<tr>
<td>InfoEvent</td>
<td>2</td>
<td>INFO</td>
<td>General informational event</td>
</tr>
<tr>
<td>EventBufferStatus</td>
<td>7</td>
<td>INFO</td>
<td>Event buffer status</td>
</tr>
</tbody>
</table>

**Note**

SentHeartbeat events are available only if MySQL Cluster was compiled with VM_TRACE enabled.

**SINGLEUSER Events**

These events are associated with entering and exiting single user mode.

<table>
<thead>
<tr>
<th>Event</th>
<th>Priority</th>
<th>Severity</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SingleUser</td>
<td>7</td>
<td>INFO</td>
<td>Entering or exiting single user mode</td>
</tr>
</tbody>
</table>
BACKUP Events

These events provide information about backups being created or restored.

<table>
<thead>
<tr>
<th>Event</th>
<th>Priority</th>
<th>Severity</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BackupStarted</td>
<td>7</td>
<td>INFO</td>

<td>Event saved</td>
</tr>
</tbody>
</table>

17.5.6.3 Using CLUSTERLOG STATISTICS in the MySQL Cluster Management Client

The NDB management client’s **CLUSTERLOG STATISTICS** command can provide a number of useful statistics in its output. Counters providing information about the state of the cluster are updated at 5-second reporting intervals by the transaction coordinator (TC) and the local query handler (LQH), and written to the cluster log.

**Transaction coordinator statistics.** Each transaction has one transaction coordinator, which is chosen by one of the following methods:

- In a round-robin fashion
- By communication proximity
- (Beginning with MySQL Cluster NDB 6.3.4:) By supplying a data placement hint when the transaction is started

![Note]

You can determine which TC selection method is used for transactions started from a given SQL node using the `ndb_optimized_node_selection` system variable.

All operations within the same transaction use the same transaction coordinator, which reports the following statistics:

- **Trans count.** This is the number transactions started in the last interval using this TC as the transaction coordinator. Any of these transactions may have committed, have been aborted, or remain uncommitted at the end of the reporting interval.

  ![Note]

  Transactions do not migrate between TCs.

- **Commit count.** This is the number of transactions using this TC as the transaction coordinator that were committed in the last reporting interval. Because some transactions committed in this reporting interval may have started in a previous reporting interval, it is possible for Commit count to be greater than Trans count.
• **Read count.** This is the number of primary key read operations using this TC as the transaction coordinator that were started in the last reporting interval, including simple reads. This count also includes reads performed as part of unique index operations. A unique index read operation generates 2 primary key read operations—one for the hidden unique index table, and 1 for the table on which the read takes place.

• **Simple read count.** This is the number of simple read operations using this TC as the transaction coordinator that were started in the last reporting interval. This is a subset of Read count. Prior to MySQL Cluster NDB 7.0, the value of Simple read count was incremented at a different point in time from Read count, which could cause it to lag behind Read count slightly, so that it was possible that Simple read count was not equal to Read count for some reporting interval, even if all reads made during that time were in fact simple reads. In MySQL Cluster NDB 7.0 and later, NDB uses a single signal (TCKEYREQ) containing all information necessary to forward the request, so these counts should no longer appear to be misaligned in such cases.

• **Write count.** This is the number of primary key write operations using this TC as the transaction coordinator that were started in the last reporting interval. This includes all inserts, updates, writes and deletes, as well as writes performed as part of unique index operations.

  **Note**
  
  A unique index update operation can generate multiple PK read and write operations on the index table and on the base table.

• **AttrInfoCount.** This is the number of 32-bit data words received in the last reporting interval for primary key operations using this TC as the transaction coordinator. For reads, this is proportional to the number of columns requested. For inserts and updates, this is proportional to the number of columns written, and the size of their data. For delete operations, this is usually zero. Unique index operations generate multiple PK operations and so increase this count. However, data words sent to describe the PK operation itself, and the key information sent, are not counted here. Attribute information sent to describe columns to read for scans, or to describe ScanFilters, is also not counted in AttrInfoCount.

• **Concurrent Operations.** This is the number of primary key or scan operations using this TC as the transaction coordinator that were started during the last reporting interval but that were not completed. Operations increment this counter when they are started and decrement it when they are completed; this occurs after the transaction commits. Dirty reads and writes—as well as failed operations—decrement this counter.

  The maximum value that Concurrent Operations can have is the maximum number of operations that a TC block can support; currently, this is \((2 \times \text{MaxNoOfConcurrentOperations}) + 16 + \text{MaxNoOfConcurrentTransactions}\). (For more information about these configuration parameters, see the Transaction Parameters section of Section 17.3.3.6, “Defining MySQL Cluster Data Nodes”.)

• **Abort count.** This is the number of transactions using this TC as the transaction coordinator that were aborted during the last reporting interval. Because some transactions that were aborted in the last reporting interval may have started in a previous reporting interval, Abort count can sometimes be greater than Trans count.

• **Scans.** This is the number of table scans using this TC as the transaction coordinator that were started during the last reporting interval. This does not include range scans (that is, ordered index scans).

• **Range scans.** This is the number of ordered index scans using this TC as the transaction coordinator that were started in the last reporting interval.

**Local query handler statistics (Operations).** There is 1 cluster event per local query handler block (that is, 1 per data node process). Operations are recorded in the LQH where the data they are operating on resides.
MySQL Cluster Log Messages

Note
A single transaction may operate on data stored in multiple LQH blocks.

The operations statistic provides the number of local operations performed by this LQH block in the last reporting interval, and includes all types of read and write operations (insert, update, write, and delete operations). This also includes operations used to replicate writes. For example, in a 2-replica cluster, the write to the primary replica is recorded in the primary LQH, and the write to the backup will be recorded in the backup LQH. Unique key operations may result in multiple local operations; however, this does not include local operations generated as a result of a table scan or ordered index scan, which are not counted.

Process scheduler statistics. In addition to the statistics reported by the transaction coordinator and local query handler, each ndbd process has a scheduler which also provides useful metrics relating to the performance of a MySQL Cluster. This scheduler runs in an infinite loop; during each loop the scheduler performs the following tasks:

1. Read any incoming messages from sockets into a job buffer.
2. Check whether there are any timed messages to be executed; if so, put these into the job buffer as well.
3. Execute (in a loop) any messages in the job buffer.
4. Send any distributed messages that were generated by executing the messages in the job buffer.
5. Wait for any new incoming messages.

Process scheduler statistics include the following:

- Mean Loop Counter. This is the number of loops executed in the third step from the preceding list. This statistic increases in size as the utilization of the TCP/IP buffer improves. You can use this to monitor changes in performance as you add new data node processes.

- Mean send size and Mean receive size. These statistics enable you to gauge the efficiency of, respectively writes and reads between nodes. The values are given in bytes. Higher values mean a lower cost per byte sent or received; the maximum value is 64K.

To cause all cluster log statistics to be logged, you can use the following command in the NDB management client:

```
ndb_mgm> ALL CLUSTERLOG STATISTICS=15
```

Note
Setting the threshold for STATISTICS to 15 causes the cluster log to become very verbose, and to grow quite rapidly in size, in direct proportion to the number of cluster nodes and the amount of activity in the MySQL Cluster.

For more information about MySQL Cluster management client commands relating to logging and reporting, see Section 17.5.6.1, “MySQL Cluster Logging Management Commands”.

17.5.7.7 MySQL Cluster Log Messages

This section contains information about the messages written to the cluster log in response to different cluster log events. It provides additional, more specific information on ndbd transporter errors.

17.5.7.1 MySQL Cluster: Messages in the Cluster Log

The following table lists the most common ndbd cluster log messages. For information about the cluster log, log events, and event types, see Section 17.5.6, “Event Reports Generated in MySQL Cluster”.

2143
MySQL Cluster Log Messages

These log messages also correspond to log event types in the MGM API; see The Ndb_logevent_type Type, for related information of interest to Cluster API developers.

17.5.8 MySQL Cluster Single User Mode

Single user mode enables the database administrator to restrict access to the database system to a single API node, such as a MySQL server (SQL node) or an instance of ndb_restore. When entering single user mode, connections to all other API nodes are closed gracefully and all running transactions are aborted. No new transactions are permitted to start.

Once the cluster has entered single user mode, only the designated API node is granted access to the database.

You can use the ALL STATUS command in the ndb_mgm client to see when the cluster has entered single user mode. Beginning with MySQL Cluster NDB 7.1.1, you can also check the status column of the ndbinfo.nodes table (see Section 17.5.10.13, “The ndbinfo nodes Table”, for more information).

Example:

```
ndb_mgm> ENTER SINGLE USER MODE 5
```

After this command has executed and the cluster has entered single user mode, the API node whose node ID is 5 becomes the cluster's only permitted user.

The node specified in the preceding command must be an API node; attempting to specify any other type of node will be rejected.

Note

When the preceding command is invoked, all transactions running on the designated node are aborted, the connection is closed, and the server must be restarted.

The command EXIT SINGLE USER MODE changes the state of the cluster’s data nodes from single user mode to normal mode. API nodes—such as MySQL Servers—waiting for a connection (that is, waiting for the cluster to become ready and available), are again permitted to connect. The API node denoted as the single-user node continues to run (if still connected) during and after the state change.

Example:

```
ndb_mgm> EXIT SINGLE USER MODE
```

There are two recommended ways to handle a node failure when running in single user mode:

- Method 1:
  1. Finish all single user mode transactions
2. Issue the `EXIT SINGLE USER MODE` command

3. Restart the cluster's data nodes

   - Method 2:
     Restart database nodes prior to entering single user mode.

### 17.5.9 Quick Reference: MySQL Cluster SQL Statements

This section discusses several SQL statements that can prove useful in managing and monitoring a MySQL server that is connected to a MySQL Cluster, and in some cases provide information about the cluster itself.

- **SHOW ENGINE NDB STATUS**, **SHOW ENGINE NDBCLUSTER STATUS**

  The output of this statement contains information about the server's connection to the cluster, creation and usage of MySQL Cluster objects, and binary logging for MySQL Cluster replication.

  See Section 13.7.5.16, “SHOW ENGINE Syntax”, for a usage example and more detailed information.

- **SHOW ENGINES**

  This statement can be used to determine whether or not clustering support is enabled in the MySQL server, and if so, whether it is active.

  See Section 13.7.5.17, “SHOW ENGINES Syntax”, for more detailed information.

**Note**

In MySQL 5.1 and later, this statement does not support a `LIKE` clause. However, you can use `LIKE` to filter queries against the `INFORMATION_SCHEMA.ENGINES` table, as discussed in the next item.

- **SELECT * FROM INFORMATION_SCHEMA.ENGINES [WHERE ENGINE LIKE 'NDB%']**

  This is the equivalent of `SHOW ENGINES`, but uses the `ENGINES` table of the `INFORMATION_SCHEMA` database (available beginning with MySQL 5.1.5). Unlike the case with the `SHOW ENGINES` statement, it is possible to filter the results using a `LIKE` clause, and to select specific columns to obtain information that may be of use in scripts. For example, the following query shows whether the server was built with `NDB` support and, if so, whether it is enabled:

```sql
mysql> SELECT SUPPORT FROM INFORMATION_SCHEMA.ENGINES
-> WHERE ENGINE LIKE 'NDB%';
```

<table>
<thead>
<tr>
<th>support</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENABLED</td>
</tr>
</tbody>
</table>

See Section 20.6, “The INFORMATION_SCHEMA ENGINES Table”, for more information.

- **SHOW VARIABLES LIKE 'NDB%'**

  This statement provides a list of most server system variables relating to the `NDB` storage engine, and their values, as shown here:

```sql
mysql> SHOW VARIABLES LIKE 'NDB%';
```

<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
</table>

---

2159
**Quick Reference: MySQL Cluster SQL Statements**

<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>ndb_autoincrement_prefetch_sz</td>
<td>32</td>
</tr>
<tr>
<td>ndb_cache_check_time</td>
<td>0</td>
</tr>
<tr>
<td>ndb_extra_logging</td>
<td>0</td>
</tr>
<tr>
<td>ndb_force_send</td>
<td>ON</td>
</tr>
<tr>
<td>ndb_index_stat_cache_entries</td>
<td>32</td>
</tr>
<tr>
<td>ndb_index_stat_enable</td>
<td>OFF</td>
</tr>
<tr>
<td>ndb_index_stat_update_freq</td>
<td>20</td>
</tr>
<tr>
<td>ndb_report_thresh_binlog_epoch_slip</td>
<td>3</td>
</tr>
<tr>
<td>ndb_report_thresh_binlog_mem_usage</td>
<td>10</td>
</tr>
<tr>
<td>ndb_use_copying_alt_table</td>
<td>OFF</td>
</tr>
<tr>
<td>ndb_use_exact_count</td>
<td>ON</td>
</tr>
<tr>
<td>ndb_use_transactions</td>
<td>ON</td>
</tr>
</tbody>
</table>

See [Section 5.1.4, “Server System Variables”](#), for more information.

- **SELECT * FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES WHERE VARIABLE_NAME LIKE 'NDB%';**

This statement is the equivalent of the `SHOW` command described in the previous item, and provides almost identical output, as shown here:

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES
   -> WHERE VARIABLE_NAME LIKE 'NDB%';
```

+-------------------------------------+----------------+
<table>
<thead>
<tr>
<th>VARIABLE_NAME</th>
<th>VARIABLE_VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB_AUTOINCREMENT_PREFETCH_SZ</td>
<td>32</td>
</tr>
<tr>
<td>NDB_CACHE_CHECK_TIME</td>
<td>0</td>
</tr>
<tr>
<td>NDB_EXTRA_LOGGING</td>
<td>0</td>
</tr>
<tr>
<td>NDB_FORCE_SEND</td>
<td>ON</td>
</tr>
<tr>
<td>NDB_INDEX_STAT_CACHE_ENTRIES</td>
<td>32</td>
</tr>
<tr>
<td>NDB_INDEX_STAT_ENABLE</td>
<td>OFF</td>
</tr>
<tr>
<td>NDB_INDEX_STAT_UPDATE_FREQ</td>
<td>20</td>
</tr>
<tr>
<td>NDB_REPORT_THRESH_BINLOG_EPOCH_SLIP</td>
<td>3</td>
</tr>
<tr>
<td>NDB_REPORT_THRESH_BINLOG_MEM_USAGE</td>
<td>10</td>
</tr>
<tr>
<td>NDB_USE_COPYING_ALT_TABLE</td>
<td>OFF</td>
</tr>
<tr>
<td>NDB_USE_EXACT_COUNT</td>
<td>ON</td>
</tr>
<tr>
<td>NDB_USE_TRANSACTIONS</td>
<td>ON</td>
</tr>
</tbody>
</table>

Unlike the case with the `SHOW` command, it is possible to select individual columns. For example:

```sql
mysql> SELECT VARIABLE_VALUE
   -> FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES
   -> WHERE VARIABLE_NAME = 'ndb_force_send';
```

+----------------+
| VARIABLE_VALUE |
|----------------+
| ON             |

See [Section 20.9, “The INFORMATION_SCHEMA GLOBAL_VARIABLES and SESSION_VARIABLES Tables”](#), and [Section 5.1.4, “Server System Variables”](#), for more information.

- **SHOW STATUS LIKE 'NDB%';**

This statement shows at a glance whether or not the MySQL server is acting as a cluster SQL node, and if so, it provides the MySQL server’s cluster node ID, the host name and port for the cluster management server to which it is connected, and the number of data nodes in the cluster, as shown here:

```sql
mysql> SHOW STATUS LIKE 'NDB%';
```

<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
If the MySQL server was built with clustering support, but it is not connected to a cluster, all rows in
the output of this statement contain a zero or an empty string:

```
mysql> SHOW STATUS LIKE 'NDB%';
| Variable_name            | Value |
+--------------------------+-------+
| Ndb_cluster_node_id      | 0     |
| Ndb_config_from_host     |       |
| Ndb_config_from_port     | 0     |
| Ndb_number_of_data_nodes | 0     |
+--------------------------+-------+
```

See also Section 13.7.5.37, “SHOW STATUS Syntax”.

- `SELECT * FROM INFORMATION_SCHEMA.GLOBAL_STATUS WHERE VARIABLE_NAME LIKE 'NDB%';`

Beginning with MySQL 5.1.12, this statement provides similar output to the `SHOW` command
discussed in the previous item. However, unlike the case with `SHOW STATUS`, it is possible using the
`SELECT` to extract values in SQL for use in scripts for monitoring and automation purposes.

See Section 20.8, “The INFORMATION_SCHEMA GLOBAL_STATUS and SESSION_STATUS Tables”, for more information.

Beginning with MySQL Cluster NDB 7.1.1, you can also query the tables in the `ndbinfo` information
database for real-time data about many MySQL Cluster operations. See Section 17.5.10, “The ndbinfo
MySQL Cluster Information Database”.

### 17.5.10 The ndbinfo MySQL Cluster Information Database

`ndbinfo` is a database containing information specific to MySQL Cluster, available beginning with
MySQL Cluster NDB 7.1.1.

This database contains a number of tables, each providing a different sort of data about MySQL
Cluster node status, resource usage, and operations. You can find more detailed information about
each of these tables in the next several sections.

`ndbinfo` is included with MySQL Cluster support in the MySQL Server; no special compilation or
configuration steps are required; the tables are created by the MySQL Server when it connects to the
cluster. You can verify that `ndbinfo` support is active in a given MySQL Server instance using `SHOW
PLUGINS`; if `ndbinfo` support is enabled, you should see a row containing `ndbinfo` in the Name
column and `ACTIVE` in the Status column, as shown here (emphasized text):

```
mysql> SHOW PLUGINS;
<table>
<thead>
<tr>
<th>Name</th>
<th>Status</th>
<th>Type</th>
<th>Library</th>
<th>License</th>
</tr>
</thead>
<tbody>
<tr>
<td>binlog</td>
<td>ACTIVE</td>
<td>STORAGE ENGINE</td>
<td>NULL</td>
<td>GPL</td>
</tr>
<tr>
<td>partition</td>
<td>ACTIVE</td>
<td>STORAGE ENGINE</td>
<td>NULL</td>
<td>GPL</td>
</tr>
<tr>
<td>ARCHIVE</td>
<td>ACTIVE</td>
<td>STORAGE ENGINE</td>
<td>NULL</td>
<td>GPL</td>
</tr>
<tr>
<td>BLACKHOLE</td>
<td>ACTIVE</td>
<td>STORAGE ENGINE</td>
<td>NULL</td>
<td>GPL</td>
</tr>
<tr>
<td>CSV</td>
<td>ACTIVE</td>
<td>STORAGE ENGINE</td>
<td>NULL</td>
<td>GPL</td>
</tr>
<tr>
<td>FEDERATED</td>
<td>DISABLED</td>
<td>STORAGE ENGINE</td>
<td>NULL</td>
<td>GPL</td>
</tr>
<tr>
<td>MEMORY</td>
<td>ACTIVE</td>
<td>STORAGE ENGINE</td>
<td>NULL</td>
<td>GPL</td>
</tr>
<tr>
<td>InnoDB</td>
<td>ACTIVE</td>
<td>STORAGE ENGINE</td>
<td>NULL</td>
<td>GPL</td>
</tr>
<tr>
<td>MyISAM</td>
<td>ACTIVE</td>
<td>STORAGE ENGINE</td>
<td>NULL</td>
<td>GPL</td>
</tr>
<tr>
<td>NRG_MYISAM</td>
<td>ACTIVE</td>
<td>STORAGE ENGINE</td>
<td>NULL</td>
<td>GPL</td>
</tr>
<tr>
<td>ndbcluster</td>
<td>ACTIVE</td>
<td>STORAGE ENGINE</td>
<td>NULL</td>
<td>GPL</td>
</tr>
</tbody>
</table>
```
You can also do this by checking the output of `SHOW ENGINES` for a row that has `ndbinfo` for `Engine` and `YES` for `Support`, as shown here (emphasized text):

```
mysql> SHOW ENGINES\G
*************************** 1. row ***************************
    Engine: ndbcluster
    Support: YES
    Comment: Clustered, fault-tolerant tables

    Engine: MyISAM
    Support: DEFAULT
    Comment: Default engine as of MySQL 3.23 with great performance
Transactions: NO
    XA: NO
    Savepoints: NO
```
If `ndbinfo` support is enabled, then you can access `ndbinfo` using SQL statements in `mysql` or another MySQL client. For example, you can see `ndbinfo` listed in the output of `SHOW DATABASES`, as shown here (emphasized text):

```sql
mysql> SHOW DATABASES;
+--------------------+
| Database           |
+--------------------+
| information_schema |
| mysql              |
| ndbinfo            |
| test               |
+--------------------+
4 rows in set (0.00 sec)
```

If the `mysqld` process was not started with the `--ndbcluster` option, `ndbinfo` is not available and is not displayed by `SHOW DATABASES`. If `mysqld` was formerly connected to a MySQL Cluster but the cluster becomes unavailable (due to events such as cluster shutdown, loss of network connectivity, and so forth), `ndbinfo` and its tables remain visible, but an attempt to access any tables (other than `blocks` or `config_params`) fails with `Got error 157 'Connection to NDB failed' from NDBINFO`.

With the exception of the `blocks` and `config_params` tables, what we refer to as `ndbinfo` “tables” are actually views generated from internal NDB tables not normally visible to the MySQL Server.

All `ndbinfo` tables are read-only, and are generated on demand when queried. Because many of them are generated in parallel by the data nodes while other are specific to a given SQL node, they are not guaranteed to provide a consistent snapshot.

In addition, pushing down of joins is not supported on `ndbinfo` tables; so joining large `ndbinfo` tables can require transfer of a large amount of data to the requesting API node, even when the query makes use of a `WHERE` clause.

Beginning with MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11, `ndbinfo` tables are not included in the query cache. (Bug #59831)

You can select the `ndbinfo` database with a `USE` statement, and then issue a `SHOW TABLES` statement to obtain a list of tables, just as for any other database, like this:

```sql
mysql> USE ndbinfo;
Database changed
mysql> SHOW TABLES;
+----------------------+
| Tables_in_ndbinfo    |
| blocks               |
| cluster_operations   |
| cluster_transactions |
| config_params        |
| counters             |
| diskpagebuffer       |
| logbuffers           |
| logspaces            |
| memoryusage          |
| nodes                |
| resources            |
+----------------------+
```

---

The ndbinfo MySQL Cluster Information Database

* *************************** 10. row ***************************
  Engine: BLACKHOLE
  Support: YES
  Comment: /dev/null storage engine (anything you write to it disappears)
  Transactions: NO
  XA: NO
  Savepoints: NO
  10 rows in set (0.00 sec)
The ndbinfo MySQL Cluster Information Database

The `diskpagebuffer` table was added in MySQL Cluster NDB 7.1.9.

The `cluster_operations`, `cluster_transactions`, `server_operations`, `server_transactions`, `threadblocks`, and `threadstat` tables were added in MySQL Cluster NDB 7.1.17.

In early versions of MySQL Cluster NDB 7.1, there was an additional `pools` table in the `ndbinfo` database; however, this table was removed in MySQL Cluster NDB 7.1.3.

You can execute `SELECT` statements against these tables, just as you would normally expect:

```
mysql> SELECT * FROM memoryusage;

+---------+---------------------+--------+------------+------------+-------------+
| node_id | memory_type         | used   | used_pages | total      | total_pages |
+---------+---------------------+--------+------------+------------+-------------+
|       5 | Data memory         | 753664 |         23 | 1073741824 |       32768 |
|       5 | Index memory        | 163840 |         20 | 1074003968 |      131104 |
|       5 | Long message buffer |   2304 |          9 |   67108864 |      262144 |
|       6 | Data memory         | 753664 |         23 | 1073741824 |       32768 |
|       6 | Index memory        | 163840 |         20 | 1074003968 |      131104 |
|       6 | Long message buffer |   2304 |          9 |   67108864 |      262144 |
+---------+---------------------+--------+------------+------------+-------------+
6 rows in set (0.02 sec)
```

More complex queries, such as the two following `SELECT` statements using the `memoryusage` table, are possible:

```
mysql> SELECT SUM(used) as 'Data Memory Used, All Nodes'
    > FROM memoryusage
    > WHERE memory_type = 'Data memory';

+-----------------------------+
| Data Memory Used, All Nodes |
| 6460                        |
+-----------------------------+
1 row in set (0.37 sec)

mysql> SELECT SUM(max) as 'Total IndexMemory Available'
    > FROM memoryusage
    > WHERE memory_type = 'Index memory';

+-----------------------------+
| Total IndexMemory Available |
| 25664                       |
+-----------------------------+
1 row in set (0.33 sec)
```

The `ndbinfo` table and column names are case sensitive (as is the name of the `ndbinfo` database itself). These identifiers are in lowercase. Trying to use the wrong lettercase results in an error, as shown in this example:

```
mysql> SELECT * FROM nodes;

+---------+--------+---------+-------------+
| node_id | uptime | status  | start_phase |
+---------+--------+---------+-------------+
|       1 | 13602  | STARTED |           0 |
|       2 |   16   | STARTED |           0 |
+---------+--------+---------+-------------+
2 rows in set (0.04 sec)
```
mysql> SELECT * FROM Nodes;
ERROR 1146 (42S02): Table 'ndbinfo.Nodes' doesn't exist

Beginning with MySQL Cluster NDB 7.1.7, mysqldump ignores ndbinfo entirely, and excludes it from any output. This is true even when using the `--databases` or `--all-databases` option.

MySQL Cluster also maintains tables in the INFORMATION_SCHEMA information database, including the FILES table which contains information about files used for MySQL Cluster Disk Data storage. For more information, see Section 20.26, “INFORMATION_SCHEMA Tables for MySQL Cluster”.

### 17.5.10.1 The ndbinfo arbitrator_validity_detail Table

The arbitrator_validity_detail table shows the view that each data node in the cluster of the arbitrator. It is a subset of the membership table.

The following table provides information about the columns in the arbitrator_validity_detail table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>This node's node ID</td>
</tr>
<tr>
<td>arbitrator</td>
<td>integer</td>
<td>Node ID of arbitrator</td>
</tr>
<tr>
<td>arb_ticket</td>
<td>string</td>
<td>Internal identifier used to track arbitration</td>
</tr>
<tr>
<td>arb_connected</td>
<td>Yes/No</td>
<td>Whether this node is connected to the arbitrator</td>
</tr>
<tr>
<td>arb_state</td>
<td>Enumeration (see text)</td>
<td>Arbitration state</td>
</tr>
</tbody>
</table>

The node ID is the same as that reported by ndb_mgm -e "SHOW".

All nodes should show the same arbitrator and arb_ticket values as well as the same arb_state value. Possible arb_state values are ARBIT_NULL, ARBIT_INIT, ARBIT_FIND, ARBIT_PREP1, ARBIT_PREP2, ARBIT_START, ARBIT_RUN, ARBIT_CHOOSE, ARBIT_CRASH, and UNKNOWN.

arb_connected shows whether the current node is connected to the arbitrator.

Like the membership and arbitrator_validity_summary tables, this table was added in MySQL Cluster NDB 7.0.37 and MySQL Cluster NDB 7.1.26.

### 17.5.10.2 The ndbinfo arbitrator_validity_summary Table

The arbitrator_validity_summary table provides a composite view of the arbitrator with regard to the cluster's data nodes.

The following table provides information about the columns in the arbitrator_validity_summary table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>arbitrator</td>
<td>integer</td>
<td>Node ID of arbitrator</td>
</tr>
<tr>
<td>arb_ticket</td>
<td>string</td>
<td>Internal identifier used to track arbitration</td>
</tr>
<tr>
<td>arb_connected</td>
<td>Yes/No</td>
<td>Whether this arbitrator is connected to the cluster</td>
</tr>
<tr>
<td>consensus_count</td>
<td>integer</td>
<td>Number of data nodes that see this node as arbitrator</td>
</tr>
</tbody>
</table>

In normal operations, this table should have only 1 row for any appreciable length of time. If it has more than 1 row for longer than a few moments, then either not all nodes are connected to the arbitrator, or all nodes are connected, but do not agree on the same arbitrator.
The arbitrator column shows the arbitrator's node ID.

arb_ticket is the internal identifier used by this arbitrator.

arb_connected shows whether this node is connected to the cluster as an arbitrator.

Like the membership and arbitrator_validity_detail tables, this table was added in MySQL Cluster NDB 7.0.37 and MySQL Cluster NDB 7.1.26.

17.5.10.3 The ndbinfo blocks Table

The blocks table is a static table which simply contains the names and internal IDs of all NDB kernel blocks (see NDB Kernel Blocks). It is for use by the other ndbinfo tables (most of which are actually views) in mapping block numbers to block names for producing human-readable output.

The following table provides information about the columns in the blocks table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>block_number</td>
<td>integer</td>
<td>Block number</td>
</tr>
<tr>
<td>block_name</td>
<td>string</td>
<td>Block name</td>
</tr>
</tbody>
</table>

To obtain a list of all block names, simply execute `SELECT block_name FROM ndbinfo.blocks`. Although this is a static table, its content can vary between different MySQL Cluster releases.

17.5.10.4 The ndbinfo cluster_operations Table

The cluster_operations table provides a per-operation (stateful primary key op) view of all activity in the MySQL Cluster from the point of view of the local data management (LQH) blocks (see The DBLQH Block).

The following table provides information about the columns in the cluster_operations table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>Node ID of reporting LQH block</td>
</tr>
<tr>
<td>block_instance</td>
<td>integer</td>
<td>LQH block instance</td>
</tr>
<tr>
<td>transid</td>
<td>integer</td>
<td>Transaction ID</td>
</tr>
<tr>
<td>operation_type</td>
<td>string</td>
<td>Operation type (see text for possible values)</td>
</tr>
<tr>
<td>state</td>
<td>string</td>
<td>Operation state (see text for possible values)</td>
</tr>
<tr>
<td>tableid</td>
<td>integer</td>
<td>Table ID</td>
</tr>
<tr>
<td>fragmentid</td>
<td>integer</td>
<td>Fragment ID</td>
</tr>
<tr>
<td>client_node_id</td>
<td>integer</td>
<td>Client node ID</td>
</tr>
<tr>
<td>client_block_ref</td>
<td>integer</td>
<td>Client block reference</td>
</tr>
<tr>
<td>tc_node_id</td>
<td>integer</td>
<td>Transaction coordinator node ID</td>
</tr>
<tr>
<td>tc_block_no</td>
<td>integer</td>
<td>Transaction coordinator block number</td>
</tr>
<tr>
<td>tc_block_instance</td>
<td>integer</td>
<td>Transaction coordinator block instance</td>
</tr>
</tbody>
</table>

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's getTransactionId() method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The operation_type column can take any one of the values READ, READ-SH, READ-EX, INSERT, UPDATE, DELETE, WRITE, UNLOCK, REFRESH, SCAN, SCAN-SH, SCAN-EX, or <unknown>.
The state column can have any one of the values ABORT_QUEUED, ABORT_STOPPED, COMMITTED, COMMIT_QUEUED, COMMIT_STOPPED, COPY_CLOSE_STOPPED, COPY_FIRST_STOPPED, COPY_STOPPED, COPY_TUPKEY, IDLE, LOG_ABORT_QUEUED, LOG_COMMIT_QUEUED, LOG_COMMIT_QUEUED_WAIT_SIGNAL, LOG_COMMIT_WRITTEN, LOG_COMMIT_WRITTEN_WAIT_SIGNAL, LOG_QUEUE, PREPARED, PREPARED_RECEIVED_COMMIT, SCAN_CHECK_STOPPED, SCAN_CLOSE_STOPPED, SCAN_FIRST_STOPPED, SCAN_RELEASE_STOPPED, SCAN_STATE_USED, SCAN_STOPPED, SCAN_TUPKEY, STOPPED, TC_NOT_CONNECTED, WAIT_ACC, WAIT_ACC_ABORT, WAIT_AI_AFTER_ABORT, WAIT_ATTR, WAIT_SCAN_AI, WAIT_TUP, WAIT_TUPKEYINFO, WAIT_TUP_COMMIT, or WAIT_TUP_TO_ABORT. (If the MySQL Server is running with ndbinfo_show_hidden enabled, you can view this list of states by selecting from the ndb$dblqh_tcconnect_state table, which is normally hidden.)

You can obtain the name of an NDB table from its table ID by checking the output of ndb_show_tables.

The fragid is the same as the partition number seen in the output of ndb_desc --extra-partition-info (short form -p).

In client_node_id and client_block_ref, client refers to a MySQL Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

This table was added in MySQL Cluster NDB 7.1.17.

### 17.5.10.5 The ndbinfo cluster_transactions Table

The cluster_transactions table shows information about all ongoing transactions in a MySQL Cluster.

The following table provides information about the columns in the cluster_transactions table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>Node ID of transaction coordinator</td>
</tr>
<tr>
<td>block_instance</td>
<td>integer</td>
<td>TC block instance</td>
</tr>
<tr>
<td>transid</td>
<td>integer</td>
<td>Transaction ID</td>
</tr>
<tr>
<td>state</td>
<td>string</td>
<td>Operation state (see text for possible values)</td>
</tr>
<tr>
<td>count_operations</td>
<td>integer</td>
<td>Number of stateful primary key operations in transaction (includes reads with locks, as well as DML operations)</td>
</tr>
<tr>
<td>outstanding_operations</td>
<td>integer</td>
<td>Operations still being executed in local data management blocks</td>
</tr>
<tr>
<td>inactive_seconds</td>
<td>integer</td>
<td>Time spent waiting for API</td>
</tr>
<tr>
<td>client_node_id</td>
<td>integer</td>
<td>Client node ID</td>
</tr>
<tr>
<td>client_block_ref</td>
<td>integer</td>
<td>Client block reference</td>
</tr>
</tbody>
</table>

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's getTransactionId() method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The state column can have any one of the values CS_ABORTING, CS_COMMITTING, CS_COMMIT_SENT, CS_COMPLETE_SENT, CSCOMPLETING, CS_CONNECTED, CS_DISCONNECTED, CS_FAIL_ABORTED, CS_FAIL_ABORTING, CS_FAIL_COMMITTED, CS_FAIL_COMMITTING, CS_FAIL_COMPLETED, CS_FAIL_PREPARED, CS PREPARE TO COMMIT, CS RECEIVING, CS_REC_COMMITTING, CS_RESTART, CS_SEND_FIRE_TRIG_REQ, CS_STARTED, CS_START_COMMITTING, CS_START_SCAN, CS_WAIT_ABORT_CONF, CS_WAIT_COMMIT_CONF, CS_WAIT_COMPLETE_CONF, CS_WAIT_FIRE_TRIG_REQ. (If the MySQL Server is running with...
The ndbinfo MySQL Cluster Information Database

In `client_node_id` and `client_block_ref`, `client` refers to a MySQL Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

This table was added in MySQL Cluster NDB 7.1.17.

17.5.10.6 The ndbinfo config_params Table

The `config_params` table is a static table which provides the names and internal ID numbers of all MySQL Cluster configuration parameters.

The following table provides information about the columns in the `config_params` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>param_number</td>
<td>integer</td>
<td>The parameter's internal ID number</td>
</tr>
<tr>
<td>param_name</td>
<td>string</td>
<td>The name of the parameter</td>
</tr>
</tbody>
</table>

Although this is a static table, its content can vary between MySQL Cluster installations, since supported parameters can vary due to differences between software releases, cluster hardware configurations, and other factors.

17.5.10.7 The ndbinfo counters Table

The `counters` table provides running totals of events such as reads and writes for specific kernel blocks and data nodes. Counts are kept from the most recent node start or restart; a node start or restart resets all counters on that node. Not all kernel blocks have all types of counters.

The following table provides information about the columns in the `counters` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>The data node ID</td>
</tr>
<tr>
<td>block_name</td>
<td>string</td>
<td>Name of the associated NDB kernel block (see NDB Kernel Blocks).</td>
</tr>
<tr>
<td>block_instance</td>
<td>integer</td>
<td>Block instance</td>
</tr>
<tr>
<td>counter_id</td>
<td>integer</td>
<td>The counter's internal ID number; normally an integer between 1 and 10, inclusive.</td>
</tr>
<tr>
<td>counter_name</td>
<td>string</td>
<td>The name of the counter. See text for names of individual counters and the NDB kernel block with which each counter is associated.</td>
</tr>
<tr>
<td>val</td>
<td>integer</td>
<td>The counter's value</td>
</tr>
</tbody>
</table>

Each counter is associated with a particular NDB kernel block. Prior to MySQL Cluster NDB 7.2.0, this was limited to either the DBLQH kernel block or the DBTC kernel block.

The `OPERATIONS` counter is associated with the DBLQH (local query handler) kernel block (see The DBLQH Block). A primary-key read counts as one operation, as does a primary-key update. For reads, there is one operation in DBLQH per operation in DBTC. For writes, there is one operation counted per replica.

The `ATTRINFO`, `TRANSACTIONS`, `COMMITS`, `READS`, `LOCAL_READS`, `SIMPLE_READS`, `WRITES`, `LOCAL_WRITES`, `ABORTS`, `TABLE_SCANS`, and `RANGE_SCANS` counters are associated with the DBTC (transaction co-ordinator) kernel block (see The DBTC Block).
**LOCAL_WRITES** and **LOCAL_READS** are primary-key operations using a transaction coordinator in a node that also holds the primary replica of the record.

The **READS** counter includes all reads. **LOCAL_READS** includes only those reads of the primary replica on the same node as this transaction coordinator. **SIMPLE_READS** includes only those reads in which the read operation is the beginning and ending operation for a given transaction. Simple reads do not hold locks but are part of a transaction, in that they observe uncommitted changes made by the transaction containing them but not of any other uncommitted transactions. Such reads are “simple” from the point of view of the TC block; since they hold no locks they are not durable, and once **DBTC** has routed them to the relevant LQH block, it holds no state for them.

**ATTRINFO** keeps a count of the number of times an interpreted program is sent to the data node. See NDB Protocol Messages, for more information about **ATTRINFO** messages in the NDB kernel.

MySQL Cluster NDB 7.2.0, as part of its implementation of distributed pushed-down joins, adds the **LOCAL_TABLE_SCANS_SENT**, **READS_RECEIVED**, **PRUNED_RANGE_SCANS_RECEIVED**, **RANGE_SCANS_RECEIVED**, **LOCAL_READS_SENT**, **REMOTE_READS_SENT**, **LOCAL_READS_SENT**, **REMOTE_RANGE_SCANS_SENT**, **READS_NOT_FOUND**, **SCAN_BATCHES_RETURNED**, **TABLE_SCANS_RECEIVED**, and **SCAN_ROWS_RETURNED** counters. These counters are associated with the **DBSPJ** (select push-down join) kernel block (see The DBSPJ Block).

A number of counters increasing the visibility of transporter overload and send buffer sizing when troubleshooting such issues were added in MySQL Cluster NDB 7.0.37 and MySQL Cluster NDB 7.1.26. (Bug #15935206) For each LQH instance, there is one instance of each counter in the following list:

- **LQHKEY_OVERLOAD**: Number of primary key requests rejected at the LQH block instance due to transporter overload
- **LQHKEY_OVERLOAD_TC**: Count of instances of **LQHKEY_OVERLOAD** where the TC node transporter was overloaded
- **LQHKEY_OVERLOAD_READER**: Count of instances of **LQHKEY_OVERLOAD** where the API reader (reads only) node was overloaded.
- **LQHKEY_OVERLOAD_NODE_PEER**: Count of instances of **LQHKEY_OVERLOAD** where the next backup data node (writes only) was overloaded
- **LQHKEY_OVERLOAD_SUBSCRIBER**: Count of instances of **LQHKEY_OVERLOAD** where a event subscriber (writes only) was overloaded.
- **LQHSCAN_SLOWDOWNS**: Count of instances where a fragment scan batch size was reduced due to scanning API transporter overload.

### 17.5.10.8 The ndbinfo diskpagebuffer Table

The **diskpagebuffer** table provides statistics about disk page buffer usage by MySQL Cluster Disk Data tables.

The following table provides information about the columns in the **diskpagebuffer** table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>The data node ID</td>
</tr>
<tr>
<td>block_instance</td>
<td>integer</td>
<td>Block instance</td>
</tr>
<tr>
<td>pages_written</td>
<td>integer</td>
<td>Number of pages written to disk.</td>
</tr>
<tr>
<td>pages_written_lcp</td>
<td>integer</td>
<td>Number of pages written by local checkpoints.</td>
</tr>
</tbody>
</table>
The ndbinfo MySQL Cluster Information Database

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pages_read</td>
<td>integer</td>
<td>Number of pages read from disk</td>
</tr>
<tr>
<td>log_waits</td>
<td>integer</td>
<td>Number of page writes waiting for log to be written to disk</td>
</tr>
<tr>
<td>page_requests_direct_return</td>
<td>integer</td>
<td>Number of requests for pages that were available in buffer</td>
</tr>
<tr>
<td>page_requests_wait_queue</td>
<td>integer</td>
<td>Number of requests that had to wait for pages to become available in buffer</td>
</tr>
<tr>
<td>page_requests_wait_io</td>
<td>integer</td>
<td>Number of requests that had to be read from pages on disk (pages were unavailable in buffer)</td>
</tr>
</tbody>
</table>

You can use this table with MySQL Cluster Disk Data tables to determine whether `DiskPageBufferMemory` is sufficiently large to allow data to be read from the buffer rather than from disk; minimizing disk seeks can help improve performance of such tables.

You can determine the proportion of reads from `DiskPageBufferMemory` to the total number of reads using a query such as this one, which obtains this ratio as a percentage:

```sql
SELECT
  node_id,
  100 * page_requests_direct_return /
  (page_requests_direct_return + page_requests_wait_io) AS hit_ratio
FROM ndbinfo.diskpagebuffer;
```

The result from this query should be similar to what is shown here, with one row for each data node in the cluster (in this example, the cluster has 4 data nodes):

```
<table>
<thead>
<tr>
<th>node_id</th>
<th>hit_ratio</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>97.6744</td>
</tr>
<tr>
<td>6</td>
<td>97.6879</td>
</tr>
<tr>
<td>7</td>
<td>98.1776</td>
</tr>
<tr>
<td>8</td>
<td>98.1343</td>
</tr>
</tbody>
</table>
```

`hit_ratio` values approaching 100% indicate that only a very small number of reads are being made from disk rather than from the buffer, which means that Disk Data read performance is approaching an optimum level. If any of these values are less than 95%, this is a strong indicator that the setting for `DiskPageBufferMemory` needs to be increased in the `config.ini` file.

**Note**
A change in `DiskPageBufferMemory` requires a rolling restart of all of the cluster's data nodes before it takes effect.

### 17.5.10.9 The ndbinfo logbuffers Table

The `logbuffer` table provides information on MySQL Cluster log buffer usage.

The following table provides information about the columns in the `logbuffers` table. For each column, the table shows the name, data type, and a brief description.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>The ID of this data node.</td>
</tr>
</tbody>
</table>
### The ndbinfo MySQL Cluster Information Database

**17.5.10.10 The ndbinfo logspaces Table**

This table provides information about MySQL Cluster log space usage.

The following table provides information about the columns in the `logspaces` table. For each column, the table shows the name, data type, and a brief description.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>The ID of this data node.</td>
</tr>
<tr>
<td>log_type</td>
<td>string</td>
<td>Type of log; one of: REDO or DD-UNDO.</td>
</tr>
<tr>
<td>log_id</td>
<td>integer</td>
<td>The log ID.</td>
</tr>
<tr>
<td>log_part</td>
<td>integer</td>
<td>The log part number.</td>
</tr>
<tr>
<td>total</td>
<td>integer</td>
<td>Total space available for this log.</td>
</tr>
<tr>
<td>used</td>
<td>integer</td>
<td>Space used by this log.</td>
</tr>
</tbody>
</table>

**17.5.10.11 The ndbinfo membership Table**

The `membership` table describes the view that each data node has of all the others in the cluster, including node group membership, president node, arbitrator, arbitrator successor, arbitrator connection states, and other information.

The following table provides information about the columns in the `membership` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>This node's node ID</td>
</tr>
<tr>
<td>group_id</td>
<td>integer</td>
<td>Node group to which this node belongs</td>
</tr>
<tr>
<td>left_node</td>
<td>integer</td>
<td>Node ID of the previous node</td>
</tr>
<tr>
<td>right_node</td>
<td>integer</td>
<td>Node ID of the next node</td>
</tr>
<tr>
<td>president</td>
<td>integer</td>
<td>President's node ID</td>
</tr>
<tr>
<td>successor</td>
<td>integer</td>
<td>Node ID of successor to president</td>
</tr>
<tr>
<td>succession_order</td>
<td>integer</td>
<td>Order in which this node succeeds to presidency</td>
</tr>
<tr>
<td>Conf_HB_order</td>
<td>integer</td>
<td>-</td>
</tr>
<tr>
<td>arbitrator</td>
<td>integer</td>
<td>Node ID of arbitrator</td>
</tr>
<tr>
<td>arb_ticket</td>
<td>string</td>
<td>Internal identifier used to track arbitration</td>
</tr>
<tr>
<td>arb_state</td>
<td>Enumeration (see text)</td>
<td>Arbitration state</td>
</tr>
<tr>
<td>arb_connected</td>
<td>Yes or No</td>
<td>Whether this node is connected to the arbitrator</td>
</tr>
<tr>
<td>connected_rank1_arbs</td>
<td>List of node IDs</td>
<td>Connected arbitrators of rank 1</td>
</tr>
<tr>
<td>connected_rank2_arbs</td>
<td>List of node IDs</td>
<td>Connected arbitrators of rank 1</td>
</tr>
</tbody>
</table>
The node ID and node group ID are the same as reported by `ndb_mgm -e "SHOW"`.

The designations "left" and "right" are used in the event log in the same way.

The **president** node is the node viewed by the current node as responsible for setting an arbitrator (see MySQL Cluster Start Phases). If the president fails or becomes disconnected, the current node expects the node whose ID is shown in the **successor** column to become the new president. The **succession_order** column shows the place in the succession queue that the current node views itself as having.

In a normal MySQL Cluster, all data nodes should see the same node as **president**, and the same node (other than the president) as its **successor**. In addition, the current president should see itself as **1** in the order of succession, the **successor** node should see itself as **2**, and so on.

All nodes should show the same **arb_ticket** values as well as the same **arb_state** values. Possible **arb_state** values are **ARBIT_NULL**, **ARBIT_INIT**, **ARBIT_FIND**, **ARBIT_PREP1**, **ARBIT_PREP2**, **ARBIT_START**, **ARBIT_RUN**, **ARBIT_CHOOSE**, **ARBIT_CRASH**, and **UNKNOWN**.

**arb_connected** shows whether this node is connected to the node shown as this node’s **arbitrator**.

The **connected_rank1_arbs** and **connected_rank2_arbs** columns each display a list of 0 or more arbitrators having an **ArbitrationRank** equal to 1, or to 2, respectively.
Note

Both management nodes and API nodes are eligible to become arbitrators.

Like the `arbitrator_validity_detail` and `arbitrator_validity_summary` tables, this table was added in MySQL Cluster NDB 7.0.37 and MySQL Cluster NDB 7.1.26.

### 17.5.10.12 The `ndbinfo memoryusage` Table

Querying this table provides information similar to that provided by the `ALL REPORT MemoryUsage` command in the `ndb_mgm` client, or logged by `ALL DUMP 1000`.

The following table provides information about the columns in the `memoryusage` table in MySQL Cluster NDB 7.1.3 and later. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>The node ID of this data node.</td>
</tr>
<tr>
<td>memory_type</td>
<td>string</td>
<td>One of <code>Data memory</code>, <code>Index memory</code>, or <code>(MySQL Cluster NDB 7.1.31 and later) Long message buffer</code>.</td>
</tr>
<tr>
<td>used</td>
<td>integer</td>
<td>Number of bytes currently used for data memory or index memory by this data node.</td>
</tr>
<tr>
<td>used_pages</td>
<td>integer</td>
<td>Number of pages currently used for data memory or index memory by this data node; see text.</td>
</tr>
<tr>
<td>total</td>
<td>integer</td>
<td>Total number of bytes of data memory or index memory available for this data node; see text.</td>
</tr>
<tr>
<td>total_pages</td>
<td>integer</td>
<td>Total number of memory pages available for data memory or index memory on this data node; see text.</td>
</tr>
</tbody>
</table>

The `total` column represents the total amount of memory in bytes available for the given resource (data memory or index memory) on a particular data node. This number should be approximately equal to the setting of the corresponding configuration parameter in the `config.ini` file.

Suppose that the cluster has 2 data nodes having node IDs `5` and `6`, and the `config.ini` file contains the following:

```ini
[ndbd default]
DataMemory = 1G
IndexMemory = 1G
```

Suppose also that the value of the `LongMessageBuffer` configuration parameter is allowed to assume its default (64 MB in MySQL Cluster NDB 7.1.31 and later).

The following query shows approximately the same values:

```sql
mysql> SELECT node_id, memory_type, total
        > FROM ndbinfo.memoryusage;

+---------+---------------------+------------+
| node_id | memory_type         | total      |
|---------|---------------------+------------+
|        5 | Data memory         | 1073741824 |
|        5 | Index memory        | 1074003968 |
|        5 | Long message buffer | 67108864   |
|        6 | Data memory         | 1073741824 |
|        6 | Index memory        | 1074003968 |
```
In this case, the total column values for index memory are slightly higher than the value set of IndexMemory due to internal rounding.

For the used_pages and total_pages columns, resources are measured in pages, which are 32K in size for DataMemory and 8K for IndexMemory. For long message buffer memory, the page size is 256 bytes.

Long message buffer information can be found in this table beginning with MySQL Cluster NDB 7.1.31; in earlier versions, only data memory and index memory were included.

MySQL Cluster NDB 7.1.2 and earlier. The remainder of this section provides information about the memoryusage table as implemented prior to MySQL Cluster NDB 7.1.3. (If you are using MySQL Cluster NDB 7.1.3 or later, refer to the beginning of this section.) For each column, the table shown here provides the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>The node ID of this data node.</td>
</tr>
<tr>
<td>memory_type</td>
<td>string</td>
<td>One of Data memory or Index memory</td>
</tr>
<tr>
<td>used</td>
<td>integer</td>
<td>Number of memory pages used; see text.</td>
</tr>
<tr>
<td>max</td>
<td>integer</td>
<td>Total number of memory pages available; see text.</td>
</tr>
</tbody>
</table>

For the used and max columns, resources are measured in pages, which (in MySQL Cluster NDB 7.1.2 and earlier) are 16K in size for DataMemory and 8K for IndexMemory. This example shows how to use this information in obtaining totals for DataMemory, IndexMemory, or both, which you can do by summing across data nodes and table columns, like this:

```
mysql> USE ndbinfo;
Database changed
mysql> SET @IPAGE := 8 * 1024;
Query OK, 0 rows affected (0.03 sec)
mysql> SET @DPAGE := 2 * @IPAGE;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT
    > @DPAGE * SUM(used) as 'Total DataMemory Used',
    > @DPAGE * SUM(max) as 'Total DataMemory Available',
    > @DPAGE * SUM(used) DIV COUNT(*) as 'Average DataMemory Used Per Node',
    > @DPAGE * SUM(max) DIV COUNT(*) as 'Average DataMemory Available Per Node'
    > FROM memoryusage WHERE memory_type = 'Data memory'
G
*************************** 1. row ***************************
Total DataMemory Used: 106102784
Total DataMemory Available: 209977344
Average DataMemory Used Per Node: 53051392
Average DataMemory Available Per Node: 104988672
1 row in set (0.34 sec)

mysql> SELECT
    > @IPAGE * SUM(used) as 'Total IndexMemory Used',
    > @IPAGE * SUM(max) as 'Total IndexMemory Available',
    > @IPAGE * SUM(used) DIV COUNT(*) as 'Average IndexMemory Used Per Node',
    > @IPAGE * SUM(max) DIV COUNT(*) as 'Average IndexMemory Available Per Node'
    > FROM memoryusage WHERE memory_type = 'INDEX_MEMORY'
G
*************************** 1. row ***************************
Total IndexMemory Used: 376832
Total IndexMemory Available: 210239488
Average IndexMemory Used Per Node: 188416
Average IndexMemory Available Per Node: 105119744
```
Prior to MySQL Cluster NDB 7.1.2, the `memory_type` column was named `DATA_MEMORY`. (Bug #50926)

### 17.5.10.13 The `ndbinfo` nodes Table

This table contains information on the status of data nodes. For each data node that is running in the cluster, a corresponding row in this table provides the node's node ID, status, and uptime. For nodes that are starting, it also shows the current start phase.

The following table provides information about the columns in the `nodes` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>node_id</code></td>
<td>integer</td>
<td>The data node's unique node ID in the cluster.</td>
</tr>
<tr>
<td><code>uptime</code></td>
<td>integer</td>
<td>Time since the node was last started, in seconds.</td>
</tr>
<tr>
<td><code>status</code></td>
<td>string</td>
<td>Current status of the data node; see text for possible values.</td>
</tr>
<tr>
<td><code>start_phase</code></td>
<td>integer</td>
<td>If the data node is starting, the current start phase.</td>
</tr>
<tr>
<td><code>config_generation</code></td>
<td>integer</td>
<td>The version of the cluster configuration file in use on this data node.</td>
</tr>
</tbody>
</table>

The `uptime` column shows the time in seconds that this node has been running since it was last started or restarted. This is a `BIGINT` value. This figure includes the time actually needed to start the node; in other words, this counter starts running the moment that `ndbd` or `ndbmtd` is first invoked; thus, even for a node that has not yet finished starting, `uptime` may show a non-zero value.

The `status` column shows the node's current status. This is one of: `NOTHING`, `CMVMI`, `STARTING`, `STARTED`, `SINGLEUSER`, `STOPPING_1`, `STOPPING_2`, `STOPPING_3`, or `STOPPING_4`. When the status is `STARTING`, you can see the current start phase in the `start_phase` column (see later in this section). `SINGLEUSER` is displayed in the `status` column for all data nodes when the cluster is in single user mode (see Section 17.5.8, "MySQL Cluster Single User Mode"). Seeing one of the `STOPPING` states does not necessarily mean that the node is shutting down but can mean rather that it is entering a new state; for example, if you put the cluster in single user mode, you can sometimes see data nodes report their state briefly as `STOPPING_2` before the status changes to `SINGLEUSER`.

The `start_phase` column uses the same range of values as those used in the output of the `ndb_mgm client node_id STATUS` command (see Section 17.5.2, "Commands in the MySQL Cluster Management Client"). If the node is not currently starting, then this column shows `0`. For a listing of MySQL Cluster start phases with descriptions, see Section 17.5.1, "Summary of MySQL Cluster Start Phases".

The `config_generation` column was added in MySQL Cluster NDB 7.0.24 and MySQL Cluster NDB 7.1.13. This column shows which version of the cluster configuration is in effect on each data node. This can be useful when performing a rolling restart of the cluster in order to make changes in configuration parameters. For example, from the output of the following `SELECT` statement, you can see that node 3 is not yet using the latest version of the cluster configuration (6) although nodes 1, 2, and 4 are doing so:

```sql
mysql> USE ndbinfo;
Database changed
```
The ndbinfo MySQL Cluster Information Database

```
mysql> SELECT * FROM nodes;
+---------+--------+---------+-------------+-------------------+
| node_id | uptime | status  | start_phase | config_generation |
+---------+--------+---------+-------------+-------------------+
|       1 |  10462 | STARTED |           0 |                 6 |
|       2 |  10460 | STARTED |           0 |                 6 |
|       3 |  10457 | STARTED |           0 |                 5 |
|       4 |  10455 | STARTED |           0 |                 6 |
+---------+--------+---------+-------------+-------------------+
2 rows in set (0.04 sec)
```

Therefore, for the case just shown, you should restart node 3 to complete the rolling restart of the cluster.

**Note**

When upgrading to MySQL Cluster NDB 7.0.24 or MySQL Cluster NDB 7.1.13 from a previous version of MySQL Cluster, you should run `mysql_upgrade` on all MySQL Servers that should connect to the cluster, in order to enable support for the new `config_generation` column. Otherwise, when you attempt to access this table, you get the warning `Table 'ndb$nodes' is defined differently in NDB, there are more columns available...

Nodes that are stopped are not accounted for in this table. Suppose that you have a MySQL Cluster with 4 data nodes (node IDs 1, 2, 3 and 4), and all nodes are running normally, then this table contains 4 rows, 1 for each data node:

```
mysql> USE ndbinfo;
Database changed
mysql> SELECT * FROM nodes;
+---------+--------+---------+-------------+-------------------+
| node_id | uptime | status  | start_phase | config_generation |
+---------+--------+---------+-------------+-------------------+
|       1 |  11776 | STARTED |           0 |                 6 |
|       2 |  11774 | STARTED |           0 |                 6 |
|       3 |  11771 | STARTED |           0 |                 6 |
|       4 |  11769 | STARTED |           0 |                 6 |
+---------+--------+---------+-------------+-------------------+
4 rows in set (0.04 sec)
```

If you shut down one of the nodes, only the nodes that are still running are represented in the output of this `SELECT` statement, as shown here:

```
ndb_mgm> 2 STOP
Node 2: Node shutdown initiated
Node 2: Node shutdown completed.
Node 2 has shutdown.
```

```
mysql> SELECT * FROM nodes;
+---------+--------+---------+-------------+-------------------+
| node_id | uptime | status  | start_phase | config_generation |
+---------+--------+---------+-------------+-------------------+
|       1 |  11807 | STARTED |           0 |                 6 |
|       3 |  11802 | STARTED |           0 |                 6 |
|       4 |  11800 | STARTED |           0 |                 6 |
+---------+--------+---------+-------------+-------------------+
3 rows in set (0.02 sec)
```

17.5.10.14 The ndbinfo pools Table

**Important**

This table was part of the original `ndbinfo` implementation, but was later removed (in MySQL Cluster NDB 7.1.3). The information in this section is now obsolete, and subject to removal in a future version of the documentation.
The `pools` table was originally intended to provide information about NDB memory pool usage, but was later removed.

For each column, this table shows the name, data type, and a brief description of each `ndbinfo.pools` column (as it appeared prior to MySQL Cluster NDB 7.1.3). Additional information can be found in the notes afterward.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>The data node's node ID.</td>
</tr>
<tr>
<td>block_name</td>
<td>string</td>
<td>Name of the NDB kernel block using this pool.</td>
</tr>
<tr>
<td>block_instance</td>
<td>integer</td>
<td>Kernel block instance ID.</td>
</tr>
<tr>
<td>pool_name</td>
<td>string</td>
<td>The name of the pool.</td>
</tr>
<tr>
<td>used</td>
<td>integer</td>
<td>Amount of the pool in use.</td>
</tr>
<tr>
<td>total</td>
<td>integer</td>
<td>Total size of the pool.</td>
</tr>
<tr>
<td>high</td>
<td>integer</td>
<td>The maximum used from this pool (since the node was last started).</td>
</tr>
<tr>
<td>entry_size</td>
<td>integer</td>
<td>The size of each object, in bytes.</td>
</tr>
<tr>
<td>param_name1</td>
<td>string</td>
<td>Name of a configuration parameter associated with this pool (or NULL); see text.</td>
</tr>
<tr>
<td>param_name2</td>
<td>string</td>
<td>Name of a configuration parameter associated with this pool (or NULL); see text.</td>
</tr>
<tr>
<td>param_name3</td>
<td>string</td>
<td>Name of a configuration parameter associated with this pool (or NULL); see text.</td>
</tr>
<tr>
<td>param_name4</td>
<td>string</td>
<td>Name of a configuration parameter associated with this pool (or NULL); see text.</td>
</tr>
</tbody>
</table>

The columns `param_name1`, `param_name2`, `param_name3`, and `param_name4` contain names of configuration parameters that are associated with a given pool. If no parameters are associated with the pool, then all 4 of these columns are NULL. For pools that are associated with configuration parameters, these columns are filled with non-NUL values, but not in any particular order.

You can use a query such as the one shown here to generate a table showing the associations of pools, NDB kernel blocks, and (where applicable) configuration parameters:

```sql
SELECT
    DISTINCT(pool_name) as 'Pool',
    block_name as 'Block',
    IF(
        (param_name1 && param_name2 && param_name3 && param_name4) IS NULL,
        '[NONE]',
        REPLACE(
            TRIM(
                CONCAT(
                    IFNULL(param_name1, ''),
                    IFNULL(CONCAT(' ', param_name2), ''),
                    IFNULL(CONCAT(' ', param_name3), ''),
                    IFNULL(CONCAT(' ', param_name4), '')
                )
            ), ' ', ', ')
    ) as 'Parameter(s)'
FROM pools ORDER BY pool_name;
```

You may also find the following stored procedure useful. It returns a list of pools associated with a given configuration parameter, along with the kernel blocks to which these pools belong. You can see
here the statement used to create this stored procedure along with sample output for some typical parameters:

```sql
DELIMITER |
CREATE PROCEDURE get_pools (p VARCHAR(50))
BEGIN
    SELECT
        DISTINCT(pool_name) as Pool,
        block_name as Block
    FROM ndbinfo.pools
    WHERE p
    IN (param_name1, param_name2, param_name3, param_name4)
    ORDER BY Pool;
END |
DELIMITER ;
CALL get_pools('MaxNoOfTables');
+-----------------+------------+
| pool_name       | block_name |
+-----------------+------------+
| Table Record    | DBDICT     |
| DictObject      | DBDICT     |
| Index           | DBTC       |
| Table           | BACKUP     |
| Trigger         | BACKUP     |
| Fragment        | BACKUP     |
| Subscriber      | SUMA       |
| Table           | SUMA       |
| Subscription    | SUMA       |
| Index           | DBTUX      |
| Descriptor page | DBTUX      |
+-----------------+------------+
11 rows in set (0.30 sec)
CALL get_pools('MaxNoOfOrderedIndexes');
+-----------------+------------+
| pool_name       | block_name |
+-----------------+------------+
| DictObject      | DBDICT     |
| Index           | DBTC       |
| Table           | BACKUP     |
| Trigger         | BACKUP     |
| Fragment        | BACKUP     |
| Index           | DBTUX      |
| Fragment        | DBTUX      |
| Descriptor page | DBTUX      |
+-----------------+------------+
8 rows in set (0.29 sec)
```

17.5.10.15 The ndbinfo resources Table

This table provides information about data node resource availability and usage.

These resources are sometimes known as super-pools.

The following table provides information about the columns in the resources table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>The unique node ID of this data node.</td>
</tr>
<tr>
<td>resource_name</td>
<td>string</td>
<td>Name of the resource; see text.</td>
</tr>
</tbody>
</table>
The ndbinfo MySQL Cluster Information Database

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>reserved</td>
<td>integer</td>
<td>The amount reserved for this resource.</td>
</tr>
<tr>
<td>used</td>
<td>integer</td>
<td>The amount actually used by this resource.</td>
</tr>
<tr>
<td>max</td>
<td>integer</td>
<td>The maximum amount of this resource used, since the node was last started.</td>
</tr>
</tbody>
</table>

The resource_name can be one of RESERVED, DISK_OPERATIONS, DISK_RECORDS, DATA_MEMORY, JOBBUFFER, FILE_BUFFERS, or TRANSPORTER_BUFFERS.

17.5.10.16 The ndbinfo server_operations Table

The server_operations table contains entries for all ongoing NDB operations that the current SQL node (MySQL Server) is currently involved in. It effectively is a subset of the cluster_operations table, in which operations for other SQL and API nodes are not shown.

The following table provides information about the columns in the server_operations table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql_connection_id</td>
<td>integer</td>
<td>MySQL Server connection ID</td>
</tr>
<tr>
<td>node_id</td>
<td>integer</td>
<td>Node ID</td>
</tr>
<tr>
<td>block_instance</td>
<td>integer</td>
<td>Block instance</td>
</tr>
<tr>
<td>transid</td>
<td>integer</td>
<td>Transaction ID</td>
</tr>
<tr>
<td>operation_type</td>
<td>string</td>
<td>Operation type (see text for possible values)</td>
</tr>
<tr>
<td>state</td>
<td>string</td>
<td>Operation state (see text for possible values)</td>
</tr>
<tr>
<td>tableid</td>
<td>integer</td>
<td>Table ID</td>
</tr>
<tr>
<td>fragmentid</td>
<td>integer</td>
<td>Fragment ID</td>
</tr>
<tr>
<td>client_node_id</td>
<td>integer</td>
<td>Client node ID</td>
</tr>
<tr>
<td>client_block_ref</td>
<td>integer</td>
<td>Client block reference</td>
</tr>
<tr>
<td>tc_node_id</td>
<td>integer</td>
<td>Transaction coordinator node ID</td>
</tr>
<tr>
<td>tc_block_no</td>
<td>integer</td>
<td>Transaction coordinator block number</td>
</tr>
<tr>
<td>tc_block_instance</td>
<td>integer</td>
<td>Transaction coordinator block instance</td>
</tr>
</tbody>
</table>

The mysql_connection_id is the same as the connection or session ID shown in the output of SHOW PROCESSLIST. It is obtained from the INFORMATION_SCHEMA table NDB_TRANSID_MYSQL_CONNECTION_MAP.

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's getTransactionId() method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The operation_type column can take any one of the values READ, READ-SH, READ-EX, INSERT, UPDATE, DELETE, WRITE, UNLOCK, REFRESH, SCAN, SCAN-SH, SCAN-EX, or <unknown>.

The state column can have any one of the values ABORT_QUEUED, ABORT_STOPPED, COMMITTED, COMMIT_QUEUED, COMMIT_STOPPED, COPY_CLOSE_STOPPED, COPY_FIRST_STOPPED, COPY_STOPPED, COPY_TUPKEY, IDLE, LOG_ABORT_QUEUED, LOG_ABORT_WRITE, LOG_COMMIT_QUEUED, LOG_COMMIT_QUEUED_WAIT_SIGNAL, LOG_COMMIT_WRITTEN, LOG_COMMIT_WRITTEN_WAIT_SIGNAL, LOG_QUEUE, PREPARED, PREPARED_RECEIVED_COMMIT, SCAN_CHECK_STOPPED, SCAN_CLOSE_STOPPED, SCAN_FIRST_STOPPED, SCAN_RELEASE_STOPPED, SCAN_STATE_USED, SCAN_STOPPED, SCAN_TUPKEY, STOPPED, TC_NOT_CONNECTED, WAIT_ACC, WAIT_ACC_ABORT, WAIT_AI_AFTER_ABORT, WAIT_ATTR,
You can obtain the name of an NDB table from its table ID by checking the output of `ndb_show_tables`.

The `fragid` is the same as the partition number seen in the output of `ndb_desc --extra-partition-info` (short form `-p`).

In `client_node_id` and `client_block_ref`, `client` refers to a MySQL Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

This table was added in MySQL Cluster NDB 7.1.17.

### 17.5.10.17 The `ndbinfo server_transactions` Table

The `server_transactions` table is subset of the `cluster_transactions` table, but includes only those transactions in which the current SQL node (MySQL Server) is a participant, while including the relevant connection IDs.

The following table provides information about the columns in the `server_transactions` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql_connection_id</td>
<td>integer</td>
<td>MySQL Server connection ID</td>
</tr>
<tr>
<td>node_id</td>
<td>integer</td>
<td>Transaction coordinator node ID</td>
</tr>
<tr>
<td>block_instance</td>
<td>integer</td>
<td>Transaction coordinator block instance</td>
</tr>
<tr>
<td>transid</td>
<td>integer</td>
<td>Transaction ID</td>
</tr>
<tr>
<td>state</td>
<td>string</td>
<td>Operation state (see text for possible values)</td>
</tr>
<tr>
<td>count_operations</td>
<td>integer</td>
<td>Number of stateful operations in the transaction</td>
</tr>
<tr>
<td>outstanding_operations</td>
<td>integer</td>
<td>Operations still being executed by local data management layer (LQH blocks)</td>
</tr>
<tr>
<td>inactive_seconds</td>
<td>integer</td>
<td>Time spent waiting for API</td>
</tr>
<tr>
<td>client_node_id</td>
<td>integer</td>
<td>Client node ID</td>
</tr>
<tr>
<td>client_block_ref</td>
<td>integer</td>
<td>Client block reference</td>
</tr>
</tbody>
</table>

The `mysql_connection_id` is the same as the connection or session ID shown in the output of `SHOW PROCESSLIST`. It is obtained from the `INFORMATION_SCHEMA` table `NDB_TRANSID_MYSQL_CONNECTION_MAP`.

The transaction ID is a unique 64-bit number which can be obtained using the NDB API's `getTransactionId()` method. (Currently, the MySQL Server does not expose the NDB API transaction ID of an ongoing transaction.)

The `state` column can have any one of the values `CS_ABORTING, CS_COMMITTING, CS_COMMIT_SENT, CS_COMPLETE_SENT, CS_COMPLETING, CS_CONNECTED, CS_DISCONNECTED, CS_FAIL_ABORTED, CS_FAIL_ABORTING, CS_FAIL_COMMITTED, CS_FAIL_COMMITTING, CS_FAIL_COMPLETED, CS_FAIL_PREPARED, CS_PREPARE_TO_COMMIT, CS_RECEIVING, CS_REC_COMMITTING, CS_RESTART, CS_SEND_FIRE_TRIG_REQ, CS_STARTED, CS_START_COMMITTING, CS_START_SCAN, CS_WAIT_ABORT_CONF, CS_WAIT_COMMIT_CONF, CS_WAIT_COMPLETE_CONF, CS_WAIT_FIRE_TRIG_REQ`. (If the MySQL Server is running with `ndbinfo_show_hidden` enabled, you can view this list of states by selecting from the `ndb$dbtc_apiconnect_state` table, which is normally hidden.)
In `client_node_id` and `client_block_ref`, `client` refers to a MySQL Cluster API or SQL node (that is, an NDB API client or a MySQL Server attached to the cluster).

This table was added in MySQL Cluster NDB 7.1.17.

### 17.5.10.18 The ndbinfo threadblocks Table

The `threadblocks` table associates data nodes, threads, and instances of NDB kernel blocks.

The following table provides information about the columns in the `threadblocks` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>Node ID</td>
</tr>
<tr>
<td>thr_no</td>
<td>integer</td>
<td>Thread ID</td>
</tr>
<tr>
<td>block_name</td>
<td>string</td>
<td>Block name</td>
</tr>
<tr>
<td>block_instance</td>
<td>integer</td>
<td>Block instance number</td>
</tr>
</tbody>
</table>

The `block_name` is one of the values found in the `block_name` column when selecting from the `ndbinfo.blocks` table. Although the list of possible values is static for a given MySQL Cluster release, the list may vary between releases.

This table was added in MySQL Cluster NDB 7.1.17.

### 17.5.10.19 The ndbinfo threadstat Table

The `threadstat` table provides a rough snapshot of statistics for threads running in the NDB kernel.

The following table provides information about the columns in the `threadstat` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>Node ID</td>
</tr>
<tr>
<td>thr_no</td>
<td>integer</td>
<td>Thread ID</td>
</tr>
<tr>
<td>thr_nm</td>
<td>string</td>
<td>Thread name</td>
</tr>
<tr>
<td>c_loop</td>
<td>string</td>
<td>Number of loops in main loop</td>
</tr>
<tr>
<td>c_exec</td>
<td>string</td>
<td>Number of signals executed</td>
</tr>
<tr>
<td>c_wait</td>
<td>string</td>
<td>Number of times waiting for additional input</td>
</tr>
<tr>
<td>c_l_sent_prioa</td>
<td>integer</td>
<td>Number of priority A signals sent to own node</td>
</tr>
<tr>
<td>c_l_sent_priob</td>
<td>integer</td>
<td>Number of priority B signals sent to own node</td>
</tr>
<tr>
<td>c_r_sent_prioa</td>
<td>integer</td>
<td>Number of priority A signals sent to remote node</td>
</tr>
<tr>
<td>c_r_sent_priob</td>
<td>integer</td>
<td>Number of priority B signals sent to remote node</td>
</tr>
<tr>
<td>os_tid</td>
<td>integer</td>
<td>OS thread ID</td>
</tr>
<tr>
<td>os_now</td>
<td>integer</td>
<td>OS time (ms)</td>
</tr>
<tr>
<td>os_ru_utime</td>
<td>integer</td>
<td>OS user CPU time (µs)</td>
</tr>
<tr>
<td>os_ru_stime</td>
<td>integer</td>
<td>OS system CPU time (µs)</td>
</tr>
<tr>
<td>os_ru_minflt</td>
<td>integer</td>
<td>OS page reclaims (soft page faults)</td>
</tr>
</tbody>
</table>
The ndbinfo MySQL Cluster Information Database

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>os_ru_majflt</td>
<td>integer</td>
<td>OS page faults (hard page faults)</td>
</tr>
<tr>
<td>os_ru_nvcswe</td>
<td>integer</td>
<td>OS voluntary context switches</td>
</tr>
<tr>
<td>os_ru_nivcswe</td>
<td>integer</td>
<td>OS involuntary context switches</td>
</tr>
</tbody>
</table>

The values of the `os_ru_utime`, `os_ru_stime`, `os_ru_minflt`, `os_ru_majflt`, `os_ru_nvcswe`, and `os_ru_nivcswe` columns are obtained using the `getrusage()` call, or the equivalent.

Since this table contains counts taken at a given point in time, for best results it is necessary to query this table periodically and store the results in an intermediate table or tables. The MySQL Server’s Event Scheduler can be employed to automate such monitoring. For more information, see Section 19.4, “Using the Event Scheduler”.

This table was added in MySQL Cluster NDB 7.1.17.

17.5.10.20 The ndbinfo transporters Table

This table contains information about NDB transporters.

The following table provides information about the columns in the `transporters` table. For each column, the table shows the name, data type, and a brief description. Additional information can be found in the notes following the table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_id</td>
<td>integer</td>
<td>This data node's unique node ID in the cluster.</td>
</tr>
<tr>
<td>remote_node_id</td>
<td>integer</td>
<td>The remote data node's node ID.</td>
</tr>
<tr>
<td>status</td>
<td>string</td>
<td>Status of the connection.</td>
</tr>
<tr>
<td>remote_address</td>
<td>string</td>
<td>Name or IP address of the remote host</td>
</tr>
<tr>
<td>bytes_sent</td>
<td>integer</td>
<td>Number of bytes sent using this connection</td>
</tr>
<tr>
<td>bytes_received</td>
<td>integer</td>
<td>Number of bytes received using this connection</td>
</tr>
<tr>
<td>connect_count</td>
<td></td>
<td>Number of times connection established on this transporter</td>
</tr>
<tr>
<td>overloaded</td>
<td></td>
<td>1 if this transporter is currently overloaded, otherwise 0</td>
</tr>
<tr>
<td>overload_count</td>
<td></td>
<td>Number of times this transporter has entered overload state since connecting</td>
</tr>
<tr>
<td>slowdown</td>
<td></td>
<td>1 if this transporter is in scan slowdown state, otherwise 0</td>
</tr>
<tr>
<td>slowdown_count</td>
<td></td>
<td>Number of times this transporter has entered scan slowdown state since connecting</td>
</tr>
</tbody>
</table>

For each running data node in the cluster, the `transporters` table displays a row showing the status of each of that node's connections with all nodes in the cluster, including itself. This information is shown in the table's status column, which can have any one of the following values: CONNECTING, CONNECTED, DISCONNECTING, or DISCONNECTED.

Connections to API and management nodes which are configured but not currently connected to the cluster are shown with status DISCONNECTED. Rows where the node_id is that of a data nodes which is not currently connected are not shown in this table. (This is similar omission of disconnected nodes in the ndbinfo.nodes table.)
The \textit{remote\_address}, \textit{bytes\_sent}, and \textit{bytes\_received} columns were added in MySQL Cluster NDB 7.0.36 and MySQL Cluster NDB 7.1.25. The \textit{remote\_address} is the host name or address for the node whose ID is shown in the \textit{remote\_node\_id} column. The \textit{bytes\_sent} from this node and \textit{bytes\_received} by this node are the numbers, respectively, of bytes sent and received by the node using this connection since it was established; for nodes whose status is \textit{CONNECTING} or \textit{DISCONNECTED}, these columns always display 0.

The \textit{connect\_count}, \textit{overloaded}, \textit{overload\_count}, \textit{slowdown}, and \textit{slowdown\_count} columns were added in MySQL Cluster NDB 7.0.37 and MySQL Cluster NDB 7.1.26. These counters are reset on connection, and retain their values after the remote node disconnects. Also beginning with MySQL Cluster NDB 7.0.37 and MySQL Cluster NDB 7.1.26, the \textit{bytes\_sent} and \textit{bytes\_received} counters are reset on connection as well, and so retain their values following disconnection. (Previously, the values in these columns were reset on disconnection.) (Bug \#15935206)

Assume you have a 5-node cluster consisting of 2 data nodes, 2 SQL nodes, and 1 management node, as shown in the output of the \texttt{SHOW} command in the \texttt{ndb\_mgm} client:

```
ndb\_mgm> \texttt{SHOW}
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
[ndbd(NDB)] 2 node(s)
id=1    @10.100.10.1 (5.1.77-ndb-7.1.37, Nodegroup: 0, *)
id=2    @10.100.10.2 (5.1.77-ndb-7.1.37, Nodegroup: 0)

[ndb\_mgmd(MGM)] 1 node(s)
id=10   @10.100.10.10 (5.1.77-ndb-7.1.37)

[mysqld(API)] 2 node(s)
id=20   @10.100.10.20 (5.1.77-ndb-7.1.37)
id=21   @10.100.10.21 (5.1.77-ndb-7.1.37)
```

There are 10 rows in the \texttt{transporters} table—5 for the first data node, and 5 for the second—assuming that all data nodes are running, as shown here:

```
mysql> \texttt{SELECT node\_id, remote\_node\_id, status} 
   -> \texttt{FROM ndbinfo.transporters;}
+---------+----------------+---------------+
| node\_id | remote\_node\_id | status        |
+---------+----------------+---------------+
|       1 |              1 | DISCONNECTED  |
|       1 |              2 | CONNECTED     |
|       1 |             10 | CONNECTED     |
|       1 |             20 | CONNECTED     |
|       1 |             21 | CONNECTED     |
|       2 |              1 | CONNECTED     |
|       2 |              2 | DISCONNECTED  |
|       2 |             10 | CONNECTED     |
|       2 |             20 | CONNECTED     |
|       2 |             21 | CONNECTED     |
+---------+----------------+---------------+
10 rows in set (0.04 sec)
```

If you shut down one of the data nodes in this cluster using the command \texttt{2 \texttt{STOP}} in the \texttt{ndb\_mgm} client, then repeat the previous query (again using the \texttt{mysql} client), this table now shows only 5 rows—1 row for each connection from the remaining management node to another node, including both itself and the data node that is currently offline—and displays \texttt{CONNECTING} for the status of each remaining connection to the data node that is currently offline, as shown here:

```
mysql> \texttt{SELECT node\_id, remote\_node\_id, status} 
   -> \texttt{FROM ndbinfo.transporters;}
+---------+----------------+---------------+
| node\_id | remote\_node\_id | status        |
+---------+----------------+---------------+
|       1 |              1 | DISCONNECTED  |
|       2 |              1 | CONNECTED     |
|       2 |              2 | DISCONNECTED  |
|       2 |             10 | CONNECTED     |
|       2 |             20 | CONNECTED     |
+---------+----------------+---------------+
3 rows in set (0.03 sec)
```

17.5.11 MySQL Cluster Security Issues

This section discusses security considerations to take into account when setting up and running MySQL Cluster.

Topics covered in this section include the following:

- MySQL Cluster and network security issues
- Configuration issues relating to running MySQL Cluster securely
- MySQL Cluster and the MySQL privilege system
- MySQL standard security procedures as applicable to MySQL Cluster

17.5.11.1 MySQL Cluster Security and Networking Issues

In this section, we discuss basic network security issues as they relate to MySQL Cluster. It is extremely important to remember that MySQL Cluster "out of the box" is not secure; you or your network administrator must take the proper steps to ensure that your cluster cannot be compromised over the network.

Cluster communication protocols are inherently insecure, and no encryption or similar security measures are used in communications between nodes in the cluster. Because network speed and latency have a direct impact on the cluster's efficiency, it is also not advisable to employ SSL or other encryption to network connections between nodes, as such schemes will effectively slow communications.

It is also true that no authentication is used for controlling API node access to a MySQL Cluster. As with encryption, the overhead of imposing authentication requirements would have an adverse impact on Cluster performance.

In addition, there is no checking of the source IP address for either of the following when accessing the cluster:

- SQL or API nodes using "free slots" created by empty [mysqld] or [api] sections in the config.ini file

This means that, if there are any empty [mysqld] or [api] sections in the config.ini file, then any API nodes (including SQL nodes) that know the management server's host name (or IP address) and port can connect to the cluster and access its data without restriction. (See Section 17.5.11.2, "MySQL Cluster and MySQL Privileges", for more information about this and related issues.)

Note

You can exercise some control over SQL and API node access to the cluster by specifying a HostName parameter for all [mysqld] and [api] sections in the config.ini file. However, this also means that, should you wish to connect an API node to the cluster from a previously unused host, you need to add an [api] section containing its host name to the config.ini file.

More information is available elsewhere in this chapter about the HostName parameter. Also see Section 17.3.1, "Quick Test Setup of MySQL Cluster", for configuration examples using HostName with API nodes.
MySQL Cluster Security Issues

- Any ndb_mgm client

This means that any cluster management client that is given the management server's host name (or IP address) and port (if not the standard port) can connect to the cluster and execute any management client command. This includes commands such as **ALL STOP** and **SHUTDOWN**.

For these reasons, it is necessary to protect the cluster on the network level. The safest network configuration for Cluster is one which isolates connections between Cluster nodes from any other network communications. This can be accomplished by any of the following methods:

1. Keeping Cluster nodes on a network that is physically separate from any public networks. This option is the most dependable; however, it is the most expensive to implement.

   We show an example of a MySQL Cluster setup using such a physically segregated network here:

   **Figure 17.10 MySQL Cluster with Hardware Firewall**

   ![MySQL Cluster with Hardware Firewall Diagram]

   This setup has two networks, one private (solid box) for the Cluster management servers and data nodes, and one public (dotted box) where the SQL nodes reside. (We show the management and data nodes connected using a gigabit switch since this provides the best performance.) Both networks are protected from the outside by a hardware firewall, sometimes also known as a network-based firewall.

   This network setup is safest because no packets can reach the cluster's management or data nodes from outside the network—and none of the cluster's internal communications can reach the outside—without going through the SQL nodes, as long as the SQL nodes do not permit any packets to be forwarded. This means, of course, that all SQL nodes must be secured against hacking attempts.

   **Important**

   With regard to potential security vulnerabilities, an SQL node is no different from any other MySQL server. See Section 6.1.3, “Making MySQL Secure Against Attackers”, for a description of techniques you can use to secure MySQL servers.

2. Using one or more software firewalls (also known as host-based firewalls) to control which packets pass through to the cluster from portions of the network that do not require access to it. In this type of setup, a software firewall must be installed on every host in the cluster which might otherwise be accessible from outside the local network.

   The host-based option is the least expensive to implement, but relies purely on software to provide protection and so is the most difficult to keep secure.
This type of network setup for MySQL Cluster is illustrated here:

**Figure 17.11 MySQL Cluster with Software Firewalls**

Using this type of network setup means that there are two zones of MySQL Cluster hosts. Each cluster host must be able to communicate with all of the other machines in the cluster, but only those hosting SQL nodes (dotted box) can be permitted to have any contact with the outside, while those in the zone containing the data nodes and management nodes (solid box) must be isolated from any machines that are not part of the cluster. Applications using the cluster and user of those applications must not be permitted to have direct access to the management and data node hosts.

To accomplish this, you must set up software firewalls that limit the traffic to the type or types shown in the following table, according to the type of node that is running on each cluster host computer:

<table>
<thead>
<tr>
<th>Type of Node to be Accessed</th>
<th>Traffic to Permit</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQL or API node</td>
<td>• It originates from the IP address of a management or data node (using any TCP or UDP port).</td>
</tr>
<tr>
<td></td>
<td>• It originates from within the network in which the cluster resides and is on the port that your application is using.</td>
</tr>
<tr>
<td>Data node or Management node</td>
<td>• It originates from the IP address of a management or data node (using any TCP or UDP port).</td>
</tr>
<tr>
<td></td>
<td>• It originates from the IP address of an SQL or API node.</td>
</tr>
</tbody>
</table>

Any traffic other than that shown in the table for a given node type should be denied.

The specifics of configuring a firewall vary from firewall application to firewall application, and are beyond the scope of this Manual. **iptables** is a very common and reliable firewall application, which is often used with **APF** as a front end to make configuration easier. You can (and should) consult the documentation for the software firewall that you employ, should you choose to
implement a MySQL Cluster network setup of this type, or of a “mixed” type as discussed under the next item.

3. It is also possible to employ a combination of the first two methods, using both hardware and software to secure the cluster—that is, using both network-based and host-based firewalls. This is between the first two schemes in terms of both security level and cost. This type of network setup keeps the cluster behind the hardware firewall, but permits incoming packets to travel beyond the router connecting all cluster hosts to reach the SQL nodes.

One possible network deployment of a MySQL Cluster using hardware and software firewalls in combination is shown here:

**Figure 17.12 MySQL Cluster with a Combination of Hardware and Software Firewalls**

In this case, you can set the rules in the hardware firewall to deny any external traffic except to SQL nodes and API nodes, and then permit traffic to them only on the ports required by your application.

Whatever network configuration you use, remember that your objective from the viewpoint of keeping the cluster secure remains the same—to prevent any unessential traffic from reaching the cluster while ensuring the most efficient communication between the nodes in the cluster.

Because MySQL Cluster requires large numbers of ports to be open for communications between nodes, the recommended option is to use a segregated network. This represents the simplest way to prevent unwanted traffic from reaching the cluster.

**Note**

If you wish to administer a MySQL Cluster remotely (that is, from outside the local network), the recommended way to do this is to use `ssh` or another secure login shell to access an SQL node host. From this host, you can then run the management client to access the management server safely, from within the Cluster’s own local network.

Even though it is possible to do so in theory, it is not recommended to use `ndb_mgm` to manage a Cluster directly from outside the local network on which the Cluster is running. Since neither authentication nor encryption takes place between the management client and the management server, this represents an extremely insecure means of managing the cluster, and is almost certain to be compromised sooner or later.
In this section, we discuss how the MySQL privilege system works in relation to MySQL Cluster and the implications of this for keeping a MySQL Cluster secure.

Standard MySQL privileges apply to MySQL Cluster tables. This includes all MySQL privilege types (SELECT privilege, UPDATE privilege, DELETE privilege, and so on) granted on the database, table, and column level. As with any other MySQL Server, user and privilege information is stored in the mysql system database. The SQL statements used to grant and revoke privileges on NDB tables, databases containing such tables, and columns within such tables are identical in all respects with the GRANT and REVOKE statements used in connection with database objects involving any (other) MySQL storage engine. The same thing is true with respect to the CREATE USER and DROP USER statements.

It is important to keep in mind that, by default, the MySQL grant tables use the MyISAM storage engine. Because of this, those tables are not duplicated or shared among MySQL servers acting as SQL nodes in a MySQL Cluster. By way of example, suppose that two SQL nodes A and B are connected to the same MySQL Cluster, which has an NDB table named mytable in a database named mydb, and that you execute an SQL statement on server A that creates a new user jon@localhost and grants this user the SELECT privilege on that table:

```sql
mysql> GRANT SELECT ON mydb.mytable
      -> TO jon@localhost IDENTIFIED BY 'mypass';
```

This user is not created on server B. For this to take place, the statement must also be run on server B. Similarly, statements run on server A and affecting the privileges of existing users on server A do not affect users on server B unless those statements are actually run on server B as well.

In other words, changes in users and their privileges do not automatically propagate between SQL nodes by default. Prior to MySQL Cluster NDB 7.2, any synchronization of privileges between SQL nodes must be done either manually or by scripting an application that periodically synchronizes the privilege tables on all SQL nodes in the cluster. In MySQL Cluster NDB 7.2 and later, you can enable automatic distribution of MySQL users and privileges across MySQL Cluster SQL nodes; see Section 17.5.14, “Distributed MySQL Privileges for MySQL Cluster”, for details.

Conversely, because there is no way in MySQL to deny privileges (privileges can either be revoked or not granted in the first place, but not denied as such), there is no special protection for NDB tables on one SQL node from users that have privileges on another SQL node. (This is true even if you are not using the automatic distribution of user privileges available in MySQL Cluster NDB 7.2 and later.) The most far-reaching example of this is the MySQL root account, which can perform any action on any database object. In combination with empty [mysqld] or [api] sections of the config.ini file, this account can be especially dangerous. To understand why, consider the following scenario:

• The config.ini file contains at least one empty [mysqld] or [api] section. This means that the MySQL Cluster management server performs no checking of the host from which a MySQL Server (or other API node) accesses the MySQL Cluster.

• There is no firewall, or the firewall fails to protect against access to the MySQL Cluster from hosts external to the network.

• The host name or IP address of the MySQL Cluster's management server is known or can be determined from outside the network.

If these conditions are true, then anyone, anywhere can start a MySQL Server with --ndbcluster --ndb-connectstring=management_host and access this MySQL Cluster. Using the MySQL root account, this person can then perform the following actions:

• Execute a SHOW DATABASES statement to obtain a list of all NDB databases

• Execute a SHOW TABLES FROM some_database statement to obtain a list of all NDB tables in a given database

• Run any legal MySQL statements on any of those tables, such as:
MySQL Cluster Security Issues

- SELECT * FROM some_table to read all the data from any table
- DELETE FROM some_table to delete all the data from a table
- DESCRIBE some_table or SHOW CREATE TABLE some_table to determine the table schema
- UPDATE some_table SET column1 = some_value to fill a table column with “garbage” data; this could actually cause much greater damage than simply deleting all the data

More insidious variations might include statements like these:

```
UPDATE some_table SET an_int_column = an_int_column + 1
```

or

```
UPDATE some_table SET a_varchar_column = REVERSE(a_varchar_column)
```

Such malicious statements are limited only by the imagination of the attacker.

The only tables that would be safe from this sort of mayhem would be those tables that were created using storage engines other than NDB, and so not visible to a “rogue” SQL node.

**Note**

A user who can log in as root can also access the INFORMATION_SCHEMA database and its tables, and so obtain information about databases, tables, stored routines, scheduled events, and any other database objects for which metadata is stored in INFORMATION_SCHEMA.

It is also a very good idea to use different passwords for the root accounts on different cluster SQL nodes (unless you are using distributed privileges as supported in MySQL Cluster NDB 7.2 and later).

In sum, you cannot have a safe MySQL Cluster if it is directly accessible from outside your local network.

**Important**

Never leave the MySQL root account password empty. This is just as true when running MySQL as a MySQL Cluster SQL node as it is when running it as a standalone (non-Cluster) MySQL Server, and should be done as part of the MySQL installation process before configuring the MySQL Server as an SQL node in a MySQL Cluster.

Prior to MySQL Cluster NDB 7.2, you should never convert the system tables in the mysql database to use the NDB storage engine. There are a number of reasons why you should not do this, but the most important reason is this: Many of the SQL statements that affect mysql tables storing information about user privileges, stored routines, scheduled events, and other database objects cease to function if these tables are changed to use any storage engine other than MyISAM. This is a consequence of various MySQL Server internals. Beginning with MySQL Cluster NDB 7.2, you can use a stored procedure provided for this purpose (see Section 17.5.14, “Distributed MySQL Privileges for MySQL Cluster”), but you are strongly advised not to attempt convert the system tables manually.

Otherwise, if you need to synchronize mysql system tables between SQL nodes, you can use standard MySQL replication to do so, or employ a script to copy table entries between the MySQL servers.

**Summary.** The two most important points to remember regarding the MySQL privilege system with regard to MySQL Cluster are:
1. **Prior to MySQL Cluster NDB 7.2.** Users and privileges established on one SQL node do not automatically exist or take effect on other SQL nodes in the cluster. Conversely, removing a user or privilege on one SQL node in the cluster does not remove the user or privilege from any other SQL nodes.

   **In MySQL Cluster NDB 7.2 and later.** You can distribute MySQL users and privileges among SQL nodes using the SQL script, and the stored procedures it contains, that are supplied for this purpose in the MySQL Cluster distribution.

2. Once a MySQL user is granted privileges on an NDB table from one SQL node in a MySQL Cluster, that user can “see” any data in that table regardless of the SQL node from which the data originated. (This is true even if you are not using the privilege distribution support available in MySQL Cluster NDB 7.2 or later.)

### 17.5.11.3 MySQL Cluster and MySQL Security Procedures

In this section, we discuss MySQL standard security procedures as they apply to running MySQL Cluster.

In general, any standard procedure for running MySQL securely also applies to running a MySQL Server as part of a MySQL Cluster. First and foremost, you should always run a MySQL Server as the `mysql` system user; this is no different from running MySQL in a standard (non-Cluster) environment. The `mysql` system account should be uniquely and clearly defined. Fortunately, this is the default behavior for a new MySQL installation. You can verify that the `mysqld` process is running as the `system user mysql` by using the system command such as the one shown here:

```bash
shell> ps aux | grep mysql
root  10467  0.0  0.1  3616  1380 pts/3    S    11:53   0:00 /bin/sh ./mysqld_safe --ndbcluster --ndb-connectstring=localhost:1186
mysql 10512  0.2  2.5  58528 26636 pts/3 S  11:53  0:00 /usr/local/mysql/libexec/mysqld --basedir=/usr/local/mysql --datadir=/usr/local/mysql/var --user=mysql --ndbcluster --ndb-connectstring=localhost:1186 --pid-file=/usr/local/mysql/var/mothra.pid --log-error=/usr/local/mysql/var/mothra.err
jon  10579  0.0  0.0   2736   688 pts/0    S+   11:54   0:00 grep mysql
```

If the `mysqld` process is running as any other user than `mysql`, you should immediately shut it down and restart it as the `mysql` user. If this user does not exist on the system, the `mysql` user account should be created, and this user should be part of the `mysql` user group; in this case, you should also make sure that the MySQL data directory on this system (as set using the `--datadir` option for `mysqld`) is owned by the `mysql` user, and that the SQL node's `my.cnf` file includes `user=mysql` in the `[mysqld]` section. Alternatively, you can start the MySQL server process with `--user=mysql` on the command line, but it is preferable to use the `my.cnf` option, since you might forget to use the command-line option and so have `mysqld` running as another user unintentionally. The `mysqld_safe` startup script forces MySQL to run as the `mysql` user.

**Important**

Never run `mysqld` as the system root user. Doing so means that potentially any file on the system can be read by MySQL, and thus—should MySQL be compromised—by an attacker.

As mentioned in the previous section (see Section 17.5.11.2, “MySQL Cluster and MySQL Privileges”), you should always set a root password for the MySQL Server as soon as you have it running. You should also delete the anonymous user account that is installed by default. You can accomplish these tasks using the following statements:

```bash
shell> mysql -u root
mysql>
mysql> UPDATE mysql.user
    ->   SET Password=PASSWORD('secure_password')
```
Be very careful when executing the `DELETE` statement not to omit the `WHERE` clause, or you risk deleting all MySQL users. Be sure to run the `FLUSH PRIVILEGES` statement as soon as you have modified the `mysql.user` table, so that the changes take immediate effect. Without `FLUSH PRIVILEGES`, the changes do not take effect until the next time that the server is restarted.

**Note**

Many of the MySQL Cluster utilities such as `ndb_show_tables`, `ndb_desc`, and `ndb_select_all` also work without authentication and can reveal table names, schemas, and data. By default these are installed on Unix-style systems with the permissions `wrxr-xr-x` (755), which means they can be executed by any user that can access the `mysql/bin` directory.

See Section 17.4, “MySQL Cluster Programs”, for more information about these utilities.

### 17.5.12 MySQL Cluster Disk Data Tables

Beginning with MySQL 5.1.6, it is possible to store the nonindexed columns of NDB tables on disk, rather than in RAM as with previous versions of MySQL Cluster.

As part of implementing MySQL Cluster Disk Data work, a number of improvements were made in MySQL Cluster for the efficient handling of very large amounts (terabytes) of data during node recovery and restart. These include a “no-steal” algorithm for synchronizing a starting node with very large data sets. For more information, see the paper *Recovery Principles of MySQL Cluster 5.1*, by MySQL Cluster developers Mikael Ronström and Jonas Oreland.

MySQL Cluster Disk Data performance can be influenced by a number of configuration parameters. For information about these parameters and their effects, see *MySQL Cluster Disk Data configuration parameters* and *MySQL Cluster Disk Data storage and GCP Stop errors*.

The performance of a MySQL Cluster that uses Disk Data storage can also be greatly improved by separating data node file systems from undo log files and tablespace data files, which can be done using symbolic links. For more information, see Section 17.5.12.2, “Using Symbolic Links with Disk Data Objects”.

### 17.5.12.1 MySQL Cluster Disk Data Objects

MySQL Cluster Disk Data storage is implemented using a number of *Disk Data objects*. These include the following:

- **Tablespaces** act as containers for other Disk Data objects.
- ** Undo log files** undo information required for rolling back transactions.
- One or more undo log files are assigned to a **log file group**, which is then assigned to a tablespace.
- **Data files** store Disk Data table data. A data file is assigned directly to a tablespace.

Undo log files and data files are actual files in the file system of each data node; by default they are placed in `ndb_node_id_fs` in the `DataDir` specified in the MySQL Cluster `config.ini` file, and where `node_id` is the data node’s node ID. It is possible to place these elsewhere by specifying either an absolute or relative path as part of the filename when creating the undo log or data file. Statements that create these files are shown later in this section.

MySQL Cluster tablespaces and log file groups are not implemented as files.
Important

Although not all Disk Data objects are implemented as files, they all share the same namespace. This means that each Disk Data object must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group both named \texttt{ddl}.

Assuming that you have already set up a MySQL Cluster with all nodes (including management and SQL nodes) running MySQL 5.1.6 or newer, the basic steps for creating a Cluster table on disk are as follows:

1. Create a log file group, and assign one or more undo log files to it (an undo log file is also sometimes referred to as an \texttt{undofile}).

   \textbf{Note}
   
   In MySQL 5.1 and later, undo log files are necessary only for Disk Data tables. They are no longer used for \texttt{NDBCLUSTER} tables that are stored only in memory.

2. Create a tablespace; assign the log file group, as well as one or more data files, to the tablespace.

3. Create a Disk Data table that uses this tablespace for data storage.

Each of these tasks can be accomplished using SQL statements in the \texttt{mysql} client or other MySQL client application, as shown in the example that follows.

1. We create a log file group named \texttt{lg\_1} using \texttt{CREATE LOGFILE GROUP}. This log file group is to be made up of two undo log files, which we name \texttt{undo\_1.log} and \texttt{undo\_2.log}, whose initial sizes are 16 MB and 12 MB, respectively. (The default initial size for an undo log file is 128 MB.) Optionally, you can also specify a size for the log file group's undo buffer, or permit it to assume the default value of 8 MB. In this example, we set the UNDO buffer's size at 2 MB. A log file group must be created with an undo log file; so we add \texttt{undo\_1.log} to \texttt{lg\_1} in this \texttt{CREATE LOGFILE GROUP} statement:

   ```sql
   CREATE LOGFILE GROUP lg_1
     ADD UNDOFILE 'undo_1.log'
     INITIAL_SIZE 16M
     UNDO_BUFFER_SIZE 2M
     ENGINE NDBCLUSTER;
   ```

   To add \texttt{undo\_2.log} to the log file group, use the following \texttt{ALTER LOGFILE GROUP} statement:

   ```sql
   ALTER LOGFILE GROUP lg_1
     ADD UNDOFILE 'undo_2.log'
     INITIAL_SIZE 12M
     ENGINE NDBCLUSTER;
   ```

Some items of note:

- The \texttt{.log} file extension used here is not required. We use it merely to make the log files easily recognizable.

- Every \texttt{CREATE LOGFILE GROUP} and \texttt{ALTER LOGFILE GROUP} statement must include an \texttt{ENGINE} clause. In MySQL 5.1 (including MySQL Cluster NDB 6.6 and 7.0 through 7.1), the permitted values for this clause are \texttt{NDBCLUSTER} and \texttt{NDB}.

Important

In MySQL 5.1.8 and later, there can exist only one log file group in the same MySQL Cluster at any given time.
MySQL Cluster Disk Data Tables

- When you add an undo log file to a log file group using `ADD UNDOFILE 'filename'`, a file with the name `filename` is created in the `ndb_node_id_fs` directory within the `DataDir` of each data node in the cluster, where `node_id` is the node ID of the data node. Each undo log file is of the size specified in the SQL statement. For example, if a MySQL Cluster has 4 data nodes, then the `ALTER LOGFILE GROUP` statement just shown creates 4 undo log files, 1 each on in the data directory of each of the 4 data nodes; each of these files is named `undo_2.log` and each file is 12 MB in size.

- `UNDO_BUFFER_SIZE` is limited by the amount of system memory available.

- For more information about the `CREATE LOGFILE GROUP` statement, see Section 13.1.14, "CREATE LOGFILE GROUP Syntax". For more information about `ALTER LOGFILE GROUP`, see Section 13.1.3, "ALTER LOGFILE GROUP Syntax".

2. Now we can create a tablespace, which contains files to be used by MySQL Cluster Disk Data tables for storing their data. A tablespace is also associated with a particular log file group. When creating a new tablespace, you must specify the log file group which it is to use for undo logging; you must also specify a data file. You can add more data files to the tablespace after the tablespace is created; it is also possible to drop data files from a tablespace (an example of dropping data files is provided later in this section).

Assume that we wish to create a tablespace named `ts_1` which uses `lg_1` as its log file group. This tablespace is to contain two data files named `data_1.dat` and `data_2.dat`, whose initial sizes are 32 MB and 48 MB, respectively. (The default value for `INITIAL_SIZE` is 128 MB.) We can do this using two SQL statements, as shown here:

```sql
CREATE TABLESPACE ts_1
  ADD DATAFILE 'data_1.dat'
  USE LOGFILE GROUP lg_1
  INITIAL_SIZE 32M
  ENGINE NDBCLUSTER;

ALTER TABLESPACE ts_1
  ADD DATAFILE 'data_2.dat'
  INITIAL_SIZE 48M
  ENGINE NDBCLUSTER;
```

The `CREATE TABLESPACE` statement creates a tablespace `ts_1` with the data file `data_1.dat`, and associates `ts_1` with log file group `lg_1`. The `ALTER TABLESPACE` adds the second data file (`data_2.dat`).

Some items of note:

- As is the case with the `.log` file extension used in this example for undo log files, there is no special significance for the `.dat` file extension; it is used merely for easy recognition of data files.

- When you add a data file to a tablespace using `ADD DATAFILE 'filename'`, a file with the name `filename` is created in the `ndb_node_id_fs` directory within the `DataDir` of each data node in the cluster, where `node_id` is the node ID of the data node. Each data file is of the size specified in the SQL statement. For example, if a MySQL Cluster has 4 data nodes, then the `ALTER TABLESPACE` statement just shown creates 4 data files, 1 each in the data directory of each of the 4 data nodes; each of these files is named `data_2.dat` and each file is 48 MB in size.

- All `CREATE TABLESPACE` and `ALTER TABLESPACE` statements must contain an `ENGINE` clause; only tables using the same storage engine as the tablespace can be created in the tablespace. In MySQL 5.1 (including MySQL Cluster NDB 6.X and 7.X through 7.1), the only permitted values for this clause are `NDBCLUSTER` and `NDB`.

2193
3. Now it is possible to create a table whose nonindexed columns are stored on disk in the tablespace ts_1:

```sql
CREATE TABLE dt_1 (
    member_id INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
    last_name VARCHAR(50) NOT NULL,
    first_name VARCHAR(50) NOT NULL,
    dob DATE NOT NULL,
    joined DATE NOT NULL,
    INDEX(last_name, first_name)
) TABLESPACE ts_1 STORAGE DISK
ENGINE NDBCLUSTER;
```

The TABLESPACE ... STORAGE DISK option tells the NDBCLUSTER storage engine to use tablespace ts_1 for disk data storage.

**Note**

Beginning with MySQL Cluster NDB 6.2.5 and MySQL Cluster NDB 6.3.2, it is also possible to specify whether an individual column is stored on disk or in memory by using a STORAGE clause as part of the column's definition in a CREATE TABLE or ALTER TABLE statement. STORAGE DISK causes the column to be stored on disk, and STORAGE MEMORY causes in-memory storage to be used. See Section 13.1.17, “CREATE TABLE Syntax”, for more information.

Once table ts_1 has been created as shown, you can perform INSERT, SELECT, UPDATE, and DELETE statements on it just as you would with any other MySQL table.

For table dt_1 as it has been defined here, only the dob and joined columns are stored on disk. This is because there are indexes on the id, last_name, and first_name columns, and so data belonging to these columns is stored in RAM. In MySQL 5.1 (including MySQL Cluster NDB 6.X and 7.X through 7.1), only nonindexed columns can be held on disk; indexes and indexed column data continue to be stored in memory. This tradeoff between the use of indexes and conservation of RAM is something you must keep in mind as you design Disk Data tables.

**Performance note.** The performance of a cluster using Disk Data storage is greatly improved if Disk Data files are kept on a separate physical disk from the data node file system. This must be done for each data node in the cluster to derive any noticeable benefit.

You may use absolute and relative file system paths with ADD UNDOFILE and ADD DATAFILE. Relative paths are calculated relative to the data node's data directory. You may also use symbolic links; see Section 17.5.12.2, “Using Symbolic Links with Disk Data Objects”, for more information and examples.

A log file group, a tablespace, and any Disk Data tables using these must be created in a particular order. The same is true for dropping any of these objects:

- A log file group cannot be dropped as long as any tablespaces are using it.
- A tablespace cannot be dropped as long as it contains any data files.
- You cannot drop any data files from a tablespace as long as there remain any tables which are using the tablespace.
- Beginning with MySQL 5.1.12, it is no longer possible to drop files created in association with a different tablespace than the one with which the files were created. (Bug #20053)
For example, to drop all the objects created so far in this section, you would use the following statements:

```
mysql> DROP TABLE dt_1;
mysql> ALTER TABLESPACE ts_1
    --> DROP DATAFILE 'data_2.dat'
    --> ENGINE NDBCLUSTER;
mysql> ALTER TABLESPACE ts_1
    --> DROP DATAFILE 'data_1.dat'
    --> ENGINE NDBCLUSTER;
mysql> DROP TABLESPACE ts_1
    --> ENGINE NDBCLUSTER;
mysql> DROP LOGFILE GROUP lg_1
    --> ENGINE NDBCLUSTER;
```

These statements must be performed in the order shown, except that the two `ALTER TABLESPACE` statements may be executed in either order.

You can obtain information about data files used by Disk Data tables by querying the `FILES` table in the `INFORMATION_SCHEMA` database. An extra "NULL row" was added to this table in MySQL 5.1.14 for providing additional information about undo log files. For more information and examples of use, see Section 20.26.1, "The INFORMATION_SCHEMA FILES Table".

Beginning with MySQL Cluster NDB 6.3.27 and MySQL Cluster NDB 7.0.8, it is also possible to view information about allocated and free disk space for each Disk Data table or table partition using the `ndb_desc` utility. For more information, see Section 17.4.10, "ndb_desc — Describe NDB Tables".

### 17.5.12.2 Using Symbolic Links with Disk Data Objects

The performance of a MySQL Cluster that uses Disk Data storage can be greatly improved by separating data node file systems from undo log files and tablespace data files and placing these on different disks. Previous to MySQL Cluster NDB 6.2.17, MySQL Cluster NDB 6.3.22, and MySQL Cluster NDB 6.4.3, there was no direct support for this in MySQL Cluster, but it was possible to achieve this separation using symbolic links as described in this section.

Beginning with MySQL Cluster NDB 6.2.17, MySQL Cluster NDB 6.3.22, and MySQL Cluster NDB 6.4.3, the data node configuration parameters `FileSystemPathDD`, `FileSystemPathDataFiles`, and `FileSystemPathUndoFiles` make the use of symbolic links for this purpose unnecessary. For information about these parameters, see Disk Data file system parameters.

Each data node in the cluster creates a file system in the directory named `ndb_node_id_fs` under the data node's `DataDir` as defined in the `config.ini` file. In this example, we assume that each data node host has 3 disks, aliased as `/data0`, `/data1`, and `/data2`, and that the cluster's `config.ini` includes the following:

```
[ndbd default]
DataDir= /data0
```

Our objective is to place all Disk Data log files in `/data1`, and all Disk Data data files in `/data2`, on each data node host.

**Note**

In this example, we assume that the cluster’s data node hosts are all using Linux operating systems. For other platforms, you may need to substitute you operating system’s commands for those shown here.

To accomplish this, perform the following steps:

- Under the data node file system create symbolic links pointing to the other drives:
shell> cd /data0/ndb_2_fs
shell> ls
D1 D10 D11 D2 D8 D9 LCP
shell> ln -s /data0 dnlogs
shell> ln -s /data1 dndata

You should now have two symbolic links:

shell> ls -l --hide=D*
  lrwxrwxrwx 1 user group   30 2007-03-19 13:58 dndata -> /data1
  lrwxrwxrwx 1 user group   30 2007-03-19 13:59 dnlogs -> /data2

We show this only for the data node with node ID 2; however, you must do this for each data node.

• Now, in the mysql client, create a log file group and tablespace using the symbolic links, as shown here:

  mysql> CREATE LOGFILE GROUP lg1
      -> ADD UNDOFILE 'dnlogs/undo1.log'
      -> INITIAL_SIZE 150M
      -> UNDO_BUFFER_SIZE = 1M
      -> ENGINE=NDBCLUSTER;

  mysql> CREATE TABLESPACE ts1
      -> ADD DATAFILE 'dndata/data1.log'
      -> USE LOGFILE GROUP lg1
      -> INITIAL_SIZE 1G
      -> ENGINE=NDBCLUSTER;

Verify that the files were created and placed correctly as shown here:

shell> cd /data1
shell> ls -l
  total 2099304
  -rw-rw-r--  1 user group 157286400 2007-03-19 14:02 undo1.dat
shell> cd /data2
shell> ls -l
  total 2099304
  -rw-rw-r--  1 user group 1073741824 2007-03-19 14:02 data1.dat

• If you are running multiple data nodes on one host, you must take care to avoid having them try to use the same space for Disk Data files. You can make this easier by creating a symbolic link in each data node file system. Suppose you are using /data0 for both data node file systems, but you wish to have the Disk Data files for both nodes on /data1. In this case, you can do something similar to what is shown here:

shell> cd /data0
shell> ls -l --hide=D* ndb_2_fs
  lrwxrwxrwx 1 user group   30 2007-03-19 14:22 ndb_2_fs -> /data1/dn2
shell> ls -l --hide=D* ndb_3_fs
  lrwxrwxrwx 1 user group   30 2007-03-19 14:22 ndb_3_fs -> /data1/dn3

shell> ls -l --hide=D* ndb_2_fs
  lrwxrwxrwx 1 user group   30 2007-03-19 14:22 dd -> /data1/dn2
shell> ls -l --hide=D* ndb_3_fs
  lrwxrwxrwx 1 user group   30 2007-03-19 14:22 dd -> /data1/dn3

• Now you can create a logfile group and tablespace using the symbolic link, like this:

  mysql> CREATE LOGFILE GROUP lg1
      -> ADD UNDOFILE 'dd/undo1.log'
      -> INITIAL_SIZE 150M
      -> UNDO_BUFFER_SIZE = 1M
      -> ENGINE=NDBCLUSTER;
Adding MySQL Cluster Data Nodes Online

17.5.12.3 MySQL Cluster Disk Data Storage Requirements

The following items apply to Disk Data storage requirements:

- Variable-length columns of Disk Data tables take up a fixed amount of space. For each row, this is equal to the space required to store the largest possible value for that column.

  For general information about calculating these values, see Section 11.7, “Data Type Storage Requirements”.

  You can obtain an estimate the amount of space available in data files and undo log files by querying the `INFORMATION_SCHEMA.FILES` table. For more information and examples, see Section 20.26.1, “The INFORMATION_SCHEMA FILES Table”.

  **Note**
  
  The `OPTIMIZE TABLE` statement does not have any effect on Disk Data tables.

- In a Disk Data table, the first 256 bytes of a TEXT or BLOB column are stored in memory; only the remainder is stored on disk.

- Each row in a Disk Data table uses 8 bytes in memory to point to the data stored on disk. This means that, in some cases, converting an in-memory column to the disk-based format can actually result in greater memory usage. For example, converting a `CHAR(4)` column from memory-based to disk-based format increases the amount of DataMemory used per row from 4 to 8 bytes.

  **Important**
  
  Starting the cluster with the `--initial` option does not remove Disk Data files. You must remove these manually prior to performing an initial restart of the cluster.

Performance of Disk Data tables can be improved by minimizing the number of disk seeks by making sure that `DiskPageBufferMemory` is of sufficient size. You can query the `diskpagebuffer` table to help determine whether the value for this parameter needs to be increased.

17.5.13 Adding MySQL Cluster Data Nodes Online

This section describes how to add MySQL Cluster data nodes “online”—that is, without needing to shut down the cluster completely and restart it as part of the process. This capability is available in MySQL Cluster NDB 7.0 (beginning with MySQL Cluster NDB 6.4.0) and later MySQL Cluster release series.
Adding MySQL Cluster Data Nodes Online

Important
Currently, you must add new data nodes to a MySQL Cluster as part of a new node group. In addition, it is not possible to change the number of replicas (or the number of nodes per node group) online.

17.5.13.1 Adding MySQL Cluster Data Nodes Online: General Issues

This section provides general information about the behavior of and current limitations in adding MySQL Cluster nodes online.

Redistribution of Data. The ability to add new nodes online includes a means to reorganize NDBCLUSTER table data and indexes so that they are distributed across all data nodes, including the new ones, by means of the ALTER ONLINE TABLE ... REORGANIZE PARTITION statement. Table reorganization of both in-memory and Disk Data tables is supported. This redistribution does not currently include unique indexes (only ordered indexes are redistributed). Prior to MySQL Cluster NDB 7.0.40 and MySQL Cluster NDB 7.1.28, BLOB table data is also not redistributed using this method (Bug #13714148).

The redistribution for NDBCLUSTER tables already existing before the new data nodes were added is not automatic, but can be accomplished using simple SQL statements in mysql or another MySQL client application. However, all data and indexes added to tables created after a new node group has been added are distributed automatically among all cluster data nodes, including those added as part of the new node group.

Partial starts. It is possible to add a new node group without all of the new data nodes being started. It is also possible to add a new node group to a degraded cluster—that is, a cluster that is only partially started, or where one or more data nodes are not running. In the latter case, the cluster must have enough nodes running to be viable before the new node group can be added.

Effects on ongoing operations. Normal DML operations using MySQL Cluster data are not prevented by the creation or addition of a new node group, or by table reorganization. However, it is not possible to perform DDL concurrently with table reorganization—that is, no other DDL statements can be issued while an ALTER TABLE ... REORGANIZE PARTITION statement is executing. In addition, during the execution of ALTER TABLE ... REORGANIZE PARTITION (or the execution of any other DDL statement), it is not possible to restart cluster data nodes.

Failure handling. Failures of data nodes during node group creation and table reorganization are handled as shown in the following table:

<table>
<thead>
<tr>
<th>Failure occurs during:</th>
<th>“Old” data nodes</th>
<th>“New” data nodes</th>
<th>System</th>
</tr>
</thead>
<tbody>
<tr>
<td>Node group creation</td>
<td>If a node other than the master fails: The creation of the node group is always rolled forward.</td>
<td>If a node other than the master fails: The creation of the node group is always rolled forward.</td>
<td>If the execution of CREATE NODEGROUP has reached the internal commit point: When restarted, the cluster includes the new node group. Otherwise, it without.</td>
</tr>
<tr>
<td></td>
<td>If the master fails:</td>
<td>If the master fails:</td>
<td>If the execution of CREATE NODEGROUP has not yet reached the internal commit point: When</td>
</tr>
<tr>
<td></td>
<td>If the internal commit point has been reached: The creation of the node group is rolled forward.</td>
<td>If the internal commit point has been reached: The creation of the node group is rolled forward.</td>
<td></td>
</tr>
</tbody>
</table>
## Adding MySQL Cluster Data Nodes Online

### Failure occurs during: Failure occurs in:

<table>
<thead>
<tr>
<th>“Old” data nodes</th>
<th>“New” data nodes</th>
<th>System</th>
</tr>
</thead>
<tbody>
<tr>
<td>• If the internal commit point has not yet been reached. The creation of the node group is rolled back</td>
<td>• If the internal commit point has not yet been reached. The creation of the node group is rolled back</td>
<td>restarted, the cluster does not include the new node group.</td>
</tr>
</tbody>
</table>

### Table reorganization

<table>
<thead>
<tr>
<th></th>
<th>“Old” data nodes</th>
<th>“New” data nodes</th>
<th>System</th>
</tr>
</thead>
<tbody>
<tr>
<td>• If a node other than the master fails: The table reorganization is always rolled forward.</td>
<td>• If a node other than the master fails: The table reorganization is always rolled forward.</td>
<td>• If the execution of an ALTER ONLINE TABLE table REORGANIZE PARTITION statement has reached the internal commit point: When the cluster is restarted, the data and indexes belonging to table are distributed using the “new” data nodes.</td>
<td></td>
</tr>
<tr>
<td>• If the master fails:</td>
<td>• If the internal commit point has been reached: The table reorganization is rolled forward.</td>
<td>• If the execution of an ALTER ONLINE TABLE table REORGANIZE PARTITION statement has not yet reached the internal commit point: When the cluster is restarted, the data and indexes belonging to table are distributed using only the “old” data nodes.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• If the internal commit point has not yet been reached. The table reorganization is rolled back.</td>
<td>• If the internal commit point has not yet been reached. The table reorganization is rolled back.</td>
<td></td>
</tr>
</tbody>
</table>

### Dropping node groups.
The ndb_mgm client supports a DROP NODEGROUP command, but it is possible to drop a node group only when no data nodes in the node group contain any data. Since there is currently no way to “empty” a specific data node or node group, this command works only the following two cases:

1. After issuing CREATE NODEGROUP in the ndb_mgm client, but before issuing any ALTER ONLINE TABLE ... REORGANIZE PARTITION statements in the mysql client.
2. After dropping all NDBCLUSTER tables using DROP TABLE.

TRUNCATE TABLE does not work for this purpose because the data nodes continue to store the table definitions.

### 17.5.13.2 Adding MySQL Cluster Data Nodes Online: Basic procedure

In this section, we list the basic steps required to add new data nodes to a MySQL Cluster. For a detailed example, see Section 17.5.13.3, “Adding MySQL Cluster Data Nodes Online: Detailed Example”.
Adding MySQL Cluster Data Nodes Online

Note
Beginning with MySQL Cluster NDB 7.0.4, this procedure applies whether you are using `ndbd` or `ndbmtd` binaries for the data node processes. Previously, this did not work with multi-threaded data nodes. (Bug #43108)

Assuming that you already have a running MySQL Cluster, adding data nodes online requires the following steps:

1. Edit the cluster configuration `config.ini` file, adding new `[ndbd]` sections corresponding to the nodes to be added. In the case where the cluster uses multiple management servers, these changes need to be made to all `config.ini` files used by the management servers.

   You must be careful that node IDs for any new data nodes added in the `config.ini` file do not overlap node IDs used by existing nodes. In the event that you have API nodes using dynamically allocated node IDs and these IDs match node IDs that you want to use for new data nodes, it is possible to force any such API nodes to “migrate”, as described later in this procedure.

2. Perform a rolling restart of all MySQL Cluster management servers.

   Important
   All management servers must be restarted with the `--reload` or `--initial` option to force the reading of the new configuration.

3. Perform a rolling restart of all existing MySQL Cluster data nodes. It is not necessary (or usually even desirable) to use `--initial` when restarting the existing data nodes.

   If you are using API nodes with dynamically allocated IDs matching any node IDs that you wish to assign to new data nodes, you must restart all API nodes (including SQL nodes) before restarting any of the data nodes processes in this step. This causes any API nodes with node IDs that were previously not explicitly assigned to relinquish those node IDs and acquire new ones.

4. Perform a rolling restart of any SQL or API nodes connected to the MySQL Cluster.

5. Start the new data nodes.

   The new data nodes may be started in any order. They can also be started concurrently, as long as they are started after the rolling restarts of all existing data nodes have been completed, and before proceeding to the next step.

6. Execute one or more `CREATE NODEGROUP` commands in the MySQL Cluster management client to create the new node group or node groups to which the new data nodes will belong.

7. Redistribute the cluster's data among all data nodes (including the new ones) by issuing an `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statement in the `mysql` client for each `NDBCLUSTER` table.

   Note
   This needs to be done only for tables already existing at the time the new node group is added. Data in tables created after the new node group is added is distributed automatically; however, data added to any given table `tbl` that existed before the new nodes were added is not distributed using the new nodes until that table has been reorganized using `ALTER ONLINE TABLE tbl REORGANIZE PARTITION`.

8. Reclaim the space freed on the “old” nodes by issuing, for each `NDBCLUSTER` table, an `OPTIMIZE TABLE` statement in the `mysql` client.

   You can add all the nodes desired, then issue several `CREATE NODEGROUP` commands in succession to add the new node groups to the cluster. Prior to MySQL Cluster NDB 7.0.16 and MySQL Cluster
Adding MySQL Cluster Data Nodes Online

NDB 7.1.5, when adding multiple new node groups to a MySQL Cluster, it was necessary to add only the nodes to be assigned to a given new node group, create that node group using `CREATE NODEGROUP`, then repeat this process for each new node group to be added to the cluster. (Bug #54497)

17.5.13.3 Adding MySQL Cluster Data Nodes Online: Detailed Example

In this section we provide a detailed example illustrating how to add new MySQL Cluster data nodes online, starting with a MySQL Cluster having 2 data nodes in a single node group and concluding with a cluster having 4 data nodes in 2 node groups.

Starting configuration. For purposes of illustration, we assume a minimal configuration, and that the cluster uses a `config.ini` file containing only the following information:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 192.168.0.1

[ndbd]
Id = 2
HostName = 192.168.0.2

[gm]
HostName = 192.168.0.10
Id = 10

[api]
Id=20
HostName = 192.168.0.20

[api]
Id=21
HostName = 192.168.0.21
```

Note

We have left a gap in the sequence between data node IDs and other nodes. This make it easier later to assign node IDs that are not already in use to data nodes which are newly added.

We also assume that you have already started the cluster using the appropriate command line or `my.cnf` options, and that running `SHOW` in the management client produces output similar to what is shown here:

```
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: 192.168.0.10:1186
Cluster Configuration
---------------------
[ndbd(NDB)] 2 node(s)
id=1 @192.168.0.1 (5.1.77-ndb-7.1.37, Nodegroup: 0, *)
id=2 @192.168.0.2 (5.1.77-ndb-7.1.37, Nodegroup: 0)

[ndbd_mgmd(MGM)] 1 node(s)
id=10 @192.168.0.10 (5.1.77-ndb-7.1.37)

[mysqld(API)] 2 node(s)
id=20 @192.168.0.20 (5.1.77-ndb-7.1.37)
id=21 @192.168.0.21 (5.1.77-ndb-7.1.37)
```

Finally, we assume that the cluster contains a single `NDBCLUSTER` table created as shown here:
USE n;

CREATE TABLE ips (  
id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,  
country_code CHAR(2) NOT NULL,  
type CHAR(4) NOT NULL,  
ip_address varchar(15) NOT NULL,  
addresses BIGINT UNSIGNED DEFAULT NULL,  
date BIGINT UNSIGNED DEFAULT NULL  
) ENGINE NDBCLUSTER;

The memory usage and related information shown later in this section was generated after inserting approximately 50000 rows into this table.

Note

In this example, we show the single-threaded ndbd being used for the data node processes. However—beginning with MySQL Cluster NDB 7.0.4—you can also apply this example, if you are using the multi-threaded ndbmtd by substituting ndbmtd for ndbd wherever it appears in the steps that follow. (Bug #43108)

Step 1: Update configuration file.  Open the cluster global configuration file in a text editor and add [ndbd] sections corresponding to the 2 new data nodes. (We give these data nodes IDs 3 and 4, and assume that they are to be run on host machines at addresses 192.168.0.3 and 192.168.0.4, respectively.) After you have added the new sections, the contents of the config.ini file should look like what is shown here, where the additions to the file are shown in bold type:

```
[nbdb default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[nbdb]
Id = 1
HostName = 192.168.0.1

[nbdb]
Id = 2
HostName = 192.168.0.2

[nbdb]
Id = 3
HostName = 192.168.0.3

[nbdb]
Id = 4
HostName = 192.168.0.4

[api]
Id=20
HostName = 192.168.0.20

[api]
Id=21
HostName = 192.168.0.21
```

Once you have made the necessary changes, save the file.

Step 2: Restart the management server.  Restarting the cluster management server requires that you issue separate commands to stop the management server and then to start it again, as follows:
1. Stop the management server using the management client `STOP` command, as shown here:

```
ndb_mgm> 10 STOP
Node 10 has shut down.
Disconnecting to allow Management Server to shutdown
```

2. Because shutting down the management server causes the management client to terminate, you must start the management server from the system shell. For simplicity, we assume that `config.ini` is in the same directory as the management server binary, but in practice, you must supply the correct path to the configuration file. You must also supply the `--reload` or `--initial` option so that the management server reads the new configuration from the file rather than its configuration cache. If your shell’s current directory is also the same as the directory where the management server binary is located, then you can invoke the management server as shown here:

```
shell> ndb_mgmd -f config.ini --reload
2008-12-08 17:29:23 [MgmSrvr] INFO -- NDB Cluster Management Server. 5.1.77-ndb-7.1.37
2008-12-08 17:29:23 [MgmSrvr] INFO -- Reading cluster configuration from 'config.ini'
```

If you check the output of `SHOW` in the management client after restarting the `ndb_mgm` process, you should now see something like this:

```
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: 192.168.0.10:1186
Cluster Configuration
---------------------
[nxdbd(NDB)] 2 node(s)
id=1 @192.168.0.1 (5.1.77-ndb-7.1.37, Nodegroup: 0, *)
id=2 @192.168.0.2 (5.1.77-ndb-7.1.37, Nodegroup: 0)
id=3 (not connected, accepting connect from 192.168.0.3)
id=4 (not connected, accepting connect from 192.168.0.4)
[nxdbd(MGM)] 1 node(s)
id=10 @192.168.0.10 (5.1.77-ndb-7.1.37)
[mysqld(API)] 2 node(s)
id=20 @192.168.0.20 (5.1.77-ndb-7.1.37)
id=21 @192.168.0.21 (5.1.77-ndb-7.1.37)
```

**Step 3: Perform a rolling restart of the existing data nodes.** This step can be accomplished entirely within the cluster management client using the `RESTART` command, as shown here:

```
ndb_mgm> 1 RESTART
Node 1: Node shutdown initiated
Node 1: Node shutdown completed, restarting, no start.
Node 1 is being restarted
ndb_mgm> Node 1: Start initiated (version 7.1.37)
Node 1: Started (version 7.1.37)
```

```
ndb_mgm> 2 RESTART
Node 2: Node shutdown initiated
Node 2: Node shutdown completed, restarting, no start.
Node 2 is being restarted
ndb_mgm> Node 2: Start initiated (version 7.1.37)
ndb_mgm> Node 2: Started (version 7.1.37)
```

---

**Important**

After issuing each `RESTART` command, wait until the management client reports `Node X: Started (version ...)` before proceeding any further.
Beginning with MySQL Cluster NDB 7.0.24 and MySQL Cluster NDB 7.1.13, you can verify that all existing data nodes were restarted using the updated configuration by checking the `ndbinfo.nodes` table in the `mysql` client.

**Step 4: Perform a rolling restart of all cluster API nodes.** Shut down and restart each MySQL server acting as an SQL node in the cluster using `mysqladmin shutdown` followed by `mysqld_safe` (or another startup script). This should be similar to what is shown here, where `password` is the MySQL root password for a given MySQL server instance:

```
shell> mysqladmin -uroot -p password shutdown
081208 20:19:56 mysqld_safe mysqld from pid file /usr/local/mysql/var/tonfisk.pid ended
shell> mysqld_safe --ndbcluster --ndb-connectstring=192.168.0.10 &
081208 20:20:06 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
081208 20:20:06 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
```

Of course, the exact input and output depend on how and where MySQL is installed on the system, as well as which options you choose to start it (and whether or not some or all of these options are specified in a `my.cnf` file).

**Step 5: Perform an initial start of the new data nodes.** From a system shell on each of the hosts for the new data nodes, start the data nodes as shown here, using the `--initial` option:

```
shell> ndbd -c 192.168.0.10 --initial
```

**Note**

Unlike the case with restarting the existing data nodes, you can start the new data nodes concurrently; you do not need to wait for one to finish starting before starting the other.

**Wait until both of the new data nodes have started before proceeding with the next step.** Once the new data nodes have started, you can see in the output of the management client `SHOW` command that they do not yet belong to any node group (as indicated with bold type here):

```
ndb_mgm> SHOW
Connected to Management Server at: 192.168.0.10:1186
Cluster Configuration
----------
[ndbd(NDB)]  2 node(s)
id=1  @192.168.0.1  (5.1.77-ndb-7.1.37, Nodegroup: 0, *)
id=2  @192.168.0.2  (5.1.77-ndb-7.1.37, Nodegroup: 0)
id=3  @192.168.0.3  (5.1.77-ndb-7.1.37, no nodegroup)
id=4  @192.168.0.4  (5.1.77-ndb-7.1.37, no nodegroup)

[ndb_mgmd(MGM)]  1 node(s)
id=10  @192.168.0.10  (5.1.77-ndb-7.1.37)

[mysqld(API)]  2 node(s)
id=20  @192.168.0.20  (5.1.77-ndb-7.1.37)
id=21  @192.168.0.21  (5.1.77-ndb-7.1.37)
```

**Step 6: Create a new node group.** You can do this by issuing a `CREATE NODEGROUP` command in the cluster management client. This command takes as its argument a comma-separated list of the node IDs of the data nodes to be included in the new node group, as shown here:

```
ndb_mgm> CREATE NODEGROUP 3,4
Nodegroup 1 created
```

By issuing `SHOW` again, you can verify that data nodes 3 and 4 have joined the new node group (again indicated in bold type):
Adding MySQL Cluster Data Nodes Online

```sql
ndb_mgm> SHOW
Connected to Management Server at: 192.168.0.10:1186
Cluster Configuration
---------------------
[ndbd(NDB)]  2 node(s)
id=1    @192.168.0.1  (5.1.77-ndb-7.1.37, Nodegroup: 0, *)
id=2    @192.168.0.2  (5.1.77-ndb-7.1.37, Nodegroup: 0)
id=3    @192.168.0.3  (5.1.77-ndb-7.1.37, Nodegroup: 1)
id=4    @192.168.0.4  (5.1.77-ndb-7.1.37, Nodegroup: 1)

[ndb_mgmd(MGM)]  1 node(s)
id=10   @192.168.0.10  (5.1.77-ndb-7.1.37)

[mysqld(API)]  2 node(s)
id=20   @192.168.0.20  (5.1.77-ndb-7.1.37)
id=21   @192.168.0.21  (5.1.77-ndb-7.1.37)
```

**Step 7: Redistribute cluster data.** When a node group is created, existing data and indexes are not automatically distributed to the new node group's data nodes, as you can see by issuing the appropriate `REPORT` command in the management client:

```sql
ndb_mgm> ALL REPORT MEMORY
Node 1: Data usage is 5%(177 32K pages of total 3200)
Node 1: Index usage is 0%(108 8K pages of total 12832)
Node 2: Data usage is 5%(177 32K pages of total 3200)
Node 2: Index usage is 0%(108 8K pages of total 12832)
Node 3: Data usage is 0%(0 32K pages of total 3200)
Node 3: Index usage is 0%(0 8K pages of total 12832)
Node 4: Data usage is 0%(0 32K pages of total 3200)
Node 4: Index usage is 0%(0 8K pages of total 12832)
```

By using `ndb_desc` with the `-p` option, which causes the output to include partitioning information, you can see that the table still uses only 2 partitions (in the *Per partition info* section of the output, shown here in bold text):

```sql
shell> ndb_desc -c 192.168.0.10 -d n ips -p
-- Attributes --
id Bigint PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
  country_code Char(2;latin1_swedish_ci) NOT NULL AT=FIXED ST=MEMORY
type Char(4;latin1_swedish_ci) NOT NULL AT=FIXED ST=MEMORY
  ip_address Varchar(15;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
date Bigunsigned NULL AT=FIXED ST=MEMORY
-- Indexes --
PRIMARY KEY(id) - UniqueHashIndex
PRIMARY(id) - OrderedIndex
-- Per partition info --
<table>
<thead>
<tr>
<th>Partition</th>
<th>Row count</th>
<th>Commit count</th>
<th>Frag fixed memory</th>
<th>Frag varsized memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>26086</td>
<td>26086</td>
<td>1572864</td>
<td>557056</td>
</tr>
<tr>
<td>1</td>
<td>26329</td>
<td>26329</td>
<td>1605632</td>
<td>557056</td>
</tr>
</tbody>
</table>
```
You can cause the data to be redistributed among all of the data nodes by performing, for each `NDBCLUSTER` table, an `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statement in the `mysql` client. After issuing the statement `ALTER ONLINE TABLE ips REORGANIZE PARTITION`, you can see using `ndb_desc` that the data for this table is now stored using 4 partitions, as shown here (with the relevant portions of the output in bold type):

```shell
shell> ndb_desc -c 192.168.0.10 -d n ips -p
-- ips --
  Version: 16777217
  Fragment type: 9
  K Value: 6
  Min load factor: 78
  Max load factor: 80
  Temporary table: no
  Number of attributes: 6
  Number of primary keys: 1
  Length of frm data: 341
  Row Checksum: 1
  Row GCI: 1
  SingleUserMode: 0
  ForceVarPart: 1
  FragmentCount: 4
  TableStatus: Retrieved
-- Attributes --
  id Bigint PRIMARY KEY DISTRIBUTION KEY AT=FIXED ST=MEMORY AUTO_INCR
  country_code Char(2;latin1_swedish_ci) NOT NULL AT=FIXED ST=MEMORY
  type Char(4;latin1_swedish_ci) NOT NULL AT=FIXED ST=MEMORY
  ip_address Varchar(15;latin1_swedish_ci) NOT NULL AT=SHORT_VAR ST=MEMORY
  addresses Bigunsigned NULL AT=FIXED ST=MEMORY
  date Bigunsigned NULL AT=FIXED ST=MEMORY
-- Indexes --
  PRIMARY KEY(id) - UniqueHashIndex
  PRIMARY(id) - OrderedIndex
-- Per partition info --
Partition  Row count  Commit count  Frag fixed memory  Frag varsized memory
  0      12981        52296         1572864             557056
  1      13236        52515         1605632             557056
  2      13105        13105         819200              294912
  3      13093        13093         819200              294912
```

Note

Normally, `ALTER [ONLINE] TABLE table_name REORGANIZE PARTITION` is used with a list of partition identifiers and a set of partition definitions to create a new partitioning scheme for a table that has already been explicitly partitioned. Its use here to redistribute data onto a new MySQL Cluster node group is an exception in this regard; when used in this way, only the name of the table is used following the `TABLE` keyword, and no other keywords or identifiers follow `REORGANIZE PARTITION`.

Prior to MySQL Cluster NDB 6.4.3, `ALTER ONLINE TABLE ... REORGANIZE PARTITION with no partition_names INTO (partition_definitions)` option did not work correctly with Disk Data tables or with in-memory `NDBCLUSTER` tables having one or more disk-based columns. (Bug #42549)

For more information, see Section 13.1.7, “ALTER TABLE Syntax”.

2206
In addition, for each table, the `ALTER ONLINE TABLE` statement should be followed by an `OPTIMIZE TABLE` to reclaim wasted space. You can obtain a list of all `NDBCLUSTER` tables using the following query against the `INFORMATION_SCHEMA.TABLES` table:

```sql
SELECT TABLE_SCHEMA, TABLE_NAME
FROM INFORMATION_SCHEMA.TABLES
WHERE ENGINE = 'NDBCLUSTER';
```

**Note**
The `INFORMATION_SCHEMA.TABLES.ENGINE` value for a MySQL Cluster table is always `NDBCLUSTER`, regardless of whether the `CREATE TABLE` statement used to create the table (or `ALTER TABLE` statement used to convert an existing table from a different storage engine) used `NDB` or `NDBCLUSTER` in its `ENGINE` option.

You can see after performing these statements in the output of `ALL REPORT MEMORY` that the data and indexes are now redistributed between all cluster data nodes, as shown here:

```
ndb_mgm> ALL REPORT MEMORY
Node 1: Data usage is 5%(176 32K pages of total 3200)
Node 1: Index usage is 0%(76 8K pages of total 12832)
Node 2: Data usage is 5%(176 32K pages of total 3200)
Node 2: Index usage is 0%(76 8K pages of total 12832)
Node 3: Data usage is 2%(80 32K pages of total 3200)
Node 3: Index usage is 0%(51 8K pages of total 12832)
Node 4: Data usage is 2%(80 32K pages of total 3200)
Node 4: Index usage is 0%(50 8K pages of total 12832)
```

**Note**
Since only one DDL operation on `NDBCLUSTER` tables can be executed at a time, you must wait for each `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statement to finish before issuing the next one.

It is not necessary to issue `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statements for `NDBCLUSTER` tables created after the new data nodes have been added; data added to such tables is distributed among all data nodes automatically. However, in `NDBCLUSTER` tables that existed prior to the addition of the new nodes, neither existing nor new data is distributed using the new nodes until these tables have been reorganized using `ALTER ONLINE TABLE ... REORGANIZE PARTITION`.

**Alternative procedure, without rolling restart.** It is possible to avoid the need for a rolling restart by configuring the extra data nodes, but not starting them, when first starting the cluster. We assume, as before, that you wish to start with two data nodes—nodes 1 and 2—in one node group and later to expand the cluster to four data nodes, by adding a second node group consisting of nodes 3 and 4:

```
[ndbd default]
DataMemory = 100M
IndexMemory = 100M
NoOfReplicas = 2
DataDir = /usr/local/mysql/var/mysql-cluster

[ndbd]
Id = 1
HostName = 192.168.0.1

[ndbd]
Id = 2
HostName = 192.168.0.2

[ndbd]
Id = 3
HostName = 192.168.0.3
```
Adding MySQL Cluster Data Nodes Online

Nodegroup = 65536   # MySQL Cluster NDB 7.0.24 and later;
                    # MySQL Cluster NDB 7.1.13 and later;
[ndbd]
Id = 4
HostName = 192.168.0.4
Nodegroup = 65536   # MySQL Cluster NDB 7.0.24 and later;
                    # MySQL Cluster NDB 7.1.13 and later;
[mgm]
HostName = 192.168.0.10
Id = 10
[api]
Id=20
HostName = 192.168.0.20
[api]
Id=21
HostName = 192.168.0.21

Prior to MySQL Cluster NDB 7.0.24 and MySQL Cluster NDB 7.1.13, you must perform the initial start of the cluster using the
--nowait-nodes option with ndbd (or ndbmt.d in MySQL Cluster NDB 7.0.4 and later) for each of the data nodes that you wish to have online immediately, so that the cluster does not wait for the remaining nodes to start:

shell> ndbd -c 192.168.0.10 --initial --nowait-nodes=3,4

Beginning with MySQL Cluster NDB 7.0.24 and MySQL Cluster NDB 7.1.13, the data nodes to be brought online at a later time (nodes 3 and 4) can be configured with NodeGroup = 65536, in which case it is not necessary to start the nodes to be started immediately (nodes 1 and 2) with the
--nowait-nodes option, so nodes 1 and 2 can each be started as shown here:

shell> ndbd -c 192.168.0.10 --initial

The data nodes configured with NodeGroup = 65536 are treated by the management server as though you had started nodes 1 and 2 using
--nowait-nodes=3,4 after waiting for a period of time determined by the setting for the StartNoNodeGroupTimeout data node configuration parameter (also introduced in MySQL Cluster NDB 7.0.24 and MySQL Cluster NDB 7.1.13). By default, this is 15 seconds (15000 milliseconds).

Note

StartNoNodegroupTimeout must be the same for all data nodes in the cluster; for this reason, you should always set it in the [ndbd default] section of the config.ini file, rather than for individual data nodes.

When you are ready to add the second node group, you need only perform the following additional steps:

1. Start data nodes 3 and 4, invoking the data node process once for each new node:

shell> ndbd -c 192.168.0.10 --initial

2. Issue the appropriate CREATE NODEGROUP command in the management client:

ndb_mgm> CREATE NODEGROUP 3,4

3. In the mysql client, issue ALTER ONLINE TABLE ... REORGANIZE PARTITION and OPTIMIZE TABLE statements for each existing NDBCLUSTER table. (As noted elsewhere in this section, existing MySQL Cluster tables cannot use the new nodes for data distribution until this has been done.)
17.5.14 Distributed MySQL Privileges for MySQL Cluster

MySQL Cluster NDB 7.2 introduces support for distributing MySQL users and privileges across all SQL nodes in a MySQL Cluster. This support is not enabled by default; you should follow the procedure outlined in this section in order to do so.

Normally, each MySQL server’s user privilege tables in the mysql database must use the MyISAM storage engine, which means that a user account and its associated privileges created on one SQL node are not available on the cluster’s other SQL nodes. In MySQL Cluster NDB 7.2 and later, an SQL file ndb_dist_priv.sql is provided with the MySQL Cluster distribution. This file can be found in the share/mysql directory in the MySQL installation directory.

The first step in enabling distributed privileges is to load this script into a MySQL Server that functions as an SQL node (which we refer to after this as the target SQL node or MySQL Server). You can do this by executing the following command from the system shell on the target SQL node after changing to its MySQL installation directory (where options stands for any additional options needed to connect to this SQL node):

```
shell> mysql options -uroot < share/mysql/ndb_dist_priv.sql
```

Importing ndb_dist_priv.sql creates a number of stored routines (six stored procedures and one stored function) in the mysql database on the target SQL node. After connecting to the SQL node in the mysql client (as the MySQL root user), you can verify that these were created as shown here:

```
mysql> SELECT ROUTINE_NAME, ROUTINE_SCHEMA, ROUTINE_TYPE
  -> FROM INFORMATION_SCHEMA.ROUTINES
  -> WHERE ROUTINE_NAME LIKE 'mysql_cluster%'
  -> ORDER BY ROUTINE_TYPE;
```

```
+---------------------------------------------+----------------+--------------+
| ROUTINE_NAME                                | ROUTINE_SCHEMA | ROUTINE_TYPE |
| mysql_cluster_privileges_are_distributed    | mysql          | FUNCTION     |
| mysql_cluster_backup_privileges             | mysql          | PROCEDURE    |
| mysql_cluster_move_grant_tables             | mysql          | PROCEDURE    |
| mysql_cluster_move_privileges               | mysql          | PROCEDURE    |
| mysql_cluster_restore_local_privileges      | mysql          | PROCEDURE    |
| mysql_cluster_restore_privileges            | mysql          | PROCEDURE    |
| mysql_cluster_restore_privileges_from_local | mysql          | PROCEDURE    |
+---------------------------------------------+----------------+--------------+
7 rows in set (0.01 sec)
```

The stored procedure named mysql_cluster_move_privileges creates backup copies of the existing privilege tables, then converts them to NDB.

mysql_cluster_move_privileges performs the backup and conversion in two steps. The first step is to call mysql_cluster_backup_privileges, which creates two sets of copies in the mysql database:

- A set of local copies that use the MyISAM storage engine. Their names are generated by adding the suffix _backup to the original privilege table names.
- A set of distributed copies that use the NDBCLUSTER storage engine. These tables are named by prefixing ndb_ and appending _backup to the names of the original tables.

After the copies are created, mysql_cluster_move_privileges invokes mysql_cluster_move_grant_tables, which contains the ALTER TABLE ... ENGINE = NDB statements that convert the mysql system tables to NDB.

Normally, you should not invoke either mysql_cluster_backup_privileges or mysql_cluster_move_grant_tables manually; these stored procedures are intended only for use by mysql_cluster_move_privileges.
Although the original privilege tables are backed up automatically, it is always a good idea to create backups manually of the existing privilege tables on all affected SQL nodes before proceeding. You can do this using `mysqldump` in a manner similar to what is shown here:

```shell
shell> mysqldump options -u root \
mysql host user db tables_priv columns_priv procs_priv proxies_priv > backup_file
```

To perform the conversion, you must be connected to the target SQL node using the `mysql` client (again, as the MySQL `root` user). Invoke the stored procedure like this:

```mysql
mysql> CALL mysql.mysql_cluster_move_privileges();
Query OK, 0 rows affected (22.32 sec)
```

Depending on the number of rows in the privilege tables, this procedure may take some time to execute. If some of the privilege tables are empty, you may see one or more `No data - zero rows fetched, selected, or processed` warnings when `mysql_cluster_move_privileges` returns. In such cases, the warnings may be safely ignored. To verify that the conversion was successful, you can use the stored function `mysql_cluster_privileges_are_distributed` as shown here:

```mysql
mysql> SELECT CONCAT(
    -> 'Conversion ',
    -> IF(mysql.mysql_cluster_privileges_are_distributed(), 'succeeded', 'failed'),
    -> '').
    -> AS Result;
+-----------------------+
<table>
<thead>
<tr>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Conversion succeeded.</td>
</tr>
</tbody>
</table>
+-----------------------+
```

`mysql_cluster_privileges_are_distributed` checks for the existence of the distributed privilege tables and returns 1 if all of the privilege tables are distributed; otherwise, it returns 0.

You can verify that the backups have been created using a query such as this one:

```mysql
mysql> SELECT TABLE_NAME, ENGINE FROM INFORMATION_SCHEMA.TABLES
    -> WHERE TABLE_SCHEMA = 'mysql' AND TABLE_NAME LIKE '%backup'
    -> ORDER BY ENGINE;
+-------------------------+------------+
| TABLE_NAME              | ENGINE     |
|-------------------------+------------+
| host_backup             | MyISAM     |
| db_backup               | MyISAM     |
| columns_priv_backup     | MyISAM     |
| user_backup             | MyISAM     |
| tables_priv_backup      | MyISAM     |
| proxies_priv_backup     | MyISAM     |
| procs_priv_backup       | MyISAM     |
| ndb_user_backup         | ndbcluster |
| ndb_tables_priv_backup  | ndbcluster |
| ndb_proxies_priv_backup | ndbcluster |
| ndb_procs_priv_backup   | ndbcluster |
| ndb_host_backup         | ndbcluster |
| ndb_db_backup           | ndbcluster |
+-------------------------+------------+
```

Once the conversion to distributed privileges has been made, any time a MySQL user account is created, dropped, or has its privileges updated on any SQL node, the changes take effect immediately on all other MySQL servers attached to the cluster. Once privileges are distributed, any new MySQL Servers that connect to the cluster automatically participate in the distribution.
Distributed MySQL Privileges for MySQL Cluster

Note

For clients connected to SQL nodes at the time that `mysql_cluster_move_privileges` is executed, you may need to execute `FLUSH PRIVILEGES` on those SQL nodes, or to disconnect and then reconnect the clients, in order for those clients to be able to see the changes in privileges.

All MySQL user privileges are distributed across all connected MySQL Servers. This includes any privileges associated with views and stored routines, even though distribution of views and stored routines themselves is not currently supported.

In the event that an SQL node becomes disconnected from the cluster while `mysql_cluster_move_privileges` is running, you must drop its privilege tables after reconnecting to the cluster, using a statement such as `DROP TABLE IF EXISTS mysql.user mysql.db mysql.tables_priv mysql.columns_priv mysql.procs_priv`. This causes the SQL node to use the shared privilege tables rather than its own local versions of them. This is not needed when connecting a new SQL node to the cluster for the first time.

In the event of an initial restart of the entire cluster (all data nodes shut down, then started again with `--initial`), the shared privilege tables are lost. If this happens, you can restore them using the original target SQL node either from the backups made by `mysql_cluster_move_privileges` or from a dump file created with `mysqldump`. If you need to use a new MySQL Server to perform the restoration, you should start it with `--skip-grant-tables` when connecting to the cluster for the first time; after this, you can restore the privilege tables locally, then distribute them again using `mysql_cluster_move_privileges`. After restoring and distributing the tables, you should restart this MySQL Server without the `--skip-grant-tables` option.

You can also restore the distributed tables using `ndb_restore --restore-privilege-tables` from a backup made using `START BACKUP` in the `ndb_mgm` client. (The MyISAM tables created by `mysql_cluster_move_privileges` are not backed up by the `START BACKUP` command.) `ndb_restore` does not restore the privilege tables by default; the `--restore-privilege-tables` option causes it to do so.

You can restore the SQL node’s local privileges using either of two procedures. `mysql_cluster_restore_privileges` works as follows:

1. If copies of the `mysql.ndb_*_backup` tables are available, attempt to restore the system tables from these.
2. Otherwise, attempt to restore the system tables from the local backups named `_backup` (without the `ndb_` prefix).

The other procedure, named `mysql_cluster_restore_local_privileges`, restores the system tables from the local backups only, without checking the `ndb_*` backups.

The system tables re-created by `mysql_cluster_restore_privileges` or `mysql_cluster_restore_local_privileges` use the MySQL server default storage engine; they are not shared or distributed in any way, and do not use MySQL Cluster’s NDB storage engine.

The additional stored procedure `mysql_cluster_restore_privileges_from_local` is intended for the use of `mysql_cluster_restore_privileges` and `mysql_cluster_restore_local_privileges`. It should not be invoked directly.

Important

Applications that access MySQL Cluster data directly, including NDB API and ClusterJ applications, are not subject to the MySQL privilege system. This means that, once you have distributed the grant tables, they can be freely accessed by such applications, just as they can any other NDB tables. In particular, you should keep in mind that NDB API and ClusterJ applications
can read and write user names, host names, password hashes, and any other contents of the distributed grant tables without any restrictions.

17.5.15 NDB API Statistics Counters and Variables

Beginning with MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11, a number of types of statistical counters relating to actions performed by or affecting Ndb objects are added. Such actions include starting and closing (or aborting) transactions; primary key and unique key operations; table, range, and pruned scans; threads blocked while waiting for the completion of various operations; and data and events sent and received by NDB CLUSTER. The counters are incremented inside the NDB kernel whenever NDB API calls are made or data is sent to or received by the data nodes. mysqld exposes these counters as system status variables; their values can be read in the output of `SHOW STATUS`, or by querying the `INFORMATION_SCHEMA.SESSION_STATUS` or `INFORMATION_SCHEMA.GLOBAL_STATUS` table. By comparing the values before and after statements operating on NDB tables, you can observe the corresponding actions taken on the API level, and thus the cost of performing the statement.

You can list all of these status variables using the following `SHOW STATUS` statement:

```sql
mysql> SHOW STATUS LIKE 'ndb_api%';
+--------------------------------------------+----------+
| Variable_name                              | Value    |
|--------------------------------------------+----------|
| Ndb_api_wait_exec_complete_count_session   | 0        |
| Ndb_api_wait_scan_result_count_session     | 0        |
| Ndb_api_wait_meta_request_count_session    | 0        |
| Ndb_api_wait_nanos_count_session           | 0        |
| Ndb_api_bytes_sent_count_session           | 0        |
| Ndb_api_bytes_received_count_session       | 0        |
| Ndb_api_trans_start_count_session          | 0        |
| Ndb_api_trans_commit_count_session         | 0        |
| Ndb_api_trans_abort_count_session          | 0        |
| Ndb_api_trans_close_count_session          | 0        |
| Ndb_api_pk_op_count_session                | 0        |
| Ndb_api_uk_op_count_session                | 0        |
| Ndb_api_table_scan_count_session           | 0        |
| Ndb_api_range_scan_count_session           | 0        |
| Ndb_api_pruned_scan_count_session          | 0        |
| Ndb_api_scan_batch_count_session           | 0        |
| Ndb_api_read_row_count_session             | 0        |
| Ndb_api_trans_local_read_row_count_session | 0        |
| Ndb_api_event_data_count_injector          | 0        |
| Ndb_api_event_nodata_count_injector        | 0        |
| Ndb_api_wait_exec_complete_count_slave     | 0        |
| Ndb_api_wait_scan_result_count_slave       | 0        |
| Ndb_api_wait_meta_request_count_slave      | 0        |
| Ndb_api_wait_nanos_count_slave             | 0        |
| Ndb_api_bytes_sent_count_slave             | 0        |
| Ndb_api_bytes_received_count_slave         | 0        |
| Ndb_api_trans_start_count_slave            | 0        |
| Ndb_api_trans_commit_count_slave           | 0        |
| Ndb_api_trans_abort_count_slave            | 0        |
| Ndb_api_trans_close_count_slave            | 0        |
| Ndb_api_pk_op_count_slave                  | 0        |
| Ndb_api_uk_op_count_slave                  | 0        |
| Ndb_api_table_scan_count_slave             | 0        |
| Ndb_api_range_scan_count_slave             | 0        |
| Ndb_api_pruned_scan_count_slave            | 0        |
| Ndb_api_scan_batch_count_slave             | 0        |
| Ndb_api_read_row_count_slave               | 0        |
| Ndb_api_trans_local_read_row_count_slave   | 0        |
| Ndb_api_wait_exec_complete_count           | 2        |
| Ndb_api_wait_scan_result_count             | 3        |
| Ndb_api_wait_meta_request_count            | 27       |
| Ndb_api_wait_nanos_count                   | 45612023 |
| Ndb_api_bytes_sent_count                   | 992      |
| Ndb_api_bytes_received_count               | 9640     |
```
These status variables are also available from the `SESSION_STATUS` and `GLOBAL_STATUS` tables of the `INFORMATION_SCHEMA` database, as shown here:

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.SESSION_STATUS
-> WHERE VARIABLE_NAME LIKE 'ndb_api%';

+--------------------------------------------+----------------+
| VARIABLE_NAME                              | VARIABLE_VALUE |
+--------------------------------------------+----------------+
| NDB_API_WAIT_EXEC_COMPLETE_COUNT_SESSION   | 2              |
| NDB_API_WAIT_SCAN_RESULT_COUNT_SESSION     | 0              |
| NDB_API_WAIT_META_REQUEST_COUNT_SESSION    | 1              |
| NDB_API_WAIT_NANOS_COUNT_SESSION           | 8144375        |
| NDB_API_BYTES_SENT_COUNT_SESSION           | 68             |
| NDB_API_BYTES_RECEIVED_COUNT_SESSION       | 84             |
| NDB_API_TRANS_START_COUNT_SESSION          | 1              |
| NDB_API_TRANS_COMMIT_COUNT_SESSION         | 1              |
| NDB_API_TRANS_ABORT_COUNT_SESSION          | 0              |
| NDB_API_TRANS_CLOSE_COUNT_SESSION          | 1              |
| NDB_API_PK_OP_COUNT_SESSION                | 1              |
| NDB_API_UK_OP_COUNT_SESSION                | 0              |
| NDB_API_TABLE_SCAN_COUNT_SESSION           | 0              |
| NDB_API_RANGE_SCAN_COUNT_SESSION           | 0              |
| NDB_API_PRUNED_SCAN_COUNT_SESSION          | 0              |
| NDB_API_SCAN_BATCH_COUNT_SESSION           | 0              |
| NDB_API_READ_ROW_COUNT_SESSION             | 1              |
| NDB_API_TRANS_LOCAL_READ_ROW_COUNT_SESSION | 1              |
| NDB_API_EVENT_DATA_COUNT_INJECTOR          | 0              |
| NDB_API_EVENT_NONDATA_COUNT_INJECTOR       | 0              |
| NDB_API_EVENT_BYTES_COUNT_INJECTOR         | 0              |
| NDB_API_WAIT_EXEC_COMPLETE_COUNT_SLAVE     | 0              |
| NDB_API_WAIT_SCAN_RESULT_COUNT_SLAVE       | 0              |
| NDB_API_WAIT_META_REQUEST_COUNT_SLAVE      | 0              |
| NDB_API_WAIT_NANOS_COUNT_SLAVE             | 0              |
| NDB_API_BYTES_SENT_COUNT_SLAVE             | 0              |
| NDB_API_BYTES_RECEIVED_COUNT_SLAVE         | 0              |
| NDB_API_TRANS_START_COUNT_SLAVE            | 0              |
| NDB_API_TRANS_COMMIT_COUNT_SLAVE           | 0              |
| NDB_API_TRANS_ABORT_COUNT_SLAVE            | 0              |
| NDB_API_TRANS_CLOSE_COUNT_SLAVE            | 0              |
| NDB_API_PK_OP_COUNT_SLAVE                  | 0              |
| NDB_API_UK_OP_COUNT_SLAVE                  | 0              |
| NDB_API_TABLE_SCAN_COUNT_SLAVE             | 0              |

</table>
NDB API Statistics Counters and Variables

Each Ndb object has its own counters. NDB API applications can read the values of the counters for use in optimization or monitoring. For multi-threaded clients which use more than one Ndb object concurrently, it is also possible to obtain a summed view of counters from all Ndb objects belonging to a given Ndb_cluster_connection.

