t1 LIMIT 1;
```

User variable names are not case sensitive. See Section 9.4, “User-Defined Variables”.

The SELECT ... INTO OUTFILE 'file_name' form of SELECT writes the selected rows to a file. The file is created on the server host, so you must have the FILE privilege to use this syntax. *file_name* cannot be an existing file, which among other things prevents files such as /etc/passwd and database tables from being destroyed. As of MySQL 5.1.6, the character_set_filesystem system variable controls the interpretation of the file name.

The SELECT ... INTO OUTFILE statement is intended primarily to let you very quickly dump a table to a text file on the server machine. If you want to create the resulting file on some other host than the server host, you normally cannot use SELECT ... INTO OUTFILE since there is no way to write a path to the file relative to the server host's file system.
However, if the MySQL client software is installed on the remote machine, you can instead use a client command such as `mysql -e "SELECT ..." > file_name` to generate the file on the client host.

It is also possible to create the resulting file on a different host other than the server host, if the location of the file on the remote host can be accessed using a network-mapped path on the server’s file system. In this case, the presence of `mysql` (or some other MySQL client program) is not required on the target host.

`SELECT ... INTO OUTFILE` is the complement of `LOAD DATA INFILE`. Column values are written converted to the character set specified in the `CHARACTER SET` clause, which is available as of MySQL 5.1.38. Prior to 5.1.38 or if no such clause is present, values are dumped using the `binary` character set. In effect, there is no character set conversion. If a result set contains columns in several character sets, the output data file will as well and you may not be able to reload the file correctly.

The syntax for the `export_options` part of the statement consists of the same `FIELDS` and `LINES` clauses that are used with the `LOAD DATA INFILE` statement. See Section 13.2.6, “LOAD DATA INFILE Syntax”, for information about the `FIELDS` and `LINES` clauses, including their default values and permissible values.

`FIELDS ESCAPED BY` controls how to write special characters. If the `FIELDS ESCAPED BY` character is not empty, it is used when necessary to avoid ambiguity as a prefix that precedes following characters on output:

- The `FIELDS ESCAPED BY` character
- The `FIELDS [OPTIONALLY] ENCLOSED BY` character
- The first character of the `FIELDS TERMINATED BY` and `LINES TERMINATED BY` values
- ASCII `NUL` (the zero-valued byte; what is actually written following the escape character is ASCII “0”, not a zero-valued byte)

The `FIELDS TERMINATED BY, ENCLOSED BY, ESCAPED BY,` or `LINES TERMINATED BY` characters must be escaped so that you can read the file back in reliably. ASCII `NUL` is escaped to make it easier to view with some pagers.

The resulting file does not have to conform to SQL syntax, so nothing else need be escaped.

If the `FIELDS ESCAPED BY` character is empty, no characters are escaped and `NULL` is output as `NULL`, not `\N`. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

Here is an example that produces a file in the comma-separated values (CSV) format used by many programs:

```sql
SELECT a,b,a+b INTO OUTFILE '/tmp/result.txt'
  FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY ''
  LINES TERMINATED BY '
'
FROM test_table;
```

If you use `INTO DUMPFILE` instead of `INTO OUTFILE`, MySQL writes only one row into the file, without any column or line termination and without performing any escape processing. This is useful if you want to store a `BLOB` value in a file.

**Note**

Any file created by `INTO OUTFILE` or `INTO DUMPFILE` is writable by all users on the server host. The reason for this is that the MySQL server cannot create a file that is owned by anyone other than the user under whose account it is running. (You should *never run mysqld as root* for this and other reasons.) The file thus must be world-writable so that you can manipulate its contents.
If the `secure_file_priv` system variable is set to a nonempty directory name, the file to be written must be located in that directory.

In the context of `SELECT ... INTO` statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log. For additional information, see Section 19.4.5, “Event Scheduler Status”.

### 13.2.8.2 JOIN Syntax

MySQL supports the following `JOIN` syntaxes for the `table_references` part of `SELECT` statements and multiple-table `DELETE` and `UPDATE` statements:

```sql
table_references:
  escaped_table_reference [, escaped_table_reference] ...

escaped_table_reference:
  table_reference
   | { OJ table_reference }

table_reference:
  table_factor
   | join_table

table_factor:
  tbl_name [[AS] alias] [index_hint_list]
  | table_subquery [AS] alias
  | ( table_references )

join_table:
  table_reference [INNER | CROSS] JOIN table_factor [join_condition]
   | table_reference STRAIGHT_JOIN table_factor
   | table_reference STRAIGHT_JOIN table_factor ON conditional_expr
   | table_reference [LEFT|RIGHT | OUTER] JOIN table_reference join_condition
   | table_reference NATURAL [LEFT|RIGHT | OUTER] JOIN table_factor

join_condition:
  ON conditional_expr
   | USING (column_list)

index_hint_list:
  index_hint [, index_hint] ...

index_hint:
  USE {INDEX|KEY} [FOR {JOIN|ORDER BY|GROUP BY}] (index_list)
   | IGNORE {INDEX|KEY} [FOR {JOIN|ORDER BY|GROUP BY}] (index_list)
   | FORCE {INDEX|KEY} [FOR {JOIN|ORDER BY|GROUP BY}] (index_list)

index_list:
  index_name [, index_name] ...
```

A table reference is also known as a join expression.

The syntax of `table_factor` is extended in comparison with the SQL Standard. The latter accepts only `table_reference`, not a list of them inside a pair of parentheses.

This is a conservative extension if we consider each comma in a list of `table_reference` items as equivalent to an inner join. For example:

```sql
SELECT * FROM t1 LEFT JOIN (t2, t3, t4)
ON {t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c}
```

is equivalent to:
SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4) ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)

In MySQL, JOIN, CROSS JOIN, and INNER JOIN are syntactic equivalents (they can replace each other). In standard SQL, they are not equivalent. INNER JOIN is used with an ON clause, CROSS JOIN is used otherwise.

In general, parentheses can be ignored in join expressions containing only inner join operations. MySQL also supports nested joins (see Section 8.2.1.9, “Nested Join Optimization”).

Index hints can be specified to affect how the MySQL optimizer makes use of indexes. For more information, see Section 8.9.3, “Index Hints”.

The following list describes general factors to take into account when writing joins.

- A table reference can be aliased using `tbl_name AS alias_name` or `tbl_name alias_name`:

```
SELECT t1.name, t2.salary
FROM employee AS t1 INNER JOIN info AS t2 ON t1.name = t2.name;
```

```
SELECT t1.name, t2.salary
FROM employee t1 INNER JOIN info t2 ON t1.name = t2.name;
```

- A `table_subquery` is also known as a subquery in the FROM clause. Such subqueries must include an alias to give the subquery result a table name. A trivial example follows; see also Section 13.2.9.8, “Subqueries in the FROM Clause”:

```
SELECT * FROM (SELECT 1, 2, 3) AS t1;
```

- INNER JOIN and , (comma) are semantically equivalent in the absence of a join condition: both produce a Cartesian product between the specified tables (that is, each and every row in the first table is joined to each and every row in the second table).

However, the precedence of the comma operator is less than that of INNER JOIN, CROSS JOIN, LEFT JOIN, and so on. If you mix comma joins with the other join types when there is a join condition, an error of the form Unknown column 'col_name' in 'on clause' may occur. Information about dealing with this problem is given later in this section.

- The `conditional_expr` used with ON is any conditional expression of the form that can be used in a WHERE clause. Generally, you should use the ON clause for conditions that specify how to join tables, and the WHERE clause to restrict which rows you want in the result set.

- If there is no matching row for the right table in the ON or USING part in a LEFT JOIN, a row with all columns set to NULL is used for the right table. You can use this fact to find rows in a table that have no counterpart in another table:

```
SELECT left_tbl.*
FROM left_tbl LEFT JOIN right_tbl ON left_tbl.id = right_tbl.id
WHERE right_tbl.id IS NULL;
```

This example finds all rows in `left_tbl` with an id value that is not present in `right_tbl` (that is, all rows in `left_tbl` with no corresponding row in `right_tbl`). This assumes that `right_tbl.id` is declared NOT NULL. See Section 8.2.1.7, “LEFT JOIN and RIGHT JOIN Optimization”.

- The USING(`column_list`) clause names a list of columns that must exist in both tables. If tables `a` and `b` both contain columns `c1, c2,` and `c3`, the following join compares corresponding columns from the two tables:

```
a LEFT JOIN b USING (c1,c2,c3)
```
SELECT Syntax

• The **NATURAL [LEFT] JOIN** of two tables is defined to be semantically equivalent to an **INNER JOIN** or a **LEFT JOIN** with a **USING** clause that names all columns that exist in both tables.

• **RIGHT JOIN** works analogously to **LEFT JOIN**. To keep code portable across databases, it is recommended that you use **LEFT JOIN** instead of **RIGHT JOIN**.

• The **{ OJ ... }** syntax shown in the join syntax description exists only for compatibility with ODBC. The curly braces in the syntax should be written literally; they are not metasyntax as used elsewhere in syntax descriptions.

```sql
SELECT left_tbl.*
FROM { OJ left_tbl LEFT OUTER JOIN right_tbl ON left_tbl.id = right_tbl.id }
WHERE right_tbl.id IS NULL;
```

As of MySQL 5.1.24, you can use other types of joins within **{ OJ ... }**, such as **INNER JOIN** or **RIGHT OUTER JOIN**. This helps with compatibility with some third-party applications, but is not official ODBC syntax.

A consequence of this change is that the parser does not permit nested **{ OJ ... }** constructs (which are not legal ODBC syntax, anyway). Queries that use such constructs should be rewritten. For example, this query is now produces an error:

```sql
SELECT * FROM
{ OJ
{ OJ a LEFT OUTER JOIN b ON a.a1=b.a1
LEFT OUTER JOIN c ON b.b1 = c.b1};
}
```

That can be replaced by any of the following rewrites:

```sql
SELECT * FROM
{ OJ a LEFT OUTER JOIN b
LEFT OUTER JOIN c ON b.b1 = c.b1 ON a.a1=b.a1};
```

The first two are legal according to ODBC, and you nest the joins inside a single **{ OJ ... }** clause. The third is standard SQL syntax, without ODBC decoration. It can be used with parentheses to emphasize the evaluation order:

```sql
SELECT * FROM
((a LEFT OUTER JOIN b ON a.a1=b.a1)
LEFT OUTER JOIN c ON b.b1 = c.b1);
```

• **STRAIGHT_JOIN** is similar to **JOIN**, except that the left table is always read before the right table. This can be used for those (few) cases for which the join optimizer puts the tables in the wrong order.

Some join examples:

```sql
SELECT * FROM table1, table2;
SELECT * FROM table1 INNER JOIN table2 ON table1.id=table2.id;
SELECT * FROM table1 LEFT JOIN table2 ON table1.id=table2.id;
SELECT * FROM table1 LEFT JOIN table2 USING (id);
SELECT * FROM table1 LEFT JOIN table2 ON table1.id=table2.id
  LEFT JOIN table3 ON table2.id=table3.id;
```
Note

Natural joins and joins with **USING**, including outer join variants, are processed according to the SQL:2003 standard. The goal was to align the syntax and semantics of MySQL with respect to **NATURAL JOIN** and **JOIN ... USING** according to SQL:2003. However, these changes in join processing can result in different output columns for some joins. Also, some queries that appeared to work correctly in older versions (prior to 5.0.12) must be rewritten to comply with the standard.

These changes have five main aspects:

- The way that MySQL determines the result columns of **NATURAL** or **USING** join operations (and thus the result of the entire **FROM** clause).
- Expansion of **SELECT *** and **SELECT tbl_name.*** into a list of selected columns.
- Resolution of column names in **NATURAL** or **USING** joins.
- Transformation of **NATURAL** or **USING** joins into **JOIN ... ON**.
- Resolution of column names in the **ON** condition of a **JOIN ... ON**.

The following list provides more detail about several effects of current join processing versus join processing in older versions. The term “previously” means “prior to MySQL 5.0.12.”

- The columns of a **NATURAL** join or a **USING** join may be different from previously. Specifically, redundant output columns no longer appear, and the order of columns for **SELECT *** expansion may be different from before.

Consider this set of statements:

```
CREATE TABLE t1 (i INT, j INT);
CREATE TABLE t2 (k INT, j INT);
INSERT INTO t1 VALUES(1,1);
INSERT INTO t2 VALUES(1,1);
SELECT * FROM t1 NATURAL JOIN t2;
SELECT * FROM t1 JOIN t2 USING (j);
```

Previously, the statements produced this output:

```
+------+------+------+
| i    | j    | k    |
+------+------+------+
| 1    | 1    | 1    |
+------+------+------+
| i    | j    | k    |
+------+------+------+
| 1    | 1    | 1    |
```

In the first **SELECT** statement, column **j** appears in both tables and thus becomes a join column, so, according to standard SQL, it should appear only once in the output, not twice. Similarly, in the second **SELECT** statement, column **j** is named in the **USING** clause and should appear only once in the output, not twice. But in both cases, the redundant column is not eliminated. Also, the order of the columns is not correct according to standard SQL.

Now the statements produce this output:

```
+----+
| i  |
+----+
```

1287
The redundant column is eliminated and the column order is correct according to standard SQL:

- First, coalesced common columns of the two joined tables, in the order in which they occur in the first table
- Second, columns unique to the first table, in order in which they occur in that table
- Third, columns unique to the second table, in order in which they occur in that table

The single result column that replaces two common columns is defined using the `COALESCE` operation. That is, for two `t1.a` and `t2.a` the resulting single join column `a` is defined as 

\[
a = \text{COALESCE}(t1.a, t2.a),
\]

where:

\[
\text{COALESCE}(x, y) = (\text{CASE WHEN V1 IS NOT NULL THEN V1 ELSE V2 END})
\]

If the join operation is any other join, the result columns of the join consists of the concatenation of all columns of the joined tables. This is the same as previously.

A consequence of the definition of coalesced columns is that, for outer joins, the coalesced column contains the value of the non-`NULL` column if one of the two columns is always `NULL`. If neither or both columns are `NULL`, both common columns have the same value, so it doesn't matter which one is chosen as the value of the coalesced column. A simple way to interpret this is to consider that a coalesced column of an outer join is represented by the common column of the inner table of a `JOIN`. Suppose that the tables `t1(a,b)` and `t2(a,c)` have the following contents:

<table>
<thead>
<tr>
<th>t1</th>
<th>t2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>x</td>
</tr>
<tr>
<td>2</td>
<td>y</td>
</tr>
</tbody>
</table>

Then:

```
mysql> SELECT * FROM t1 NATURAL LEFT JOIN t2;
+---+---+---+
| a | b | c |
+---+---+---+
| 1 | x | NULL |
| 2 | y | z  |
+---+---+---+
```

Here column `a` contains the values of `t1.a`.

```
mysql> SELECT * FROM t1 NATURAL RIGHT JOIN t2;
+---+---+---+
| a | c | b |
+---+---+---+
| 2 | z | y |
| 3 | w | NULL |
+---+---+---+
```

Here column `a` contains the values of `t2.a`.
SELECT Syntax

Compare these results to the otherwise equivalent queries with JOIN ... ON:

```sql
mysql> SELECT * FROM t1 LEFT JOIN t2 ON (t1.a = t2.a);
+------+------+------+------+
<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>a</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>x</td>
<td>NULL</td>
<td>NULL</td>
</tr>
<tr>
<td>2</td>
<td>y</td>
<td>2</td>
<td>z</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
+------+------+------+------+
```

```sql
mysql> SELECT * FROM t1 RIGHT JOIN t2 ON (t1.a = t2.a);
+------+------+------+------+
<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>a</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>y</td>
<td>2</td>
<td>z</td>
</tr>
<tr>
<td>NULL</td>
<td>NULL</td>
<td>3</td>
<td>w</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
+------+------+------+------+
```

• Previously, a USING clause could be rewritten as an ON clause that compares corresponding columns. For example, the following two clauses were semantically identical:

```sql
a LEFT JOIN b USING (c1,c2,c3)
a LEFT JOIN b ON a.c1=b.c1 AND a.c2=b.c2 AND a.c3=b.c3
```

Now the two clauses no longer are quite the same:

• With respect to determining which rows satisfy the join condition, both joins remain semantically identical.

• With respect to determining which columns to display for SELECT * expansion, the two joins are not semantically identical. The USING join selects the coalesced value of corresponding columns, whereas the ON join selects all columns from all tables. For the preceding USING join, SELECT * selects these values:

```sql
COALESCE(a.c1,b.c1), COALESCE(a.c2,b.c2), COALESCE(a.c3,b.c3)
```

For the ON join, SELECT * selects these values:

```sql
a.c1, a.c2, a.c3, b.c1, b.c2, b.c3
```

With an inner join, COALESCE (a.c1, b.c1) is the same as either a.c1 or b.c1 because both columns will have the same value. With an outer join (such as LEFT JOIN), one of the two columns can be NULL. That column will be omitted from the result.

• The evaluation of multi-way natural joins differs in a very important way that affects the result of NATURAL or USING joins and that can require query rewriting. Suppose that you have three tables t1(a,b), t2(c,b), and t3(a,c) that each have one row: t1(1,2), t2(10,2), and t3(7,10). Suppose also that you have this NATURAL JOIN on the three tables:

```sql
SELECT ... FROM t1 NATURAL JOIN t2 NATURAL JOIN t3;
```

Previously, the left operand of the second join was considered to be t2, whereas it should be the nested join (t1 NATURAL JOIN t2). As a result, the columns of t3 are checked for common columns only in t2, and, if t3 has common columns with t1, these columns are not used as equi-join columns. Thus, previously, the preceding query was transformed to the following equi-join:

```sql
SELECT ... FROM t1, t2, t3
WHERE t1.b = t2.b AND t2.c = t3.c;
```
That join is missing one more equi-join predicate \((t1.a = t3.a)\). As a result, it produces one row, not the empty result that it should. The correct equivalent query is this:

```
SELECT ... FROM t1, t2, t3
  WHERE t1.b = t2.b AND t2.c = t3.c AND t1.a = t3.a;
```

If you require the same query result in current versions of MySQL as in older versions, rewrite the natural join as the first equi-join.

- Previously, the comma operator (,) and `JOIN` both had the same precedence, so the join expression `t1, t2 JOIN t3` was interpreted as `((t1, t2) JOIN t3)`. Now `JOIN` has higher precedence, so the expression is interpreted as `(t1, (t2 JOIN t3))`. This change affects statements that use an `ON` clause, because that clause can refer only to columns in the operands of the join, and the change in precedence changes interpretation of what those operands are.

Example:

```
CREATE TABLE t1 (i1 INT, j1 INT);
CREATE TABLE t2 (i2 INT, j2 INT);
CREATE TABLE t3 (i3 INT, j3 INT);
INSERT INTO t1 VALUES(1,1);
INSERT INTO t2 VALUES(1,1);
INSERT INTO t3 VALUES(1,1);
SELECT * FROM t1, t2 JOIN t3 ON (t1.i1 = t3.i3);
```

Previously, the `SELECT` was legal due to the implicit grouping of `t1,t2` as `(t1,t2)`. Now the `JOIN` takes precedence, so the operands for the `ON` clause are `t2` and `t3`. Because `t1.i1` is not a column in either of the operands, the result is an Unkown column 't1.i1' in 'on clause' error. To allow the join to be processed, group the first two tables explicitly with parentheses so that the operands for the `ON` clause are `(t1,t2)` and `t3`:

```
SELECT * FROM (t1, t2) JOIN t3 ON (t1.i1 = t3.i3);
```

Alternatively, avoid the use of the comma operator and use `JOIN` instead:

```
SELECT * FROM t1 JOIN t2 JOIN t3 ON (t1.i1 = t3.i3);
```

This change also applies to statements that mix the comma operator with `INNER JOIN`, `CROSS JOIN`, `LEFT JOIN`, and `RIGHT JOIN`, all of which now have higher precedence than the comma operator.

- Previously, the `ON` clause could refer to columns in tables named to its right. Now an `ON` clause can refer only to its operands.

Example:

```
CREATE TABLE t1 (i1 INT);
CREATE TABLE t2 (i2 INT);
CREATE TABLE t3 (i3 INT);
SELECT * FROM t1 JOIN t2 JOIN t3 ON (i1 = i3);
```

Previously, the `SELECT` statement was legal. Now the statement fails with an Unknown column 'i3' in 'on clause' error because `i3` is a column in `t3`, which is not an operand of the `ON` clause. The statement should be rewritten as follows:

```
SELECT * FROM t1 JOIN t2 JOIN t3 ON (i1 = i3);
```
• Resolution of column names in \texttt{NATURAL} or \texttt{USING} joins is different than previously. For column names that are outside the \texttt{FROM} clause, MySQL now handles a superset of the queries compared to previously. That is, in cases when MySQL formerly issued an error that some column is ambiguous, the query now is handled correctly. This is due to the fact that MySQL now treats the common columns of \texttt{NATURAL} or \texttt{USING} joins as a single column, so when a query refers to such columns, the query compiler does not consider them as ambiguous.

Example:

\begin{verbatim}
SELECT * FROM t1 NATURAL JOIN t2 WHERE b > 1;
\end{verbatim}

Previously, this query would produce an error \texttt{ERROR 1052 (23000): Column 'b' in where clause is ambiguous}. Now the query produces the correct result:

\begin{verbatim}
+------+------+------+
| b    | c    | y    |
+------+------+------+
| 4    | 2    | 3    |
+------+------+------+
\end{verbatim}

One extension of MySQL compared to the SQL:2003 standard is that MySQL enables you to qualify the common (coalesced) columns of \texttt{NATURAL} or \texttt{USING} joins (just as previously), while the standard disallows that.

### 13.2.8.3 UNION Syntax

\begin{verbatim}
SELECT ... UNION [ALL | DISTINCT] SELECT ... [UNION [ALL | DISTINCT] SELECT ...]
\end{verbatim}

\texttt{UNION} is used to combine the result from multiple \texttt{SELECT} statements into a single result set.

The column names from the first \texttt{SELECT} statement are used as the column names for the results returned. Selected columns listed in corresponding positions of each \texttt{SELECT} statement should have the same data type. (For example, the first column selected by the first statement should have the same type as the first column selected by the other statements.)

If the data types of corresponding \texttt{SELECT} columns do not match, the types and lengths of the columns in the \texttt{UNION} result take into account the values retrieved by all of the \texttt{SELECT} statements. For example, consider the following:

\begin{verbatim}
mysql> SELECT REPEAT('a',1) UNION SELECT REPEAT('b',10);
+---------------+
| REPEAT('a',1) |
+---------------+
| a             |
| bbbbbbbbbbbb |
+---------------+
\end{verbatim}

(In some earlier versions of MySQL, only the type and length from the first \texttt{SELECT} would have been used and the second row would have been truncated to a length of 1.)

The \texttt{SELECT} statements are normal select statements, but with the following restrictions:

• Only the last \texttt{SELECT} statement can use \texttt{INTO OUTFILE}. (However, the entire \texttt{UNION} result is written to the file.)

• \texttt{HIGH_PRIORITY} cannot be used with \texttt{SELECT} statements that are part of a \texttt{UNION}. If you specify it for the first \texttt{SELECT}, it has no effect. If you specify it for any subsequent \texttt{SELECT} statements, a syntax error results.
The default behavior for `UNION` is that duplicate rows are removed from the result. The optional `DISTINCT` keyword has no effect other than the default because it also specifies duplicate-row removal. With the optional `ALL` keyword, duplicate-row removal does not occur and the result includes all matching rows from all the `SELECT` statements.

You can mix `UNION ALL` and `UNION DISTINCT` in the same query. Mixed `UNION` types are treated such that a `DISTINCT` union overrides any `ALL` union to its left. A `DISTINCT` union can be produced explicitly by using `UNION DISTINCT` or implicitly by using `UNION` with no following `DISTINCT` or `ALL` keyword.

To apply `ORDER BY` or `LIMIT` to an individual `SELECT`, place the clause inside the parentheses that enclose the `SELECT`:

```sql
(SELECT a FROM t1 WHERE a=10 AND B=1 ORDER BY a LIMIT 10)
UNION
(SELECT a FROM t2 WHERE a=11 AND B=2 ORDER BY a LIMIT 10);
```

However, use of `ORDER BY` for individual `SELECT` statements implies nothing about the order in which the rows appear in the final result because `UNION` by default produces an unordered set of rows. Therefore, the use of `ORDER BY` in this context is typically in conjunction with `LIMIT`, so that it is used to determine the subset of the selected rows to retrieve for the `SELECT`, even though it does not necessarily affect the order of those rows in the final `UNION` result. If `ORDER BY` appears without `LIMIT` in a `SELECT`, it is optimized away because it will have no effect anyway.

To use an `ORDER BY` or `LIMIT` clause to sort or limit the entire `UNION` result, parenthesize the individual `SELECT` statements and place the `ORDER BY` or `LIMIT` after the last one. The following example uses both clauses:

```sql
(SELECT a FROM t1 WHERE a=10 AND B=1)
UNION
(SELECT a FROM t2 WHERE a=11 AND B=2)
ORDER BY a LIMIT 10;
```

A statement without parentheses is equivalent to one parenthesized as just shown.

This kind of `ORDER BY` cannot use column references that include a table name (that is, names in `tbl_name.col_name` format). Instead, provide a column alias in the first `SELECT` statement and refer to the alias in the `ORDER BY`. (Alternatively, refer to the column in the `ORDER BY` using its column position. However, use of column positions is deprecated.)

Also, if a column to be sorted is aliased, the `ORDER BY` clause must refer to the alias, not the column name. The first of the following statements will work, but the second will fail with an Unknown column 'a' in 'order clause' error:

```sql
(SELECT a AS b FROM t) UNION (SELECT ...) ORDER BY b;
(SELECT a AS b FROM t) UNION (SELECT ...) ORDER BY a;
```

To cause rows in a `UNION` result to consist of the sets of rows retrieved by each `SELECT` one after the other, select an additional column in each `SELECT` to use as a sort column and add an `ORDER BY` following the last `SELECT`:

```sql
(SELECT 1 AS sort_col, col1a, col1b, ... FROM t1)
UNION
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col;
```

To additionally maintain sort order within individual `SELECT` results, add a secondary column to the `ORDER BY` clause:

```sql
(SELECT 1 AS sort_col, col1a, col1b, ... FROM t1)
```
Use of an additional column also enables you to determine which \texttt{SELECT} each row comes from. Extra columns can provide other identifying information as well, such as a string that indicates a table name.

### 13.2.9 Subquery Syntax

A subquery is a \texttt{SELECT} statement within another statement.

All subquery forms and operations that the SQL standard requires are supported, as well as a few features that are MySQL-specific.

Here is an example of a subquery:

\begin{verbatim}
SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
\end{verbatim}

In this example, \texttt{SELECT * FROM t1 ...} is the \textit{outer query} (or \textit{outer statement}), and \texttt{(SELECT column1 FROM t2)} is the \textit{subquery}. We say that the subquery is \textit{nested} within the outer query, and in fact it is possible to nest subqueries within other subqueries, to a considerable depth. A subquery must always appear within parentheses.

The main advantages of subqueries are:

\begin{itemize}
\item They allow queries that are \textit{structured} so that it is possible to isolate each part of a statement.
\item They provide alternative ways to perform operations that would otherwise require complex joins and unions.
\item Many people find subqueries more readable than complex joins or unions. Indeed, it was the innovation of subqueries that gave people the original idea of calling the early SQL “Structured Query Language.”
\end{itemize}

Here is an example statement that shows the major points about subquery syntax as specified by the SQL standard and supported in MySQL:

\begin{verbatim}
DELETE FROM t1
WHERE s11 > ANY
(SELECT COUNT(*) /* no hint */ FROM t2
WHERE NOT EXISTS
(SELECT * FROM t3
WHERE ROW(5*t2.s1,77)=
(SELECT 50,11*s1 FROM t4 UNION SELECT 50,77 FROM
(SELECT * FROM t5) AS t5));
\end{verbatim}

A subquery can return a scalar (a single value), a single row, a single column, or a table (one or more rows of one or more columns). These are called scalar, column, row, and table subqueries. Subqueries that return a particular kind of result often can be used only in certain contexts, as described in the following sections.

There are few restrictions on the type of statements in which subqueries can be used. A subquery can contain many of the keywords or clauses that an ordinary \texttt{SELECT} can contain: \texttt{DISTINCT}, \texttt{GROUP BY}, \texttt{ORDER BY}, \texttt{LIMIT}, joins, index hints, \texttt{UNION} constructs, comments, functions, and so on.

A subquery's outer statement can be any one of: \texttt{SELECT}, \texttt{INSERT}, \texttt{UPDATE}, \texttt{DELETE}, \texttt{SET}, or \texttt{DO}.

In MySQL, you cannot modify a table and select from the same table in a subquery. This applies to statements such as \texttt{DELETE}, \texttt{INSERT}, \texttt{REPLACE}, \texttt{UPDATE}, and (because subqueries can be used in the \texttt{SET} clause) \texttt{LOAD DATA INFILE}.

For information about how the optimizer handles subqueries, see Section 8.2.1.14, “Optimizing Subqueries with EXISTS Strategy”. For a discussion of restrictions on subquery use, including
performance issues for certain forms of subquery syntax, see Section C.3, “Restrictions on Subqueries”.

### 13.2.9.1 The Subquery as Scalar Operand

In its simplest form, a subquery is a scalar subquery that returns a single value. A scalar subquery is a simple operand, and you can use it almost anywhere a single column value or literal is legal, and you can expect it to have those characteristics that all operands have: a data type, a length, an indication that it can be NULL, and so on. For example:

```
CREATE TABLE t1 (s1 INT, s2 CHAR(5) NOT NULL);
INSERT INTO t1 VALUES(100, 'abcde');
SELECT (SELECT s2 FROM t1);
```

The subquery in this `SELECT` returns a single value (`'abcde'`) that has a data type of `CHAR`, a length of 5, a character set and collation equal to the defaults in effect at `CREATE TABLE` time, and an indication that the value in the column can be `NULL`. Nullability of the value selected by a scalar subquery is not copied because if the subquery result is empty, the result is `NULL`. For the subquery just shown, if `t1` were empty, the result would be `NULL` even though `s2` is `NOT NULL`.

There are a few contexts in which a scalar subquery cannot be used. If a statement permits only a literal value, you cannot use a subquery. For example, `LIMIT` requires literal integer arguments, and `LOAD DATA INFILE` requires a literal string file name. You cannot use subqueries to supply these values.

When you see examples in the following sections that contain the rather spartan construct `(SELECT column1 FROM t1)`, imagine that your own code contains much more diverse and complex constructions.

Suppose that we make two tables:

```
CREATE TABLE t1 (s1 INT);
INSERT INTO t1 VALUES (1);
CREATE TABLE t2 (s1 INT);
INSERT INTO t2 VALUES (2);
```

Then perform a `SELECT`:

```
SELECT (SELECT s1 FROM t2) FROM t1;
```

The result is `2` because there is a row in `t2` containing a column `s1` that has a value of `2`.

A scalar subquery can be part of an expression, but remember the parentheses, even if the subquery is an operand that provides an argument for a function. For example:

```
SELECT UPPER((SELECT s1 FROM t1)) FROM t2;
```

### 13.2.9.2 Comparisons Using Subqueries

The most common use of a subquery is in the form:

```
non_subquery_operand comparison_operator (subquery)
```

Where `comparison_operator` is one of these operators:

- `=`  `>`  `>=`  `<=`  `<`  `<>`  `!=`  `<=>`

For example:
Subquery Syntax

MySQL also permits this construct:

```sql
non_subquery_operand LIKE {subquery}
```

At one time the only legal place for a subquery was on the right side of a comparison, and you might still find some old DBMSs that insist on this.

Here is an example of a common-form subquery comparison that you cannot do with a join. It finds all the rows in table `t1` for which the `column1` value is equal to a maximum value in table `t2`:

```sql
SELECT * FROM t1
WHERE column1 = (SELECT MAX(column2) FROM t2);
```

Here is another example, which again is impossible with a join because it involves aggregating for one of the tables. It finds all rows in table `t1` containing a value that occurs twice in a given column:

```sql
SELECT * FROM t1 AS t
WHERE 2 = (SELECT COUNT(*) FROM t1 WHERE t1.id = t.id);
```

For a comparison of the subquery to a scalar, the subquery must return a scalar. For a comparison of the subquery to a row constructor, the subquery must be a row subquery that returns a row with the same number of values as the row constructor. See Section 13.2.9.5, "Row Subqueries".

### 13.2.9.3 Subqueries with ANY, IN, or SOME

**Syntax:**

```sql
operand comparison_operator ANY (subquery)
operand IN (subquery)
operand comparison_operator SOME (subquery)
```

Where `comparison_operator` is one of these operators:

```
=  >  >=  <=  <>  !=
```

The `ANY` keyword, which must follow a comparison operator, means “return `TRUE` if the comparison is `TRUE` for `ANY` of the values in the column that the subquery returns.” For example:

```sql
SELECT s1 FROM t1 WHERE s1 > ANY (SELECT s1 FROM t2);
```

Suppose that there is a row in table `t1` containing `(10)`. The expression is `TRUE` if table `t2` contains `(21,14,7)` because there is a value `7` in `t2` that is less than `10`. The expression is `FALSE` if table `t2` contains `(20,10)`, or if table `t2` is empty. The expression is `unknown` (that is, `NULL`) if table `t2` contains `(NULL,NULL,NULL)`.

When used with a subquery, the word `IN` is an alias for `= ANY`. Thus, these two statements are the same:

```sql
SELECT s1 FROM t1 WHERE s1 = ANY (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 IN (SELECT s1 FROM t2);
```

**IN** and **ANY** are not synonyms when used with an expression list. **IN** can take an expression list, but **= ANY** cannot. See Section 12.3.2, "Comparison Functions and Operators".

**NOT IN** is not an alias for `< ANY`, but for `< ALL`. See Section 13.2.9.4, "Subqueries with ALL".
The word **SOME** is an alias for **ANY**. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 <> ANY (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 <> SOME (SELECT s1 FROM t2);
```

Use of the word **SOME** is rare, but this example shows why it might be useful. To most people, the English phrase “a is not equal to any b” means “there is no b which is equal to a,” but that is not what is meant by the SQL syntax. The syntax means “there is some b to which a is not equal.” Using `<>` **SOME** instead helps ensure that everyone understands the true meaning of the query.

### 13.2.9.4 Subqueries with ALL

**Syntax:**

```
operand comparison_operator ALL (subquery)
```

The word **ALL**, which must follow a comparison operator, means “return TRUE if the comparison is TRUE for ALL of the values in the column that the subquery returns.” For example:

```
SELECT s1 FROM t1 WHERE s1 > ALL (SELECT s1 FROM t2);
```

Suppose that there is a row in table **t1** containing **(10)**. The expression is **TRUE** if table **t2** contains **(-5, 0, +5)** because **10** is greater than all three values in **t2**. The expression is **FALSE** if table **t2** contains **(12, 6, NULL, -100)** because there is a single value **12** in table **t2** that is greater than **10**. The expression is **unknown** (that is, **NULL**) if table **t2** contains **(0, NULL, 1)**.

Finally, the expression is **TRUE** if table **t2** is empty. So, the following expression is **TRUE** when table **t2** is empty:

```
SELECT * FROM t1 WHERE 1 > ALL (SELECT s1 FROM t2);
```

But this expression is **NULL** when table **t2** is empty:

```
SELECT * FROM t1 WHERE 1 > (SELECT s1 FROM t2);
```

In addition, the following expression is **NULL** when table **t2** is empty:

```
SELECT * FROM t1 WHERE 1 > ALL (SELECT MAX(s1) FROM t2);
```

In general, **tables containing NULL values and empty tables** are “edge cases.” When writing subqueries, always consider whether you have taken those two possibilities into account.

**NOT IN** is an alias for `<>` **ALL**. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 <> ALL (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 NOT IN (SELECT s1 FROM t2);
```

### 13.2.9.5 Row Subqueries

Scalar or column subqueries return a single value or a column of values. A **row subquery** is a subquery variant that returns a single row and can thus return more than one column value. Legal operators for row subquery comparisons are:

```
=  >  <  >=  <=  <>  !=  <=>
```

Here are two examples:
**Subquery Syntax**

For both queries, if the table \textit{t2} contains a single row with \textit{id} = 10, the subquery returns a single row. If this row has \textit{col3} and \textit{col4} values equal to the \textit{col1} and \textit{col2} values of any rows in \textit{t1}, the \textit{WHERE} expression is \textit{TRUE} and each query returns those \textit{t1} rows. If the \textit{t2} row \textit{col3} and \textit{col4} values are not equal the \textit{col1} and \textit{col2} values of any \textit{t1} row, the expression is \textit{FALSE} and the query returns an empty result set. The expression is \textit{unknown} (that is, \textit{NULL}) if the subquery produces no rows. An error occurs if the subquery produces multiple rows because a row subquery can return at most one row.

For information about how each operator works for row comparisons, see Section 12.3.2, “Comparison Functions and Operators”.

The expressions \( (1,2) \) and \textit{ROW}(\(1,2\)) are sometimes called \textit{row constructors}. The two are equivalent. The row constructor and the row returned by the subquery must contain the same number of values.

A row constructor is used for comparisons with subqueries that return two or more columns. When a subquery returns a single column, this is regarded as a scalar value and not as a row, so a row constructor cannot be used with a subquery that does not return at least two columns. Thus, the following query fails with a syntax error:

```sql
SELECT * FROM t1 WHERE \textit{ROW}(1) = (SELECT \textit{column1} FROM t2)
```

Row constructors are legal in other contexts. For example, the following two statements are semantically equivalent:

```sql
SELECT * FROM t1 WHERE (\textit{column1},\textit{column2}) = (1,1);
SELECT * FROM t1 WHERE \textit{column1} = 1 AND \textit{column2} = 1;
```

Prior to MySQL 5.1.12, only the second of the preceding two expressions could be optimized.

The following query answers the request, “find all rows in table \textit{t1} that also exist in table \textit{t2}”:

```sql
SELECT \textit{column1},\textit{column2},\textit{column3}
FROM t1
WHERE (\textit{column1},\textit{column2},\textit{column3}) IN
  (SELECT \textit{column1},\textit{column2},\textit{column3} FROM t2);
```

For more information about the optimizer and row constructors, see Section 8.2.1.16, “Row Constructor Expression Optimization”

### 13.2.9.6 Subqueries with EXISTS or NOT EXISTS

If a subquery returns any rows at all, \textit{EXISTS subquery} is \textit{TRUE}, and \textit{NOT EXISTS subquery} is \textit{FALSE}. For example:

```sql
SELECT \textit{column1} FROM t1 WHERE \textit{EXISTS} (SELECT * FROM t2);
```

Traditionally, an \textit{EXISTS} subquery starts with \texttt{SELECT *}, but it could begin with \texttt{SELECT 5} or \texttt{SELECT \textit{column1}} or anything at all. MySQL ignores the \texttt{SELECT} list in such a subquery, so it makes no difference.

For the preceding example, if \textit{t2} contains any rows, even rows with nothing but \texttt{NULL} values, the \textit{EXISTS} condition is \textit{TRUE}. This is actually an unlikely example because a \texttt{[NOT] EXISTS} subquery almost always contains correlations. Here are some more realistic examples:
Subquery Syntax

- What kind of store is present in one or more cities?

```sql
SELECT DISTINCT store_type FROM stores
WHERE EXISTS (SELECT * FROM cities_stores
WHERE cities_stores.store_type = stores.store_type);
```

- What kind of store is present in no cities?

```sql
SELECT DISTINCT store_type FROM stores
WHERE NOT EXISTS (SELECT * FROM cities_stores
WHERE cities_stores.store_type = stores.store_type);
```

- What kind of store is present in all cities?

```sql
SELECT DISTINCT store_type FROM stores s1
WHERE NOT EXISTS (
    SELECT * FROM cities WHERE NOT EXISTS (
        SELECT * FROM cities_stores
        WHERE cities_stores.city = cities.city
        AND cities_stores.store_type = stores.store_type)
);
```

The last example is a double-nested `NOT EXISTS` query. That is, it has a `NOT EXISTS` clause within a `NOT EXISTS` clause. Formally, it answers the question “does a city exist with a store that is not in `Stores`”? But it is easier to say that a nested `NOT EXISTS` answers the question “is $x$ TRUE for all $y$?”

13.2.9.7 Correlated Subqueries

A **correlated subquery** is a subquery that contains a reference to a table that also appears in the outer query. For example:

```sql
SELECT * FROM t1
WHERE column1 = ANY (SELECT column1 FROM t2
WHERE t2.column2 = t1.column2);
```

Notice that the subquery contains a reference to a column of `t1`, even though the subquery’s `FROM` clause does not mention a table `t1`. So, MySQL looks outside the subquery, and finds `t1` in the outer query.

Suppose that table `t1` contains a row where `column1 = 5` and `column2 = 6`; meanwhile, table `t2` contains a row where `column1 = 5` and `column2 = 7`. The simple expression ... WHERE `column1 = ANY (SELECT column1 FROM t2)` would be TRUE, but in this example, the `WHERE` clause within the subquery is FALSE (because $(5,6)$ is not equal to $(5,7)$), so the expression as a whole is FALSE.

**Scoping rule:** MySQL evaluates from inside to outside. For example:

```sql
SELECT column1 FROM t1 AS x
WHERE x.column1 = (SELECT column1 FROM t2 AS x
    WHERE x.column1 = (SELECT column1 FROM t3
        WHERE x.column2 = t3.column1));
```

In this statement, `x.column2` must be a column in table `t2` because `SELECT column1 FROM t2 AS x ...` renames `t2`. It is not a column in table `t1` because `SELECT column1 FROM t1 ...` is an outer query that is farther out.

For subqueries in **HAVING** or **ORDER BY** clauses, MySQL also looks for column names in the outer select list.

For certain cases, a correlated subquery is optimized. For example:
Subquery Syntax

val IN (SELECT key_val FROM tbl_name WHERE correlated_condition)

Otherwise, they are inefficient and likely to be slow. Rewriting the query as a join might improve performance.

Aggregate functions in correlated subqueries may contain outer references, provided the function contains nothing but outer references, and provided the function is not contained in another function or expression.

13.2.9.8 Subqueries in the FROM Clause

Subqueries are legal in a SELECT statement's FROM clause. The actual syntax is:

```
SELECT ... FROM (subquery) [AS] name ...
```

The [AS] name clause is mandatory, because every table in a FROM clause must have a name. Any columns in the subquery select list must have unique names.

For the sake of illustration, assume that you have this table:

```
CREATE TABLE t1 (s1 INT, s2 CHAR(5), s3 FLOAT);
```

Here is how to use a subquery in the FROM clause, using the example table:

```
INSERT INTO t1 VALUES (1,'1',1.0);
INSERT INTO t1 VALUES (2,'2',2.0);
SELECT sb1,sb2,sb3
FROM (SELECT s1 AS sb1, s2 AS sb2, s3*2 AS sb3 FROM t1) AS sb
WHERE sb1 > 1;
```

Result: 2, '2', 4.0.

Here is another example: Suppose that you want to know the average of a set of sums for a grouped table. This does not work:

```
SELECT AVG(SUM(column1)) FROM t1 GROUP BY column1;
```

However, this query provides the desired information:

```
SELECT AVG(sum_column1)
FROM (SELECT SUM(column1) AS sum_column1
     FROM t1 GROUP BY column1) AS t1;
```

Notice that the column name used within the subquery (sum_column1) is recognized in the outer query.

Subqueries in the FROM clause can return a scalar, column, row, or table. Subqueries in the FROM clause cannot be correlated subqueries, unless used within the ON clause of a JOIN operation.

Subqueries in the FROM clause are executed even for the EXPLAIN statement (that is, derived temporary tables are materialized). This occurs because upper-level queries need information about all tables during the optimization phase, and the table represented by a subquery in the FROM clause is unavailable unless the subquery is executed.

It is possible under certain circumstances to modify table data using EXPLAIN SELECT. This can occur if the outer query accesses any tables and an inner query invokes a stored function that changes one or more rows of a table. Suppose that there are two tables t1 and t2 in database d1, created as shown here:

```
CREATE TABLE t1 (s1 INT, s2 CHAR(5), s3 FLOAT);
```

```
CREATE TABLE t2 (s1 INT, s2 CHAR(5), s3 FLOAT);
```
Now we create a stored function `f1` which modifies `t2`:

```sql
mysql> DELIMITER //
mysql> CREATE FUNCTION f1(p1 INT) RETURNS INT
    -> BEGIN
    ->     INSERT INTO t2 VALUES (p1);
    ->     RETURN p1;
    -> END //
Query OK, 0 rows affected (0.01 sec)
mysql> DELIMITER ;
```

Referencing the function directly in an `EXPLAIN SELECT` does not have any effect on `t2`, as shown here:

```sql
mysql> SELECT * FROM t2;
Empty set (0.00 sec)
mysql> EXPLAIN SELECT f1(5);
+----+-------------+-------+------+---------------+------+---------+------+------+----------------+
<table>
<thead>
<tr>
<th>id</th>
<th>select_type</th>
<th>table</th>
<th>type</th>
<th>possible_keys</th>
<th>key</th>
<th>key_len</th>
<th>ref</th>
<th>rows</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>SIMPLE</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>No tables used</td>
</tr>
</tbody>
</table>
+----+-------------+-------+------+---------------+------+---------+------+------+----------------+
1 row in set (0.00 sec)
mysql> SELECT * FROM t2;
Empty set (0.00 sec)
```

This is because the `SELECT` statement did not reference any tables, as can be seen in the `table` and `Extra` columns of the output. This is also true of the following nested `SELECT`:

```sql
mysql> EXPLAIN SELECT NOW() AS a1, (SELECT f1(5)) AS a2;
+----+-------------+-------+------+---------------+------+---------+------+------+----------------+
<table>
<thead>
<tr>
<th>id</th>
<th>select_type</th>
<th>table</th>
<th>type</th>
<th>possible_keys</th>
<th>key</th>
<th>key_len</th>
<th>ref</th>
<th>rows</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>PRIMARY</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>No tables used</td>
</tr>
</tbody>
</table>
+----+-------------+-------+------+---------------+------+---------+------+------+----------------+
1 row in set, 1 warning (0.00 sec)
mysql> SHOW WARNINGS;
+-------+------+------------------------------------------+
<table>
<thead>
<tr>
<th>Level</th>
<th>Code</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>Note</td>
<td>1249</td>
<td>Select 2 was reduced during optimization</td>
</tr>
</tbody>
</table>
+-------+------|------------------------------------------+
1 row in set (0.00 sec)
mysql> SELECT * FROM t2;
Empty set (0.00 sec)
```

However, if the outer `SELECT` references any tables, the optimizer executes the statement in the subquery as well:
Subquery Syntax

```sql
mysql> EXPLAIN SELECT * FROM t1 AS a1, (SELECT f1(5)) AS a2;
+----+-------------+------------+--------+---------------+------+---------+------+------+---------------------+
<table>
<thead>
<tr>
<th>id</th>
<th>select_type</th>
<th>table</th>
<th>type</th>
<th>possible_keys</th>
<th>key</th>
<th>key_len</th>
<th>ref</th>
<th>rows</th>
<th>Extra</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>PRIMARY</td>
<td>a1</td>
<td>system</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>0</td>
<td>const row not found</td>
</tr>
<tr>
<td>1</td>
<td>PRIMARY</td>
<td>&lt;derived2&gt;</td>
<td>system</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>DERIVED</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>NULL</td>
<td>No tables used</td>
</tr>
</tbody>
</table>
+----+-------------+------------+--------+---------------+------|---------|------|------|---------------------+
3 rows in set (0.00 sec)
```

This also means that an `EXPLAIN SELECT` statement such as the one shown here may take a long time to execute because the `BENCHMARK()` function is executed once for each row in `t1`:

```sql
EXPLAIN SELECT * FROM t1 AS a1, (SELECT BENCHMARK(1000000, MD5(NOW())));
```

### 13.2.9.9 Subquery Errors

There are some errors that apply only to subqueries. This section describes them.

- Unsupported subquery syntax:
  ```sql
  ERROR 1235 (ER_NOT_SUPPORTED_YET)
  SQLSTATE = 42000
  Message = "This version of MySQL doesn't yet support 'LIMIT & IN/ALL/ANY/SOME subquery'"
  ``
  This means that MySQL does not support statements of the following form:
  ```sql
  SELECT * FROM t1 WHERE s1 IN (SELECT s2 FROM t2 ORDER BY s1 LIMIT 1)
  ```

- Incorrect number of columns from subquery:
  ```sql
  ERROR 1241 (ER_OPERAND_COL)
  SQLSTATE = 21000
  Message = "Operand should contain 1 column(s)"
  ```
  This error occurs in cases like this:
  ```sql
  SELECT (SELECT column1, column2 FROM t2) FROM t1;
  ```

  You may use a subquery that returns multiple columns, if the purpose is row comparison. In other contexts, the subquery must be a scalar operand. See Section 13.2.9.5, “Row Subqueries”.

- Incorrect number of rows from subquery:
  ```sql
  ERROR 1242 (ER_SUBSELECT_NO_1_ROW)
  SQLSTATE = 21000
  Message = "Subquery returns more than 1 row"
  ```
  This error occurs for statements where the subquery must return at most one row but returns multiple rows. Consider the following example:
  ```sql
  SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
  ```
If `SELECT column1 FROM t2` returns just one row, the previous query will work. If the subquery returns more than one row, error 1242 will occur. In that case, the query should be rewritten as:

```
SELECT * FROM t1 WHERE column1 = ANY (SELECT column1 FROM t2);
```

- Incorrectly used table in subquery:

```
Error 1093 (ER_UPDATE_TABLE_USED)
SQLSTATE = HY000
Message = "You can't specify target table 'x' for update in FROM clause"
```

This error occurs in cases such as the following, which attempts to modify a table and select from the same table in the subquery:

```
UPDATE t1 SET column2 = (SELECT MAX(column1) FROM t1);
```

You can use a subquery for assignment within an `UPDATE` statement because subqueries are legal in `UPDATE` and `DELETE` statements as well as in `SELECT` statements. However, you cannot use the same table (in this case, table `t1`) for both the subquery `FROM` clause and the update target.

For nontransactional storage engines, data modifications made before the error was encountered are preserved.

### 13.2.9.10 Optimizing Subqueries

Development is ongoing, so no optimization tip is reliable for the long term. The following list provides some interesting tricks that you might want to play with:

- Use subquery clauses that affect the number or order of the rows in the subquery. For example:

```
SELECT * FROM t1 WHERE t1.column1 IN (SELECT column1 FROM t2 ORDER BY column1);
SELECT * FROM t1 WHERE t1.column1 IN (SELECT DISTINCT column1 FROM t2);
SELECT * FROM t1 WHERE EXISTS (SELECT * FROM t2 LIMIT 1);
```

- Replace a join with a subquery. For example, try this:

```
SELECT DISTINCT column1 FROM t1 WHERE t1.column1 IN (SELECT column1 FROM t2);
```

Instead of this:

```
SELECT DISTINCT t1.column1 FROM t1, t2 WHERE t1.column1 = t2.column1;
```

- Some subqueries can be transformed to joins for compatibility with older versions of MySQL that do not support subqueries. However, in some cases, converting a subquery to a join may improve performance. See Section 13.2.9.11, “Rewriting Subqueries as Joins”.

- Move clauses from outside to inside the subquery. For example, use this query:

```
SELECT * FROM t1 WHERE s1 IN (SELECT s1 FROM t1 UNION ALL SELECT s1 FROM t2);
```

Instead of this query:
Subquery Syntax

```sql
SELECT * FROM t1
  WHERE s1 IN (SELECT s1 FROM t1) OR s1 IN (SELECT s1 FROM t2);
```

For another example, use this query:

```sql
SELECT (SELECT column1 + 5 FROM t1) FROM t2;
```

Instead of this query:

```sql
SELECT (SELECT column1 FROM t1) + 5 FROM t2;
```

- Use a row subquery instead of a correlated subquery. For example, use this query:

```sql
SELECT * FROM t1
  WHERE (column1,column2) IN (SELECT column1,column2 FROM t2);
```

Instead of this query:

```sql
SELECT * FROM t1
  WHERE EXISTS (SELECT * FROM t2 WHERE t2.column1=t1.column1
    AND t2.column2=t1.column2);
```

- Use \( \text{NOT} \ (a = \text{ANY} (...) \) \) rather than \( a <> \text{ALL} (...) \).

- Use \( x = \text{ANY} \ \text{(table containing \((1,2)\))} \) rather than \( x=1 \ \text{OR} \ x=2. \)

- Use \( \text{ANY} \) rather than \( \text{EXISTS} \).

- For uncorrelated subqueries that always return one row, \( \text{IN} \) is always slower than \( = \). For example, use this query:

```sql
SELECT * FROM t1
  WHERE t1.col_name = (SELECT a FROM t2 WHERE b = some_const);
```

Instead of this query:

```sql
SELECT * FROM t1
  WHERE t1.col_name IN (SELECT a FROM t2 WHERE b = some_const);
```

These tricks might cause programs to go faster or slower. Using MySQL facilities like the `BENCHMARK()` function, you can get an idea about what helps in your own situation. See Section 12.14, “Information Functions”.

Some optimizations that MySQL itself makes are:

- MySQL executes uncorrelated subqueries only once. Use `EXPLAIN` to make sure that a given subquery really is uncorrelated.

- MySQL rewrites \( \text{IN}, \text{ALL}, \text{ANY}, \) and \( \text{SOME} \) subqueries in an attempt to take advantage of the possibility that the select-list columns in the subquery are indexed.

- MySQL replaces subqueries of the following form with an index-lookup function, which `EXPLAIN` describes as a special join type \( \text{(unique_subquery or index_subquery)} \):

  ```sql
  ... \text{IN} (SELECT indexed_column FROM single_table ...)
  ```

- MySQL enhances expressions of the following form with an expression involving `MIN()` or `MAX()`, unless \( \text{NULL} \) values or empty sets are involved:
For example, this **WHERE** clause:

```
WHERE 5 > ALL (SELECT x FROM t)
```

might be treated by the optimizer like this:

```
WHERE 5 > (SELECT MAX(x) FROM t)
```

See also *MySQL Internals: How MySQL Transforms Subqueries*.

### 13.2.9.11 Rewriting Subqueries as Joins

Sometimes there are other ways to test membership in a set of values than by using a subquery. Also, on some occasions, it is not only possible to rewrite a query without a subquery, but it can be more efficient to make use of some of these techniques rather than to use subqueries. One of these is the **IN()** construct:

For example, this query:

```
SELECT * FROM t1 WHERE id IN (SELECT id FROM t2);
```

Can be rewritten as:

```
SELECT DISTINCT t1.* FROM t1, t2 WHERE t1.id=t2.id;
```

The queries:

```
SELECT * FROM t1 WHERE id NOT IN (SELECT id FROM t2);
SELECT * FROM t1 WHERE NOT EXISTS (SELECT id FROM t2 WHERE t1.id=t2.id);
```

Can be rewritten as:

```
SELECT table1.*
    FROM table1 LEFT JOIN table2 ON table1.id=table2.id
    WHERE table2.id IS NULL;
```

A **LEFT [OUTER] JOIN** can be faster than an equivalent subquery because the server might be able to optimize it better—a fact that is not specific to MySQL Server alone. Prior to SQL-92, outer joins did not exist, so subqueries were the only way to do certain things. Today, MySQL Server and many other modern database systems offer a wide range of outer join types.

MySQL Server supports multiple-table **DELETE** statements that can be used to efficiently delete rows based on information from one table or even from many tables at the same time. Multiple-table **UPDATE** statements are also supported. See Section 13.2.2, “DELETE Syntax”, and Section 13.2.10, “UPDATE Syntax”.

### 13.2.10 UPDATE Syntax

**Single-table syntax:**

```
UPDATE [LOW_PRIORITY] [IGNORE]  
        table_reference  
        SET col_name1=[expr1][DEFAULT] [, col_name2=[expr2][DEFAULT]] ...  
        [WHERE where_condition]  
        [ORDER BY ...]  
        [LIMIT row_count]
```
UPDATE Syntax

Multiple-table syntax:

```
UPDATE [LOW_PRIORITY] [IGNORE] table_references
    SET col_name1={expr1|DEFAULT} [, col_name2={expr2|DEFAULT}] ...
    [WHERE where_condition]
```

For the single-table syntax, the UPDATE statement updates columns of existing rows in the named table with new values. The SET clause indicates which columns to modify and the values they should be given. Each value can be given as an expression, or the keyword DEFAULT to set a column explicitly to its default value. The WHERE clause, if given, specifies the conditions that identify which rows to update. With no WHERE clause, all rows are updated. If the ORDER BY clause is specified, the rows are updated in the order that is specified. The LIMIT clause places a limit on the number of rows that can be updated.

For the multiple-table syntax, UPDATE updates rows in each table named in table_references that satisfy the conditions. Each matching row is updated once, even if it matches the conditions multiple times. For multiple-table syntax, ORDER BY and LIMIT cannot be used.

where_condition is an expression that evaluates to true for each row to be updated. For expression syntax, see Section 9.5, "Expression Syntax".

table_references and where_condition are specified as described in Section 13.2.8, "SELECT Syntax".

You need the UPDATE privilege only for columns referenced in an UPDATE that are actually updated. You need only the SELECT privilege for any columns that are read but not modified.

The UPDATE statement supports the following modifiers:

- With the LOW_PRIORITY keyword, execution of the UPDATE is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as MyISAM, MEMORY, and MERGE).
- With the IGNORE keyword, the update statement does not abort even if errors occur during the update. Rows for which duplicate-key conflicts occur on a unique key value are not updated. Rows updated to values that would cause data conversion errors are updated to the closest valid values instead.

If you access a column from the table to be updated in an expression, UPDATE uses the current value of the column. For example, the following statement sets col1 to one more than its current value:

```
UPDATE t1 SET col1 = col1 + 1;
```

The second assignment in the following statement sets col2 to the current (updated) col1 value, not the original col1 value. The result is that col1 and col2 have the same value. This behavior differs from standard SQL.

```
UPDATE t1 SET col1 = col1 + 1, col2 = col1;
```

Single-table UPDATE assignments are generally evaluated from left to right. For multiple-table updates, there is no guarantee that assignments are carried out in any particular order.

If you set a column to the value it currently has, MySQL notices this and does not update it.

If you update a column that has been declared NOT NULL by setting to NULL, an error occurs if strict SQL mode is enabled; otherwise, the column is set to the implicit default value for the column data type and the warning count is incremented. The implicit default value is 0 for numeric types, the empty string (""") for string types, and the "zero" value for date and time types. See Section 11.6, "Data Type Default Values".
**UPDATE** returns the number of rows that were actually changed. The `mysql_info()` C API function returns the number of rows that were matched and updated and the number of warnings that occurred during the **UPDATE**.

You can use **LIMIT row_count** to restrict the scope of the **UPDATE**. A **LIMIT** clause is a row-matched restriction. The statement stops as soon as it has found `row_count` rows that satisfy the **WHERE** clause, whether or not they actually were changed.

If an **UPDATE** statement includes an **ORDER BY** clause, the rows are updated in the order specified by the clause. This can be useful in certain situations that might otherwise result in an error. Suppose that a table `t` contains a column `id` that has a unique index. The following statement could fail with a duplicate-key error, depending on the order in which rows are updated:

```
UPDATE t SET id = id + 1;
```

For example, if the table contains 1 and 2 in the `id` column and 1 is updated to 2 before 2 is updated to 3, an error occurs. To avoid this problem, add an **ORDER BY** clause to cause the rows with larger `id` values to be updated before those with smaller values:

```
UPDATE t SET id = id + 1 ORDER BY id DESC;
```

You can also perform **UPDATE** operations covering multiple tables. However, you cannot use **ORDER BY** or **LIMIT** with a multiple-table **UPDATE**. The **table_references** clause lists the tables involved in the join. Its syntax is described in Section 13.2.8.2, “JOIN Syntax”. Here is an example:

```
UPDATE items, month SET items.price = month.price
WHERE items.id = month.id;
```

The preceding example shows an inner join that uses the comma operator, but multiple-table **UPDATE** statements can use any type of join permitted in **SELECT** statements, such as **LEFT JOIN**.

If you use a multiple-table **UPDATE** statement involving InnoDB tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, update a single table and rely on the **ON UPDATE** capabilities that InnoDB provides to cause the other tables to be modified accordingly. See Section 14.6.6.6, “InnoDB and FOREIGN KEY Constraints”.

You cannot update a table and select from the same table in a subquery.

Index hints (see Section 8.9.3, “Index Hints”) are accepted but ignored for **UPDATE** statements.

An **UPDATE** on a partitioned table using a storage engine such as MyISAM that employs table-level locks locks all partitions of the table. This does not occur with tables using storage engines such as InnoDB that employ row-level locking. This issue is resolved in MySQL 5.6. See Section 18.5.4, “Partitioning and Table-Level Locking”, for more information.

### 13.3 MySQL Transactional and Locking Statements

MySQL supports local transactions (within a given client session) through statements such as **SET autocommit**, **START TRANSACTION**, **COMMIT**, and **ROLLBACK**. See Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”. XA transaction support enables MySQL to participate in distributed transactions as well. See Section 13.3.7, “XA Transactions”.

#### 13.3.1 START TRANSACTION, COMMIT, and ROLLBACK Syntax

```
START TRANSACTION [WITH CONSISTENT SNAPSHOT]
BEGIN [WORK]
```
### COMMIT [WORK] [AND [NO] CHAIN] [([NO] RELEASE]
### ROLLBACK [WORK] [AND [NO] CHAIN] [([NO] RELEASE]
### SET autocommit = {0 | 1}

These statements provide control over use of transactions:

- **START TRANSACTION** or **BEGIN** start a new transaction.
- **COMMIT** commits the current transaction, making its changes permanent.
- **ROLLBACK** rolls back the current transaction, canceling its changes.
- **SET autocommit** disables or enables the default autocommit mode for the current session.

By default, MySQL runs with **autocommit** mode enabled. This means that as soon as you execute a statement that updates (modifies) a table, MySQL stores the update on disk to make it permanent. The change cannot be rolled back.

To disable autocommit mode implicitly for a single series of statements, use the **START TRANSACTION** statement:

```sql
START TRANSACTION;
SELECT @A:=SUM(salary) FROM table1 WHERE type=1;
UPDATE table2 SET summary=@A WHERE type=1;
COMMIT;
```

With **START TRANSACTION**, autocommit remains disabled until you end the transaction with **COMMIT** or **ROLLBACK**. The autocommit mode then reverts to its previous state.

You can also begin a transaction like this:

```sql
START TRANSACTION WITH CONSISTENT SNAPSHOT;
```

The **WITH CONSISTENT SNAPSHOT** option starts a consistent read for storage engines that are capable of it. This applies only to InnoDB. The effect is the same as issuing a **START TRANSACTION** followed by a **SELECT** from any InnoDB table. See Section 14.6.4.4, “Consistent Nonlocking Reads”. The **WITH CONSISTENT SNAPSHOT** option does not change the current transaction isolation level, so it provides a consistent snapshot only if the current isolation level is one that permits a consistent read. The only isolation level that permits a consistent read is **REPEATABLE READ**. For all other isolation levels, the **WITH CONSISTENT SNAPSHOT** clause is ignored.

### Important

Many APIs used for writing MySQL client applications (such as JDBC) provide their own methods for starting transactions that can (and sometimes should) be used instead of sending a **START TRANSACTION** statement from the client. See Chapter 21, Connectors and APIs, or the documentation for your API, for more information.

To disable autocommit mode explicitly, use the following statement:

```sql
SET autocommit=0;
```

After disabling autocommit mode by setting the **autocommit** variable to zero, changes to transaction-safe tables (such as those for InnoDB or NDBCLUSTER) are not made permanent immediately. You must use **COMMIT** to store your changes to disk or **ROLLBACK** to ignore the changes.

**autocommit** is a session variable and must be set for each session. To disable autocommit mode for each new connection, see the description of the **autocommit** system variable at Section 5.1.4, “Server System Variables”.

---

1307
START TRANSACTION, COMMIT, and ROLLBACK Syntax

BEGIN and BEGIN WORK are supported as aliases of START TRANSACTION for initiating a transaction. START TRANSACTION is standard SQL syntax and is the recommended way to start an ad-hoc transaction.

The BEGIN statement differs from the use of the BEGIN keyword that starts a BEGIN ... END compound statement. The latter does not begin a transaction. See Section 13.6.1, “BEGIN ... END Compound-Statement Syntax”.

Note

Within all stored programs (stored procedures and functions, triggers, and events), the parser treats BEGIN [WORK] as the beginning of a BEGIN ... END block. Begin a transaction in this context with START TRANSACTION instead.

The optional WORK keyword is supported for COMMIT and ROLLBACK, as are the CHAIN and RELEASE clauses. CHAIN and RELEASE can be used for additional control over transaction completion. The value of the completion_type system variable determines the default completion behavior. See Section 5.1.4, “Server System Variables”.

The AND CHAIN clause causes a new transaction to begin as soon as the current one ends, and the new transaction has the same isolation level as the just-terminated transaction. The RELEASE clause causes the server to disconnect the current client session after terminating the current transaction. Including the NO keyword suppresses CHAIN or RELEASE completion, which can be useful if the completion_type system variable is set to cause chaining or release completion by default.

Beginning a transaction causes any pending transaction to be committed. See Section 13.3.3, “Statements That Cause an Implicit Commit”, for more information.

Beginning a transaction also causes table locks acquired with LOCK TABLES to be released, as though you had executed UNLOCK TABLES. Beginning a transaction does not release a global read lock acquired with FLUSH TABLES WITH READ LOCK.

For best results, transactions should be performed using only tables managed by a single transaction-safe storage engine. Otherwise, the following problems can occur:

• If you use tables from more than one transaction-safe storage engine (such as InnoDB), and the transaction isolation level is not SERIALIZABLE, it is possible that when one transaction commits, another ongoing transaction that uses the same tables will see only some of the changes made by the first transaction. That is, the atomicity of transactions is not guaranteed with mixed engines and inconsistencies can result. (If mixed-engine transactions are infrequent, you can use SET TRANSACTION ISOLATION LEVEL to set the isolation level to SERIALIZABLE on a per-transaction basis as necessary.)

• If you use tables that are not transaction-safe within a transaction, changes to those tables are stored at once, regardless of the status of autocommit mode.

• If you issue a ROLLBACK statement after updating a nontransactional table within a transaction, an ER_WARNING_NOT_COMPLETE_ROLLBACK warning occurs. Changes to transaction-safe tables are rolled back, but not changes to nontransactional tables.

Each transaction is stored in the binary log in one chunk, upon COMMIT. Transactions that are rolled back are not logged. (Exception: Modifications to nontransactional tables cannot be rolled back. If a transaction that is rolled back includes modifications to nontransactional tables, the entire transaction is logged with a ROLLBACK statement at the end to ensure that modifications to the nontransactional tables are replicated.) See Section 5.4.4, “The Binary Log”.

You can change the isolation level for transactions with the SET TRANSACTION statement. See Section 13.3.6, “SET TRANSACTION Syntax”. 
Rolling back can be a slow operation that may occur implicitly without the user having explicitly asked for it (for example, when an error occurs). Because of this, `SHOW PROCESSLIST` displays `Rolling back` in the `State` column for the session, not only for explicit rollbacks performed with the `ROLLBACK` statement but also for implicit rollbacks.

**Note**

Beginning with MySQL 5.1.36, `BEGIN`, `COMMIT`, and `ROLLBACK` are no longer affected by `--replicate-do-db` or `--replicate-ignore-db` rules. (Bug #43263)

### 13.3.2 Statements That Cannot BeRolled Back

Some statements cannot be rolled back. In general, these include data definition language (DDL) statements, such as those that create or drop databases, those that create, drop, or alter tables or stored routines.

You should design your transactions not to include such statements. If you issue a statement early in a transaction that cannot be rolled back, and then another statement later fails, the full effect of the transaction cannot be rolled back in such cases by issuing a `ROLLBACK` statement.

### 13.3.3 Statements That Cause an Implicit Commit

The statements listed in this section (and any synonyms for them) implicitly end any transaction active in the current session, as if you had done a `COMMIT` before executing the statement.

- **Data definition language (DDL) statements that define or modify database objects.** `ALTER DATABASE ... UPGRADE DATA DIRECTORY NAME`, `ALTER EVENT`, `ALTER PROCEDURE`, `ALTER SERVER`, `ALTER TABLE`, `CREATE DATABASE`, `CREATE EVENT`, `CREATE INDEX`, `CREATE PROCEDURE`, `CREATE SERVER`, `CREATE TABLE`, `DROP DATABASE`, `DROP EVENT`, `DROP INDEX`, `DROP PROCEDURE`, `DROP SERVER`, `DROP TABLE`, `RENAME TABLE`, `TRUNCATE TABLE`.

  `ALTER FUNCTION`, `CREATE FUNCTION` and `DROP FUNCTION` also cause an implicit commit when used with stored functions, but not with user-defined functions. (`ALTER FUNCTION` can only be used with stored functions.)

  `CREATE TABLE` and `DROP TABLE` statements do not commit a transaction if the `TEMPORARY` keyword is used. (This does not apply to other operations on temporary tables such as `ALTER TABLE` and `CREATE INDEX`, which do cause a commit.) However, although no implicit commit occurs, neither can the statement be rolled back, which means that the use of such statements causes transactional atomicity to be violated. For example, if you use `CREATE TEMPORARY TABLE` and then roll back the transaction, the table remains in existence.

  The `CREATE TABLE` statement in InnoDB is processed as a single transaction. This means that a `ROLLBACK` from the user does not undo `CREATE TABLE` statements the user made during that transaction.

  Beginning with MySQL 5.1.3, `ALTER VIEW`, `CREATE TRIGGER`, `CREATE VIEW`, `DROP TRIGGER`, and `DROP VIEW` cause an implicit commit.

  Beginning with MySQL 5.1.15, `CREATE TABLE ... SELECT` causes an implicit commit before and after the statement is executed when you are creating nontemporary tables. (No commit occurs for `CREATE TEMPORARY TABLE ... SELECT`.) This is to prevent an issue during replication where the table could be created on the master after a rollback, but fail to be recorded in the binary log, and therefore not replicated to the slave. For more information, see Bug #22865.

- **Statements that implicitly use or modify tables in the `mysql` database.** Beginning with MySQL 5.1.3, `CREATE USER`, `DROP USER`, and `RENAME USER` cause an implicit commit. Beginning with MySQL 5.1.23, `GRANT`, `REVOKE`, and `SET PASSWORD` statements cause an implicit commit.
• **Transaction-control and locking statements.** *BEGIN, LOCK TABLES, SET autocommit = 1* (if the value is not already 1), *START TRANSACTION, UNLOCK TABLES.*

  UNLOCK TABLES commits a transaction only if any tables currently have been locked with LOCK TABLES. This does not occur for UNLOCK TABLES following `FLUSH TABLES WITH READ LOCK` because the latter statement does not acquire table-level locks.

  Transactions cannot be nested. This is a consequence of the implicit commit performed for any current transaction when you issue a `START TRANSACTION` statement or one of its synonyms.

  Statements that cause an implicit commit cannot be used in an XA transaction while the transaction is in an **ACTIVE** state.

  The `BEGIN` statement differs from the use of the `BEGIN` keyword that starts a `BEGIN ... END` compound statement. The latter does not cause an implicit commit. See Section 13.6.1, “BEGIN ... END Compound-Statement Syntax”.

• **Data loading statements.** *LOAD DATA INFILE*. Before MySQL 5.1.12, `LOAD DATA INFILE` caused an implicit commit for all storage engines. As of MySQL 5.1.12, it causes an implicit commit only for tables using the **NDB** storage engine. For more information, see Bug #11151.

• **Administrative statements.** *CACHE INDEX, LOAD INDEX INTO CACHE*. Beginning with MySQL 5.1.10, `ANALYZE TABLE, CHECK TABLE, OPTIMIZE TABLE, and REPAIR TABLE` cause an implicit commit.

### 13.3.4 SAVEPOINT, ROLLBACK TO SAVEPOINT, and RELEASE SAVEPOINT Syntax

**SAVEPOINT** *identifier*

**ROLLBACK** [NO] [WORK] TO [SAVEPOINT] *identifier*

**RELEASE SAVEPOINT** *identifier*

InnoDB supports the SQL statements `SAVEPOINT, ROLLBACK TO SAVEPOINT, RELEASE SAVEPOINT` and the optional `NO WORK` keyword for **ROLLBACK**.

The **SAVEPOINT** statement sets a named transaction savepoint with a name of *identifier*. If the current transaction has a savepoint with the same name, the old savepoint is deleted and a new one is set.

The **ROLLBACK TO SAVEPOINT** statement rolls back a transaction to the named savepoint without terminating the transaction. Modifications that the current transaction made to rows after the savepoint was set are undone in the rollback, but InnoDB does not release the row locks that were stored in memory after the savepoint. (For a new inserted row, the lock information is carried by the transaction ID stored in the row; the lock is not separately stored in memory. In this case, the row lock is released in the undo.) Savepoints that were set at a later time than the named savepoint are deleted.

If the **ROLLBACK TO SAVEPOINT** statement returns the following error, it means that no savepoint with the specified name exists:

**ERROR 1305 (42000): SAVEPOINT identifier does not exist**

The **RELEASE SAVEPOINT** statement removes the named savepoint from the set of savepoints of the current transaction. No commit or rollback occurs. It is an error if the savepoint does not exist.

All savepoints of the current transaction are deleted if you execute a **COMMIT**, or a **ROLLBACK** that does not name a savepoint.

A new savepoint level is created when a stored function is invoked or a trigger is activated. The savepoints on previous levels become unavailable and thus do not conflict with savepoints on the new
level. When the function or trigger terminates, any savepoints it created are released and the previous
savepoint level is restored.

### 13.3.5 LOCK TABLES and UNLOCK TABLES Syntax

**LOCK TABLES**

```sql
lock_type: READ [LOCAL] | [LOW_PRIORITY] WRITE
```

**UNLOCK TABLES**

MySQL enables client sessions to acquire table locks explicitly for the purpose of cooperating with
other sessions for access to tables, or to prevent other sessions from modifying tables during periods
when a session requires exclusive access to them. A session can acquire or release locks only for
itself. One session cannot acquire locks for another session or release locks held by another session.

Locks may be used to emulate transactions or to get more speed when updating tables. This is
explained in more detail later in this section.

**LOCK TABLES** explicitly acquires table locks for the current client session. Table locks can be acquired
for base tables or views. You must have the **LOCK TABLES** privilege, and the **SELECT** privilege for
each object to be locked.

For view locking, **LOCK TABLES** adds all base tables used in the view to the set of tables to be locked
and locks them automatically. If you lock a table explicitly with **LOCK TABLES**, any tables used in
triggers are also locked implicitly, as described in Section 13.3.5.2, “LOCK TABLES and Triggers”.

**UNLOCK TABLES** explicitly releases any table locks held by the current session. **LOCK TABLES**
implicitly releases any table locks held by the current session before acquiring new locks.

Another use for **UNLOCK TABLES** is to release the global read lock acquired with the **FLUSH
TABLES WITH READ LOCK** statement, which enables you to lock all tables in all databases. See
Section 13.7.6.3, “FLUSH Syntax”. (This is a very convenient way to get backups if you have a file
system such as Veritas that can take snapshots in time.)

A table lock protects only against inappropriate reads or writes by other sessions. The session
holding the lock, even a read lock, can perform table-level operations such as **DROP TABLE**. Truncate
operations are not transaction-safe, so an error occurs if the session attempts one during an active
transaction or while holding a table lock.

The following discussion applies only to non-**TEMPORARY** tables. **LOCK TABLES** is permitted (but
ignored) for a **TEMPORARY** table. The table can be accessed freely by the session within which it was
created, regardless of what other locking may be in effect. No lock is necessary because no other
session can see the table.

For information about other conditions on the use of **LOCK TABLES** and statements that cannot
be used while **LOCK TABLES** is in effect, see Section 13.3.5.3, “Table-Locking Restrictions and
Conditions”

**Rules for Lock Acquisition**

To acquire table locks within the current session, use the **LOCK TABLES** statement. The following lock
types are available:

**READ [LOCAL] lock:**

- The session that holds the lock can read the table (but not write it).
LOCK TABLES and UNLOCK TABLES Syntax

- Multiple sessions can acquire a `READ` lock for the table at the same time.
- Other sessions can read the table without explicitly acquiring a `READ` lock.
- The `LOCAL` modifier enables nonconflicting `INSERT` statements (concurrent inserts) by other sessions to execute while the lock is held. (See Section 8.11.3, "Concurrent Inserts"). However, `READ LOCAL` cannot be used if you are going to manipulate the database using processes external to the server while you hold the lock. For InnoDB tables, `READ LOCAL` is the same as `READ`.

`[LOW_PRIORITY] WRITE` lock:
- The session that holds the lock can read and write the table.
- Only the session that holds the lock can access the table. No other session can access it until the lock is released.
- Lock requests for the table by other sessions block while the `WRITE` lock is held.
- The `LOW_PRIORITY` modifier affects lock scheduling if the `WRITE` lock request must wait, as described later.

If the `LOCK TABLES` statement must wait due to locks held by other sessions on any of the tables, it blocks until all locks can be acquired.

A session that requires locks must acquire all the locks that it needs in a single `LOCK TABLES` statement. While the locks thus obtained are held, the session can access only the locked tables. For example, in the following sequence of statements, an error occurs for the attempt to access `t2` because it was not locked in the `LOCK TABLES` statement:

```sql
mysql> LOCK TABLES t1 READ;
mysql> SELECT COUNT(*) FROM t1;
+----------+
| COUNT(*) |
+----------+
|        3 |
mysql> SELECT COUNT(*) FROM t2;
ERROR 1100 (HY000): Table 't2' was not locked with LOCK TABLES
```

Tables in the `INFORMATION_SCHEMA` database are an exception. They can be accessed without being locked explicitly even while a session holds table locks obtained with `LOCK TABLES`.

You cannot refer to a locked table multiple times in a single query using the same name. Use aliases instead, and obtain a separate lock for the table and each alias:

```sql
mysql> LOCK TABLE t WRITE, t AS t1 READ;
mysql> SELECT * FROM t AS t1;
ERROR 1100 (HY000): Table 't' was not locked with LOCK TABLES
mysql> INSERT INTO t SELECT * FROM t AS t1;
```

The error occurs for the first `INSERT` because there are two references to the same name for a locked table. The second `INSERT` succeeds because the references to the table use different names.

If your statements refer to a table by means of an alias, you must lock the table using that same alias. It does not work to lock the table without specifying the alias:

```sql
mysql> LOCK TABLE t READ;
mysql> SELECT * FROM t AS myalias;
ERROR 1100: Table 'myalias' was not locked with LOCK TABLES
```

Conversely, if you lock a table using an alias, you must refer to it in your statements using that alias:
**LOCK TABLES and UNLOCK TABLES Syntax**

```sql
mysql> LOCK TABLE t AS myalias READ;
mysql> SELECT * FROM t;
ERROR 1100: Table 't' was not locked with LOCK TABLES
mysql> SELECT * FROM t AS myalias;
```

**WRITE** locks normally have higher priority than **READ** locks to ensure that updates are processed as soon as possible. This means that if one session obtains a **READ** lock and then another session requests a **WRITE** lock, subsequent **READ** lock requests wait until the session that requested the **WRITE** lock has obtained the lock and released it. A request for a **LOW_PRIORITY WRITE** lock, by contrast, permits subsequent **READ** lock requests by other sessions to be satisfied first if they occur while the **LOW_PRIORITY WRITE** request is waiting. You should use **LOW_PRIORITY WRITE** locks only if you are sure that eventually there will be a time when no sessions have a **READ** lock. For **InnoDB** tables in transactional mode (autocommit = 0), a waiting **LOW_PRIORITY WRITE** lock acts like a regular **WRITE** lock and causes subsequent **READ** lock requests to wait.

**LOCK TABLES** acquires locks as follows:

1. Sort all tables to be locked in an internally defined order. From the user standpoint, this order is undefined.
2. If a table is to be locked with a read and a write lock, put the write lock request before the read lock request.
3. Lock one table at a time until the session gets all locks.

This policy ensures that table locking is deadlock free. There are, however, other things you need to be aware of about this policy: If you are using a **LOW_PRIORITY WRITE** lock for a table, it means only that MySQL waits for this particular lock until there are no other sessions that want a **READ** lock. When the session has gotten the **WRITE** lock and is waiting to get the lock for the next table in the lock table list, all other sessions wait for the **WRITE** lock to be released. If this becomes a serious problem with your application, you should consider converting some of your tables to transaction-safe tables.

**Note**

**LOCK TABLES** or **UNLOCK TABLES**, when applied to a partitioned table, always locks or unlocks the entire table. See Section 18.5.4, “Partitioning and Table-Level Locking”.

**Rules for Lock Release**

When the table locks held by a session are released, they are all released at the same time. A session can release its locks explicitly, or locks may be released implicitly under certain conditions.

- A session can release its locks explicitly with **UNLOCK TABLES**.
- If a session issues a **LOCK TABLES** statement to acquire a lock while already holding locks, its existing locks are released implicitly before the new locks are granted.
- If a session begins a transaction (for example, with **START TRANSACTION**), an implicit **UNLOCK TABLES** is performed, which causes existing locks to be released. (For additional information about the interaction between table locking and transactions, see Section 13.3.5.1, “Interaction of Table Locking and Transactions”.)

If the connection for a client session terminates, whether normally or abnormally, the server implicitly releases all table locks held by the session (transactional and nontransactional). If the client reconnects, the locks will no longer be in effect. In addition, if the client had an active transaction, the server rolls back the transaction upon disconnect, and if reconnect occurs, the new session begins with autocommit enabled. For this reason, clients may wish to disable auto-reconnect. With auto-reconnect in effect, the client is not notified if reconnect occurs but any table locks or current transaction will have been lost. With auto-reconnect disabled, if the connection drops, an error occurs for the next statement
issued. The client can detect the error and take appropriate action such as reacquiring the locks or redoing the transaction. See Section 21.8.15, “Controlling Automatic Reconnection Behavior”.

Note

If you use ALTER TABLE on a locked table, it may become unlocked. For example, if you attempt a second ALTER TABLE operation, the result may be an error Table 'tbi_name' was not locked with LOCK TABLES. To handle this, lock the table again prior to the second alteration. See also Section B.5.6.1, “Problems with ALTER TABLE”.

13.3.5 Interaction of Table Locking and Transactions

LOCK TABLES and UNLOCK TABLES interact with the use of transactions as follows:

• LOCK TABLES is not transaction-safe and implicitly commits any active transaction before attempting to lock the tables.

• UNLOCK TABLES implicitly commits any active transaction, but only if LOCK TABLES has been used to acquire table locks. For example, in the following set of statements, UNLOCK TABLES releases the global read lock but does not commit the transaction because no table locks are in effect:

```
FLUSH TABLES WITH READ LOCK;
START TRANSACTION;
SELECT ... ;
UNLOCK TABLES;
```

• Beginning a transaction (for example, with START TRANSACTION) implicitly commits any current transaction and releases existing table locks.

• FLUSH TABLES WITH READ LOCK acquires a global read lock and not table locks, so it is not subject to the same behavior as LOCK TABLES and UNLOCK TABLES with respect to table locking and implicit commits. For example, START TRANSACTION does not release the global read lock. See Section 13.7.6.3, “FLUSH Syntax”.

• Other statements that implicitly cause transactions to be committed do not release existing table locks. For a list of such statements, see Section 13.3.3, “Statements That Cause an Implicit Commit”.

• The correct way to use LOCK TABLES and UNLOCK TABLES with transactional tables, such as InnoDB tables, is to begin a transaction with SET autocommit = 0 (not START TRANSACTION) followed by LOCK TABLES, and to not call UNLOCK TABLES until you commit the transaction explicitly. For example, if you need to write to table t1 and read from table t2, you can do this:

```
SET autocommit=0;
LOCK TABLES t1 WRITE, t2 READ, ...;
... do something with tables t1 and t2 here ...
COMMIT;
UNLOCK TABLES;
```

When you call LOCK TABLES, InnoDB internally takes its own table lock, and MySQL takes its own table lock. InnoDB releases its internal table lock at the next commit, but for MySQL to release its table lock, you have to call UNLOCK TABLES. You should not have autocommit = 1, because then InnoDB releases its internal table lock immediately after the call of LOCK TABLES, and deadlocks can very easily happen. InnoDB does not acquire the internal table lock at all if autocommit = 1, to help old applications avoid unnecessary deadlocks.

• ROLLBACK does not release table locks.

13.3.5.2 LOCK TABLES and Triggers

If you lock a table explicitly with LOCK TABLES, any tables used in triggers are also locked implicitly:
• The locks are taken as the same time as those acquired explicitly with the `LOCK TABLES` statement.

• The lock on a table used in a trigger depends on whether the table is used only for reading. If so, a read lock suffices. Otherwise, a write lock is used.

• If a table is locked explicitly for reading with `LOCK TABLES`, but needs to be locked for writing because it might be modified within a trigger, a write lock is taken rather than a read lock. (That is, an implicit write lock needed due to the table’s appearance within a trigger causes an explicit read lock request for the table to be converted to a write lock request.)

Suppose that you lock two tables, `t1` and `t2`, using this statement:

```sql
LOCK TABLES t1 WRITE, t2 READ;
```

If `t1` or `t2` have any triggers, tables used within the triggers will also be locked. Suppose that `t1` has a trigger defined like this:

```sql
CREATE TRIGGER t1_a_ins AFTER INSERT ON t1 FOR EACH ROW
BEGIN
  UPDATE t4 SET count = count+1
  WHERE id = NEW.id AND EXISTS (SELECT a FROM t3);
  INSERT INTO t2 VALUES(1, 2);
END;
```

The result of the `LOCK TABLES` statement is that `t1` and `t2` are locked because they appear in the statement, and `t3` and `t4` are locked because they are used within the trigger:

• `t1` is locked for writing per the `WRITE` lock request.

• `t2` is locked for writing, even though the request is for a `READ` lock. This occurs because `t2` is inserted into within the trigger, so the `READ` request is converted to a `WRITE` request.

• `t3` is locked for reading because it is only read from within the trigger.

• `t4` is locked for writing because it might be updated within the trigger.

### 13.3.5.3 Table-Locking Restrictions and Conditions

You can safely use `KILL` to terminate a session that is waiting for a table lock. See Section 13.7.6.4, “KILL Syntax”.

You should not lock any tables that you are using with `INSERT DELAYED`. An `INSERT DELAYED` in this case results in an error because the insert must be handled by a separate thread, not by the session which holds the lock.

`LOCK TABLES` and `UNLOCK TABLES` cannot be used within stored programs.

For some operations, system tables in the `mysql` database must be accessed. For example, the `HELP` statement requires the contents of the server-side help tables, and `CONVERT_TZ()` might need to read the time zone tables. Before MySQL 5.1.17, to perform such operations while a `LOCK TABLES` statement is in effect, you must also lock the requisite system tables explicitly or a lock error occurs. As of 5.1.17, the server implicitly locks the system tables for reading as necessary so that you need not lock them explicitly. These tables are treated as just described:

```
mysql.help_category
mysql.help_keyword
mysql.help_relation
mysql.help_topic
mysql.proc
mysql.time_zone
```
If you want to explicitly place a WRITE lock on any of those tables with a LOCK TABLES statement, the table must be the only one locked; no other table can be locked with the same statement.

Normally, you do not need to lock tables, because all single UPDATE statements are atomic; no other session can interfere with any other currently executing SQL statement. However, there are a few cases when locking tables may provide an advantage:

- If you are going to run many operations on a set of MyISAM tables, it is much faster to lock the tables you are going to use. Locking MyISAM tables speeds up inserting, updating, or deleting on them because MySQL does not flush the key cache for the locked tables until UNLOCK TABLES is called. Normally, the key cache is flushed after each SQL statement.

  The downside to locking the tables is that no session can update a READ-locked table (including the one holding the lock) and no session can access a WRITE-locked table other than the one holding the lock.

- If you are using tables for a nontransactional storage engine, you must use LOCK TABLES if you want to ensure that no other session modifies the tables between a SELECT and an UPDATE. The example shown here requires LOCK TABLES to execute safely:

```
LOCK TABLES trans READ, customer WRITE;
SELECT SUM(value) FROM trans WHERE customer_id=some_id;
UPDATE customer
  SET total_value=sum_from_previous_statement
  WHERE customer_id=some_id;
UNLOCK TABLES;
```

Without LOCK TABLES, it is possible that another session might insert a new row in the trans table between execution of the SELECT and UPDATE statements.

You can avoid using LOCK TABLES in many cases by using relative updates (UPDATE customer SET value=value+new_value) or the LAST_INSERT_ID() function. See Section 1.8.2.3, “Transactions and Atomic Operations”.

You can also avoid locking tables in some cases by using the user-level advisory lock functions GET_LOCK() and RELEASE_LOCK(). These locks are saved in a hash table in the server and implemented with pthread_mutex_lock() and pthread_mutex_unlock() for high speed. See Section 12.16, “Miscellaneous Functions”.

See Section 8.11.1, “Internal Locking Methods”, for more information on locking policy.

### 13.3.6 SET TRANSACTION Syntax

```
SET [GLOBAL | SESSION] TRANSACTION ISOLATION LEVEL {
  REPEATABLE READ
  | READ COMMITTED
  | READ UNCOMMITTED
  | SERIALIZABLE
}
```

This statement sets the transaction isolation level, used for operations on InnoDB tables.

### Scope of the Isolation Level

You can set the isolation level globally, for the current session, or for the next transaction:
SET TRANSACTION Syntax

- With the `GLOBAL` keyword, the statement sets the default transaction level globally for all subsequent sessions. Existing sessions are unaffected.

- With the `SESSION` keyword, the statement sets the default transaction level for all subsequent transactions performed within the current session.

- Without any `SESSION` or `GLOBAL` keyword, the statement sets the isolation level for the next (not started) transaction performed within the current session. Subsequent transactions revert to using the `SESSION` isolation level.

A change to the global default isolation level requires the `SUPER` privilege. Any session is free to change its session isolation level (even in the middle of a transaction), or the isolation level for its next transaction.

**SET TRANSACTION ISOLATION LEVEL** without `GLOBAL` or `SESSION` is not permitted while there is an active transaction:

```sql
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.02 sec)

mysql> SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;
ERROR 1568 (25001): Transaction isolation level can't be changed while a transaction is in progress
```

To set the global default isolation level at server startup, use the `--transaction-isolation=level` option to `mysqld` on the command line or in an option file. Values of `level` for this option use dashes rather than spaces, so the permissible values are `READ-UNCOMMITTED`, `READ-COMMITTED`, `REPEATABLE-READ`, or `SERIALIZABLE`. For example, to set the default isolation level to `REPEATABLE READ`, use these lines in the `[mysqld]` section of an option file:

```ini
[mysqld]
transaction-isolation = REPEATABLE-READ
```

It is possible to check or set the global and session transaction isolation levels at runtime by using the `tx_isolation` system variable:

```sql
SELECT @@GLOBAL.tx_isolation, @@tx_isolation;
SET GLOBAL tx_isolation='REPEATABLE-READ';
SET SESSION tx_isolation='SERIALIZABLE';
```

Details and Usage of Isolation Levels

**InnoDB** supports each of the transaction isolation levels described here using different locking strategies. You can enforce a high degree of consistency with the default `REPEATABLE READ` level, for operations on crucial data where ACID compliance is important. Or you can relax the consistency rules with `READ COMMITTED` or even `READ UNCOMMITTED`, in situations such as bulk reporting where precise consistency and repeatable results are less important than minimizing the amount of overhead for locking. `SERIALIZABLE` enforces even stricter rules than `REPEATABLE READ`, and is used mainly in specialized situations, such as with XA transactions and for troubleshooting issues with concurrency and deadlocks.