Four sets of these counters are exposed. One set applies to the current session only; the other 3 are global. This is in spite of the fact that their values can be obtained as either session or global status variables in the mysql client. This means that specifying the SESSION or GLOBAL keyword with SHOW STATUS has no effect on the values reported for NDB API statistics status variables, and the value for each of these variables is the same whether the value is obtained from the equivalent column of the SESSION_STATUS or the GLOBAL_STATUS table.

- **Session counters (session specific)**
  
  Session counters relate to the Ndb objects in use by (only) the current session. Use of such objects by other MySQL clients does not influence these counts.

  In order to minimize confusion with standard MySQL session variables, we refer to the variables that correspond to these NDB API session counters as "_session variables", with a leading underscore.

- **Slave counters (global)**
  
  This set of counters relates to the Ndb objects used by the replication slave SQL thread, if any. If this mysqld does not act as a replication slave, or does not use NDB tables, then all of these counts are 0.

  We refer to the related status variables as “_slave variables” (with a leading underscore).

- **Injector counters (global)**
  
  Injector counters relate to the Ndb object used to listen to cluster events by the binary log injector thread. Even when not writing a binary log, mysqld processes attached to a MySQL Cluster continue to listen for some events, such as schema changes.

  We refer to the status variables that correspond to NDB API injector counters as "_injector variables" (with a leading underscore).

- **Server (Global) counters (global)**
  
  This set of counters relates to all Ndb objects currently used by this mysqld. This includes all MySQL client applications, the slave SQL thread (if any), the binlog injector, and the NDB utility thread.

  We refer to the status variables that correspond to these counters as “global variables” or “mysqld-level variables”.

You can obtain values for a particular set of variables by additionally filtering for the substring session, slave, or injector in the variable name (along with the common prefix Ndb_api). For _session variables, this can be done as shown here:
NDB API Statistics Counters and Variables

To obtain a listing of the NDB API `mysqld`-level status variables, filter for variable names beginning with `ndb_api` and ending in `_count`, like this:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.SESSION_STATUS
    -> WHERE VARIABLE_NAME LIKE 'ndb_api%count';
```

```
+------------------------------------+----------------+
| VARIABLE_NAME                      | VARIABLE_VALUE |
+------------------------------------+----------------+
| NDB_API_WAIT_EXEC_COMPLETE_COUNT   | 4              |
| NDB_API_WAIT_SCAN_RESULT_COUNT     | 3              |
| NDB_API_WAIT_META_REQUEST_COUNT    | 28             |
| NDB_API_WAIT_NANOS_COUNT           | 53756398       |
| NDB_API_BYTES_SENT_COUNT           | 1060           |
| NDB_API_BYTES_RECEIVED_COUNT       | 9724           |
| NDB_API_TRANS_START_COUNT          | 3              |
| NDB_API_TRANS_COMMIT_COUNT         | 2              |
| NDB_API_TRANS_ABORT_COUNT          | 0              |
| NDB_API_TRANS_CLOSE_COUNT          | 3              |
| NDB_API_PK_OP_COUNT                | 2              |
| NDB_API_UK_OP_COUNT                | 0              |
| NDB_API_TABLE_SCAN_COUNT           | 1              |
| NDB_API_RANGE_SCAN_COUNT           | 0              |
| NDB_API_PRUNED_SCAN_COUNT          | 0              |
| NDB_API_SCAN_BATCH_COUNT           | 0              |
| NDB_API_READ_ROW_COUNT             | 1              |
| NDB_API_TRANS_LOCAL_READ_ROW_COUNT | 2              |
| NDB_API_EVENT_DATA_COUNT           | 0              |
| NDB_API_EVENT_NONDATA_COUNT        | 0              |
| NDB_API_EVENT_BYTES_COUNT          | 0              |
+------------------------------------+----------------+
21 rows in set (0.09 sec)
```

Not all counters are reflected in all 4 sets of status variables. For the event counters `DataEventsRecvdCount`, `NondataEventsRecvdCount`, and `EventBytesRecvdCount`, only `_injector` and `mysqld`-level NDB API status variables are available:

```
mysql> SHOW STATUS LIKE 'ndb_api%event%';
```

```
+------------------------------------+-------+
| VARIABLE_NAME                      | Value |
+------------------------------------+-------+
| Ndb_api_event_data_count_injector  | 0     |
| Ndb_api_event_nondata_count_injector | 0     |
| Ndb_api_event_bytes_count_injector | 0     |
+------------------------------------+-------+
```
### NDB API Statistics Counters and Variables

<table>
<thead>
<tr>
<th>Counter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WaitExecCompleteCount</td>
<td>Number of times thread has been blocked while waiting for execution of an operation to complete. Includes all <code>execute()</code> calls as well as implicit executes for blob operations and auto-increment not visible to clients.</td>
</tr>
<tr>
<td>WaitScanResultCount</td>
<td>Number of times thread has been blocked while waiting for a scan-based signal, such waiting for additional results, or for a scan to close.</td>
</tr>
<tr>
<td>WaitMetaRequestCount</td>
<td>Number of times thread has been blocked waiting for a metadata-based signal; this can occur when waiting for a DDL operation or for an epoch to be started (or ended).</td>
</tr>
</tbody>
</table>

#### Status Variables (by statistic type):

- Session
- Slave
- Injector
- Server

<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ndb_api_wait_exec_complete_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_wait_exec_complete_count_slave</td>
<td>0</td>
</tr>
<tr>
<td>[none]</td>
<td></td>
</tr>
<tr>
<td>Ndb_api_wait_exec_complete_count</td>
<td>0</td>
</tr>
</tbody>
</table>

3 rows in set (0.00 sec)

_injector_ status variables are not implemented for any other NDB API counters, as shown here:

```sql
SHOW STATUS LIKE 'ndb_api\%injector\%';
```

<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ndb_api_event_data_count_injector</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_event_nondata_count_injector</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_event_bytes_count_injector</td>
<td>0</td>
</tr>
</tbody>
</table>

3 rows in set (0.00 sec)

The names of the status variables can easily be associated with the names of the corresponding counters. Each NDB API statistics counter is listed in the following table with a description as well as the names of any MySQL server status variables corresponding to this counter.
## NDB API Statistics Counters and Variables

<table>
<thead>
<tr>
<th>Counter Name</th>
<th>Description</th>
<th>Status Variables (by statistic type):</th>

</tbody>
</table>
### NDB API Statistics Counters and Variables

#### Counter Name

**Description**

**Status Variables (by statistic type):**

- **Session**
- **Slave**
- **Injector**
- **Server**

**NondataEventsRecvdCount**

Number of events received, other than row change events.

- [none]
- [none]
- Ndb_api_event_nondata_count_injector
- Ndb_api_event_nondata_count

**EventBytesRecvdCount**

Number of bytes of events received.

- [none]
- [none]
- Ndb_api_event_bytes_count_injector
- Ndb_api_event_bytes_count

To see all counts of committed transactions—that is, all `TransCommitCount` counter status variables—you can filter the results of `SHOW STATUS` for the substring `trans_commit_count`, like this:

```sql
mysql> SHOW STATUS LIKE '%trans_commit_count%';
+------------------------------------+-------+
| Variable_name                      | Value |
+------------------------------------+-------+
| Ndb_api_trans_commit_count_session | 1     |
| Ndb_api_trans_commit_count_slave   | 0     |
| Ndb_api_trans_commit_count         | 2     |
+------------------------------------+-------+
3 rows in set (0.00 sec)
```

From this you can determine that 1 transaction has been committed in the current `mysql` client session, and 2 transactions have been committed on this `mysqld` since it was last restarted.

You can see how various NDB API counters are incremented by a given SQL statement by comparing the values of the corresponding `_session` status variables immediately before and after performing the statement. In this example, after getting the initial values from `SHOW STATUS`, we create in the `test` database an NDB table, named `t`, that has a single column:

```sql
mysql> SHOW STATUS LIKE 'ndb_api\session?';
| Variable_name                              | Value  |
+--------------------------------------------+--------+
| Ndb_api_wait_exec_complete_count_session   | 2      |
| Ndb_api_wait_scan_result_count_session     | 0      |
| Ndb_api_wait_meta_request_count_session    | 3      |
| Ndb_api_wait_nanos_count_session           | 820705 |
| Ndb_api_bytes_sent_count_session           | 132    |
| Ndb_api_bytes_received_count_session       | 372    |
| Ndb_api_trans_start_count_session          | 1      |
| Ndb_api_trans_commit_count_session         | 1      |
| Ndb_api_trans_abort_count_session          | 0      |
```
NDB API Statistics Counters and Variables

<table>
<thead>
<tr>
<th>Variable_name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ndb_api_trans_close_count_session</td>
<td>1</td>
</tr>
<tr>
<td>Ndb_api_pk_op_count_session</td>
<td>1</td>
</tr>
<tr>
<td>Ndb_api_uk_op_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_table_scan_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_range_scan_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_pruned_scan_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_scan_batch_count_session</td>
<td>0</td>
</tr>
<tr>
<td>Ndb_api_read_row_count_session</td>
<td>1</td>
</tr>
<tr>
<td>Ndb_api_trans_local_read_row_count_session</td>
<td>1</td>
</tr>
</tbody>
</table>

18 rows in set (0.00 sec)

mysql> USE test;
Database changed
mysql> CREATE TABLE t (c INT) ENGINE NDBCLUSTER;
Query OK, 0 rows affected (0.85 sec)

Now you can execute a new `SHOW STATUS` statement and observe the changes, as shown here (with the changed rows highlighted in the output):

```
mysql> SHOW STATUS LIKE 'ndb_api%session%';
+--------------------------------------------+-----------+
| Variable_name                              | Value     |
+--------------------------------------------+-----------+
| Ndb_api_wait_exec_complete_count_session   | 8         |
| Ndb_api_wait_scan_result_count_session     | 0         |
| Ndb_api_wait_meta_request_count_session    | 17        |
| Ndb_api_wait_nanos_count_session           | 706871709 |
| Ndb_api_bytes_sent_count_session           | 2376      |
| Ndb_api_bytes_received_count_session       | 3844      |
| Ndb_api_trans_start_count_session          | 4         |
| Ndb_api_trans_commit_count_session         | 4         |
| Ndb_api_trans_abort_count_session          | 0         |
| Ndb_api_trans_close_count_session          | 4         |
| Ndb_api_pk_op_count_session                | 6         |
| Ndb_api_uk_op_count_session                | 0         |
| Ndb_api_table_scan_count_session           | 1         |
| Ndb_api_range_scan_count_session           | 0         |
| Ndb_api_pruned_scan_count_session          | 0         |
| Ndb_api_scan_batch_count_session           | 0         |
| Ndb_api_read_row_count_session             | 2         |
| Ndb_api_trans_local_read_row_count_session | 1         |
+--------------------------------------------+-----------+
18 rows in set (0.00 sec)
```

Similarly, you can see the changes in the NDB API statistics counters caused by inserting a row into `t`:

```
mysql> INSERT INTO t VALUES (100);
Query OK, 1 row affected (0.00 sec)
mysql> SHOW STATUS LIKE 'ndb_api%session%';
+--------------------------------------------+-----------+
| Variable_name                              | Value     |
+--------------------------------------------+-----------+
| Ndb_api_wait_exec_complete_count_session   | 11        |
| Ndb_api_wait_scan_result_count_session     | 6         |
| Ndb_api_wait_meta_request_count_session    | 20        |
| Ndb_api_wait_nanos_count_session           | 70370418  |
| Ndb_api_bytes_sent_count_session           | 2724      |
| Ndb_api_bytes_received_count_session       | 4116      |
| Ndb_api_trans_start_count_session          | 7         |
| Ndb_api_trans_commit_count_session         | 6         |
| Ndb_api_trans_abort_count_session          | 0         |
| Ndb_api_trans_close_count_session          | 7         |
| Ndb_api_pk_op_count_session                | 8         |
| Ndb_api_uk_op_count_session                | 0         |
| Ndb_api_table_scan_count_session           | 1         |
+--------------------------------------------+-----------+
18 rows in set (0.00 sec)
```

```
MySQL Cluster Replication

In MySQL Cluster, replication is conceptually very similar but can be more complex in practice, as it may be extended to cover a number of different configurations including replicating between two complete clusters. Although a MySQL Cluster itself depends on the NDB storage engine for clustering functionality, it is not necessary to use NDB as the storage engine for the slave's copies of the replicated tables (see Replication from NDB to other storage engines). However, for maximum availability, it is possible (and preferable) to replicate from one MySQL Cluster to another, and it is this scenario that we discuss, as shown in the following figure:

17.6 MySQL Cluster Replication

Previous to MySQL 5.1.6, asynchronous replication, more usually referred to simply as “replication”, was not available when using MySQL Cluster. MySQL 5.1.6 introduces master-slave replication of this type for MySQL Cluster databases. This section explains how to set up and manage a configuration wherein one group of computers operating as a MySQL Cluster replicates to a second computer or group of computers. We assume some familiarity on the part of the reader with standard MySQL replication as discussed elsewhere in this Manual. (See Chapter 16, Replication).

Normal (non-clustered) replication involves a “master” server and a “slave” server, the master being the source of the operations and data to be replicated and the slave being the recipient of these. In MySQL Cluster, replication is conceptually very similar but can be more complex in practice, as it may be extended to cover a number of different configurations including replicating between two complete clusters.
In this scenario, the replication process is one in which successive states of a master cluster are logged and saved to a slave cluster. This process is accomplished by a special thread known as the NDB binlog injector thread, which runs on each MySQL server and produces a binary log (binlog). This thread ensures that all changes in the cluster producing the binary log—and not just those changes that are effected through the MySQL Server—are inserted into the binary log with the correct serialization order. We refer to the MySQL replication master and replication slave servers as replication servers or replication nodes, and the data flow or line of communication between them as a replication channel.

For information about performing point-in-time recovery with MySQL Cluster and MySQL Cluster Replication, see Section 17.6.9.2, “Point-In-Time Recovery Using MySQL Cluster Replication”.

**NDB API _slave status variables.** Beginning with MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11, NDB API counters provide enhanced monitoring capabilities on MySQL Cluster replication slaves. These are implemented as NDB statistics _slave status variables, as seen in the output of SHOW STATUS, or in the results of queries against the SESSION_STATUS or GLOBAL_STATUS table in a mysql client session connected to a MySQL Server that is acting as a slave in MySQL Cluster Replication. By comparing the values of these status variables before and after the execution of statements affecting replicated NDB tables, you can observe the corresponding actions taken on the NDB API level by the slave, which can be useful when monitoring or troubleshooting MySQL Cluster Replication. Section 17.5.15, “NDB API Statistics Counters and Variables”, provides additional information.

**Replication from NDB to non-NDB tables.** It is possible to replicate NDB tables from a MySQL Cluster acting as the master to tables using other MySQL storage engines such as InnoDB or MyISAM on a slave mysqld. This is subject to a number of conditions; see Replication from NDB to other storage engines, and Replication from NDB to a nontransactional storage engine, for more information.

### 17.6.1 MySQL Cluster Replication: Abbreviations and Symbols

Throughout this section, we use the following abbreviations or symbols for referring to the master and slave clusters, and to processes and commands run on the clusters or cluster nodes:

<table>
<thead>
<tr>
<th>Symbol or Abbreviation</th>
<th>Description (Refers to...)</th>
</tr>
</thead>
<tbody>
<tr>
<td>M</td>
<td>The cluster serving as the (primary) replication master</td>
</tr>
<tr>
<td>S</td>
<td>The cluster acting as the (primary) replication slave</td>
</tr>
</tbody>
</table>
17.6.2 General Requirements for MySQL Cluster Replication

A replication channel requires two MySQL servers acting as replication servers (one each for the master and slave). For example, this means that in the case of a replication setup with two replication channels (to provide an extra channel for redundancy), there will be a total of four replication nodes, two per cluster.

Replication of a MySQL Cluster as described in this section and those following is dependent on row-based replication. This means that the replication master MySQL server must be started with `--binlog-format=ROW` or `--binlog-format=MIXED`, as described in Section 17.6.6, “Starting MySQL Cluster Replication (Single Replication Channel)”. For general information about row-based replication, see Section 16.1.2, “Replication Formats”.

**Important**

If you attempt to use MySQL Cluster Replication with `--binlog-format=STATEMENT`, replication fails to work properly because the `ndb_binlog_index` table on the master and the `epoch` column of the `ndb_apply_status` table on the slave are not updated (see Section 17.6.4, “MySQL Cluster Replication Schema and Tables”). Instead, only updates on the MySQL server acting as the replication master propagate to the slave, and no updates from any other SQL nodes on the master cluster are replicated.

In all MySQL Cluster NDB 6.x and 7.x releases, the default value for the `--binlog-format` option is `MIXED`.

Each MySQL server used for replication in either cluster must be uniquely identified among all the MySQL replication servers participating in either cluster (you cannot have replication servers on both the master and slave clusters sharing the same ID). This can be done by starting each SQL node using the `--server-id=id` option, where `id` is a unique integer. Although it is not strictly necessary, we will assume for purposes of this discussion that all MySQL Cluster binaries are of the same release version.

It is generally true in MySQL Replication that both MySQL servers (`mysqld` processes) involved must be compatible with one another with respect to both the version of the replication protocol used and the SQL feature sets which they support (see Section 16.4.2, “Replication Compatibility Between MySQL Versions”). It is due to such differences between the binaries in the MySQL Cluster and MySQL Server
5.1 distributions that MySQL Cluster Replication has the additional requirement that both `mysqld` binaries come from a MySQL Cluster distribution. The simplest and easiest way to assure that the `mysqld` servers are compatible is to use the same MySQL Cluster distribution for all master and slave `mysqld` binaries.

We assume that the slave server or cluster is dedicated to replication of the master, and that no other data is being stored on it.

All NDB tables being replicated must be created using a MySQL server and client. Tables and other database objects created using the NDB API (with, for example, `Dictionary::createTable()` are not visible to a MySQL server and so are not replicated. Updates by NDB API applications to existing tables that were created using a MySQL server can be replicated.

**Note**

It is possible to replicate a MySQL Cluster using statement-based replication. However, in this case, the following restrictions apply:

- All updates to data rows on the cluster acting as the master must be directed to a single MySQL server.
- It is not possible to replicate a cluster using multiple simultaneous MySQL replication processes.
- Only changes made at the SQL level are replicated.

These are in addition to the other limitations of statement-based replication as opposed to row-based replication; see Section 16.1.2.1, "Advantages and Disadvantages of Statement-Based and Row-Based Replication", for more specific information concerning the differences between the two replication formats.

### 17.6.3 Known Issues in MySQL Cluster Replication

This section discusses known problems or issues when using replication with MySQL Cluster in MySQL 5.1 (including MySQL Cluster NDB 6.X and 7.X through 7.1).

**Loss of master-slave connection.** A loss of connection can occur either between the replication master SQL node and the replication slave SQL node, or between the replication master SQL node and the data nodes in the master cluster. In the latter case, this can occur not only as a result of loss of physical connection (for example, a broken network cable), but due to the overflow of data node event buffers; if the SQL node is too slow to respond, it may be dropped by the cluster (this is controllable to some degree by adjusting the `MaxBufferedEpochs` and `TimeBetweenEpochs` configuration parameters). If this occurs, it is entirely possible for new data to be inserted into the master cluster without being recorded in the replication master's binary log. For this reason, to guarantee high availability, it is extremely important to maintain a backup replication channel, to monitor the primary channel, and to fail over to the secondary replication channel when necessary to keep the slave cluster synchronized with the master. MySQL Cluster is not designed to perform such monitoring on its own; for this, an external application is required.

Prior to MySQL 5.1.18, a MySQL Cluster replication slave `mysqld` had no way of detecting that the connection from the master had been interrupted. For this reason, it was possible for the slave to become inconsistent with the master.

Beginning with MySQL 5.1.18, the replication master issues a "gap" event when connecting or reconnecting to the master cluster. (A gap event is a type of "incident event," which indicates an incident that occurs that affects the contents of the database but that cannot easily be represented as a set of changes. Examples of incidents are server crashes, database resynchronization, (some) software updates, and (some) hardware changes.) When the slave encounters a gap in the replication
log, it stops with an error message. This message is available in the output of `SHOW SLAVE STATUS`, and indicates that the SQL thread has stopped due to an incident registered in the replication stream, and that manual intervention is required. See Section 17.6.8, “Implementing Failover with MySQL Cluster Replication”, for more information about what to do in such circumstances.

**Important**

Because MySQL Cluster is not designed on its own to monitor replication status or provide failover, if high availability is a requirement for the slave server or cluster, then you must set up multiple replication lines, monitor the master `mysqld` on the primary replication line, and be prepared fail over to a secondary line if and as necessary. This must be done manually, or possibly by means of a third-party application. For information about implementing this type of setup, see Section 17.6.7, “Using Two Replication Channels for MySQL Cluster Replication”, and Section 17.6.8, “Implementing Failover with MySQL Cluster Replication”.

However, if you are replicating from a standalone MySQL server to a MySQL Cluster, one channel is usually sufficient.

**Multibyte character sets.** Previously, there were several known issues with regard to the use of multibyte characters sets with MySQL Cluster Replication. These were resolved in MySQL 5.1.21, MySQL Cluster NDB 6.2.14, and MySQL Cluster NDB 6.3.11. (See Bug #27404 and Bug #29562.)

**Circular replication.** Prior to MySQL 5.1.18, circular replication was not supported with MySQL Cluster replication, due to the fact that all log events created in a particular MySQL Cluster were wrongly tagged with the server ID of the MySQL server used as master and not with the server ID of the originating server.

Beginning with MySQL 5.1.18, this limitation is lifted, as discussed in the next few paragraphs, in which we consider the example of a replication setup involving three MySQL Clusters numbered 1, 2, and 3, in which Cluster 1 acts as the replication master for Cluster 2, Cluster 2 acts as the master for Cluster 3, and Cluster 3 acts as the master for Cluster 1. Each cluster has two SQL nodes, with SQL nodes A and B belonging to Cluster 1, SQL nodes C and D belonging to Cluster 2, and SQL nodes E and F belonging to Cluster 3.

Circular replication using these clusters is supported as long as the following conditions are met:

- The SQL nodes on all masters and slaves are the same
- All SQL nodes acting as replication masters and slaves are started using the `--log-slave-updates` option

This type of circular replication setup is shown in the following diagram:
In this scenario, SQL node A in Cluster 1 replicates to SQL node C in Cluster 2; SQL node C replicates to SQL node E in Cluster 3; SQL node E replicates to SQL node A. In other words, the replication line (indicated by the red arrows in the diagram) directly connects all SQL nodes used as replication masters and slaves.

It should also be possible to set up circular replication in which not all master SQL nodes are also slaves, as shown here:
In this case, different SQL nodes in each cluster are used as replication masters and slaves. However, you must not start any of the SQL nodes using `--log-slave-updates`). This type of circular replication scheme for MySQL Cluster, in which the line of replication (again indicated by the red arrows in the diagram) is discontinuous, should be possible, but it should be noted that it has not yet been thoroughly tested and must therefore still be considered experimental.

**Note**

Beginning with MySQL 5.1.24, the [NDB](https://dev.mysql.com/doc/refman/5.7/en/ha-ndbcluster.html) storage engine uses *idempotent execution mode*, which suppresses duplicate-key and other errors that otherwise break circular replication of MySQL Cluster. This is equivalent to setting the global `slave_exec_mode` system variable to `IDEMPOTENT`, although this is not necessary in MySQL Cluster replication, since MySQL Cluster now sets this variable automatically and ignores any attempts to set it explicitly. (Bug #31609)

**MySQL Cluster replication and primary keys.** In MySQL 5.1.6, only those [NDB](https://dev.mysql.com/doc/refman/5.7/en/ha-ndbcluster.html) tables having explicit primary keys could be replicated. This limitation was lifted in MySQL 5.1.7. However, in the event of a node failure, errors in replication of [NDB](https://dev.mysql.com/doc/refman/5.7/en/ha-ndbcluster.html) tables without primary keys can still occur, due to the possibility of duplicate rows being inserted in such cases. For this reason, it is highly recommended that all [NDB](https://dev.mysql.com/doc/refman/5.7/en/ha-ndbcluster.html) tables being replicated have primary keys.

**MySQL Cluster Replication and Unique Keys.** Prior to MySQL Cluster NDB 7.0.25 and MySQL Cluster NDB 7.1.14, operations that updated values of unique key columns of [NDB](https://dev.mysql.com/doc/refman/5.7/en/ha-ndbcluster.html) tables could result in duplicate-key errors when replicated. This was due to the ordering of row events in the binary log according to the partitioning of the base table, which meant that they could appear in a different order from that in which they were originally executed. (Bug #11756082)
In MySQL Cluster NDB 7.0.25, MySQL Cluster NDB 7.1.14, and later, this issue is solved for replication between NDB tables by deferring unique key checks until after all table row updates have been performed.

Deferring constraints in this way is currently supported only by NDB. Thus, updates of unique keys when replicating from NDB to a different storage engine such as MyISAM or InnoDB are still not supported.

The problem encountered when replicating without deferred checking of unique key updates can be illustrated using NDB table such as t, is created and populated on the master (and replicated to a slave that does not support deferred unique key updates) as shown here:

```sql
CREATE TABLE t (  
    p INT PRIMARY KEY,  
    c INT,  
    UNIQUE KEY u (c)  
) ENGINE NDB;

INSERT INTO t  
VALUES (1,1), (2,2), (3,3), (4,4), (5,5);
```

The following UPDATE statement on t succeeded on the master, since the rows affected are processed in the order determined by the ORDER BY option, performed over the entire table:

```sql
UPDATE t SET c = c - 1 ORDER BY p;
```

However, the same statement failed with a duplicate key error or other constraint violation on the slave, because the ordering of the row updates was done for one partition at a time, rather than for the table as a whole.

**Note**

In MySQL 5.1.6 and later, every NDB table is implicitly partitioned by key when it is created. This also applies to all MySQL Cluster NDB 6.x and MySQL Cluster NDB 7.x releases. See Section 18.2.4, “KEY Partitioning”, for more information.

**Restarting with --initial.** Restarting the cluster with the --initial option causes the sequence of GCI and epoch numbers to start over from 0. (This is generally true of MySQL Cluster and not limited to replication scenarios involving Cluster.) The MySQL servers involved in replication should in this case be restarted. After this, you should use the RESET MASTER and RESET SLAVE statements to clear the invalid ndb_binlog_index and ndb_apply_status tables, respectively.

**auto_increment_offset and auto_increment_increment variables.** The use of the auto_increment_offset and auto_increment_increment server system variables is supported beginning with MySQL 5.1.20. Previously, these produced unpredictable results when used with NDB tables or MySQL Cluster replication.

**Replication from NDB to other storage engines.** It is possible to replicate an NDB table on the master to a table using a different storage engine on the slave, taking into account the restrictions listed here:

- Multi-master and circular replication are not supported (tables on both the master and the slave must use the NDB storage engine for this to work).
- Using a storage engine which does not perform binary logging for slave tables requires special handling.
- Use of a nontransactional storage engine for slave tables also requires special handling.
- The master mysqld must be started with --ndb-log-update-as-write=0 or --ndb-log-update-as-write=OFF.
The next few paragraphs provide additional information about each of the issues just described.

**Multiple masters not supported when replicating NDB to other storage engines.**  For replication from NDB to a different storage engine, the relationship between the two databases must be a simple master-slave one. This means that circular or master-master replication is not supported between MySQL Cluster and other storage engines.

In addition, it is not possible to configure more than one replication channel when replicating between NDB and a different storage engine. (However, a MySQL Cluster database can simultaneously replicate to multiple slave MySQL Cluster databases.) If the master uses NDB tables, it is still possible to have more than one MySQL Server maintain a binary log of all changes; however, for the slave to change masters (fail over), the new master-slave relationship must be explicitly defined on the slave.

**Replicating NDB to a slave storage engine that does not perform binary logging.**  If you attempt to replicate from a MySQL Cluster to a slave that uses a storage engine that does not handle its own binary logging, the replication process aborts with the error `Binary logging not possible ... Statement cannot be written atomically since more than one engine involved and at least one engine is self-logging` (Error 1595). It is possible to work around this issue in one of the following ways:

- **Turn off binary logging on the slave.**  This can be accomplished by setting `sql_log_bin = 0`.

- **Change the storage engine used for the mysql.ndb_apply_status table.**  Causing this table to use an engine that does not handle its own binary logging can also eliminate the conflict. This can be done by issuing a statement such as `ALTER TABLE mysql.ndb_apply_status ENGINE=MyISAM` on the slave. It is safe to do this when using a non-NDB storage engine on the slave, since you do not then need to worry about keeping multiple slave SQL nodes synchronized.

- **Filter out changes to the mysql.ndb_apply_status table on the slave.**  This can be done by starting the slave SQL node with `--replicate-ignore-table=mysql.ndb_apply_status`. If you need for other tables to be ignored by replication, you might wish to use an appropriate `--replicate-wild-ignore-table` option instead.

**Important**

You should *not* disable replication or binary logging of `mysql.ndb_apply_status` or change the storage engine used for this table when replicating from one MySQL Cluster to another. See Replication and binary log filtering rules with replication between MySQL Clusters, for details.

**Replication from NDB to a nontransactional storage engine.**  When replicating from NDB to a nontransactional storage engine such as MyISAM, you may encounter unnecessary duplicate key errors when replicating `INSERT ... ON DUPLICATE KEY UPDATE` statements. You can suppress these in MySQL Cluster NDB 6.2 and later MySQL Cluster releases by using `--ndb-log-update-as-write=0`, which forces updates to be logged as writes (rather than as updates).

In addition, when replicating from NDB to a storage engine that does not implement transactions, if the slave fails to apply any row changes from a given transaction, it does not roll back the rest of the transaction. (This is true when replicating tables using any transactional storage engine—not only NDB—to a nontransactional storage engine.) Because of this, it cannot be guaranteed that transactional consistency will be maintained on the slave in such cases.

**Replication and binary log filtering rules with replication between MySQL Clusters.**  If you are using any of the options `--replicate-do-*,--replicate-ignore-*,--binlog-do-db, or --binlog-ignore-db` to filter databases or tables being replicated, care must be taken not to block replication or binary logging of the `mysql.ndb_apply_status`, which is required for replication between MySQL Clusters to operate properly. In particular, you must keep in mind the following:

1. Using `--replicate-do-db=db_name` (and no other `--replicate-do-*` or `--replicate-ignore-*` options) means that only tables in database `db_name` are replicated. In this case, you should also use `--replicate-do-db=mysql,--binlog-do-db=mysql, or --replicate-
do-table=mysql.ndb_apply_status to ensure that mysql.ndb_apply_status is populated on slaves.

Using --binlog-do-db=db_name (and no other --binlog-do-db options) means that changes only to tables in database db_name are written to the binary log. In this case, you should also use --replicate-do-db=mysql, --binlog-do-db=mysql, or --replicate-do-table=mysql.ndb_apply_status to ensure that mysql.ndb_apply_status is populated on slaves.

2. Using --replicate-ignore-db=mysql means that no tables in the mysql database are replicated. In this case, you should also use --replicate-do-table=mysql.ndb_apply_status to ensure that mysql.ndb_apply_status is replicated.

Using --binlog-ignore-db=mysql means that no changes to tables in the mysql database are written to the binary log. In this case, you should also use --replicate-do-table=mysql.ndb_apply_status to ensure that mysql.ndb_apply_status is replicated.

You should also remember that each replication rule requires the following:

1. Its own --replicate-do-* or --replicate-ignore-* option, and that multiple rules cannot be expressed in a single replication filtering option. For information about these rules, see Section 16.1.3, “Replication and Binary Logging Options and Variables”.

2. Its own --binlog-do-db or --binlog-ignore-db option, and that multiple rules cannot be expressed in a single binary log filtering option. For information about these rules, see Section 5.4.4, “The Binary Log”.

If you are replicating a MySQL Cluster to a slave that uses a storage engine other than NDB, the considerations just given previously may not apply, as discussed elsewhere in this section.

MySQL Cluster Replication and IPv6. Currently, the NDB API and MGM API do not support IPv6. However, beginning with MySQL Cluster NDB 6.4.1, MySQL Servers—including those acting as SQL nodes in a MySQL Cluster—can use IPv6 to contact other MySQL Servers. This means that you can replicate between MySQL Clusters using IPv6 to connect the master and slave SQL nodes as shown by the dotted arrow in the following diagram:

Figure 17.16 Replication Between SQL Nodes Connected Using IPv6

However, all connections originating within the MySQL Cluster—represented in the preceding diagram by solid arrows—must use IPv4. In other words, all MySQL Cluster data nodes, management servers,
and management clients must be accessible from one another using IPv4. In addition, SQL nodes must use IPv4 to communicate with the cluster.

Since there is currently no support in the NDB and MGM APIs for IPv6, any applications written using these APIs must also make all connections using IPv4.

**Attribute promotion and demotion.** Formerly, support in MySQL Cluster for type conversions between columns of similar but different types on the master and the slave was extremely limited. However, starting with MySQL Cluster NDB 6.3.33, 7.0.14, and 7.1.3, MySQL Cluster Replication includes support for attribute promotion and demotion. The implementation of the latter distinguishes between lossy and non-lossy type conversions, and their use on the slave can be controlled by setting the `slave_type_conversions` global server system variable.

For more information about attribute promotion and demotion in MySQL Cluster, see Attribute promotion and demotion (MySQL Cluster).

### 17.6.4 MySQL Cluster Replication Schema and Tables

Replication in MySQL Cluster makes use of a number of dedicated tables in the `mysql` database on each MySQL Server instance acting as an SQL node in both the cluster being replicated and the replication slave (whether the slave is a single server or a cluster). These tables are created during the MySQL installation process by the `mysql_install_db` script, and include a table for storing the binary log’s indexing data. Since the `ndb_binlog_index` table is local to each MySQL server and does not participate in clustering, it uses the MyISAM storage engine. This means that it must be created separately on each `mysqld` participating in the master cluster. (However, the binary log itself contains updates from all MySQL servers in the cluster to be replicated.) This table is defined as follows:

```sql
CREATE TABLE `ndb_binlog_index` (
    `Position`  BIGINT(20) UNSIGNED NOT NULL,  
    `File`      VARCHAR(255) NOT NULL,  
    `epoch`     BIGINT(20) UNSIGNED NOT NULL, 
    `inserts`   BIGINT(20) UNSIGNED NOT NULL,  
    `updates`   BIGINT(20) UNSIGNED NOT NULL,  
    `deletes`   BIGINT(20) UNSIGNED NOT NULL,  
    `schemaops` BIGINT(20) UNSIGNED NOT NULL, 
    `next_position` bigint(20) unsigned NOT NULL,  
    `next_file` varchar(255) NOT NULL,  
    PRIMARY KEY (`epoch`)  
) ENGINE=MYISAM DEFAULT CHARSET=latin1;
```

The size of this table is dependent on the number of epochs per binary log file and the number of binary log files. The number of epochs per binary log file normally depends on the amount of binary log generated per epoch and the size of the binary log file, with smaller epochs resulting in more epochs per file. You should be aware that empty epochs produce inserts to the `ndb_binlog_index` table, even when the `--ndb-log-empty-epochs` option is `OFF`, meaning that the number of entries per file depends on the length of time that the file is in use; that is,

\[
[number\ of\ epochs\ per\ file] = \frac{[time\ spent\ per\ file]}{TimeBetweenEpochs}
\]

A busy MySQL Cluster writes to the binary log regularly and presumably rotates binary log files more quickly than a quiet one. This means that a “quiet” MySQL Cluster with `--ndb-log-empty-epochs=ON` can actually have a much higher number of `ndb_binlog_index` rows per file than one with a great deal of activity.

When `mysqld` is started with the `--ndb-log-orig` option, the `orig_server_id` and `orig_epoch` columns store, respectively, the ID of the server on which the event originated and the epoch in which the event took place on the originating server, which is useful in MySQL Cluster replication setups employing multiple masters. The `SELECT` statement used to find the closest binlog position to the highest applied epoch on the slave in a multi-master setup (see Section 17.6.10, “MySQL Cluster
Replication: Multi-Master and Circular Replication) employs these two columns, which are not indexed. This can lead to performance issues when trying to fail over, since the query must perform a table scan, especially when the master has been running with `--ndb-log-empty-epochs=ON`. You can improve multi-master failover times by adding an index to these columns, as shown here:

```sql
ALTER TABLE mysql.ndb_binlog_index
    ADD INDEX orig_lookup USING BTREE (orig_server_id, orig_epoch);
```

Adding this index provides no benefit when replicating from a single master to a single slave, since the query used to get the binary log position in such cases makes no use of `orig_server_id` or `orig_epoch`.

The `next_position` and `next_file` columns were added in MySQL Cluster NDB 7.2.6; see Section 17.6.8, “Implementing Failover with MySQL Cluster Replication”, for more information about using these columns.

Important
Prior to MySQL 5.1.14, the `ndb_binlog_index` table was known as `binlog_index`, and was kept in a separate `cluster` database, which in MySQL 5.1.7 and earlier was known as the `cluster_replication` database. Similarly, the `ndb_apply_status` and `ndb_schema` tables were known as `apply_status` and `schema`, and were also found in the `cluster` (earlier `cluster_replication`) database. However, beginning with MySQL 5.1.14, all MySQL Cluster replication tables reside in the `mysql` system database.

Beginning with MySQL Cluster NDB 6.3.2, this table has been changed to facilitate 3-way replication recovery. Two columns `orig_server_id` and `orig_epoch` have been added to this table; when `mysqld` is started with the `--ndb-log-orig` option, these columns store, respectively, the ID of the server on which the event originated and the epoch in which the event took place on the originating server. In addition, the table's primary key now includes these two columns. The modified table definition is shown here:

```sql
CREATE TABLE `ndb_binlog_index` (
    `Position` BIGINT(20) UNSIGNED NOT NULL,
    `File` VARCHAR(255) NOT NULL,
    `epoch` BIGINT(20) UNSIGNED NOT NULL,
    `inserts` INT(10) UNSIGNED NOT NULL,
    `updates` INT(10) UNSIGNED NOT NULL,
    `deletes` INT(10) UNSIGNED NOT NULL,
    `schemaops` INT(10) UNSIGNED NOT NULL,
    `orig_server_id` INT(10) UNSIGNED NOT NULL,
    `orig_epoch` BIGINT(20) UNSIGNED NOT NULL,
    `gci` INT(10) UNSIGNED NOT NULL,
    `next_position` bigint(20) unsigned NOT NULL,
    `next_file` varchar(255) NOT NULL,
    PRIMARY KEY (`epoch`, `orig_server_id`, `orig_epoch`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1;
```

The `gci` column was added in MySQL Cluster NDB 6.2.6 and MySQL Cluster NDB 6.3.2.

The `next_position` and `next_file` columns were added in MySQL Cluster NDB 7.0.33 and MySQL Cluster NDB 7.1.22; see Section 17.6.8, “Implementing Failover with MySQL Cluster Replication”, for more information about using these columns.

The following figure shows the relationship of the MySQL Cluster replication master server, its binlog injector thread, and the `mysql.ndb_binlog_index` table.
An additional table, named `ndb_apply_status`, is used to keep a record of the operations that have been replicated from the master to the slave. Unlike the case with `ndb_binlog_index`, the data in this table is not specific to any one SQL node in the (slave) cluster, and so `ndb_apply_status` can use the NDBCLUSTER storage engine, as shown here:

```sql
CREATE TABLE `ndb_apply_status` (
    `server_id`   INT(10) UNSIGNED NOT NULL,
    `epoch`       BIGINT(20) UNSIGNED NOT NULL,
    `log_name`    VARCHAR(255) CHARACTER SET latin1 COLLATE latin1_bin NOT NULL,
    `start_pos`   BIGINT(20) UNSIGNED NOT NULL,
    `end_pos`     BIGINT(20) UNSIGNED NOT NULL,
    PRIMARY KEY (`server_id`) USING HASH
) ENGINE=NDBCLUSTER   DEFAULT CHARSET=latin1;
```

The `ndb_apply_status` table is populated only on slaves, which means that, on the master, this table never contains any rows; thus, there is no need to allow for DataMemory or IndexMemory to be allotted to `ndb_apply_status` there.

Because this table is populated from data originating on the master, it should be allowed to replicate; any replication filtering or binary log filtering rules that inadvertently prevent the slave from updating `ndb_apply_status` or the master from writing into the binary log may prevent replication between clusters from operating properly. For more information about potential problems arising from such filtering rules, see Replication and binary log filtering rules with replication between MySQL Clusters.

The `log_name`, `start_pos`, and `end_pos` columns were added in MySQL 5.1.18.

**Important**

If you are using MySQL Cluster replication, see Section 17.2.7.3, “Upgrade and downgrade compatibility: MySQL 5.1” before upgrading to MySQL 5.1.18 or later from an earlier version.

The `ndb_binlog_index` and `ndb_apply_status` tables are created in the `mysql` database because they should not be explicitly replicated by the user. User intervention is normally not
required to create or maintain either of these tables, since both ndb_binlog_index and the ndb_apply_status are maintained by the NDB binary log (binlog) injector thread. This keeps the master mysqld process updated to changes performed by the NDB storage engine. The NDB binlog injector thread receives events directly from the NDB storage engine. The NDB injector is responsible for capturing all the data events within the cluster, and ensures that all events which change, insert, or delete data are recorded in the ndb_binlog_index table. The slave I/O thread transfers the events from the master’s binary log to the slave’s relay log.

However, it is advisable to check for the existence and integrity of these tables as an initial step in preparing a MySQL Cluster for replication. It is possible to view event data recorded in the binary log by querying the mysql.ndb_binlog_index table directly on the master. This can be also be accomplished using the SHOW BINLOG EVENTS statement on either the replication master or slave MySQL servers. (See Section 13.7.5.3, “SHOW BINLOG EVENTS Syntax”.)

You can also obtain useful information from the output of SHOW ENGINE NDB STATUS.

The ndb_schema table is used to track schema changes made to NDB tables. It is defined as shown here:

```sql
CREATE TABLE ndb_schema (  `db` VARBINARY(63) NOT NULL,  `name` VARBINARY(63) NOT NULL,  `slock` BINARY(32) NOT NULL,  `query` BLOB NOT NULL,  `node_id` INT UNSIGNED NOT NULL,  `epoch` BIGINT UNSIGNED NOT NULL,  `id` INT UNSIGNED NOT NULL,  `version` INT UNSIGNED NOT NULL,  `type` INT UNSIGNED NOT NULL,  PRIMARY KEY USING HASH (db,name) ) ENGINE=NDB   DEFAULT CHARSET=latin1;
```

Unlike the two tables previously mentioned in this section, the ndb_schema table is not visible either to MySQL SHOW statements, or in any INFORMATION_SCHEMA tables; however, it can be seen in the output of ndb_show_tables, as shown here:

```
shell> ndb_show_tables -t 2
id   type             state   logging database  schema   name
4    UserTable        Online   Yes     mysql        def      ndb_apply_status
5    UserTable        Online   Yes     ndbworld     def      city
6    UserTable        Online   Yes     ndbworld     def      country
3    UserTable        Online   Yes     mysql        def      NDB$BLOB_2_3
7    UserTable        Online   Yes     ndbworld     def      countrylanguage
2    UserTable        Online   Yes     mysql        def      ndb_schema
NDBT_ProgramExit: 0 - OK
```

It is also possible to SELECT from this table in mysql and other MySQL client applications, as shown here:

```
mysql> SELECT * FROM mysql.ndb_schema WHERE name='city' \G
*************************** 1. row ***************************
   db: ndbworld
  name: city
  slock:
  query: alter table city engine=ndb
node_id: 4
   epoch: 0
     id: 0
version: 0
    type: 7
1 row in set (0.00 sec)
```

This can sometimes be useful when debugging applications.
When performing schema changes on NDB tables, applications should wait until the ALTER TABLE statement has returned in the MySQL client connection that issued the statement before attempting to use the updated definition of the table.

The ndb_schema table was added in MySQL 5.1.8.

Beginning with MySQL 5.1.14, if the ndb_apply_status table or the ndb_schema table does not exist on the slave, ndb_restore re-creates the missing table or tables (Bug #14612).

Conflict resolution for MySQL Cluster Replication requires the presence of an additional mysql.ndb_replication table. Currently, this table must be created manually. For information about how to do this, see Section 17.6.11, “MySQL Cluster Replication Conflict Resolution”.

### 17.6.5 Preparing the MySQL Cluster for Replication

Preparing the MySQL Cluster for replication consists of the following steps:

1. Check all MySQL servers for version compatibility (see Section 17.6.2, “General Requirements for MySQL Cluster Replication”).

2. Create a slave account on the master Cluster with the appropriate privileges:

   ```sql
   mysql>
   GRANT REPLICATION SLAVE
   ON *.* TO 'slave_user'@'slave_host'
   IDENTIFIED BY 'slave_password';
   ```

   In the previous statement, `slave_user` is the slave account user name, `slave_host` is the host name or IP address of the replication slave, and `slave_password` is the password to assign to this account.

   For example, to create a slave user account with the name “myslave,” logging in from the host named “rep-slave,” and using the password “53cr37,” use the following GRANT statement:

   ```sql
   mysql>
   GRANT REPLICATION SLAVE
   ON *.* TO 'myslave'@'rep-slave'
   IDENTIFIED BY '53cr37';
   ```

   For security reasons, it is preferable to use a unique user account—not employed for any other purpose—for the replication slave account.

3. Configure the slave to use the master. Using the MySQL Monitor, this can be accomplished with the CHANGE MASTER TO statement:

   ```sql
   mysql>
   CHANGE MASTER TO
   MASTER_HOST='master_host',
   MASTER_PORT=master_port,
   MASTER_USER='slave_user',
   MASTER_PASSWORD='slave_password';
   ```

   In the previous statement, `master_host` is the host name or IP address of the replication master, `master_port` is the port for the slave to use for connecting to the master, `slave_user` is the user name set up for the slave on the master, and `slave_password` is the password set for that user account in the previous step.

   For example, to tell the slave to replicate from the MySQL server whose host name is “rep-master,” using the replication slave account created in the previous step, use the following statement:

   ```sql
   mysql>
   CHANGE MASTER TO
   MASTER_HOST='rep-master',
   MASTER_PORT=3306,
   MASTER_USER='myslave',
   MASTER_PASSWORD='53cr37';
   ```
Starting MySQL Cluster Replication (Single Replication Channel)

mysql> CHANGE MASTER TO
   -> MASTER_HOST='rep-master',
   -> MASTER_PORT=3306,
   -> MASTER_USER='myslave',
   -> MASTER_PASSWORD='53cr37';

For a complete list of options that can be used with this statement, see Section 13.4.2.1, “CHANGE MASTER TO Syntax”.

To provide replication backup capability, you also need to add an --ndb-connectstring option to the slave's my.cnf file prior to starting the replication process. See Section 17.6.9, “MySQL Cluster Backups With MySQL Cluster Replication”, for details.

For additional options that can be set in my.cnf for replication slaves, see Section 16.1.3, “Replication and Binary Logging Options and Variables”.

4. If the master cluster is already in use, you can create a backup of the master and load this onto the slave to cut down on the amount of time required for the slave to synchronize itself with the master. If the slave is also running MySQL Cluster, this can be accomplished using the backup and restore procedure described in Section 17.6.9, “MySQL Cluster Backups With MySQL Cluster Replication”.

ndb-connectstring=management_host[:port]

In the event that you are not using MySQL Cluster on the replication slave, you can create a backup with this command on the replication master:

shell> mysqldump --master-data=1

Then import the resulting data dump onto the slave by copying the dump file over to the slave. After this, you can use the mysql client to import the data from the dumpfile into the slave database as shown here, where dump_file is the name of the file that was generated using mysqldump on the master, and db_name is the name of the database to be replicated:

shell> mysql -u root -p db_name < dump_file

For a complete list of options to use with mysqldump, see Section 4.5.4, “mysqldump — A Database Backup Program”.

Note

If you copy the data to the slave in this fashion, you should make sure that the slave is started with the --skip-slave-start option on the command line, or else include skip-slave-start in the slave's my.cnf file to keep it from trying to connect to the master to begin replicating before all the data has been loaded. Once the data loading has completed, follow the additional steps outlined in the next two sections.

5. Ensure that each MySQL server acting as a replication master is configured with a unique server ID, and with binary logging enabled, using the row format. (See Section 16.1.2, “Replication Formats”.) These options can be set either in the master server's my.cnf file, or on the command line when starting the master mysqld process. See Section 17.6.6, “Starting MySQL Cluster Replication (Single Replication Channel)”, for information regarding the latter option.

17.6.6 Starting MySQL Cluster Replication (Single Replication Channel)

This section outlines the procedure for starting MySQL Cluster replication using a single replication channel.

1. Start the MySQL replication master server by issuing this command:
Starting MySQL Cluster Replication (Single Replication Channel)

shell> mysqld --ndbcluster --server-id=id \ 
    --log-bin --binlog-format=ROW &

In the previous statement, \textit{id} is this server's unique ID (see Section 17.6.2, “General Requirements for MySQL Cluster Replication”). This starts the server's \texttt{mysqld} process with binary logging enabled using the proper logging format.

\begin{itemize}
  \item \textbf{Note}\hfill
  \textcolor{red}{You can also start the master with} \texttt{--binlog-format=MIXED}, in which case row-based replication is used automatically when replicating between clusters. \texttt{STATEMENT} based binary logging is not supported for MySQL Cluster Replication (see Section 17.6.2, “General Requirements for MySQL Cluster Replication”).
\end{itemize}

2. Start the MySQL replication slave server as shown here:

shell> mysqld --ndbcluster --server-id=id &

In the command just shown, \textit{id} is the slave server's unique ID. It is not necessary to enable logging on the replication slave.

\begin{itemize}
  \item \textbf{Note}\hfill
  \textcolor{red}{You should use the} \texttt{--skip-slave-start} option with this command or else you should include \texttt{skip-slave-start} in the slave server's \texttt{my.cnf} file, unless you want replication to begin immediately. With the use of this option, the start of replication is delayed until the appropriate \texttt{START SLAVE} statement has been issued, as explained in Step 4 below.
\end{itemize}

3. It is necessary to synchronize the slave server with the master server's replication binary log. If binary logging has not previously been running on the master, run the following statement on the slave:

\begin{verbatim}
mysql> CHANGE MASTER TO 
    
    -> MASTER_LOG_FILE='',
    
    -> MASTER_LOG_POS=4;
\end{verbatim}

This instructs the slave to begin reading the master's binary log from the log's starting point. Otherwise—that is, if you are loading data from the master using a backup—see Section 17.6.8, “Implementing Failover with MySQL Cluster Replication”, for information on how to obtain the correct values to use for \texttt{MASTER_LOG_FILE} and \texttt{MASTER_LOG_POS} in such cases.

4. Finally, you must instruct the slave to begin applying replication by issuing this command from the \texttt{mysql} client on the replication slave:

\begin{verbatim}
mysql> START SLAVE;
\end{verbatim}

This also initiates the transmission of replication data from the master to the slave.

It is also possible to use two replication channels, in a manner similar to the procedure described in the next section; the differences between this and using a single replication channel are covered in Section 17.6.7, “Using Two Replication Channels for MySQL Cluster Replication”.