The following list describes how MySQL supports the different transaction levels. The list goes from the most commonly used level to the least used.

- **REPEATABLE READ**

  This is the default isolation level for **InnoDB**. For consistent reads, there is an important difference from the `READ COMMITTED` isolation level: All consistent reads within the same transaction read the snapshot established by the first read. This convention means that if you issue several plain
(nonlocking) `SELECT` statements within the same transaction, these `SELECT` statements are consistent also with respect to each other. See Section 14.6.4.4, "Consistent Nonlocking Reads".

For locking reads (`SELECT` with `FOR UPDATE` or `LOCK IN SHARE MODE`), `UPDATE`, and `DELETE` statements, locking depends on whether the statement uses a unique index with a unique search condition, or a range-type search condition. For a unique index with a unique search condition, `InnoDB` locks only the index record found, not the gap before it. For other search conditions, `InnoDB` locks the index range scanned, using gap locks or next-key (gap plus index-record) locks to block insertions by other sessions into the gaps covered by the range.

- **READ COMMITTED**

  A somewhat Oracle-like isolation level with respect to consistent (nonlocking) reads: Each consistent read, even within the same transaction, sets and reads its own fresh snapshot. See Section 14.6.4.4, "Consistent Nonlocking Reads".

  For locking reads (`SELECT` with `FOR UPDATE` or `LOCK IN SHARE MODE`), `UPDATE` statements, and `DELETE` statements, `InnoDB` locks only index records, not the gaps before them, and thus permits the free insertion of new records next to locked records.

  **Note**

  In MySQL 5.1, when `READ COMMITTED` isolation level is used or the `innodb_locks_unsafe_for_binlog` system variable is enabled, there is no `InnoDB` gap locking except for foreign-key constraint checking and duplicate-key checking. Also, record locks for nonmatching rows are released after MySQL has evaluated the `WHERE` condition.

  As of MySQL 5.1, if you use `READ COMMITTED` or enable `innodb_locks_unsafe_for_binlog`, you must use row-based binary logging.

- **READ UNCOMMITTED**

  `SELECT` statements are performed in a nonlocking fashion, but a possible earlier version of a row might be used. Thus, using this isolation level, such reads are not consistent. This is also called a "dirty read." Otherwise, this isolation level works like `READ COMMITTED`.

- **SERIALIZABLE**

  This level is like `REPEATABLE READ`, but `InnoDB` implicitly converts all plain `SELECT` statements to `SELECT ... LOCK IN SHARE MODE` if `autocommit` is disabled. If `autocommit` is enabled, the `SELECT` is its own transaction. It therefore is known to be read only and can be serialized if performed as a consistent (nonlocking) read and need not block for other transactions. (To force a plain `SELECT` to block if other transactions have modified the selected rows, disable `autocommit`.)

  For additional information about isolation levels and `InnoDB` transactions, see Section 14.6.4, "InnoDB Transaction Model and Locking".

### 13.3.7 XA Transactions

Support for XA transactions is available for the `InnoDB` storage engine. The MySQL XA implementation is based on the X/Open CAE document *Distributed Transaction Processing: The XA Specification*. This document is published by The Open Group and available at [http://www.opengroup.org/public/pubs/catalog/c193.htm](http://www.opengroup.org/public/pubs/catalog/c193.htm). Limitations of the current XA implementation are described in Section C.5, "Restrictions on XA Transactions".

On the client side, there are no special requirements. The XA interface to a MySQL server consists of SQL statements that begin with the `XA` keyword. MySQL client programs must be able to send SQL statements and to understand the semantics of the XA statement interface. They do not need be linked against a recent client library. Older client libraries also will work.
Among the MySQL Connectors, MySQL Connector/J 5.0.0 supports XA directly (by means of a class interface that handles the XA SQL statement interface for you).

XA supports distributed transactions, that is, the ability to permit multiple separate transactional resources to participate in a global transaction. Transactional resources often are RDBMSs but may be other kinds of resources.

A global transaction involves several actions that are transactional in themselves, but that all must either complete successfully as a group, or all be rolled back as a group. In essence, this extends ACID properties “up a level” so that multiple ACID transactions can be executed in concert as components of a global operation that also has ACID properties. (As with nondistributed transactions, **SERIALIZABLE** may be preferred if your applications are sensitive to read phenomena. **REPEATABLE READ** may not be sufficient for distributed transactions.)

Some examples of distributed transactions:

- An application may act as an integration tool that combines a messaging service with an RDBMS. The application makes sure that transactions dealing with message sending, retrieval, and processing that also involve a transactional database all happen in a global transaction. You can think of this as “transactional email.”

- An application performs actions that involve different database servers, such as a MySQL server and an Oracle server (or multiple MySQL servers), where actions that involve multiple servers must happen as part of a global transaction, rather than as separate transactions local to each server.

- A bank keeps account information in an RDBMS and distributes and receives money through automated teller machines (ATMs). It is necessary to ensure that ATM actions are correctly reflected in the accounts, but this cannot be done with the RDBMS alone. A global transaction manager integrates the ATM and database resources to ensure overall consistency of financial transactions.

Applications that use global transactions involve one or more Resource Managers and a Transaction Manager:

- A Resource Manager (RM) provides access to transactional resources. A database server is one kind of resource manager. It must be possible to either commit or roll back transactions managed by the RM.

- A Transaction Manager (TM) coordinates the transactions that are part of a global transaction. It communicates with the RMs that handle each of these transactions. The individual transactions within a global transaction are “branches” of the global transaction. Global transactions and their branches are identified by a naming scheme described later.

The MySQL implementation of XA MySQL enables a MySQL server to act as a Resource Manager that handles XA transactions within a global transaction. A client program that connects to the MySQL server acts as the Transaction Manager.

To carry out a global transaction, it is necessary to know which components are involved, and bring each component to a point when it can be committed or rolled back. Depending on what each component reports about its ability to succeed, they must all commit or roll back as an atomic group. That is, either all components must commit, or all components must roll back. To manage a global transaction, it is necessary to take into account that any component or the connecting network might fail.

The process for executing a global transaction uses two-phase commit (2PC). This takes place after the actions performed by the branches of the global transaction have been executed.

1. In the first phase, all branches are prepared. That is, they are told by the TM to get ready to commit. Typically, this means each RM that manages a branch records the actions for the branch in stable storage. The branches indicate whether they are able to do this, and these results are used for the second phase.
2. In the second phase, the TM tells the RMs whether to commit or roll back. If all branches indicated when they were prepared that they will be able to commit, all branches are told to commit. If any branch indicated when it was prepared that it will not be able to commit, all branches are told to roll back.

In some cases, a global transaction might use one-phase commit (1PC). For example, when a Transaction Manager finds that a global transaction consists of only one transactional resource (that is, a single branch), that resource can be told to prepare and commit at the same time.

13.3.7.1 XA Transaction SQL Syntax

To perform XA transactions in MySQL, use the following statements:

```
XA {START|BEGIN} xid [JOIN|RESUME]
XA END xid [SUSPEND [FOR MIGRATE]]
XA PREPARE xid
XA COMMIT xid [ONE PHASE]
XA ROLLBACK xid
XA RECOVER
```

For `XA START`, the `JOIN` and `RESUME` clauses are not supported.

For `XA END` the `SUSPEND [FOR MIGRATE]` clause is not supported.

Each XA statement begins with the `XA` keyword, and most of them require an `xid` value. An `xid` is an XA transaction identifier. It indicates which transaction the statement applies to. `xid` values are supplied by the client, or generated by the MySQL server. An `xid` value has from one to three parts:

```
xid: gtrid [, bqual [, formatID ]]
```

`gtrid` is a global transaction identifier, `bqual` is a branch qualifier, and `formatID` is a number that identifies the format used by the `gtrid` and `bqual` values. As indicated by the syntax, `bqual` and `formatID` are optional. The default `bqual` value is `' '` if not given. The default `formatID` value is 1 if not given.

`gtrid` and `bqual` must be string literals, each up to 64 bytes (not characters) long. `gtrid` and `bqual` can be specified in several ways. You can use a quoted string (`'ab'`), hex string (`X'6162'`, `0x6162`), or bit value (`b'nnnn'`).

`formatID` is an unsigned integer.

The `gtrid` and `bqual` values are interpreted in bytes by the MySQL server's underlying XA support routines. However, while an SQL statement containing an XA statement is being parsed, the server works with some specific character set. To be safe, write `gtrid` and `bqual` as hex strings.

`xid` values typically are generated by the Transaction Manager. Values generated by one TM must be different from values generated by other TMs. A given TM must be able to recognize its own `xid` values in a list of values returned by the `XA RECOVER` statement.

For `XA START xid` starts an XA transaction with the given `xid` value. Each XA transaction must have a unique `xid` value, so the value must not currently be used by another XA transaction. Uniqueness is assessed using the `gtrid` and `bqual` values. All following XA statements for the XA transaction must be specified using the same `xid` value as that given in the `XA START` statement. If you use any of those statements but specify an `xid` value that does not correspond to some existing XA transaction, an error occurs.
One or more XA transactions can be part of the same global transaction. All XA transactions within a given global transaction must use the same `gtrid` value in the `xid` value. For this reason, `gtrid` values must be globally unique so that there is no ambiguity about which global transaction a given XA transaction is part of. The `bqual` part of the `xid` value must be different for each XA transaction within a global transaction. (The requirement that `bqual` values be different is a limitation of the current MySQL XA implementation. It is not part of the XA specification.)

The `XA RECOVER` statement returns information for those XA transactions on the MySQL server that are in the `PREPARED` state. (See Section 13.3.7.2, “XA Transaction States”. The output includes a row for each such XA transaction on the server, regardless of which client started it.

`XA RECOVER` output rows look like this (for an example `xid` value consisting of the parts 'abc', 'def', and 7):

```
mysql> XA RECOVER;
+----------+--------------+--------------+--------+
<table>
<thead>
<tr>
<th>formatID</th>
<th>gtrid_length</th>
<th>bqual_length</th>
<th>data</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>3</td>
<td>3</td>
<td>abcdef</td>
</tr>
</tbody>
</table>
+----------+--------------+--------------+--------+
```

The output columns have the following meanings:

- `formatID` is the `formatID` part of the transaction `xid`
- `gtrid_length` is the length in bytes of the `gtrid` part of the `xid`
- `bqual_length` is the length in bytes of the `bqual` part of the `xid`
- `data` is the concatenation of the `gtrid` and `bqual` parts of the `xid`

### 13.3.7.2 XA Transaction States

An XA transaction progresses through the following states:

1. Use `XA START` to start an XA transaction and put it in the `ACTIVE` state.

2. For an `ACTIVE` XA transaction, issue the SQL statements that make up the transaction, and then issue an `XA END` statement. `XA END` puts the transaction in the `IDLE` state.

3. For an `IDLE` XA transaction, you can issue either an `XA PREPARE` statement or an `XA COMMIT ... ONE PHASE` statement:
   - `XA PREPARE` puts the transaction in the `PREPARED` state. An `XA RECOVER` statement at this point will include the transaction's `xid` value in its output, because `XA RECOVER` lists all XA transactions that are in the `PREPARED` state.
   - `XA COMMIT ... ONE PHASE` prepares and commits the transaction. The `xid` value will not be listed by `XA RECOVER` because the transaction terminates.

4. For a `PREPARED` XA transaction, you can issue an `XA COMMIT` statement to commit and terminate the transaction, or `XA ROLLBACK` to roll back and terminate the transaction.

Here is a simple XA transaction that inserts a row into a table as part of a global transaction:

```
mysql> XA START 'xatest';
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO mytable (i) VALUES(10);
Query OK, 1 row affected (0.04 sec)
mysql> XA END 'xatest';
```

1321
Within the context of a given client connection, XA transactions and local (non-XA) transactions are mutually exclusive. For example, if `XA START` has been issued to begin an XA transaction, a local transaction cannot be started until the XA transaction has been committed or rolled back. Conversely, if a local transaction has been started with `START TRANSACTION`, no XA statements can be used until the transaction has been committed or rolled back.

If an XA transaction is in the `ACTIVE` state, you cannot issue any statements that cause an implicit commit. That would violate the XA contract because you could not roll back the XA transaction. You will receive the following error if you try to execute such a statement:

```
ERROR 1399 (XAE07): XAER_RMFAIL: The command cannot be executed when global transaction is in the ACTIVE state
```

Statements to which the preceding remark applies are listed at Section 13.3.3, "Statements That Cause an Implicit Commit".

### 13.4 Replication Statements

Replication can be controlled through the SQL interface using the statements described in this section. One group of statements controls master servers, the other controls slave servers.

#### 13.4.1 SQL Statements for Controlling Master Servers

This section discusses statements for managing master replication servers. Section 13.4.2, "SQL Statements for Controlling Slave Servers", discusses statements for managing slave servers.

In addition to the statements described here, the following `SHOW` statements are used with master servers in replication. For information about these statements, see Section 13.7.5, "SHOW Syntax".

- `SHOW BINARY LOGS`
- `SHOW BINLOG EVENTS`
- `SHOW MASTER STATUS`
- `SHOW SLAVE HOSTS`

#### 13.4.1.1 PURGE BINARY LOGS Syntax

```
PURGE { BINARY | MASTER } LOGS
   { TO 'log_name' | BEFORE datetime_expr }
```

The binary log is a set of files that contain information about data modifications made by the MySQL server. The log consists of a set of binary log files, plus an index file (see Section 5.4.4, "The Binary Log").

The `PURGE BINARY LOGS` statement deletes all the binary log files listed in the log index file prior to the specified log file name or date. `BINARY` and `MASTER` are synonyms. Deleted log files also are removed from the list recorded in the index file, so that the given log file becomes the first in the list.

This statement has no effect if the server was not started with the `--log-bin` option to enable binary logging.
Examples:

```
PURGE BINARY LOGS TO 'mysql-bin.010';
PURGE BINARY LOGS BEFORE '2008-04-02 22:46:26';
```

The `BEFORE` variant's `datetime_expr` argument should evaluate to a `DATETIME` value (a value in 'YYYY-MM-DD hh:mm:ss' format).

This statement is safe to run while slaves are replicating. You need not stop them. If you have an active slave that currently is reading one of the log files you are trying to delete, this statement does nothing and fails with an error. However, if a slave is not connected and you happen to purge one of the log files it has yet to read, the slave will be unable to replicate after it reconnects.

To safely purge binary log files, follow this procedure:

1. On each slave server, use `SHOW SLAVE STATUS` to check which log file it is reading.
2. Obtain a listing of the binary log files on the master server with `SHOW BINARY LOGS`.
3. Determine the earliest log file among all the slaves. This is the target file. If all the slaves are up to date, this is the last log file on the list.
4. Make a backup of all the log files you are about to delete. (This step is optional, but always advisable.)
5. Purge all log files up to but not including the target file.

You can also set the `expire_logs_days` system variable to expire binary log files automatically after a given number of days (see Section 5.1.4, “Server System Variables”). If you are using replication, you should set the variable no lower than the maximum number of days your slaves might lag behind the master.

Prior to MySQL 5.1.24, `PURGE BINARY LOGS TO` and `PURGE BINARY LOGS BEFORE` did not behave in the same way (and neither one behaved correctly) when binary log files listed in the `.index` file had been removed from the system by some other means (such as using `rm` on Linux). Beginning with MySQL 5.1.24, both variants of the statement fail with an error in such cases. (Bug #18199, Bug #18453) To handle such errors, edit the `.index` file (which is a simple text file) manually to ensure that it lists only the binary log files that are actually present, then run again the `PURGE BINARY LOGS` statement that failed.

### 13.4.1.2 RESET MASTER Syntax

```
RESET MASTER
```

Deletes all binary log files listed in the index file, resets the binary log index file to be empty, and creates a new binary log file. This statement is intended to be used only when the master is started for the first time.

**Important**

The effects of `RESET MASTER` differ from those of `PURGE BINARY LOGS` in 2 key ways:

1. `RESET MASTER` removes all binary log files that are listed in the index file, leaving only a single, empty binary log file with a numeric suffix of `.000001`, whereas the numbering is not reset by `PURGE BINARY LOGS`.
2. `RESET MASTER` is *not* intended to be used while any replication slaves are running. The behavior of `RESET MASTER` when used while slaves are
running is undefined (and thus unsupported), whereas **PURGE BINARY LOGS** may be safely used while replication slaves are running.

See also Section 13.4.1.1, “PURGE BINARY LOGS Syntax”.

**RESET MASTER** can prove useful when you first set up the master and the slave, so that you can verify the setup as follows:

1. Start the master and slave, and start replication (see Section 16.1.1, “How to Set Up Replication”).
2. Execute a few test queries on the master.
3. Check that the queries were replicated to the slave.
4. When replication is running correctly, issue **STOP SLAVE** followed by **RESET SLAVE** on the slave, then verify that any unwanted data no longer exists on the slave.
5. Issue **RESET MASTER** on the master to clean up the test queries.

After verifying the setup and getting rid of any unwanted and log files generated by testing, you can start the slave and begin replicating.

### 13.4.1.3 SET sql_log_bin Syntax

```sql
SET sql_log_bin = {0|1}
```

Disables or enables binary logging for the current session (sql_log_bin is a session variable) if the client has the **SUPER** privilege. The statement fails with an error if the client does not have that privilege.

### 13.4.2 SQL Statements for Controlling Slave Servers

This section discusses statements for managing slave replication servers. Section 13.4.1, “SQL Statements for Controlling Master Servers”, discusses statements for managing master servers.

In addition to the statements described here, **SHOW SLAVE STATUS** is also used with replication slaves. For information about this statement, see Section 13.7.5.36, “SHOW SLAVE STATUS Syntax”.

### 13.4.2.1 CHANGE MASTER TO Syntax

```sql
CHANGE MASTER TO option [, option] ...
```

**option:**
- `MASTER_BIND = 'interface_name'`
- `MASTER_HOST = 'host_name'`
- `MASTER_USER = 'user_name'`
- `MASTER_PASSWORD = 'password'`
- `MASTER_PORT = port_num`
- `MASTERCONNECT_RETRY = interval`
- `MASTER_HEARTBEAT_PERIOD = interval`
- `MASTER_LOG_FILE = 'master_log_name'`
- `MASTER_LOG_POS = master_log_pos`
- `RELAY_LOG_FILE = 'relay_log_name'`
- `RELAY_LOG_POS = relay_log_pos`
- `MASTER_SSL = {0|1}`
- `MASTER_SSL_CA = 'ca_file_name'`
- `MASTER_SSL_CAPATH = 'ca_directory_name'`
- `MASTER_SSL_CERT = 'cert_file_name'`
- `MASTER_SSL_KEY = 'key_file_name'`
- `MASTER_SSL_CIPHER = 'cipher_list'`
- `MASTER_SSL_VERIFY_SERVER_CERT = {0|1}`
- `IGNORE_SERVER_IDS = (server_id_list)`

**server_id_list:**
SQL Statements for Controlling Slave Servers

```
[server_id [, server_id] ... ]
```

**CHANGE MASTER TO** changes the parameters that the slave server uses for connecting to the master server, for reading the master binary log, and reading the slave relay log. It also updates the contents of the **master.info** and **relay-log.info** files. To use **CHANGE MASTER TO**, the slave replication threads must be stopped (use **STOP SLAVE** if necessary).

Options not specified retain their value, except as indicated in the following discussion. Thus, in most cases, there is no need to specify options that do not change. For example, if the password to connect to your MySQL master has changed, you just need to issue these statements to tell the slave about the new password:

```
STOP SLAVE; -- if replication was running
CHANGE MASTER TO MASTER_PASSWORD='new3cret';
START SLAVE; -- if you want to restart replication
```

**MASTER_HOST**, **MASTER_USER**, **MASTER_PASSWORD**, and **MASTER_PORT** provide information to the slave about how to connect to its master:

- **MASTER_HOST** and **MASTER_PORT** are the host name (or IP address) of the master host and its TCP/IP port.

  **Note**
  Replication cannot use Unix socket files. You must be able to connect to the master MySQL server using TCP/IP.

If you specify the **MASTER_HOST** or **MASTER_PORT** option, the slave assumes that the master server is different from before (even if the option value is the same as its current value.) In this case, the old values for the master binary log file name and position are considered no longer applicable, so if you do not specify **MASTER_LOG_FILE** and **MASTER_LOG_POS** in the statement, **MASTER_LOG_FILE=''** and **MASTER_LOG_POS=4** are silently appended to it.

Setting **MASTER_HOST=''** (that is, setting its value explicitly to an empty string) is not the same as not setting **MASTER_HOST** at all. Setting this option to an empty string causes **START SLAVE** subsequently to fail. This issue is addressed in MySQL 5.5. (Bug #28796)

- **MASTER_USER** and **MASTER_PASSWORD** are the user name and password of the account to use for connecting to the master.

  The password used for a MySQL Replication slave account in a **CHANGE MASTER TO** statement is limited to 32 characters in length; if the password is longer, the statement succeeds, but any excess characters are silently truncated. This is an issue specific to MySQL Replication, which is fixed in MySQL 5.7. (Bug #11752299, Bug #43439)

  The text of a running **CHANGE MASTER TO** statement, including values for **MASTER_USER** and **MASTER_PASSWORD**, can be seen in the output of a concurrent **SHOW PROCESSLIST** statement.

The **MASTER_SSL_**xxx options provide information about using SSL for the connection. They correspond to the **--ssl-**xxx options described in **Section 6.4.5, “Command Options for Secure Connections”,** and **Section 16.3.7, “Setting Up Replication to Use Secure Connections”**. **MASTER_SSL_VERIFY_SERVER_CERT** was added in MySQL 5.1.18. These options can be changed even on slaves that are compiled without SSL support. They are saved to the **master.info** file, but are ignored if the slave does not have SSL support enabled.

**MASTER_CONNECT_RETRY** specifies how many seconds to wait between connect retries. The default is 60. The number of reconnection attempts is limited by the **--master-retry-count** server option; for more information, see **Section 16.1.3, “Replication and Binary Logging Options and Variables”**.

The next two options (**MASTER_BIND** and **MASTER_HEARTBEAT_PERIOD**) are available in MySQL Cluster NDB 6.3 and later, but are not supported in mainline MySQL 5.1.
**MASTER BIND** is for use on replication slaves having multiple network interfaces, and determines which of the slave's network interfaces is chosen for connecting to the master.

The ability to bind a replication slave to specific network interface was added in MySQL Cluster NDB 6.3.4.

**MASTER HEARTBEAT PERIOD** sets the interval in seconds between replication heartbeats. Whenever the master's binary log is updated with an event, the waiting period for the next heartbeat is reset. _interval_ is a decimal value having the range 0 to 4294967 seconds and a resolution in milliseconds; the smallest nonzero value is 0.001. Heartbeats are sent by the master only if there are no unsent events in the binary log file for a period longer than _interval_.

Setting _interval_ to 0 disables heartbeats altogether. The default value for _interval_ is equal to the value of `slave_net_timeout` divided by 2.

Setting `@global.slave_net_timeout` to a value less than that of the current heartbeat interval results in a warning being issued. The effect of issuing `RESET SLAVE` on the heartbeat interval is to reset it to the default value.

**MASTER HEARTBEAT PERIOD** was added in MySQL Cluster NDB 6.3.4.

**MASTER_LOG_FILE** and **MASTER_LOG_POS** are the coordinates at which the slave I/O thread should begin reading from the master the next time the thread starts. **RELAY_LOG_FILE** and **RELAY_LOG_POS** are the coordinates at which the slave SQL thread should begin reading from the relay log the next time the thread starts. If you specify either of **MASTER_LOG_FILE** or **MASTER_LOG_POS**, you cannot specify **RELAY_LOG_FILE** or **RELAY_LOG_POS**. If neither of **MASTER_LOG_FILE** or **MASTER_LOG_POS** is specified, the slave uses the last coordinates of the slave SQL thread before **CHANGE MASTER TO** was issued. This ensures that there is no discontinuity in replication, even if the slave SQL thread was late compared to the slave I/O thread, when you merely want to change, say, the password to use.

**CHANGE MASTER TO** deletes all relay log files and starts a new one, unless you specify **RELAY_LOG_FILE** or **RELAY_LOG_POS**. In that case, relay log files are kept; the `relay_log_purge` global variable is set silently to 0.

**IGNORE_SERVER_IDS** was added in MySQL Cluster NDB 6.1.29, MySQL Cluster NDB 6.3.31, MySQL Cluster NDB 7.0.11, and MySQL Cluster NDB 7.1.0 (see Bug #47037). This option takes a comma-separated list of 0 or more server IDs. Events originating from the corresponding servers are ignored, with the exception of log rotation and deletion events, which are still recorded in the relay log.

In circular replication, the originating server normally acts as the terminator of its own events, so that they are not applied more than once. Thus, this option is useful in circular replication when one of the servers in the circle is removed. Suppose that you have a circular replication setup with 4 servers, having server IDs 1, 2, 3, and 4, and server 3 fails. When bridging the gap by starting replication from server 2 to server 4, you can include `IGNORE_SERVER_IDS = (3)` in the **CHANGE MASTER TO** statement that you issue on server 4 to tell it to use server 2 as its master instead of server 3. Doing so causes it to ignore and not to propagate any statements that originated with the server that is no longer in use.

If a **CHANGE MASTER TO** statement is issued without any **IGNORE_SERVER_IDS** option, any existing list is preserved; `RESET SLAVE` also has no effect on the server ID list. To clear the list of ignored servers, it is necessary to use the option with an empty list:

```
CHANGE MASTER TO IGNORE_SERVER_IDS = ();
```

If **IGNORE_SERVER_IDS** contains the server's own ID and the server was started with the `--replicate-same-server-id` option enabled, an error results.

Beginning with MySQL 5.1.47, invoking **CHANGE MASTER TO** causes the previous values for **MASTER_HOST**, **MASTER_PORT**, **MASTER_LOG_FILE**, and **MASTER_LOG_POS** to be written to the error log, along with other information about the slave's state prior to execution.
**CHANGE MASTER TO** is useful for setting up a slave when you have the snapshot of the master and have recorded the master binary log coordinates corresponding to the time of the snapshot. After loading the snapshot into the slave to synchronize it with the master, you can run `CHANGE MASTER TO MASTER_LOG_FILE='log_name', MASTER_LOG_POS=log_pos` on the slave to specify the coordinates at which the slave should begin reading the master binary log.

The following example changes the master server the slave uses and establishes the master binary log coordinates from which the slave begins reading. This is used when you want to set up the slave to replicate the master:

```sql
CHANGE MASTER TO
  MASTER_HOST='master2.mycompany.com',
  MASTER_USER='replication',
  MASTER_PASSWORD='bigs3cret',
  MASTER_PORT=3306,
  MASTER_LOG_FILE='master2-bin.001',
  MASTER_LOG_POS=4,
  MASTER_CONNECT_RETRY=10;
```

The next example shows an operation that is less frequently employed. It is used when the slave has relay log files that you want it to execute again for some reason. To do this, the master need not be reachable. You need only use `CHANGE MASTER TO` and start the SQL thread (`START SLAVE SQL_THREAD`):

```sql
CHANGE MASTER TO
  RELAY_LOG_FILE='slave-relay-bin.006',
  RELAY_LOG_POS=4025;
```

You can even use the second operation in a nonreplication setup with a standalone, nonslave server for recovery following a crash. Suppose that your server has crashed and you have restored it from a backup. You want to replay the server's own binary log files (not relay log files, but regular binary log files), named (for example) `myhost-bin.*`. First, make a backup copy of these binary log files in some safe place, in case you don't exactly follow the procedure below and accidentally have the server purge the binary log. Use `SET GLOBAL relay_log_purge=0` for additional safety. Then start the server without the --log-bin option, instead, use the --replicate-same-server-id, --relay-log=myhost-bin (to make the server believe that these regular binary log files are relay log files) and --skip-slave-start options. After the server starts, issue these statements:

```sql
CHANGE MASTER TO
  RELAY_LOG_FILE='myhost-bin.153',
  RELAY_LOG_POS=410,
  MASTER_HOST='some_dummy_string';
START SLAVE SQL_THREAD;
```

The server reads and executes its own binary log files, thus achieving crash recovery. Once the recovery is finished, run `STOP SLAVE`, shut down the server, delete the master.info and relay-log.info files, and restart the server with its original options.

Specifying the `MASTER_HOST` option (even with a dummy value) is required to make the server think it is a slave.

The following table shows the maximum permissible length for the string-valued options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Maximum Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>MASTER_HOST</td>
<td>60</td>

13.4.2.2 LOAD DATA FROM MASTER Syntax

Note
This feature is deprecated and should be avoided. It is subject to removal in a future version of MySQL.

Since the current implementation of LOAD DATA FROM MASTER and LOAD TABLE FROM MASTER is very limited, these statements are deprecated as of MySQL 4.1 and removed in MySQL 5.5.

The recommended alternative solution to using LOAD DATA FROM MASTER or LOAD TABLE FROM MASTER is using mysqldump or mysqlhotcopy. The latter requires Perl and two Perl modules (DBI and DBD:mysql) and works for MyISAM and ARCHIVE tables only. With mysqldump, you can create SQL dumps on the master and pipe (or copy) these to a mysql client on the slave. This has the advantage of working for all storage engines, but can be quite slow, since it works using SELECT.

This statement takes a snapshot of the master and copies it to the slave. It updates the values of MASTER_LOG_FILE and MASTER_LOG_POS so that the slave starts replicating from the correct position. Any table and database exclusion rules specified with the --replicate-*-do-* and --replicate-*-ignore-* options are honored. --replicate-rewrite-db is not taken into account because a user could use this option to set up a nonunique mapping such as --replicate-rewrite-db="db1->db3" and --replicate-rewrite-db="db2->db3", which would confuse the slave when loading tables from the master.

Use of this statement is subject to the following conditions:

- It works only for MyISAM tables. Attempting to load a non-MyISAM table results in the following error:

  ERROR 1189 (08S01): Net error reading from master

- It acquires a global read lock on the master while taking the snapshot, which prevents updates on the master during the load operation.

If you are loading large tables, you might have to increase the values of net_read_timeout and net_write_timeout on both the master and slave servers. See Section 5.1.4, “Server System Variables”.

LOAD DATA FROM MASTER does not copy any tables from the mysql database. This makes it easy to have different users and privileges on the master and the slave.

To use LOAD DATA FROM MASTER, the replication account that is used to connect to the master must have the RELOAD and SUPER privileges on the master and the SELECT privilege for all master tables you want to load. All master tables for which the user does not have the SELECT privilege are ignored by LOAD DATA FROM MASTER. This is because the master hides them from the user: LOAD DATA FROM MASTER calls SHOW DATABASES to know the master databases to load, but SHOW DATABASES returns only databases for which the user has some privilege. See Section 13.7.5.15, “SHOW DATABASES Syntax”. On the slave side, the user that issues LOAD DATA FROM MASTER must have privileges for dropping and creating the databases and tables that are copied.
13.4.2.3 LOAD TABLE tbl_name FROM MASTER Syntax

```
LOAD TABLE tbl_name FROM MASTER
```

Note
This feature is deprecated and should be avoided. It is subject to removal in a future version of MySQL.

Since the current implementation of LOAD DATA FROM MASTER and LOAD TABLE FROM MASTER is very limited, these statements are deprecated as of MySQL 4.1 and removed in MySQL 5.5.

The recommended alternative solution to using LOAD DATA FROM MASTER or LOAD TABLE FROM MASTER is using mysqldump or mysqlhotcopy. The latter requires Perl and two Perl modules (DBI and DBD:mysql) and works for MyISAM and ARCHIVE tables only. With mysqldump, you can create SQL dumps on the master and pipe (or copy) these to a mysql client on the slave. This has the advantage of working for all storage engines, but can be quite slow, since it works using SELECT.

Transfers a copy of the table from the master to the slave. This statement is implemented mainly debugging LOAD DATA FROM MASTER operations. To use LOAD TABLE, the account used for connecting to the master server must have the RELOAD and SUPER privileges on the master and the SELECT privilege for the master table to load. On the slave side, the user that issues LOAD TABLE FROM MASTER must have privileges for dropping and creating the table.

The conditions for LOAD DATA FROM MASTER apply here as well. For example, LOAD TABLE FROM MASTER works only for MyISAM tables. The timeout notes for LOAD DATA FROM MASTER apply as well.

13.4.2.4 MASTER_POS_WAIT() Syntax

```
SELECT MASTER_POS_WAIT('master_log_file', master_log_pos [, timeout])
```

This is actually a function, not a statement. It is used to ensure that the slave has read and executed events up to a given position in the master’s binary log. See Section 12.16, “Miscellaneous Functions”, for a full description.

13.4.2.5 RESET SLAVE Syntax

```
RESET SLAVE
```

RESET SLAVE makes the slave forget its replication position in the master's binary log. This statement is meant to be used for a clean start: It deletes the master.info and relay-log.info files, all the relay log files, and starts a new relay log file. To use RESET SLAVE, the slave replication threads must be stopped (use STOP SLAVE if necessary).

Note
All relay log files are deleted, even if they have not been completely executed by the slave SQL thread. (This is a condition likely to exist on a replication slave if you have issued a STOP SLAVE statement or if the slave is highly loaded.)

If any startup options for setting connection parameters (such as master host, master port, master user, and master password) are in use, then any corresponding connection information stored in the master.info file is immediately reset using the values specified for these options. Options for which values are not specified are cleared. However, since these options are deprecated in MySQL 5.1 and removed altogether from MySQL 5.5, you are encouraged to use a CHANGE MASTER TO statement instead to reset the connection parameters. (If you do not use the startup options, you must issue CHANGE MASTER TO in such cases if you do not want the connection settings to be cleared.)
If the slave SQL thread was in the middle of replicating temporary tables when it was stopped, and \texttt{RESET SLAVE} is issued, these replicated temporary tables are deleted on the slave.

\begin{quote}
\textbf{Note}
When used on a MySQL Cluster replication slave SQL node, \texttt{RESET SLAVE} clears the \texttt{mysql.ndb_apply_status} table. You should keep in mind when using this statement that \texttt{ndb_apply_status} uses the NDB storage engine and so is shared by all SQL nodes attached to the slave cluster.
\end{quote}

### 13.4.2.6 SET GLOBAL sql_slave_skip_counter Syntax

\begin{syntax}
\texttt{SET GLOBAL sql_slave_skip_counter = N}
\end{syntax}

This statement skips the next \(N\) events from the master. This is useful for recovering from replication stops caused by a statement.

This statement is valid only when the slave threads are not running. Otherwise, it produces an error.

When using this statement, it is important to understand that the binary log is actually organized as a sequence of groups known as \textit{event groups}. Each event group consists of a sequence of events.

- For transactional tables, an event group corresponds to a transaction.
- For nontransactional tables, an event group corresponds to a single SQL statement.

\begin{quote}
\textbf{Note}
A single transaction can contain changes to both transactional and nontransactional tables.
\end{quote}

When you use \texttt{SET GLOBAL sql_slave_skip_counter} to skip events and the result is in the middle of a group, the slave continues to skip events until it reaches the end of the group. Execution then starts with the next event group.

Beginning with MySQL 5.1.47, issuing this statement causes the previous values of \texttt{RELAY_LOG_FILE}, \texttt{RELAY_LOG_POS}, and \texttt{sql_slave_skip_counter} to be written to the error log.

### 13.4.2.7 START SLAVE Syntax

\begin{syntax}
\texttt{START SLAVE \[thread_types\]}
\texttt{START SLAVE [SQL_THREAD] UNTIL MASTER_LOG_FILE = 'log_name', MASTER_LOG_POS = log_pos}
\texttt{START SLAVE [SQL_THREAD] UNTIL RELAY_LOG_FILE = 'log_name', RELAY_LOG_POS = log_pos}
\texttt{thread_types: [thread_type [, thread_type] ... ]}
\texttt{thread_type: IO_THREAD | SQL_THREAD}
\end{syntax}

\texttt{START SLAVE} with no \texttt{thread_type} options starts both of the slave threads. The I/O thread reads events from the master server and stores them in the relay log. The SQL thread reads events from the relay log and executes them. \texttt{START SLAVE} requires the \texttt{SUPER} privilege.

If \texttt{START SLAVE} succeeds in starting the slave threads, it returns without any error. However, even in that case, it might be that the slave threads start and then later stop (for example, because they do not manage to connect to the master or read its binary log, or some other problem). \texttt{START SLAVE} does not warn you about this. You must check the slave’s error log for error messages generated by the slave threads, or check that they are running satisfactorily with \texttt{SHOW SLAVE STATUS}. 
START SLAVE sends an acknowledgment to the user after both the I/O thread and the SQL thread have started. However, the I/O thread may not yet have connected. For this reason, a successful START SLAVE causes SHOW SLAVE STATUS to show Slave_SQL_Running=Yes, but this does not guarantee that Slave_IO_Running=Yes (because Slave_IO_Running=Yes only if the I/O thread is running and connected). For more information, see Section 13.7.5.36, “SHOW SLAVE STATUS Syntax”, and Section 16.1.4.1, “Checking Replication Status”.

You can add IO_THREAD and SQL_THREAD options to the statement to name which of the threads to start.

An UNTIL clause may be added to specify that the slave should start and run until the SQL thread reaches a given point in the master binary log or in the slave relay log. When the SQL thread reaches that point, it stops. If the SQL_THREAD option is specified in the statement, it starts only the SQL thread. Otherwise, it starts both slave threads. If the SQL thread is running, the UNTIL clause is ignored and a warning is issued.

For an UNTIL clause, you must specify both a log file name and position. Do not mix master and relay log options.

Any UNTIL condition is reset by a subsequent STOP SLAVE statement, a START SLAVE statement that includes no UNTIL clause, or a server restart.

The UNTIL clause can be useful for debugging replication, or to cause replication to proceed until just before the point where you want to avoid having the slave replicate an event. For example, if an unwise DROP TABLE statement was executed on the master, you can use UNTIL to tell the slave to execute up to that point but no farther. To find what the event is, use mysqlbinlog with the master binary log or slave relay log, or by using a SHOW BINLOG EVENTS statement.

If you are using UNTIL to have the slave process replicated queries in sections, it is recommended that you start the slave with the --skip-slave-start option to prevent the SQL thread from running when the slave server starts. It is probably best to use this option in an option file rather than on the command line, so that an unexpected server restart does not cause it to be forgotten.

The SHOW SLAVE STATUS statement includes output fields that display the current values of the UNTIL condition.

In old versions of MySQL (before 4.0.5), this statement was called SLAVE_START. This usage is still accepted in MySQL 5.1 for backward compatibility, but is deprecated and is removed in MySQL 5.6.

13.4.2.8 STOP SLAVE Syntax

```
STOP SLAVE [thread_types]
```

```
thread_types:
   [thread_type [, thread_type] ... ]

thread_type: IO_THREAD | SQL_THREAD
```

Stops the slave threads. STOP SLAVE requires the SUPER privilege. Recommended best practice is to execute STOP SLAVE on the slave before stopping the slave server (see Section 5.1.11, “The Server Shutdown Process”, for more information).

When using the row-based logging format: Prior to MySQL 5.1.35, you should always execute STOP SLAVE on the slave before stopping the slave server to help avoid the possibility of an inconsistent slave; in MySQL 5.1.35 and later, you should execute this statement on the slave prior to shutting down the slave server if you are replicating any tables that use a nontransactional storage engine (see the Note later in this section). In MySQL 5.1.55 and later, you can also use STOP SLAVE SQL_THREAD for this purpose.

Like START SLAVE, this statement may be used with the IO_THREAD and SQL_THREAD options to name the thread or threads to be stopped.
Note

The transactional behavior of `STOP SLAVE` changed in MySQL 5.1.35. Previously, it took effect immediately. Beginning with MySQL 5.1.35, it waits until any current replication event group affecting one or more nontransactional tables has finished executing (if there is any such replication group), or until the user issues a `KILL QUERY` or `KILL CONNECTION` statement. (Bug #319, Bug #38205)

In old versions of MySQL (before 4.0.5), this statement was called `SLAVE STOP`. This usage is still accepted in MySQL 5.1 for backward compatibility, but is deprecated and is removed in MySQL 5.6.

13.5 SQL Syntax for Prepared Statements

MySQL 5.1 provides support for server-side prepared statements. This support takes advantage of the efficient client/server binary protocol, provided that you use an appropriate client programming interface. Candidate interfaces include the MySQL C API client library (for C programs), MySQL Connector/J (for Java programs), and MySQL Connector/Net. For example, the C API provides a set of function calls that make up its prepared statement API. See Section 21.8.8, “C API Prepared Statements”. Other language interfaces can provide support for prepared statements that use the binary protocol by linking in the C client library, one example being the `mysqli` extension, available in PHP 5.0 and later.

An alternative SQL interface to prepared statements is available. This interface is not as efficient as using the binary protocol through a prepared statement API, but requires no programming because it is available directly at the SQL level:

- You can use it when no programming interface is available to you.
- You can use it from any program that enables you to send SQL statements to the server to be executed, such as the `mysql` client program.
- You can use it even if the client is using an old version of the client library. The only requirement is that you be able to connect to a server that is recent enough to support SQL syntax for prepared statements.

SQL syntax for prepared statements is intended to be used for situations such as these:

- You want to test how prepared statements work in your application before coding it.
- An application has problems executing prepared statements and you want to determine interactively what the problem is.
- You want to create a test case that describes a problem you are having with prepared statements, so that you can file a bug report.
- You need to use prepared statements but do not have access to a programming API that supports them.

SQL syntax for prepared statements is based on three SQL statements:

- `PREPARE` prepares a statement for execution (see Section 13.5.1, “PREPARE Syntax”).
- `EXECUTE` executes a prepared statement (see Section 13.5.2, “EXECUTE Syntax”).
- `DEALLOCATE PREPARE` releases a prepared statement (see Section 13.5.3, “DEALLOCATE PREPARE Syntax”).

The following examples show two equivalent ways of preparing a statement that computes the hypotenuse of a triangle given the lengths of the two sides.
The first example shows how to create a prepared statement by using a string literal to supply the text of the statement:

```sql
mysql> PREPARE stmt1 FROM 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
mysql> SET @a = 3;
mysql> SET @b = 4;
mysql> EXECUTE stmt1 USING @a, @b;
+------------+
| hypotenuse |
+------------+
|          5 |
+------------+
mysql> DEALLOCATE PREPARE stmt1;
```

The second example is similar, but supplies the text of the statement as a user variable:

```sql
mysql> SET @s = 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
mysql> PREPARE stmt2 FROM @s;
mysql> SET @a = 6;
mysql> SET @b = 8;
mysql> EXECUTE stmt2 USING @a, @b;
+------------+
| hypotenuse |
+------------+
|         10 |
+------------+
mysql> DEALLOCATE PREPARE stmt2;
```

Here is an additional example that demonstrates how to choose the table on which to perform a query at runtime, by storing the name of the table as a user variable:

```sql
mysql> USE test;
mysql> CREATE TABLE t1 (a INT NOT NULL);
mysql> INSERT INTO t1 VALUES (4), (8), (11), (32), (80);
mysql> SET @table = 't1';
mysql> SET @s = CONCAT('SELECT * FROM ', @table);
mysql> PREPARE stmt3 FROM @s;
mysql> EXECUTE stmt3;
+----+
| a  |

mysql> DEALLOCATE PREPARE stmt3;
```

A prepared statement is specific to the session in which it was created. If you terminate a session without deallocating a previously prepared statement, the server deallocates it automatically.

A prepared statement is also global to the session. If you create a prepared statement within a stored routine, it is not deallocated when the stored routine ends.

To guard against too many prepared statements being created simultaneously, set the `max_prepared_stmt_count` system variable. To prevent the use of prepared statements, set the value to 0.

The following SQL statements can be used in prepared statements:

```sql
ALTER TABLE
CALL
```
<table>
<thead>
<tr>
<th>SQL Syntax for Prepared Statements</th>
</tr>
</thead>
</table>

**SQL Syntax for Prepared Statements**

<table>
<thead>
<tr>
<th>COMMIT</th>
</tr>
</thead>
<tbody>
<tr>
<td>{CREATE</td>
</tr>
<tr>
<td>{CREATE</td>
</tr>
<tr>
<td>{CREATE</td>
</tr>
<tr>
<td>DELETE</td>
</tr>
<tr>
<td>DO</td>
</tr>
<tr>
<td>INSERT</td>
</tr>
<tr>
<td>REPLACE</td>
</tr>
<tr>
<td>SELECT</td>
</tr>
<tr>
<td>SHOW (most variants)</td>
</tr>
<tr>
<td>TRUNCATE TABLE</td>
</tr>
<tr>
<td>UPDATE</td>
</tr>
</tbody>
</table>

**As of MySQL 5.1.10, the following additional statements are supported:**

| ANALYZE TABLE |
| OPTIMIZE TABLE |
| REPAIR TABLE |

**As of MySQL 5.1.12, the following additional statements are supported:**

| CACHE INDEX |
| CHANGE MASTER |
| CHECKSUM (TABLE | TABLES) |
| (CREATE | RENAME | DROP) DATABASE |
| (CREATE | RENAME | DROP) USER |
| FLUSH (TABLE | TABLES | TABLES WITH READ LOCK | HOSTS | PRIVILEGES | LOGS | STATUS | MASTER | SLAVE | DES_KEY_FILE | USER_RESOURCES) |
| GRANT |
| INSTALL PLUGIN |
| KILL |
| LOAD INDEX INTO CACHE |
| RESET {MASTER | SLAVE | QUERY CACHE} |
| REVOKE |
| SHOW {AUTHORS | CONTRIBUTORS | WARNINGS | ERRORS} |
| SHOW BINLOG EVENTS |
| SHOW CREATE (PROCEDURE | FUNCTION | EVENT | TABLE | VIEW) |
| SHOW {MASTER | BINARY} LOGS |
| SHOW {MASTER | SLAVE} STATUS |
| SLAVE {START | STOP} |
| UNINSTALL PLUGIN |

**Other statements are not supported in MySQL 5.1.**

Generally, statements not permitted in SQL prepared statements are also not permitted in stored programs. Exceptions are noted in Section C.1, “Restrictions on Stored Programs”.

Metadata changes to tables or views referred to by prepared statements are detected and cause automatic repreparation of the statement when it is next executed. For more information, see Section 13.5.4, “Automatic Prepared Statement Repreparation”.

Placeholders can be used for the arguments of the LIMIT clause when using prepared statements. See Section 13.2.8, “SELECT Syntax”.

In prepared CALL statements used with PREPARE and EXECUTE, placeholder support for OUT and INOUT parameters is not available in MySQL 5.1. See Section 13.2.1, “CALL Syntax”, for an example and a workaround. Placeholders can be used for IN parameters regardless of version.

SQL syntax for prepared statements cannot be used in nested fashion. That is, a statement passed to PREPARE cannot itself be a PREPARE, EXECUTE, or DEALLOCATE PREPARE statement.

SQL syntax for prepared statements is distinct from using prepared statement API calls. For example, you cannot use the mysql_stmt_prepare() C API function to prepare a PREPARE, EXECUTE, or DEALLOCATE PREPARE statement.
SQL syntax for prepared statements can be used within stored procedures, but not in stored functions or triggers. However, a cursor cannot be used for a dynamic statement that is prepared and executed with `PREPARE` and `EXECUTE`. The statement for a cursor is checked at cursor creation time, so the statement cannot be dynamic.

SQL syntax for prepared statements does not support multi-statements (that is, multiple statements within a single string separated by `;` characters).

Before MySQL 5.1.17, prepared statements do not use the query cache. As of 5.1.17, prepared statements use the query cache under the conditions described in Section 8.10.3.1, “How the Query Cache Operates”.

To write C programs that use the `CALL` SQL statement to execute stored procedures that contain prepared statements, the `CLIENT_MULTI_RESULTS` flag must be enabled. This is because each `CALL` returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure.

`CLIENT_MULTI_RESULTS` can be enabled when you call `mysql_real_connect()`, either explicitly by passing the `CLIENT_MULTI_RESULTS` flag itself, or implicitly by passing `CLIENT_MULTI_STATEMENTS` (which also enables `CLIENT_MULTI_RESULTS`). For additional information, see Section 13.2.1, “CALL Syntax”.

### 13.5.1 PREPARE Syntax

```
PREPARE stmt_name FROM preparable_stmt
```

The `PREPARE` statement prepares a SQL statement and assigns it a name, `stmt_name`, by which to refer to the statement later. The prepared statement is executed with `EXECUTE` and released with `DEALLOCATE PREPARE`. For examples, see Section 13.5, “SQL Syntax for Prepared Statements”.

Statement names are not case sensitive. `preparable_stmt` is either a string literal or a user variable that contains the text of the SQL statement. The text must represent a single statement, not multiple statements. Within the statement, `?` characters can be used as parameter markers to indicate where data values are to be bound to the query later when you execute it. The `?` characters should not be enclosed within quotation marks, even if you intend to bind them to string values. Parameter markers can be used only where data values should appear, not for SQL keywords, identifiers, and so forth.

If a prepared statement with the given name already exists, it is deallocated implicitly before the new statement is prepared. This means that if the new statement contains an error and cannot be prepared, an error is returned and no statement with the given name exists.

The scope of a prepared statement is the session within which it is created, which as several implications:

- A prepared statement created in one session is not available to other sessions.
- When a session ends, whether normally or abnormally, its prepared statements no longer exist. If auto-reconnect is enabled, the client is not notified that the connection was lost. For this reason, clients may wish to disable auto-reconnect. See Section 21.8.15, “Controlling Automatic Reconnection Behavior”.
- A prepared statement created within a stored program continues to exist after the program finishes executing and can be executed outside the program later.
- A statement prepared in stored program context cannot refer to stored procedure or function parameters or local variables because they go out of scope when the program ends and would be unavailable were the statement to be executed later outside the program. As a workaround, refer instead to user-defined variables, which also have session scope; see Section 9.4, “User-Defined Variables”.
13.5.2 EXECUTE Syntax

```
EXECUTE stmt_name
    [USING @var_name [, @var_name] ...]
```

After preparing a statement with `PREPARE`, you execute it with an `EXECUTE` statement that refers to the prepared statement name. If the prepared statement contains any parameter markers, you must supply a `USING` clause that lists user variables containing the values to be bound to the parameters. Parameter values can be supplied only by user variables, and the `USING` clause must name exactly as many variables as the number of parameter markers in the statement.

You can execute a given prepared statement multiple times, passing different variables to it or setting the variables to different values before each execution.

For examples, see Section 13.5, “SQL Syntax for Prepared Statements”.

13.5.3 DEALLOCATE PREPARE Syntax

```
(DEALLOCATE | DROP) PREPARE stmt_name
```

To deallocate a prepared statement produced with `PREPARE`, use a `DEALLOCATE PREPARE` statement that refers to the prepared statement name. Attempting to execute a prepared statement after deallocating it results in an error.

For examples, see Section 13.5, “SQL Syntax for Prepared Statements”.

13.5.4 Automatic Prepared Statement Repreparation

As of MySQL 5.1.25, metadata changes to tables or views referred to by prepared statements are detected and cause automatic repreparation of the statement when it is next executed. This applies to prepared statements processed at the SQL level (using the `PREPARE` statement) and those processed using the binary client/server protocol (using the `mysql_stmt_prepare()` C API function).

The server attempts repreparation up to three times. An error occurs if all attempts fail.

Metadata changes occur for DDL statements such as those that create, drop, alter, rename, or truncate tables, or that analyze, optimize, or repair tables. Repreparation also occurs after referenced tables or views are flushed from the table definition cache, either implicitly to make room for new entries in the cache, or explicitly due to `FLUSH TABLES`.

Table content changes (for example, with `INSERT` or `UPDATE`) do not cause repreparation, nor do `SELECT` statements.

Repreparation is automatic, but to the extent that it occurs, diminishes prepared statement performance.

Repreparation uses the default database and SQL mode that were in effect for the original preparation.

The `Com_stmt_reprepare` status variable tracks the number of repreparations.

An incompatibility with older versions of MySQL (before 5.1.25) is that a prepared statement may return a different set of columns or different column types from one execution to the next. For example, if the prepared statement is `SELECT * FROM t1`, altering `t1` to contain a different number of columns causes the next execution to return a number of columns different from the previous execution.

Older versions of the client library cannot handle this change in behavior. For applications that use prepared statements with a server that performs automatic repreparation, an upgrade to the new client library is strongly recommended.
13.6 MySQL Compound-Statement Syntax

This section describes the syntax for the `BEGIN ... END` compound statement and other statements that can be used in the body of stored programs: Stored procedures and functions, triggers, and events. These objects are defined in terms of SQL code that is stored on the server for later invocation (see Chapter 19, Stored Programs and Views).

A compound statement is a block that can contain other blocks; declarations for variables, condition handlers, and cursors; and flow control constructs such as loops and conditional tests.

13.6.1 BEGIN ... END Compound-Statement Syntax

```
[begin_label:] BEGIN
[statement_list]
END [end_label]
```

`BEGIN ... END` syntax is used for writing compound statements, which can appear within stored programs (stored procedures and functions, triggers, and events). A compound statement can contain multiple statements, enclosed by the `BEGIN` and `END` keywords. `statement_list` represents a list of one or more statements, each terminated by a semicolon (`;`) statement delimiter. The `statement_list` itself is optional, so the empty compound statement (`BEGIN END`) is legal.

`BEGIN ... END` blocks can be nested.

Use of multiple statements requires that a client is able to send statement strings containing the `;` statement delimiter. In the `mysql` command-line client, this is handled with the `delimiter` command. Changing the `;` end-of-statement delimiter (for example, to `//`) permit `;` to be used in a program body. For an example, see Section 19.1, “Defining Stored Programs”.

A `BEGIN ... END` block can be labeled. See Section 13.6.2, “Statement Label Syntax”.

The optional `[NOT] ATOMIC` clause is not supported. This means that no transactional savepoint is set at the start of the instruction block and the `BEGIN` clause used in this context has no effect on the current transaction.

**Note**

Within all stored programs, the parser treats `BEGIN [WORK]` as the beginning of a `BEGIN ... END` block. To begin a transaction in this context, use `START TRANSACTION` instead.

13.6.2 Statement Label Syntax

```
[begin_label:] BEGIN
[statement_list]
END [end_label]

[begin_label:] LOOP
statement_list
END LOOP [end_label]

[begin_label:] REPEAT
statement_list
UNTIL search_condition
END REPEAT [end_label]

[begin_label:] WHILE search_condition DO
statement_list
END WHILE [end_label]
```

Labels are permitted for `BEGIN ... END` blocks and for the `LOOP`, `REPEAT`, and `WHILE` statements. Label use for those statements follows these rules:
• `begin_label` must be followed by a colon.

• `begin_label` can be given without `end_label`. If `end_label` is present, it must be the same as `begin_label`.

• `end_label` cannot be given without `begin_label`.

• Labels at the same nesting level must be distinct.

• Labels can be up to 16 characters long.

To refer to a label within the labeled construct, use an `ITERATE` or `LEAVE` statement. The following example uses those statements to continue iterating or terminate the loop:

```sql
CREATE PROCEDURE doiterate(pl INT)
BEGIN
  label1: LOOP
    SET pl = pl + 1;
    IF pl < 10 THEN ITERATE label1; END IF;
    LEAVE label1;
  END LOOP label1;
END;
```

The scope of a block label does not include the code for handlers declared within the block. For details, see Section 13.6.7.2, “DECLARE ... HANDLER Syntax”.

### 13.6.3 DECLARE Syntax

The `DECLARE` statement is used to define various items local to a program:

• Local variables. See Section 13.6.4, “Variables in Stored Programs”.

• Conditions and handlers. See Section 13.6.7, “Condition Handling”.

• Cursors. See Section 13.6.6, “Cursors”.

`DECLARE` is permitted only inside a `BEGIN ... END` compound statement and must be at its start, before any other statements.

Declarations must follow a certain order. Cursor declarations must appear before handler declarations. Variable and condition declarations must appear before cursor or handler declarations.

### 13.6.4 Variables in Stored Programs

System variables and user-defined variables can be used in stored programs, just as they can be used outside stored-program context. In addition, stored programs can use `DECLARE` to define local variables, and stored routines (procedures and functions) can be declared to take parameters that communicate values between the routine and its caller.

• To declare local variables, use the `DECLARE` statement, as described in Section 13.6.4.1, “Local Variable DECLARE Syntax”.

• Variables can be set directly with the `SET` statement. See Section 13.7.4.1, “SET Syntax for Variable Assignment”.

• Results from queries can be retrieved into local variables using `SELECT ... INTO var_list` or by opening a cursor and using `FETCH ... INTO var_list`. See Section 13.2.8.1, “SELECT ... INTO Syntax”, and Section 13.6.6, “Cursors”.

For information about the scope of local variables and how MySQL resolves ambiguous names, see Section 13.6.4.2, “Local Variable Scope and Resolution”.

1338
Variables in Stored Programs

13.6.4.1 Local Variable DECLARE Syntax

```
DECLARE var_name [, var_name] ... type [DEFAULT value]
```

This statement declares local variables within stored programs. To provide a default value for a variable, include a `DEFAULT` clause. The value can be specified as an expression; it need not be a constant. If the `DEFAULT` clause is missing, the initial value is `NULL`.

Local variables are treated like stored routine parameters with respect to data type and overflow checking. See Section 13.1.15, “CREATE PROCEDURE and CREATE FUNCTION Syntax”.

Variable declarations must appear before cursor or handler declarations.

Local variable names are not case sensitive. Permissible characters and quoting rules are the same as for other identifiers, as described in Section 9.2, “Schema Object Names”.

The scope of a local variable is the `BEGIN ... END` block within which it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

For examples of variable declarations, see Section 13.6.4.2, “Local Variable Scope and Resolution”.

13.6.4.2 Local Variable Scope and Resolution

The scope of a local variable is the `BEGIN ... END` block within which it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

Because local variables are in scope only during stored program execution, references to them are not permitted in prepared statements created within a stored program. Prepared statement scope is the current session, not the stored program, so the statement could be executed after the program ends, at which point the variables would no longer be in scope. For example, `SELECT ... INTO local_var` cannot be used as a prepared statement. This restriction also applies to stored procedure and function parameters. See Section 13.5.1, “PREPARE Syntax”.

A local variable should not have the same name as a table column. If an SQL statement, such as a `SELECT ... INTO` statement, contains a reference to a column and a declared local variable with the same name, MySQL currently interprets the reference as the name of a variable. Consider the following procedure definition:

```
CREATE PROCEDURE sp1 (x VARCHAR(5))
BEGIN
    DECLARE xname VARCHAR(5) DEFAULT 'bob';
    DECLARE newname VARCHAR(5);
    DECLARE xid INT;

    SELECT xname, id INTO newname, xid
        FROM table1 WHERE xname = xname;
    SELECT newname;
END;
```

MySQL interprets `xname` in the `SELECT` statement as a reference to the `xname` variable rather than the `xname` column. Consequently, when the procedure `sp1()` is called, the `newname` variable returns the value 'bob' regardless of the value of the `table1.xname` column.

Similarly, the cursor definition in the following procedure contains a `SELECT` statement that refers to `xname`. MySQL interprets this as a reference to the variable of that name rather than a column reference.
CREATE PROCEDURE sp2 (x VARCHAR(5))
BEGIN
    DECLARE xname VARCHAR(5) DEFAULT 'bob';
    DECLARE newname VARCHAR(5);
    DECLARE xid INT;
    DECLARE done TINYINT DEFAULT 0;
    DECLARE cur1 CURSOR FOR SELECT xname, id FROM table1;
    DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = 1;
    OPEN cur1;
    read_loop: LOOP
        FETCH FROM cur1 INTO newname, xid;
        IF done THEN LEAVE read_loop; END IF;
        SELECT newname;
    END LOOP;
    CLOSE cur1;
END;

See also Section C.1, “Restrictions on Stored Programs”.

13.6.5 Flow Control Statements

MySQL supports the `IF`, `CASE`, `ITERATE`, `LEAVE LOOP`, `WHILE`, and `REPEAT` constructs for flow control within stored programs. It also supports `RETURN` within stored functions.

Many of these constructs contain other statements, as indicated by the grammar specifications in the following sections. Such constructs may be nested. For example, an `IF` statement might contain a `WHILE` loop, which itself contains a `CASE` statement.

MySQL does not support `FOR` loops.

13.6.5.1 CASE Syntax

```plaintext
CASE case_value
    WHEN when_value THEN statement_list
    [WHEN when_value THEN statement_list] ...
    [ELSE statement_list]
END CASE
```

Or:

```plaintext
CASE
    WHEN search_condition THEN statement_list
    [WHEN search_condition THEN statement_list] ...
    [ELSE statement_list]
END CASE
```

The `CASE` statement for stored programs implements a complex conditional construct.

**Note**

There is also a `CASE expression`, which differs from the `CASE statement` described here. See Section 12.4, “Control Flow Functions”. The `CASE` statement cannot have an `ELSE NULL` clause, and it is terminated with `END CASE` instead of `END`.

For the first syntax, `case_value` is an expression. This value is compared to the `when_value` expression in each `WHEN` clause until one of them is equal. When an equal `when_value` is found, the corresponding `THEN` clause `statement_list` executes. If no `when_value` is equal, the `ELSE` clause `statement_list` executes, if there is one.

This syntax cannot be used to test for equality with `NULL` because `NULL = NULL` is false. See Section 3.3.4.6, “Working with NULL Values”.
For the second syntax, each `WHEN` clause `search_condition` expression is evaluated until one is true, at which point its corresponding `THEN` clause `statement_list` executes. If no `search_condition` is equal, the `ELSE` clause `statement_list` executes, if there is one.

If no `when_value` or `search_condition` matches the value tested and the `CASE` statement contains no `ELSE` clause, a `Case not found for CASE statement` error results.

Each `statement_list` consists of one or more SQL statements; an empty `statement_list` is not permitted.

To handle situations where no value is matched by any `WHEN` clause, use an `ELSE` containing an empty `BEGIN ... END` block, as shown in this example. (The indentation used here in the `ELSE` clause is for purposes of clarity only, and is not otherwise significant.)

```
DELIMITER |
CREATE PROCEDURE p()
BEGIN
    DECLARE v INT DEFAULT 1;
    CASE v
        WHEN 2 THEN SELECT v;
        WHEN 3 THEN SELECT 0;
        ELSE BEGIN END;
    END CASE;
END;
```

### 13.6.5.2 IF Syntax

```
IF `search_condition` THEN `statement_list`
    [ELSEIF `search_condition` THEN `statement_list`] ... 
    [ELSE `statement_list`]
END IF
```

The `IF` statement for stored programs implements a basic conditional construct.

**Note**

There is also an `IF()` function, which differs from the `IF statement` described here. See Section 12.4, “Control Flow Functions”. The `IF` statement can have `THEN`, `ELSE`, and `ELSEIF` clauses, and it is terminated with `END IF`.

If the `search_condition` evaluates to true, the corresponding `THEN` or `ELSEIF` clause `statement_list` executes. If no `search_condition` matches, the `ELSE` clause `statement_list` executes.

Each `statement_list` consists of one or more SQL statements; an empty `statement_list` is not permitted.

An `IF ... END IF` block, like all other flow-control blocks used within stored programs, must be terminated with a semicolon, as shown in this example:

```
DELIMITER //
CREATE FUNCTION SimpleCompare(n INT, m INT)
    RETURNS VARCHAR(20)
BEGIN
    DECLARE s VARCHAR(20);
```
Flow Control Statements

IF n > m THEN SET s = '>'; ELSEIF n = m THEN SET s = '='; ELSE SET s = '<'; END IF;

SET s = CONCAT(n, ' ', s, ' ', m);

RETURN s;
END //
DELIMITER ;

As with other flow-control constructs, IF ... END IF blocks may be nested within other flow-control constructs, including other IF statements. Each IF must be terminated by its own END IF followed by a semicolon. You can use indentation to make nested flow-control blocks more easily readable by humans (although this is not required by MySQL), as shown here:

DELIMITER //
CREATE FUNCTION VerboseCompare (n INT, m INT) RETURNS VARCHAR(50)
BEGIN
DECLARE s VARCHAR(50);

IF n = m THEN SET s = 'equals'; ELSE IF n > m THEN SET s = 'greater'; ELSE SET s = 'less'; END IF;

SET s = CONCAT('is ', s, ' than'); END IF;

SET s = CONCAT(n, ' ', s, ' ', m, '.');

RETURN s;
END //
DELIMITER ;

In this example, the inner IF is evaluated only if n is not equal to m.

13.6.5.3 ITERATE Syntax

ITERATE label

ITERATE can appear only within LOOP, REPEAT, and WHILE statements. ITERATE means “start the loop again.”

For an example, see Section 13.6.5.5, “LOOP Syntax”.

13.6.5.4 LEAVE Syntax

LEAVE label

This statement is used to exit the flow control construct that has the given label. If the label is for the outermost stored program block, LEAVE exits the program.

LEAVE can be used within BEGIN ... END or loop constructs (LOOP, REPEAT, WHILE).

For an example, see Section 13.6.5.5, “LOOP Syntax”.

13.6.5.5 LOOP Syntax
LOOP implements a simple loop construct, enabling repeated execution of the statement list, which consists of one or more statements, each terminated by a semicolon (;) statement delimiter. The statements within the loop are repeated until the loop is terminated. Usually, this is accomplished with a LEAVE statement. Within a stored function, RETURN can also be used, which exits the function entirely.

Neglecting to include a loop-termination statement results in an infinite loop.

A LOOP statement can be labeled. For the rules regarding label use, see Section 13.6.2, “Statement Label Syntax”.

Example:

```sql
CREATE PROCEDURE doiterate(p1 INT)
BEGIN
  label1: LOOP
    SET p1 = p1 + 1;
    IF p1 < 10 THEN
      ITERATE label1;
    END IF;
    LEAVE label1;
  END LOOP label1;
  SET @x = p1;
END;
```

### 13.6.5.6 REPEAT Syntax

The statement list within a REPEAT statement is repeated until the search_condition expression is true. Thus, a REPEAT always enters the loop at least once. statement_list consists of one or more statements, each terminated by a semicolon (;) statement delimiter.

A REPEAT statement can be labeled. For the rules regarding label use, see Section 13.6.2, “Statement Label Syntax”.

Example:

```sql
mysql> delimiter //
mysql> CREATE PROCEDURE dorepeat(p1 INT)
  -> BEGIN
  ->  SET @x = 0;
  ->  REPEAT
  ->    SET @x = @x + 1;
  ->  UNTIL @x > p1 END REPEAT;
  -> END
  -> //
Query OK, 0 rows affected (0.00 sec)
mysql> CALL dorepeat(1000)//
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT @x//
+--------+
| @x     |
+--------+
```
13.6.5.7 RETURN Syntax

```
RETURN expr
```

The `RETURN` statement terminates execution of a stored function and returns the value `expr` to the function caller. There must be at least one `RETURN` statement in a stored function. There may be more than one if the function has multiple exit points.

This statement is not used in stored procedures, triggers, or events. The `LEAVE` statement can be used to exit a stored program of those types.

13.6.5.8 WHILE Syntax

```
[begin_label:] WHILE search_condition DO
  statement_list
END WHILE [end_label]
```

The statement list within a `WHILE` statement is repeated as long as the `search_condition` expression is true. `statement_list` consists of one or more SQL statements, each terminated by a semicolon (`;`) statement delimiter.

A `WHILE` statement can be labeled. For the rules regarding label use, see Section 13.6.2, “Statement Label Syntax”.

Example:

```
CREATE PROCEDURE dowhile()
BEGIN
  DECLARE v1 INT DEFAULT 5;
  WHILE v1 > 0 DO
    ... v1 = v1 - 1;
  END WHILE;
END;
```

13.6.6 Cursors

MySQL supports cursors inside stored programs. The syntax is as in embedded SQL. Cursors have these properties:

- Asensitive: The server may or may not make a copy of its result table
- Read only: Not updatable
- Nonscrollable: Can be traversed only in one direction and cannot skip rows

Cursor declarations must appear before handler declarations and after variable and condition declarations.

Example:

```
CREATE PROCEDURE curdemo()
BEGIN
  DECLARE done INT DEFAULT FALSE;
  DECLARE a CHAR(16);
```
DECLARE b, c INT;
DECLARE cur1 CURSOR FOR SELECT id, data FROM test.t1;
DECLARE cur2 CURSOR FOR SELECT i FROM test.t2;
DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = TRUE;

OPEN cur1;
OPEN cur2;

read_loop: LOOP
  FETCH cur1 INTO a, b;
  FETCH cur2 INTO c;
  IF done THEN
    LEAVE read_loop;
  END IF;
  IF b < c THEN
    INSERT INTO test.t3 VALUES (a, b);
  ELSE
    INSERT INTO test.t3 VALUES (a, c);
  END IF;
END LOOP;

CLOSE cur1;
CLOSE cur2;
END;

13.6.6.1 Cursor CLOSE Syntax

CLOSE cursor_name

This statement closes a previously opened cursor. For an example, see Section 13.6.6, “Cursors”.

An error occurs if the cursor is not open.

If not closed explicitly, a cursor is closed at the end of the BEGIN ... END block in which it was declared.

13.6.6.2 Cursor DECLARE Syntax

DECLARE cursor_name CURSOR FOR select_statement

This statement declares a cursor and associates it with a SELECT statement that retrieves the rows to be traversed by the cursor. To fetch the rows later, use a FETCH statement. The number of columns retrieved by the SELECT statement must match the number of output variables specified in the FETCH statement.

The SELECT statement cannot have an INTO clause.

Cursor declarations must appear before handler declarations and after variable and condition declarations.

A stored program may contain multiple cursor declarations, but each cursor declared in a given block must have a unique name. For an example, see Section 13.6.6, “Cursors”.

For information available through SHOW statements, it is possible in many cases to obtain equivalent information by using a cursor with an INFORMATION_SCHEMA table.

13.6.6.3 Cursor FETCH Syntax

FETCH [[NEXT FROM] cursor_name INTO var_name [, var_name] ...]

This statement fetches the next row for the SELECT statement associated with the specified cursor (which must be open), and advances the cursor pointer. If a row exists, the fetched columns are stored
in the named variables. The number of columns retrieved by the `SELECT` statement must match the
number of output variables specified in the `FETCH` statement.

If no more rows are available, a No Data condition occurs with SQLSTATE value '02000'. To detect
this condition, you can set up a handler for it (or for a `NOT FOUND` condition). For an example, see
Section 13.6.6, “Cursors”.

13.6.6.4 Cursor OPEN Syntax

```
OPEN cursor_name
```

This statement opens a previously declared cursor. For an example, see Section 13.6.6, “Cursors”.

13.6.7 Condition Handling

Conditions may arise during stored program execution that require special handling, such as exiting the
current program block or continuing execution. Handlers can be defined for general conditions such as
warnings or exceptions, or for specific conditions such as a particular error code. Specific conditions
can be assigned names and referred to that way in handlers.

To name a condition, use the `DECLARE ... CONDITION` statement. To declare a handler, use the
`DECLARE ... HANDLER` statement. See Section 13.6.7.1, “DECLARE ... CONDITION Syntax”, and
Section 13.6.7.2, “DECLARE ... HANDLER Syntax”.

Other statements related to conditions are `SIGNAL`, `RESIGNAL`, and `GET DIAGNOSTICS`. The `SIGNAL`
and `RESIGNAL` statements are not supported until MySQL 5.5. The `GET DIAGNOSTICS` statement is
not supported until MySQL 5.6.

Before MySQL 5.6.3, if a statement that generates a warning or error causes a condition handler to
be invoked, the handler may not clear the diagnostic area. This might lead to the appearance that the
handler was not invoked. The following discussion demonstrates the issue and provides a workaround.

Suppose that a table `t1` is empty. The following procedure selects from it, raising a No Data condition:

```
CREATE PROCEDURE p1()
BEGIN
    DECLARE a INT;
    DECLARE CONTINUE HANDLER FOR NOT FOUND
    BEGIN
        SET @handler_invoked = 1;
    END;
    SELECT c1 INTO a FROM t1;
END;
```

As can be seen from the following sequence of statements, the condition is not cleared by handler
invocation (otherwise, the `SHOW WARNINGS` output would be empty). But as can be seen by the value
of `@handler_invoked`, the handler was indeed invoked (otherwise its value would be 0).

```
mysql> SET @handler_invoked = 0;
Query OK, 0 rows affected (0.00 sec)

mysql> CALL p1();
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+---------+------+-----------------------------------------------------+
| Level   | Code | Message                                             |
+---------+------+-----------------------------------------------------+
| Warning | 1329 | No data - zero rows fetched, selected, or processed |
+---------+------+-----------------------------------------------------+
1 row in set (0.00 sec)
```
There are two ways to work around this issue:

- Add an extra dummy statement that clears warnings at the end of the condition handler:

```sql
CREATE PROCEDURE p1()
BEGIN
    DECLARE a INT;
    DECLARE CONTINUE HANDLER FOR NOT FOUND
    BEGIN
        SET @handler_invoked = 1;
        SELECT 1 FROM (SELECT 1) AS t;
        END;
    SELECT c1 INTO a FROM t1;
END;
```

This works for **CONTINUE** and **EXIT** handlers.

- Put an extra dummy statement that clears warnings following the statement that causes handler activation:

```sql
CREATE PROCEDURE p1()
BEGIN
    DECLARE a INT;
    DECLARE CONTINUE HANDLER FOR NOT FOUND
    BEGIN
        SET @handler_invoked = 1;
        SELECT 1 FROM (SELECT 1) AS t;
        END;
    SELECT c1 INTO a FROM t1;
END;
```

This works only for **CONTINUE** handlers.

This issue is resolved as of MySQL 5.6.3 and no workaround is needed.

### 13.6.7.1 DECLARE ... CONDITION Syntax

```
DECLARE condition_name CONDITION FOR condition_value
```

<table>
<thead>
<tr>
<th>condition_value:</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql_error_code</td>
</tr>
<tr>
<td>SQLSTATE [VALUE] sqlstate_value</td>
</tr>
</tbody>
</table>

The **DECLARE ... CONDITION** statement declares a named error condition, associating a name with a condition that needs specific handling. The name can be referred to in a subsequent **DECLARE ... HANDLER** statement (see Section 13.6.7.2, “DECLARE ... HANDLER Syntax”).

Condition declarations must appear before cursor or handler declarations.

The **condition_value** for **DECLARE ... CONDITION** indicates the specific condition or class of conditions to associate with the condition name. It can take the following forms:

- **mysql_error_code**: An integer literal indicating a MySQL error code, such as 1051 to specify “unknown table”: 
DECLARE CONTINUE HANDLER FOR 1051
    BEGIN
        -- body of handler
    END;

Do not use MySQL error code 0 because that indicates success rather than an error condition. For a list of MySQL error codes, see Section B.3, “Server Error Codes and Messages”.

- **SQLSTATE [VALUE]** sqlstate_value: A 5-character string literal indicating an SQLSTATE value, such as '42S01' to specify “unknown table”:

```
DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
    BEGIN
        -- body of handler
    END;
```

Do not use SQLSTATE values that begin with '00' because those indicate success rather than an error condition. For a list of SQLSTATE values, see Section B.3, “Server Error Codes and Messages”.

Using names for conditions can help make stored program code clearer. For example, this handler applies to attempts to drop a nonexistent table, but that is apparent only if you know that 1051 is the MySQL error code for “unknown table”:

```
DECLARE CONTINUE HANDLER FOR 1051
    BEGIN
        -- body of handler
    END;
```

By declaring a name for the condition, the purpose of the handler is more readily seen:

```
DECLARE no_such_table CONDITION FOR 1051;
DECLARE CONTINUE HANDLER FOR no_such_table
    BEGIN
        -- body of handler
    END;
```

Here is a named condition for the same condition, but based on the corresponding SQLSTATE value rather than the MySQL error code:

```
DECLARE no_such_table CONDITION FOR SQLSTATE '42S02';
DECLARE CONTINUE HANDLER FOR no_such_table
    BEGIN
        -- body of handler
    END;
```

### 13.6.7.2 DECLARE ... HANDLER Syntax

```
DECLARE handler_action HANDLER
    FOR condition_value [, condition_value] ...
    statement

handler_action:
    CONTINUE
    | EXIT
    | UNDO

condition_value:
    mysql_error_code
    | SQLSTATE [VALUE] sqlstate_value
    | condition_name
    | SQLWARNING
    | NOT FOUND
```
The `DECLARE ... HANDLER` statement specifies a handler that deals with one or more conditions. If one of these conditions occurs, the specified statement executes. The statement can be a simple statement such as `SET var_name = value`, or a compound statement written using `BEGIN` and `END` (see Section 13.6.1, “BEGIN ... END Compound-Statement Syntax”).

Handler declarations must appear after variable or condition declarations.

The `handler_action` value indicates what action the handler takes after execution of the handler statement:

- **CONTINUE**: Execution of the current program continues.
- **EXIT**: Execution terminates for the `BEGIN ... END` compound statement in which the handler is declared. This is true even if the condition occurs in an inner block.
- **UNDO**: Not supported.

The `condition_value` for `DECLARE ... HANDLER` indicates the specific condition or class of conditions that activates the handler. It can take the following forms:

- **mysql_error_code**: An integer literal indicating a MySQL error code.
  
  Do not use MySQL error code 0 because that indicates success rather than an error condition. For a list of MySQL error codes, see Section B.3, “Server Error Codes and Messages”.

- **SQLSTATE [VALUE] sqlstate_value**: A 5-character string literal indicating an SQLSTATE value.
  
  Do not use SQLSTATE values that begin with '00' because those indicate success rather than an error condition. For a list of SQLSTATE values, see Section B.3, “Server Error Codes and Messages”.

- **condition_name**: A condition name previously specified with `DECLARE ... CONDITION`. A condition name can be associated with a MySQL error code or SQLSTATE value. See Section 13.6.7.1, “DECLARE ... CONDITION Syntax”.

- **SQLWARNING**: Shorthand for the class of SQLSTATE values that begin with '01'.

```
DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
BEGIN
  -- body of handler
END;
```

- **NOT FOUND**: Shorthand for the class of SQLSTATE values that begin with '02'. This is relevant within the context of cursors and is used to control what happens when a cursor reaches the end of a data set. If no more rows are available, a No Data condition occurs with SQLSTATE value '02000'. To detect this condition, you can set up a handler for it or for a `NOT FOUND` condition.

```
DECLARE CONTINUE HANDLER FOR NOT FOUND
BEGIN
  -- body of handler
END;
```

For another example, see Section 13.6.6, “Cursors”. The `NOT FOUND` condition also occurs for `SELECT ... INTO var_list` statements that retrieve no rows.

- **SQLEXCEPTION**: Shorthand for the class of SQLSTATE values that do not begin with '00', '01', or '02'.

```
DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
```
If a condition occurs for which no handler has been declared, the action taken depends on the condition class:

- For `SQLEXCEPTION` conditions, the stored program terminates at the statement that raised the condition, as if there were an `EXIT` handler. If the program was called by another stored program, the calling program handles the condition using the handler selection rules applied to its own handlers.

- For `SQLWARNING` or `NOT FOUND` conditions, the program continues executing, as if there were a `CONTINUE` handler.

The following example uses a handler for SQLSTATE '23000', which occurs for a duplicate-key error:

```sql
mysql> CREATE TABLE test.t (s1 INT, PRIMARY KEY (s1));
Query OK, 0 rows affected (0.00 sec)
mysql> delimiter //
mysql> CREATE PROCEDURE handlerdemo ()
-> BEGIN
-> DECLARE CONTINUE HANDLER FOR SQLSTATE '23000' SET @x2 = 1;
-> SET @x = 1;
-> INSERT INTO test.t VALUES (1);
-> SET @x = 2;
-> INSERT INTO test.t VALUES (1);
-> SET @x = 3;
-> END;
-> //
Query OK, 0 rows affected (0.00 sec)
mysql> CALL handlerdemo();
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT @x //
+------+
| @x   |
+------+
| 3    |
+------+
1 row in set (0.00 sec)
```

Notice that `@x` is 3 after the procedure executes, which shows that execution continued to the end of the procedure after the error occurred. If the `DECLARE ... HANDLER` statement had not been present, MySQL would have taken the default action (EXIT) after the second `INSERT` failed due to the `PRIMARY KEY` constraint, and `SELECT @x` would have returned 2.

To ignore a condition, declare a `CONTINUE` handler for it and associate it with an empty block. For example:

```
DECLARE CONTINUE HANDLER FOR SQLWARNING BEGIN END;
```

The scope of a block label does not include the code for handlers declared within the block. Therefore, the statement associated with a handler cannot use `ITERATE` or `LEAVE` to refer to labels for blocks that enclose the handler declaration. Consider the following example, where the `REPEAT` block has a label of `retry`:

```
CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 3;
  retry:
```
REPEAT
  BEGIN
    DECLARE CONTINUE HANDLER FOR SQLWARNING BEGIN
      ITERATE retry;   # illegal
    END;
    IF i < 0 THEN
      LEAVE retry;     # legal
    END IF;
    SET i = i - 1;
  END;
UNTIL FALSE END REPEAT;

The retry label is in scope for the IF statement within the block. It is not in scope for the CONTINUE handler, so the reference there is invalid and results in an error:

ERROR 1308 (42000): LEAVE with no matching label: retry

To avoid references to outer labels in handlers, use one of these strategies:

- To leave the block, use an EXIT handler. If no block cleanup is required, the BEGIN ... END handler body can be empty:

  DECLARE EXIT HANDLER FOR SQLWARNING BEGIN END;

Otherwise, put the cleanup statements in the handler body:

  DECLARE EXIT HANDLER FOR SQLWARNING
  BEGIN
    block cleanup statements
  END;

- To continue execution, set a status variable in a CONTINUE handler that can be checked in the enclosing block to determine whether the handler was invoked. The following example uses the variable done for this purpose:

  CREATE PROCEDURE p ()
  BEGIN
    DECLARE i INT DEFAULT 3;
    DECLARE done INT DEFAULT FALSE;
    retry:
    REPEAT
      BEGIN
        DECLARE CONTINUE HANDLER FOR SQLWARNING BEGIN
          SET done = TRUE;
        END;
        IF done OR i < 0 THEN
          LEAVE retry;
        END IF;
        SET i = i - 1;
      END;
    UNTIL FALSE END REPEAT;
  END;

13.7 Database Administration Statements

13.7.1 Account Management Statements

MySQL account information is stored in the tables of the mysql database. This database and the access control system are discussed extensively in Chapter 5, MySQL Server Administration, which you should consult for additional details.
Important

Some releases of MySQL introduce changes to the structure of the grant tables to add new privileges or features. To ensure that you can take advantage of any new capabilities, update your grant tables to have the current structure whenever you update to a new version of MySQL. See Section 4.4.8, “mysql_upgrade — Check and Upgrade MySQL Tables”.

In MySQL 5.1 and later, when the read_only system variable is enabled, account-management statements require the SUPER privilege, in addition to any other required privileges. This is because they modify tables in the mysql database.

13.7.1.1 CREATE USER Syntax

```
CREATE USER user_specification [, user_specification] ...

user_specification:
    user [ identified_option ]

identified_option: {
    IDENTIFIED BY 'auth_string'
    | IDENTIFIED BY PASSWORD 'hash_string'
}
```

The CREATE USER statement creates new MySQL accounts. An error occurs if you try to create an account that already exists.

To use CREATE USER, you must have the global CREATE USER privilege or the INSERT privilege for the mysql database. In MySQL 5.1 and later, when the read_only system variable is enabled, CREATE USER additionally requires the SUPER privilege.

For each account, CREATE USER creates a new row in the mysql.user table with no privileges. Depending on the syntax used, CREATE USER may also assign the account a password.

Each user_specification clause consists of an account name and information about how authentication occurs for clients that use the account. This part of CREATE USER syntax is shared with GRANT, so the description here applies to GRANT as well.

Each account name uses the format described in Section 6.2.3, “Specifying Account Names”. For example:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'mypass';
```

If you specify only the user name part of the account name, a host name part of '%' is used.

CREATE USER examples:

- To enable the user to connect with no password, include no IDENTIFIED BY clause:

```
CREATE USER 'jeffrey'@'localhost';
```

- To assign a password, use IDENTIFIED BY with the literal cleartext password value:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'mypass';
```

- To avoid specifying the cleartext password if you know its hash value (the value that PASSWORD() would return for the password), specify the hash value preceded by the keyword PASSWORD:

```
CREATE USER 'jeffrey'@'localhost'
```
Identified by password '*90E462C37378CED12064BB3388B27D2BA3A9B689';

For additional information about setting passwords, see Section 6.3.5, "Assigning Account Passwords".

Important

CREATE USER may be recorded in server logs or on the client side in a history file such as ~/.mysql_history, which means that cleartext passwords may be read by anyone having read access to that information. For information about password logging in the server logs, see Section 6.1.2.3, "Passwords and Logging". For similar information about client-side logging, see Section 4.5.1.3, "mysql Logging".

13.7.1.2 DROP USER Syntax

DROP USER user [, user] ...

The DROP USER statement removes one or more MySQL accounts and their privileges. It removes privilege rows for the account from all grant tables. An error occurs for accounts that do not exist.

To use DROP USER, you must have the global CREATE USER privilege or the DELETE privilege for the mysql database. In MySQL 5.1 and later, when the read_only system variable is enabled, DROP USER additionally requires the SUPER privilege.

Each account name uses the format described in Section 6.2.3, "Specifying Account Names". For example:

DROP USER 'jeffrey'@'localhost';

If you specify only the user name part of the account name, a host name part of '%' is used.

Important

DROP USER does not automatically close any open user sessions. Rather, in the event that a user with an open session is dropped, the statement does not take effect until that user's session is closed. Once the session is closed, the user is dropped, and that user's next attempt to log in will fail. This is by design.

DROP USER does not automatically drop or invalidate databases or objects within them that the old user created. This includes stored programs or views for which the DEFINER attribute names the dropped user. Attempts to access such objects may produce an error if they execute in definer security context. (For information about security context, see Section 19.6, "Access Control for Stored Programs and Views".)

13.7.1.3 GRANT Syntax

GRANT

priv_type [{column_list}]
    [, priv_type [{column_list}]] ...
ON [object_type] priv_level
TO user_specification [, user_specification] ...
[REQUIRE {NONE | tls_option [[AND] tls_option] ...}]
[WITH {GRANT OPTION | resource_option} ...]

object_type: {
    TABLE
    | FUNCTION
    | PROCEDURE
}

priv_level: {
    *
}
The `GRANT` statement grants privileges to MySQL user accounts. `GRANT` also serves to specify other account characteristics such as use of secure connections and limits on access to server resources.

To use `GRANT`, you must have the `GRANT OPTION` privilege, and you must have the privileges that you are granting. In MySQL 5.1 and later, when the `read_only` system variable is enabled, `GRANT` additionally requires the `SUPER` privilege.

The `REVOKE` statement is related to `GRANT` and enables administrators to remove account privileges. See Section 13.7.1.5, “REVOKE Syntax”.