Beginning with MySQL Cluster NDB 6.2.3, it is possible to improve cluster replication performance by enabling \texttt{batched updates}. This can be accomplished by setting the \texttt{slave_allow_batching} system variable on the slave \texttt{mysqld} processes. Normally, updates are applied as soon as they are received. However, the use of batching causes updates to be applied in 32 KB batches, which can result in higher throughput and less CPU usage, particularly where individual updates are relatively small.
Note

Slave batching works on a per-epoch basis; updates belonging to more than one transaction can be sent as part of the same batch.

All outstanding updates are applied when the end of an epoch is reached, even if the updates total less than 32 KB.

Batching can be turned on and off at runtime. To activate it at runtime, you can use either of these two statements:

```sql
SET GLOBAL slave_allow_batching = 1;
SET GLOBAL slave_allow_batching = ON;
```

If a particular batch causes problems (such as a statement whose effects do not appear to be replicated correctly), slave batching can be deactivated using either of the following statements:

```sql
SET GLOBAL slave_allow_batching = 0;
SET GLOBAL slave_allow_batching = OFF;
```

You can check whether slave batching is currently being used by means of an appropriate `SHOW VARIABLES` statement, like this one:

```sql
mysql> SHOW VARIABLES LIKE 'slave%';
+---------------------------+-------+
| Variable_name             | Value |
+---------------------------+-------+
| slave_allow_batching      | ON    |
| slave_compressed_protocol | OFF   |
| slave_load_tmpdir         | /tmp  |
| slave_net_timeout         | 3600  |
| slave_skip_errors         | OFF   |
| slave_transaction_retries | 10    |
+---------------------------+-------+
6 rows in set (0.00 sec)
```

### 17.6.7 Using Two Replication Channels for MySQL Cluster Replication

In a more complete example scenario, we envision two replication channels to provide redundancy and thereby guard against possible failure of a single replication channel. This requires a total of four replication servers, two masters for the master cluster and two slave servers for the slave cluster. For purposes of the discussion that follows, we assume that unique identifiers are assigned as shown here:

<table>
<thead>
<tr>
<th>Server ID</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Master - primary replication channel (M)</td>
</tr>
<tr>
<td>2</td>
<td>Master - secondary replication channel (M)</td>
</tr>
<tr>
<td>3</td>
<td>Slave - primary replication channel (S)</td>
</tr>
<tr>
<td>4</td>
<td>Slave - secondary replication channel (S)</td>
</tr>
</tbody>
</table>

Setting up replication with two channels is not radically different from setting up a single replication channel. First, the `mysqld` processes for the primary and secondary replication masters must be started, followed by those for the primary and secondary slaves. Then the replication processes may be initiated by issuing the `START SLAVE` statement on each of the slaves. The commands and the order in which they need to be issued are shown here:

1. Start the primary replication master:
Implementing Failover with MySQL Cluster Replication

2. Start the secondary replication master:

```shell
M$> mysqld --ndbcluster --server-id=1 \
   --log-bin --binlog-format=ROW &
```

3. Start the primary replication slave server:

```shell
S$> mysqld --ndbcluster --server-id=3 \
   --skip-slave-start &
```

4. Start the secondary replication slave:

```shell
S'$> mysqld --ndbcluster --server-id=4 \
   --skip-slave-start &
```

5. Finally, initiate replication on the primary channel by executing the `START SLAVE` statement on the primary slave as shown here:

```sql
mysql S$> START SLAVE;
```

**Warning**

Only the primary channel is to be started at this point. The secondary replication channel is to be started only in the event that the primary replication channel fails, as described in Section 17.6.8, “Implementing Failover with MySQL Cluster Replication”. Running multiple replication channels simultaneously can result in unwanted duplicate records being created on the replication slaves.

As mentioned previously, it is not necessary to enable binary logging on replication slaves.

### 17.6.8 Implementing Failover with MySQL Cluster Replication

In the event that the primary Cluster replication process fails, it is possible to switch over to the secondary replication channel. The following procedure describes the steps required to accomplish this.

1. Obtain the time of the most recent global checkpoint (GCP). That is, you need to determine the most recent epoch from the `ndb_apply_status` table on the slave cluster, which can be found using the following query:

```sql
mysql S'$> SELECT @latest:=MAX(epoch) \
   FROM mysql.ndb_apply_status;
```

2. Using the information obtained from the query shown in Step 1, obtain the corresponding records from the `ndb_binlog_index` table on the master cluster.

Prior to MySQL Cluster NDB 7.0.33 and MySQL Cluster 7.1.22, you should use the following query to accomplish this task:

```sql
mysql M'$> SELECT @file:=SUBSTRING_INDEX(File, '/', -1), @pos:=Position \
   FROM mysql.ndb_binlog_index \
   WHERE epoch > @latest \
   ORDER BY epoch ASC LIMIT 1;
```
Beginning with MySQL Cluster NDB 7.0.33 and MySQL Cluster NDB 7.1.22, you can take advantage of the improved binary logging of DDL statements implemented in those and later versions by using the following query to obtain the needed records from the master's `ndb_binlog_index` table:

```sql
mysql>
SELECT
    @file:=SUBSTRING_INDEX(next_file, '/', -1),
    @pos:=next_position
FROM mysql.ndb_binlog_index
WHERE epoch = @latest
ORDER BY epoch ASC LIMIT 1;
```

In either case, these are the records saved on the master since the failure of the primary replication channel. We have employed a user variable `@latest` here to represent the value obtained in Step 1. Of course, it is not possible for one `mysqld` instance to access user variables set on another server instance directly. These values must be “plugged in” to the second query manually or in application code.

**Important**

If (and only if) you use the second of the two queries just shown against `ndb_binlog_index` (that is, the query that employs the `next_position` and `next_file` columns), you must ensure that the slave `mysqld` is started with `--slave-skip-errors=ddl_exist_errors` before executing `START SLAVE`. Otherwise, replication may stop with duplicate DDL errors.

3. Now it is possible to synchronize the secondary channel by running the following query on the secondary slave server:

```sql
mysql>
CHANGE MASTER TO
    MASTER_LOG_FILE='@file',
    MASTER_LOG_POS=@pos;
```

Again we have employed user variables (in this case `@file` and `@pos`) to represent the values obtained in Step 2 and applied in Step 3; in practice these values must be inserted manually or using application code that can access both of the servers involved.

**Note**

@file is a string value such as `/var/log/mysql/replication-master-bin.00001`, and so must be quoted when used in SQL or application code. However, the value represented by @pos must not be quoted. Although MySQL normally attempts to convert strings to numbers, this case is an exception.

4. You can now initiate replication on the secondary channel by issuing the appropriate command on the secondary slave `mysqld`:

```sql
mysql>
START SLAVE;
```

Once the secondary replication channel is active, you can investigate the failure of the primary and effect repairs. The precise actions required to do this will depend upon the reasons for which the primary channel failed.

**Warning**

The secondary replication channel is to be started only if and when the primary replication channel has failed. Running multiple replication channels
simultaneously can result in unwanted duplicate records being created on the replication slaves.

If the failure is limited to a single server, it should (in theory) be possible to replicate from \( M \) to \( S' \), or from \( M' \) to \( S \); however, this has not yet been tested.

### 17.6.9 MySQL Cluster Backups With MySQL Cluster Replication

This section discusses making backups and restoring from them using MySQL Cluster replication. We assume that the replication servers have already been configured as covered previously (see Section 17.6.5, “Preparing the MySQL Cluster for Replication”, and the sections immediately following). This having been done, the procedure for making a backup and then restoring from it is as follows:

1. There are two different methods by which the backup may be started.

   - **Method A.** This method requires that the cluster backup process was previously enabled on the master server, prior to starting the replication process. This can be done by including the following line in a `[mysql_cluster]` section in the `my.cnf` file, where `management_host` is the IP address or host name of the NDB management server for the master cluster, and `port` is the management server's port number:
     
     ```
     ndb-connectstring=management_host[:port]
     ```

     **Note**
     
     The port number needs to be specified only if the default port (1186) is not being used. See Section 17.2.3, “Initial Configuration of MySQL Cluster”, for more information about ports and port allocation in MySQL Cluster.

     In this case, the backup can be started by executing this statement on the replication master:

     ```
     ndb_mgm -e "START BACKUP"
     ```

   - **Method B.** If the `my.cnf` file does not specify where to find the management host, you can start the backup process by passing this information to the NDB management client as part of the `START BACKUP` command. This can be done as shown here, where `management_host` and `port` are the host name and port number of the management server:

     ```
     ndb_mgm management_host:port -e "START BACKUP"
     ```

     In our scenario as outlined earlier (see Section 17.6.5, “Preparing the MySQL Cluster for Replication”), this would be executed as follows:

     ```
     ndb_mgm rep-master:1186 -e "START BACKUP"
     ```

2. Copy the cluster backup files to the slave that is being brought on line. Each system running an `ndbd` process for the master cluster will have cluster backup files located on it, and all of these files must be copied to the slave to ensure a successful restore. The backup files can be copied into any directory on the computer where the slave management host resides, so long as the MySQL and NDB binaries have read permissions in that directory. In this case, we will assume that these files have been copied into the directory `/var/BACKUPS/BACKUP-1`.

   It is not necessary that the slave cluster have the same number of `ndbd` processes (data nodes) as the master; however, it is highly recommended this number be the same. It is necessary that the slave be started with the `--skip-slave-start` option, to prevent premature startup of the replication process.

3. Create any databases on the slave cluster that are present on the master cluster that are to be replicated to the slave.
MySQL Cluster Backups With MySQL Cluster Replication

4. Reset the slave cluster using this statement in the MySQL Monitor:

```sql
mysql> RESET SLAVE;
```

5. You can now start the cluster restoration process on the replication slave using the `ndb_restore` command for each backup file in turn. For the first of these, it is necessary to include the `-m` option to restore the cluster metadata:

```bash
shell> ndb_restore -c slave_host:port -n node-id \n    -b backup-id -m -r dir
```

`dir` is the path to the directory where the backup files have been placed on the replication slave. For the `ndb_restore` commands corresponding to the remaining backup files, the `-m` option should not be used.

For restoring from a master cluster with four data nodes (as shown in the figure in Section 17.6, “MySQL Cluster Replication”) where the backup files have been copied to the directory `/var/BACKUPS/BACKUP-1`, the proper sequence of commands to be executed on the slave might look like this:

```bash
shell> ndb_restore -c rep-slave:1186 -n 2 -b 1 -m \n    -r ./var/BACKUPS/BACKUP-1
shell> ndb_restore -c rep-slave:1186 -n 3 -b 1 \n    -r ./var/BACKUPS/BACKUP-1
shell> ndb_restore -c rep-slave:1186 -n 4 -b 1 \n    -r ./var/BACKUPS/BACKUP-1
shell> ndb_restore -c rep-slave:1186 -n 5 -b 1 -e \n    -r ./var/BACKUPS/BACKUP-1
```

Important

The `-e` (or `--restore_epoch`) option in the final invocation of `ndb_restore` in this example is required in order that the epoch is written to the slave `mysql.ndb_apply_status`. Without this information, the slave will not be able to synchronize properly with the master. (See Section 17.4.20, “ndb_restore — Restore a MySQL Cluster Backup”.)

6. Now you need to obtain the most recent epoch from the `ndb_apply_status` table on the slave (as discussed in Section 17.6.8, “Implementing Failover with MySQL Cluster Replication”):

```sql
mysql> SELECT @latest:=MAX(epoch) FROM mysql.ndb_apply_status;
```

7. Using `@latest` as the epoch value obtained in the previous step, you can obtain the correct starting position `@pos` in the correct binary log file `@file` from the master’s `mysql.ndb_binlog_index` table using the query shown here:

```sql
mysql> SELECT 
    -> @file:=SUBSTRING_INDEX(File, '/', -1), 
    -> @pos:=Position 
    FROM mysql.ndb_binlog_index 
    WHERE epoch > @latest 
    ORDER BY epoch ASC LIMIT 1;
```
In the event that there is currently no replication traffic, you can get this information by running `SHOW MASTER STATUS` on the master and using the value in the `Position` column for the file whose name has the suffix with the greatest value for all files shown in the `File` column. However, in this case, you must determine this and supply it in the next step manually or by parsing the output with a script.

8. Using the values obtained in the previous step, you can now issue the appropriate `CHANGE MASTER TO` statement in the slave's `mysql` client:

```
mysql> CHANGE MASTER TO
    -> MASTER_LOG_FILE='@file',
    -> MASTER_LOG_POS=@pos;
```

9. Now that the slave “knows” from what point in which `binlog` file to start reading data from the master, you can cause the slave to begin replicating with this standard MySQL statement:

```
mysql> START SLAVE;
```

To perform a backup and restore on a second replication channel, it is necessary only to repeat these steps, substituting the host names and IDs of the secondary master and slave for those of the primary master and slave replication servers where appropriate, and running the preceding statements on them.

For additional information on performing Cluster backups and restoring Cluster from backups, see Section 17.5.3, “Online Backup of MySQL Cluster”.

### 17.6.9.1 MySQL Cluster Replication: Automating Synchronization of the Replication Slave to the Master Binary Log

It is possible to automate much of the process described in the previous section (see Section 17.6.9, “MySQL Cluster Backups With MySQL Cluster Replication”). The following Perl script `reset-slave.pl` serves as an example of how you can do this.
my $m_host = '';  
my $m_port = '';  
my $m_user = '';  
my $m_pass = '';  
my $s_host = '';  
my $s_port = '';  
my $s_user = '';  
my $s_pass = '';  
my $dbhM = '';  
my $dbhS = '';  

sub CollectCommandPromptInfo;  
sub ConnectToDatabases;  
sub DisconnectFromDatabases;  
sub GetSlaveEpoch;  
sub GetMasterInfo;  
sub UpdateSlave;  

sub CollectCommandPromptInfo {  
### Check that user has supplied correct number of command line args  
die "Usage:
    reset-slave >master MySQL host< >master MySQL port< \n    >master user< >master pass< >slave MySQL host< \n    >slave MySQL port< >slave user< >slave pass< \n
    All 8 arguments must be passed. Use BLANK for NULL passwords\n" unless @ARGV == 8;  

$m_host = $ARGV[0];  
$m_port = $ARGV[1];  
$m_user = $ARGV[2];  
$m_pass = $ARGV[3];  
$s_host = $ARGV[4];  
$s_port = $ARGV[5];  
$s_user = $ARGV[6];  
$s_pass = $ARGV[7];  

if ($m_pass eq "BLANK") { $m_pass = ''; }  
if ($s_pass eq "BLANK") { $s_pass = ''; }

sub ConnectToDatabases {  
### Connect to both master and slave cluster databases  

### Connect to master

                         MASTER_LOG_FILE='$binlog',
                         MASTER_LOG_POS=$binpos;")
      or die "Prepare to CHANGE MASTER error: ", $dbhS->errstr;
  $sth->execute
      or die "CHANGE MASTER on slave error: ", $sth->errstr;
  $sth->finish;
17.6.9.2 Point-In-Time Recovery Using MySQL Cluster Replication

*Point-in-time* recovery—that is, recovery of data changes made since a given point in time—is performed after restoring a full backup that returns the server to its state when the backup was made. Performing point-in-time recovery of MySQL Cluster tables with MySQL Cluster and MySQL Cluster Replication can be accomplished using a native NDB data backup (taken by issuing CREATE BACKUP in the ndb_mgm client) and restoring the ndb_binlog_index table (from a dump made using mysqldump).

To perform point-in-time recovery of MySQL Cluster, it is necessary to follow the steps shown here:

1. Back up all NDB databases in the cluster, using the START BACKUP command in the ndb_mgm client (see Section 17.5.3, “Online Backup of MySQL Cluster”).

2. At some later point, prior to restoring the cluster, make a backup of the mysql.ndb_binlog_index table. It is probably simplest to use mysqldump for this task. Also back up the binary log files at this time.

   This backup should be updated regularly—perhaps even hourly—depending on your needs.

3. (*Catastrophic failure or error occurs.*)

4. Locate the last known good backup.

5. Clear the data node file systems (using ndbd --initial or, in MySQL Cluster NDB 7.0 and later, ndbmtd --initial).

   **Note**
   MySQL Cluster Disk Data tablespace and log files are not removed by --initial. You must delete these manually.

6. Use DROP TABLE or TRUNCATE TABLE with the mysql.ndb_binlog_index table.

7. Execute ndb_restore, restoring all data. You must include the --restore_epoch option when you run ndb_restore, so that the ndb_apply_status table is populated correctly. (See Section 17.4.20, “ndb_restore — Restore a MySQL Cluster Backup”, for more information.)

8. Restore the ndb_binlog_index table from the output of mysqldump and restore the binary log files from backup, if necessary.

9. Find the epoch applied most recently—that is, the maximum epoch column value in the ndb_apply_status table—as the user variable @LATEST_EPOCH (emphasized):

   ```sql
   SELECT @LATEST_EPOCH:=MAX(epoch)
   FROM mysql.ndb_apply_status;
   ```

10. Find the latest binary log file (@FIRST_FILE) and position (Position column value) within this file that correspond to @LATEST_EPOCH in the ndb_binlog_index table:

    ```sql
    SELECT Position, @FIRST_FILE:=File
    FROM mysql.ndb_binlog_index
    WHERE epoch > @LATEST_EPOCH ORDER BY epoch ASC LIMIT 1;
    ```

11. Using mysqlbinlog, replay the binary log events from the given file and position up to the point of the failure. (See Section 4.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”.)
See also Section 7.5, “Point-in-Time (Incremental) Recovery Using the Binary Log”, for more information about the binary log, replication, and incremental recovery.

17.6.10 MySQL Cluster Replication: Multi-Master and Circular Replication

Beginning with MySQL 5.1.18, it is possible to use MySQL Cluster in multi-master replication, including circular replication between a number of MySQL Clusters.

Note

Prior to MySQL 5.1.18, multi-master replication including circular replication was not supported with MySQL Cluster replication. This was because log events created in a particular MySQL Cluster were wrongly tagged with the server ID of the master rather than the server ID of the originating server.

Circular replication example. In the next few paragraphs we consider the example of a replication setup involving three MySQL Clusters numbered 1, 2, and 3, in which Cluster 1 acts as the replication master for Cluster 2, Cluster 2 acts as the master for Cluster 3, and Cluster 3 acts as the master for Cluster 1. Each cluster has two SQL nodes, with SQL nodes A and B belonging to Cluster 1, SQL nodes C and D belonging to Cluster 2, and SQL nodes E and F belonging to Cluster 3.

Circular replication using these clusters is supported as long as the following conditions are met:

• The SQL nodes on all masters and slaves are the same

• All SQL nodes acting as replication masters and slaves are started using the \texttt{--log-slave-updates} option

This type of circular replication setup is shown in the following diagram:
In this scenario, SQL node A in Cluster 1 replicates to SQL node C in Cluster 2; SQL node C replicates to SQL node E in Cluster 3; SQL node E replicates to SQL node A. In other words, the replication line (indicated by the red arrows in the diagram) directly connects all SQL nodes used as replication masters and slaves.

It is also possible to set up circular replication in such a way that not all master SQL nodes are also slaves, as shown here:
In this case, different SQL nodes in each cluster are used as replication masters and slaves. However, you must not start any of the SQL nodes using --log-slave-updates. This type of circular replication scheme for MySQL Cluster, in which the line of replication (again indicated by the red arrows in the diagram) is discontinuous, should be possible, but it should be noted that it has not yet been thoroughly tested and must therefore still be considered experimental.

**Using NDB-native backup and restore to initialize a slave MySQL Cluster.** When setting up circular replication, it is possible to initialize the slave cluster by using the management client BACKUP command on one MySQL Cluster to create a backup and then applying this backup on another MySQL Cluster using ndb_restore. However, this does not automatically create binary logs on the second MySQL Cluster's SQL node acting as the replication slave. In order to cause the binary logs to be created, you must issue a SHOW TABLES statement on that SQL node; this should be done prior to running START SLAVE.

This is a known issue which we intend to address in a future release.

**Multi-master failover example.** In this section, we discuss failover in a multi-master MySQL Cluster replication setup with three MySQL Clusters having server IDs 1, 2, and 3. In this scenario, Cluster 1 replicates to Clusters 2 and 3; Cluster 2 also replicates to Cluster 3. This relationship is shown here:
In other words, data replicates from Cluster 1 to Cluster 3 through 2 different routes: directly, and by way of Cluster 2.

Not all MySQL servers taking part in multi-master replication must act as both master and slave, and a given MySQL Cluster might use different SQL nodes for different replication channels. Such a case is shown here:

MySQL servers acting as replication slaves must be run with the `--log-slave-updates` option. Which `mysqld` processes require this option is also shown in the preceding diagram.

**Note**

Using the `--log-slave-updates` option has no effect on servers not being run as replication slaves.

The need for failover arises when one of the replicating clusters goes down. In this example, we consider the case where Cluster 1 is lost to service, and so Cluster 3 loses 2 sources of updates from Cluster 1. Because replication between MySQL Clusters is asynchronous, there is no guarantee that Cluster 3’s updates originating directly from Cluster 1 are more recent than those received through Cluster 2. You can handle this by ensuring that Cluster 3 catches up to Cluster 2 with regard to updates from Cluster 1. In terms of MySQL servers, this means that you need to replicate any outstanding updates from MySQL server C to server F.
On server C, perform the following queries:

```sql
mysqlC> SELECT @latest:=MAX(epoch)
      -> FROM mysql.ndb_apply_status
      -> WHERE server_id=1;

mysqlC> SELECT
      -> @file:=SUBSTRING_INDEX(File, '/', -1),
      -> @pos:=Position
      -> FROM mysql.ndb_binlog_index
      -> WHERE orig_epoch >= @latest
      -> AND orig_server_id = 1
      -> ORDER BY epoch ASC LIMIT 1;
```

Note
You can improve the performance of this query, and thus likely speed up failover times significantly, by adding the appropriate index to the `ndb_binlog_index` table. See Section 17.6.4, “MySQL Cluster Replication Schema and Tables”, for more information.

Copy over the values for `@file` and `@pos` manually from server C to server F (or have your application perform the equivalent). Then, on server F, execute the following `CHANGE MASTER TO` statement:

```sql
mysqlF> CHANGE MASTER TO
      -> MASTER_HOST = 'serverC'
      -> MASTER_LOG_FILE='@file',
      -> MASTER_LOG_POS=@pos;
```

Once this has been done, you can issue a `START SLAVE` statement on MySQL server F, and any missing updates originating from server B will be replicated to server F.

Beginning with MySQL Cluster MySQL Cluster NDB 6.1.29, MySQL Cluster NDB 6.3.31, MySQL Cluster NDB 7.0.11, and MySQL Cluster NDB 7.1.0, the `CHANGE MASTER TO` statement also supports an `IGNORE_SERVER_IDS` option which takes a comma-separated list of server IDs and causes events originating from the corresponding servers to be ignored. For more information, see Section 13.4.2.1, “CHANGE MASTER TO Syntax”, and Section 13.7.5.36, “SHOW SLAVE STATUS Syntax”.

17.6.11 MySQL Cluster Replication Conflict Resolution

When using a replication setup involving multiple masters (including circular replication), it is possible that different masters may try to update the same row on the slave with different data. Conflict resolution in MySQL Cluster Replication provides a means of resolving such conflicts by permitting a user-defined resolution column to be used to determine whether or not an update on a given master should be applied on the slave.

Some types of conflict resolution supported by MySQL Cluster (`NDB$OLD()`, `NDB$MAX()`, `NDB$MAX_DELETE_WIN()`) implement this user-defined column as a “timestamp” column (although its type cannot be `TIMESTAMP`, as explained later in this section). These types of conflict resolution are always applied a row-by-row basis rather than a transactional basis. The epoch-based conflict resolution functions introduced in MySQL Cluster NDB 7.1.16 (`NDB$EPOCH()` and `NDB$EPOCH_TRANS()`) compare the order in which epochs are replicated (and thus these functions are transactional). Different methods can be used to compare resolution column values on the slave when conflicts occur, as explained later in this section; the method used can be set on a per-table basis.

You should also keep in mind that it is the application’s responsibility to ensure that the resolution column is correctly populated with relevant values, so that the resolution function can make the appropriate choice when determining whether to apply an update.

Requirements. Preparations for conflict resolution must be made on both the master and the slave. These tasks are described in the following list:
MySQL Cluster Replication Conflict Resolution

• On the master writing the binary logs, you must determine which columns are sent (all columns or only those that have been updated). This is done for the MySQL Server as a whole by applying the `mysqld` startup option `--ndb-log-updated-only` (described later in this section) or on a per-table basis by entries in the `mysql.ndb_replication` table (see The ndb_replication system table).

  **Note**

  If you are replicating tables with very large columns (such as `TEXT` or `BLOB` columns), `--ndb-log-updated-only` can also be useful for reducing the size of the master and slave binary logs and avoiding possible replication failures due to exceeding `max_allowed_packet`.

  See Section 16.4.1.21, “Replication and max_allowed_packet”, for more information about this issue.

• On the slave, you must determine which type of conflict resolution to apply (“latest timestamp wins”, “same timestamp wins”, or none). This is done using the `mysql.ndb_replication` system table, on a per-table basis (see The ndb_replication system table).

• Prior to MySQL Cluster NDB 7.0.31 and MySQL Cluster NDB 7.1.20, conflict detection and resolution did not always work properly unless set up for NDB tables created on the same server only (Bug #13578660).

When using the functions `NDB$OLD()`, `NDB$MAX()`, and `NDB$MAX_DELETE_WIN()` for timestamp-based conflict resolution, we often refer to the column used for determining updates as a “timestamp” column, but the data type of this column is never `TIMESTAMP`; rather, its data type should be `INT` (INTEGER) or `BIGINT`. The “timestamp” column should also be `UNSIGNED` and `NOT NULL`.

**Master column control.** We can see update operations in terms of “before” and “after” images—that is, the states of the table before and after the update is applied. Normally, when updating a table with a primary key, the “before” image is not of great interest; however, when we need to determine on a per-update basis whether or not to use the updated values on a replication slave, we need to make sure that both images are written to the master’s binary log. This is done with the `--ndb-log-update-as-write` option for `mysqld`, as described later in this section.

**Important**

Whether logging of complete rows or of updated columns only is done is decided when the MySQL server is started, and cannot be changed online; you must either restart `mysqld`, or start a new `mysqld` instance with different logging options.

### Logging Full or Partial Rows (--ndb-log-updated-only Option)

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.19-ndb-6.3.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ndb-log-updated-only</code></td>
</tr>
<tr>
<td><strong>System Variable</strong></td>
<td><strong>Name</strong> <code>ndb_log_updated_only</code></td>
</tr>
<tr>
<td></td>
<td><strong>Variable</strong> <code>ndb_log_updated_only</code></td>
</tr>
<tr>
<td></td>
<td><strong>Scope</strong> <code>Global</code></td>
</tr>
<tr>
<td></td>
<td><strong>Dynamic</strong> <code>Yes</code></td>
</tr>
<tr>
<td></td>
<td><strong>Variable</strong></td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td><strong>Type</strong> <code>boolean</code></td>
</tr>
<tr>
<td></td>
<td><strong>Default</strong> <code>ON</code></td>
</tr>
</tbody>
</table>

For purposes of conflict resolution, there are two basic methods of logging rows, as determined by the setting of the `--ndb-log-updated-only` option for `mysqld`: 
MySQL Cluster Replication Conflict Resolution

- Log complete rows
- Log only column data that has been updated—that is, column data whose value has been set, regardless of whether or not this value was actually changed. This is the default behavior.

It is usually sufficient—and more efficient—to log updated columns only; however, if you need to log full rows, you can do so by setting `--ndb-log-updated-only` to 0 or OFF.

--ndb-log-update-as-write Option: Logging Changed Data as Updates

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.1.22-ndb-6.2.5</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--ndb-log-update-as-write</code></td>
</tr>
<tr>
<td>System Variable</td>
<td><code>ndb_log_update_as_write</code></td>
</tr>
<tr>
<td>Name</td>
<td>Global</td>
</tr>
<tr>
<td>Variable</td>
<td>DynamicYes</td>
</tr>
<tr>
<td>Scope</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>ON</td>
</tr>
</tbody>
</table>

The setting of the MySQL Server's `--ndb-log-update-as-write` option determines whether logging is performed with or without the “before” image. Because conflict resolution is done in the MySQL Server's update handler, it is necessary to control logging on the master such that updates are updates and not writes; that is, such that updates are treated as changes in existing rows rather than the writing of new rows (even though these replace existing rows). This option is turned on by default; in other words, updates are treated as writes. (That is, updates are by default written as `write_row` events in the binary log, rather than as `update_row` events.)

To turn off the option, start the master `mysqld` with `--ndb-log-update-as-write=0` or `--ndb-log-update-as-write=OFF`. You must do this when replicating from NDB tables to tables using a different storage engine; see Replication from NDB to other storage engines.

Conflict resolution control. Conflict resolution is usually enabled on the server where conflicts can occur. Like logging method selection, it is enabled by entries in the `mysql.ndb_replication` table.

The `ndb_replication` system table. To enable conflict resolution, it is necessary to create an `ndb_replication` table in the `mysql` system database on the master, the slave, or both, depending on the conflict resolution type and method to be employed. This table is used to control logging and conflict resolution functions on a per-table basis, and has one row per table involved in replication. `ndb_replication` is created and filled with control information on the server where the conflict is to be resolved. In a simple master-slave setup where data can also be changed locally on the slave this will typically be the slave. In a more complex master-master (2-way) replication schema this will usually be all of the masters involved. Each row in `mysql.ndb_replication` corresponds to a table being replicated, and specifies how to log and resolve conflicts (that is, which conflict resolution function, if any, to use) for that table. The definition of the `mysql.ndb_replication` table is shown here:

```
CREATE TABLE mysql.ndb_replication  (
  db VARBINARY(63),
  table_name VARBINARY(63),
  server_id INT UNSIGNED,
  binlog_type INT UNSIGNED,
  conflict_fn VARBINARY(128),
  PRIMARY KEY USING HASH (db, table_name, server_id)
) ENGINE=NDB
PARTITION BY KEY(db,table_name);
```

The columns in this table are described in the next few paragraphs.
db. The name of the database containing the table to be replicated.

Beginning with MySQL Cluster NDB 7.0.31 and MySQL Cluster NDB 7.1.20, you may employ either or both of the wildcards _ and % as part of the database name. Matching is similar to what is implemented for the LIKE operator.

table_name. The name of the table to be replicated.

Beginning with MySQL Cluster NDB 7.0.31 and MySQL Cluster NDB 7.1.20, the table name may include either or both of the wildcards _ and %. Matching is similar to what is implemented for the LIKE operator.

server_id. The unique server ID of the MySQL instance (SQL node) where the table resides.

binlog_type. The type of binary logging to be employed. This is determined as shown in the following table:

<table>
<thead>
<tr>
<th>Value</th>
<th>Internal Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>NBT_DEFAULT</td>
<td>Use server default</td>
</tr>
<tr>
<td>1</td>
<td>NBT_NO_LOGGING</td>
<td>Do not log this table in the binary log</td>
</tr>
<tr>
<td>2</td>
<td>NBT_UPDATED_ONLY</td>
<td>Only updated attributes are logged</td>
</tr>
<tr>
<td>3</td>
<td>NBT_FULL</td>
<td>Log full row, even if not updated (MySQL server default behavior)</td>
</tr>
<tr>
<td>4</td>
<td>NBT_USE_UPDATE</td>
<td>(For generating NBT_UPDATED_ONLY_USE_UPDATE and NBT_FULL_USE_UPDATE values only—not intended for separate use)</td>
</tr>
<tr>
<td>5</td>
<td>[Not used]</td>
<td>---</td>
</tr>
<tr>
<td>6</td>
<td>NBT_UPDATED_ONLY_USE_UPDATE (equal to NBT_UPDATED_ONLY</td>
<td>NBT_USE_UPDATE)</td>
</tr>
<tr>
<td>7</td>
<td>NBT_FULL_USE_UPDATE (equal to NBT_FULL</td>
<td>NBT_USE_UPDATE)</td>
</tr>
</tbody>
</table>

conflict_fn. The conflict resolution function to be applied. This function must be specified as one of those shown in the following list:

- NDB$OLD(column_name)
- NDB$MAX(column_name)
- NDB$MAX_DELETE_WIN(column_name)
- NDB$EPOCH() and NDB$EPOCH_TRANS() (MySQL Cluster NDB 7.1.16 and later)
- NDB$EPOCH_TRANS() (MySQL Cluster NDB 7.1.16 and later)
- NULL: Indicates that conflict resolution is not to be used for the corresponding table.

These functions are described in the next few paragraphs.

NDB$OLD(column_name). If the value of column_name is the same on both the master and the slave, then the update is applied; otherwise, the update is not applied on the slave and an exception is written to the log. This is illustrated by the following pseudocode:

```python
if (master_old_column_value == slave_current_column_value)
    apply_update();
```
This function can be used for “same value wins” conflict resolution. This type of conflict resolution ensures that updates are not applied on the slave from the wrong master.

**Important**
The column value from the master’s “before” image is used by this function.

**NDB$MAX(column_name).** If the “timestamp” column value for a given row coming from the master is higher than that on the slave, it is applied; otherwise it is not applied on the slave. This is illustrated by the following pseudocode:

```sql
if (master_new_column_value > slave_current_column_value)
    apply_update();
```

This function can be used for “greatest timestamp wins” conflict resolution. This type of conflict resolution ensures that, in the event of a conflict, the version of the row that was most recently updated is the version that persists.

**Important**
The column value from the master’s “after” image is used by this function.

**NDB$MAX_DELETE_WIN(column_name).** This is a variation on **NDB$MAX().** Due to the fact that no timestamp is available for a delete operation, a delete using **NDB$MAX()** is in fact processed as **NDB$OLD.** However, for some use cases, this is not optimal. For **NDB$MAX_DELETE_WIN(),** if the “timestamp” column value for a given row adding or updating an existing row coming from the master is higher than that on the slave, it is applied. However, delete operations are treated as always having the higher value. This is illustrated in the following pseudocode:

```sql
if ( (master_new_column_value > slave_current_column_value) ||
    operation.type == "delete")
    apply_update();
```

This function can be used for “greatest timestamp, delete wins” conflict resolution. This type of conflict resolution ensures that, in the event of a conflict, the version of the row that was deleted or (otherwise) most recently updated is the version that persists.

**Note**
As with **NDB$MAX(),** the column value from the master’s “after” image is the value used by this function.

**NDB$EPOCH() and NDB$EPOCH_TRANS().** The **NDB$EPOCH()** function, available beginning with MySQL Cluster NDB 7.1.16, tracks the order in which replicated epochs are applied on a slave MySQL Cluster relative to changes originating on the slave. This relative ordering is used to determine whether changes originating on the slave are concurrent with any changes that originate locally, and are therefore potentially in conflict.

Most of what follows in the description of **NDB$EPOCH()** also applies to **NDB$EPOCH_TRANS().** Any exceptions are noted in the text.

**NDB$EPOCH()** is asymmetric, operating on one MySQL Cluster in a two-cluster circular replication configuration (sometimes referred to as “active-active” replication). We refer here to cluster on which it operates as the primary, and the other as the secondary. The slave on the primary is responsible for detecting and handling conflicts, while the slave on the secondary is not involved in any conflict detection or handling.
When the slave on the primary detects conflicts, it injects events into its own binary log to compensate for these; this ensures that the secondary MySQL Cluster eventually realigns itself with the primary and so keeps the primary and secondary from diverging. This compensation and realignment mechanism requires that the primary MySQL Cluster always wins any conflicts with the secondary—that is, that the primary's changes are always used rather than those from the secondary in event of a conflict. This "primary always wins" rule has the following implications:

- Operations that change data, once committed on the primary, are fully persistent and will not be undone or rolled back by conflict detection and resolution.
- Data read from the primary is fully consistent. Any changes committed on the Primary (locally or from the slave) will not be reverted later.
- Operations that change data on the secondary may later be reverted if the primary determines that they are in conflict.
- Individual rows read on the secondary are self-consistent at all times, each row always reflecting either a state committed by the secondary, or one committed by the primary.
- Sets of rows read on the secondary may not necessarily be consistent at a given single point in time. For \texttt{NDB$EPOCH\_TRANS()}, this is a transient state; for \texttt{NDB$EPOCH()}, it can be a persistent state.
- Assuming a period of sufficient length without any conflicts, all data on the secondary MySQL Cluster (eventually) becomes consistent with the primary's data.

\texttt{NDB$EPOCH()} and \texttt{NDB$EPOCH\_TRANS()} do not require any user schema modifications, or application changes to provide conflict detection. However, careful thought must be given to the schema used, and the access patterns used, to verify that the complete system behaves within specified limits.

Each of the \texttt{NDB$EPOCH()} and \texttt{NDB$EPOCH\_TRANS()} functions can take an optional parameter; this is the number of bits to use to represent the lower 32 bits of the epoch, and should be set to no less than \texttt{CEIL( LOG2( TimeBetweenGlobalCheckpoints / TimeBetweenEpochs ), 1)}.

For the default values of these configuration parameters (2000 and 100 milliseconds, respectively), this gives a value of 5 bits, so the default value (6) should be sufficient, unless other values are used for \texttt{TimeBetweenGlobalCheckpoints}, \texttt{TimeBetweenEpochs}, or both. A value that is too small can result in false positives, while one that is too large could lead to excessive wasted space in the database.

Both \texttt{NDB$EPOCH()} and \texttt{NDB$EPOCH\_TRANS()} insert entries for conflicting rows into the relevant exceptions tables, provided that these tables have been defined according to the same exception table schema rules as described elsewhere in this section (see \texttt{NDB$OLD(column\_name)}). Note that you need to create any exception table before creating the table with which it is to be used.

As with the other conflict detection functions discussed in this section, \texttt{NDB$EPOCH()} and \texttt{NDB$EPOCH\_TRANS()} are activated by including relevant entries in the \texttt{mysql.ndb_replication} table (see \texttt{The ndb\_replication system table}). The roles of the primary and secondary MySQL Clusters in this scenario are fully determined by \texttt{mysql.ndb_replication} table entries.

Because the conflict detection algorithms employed by \texttt{NDB$EPOCH()} and \texttt{NDB$EPOCH\_TRANS()} are asymmetric, you must use different values for the primary slave's and secondary slave's server_id entries.

Prior to MySQL Cluster NDB 7.1.32, conflict between \texttt{DELETE} operations were handled like those for \texttt{UPDATE} operations, and within the same epoch were considered in conflict. In MySQL Cluster NDB 7.1.32 and later, a conflict between \texttt{DELETE} operations alone is not sufficient to trigger a conflict using \texttt{NDB$EPOCH()} or \texttt{NDB$EPOCH\_TRANS()}, and the relative placement within epochs does not matter. (Bug *18454499)}
MySQL Cluster NDB 7.1.16 introduces several status variables that can be used to monitor NDB$EPOCH() and NDB$EPOCH_TRANS() conflict detection. You can see how many rows have been found in conflict by NDB$EPOCH() since this slave was last restarted from the current value of the Ndb_conflict_fn_epoch system status variable.

Ndb_conflict_fn_epoch_trans provides the number of rows that have been found directly in conflict by NDB$EPOCH_TRANS(); the number of rows actually realigned, including those affected due to their membership in or dependency on the same transactions as other conflicting rows, is given by Ndb_conflict_trans_row_reject_count.

For more information, see MySQL Cluster Status Variables.

Limitations on NDB$EPOCH(). The following limitations currently apply when using NDB$EPOCH() to perform conflict detection:

- Conflicts are detected using MySQL Cluster epoch boundaries, with granularity proportional to TimeBetweenEpochs (default: 100 milliseconds). The minimum conflict window is the minimum time during which concurrent updates to the same data on both clusters always report a conflict. This is always a nonzero length of time, and is roughly proportional to 2 * (latency + queueing + TimeBetweenEpochs). This implies that—assuming the default for TimeBetweenEpochs and ignoring any latency between clusters (as well as any queuing delays)—the minimum conflict window size is approximately 200 milliseconds. This minimum window should be considered when looking at expected application “race” patterns.

- Additional storage is required for tables using the NDB$EPOCH() and NDB$EPOCH_TRANS() functions; from 1 to 32 bits extra space per row is required, depending on the value passed to the function.

- Conflicts between delete operations may result in divergence between the primary and secondary. When a row is deleted on both clusters concurrently, the conflict can be detected, but is not recorded, since the row is deleted. This means that further conflicts during the propagation of any subsequent realignment operations will not be detected, which can lead to divergence.

  Deletes should be externally serialized, or routed to one cluster only. Alternatively, a separate row should be updated transactionally with such deletes and any inserts that follow them, so that conflicts can be tracked across row deletes. This may require changes in applications.

- Only two MySQL Clusters in a circular “active-active” configuration are currently supported when using NDB$EPOCH() or NDB$EPOCH_TRANS() for conflict detection.

- Tables having BLOB or TEXT columns are not currently supported with NDB$EPOCH() or NDB$EPOCH_TRANS().

NDB$EPOCH_TRANS(). NDB$EPOCH_TRANS() extends the NDB$EPOCH() function, and, like NDB$EPOCH(), is available beginning with MySQL Cluster NDB 7.1.16. Conflicts are detected and handled in the same way using the “primary wins all” rule (see NDB$EPOCH() and NDB$EPOCH_TRANS()) but with the extra condition that any other rows updated in the same transaction in which the conflict occurred are also regarded as being in conflict. In other words, where NDB$EPOCH() realigns individual conflicting rows on the secondary, NDB$EPOCH_TRANS() realigns conflicting transactions.

In addition, any transactions which are detectably dependent on a conflicting transaction are also regarded as being in conflict, these dependencies being determined by the contents of the secondary cluster’s binary log. Since the binary log contains only data modification operations (inserts, updates, and deletes), only overlapping data modifications are used to determine dependencies between transactions.

NDB$EPOCH_TRANS() is subject to the same conditions and limitations as NDB$EPOCH(), and in addition requires that Version 2 binary log row events are used (--log-bin-use-v1-row-events equal to 0), which adds a storage overhead of 2 bytes per event in the binary log. In addition, all
transaction IDs must be recorded in the secondary's binary log (\texttt{--ndb-log-transaction-id} option), which adds a further variable overhead (up to 13 bytes per row).

See \texttt{NDB$EPOCH()} and \texttt{NDB$EPOCH\_TRANS()}.

**Status information.** Beginning with MySQL Cluster NDB 6.3.3, a server status variable \texttt{Ndb\_conflict\_fn\_max} provides a count of the number of times that a row was not applied on the current SQL node due to “greatest timestamp wins” conflict resolution since the last time that \texttt{mysqld} was started.

Beginning with MySQL Cluster NDB 6.3.4, the number of times that a row was not applied as the result of “same timestamp wins” conflict resolution on a given \texttt{mysqld} since the last time it was restarted is given by the global status variable \texttt{Ndb\_conflict\_fn\_old}. In addition to incrementing \texttt{Ndb\_conflict\_fn\_old}, the primary key of the row that was not used is inserted into an exceptions table, as explained later in this section.

**Exceptions table.** To use the \texttt{NDB$OLD()} conflict resolution function, it is also necessary to create an exceptions table corresponding to each NDB table for which this type of conflict resolution is to be employed. This is also true when using \texttt{NDB$EPOCH()} or \texttt{NDB$EPOCH\_TRANS()} in MySQL Cluster NDB 7.1.16 and later. The name of this table is that of the table for which conflict resolution is to be applied, with the string \$EX appended. (For example, if the name of the original table is \texttt{mytable}, the name of the corresponding exception table name should be \texttt{mytable$EX}.) This table is created as follows:

```
CREATE TABLE original_table$EX (  
  server_id INT UNSIGNED,  
  master_server_id INT UNSIGNED,  
  master_epoch BIGINT UNSIGNED,  
  count INT UNSIGNED,  
  original_table_pk_columns,  
  [additional_columns,]  
  PRIMARY KEY(server_id, master_server_id, master_epoch, count)  
) ENGINE=NDB;
```

The first four columns are required. Following these columns, the columns making up the original table's primary key should be copied in the order in which they are used to define the primary key of the original table.

**Note**

The names of the first four columns and the columns matching the original table's primary key columns are not critical; however, we suggest for reasons of clarity and consistency, that you use the names shown here for the \texttt{server_id}, \texttt{master_server_id}, \texttt{master_epoch}, and \texttt{count} columns, and that you use the same names as in the original table for the columns matching those in the original table's primary key.

The data types for the columns duplicating the primary key columns of the original table should be the same as for (or larger than) the original columns.

Additional columns may optionally be defined following these columns, but not before any of them; any such extra columns cannot be \texttt{NOT NULL}. The exception table's primary key must be defined as shown. The exception table must use the NDB storage engine. An example that uses \texttt{NDB$OLD()} with an exceptions table is shown later in this section.

**Important**

The \texttt{mysql.ndb_replication} table is read when a data table is set up for replication, so the row corresponding to a table to be replicated must be inserted into \texttt{mysql.ndb_replication} before the table to be replicated is created.
Examples

The following examples assume that you have already a working MySQL Cluster replication setup, as described in Section 17.6.5, “Preparing the MySQL Cluster for Replication”, and Section 17.6.6, “Starting MySQL Cluster Replication (Single Replication Channel)

NDB$MAX() example. Suppose you wish to enable “greatest timestamp wins” conflict resolution on table test.t1, using column mycol as the “timestamp”. This can be done using the following steps:

1. Make sure that you have started the master mysqld with --ndb-log-update-as-write=OFF.
2. On the master, perform this INSERT statement:

```sql
INSERT INTO mysql.ndb_replication
VALUES ('test', 't1', 0, NULL, 'NDB$MAX(mycol)');
```

Inserting a 0 into the server_id indicates that all SQL nodes accessing this table should use conflict resolution. If you want to use conflict resolution on a specific mysqld only, use the actual server ID.

Inserting NULL into the binlog_type column has the same effect as inserting 0 (NBT_DEFAULT); the server default is used.

3. Create the test.t1 table:

```sql
CREATE TABLE test.t1 (mycol INT UNSIGNED)
) ENGINE=NDB;
```

Now, when updates are done on this table, conflict resolution is applied, and the version of the row having the greatest value for mycol is written to the slave.

Note

Other binlog_type options—such as NBT_UPDATED_ONLY_USE_UPDATE should be used to control logging on the master using the ndb_replication table rather than by using command-line options.

NDB$OLD() example. Suppose an NDB table such as the one defined here is being replicated, and you wish to enable “same timestamp wins” conflict resolution for updates to this table:

```sql
CREATE TABLE test.t2  (a INT UNSIGNED NOT NULL,
  b CHAR(25) NOT NULL,
  mycol INT UNSIGNED NOT NULL,
) ENGINE=NDB;
```

The following steps are required, in the order shown:

1. First—and prior to creating test.t2—you must insert a row into the mysql.ndb_replication table, as shown here:

```sql
INSERT INTO mysql.ndb_replication
VALUES ('test', 't2', 0, NULL, 'NDB$OLD(mycol)');
```

Possible values for the binlog_type column are shown earlier in this section. The value 'NDB $OLD(mycol)' should be inserted into the conflict_fn column.
2. Create an appropriate exceptions table for `test.t2`. The table creation statement shown here includes all required columns; any additional columns must be declared following these columns, and before the definition of the table's primary key.

```sql
CREATE TABLE test.t2$EX  (
    server_id SMALLINT UNSIGNED,
    master_server_id INT UNSIGNED,
    master_epoch BIGINT UNSIGNED,
    count BIGINT UNSIGNED,
    a INT UNSIGNED NOT NULL,
    b CHAR(25) NOT NULL,
    [additional_columns,]
    PRIMARY KEY(server_id, master_server_id, master_epoch, count)
)   ENGINE=NDB;
```

3. Create the table `test.t2` as shown previously.

These steps must be followed for every table for which you wish to perform conflict resolution using `NDB$OLD()`. For each such table, there must be a corresponding row in `mysql.ndb_replication`, and there must be an exceptions table in the same database as the table being replicated.

**17.7 MySQL Cluster NDB 6.1 - 7.1 Release Notes**

MySQL Cluster release notes are no longer published in the MySQL Reference Manual.

This chapter discusses MySQL's implementation of user-defined partitioning. You can determine whether your MySQL Server supports partitioning by means of a SHOW VARIABLES statement such as this one:

```
Note
The have_partitioning variable is deprecated, and removed in MySQL 5.6.1.
```

```
mysql> SHOW VARIABLES LIKE '%partition%';
+-------------------+-------+
| Variable_name     | Value |
+-------------------+-------+
| have_partitioning | YES   |
+-------------------+-------+
1 row in set (0.00 sec)
```

```
Note
Prior to MySQL 5.1.6, this variable was named have_partition_engine. (Bug #16718)
```

You can also check the output of the SHOW PLUGINS statement, like this:

```
mysql> SHOW PLUGINS;
+------------+----------+----------------+---------+---------+
| Name       | Status   | Type           | Library | License |
+------------+----------+----------------+---------+---------+
| binlog     | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| partition  | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| ARCHIVE    | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| BLACKHOLE  | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
| CSV        | ACTIVE   | STORAGE ENGINE | NULL    | GPL     |
+------------+----------+----------------+---------+---------+
```

2263
In MySQL 5.1.5 and later, you can also check the INFORMATION_SCHEMA.PLUGINS table with a query similar to this one:

```
mysql> SELECT PLUGIN_NAME as Name, PLUGIN_VERSION as Version, PLUGIN_STATUS as Status 
FROM INFORMATION_SCHEMA.PLUGINS 
WHERE PLUGIN_TYPE='STORAGE ENGINE';
```

Whichsoever of the preceding statements you employ, if you do not see the `partition` plugin listed with the value `ACTIVE` for the Status column in the output (shown in bold text in each of the examples just given), then your version of MySQL was not built with partitioning support.

MySQL 5.1 Community binaries provided by Oracle include partitioning support. For information about partitioning support offered in MySQL Enterprise Edition binaries, see Chapter 23, MySQL Enterprise Edition.

If you are compiling MySQL 5.1 from source, the build must be configured using `--with-partition` to enable partitioning. Using `--with-plugins=max` to configure the build includes this option automatically. For more information, see Section 2.11, “Installing MySQL from Source”.

If your MySQL binary is built with partitioning support, nothing further needs to be done to enable it (for example, no special entries are required in your `my.cnf` file).

If you want to disable partitioning support, you can start the MySQL Server with the `--skip-partition` option, in which case the value of `have_partitioning` is `DISABLED`. When partitioning support is disabled, you can see any existing partitioned tables and drop them (although doing this is not advised), but you cannot otherwise manipulate them or access their data.

See Section 18.1, “Overview of Partitioning in MySQL”, for an introduction to partitioning and partitioning concepts.

MySQL supports several types of partitioning as well as subpartitioning; see Section 18.2, “Partitioning Types”, and Section 18.2.5, “Subpartitioning”.

Section 18.3, “Partition Management”, covers methods of adding, removing, and altering partitions in existing partitioned tables.

Section 18.3.3, “Maintenance of Partitions”, discusses table maintenance commands for use with partitioned tables.
Beginning with MySQL 5.1.6, the `PARTITIONS` table in the `INFORMATION_SCHEMA` database provides information about partitions and partitioned tables. See Section 20.11, “The INFORMATION_SCHEMA PARTITIONS Table”, for more information; for some examples of queries against this table, see Section 18.2.6, “How MySQL Partitioning Handles NULL”.

**Important**

Partitioned tables created with MySQL versions prior to 5.1.6 cannot be read by a 5.1.6 or later MySQL Server. In addition, the `INFORMATION_SCHEMA.TABLES` table cannot be used if such tables are present on a 5.1.6 server. Beginning with MySQL 5.1.7, a suitable warning message is generated instead, to alert the user that incompatible partitioned tables have been found by the server.

If you are using partitioned tables which were created in MySQL 5.1.5 or earlier, be sure to see the Release Notes for MySQL 5.1.6 for more information and suggested workarounds before upgrading to MySQL 5.1.6 or later.

For known issues with partitioning in MySQL 5.1, see Section 18.5, “Restrictions and Limitations on Partitioning”.

You may also find the following resources to be useful when working with partitioned tables.

**Additional Resources.** Other sources of information about user-defined partitioning in MySQL include the following:

- **MySQL Partitioning Forum**
  
  This is the official discussion forum for those interested in or experimenting with MySQL Partitioning technology. It features announcements and updates from MySQL developers and others. It is monitored by members of the Partitioning Development and Documentation Teams.

- **Mikael Ronström's Blog**
  
  MySQL Partitioning Architect and Lead Developer Mikael Ronström frequently posts articles here concerning his work with MySQL Partitioning and MySQL Cluster.

- **PlanetMySQL**
  
  A MySQL news site featuring MySQL-related blogs, which should be of interest to anyone using my MySQL. We encourage you to check here for links to blogs kept by those working with MySQL Partitioning, or to have your own blog added to those covered.

MySQL 5.1 binaries are available from [http://dev.mysql.com/downloads/mysql/5.1.html](http://dev.mysql.com/downloads/mysql/5.1.html). However, for the latest partitioning bugfixes and feature additions, you can obtain the source from our Bazaar repository. To enable partitioning, you need to compile the server using the `--with-partition` option. For more information about building MySQL, see Section 2.11, “Installing MySQL from Source”. If you have problems compiling a partitioning-enabled MySQL 5.1 build, check the MySQL Partitioning Forum and ask for assistance there if you do not find a solution to your problem already posted.

### 18.1 Overview of Partitioning in MySQL

This section provides a conceptual overview of partitioning in MySQL 5.1.

For information on partitioning restrictions and feature limitations, see Section 18.5, “Restrictions and Limitations on Partitioning”.

The SQL standard does not provide much in the way of guidance regarding the physical aspects of data storage. The SQL language itself is intended to work independently of any data structures or media underlying the schemas, tables, rows, or columns with which it works. Nonetheless, most advanced database management systems have evolved some means of determining the physical...
Overview of Partitioning in MySQL

location to be used for storing specific pieces of data in terms of the file system, hardware or even both. In MySQL, the InnoDB storage engine has long supported the notion of a tablespace, and the MySQL Server, even prior to the introduction of partitioning, could be configured to employ different physical directories for storing different databases (see Section 8.12.4, “Using Symbolic Links”, for an explanation of how this is done).

**Partitioning** takes this notion a step further, by enabling you to distribute portions of individual tables across a file system according to rules which you can set largely as needed. In effect, different portions of a table are stored as separate tables in different locations. The user-selected rule by which the division of data is accomplished is known as a *partitioning function*, which in MySQL can be the modulus, simple matching against a set of ranges or value lists, an internal hashing function, or a linear hashing function. The function is selected according to the partitioning type specified by the user, and takes as its parameter the value of a user-supplied expression. This expression can be a column value, a function acting on one or more column values, or a set of one or more column values, depending on the type of partitioning that is used.

In the case of **RANGE**, **LIST**, and **LINEAR HASH** partitioning, the value of the partitioning column is passed to the partitioning function, which returns an integer value representing the number of the partition in which that particular record should be stored. This function must be nonconstant and nonrandom. It may not contain any queries, but may use an SQL expression that is valid in MySQL, as long as that expression returns either **NULL** or an integer **intval** such that

- \( -\text{MAXVALUE} <= \text{intval} <= \text{MAXVALUE} \)

(\(\text{MAXVALUE}\) is used to represent the least upper bound for the type of integer in question. \( -\text{MAXVALUE} \) represents the greatest lower bound.)

For **LINEAR KEY**, the partitioning expression consists of a list of one or more columns, and the partitioning function is supplied by MySQL.

For more information about permitted partitioning column types and partitioning functions, see Section 18.2, “Partitioning Types”, as well as Section 13.1.17, “CREATE TABLE Syntax”, which provides partitioning syntax descriptions and additional examples. For information about restrictions on partitioning functions, see Section 18.5.3, “Partitioning Limitations Relating to Functions”.

This is known as **horizontal partitioning**—that is, different rows of a table may be assigned to different physical partitions. MySQL 5.1 does not support **vertical partitioning**, in which different columns of a table are assigned to different physical partitions. There are no plans at this time to introduce vertical partitioning into MySQL.

For information about determining whether your MySQL Server binary supports user-defined partitioning, see Chapter 18, *Partitioning*.

For creating partitioned tables, you can use most storage engines that are supported by your MySQL server; the MySQL partitioning engine runs in a separate layer and can interact with any of these. In MySQL 5.1, all partitions of the same partitioned table must use the same storage engine; for example, you cannot use MyISAM for one partition and InnoDB for another. However, there is nothing preventing you from using different storage engines for different partitioned tables on the same MySQL server or even in the same database.

MySQL partitioning cannot be used with the **MERGE** or **CSV** storage engines. Beginning with MySQL 5.1.15, **FEDERATED** tables also cannot be partitioned (Bug #22451). Prior to MySQL 5.1.6, it was also not feasible to create a partitioned table using the **BLACKHOLE** storage engine (Bug #14524). See Section 18.5.2, “Partitioning Limitations Relating to Storage Engines”.

Partitioning by **KEY** or **LINEAR KEY** is possible with **NDBCLUSTER**, but other types of user-defined partitioning are not supported for tables using this storage engine. In addition, an **NDBCLUSTER** table that employs user-defined partitioning must have an explicit primary key, and any columns referenced in the table’s partitioning expression must be part of the primary key. However, if no columns are listed in the **PARTITION BY KEY** or **PARTITION BY LINEAR KEY** clause of the **CREATE TABLE** or **ALTER TABLE** command.
TABLE statement used to create or modify a user-partitioned NDBCLUSTER table, then the table is not required to have an explicit primary key. For more information, see Section 17.1.6.1, “Noncompliance with SQL Syntax in MySQL Cluster”.

To employ a particular storage engine for a partitioned table, it is necessary only to use the [STORAGE] ENGINE option just as you would for a nonpartitioned table. However, you should keep in mind that [STORAGE] ENGINE (and other table options) need to be listed before any partitioning options are used in a CREATE TABLE statement. This example shows how to create a table that is partitioned by hash into 6 partitions and which uses the InnoDB storage engine:

```
CREATE TABLE ti (id INT, amount DECIMAL(7,2), tr_date DATE)
  ENGINE=INNODB
  PARTITION BY HASH( MONTH(tr_date) )
  PARTITIONS 6;
```

Each PARTITION clause can include a [STORAGE] ENGINE option, but in MySQL 5.1 this has no effect.

---

Important

Partitioning applies to all data and indexes of a table; you cannot partition only the data and not the indexes, or vice versa, nor can you partition only a portion of the table.

Data and indexes for each partition can be assigned to a specific directory using the DATA DIRECTORY and INDEX DIRECTORY options for the PARTITION clause of the CREATE TABLE statement used to create the partitioned table.

Prior to MySQL 5.1.18, these options were permitted even when the NO_DIR_IN_CREATE server SQL mode was in effect (Bug #24633).

The DATA DIRECTORY and INDEX DIRECTORY options have no effect when defining partitions for tables using the InnoDB storage engine. DATA DIRECTORY and INDEX DIRECTORY are not supported for individual partitions or subpartitions on Windows. Beginning with MySQL 5.1.24, these options are ignored on Windows, except that a warning is generated (Bug #30459).

All columns used in the table’s partitioning expression must be part of every unique key that the table may have, including any primary key. This means that a table such as this one, created by the following SQL statement, cannot be partitioned:

```
CREATE TABLE tnp (
  id INT NOT NULL AUTO_INCREMENT,
  ref BIGINT NOT NULL,
  name VARCHAR(255),
  PRIMARY KEY pk (id),
  UNIQUE KEY uk (name)
);
```

Because the keys pk and uk have no columns in common, there are no columns available for use in a partitioning expression. Possible workarounds in this situation include adding the name column to the table’s primary key, adding the id column to uk, or simply removing the unique key altogether. See Section 18.5.1, “Partitioning Keys, Primary Keys, and Unique Keys”, for more information.

In addition, MAX_ROWS and MIN_ROWS can be used to determine the maximum and minimum numbers of rows, respectively, that can be stored in each partition. The MAX_ROWS option can be useful for causing MySQL Cluster tables to be created with extra partitions, thus allowing for greater storage of hash indexes. See the documentation for the DataMemory data node configuration parameter, as well as Section 17.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”, for more information.
Some advantages of partitioning are listed here:

- Partitioning makes it possible to store more data in one table than can be held on a single disk or file system partition.

- Data that loses its usefulness can often be easily removed from a partitioned table by dropping the partition (or partitions) containing only that data. Conversely, the process of adding new data can in some cases be greatly facilitated by adding one or more new partitions for storing specifically that data.

- Some queries can be greatly optimized in virtue of the fact that data satisfying a given \texttt{WHERE} clause can be stored only on one or more partitions, which automatically excludes any remaining partitions from the search. Because partitions can be altered after a partitioned table has been created, you can reorganize your data to enhance frequent queries that may not have been often used when the partitioning scheme was first set up. This ability to exclude non-matching partitions (and thus any rows they contain) is often referred to as \textit{partition pruning}, and was implemented in MySQL 5.1.6. For more information, see Section 18.4, “Partition Pruning”.

Other benefits usually associated with partitioning include those in the following list. These features are not currently implemented in MySQL Partitioning, but are high on our list of priorities.

- Queries involving aggregate functions such as \texttt{SUM()} and \texttt{COUNT()} can easily be parallelized. A simple example of such a query might be \texttt{SELECT salesperson_id, COUNT(orders) as order_total FROM sales GROUP BY salesperson_id;}. By “parallelized,” we mean that the query can be run simultaneously on each partition, and the final result obtained merely by summing the results obtained for all partitions.

- Achieving greater query throughput in virtue of spreading data seeks over multiple disks.

Be sure to check this section and chapter frequently for updates as MySQL Partitioning development continues.

### 18.2 Partitioning Types

This section discusses the types of partitioning which are available in MySQL 5.1. These include the types listed here:

- **RANGE partitioning.** This type of partitioning assigns rows to partitions based on column values falling within a given range. See Section 18.2.1, “RANGE Partitioning”.

- **LIST partitioning.** Similar to partitioning by \texttt{RANGE}, except that the partition is selected based on columns matching one of a set of discrete values. See Section 18.2.2, “LIST Partitioning”.

- **HASH partitioning.** With this type of partitioning, a partition is selected based on the value returned by a user-defined expression that operates on column values in rows to be inserted into the table. The function may consist of any expression valid in MySQL that yields a nonnegative integer value. An extension to this type, \texttt{LINEAR HASH}, is also available. See Section 18.2.3, “HASH Partitioning”.

- **KEY partitioning.** This type of partitioning is similar to partitioning by \texttt{HASH}, except that only one or more columns to be evaluated are supplied, and the MySQL server provides its own hashing function. These columns can contain other than integer values, since the hashing function supplied by MySQL guarantees an integer result regardless of the column data type. An extension to this type, \texttt{LINEAR KEY}, is also available. See Section 18.2.4, “KEY Partitioning”.

A very common use of database partitioning is to segregate data by date. Some database systems support explicit date partitioning, which MySQL does not implement in 5.1. However, it is not difficult in MySQL to create partitioning schemes based on \texttt{DATE}, \texttt{TIME}, or \texttt{DATETIME} columns, or based on expressions making use of such columns.
When partitioning by **KEY** or **LINEAR KEY**, you can use a **DATE**, **TIME**, or **DATETIME** column as the partitioning column without performing any modification of the column value. For example, this table creation statement is perfectly valid in MySQL:

```sql
CREATE TABLE members (  
    firstname VARCHAR(25) NOT NULL,  
    lastname VARCHAR(25) NOT NULL,  
    username VARCHAR(16) NOT NULL,  
    email VARCHAR(35),  
    joined DATE NOT NULL  
)  
PARTITION BY KEY(joined)  
PARTITIONS 6;
```

MySQL’s other partitioning types, however, require a partitioning expression that yields an integer value or **NULL**. If you wish to use date-based partitioning by **RANGE**, **LIST**, **HASH**, or **LINEAR HASH**, you can simply employ a function that operates on a **DATE**, **TIME**, or **DATETIME** column and returns such a value, as shown here:

```sql
CREATE TABLE members (  
    firstname VARCHAR(25) NOT NULL,  
    lastname VARCHAR(25) NOT NULL,  
    username VARCHAR(16) NOT NULL,  
    email VARCHAR(35),  
    joined DATE NOT NULL  
)  
PARTITION BY RANGE( YEAR(joined) ) (  
    PARTITION p0 VALUES LESS THAN (1960),  
    PARTITION p1 VALUES LESS THAN (1970),  
    PARTITION p2 VALUES LESS THAN (1980),  
    PARTITION p3 VALUES LESS THAN (1990),  
    PARTITION p4 VALUES LESS THAN MAXVALUE  
);
```

Additional examples of partitioning using dates may be found in the following sections of this chapter:

- Section 18.2.1, “RANGE Partitioning”
- Section 18.2.3, “HASH Partitioning”
- Section 18.2.3.1, “LINEAR HASH Partitioning”

For more complex examples of date-based partitioning, see the following sections:

- Section 18.4, “Partition Pruning”
- Section 18.2.5, “Subpartitioning”

MySQL partitioning is optimized for use with the **TO_DAYS()** and **YEAR()** functions. However, you can use other date and time functions that return an integer or **NULL**, such as **WEEKDAY()**, **DAYOFYEAR()**, or **MONTH()**. See Section 12.7, “Date and Time Functions”, for more information about such functions.

It is important to remember—regardless of the type of partitioning that you use—that partitions are always numbered automatically and in sequence when created, starting with 0. When a new row is inserted into a partitioned table, it is these partition numbers that are used in identifying the correct partition. For example, if your table uses 4 partitions, these partitions are numbered 0, 1, 2, and 3. For the **RANGE** and **LIST** partitioning types, it is necessary to ensure that there is a partition defined for each partition number. For **HASH** partitioning, the user function employed must return an integer value greater than 0. For **KEY** partitioning, this issue is taken care of automatically by the hashing function which the MySQL server employs internally.

Names of partitions generally follow the rules governing other MySQL identifiers, such as those for tables and databases. However, you should note that partition names are not case-sensitive. For example, the following **CREATE TABLE** statement fails as shown:
Failure occurs because MySQL sees no difference between the partition names mypart and MyPart.

When you specify the number of partitions for the table, this must be expressed as a positive, nonzero integer literal with no leading zeros, and may not be an expression such as 0.8E+01 or 6-2, even if it evaluates to an integer value. (Beginning with MySQL 5.1.12, decimal fractions are no longer truncated, but instead are prohibited entirely.)

In the sections that follow, we do not necessarily provide all possible forms for the syntax that can be used for creating each partition type; this information may be found in Section 13.1.17, “CREATE TABLE Syntax”.

### 18.2.1 RANGE Partitioning

A table that is partitioned by range is partitioned in such a way that each partition contains rows for which the partitioning expression value lies within a given range. Ranges should be contiguous but not overlapping, and are defined using the VALUES LESS THAN operator. For the next few examples, suppose that you are creating a table such as the following to hold personnel records for a chain of 20 video stores, numbered 1 through 20:

```
CREATE TABLE employees (  
id INT NOT NULL,  
fname VARCHAR(30),  
lname VARCHAR(30),  
hired DATE NOT NULL DEFAULT '1970-01-01',  
separated DATE NOT NULL DEFAULT '9999-12-31',  
job_code INT NOT NULL,  
store_id INT NOT NULL
);
```

**Note**

The `employees` table used here has no primary or unique keys. While the examples work as shown for purposes of the present discussion, you should keep in mind that tables are extremely likely in practice to have primary keys, unique keys, or both, and that allowable choices for partitioning columns depend on the columns used for these keys, if any are present. For a discussion of these issues, see Section 18.5.1, “Partitioning Keys, Primary Keys, and Unique Keys”.

This table can be partitioned by range in a number of ways, depending on your needs. One way would be to use the `store_id` column. For instance, you might decide to partition the table 4 ways by adding a PARTITION BY RANGE clause as shown here:

```
CREATE TABLE employees (  
id INT NOT NULL,  
fname VARCHAR(30),  
lname VARCHAR(30),  
hired DATE NOT NULL DEFAULT '1970-01-01',  
separated DATE NOT NULL DEFAULT '9999-12-31',  
job_code INT NOT NULL,  
store_id INT NOT NULL
) PARTITION BY RANGE (store_id) (
    PARTITION p0 VALUES LESS THAN (6),  
    PARTITION p1 VALUES LESS THAN (11),  
    PARTITION p2 VALUES LESS THAN (16),
```

```
In this partitioning scheme, all rows corresponding to employees working at stores 1 through 5 are stored in partition \textit{p0}, to those employed at stores 6 through 10 are stored in partition \textit{p1}, and so on. Note that each partition is defined in order, from lowest to highest. This is a requirement of the \textbf{PARTITION BY RANGE} syntax; you can think of it as being analogous to a series of \texttt{if} ... \texttt{elseif} ... statements in C or Java in this regard.

It is easy to determine that a new row containing the data \((72, 'Mitchell', 'Wilson', '1998-06-25', NULL, 13)\) is inserted into partition \textit{p2}, but what happens when your chain adds a 21\textsuperscript{st} store? Under this scheme, there is no rule that covers a row whose \texttt{store_id} is greater than 20, so an error results because the server does not know where to place it. You can keep this from occurring by using a “catchall” \texttt{VALUES LESS THAN} clause in the \texttt{CREATE TABLE} statement that provides for all values greater than the highest value explicitly named:

```sql
CREATE TABLE employees (  
id INT NOT NULL,
fname VARCHAR(30),
lname VARCHAR(30),
hired DATE NOT NULL DEFAULT '1970-01-01',
separated DATE NOT NULL DEFAULT '9999-12-31',
job_code INT NOT NULL,
store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (  
  PARTITION p0 VALUES LESS THAN (6),
  PARTITION p1 VALUES LESS THAN (11),
  PARTITION p2 VALUES LESS THAN (16),
  PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

\textbf{Note}

Another way to avoid an error when no matching value is found is to use the \texttt{IGNORE} keyword as part of the \texttt{INSERT} statement. For an example, see Section 18.2.2, “LIST Partitioning”. Also see Section 13.2.5, “INSERT Syntax”, for general information about \texttt{IGNORE}.

\texttt{MAXVALUE} represents an integer value that is always greater than the largest possible integer value (in mathematical language, it serves as a \textit{least upper bound}). Now, any rows whose \texttt{store_id} column value is greater than or equal to 16 (the highest value defined) are stored in partition \textit{p3}. At some point in the future—when the number of stores has increased to 25, 30, or more—you can use an \texttt{ALTER TABLE} statement to add new partitions for stores 21-25, 26-30, and so on (see Section 18.3, “Partition Management”, for details of how to do this).

In much the same fashion, you could partition the table based on employee job codes—that is, based on ranges of \texttt{job_code} column values. For example—assuming that two-digit job codes are used for regular (in-store) workers, three-digit codes are used for office and support personnel, and four-digit codes are used for management positions—you could create the partitioned table using the following statement:

```sql
CREATE TABLE employees (  
id INT NOT NULL,
fname VARCHAR(30),
lname VARCHAR(30),
hired DATE NOT NULL DEFAULT '1970-01-01',
separated DATE NOT NULL DEFAULT '9999-12-31',
job_code INT NOT NULL,
store_id INT NOT NULL
)
PARTITION BY RANGE (job_code) (  
  PARTITION p0 VALUES LESS THAN (100),
  PARTITION p1 VALUES LESS THAN (1000),
  PARTITION p2 VALUES LESS THAN (10000),
  PARTITION p3 VALUES LESS THAN MAXVALUE
);
```
In this instance, all rows relating to in-store workers would be stored in partition \texttt{p0}, those relating to office and support staff in \texttt{p1}, and those relating to managers in partition \texttt{p2}.

It is also possible to use an expression in VALUES \texttt{LESS THAN} clauses. However, MySQL must be able to evaluate the expression's return value as part of a \texttt{LESS THAN} (<) comparison.

Rather than splitting up the table data according to store number, you can use an expression based on one of the two DATE columns instead. For example, let us suppose that you wish to partition based on the year that each employee left the company; that is, the value of \texttt{YEAR(separated)}. An example of a \texttt{CREATE TABLE} statement that implements such a partitioning scheme is shown here:

```sql
CREATE TABLE employees (  
id INT NOT NULL,  
fname VARCHAR(30),  
lname VARCHAR(30),  
hired DATE NOT NULL DEFAULT '1970-01-01',  
separated DATE NOT NULL DEFAULT '9999-12-31',  
job_code INT,  
store_id INT  )  
PARTITION BY RANGE ( YEAR(separated) ) (    
    PARTITION p0 VALUES LESS THAN (1991),    
    PARTITION p1 VALUES LESS THAN (1996),    
    PARTITION p2 VALUES LESS THAN (2001),    
    PARTITION p3 VALUES LESS THAN MAXVALUE  )  
);  
```

In this scheme, for all employees who left before 1991, the rows are stored in partition \texttt{p0}; for those who left in the years 1991 through 1995, in \texttt{p1}; for those who left in the years 1996 through 2000, in \texttt{p2}; and for any workers who left after the year 2000, in \texttt{p3}.

Beginning with MySQL 5.1.43, it is also possible to partition a table by \texttt{RANGE} based on the value of a TIMESTAMP column, using the \texttt{UNIX_TIMESTAMP()} function, as shown in this example:

```sql
CREATE TABLE quarterly_report_status (  
report_id INT NOT NULL,  
report_status VARCHAR(20) NOT NULL,  
report_updated TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP  
)  
PARTITION BY RANGE ( UNIX_TIMESTAMP(report_updated) ) (    
    PARTITION p0 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-01-01 00:00:00') ),    
    PARTITION p1 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-04-01 00:00:00') ),    
    PARTITION p2 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-07-01 00:00:00') ),    
    PARTITION p3 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-10-01 00:00:00') ),    
    PARTITION p4 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-01-01 00:00:00') ),    
    PARTITION p5 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-04-01 00:00:00') ),    
    PARTITION p6 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-07-01 00:00:00') ),    
    PARTITION p7 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-10-01 00:00:00') ),    
    PARTITION p8 VALUES LESS THAN ( UNIX_TIMESTAMP('2010-01-01 00:00:00') ),    
    PARTITION p9 VALUES LESS THAN (MAXVALUE)  
)  
);  
```

Also beginning with MySQL 5.1.43, any other expressions involving TIMESTAMP values are not permitted. (See Bug \#42849.)

\textbf{Note}

It is also possible in MySQL 5.1.43 and later to use \texttt{UNIX_TIMESTAMP(timestamp_column)} as a partitioning expression for tables that are partitioned by \texttt{LIST}. However, it is usually not practical to do so.

Range partitioning is particularly useful when one or more of the following conditions is true:
• You want or need to delete “old” data. If you are using the partitioning scheme shown previously for the `employees` table, you can simply use `ALTER TABLE employees DROP PARTITION p0;` to delete all rows relating to employees who stopped working for the firm prior to 1991. (See Section 13.1.7, “ALTER TABLE Syntax”, and Section 18.3, “Partition Management”, for more information.) For a table with a great many rows, this can be much more efficient than running a `DELETE` query such as `DELETE FROM employees WHERE YEAR(separated) <= 1990;`.

• You want to use a column containing date or time values, or containing values arising from some other series.

• You frequently run queries that depend directly on the column used for partitioning the table. For example, when executing a query such as `EXPLAIN PARTITIONS SELECT COUNT(*) FROM employees WHERE separated BETWEEN '2000-01-01' AND '2000-12-31' GROUP BY store_id;`, MySQL can quickly determine that only partition `p2` needs to be scanned because the remaining partitions cannot contain any records satisfying the `WHERE` clause. See Section 18.4, “Partition Pruning”, for more information about how this is accomplished.

18.2.2 LIST Partitioning

List partitioning in MySQL is similar to range partitioning in many ways. As in partitioning by `RANGE`, each partition must be explicitly defined. The chief difference between the two types of partitioning is that, in list partitioning, each partition is defined and selected based on the membership of a column value in one of a set of value lists, rather than in one of a set of contiguous ranges of values. This is done by using `PARTITION BY LIST(expr)` where `expr` is a column value or an expression based on a column value and returning an integer value, and then defining each partition by means of a `VALUES IN (value_list)`, where `value_list` is a comma-separated list of integers.

Note

In MySQL 5.1, it is possible to match against only a list of integers (and possibly `NULL`—see Section 18.2.6, “How MySQL Partitioning Handles NULL”) when partitioning by `LIST`.

Unlike the case with partitions defined by range, list partitions do not need to be declared in any particular order. For more detailed syntactical information, see Section 13.1.17, “CREATE TABLE Syntax”.

For the examples that follow, we assume that the basic definition of the table to be partitioned is provided by the `CREATE TABLE` statement shown here:

```sql
CREATE TABLE employees (  
    id INT NOT NULL,  
    fname VARCHAR(30),  
    lname VARCHAR(30),  
    hired DATE NOT NULL DEFAULT '1970-01-01',  
    separated DATE NOT NULL DEFAULT '9999-12-31',  
    job_code INT,  
    store_id INT  
);
```

(This is the same table used as a basis for the examples in Section 18.2.1, “RANGE Partitioning”.)

Suppose that there are 20 video stores distributed among 4 franchises as shown in the following table.

<table>
<thead>
<tr>
<th>Region</th>
<th>Store ID Numbers</th>
</tr>
</thead>
<tbody>
<tr>
<td>North</td>
<td>3, 5, 6, 9, 17</td>
</tr>
<tr>
<td>East</td>
<td>1, 2, 10, 11, 19, 20</td>
</tr>
<tr>
<td>West</td>
<td>4, 12, 13, 14, 18</td>
</tr>
<tr>
<td>Central</td>
<td>7, 8, 15, 16</td>
</tr>
</tbody>
</table>
To partition this table in such a way that rows for stores belonging to the same region are stored in the same partition, you could use the `CREATE TABLE` statement shown here:

```sql
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)
PARTITION BY LIST(store_id) {
    PARTITION pNorth VALUES IN (3,5,6,9,17),
    PARTITION pEast VALUES IN (1,2,10,11,19,20),
    PARTITION pWest VALUES IN (4,12,13,14,18),
    PARTITION pCentral VALUES IN (7,8,15,16)
};
```

This makes it easy to add or drop employee records relating to specific regions to or from the table. For instance, suppose that all stores in the West region are sold to another company. All rows relating to employees working at stores in that region can be deleted with an `ALTER TABLE employees DROP PARTITION pWest` statement, which can be executed much more efficiently than the equivalent `DELETE` statement (`DELETE FROM employees WHERE store_id IN (4,12,13,14,18)`). However, the `ALTER TABLE ... DROP PARTITION` statement also removes the partition itself from the definition for the table, and you must execute an `ALTER TABLE ... ADD PARTITION` statement to restore the table's original partitioning scheme. (This problem is resolved in MySQL 5.5, which adds the `ALTER TABLE ... TRUNCATE PARTITION` statement for removing all rows from a given partition without affecting the table definition.)

As with `RANGE` partitioning, it is possible to combine `LIST` partitioning with partitioning by hash or key to produce a composite partitioning (subpartitioning). See Section 18.2.5, "Subpartitioning".

Unlike the case with `RANGE` partitioning, there is no “catch-all” such as `MAXVALUE`; all expected values for the partitioning expression should be covered in `PARTITION ... VALUES IN (...)` clauses. An `INSERT` statement containing an unmatched partitioning column value fails with an error, as shown in this example:

```sql
mysql> CREATE TABLE h2 (
    -> c1 INT,
    -> c2 INT
    ->
    ->)
    -> PARTITION BY LIST(c1) {
    -> PARTITION p0 VALUES IN (1, 4, 7),
    -> PARTITION p1 VALUES IN (2, 5, 8)
    ->
    ->);
Query OK, 0 rows affected (0.11 sec)

mysql> INSERT INTO h2 VALUES (3, 5);
ERROR 1525 (HY000): Table has no partition for value 3
```

When inserting multiple rows using a single `INSERT` statement the behavior depends on whether the table uses a transactional storage engine. For an InnoDB table, the statement is considered a single transaction, so the presence of any unmatched values causes the statement to fail completely, and no rows are inserted. For a table using a nontransactional storage engine such as MyISAM, any rows coming before the row containing the unmatched value are inserted, but any coming after it are not.

You can cause this type of error to be ignored by using the `IGNORE` keyword. If you do so, rows containing unmatched partitioning column values are not inserted, but any rows with matching values are inserted, and no errors are reported:

```sql
mysql> TRUNCATE h2;
Query OK, 1 row affected (0.00 sec)
```

2274
HASH Partitioning

Partitioning by **HASH** is used primarily to ensure an even distribution of data among a predetermined number of partitions. With range or list partitioning, you must specify explicitly into which partition a given column value or set of column values is to be stored; with hash partitioning, MySQL takes care of this for you, and you need only specify a column value or expression based on a column value to be hashed and the number of partitions into which the partitioned table is to be divided.

To partition a table using **HASH** partitioning, it is necessary to append to the **CREATE TABLE** statement a **PARTITION BY HASH (expr)** clause, where **expr** is an expression that returns an integer. This can simply be the name of a column whose type is one of MySQL’s integer types. In addition, you most likely want to follow this with **PARTITIONS num**, where **num** is a positive integer representing the number of partitions into which the table is to be divided.

**Note**

For simplicity, the tables in the examples that follow do not use any keys. You should be aware that, if a table has any unique keys, every column used in the partitioning expression for this table must be part of every unique key, including the primary key. See Section 18.5.1, “Partitioning Keys, Primary Keys, and Unique Keys”, for more information.

The following statement creates a table that uses hashing on the **store_id** column and is divided into 4 partitions:

```sql
CREATE TABLE employees (  
id INT NOT NULL,  
fname VARCHAR(30),  
lname VARCHAR(30),  
hired DATE NOT NULL DEFAULT '1970-01-01',  
separated DATE NOT NULL DEFAULT '9999-12-31',  
job_code INT,  
store_id INT  
)  
PARTITION BY HASH(store_id)  
PARTITIONS 4;
```

If you do not include a **PARTITIONS** clause, the number of partitions defaults to **1**.

Using the **PARTITIONS** keyword without a number following it results in a syntax error.

You can also use an SQL expression that returns an integer for **expr**. For instance, you might want to partition based on the year in which an employee was hired. This can be done as shown here:

```sql
CREATE TABLE employees (  
id INT NOT NULL,  
```
expr must return a nonconstant, nonrandom integer value (in other words, it should be varying but deterministic), and must not contain any prohibited constructs as described in Section 18.5, “Restrictions and Limitations on Partitioning”. You should also keep in mind that this expression is evaluated each time a row is inserted or updated (or possibly deleted); this means that very complex expressions may give rise to performance issues, particularly when performing operations (such as batch inserts) that affect a great many rows at one time.

The most efficient hashing function is one which operates upon a single table column and whose value increases or decreases consistently with the column value, as this allows for “pruning” on ranges of partitions. That is, the more closely that the expression varies with the value of the column on which it is based, the more efficiently MySQL can use the expression for hash partitioning.

For example, where date_col is a column of type DATE, then the expression TO_DAYS(date_col) is said to vary directly with the value of date_col, because for every change in the value of date_col, the value of the expression changes in a consistent manner. The variance of the expression YEAR(date_col) with respect to date_col is not quite as direct as that of TO_DAYS(date_col), because not every possible change in date_col produces an equivalent change in YEAR(date_col). Even so, YEAR(date_col) is a good candidate for a hashing function, because it varies directly with a portion of date_col and there is no possible change in date_col that produces a disproportionate change in YEAR(date_col).

By way of contrast, suppose that you have a column named int_col whose type is INT. Now consider the expression POW(5-int_col,3) + 6. This would be a poor choice for a hashing function because a change in the value of int_col is not guaranteed to produce a proportional change in the value of the expression. Changing the value of int_col by a given amount can produce by widely different changes in the value of the expression. For example, changing int_col from 5 to 6 produces a change of −1 in the value of the expression, but changing the value of int_col from 6 to 7 produces a change of −7 in the expression value.

In other words, the more closely the graph of the column value versus the value of the expression follows a straight line as traced by the equation y=cx where c is some nonzero constant, the better the expression is suited to hashing. This has to do with the fact that the more nonlinear an expression is, the more uneven the distribution of data among the partitions it tends to produce.

In theory, pruning is also possible for expressions involving more than one column value, but determining which of such expressions are suitable can be quite difficult and time-consuming. For this reason, the use of hashing expressions involving multiple columns is not particularly recommended.

When PARTITION BY HASH is used, MySQL determines which partition of num partitions to use based on the modulus of the result of the user function. In other words, for an expression expr, the partition in which the record is stored is partition number $N$, where $N = \text{MOD}(expr, \text{num})$. Suppose that table t1 is defined as follows, so that it has 4 partitions:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
    PARTITION BY HASH( YEAR(col3) )
    PARTITIONS 4;
```

If you insert a record into t1 whose col3 value is '2005-09-15', then the partition in which it is stored is determined as follows:
MySQL 5.1 also supports a variant of HASH partitioning known as *linear hashing* which employs a more complex algorithm for determining the placement of new rows inserted into the partitioned table. See Section 18.2.3.1, "LINEAR HASH Partitioning", for a description of this algorithm.

The user function is evaluated each time a record is inserted or updated. It may also—depending on the circumstances—be evaluated when records are deleted.

**Note**

If a table to be partitioned has a UNIQUE key, then any columns supplied as arguments to the HASH user function or to the KEY'S column_list must be part of that key.

### 18.2.3.1 LINEAR HASH Partitioning

MySQL also supports linear hashing, which differs from regular hashing in that linear hashing utilizes a linear powers-of-two algorithm whereas regular hashing employs the modulus of the hashing function's value.

Syntactically, the only difference between linear-hash partitioning and regular hashing is the addition of the LINEAR keyword in the PARTITION BY clause, as shown here:

```sql
CREATE TABLE employees (  
id INT NOT NULL,  
fname VARCHAR(30),  
lname VARCHAR(30),  
hired DATE NOT NULL DEFAULT '1970-01-01',  
separated DATE NOT NULL DEFAULT '9999-12-31',  
job_code INT,  
store_id INT  )  
PARTITION BY LINEAR HASH( YEAR(hired) )  
PARTITIONS 4;
```

Given an expression `expr`, the partition in which the record is stored when linear hashing is used is partition number `N` from among `num` partitions, where `N` is derived according to the following algorithm:

1. Find the next power of 2 greater than `num`. We call this value `V`; it can be calculated as:

   $$V = \text{POWER}(2, \text{CEILING} (\log(2, \text{num})))$$

   (Suppose that `num` is 13. Then \(\log(2,13)\) is 3.7004397181411. \(\text{CEILING}(3.7004397181411)\) is 4, and \(V = \text{POWER}(2,4)\), which is 16.)

2. Set \(N = F(\text{column_list}) \& (V - 1)\).

3. While \(N >= \text{num}\):

   • Set \(V = \text{CEIL}(V/2)\)
   • Set \(N = N \& (V - 1)\)

Suppose that the table `t1`, using linear hash partitioning and having 6 partitions, is created using this statement:

```sql
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)  
PARTITION BY LINEAR HASH( YEAR(col3) )  
PARTITIONS 6;
```
Now assume that you want to insert two records into `t1` having the `col3` column values '2003-04-14' and '1998-10-19'. The partition number for the first of these is determined as follows:

\[ V = \text{POWER}(2, \text{CEILING}(\text{LOG}(2,6))) = 8 \]
\[ N = \text{YEAR('2003-04-14')} & (8 - 1) \]
\[ = 2003 & 7 \]
\[ = 3 \]
\[ (3 >= 6 \text{ is FALSE: record stored in partition } #3) \]

The number of the partition where the second record is stored is calculated as shown here:

\[ V = 8 \]
\[ N = \text{YEAR('1998-10-19')} & (8-1) \]
\[ = 1998 & 7 \]
\[ = 6 \]
\[ (6 >= 6 \text{ is TRUE: additional step required}) \]
\[ N = 6 & \text{CEILING}(8 / 2) \]
\[ = 6 & 3 \]
\[ = 2 \]
\[ (2 >= 6 \text{ is FALSE: record stored in partition } #2) \]

The advantage in partitioning by linear hash is that the adding, dropping, merging, and splitting of partitions is made much faster, which can be beneficial when dealing with tables containing extremely large amounts (terabytes) of data. The disadvantage is that data is less likely to be evenly distributed between partitions as compared with the distribution obtained using regular hash partitioning.

### 18.2.4 KEY Partitioning

Partitioning by key is similar to partitioning by hash, except that where hash partitioning employs a user-defined expression, the hashing function for key partitioning is supplied by the MySQL server. MySQL Cluster uses `MD5()` for this purpose; for tables using other storage engines, the server employs its own internal hashing function which is based on the same algorithm as `PASSWORD()`.

The syntax rules for `CREATE TABLE ... PARTITION BY KEY` are similar to those for creating a table that is partitioned by hash. The major differences are listed here:

- **KEY** is used rather than **HASH**.

- **KEY** takes only a list of one or more column names. Beginning with MySQL 5.1.5, the column or columns used as the partitioning key must comprise part or all of the table's primary key, if the table has one.

Beginning with MySQL 5.1.6, **KEY** takes a list of zero or more column names. Where no column name is specified as the partitioning key, the table's primary key is used, if there is one. For example, the following `CREATE TABLE` statement is valid in MySQL 5.1.6 or later:

```sql
CREATE TABLE k1 (
    id INT NOT NULL PRIMARY KEY,
    name VARCHAR(20)
) PARTITION BY KEY() PARTITIONS 2;
```

If there is no primary key but there is a unique key, then the unique key is used for the partitioning key:
CREATE TABLE k1 (  id INT NOT NULL,  name VARCHAR(20),  UNIQUE KEY (id) )  PARTITION BY KEY()  PARTITIONS 2;

However, if the unique key column were not defined as NOT NULL, then the previous statement would fail.

In both of these cases, the partitioning key is the id column, even though it is not shown in the output of SHOW CREATE TABLE or in the PARTITION_EXPRESSION column of the INFORMATION_SCHEMA.PARTITIONS table.

Unlike the case with other partitioning types, columns used for partitioning by KEY are not restricted to integer or NULL values. For example, the following CREATE TABLE statement is valid:

CREATE TABLE tm1 (  s1 CHAR(32) PRIMARY KEY  )  PARTITION BY KEY(s1)  PARTITIONS 10;

The preceding statement would not be valid, were a different partitioning type to be specified. (In this case, simply using PARTITION BY KEY() would also be valid and have the same effect as PARTITION BY KEY(s1), since s1 is the table's primary key.)

For additional information about this issue, see Section 18.5, “Restrictions and Limitations on Partitioning”.

Note

Also beginning with MySQL 5.1.6, tables using the NDBCLUSTER storage engine are implicitly partitioned by KEY, again using the table's primary key as the partitioning key. In the event that the MySQL Cluster table has no explicit primary key, the “hidden” primary key generated by the NDBCLUSTER storage engine for each MySQL Cluster table is used as the partitioning key.

Beginning with MySQL Cluster NDB 6.2.18, MySQL Cluster NDB 6.3.25, and MySQL Cluster NDB 7.0.6, if you define an explicit partitioning scheme for an NDBCLUSTER table, the table must have an explicit primary key, and any columns used in the partitioning expression must be part of this key. However, if the table uses an “empty” partitioning expression—that is, PARTITION BY KEY() with no column references—then no explicit primary key is required.

You can observe this partitioning using the ndb_desc utility (with the -p option).

Important

For a key-partitioned table using any MySQL storage engine other than NDBCLUSTER, you cannot execute an ALTER TABLE DROP PRIMARY KEY, as doing so generates the error ERROR 1466 (HY000): Field in list of fields for partition function not found in table. This is not an issue for MySQL Cluster tables which are partitioned by KEY; in such cases, the table is reorganized using the “hidden” primary key as the table's new partitioning key. See Chapter 17, MySQL Cluster NDB 6.1 - 7.1.

It is also possible to partition a table by linear key. Here is a simple example:
Using \texttt{LINEAR} has the same effect on \texttt{KEY} partitioning as it does on \texttt{HASH} partitioning, with the partition number being derived using a powers-of-two algorithm rather than modulo arithmetic. See Section 18.2.3.1, “LINEAR HASH Partitioning”, for a description of this algorithm and its implications.

### 18.2.5 Subpartitioning

Subpartitioning—also known as \textit{composite partitioning}—is the further division of each partition in a partitioned table. Consider the following \texttt{CREATE TABLE} statement:

```sql
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE( YEAR(purchased) )
SUBPARTITION BY HASH( TO_DAYS(purchased) )
SUBPARTITIONS 2 {
    PARTITION p0 VALUES LESS THAN (1990),
    PARTITION p1 VALUES LESS THAN (2000),
    PARTITION p2 VALUES LESS THAN MAXVALUE
};
```

Table \texttt{ts} has 3 \texttt{RANGE} partitions. Each of these partitions—\texttt{p0}, \texttt{p1}, and \texttt{p2}—is further divided into 2 subpartitions. In effect, the entire table is divided into $3 \times 2 = 6$ partitions. However, due to the action of the \texttt{PARTITION BY RANGE} clause, the first 2 of these store only those records with a value less than 1990 in the \texttt{purchased} column.

In MySQL 5.1, it is possible to subpartition tables that are partitioned by \texttt{RANGE} or \texttt{LIST}. Subpartitions may use either \texttt{HASH} or \texttt{KEY} partitioning. This is also known as \textit{composite partitioning}.

**Note**

\texttt{SUBPARTITION BY HASH} and \texttt{SUBPARTITION BY KEY} generally follow the same syntax rules as \texttt{PARTITION BY HASH} and \texttt{PARTITION BY KEY}, respectively. An exception to this is that \texttt{SUBPARTITION BY KEY} (unlike \texttt{PARTITION BY KEY}) does not currently support a default column, so the column used for this purpose must be specified, even if the table has an explicit primary key. This is a known issue which we are working to address; see Issues with subpartitions, for more information and an example.

It is also possible to define subpartitions explicitly using \texttt{SUBPARTITION} clauses to specify options for individual subpartitions. For example, a more verbose fashion of creating the same table \texttt{ts} as shown in the previous example would be:

```sql
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE( YEAR(purchased) )
SUBPARTITION BY HASH( TO_DAYS(purchased) ) {
    PARTITION p0 VALUES LESS THAN (1990) {
        SUBPARTITION s0,
        SUBPARTITION s1
    },
    PARTITION p1 VALUES LESS THAN (2000) {
        SUBPARTITION s2,
        SUBPARTITION s3
    },
    PARTITION p2 VALUES LESS THAN MAXVALUE {
        SUBPARTITION s4,
    }
};
```
Some syntactical items of note are listed here:

- Each partition must have the same number of subpartitions.
- If you explicitly define any subpartitions using `SUBPARTITION` on any partition of a partitioned table, you must define them all. In other words, the following statement will fail:

```sql
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE( YEAR(purchased) )
SUBPARTITION BY HASH( TO_DAYS(purchased) )
(PARTITION p0 VALUES LESS THAN (1990) {
  SUBPARTITION s0,
  SUBPARTITION s1
},
PARTITION p1 VALUES LESS THAN (2000),
PARTITION p2 VALUES LESS THAN MAXVALUE {
  SUBPARTITION s2,
  SUBPARTITION s3
});
```

This statement would still fail even if it included a `SUBPARTITIONS 2` clause.

- Each `SUBPARTITION` clause must include (at a minimum) a name for the subpartition. Otherwise, you may set any desired option for the subpartition or allow it to assume its default setting for that option.

- In MySQL 5.1.7 and earlier, names of subpartitions were required to be unique within each partition, but did not have to be unique within the table as a whole. Beginning with MySQL 5.1.8, subpartition names must be unique across the entire table. For example, the following `CREATE TABLE` statement is valid in MySQL 5.1.8 and later:

```sql
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE( YEAR(purchased) )
SUBPARTITION BY HASH( TO_DAYS(purchased) )
(PARTITION p0 VALUES LESS THAN (1990) {
  SUBPARTITION s0
},
PARTITION p1 VALUES LESS THAN (2000),
PARTITION p2 VALUES LESS THAN MAXVALUE {
  SUBPARTITION s4,
  SUBPARTITION s5
});
```

(The previous statement is also valid for versions of MySQL prior to 5.1.8.)

Subpartitions can be used with especially large tables to distribute data and indexes across many disks. Suppose that you have 6 disks mounted as `/disk0`, `/disk1`, `/disk2`, and so on. Now consider the following example:

```sql
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE( YEAR(purchased) )
SUBPARTITION BY HASH( TO_DAYS(purchased) )
(PARTITION p0 VALUES LESS THAN (1990) {
  SUBPARTITION s0
  DATA DIRECTORY = '/disk0/data'
},
```
Subpartitioning

CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE(YEAR(purchased))
SUBPARTITION BY HASH(TO_DAYS(purchased))
PARTITION p0 VALUES LESS THAN (1990) {
  SUBPARTITION s0a
  DATA DIRECTORY = '/disk0'
  INDEX DIRECTORY = '/disk1',
  SUBPARTITION s0b
  DATA DIRECTORY = '/disk2'
  INDEX DIRECTORY = '/disk3'
},
PARTITION p1 VALUES LESS THAN (2000) {
  SUBPARTITION s1a
  DATA DIRECTORY = '/disk4'
  INDEX DIRECTORY = '/disk4/idx',
  SUBPARTITION s1b
  DATA DIRECTORY = '/disk5'
  INDEX DIRECTORY = '/disk5/idx'
},
PARTITION p2 VALUES LESS THAN MAXVALUE {
  SUBPARTITION s2a,
  SUBPARTITION s2b,
}
);

In this case, a separate disk is used for the data and for the indexes of each RANGE. Many other variations are possible; another example might be:

Here, the storage is as follows:

- Rows with purchased dates from before 1990 take up a vast amount of space, so are split up 4 ways, with a separate disk dedicated to the data and to the indexes for each of the two subpartitions (s0a and s0b) making up partition p0. In other words:
  - The data for subpartition s0a is stored on disk0.
  - The indexes for subpartition s0a are stored on disk1.
  - The data for subpartition s0b is stored on disk2.
  - The indexes for subpartition s0b are stored on disk3.

- Rows containing dates ranging from 1990 to 1999 (partition p1) do not require as much room as those from before 1990. These are split between 2 disks (/disk4 and /disk5) rather than 4 disks as with the legacy records stored in p0:
• Data and indexes belonging to p1’s first subpartition (s1a) are stored on /disk4—the data in /disk4/data, and the indexes in /disk4/idx.

• Data and indexes belonging to p1’s second subpartition (s1b) are stored on /disk5—the data in /disk5/data, and the indexes in /disk5/idx.

• Rows reflecting dates from the year 2000 to the present (partition p2) do not take up as much space as required by either of the two previous ranges. Currently, it is sufficient to store all of these in the default location.

In future, when the number of purchases for the decade beginning with the year 2000 grows to a point where the default location no longer provides sufficient space, the corresponding rows can be moved using an ALTER TABLE ... REORGANIZE PARTITION statement. See Section 18.3, “Partition Management”, for an explanation of how this can be done.

Beginning with MySQL 5.1.18, the DATA DIRECTORY and INDEX DIRECTORY options are not permitted in partition definitions when the NO_DIR_IN_CREATE server SQL mode is in effect. However, this not true when defining subpartitions; this is a known issue which is fixed in MySQL 5.5 (Bug #42954).

18.2.6 How MySQL Partitioning Handles NULL

Partitioning in MySQL does nothing to disallow NULL as the value of a partitioning expression, whether it is a column value or the value of a user-supplied expression. Even though it is permitted to use NULL as the value of an expression that must otherwise yield an integer, it is important to keep in mind that NULL is not a number. Beginning with MySQL 5.1.8, the partitioning implementation treats NULL as being less than any non-NUL value, just as ORDER BY does.

This means that treatment of NULL varies between partitioning of different types, and may produce behavior which you do not expect if you are not prepared for it. This being the case, we discuss in this section how each MySQL partitioning type handles NULL values when determining the partition in which a row should be stored, and provide examples for each.

Handling of NULL with RANGE partitioning. If you insert a row into a table partitioned by RANGE such that the column value used to determine the partition is NULL, the row is inserted into the lowest partition. Consider these two tables in a database named p, created as follows:

```sql
mysql> CREATE TABLE t1 (  -> c1 INT,  -> c2 VARCHAR(20)  -> )  -> PARTITION BY RANGE(c1) {  -> PARTITION p0 VALUES LESS THAN (0),  -> PARTITION p1 VALUES LESS THAN (10),  -> PARTITION p2 VALUES LESS THAN MAXVALUE  -> };
Query OK, 0 rows affected (0.09 sec)

mysql> CREATE TABLE t2 (  -> c1 INT,  -> c2 VARCHAR(20)  -> )  -> PARTITION BY RANGE(c1) {  -> PARTITION p0 VALUES LESS THAN (-5),  -> PARTITION p1 VALUES LESS THAN (0),  -> PARTITION p2 VALUES LESS THAN (10),  -> PARTITION p3 VALUES LESS THAN MAXVALUE  -> };
Query OK, 0 rows affected (0.09 sec)
```

You can see the partitions created by these two CREATE TABLE statements using the following query against the PARTITIONS table in the INFORMATION_SCHEMA database:
How MySQL Partitioning Handles NULL

mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 't_';
+------------+----------------+------------+----------------+-------------+
<table>
<thead>
<tr>
<th>TABLE_NAME</th>
<th>PARTITION_NAME</th>
<th>TABLE_ROWS</th>
<th>AVG_ROW_LENGTH</th>
<th>DATA_LENGTH</th>
</tr>
</thead>
<tbody>
<tr>
<td>t1</td>
<td>p0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>t1</td>
<td>p1</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>t1</td>
<td>p2</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>t2</td>
<td>p0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>t2</td>
<td>p1</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>t2</td>
<td>p2</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>t2</td>
<td>p3</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>
+------------+----------------+------------+----------------+-------------+
7 rows in set (0.00 sec)

(For more information about this table, see Section 20.11, “The INFORMATION_SCHEMA PARTITIONS Table.”) Now let us populate each of these tables with a single row containing a NULL in the column used as the partitioning key, and verify that the rows were inserted using a pair of SELECT statements:

mysql> INSERT INTO t1 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM t1;
+------+--------+
| id   | name   |
| NULL | mothra |
+------+--------+
1 row in set (0.00 sec)

mysql> SELECT * FROM t2;
+------+--------+
| id   | name   |
| NULL | mothra |
+------+--------+
1 row in set (0.00 sec)

You can see which partitions are used to store the inserted rows by rerunning the previous query against INFORMATION_SCHEMA.PARTITIONS and inspecting the output:

mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 't_';
+------------+----------------+------------+----------------+-------------+
<table>
<thead>
<tr>
<th>TABLE_NAME</th>
<th>PARTITION_NAME</th>
<th>TABLE_ROWS</th>
<th>AVG_ROW_LENGTH</th>
<th>DATA_LENGTH</th>
</tr>
</thead>
<tbody>
<tr>
<td>t1</td>
<td>p0</td>
<td>1</td>
<td>20</td>
<td>20</td>
</tr>
<tr>
<td>t1</td>
<td>p1</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>t1</td>
<td>p2</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>t2</td>
<td>p0</td>
<td>1</td>
<td>20</td>
<td>20</td>
</tr>
<tr>
<td>t2</td>
<td>p1</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>t2</td>
<td>p2</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>t2</td>
<td>p3</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>
+------------+----------------+------------+----------------+-------------+
7 rows in set (0.01 sec)

You can also demonstrate that these rows were stored in the lowest partition of each table by dropping these partitions, and then re-running the SELECT statements:

mysql> ALTER TABLE t1 DROP PARTITION p0;
Important

Prior to MySQL 5.1.8, RANGE partitioning treated a partitioning expression value of NULL as 0 with respect to determining placement. (The only way to circumvent this behavior was to design tables so as not to permit nulls, usually by declaring columns NOT NULL.) If you have a RANGE partitioning scheme that depends on this earlier behavior, you must re-implement it when upgrading to MySQL 5.1.8 or later. (Bug #15447)

NULL is also treated in this way for partitioning expressions that use SQL functions. Suppose that we define a table using a CREATE TABLE statement such as this one:

```sql
CREATE TABLE tndate (
    id INT,
    dt DATE
) PARTITION BY RANGE( YEAR(dt) ) (
    PARTITION p0 VALUES LESS THAN (1990),
    PARTITION p1 VALUES LESS THAN (2000),
    PARTITION p2 VALUES LESS THAN MAXVALUE
);
```

As with other MySQL functions, YEAR(NULL) returns NULL. A row with a dt column value of NULL is treated as though the partitioning expression evaluated to a value less than any other value, and so is inserted into partition p0.

Handling of NULL with LIST partitioning. A table that is partitioned by LIST admits NULL values if and only if one of its partitions is defined using that value-list that contains NULL. The converse of this is that a table partitioned by LIST which does not explicitly use NULL in a value list rejects rows resulting in a NULL value for the partitioning expression, as shown in this example:

```sql
mysql> CREATE TABLE ts1 (
    -> c1 INT,
    -> c2 VARCHAR(20)
    -> )
    -> ) PARTITION BY LIST(c1) (  
    -> PARTITION p0 VALUES IN (0, 3, 6),
    -> PARTITION p1 VALUES IN (1, 4, 7),
    -> PARTITION p2 VALUES IN (2, 5, 8)
    -> )
Query OK, 0 rows affected (0.01 sec)
```

mysql> INSERT INTO ts1 VALUES (9, 'mothra');
ERROR 1504 (HY000): Table has no partition for value 9

mysql> INSERT INTO ts1 VALUES (NULL, 'mothra');
ERROR 1504 (HY000): Table has no partition for value NULL

Only rows having a c1 value between 0 and 8 inclusive can be inserted into ts1. NULL falls outside this range, just like the number 9. We can create tables ts2 and ts3 having value lists containing NULL, as shown here:

```sql
mysql> CREATE TABLE ts2 (  
```
How MySQL Partitioning Handles NULL

When defining value lists for partitioning, you can (and should) treat NULL just as you would any other value. For example, both `VALUES IN (NULL)` and `VALUES IN (1, 4, 7, NULL)` are valid, as are `VALUES IN (1, NULL, 4, 7), VALUES IN (NULL, 1, 4, 7)`, and so on. You can insert a row having NULL for column `c1` into each of the tables `ts2` and `ts3`:

```sql
mysql> INSERT INTO ts2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)
mysql> INSERT INTO ts3 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)
```

By issuing the appropriate query against `INFORMATION_SCHEMA.PARTITIONS`, you can determine which partitions were used to store the rows just inserted (we assume, as in the previous examples, that the partitioned tables were created in the `p` database):

```sql
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
FROM INFORMATION_SCHEMA.PARTITIONS
WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 'ts_';
```

As shown earlier in this section, you can also verify which partitions were used for storing the rows by deleting these partitions and then performing a `SELECT`. Handling of NULL with HASH and KEY partitioning. NULL is handled somewhat differently for tables partitioned by HASH or KEY. In these cases, any partition expression that yields a NULL value is treated as though its return value were zero. We can verify this behavior by examining the effects on the file system of creating a table partitioned by HASH and populating it with a record containing appropriate values. Suppose that you have a table `th` (also in the `p` database) created using the following statement:

```sql
mysql> CREATE TABLE th (  
    -> c1 INT,
"
The partitions belonging to this table can be viewed using the query shown here:

```sql
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
    -> FROM INFORMATION_SCHEMA.PARTITIONS
    -> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME = 'th';
```

<table>
<thead>
<tr>
<th>TABLE_NAME</th>
<th>PARTITION_NAME</th>
<th>TABLE_ROWS</th>
<th>AVG_ROW_LENGTH</th>
<th>DATA_LENGTH</th>
</tr>
</thead>
<tbody>
<tr>
<td>th</td>
<td>p0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>th</td>
<td>p1</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

2 rows in set (0.00 sec)

Note that `TABLE_ROWS` for each partition is 0. Now insert two rows into `th` whose `c1` column values are `NULL` and 0, and verify that these rows were inserted, as shown here:

```sql
mysql> INSERT INTO th VALUES (NULL, 'mothra'), (0, 'gigan');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM th;
```

<table>
<thead>
<tr>
<th>c1</th>
<th>c2</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL</td>
<td>mothra</td>
</tr>
<tr>
<td>0</td>
<td>gigan</td>
</tr>
</tbody>
</table>

2 rows in set (0.01 sec)

Recall that for any integer `N`, the value of `NULL MOD N` is always `NULL`. For tables that are partitioned by `HASH` or `KEY`, this result is treated for determining the correct partition as 0. Checking the `INFORMATION_SCHEMA.PARTITIONS` table once again, we can see that both rows were inserted into partition `p0`:

```sql
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
    -> FROM INFORMATION_SCHEMA.PARTITIONS
    -> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME = 'th';
```

<table>
<thead>
<tr>
<th>TABLE_NAME</th>
<th>PARTITION_NAME</th>
<th>TABLE_ROWS</th>
<th>AVG_ROW_LENGTH</th>
<th>DATA_LENGTH</th>
</tr>
</thead>
<tbody>
<tr>
<td>th</td>
<td>p0</td>
<td>2</td>
<td>20</td>
<td>20</td>
</tr>
<tr>
<td>th</td>
<td>p1</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

2 rows in set (0.00 sec)

If you repeat this example using `PARTITION BY KEY` in place of `PARTITION BY HASH` in the definition of the table, you can verify easily that `NULL` is also treated like 0 for this type of partitioning.