Normally, a database administrator first uses `CREATE USER` to create an account, then `GRANT` to define its privileges and characteristics. For example:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'mypass';
GRANT ALL ON db1.* TO 'jeffrey'@'localhost';
GRANT SELECT ON db2.invoice TO 'jeffrey'@'localhost';
GRANT USAGE ON *.* TO 'jeffrey'@'localhost' WITH MAX_QUERIES_PER_HOUR 90;
```

Note

Examples shown here include no `IDENTIFIED` clause. It is assumed that you establish passwords with `CREATE USER` at account-creation time to avoid creating insecure accounts.

If an account named in a `GRANT` statement does not already exist, `GRANT` may create it under the conditions described later in the discussion of the `NO_AUTO_CREATE_USER` SQL mode.

From the `mysql` program, `GRANT` responds with `Query OK, 0 rows affected` when executed successfully. To determine what privileges result from the operation, use `SHOW GRANTS`. See Section 13.7.5.22, “SHOW GRANTS Syntax”.

There are several aspects to the `GRANT` statement, described under the following topics in this section:

- Privileges Supported by MySQL
- Global Privileges
Account Management Statements

- Database Privileges
- Table Privileges
- Column Privileges
- Stored Routine Privileges
- Account Names and Passwords
- Implicit Account Creation
- Other Account Characteristics
- MySQL and Standard SQL Versions of GRANT

GRANT supports host names up to 60 characters long. Database, table, column, and routine names can be up to 64 characters. User names can be up to 16 characters.

**Warning**

The permissible length for user names cannot be changed by altering the `mysql.user` table. Attempting to do so results in unpredictable behavior which may even make it impossible for users to log in to the MySQL server. You should never alter the structure of tables in the `mysql` database in any manner whatsoever except by means of the procedure described in Section 4.4.8, "mysql_upgrade — Check and Upgrade MySQL Tables".

**Important**

GRANT may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about password logging in the server logs, see Section 6.1.2.3, “Passwords and Logging”. For similar information about client-side logging, see Section 4.5.1.3, “mysql Logging”.

**Privileges Supported by MySQL**

The following table summarizes the permissible `priv_type` privilege types that can be specified for the GRANT and REVOKE statements, and the levels at which each privilege can be granted. For additional information about these privileges, see Section 6.2.1, “Privileges Provided by MySQL”.

**Table 13.2 Permissible Privileges for GRANT and REVOKE**

<table>
<thead>
<tr>
<th>Privilege</th>
<th>Meaning and Grantable Levels</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL [PRIVILEGES]</td>
<td>Grant all privileges at specified access level except GRANT OPTION</td>
</tr>
<tr>
<td>ALTER</td>
<td>Enable use of ALTER TABLE. Levels: Global, database, table.</td>
</tr>
<tr>
<td>ALTER ROUTINE</td>
<td>Enable stored routines to be altered or dropped. Levels: Global, database, procedure.</td>
</tr>
<tr>
<td>CREATE</td>
<td>Enable database and table creation. Levels: Global, database, table.</td>
</tr>
<tr>
<td>CREATE ROUTINE</td>
<td>Enable stored routine creation. Levels: Global, database.</td>
</tr>
<tr>
<td>CREATE TEMPORARY TABLES</td>
<td>Enable use of CREATE TEMPORARY TABLE. Levels: Global, database.</td>
</tr>
<tr>
<td>CREATE USER</td>
<td>Enable use of CREATE USER, DROP USER, RENAME USER, and REVOKE ALL PRIVILEGES. Level: Global.</td>
</tr>
<tr>
<td>CREATE VIEW</td>
<td>Enable views to be created or altered. Levels: Global, database, table.</td>
</tr>
<tr>
<td>DELETE</td>
<td>Enable use of DELETE. Level: Global, database, table.</td>
</tr>
<tr>
<td>Privilege</td>
<td>Meaning and Grantable Levels</td>
</tr>
<tr>
<td>-----------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>DROP</td>
<td>Enable databases, tables, and views to be dropped. Levels: Global, database, table.</td>
</tr>
<tr>
<td>EVENT</td>
<td>Enable use of events for the Event Scheduler. Levels: Global, database.</td>
</tr>
<tr>
<td>EXECUTE</td>
<td>Enable the user to execute stored routines. Levels: Global, database, table.</td>
</tr>
<tr>
<td>FILE</td>
<td>Enable the user to cause the server to read or write files. Level: Global.</td>
</tr>
<tr>
<td>GRANT OPTION</td>
<td>Enable privileges to be granted to or removed from other accounts. Levels: Global, database, table, procedure.</td>
</tr>
<tr>
<td>INDEX</td>
<td>Enable indexes to be created or dropped. Levels: Global, database, table.</td>
</tr>
<tr>
<td>INSERT</td>
<td>Enable use of INSERT. Levels: Global, database, table, column.</td>
</tr>
<tr>
<td>LOCK TABLES</td>
<td>Enable use of LOCK TABLES on tables for which you have the SELECT privilege. Levels: Global, database.</td>
</tr>
<tr>
<td>PROCESS</td>
<td>Enable the user to see all processes with SHOW PROCESSLIST. Level: Global.</td>
</tr>
<tr>
<td>REFERENCES</td>
<td>Not implemented</td>
</tr>
<tr>
<td>RELOAD</td>
<td>Enable use of FLUSH operations. Level: Global.</td>
</tr>
<tr>
<td>REPLICATION CLIENT</td>
<td>Enable the user to ask where master or slave servers are. Level: Global.</td>
</tr>
<tr>
<td>REPLICATION SLAVE</td>
<td>Enable replication slaves to read binary log events from the master. Level: Global.</td>
</tr>
<tr>
<td>SELECT</td>
<td>Enable use of SELECT. Levels: Global, database, table, column.</td>
</tr>
<tr>
<td>SHOW DATABASES</td>
<td>Enable SHOW DATABASES to show all databases. Level: Global.</td>
</tr>
<tr>
<td>SHOW VIEW</td>
<td>Enable use of SHOW CREATE VIEW. Levels: Global, database, table.</td>
</tr>
<tr>
<td>SHUTDOWN</td>
<td>Enable use of mysqladmin shutdown. Level: Global.</td>
</tr>
<tr>
<td>SUPER</td>
<td>Enable use of other administrative operations such as CHANGE MASTER TO, KILL, PURGE BINARY LOGS, SET GLOBAL, and mysqladmin debug command. Level: Global.</td>
</tr>
<tr>
<td>TRIGGER</td>
<td>Enable trigger operations. Levels: Global, database, table.</td>
</tr>
<tr>
<td>UPDATE</td>
<td>Enable use of UPDATE. Levels: Global, database, table, column.</td>
</tr>
<tr>
<td>USAGE</td>
<td>Synonym for “no privileges”</td>
</tr>
</tbody>
</table>

The EVENT and TRIGGER privileges were added in MySQL 5.1.6. A trigger is associated with a table, so to create or drop a trigger, you must have the TRIGGER privilege for the table, not the trigger. (Before MySQL 5.1.6, the SUPER privilege was required to create or drop triggers.)

In GRANT statements, the ALL [PRIVILEGES] privilege is named by itself and cannot be specified along with other privileges. It stands for all privileges available for the level at which privileges are to be granted except for the GRANT OPTION privilege.

USAGE can be specified to create a user that has no privileges, or to specify the REQUIRE or WITH clauses for an account without changing its existing privileges.

MySQL account information is stored in the tables of the mysql database. For additional details, consult Section 6.2, "The MySQL Access Privilege System", which discusses the mysql database and the access control system extensively.

If the grant tables hold privilege rows that contain mixed-case database or table names and the lower_case_table_names system variable is set to a nonzero value, REVOKE cannot be used to
revoke these privileges. It will be necessary to manipulate the grant tables directly. (GRANT will not create such rows when lower_case_table_names is set, but such rows might have been created prior to setting that variable.)

Privileges can be granted at several levels, depending on the syntax used for the ON clause. For REVOKE, the same ON syntax specifies which privileges to remove.

For the global, database, table, and routine levels, GRANT ALL assigns only the privileges that exist at the level you are granting. For example, GRANT ALL ON db_name.* is a database-level statement, so it does not grant any global-only privileges such as FILE. Granting ALL does not assign the GRANT OPTION privilege.

The object_type clause, if present, should be specified as TABLE, FUNCTION, or PROCEDURE when the following object is a table, a stored function, or a stored procedure.

The privileges for a database, table, column, or routine are formed additively as the logical OR of the privileges at each of the privilege levels. For example, if a user has a global SELECT privilege, the privilege cannot be denied by an absence of the privilege at the database, table, or column level. Details of the privilege-checking procedure are presented in Section 6.2.5, “Access Control, Stage 2: Request Verification”.

If you are using table, column, or routine privileges for even one user, the server examines table, column, and routine privileges for all users and this slows down MySQL a bit. Similarly, if you limit the number of queries, updates, or connections for any users, the server must monitor these values.

MySQL enables you to grant privileges on databases or tables that do not exist. For tables, the privileges to be granted must include the CREATE privilege. This behavior is by design, and is intended to enable the database administrator to prepare user accounts and privileges for databases or tables that are to be created at a later time.

Important

MySQL does not automatically revoke any privileges when you drop a database or table. However, if you drop a routine, any routine-level privileges granted for that routine are revoked.

Global Privileges

Global privileges are administrative or apply to all databases on a given server. To assign global privileges, use ON *.* syntax:

```
GRANT ALL ON *.* TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON *.* TO 'someuser'@'somehost';
```

Before MySQL 5.1.12, privileges also are assigned at the global level if you use ON * syntax and you have not selected a default database. As of 5.1.12, ON * requires a default database and produces an error if there is none.

The CREATE USER, FILE, PROCESS, RELOAD, REPLICATION CLIENT, REPLICATION SLAVE, SHOW DATABASES, SHUTDOWN, and SUPER privileges are administrative and can only be granted globally.

Other privileges can be granted globally or at more specific levels.

MySQL stores global privileges in the mysql.user table.

Database Privileges

Database privileges apply to all objects in a given database. To assign database-level privileges, use ON db_name.* syntax:
Account Management Statements

GRANT ALL ON mydb.* TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON mydb.* TO 'someuser'@'somehost';

If you use `ON *` syntax (rather than `ON *.*`) and you have selected a default database, privileges are assigned at the database level for the default database. An error occurs if there is no default database.

The `CREATE, DROP, EVENT, GRANT OPTION, and LOCK TABLES` privileges can be specified at the database level. Table or routine privileges also can be specified at the database level, in which case they apply to all tables or routines in the database.

MySQL stores database privileges in the `mysql.db` table.

Table Privileges

Table privileges apply to all columns in a given table. To assign table-level privileges, use `ON db_name.tbl_name` syntax:

GRANT ALL ON mydb.mytbl TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON mydb.mytbl TO 'someuser'@'somehost';

If you specify `tbl_name` rather than `db_name.tbl_name`, the statement applies to `tbl_name` in the default database. An error occurs if there is no default database.

The permissible `priv_type` values at the table level are `ALTER, CREATE VIEW, CREATE, DELETE, DROP, GRANT OPTION, INDEX, INSERT, SELECT, SHOW VIEW, TRIGGER, and UPDATE.`

MySQL stores table privileges in the `mysql.tables_priv` table.

Column Privileges

Column privileges apply to single columns in a given table. Each privilege to be granted at the column level must be followed by the column or columns, enclosed within parentheses.

GRANT SELECT (col1), INSERT (col1,col2) ON mydb.mytbl TO 'someuser'@'somehost';

The permissible `priv_type` values for a column (that is, when you use a `column_list` clause) are `INSERT, SELECT, and UPDATE`.

MySQL stores column privileges in the `mysql.columns_priv` table.

Stored Routine Privileges

The `ALTER ROUTINE, CREATE ROUTINE, EXECUTE, and GRANT OPTION` privileges apply to stored routines (procedures and functions). They can be granted at the global and database levels. Except for `CREATE ROUTINE`, these privileges can be granted at the routine level for individual routines.

GRANT CREATE ROUTINE ON mydb.* TO 'someuser'@'somehost';
GRANT EXECUTE ON PROCEDURE mydb.myproc TO 'someuser'@'somehost';

The permissible `priv_type` values at the routine level are `ALTER ROUTINE, EXECUTE, and GRANT OPTION`. `CREATE ROUTINE` is not a routine-level privilege because you must have this privilege to create a routine in the first place.

MySQL stores routine-level privileges in the `mysql.procs_priv` table.

Account Names and Passwords

The `user_specification` clause names a user and optionally provides authentication information such as a password.
The user value indicates the MySQL account to which the GRANT statement applies. To accommodate granting rights to users from arbitrary hosts, MySQL supports specifying the user value in the form user_name@host_name. If a user_name or host_name value is legal as an unquoted identifier, you need not quote it. However, quotation marks are necessary to specify a user_name string containing special characters (such as "-"), or a host_name string containing special characters or wildcard characters (such as "%"); for example, 'test-user'@'%.com'. Quote the user name and host name separately.

You can specify wildcards in the host name. For example, user_name@'%.example.com' applies to user_name for any host in the example.com domain, and user_name@'192.168.1.%' applies to user_name for any host in the 192.168.1 class C subnet.

The simple form user_name is a synonym for user_name@'%'.

MySQL does not support wildcards in user names. To refer to an anonymous user, specify an account with an empty user name with the GRANT statement:

```
GRANT ALL ON test.* TO ''@'localhost' ...;
```

In this case, any user who connects from the local host with the correct password for the anonymous user will be permitted access, with the privileges associated with the anonymous-user account.

For additional information about user name and host name values in account names, see Section 6.2.3, “Specifying Account Names”.

To specify quoted values, quote database, table, column, and routine names as identifiers. Quote user names and host names as identifiers or as strings. Quote passwords as strings. For string-quoting and identifier-quoting guidelines, see Section 9.1.1, “String Literals”, and Section 9.2, “Schema Object Names”.

The "_" and "%" wildcards are permitted when specifying database names in GRANT statements that grant privileges at the global or database levels. This means, for example, that if you want to use a "_" character as part of a database name, you should specify it as "\_" in the GRANT statement, to prevent the user from being able to access additional databases matching the wildcard pattern; for example, GRANT ... ON `foo\_bar`.* TO ....

---

**Warning**

If you permit anonymous users to connect to the MySQL server, you should also grant privileges to all local users as user_name@localhost. Otherwise, the anonymous user account for localhost in the mysql.user table (created during MySQL installation) is used when named users try to log in to the MySQL server from the local machine. For details, see Section 6.2.4, “Access Control, Stage 1: Connection Verification”.

To determine whether the preceding warning applies to you, execute the following query, which lists any anonymous users:

```
SELECT Host, User FROM mysql.user WHERE User='';
```

To avoid the problem just described, delete the local anonymous user account using this statement:

```
DROP USER ''@'localhost';
```

To indicate how a user should authenticate when connecting to the server, the user_specification value may include an IDENTIFIED clause to specify a password. Syntax of the user specification
is the same as for the CREATE USER statement. For details, see Section 13.7.1.1, "CREATE USER Syntax".

When IDENTIFIED BY is present and you have the global grant privilege (GRANT OPTION), the password becomes the new password for the account, even if the account exists and already has a password. Without IDENTIFIED BY, the account password remains unchanged.

If the NO_AUTO_CREATE_USER SQL mode is not enabled and the account named in a GRANT statement does not exist in the mysql.user table, GRANT creates it. If you specify no IDENTIFIED BY clause or provide an empty password, the user has no password. This is very insecure.

If NO_AUTO_CREATE_USER is enabled and the account does not exist, GRANT fails and does not create the account unless the IDENTIFIED BY clause is given to provide a nonempty password.

Other Account Characteristics

MySQL can check X509 certificate attributes in addition to the usual authentication that is based on the user name and credentials. For background information on the use of SSL with MySQL, see Section 6.4, "Using Secure Connections".

The optional REQUIRE clause specifies SSL-related options for a MySQL account, using one or more tls_option values.

Implicit Account Creation

GRANT permits these tls_option values:

- **NONE**
  Indicates that the account has no SSL or X509 requirements. Unencrypted connections are permitted if the user name and password are valid. However, encrypted connections can also be used, at the client's option, if the client has the proper certificate and key files. That is, the client need not specify any SSL command options, in which case the connection will be unencrypted. To use an encrypted connection, the client must specify either the --ssl-ca option, or all three of the --ssl-ca, --ssl-key, and --ssl-cert options.

  NONE is the default if no SSL-related REQUIRE options are specified.

- **SSL**
  Tells the server to permit only encrypted connections for the account.

  ```sql
  GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  REQUIRE SSL;
  ```

  To connect, the client must specify the --ssl-ca option to authenticate the server certificate, and may additionally specify the --ssl-key and --ssl-cert options. If neither the --ssl-ca option nor --ssl-capath option is specified, the client does not authenticate the server certificate.

- **X509**
  Requires that the client must have a valid certificate but the exact certificate, issuer, and subject do not matter. The only requirement is that it should be possible to verify its signature with one of the CA certificates. Use of X509 certificates always implies encryption, so the SSL option is unnecessary in this case.

  ```sql
  GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  REQUIRE X509;
  ```

  The client must specify the --ssl-key and --ssl-cert options to connect. (It is recommended but not required that --ssl-ca also be specified so that the public certificate provided by the server...
Account Management Statements

can be verified.) This is true for **ISSUER** and **SUBJECT** as well because those **REQUIRE** options imply the requirements of **X509**.

- **ISSUER 'issuer'**

Places the restriction on connection attempts that the client must present a valid X509 certificate issued by CA 'issuer'. If the client presents a certificate that is valid but has a different issuer, the server rejects the connection. Use of X509 certificates always implies encryption, so the **SSL** option is unnecessary in this case.

Because **ISSUER** implies the requirements of **X509**, the client must specify the **--ssl-key** and **--ssl-cert** options to connect. (It is recommended but not required that **--ssl-ca** also be specified so that the public certificate provided by the server can be verified.)

```sql
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  REQUIRE ISSUER '/C=SE/ST=Stockholm/L=Stockholm/
  O=MySQL/CN=CA/emailAddress=ca@example.com';
```

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>If MySQL is linked against a version of OpenSSL older than 0.9.6h, use 'Email' rather than 'emailAddress' in the 'issuer' value.</td>
</tr>
</tbody>
</table>

- **SUBJECT 'subject'**

Places the restriction on connection attempts that the client must present a valid X509 certificate containing the subject 'subject'. If the client presents a certificate that is valid but has a different subject, the server rejects the connection. Use of X509 certificates always implies encryption, so the **SSL** option is unnecessary in this case.

Because **SUBJECT** implies the requirements of **X509**, the client must specify the **--ssl-key** and **--ssl-cert** options to connect. (It is recommended but not required that **--ssl-ca** also be specified so that the public certificate provided by the server can be verified.)

```sql
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/
  O=MySQL demo client certificate/
  CN=client/emailAddress=client@example.com';
```

MySQL does a simple string comparison of the 'subject' value to the value in the certificate, so lettercase and component ordering must be given exactly as present in the certificate.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>Regarding 'emailAddress', see the note in the description of <strong>REQUIRE ISSUER</strong>.</td>
</tr>
</tbody>
</table>

- **CIPHER 'cipher'**

Requests a specific cipher method for encrypting connections. This option is needed to ensure that ciphers and key lengths of sufficient strength are used. SSL itself can be weak if old algorithms using short encryption keys are used.

```sql
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  REQUIRE CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

The **SUBJECT**, **ISSUER**, and **CIPHER** options can be combined in the **REQUIRE** clause like this:

```sql
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/
  O=MySQL demo client certificate/;
```
The order of the options does not matter, but no option can be specified twice. The `AND` keyword is optional between `REQUIRE` options.

The optional `WITH` clause is used for these purposes:

- To enable a user to grant privileges to other users
- To specify resource limits for a user

The `WITH GRANT OPTION` clause gives the user the ability to give to other users any privileges the user has at the specified privilege level.

To grant the `GRANT OPTION` privilege to an account without otherwise changing its privileges, do this:

```
GRANT USAGE ON *.* TO 'someuser'@'somehost' WITH GRANT OPTION;
```

Be careful to whom you give the `GRANT OPTION` privilege because two users with different privileges may be able to combine privileges!

You cannot grant another user a privilege which you yourself do not have; the `GRANT OPTION` privilege enables you to assign only those privileges which you yourself possess.

Be aware that when you grant a user the `GRANT OPTION` privilege at a particular privilege level, any privileges the user possesses (or may be given in the future) at that level can also be granted by that user to other users. Suppose that you grant a user the `INSERT` privilege on a database. If you then grant the `SELECT` privilege on the database and specify `WITH GRANT OPTION`, that user can give to other users not only the `SELECT` privilege, but also `INSERT`. If you then grant the `UPDATE` privilege to the user on the database, the user can grant `INSERT`, `SELECT`, and `UPDATE`.

For a nonadministrative user, you should not grant the `ALTER` privilege globally or for the `mysql` database. If you do that, the user can try to subvert the privilege system by renaming tables!

For additional information about security risks associated with particular privileges, see Section 6.2.1, “Privileges Provided by MySQL”.

It is possible to place limits on use of server resources by an account, as discussed in Section 6.3.4, “Setting Account Resource Limits”. To do so, use a `WITH` clause that specifies one or more `resource_option` values. Limits not specified retain their current values.

```
GRANT permits these resource_option values:

- MAX QUERIES PER HOUR count, MAX UPDATES PER HOUR count,
  MAX CONNECTIONS PER HOUR count

These options restrict the number of queries, updates, and connections to the server permitted to this account during any given one-hour period. (Queries for which results are served from the query cache do not count against the MAX QUERIES PER HOUR limit.) If count is 0 (the default), this means that there is no limitation for the account.

- MAX USER CONNECTIONS count

Restricts the maximum number of simultaneous connections to the server by the account. A nonzero count specifies the limit for the account explicitly. If count is 0 (the default), the server determines the number of simultaneous connections for the account from the global value of the max_user_connections system variable. If max_user_connections is also zero, there is no limit for the account.
```
If a given resource limit is specified multiple times, the last instance takes precedence.

To specify resource limits for an existing user without affecting existing privileges, use `GRANT USAGE` at the global level (`ON *.*`) and name the limits to be changed. For example:

```
GRANT USAGE ON *.* TO ... WITH MAX_QUERIES_PER_HOUR 500 MAX_UPDATES_PER_HOUR 100;
```

### MySQL and Standard SQL Versions of GRANT

The biggest differences between the MySQL and standard SQL versions of `GRANT` are:

- MySQL associates privileges with the combination of a host name and user name and not with only a user name.
- Standard SQL does not have global or database-level privileges, nor does it support all the privilege types that MySQL supports.
- MySQL does not support the standard SQL `UNDER` privilege.
- Standard SQL privileges are structured in a hierarchical manner. If you remove a user, all privileges the user has been granted are revoked. This is also true in MySQL if you use `DROP USER`. See Section 13.7.1.2, “DROP USER Syntax”.
- In standard SQL, when you drop a table, all privileges for the table are revoked. In standard SQL, when you revoke a privilege, all privileges that were granted based on that privilege are also revoked. In MySQL, privileges can be dropped only with explicit `DROP USER` or `REVOKE` statements or by manipulating the MySQL grant tables directly.
- In MySQL, it is possible to have the `INSERT` privilege for only some of the columns in a table. In this case, you can still execute `INSERT` statements on the table, provided that you insert values only for those columns for which you have the `INSERT` privilege. The omitted columns are set to their implicit default values if strict SQL mode is not enabled. In strict mode, the statement is rejected if any of the omitted columns have no default value. (Standard SQL requires you to have the `INSERT` privilege on all columns.) For information about strict SQL mode and implicit default values, see Section 5.1.7, “Server SQL Modes”, and Section 11.6, “Data Type Default Values”.

### 13.7.1.4 RENAME USER Syntax

```
RENAME USER old_user TO new_user [, old_user TO new_user] ...
```

The `RENAME USER` statement renames existing MySQL accounts. An error occurs for old accounts that do not exist or new accounts that already exist.

To use `RENAME USER`, you must have the global `CREATE USER` privilege or the `UPDATE` privilege for the `mysql` database. In MySQL 5.1 and later, when the `read_only` system variable is enabled, `RENAME USER` additionally requires the `SUPER` privilege.

Each account name uses the format described in Section 6.2.3, “Specifying Account Names”. For example:

```
RENAME USER 'jeffrey'@'localhost' TO 'jeff'@'127.0.0.1';
```

If you specify only the user name part of the account name, a host name part of `%` is used.

`RENAME USER` causes the privileges held by the old user to be those held by the new user. However, `RENAME USER` does not automatically drop or invalidate databases or objects within them that the old
user created. This includes stored programs or views for which the DEFINER attribute names the old user. Attempts to access such objects may produce an error if they execute in definer security context. (For information about security context, see Section 19.6, “Access Control for Stored Programs and Views”.)

The privilege changes take effect as indicated in Section 6.2.6, “When Privilege Changes Take Effect”.

13.7.1.5 REVOKE Syntax

The REVOKE statement enables system administrators to revoke privileges from MySQL accounts.

In MySQL 5.1 and later, when the read_only system variable is enabled, REVOKE requires the SUPER privilege in addition to any other required privileges described in the following discussion.

Each account name uses the format described in Section 6.2.3, “Specifying Account Names”. For example:

```sql
REVOKE INSERT ON *.* FROM 'jeffrey'@'localhost';
```

If you specify only the user name part of the account name, a host name part of '%' is used.

For details on the levels at which privileges exist, the permissible `priv_type` and `priv_level` values, and the syntax for specifying users and passwords, see Section 13.7.1.3, “GRANT Syntax”.

To use the first REVOKE syntax, you must have the GRANT OPTION privilege, and you must have the privileges that you are revoking.

To revoke all privileges, use the second syntax, which drops all global, database, table, column, and routine privileges for the named user or users:

```sql
REVOKE ALL PRIVILEGES, GRANT OPTION FROM user [, user] ...
```

To use this REVOKE syntax, you must have the global CREATE USER privilege or the UPDATE privilege for the mysql database.

REVOKE removes privileges, but does not drop mysql.user table entries. To remove a user account entirely, use DROP USER (see Section 13.7.1.2, “DROP USER Syntax”) or DELETE.

If the grant tables hold privilege rows that contain mixed-case database or table names and the lower_case_table_names system variable is set to a nonzero value, REVOKE cannot be used to revoke these privileges. It will be necessary to manipulate the grant tables directly. (GRANT will not create such rows when lower_case_table_names is set, but such rows might have been created prior to setting the variable.)

When successfully executed from the mysql program, REVOKE responds with Query OK, 0 rows affected. To determine what privileges result from the operation, use SHOW GRANTS. See Section 13.7.5.22, “SHOW GRANTS Syntax”.

13.7.1.6 SET PASSWORD Syntax
The `SET PASSWORD` statement assigns a password to a MySQL user account, specified as either a cleartext (unencrypted) or encrypted value:

- `'auth_string'` represents a cleartext password.
- `'hash_string'` represents an encrypted password.

`SET PASSWORD` can be used with or without an explicitly named user account:

- With a **FOR** `user` clause, the statement sets the password for the named account, which must exist:

  ```sql
  SET PASSWORD FOR 'jeffrey'@'localhost' = password_option;
  ```

  In this case, you must have the **UPDATE** privilege for the **mysql** database.

- With no **FOR** `user` clause, the statement sets the password for the current user:

  ```sql
  SET PASSWORD = password_option;
  ```

  Any client who connects to the server using a nonanonymous account can change the password for that account. To see which account the server authenticated you as, invoke the `CURRENT_USER()` function:

  ```sql
  SELECT CURRENT_USER();
  ```

In MySQL 5.1 and later, when the `read_only` system variable is enabled, `SET PASSWORD` requires the `SUPER` privilege in addition to any other required privileges.

If a **FOR** `user` clause is given, the account name uses the format described in Section 6.2.3, "Specifying Account Names". The `user` value should be given as `'user_name'@'host_name'`, where `'user_name'` and `'host_name'` are exactly as listed in the `User` and `Host` columns of the account's `mysql.user` table row. If you specify only a user name, a host name of `%` is used. For example, to set the password for an account with `User` and `Host` column values of 'bob' and '%.example.org', write the statement like this:

```sql
SET PASSWORD FOR 'bob'@'%.example.org' = PASSWORD('auth_string');
```

The password can be specified in these ways:

- Using the `PASSWORD()` function

  The `'auth_string'` function argument is the cleartext (unencrypted) password. `PASSWORD()` hashes the password and returns the encrypted password string for storage in the `mysql.user` account row.

  The `PASSWORD()` function hashes the password using the hashing method determined by the value of the `old_passwords` system variable value. For descriptions of the permitted values, see Section 5.1.4, "Server System Variables".

- Using the `OLD_PASSWORD()` function:

  The `OLD_PASSWORD()` function
The 'auth_string' function argument is the cleartext (unencrypted) password. OLD_PASSWORD() hashes the password using pre-4.1 hashing and returns the encrypted password string for storage in the mysql.user account row.

- Using an already encrypted password string

The password is specified as a string literal. It must represent the already encrypted password value, in the hash format required by the authentication method used for the account.

For more information about setting passwords, see Section 6.3.5, “Assigning Account Passwords”.

**Important**

SET PASSWORD may be recorded in server logs or on the client side in a history file such as ~/.mysql_history, which means that cleartext passwords may be read by anyone having read access to that information. For information about password logging in the server logs, see Section 6.1.2.3, “Passwords and Logging”. For similar information about client-side logging, see Section 4.5.1.3, “mysql Logging”.

**Caution**

If you are connecting to a MySQL 4.1 or later server using a pre-4.1 client program, do not change your password without first reading Section 6.1.2.4, “Password Hashing in MySQL”. The default password hashing format changed in MySQL 4.1, and if you change your password, it might be stored using a hashing format that pre-4.1 clients cannot generate, thus preventing you from connecting to the server afterward.

If you are using MySQL Replication, be aware that, currently, a password used by a replication slave as part of a CHANGE MASTER TO statement is effectively limited to 32 characters in length; if the password is longer, any excess characters are truncated. This is not due to any limit imposed by the MySQL Server generally, but rather is an issue specific to MySQL Replication. (For more information, see Bug #43439.)

13.7.2 Table Maintenance Statements

13.7.2.1 ANALYZE TABLE Syntax

```
ANALYZE [NO_WRITE_TO_BINLOG | LOCAL] TABLE
tbl_name [ , tbl_name ] ...  
```

**ANALYZE TABLE** analyzes and stores the key distribution for a table. During the analysis, the table is locked with a read lock for InnoDB and MyISAM. This statement works with InnoDB, NDB, and MyISAM tables. For MyISAM tables, this statement is equivalent to using myisamchk --analyze. This statement does not work with views.

For more information on how the analysis works within InnoDB, see Section 14.6.6.7, “Limits on InnoDB Tables”.

MySQL uses the stored key distribution to decide the order in which tables should be joined when you perform a join on something other than a constant. In addition, key distributions can be used when deciding which indexes to use for a specific table within a query.

This statement requires SELECT and INSERT privileges for the table.

Beginning with MySQL 5.1.27, **ANALYZE TABLE** is also supported for partitioned tables. Also beginning with MySQL 5.1.27, you can use ALTER TABLE ... ANALYZE PARTITION to analyze
one or more partitions; for more information, see Section 13.1.7, “ALTER TABLE Syntax”, and Section 18.3.3, “Maintenance of Partitions”.

**ANALYZE TABLE** returns a result set with the following columns.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table name</td>
</tr>
<tr>
<td>Op</td>
<td><strong>Always analyze</strong></td>
</tr>
<tr>
<td><strong>Msg_type</strong></td>
<td>status, error, info, note, or warning</td>
</tr>
<tr>
<td><strong>Msg_text</strong></td>
<td>An informational message</td>
</tr>
</tbody>
</table>

You can check the stored key distribution with the **SHOW INDEX** statement. See Section 13.7.5.23, “SHOW INDEX Syntax”.

If the table has not changed since the last **ANALYZE TABLE** statement, the table is not analyzed again.

By default, the server writes **ANALYZE TABLE** statements to the binary log so that they replicate to replication slaves. To suppress logging, specify the optional **NO_WRITE_TO_BINLOG** keyword or its alias **LOCAL**.

### 13.7.2.2 BACKUP TABLE Syntax

**BACKUP TABLE** copies to the backup directory the minimum number of table files needed to restore the table, after flushing any buffered changes to disk. The statement works only for **MyISAM** tables; it does not work for views. **BACKUP TABLE** works by copying the table's `.frm` definition and `.MYD` data files. The `.MYI` index file can be rebuilt from those two files. The directory should be specified as a full path name. To restore the table, use **RESTORE TABLE**.

During the backup, a read lock is held for each table, one at time, as they are being backed up. If you want to back up several tables as a snapshot (preventing any of them from being changed during the backup operation), issue a **LOCK TABLES** statement first, to obtain a read lock for all tables in the group.

**BACKUP TABLE** returns a result set with the following columns.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table name</td>
</tr>
<tr>
<td>Op</td>
<td><strong>Always backup</strong></td>
</tr>
<tr>
<td><strong>Msg_type</strong></td>
<td>status, error, info, note, or warning</td>
</tr>
<tr>
<td><strong>Msg_text</strong></td>
<td>An informational message</td>
</tr>
</tbody>
</table>

### 13.7.2.3 CHECK TABLE Syntax

**CHECK TABLE** copies to the backup directory the minimum number of table files needed to restore the table, after flushing any buffered changes to disk. The statement works only for **MyISAM** tables; it does not work for views. **BACKUP TABLE** works by copying the table's `.frm` definition and `.MYD` data files. The `.MYI` index file can be rebuilt from those two files. The directory should be specified as a full path name. To restore the table, use **RESTORE TABLE**.

During the backup, a read lock is held for each table, one at time, as they are being backed up. If you want to back up several tables as a snapshot (preventing any of them from being changed during the backup operation), issue a **LOCK TABLES** statement first, to obtain a read lock for all tables in the group.

**BACKUP TABLE** returns a result set with the following columns.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table name</td>
</tr>
<tr>
<td>Op</td>
<td><strong>Always backup</strong></td>
</tr>
<tr>
<td><strong>Msg_type</strong></td>
<td>status, error, info, note, or warning</td>
</tr>
<tr>
<td><strong>Msg_text</strong></td>
<td>An informational message</td>
</tr>
</tbody>
</table>
CHECK TABLE checks a table or tables for errors. CHECK TABLE works for InnoDB, MyISAM, and ARCHIVE tables. Starting with MySQL 5.1.9, CHECK TABLE is also valid for CSV tables, see Section 14.13, “The CSV Storage Engine”. For MyISAM tables, the key statistics are updated as well.

CHECK TABLE can also check views for problems, such as tables that are referenced in the view definition that no longer exist.

Beginning with MySQL 5.1.27, CHECK TABLE is also supported for partitioned tables. Also beginning with MySQL 5.1.27, you can use ALTER TABLE ... CHECK PARTITION to check one or more partitions; for more information, see Section 13.1.7, “ALTER TABLE Syntax”, and Section 18.3.3, “Maintenance of Partitions”.

Output

CHECK TABLE returns a result set with the following columns.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table name</td>
</tr>
<tr>
<td>Op</td>
<td>Always check</td>
</tr>
<tr>
<td>Msg_type</td>
<td>status, error, info, note, or warning</td>
</tr>
<tr>
<td>Msg_text</td>
<td>An informational message</td>
</tr>
</tbody>
</table>

The statement might produce many rows of information for each checked table. The last row has a Msg_type value of status and the Msg_text normally should be OK. If you don’t get OK, or Table is already up to date for a MyISAM table, you should normally run a repair of the table. See Section 7.6, “MyISAM Table Maintenance and Crash Recovery”. Table is already up to date means that the storage engine for the table indicated that there was no need to check the table.

Checking Version Compatibility

The FOR UPGRADE option checks whether the named tables are compatible with the current version of MySQL. This option was added in MySQL 5.1.7. With FOR UPGRADE, the server checks each table to determine whether there have been any incompatible changes in any of the table’s data types or indexes since the table was created. If not, the check succeeds. Otherwise, if there is a possible incompatibility, the server runs a full check on the table (which might take some time). If the full check succeeds, the server marks the table’s .frm file with the current MySQL version number. Marking the .frm file ensures that further checks for the table with the same version of the server will be fast.

Incompatibilities might occur because the storage format for a data type has changed or because its sort order has changed. Our aim is to avoid these changes, but occasionally they are necessary to correct problems that would be worse than an incompatibility between releases.

FOR UPGRADE discovers these incompatibilities:

- The indexing order for end-space in TEXT columns for InnoDB and MyISAM tables changed between MySQL 4.1 and 5.0.
- The storage method of the new DECIMAL data type changed between MySQL 5.0.3 and 5.0.5.
- As of MySQL 5.1.25, if your table was created by a different version of the MySQL server than the one you are currently running, FOR UPGRADE indicates that the table has an .frm file with an incompatible version. In this case, the result set returned by CHECK TABLE contains a line with a
Msg_type value of error and a Msg_text value of Table upgrade required. Please do "REPAIR TABLE `tbl_name`" to fix it!

- Changes are sometimes made to character sets or collations that require table indexes to be rebuilt. For details about these changes and when FOR_UPGRADE detects them, see Section 2.13.3, “Checking Whether Tables or Indexes Must Be Rebuilt”.

### Checking Data Consistency

The following table shows the other check options that can be given. These options are passed to the storage engine, which may use them or not.

<table>
<thead>
<tr>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>QUICK</td>
<td>Do not scan the rows to check for incorrect links. Applies to InnoDB and MyISAM tables and views.</td>
</tr>
<tr>
<td>FAST</td>
<td>Check only tables that have not been closed properly. Applies only to MyISAM tables and views; ignored for InnoDB.</td>
</tr>
<tr>
<td>CHANGED</td>
<td>Check only tables that have been changed since the last check or that have not been closed properly. Applies only to MyISAM tables and views; ignored for InnoDB.</td>
</tr>
<tr>
<td>MEDIUM</td>
<td>Scan rows to verify that deleted links are valid. This also calculates a key checksum for the rows and verifies this with a calculated checksum for the keys. Applies only to MyISAM tables and views; ignored for InnoDB.</td>
</tr>
<tr>
<td>EXTENDED</td>
<td>Do a full key lookup for all keys for each row. This ensures that the table is 100% consistent, but takes a long time. Applies only to MyISAM tables and views; ignored for InnoDB.</td>
</tr>
</tbody>
</table>

If none of the options QUICK, MEDIUM, or EXTENDED are specified, the default check type for dynamic-format MyISAM tables is MEDIUM. This has the same result as running myisamchk --medium-check tbl_name on the table. The default check type also is MEDIUM for static-format MyISAM tables, unless CHANGED or FAST is specified. In that case, the default is QUICK. The row scan is skipped for CHANGED and FAST because the rows are very seldom corrupted.

You can combine check options, as in the following example that does a quick check on the table to determine whether it was closed properly:

```
CHECK TABLE test_table FAST QUICK;
```

**Note**

CHECK TABLE may change the table if the table is marked as “corrupted” or “not closed properly” but CHECK TABLE does not find any problems in the table. In this case, CHECK TABLE marks the table as okay.

If a table is corrupted, the problem is most likely in the indexes and not in the data part. All of the preceding check types check the indexes thoroughly and should thus find most errors.

If you just want to check a table that you assume is okay, you should use no check options or the QUICK option. The latter should be used when you are in a hurry and can take the very small risk that QUICK does not find an error in the data file. (In most cases, under normal usage, MySQL should find any error in the data file. If this happens, the table is marked as “corrupted” and cannot be used until it is repaired.)

FAST and CHANGED are mostly intended to be used from a script (for example, to be executed from cron) if you want to check tables from time to time. In most cases, FAST is to be preferred over CHANGED. (The only case when it is not preferred is when you suspect that you have found a bug in the MyISAM code.)
EXTENDED is to be used only after you have run a normal check but still get strange errors from a table when MySQL tries to update a row or find a row by key. This is very unlikely if a normal check has succeeded.

Use of CHECK TABLE ... EXTENDED might influence the execution plan generated by the query optimizer.

Some problems reported by CHECK TABLE cannot be corrected automatically:

• Found row where the auto_increment column has the value 0.

   This means that you have a row in the table where the AUTO_INCREMENT index column contains the value 0. (It is possible to create a row where the AUTO_INCREMENT column is 0 by explicitly setting the column to 0 with an UPDATE statement.)

   This is not an error in itself, but could cause trouble if you decide to dump the table and restore it or do an ALTER TABLE on the table. In this case, the AUTO_INCREMENT column changes value according to the rules of AUTO_INCREMENT columns, which could cause problems such as a duplicate-key error.

   To get rid of the warning, execute an UPDATE statement to set the column to some value other than 0.

InnoDB Details

The following notes apply to InnoDB tables:

• If CHECK TABLE encounters errors in InnoDB tables or indexes, it reports an error, and usually marks the index and sometimes marks the table as corrupted, preventing further use of the index or table.

• If CHECK TABLE encounters a corrupt page, the server exits to prevent error propagation (Bug #10132).

• If CHECK TABLE finds the wrong number of entries in a secondary index, it reports an error but does not cause a server exit or prevent access to the file.

• CHECK TABLE surveys the index page structure, then surveys each key entry. It does not validate the key pointer to a clustered record or follow the path for BLOB pointers.

• When an InnoDB table is stored in its own .ibd file in file-per-table mode, the first 3 pages of the .ibd file contain header information rather than table or index data. The CHECK TABLE statement does not detect inconsistencies that affect only the header data. To verify the entire contents of an InnoDB .ibd file, use the innochecksum command.

• When running CHECK TABLE on large InnoDB tables, other threads may be blocked during CHECK TABLE execution. To avoid timeouts, the semaphore wait threshold (600 seconds) is extended by 2 hours (7200 seconds) for CHECK TABLE operations. If InnoDB detects semaphore waits of 240 seconds or more it starts printing InnoDB monitor output to the error log. If a lock request extends beyond the semaphore wait threshold, InnoDB will abort the process. To avoid the possibility of a semaphore wait timeout entirely, you can run CHECK TABLE QUICK instead of CHECK TABLE.

13.7.2.4 CHECKSUM TABLE Syntax

CHECKSUM TABLE tbl_name [, tbl_name] ... [ QUICK | EXTENDED ]

CHECKSUM TABLE reports a table checksum.

This statement is not supported for views. If you run CHECKSUM TABLE against a view, the Checksum column value is always NULL, and a warning is returned.
With **QUICK**, the live table checksum is reported if it is available, or **NULL** otherwise. This is very fast. A live checksum is enabled by specifying the **CHECKSUM=1** table option when you create the table; currently, this is supported only for **MyISAM** tables. See Section 13.1.17, “CREATE TABLE Syntax”.

With **EXTENDED**, the entire table is read row by row and the checksum is calculated. This can be very slow for large tables.

If neither **QUICK** nor **EXTENDED** is specified, MySQL returns a live checksum if the table storage engine supports it and scans the table otherwise.

For a nonexistent table, **CHECKSUM TABLE** returns **NULL** and generates a warning.

In MySQL 5.1, **CHECKSUM TABLE** returns 0 for partitioned tables unless you include the **EXTENDED** option. This issue is resolved in MySQL 5.6. (Bug #11933226, Bug #60681)

The checksum value depends on the table row format. If the row format changes, the checksum also changes. For example, the storage format for **VARCHAR** changed between MySQL 4.1 and 5.0, so if a 4.1 table is upgraded to MySQL 5.0, the checksum value may change.

**Important**

If the checksums for two tables are different, then it is almost certain that the tables are different in some way. However, because the hashing function used by **CHECKSUM TABLE** is not guaranteed to be collision-free, there is a slight chance that two tables which are not identical can produce the same checksum.

### 13.7.2.5 OPTIMIZE TABLE Syntax

```
OPTIMIZE [NO_WRITE_TO_BINLOG | LOCAL] TABLE
  tbl_name [, tbl_name] ...  
```

Reorganizes the physical storage of table data and associated index data, to reduce storage space and improve I/O efficiency when accessing the table. The exact changes made to each table depend on the **storage engine** used by that table. This statement does not work with views.

**Use** **OPTIMIZE TABLE** in these cases, depending on the type of table:

- After doing substantial insert, update, or delete operations on an **InnoDB** table that has its own `.ibd` file because it was created with the **innodb_file_per_table** option enabled. The table and indexes are reorganized, and disk space can be reclaimed for use by the operating system.

- After deleting a large part of a **MyISAM** or **ARCHIVE** table, or making many changes to a **MyISAM** or **ARCHIVE** table with variable-length rows (tables that have **VARCHAR**, **VARBINARY**, **BLOB**, or **TEXT** columns). Deleted rows are maintained in a linked list and subsequent **INSERT** operations reuse old row positions. You can use **OPTIMIZE TABLE** to reclaim the unused space and to defragment the data file. After extensive changes to a table, this statement may also improve performance of statements that use the table, sometimes significantly.

This statement requires **SELECT** and **INSERT** privileges for the table.

Beginning with MySQL 5.1.27, **OPTIMIZE TABLE** is also supported for partitioned tables. For information about using this statement with partitioned tables and table partitions, see Section 18.3.3, “Maintenance of Partitions”.

**OPTIMIZE TABLE** works for **MyISAM**, **InnoDB**, and **ARCHIVE** tables. Beginning with MySQL Cluster NDB 6.3.7, **OPTIMIZE TABLE** is also supported for dynamic columns of in-memory **NDB** tables. It does not work for Disk Data tables. The performance of **OPTIMIZE** on Cluster tables can be tuned by adjusting the value of the **ndb_optimization_delay** system variable, which controls the number of milliseconds to wait between processing batches of rows by **OPTIMIZE TABLE**. For more information, see Section 17.1.6.11, “Previous MySQL Cluster Issues Resolved in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x”.

1371
Beginning with MySQL Cluster NDB 6.3.8, `OPTIMIZE TABLE` can be interrupted by (for example) killing the SQL thread performing the `OPTIMIZE` operation.

By default, `OPTIMIZE TABLE` does not work for tables created using any other storage engine and returns a result indicating this lack of support. You can make `OPTIMIZE TABLE` work for other storage engines by starting `mysql` with the `--skip-new` option. In this case, `OPTIMIZE TABLE` is just mapped to `ALTER TABLE`.

For **MyISAM** tables, `OPTIMIZE TABLE` works as follows:

1. If the table has deleted or split rows, repair the table.
2. If the index pages are not sorted, sort them.
3. If the table's statistics are not up to date (and the repair could not be accomplished by sorting the index), update them.

For **InnoDB** tables, `OPTIMIZE TABLE` is mapped to `ALTER TABLE`, which rebuilds the table to update index statistics and free unused space in the clustered index. Beginning with MySQL 5.1.27, this is displayed in the output of `OPTIMIZE TABLE` when you run it on an InnoDB table, as shown here:

```sql
mysql> OPTIMIZE TABLE foo;
+----------+----------+----------+-------------------------------------------------------------------+
| Table    | Op       | Msg_type | Msg_text                                                          |
+----------+----------+----------+-------------------------------------------------------------------+
| test.foo | optimize | note     | Table does not support optimize, doing recreate + analyze instead |
| test.foo | optimize | status   | OK                                                                |
+----------+----------+----------+-------------------------------------------------------------------+
```

You can make `OPTIMIZE TABLE` work on other storage engines by starting `mysql` `--skip-new` option. In this case, `OPTIMIZE TABLE` is just mapped to `ALTER TABLE`.

`OPTIMIZE TABLE` returns a result set with the following columns.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table name</td>
</tr>
<tr>
<td>Op</td>
<td>Always optimize</td>
</tr>
<tr>
<td>Msg_type</td>
<td>status, error, info, note, or warning</td>
</tr>
<tr>
<td>Msg_text</td>
<td>An informational message</td>
</tr>
</tbody>
</table>

Note that MySQL locks the table during the time `OPTIMIZE TABLE` is running.

By default, the server writes `OPTIMIZE TABLE` statements to the binary log so that they replicate to replication slaves. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

`OPTIMIZE TABLE` does not sort R-tree indexes, such as spatial indexes on `POINT` columns. (Bug #23578)

As of MySQL 5.1.50, `OPTIMIZE TABLE` table catches and throws any errors that occur while copying table statistics from the old file to the newly created file. For example, if the user ID of the owner of the `.frm`, `.MYD`, or `.MYI` file is different from the user ID of the `mysql` process, `OPTIMIZE TABLE` generates a "cannot change ownership of the file" error unless `mysql` is started by the `root` user.

### 13.7.2.6 REPAIR TABLE Syntax

```
REPAIR [NO_WRITE_TO_BINLOG | LOCAL] TABLE
tbl_name [, tbl_name] ...
```
**REPAIR TABLE** repairs a possibly corrupted table. By default, it has the same effect as `myisamchk --recover tbl_name`. `REPAIR TABLE` works for **MyISAM** and for **ARCHIVE** tables. Starting with MySQL 5.1.9, `REPAIR` is also valid for **CSV** tables. See Section 14.5, “The MyISAM Storage Engine”, Section 14.12, “The ARCHIVE Storage Engine”, and Section 14.13, “The CSV Storage Engine”. This statement does not work with views.

This statement requires **SELECT** and **INSERT** privileges for the table.

Beginning with MySQL 5.1.27, **REPAIR TABLE** is also supported for partitioned tables. However, the **USE_FRM** option cannot be used with this statement on a partitioned table.

Also beginning with MySQL 5.1.27, you can use `ALTER TABLE ... REPAIR PARTITION` to repair one or more partitions; for more information, see Section 13.1.7, “ALTER TABLE Syntax”, and Section 18.3.3, “Maintenance of Partitions”.

Normally, you should never have to run **REPAIR TABLE**. However, if disaster strikes, this statement is very likely to get back all your data from a **MyISAM** table. If your tables become corrupted often, you should try to find the reason for it, to eliminate the need to use **REPAIR TABLE**. See Section B.5.3.3, “What to Do If MySQL Keeps Crashing”, and Section 14.5.4, “MyISAM Table Problems”.