### 18.3 Partition Management

MySQL 5.1 provides a number of ways to modify partitioned tables. It is possible to add, drop, redefine, merge, or split existing partitions. All of these actions can be carried out using the partitioning extensions to the `ALTER TABLE` statement. There are also ways to obtain information about partitioned tables and partitions. We discuss these topics in the sections that follow.

- For information about partition management in tables partitioned by `RANGE` or `LIST`, see Section 18.3.1, “Management of RANGE and LIST Partitions.”
• For a discussion of managing HASH and KEY partitions, see Section 18.3.2, "Management of HASH and KEY Partitions".

• See Section 18.3.4, "Obtaining Information About Partitions", for a discussion of mechanisms provided in MySQL 5.1 for obtaining information about partitioned tables and partitions.

• For a discussion of performing maintenance operations on partitions, see Section 18.3.3, "Maintenance of Partitions".

Note

In MySQL 5.1, all partitions of a partitioned table must have the same number of subpartitions, and it is not possible to change the subpartitioning once the table has been created.

The statement ALTER TABLE ... PARTITION BY ... is available and is functional beginning with MySQL 5.1.6; previously in MySQL 5.1, this was accepted as valid syntax, but the statement did nothing.

To change a table's partitioning scheme, it is necessary only to use the ALTER TABLE statement with a partition_options clause. This clause has the same syntax as that as used with CREATE TABLE for creating a partitioned table, and always begins with the keywords PARTITION BY. Suppose that you have a table partitioned by range using the following CREATE TABLE statement:

```
CREATE TABLE trb3 (id INT, name VARCHAR(50), purchased DATE)
PARTITION BY RANGE( YEAR(purchased) )
  (PARTITION p0 VALUES LESS THAN (1990),
   PARTITION p1 VALUES LESS THAN (1995),
   PARTITION p2 VALUES LESS THAN (2000),
   PARTITION p3 VALUES LESS THAN (2005));
```

To repartition this table so that it is partitioned by key into two partitions using the id column value as the basis for the key, you can use this statement:

```
ALTER TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;
```

This has the same effect on the structure of the table as dropping the table and re-creating it using CREATE TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;

In MySQL 5.1.7 and earlier MySQL 5.1 releases, ALTER TABLE ... ENGINE = ... removed all partitioning from the affected table. Beginning with MySQL 5.1.8, this statement changes only the storage engine used by the table, and leaves the table's partitioning scheme intact. As of MySQL 5.1.8, use ALTER TABLE ... REMOVE PARTITIONING to remove a table's partitioning. See Section 13.1.7, "ALTER TABLE Syntax".

Important

Only a single PARTITION BY, ADD PARTITION, DROP PARTITION, REORGANIZE PARTITION, or COALESCE PARTITION clause can be used in a given ALTER TABLE statement. If you (for example) wish to drop a partition and reorganize a table's remaining partitions, you must do so in two separate ALTER TABLE statements (one using DROP PARTITION and then a second one using REORGANIZE PARTITIONS).

18.3.1 Management of RANGE and LIST Partitions

Range and list partitions are very similar with regard to how the adding and dropping of partitions are handled. For this reason we discuss the management of both sorts of partitioning in this section. For information about working with tables that are partitioned by hash or key, see Section 18.3.2.
"Management of HASH and KEY Partitions". Dropping a **RANGE** or **LIST** partition is more straightforward than adding one, so we discuss this first.

Dropping a partition from a table that is partitioned by either **RANGE** or by **LIST** can be accomplished using the **ALTER TABLE** statement with a **DROP PARTITION** clause. Here is a very basic example, which supposes that you have already created a table which is partitioned by range and then populated with 10 records using the following **CREATE TABLE** and **INSERT** statements:

```sql
mysql> CREATE TABLE tr (id INT, name VARCHAR(50), purchased DATE)
Query OK, 0 rows affected (0.01 sec)
```

```sql
mysql> INSERT INTO tr VALUES
    -> (1, 'desk organiser', '2003-10-15'),
    -> (2, 'CD player', '1993-11-05'),
    -> (3, 'TV set', '1996-03-10'),
    -> (4, 'bookcase', '1982-01-10'),
    -> (5, 'exercise bike', '2004-05-09'),
    -> (6, 'sofa', '1987-06-05'),
    -> (7, 'popcorn maker', '2001-11-22'),
    -> (8, 'aquarium', '1992-08-04'),
    -> (9, 'study desk', '1984-09-16'),
    -> (10, 'lava lamp', '1998-12-25');
Query OK, 10 rows affected (0.01 sec)
```

You can see which items should have been inserted into partition **p2** as shown here:

```sql
mysql> SELECT * FROM tr
    -> WHERE purchased BETWEEN '1995-01-01' AND '1999-12-31';
```

<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
<th>purchased</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>TV set</td>
<td>1996-03-10</td>
</tr>
<tr>
<td>10</td>
<td>lava lamp</td>
<td>1998-12-25</td>
</tr>
</tbody>
</table>

2 rows in set (0.00 sec)

To drop the partition named **p2**, execute the following command:

```sql
mysql> ALTER TABLE tr DROP PARTITION p2;
Query OK, 0 rows affected (0.03 sec)
```

**Note**

The **NDBCLUSTER** storage engine does not support **ALTER TABLE ... DROP PARTITION**. It does, however, support the other partitioning-related extensions to **ALTER TABLE** that are described in this chapter.

It is very important to remember that, **when you drop a partition, you also delete all the data that was stored in that partition**. You can see that this is the case by re-running the previous **SELECT** query:

```sql
mysql> SELECT * FROM tr WHERE purchased
    -> BETWEEN '1995-01-01' AND '1999-12-31';
```

Empty set (0.00 sec)

Because of this, the requirement was added in MySQL 5.1.10 that you have the **DROP** privilege for a table before you can execute **ALTER TABLE ... DROP PARTITION** on that table.

If you wish to drop all data from all partitions while preserving the table definition and its partitioning scheme, use the **TRUNCATE TABLE** statement. (See **Section 13.1.34, "TRUNCATE TABLE Syntax"**.)
If you intend to change the partitioning of a table without losing data, use `ALTER TABLE ... REORGANIZE PARTITION` instead. See below or in Section 13.1.7, “ALTER TABLE Syntax”, for information about `REORGANIZE PARTITION`.

If you now execute a `SHOW CREATE TABLE` statement, you can see how the partitioning makeup of the table has been changed:

```sql
mysql> SHOW CREATE TABLE tr;
```

```
*************************** 1. row ***************************
Table: tr
Create Table: CREATE TABLE `tr` (
  `id` int(11) default NULL,
  `name` varchar(50) default NULL,
  `purchased` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE ( YEAR(purchased) ) (
  PARTITION p0 VALUES LESS THAN (1990) ENGINE = MyISAM,
  PARTITION p1 VALUES LESS THAN (1995) ENGINE = MyISAM,
  PARTITION p3 VALUES LESS THAN (2005) ENGINE = MyISAM
)
1 row in set (0.01 sec)
```

When you insert new rows into the changed table with `purchased` column values between '1995-01-01' and '2004-12-31' inclusive, those rows will be stored in partition `p3`. You can verify this as follows:

```sql
mysql> INSERT INTO tr VALUES (11, 'pencil holder', '1995-07-12');
Query OK, 1 row affected (0.00 sec)
mysql> SELECT * FROM tr WHERE purchased BETWEEN '1995-01-01' AND '2004-12-31';
```

```
+------+----------------+------------+
<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
<th>purchased</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>pencil holder</td>
<td>1995-07-12</td>
</tr>
<tr>
<td>1</td>
<td>desk organiser</td>
<td>2003-10-15</td>
</tr>
<tr>
<td>5</td>
<td>exercise bike</td>
<td>2004-05-09</td>
</tr>
<tr>
<td>7</td>
<td>popcorn maker</td>
<td>2001-11-22</td>
</tr>
</tbody>
</table>
+------+----------------+------------+
4 rows in set (0.00 sec)
```

```sql
mysql> ALTER TABLE tr DROP PARTITION p3;
Query OK, 0 rows affected (0.03 sec)
```

```sql
mysql> SELECT * FROM tr WHERE purchased BETWEEN '1995-01-01' AND '2004-12-31';
```

Empty set (0.00 sec)

Note that the number of rows dropped from the table as a result of `ALTER TABLE ... DROP PARTITION` is not reported by the server as it would be by the equivalent `DELETE` query.

Dropping `LIST` partitions uses exactly the same `ALTER TABLE ... DROP PARTITION` syntax as used for dropping `RANGE` partitions. However, there is one important difference in the effect this has on your use of the table afterward: You can no longer insert into the table any rows having any of the values that were included in the value list defining the deleted partition. (See Section 18.2.2, “LIST Partitioning”, for an example.)

To add a new range or list partition to a previously partitioned table, use the `ALTER TABLE ... ADD PARTITION` statement. For tables which are partitioned by `RANGE`, this can be used to add a new range to the end of the list of existing partitions. Suppose that you have a partitioned table containing membership data for your organization, which is defined as follows:

```sql
CREATE TABLE members (
  id INT,
  fname VARCHAR(25),
...
Management of RANGE and LIST Partitions

```sql
CREATE TABLE members (  
  id int(11) DEFAULT NULL,  
  fname varchar(25) DEFAULT NULL,  
  lname VARCHAR(25),  
  dob DATE  
) PARTITION BY RANGE( YEAR(dob) ) (  
  PARTITION p0 VALUES LESS THAN (1970),  
  PARTITION p1 VALUES LESS THAN (1980),  
  PARTITION p2 VALUES LESS THAN (1990)  
);
```

Suppose further that the minimum age for members is 16. As the calendar approaches the end of 2005, you realize that you will soon be admitting members who were born in 1990 (and later in years to come). You can modify the `members` table to accommodate new members born in the years 1990 to 1999 as shown here:

```sql
ALTER TABLE members ADD PARTITION (PARTITION p3 VALUES LESS THAN (2000));
```

With tables that are partitioned by range, you can use `ADD PARTITION` to add new partitions to the high end of the partitions list only. Trying to add a new partition in this manner between or before existing partitions results in an error as shown here:

```sql
mysql> ALTER TABLE members  
> ADD PARTITION (PARTITION n VALUES LESS THAN (1960));
ERROR 1463 (HY000): VALUES LESS THAN value must be strictly increasing for each partition
```

You can work around this problem by reorganizing the first partition into two new ones that split the range between them, like this:

```sql
ALTER TABLE members  
  REORGANIZE PARTITION p0 INTO (  
  PARTITION n0 VALUES LESS THAN (1960),  
  PARTITION n1 VALUES LESS THAN (1970)  
);
```

Using `SHOW CREATE TABLE` you can see that the `ALTER TABLE` statement has had the desired effect:

```sql
mysql> SHOW CREATE TABLE members\G
*************************** 1. row ***************************
  Table: members
  Create Table: CREATE TABLE `members` (  
    `id` int(11) DEFAULT NULL,  
    `fname` varchar(25) DEFAULT NULL,  
    `lname` varchar(25) DEFAULT NULL,  
    `dob` date DEFAULT NULL  
  ) ENGINE=InnoDB DEFAULT CHARSET=latin1  
  /*!50100 PARTITION BY RANGE ( YEAR(dob))  
  (PARTITION n0 VALUES LESS THAN (1960) ENGINE = MyISAM,  
  PARTITION n1 VALUES LESS THAN (1970) ENGINE = MyISAM,  
  PARTITION p1 VALUES LESS THAN (1980) ENGINE = MyISAM,  
  PARTITION p2 VALUES LESS THAN (1990) ENGINE = MyISAM,  
  PARTITION p3 VALUES LESS THAN (2000) ENGINE = MyISAM) */
1 row in set (0.00 sec)
```

See also Section 13.1.7.1, “ALTER TABLE Partition Operations”.

You can also use `ALTER TABLE ... ADD PARTITION` to add new partitions to a table that is partitioned by `LIST`. Suppose a table `tt` is defined using the following `CREATE TABLE` statement:

```sql
CREATE TABLE tt (  
  id INT,  
  data INT
)```
PARTITION BY LIST(data) (  
    PARTITION p0 VALUES IN (5, 10, 15),  
    PARTITION p1 VALUES IN (6, 12, 18) 
);  

You can add a new partition in which to store rows having the data column values 7, 14, and 21 as shown:

```
ALTER TABLE tt ADD PARTITION (PARTITION p2 VALUES IN (7, 14, 21));
```

Note that you cannot add a new LIST partition encompassing any values that are already included in the value list of an existing partition. If you attempt to do so, an error will result:

```
mysql> ALTER TABLE tt ADD PARTITION (PARTITION np VALUES IN (4, 8, 12));
ERROR 1465 (HY000): Multiple definition of same constant »
```

Because any rows with the data column value 12 have already been assigned to partition p1, you cannot create a new partition on table tt that includes 12 in its value list. To accomplish this, you could drop p1, and add np and then a new p1 with a modified definition. However, as discussed earlier, this would result in the loss of all data stored in p1—and it is often the case that this is not what you really want to do. Another solution might appear to be to make a copy of the table with the new partitioning and to copy the data into it using CREATE TABLE ... SELECT ..., then drop the old table and rename the new one, but this could be very time-consuming when dealing with a large amounts of data. This also might not be feasible in situations where high availability is a requirement.

Beginning with MySQL 5.1.6, you can add multiple partitions in a single ALTER TABLE ... ADD PARTITION statement as shown here:

```
CREATE TABLE employees (  
    id INT NOT NULL,  
    fname VARCHAR(50) NOT NULL,  
    lname VARCHAR(50) NOT NULL,  
    hired DATE NOT NULL  
)  
PARTITION BY RANGE( YEAR(hired) ) (  
    PARTITION p1 VALUES LESS THAN (1991),  
    PARTITION p2 VALUES LESS THAN (1996),  
    PARTITION p3 VALUES LESS THAN (2001),  
    PARTITION p4 VALUES LESS THAN (2005)  
);  
ALTER TABLE employees ADD PARTITION (  
    PARTITION p5 VALUES LESS THAN (2010),  
    PARTITION p6 VALUES LESS THAN MAXVALUE  
);
```

Fortunately, MySQL's partitioning implementation provides ways to redefine partitions without losing data. Let us look first at a couple of simple examples involving RANGE partitioning. Recall the members table which is now defined as shown here:

```
mysql> SHOW CREATE TABLE members\G
*************************** 1. row ***************************
Table: members
Create Table: CREATE TABLE `members` (  
`id` int(11) default NULL,  
`fname` varchar(25) default NULL,  
`lname` varchar(25) default NULL,  
`dob` date default NULL  
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE ( YEAR(dob) ) (  
    PARTITION p0 VALUES LESS THAN (1970) ENGINE = MyISAM,  
    PARTITION p1 VALUES LESS THAN (1980) ENGINE = MyISAM,  
```
PARTITION p2 VALUES LESS THAN (1990) ENGINE = MyISAM.
PARTITION p3 VALUES LESS THAN (2000) ENGINE = MyISAM
)

Suppose that you would like to move all rows representing members born before 1960 into a separate partition. As we have already seen, this cannot be done using ALTER TABLE ... ADD PARTITION. However, you can use another partition-related extension to ALTER TABLE to accomplish this:

ALTER TABLE members REORGANIZE PARTITION p0 INTO (
  PARTITION s0 VALUES LESS THAN (1960),
  PARTITION s1 VALUES LESS THAN (1970)
);

In effect, this command splits partition p0 into two new partitions s0 and s1. It also moves the data that was stored in p0 into the new partitions according to the rules embodied in the two PARTITION ... VALUES ... clauses, so that s0 contains only those records for which YEAR(dob) is less than 1960 and s1 contains those rows in which YEAR(dob) is greater than or equal to 1960 but less than 1970.

A REORGANIZE PARTITION clause may also be used for merging adjacent partitions. You can return the members table to its previous partitioning as shown here:

ALTER TABLE members REORGANIZE PARTITION s0,s1 INTO (
  PARTITION p0 VALUES LESS THAN (1970)
);

No data is lost in splitting or merging partitions using REORGANIZE PARTITION. In executing the above statement, MySQL moves all of the records that were stored in partitions s0 and s1 into partition p0.

The general syntax for REORGANIZE PARTITION is shown here:

ALTER TABLE tbl_name
  REORGANIZE PARTITION partition_list
  INTO (partition_definitions);

Here, tbl_name is the name of the partitioned table, and partition_list is a comma-separated list of names of one or more existing partitions to be changed. partition_definitions is a comma-separated list of new partition definitions, which follow the same rules as for the partition_definitions list used in CREATE TABLE (see Section 13.1.17, “CREATE TABLE Syntax”). It should be noted that you are not limited to merging several partitions into one, or to splitting one partition into many, when using REORGANIZE PARTITION. For example, you can reorganize all four partitions of the members table into two, as follows:

ALTER TABLE members REORGANIZE PARTITION p0,p1,p2,p3 INTO (
  PARTITION m0 VALUES LESS THAN (1980),
  PARTITION m1 VALUES LESS THAN (2000)
);

You can also use REORGANIZE PARTITION with tables that are partitioned by LIST. Let us return to the problem of adding a new partition to the list-partitioned tt table and failing because the new partition had a value that was already present in the value-list of one of the existing partitions. We can handle this by adding a partition that contains only nonconflicting values, and then reorganizing the new partition and the existing one so that the value which was stored in the existing one is now moved to the new one:

ALTER TABLE tt ADD PARTITION (PARTITION np VALUES IN (4, 8));
ALTER TABLE tt REORGANIZE PARTITION p1,np INTO (  
  PARTITION p1 VALUES IN (6, 18),
  PARTITION np VALUES in (4, 8, 12)
);
Here are some key points to keep in mind when using `ALTER TABLE ... REORGANIZE PARTITION` to repartition tables that are partitioned by `RANGE` or `LIST`:

- The `PARTITION` clauses used to determine the new partitioning scheme are subject to the same rules as those used with a `CREATE TABLE` statement.

Most importantly, you should remember that the new partitioning scheme cannot have any overlapping ranges (applies to tables partitioned by `RANGE`) or sets of values (when reorganizing tables partitioned by `LIST`).

**Note**
Prior to MySQL 5.1.4, you could not reuse the names of existing partitions in the `INTO` clause, even when those partitions were being dropped or redefined. See the Release Notes for MySQL 5.1.4 for more information.

- The combination of partitions in the `partition_definitions` list should account for the same range or set of values overall as the combined partitions named in the `partition_list`.

For instance, in the `members` table used as an example in this section, partitions `p1` and `p2` together cover the years 1980 through 1999. Therefore, any reorganization of these two partitions should cover the same range of years overall.

- For tables partitioned by `RANGE`, you can reorganize only adjacent partitions; you cannot skip over range partitions.

For instance, you could not reorganize the `members` table used as an example in this section using a statement beginning with `ALTER TABLE members REORGANIZE PARTITION p0,p2 INTO ...` because `p0` covers the years prior to 1970 and `p2` the years from 1990 through 1999 inclusive, and thus the two are not adjacent partitions.

- You cannot use `REORGANIZE PARTITION` to change the table’s partitioning type; that is, you cannot (for example) change `RANGE` partitions to `HASH` partitions or vice versa. You also cannot use this command to change the partitioning expression or column. To accomplish either of these tasks without dropping and re-creating the table, you can use `ALTER TABLE ... PARTITION BY ....` For example:

```
ALTER TABLE members
    PARTITION BY HASH( YEAR(dob) )
    PARTITIONS 8;
```

### 18.3.2 Management of HASH and KEY Partitions

Tables which are partitioned by hash or by key are very similar to one another with regard to making changes in a partitioning setup, and both differ in a number of ways from tables which have been partitioned by range or list. For that reason, this section addresses the modification of tables partitioned by hash or by key only. For a discussion of adding and dropping of partitions of tables that are partitioned by range or list, see Section 18.3.1, “Management of RANGE and LIST Partitions”.

You cannot drop partitions from tables that are partitioned by `HASH` or `KEY` in the same way that you can from tables that are partitioned by `RANGE` or `LIST`. However, you can merge `HASH` or `KEY` partitions using the `ALTER TABLE ... COALESCE PARTITION` statement. Suppose that you have a table containing data about clients, which is divided into twelve partitions. The `clients` table is defined as shown here:

```
CREATE TABLE clients {
    id INT,
    fname VARCHAR(30),
    lname VARCHAR(30),
    signed DATE
}
```
PARTITION BY HASH(MONTH(signed))
PARTITIONS 12;

To reduce the number of partitions from twelve to eight, execute the following `ALTER TABLE` command:

```sql
mysql> ALTER TABLE clients COALESCE PARTITION 4;
Query OK, 0 rows affected (0.02 sec)
```

`COALESCE` works equally well with tables that are partitioned by `HASH`, `KEY`, `LINEAR HASH`, or `LINEAR KEY`. Here is an example similar to the previous one, differing only in that the table is partitioned by `LINEAR KEY`:

```sql
mysql> CREATE TABLE clients_lk (
  -> id INT,
  -> fname VARCHAR(30),
  -> lname VARCHAR(30),
  -> signed DATE
  -> )
  -> PARTITION BY LINEAR KEY(signed)
  -> PARTITIONS 12;
Query OK, 0 rows affected (0.03 sec)

mysql> ALTER TABLE clients_lk COALESCE PARTITION 4;
Query OK, 0 rows affected (0.06 sec)
```

Note that the number following `COALESCE PARTITION` is the number of partitions to merge into the remainder—in other words, it is the number of partitions to remove from the table.

If you attempt to remove more partitions than the table has, the result is an error like the one shown:

```sql
mysql> ALTER TABLE clients COALESCE PARTITION 18;
ERROR 1478 (HY000): Cannot remove all partitions, use DROP TABLE instead
```

To increase the number of partitions for the `clients` table from 12 to 18, use `ALTER TABLE ... ADD PARTITION` as shown here:

```sql
ALTER TABLE clients ADD PARTITION PARTITIONS 6;
```

18.3.3 Maintenance of Partitions

A number of table and partition maintenance tasks can be carried out using SQL statements intended for such purposes on partitioned tables in MySQL 5.1.

Table maintenance of partitioned tables can be accomplished using the statements `CHECK TABLE`, `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `REPAIR TABLE`, which are supported for partitioned tables as of MySQL 5.1.27.

Also beginning with MySQL 5.1.27, you can use a number of extensions to `ALTER TABLE` for performing operations of this type on one or more partitions directly, as described in the following list:

- **Rebuilding partitions.** Rebuilds the partition; this has the same effect as dropping all records stored in the partition, then reinserting them. This can be useful for purposes of defragmentation.

  Example:

  ```sql
  ALTER TABLE t1 REBUILD PARTITION p0, p1;
  ```

- **Optimizing partitions.** If you have deleted a large number of rows from a partition or if you have made many changes to a partitioned table with variable-length rows (that is, having `VARCHAR`, `BLOB`,...
or TEXT columns), you can use `ALTER TABLE ... OPTIMIZE PARTITION` to reclaim any unused space and to defragment the partition data file.

Example:

```
ALTER TABLE t1 OPTIMIZE PARTITION p0, p1;
```

Using `OPTIMIZE PARTITION` on a given partition is equivalent to running `CHECK PARTITION`, `ANALYZE PARTITION`, and `REPAIR PARTITION` on that partition.

Some MySQL storage engines, including InnoDB, do not support per-partition optimization; in these cases, `ALTER TABLE ... OPTIMIZE PARTITION` rebuilds the entire table. In MySQL 5.1.68 and later, running this statement on such a table causes the entire table to be rebuilt and analyzed, and an appropriate warning to be issued. (Bug #11751825, Bug #42822) Use `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION` instead, to avoid this issue.

- **Analyzing partitions.** This reads and stores the key distributions for partitions.

Example:

```
ALTER TABLE t1 ANALYZE PARTITION p3;
```

- **Repairing partitions.** This repairs corrupted partitions.

Example:

```
ALTER TABLE t1 REPAIR PARTITION p0,p1;
```

- **Checking partitions.** You can check partitions for errors in much the same way that you can use `CHECK TABLE` with nonpartitioned tables.

Example:

```
ALTER TABLE trb3 CHECK PARTITION p1;
```

This command will tell you if the data or indexes in partition p1 of table t1 are corrupted. If this is the case, use `ALTER TABLE ... REPAIR PARTITION` to repair the partition.

Each of the statements in the list just shown also supports the keyword `ALL` in place of the list of partition names. Using `ALL` causes the statement to act on all partitions in the table.

**Note**

The statements `ALTER TABLE ... ANALYZE PARTITION`, `ALTER TABLE ... CHECK PARTITION`, `ALTER TABLE ... OPTIMIZE PARTITION`, and `ALTER TABLE ... REPAIR PARTITION` were originally introduced in MySQL 5.1.5, but did not work properly and were disabled in MySQL 5.1.24. They were re-introduced in MySQL 5.1.27. (Bug #20129) The use of these partitioning-specific `ALTER TABLE` statements with tables which are not partitioned is not supported; beginning with MySQL 5.1.31, it is expressly not permitted. (Bug #39434)

`ALTER TABLE ... REBUILD PARTITION` was also introduced in MySQL 5.1.5.

The use of `mysqlcheck` and `myisamchk` is not supported with partitioned tables.

`ANALYZE`, `CHECK`, `OPTIMIZE`, `REBUILD`, `REPAIR`, and `TRUNCATE` operations are not supported for subpartitions.
18.3.4 Obtaining Information About Partitions

This section discusses obtaining information about existing partitions, which can be done in a number of ways. Methods of obtaining such information include the following:

- Using the `SHOW CREATE TABLE` statement to view the partitioning clauses used in creating a partitioned table.
- Using the `SHOW TABLE STATUS` statement to determine whether a table is partitioned.
- Querying the `INFORMATION_SCHEMA.PARTITIONS` table.
- Using the statement `EXPLAIN PARTITIONS SELECT` to see which partitions are used by a given `SELECT`.

As discussed elsewhere in this chapter, `SHOW CREATE TABLE` includes in its output the `PARTITION` clause used to create a partitioned table. For example:

```
mysql> SHOW CREATE TABLE trb3\G
*************************** 1. row ***************************
Table: trb3
Create Table: CREATE TABLE `trb3` (
  `id` int(11) default NULL,
  `name` varchar(50) default NULL,
  `purchased` date default NULL,
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE (YEAR(purchased)) (
  PARTITION p0 VALUES LESS THAN (1990) ENGINE = MyISAM,
  PARTITION p1 VALUES LESS THAN (1995) ENGINE = MyISAM,
  PARTITION p2 VALUES LESS THAN (2000) ENGINE = MyISAM,
  PARTITION p3 VALUES LESS THAN (2005) ENGINE = MyISAM
) ENGINE=MyISAM DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

**Note**

In early MySQL 5.1 releases, the `PARTITIONS` clause was not shown for tables partitioned by `HASH` or `KEY`. This issue was fixed in MySQL 5.1.6.

`SHOW TABLE STATUS` works with partitioned tables. Beginning with MySQL 5.1.9, its output is the same as that for nonpartitioned tables, except that the `Create_options` column contains the string `partitioned`. In MySQL 5.1.8 and earlier, the `Engine` column always contained the value `PARTITION`; beginning with MySQL 5.1.9, this column contains the name of the storage engine used by all partitions of the table. (See Section 13.7.5.38, “SHOW TABLE STATUS Syntax”, for more information about this statement.)

You can also obtain information about partitions from `INFORMATION_SCHEMA`, which contains a `PARTITIONS` table. See Section 20.11, “The INFORMATION_SCHEMA PARTITIONS Table”.

Beginning with MySQL 5.1.5, it is possible to determine which partitions of a partitioned table are involved in a given `SELECT` query using `EXPLAIN PARTITIONS`. The `PARTITIONS` keyword adds a `partitions` column to the output of `EXPLAIN` listing the partitions from which records would be matched by the query.

Suppose that you have a table `trb1` created and populated as follows:

```
CREATE TABLE trb1 (id INT, name VARCHAR(50), purchased DATE)
PARTITION BY RANGE(id)
(
  PARTITION p0 VALUES LESS THAN (3),
  PARTITION p1 VALUES LESS THAN (7),
  PARTITION p2 VALUES LESS THAN (9),
  PARTITION p3 VALUES LESS THAN (11)
```
You can see which partitions are used in a query such as `SELECT * FROM trb1;`, as shown here:

```
mysql> EXPLAIN PARTITIONS SELECT * FROM trb1
+----+
| id | select_type: SIMPLE |
|----|
+----+
| 1  |
+----+
| table: trb1 |
| partitions: p0,p1,p2,p3 |
| type: ALL |
| possible_keys: NULL |
| key: NULL |
| key_len: NULL |
| ref: NULL |
| rows: 10 |
+----+
| Extra: Using filesort |
```

In this case, all four partitions are searched. However, when a limiting condition making use of the partitioning key is added to the query, you can see that only those partitions containing matching values are scanned, as shown here:

```
mysql> EXPLAIN PARTITIONS SELECT * FROM trb1 WHERE id < 5
+----+
| id | select_type: SIMPLE |
|----|
+----+
| 1  |
+----+
| table: trb1 |
| partitions: p0,p1 |
| type: range |
| possible_keys: PRIMARY |
| key: PRIMARY |
| key_len: 4 |
| ref: NULL |
| rows: 7 |
+----+
| Extra: Using where |
```

`EXPLAIN PARTITIONS` provides information about keys used and possible keys, just as with the standard `EXPLAIN SELECT` statement:

```
mysql> ALTER TABLE trb1 ADD PRIMARY KEY (id);
Query OK, 10 rows affected (0.03 sec)
Records: 10 Duplicates: 0 Warnings: 0

mysql> EXPLAIN PARTITIONS SELECT * FROM trb1 WHERE id < 5
+----+
| id | select_type: SIMPLE |
|----|
+----+
| 1  |
+----+
| table: trb1 |
| partitions: p0,p1 |
| type: range |
| possible_keys: PRIMARY |
| key: PRIMARY |
| key_len: 4 |
| ref: NULL |
| rows: 7 |
+----+
| Extra: Using where |
```

});

INSERT INTO trb1 VALUES
(1, 'desk organiser', '2003-10-15'),
(2, 'CD player', '1993-11-05'),
(3, 'TV set', '1996-03-10'),
(4, 'bookcase', '1982-01-10'),
(5, 'exercise bike', '2004-05-09'),
(6, 'sofa', '1987-06-05'),
(7, 'popcorn maker', '2001-11-22'),
(8, 'aquarium', '1992-08-04'),
(9, 'study desk', '1984-09-16'),
(10, 'lava lamp', '1998-12-25');
You should take note of the following restrictions and limitations on `EXPLAIN PARTITIONS`:

- You cannot use the `PARTITIONS` and `EXTENDED` keywords together in the same `EXPLAIN` ... `SELECT` statement. Attempting to do so produces a syntax error.

- If `EXPLAIN PARTITIONS` is used to examine a query against a nonpartitioned table, no error is produced, but the value of the `partitions` column is always `NULL`.

As of MySQL 5.1.28, the `rows` column of `EXPLAIN PARTITIONS` output always displays the total number of rows in the table. Previously, this was the number of matching rows (see Bug #35745).

See also Section 13.8.2, “EXPLAIN Syntax”.

### 18.4 Partition Pruning

This section discusses an optimization known as **partition pruning**, which was implemented for partitioned tables in MySQL 5.1.6. The core concept behind partition pruning is relatively simple, and can be described as “Do not scan partitions where there can be no matching values”. Suppose that you have a partitioned table `t1` defined by this statement:

```sql
CREATE TABLE t1 (  
    fname VARCHAR(50) NOT NULL,  
    lname VARCHAR(50) NOT NULL,  
    region_code TINYINT UNSIGNED NOT NULL,  
    dob DATE NOT NULL  
)  
PARTITION BY RANGE( region_code ) (  
    PARTITION p0 VALUES LESS THAN (64),  
    PARTITION p1 VALUES LESS THAN (128),  
    PARTITION p2 VALUES LESS THAN (192),  
    PARTITION p3 VALUES LESS THAN MAXVALUE  
);
```

Consider the case where you wish to obtain results from a query such as this one:

```sql
SELECT fname, lname, region_code, dob  
FROM t1  
WHERE region_code > 125 AND region_code < 130;
```

It is easy to see that none of the rows which ought to be returned will be in either of the partitions `p0` or `p3`; that is, we need to search only in partitions `p1` and `p2` to find matching rows. By doing so, it is possible to expend much less time and effort in finding matching rows than would be required to scan all partitions in the table. This “cutting away” of unneeded partitions is known as **pruning**. When the optimizer can make use of partition pruning in performing a query, execution of the query can be an order of magnitude faster than the same query against a nonpartitioned table containing the same column definitions and data.

- **Note**
  
  When pruning is performed on a partitioned `MyISAM` table, all partitions are opened, whether or not they are examined, due to the design of the `MyISAM` storage engine. This means that you must have a sufficient number of file descriptors available to cover all partitions of the table. See `MyISAM` and `partition file descriptor usage`.
  
  This limitation does not apply to partitioned tables using other MySQL storage engines such as `InnoDB`.

The query optimizer can perform pruning whenever a `WHERE` condition can be reduced to either one of the following two cases:

- `partition_column = constant`
Partition Pruning

- \textit{partition\_column} \texttt{IN (constant1, constant2, ..., constantN)}

In the first case, the optimizer simply evaluates the partitioning expression for the value given, determines which partition contains that value, and scans only this partition. In many cases, the equal sign can be replaced with another arithmetic comparison, including \texttt{<, >, <=, >=, and <>}. Some queries using \texttt{BETWEEN} in the \texttt{WHERE} clause can also take advantage of partition pruning. See the examples later in this section.

In the second case, the optimizer evaluates the partitioning expression for each value in the list, creates a list of matching partitions, and then scans only the partitions in this partition list.

Pruning can also be applied to short ranges, which the optimizer can convert into equivalent lists of values. For instance, in the previous example, the \texttt{WHERE} clause can be converted to \texttt{WHERE region\_code \texttt{IN (126, 127, 128, 129)}}. Then the optimizer can determine that the first two values in the list are found in partition \texttt{p1}, the remaining two values in partition \texttt{p2}, and that the other partitions contain no relevant values and so do not need to be searched for matching rows.

This type of optimization can be applied whenever the partitioning expression consists of an equality or a range which can be reduced to a set of equalities, or when the partitioning expression represents an increasing or decreasing relationship. Pruning can also be applied for tables partitioned on a \texttt{DATE} or \texttt{DATETIME} column when the partitioning expression uses the \texttt{YEAR()} or \texttt{TO\_DAYS()} function.

Suppose that table \texttt{t2}, defined as shown here, is partitioned on a \texttt{DATE} column:

```sql
CREATE TABLE t2 (
    fname VARCHAR(50) NOT NULL,
    lname VARCHAR(50) NOT NULL,
    region\_code TINYINT UNSIGNED NOT NULL,
    dob DATE NOT NULL
)
PARTITION BY RANGE ( YEAR(dob) ) {
    PARTITION d0 VALUES LESS THAN (1970),
    PARTITION d1 VALUES LESS THAN (1975),
    PARTITION d2 VALUES LESS THAN (1980),
    PARTITION d3 VALUES LESS THAN (1985),
    PARTITION d4 VALUES LESS THAN (1990),
    PARTITION d5 VALUES LESS THAN (2000),
    PARTITION d6 VALUES LESS THAN (2005),
    PARTITION d7 VALUES LESS THAN MAXVALUE
};
```

The following queries on \texttt{t2} can make use of partition pruning:

```sql
SELECT * FROM t2 WHERE dob = '1982-06-23';
SELECT * FROM t2 WHERE dob BETWEEN '1991-02-15' AND '1997-04-25';
SELECT * FROM t2 WHERE dob >= '1984-06-21' AND dob <= '1999-06-21'
```

In the case of the last query, the optimizer can also act as follows:

1. \textit{Find the partition containing the low end of the range.}
   
   \texttt{YEAR('1984-06-21')} yields the value \texttt{1984}, which is found in partition \texttt{d3}.

2. \textit{Find the partition containing the high end of the range.}
   
   \texttt{YEAR('1999-06-21')} evaluates to \texttt{1999}, which is found in partition \texttt{d5}.

3. \textit{Scan only these two partitions and any partitions that may lie between them.}

   In this case, this means that only partitions \texttt{d3}, \texttt{d4}, and \texttt{d5} are scanned. The remaining partitions may be safely ignored (and are ignored).
Partition Pruning

Important

Invalid DATE and DATETIME values referenced in the WHERE clause of a query on a partitioned table are treated as NULL. This means that a query such as `SELECT * FROM partitioned_table WHERE date_column < '2008-12-00'` does not return any values (see Bug #40972).

So far, we have looked only at examples using RANGE partitioning, but pruning can be applied with other partitioning types as well.

Consider a table that is partitioned by LIST, where the partitioning expression is increasing or decreasing, such as the table `t3` shown here. (In this example, we assume for the sake of brevity that the `region_code` column is limited to values between 1 and 10 inclusive.)

```sql
CREATE TABLE t3 (    fname VARCHAR(50) NOT NULL,    lname VARCHAR(50) NOT NULL,    region_code TINYINT UNSIGNED NOT NULL,    dob DATE NOT NULL )    PARTITION BY LIST(region_code) (        PARTITION r0 VALUES IN (1, 3),        PARTITION r1 VALUES IN (2, 5, 8),        PARTITION r2 VALUES IN (4, 9),        PARTITION r3 VALUES IN (6, 7, 10)    );
```

For a query such as `SELECT * FROM t3 WHERE region_code BETWEEN 1 AND 3`, the optimizer determines in which partitions the values 1, 2, and 3 are found (r0 and r1) and skips the remaining ones (r2 and r3).

For tables that are partitioned by HASH or [LINEAR] KEY, partition pruning is also possible in cases in which the WHERE clause uses a simple = relation against a column used in the partitioning expression. Consider a table created like this:

```sql
CREATE TABLE t4 (    fname VARCHAR(50) NOT NULL,    lname VARCHAR(50) NOT NULL,    region_code TINYINT UNSIGNED NOT NULL,    dob DATE NOT NULL )    PARTITION BY KEY(region_code) PARTITIONS 8;
```

Any query, such as this one, that compares a column value with a constant can be pruned:

```sql
SELECT * FROM t4 WHERE region_code = 7;
```

Pruning can also be employed for short ranges, because the optimizer can turn such conditions into IN relations. For example, using the same table `t4` as defined previously, queries such as these can be pruned:

```sql
SELECT * FROM t4 WHERE region_code > 2 AND region_code < 6;
SELECT * FROM t4 WHERE region_code BETWEEN 3 AND 5;
```

In both these cases, the WHERE clause is transformed by the optimizer into WHERE region_code IN (3, 4, 5).

Important

This optimization is used only if the range size is smaller than the number of partitions. Consider this query:
SELECT * FROM t4 WHERE region_code BETWEEN 4 AND 12;

The range in the WHERE clause covers 9 values (4, 5, 6, 7, 8, 9, 10, 11, 12), but t4 has only 8 partitions. This means that the previous query cannot be pruned.

When a table is partitioned by HASH or [LINEAR] KEY, pruning can be used only on integer columns. For example, this query on table t4 cannot use pruning because dob is a DATE column:

SELECT * FROM t4 WHERE dob >= '2001-04-14' AND dob <= '2005-10-15';

However, if the table stores year values in an INT column, then a query having WHERE year_col >= 2001 AND year_col <= 2005 can be pruned.

For a table that is partitioned by KEY, has a composite primary key, and uses a composite partitioning key, it is possible to perform pruning for queries meeting the following two criteria:

• The query must have a WHERE clause of the form pkcol1 = c1 AND pkcol2 = c2 AND ... pkcolN = cN, where pkcol1 ... pkcolN are the partitioning key columns and c1 ... cN are constant values.

• All columns of the partitioning key must be referenced in the WHERE clause.

For example, suppose a table named cities is created as shown here:

CREATE TABLE cities {
    id INT NOT NULL AUTO_INCREMENT,
    name CHAR(35) NOT NULL DEFAULT '',
    country_code CHAR(3) NOT NULL DEFAULT '',
    district CHAR(20) NOT NULL DEFAULT '',
    population INT NOT NULL DEFAULT 0,
    PRIMARY KEY (ID, Population)
} PARTITION BY KEY () PARTITIONS 8;

(Note that PARTITION BY KEY() is equivalent in this case to PARTITION BY KEY(id, population).)

Only a query that references both the id and population columns of this table can be pruned, as shown here:

mysql> SELECT * FROM cities WHERE id = 101;
<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
<th>country_code</th>
<th>district</th>
<th>population</th>
</tr>
</thead>
<tbody>
<tr>
<td>101</td>
<td>Godoy Cruz</td>
<td>ARG</td>
<td>Mendoza</td>
<td>206998</td>
</tr>
</tbody>
</table>
1 row in set (0.00 sec)

mysql> SELECT * FROM cities WHERE population = 206998;
<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
<th>country_code</th>
<th>district</th>
<th>population</th>
</tr>
</thead>
<tbody>
<tr>
<td>101</td>
<td>Godoy Cruz</td>
<td>ARG</td>
<td>Mendoza</td>
<td>206998</td>
</tr>
</tbody>
</table>
1 row in set (0.00 sec)

mysql> EXPLAIN PARTITIONS SELECT * FROM cities WHERE id = 101\G
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: cities
partitions: p0,p1,p2,p3,p4,p5,p6,p7
type: ref
Restrictions and Limitations on Partitioning

This section discusses current restrictions and limitations on MySQL partitioning support.

Prohibited constructs. Beginning with MySQL 5.1.12, the following constructs are not permitted in partitioning expressions:

- Stored procedures, stored functions, UDFs, or plugins.
- Declared variables or user variables.

For a list of SQL functions which are permitted in partitioning expressions, see Section 18.5.3, "Partitioning Limitations Relating to Functions".

Arithmetic and logical operators. Use of the arithmetic operators +, −, and * is permitted in partitioning expressions. However, the result must be an integer value or NULL (except in the case of [LINEAR] KEY partitioning, as discussed elsewhere in this chapter; see Section 18.2, "Partitioning Types", for more information).

Beginning with MySQL 5.1.23, the DIV operator is also supported, and the / operator is not permitted. (Bug #30188, Bug #33182)

Beginning with MySQL 5.1.12, the bit operators |, &, ^, <<, >>, and ~ are not permitted in partitioning expressions.

HANDLER statements. In MySQL 5.1, the HANDLER statement is not supported with partitioned tables.
Restrictions and Limitations on Partitioning

Server SQL mode.  Tables employing user-defined partitioning do not preserve the SQL mode in effect at the time that they were created. As discussed in Section 5.1.7, "Server SQL Modes", the results of many MySQL functions and operators may change according to the server SQL mode. Therefore, a change in the SQL mode at any time after the creation of partitioned tables may lead to major changes in the behavior of such tables, and could easily lead to corruption or loss of data. For these reasons, it is strongly recommended that you never change the server SQL mode after creating partitioned tables.

Examples.  The following examples illustrate some changes in behavior of partitioned tables due to a change in the server SQL mode:

1. Error handling.  Suppose that you create a partitioned table whose partitioning expression is one such as \texttt{column DIV 0} or \texttt{column MOD 0}, as shown here:

   \begin{verbatim}
   mysql> CREATE TABLE tn (c1 INT)
   -> PARTITION BY LIST(1 DIV c1) (  
   -> PARTITION p0 VALUES IN (NULL),
   -> PARTITION p1 VALUES IN (1)  
   -> );
   Query OK, 0 rows affected (0.05 sec)
   \end{verbatim}

   The default behavior for MySQL is to return \texttt{NULL} for the result of a division by zero, without producing any errors:

   \begin{verbatim}
   mysql> SELECT @@sql_mode;
   +------------+
   | @@sql_mode |
   +------------+
   |            |
   +------------+
   1 row in set (0.00 sec)
   mysql> INSERT INTO tn VALUES (NULL), (0), (1);
   Query OK, 3 rows affected (0.00 sec)
   Records: 3  Duplicates: 0  Warnings: 0
   \end{verbatim}

   However, changing the server SQL mode to treat division by zero as an error and to enforce strict error handling causes the same \texttt{INSERT} statement to fail, as shown here:

   \begin{verbatim}
   mysql> SET sql_mode='STRICT_ALL_TABLES,ERROR_FOR_DIVISION_BY_ZERO';
   Query OK, 0 rows affected (0.00 sec)
   mysql> INSERT INTO tn VALUES (NULL), (0), (1);
   ERROR 1365 (22012): Division by 0
   \end{verbatim}

2. Table accessibility.  Sometimes a change in the server SQL mode can make partitioned tables unusable. The following \texttt{CREATE TABLE} statement can be executed successfully only if the \texttt{NO_UNSIGNED_SUBTRACTION} mode is in effect:

   \begin{verbatim}
   mysql> SELECT @@sql_mode;
   +------------+
   | @@sql_mode |
   +------------+
   |            |
   +------------+
   1 row in set (0.00 sec)
   mysql> CREATE TABLE tu (c1 BIGINT UNSIGNED)
   -> PARTITION BY RANGE(c1 - 10) (  
   -> PARTITION p0 VALUES LESS THAN (-5),
   -> PARTITION p1 VALUES LESS THAN (0),
   -> PARTITION p2 VALUES LESS THAN (5),
   -> PARTITION p3 VALUES LESS THAN (10),
   -> );
   Query OK, 0 rows affected (0.00 sec)
   \end{verbatim}
Restrictions and Limitations on Partitioning

```sql
-> PARTITION p4 VALUES LESS THAN (MAXVALUE);
ERROR 1563 (HY000): Partition constant is out of partition function domain

mysql> SET sql_mode='NO UNSIGNED_SUBTRACTION';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@sql_mode;
+-------------------------+
<table>
<thead>
<tr>
<th>@@sql_mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>NO UNSIGNED_SUBTRACTION</td>
</tr>
</tbody>
</table>
+-------------------------+
1 row in set (0.00 sec)

mysql> CREATE TABLE tu (c1 BIGINT UNSIGNED)
-> PARTITION BY RANGE(c1 - 10) {
-> PARTITION p0 VALUES LESS THAN (-5),
-> PARTITION p1 VALUES LESS THAN (0),
-> PARTITION p2 VALUES LESS THAN (5),
-> PARTITION p3 VALUES LESS THAN (10),
-> PARTITION p4 VALUES LESS THAN (MAXVALUE)
-> );
Query OK, 0 rows affected (0.05 sec)