---

**Caution**

It is best to make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors. See Chapter 7, *Backup and Recovery*.

**Warning**

If the server crashes during a **REPAIR TABLE** operation, it is essential after restarting it that you immediately execute another **REPAIR TABLE** statement for the table before performing any other operations on it. In the worst case, you might have a new clean index file without information about the data file, and then the next operation you perform could overwrite the data file. This is an unlikely but possible scenario that underscores the value of making a backup first.

**REPAIR TABLE** returns a result set with the following columns.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table name</td>
</tr>
<tr>
<td>Op</td>
<td>Always repair</td>
</tr>
<tr>
<td>Msg_type</td>
<td>status, error, info, note, or warning</td>
</tr>
<tr>
<td>Msg_text</td>
<td>An informational message</td>
</tr>
</tbody>
</table>

The **REPAIR TABLE** statement might produce many rows of information for each repaired table. The last row has a **Msg_type** value of **status** and **Msg_test** normally should be **OK**. If you do not get **OK** for a **MyISAM** table, you should try repairing it with `myisamchk --safe-recover`. (**REPAIR TABLE** does not implement all the options of `myisamchk`.) With `myisamchk --safe-recover`, you can also use options that **REPAIR TABLE** does not support, such as `--max-record-length`.

If you use the **QUICK** option, **REPAIR TABLE** tries to repair only the index file, and not the data file. This type of repair is like that done by `myisamchk --recover --quick`.

If you use the **EXTENDED** option, MySQL creates the index row by row instead of creating one index at a time with sorting. This type of repair is like that done by `myisamchk --safe-recover`.
The **USE_FRM** option is available for use if the **.MYI** index file is missing or if its header is corrupted. This option tells MySQL not to trust the information in the **.MYI** file header and to re-create it using information from the **.frm** file. This kind of repair cannot be done with **myisamchk**.

**Note**

Use the **USE_FRM** option only if you cannot use regular **REPAIR** modes! Telling the server to ignore the **.MYI** file makes important table metadata stored in the **.MYI** unavailable to the repair process, which can have deleterious consequences:

- The current **AUTO_INCREMENT** value is lost.
- The link to deleted records in the table is lost, which means that free space for deleted records will remain unoccupied thereafter.
- The **.MYI** header indicates whether the table is compressed. If the server ignores this information, it cannot tell that a table is compressed and repair can cause change or loss of table contents. This means that **USE_FRM** should not be used with compressed tables. That should not be necessary, anyway: Compressed tables are read only, so they should not become corrupt.

**Caution**

As of MySQL 5.1.25, if you use **USE_FRM** for a table that was created by a different version of the MySQL server than the one you are currently running, **REPAIR TABLE** will not attempt to repair the table. In this case, the result set returned by **REPAIR TABLE** contains a line with a **Msg_type** value of **error** and a **Msg_text** value of **Failed repairing incompatible .FRM file**.

Prior to MySQL 5.1.25, **do not use **USE_FRM** if your table was created by a different version of the MySQL server. Doing so risks the loss of all rows in the table. It is particularly dangerous to use **USE_FRM** after the server returns this message:

```sql
Table upgrade required. Please do
"REPAIR TABLE `tbl_name`"
or dump/reload to fix it!
```

If **USE_FRM** is not used, **REPAIR TABLE** checks the table to see whether an upgrade is required. If so, it performs the upgrade, following the same rules as **CHECK TABLE ... FOR UPGRADE**. See Section 13.7.2.3, “CHECK TABLE Syntax”, for more information. As of MySQL 5.1.25, **REPAIR TABLE** without **USE_FRM** upgrades the **.frm** file to the current version.

By default, the server writes **REPAIR TABLE** statements to the binary log so that they replicate to replication slaves. To suppress logging, specify the optional **NO_WRITE_TO_BINLOG** keyword or its alias **LOCAL**.

**Important**

In the event that a table on the master becomes corrupted and you run **REPAIR TABLE** on it, any resulting changes to the original table are not propagated to slaves.

You may be able to increase **REPAIR TABLE** performance by setting certain system variables. See Section 8.5.3, “Speed of REPAIR TABLE Statements”.

As of MySQL 5.1.50, **REPAIR TABLE** table catches and throws any errors that occur while copying table statistics from the old corrupted file to the newly created file. For example, if the user ID of the owner of the **.frm**, **.MYD**, or **.MYI** file is different from the user ID of the **mysql** process, **REPAIR**
TABLE generates a "cannot change ownership of the file" error unless mysql is started by the root user.

13.7.2.7 RESTORE TABLE Syntax

```
RESTORE TABLE tbl_name [, tbl_name] ... FROM '/path/to/backup/directory'
```

Note
This statement is deprecated and is removed in MySQL 5.5.

RESTORE TABLE restores the table or tables from a backup that was made with BACKUP TABLE. The directory should be specified as a full path name.

Existing tables are not overwritten; if you try to restore over an existing table, an error occurs. Just as for BACKUP TABLE, RESTORE TABLE currently works only for MyISAM tables. Restored tables are not replicated from master to slave. If there is an existing view of the same name, the view is overwritten (views cannot be backed up using BACKUP TABLE).

The backup for each table consists of its .frm format file and .MYD data file. The restore operation restores those files, and then uses them to rebuild the .MYI index file. Restoring takes longer than backing up due to the need to rebuild the indexes. The more indexes the table has, the longer it takes.

RESTORE TABLE returns a result set with the following columns.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table name</td>
</tr>
<tr>
<td>Op</td>
<td>Always restore</td>
</tr>
<tr>
<td>Msg_type</td>
<td>status, error, info, note, or warning</td>
</tr>
<tr>
<td>Msg_text</td>
<td>An informational message</td>
</tr>
</tbody>
</table>

13.7.3 Plugin and User-Defined Function Statements

13.7.3.1 CREATE FUNCTION Syntax for User-Defined Functions

```
CREATE [AGGREGATE] FUNCTION function_name 
RETURNS {STRING|INTEGER|REAL|DECIMAL}
SONAME shared_library_name
```

A user-defined function (UDF) is a way to extend MySQL with a new function that works like a native (built-in) MySQL function such as ABS() or CONCAT().

`function_name` is the name that should be used in SQL statements to invoke the function. The RETURNS clause indicates the type of the function’s return value. DECIMAL is a legal value after RETURNS, but currently DECIMAL functions return string values and should be written like STRING functions.

`shared_library_name` is the base name of the shared object file that contains the code that implements the function. The file must be located in the plugin directory. This directory is given by the value of the plugin_dir system variable.

Note
This is a change in MySQL 5.1. For earlier versions of MySQL, the shared object can be located in any directory that is searched by your system's
To create a function, you must have the `INSERT` privilege for the `mysql` database. This is necessary because `CREATE FUNCTION` adds a row to the `mysql.func` system table that records the function's name, type, and shared library name. If you do not have this table, you should run the `mysql_upgrade` command to create it. See Section 22.3.2.5, “UDF Compiling and Installing”.

An active function is one that has been loaded with `CREATE FUNCTION` and not removed with `DROP FUNCTION`. All active functions are reloaded each time the server starts, unless you start `mysqld` with the `--skip-grant-tables` option. In this case, UDF initialization is skipped and UDFs are unavailable.

For instructions on writing user-defined functions, see Section 22.3.2, “Adding a New User-Defined Function”. For the UDF mechanism to work, functions must be written in C or C++ (or another language that can use C calling conventions), your operating system must support dynamic loading and you must have compiled `mysqld` dynamically (not statically).

An `AGGREGATE` function works exactly like a native MySQL aggregate (summary) function such as `SUM` or `COUNT()`. For `AGGREGATE` to work, your `mysql.func` table must contain a `type` column. If your `mysql.func` table does not have this column, you should run the `mysql_upgrade` program to create it (see Section 4.4.8, “mysql_upgrade — Check and Upgrade MySQL Tables”).

To upgrade the shared library associated with a UDF, issue a `DROP FUNCTION` statement, upgrade the shared library, and then issue a `CREATE FUNCTION` statement. If you upgrade the shared library first and then use `DROP FUNCTION`, the server may crash.

**13.7.3.2 DROP FUNCTION Syntax**

```
DROP FUNCTION function_name
```

This statement drops the user-defined function (UDF) named `function_name`.

To drop a function, you must have the `DELETE` privilege for the `mysql` database. This is because `DROP FUNCTION` removes a row from the `mysql.func` system table that records the function's name, type, and shared library name.

To upgrade the shared library associated with a UDF, issue a `DROP FUNCTION` statement, upgrade the shared library, and then issue a `CREATE FUNCTION` statement. If you upgrade the shared library first and then use `DROP FUNCTION`, the server may crash.

`DROP FUNCTION` is also used to drop stored functions (see Section 13.1.26, “DROP PROCEDURE and DROP FUNCTION Syntax”).

**13.7.3.3 INSTALL PLUGIN Syntax**

```
INSTALL PLUGIN plugin_name SONAME 'shared_library_name'
```

This statement installs a server plugin. It requires the `INSERT` privilege for the `mysql.plugin` table.

`plugin_name` is the name of the plugin as defined in the plugin descriptor structure contained in the library file (see Section 22.2.4.2, “Plugin Data Structures”). Plugin names are not case sensitive.
For maximal compatibility, plugin names should be limited to ASCII letters, digits, and underscore because they are used in C source files, shell command lines, M4 and Bourne shell scripts, and SQL environments.

`shared_library_name` is the name of the shared library that contains the plugin code. The name includes the file name extension (for example, `libmyplugin.so`, `libmyplugin.dll`, or `libmyplugin.dylib`).

The shared library must be located in the plugin directory (the directory named by the `plugin_dir` system variable). The library must be in the plugin directory itself, not in a subdirectory. By default, `plugin_dir` is the plugin directory under the directory named by the `pkglibdir` configuration variable, but it can be changed by setting the value of `plugin_dir` at server startup. For example, set its value in a `my.cnf` file:

```
[mysql]
plugin_dir=/path/to/plugin/directory
```

If the value of `plugin_dir` is a relative path name, it is taken to be relative to the MySQL base directory (the value of the `basedir` system variable).

`INSTALL PLUGIN` loads and initializes the plugin code to make the plugin available for use. A plugin is initialized by executing its initialization function, which handles any setup that the plugin must perform before it can be used. When the server shuts down, it executes the deinitialization function for each plugin that is loaded so that the plugin has a chance to perform any final cleanup.

`INSTALL PLUGIN` also registers the plugin by adding a line that indicates the plugin name and library file name to the `mysql.plugin` table. At server startup, the server loads and initializes any plugin that is listed in the `mysql.plugin` table. This means that a plugin is installed with `INSTALL PLUGIN` only once, not every time the server starts. Plugin loading at startup does not occur if the server is started with the `--skip-grant-tables` option.

A plugin library can contain multiple plugins. For each of them to be installed, use a separate `INSTALL PLUGIN` statement. Each statement names a different plugin, but all of them specify the same library name.

As of MySQL 5.1.33, `INSTALL PLUGIN` causes the server to read option (`my.cnf`) files just as during server startup. This enables the plugin to pick up any relevant options from those files. It is possible to add plugin options to an option file even before loading a plugin (if the `loose` prefix is used). It is also possible to uninstall a plugin, edit `my.cnf`, and install the plugin again. Restarting the plugin this way enables it to the new option values without a server restart.

Before MySQL 5.1.33, a plugin is started with each option set to its default value.

For options that control individual plugin loading at server startup, see Section 5.1.8.1, “Installing and Uninstalling Plugins”. If you need to load plugins for a single server startup when the `--skip-grant-tables` option is given (which tells the server not to read system tables), use the `--plugin-load` option. See Section 5.1.3, “Server Command Options”.

To remove a plugin, use the `UNINSTALL PLUGIN` statement.

For additional information about plugin loading, see Section 5.1.8.1, “Installing and Uninstalling Plugins”.

To see what plugins are installed, use the `SHOW PLUGINS` statement or query the `INFORMATION_SCHEMA.PLUGINS` table.

If you recompile a plugin library and need to reinstall it, you can use either of the following methods:

- Use `UNINSTALL PLUGIN` to uninstall all plugins in the library, install the new plugin library file in the plugin directory, and then use `INSTALL PLUGIN` to install all plugins in the library. This
procedure has the advantage that it can be used without stopping the server. However, if the plugin library contains many plugins, you must issue many `INSTALL PLUGIN` and `UNINSTALL PLUGIN` statements.

- Stop the server, install the new plugin library file in the plugin directory, and restart the server.

### 13.7.3.4 UNINSTALL PLUGIN Syntax

```
UNINSTALL PLUGIN plugin_name
```

This statement removes an installed server plugin. It requires the `DELETE` privilege for the `mysql.plugin` table. `UNINSTALL PLUGIN` is the complement of `INSTALL PLUGIN`.

`plugin_name` must be the name of some plugin that is listed in the `mysql.plugin` table. The server executes the plugin's deinitialization function and removes the row for the plugin from the `mysql.plugin` table, so that subsequent server restarts will not load and initialize the plugin.

`UNINSTALL PLUGIN` does not remove the plugin's shared library file.

You cannot uninstall a plugin if any table that uses it is open.

Plugin removal has implications for the use of associated tables. For example, if a full-text parser plugin is associated with a `FULLTEXT` index on the table, uninstalling the plugin makes the table unusable. Any attempt to access the table results in an error. The table cannot even be opened, so you cannot drop an index for which the plugin is used. This means that uninstalling a plugin is something to do with care unless you do not care about the table contents. If you are uninstalling a plugin with no intention of reinstalling it later and you care about the table contents, you should dump the table with `mysqldump` and remove the `WITH PARSER` clause from the dumped `CREATE TABLE` statement so that you can reload the table later. If you do not care about the table, `DROP TABLE` can be used even if any plugins associated with the table are missing.

For additional information about plugin loading, see Section 5.1.8.1, “Installing and Uninstalling Plugins”.

### 13.7.4 SET Syntax

The `SET` statement has several forms:

- `SET var_name = value` enables you to assign values to variables that affect the operation of the server or clients. See Section 13.7.4.1, “SET Syntax for Variable Assignment”.

- `SET CHARACTER SET` and `SET NAMES` assign values to character set and collation variables associated with the current connection to the server. See Section 13.7.4.2, “SET CHARACTER SET Syntax”, and Section 13.7.4.3, “SET NAMES Syntax”.

- `SET PASSWORD` assigns account passwords. See Section 13.7.1.6, “SET PASSWORD Syntax”.

- `SET TRANSACTION ISOLATION LEVEL` sets the isolation level for transaction processing. See Section 13.3.6, “SET TRANSACTION Syntax”.

#### 13.7.4.1 SET Syntax for Variable Assignment

```
SET variable_assignment [, variable_assignment] ... 
```

```
variable_assignment:
    user_var_name = expr
    param_name = expr
    local_var_name = expr
    | [GLOBAL | SESSION]
    system_var_name = expr
    | [@@global. | @@session. | @@]
```
SET Syntax

**SET** syntax for variable assignment enables you to assign values to different types of variables that affect the operation of the server or clients:

- System variables. See Section 5.1.4, “Server System Variables”. System variables also can be set at server startup, as described in Section 5.1.5, “Using System Variables”. (To display system variables names and values, use the `SHOW VARIABLES` statement; see Section 13.7.5.41, “SHOW VARIABLES Syntax”.)

- User-defined variables. See Section 9.4, “User-Defined Variables”.

- Stored procedure and function parameters, and stored program local variables. See Section 13.6.4, “Variables in Stored Programs”.

Older versions of MySQL employed **SET OPTION**, but this syntax is deprecated in favor of **SET** without **OPTION**.

A **SET** statement that assigns variable values is not written to the binary log, so it affects only the host on which you execute it in replication scenarios. To affect all replication hosts, execute the statement on each one.

The following discussion shows the different **SET** syntaxes for setting variables. The examples use the `=` assignment operator, but the `:=` assignment operator is also permitted for this purpose.

A user variable is written as `@var_name` and can be set as follows:

```
SET @var_name = expr;
```

Examples:

```
SET @name = 43;
SET @total_tax = (SELECT SUM(tax) FROM taxable_transactions);
```

The **expr** can range from simple (a literal value) to more complex (the value returned by a scalar subquery).

**SET** applies to parameters and local variables within the context of the stored object within which they are defined. The following procedure uses the `counter` local variable as a loop counter:

```
CREATE PROCEDURE p()
BEGIN
  DECLARE counter INT DEFAULT 0;
  WHILE counter < 10 DO
    -- ... do work ...
    SET counter = counter + 1;
  END WHILE;
END;
```

Many system variables are dynamic and can be changed at runtime by using the **SET** statement. For a list, see Section 5.1.5.2, “Dynamic System Variables”. To change a system variable with **SET**, refer to it by name, optionally preceded by a modifier:

- To indicate that a variable is a global variable, precede its name by the `GLOBAL` keyword or the `@@global` qualifier:

```
SET GLOBAL max_connections = 1000;
SET @@global.max_connections = 1000;
```
The `SUPER` privilege is required to set global variables.

- To indicate that a variable is a session variable, precede its name by the `SESSION` keyword or either the `@@session.` or `@@` qualifier:

```sql
SET SESSION sql_mode = 'TRADITIONAL';
SET @@session.sql_mode = 'TRADITIONAL';
SET @@sql_mode = 'TRADITIONAL';
```

Setting a session variable normally requires no special privilege, although there are exceptions that require the `SUPER` privilege (such as `sql_log_bin`). A client can change its own session variables, but not those of any other client.

- `LOCAL` and `@@local.` are synonyms for `SESSION` and `@@session.`.

- If no modifier is present, `SET` changes the session variable. If the variable has no session value, an error occurs.

```sql
mysql> SET max_connections = 1000;
ERROR 1229 (HY000): Variable 'max_connections' is a GLOBAL variable and should be set with SET GLOBAL
```

- An error occurs if you:
  - Use `SET GLOBAL` (or `@@global.`) when setting a variable that has only a session value
  - Omit `GLOBAL` (or `@@global.`) or `PERSIST` (or `@@persist.`) when setting a variable that has only a global value
  - Use `SET SESSION` (or `@@SESSION.`) when setting a variable that has only a global value

The preceding modifiers apply only to system variables. It is not permitted to apply them to user-defined variables, stored procedure or function parameters, or stored program local variables. An error occurs for such attempts.

A `SET` statement can contain multiple variable assignments, separated by commas. This statement assigns values to a user-defined variable and a system variable:

```sql
SET @x = 1, SESSION sql_mode = '';
```

If you set multiple system variables, the most recent `GLOBAL` or `SESSION` modifier in the statement is used for following assignments that have no modifier specified.

Examples of multiple-variable assignment:

```sql
SET GLOBAL sort_buffer_size = 1000000, SESSION sort_buffer_size = 1000000;
SET @@global.sort_buffer_size = 1000000, @@local.sort_buffer_size = 1000000;
SET GLOBAL max_connections = 100, sort_buffer_size = 1000000;
```

If any variable assignment in a `SET` statement fails, the entire statement fails and no variables are changed.

If you change a session system variable, the value remains in effect within your session until you change the variable to a different value or the session ends. The change has no effect on other sessions.

If you change a global system variable, the value is remembered and used for new connections until you change the variable to a different value or the server restarts. The change is visible to any client that accesses the global variable. However, the change affects the corresponding session variable
only for clients that connect after the change. The global variable change does not affect the session
variable for any client that is currently connected (not even the session within which the `SET GLOBAL
statement occurred).

To make a global system variable setting permanent so that it applies across server restarts, you
should also set it in an option file.

To set a `GLOBAL` value to the compiled-in MySQL default value or a `SESSION` variable to the current
 corresponding `GLOBAL` value, set the variable to the value `DEFAULT`. For example, the following two
 statements are identical in setting the session value of `max_join_size` to the current global value:

```
SET @@session.max_join_size=DEFAULT;
SET @@session.max_join_size=@@global.max_join_size;
```

Not all system variables can be set to `DEFAULT`. In such cases, assigning `DEFAULT` results in an error.

It is not permitted to assign `DEFAULT` to user-defined variables, and not supported for stored procedure
 or function parameters or stored program local variables. This results in an error for user-defined
 variables, and the results are undefined for parameters or local variables.

To refer to the value of a system variable in expressions, use one of the `@@`-modifiers. For example, you
 can retrieve values in a `SELECT` statement like this:

```
SELECT @@global.sql_mode, @@session.sql_mode, @@sql_mode;
```

When you refer to a system variable in an expression as `@@var_name` (that is, when you do not
 specify `@@global.` or `@@session.`), MySQL returns the session value if it exists and the global value
 otherwise. This differs from `SET @@var_name = value`, which always refers to the session value.

The `SET ONE_SHOT` syntax is only for internal use for replication: `mysqlbinlog` uses `SET ONE_SHOT`
 to modify temporarily the values of character set, collation, and time zone variables to reflect at
 rollforward what they were originally. `ONE_SHOT` is for internal use only and is deprecated for MySQL
 5.0 and up.

`ONE_SHOT` is intended for use only with the permitted set of variables. With other variables, an error
 occurs:

```
mysql> SET ONE_SHOT max_allowed_packet = 1;
ERROR 1382 (HY000): The 'SET ONE_SHOT' syntax is reserved for purposes
internal to the MySQL server
```

If `ONE_SHOT` is used with the permitted variables, it changes the variables as requested, but only for
 the next non-`SET` statement. After that, the server resets all character set, collation, and time zone-
 related system variables to their previous values. Example:

```
mysql> SET ONE_SHOT character_set_connection = latin5;
mysql> SET ONE_SHOT collation_connection = latin5_turkish_ci;
mysql> SHOW VARIABLES LIKE '%_connection';
+--------------------------+-------------------+
| Variable_name            | Value             |
|--------------------------+-------------------+
| character_set_connection | latin5            |
| collation_connection     | latin5_turkish_ci |
+--------------------------+-------------------+
mysql> SHOW VARIABLES LIKE '%_connection';
+--------------------------+-------------------+
| Variable_name            | Value             |
|--------------------------+-------------------+
```
13.7.4.2 SET CHARACTER SET Syntax

```
SET {CHARACTER SET | CHARSET}
{charset_name | DEFAULT}
```

This statement maps all strings sent between the server and the current client with the given mapping. `SET CHARACTER SET` sets three session system variables: `character_set_client` and `character_set_results` are set to the given character set, and `character_set_connection` to the value of `character_set_database`. See Section 10.1.4, "Connection Character Sets and Collations".

The default character set mapping can be restored by using the value `DEFAULT`. The default depends on the server configuration.

`ucs2` cannot be used as a client character set, which means that it does not work for `SET CHARACTER SET`.

13.7.4.3 SET NAMES Syntax

```
SET NAMES {'charset_name'
[COLLATE 'collation_name'] | DEFAULT}
```

This statement sets the three session system variables `character_set_client`, `character_set_connection`, and `character_set_results` to the given character set. Setting `character_set_connection` to `charset_name` also sets `collation_connection` to the default collation for `charset_name`. The optional `COLLATE` clause may be used to specify a collation explicitly. See Section 10.1.4, "Connection Character Sets and Collations".

The default mapping can be restored by using a value of `DEFAULT`. The default depends on the server configuration.

`ucs2` cannot be used as a client character set, which means that it does not work for `SET NAMES`.

13.7.5 SHOW Syntax

```
SHOW has many forms that provide information about databases, tables, columns, or status information about the server. This section describes those following:

SHOW AUTHORS
SHOW {BINARY | MASTER} LOGS
SHOW BINLOG EVENTS [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
SHOW CHARACTER SET [like_or_where]
SHOW COLLATION [like_or_where]
SHOW [FULL] COLUMNS FROM tbl_name [FROM db_name] [like_or_where]
SHOW CONTRIBUTORS
SHOW CREATE DATABASE db_name
SHOW CREATE EVENT event_name
SHOW CREATE FUNCTION func_name
SHOW CREATE PROCEDURE proc_name
SHOW CREATE TABLE tbl_name
SHOW CREATE TRIGGER trigger_name
SHOW CREATE VIEW view_name
SHOW DATABASES [like_or_where]
SHOW DATABASES [like_or_where]
SHOW ENGINE engine_name {STATUS | MUTEX}
SHOW [STORAGE] ENGINES
SHOW ERRORS [LIMIT [offset,] row_count]
SHOW EVENTS
SHOW FUNCTION CODE func_name
```
SHOW Function Status [like_or_where]
SHOW GRANTS FOR user
SHOW INDEX FROM tbl_name [FROM db_name]
SHOW INNODB STATUS
SHOW MASTER STATUS
SHOW OPEN TABLES [FROM db_name] [like_or_where]
SHOW PLUGINS
SHOW PROCEDURE CODE proc_name
SHOW PROCEDURE STATUS [like_or_where]
SHOW PRIVILEGES
SHOW [FULL] PROCESSLIST
SHOW PROFILE [types] [FOR QUERY n] [OFFSET n] [LIMIT n]
SHOW PROCESSES
SHOW SCHEDULER STATUS
SHOW SLAVE HOSTS
SHOW SLAVE STATUS
SHOW TABLE STATUS [FROM db_name] [like_or_where]
SHOW TRIGGERS [FROM db_name] [like_or_where]
SHOW [GLOBAL | SESSION] VARIABLES [like_or_where]
SHOW WARNINGS [LIMIT [offset,] row_count]

like_or_where:
    LIKE 'pattern'
    WHERE expr

If the syntax for a given SHOW statement includes a LIKE 'pattern' part, 'pattern' is a string that can contain the SQL "%" and "_" wildcard characters. The pattern is useful for restricting statement output to matching values.

Several SHOW statements also accept a WHERE clause that provides more flexibility in specifying which rows to display. See Section 20.27, "Extensions to SHOW Statements".

Many MySQL APIs (such as PHP) enable you to treat the result returned from a SHOW statement as you would a result set from a SELECT; see Chapter 21, Connectors and APIs, or your API documentation for more information. In addition, you can work in SQL with results from queries on tables in the INFORMATION_SCHEMA database, which you cannot easily do with results from SHOW statements. See Chapter 20, INFORMATION_SCHEMA Tables.

13.7.5.1 SHOW AUTHORS Syntax

SHOW AUTHORS

The SHOW AUTHORS statement displays information about the people who work on MySQL. For each author, it displays Name, Location, and Comment values.

This statement was added in MySQL 5.1.3.

13.7.5.2 SHOW BINARY LOGS Syntax

SHOW BINARY LOGS
SHOW MASTER LOGS

Lists the binary log files on the server. This statement is used as part of the procedure described in Section 13.4.1.1, "PURGE BINARY LOGS Syntax", that shows how to determine which logs can be purged.

mysql> SHOW BINARY LOGS;
+---------------+-----------+
| Log_name      | File_size |
+---------------+-----------+
| binlog.000015 | 724935    |

1383
SHOW Syntax

<table>
<thead>
<tr>
<th>binlog.000016</th>
<th>733481</th>
</tr>
</thead>
</table>

SHOW MASTER LOGS is equivalent to SHOW BINARY LOGS.

In MySQL 5.1.63 and earlier, the SUPER privilege was required to use this statement. Starting with MySQL 5.1.64, a user with the REPLICATION CLIENT privilege may also execute this statement.

13.7.5.3 SHOW BINLOG EVENTS Syntax

SHOW BINLOG EVENTS
   [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]

Shows the events in the binary log. If you do not specify 'log_name', the first binary log is displayed.

The LIMIT clause has the same syntax as for the SELECT statement. See Section 13.2.8, “SELECT Syntax”.

Note

Issuing a SHOW BINLOG EVENTS with no LIMIT clause could start a very time- and resource-consuming process because the server returns to the client the complete contents of the binary log (which includes all statements executed by the server that modify data). As an alternative to SHOW BINLOG EVENTS, use the mysqlbinlog utility to save the binary log to a text file for later examination and analysis. See Section 4.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”.

Note

Some events relating to the setting of user and system variables are not included in the output from SHOW BINLOG EVENTS. To get complete coverage of events within a binary log, use mysqlbinlog.

13.7.5.4 SHOW CHARACTER SET Syntax

SHOW CHARACTER SET
   [LIKE 'pattern'] [WHERE expr]

The SHOW CHARACTER SET statement shows all available character sets. The LIKE clause, if present, indicates which character set names to match. The WHERE clause can be given to select rows using more general conditions, as discussed in Section 20.27, “Extensions to SHOW Statements”. For example:

```
mysql> SHOW CHARACTER SET LIKE 'latin%';
+---------+-----------------------------+-------------------+--------+
| Charset | Description                 | Default collation | Maxlen |
+---------+-----------------------------+-------------------+--------+
| latin1  | cp1252 West European        | latin1_swedish_ci |      1 |
| latin2  | ISO 8859-2 Central European | latin2_general_ci |      1 |
| latin5  | ISO 8859-9 Turkish          | latin5_turkish_ci |      1 |
| latin7  | ISO 8859-13 Baltic          | latin7_general_ci |      1 |
+---------+-----------------------------+-------------------+--------+
```

The Maxlen column shows the maximum number of bytes required to store one character.

The filename character set is for internal use only; consequently, SHOW CHARACTER SET does not display it.

13.7.5.5 SHOW COLLATION Syntax
SHOW COLLATION
  [LIKE 'pattern' | WHERE expr]

This statement lists collations supported by the server. By default, the output from SHOW COLLATION includes all available collations. The LIKE clause, if present, indicates which collation names to match. The WHERE clause can be given to select rows using more general conditions, as discussed in Section 20.27, “Extensions to SHOW Statements”. For example:

```sql
mysql> SHOW COLLATION WHERE Charset = 'latin1';
+-------------------+---------+----+---------+----------+---------+
| Collation          | Charset | Id | Default | Compiled | Sortlen |
+-------------------+---------+----+---------+----------+---------+
| latin1_german1_ci | latin1  |  5 |         | Yes      |       1 |
| latin1_swedish_ci | latin1  |  8 | Yes     | Yes      |       1 |
| latin1_danish_ci  | latin1  | 15 |         | Yes      |       1 |
| latin1_german2_ci | latin1  | 31 |         | Yes      |       2 |
| latin1_bin        | latin1  | 47 |         | Yes      |       1 |
| latin1_general_ci | latin1  | 48 |         | Yes      |       1 |
| latin1_general_cs | latin1  | 49 |         | Yes      |       1 |
| latin1_spanish_ci | latin1  | 94 |         | Yes      |       1 |
+-------------------+---------+----+---------+----------+---------+
```

The Collation and Charset columns indicate the names of the collation and the character set with which it is associated. Id is the collation ID. Default indicates whether the collation is the default for its character set. Compiled indicates whether the character set is compiled into the server. Sortlen is related to the amount of memory required to sort strings expressed in the character set.

To see the default collation for each character set, use the following statement. Default is a reserved word, so to use it as an identifier, it must be quoted as such:

```sql
mysql> SHOW COLLATION WHERE `Default` = 'Yes';
+---------------------+----------+----+---------+----------+---------+
| Collation            | Charset  | Id | Default | Compiled | Sortlen |
+---------------------+----------+----+---------+----------+---------+
| big5_chinese_ci     | big5     |  1 | Yes     | Yes      |       1 |
| dec8_swedish_ci     | dec8     |  3 | Yes     | Yes      |       1 |
| cp850_general_ci    | cp850    |  4 | Yes     | Yes      |       1 |
| hp8_english_ci      | hp8      |  6 | Yes     | Yes      |       1 |
| koi8r_general_ci    | koi8r    |  7 | Yes     | Yes      |       1 |
| latin1_swedish_ci   | latin1   |  8 | Yes     | Yes      |       1 |
+---------------------+----------+----+---------+----------+---------+
```

13.7.5.6 SHOW COLUMNS Syntax

SHOW [FULL] COLUMNS {FROM | IN} tbl_name [{FROM | IN} db_name]
  [LIKE 'pattern' | WHERE expr]

SHOW COLUMNS displays information about the columns in a given table. It also works for views. The LIKE clause, if present, indicates which column names to match. The WHERE clause can be given to select rows using more general conditions, as discussed in Section 20.27, “Extensions to SHOW Statements”.

```sql
mysql> SHOW COLUMNS FROM City;
+------------+----------+------+-----+---------+----------------+
| Field      | Type     | Null | Key | Default | Extra          |
+------------+----------+------+-----+---------+----------------+
| Id         | int(11)  | NO   | PRI | NULL    | auto_increment |
| Name       | char(35) | NO   |     |         |                |
| Country    | char(3)  | NO   | UNI |         |                |
| District   | char(20) | YES  | MUL |         |                |
| Population | int(11)  | NO   |     | 0       |                |
+------------+----------+------+-----+---------+----------------+
5 rows in set (0.00 sec)
```
If the data types differ from what you expect them to be based on a `CREATE TABLE` statement, note that MySQL sometimes changes data types when you create or alter a table. The conditions under which this occurs are described in Section 13.1.17.4, “Silent Column Specification Changes”.

The `FULL` keyword causes the output to include the column collation and comments, as well as the privileges you have for each column.

You can use `db_name.tbl_name` as an alternative to the `tbl_name FROM db_name` syntax. In other words, these two statements are equivalent:

```sql
mysql> SHOW COLUMNS FROM mytable FROM mydb;
mysql> SHOW COLUMNS FROM mydb.mytable;
```

SHOW COLUMNS displays the following values for each table column:

- **Field** indicates the column name.
- **Type** indicates the column data type.
- **Collation** indicates the collation for nonbinary string columns, or `NULL` for other columns. This value is displayed only if you use the `FULL` keyword.
- The **Null** field contains `YES` if `NULL` values can be stored in the column, `NO` if not.
- The **Key** field indicates whether the column is indexed:
  - If **Key** is empty, the column either is not indexed or is indexed only as a secondary column in a multiple-column, nonunique index.
  - If **Key** is `PRI`, the column is a PRIMARY KEY or is one of the columns in a multiple-column PRIMARY KEY.
  - If **Key** is `UNI`, the column is the first column of a UNIQUE index. (A UNIQUE index permits multiple `NULL` values, but you can tell whether the column permits `NULL` by checking the Null field.)
  - If **Key** is `MUL`, the column is the first column of a nonunique index in which multiple occurrences of a given value are permitted within the column.
- If more than one of the **Key** values applies to a given column of a table, **Key** displays the one with the highest priority, in the order PRI, UNI, MUL.
- A UNIQUE index may be displayed as PRI if it cannot contain `NULL` values and there is no PRIMARY KEY in the table. A UNIQUE index may display as MUL if several columns form a composite UNIQUE index; although the combination of the columns is unique, each column can still hold multiple occurrences of a given value.
- The **Default** field indicates the default value that is assigned to the column. This is `NULL` if the column has an explicit default of `NULL`. As of MySQL 5.1.23, Default is also `NULL` if the column definition has no `DEFAULT` clause.
- The **Extra** field contains any additional information that is available about a given column. The value is nonempty in these cases: `auto_increment` for columns that have the `AUTO_INCREMENT` attribute; as of MySQL 5.1.23, `on update CURRENT_TIMESTAMP` for `TIMESTAMP` columns that have the `ON UPDATE CURRENT_TIMESTAMP` attribute.
- **Privileges** indicates the privileges you have for the column. This value is displayed only if you use the `FULL` keyword.
- **Comment** indicates any comment the column has. This value is displayed only if you use the `FULL` keyword.
SHOW Syntax

SHOW FIELDS is a synonym for SHOW COLUMNS. You can also list a table's columns with the mysqlshow db_name tbl_name command.

The DESCRIBE statement provides information similar to SHOW COLUMNS. See Section 13.8.1, “DESCRIBE Syntax”.

The SHOW CREATE TABLE, SHOW TABLE STATUS, and SHOW INDEX statements also provide information about tables. See Section 13.7.5, “SHOW Syntax”.

13.7.5.7 SHOW CONTRIBUTORS Syntax

SHOW CONTRIBUTORS

The SHOW CONTRIBUTORS statement displays information about the people who contribute to MySQL source or to causes that we support. For each contributor, it displays Name, Location, and Comment values.

This statement was added in MySQL 5.1.12.

13.7.5.8 SHOW CREATE DATABASE Syntax

SHOW CREATE {DATABASE | SCHEMA} [IF NOT EXISTS] db_name

Shows the CREATE DATABASE statement that creates the named database. If the SHOW statement includes an IF NOT EXISTS clause, the output too includes such a clause. SHOW CREATE SCHEMA is a synonym for SHOW CREATE DATABASE.

mysql> SHOW CREATE DATABASE test\G
*************************** 1. row ***************************
Database: test
Create Database: CREATE DATABASE `test`
/*!40100 DEFAULT CHARACTER SET latin1 */
mysql>

13.7.5.9 SHOW CREATE EVENT Syntax

SHOW CREATE EVENT event_name

This statement displays the CREATE EVENT statement needed to re-create a given event. It requires the EVENT privilege for the database from which the event is to be shown. For example (using the same event e_daily defined and then altered in Section 13.7.5.19, “SHOW EVENTS Syntax”):

mysql> SHOW CREATE EVENT test.e_daily\G
*************************** 1. row ***************************
Event: e_daily
  sql_mode:
  time_zone: SYSTEM
Create Event: CREATE EVENT `e_daily`
  ON SCHEDULE EVERY 1 DAY
  STARTS CURRENT_TIMESTAMP + INTERVAL 6 HOUR
  ON COMPLETION NOT PRESERVE
  ENABLE
COMMENT 'Saves total number of sessions then clears the table each day'
DO BEGIN
    INSERT INTO site_activity.totals (time, total)
    SELECT CURRENT_TIMESTAMP, COUNT(*)
    FROM site_activity.sessions;
    DELETE FROM site_activity.sessions;
END

character_set_client is the session value of the character_set_client system variable when the event was created. collation_connection is the session value of the collation_connection system variable when the event was created. Database Collation is the collation of the database with which the event is associated. These columns were added in MySQL 5.1.21.

Note that the output reflects the current status of the event (ENABLE) rather than the status with which it was created.

This statement was implemented in MySQL 5.1.6.

13.7.5.10 SHOW CREATE FUNCTION Syntax

SHOW CREATE FUNCTION func_name

This statement is similar to SHOW CREATE PROCEDURE but for stored functions. See Section 13.7.5.11, "SHOW CREATE PROCEDURE Syntax".

13.7.5.11 SHOW CREATE PROCEDURE Syntax

SHOW CREATE PROCEDURE proc_name

This statement is a MySQL extension. It returns the exact string that can be used to re-create the named stored procedure. A similar statement, SHOW CREATE FUNCTION, displays information about stored functions (see Section 13.7.5.10, "SHOW CREATE FUNCTION Syntax").

To use either statement, you must be the user named in the routine DEFINER clause or have SELECT access to the mysql.proc table. If you do not have privileges for the routine itself, the value displayed for the Create Procedure or Create Function field will be NULL.
SHOW Syntax

character_set_client is the session value of the character_set_client system variable when the routine was created. collation_connection is the session value of the collation_connection system variable when the routine was created. Database Collation is the collation of the database with which the routine is associated. These columns were added in MySQL 5.1.21.

13.7.5.12 SHOW CREATE TABLE Syntax

SHOW CREATE TABLE tbl_name

Shows the CREATE TABLE statement that creates the named table. To use this statement, you must have some privilege for the table. This statement also works with views.

mysql> SHOW CREATE TABLE t

*************************** 1. row ***************************
Table: t
Create Table: CREATE TABLE t(
  id INT(11) default NULL auto_increment,
  s char(60) default NULL,
  PRIMARY KEY (id)
) ENGINE=MyISAM

SHOW CREATE TABLE quotes table and column names according to the value of the sql_quote_show_create option. See Section 5.1.4, “Server System Variables”.

13.7.5.13 SHOW CREATE TRIGGER Syntax

SHOW CREATE TRIGGER trigger_name

This statement shows the CREATE TRIGGER statement that creates the named trigger. This statement requires the TRIGGER privilege for the table associated with the trigger.

mysql> SHOW CREATE TRIGGER ins_sum

*************************** 1. row ***************************
Trigger: ins_sum
sql_mode: SQL Original Statement: CREATE DEFINER=`me`@`localhost` TRIGGER ins_sum
BEFORE INSERT ON account
  FOR EACH ROW SET @sum = @sum + NEW.amount
character_set_client: latin1
collation_connection: latin1_swedish_ci
Database Collation: latin1_swedish_ci

SHOW CREATE TRIGGER output has the following columns:

• Trigger: The trigger name.
• sql_mode: The SQL mode in effect when the trigger executes.
• SQL Original Statement: The CREATE TRIGGER statement that defines the trigger.
• character_set_client: The session value of the character_set_client system variable when the trigger was created.
• collation_connection: The session value of the collation_connection system variable when the trigger was created.
• Database Collation: The collation of the database with which the trigger is associated.

SHOW CREATE TRIGGER output has the following columns:

• Trigger: The trigger name.
SHOW Syntax

- **sql_mode**: The SQL mode in effect when the trigger executes.
- **SQL Original Statement**: The statement to be executed when the trigger activates.
- **character_set_client**: The session value of the character_set_client system variable when the trigger was created.
- **collation_connection**: The session value of the collation_connection system variable when the trigger was created.
- **Database Collation**: The collation of the database with which the trigger is associated.

**SHOW CREATE TRIGGER** was added in MySQL 5.1.21.

You can also obtain information about trigger objects from INFORMATION_SCHEMA, which contains a TRIGGERS table. See Section 20.23, "The INFORMATION_SCHEMA TRIGGERS Table".

### 13.7.5.14 SHOW CREATE VIEW Syntax

**SHOW CREATE VIEW** *view_name*

This statement shows the CREATE VIEW statement that creates the named view.

```
SHOW CREATE VIEW v
```

```
View: v
Create View: CREATE ALGORITHM=UNDEFINED
DEFINER=`bob`@`localhost`
SQL SECURITY DEFINER VIEW
`v` AS select 1 AS `a`,2 AS `b`
character_set_client: latin1
collation_connection: latin1_swedish_ci
```

**character_set_client** is the session value of the character_set_client system variable when the view was created. **collation_connection** is the session value of the collation_connection system variable when the view was created. These columns were added in MySQL 5.1.21.

Use of **SHOW CREATE VIEW** requires the SHOW VIEW privilege and the SELECT privilege for the view in question.

You can also obtain information about view objects from INFORMATION_SCHEMA, which contains a VIEWS table. See Section 20.25, "The INFORMATION_SCHEMA VIEWS Table".

MySQL lets you use different sql_mode settings to tell the server the type of SQL syntax to support. For example, you might use the ANSI SQL mode to ensure MySQL correctly interprets the standard SQL concatenation operator, the double bar (||), in your queries. If you then create a view that concatenates items, you might worry that changing the sql_mode setting to a value different from ANSI could cause the view to become invalid. But this is not the case. No matter how you write out a view definition, MySQL always stores it the same way, in a canonical form. Here is an example that shows how the server changes a double bar concatenation operator to a CONCAT() function:

```
mysql> SET sql_mode = 'ANSI';
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> CREATE VIEW test.v AS SELECT 'a' || 'b' as col1;
Query OK, 0 rows affected (0.01 sec)
```

```
mysql> SHOW CREATE VIEW test.v
```

```
View: v
Create View: CREATE VIEW "v" AS select CONCAT('a','b') AS "col1"
...```
The advantage of storing a view definition in canonical form is that changes made later to the value of `sql_mode` will not affect the results from the view. However an additional consequence is that comments prior to `SELECT` are stripped from the definition by the server.

### 13.7.5.15 SHOW DATABASES Syntax

```sql
SHOW {DATABASES | SCHEMAS} [LIKE 'pattern' | WHERE expr]
```

`SHOW DATABASES` lists the databases on the MySQL server host. `SHOW SCHEMAS` is a synonym for `SHOW DATABASES`. The `LIKE` clause, if present, indicates which database names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 20.27, “Extensions to SHOW Statements”.

You see only those databases for which you have some kind of privilege, unless you have the global `SHOW DATABASES` privilege. You can also get this list using the `mysqlshow` command.

If the server was started with the `--skip-show-database` option, you cannot use this statement at all unless you have the `SHOW DATABASES` privilege.

MySQL implements databases as directories in the data directory, so this statement simply lists directories in that location. However, the output may include names of directories that do not correspond to actual databases.

### 13.7.5.16 SHOW ENGINE Syntax

```sql
SHOW ENGINE engine_name {STATUS | MUTEX}
```

`SHOW ENGINE` displays operational information about a storage engine. It requires the `PROCESS` privilege. The statement has these variants:

- `SHOW ENGINE INNODB STATUS`
- `SHOW ENGINE INNODB MUTEX`
- `SHOW ENGINE (NDB | NDBCLUSTER) STATUS`

Older (and now deprecated) synonyms are `SHOW INNODB STATUS` for `SHOW ENGINE INNODB STATUS` and `SHOW MUTEX STATUS` for `SHOW ENGINE INNODB MUTEX`. `SHOW INNODB STATUS` and `SHOW MUTEX STATUS` are removed in MySQL 5.5.

In MySQL 5.0, `SHOW ENGINE INNODB MUTEX` is invoked as `SHOW MUTEX STATUS`. The latter statement displays similar information but in a somewhat different output format.

- `SHOW ENGINE BDB LOGS` formerly displayed status information about BDB log files. As of MySQL 5.1.12, the BDB storage engine is not supported, and this statement produces a warning.

- `SHOW ENGINE INNODB STATUS` displays extensive information from the standard InnoDB Monitor about the state of the InnoDB storage engine. For information about the standard monitor and other InnoDB Monitors that provide information about InnoDB processing, see Section 14.6.9, “InnoDB Monitors”.

- `SHOW ENGINE INNODB MUTEX` displays InnoDB mutex statistics. From MySQL 5.1.2 to 5.1.14, the statement displays the following output fields:
  - Type
    - Always InnoDB.
  - Name
The mutex name and the source file where it is implemented. Example: `pool->mutex:mem0pool.c`

The mutex name indicates its purpose. For example, the `log_sys` mutex is used by the InnoDB logging subsystem and indicates how intensive logging activity is. The `buf_pool` mutex protects the InnoDB buffer pool.

**Status**

The mutex status. The fields contains several values:

- **count** indicates how many times the mutex was requested.
- **spin_waits** indicates how many times the spinlock had to run.
- **spin_rounds** indicates the number of spinlock rounds. (**spin_rounds** divided by **spin_waits** provides the average round count.)
- **os_waits** indicates the number of operating system waits. This occurs when the spinlock did not work (the mutex was not locked during the spinlock and it was necessary to yield to the operating system and wait).
- **os_yields** indicates the number of times a thread trying to lock a mutex gave up its timeslice and yielded to the operating system (on the presumption that permitting other threads to run will free the mutex so that it can be locked).
- **os_wait_times** indicates the amount of time (in ms) spent in operating system waits, if the `timed_mutexes` system variable is 1 (ON). If `timed_mutexes` is 0 (OFF), timing is disabled, so `os_wait_times` is 0. `timed_mutexes` is off by default.

From MySQL 5.1.15 on, the statement displays the following output fields:

- **Type**
  
  Always InnoDB.

- **Name**
  
  The source file where the mutex is implemented, and the line number in the file where the mutex is created. The line number is specific to your version of MySQL.

- **Status**
  
  This field displays the same values as previously described (`count, spin_waits, spin_rounds, os_waits, os_yields, os_wait_times`), but only if `UNIV_DEBUG` was defined at MySQL compilation time (for example, in `include/univ.i` in the InnoDB part of the MySQL source tree). If `UNIV_DEBUG` was not defined, the statement displays only the `os_waits` value. In the latter case (without `UNIV_DEBUG`), the information on which the output is based is insufficient to distinguish regular mutexes and mutexes that protect rw-locks (which permit multiple readers or a single writer). Consequently, the output may appear to contain multiple rows for the same mutex.

Information from this statement can be used to diagnose system problems. For example, large values of `spin_waits` and `spin_rounds` may indicate scalability problems.

If the server has the NDBCLUSTER storage engine enabled, `SHOW ENGINE NDB STATUS` displays cluster status information such as the number of connected data nodes, the cluster connectstring, and cluster binary log epochs, as well as counts of various Cluster API objects created by the MySQL Server when connected to the cluster. Sample output from this statement is shown here:

```
mysql> SHOW ENGINE NDB STATUS;
```

SHOW Syntax

<table>
<thead>
<tr>
<th>Type</th>
<th>Name</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>ndbcluster</td>
<td>connection</td>
<td>cluster_node_id=7, connected_host=192.168.0.103, connected_port=1186, number_of_data_nodes=4, number_of_ready_data_nodes=3, connect_count=0</td>
</tr>
<tr>
<td>ndbcluster</td>
<td>NdbTransaction</td>
<td>created=6, free=0, sizeof=212</td>
</tr>
<tr>
<td>ndbcluster</td>
<td>NdbOperation</td>
<td>created=8, free=8, sizeof=660</td>
</tr>
<tr>
<td>ndbcluster</td>
<td>NdbIndexScanOperation</td>
<td>created=1, free=1, sizeof=744</td>
</tr>
<tr>
<td>ndbcluster</td>
<td>NdbIndexOperation</td>
<td>created=0, free=0, sizeof=664</td>
</tr>
<tr>
<td>ndbcluster</td>
<td>NdbRecAttr</td>
<td>created=1285, free=1285, sizeof=60</td>
</tr>
<tr>
<td>ndbcluster</td>
<td>NdbApiSignal</td>
<td>created=16, free=16, sizeof=136</td>
</tr>
<tr>
<td>ndbcluster</td>
<td>NdbLabel</td>
<td>created=0, free=0, sizeof=196</td>
</tr>
<tr>
<td>ndbcluster</td>
<td>NdbBranch</td>
<td>created=0, free=0, sizeof=24</td>
</tr>
<tr>
<td>ndbcluster</td>
<td>NdbSubroutine</td>
<td>created=0, free=0, sizeof=68</td>
</tr>
<tr>
<td>ndbcluster</td>
<td>NdbCall</td>
<td>created=0, free=0, sizeof=16</td>
</tr>
<tr>
<td>ndbcluster</td>
<td>NdbBlob</td>
<td>created=4, free=0, sizeof=68</td>
</tr>
<tr>
<td>ndbcluster</td>
<td>binlog</td>
<td>latest_epoch=155467, latest_trans_epoch=148126,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>latest_received_binlog_epoch=0, latest_handled_binlog_epoch=0,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>latest_applied_binlog_epoch=0</td>
</tr>
</tbody>
</table>

The rows with connection and binlog in the Name column were added to the output of this statement in MySQL 5.1. The Status column in each of these rows provides information about the MySQL server's connection to the cluster and about the cluster binary log's status, respectively. The Status information is in the form of comma-delimited set of name/value pairs.

The connection row's Status column contains the name/value pairs described in the following table.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>cluster_node_id</td>
<td>The node ID of the MySQL server in the cluster</td>
</tr>
<tr>
<td>connected_host</td>
<td>The host name or IP address of the cluster management server to which the MySQL server is connected</td>
</tr>
<tr>
<td>connected_port</td>
<td>The port used by the MySQL server to connect to the management server (connected_host)</td>
</tr>
<tr>
<td>number_of_data_nodes</td>
<td>The number of data nodes configured for the cluster (that is, the number of [ndbd] sections in the cluster config.ini file)</td>
</tr>
<tr>
<td>number_of_ready_data_nodes</td>
<td>The number of data nodes in the cluster that are actually running</td>
</tr>
<tr>
<td>connect_count</td>
<td>The number of times this mysqld has connected or reconnected to cluster data nodes</td>
</tr>
</tbody>
</table>

The binlog row's Status column contains information relating to MySQL Cluster Replication. The name/value pairs it contains are described in the following table.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>latest_epoch</td>
<td>The most recent epoch most recently run on this MySQL server (that is, the sequence number of the most recent transaction run on the server)</td>
</tr>
<tr>
<td>latest_trans_epoch</td>
<td>The most recent epoch processed by the cluster's data nodes</td>
</tr>
<tr>
<td>latest_received_binlog_epoch</td>
<td>The most recent epoch received by the binary log thread</td>
</tr>
<tr>
<td>latest_handled_binlog_epoch</td>
<td>The most recent epoch processed by the binary log thread (for writing to the binary log)</td>
</tr>
<tr>
<td>latest_applied_binlog_epoch</td>
<td>The most recent epoch actually written to the binary log</td>
</tr>
</tbody>
</table>

See Section 17.6, “MySQL Cluster Replication”, for more information.
The remaining rows from the output of `SHOW ENGINE NDB STATUS` which are most likely to prove useful in monitoring the cluster are listed here by Name:

- **NdbTransaction**: The number and size of `NdbTransaction` objects that have been created. An `NdbTransaction` is created each time a table schema operation (such as `CREATE TABLE` or `ALTER TABLE`) is performed on an `NDB` table.

- **NdbOperation**: The number and size of `NdbOperation` objects that have been created.

- **NdbIndexScanOperation**: The number and size of `NdbIndexScanOperation` objects that have been created.

- **NdbIndexOperation**: The number and size of `NdbIndexOperation` objects that have been created.

- **NdbRecAttr**: The number and size of `NdbRecAttr` objects that have been created. In general, one of these is created each time a data manipulation statement is performed by an SQL node.

- **NdbBlob**: The number and size of `NdbBlob` objects that have been created. An `NdbBlob` is created for each new operation involving a `BLOB` column in an `NDB` table.

- **NdbReceiver**: The number and size of any `NdbReceiver` object that have been created. The number in the `created` column is the same as the number of data nodes in the cluster to which the MySQL server has connected.

**Note**

`SHOW ENGINE NDB STATUS` returns an empty result if no operations involving `NDB` tables have been performed during the current session by the MySQL client accessing the SQL node on which this statement is run.

### 13.7.5.17 SHOW ENGINES Syntax

**SHOW [STORAGE] ENGINES**

`SHOW ENGINES` displays status information about the server's storage engines. This is particularly useful for checking whether a storage engine is supported, or to see what the default engine is. This information can also be obtained from the `INFORMATION_SCHEMA ENGINES` table. See Section 20.6, "The INFORMATION_SCHEMA ENGINES Table".

`SHOW TABLE TYPES` is a synonym, but is deprecated and is removed in MySQL 5.5.

```sql
mysql> SHOW ENGINES\G
*************************** 1. row ***************************
    Engine: MEMORY
    Support: YES
    Comment: Hash based, stored in memory, useful for temporary tables
Transactions: NO
XA: NO
Savepoints: NO
*************************** 2. row ***************************
    Engine: MyISAM
    Support: DEFAULT
    Comment: Default engine as of MySQL 3.23 with great performance
Transactions: NO
XA: NO
Savepoints: NO
*************************** 3. row ***************************
    Engine: InnoDB
    Support: YES
    Comment: Supports transactions, row-level locking, and foreign keys
Transactions: YES
XA: YES
```
SHOW Syntax

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>YES</td>
<td>The engine is supported and is active</td>
</tr>
<tr>
<td>DEFAULT</td>
<td>Like YES, plus this is the default engine</td>
</tr>
<tr>
<td>NO</td>
<td>The engine is not supported</td>
</tr>
<tr>
<td>DISABLED</td>
<td>The engine is supported but has been disabled</td>
</tr>
</tbody>
</table>

A value of **NO** means that the server was compiled without support for the engine, so it cannot be enabled at runtime.

A value of **DISABLED** occurs either because the server was started with an option that disables the engine, or because not all options required to enable it were given. In the latter case, the error log file should contain a reason indicating why the option is disabled. See Section 5.4.2, “The Error Log”.

You might also see **DISABLED** for a storage engine if the server was compiled to support it, but was started with a **--skip-engine_name** option. For the **NDBCLUSTER** storage engine, **DISABLED** means the server was compiled with support for MySQL Cluster, but was not started with the **--ndbcluster** option.

The output from **SHOW ENGINES** may vary according to the MySQL version used and other factors. The values shown in the **Support** column indicate the server's level of support for the storage engine, as shown in the following table.
All MySQL servers support MyISAM tables, because MyISAM is the default storage engine. It is not possible to disable MyISAM.

The Transactions, XA, and Savepoints columns were added in MySQL 5.1.2. They indicate whether the storage engine supports transactions, XA transactions, and savepoints, respectively.

### 13.7.5.18 SHOW ERRORS Syntax

```
SHOW ERRORS [LIMIT [offset,] row_count]
SHOW COUNT(*) ERRORS
```

SHOW ERRORS is a diagnostic statement that is similar to SHOW WARNINGS, except that it displays information only for errors, rather than for errors, warnings, and notes.

The LIMIT clause has the same syntax as for the SELECT statement. See Section 13.2.8, “SELECT Syntax”.

The SHOW COUNT(*) ERRORS statement displays the number of errors. You can also retrieve this number from the error_count variable:

```
SHOW COUNT(*) ERRORS;
SELECT @@error_count;
```

SHOW ERRORS and error_count apply only to errors, not warnings or notes. In other respects, they are similar to SHOW WARNINGS and warning_count. In particular, SHOW ERRORS cannot display information for more than max_error_count messages, and error_count can exceed the value of max_error_count if the number of errors exceeds max_error_count.

For more information, see Section 13.7.5.42, “SHOW WARNINGS Syntax”.

### 13.7.5.19 SHOW EVENTS Syntax

```
SHOW EVENTS [{FROM | IN} schema_name] [LIKE 'pattern' | WHERE expr]
```

This statement displays information about Event Manager events. It requires the EVENT privilege for the database from which the events are to be shown.

In its simplest form, SHOW EVENTS lists all of the events in the current schema:

```
mysql> SELECT CURRENT_USER(), SCHEMA();
+----------------+----------+
| CURRENT_USER() | SCHEMA() |
+----------------+----------+
| jon@ghidora    | myschema |
+----------------+----------+
1 row in set (0.00 sec)
mysql> SHOW EVENTS\G
*************************** 1. row ***************************
Db: myschema
Name: e_daily
Definer: jon@ghidora
Time zone: SYSTEM
Type: RECURRING
Execute at: NULL
Interval value: 10
Interval field: SECOND
Starts: 2006-02-09 10:41:23
Ends: NULL
Status: ENABLED
Originator: 0
character_set_client: latin1
```
To see events for a specific schema, use the `FROM` clause. For example, to see events for the `test` schema, use the following statement:

```
SHOW EVENTS FROM test;
```

The `LIKE` clause, if present, indicates which event names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 20.27, “Extensions to SHOW Statements”.

`SHOW EVENTS` output has the following columns:

- **Db**: The schema (database) on which the event is defined.
- **Name**: The name of the event.
- **Time zone**: The event time zone, which is the time zone used for scheduling the event and that is in effect within the event as it executes. The default value is `SYSTEM`.
  This column was added in MySQL 5.1.17. See the Release Notes for MySQL 5.1.17 for important information if you are using the Event Scheduler and are upgrading to MySQL 5.1.17 or later from an earlier version.
- **Definer**: The account of the user who created the event, in `user_name@host_name` format.
- **Type**: The event repetition type, either `ONE TIME` (transient) or `RECURRING` (repeating).
- **Execute At**: The date and time when a transient event is set to execute. Shown as a `DATETIME` value.
  For a recurring event, the value of this column is always `NULL`.
- **Interval Value**: For a recurring event, the number of intervals to wait between event executions.
  For a transient event, the value of this column is always `NULL`.
- **Interval Field**: The time units used for the interval which a recurring event waits before repeating.
  For a transient event, the value of this column is always `NULL`.
- **Starts**: The start date and time for a recurring event. This is displayed as a `DATETIME` value, and is `NULL` if no start date and time are defined for the event. (Prior to MySQL 5.1.8, it defaulted to `0000-00-00 00:00:00` in such cases.)
  For a transient event, this column is always `NULL`.
- **Ends**: The end date and time for a recurring event. This is displayed as a `DATETIME` value, and defaults to `NULL` if no end date and time is defined for the event.
  For a transient event, this column is always `NULL`.
- **Status**: The event status. One of `ENABLED`, `DISABLED`, or `SLAVESIDE_DISABLED`.
  `SLAVESIDE_DISABLED` was added in MySQL 5.1.18. This value indicates that the creation of the event occurred on another MySQL server acting as a replication master and replicated to the current MySQL server which is acting as a slave, but the event is not presently being executed on the slave.
- **Originator**: The server ID of the MySQL server on which the event was created. Defaults to 0. This column was added in MySQL 5.1.18.
SHOW Syntax

- **character_set_client** is the session value of the `character_set_client` system variable when the routine was created. **collation_connection** is the session value of the `collation_connection` system variable when the routine was created. **Database Collation** is the collation of the database with which the routine is associated. These columns were added in MySQL 5.1.21.

For more information about **SLAVE_DISABLED** and the **Originator** column, see Section 16.4.1.12, “Replication of Invoked Features”.

The event action statement is not shown in the output of **SHOW EVENTS**. Use **SHOW CREATE EVENT** or the **INFORMATION_SCHEMA.EVENTS** table.

Times displayed by **SHOW EVENTS** are given in the event time zone (or UTC prior to MySQL 5.1.17), as discussed in Section 19.4.4, “Event Metadata”.

The columns in the output of **SHOW EVENTS** are similar to, but not identical to the columns in the **INFORMATION_SCHEMA.EVENTS** table. See Section 20.7, “The INFORMATION_SCHEMA EVENTS Table”.

**SHOW EVENTS** was added in MySQL 5.1.6.

**Note**

In MySQL 5.1.11 and earlier, **SHOW EVENTS** displayed only those events for which the current user was the definer, and the **SHOW FULL EVENTS** statement was used for viewing events defined by all users on a given schema. **SHOW FULL EVENTS** was removed in MySQL 5.1.12.

### 13.7.5.20 SHOW FUNCTION CODE Syntax

```
SHOW FUNCTION CODE func_name
```

This statement is similar to **SHOW PROCEDURE CODE** but for stored functions. See Section 13.7.5.29, “SHOW PROCEDURE CODE Syntax”.

### 13.7.5.21 SHOW FUNCTION STATUS Syntax

```
SHOW FUNCTION STATUS [LIKE 'pattern'] [WHERE expr]
```

This statement is similar to **SHOW PROCEDURE STATUS** but for stored functions. See Section 13.7.5.30, “SHOW PROCEDURE STATUS Syntax”.

### 13.7.5.22 SHOW GRANTS Syntax

```
SHOW GRANTS [FOR user]
```

This statement displays the **GRANT** statement or statements that must be issued to duplicate the privileges that are granted to a MySQL user account. **SHOW GRANTS** requires the **SELECT** privilege for the **mysql** database, except to see the privileges for the current user.

To name the account, use the same format as for the **GRANT** statement; for example, `"jeffrey"@'localhost'`. If you specify only the user name part of the account name, a host name part of `'%'` is used. For additional information about specifying account names, see Section 13.7.1.3, “GRANT Syntax”.

```
mysql> SHOW GRANTS FOR 'root'@'localhost';
+---------------------------------------------------------------------+
| Grants for root@localhost                                          |
+---------------------------------------------------------------------+
```
SHOW Syntax

To display the privileges granted to the account that you are using to connect to the server, you can use any of the following statements:

```
SHOW GRANTS;
SHOW GRANTS FOR CURRENT_USER;
SHOW GRANTS FOR CURRENT_USER();
```

As of MySQL 5.1.12, if `SHOW GRANTS FOR CURRENT_USER` (or any of the equivalent syntaxes) is used in `DEFINER` context, such as within a stored procedure that is defined with `SQL SECURITY DEFINER), the grants displayed are those of the definer and not the invoker.

`SHOW GRANTS` displays only the privileges granted explicitly to the named account. Other privileges that might be available to the account are not displayed. For example, if an anonymous account exists, the named account might be able to use its privileges, but `SHOW GRANTS` will not display them.

### 13.7.5.23 SHOW INDEX Syntax

```
SHOW {INDEX | INDEXES | KEYS} {FROM | IN} tbl_name [{FROM | IN} db_name] [WHERE expr]
```

`SHOW INDEX` returns table index information. The format resembles that of the `SQLStatistics` call in ODBC.

`SHOW INDEX` returns the following fields:

- **Table**
  
  The name of the table.

- **Non_unique**

  0 if the index cannot contain duplicates, 1 if it can.

- **Key_name**

  The name of the index. If the index is the primary key, the name is always `PRIMARY`.

- **Seq_in_index**

  The column sequence number in the index, starting with 1.

- **Column_name**

  The column name.

- **Collation**

  How the column is sorted in the index. In MySQL, this can have values “A” (Ascending) or `NULL` (Not sorted).

- **Cardinality**

  An estimate of the number of unique values in the index. This is updated by running `ANALYZE TABLE` or `myisamchk -a`. `Cardinality` is counted based on statistics stored as integers, so the value is not necessarily exact even for small tables. The higher the cardinality, the greater the chance that MySQL uses the index when doing joins.
• **Sub_part**
  
The index prefix. That is, the number of indexed characters if the column is only partly indexed, **NULL** if the entire column is indexed.

  **Note**
  
  Prefix limits are measured in bytes, whereas the prefix length in `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements is interpreted as number of characters for nonbinary string types (**CHAR**, **VARCHAR**, **TEXT**) and number of bytes for binary string types (**BINARY**, **VARBINARY**, **BLOB**). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

  For additional information about index prefixes, see Section 13.1.13, “CREATE INDEX Syntax”.

• **Packed**
  
  Indicates how the key is packed. **NULL** if it is not.

• **Null**
  
  Contains **YES** if the column may contain **NULL** values and ‘’ if not.

• **Index_type**
  
  The index method used (**BTREE**, **FULLTEXT**, **HASH**, **RTREE**).

• **Comment**
  
  Information about the index not described in its own column, such as **disabled** if the index is disabled.

You can use `db_name.tbl_name` as an alternative to the `tbl_name` FROM `db_name` syntax. These two statements are equivalent:

```
SHOW INDEX FROM mytable FROM mydb;
SHOW INDEX FROM mydb.mytable;
```

The **WHERE** clause can be given to select rows using more general conditions, as discussed in Section 20.27, “Extensions to SHOW Statements”.

You can also list a table's indexes with the `mysqlshow -k db_name tbl_name` command.

### 13.7.5.24 SHOW INNODB STATUS Syntax

```
SHOW INNODB STATUS
```

In MySQL 5.1, this is a deprecated synonym for `SHOW ENGINE INNODB STATUS`. See Section 13.7.5.16, “SHOW ENGINE Syntax”. `SHOW INNODB STATUS` is removed in MySQL 5.5.

### 13.7.5.25 SHOW MASTER STATUS Syntax

```
SHOW MASTER STATUS
```

This statement provides status information about the binary log files of the master. It requires either the **SUPER** or **REPLICATION CLIENT** privilege.

**Example:**
SHOW Syntax

```sql
mysql> SHOW MASTER STATUS;
+---------------+----------+--------------+------------------+
| File          | Position | Binlog_Do_DB | Binlog_Ignore_DB |
| mysql-bin.003 | 73       | test         | manual,mysql     |
+---------------+----------+--------------+------------------+
```

### 13.7.5.26 SHOW OPEN TABLES Syntax

```sql
SHOW OPEN TABLES [(FROM | IN) db_name] [LIKE 'pattern' | WHERE expr]
```

**SHOW OPEN TABLES** lists the non-TEMPORARY tables that are currently open in the table cache. See Section 8.4.3.1, “How MySQL Opens and Closes Tables”. The **WHERE** clause can be given to select rows using more general conditions, as discussed in Section 20.27, “Extensions to SHOW Statements”.

The **FROM** and **LIKE** clauses may be used beginning with MySQL 5.1.24. The **LIKE** clause, if present, indicates which table names to match. The **FROM** clause, if present, restricts the tables shown to those present in the **db_name** database.

**SHOW OPEN TABLES** output has the following columns:

- **Database**
  
  The database containing the table.

- **Table**
  
  The table name.

- **In_use**
  
  The number of table locks or lock requests there are for the table. For example, if one client acquires a lock for a table using `LOCK TABLE t1 WRITE`, `In_use` will be 1. If another client issues `LOCK TABLE t1 WRITE` while the table remains locked, the client will block waiting for the lock, but the lock request causes `In_use` to be 2. If the count is zero, the table is open but not currently being used. `In_use` is also increased by the **HANDLER ... OPEN** statement and decreased by **HANDLER ... CLOSE**.

- **Name_locked**
  
  Whether the table name is locked. Name locking is used for operations such as dropping or renaming tables.

### 13.7.5.27 SHOW PLUGINS Syntax

```sql
SHOW PLUGINS
```

**SHOW PLUGINS** displays information about server plugins. Plugin information is also available in the **INFORMATION_SCHEMA.PLUGINS** table. See Section 20.12, “The INFORMATION_SCHEMA PLUGINS Table”.

Example of **SHOW PLUGINS** output:

```sql
mysql> SHOW PLUGINS\G
*************************** 1. row ***************************
Name: binlog
Status: ACTIVE
Type: STORAGE ENGINE
Library: NULL
License: GPL
```
SHOW Syntax

SHOW PLUGINS output has the following columns:

- **Name**: The name used to refer to the plugin in statements such as INSTALL PLUGIN and UNINSTALL PLUGIN.
- **Status**: The plugin status, one of ACTIVE, INACTIVE, DISABLED, or DELETED.
- **Type**: The type of plugin, such as STORAGE ENGINE or INFORMATION_SCHEMA.
- **Library**: The name of the plugin shared object file. This is the name used to refer to the plugin file in statements such as INSTALL PLUGIN and UNINSTALL PLUGIN. This file is located in the directory named by the plugin_dir system variable. If the library name is NULL, the plugin is compiled in and cannot be uninstalled with UNINSTALL PLUGIN.
- **License**: How the plugin is licensed; for example, GPL.

For plugins installed with INSTALL PLUGIN, the Name and Library values are also registered in the mysql.plugin table.

For information about plugin data structures that form the basis of the information displayed by SHOW PLUGINS, see Section 22.2, “The MySQL Plugin API”.

SHOW PLUGIN was added in MySQL 5.1.5 and renamed to SHOW PLUGINS in 5.1.9. SHOW PLUGIN is deprecated as of 5.1.9 and generates a warning, and is removed in MySQL 5.5.)

13.7.5.28 SHOW PRIVILEGES Syntax

SHOW PRIVILEGES shows the list of system privileges that the MySQL server supports. The exact list of privileges depends on the version of your server.

```
mysql> SHOW PRIVILEGES\G
*************************** 1. row ***************************
Privilege: Alter
  Context: Tables
  Comment: To alter the table
*************************** 2. row ***************************
Privilege: Alter routine
  Context: Functions, Procedures
  Comment: To alter or drop stored functions/procedures
*************************** 3. row ***************************
Privilege: Create
  Context: Databases, Tables, Indexes
  Comment: To create new databases and tables
```
SHOW Syntax

Privileges belonging to a specific user are displayed by the `SHOW GRANTS` statement. See Section 13.7.5.22, “SHOW GRANTS Syntax”, for more information.

### 13.7.5.29 SHOW PROCEDURE CODE Syntax

```sql
SHOW PROCEDURE CODE proc_name
```

This statement is a MySQL extension that is available only for servers that have been built with debugging support. It displays a representation of the internal implementation of the named stored procedure. A similar statement, `SHOW FUNCTION CODE`, displays information about stored functions (see Section 13.7.5.20, “SHOW FUNCTION CODE Syntax”).

To use either statement, you must be the owner of the routine or have `SELECT` access to the `mysql.proc` table.

If the named routine is available, each statement produces a result set. Each row in the result set corresponds to one “instruction” in the routine. The first column is `Pos`, which is an ordinal number beginning with 0. The second column is `Instruction`, which contains an SQL statement (usually changed from the original source), or a directive which has meaning only to the stored-routine handler.

```sql
mysql> DELIMITER //
mysql> CREATE PROCEDURE p1 ()
    
    BEGIN
    
    DECLARE fanta INT DEFAULT 55;
    DROP TABLE t2;
    LOOP
    INSERT INTO t3 VALUES (fanta);
    END LOOP;
    END//
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW PROCEDURE CODE p1//
```

In this example, the nonexecutable `BEGIN` and `END` statements have disappeared, and for the `DECLARE variable_name` statement, only the executable part appears (the part where the default is assigned). For each statement that is taken from source, there is a code word `stmt` followed by a type (9 means `DROP`, 5 means `INSERT`, and so on). The final row contains an instruction `jump 2`, meaning `GOTO instruction #2`.

These statements were added in MySQL 5.1.3.

### 13.7.5.30 SHOW PROCEDURE STATUS Syntax

```sql
SHOW PROCEDURE STATUS
    [LIKE 'pattern' | WHERE expr]
```
This statement is a MySQL extension. It returns characteristics of a stored procedure, such as the database, name, type, creator, creation and modification dates, and character set information. A similar statement, `SHOW FUNCTION STATUS`, displays information about stored functions (see Section 13.7.5.21, “SHOW FUNCTION STATUS Syntax”).

The `LIKE` clause, if present, indicates which procedure or function names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 20.27, “Extensions to SHOW Statements”.

```sql
mysql> SHOW PROCEDURE STATUS LIKE 'sp1'
*************************** 1. row ***************************
    Db: test
    Name: sp1
    Type: PROCEDURE
    Definer: testuser@localhost
    Modified: 2004-08-03 15:29:37
    Created: 2004-08-03 15:29:37
    Security_type: DEFINER
    Comment:
    character_set_client: latin1
    collation_connection: latin1_swedish_ci
    Database Collation: latin1_swedish_ci
```

`character_set_client` is the session value of the `character_set_client` system variable when the routine was created. `collation_connection` is the session value of the `collation_connection` system variable when the routine was created. `Database Collation` is the collation of the database with which the routine is associated. These columns were added in MySQL 5.1.21.

You can also get information about stored routines from the `ROUTINES` table in `INFORMATION_SCHEMA`. See Section 20.16, “The INFORMATION_SCHEMA ROUTINES Table”.

### 13.7.5.31 SHOW PROCESSLIST Syntax

`SHOW [FULL] PROCESSLIST`

`SHOW PROCESSLIST` shows you which threads are running. You can also get this information from the `INFORMATION_SCHEMA PROCESSLIST` table or the `mysqladmin processlist` command. If you have the `PROCESS` privilege, you can see all threads. Otherwise, you can see only your own threads (that is, threads associated with the MySQL account that you are using). If you do not use the `FULL` keyword, only the first 100 characters of each statement are shown in the `Info` field.

This statement is very useful if you get the “too many connections” error message and want to find out what is going on. MySQL reserves one extra connection to be used by accounts that have the `SUPER` privilege, to ensure that administrators should always be able to connect and check the system (assuming that you are not giving this privilege to all your users).

Threads can be killed with the `KILL` statement. See Section 13.7.6.4, “KILL Syntax”.

Here is an example of `SHOW PROCESSLIST` output:

```sql
mysql> SHOW FULL PROCESSLIST\G
*************************** 1. row ***************************
    Id: 1
    User: system user
    Host: 
    db: NULL
    Command: Connect
    Time: 1030455
    State: Waiting for master to send event
    Info: NULL
```

```sql
*************************** 2. row ***************************
    Id: 2
```
The columns produced by `SHOW PROCESSLIST` have the following meanings:

- **Id**
  
  The connection identifier. This is the same type of value displayed in the `ID` column of the `INFORMATION_SCHEMA.PROCESSLIST` table and returned by the `CONNECTION_ID()` function.

- **User**
  
  The MySQL user who issued the statement. If this is `system user`, it refers to a nonclient thread spawned by the server to handle tasks internally. This could be the I/O or SQL thread used on replication slaves or a delayed-row handler. `unauthenticated user` refers to a thread that has become associated with a client connection but for which authentication of the client user has not yet been done. `event_scheduler` refers to the thread that monitors scheduled events. For `system user`, there is no host specified in the `Host` column.

- **Host**
  
  The host name of the client issuing the statement (except for `system user` where there is no host). `SHOW PROCESSLIST` reports the host name for TCP/IP connections in `host_name:client_port` format to make it easier to determine which client is doing what.

- **db**
  
  The default database, if one is selected, otherwise `NULL`.

- **Command**
  
  The type of command the thread is executing. For descriptions for thread commands, see Section 8.14, “Examining Thread Information”. The value of this column corresponds to the `COM_`xxx
commands of the client/server protocol and \texttt{Com	extunderscore \_xxx} status variables. See Section 5.1.6, “Server Status Variables”

- **Time**

  The time in seconds that the thread has been in its current state. For a slave SQL thread, the value is the number of seconds between the timestamp of the last replicated event and the real time of the slave machine. See Section 16.2.1, “Replication Implementation Details”.

- **State**

  An action, event, or state that indicates what the thread is doing. Descriptions for \texttt{State} values can be found at Section 8.14, “Examining Thread Information”.

  Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that needs to be investigated.

  For the \texttt{SHOW PROCESSLIST} statement, the value of \texttt{State} is \texttt{NULL}.

- **Info**

  The statement the thread is executing, or \texttt{NULL} if it is not executing any statement. The statement might be the one sent to the server, or an innermost statement if the statement executes other statements. For example, if a \texttt{CALL} statement executes a stored procedure that is executing a \texttt{SELECT} statement, the \texttt{Info} value shows the \texttt{SELECT} statement.

13.7.5.32 SHOW PROFILE Syntax

```sql
SHOW PROFILE [\texttt{type} [\texttt{type} ...]]
[\texttt{FOR QUERY} \texttt{n}]
[\texttt{LIMIT} \texttt{row\_count} [\texttt{OFFSET} \texttt{offset}]]
```

\texttt{type}:

- \texttt{ALL}
  - \texttt{BLOCK\ IO}
  - \texttt{CONTEXT\ SWITCHES}
  - \texttt{CPU}
  - \texttt{IPC}
  - \texttt{MEMORY}
  - \texttt{PAGE\ FAULTS}
  - \texttt{SOURCE}
  - \texttt{SWAPS}

The \texttt{SHOW PROFILE} and \texttt{SHOW PROFILES} statements display profiling information that indicates resource usage for statements executed during the course of the current session. Profiling is controlled by the \texttt{profiling} session variable, which has a default value of 0 (\texttt{OFF}). Profiling is enabled by setting \texttt{profiling} to 1 or \texttt{ON}:

```
mysql> \texttt{SET profiling = 1;}
```

\texttt{SHOW PROFILES} displays a list of the most recent statements sent to the server. The size of the list is controlled by the \texttt{profiling\_history\_size} session variable, which has a default value of 15. The maximum value is 100. Setting the value to 0 has the practical effect of disabling profiling.

All statements are profiled except \texttt{SHOW PROFILE} and \texttt{SHOW PROFILES}, so you will find neither of those statements in the profile list. Malformed statements are profiled. For example, \texttt{SHOW PROFILING} is an illegal statement, and a syntax error occurs if you try to execute it, but it will show up in the profiling list. \texttt{SHOW PROFILE} displays detailed information about a single statement. Without the \texttt{FOR QUERY} \texttt{n} clause, the output pertains to the most recently executed statement. If \texttt{FOR QUERY} \texttt{n} is included, \texttt{SHOW
**PROFILE** displays information for statement \( n \). The values of \( n \) correspond to the Query_ID values displayed by **SHOW PROFILES**.

The **LIMIT row_count** clause may be given to limit the output to row_count rows. If **LIMIT** is given, **OFFSET offset** may be added to begin the output offset rows into the full set of rows.

By default, **SHOW PROFILE** displays **Status** and **Duration** columns. The **Status** values are like the **State** values displayed by **SHOW PROCESSLIST**, although there might be some minor differences in interpretation for the two statements for some status values (see Section 8.14, “Examining Thread Information”).

Optional **type** values may be specified to display specific additional types of information:

- **ALL** displays all information
- **BLOCK IO** displays counts for block input and output operations
- **CONTEXT SWITCHES** displays counts for voluntary and involuntary context switches
- **CPU** displays user and system CPU usage times
- **IPC** displays counts for messages sent and received
- **MEMORY** is not currently implemented
- **PAGE FAULTS** displays counts for major and minor page faults
- **SOURCE** displays the names of functions from the source code, together with the name and line number of the file in which the function occurs
- **SWAPS** displays swap counts

Profiling is enabled per session. When a session ends, its profiling information is lost.
Note
Profiling is only partially functional on some architectures. For values that depend on the getrusage() system call, NULL is returned on systems such as Windows that do not support the call. In addition, profiling is per process and not per thread. This means that activity on threads within the server other than your own may affect the timing information that you see.

SHOW PROFILES and SHOW PROFILE were added in MySQL 5.1.24 (but were not added to binary distributions by default until 5.1.28).

You can also get profiling information from the PROFILING table in INFORMATION_SCHEMA. See Section 20.14, "The INFORMATION_SCHEMA PROFILING Table". For example, the following queries produce the same result:

SHOW PROFILE FOR QUERY 2;

SELECT STATE, FORMAT(DURATION, 6) AS DURATION
FROM INFORMATION_SCHEMA.PROFILING
WHERE QUERY_ID = 2 ORDER BY SEQ;

13.7.53 SHOW PROFILES Syntax

SHOW PROFILES

The SHOW PROFILES statement, together with SHOW PROFILE, displays profiling information that indicates resource usage for statements executed during the course of the current session. For more information, see Section 13.7.52, "SHOW PROFILE Syntax".

13.7.54 SHOW SCHEDULER STATUS Syntax

SHOW SCHEDULER STATUS
SHOW Syntax

This statement provides debugging information regarding the Event Scheduler's state. It is supported only in \(-debug\) builds of MySQL 5.1.11, and was removed in 5.1.12 and subsequent releases.

Sample output is shown here:

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>scheduler state</td>
<td>INITIALIZED</td>
</tr>
<tr>
<td>thread_id</td>
<td>NULL</td>
</tr>
<tr>
<td>scheduler last locked at</td>
<td>init_scheduler::313</td>
</tr>
<tr>
<td>scheduler last unlocked at</td>
<td>init_scheduler::318</td>
</tr>
<tr>
<td>scheduler waiting on condition</td>
<td>0</td>
</tr>
<tr>
<td>scheduler workers count</td>
<td>0</td>
</tr>
<tr>
<td>scheduler executed events</td>
<td>0</td>
</tr>
<tr>
<td>scheduler data locked</td>
<td>0</td>
</tr>
<tr>
<td>queue element count</td>
<td>1</td>
</tr>
<tr>
<td>queue data locked</td>
<td>0</td>
</tr>
<tr>
<td>queue data attempting lock</td>
<td>0</td>
</tr>
<tr>
<td>queue last locked at</td>
<td>create_event::218</td>
</tr>
<tr>
<td>queue last unlocked at</td>
<td>create_event::222</td>
</tr>
<tr>
<td>queue last attempted lock at</td>
<td>::0</td>
</tr>
<tr>
<td>queue waiting on condition</td>
<td>0</td>
</tr>
<tr>
<td>next activation at</td>
<td>00-00-00 00:00:00</td>
</tr>
</tbody>
</table>

In MySQL 5.1.12 and later, this information can be obtained using `mysqladmin debug`. (See Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”.) For more information about obtaining Event Scheduler status information, see Section 19.4.5, “Event Scheduler Status”.

13.7.5.35 SHOW SLAVE HOSTS Syntax

SHOW SLAVE HOSTS

Displays a list of replication slaves currently registered with the master. Only slaves started with the \(--report-host=host_name\) option are visible in this list.

SHOW SLAVE HOSTS should be executed on a server that acts as a replication master. The statement displays information about servers that are or have been connected as replication slaves, with each row of the result corresponding to one slave server, as shown here:

```
mysql> SHOW SLAVE HOSTS;
+------------+-----------+------+-----------+
| Server_id  | Host      | Port | Master_id |
+------------+-----------+------+-----------+
| 192168010  | iconnect2 | 3306 | 192168011 |
| 1921680101 | athena    | 3306 | 192168011 |
+------------+-----------+------+-----------+
```

- **Server_id**: The unique server ID of the slave server, as configured in the slave server's option file, or on the command line with \(--server-id=value\).
- **Host**: The host name of the slave server as specified on the slave with the \(--report-host\) option. This can differ from the machine name as configured in the operating system.
- **User**: The slave server user name as, specified on the slave with the \(--report-user\) option. Statement output includes this column only if the master server is started with the \(--show-slave-auth-info\) option.
- **Password**: The slave server password as, specified on the slave with the \(--report-password\) option. Statement output includes this column only if the master server is started with the \(--show-slave-auth-info\) option.
- **Port**: The port on the master to which the slave server is listening, as specified on the slave with the \(--report-port\) option.
• **Master_id**: The unique server ID of the master server that the slave server is replicating from. This is the server ID of the server on which `SHOW SLAVE HOSTS` is executed, so this same value is listed for each row in the result.

Some MySQL versions report another variable, `Rpl_recovery_rank`. This variable was never used, and was eventually removed. (Bug #13963)

## 13.7.5.36 SHOW SLAVE STATUS Syntax

### SHOW SLAVE STATUS

This statement provides status information on essential parameters of the slave threads. It requires either the `SUPER` or `REPLICATION CLIENT` privilege.

If you issue this statement using the `mysql` client, you can use a `\G` statement terminator rather than a semicolon to obtain a more readable vertical layout:

```sql
mysql> SHOW SLAVE STATUS\G
*************************** 1. row ***************************
Slave_IO_State: Waiting for master to send event
Master_Host: localhost
Master_User: root
Master_Port: 3306
Connect_Retry: 3
Master_Log_File: gbichot-bin.005
Read_Master_Log_Pos: 79
Relay_Log_File: gbichot-relay-bin.005
Relay_Log_Pos: 548
Relay_Master_Log_File: gbichot-bin.005
Slave_IO_Running: Yes
Slave_SQL_Running: Yes
Replicate_Do_DB:
Replicate_Ignore_DB:
Replicate_Do_Table:
Replicate_Ignore_Table:
Replicate_Wild_Do_Table:
Replicate_Wild_Ignore_Table:
Last_Errno: 0
Last_Error:
Skip_Counter: 0
Exec_Master_Log_Pos: 79
Relay_Log_Space: 552
Until_Condition: None
Until_Log_File:
Until_Log_Pos: 0
Master_SSL_Allowed: No
Master_SSL_CA_File:
Master_SSL_CA_Path:
Master_SSL_Cert:
Master_SSL_Cipher:
Master_SSL_Key:
Seconds_Behind_Master: 8
Master_SSL_VERIFY_SERVER_CERT: No
Last_IO_Errno: 0
Last_IO_Error:
Last_SQL_Errno: 0
Last_SQL_Error:
```

The following list describes the fields returned by `SHOW SLAVE STATUS`. For additional information about interpreting their meanings, see **Section 16.1.4.1, “Checking Replication Status”**.

- **Slave_IO_State**

  A copy of the **State** field of the `SHOW PROCESSLIST` output for the slave I/O thread. This tells you what the thread is doing: trying to connect to the master, waiting for events from the master, reconnecting to the master, and so on. For a listing of possible states, see **Section 8.14.6, “Replication Slave I/O Thread States”**.
SHOW Syntax

- **Master_Host**
  The master host that the slave is connected to.

- **Master_User**
  The user name of the account used to connect to the master.

- **Master_Port**
  The port used to connect to the master.

- **Connect_Retry**
  The number of seconds between connect retries (default 60). This can be set with the `CHANGE MASTER TO` statement or `--master-connect-retry` option.

- **Master_Log_File**
  The name of the master binary log file from which the I/O thread is currently reading.

- **Read_Master_Log_Pos**
  The position in the current master binary log file up to which the I/O thread has read.

- **Relay_Log_File**
  The name of the relay log file from which the SQL thread is currently reading and executing.

- **Relay_Log_Pos**
  The position in the current relay log file up to which the SQL thread has read and executed.

- **Relay_Master_Log_File**
  The name of the master binary log file containing the most recent event executed by the SQL thread.

- **Slave_IO_Running**
  Whether the I/O thread is started and has connected successfully to the master. Internally, the state of this thread is represented by one of the following three values:

  - **MYSQL_SLAVE_NOT_RUN.** The slave I/O thread is not running. For this state, `Slave_IO_Running` is `No`.

  - **MYSQL_SLAVE_RUN_NOT_CONNECT.** The slave I/O thread is running, but is not connected to a replication master. For this state, `Slave_IO_Running` depends on the server version as shown in the following table.

    | MySQL Version                                  | Slave_IO_Running |
    |-----------------------------------------------|-------------------|
    | 4.1 (4.1.13 and earlier); 5.0 (5.0.11 and earlier) | Yes               |
    | 4.1 (4.1.14 and later); 5.0 (5.0.12 and later)   | No                |
    | 5.1 (5.1.45 and earlier)                       | No                |
    | 5.1 (5.1.46 and later); 5.5                    | Connecting        |

  - **MYSQL_SLAVE_RUN_CONNECT.** The slave I/O thread is running, and is connected to a replication master. For this state, `Slave_IO_Running` is `Yes`.

Beginning with MySQL 5.1.46, the value of the `Slave_running` system status variable corresponds with this value. (Bug #30703)

- **Slave_SQL_Running**
Whether the SQL thread is started.

- **Replicate_Do_DB, Replicate_Ignore_DB**

  The lists of databases that were specified with the `--replicate-do-db` and `--replicate-ignore-db` options, if any.

- **Replicate_Do_Table, Replicate_Ignore_Table, Replicate_Wild_Do_Table, Replicate_Wild_Ignore_Table**

  The lists of tables that were specified with the `--replicate-do-table`, `--replicate-ignore-table`, `--replicate-wild-do-table`, and `--replicate-wild-ignore-table` options, if any.

- **Last_Errno, Last_Error**

  As of MySQL 5.1.20, these columns are aliases for `Last_SQL_Errno` and `Last_SQL_Error`. Before 5.1.20, they indicate the error number and error message returned by the most recently executed statement. An error number of 0 and message of the empty string mean “no error.” If the `Last_Error` value is not empty, the error values also appear in the slave's error log.

  Beginning with MySQL 5.1.37, and with MySQL Cluster NDB 6.2.17, MySQL Cluster NDB 6.3.23, and MySQL Cluster NDB 6.4.3: Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns. (Bug #34654, Bug #44270)

  **Note**

  When the slave SQL thread receives an error, it reports the error first, then stops the SQL thread. This means that there is a small window of time during which `SHOW SLAVE STATUS` shows a nonzero value for `Last_SQL_Errno` even though `Slave_SQL_Running` still displays `Yes`.

- **Skip_Counter**

  The current value of the `sql_slave_skip_counter` system variable. See Section 13.4.2.6, “SET GLOBAL sql_slave_skip_counter Syntax”.

- **Exec_Master_Log_Pos**

  The position in the current master binary log file to which the SQL thread has read and executed, marking the start of the next transaction or event to be processed. You can use this value with the `CHANGE MASTER TO` statement’s `MASTER_LOG_POS` option when starting a new slave from an existing slave, so that the new slave reads from this point. The coordinates given by `(Relay_Master_Log_File, Exec_Master_Log_Pos)` in the master’s binary log correspond to the coordinates given by `(Relay_Log_File, Relay_Log_Pos)` in the relay log.

- **Relay_Log_Space**

  The total combined size of all existing relay log files.

- **Until_Condition, Until_Log_File, Until_Log_Pos**

  The values specified in the UNTIL clause of the `START SLAVE` statement.

  **Until_Condition** has these values:

  - **None** if no UNTIL clause was specified
  - **Master** if the slave is reading until a given position in the master's binary log
  - **Relay** if the slave is reading until a given position in its relay log
Until Log File and Until Log Pos indicate the log file name and position that define the coordinates at which the SQL thread stops executing.

- Master_SSL_Allowed, Master_SSL_CA_File, Master_SSL_CA_Path, Master_SSL_Cert, Master_SSL_Cipher, Master_SSL_Key, Master_SSL_Verify_Server_Cert

These fields show the SSL parameters used by the slave to connect to the master, if any.

- Master_SSL_Allowed has these values:
  - Yes if an SSL connection to the master is permitted
  - No if an SSL connection to the master is not permitted
  - Ignored if an SSL connection is permitted but the slave server does not have SSL support enabled

The values of the other SSL-related fields correspond to the values of the MASTER_SSL_CA, MASTER_SSL_CAPATH, MASTER_SSL_CERT, MASTER_SSL_CIPHER, MASTER_SSL_KEY, and MASTER_SSL_VERIFY_SERVER_CERT options to the CHANGE MASTER TO statement. See Section 13.4.2.1, “CHANGE MASTER TO Syntax”. MASTER_SSL_VERIFY_SERVER_CERT was added in MySQL 5.1.18.

- Seconds_Behind_Master

This field is an indication of how “late” the slave is:

- When the slave is actively processing updates, this field shows the difference between the current timestamp on the slave and the original timestamp logged on the master for the event currently being processed on the slave.

- When no event is currently being processed on the slave, this value is 0.

In essence, this field measures the time difference in seconds between the slave SQL thread and the slave I/O thread. If the network connection between master and slave is fast, the slave I/O thread is very close to the master, so this field is a good approximation of how late the slave SQL thread is compared to the master. If the network is slow, this is not a good approximation; the slave SQL thread may quite often be caught up with the slow-reading slave I/O thread, so Seconds_Behind_Master often shows a value of 0, even if the I/O thread is late compared to the master. In other words, this column is useful only for fast networks.

This time difference computation works even if the master and slave do not have identical clock times, provided that the difference, computed when the slave I/O thread starts, remains constant from then on. Any changes—including NTP updates—can lead to clock skews that can make calculation of Seconds_Behind_Master less reliable.

This field is NULL (undefined or unknown) if the slave SQL thread is not running, or if the slave I/O thread is not running or is not connected to the master. For example, if the slave I/O thread is running but is not connected to the master and is sleeping for the number of seconds given by the CHANGE MASTER TO statement or --master-connect-retry option (default 60) before reconnecting, the value is NULL. This is because the slave cannot know what the master is doing, and so cannot say reliably how late it is.

The value of Seconds_Behind_Master is based on the timestamps stored in events, which are preserved through replication. This means that if a master M1 is itself a slave of M0, any event from M1’s binary log that originates from M0’s binary log has M0’s timestamp for that event. This enables MySQL to replicate TIMESTAMP successfully. However, the problem for Seconds_Behind_Master is that if M1 also receives direct updates from clients, the Seconds_Behind_Master value randomly fluctuates because sometimes the last event from M1 originates from M0 and sometimes is the result of a direct update on M1.
• **Last_IO_Errno, Last_IO_Error**

The error number and error message of the most recent error that caused the I/O thread to stop. An error number of 0 and message of the empty string mean “no error.” If the `Last_IO_Error` value is not empty, the error values also appear in the slave’s error log. These columns were added in MySQL 5.1.20.

**MySQL Cluster.** Beginning with MySQL Cluster NDB 6.2.17, 6.3.23, and 6.4.3: Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns. This applies to MySQL Cluster only. (Bug #34654)

• **Last_SQL_Errno, Last_SQL_Error**

The error number and error message of the most recent error that caused the SQL thread to stop. An error number of 0 and message of the empty string mean “no error.” If the `Last_SQL_Error` value is not empty, the error values also appear in the slave’s error log. These columns were added in MySQL 5.1.20.

Example:

```plaintext
Last_SQL_Errno: 1051
Last_SQL_Error: error 'Unknown table 'z'' on query 'drop table z'
```

The message indicates that the table `z` existed on the master and was dropped there, but it did not exist on the slave, so `DROP TABLE` failed on the slave. (This might occur, for example, if you forget to copy the table to the slave when setting up replication.)

**MySQL Cluster.** Beginning with MySQL Cluster NDB 6.2.17, 6.3.23, and 6.4.3: Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns. This applies to MySQL Cluster only. (Bug #34654)

• **Replicate_Ignore_Server_Ids (MySQL Cluster only)**

Beginning with MySQL Cluster NDB 6.1.29, MySQL Cluster NDB 6.3.31, MySQL Cluster NDB 7.0.11, and MySQL Cluster NDB 7.1.0, you can tell a slave to ignore events from 0 or more masters using the `IGNORE_SERVER_IDS` option in a `CHANGE MASTER TO` statement. (See Bug #47037.) This is normally of interest only when using a circular or other multi-master replication setup.

The message shown for `Replicate_Ignore_Server_Ids` consists of a space-delimited list of one or more numbers, the first value indicating the number of servers to be ignored; if not 0 (the default), this server-count value is followed by the actual server IDs. For example, if a `CHANGE MASTER TO` statement containing the `IGNORE_SERVER_IDS = (2, 6, 9)` option has been issued to tell a slave to ignore masters having the server ID 2, 6, or 9, that information appears as shown here:

```plaintext
Replicate_Ignore_Server_Ids: 3 2 6 9
```

`Replicate_Ignore_Server_Ids` filtering is performed by the I/O thread, rather than by the SQL thread, which means that events which are filtered out are not written to the relay log. This differs from the filtering actions taken by server options such `--replicate-do-table`, which apply to the SQL thread.

### 13.7.5.37 SHOW STATUS Syntax

```
SHOW [GLOBAL | SESSION] STATUS
[LIKE 'pattern' | WHERE expr]
```

`SHOW STATUS` provides server status information (see Section 5.1.6, “Server Status Variables”). This statement does not require any privilege. It requires only the ability to connect to the server.
Status variable information is also available from these sources:

- The `GLOBAL_STATUS` and `SESSION_STATUS` tables. See Section 20.8, “The INFORMATION_SCHEMA GLOBAL_STATUS and SESSION_STATUS Tables”.

- The `mysqladmin extended-status` command. See Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”.

For `SHOW STATUS`, a `LIKE` clause, if present, indicates which variable names to match. A `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 20.27, “Extensions to SHOW Statements”.

`SHOW STATUS` accepts an optional `GLOBAL` or `SESSION` variable scope modifier:

- With a `GLOBAL` modifier, the statement displays the global status values. A global status variable may represent status for some aspect of the server itself (for example, `Aborted_connects`), or the aggregated status over all connections to MySQL (for example, `Bytes_received` and `Bytes_sent`). If a variable has no global value, the session value is displayed.

- With a `SESSION` modifier, the statement displays the status variable values for the current connection. If a variable has no session value, the global value is displayed. `LOCAL` is a synonym for `SESSION`.

- If no modifier is present, the default is `SESSION`.

The scope for each status variable is listed at Section 5.1.6, “Server Status Variables”.

Each invocation of the `SHOW STATUS` statement uses an internal temporary table and increments the global `Created_tmp_tables` value.

Partial output is shown here. The list of names and values may differ for your server. The meaning of each variable is given in Section 5.1.6, “Server Status Variables”.

```
mysql> SHOW STATUS;
+--------------------------+------------+
| Variable_name            | Value      |
+--------------------------+------------+
| Aborted_clients          | 0          |
| Aborted_connects         | 0          |
| Bytes_received           | 155372598  |
| Bytes_sent               | 1176560426 |
| Connections              | 30023      |
| Created_tmp_disk_tables  | 0          |
| Created_tmp_tables       | 8340       |
| Created_tmp_files        | 60         |
| ...                      |            |
| Opened_tables            | 1          |
| Open_files               | 2          |
| Open_streams             | 0          |
| Opened_tables            | 44600      |
| Questions                | 2026873    |
| ...                      |            |
| Table_locks_immediate    | 1920382    |
| Table_locks_waited       | 0          |
| Threads_cached           | 0          |
| Threads_created          | 30022      |
| Threads_connected        | 1          |
| Threads_running          | 1          |
| Uptime                   | 80380      |
+--------------------------+------------+
```

With a `LIKE` clause, the statement displays only rows for those variables with names that match the pattern:

```
mysql> SHOW STATUS LIKE 'Key\%';
```
13.7.5.38 SHOW TABLE STATUS Syntax

SHOW TABLE STATUS [(FROM | IN) db_name] [LIKE 'pattern' | WHERE expr]

SHOW TABLE STATUS works like SHOW TABLES, but provides a lot of information about each non-TEMPORARY table. You can also get this list using the mysqlshow --status db_name command. The LIKE clause, if present, indicates which table names to match. The WHERE clause can be given to select rows using more general conditions, as discussed in Section 20.27, “Extensions to SHOW Statements”.

This statement also displays information about views.

SHOW TABLE STATUS output has the following columns:

- **Name**
  The name of the table.

- **Engine**
  The storage engine for the table. See Chapter 14, Storage Engines.

- **Version**
  The version number of the table’s .frm file.

- **Row_format**
  The row-storage format (Fixed, Dynamic, Compressed, Redundant, Compact). For MyISAM tables, (Dynamic corresponds to what myisamchk -dvv reports as Packed. The format of InnoDB tables is reported as Redundant or Compact. For the Barracuda file format of the InnoDB Plugin, the format may be Compressed or Dynamic.

- **Rows**
  The number of rows. Some storage engines, such as MyISAM, store the exact count. For other storage engines, such as InnoDB, this value is an approximation, and may vary from the actual value by as much as 40 to 50%. In such cases, use SELECT COUNT(*) to obtain an accurate count.

  The Rows value is NULL for tables in the INFORMATION_SCHEMA database.

- **Avg_row_length**
  The average row length.

- **Data_length**
  For MyISAM, Data_length is the length of the data file, in bytes.

  For InnoDB, Data_length is the approximate amount of memory allocated for the clustered index, in bytes. Specifically, it is the clustered index size, in pages, multiplied by the InnoDB page size.
Refer to the notes at the end of this section for information regarding other storage engines.

- **Max_data_length**

For *MyISAM*, **Max_data_length** is maximum length of the data file. This is the total number of bytes of data that can be stored in the table, given the data pointer size used.

Unused for *InnoDB*.

Refer to the notes at the end of this section for information regarding other storage engines.

- **Index_length**

For *MyISAM*, **Index_length** is the length of the index file, in bytes.

For *InnoDB*, **Index_length** is the approximate amount of memory allocated for non-clustered indexes, in bytes. Specifically, it is the sum of non-clustered index sizes, in pages, multiplied by the *InnoDB* page size.

Refer to the notes at the end of this section for information regarding other storage engines.

- **Data_free**

The number of allocated but unused bytes.

Beginning with MySQL 5.1.24, this information is also shown for *InnoDB* tables (previously, it was in the Comment value). *InnoDB* tables report the free space of the tablespace to which the table belongs. For a table located in the shared tablespace, this is the free space of the shared tablespace. If you are using multiple tablespaces and the table has its own tablespace, the free space is for only that table. Free space means the number of bytes in completely free extents minus a safety margin. Even if free space displays as 0, it may be possible to insert rows as long as new extents need not be allocated.

For partitioned tables, this value is only an estimate and may not be absolutely correct. A more accurate method of obtaining this information in such cases is to query the INFORMATION_SCHEMA.PARTITIONS table, as shown in this example:

```sql
SELECT SUM(DATA_FREE) 
FROM INFORMATION_SCHEMA.PARTITIONS 
WHERE TABLE_SCHEMA = 'mydb' 
AND TABLE_NAME = 'mytable';
```

For more information, see Section 20.11, “The INFORMATION_SCHEMA PARTITIONS Table”.

- **Auto_increment**

  The next AUTO_INCREMENT value.

- **Create_time**

  When the table was created.

- **Update_time**

  When the data file was last updated. For some storage engines, this value is NULL. For example, *InnoDB* stores multiple tables in its system tablespace and the data file timestamp does not apply. Even with file-per-table mode with each *InnoDB* table in a separate .ibd file, change buffering can delay the write to the data file, so the file modification time is different from the time of the last insert, update, or delete. For *MyISAM*, the data file timestamp is used; however, on Windows the timestamp is not updated by updates so the value is inaccurate.
SHOW Syntax

• **Check_time**

  When the table was last checked. Not all storage engines update this time, in which case the value is always **NULL**.

• **Collation**

  The table’s character set and collation.

• **Checksum**

  The live checksum value (if any).

• **Create_options**

  Extra options used with `CREATE TABLE`. The original options supplied when `CREATE TABLE` is called are retained and the options reported here may differ from the active table settings and options.

• **Comment**

  The comment used when creating the table (or information as to why MySQL could not access the table information).

  Before MySQL 5.1.24, free space for **InnoDB** tables is reported in the comment. As of 5.1.24, it is reported in the **Data_free** column.

**Notes:**

• For **MEMORY** tables, the **Data_length**, **Max_data_length**, and **Index_length** values approximate the actual amount of allocated memory. The allocation algorithm reserves memory in large amounts to reduce the number of allocation operations.

• For **NDBCLUSTER** tables, the output of this statement shows appropriate values for the **Avg_row_length** and **Data_length** columns, with the exception that **BLOB** columns are not taken into account. Prior to MySQL 5.1.21, the number of MySQL Cluster replicas was shown in the **Comment** column as **number_of_replicas** (Bug #11379).

• For views, all the fields displayed by **SHOW TABLE STATUS** are **NULL** except that **Name** indicates the view name and **Comment** says **view**.

**13.7.5.39 SHOW TABLES Syntax**

```sql
SHOW [FULL] TABLES [[FROM | IN] db_name] [LIKE 'pattern' | WHERE expr]
```

**SHOW TABLES** lists the non-**TEMPORARY** tables in a given database. You can also get this list using the `mysqlshow db_name` command. The **LIKE** clause, if present, indicates which table names to match. The **WHERE** clause can be given to select rows using more general conditions, as discussed in Section 20.27, “Extensions to SHOW Statements”.

Matching performed by the **LIKE** clause is dependent on the setting of the **lower_case_table_names** system variable.

This statement also lists any views in the database. The **FULL** modifier is supported such that **SHOW FULL TABLES** displays a second output column. Values for the second column are **BASE TABLE** for a table and **VIEW** for a view.

If you have no privileges for a base table or view, it does not show up in the output from **SHOW TABLES** or `mysqlshow db_name`.
SHOW TRIGGERS Syntax

SHOW TRIGGERS Syntax

SHOW TRIGGERS [{FROM | IN} db_name] [LIKE 'pattern' | WHERE expr]

SHOW TRIGGERS lists the triggers currently defined for tables in a database (the default database unless a FROM clause is given). This statement returns results only for databases and tables for which you have the TRIGGER privilege, or (prior to MySQL 5.1.23) if you have the SUPER privilege. The LIKE clause, if present, indicates which table names to match (not trigger names) and causes the statement to display triggers for those tables. The WHERE clause can be given to select rows using more general conditions, as discussed in Section 20.27, “Extensions to SHOW Statements”.

For the trigger ins_sum as defined in Section 19.3, “Using Triggers”, the output of this statement is as shown here:

```
mysql> SHOW TRIGGERS LIKE 'acc%'

*************************** 1. row ***************************
Trigger: ins_sum
Event: INSERT
Table: account
Statement: SET @sum = @sum + NEW.amount
Timing: BEFORE
Created: NULL
sql_mode: 
Definer: me@localhost
character_set_client: latin1
collation_connection: latin1_swedish_ci
Database Collation: latin1_swedish_ci
```

SHOW TRIGGERS output has the following columns:

- **Trigger**: The trigger name.
- **Event**: The type of operation that causes trigger activation. The value is 'INSERT', 'UPDATE', or 'DELETE'.
- **Table**: The table for which the trigger is defined.
- **Statement**: The trigger body; that is, the statement executed when the trigger activates.
- **Timing**: Whether the trigger activates before or after the triggering event. The value is 'BEFORE' or 'AFTER'.
- **Created**: The value of this column is always NULL.
- **sql_mode**: The SQL mode in effect when the trigger executes.
- **Definer**: The account of the user who created the trigger, in 'user_name'@'host_name' format.
- **character_set_client**: The session value of the character_set_client system variable when the trigger was created. This column was added in MySQL 5.1.21.
- **collation_connection**: The session value of the collation_connection system variable when the trigger was created. This column was added in MySQL 5.1.21.
- **Database Collation**: The collation of the database with which the trigger is associated. This column was added in MySQL 5.1.21.

You can also obtain information about trigger objects from INFORMATION_SCHEMA, which contains a TRIGGERS table. See Section 20.23, “The INFORMATION_SCHEMA TRIGGERS Table”.

SHOW VARIABLES Syntax

13.7.5.41
SHOW Syntax

SHOW [GLOBAL | SESSION] VARIABLES
[LIKE 'pattern' | WHERE expr]

SHOW VARIABLES shows the values of MySQL system variables (see Section 5.1.4, “Server System Variables”). This statement does not require any privilege. It requires only the ability to connect to the server.

System variable information is also available from these sources:

- The GLOBAL_VARIABLES and SESSION_VARIABLES tables. See Section 20.9, “The INFORMATION_SCHEMA GLOBAL_VARIABLES and SESSION_VARIABLES Tables”.
- The mysqladmin variables command. See Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”.

For SHOW VARIABLES, a LIKE clause, if present, indicates which variable names to match. A WHERE clause can be given to select rows using more general conditions, as discussed in Section 20.27, “Extensions to SHOW Statements”.

SHOW VARIABLES accepts an optional GLOBAL or SESSION variable scope modifier:

- With a GLOBAL modifier, the statement displays global system variable values. These are the values used to initialize the corresponding session variables for new connections to MySQL. If a variable has no global value, the session value is displayed.
- With a SESSION modifier, the statement displays the system variable values that are in effect for the current connection. If a variable has no session value, the global value is displayed. LOCAL is a synonym for SESSION.
- If no modifier is present, the default is SESSION.

The scope for each system variable is listed at Section 5.1.4, “Server System Variables”.

SHOW VARIABLES is subject to a version-dependent display-width limit. For variables with very long values that are not completely displayed, use SELECT as a workaround. For example:

```
SELECT @@GLOBAL.innodb_data_file_path;
```

Most system variables can be set at server startup (read-only variables such as version_comment are exceptions). Many can be changed at runtime with the SET statement. See Section 5.1.5, “Using System Variables”, and Section 13.7.4.1, “SET Syntax for Variable Assignment”.

Partial output is shown here. The list of names and values may differ for your server. Section 5.1.4, “Server System Variables”, describes the meaning of each variable, and Section 8.12.2, “Tuning Server Parameters”, provides information about tuning them.

```
mysql> SHOW VARIABLES;
+-----------------+---------------------------+
| Variable_name   | Value                     |
|-----------------+---------------------------+
| auto_increment_increment | 1                         |
| auto_increment_offset      | 1                         |
| automatic_sp_privileges    | ON                        |
| back_log            | 50                        |
| basedir            | /home/jon/bin/mysql-5.1/  |
| binlog_cache_size   | 32768                     |
| bulk_insert_buffer_size| 8388608                  |
| character_set_client | latin1                    |
| character_set_connection| latin1                   |
```
SHOW Syntax

With a LIKE clause, the statement displays only rows for those variables with names that match the pattern. To obtain the row for a specific variable, use a LIKE clause as shown:

```
SHOW VARIABLES LIKE 'max_join_size';
SHOW SESSION VARIABLES LIKE 'max_join_size';
```

To get a list of variables whose name match a pattern, use the “%” wildcard character in a LIKE clause:

```
SHOW VARIABLES LIKE '%size%';
SHOW GLOBAL VARIABLES LIKE '%size%';
```

Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because “_” is a wildcard that matches any single character, you should escape it as “\_” to match it literally. In practice, this is rarely necessary.

13.7.5.42 SHOW WARNINGS Syntax

```
SHOW WARNINGS [LIMIT [offset,] row_count]
SHOW COUNT(*) WARNINGS
```

SHOW WARNINGS is a diagnostic statement that displays information about the conditions (errors, warnings, and notes) resulting from executing a statement in the current session. Warnings are generated for DML statements such as INSERT, UPDATE, and LOAD DATA INFILE as well as DDL statements such as CREATE TABLE and ALTER TABLE.

The LIMIT clause has the same syntax as for the SELECT statement. See Section 13.2.8, “SELECT Syntax”.

SHOW WARNINGS is also used following EXPLAIN EXTENDED, to display the extra information generated by EXPLAIN when the EXTENDED keyword is used. See Section 8.8.3, “EXPLAIN EXTENDED Output Format”.

SHOW WARNINGS displays information about the conditions resulting from the most recent statement in the current session that generated messages. It shows nothing if the most recent statement used a table and generated no messages. (That is, statements that use a table but generate no messages
clear the message list.) Statements that do not use tables and do not generate messages have no
effect on the message list.

The SHOW COUNT(*) WARNINGS diagnostic statement displays the total number of errors, warnings,
and notes. You can also retrieve this number from the warning_count system variable:

```
SHOW COUNT(*) WARNINGS;
SELECT @@warning_count;
```

A related diagnostic statement, SHOW ERRORS, shows only error conditions (it excludes warnings
and notes), and SHOW COUNT(*) ERRORS statement displays the total number of errors. See
Section 13.7.5.18, “SHOW ERRORS Syntax”.

Here is a simple example that shows data-conversion warnings for INSERT:

```
mysql> CREATE TABLE t1 (a TINYINT NOT NULL, b CHAR(4));
Query OK, 0 rows affected (0.05 sec)
mysql> INSERT INTO t1 VALUES(10,'mysql'), (NULL,'test'), (300,'xyz');
Query OK, 3 rows affected, 3 warnings (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 3
mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Warning
Code: 1265
Message: Data truncated for column 'b' at row 1
*************************** 2. row ***************************
Level: Warning
Code: 1048
Message: Column 'a' cannot be null
*************************** 3. row ***************************
Level: Warning
Code: 1264
Message: Out of range value for column 'a' at row 3
3 rows in set (0.00 sec)
```

The max_error_count system variable controls the maximum number of error, warning, and note
messages for which the server stores information, and thus the number of messages that SHOW
WARNINGS displays. To change the number of messages the server can store, change the value of
max_error_count. The default is 64.

max_error_count controls only how many messages are stored, not how many are counted. The
value of warning_count is not limited by max_error_count, even if the number of messages
generated exceeds max_error_count. The following example demonstrates this. The ALTER TABLE
statement produces three warning messages (strict SQL mode is disabled for the example to prevent
an error from occurring after a single conversion issue). Only one message is stored and displayed
because max_error_count has been set to 1, but all three are counted (as shown by the value of
warning_count):

```
mysql> SHOW VARIABLES LIKE 'max_error_count';
+-----------------+-------+
| Variable_name   | Value |
+-----------------+-------+
| max_error_count | 64    |
+-----------------+-------+
1 row in set (0.00 sec)
mysql> SET max_error_count=1, sql_mode = '';
Query OK, 0 rows affected (0.00 sec)
mysql> ALTER TABLE t1 MODIFY b CHAR;
Query OK, 3 rows affected, 3 warnings (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 3
```
### 13.7.6 Other Administrative Statements

#### 13.7.6.1 BINLOG Syntax
Other Administrative Statements

**BINLOG 'str'**

**BINLOG** is an internal-use statement. It is generated by the `mysqlbinlog` program as the printable representation of certain events in binary log files. (See Section 4.6.7, "mysqlbinlog — Utility for Processing Binary Log Files"). The 'str' value is a base 64-encoded string that the server decodes to determine the data change indicated by the corresponding event. This statement requires the **SUPER** privilege. It was added in MySQL 5.1.5.

### 13.7.6.2 CACHE INDEX Syntax

```plaintext
CACHE INDEX
  tbl_index_list [, tbl_index_list] ...
  IN key_cache_name

tbl_index_list:
  tbl_name [[INDEX|KEY] (index_name[, index_name] ...)]
```

The **CACHE INDEX** statement assigns table indexes to a specific key cache. It is used only for **MyISAM** tables. After the indexes have been assigned, they can be preloaded into the cache if desired with **LOAD INDEX INTO CACHE**.

The following statement assigns indexes from the tables **t1**, **t2**, and **t3** to the key cache named **hot_cache**:

```sql
mysql> CACHE INDEX t1, t2, t3 IN hot_cache;
```

<table>
<thead>
<tr>
<th>Table</th>
<th>Op</th>
<th>Msg_type</th>
<th>Msg_text</th>
</tr>
</thead>
<tbody>
<tr>
<td>test.t1</td>
<td>assign_to_keycache</td>
<td>status</td>
<td>OK</td>
</tr>
<tr>
<td>test.t2</td>
<td>assign_to_keycache</td>
<td>status</td>
<td>OK</td>
</tr>
<tr>
<td>test.t3</td>
<td>assign_to_keycache</td>
<td>status</td>
<td>OK</td>
</tr>
</tbody>
</table>

The syntax of **CACHE INDEX** enables you to specify that only particular indexes from a table should be assigned to the cache. The current implementation assigns all the table's indexes to the cache, so there is no reason to specify anything other than the table name.

The key cache referred to in a **CACHE INDEX** statement can be created by setting its size with a parameter setting statement or in the server parameter settings. For example:

```sql
mysql> SET GLOBAL keycache1.key_buffer_size=128*1024;
```

Key cache parameters can be accessed as members of a structured system variable. See Section 5.1.5.1, "Structured System Variables".

A key cache must exist before you can assign indexes to it:

```sql
mysql> CACHE INDEX t1 IN non_existent_cache;
ERROR 1284 (HY000): Unknown key cache 'non_existent_cache'
```

By default, table indexes are assigned to the main (default) key cache created at the server startup. When a key cache is destroyed, all indexes assigned to it become assigned to the default key cache again.

Index assignment affects the server globally: If one client assigns an index to a given cache, this cache is used for all queries involving the index, no matter which client issues the queries.

### 13.7.6.3 FLUSH Syntax

```plaintext
FLUSH [NO_WRITE_TO_BINLOG | LOCAL]
```
The `FLUSH` statement has several variant forms that clear or reload various internal caches, flush tables, or acquire locks. To execute `FLUSH`, you must have the `RELOAD` privilege.

By default, the server writes `FLUSH` statements to the binary log so that they replicate to replication slaves. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

**Note**

FLUSH LOGS, FLUSH MASTER, FLUSH SLAVE, and FLUSH TABLES WITH READ LOCK are not written to the binary log in any case because they would cause problems if replicated to a slave.

Sending a `SIGHUP` signal to the server causes several flush operations to occur that are similar to various forms of the `FLUSH` statement. See Section 5.1.10, “Server Response to Signals”.

The `FLUSH` statement causes an implicit commit. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

The `RESET` statement is similar to `FLUSH`. See Section 13.7.6.6, “RESET Syntax”, for information about using the `RESET` statement with replication.

`flush_option` can be any of the following items:

- **DES_KEY_FILE**
  Reloads the DES keys from the file that was specified with the `--des-key-file` option at server startup time.

- **HOSTS**
  Empties the host cache. You should flush the host cache if some of your hosts change IP address or if the error message *Host 'host_name' is blocked* occurs. (See Section B.5.2.6, “Host 'host_name' is blocked”.) When more than `max_connect_errors` errors occur successively for a given host while connecting to the MySQL server, MySQL assumes that something is wrong and blocks the host from further connection requests. Flushing the host cache enables further connection attempts from the host. The default value of `max_connect_errors` is 10. To avoid this error message, start the server with `max_connect_errors` set to a large value.

- **LOGS**
  Closes and reopens all log files. If binary logging is enabled, the sequence number of the binary log file is incremented by one relative to the previous file.

Prior to MySQL 5.1.51, if you flush the logs using `FLUSH LOGS` and `mysqld` is writing the error log to a file (for example, if it was started with the `--log-error` option), log file renaming may occur, as described in Section 5.4.2, “The Error Log”.

`FLUSH LOGS` has no effect on tables used for the general query log or for the slow query log (see Section 5.4.1, “Selecting General Query and Slow Query Log Output Destinations”).

- **MASTER**
  Deletes all binary logs, resets the binary log index file and creates a new binary log. `FLUSH MASTER` is deprecated in favor of `RESET MASTER`. `FLUSH MASTER` is still accepted in MySQL 5.1 for backward compatibility, but is removed in MySQL 5.6. See Section 13.4.1.2, “RESET MASTER Syntax”.

- **PRIVILEGES**
  Reloads the privileges from the grant tables in the `mysql` database.
The server caches information in memory as a result of \texttt{GRANT}, \texttt{CREATE USER}, \texttt{CREATE SERVER}, and \texttt{INSTALL PLUGIN} statements. This memory is not released by the corresponding \texttt{REVOKE}, \texttt{DROP USER}, \texttt{DROP SERVER}, and \texttt{UNINSTALL PLUGIN} statements, so for a server that executes many instances of the statements that cause caching, there will be an increase in memory use. This cached memory can be freed with \texttt{FLUSH PRIVILEGES}.

- **QUERY CACHE**

  Defragment the query cache to better utilize its memory. \texttt{FLUSH QUERY CACHE} does not remove any queries from the cache, unlike \texttt{FLUSH TABLES} or \texttt{RESET QUERY CACHE}.

- **SLAVE**

  Resets all replication slave parameters, including relay log files and replication position in the master's binary logs. \texttt{FLUSH SLAVE} is deprecated in favor of \texttt{RESET SLAVE}. \texttt{FLUSH SLAVE} is still accepted in MySQL 5.1 for backward compatibility, but is removed in MySQL 5.6. See Section 13.4.2.5, “RESET SLAVE Syntax”.

- **STATUS**

  This option adds the current thread's session status variable values to the global values and resets the session values to zero. Some global variables may be reset to zero as well. It also resets the counters for key caches (default and named) to zero and sets \texttt{Max_used_connections} to the current number of open connections. This is something you should use only when debugging a query. See Section 1.7, “How to Report Bugs or Problems”.

- **TABLES**

  \texttt{FLUSH TABLES} flushes tables, and, depending on the variant used, acquires locks. The permitted syntax is discussed later in this section.

- **USER_RESOURCES**

  Resets all per-hour user resources to zero. This enables clients that have reached their hourly connection, query, or update limits to resume activity immediately. \texttt{FLUSH USER_RESOURCES} does not apply to the limit on maximum simultaneous connections. See Section 6.3.4, “Setting Account Resource Limits”.

The \texttt{mysqladmin} utility provides a command-line interface to some flush operations, using commands such as \texttt{flush-hosts}, \texttt{flush-logs}, \texttt{flush-privileges}, \texttt{flush-status}, and \texttt{flush-tables}. See Section 4.5.2, “\texttt{mysqladmin} — Client for Administering a MySQL Server”.

**Note**

It is not possible to issue \texttt{FLUSH} statements within stored functions or triggers. However, you may use \texttt{FLUSH} in stored procedures, so long as these are not called from stored functions or triggers. See Section C.1, “Restrictions on Stored Programs”.

**FLUSH TABLES Syntax**

\texttt{FLUSH TABLES} has several forms, described following. \texttt{FLUSH TABLE} is a synonym for \texttt{FLUSH TABLES}, except that \texttt{TABLE} does not work with the \texttt{WITH READ LOCK} variant.

- **FLUSH TABLES**

  Closes all open tables, forces all tables in use to be closed, and flushes the query cache. \texttt{FLUSH TABLES} also removes all query results from the query cache, like the \texttt{RESET QUERY CACHE} statement.

- **FLUSH TABLES \texttt{tbl_name}[, \texttt{tbl_name}] ...**
With a list of one or more comma-separated table names, this statement is like `FLUSH TABLES` with no names except that the server flushes only the named tables. No error occurs if a named table does not exist.

- **`FLUSH TABLES WITH READ LOCK`**

Closes all open tables and locks all tables for all databases with a global read lock. This is a very convenient way to get backups if you have a file system such as Veritas or ZFS that can take snapshots in time. Use `UNLOCK TABLES` to release the lock.

`FLUSH TABLES WITH READ LOCK` acquires a global read lock and not table locks, so it is not subject to the same behavior as `LOCK TABLES` and `UNLOCK TABLES` with respect to table locking and implicit commits:

- `UNLOCK TABLES` implicitly commits any active transaction only if any tables currently have been locked with `LOCK TABLES`. The commit does not occur for `UNLOCK TABLES` following `FLUSH TABLES WITH READ LOCK` because the latter statement does not acquire table locks.

- Beginning a transaction causes table locks acquired with `LOCK TABLES` to be released, as though you had executed `UNLOCK TABLES`. Beginning a transaction does not release a global read lock acquired with `FLUSH TABLES WITH READ LOCK`.

`FLUSH TABLES WITH READ LOCK` does not prevent the server from inserting rows into the log tables (see Section 5.4.1, “Selecting General Query and Slow Query Log Output Destinations”).

### 13.7.6.4 KILL Syntax

```
KILL [CONNECTION | QUERY] processlist_id
```

Each connection to `mysqld` runs in a separate thread. You can kill a thread with the `KILL processlist_id` statement.

Thread processlist identifiers can be determined from the `ID` column of the `INFORMATION_SCHEMA.PROCESSLIST` table and the `Id` column of `SHOW PROCESSLIST` output. The value for the current thread is returned by the `CONNECTION_ID()` function.

`KILL` permits an optional `CONNECTION` or `QUERY` modifier:

- **`KILL CONNECTION`** is the same as `KILL` with no modifier: It terminates the connection associated with the given `processlist_id`, after terminating any statement the connection is executing.

- **`KILL QUERY`** terminates the statement the connection is currently executing, but leaves the connection itself intact.

If you have the `PROCESS` privilege, you can see all threads. If you have the `SUPER` privilege, you can kill all threads and statements. Otherwise, you can see and kill only your own threads and statements.

You can also use the `mysqladmin processlist` and `mysqladmin kill` commands to examine and kill threads.

**Note**

You cannot use `KILL` with the Embedded MySQL Server library because the embedded server merely runs inside the threads of the host application. It does not create any connection threads of its own.

When you use `KILL`, a thread-specific kill flag is set for the thread. In most cases, it might take some time for the thread to die because the kill flag is checked only at specific intervals:

- During `SELECT` operations, for `ORDER BY` and `GROUP BY` loops, the flag is checked after reading a block of rows. If the kill flag is set, the statement is aborted.
• During `ALTER TABLE` operations, the kill flag is checked before each block of rows are read from the original table. If the kill flag was set, the statement is aborted and the temporary table is deleted.

• During `UPDATE` or `DELETE` operations, the kill flag is checked after each block read and after each updated or deleted row. If the kill flag is set, the statement is aborted. If you are not using transactions, the changes are not rolled back.

• `GET_LOCK()` aborts and returns `NULL`.

• An `INSERT DELAYED` thread quickly flushes (inserts) all rows it has in memory and then terminates.

• If the thread is in the table lock handler (state: `Locked`), the table lock is quickly aborted.

• If the thread is waiting for free disk space in a write call, the write is aborted with a “disk full” error message.

**Warning**

Killing a `REPAIR TABLE` or `OPTIMIZE TABLE` operation on a `MyISAM` table results in a table that is corrupted and unusable. Any reads or writes to such a table fail until you optimize or repair it again (without interruption).

### 13.7.6.5 LOAD INDEX INTO CACHE Syntax

```
LOAD INDEX INTO CACHE
tbl_index_list [, tbl_index_list] ...

tbl_index_list:
tbl_name
  [[INDEX|KEY] (index_name[, index_name] ...)]
  [IGNORE LEAVES]
```

The `LOAD INDEX INTO CACHE` statement preloads a table index into the key cache to which it has been assigned by an explicit `CACHE INDEX` statement, or into the default key cache otherwise. `LOAD INDEX INTO CACHE` is used only for `MyISAM` tables. It is not supported for tables having user-defined partitioning (see Section 18.5, “Restrictions and Limitations on Partitioning”).

The `IGNORE LEAVES` modifier causes only blocks for the nonleaf nodes of the index to be preloaded.

The following statement preloads nodes (index blocks) of indexes for the tables `t1` and `t2`:

```
mysql> LOAD INDEX INTO CACHE t1, t2 IGNORE LEAVES;
+---------+--------------+----------+----------+
| Table   | Op           | Msg_type | Msg_text |
+---------+--------------+----------+----------+
| test.t1 | preload_keys | status   | OK       |
| test.t2 | preload_keys | status   | OK       |
+---------+--------------+----------+----------+
```

This statement preloads all index blocks from `t1`. It preloads only blocks for the nonleaf nodes from `t2`.

The syntax of `LOAD INDEX INTO CACHE` enables you to specify that only particular indexes from a table should be preloaded. The current implementation preloads all the table’s indexes into the cache, so there is no reason to specify anything other than the table name.

`LOAD INDEX INTO CACHE ... IGNORE LEAVES` fails unless all indexes in a table have the same block size. (Prior to MySQL 5.1.19, it fails even without `IGNORE LEAVES`.) You can determine index block sizes for a table by using `myisamchk -dv` and checking the `Blocksize` column.

### 13.7.6.6 RESET Syntax

```
RESET reset_option [, reset_option] ...
```
The `RESET` statement is used to clear the state of various server operations. You must have the `RELOAD` privilege to execute `RESET`.

`RESET` acts as a stronger version of the `FLUSH` statement. See Section 13.7.6.3, “FLUSH Syntax”.

The `RESET` statement causes an implicit commit. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

`reset_option` can be any of the following:

- **MASTER**
  Deletes all binary logs listed in the index file, resets the binary log index file to be empty, and creates a new binary log file.

- **QUERY CACHE**
  Removes all query results from the query cache.

- **SLAVE**
  Makes the slave forget its replication position in the master binary logs. Also resets the relay log by deleting any existing relay log files and beginning a new one.

13.8 MySQL Utility Statements

13.8.1 DESCRIBE Syntax

The `DESCRIBE` and `EXPLAIN` statements are synonyms, used either to obtain information about table structure or query execution plans. For more information, see Section 13.7.5.6, “SHOW COLUMNS Syntax”, and Section 13.8.2, “EXPLAIN Syntax”.

13.8.2 EXPLAIN Syntax

```
{EXPLAIN | DESCRIBE | DESC} 
  tbl_name [col_name | wild]
{EXPLAIN | DESCRIBE | DESC} 
  [explain_type] SELECT select_options 
explain_type: {EXTENDED | PARTITIONS}
```

The `DESCRIBE` and `EXPLAIN` statements are synonyms. In practice, the `DESCRIBE` keyword is more often used to obtain information about table structure, whereas `EXPLAIN` is used to obtain a query execution plan (that is, an explanation of how MySQL would execute a query). The following discussion uses the `DESCRIBE` and `EXPLAIN` keywords in accordance with those uses, but the MySQL parser treats them as completely synonymous.

Obtaining Table Structure Information

`DESCRIBE` provides information about the columns in a table:

```
mysql> DESCRIBE City;
+------------+----------+------+-----+---------+----------------+
| Field      | Type     | Null | Key | Default | Extra          |
+------------+----------+------+-----+---------+----------------+
| Id         | int(11)  | NO   | PRI | NULL    | auto_increment |
| Name       | char(35) | NO   |     |         |                |
| Country    | char(3)  | NO   | UNI | NULL    |                |
| District   | char(20) | YES  | MUL | NULL    |                |
| Population | int(11)  | NO   |     | 0       |                |
```
DESCRIBE is a shortcut for SHOW COLUMNS. These statements also display information for views. The description for SHOW COLUMNS provides more information about the output columns. See Section 13.7.5.6, “SHOW COLUMNS Syntax”.

By default, DESCRIBE displays information about all columns in the table. col_name, if given, is the name of a column in the table. In this case, the statement displays information only for the named column. wild, if given, is a pattern string. It can contain the SQL "%" and "_" wildcard characters. In this case, the statement displays output only for the columns with names matching the string. There is no need to enclose the string within quotation marks unless it contains spaces or other special characters.

The DESCRIBE statement is provided for compatibility with Oracle.

The SHOW CREATE TABLE, SHOW TABLE STATUS, and SHOW INDEX statements also provide information about tables. See Section 13.7.5, “SHOW Syntax”.

Obtaining Execution Plan Information

The EXPLAIN statement provides information about how MySQL executes statements:

• When you precede a SELECT statement with the keyword EXPLAIN, MySQL displays information from the optimizer about the statement execution plan. That is, MySQL explains how it would process the statement, including information about how tables are joined and in which order. For information about using EXPLAIN to obtain execution plan information, see Section 8.8.2, “EXPLAIN Output Format”.

• EXPLAIN EXTENDED can be used to obtain additional execution plan information. See Section 8.8.3, “EXPLAIN EXTENDED Output Format”.

• As of MySQL 5.1.5, EXPLAIN PARTITIONS is useful for examining queries involving partitioned tables. See Section 18.3.4, “Obtaining Information About Partitions”.

With the help of EXPLAIN, you can see where you should add indexes to tables so that the statement executes faster by using indexes to find rows. You can also use EXPLAIN to check whether the optimizer joins the tables in an optimal order. To give a hint to the optimizer to use a join order corresponding to the order in which the tables are named in a SELECT statement, begin the statement with SELECT STRAIGHT_JOIN rather than just SELECT. (See Section 13.2.8, “SELECT Syntax”.)

If you have a problem with indexes not being used when you believe that they should be, run ANALYZE TABLE to update table statistics, such as cardinality of keys, that can affect the choices the optimizer makes. See Section 13.7.2.1, “ANALYZE TABLE Syntax”.

13.8.3 HELP Syntax

HELP 'search_string'

The HELP statement returns online information from the MySQL Reference manual. Its proper operation requires that the help tables in the mysql database be initialized with help topic information (see Section 5.1.9, “Server-Side Help”).

The HELP statement searches the help tables for the given search string and displays the result of the search. The search string is not case sensitive.

The search string can contain the wildcard characters “%” and “_”. These have the same meaning as for pattern-matching operations performed with the LIKE operator. For example, HELP 'rep%' returns a list of topics that begin with rep.

The HELP statement understands several types of search strings:
HELP Syntax

- At the most general level, use contents to retrieve a list of the top-level help categories:

  ```
  HELP 'contents'
  ```

- For a list of topics in a given help category, such as Data Types, use the category name:

  ```
  HELP 'data types'
  ```

- For help on a specific help topic, such as the ASCII() function or the CREATE TABLE statement, use the associated keyword or keywords:

  ```
  HELP 'ascii'
  HELP 'create table'
  ```

In other words, the search string matches a category, many topics, or a single topic. You cannot necessarily tell in advance whether a given search string will return a list of items or the help information for a single help topic. However, you can tell what kind of response HELP returned by examining the number of rows and columns in the result set.

The following descriptions indicate the forms that the result set can take. Output for the example statements is shown using the familiar “tabular” or “vertical” format that you see when using the mysql client, but note that mysql itself reformats HELP result sets in a different way.

- Empty result set
  No match could be found for the search string.

- Result set containing a single row with three columns
  This means that the search string yielded a hit for the help topic. The result has three columns:
  - name: The topic name.
  - description: Descriptive help text for the topic.
  - example: Usage example or examples. This column might be blank.

  **Example:** HELP 'replace'

  Yields:

  ```
  name: REPLACE
description: Syntax:
REPLACE(str,from_str,to_str)
```

  Returns the string str with all occurrences of the string from_str replaced by the string to_str. REPLACE() performs a case-sensitive match when searching for from_str.

  ```
  example: mysql> SELECT REPLACE('www.mysql.com', 'w', 'Ww');
  -> 'WwWwWw.mysql.com'
  ```

- Result set containing multiple rows with two columns
  This means that the search string matched many help topics. The result set indicates the help topic names:
  - name: The help topic name.
  - is_it_category: Y if the name represents a help category, N if it does not. If it does not, the name value when specified as the argument to the HELP statement should yield a single-row result set containing a description for the named item.
Example: HELP 'status'

Yields:

| name                  | is_it_category |
|-----------------------+----------------|
| SHOW                  | N              |
| SHOW ENGINE           | N              |
| SHOW INNODB STATUS    | N              |
| SHOW MASTER STATUS    | N              |
| SHOW PROCEDURE STATUS | N              |
| SHOW SLAVE STATUS     | N              |
| SHOW STATUS           | N              |
| SHOW TABLE STATUS     | N              |

- Result set containing multiple rows with three columns
This means the search string matches a category. The result set contains category entries:
- source_category_name: The help category name.
- name: The category or topic name
- is_it_category: Y if the name represents a help category, N if it does not. If it does not, the name value when specified as the argument to the HELP statement should yield a single-row result set containing a description for the named item.

Example: HELP 'functions'

Yields:

<table>
<thead>
<tr>
<th>source_category_name</th>
<th>name</th>
<th>is_it_category</th>
</tr>
</thead>
<tbody>
<tr>
<td>Functions</td>
<td>CREATE FUNCTION</td>
<td>N</td>
</tr>
<tr>
<td>Functions</td>
<td>DROP FUNCTION</td>
<td>N</td>
</tr>
<tr>
<td>Functions</td>
<td>Bit Functions</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>Comparison operators</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>Control flow functions</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>Date and Time Functions</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>Encryption Functions</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>Information Functions</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>Logical operators</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>Miscellaneous Functions</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>Numeric Functions</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>String Functions</td>
<td>Y</td>
</tr>
</tbody>
</table>

Before MySQL 5.1.17, if you intend to use the HELP statement while other tables are locked with LOCK TABLES, you must also lock the required mysql.help_xxx tables. See Section 13.3.5, “LOCK TABLES and UNLOCK TABLES Syntax”.

13.8.4 USE Syntax

USE db_name

The USE db_name statement tells MySQL to use the db_name database as the default (current) database for subsequent statements. The database remains the default until the end of the session or another USE statement is issued:
USE db1;
SELECT COUNT(*) FROM mytable;  # selects from db1.mytable
USE db2;
SELECT COUNT(*) FROM mytable;  # selects from db2.mytable

Making a particular database the default by means of the `USE` statement does not preclude you from accessing tables in other databases. The following example accesses the `author` table from the `db1` database and the `editor` table from the `db2` database:

USE db1;
SELECT author_name,editor_name FROM author,db2.editor
    WHERE author.editor_id = db2.editor.editor_id;