If you remove the NO UNSIGNED_SUBTRACTION server SQL mode after creating tu, you may no longer be able to access this table:

mysql> SET sql_mode='';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM tu;
ERROR 1563 (HY000): Partition constant is out of partition function domain

mysql> INSERT INTO tu VALUES (20);
ERROR 1563 (HY000): Partition constant is out of partition function domain
```

Server SQL modes also impact replication of partitioned tables. Differing SQL modes on master and slave can lead to partitioning expressions being evaluated differently; this can cause the distribution of data among partitions to be different in the master's and slave's copies of a given table, and may even cause inserts into partitioned tables that succeed on the master to fail on the slave. For best results, you should always use the same server SQL mode on the master and on the slave.

Performance considerations. Some affects of partitioning operations on performance are given in the following list:

- **File system operations.** Partitioning and repartitioning operations (such as `ALTER TABLE` with `PARTITION BY ...`, `REORGANIZE PARTITIONS`, or `REMOVE PARTITIONING`) depend on file system operations for their implementation. This means that the speed of these operations is affected by such factors as file system type and characteristics, disk speed, swap space, file handling efficiency of the operating system, and MySQL server options and variables that relate to file handling. In particular, you should make sure that `large_files_support` is enabled and that `open_files_limit` is set properly. For partitioned tables using the MyISAM storage engine, increasing `myisam_max_sort_file_size` may improve performance; partitioning and repartitioning operations involving InnoDB tables may be made more efficient by enabling `innodb_file_per_table`.

See also Maximum number of partitions.

- **MyISAM and partition file descriptor usage.** For a partitioned MyISAM table, MySQL uses 2 file descriptors for each partition, for each such table that is open. This means that you need many more file descriptors to perform operations on a partitioned MyISAM table than on a table which is identical to it except that the latter table is not partitioned, particularly when performing `ALTER TABLE` operations that change the table's partitioning scheme.

Assume a MyISAM table `t` with 100 partitions, such as the table created by this SQL statement:
Restrictions and Limitations on Partitioning

CREATE TABLE t (c1 VARCHAR(50))
PARTITION BY KEY (c1) PARTITIONS 100
ENGINE=MYISAM;

Note
For brevity, we use KEY partitioning for the table shown in this example, but file descriptor usage as described here applies to all partitioned MyISAM tables, regardless of the type of partitioning that is employed. Partitioned tables using other storage engines such as InnoDB are not affected by this issue.

Now assume that you wish to repartition t so that it has 101 partitions, using the statement shown here:

ALTER TABLE t PARTITION BY KEY (c1) PARTITIONS 101;

To process this ALTER TABLE statement, MySQL uses 402 file descriptors—that is, two for each of the 100 original partitions, plus two for each of the 101 new partitions. This is because all partitions (old and new) must be opened concurrently during the reorganization of the table data. It is recommended that, if you expect to perform such operations, you should make sure that --open-files-limit is not set too low to accommodate them.

• Table locks. The process executing a partitioning operation on a table takes a write lock on the table. Reads from such tables are relatively unaffected; pending INSERT and UPDATE operations are performed as soon as the partitioning operation has completed.

• Storage engine. Partitioning operations, queries, and update operations generally tend to be faster with MyISAM tables than with InnoDB or NDB tables.

• Indexes; partition pruning. As with nonpartitioned tables, proper use of indexes can speed up queries on partitioned tables significantly. In addition, designing partitioned tables and queries on these tables to take advantage of partition pruning can improve performance dramatically. See Section 18.4, “Partition Pruning”, for more information.

• Performance with LOAD DATA. Prior to MySQL 5.1.23, LOAD DATA performed very poorly when importing into partitioned tables. The statement now uses buffering to improve performance; however, the buffer uses 130 KB memory per partition to achieve this. (Bug #26527)

Maximum number of partitions.
The maximum possible number of partitions for a given table (that does not use the NDB storage engine) is 1024. This number includes subpartitions.

The maximum possible number of user-defined partitions for a table using the NDBCLUSTER storage engine is determined according to the version of the MySQL Cluster software being used, the number of data nodes, and other factors. See NDB and user-defined partitioning, for more information.

If, when creating tables with a large number of partitions (but less than the maximum), you encounter an error message such as Got error ... from storage engine: Out of resources when opening file, you may be able to address the issue by increasing the value of the open_files_limit system variable. However, this is dependent on the operating system, and may not be possible or advisable on all platforms; see Section B.5.2.18, “File Not Found and Similar Errors”, for more information. In some cases, using large numbers (hundreds) of partitions may also not be advisable due to other concerns, so using more partitions does not automatically lead to better results.

See also File system operations.

Foreign keys not supported for partitioned InnoDB tables.
Partitioned tables using the InnoDB storage engine do not support foreign keys. More specifically, this means that the following two statements are true:
1. No definition of an InnoDB table employing user-defined partitioning may contain foreign key references; no InnoDB table whose definition contains foreign key references may be partitioned.

2. No InnoDB table definition may contain a foreign key reference to a user-partitioned table; no InnoDB table with user-defined partitioning may contain columns referenced by foreign keys.

The scope of the restrictions just listed includes all tables that use the InnoDB storage engine. CREATE TABLE and ALTER TABLE statements that would result in tables violating these restrictions are not allowed.

**ALTER TABLE ... ORDER BY.** An ALTER TABLE ... ORDER BY column statement run against a partitioned table causes ordering of rows only within each partition.

**Effects on REPLACE statements by modification of primary keys.** It can be desirable in some cases (see Section 18.5.1, “Partitioning Keys, Primary Keys, and Unique Keys”) to modify a table's primary key. Be aware that, if your application uses REPLACE statements and you do this, the results of these statements can be drastically altered. See Section 13.2.7, “REPLACE Syntax”, for more information and an example.

**FULLTEXT indexes.** Partitioned tables do not support FULLTEXT indexes or searches. This includes partitioned tables employing the MyISAM storage engine.

**Spatial columns.** Columns with spatial data types such as POINT or GEOMETRY cannot be used in partitioned tables.

**Temporary tables.** As of MySQL 5.1.8, temporary tables cannot be partitioned. (Bug #17497)

**Log tables.** Beginning with MySQL 5.1.20, it is no longer possible to partition the log tables; beginning with that version, an ALTER TABLE ... PARTITION BY ... statement on such a table fails with an error. (Bug #27816)

**Data type of partitioning key.** A partitioning key must be either an integer column or an expression that resolves to an integer. Expressions employing ENUM columns cannot be used. The column or expression value may also be NULL. (See Section 18.2.6, “How MySQL Partitioning Handles NULL”.)

The lone exception to this restriction occurs when partitioning by [LINEAR] KEY, it is possible to use columns of any valid MySQL data type other than TEXT or BLOB as partitioning keys, because MySQL’s internal key-hashing functions produce the correct data type from these types. For example, the following two CREATE TABLE statements are valid:

```
CREATE TABLE tkc (c1 CHAR)
PARTITION BY KEY(c1)
PARTITIONS 4;

CREATE TABLE tke
  ( c1 ENUM('red', 'orange', 'yellow', 'green', 'blue', 'indigo', 'violet') )
PARTITION BY LINEAR KEY(c1)
PARTITIONS 6;
```

**Subqueries.** A partitioning key may not be a subquery, even if that subquery resolves to an integer value or NULL.

**Issues with subpartitions.** Subpartitions must use HASH or KEY partitioning. Only RANGE and LIST partitions may be subpartitioned; HASH and KEY partitions cannot be subpartitioned.

**SUBPARTITION BY KEY** requires that the subpartitioning column or columns be specified explicitly, unlike the case with PARTITION BY KEY, where it can be omitted (in which case the table's primary key column is used by default). Consider the table created by this statement:
You can create a table having the same columns, partitioned by `KEY`, using a statement such as this one:

```sql
CREATE TABLE ts (
    id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    name VARCHAR(30)
) PARTITION BY KEY()
PARTITIONS 4;
```

The previous statement is treated as though it had been written like this, with the table’s primary key column used as the partitioning column:

```sql
CREATE TABLE ts (
    id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    name VARCHAR(30)
) PARTITION BY KEY(id)
PARTITIONS 4;
```

However, the following statement that attempts to create a subpartitioned table using the default column as the subpartitioning column fails, and the column must be specified for the statement to succeed, as shown here:

```sql
mysql> CREATE TABLE ts ( id INT NOT NULL AUTO_INCREMENT PRIMARY KEY, name VARCHAR(30) ) PARTITION BY RANGE(id) SUBPARTITION BY KEY() SUBPARTITIONS 4 ( PARTITION p0 VALUES LESS THAN (100), PARTITION p1 VALUES LESS THAN (MAXVALUE) )
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that corresponds to your MySQL server version for the right syntax to use near ')' mysql> CREATE TABLE ts ( id INT NOT NULL AUTO_INCREMENT PRIMARY KEY, name VARCHAR(30) ) PARTITION BY RANGE(id) SUBPARTITION BY KEY(id) SUBPARTITIONS 4 ( PARTITION p0 VALUES LESS THAN (100), PARTITION p1 VALUES LESS THAN (MAXVALUE) )
Query OK, 0 rows affected (0.07 sec)
```

This is a known issue (see Bug #51470).

**Query cache not supported.**

The query cache is not supported for partitioned tables. Beginning with MySQL 5.1.63, the query cache is automatically disabled for queries involving partitioned tables, and cannot be enabled for such queries. (Bug #53775)

**Key cache not supported.**
Caching is not supported for partitioned tables. The `CACHE_INDEX` and `LOAD_INDEX INTO CACHE` statements, when you attempt to use them on tables having user-defined partitioning, fail with the errors `The storage engine for the table doesn't support assign_to_keycache` and `The storage engine for the table doesn't support preload_keys`, respectively. This issue is fixed in MySQL 5.5.

**DELAYED option not supported.** Use of `INSERT DELAYED` to insert rows into a partitioned table is not supported. Beginning with MySQL 5.1.23, attempting to do so fails with an error (see Bug #31210).

**DATA DIRECTORY and INDEX DIRECTORY options.** `DATA DIRECTORY` and `INDEX DIRECTORY` are subject to the following restrictions when used with partitioned tables:

- Beginning with MySQL 5.1.23, table-level `DATA DIRECTORY` and `INDEX DIRECTORY` options are ignored (see Bug #32091).
- On Windows, the `DATA DIRECTORY` and `INDEX DIRECTORY` options are not supported for individual partitions or subpartitions (Bug #30459).

**Repairing and rebuilding partitioned tables.** The statements `CHECK TABLE`, `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `REPAIR TABLE` are supported for partitioned tables beginning with MySQL 5.1.27. (See Bug #20129.)

In addition, you can use `ALTER TABLE ... REBUILD PARTITION` to rebuild one or more partitions of a partitioned table; `ALTER TABLE ... REORGANIZE PARTITION` also causes partitions to be rebuilt. Both of these statements were added in MySQL 5.1.5. See Section 13.1.7, “ALTER TABLE Syntax”, for more information about these two statements.

`mysqlcheck`, `myisamchk`, and `myisampack` are not supported with partitioned tables.

### 18.5.1 Partitioning Keys, Primary Keys, and Unique Keys

This section discusses the relationship of partitioning keys with primary keys and unique keys. The rule governing this relationship can be expressed as follows: All columns used in the partitioning expression for a partitioned table must be part of every unique key that the table may have.

In other words, **every unique key on the table must use every column in the table's partitioning expression**. (This also includes the table's primary key, since it is by definition a unique key. This particular case is discussed later in this section.) For example, each of the following table creation statements is invalid:

```sql
CREATE TABLE t1 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  UNIQUE KEY (col1, col2)
) PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t2 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  UNIQUE KEY (col1),
  UNIQUE KEY (col3)
) PARTITION BY HASH(col1 + col3)
PARTITIONS 4;
```

In each case, the proposed table would have at least one unique key that does not include all columns used in the partitioning expression.
Each of the following statements is valid, and represents one way in which the corresponding invalid table creation statement could be made to work:

```sql
CREATE TABLE t1 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    UNIQUE KEY (col1, col2, col3)
) PARTITION BY HASH(col3) PARTITIONS 4;
```

```sql
CREATE TABLE t2 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    UNIQUE KEY (col1, col3)
) PARTITION BY HASH(col1 + col3) PARTITIONS 4;
```

This example shows the error produced in such cases:

```sql
mysql> CREATE TABLE t3 (
    -> col1 INT NOT NULL,
    -> col2 DATE NOT NULL,
    -> col3 INT NOT NULL,
    -> col4 INT NOT NULL,
    -> UNIQUE KEY (col1, col2),
    -> UNIQUE KEY (col3)
    -> ) PARTITION BY HASH(col1 + col3) PARTITIONS 4;
ERROR 1491 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function
```

The `CREATE TABLE` statement fails because both `col1` and `col3` are included in the proposed partitioning key, but neither of these columns is part of both of unique keys on the table. This shows one possible fix for the invalid table definition:

```sql
mysql> CREATE TABLE t3 (
    -> col1 INT NOT NULL,
    -> col2 DATE NOT NULL,
    -> col3 INT NOT NULL,
    -> col4 INT NOT NULL,
    -> UNIQUE KEY (col1, col2, col3),
    -> UNIQUE KEY (col3)
    -> ) PARTITION BY HASH(col3) PARTITIONS 4;
Query OK, 0 rows affected (0.05 sec)
```

In this case, the proposed partitioning key `col3` is part of both unique keys, and the table creation statement succeeds.

The following table cannot be partitioned at all, because there is no way to include in a partitioning key any columns that belong to both unique keys:

```sql
CREATE TABLE t4 (
    col1 INT NOT NULL,
    col2 INT NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    UNIQUE KEY (col1, col3),
    UNIQUE KEY (col2, col4)
```
Since every primary key is by definition a unique key, this restriction also includes the table’s primary key, if it has one. For example, the next two statements are invalid:

```
CREATE TABLE t5 (  
  col1 INT NOT NULL,  
  col2 DATE NOT NULL,  
  col3 INT NOT NULL,  
  col4 INT NOT NULL,  
  PRIMARY KEY(col1, col2)  
)  
PARTITION BY HASH(col3)  
PARTITIONS 4;
CREATE TABLE t6 (  
  col1 INT NOT NULL,  
  col2 DATE NOT NULL,  
  col3 INT NOT NULL,  
  col4 INT NOT NULL,  
  PRIMARY KEY(col1, col3),  
  UNIQUE KEY(col2)  
)  
PARTITION BY HASH(YEAR(col2))  
PARTITIONS 4;
```

In both cases, the primary key does not include all columns referenced in the partitioning expression. However, both of the next two statements are valid:

```
CREATE TABLE t7 (  
  col1 INT NOT NULL,  
  col2 DATE NOT NULL,  
  col3 INT NOT NULL,  
  col4 INT NOT NULL,  
  PRIMARY KEY(col1, col2)  
)  
PARTITION BY HASH(col1 + YEAR(col2))  
PARTITIONS 4;
CREATE TABLE t8 (  
  col1 INT NOT NULL,  
  col2 DATE NOT NULL,  
  col3 INT NOT NULL,  
  col4 INT NOT NULL,  
  PRIMARY KEY(col1, col2, col4),  
  UNIQUE KEY(col2, col1)  
)  
PARTITION BY HASH(col1 + YEAR(col2))  
PARTITIONS 4;
```

If a table has no unique keys—this includes having no primary key—then this restriction does not apply, and you may use any column or columns in the partitioning expression as long as the column type is compatible with the partitioning type.

For the same reason, you cannot later add a unique key to a partitioned table unless the key includes all columns used by the table’s partitioning expression. Consider the partitioned table created as shown here:

```
mysql> CREATE TABLE t_no_pk (c1 INT, c2 INT)  
    -> PARTITION BY RANGE(c1) (  
    ->     PARTITION p0 VALUES LESS THAN (10),  
    ->     PARTITION p1 VALUES LESS THAN (20),  
    ->     PARTITION p2 VALUES LESS THAN (30),  
    ->     PARTITION p3 VALUES LESS THAN (40)  
    -> );  
Query OK, 0 rows affected (0.12 sec)
```
It is possible to add a primary key to `t_no_pk` using either of these `ALTER TABLE` statements:

```sql
# possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1);
Query OK, 0 rows affected (0.13 sec)
Records: 0  Duplicates: 0  Warnings: 0

# drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
Query OK, 0 rows affected (0.10 sec)
Records: 0  Duplicates: 0  Warnings: 0

# use another possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1, c2);
Query OK, 0 rows affected (0.12 sec)
Records: 0  Duplicates: 0  Warnings: 0

# drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
Query OK, 0 rows affected (0.09 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

However, the next statement fails, because `c1` is part of the partitioning key, but is not part of the proposed primary key:

```sql
# fails with error 1503
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c2);
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function
```

Since `t_no_pk` has only `c1` in its partitioning expression, attempting to add a unique key on `c2` alone fails. However, you can add a unique key that uses both `c1` and `c2`.

These rules also apply to existing nonpartitioned tables that you wish to partition using `ALTER TABLE ... PARTITION BY`. Consider a table `np_pk` created as shown here:

```sql
mysql> CREATE TABLE np_pk (
  ->   id INT NOT NULL AUTO_INCREMENT,
  ->   name VARCHAR(50),
  ->   added DATE,
  ->   PRIMARY KEY (id)
  -> )
Query OK, 0 rows affected (0.08 sec)
```

The following `ALTER TABLE` statement fails with an error, because the `added` column is not part of any unique key in the table:

```sql
mysql> ALTER TABLE np_pk
  ->   PARTITION BY HASH( TO_DAYS(added) )
  ->   PARTITIONS 4;
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function
```

However, this statement using the `id` column for the partitioning column is valid, as shown here:

```sql
mysql> ALTER TABLE np_pk
  ->   PARTITION BY HASH(id)
  ->   PARTITIONS 4;
Query OK, 0 rows affected (0.11 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

In the case of `np_pk`, the only column that may be used as part of a partitioning expression is `id`; if you wish to partition this table using any other column or columns in the partitioning expression, you must first modify the table, either by adding the desired column or columns to the primary key, or by dropping the primary key altogether.
18.5.2 Partitioning Limitations Relating to Storage Engines

The following limitations apply to the use of storage engines with user-defined partitioning of tables.

**MERGE storage engine.** User-defined partitioning and the MERGE storage engine are not compatible. Tables using the MERGE storage engine cannot be partitioned. Partitioned tables cannot be merged.

**FEDERATED storage engine.** Partitioning of FEDERATED tables is not supported. Beginning with MySQL 5.1.15, it is not possible to create partitioned FEDERATED tables at all.

**CSV storage engine.** Partitioned tables using the CSV storage engine are not supported. Starting with MySQL 5.1.12, it is not possible to create partitioned CSV tables at all.

**BLACKHOLE storage engine.** Prior to MySQL 5.1.6, tables using the BLACKHOLE storage engine also could not be partitioned.

**InnoDB storage engine.** InnoDB foreign keys and MySQL partitioning are not compatible. Partitioned InnoDB tables cannot have foreign key references, nor can they have columns referenced by foreign keys. InnoDB tables which have or which are referenced by foreign keys cannot be partitioned.

In addition, `ALTER TABLE ... OPTIMIZE PARTITION` does not work correctly with partitioned tables that use the InnoDB storage engine. Use `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION`, instead, for such tables. For more information, see Section 13.1.7.1, “ALTER TABLE Partition Operations”.

**User-defined partitioning and the NDB storage engine (MySQL Cluster).** Partitioning by KEY (including LINEAR KEY) is the only type of partitioning supported for the NDBCLUSTER storage engine. Beginning with MySQL 5.1.12, it is not possible under normal circumstances to create a MySQL Cluster table using any partitioning type other than [LINEAR] KEY, and attempting to do so fails with an error.

*Exception (not for production):* It is possible to override this restriction by setting the `new` system variable on MySQL Cluster SQL nodes to ON. If you choose to do this, you should be aware that tables using partitioning types other than [LINEAR] KEY are not supported in production. *In such cases, you can create and use tables with partitioning types other than KEY or LINEAR KEY, but you do this entirely at your own risk.*

The maximum number of partitions that can be defined for an NDBCLUSTER table depends on the number of data nodes and node groups in the cluster, the version of the MySQL Cluster software in use, and other factors. See NDB and user-defined partitioning, for more information.

The maximum amount of fixed-size data that can be stored per partition in an NDB table is 16 GB.

Beginning with MySQL Cluster NDB 6.2.18, MySQL Cluster NDB 6.3.25, and MySQL Cluster NDB 7.0.6, `CREATE TABLE` and `ALTER TABLE` statements that would cause a user-partitioned NDBCLUSTER table not to meet either or both of the following two requirements are not permitted, and fail with an error (Bug #40709):

1. The table must have an explicit primary key.
2. All columns listed in the table’s partitioning expression must be part of the primary key.

*Exception.* If a user-partitioned NDBCLUSTER table is created using an empty column-list (that is, using `PARTITION BY KEY()` or `PARTITION BY LINEAR KEY()`), then no explicit primary key is required.

**Upgrading partitioned tables.** When performing an upgrade, tables which are partitioned by KEY and which use any storage engine other than NDBCLUSTER must be dumped and reloaded.
**Partitioning Limitations Relating to Functions**

**Same storage engine for all partitions.** All partitions of a partitioned table must use the same storage engine and it must be the same storage engine used by the table as a whole. In addition, if one does not specify an engine on the table level, then one must do either of the following when creating or altering a partitioned table:

- Do not specify any engine for any partition or subpartition
- Specify the engine for all partitions or subpartitions

### 18.5.3 Partitioning Limitations Relating to Functions

This section discusses limitations in MySQL Partitioning relating specifically to functions used in partitioning expressions.

Beginning with MySQL 5.1.12, only the MySQL functions allowed in the following table are allowed in partitioning expressions.

<table>
<thead>
<tr>
<th>Function</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABS()</td>
<td></td>
</tr>
<tr>
<td>CEILING() (see CEILING() and FLOOR())</td>
<td></td>
</tr>
<tr>
<td>DAYOFMONTH()</td>
<td></td>
</tr>
<tr>
<td>DAYOFYEAR()</td>
<td></td>
</tr>
<tr>
<td>DATEDIFF()</td>
<td></td>
</tr>
<tr>
<td>EXTRACT() (see EXTRACT() function with WEEK specifier)</td>
<td></td>
</tr>
<tr>
<td>FLOOR() (see CEILING() and FLOOR())</td>
<td></td>
</tr>
<tr>
<td>HOUR()</td>
<td></td>
</tr>
<tr>
<td>MICROSECOND()</td>
<td></td>
</tr>
<tr>
<td>MINUTE()</td>
<td></td>
</tr>
<tr>
<td>MOD()</td>
<td></td>
</tr>
<tr>
<td>MONTH()</td>
<td></td>
</tr>
<tr>
<td>QUARTER()</td>
<td></td>
</tr>
<tr>
<td>SECOND()</td>
<td></td>
</tr>
<tr>
<td>TIME_TO_SEC()</td>
<td></td>
</tr>
<tr>
<td>TO_DAYS()</td>
<td></td>
</tr>
<tr>
<td>UNIX_TIMESTAMP() (permitted in MySQL 5.1.43 and later, with TIMESTAMP columns)</td>
<td></td>
</tr>
<tr>
<td>WEEKDAY()</td>
<td></td>
</tr>
<tr>
<td>YEAR()</td>
<td></td>
</tr>
<tr>
<td>YEARWEEK()</td>
<td></td>
</tr>
</tbody>
</table>

In MySQL 5.1, range optimization can be used only for the TO_DAYS() and YEAR() functions. See Section 18.4, “Partition Pruning”, for more information.

**CEILING() and FLOOR().** Each of these functions returns an integer only if it is passed an argument of an exact numeric type, such as one of the INT types or DECIMAL. This means, for example, that the following `CREATE TABLE` statement fails with an error, as shown here:

```sql
mysql> CREATE TABLE t (c FLOAT) PARTITION BY LIST( FLOOR(c) ) (  
   -> PARTITION p0 VALUES IN (1,3,5),  
   -> PARTITION p1 VALUES IN (2,4,6)  
   -> );
ERROR 1490 (HY000): The PARTITION function returns the wrong type
```

**EXTRACT() function with WEEK specifier.** The value returned by the EXTRACT() function, when used as `EXTRACT(WEEK FROM col)`, depends on the value of the default_week_format system variable. For this reason, beginning with MySQL 5.1.55, EXTRACT() is no longer permitted as a partitioning function when it specifies the unit as WEEK. (Bug #54483)

See Section 12.6.2, “Mathematical Functions”, for more information about the return types of these functions, as well as Section 11.2, “Numeric Types”.

### 18.5.4 Partitioning and Table-Level Locking

For storage engines such as MyISAM that actually execute table-level locks when executing DML or DDL statements, such a statement affecting a partitioned table imposes a lock on the table as a whole; that is, all partitions are locked until the statement was finished. For example, a SELECT from a partitioned MyISAM table causes a lock on the entire table.
In practical terms, what this means is that the statements discussed later in this section tend to execute more slowly as the number of partitions increases. This limitation is greatly reduced in MySQL 5.6, with the introduction of **partition lock pruning** in MySQL 5.6.6.

This is not true for statements effecting partitioned tables using storage engines such as **InnoDB**, that employ row-level locking and do not actually perform (or need to perform) the locks prior to partition pruning.

The next few paragraphs discuss the effects of MySQL statements on partitioned tables using storage engines that employ table-level locks.

### DML statements

**SELECT** statements lock the entire table. **SELECT** statements containing unions or joins lock all tables named in the union or join.

**UPDATE** also locks the entire table.

**REPLACE** and **INSERT** (including **INSERT ... ON DUPLICATE KEY UPDATE**) lock the entire table.

**INSERT ... SELECT** locks both the source table and the target table.

**Note**

**INSERT DELAYED** is not supported for partitioned tables.

A **LOAD DATA** statement on a partitioned table locks the entire table.

A trigger on a partitioned table, once activated, locks the entire table.

### DDL statements

**CREATE VIEW** causes a lock on any partitioned table from which it reads.

**ALTER TABLE** locks the affected partitioned table.

### Other statements

**LOCK TABLES** locks all partitions of a partitioned table.

Evaluating the **expr** in a **CALL stored_procedure(expr)** statement locks all partitions of any partitioned table referenced by **expr**.

**ALTER TABLE** also takes a metadata lock on the table level.

This chapter discusses stored programs and views, which are database objects defined in terms of SQL code that is stored on the server for later execution.

Stored programs include these objects:

- Stored routines, that is, stored procedures and functions. A stored procedure is invoked using the CALL statement. A procedure does not have a return value but can modify its parameters for later inspection by the caller. It can also generate result sets to be returned to the client program. A stored function is used much like a built-in function. you invoke it in an expression and it returns a value during expression evaluation.

- Triggers. A trigger is a named database object that is associated with a table and that is activated when a particular event occurs for the table, such as an insert or update.

- Events. An event is a task that the server runs according to schedule.

Views are stored queries that when referenced produce a result set. A view acts as a virtual table.

This chapter describes how to use stored programs and views. The following sections provide additional information about SQL syntax for statements related to these objects:

- For each object type, there are CREATE, ALTER, and DROP statements that control which objects exist and how they are defined. See Section 13.1, “Data Definition Statements”.

- The CALL statement is used to invoke stored procedures. See Section 13.2.1, “CALL Syntax”.

- Stored program definitions include a body that may use compound statements, loops, conditionals, and declared variables. See Section 13.6, “MySQL Compound-Statement Syntax”.

2317
19.1 Defining Stored Programs

Each stored program contains a body that consists of an SQL statement. This statement may be a compound statement made up of several statements separated by semicolon (; ) characters. For example, the following stored procedure has a body made up of a BEGIN ... END block that contains a SET statement and a REPEAT loop that itself contains another SET statement:

```sql
CREATE PROCEDURE dorepeat(p1 INT)
BEGIN
    SET @x = 0;
    REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
END;
```

If you use the mysql client program to define a stored program containing semicolon characters, a problem arises. By default, mysql itself recognizes the semicolon as a statement delimiter, so you must redefine the delimiter temporarily to cause mysql to pass the entire stored program definition to the server.

To redefine the mysql delimiter, use the delimiter command. The following example shows how to do this for the dorepeat() procedure just shown. The delimiter is changed to // to enable the entire definition to be passed to the server as a single statement, and then restored to ; before invoking the procedure. This enables the ; delimiter used in the procedure body to be passed through to the server rather than being interpreted by mysql itself.

```sql
mysql> delimiter //
mysql> CREATE PROCEDURE dorepeat(p1 INT)
    -> BEGIN
    -> SET @x = 0;
    -> REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
    -> END
    -> //
Query OK, 0 rows affected (0.00 sec)
mysql> delimiter ;
```

You can redefine the delimiter to a string other than //, and the delimiter can consist of a single character or multiple characters. You should avoid the use of the backslash ("\") character because that is the escape character for MySQL.

The following is an example of a function that takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use delimiter because the function definition contains no internal ; statement delimiters:

```sql
mysql> CREATE FUNCTION hello (s CHAR(20))
    -> RETURNS CHAR(50) DETERMINISTIC
    -> RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT hello('world');
```

You can redefine the delimiter to a string other than //, and the delimiter can consist of a single character or multiple characters. You should avoid the use of the backslash ("\") character because that is the escape character for MySQL.
19.2 Using Stored Routines (Procedures and Functions)

Stored routines (procedures and functions) are supported in MySQL 5.1. A stored routine is a set of SQL statements that can be stored in the server. Once this has been done, clients don't need to keep reissuing the individual statements but can refer to the stored routine instead.

Stored routines require the `proc` table in the `mysql` database. This table is created during the MySQL 5.1 installation procedure. If you are upgrading to MySQL 5.1 from an earlier version, be sure to update your grant tables to make sure that the `proc` table exists. See Section 4.4.8, "mysql_upgrade — Check and Upgrade MySQL Tables".

Stored routines can be particularly useful in certain situations:

- When multiple client applications are written in different languages or work on different platforms, but need to perform the same database operations.

- When security is paramount. Banks, for example, use stored procedures and functions for all common operations. This provides a consistent and secure environment, and routines can ensure that each operation is properly logged. In such a setup, applications and users would have no access to the database tables directly, but can only execute specific stored routines.

Stored routines can provide improved performance because less information needs to be sent between the server and the client. The tradeoff is that this does increase the load on the database server because more of the work is done on the server side and less is done on the client (application) side. Consider this if many client machines (such as Web servers) are serviced by only one or a few database servers.

Stored routines also enable you to have libraries of functions in the database server. This is a feature shared by modern application languages that enable such design internally (for example, by using classes). Using these client application language features is beneficial for the programmer even outside the scope of database use.

MySQL follows the SQL:2003 syntax for stored routines, which is also used by IBM's DB2. All syntax described here is supported and any limitations and extensions are documented where appropriate.

Additional Resources

- You may find the Stored Procedures User Forum of use when working with stored procedures and functions.

- For answers to some commonly asked questions regarding stored routines in MySQL, see Section A.4, "MySQL 5.1 FAQ: Stored Procedures and Functions".

- There are some restrictions on the use of stored routines. See Section C.1, "Restrictions on Stored Programs".

- Binary logging for stored routines takes place as described in Section 19.7, "Binary Logging of Stored Programs".

19.2.1 Stored Routine Syntax

A stored routine is either a procedure or a function. Stored routines are created with the `CREATE PROCEDURE` and `CREATE FUNCTION` statements (see Section 13.1.15, "CREATE PROCEDURE and CREATE FUNCTION Syntax"). A procedure is invoked using a `CALL` statement (see Section 13.2.1, "CALL Syntax"), and can only pass back values using output variables. A function can be called from inside a statement just like any other function (that is, by invoking the function's name), and can return
a scalar value. The body of a stored routine can use compound statements (see Section 13.6, “MySQL Compound-Statement Syntax”).

Stored routines can be dropped with the `DROP PROCEDURE` and `DROP FUNCTION` statements (see Section 13.1.26, “DROP PROCEDURE and DROP FUNCTION Syntax”), and altered with the `ALTER PROCEDURE` and `ALTER FUNCTION` statements (see Section 13.1.5, “ALTER PROCEDURE Syntax”).

A stored procedure or function is associated with a particular database. This has several implications:

- When the routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). `USE` statements within stored routines are not permitted.

- You can qualify routine names with the database name. This can be used to refer to a routine that is not in the current database. For example, to invoke a stored procedure `p` or function `f` that is associated with the `test` database, you can say `CALL test.p()` or `test.f()`.

- When a database is dropped, all stored routines associated with it are dropped as well.

Stored functions cannot be recursive.

Recursion in stored procedures is permitted but disabled by default. To enable recursion, set the `max_sp_recursion_depth` server system variable to a value greater than zero. Stored procedure recursion increases the demand on thread stack space. If you increase the value of `max_sp_recursion_depth`, it may be necessary to increase thread stack size by increasing the value of `thread_stack` at server startup. See Section 5.1.4, “Server System Variables”, for more information.

MySQL supports a very useful extension that enables the use of regular `SELECT` statements (that is, without using cursors or local variables) inside a stored procedure. The result set of such a query is simply sent directly to the client. Multiple `SELECT` statements generate multiple result sets, so the client must use a MySQL client library that supports multiple result sets. This means the client must use a client library from a version of MySQL at least as recent as 4.1. The client should also specify the `CLIENT_MULTI_RESULTS` option when it connects. For C programs, this can be done with the `mysql_real_connect()` C API function. See Section 21.8.7.52, “mysql_real_connect()”, and Section 21.8.16, “C API Support for Multiple Statement Execution”.

### 19.2.2 Stored Routines and MySQL Privileges

The MySQL grant system takes stored routines into account as follows:

- The `CREATE ROUTINE` privilege is needed to create stored routines.

- The `ALTER ROUTINE` privilege is needed to alter or drop stored routines. This privilege is granted automatically to the creator of a routine if necessary, and dropped from the creator when the routine is dropped.

- The `EXECUTE` privilege is required to execute stored routines. However, this privilege is granted automatically to the creator of a routine if necessary (and dropped from the creator when the routine is dropped). Also, the default `SQL SECURITY` characteristic for a routine is `DEFINER`, which enables users who have access to the database with which the routine is associated to execute the routine.

- If the `automatic_sp_privileges` system variable is 0, the `EXECUTE` and `ALTER ROUTINE` privileges are not automatically granted to and dropped from the routine creator.

- The creator of a routine is the account used to execute the `CREATE` statement for it. This might not be the same as the account named as the `DEFINER` in the routine definition.

The server manipulates the `mysql.proc` table in response to statements that create, alter, or drop stored routines. It is not supported that the server will notice manual manipulation of this table.

### 19.2.3 Stored Routine Metadata
Metadata about stored routines can be obtained as follows:

- Query the `ROUTINES` table of the `INFORMATION_SCHEMA` database. See Section 20.16, “The INFORMATION_SCHEMA ROUTINES Table”.

- Use the `SHOW CREATE PROCEDURE` and `SHOW CREATE FUNCTION` statements to see routine definitions. See Section 13.7.5.11, “SHOW CREATE PROCEDURE Syntax”.

- Use the `SHOW PROCEDURE STATUS` and `SHOW FUNCTION STATUS` statements to see routine characteristics. See Section 13.7.5.30, “SHOW PROCEDURE STATUS Syntax”.

- `INFORMATION_SCHEMA` does not have a `PARAMETERS` table until MySQL 5.5, so applications that need to acquire routine parameter information at runtime must use workarounds such as parsing the output of `SHOW CREATE` statements or the `param_list` column of the `mysql.proc` table. `param_list` contents can be processed from within a stored routine, unlike the output from `SHOW`.

### 19.2.4 Stored Procedures, Functions, Triggers, and LAST_INSERT_ID()

Within the body of a stored routine (procedure or function) or a trigger, the value of `LAST_INSERT_ID()` changes the same way as for statements executed outside the body of these kinds of objects (see Section 12.14, “Information Functions”). The effect of a stored routine or trigger upon the value of `LAST_INSERT_ID()` that is seen by following statements depends on the kind of routine:

- If a stored procedure executes statements that change the value of `LAST_INSERT_ID()`, the changed value is seen by statements that follow the procedure call.

- For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so following statements do not see a changed value.

### 19.3 Using Triggers

A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. Some uses for triggers are to perform checks of values to be inserted into a table or to perform calculations on values involved in an update.

A trigger is defined to activate when a statement inserts, updates, or deletes rows in the associated table. These row operations are trigger events. For example, rows can be inserted by `INSERT` or `LOAD DATA` statements, and an insert trigger activates for each inserted row. A trigger can be set to activate either before or after the trigger event. For example, you can have a trigger activate before each row that is inserted into a table or after each row that is updated.

**Important**

MySQL triggers activate only for changes made to tables by SQL statements. They do not activate for changes in views, nor by changes to tables made by APIs that do not transmit SQL statements to the MySQL Server. This means that:

- Triggers are not activated by changes in `INFORMATION_SCHEMA` tables, because these tables are actually views.

- Triggers are not activated by updates made using the `NDB` API.

To use triggers if you have upgraded to MySQL 5.1 from an older release that did not support triggers, you should upgrade your grant tables so that they contain the trigger-related privileges. See Section 4.4.8, “mysql_upgrade — Check and Upgrade MySQL Tables”.

The following sections describe the syntax for creating and dropping triggers, show some examples of how to use them, and indicate how to obtain trigger metadata.
Additional Resources

- You may find the Triggers User Forum of use when working with triggers.

- For answers to commonly asked questions regarding triggers in MySQL, see Section A.5, “MySQL 5.1 FAQ: Triggers”.

- There are some restrictions on the use of triggers; see Section C.1, “Restrictions on Stored Programs”.

- Binary logging for triggers takes place as described in Section 19.7, “BinaryLogging of Stored Programs”.

19.3.1 Trigger Syntax and Examples

To create a trigger or drop a trigger, use the CREATE_TRIGGER or DROP_TRIGGER statement, described in Section 13.1.19, “CREATE TRIGGER Syntax”, and Section 13.1.30, “DROP TRIGGER Syntax”.

Here is a simple example that associates a trigger with a table, to activate for INSERT operations. The trigger acts as an accumulator, summing the values inserted into one of the columns of the table.

```
mysql> CREATE TABLE account (acct_num INT, amount DECIMAL(10,2));
Query OK, 0 rows affected (0.03 sec)
mysql> CREATE TRIGGER ins_sum BEFORE INSERT ON account
    -> FOR EACH ROW SET @sum = @sum + NEW.amount;
Query OK, 0 rows affected (0.06 sec)
```

The CREATE TRIGGER statement creates a trigger named ins_sum that is associated with the account table. It also includes clauses that specify the trigger action time, the triggering event, and what to do when the trigger activates:

- The keyword BEFORE indicates the trigger action time. In this case, the trigger activates before each row inserted into the table. The other permitted keyword here is AFTER.

- The keyword INSERT indicates the trigger event; that is, the type of operation that activates the trigger. In the example, INSERT operations cause trigger activation. You can also create triggers for DELETE and UPDATE operations.

- The statement following FOR EACH ROW defines the trigger body; that is, the statement to execute each time the trigger activates, which occurs once for each row affected by the triggering event. In the example, the trigger body is a simple SET that accumulates into a user variable the values inserted into the amount column. The statement refers to the column as NEW.amount which means “the value of the amount column to be inserted into the new row.”

To use the trigger, set the accumulator variable to zero, execute an INSERT statement, and then see what value the variable has afterward:

```
mysql> SET @sum = 0;
mysql> INSERT INTO account VALUES(137,14.98),(141,1937.50),(97,-100.00);
mysql> SELECT @sum AS 'Total amount inserted';
+-----------------------+
| Total amount inserted |
| 1852.48               |
+-----------------------+
```

In this case, the value of @sum after the INSERT statement has executed is \(14.98 + 1937.50 - 100\), or \(1852.48\).

To destroy the trigger, use a DROP_TRIGGER statement. You must specify the schema name if the trigger is not in the default schema:
If you drop a table, any triggers for the table are also dropped.

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

In addition to the requirement that trigger names be unique for a schema, there are other limitations on the types of triggers you can create. In particular, there cannot be multiple triggers for a given table that have the same trigger event and action time. For example, you cannot have two \texttt{BEFORE UPDATE} triggers for a table. To work around this, you can define a trigger that executes multiple statements by using the \texttt{BEGIN ... END} compound statement construct after \texttt{FOR EACH ROW}. (An example appears later in this section.)

Within the trigger body, the \texttt{OLD} and \texttt{NEW} keywords enable you to access columns in the rows affected by a trigger. \texttt{OLD} and \texttt{NEW} are MySQL extensions to triggers; they are not case sensitive.

In an \texttt{INSERT} trigger, only \texttt{NEW.\texttt{col\_name}} can be used; there is no old row. In a \texttt{DELETE} trigger, only \texttt{OLD.\texttt{col\_name}} can be used; there is no new row. In an \texttt{UPDATE} trigger, you can use \texttt{OLD.\texttt{col\_name}} to refer to the columns of a row before it is updated and \texttt{NEW.\texttt{col\_name}} to refer to the columns of the row after it is updated.

A column named with \texttt{OLD} is read only. You can refer to it (if you have the \texttt{SELECT} privilege), but not modify it. You can refer to a column named with \texttt{NEW} if you have the \texttt{SELECT} privilege for it. In a \texttt{BEFORE} trigger, you can also change its value with \texttt{SET NEW.\texttt{col\_name}} = \texttt{value} if you have the \texttt{UPDATE} privilege for it. This means you can use a trigger to modify the values to be inserted into a new row or used to update a row. (Such a \texttt{SET} statement has no effect in an \texttt{AFTER} trigger because the row change will have already occurred.)

In a \texttt{BEFORE} trigger, the \texttt{NEW} value for an \texttt{AUTO_INCREMENT} column is 0, not the sequence number that is generated automatically when the new row actually is inserted.

By using the \texttt{BEGIN ... END} construct, you can define a trigger that executes multiple statements. Within the \texttt{BEGIN} block, you also can use other syntax that is permitted within stored routines such as conditionals and loops. However, just as for stored routines, if you use the \texttt{mysql} program to define a trigger that executes multiple statements, it is necessary to redefine the \texttt{mysql} statement delimiter so that you can use the \texttt{;} statement delimiter within the trigger definition. The following example illustrates these points. It defines an \texttt{UPDATE} trigger that checks the new value to be used for updating each row, and modifies the value to be within the range from 0 to 100. This must be a \texttt{BEFORE} trigger because the value must be checked before it is used to update the row:

```sql
mysql> delimiter //
mysql> CREATE TRIGGER upd_check BEFORE UPDATE ON account
    -> FOR EACH ROW
    -> BEGIN
    ->     IF NEW.amount < 0 THEN
    ->         SET NEW.amount = 0;
    ->     ELSEIF NEW.amount > 100 THEN
    ->         SET NEW.amount = 100;
    ->     END IF;
    -> END;//
mysql> delimiter ;
```

It can be easier to define a stored procedure separately and then invoke it from the trigger using a simple \texttt{CALL} statement. This is also advantageous if you want to execute the same code from within several triggers.

There are limitations on what can appear in statements that a trigger executes when activated:

- The trigger cannot use the \texttt{CALL} statement to invoke stored procedures that return data to the client or that use dynamic SQL. (Stored procedures are permitted to return data to the trigger through \texttt{OUT} or \texttt{INOUT} parameters.)
Trigger Syntax and Examples

- The trigger cannot use statements that explicitly or implicitly begin or end a transaction, such as `START TRANSACTION, COMMIT, or ROLLBACK`. (*ROLLBACK to SAVEPOINT* is permitted because it does not end a transaction.).

See also Section C.1, “Restrictions on Stored Programs”.

MySQL handles errors during trigger execution as follows:

- If a *BEFORE* trigger fails, the operation on the corresponding row is not performed.

- A *BEFORE* trigger is activated by the *attempt* to insert or modify the row, regardless of whether the attempt subsequently succeeds.

- An *AFTER* trigger is executed only if any *BEFORE* triggers and the row operation execute successfully.

- An error during either a *BEFORE* or *AFTER* trigger results in failure of the entire statement that caused trigger invocation.

- For transactional tables, failure of a statement should cause rollback of all changes performed by the statement. Failure of a trigger causes the statement to fail, so trigger failure also causes rollback. For nontransactional tables, such rollback cannot be done, so although the statement fails, any changes performed prior to the point of the error remain in effect.

In MySQL 5.1, triggers can contain direct references to tables by name, such as the trigger named testref shown in this example:

```sql
CREATE TABLE test1(a1 INT);
CREATE TABLE test2(a2 INT);
CREATE TABLE test3(a3 INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
CREATE TABLE test4(
a4 INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
b4 INT DEFAULT 0
);
delimiter |

CREATE TRIGGER testref BEFORE INSERT ON test1
FOR EACH ROW
BEGIN
    INSERT INTO test2 SET a2 = NEW.a1;
    DELETE FROM test3 WHERE a3 = NEW.a1;
    UPDATE test4 SET b4 = b4 + 1 WHERE a4 = NEW.a1;
END;
delimiter |

INSERT INTO test3 (a3) VALUES
(NULL), (NULL), (NULL), (NULL), (NULL),
(NULL), (NULL), (NULL), (NULL), (NULL),
(NULL), (NULL), (NULL), (NULL), (NULL);

INSERT INTO test4 (a4) VALUES
(0), (0), (0), (0), (0), (0), (0), (0), (0), (0),
(0), (0), (0), (0), (0), (0), (0);```

Suppose that you insert the following values into table test1 as shown here:

```
mysql> INSERT INTO test1 VALUES
    -> (1), (3), (1), (7), (1), (8), (4), (4);
Query OK, 8 rows affected (0.01 sec)
Records: 8  Duplicates: 0  Warnings: 0
```

As a result, the four tables contain the following data:

```
mysql> SELECT * FROM test1;
+------+---
| a1   |   |
+------+---
| 1     |   |
| 3     |   |
| 1     |   |
| 7     |   |
| 1     |   |
| 8     |   |
| 4     |   |
| 4     |   |
+------+---
```
19.3.2 Trigger Metadata

Metadata about triggers can be obtained as follows:

• Query the TRIGGERS table of the INFORMATION_SCHEMA database. See Section 20.23, “The INFORMATION_SCHEMA TRIGGERS Table”.

• Use the SHOW CREATE TRIGGER statement. See Section 13.7.5.13, “SHOW CREATE TRIGGER Syntax”.

• Use the SHOW TRIGGERS statement. See Section 13.7.5.40, “SHOW TRIGGERS Syntax”.

19.4 Using the Event Scheduler
The MySQL Event Scheduler manages the scheduling and execution of events: Tasks that run according to schedule. Event support was added in MySQL 5.1.6. The following discussion covers the Event Scheduler and is divided into the following sections:

- **Section 19.4.1, “Event Scheduler Overview”,** provides an introduction to and conceptual overview of MySQL Events.

- **Section 19.4.3, “Event Syntax”,** discusses the SQL statements for creating, altering, and dropping MySQL Events.

- **Section 19.4.4, “Event Metadata”,** shows how to obtain information about events and how this information is stored by the MySQL Server.

- **Section 19.4.6, “The Event Scheduler and MySQL Privileges”,** discusses the privileges required to work with events and the ramifications that events have with regard to privileges when executing.

Stored routines require the *event* table in the *mysql* database. This table is created during the MySQL 5.1 installation procedure. If you are upgrading to MySQL 5.1 from an earlier version, be sure to update your grant tables to make sure that the *event* table exists. See **Section 4.4.8, “mysql_upgrade — Check and Upgrade MySQL Tables”.**

**Additional Resources**

- You may find the MySQL Event Scheduler User Forum of use when working with scheduled events.

- There are some restrictions on the use of events; see **Section C.1, “Restrictions on Stored Programs”.**

- Binary logging for events takes place as described in **Section 19.7, “Binary Logging of Stored Programs”.**

### 19.4.1 Event Scheduler Overview

MySQL Events are tasks that run according to a schedule. Therefore, we sometimes refer to them as scheduled events. When you create an event, you are creating a named database object containing one or more SQL statements to be executed at one or more regular intervals, beginning and ending at a specific date and time. Conceptually, this is similar to the idea of the Unix *crontab* (also known as a “cron job”) or the Windows Task Scheduler.

Scheduled tasks of this type are also sometimes known as “temporal triggers”, implying that these are objects that are triggered by the passage of time. While this is essentially correct, we prefer to use the term events to avoid confusion with triggers of the type discussed in **Section 19.3, “Using Triggers”.** Events should more specifically not be confused with “temporary triggers”. Whereas a trigger is a database object whose statements are executed in response to a specific type of event that occurs on a given table, a (scheduled) event is an object whose statements are executed in response to the passage of a specified time interval.

While there is no provision in the SQL Standard for event scheduling, there are precedents in other database systems, and you may notice some similarities between these implementations and that found in the MySQL Server.

MySQL Events have the following major features and properties:

- In MySQL 5.1.12 and later, an event is uniquely identified by its name and the schema to which it is assigned. (Previously, an event was also unique to its definer.)

- An event performs a specific action according to a schedule. This action consists of an SQL statement, which can be a compound statement in a **BEGIN ... END** block if desired (see **Section 13.6, “MySQL Compound-Statement Syntax”.**) An event’s timing can be either **one-time** or **recurrent**. A one-time event executes one time only. A recurrent event repeats its action at a regular interval, and the schedule for a recurring event can be assigned a specific start day and time.
end day and time, both, or neither. (By default, a recurring event's schedule begins as soon as it is created, and continues indefinitely, until it is disabled or dropped.)

If a repeating event does not terminate within its scheduling interval, the result may be multiple instances of the event executing simultaneously. If this is undesirable, you should institute a mechanism to prevent simultaneous instances. For example, you could use the GET_LOCK() function, or row or table locking.

- Users can create, modify, and drop scheduled events using SQL statements intended for these purposes. Syntactically invalid event creation and modification statements fail with an appropriate error message. A user may include statements in an event's action which require privileges that the user does not actually have. The event creation or modification statement succeeds but the event's action fails. See Section 19.4.6, “The Event Scheduler and MySQL Privileges” for details.

- Many of the properties of an event can be set or modified using SQL statements. These properties include the event's name, timing, persistence (that is, whether it is preserved following the expiration of its schedule), status (enabled or disabled), action to be performed, and the schema to which it is assigned. See Section 13.1.2, “ALTER EVENT Syntax”.

The default definer of an event is the user who created the event, unless the event has been altered, in which case the definer is the user who issued the last ALTER EVENT statement affecting that event. An event can be modified by any user having the EVENT privilege on the database for which the event is defined. (Prior to MySQL 5.1.12, only an event's definer, or a user having privileges on the mysql.event table, could modify a given event.) See Section 19.4.6, “The Event Scheduler and MySQL Privileges”.

- An event's action statement may include most SQL statements permitted within stored routines. For restrictions, see Section C.1, “Restrictions on Stored Programs”.

### 19.4.2 Event Scheduler Configuration

Events are executed by a special event scheduler thread; when we refer to the Event Scheduler, we actually refer to this thread. When running, the event scheduler thread and its current state can be seen by users having the PROCESS privilege in the output of SHOW PROCESSLIST, as shown in the discussion that follows.

The global event_scheduler system variable determines whether the Event Scheduler is enabled and running on the server. Beginning with MySQL 5.1.12, it has one of these 3 values, which affect event scheduling as described here:

- **OFF**: The Event Scheduler is stopped. The event scheduler thread does not run, is not shown in the output of SHOW PROCESSLIST, and no scheduled events are executed. OFF is the default value for event_scheduler.

  When the Event Scheduler is stopped (event_scheduler is OFF), it can be started by setting the value of event_scheduler to ON. (See next item.)

- **ON**: The Event Scheduler is started; the event scheduler thread runs and executes all scheduled events.

  When the Event Scheduler is ON, the event scheduler thread is listed in the output of SHOW PROCESSLIST as a daemon process, and its state is represented as shown here:

```
mysql> SHOW PROCESSLIST\G
*************************** 1. row ***************************
  Id: 1
  User: root
  Host: localhost
  db: NULL
  Command: Query
  Time: 0
```
Event Scheduler Configuration

---

**State:** NULL  
**Info:** show processlist  

<table>
<thead>
<tr>
<th>Id</th>
<th>2</th>
</tr>
</thead>
<tbody>
<tr>
<td>User</td>
<td>event_scheduler</td>
</tr>
<tr>
<td>Host</td>
<td>localhost</td>
</tr>
<tr>
<td>db</td>
<td>NULL</td>
</tr>
<tr>
<td>Command</td>
<td>Daemon</td>
</tr>
<tr>
<td>Time</td>
<td>3</td>
</tr>
<tr>
<td>State:</td>
<td>Waiting for next activation</td>
</tr>
<tr>
<td>Info:</td>
<td>NULL</td>
</tr>
</tbody>
</table>

2 rows in set (0.00 sec)

Event scheduling can be stopped by setting the value of `event_scheduler` to OFF.

- **DISABLED:** This value renders the Event Scheduler nonoperational. When the Event Scheduler is DISABLED, the event scheduler thread does not run (and so does not appear in the output of `SHOW PROCESSLIST`). In addition, the Event Scheduler state cannot be changed at runtime.

If the Event Scheduler status has not been set to DISABLED, `event_scheduler` can be toggled between ON and OFF (using `SET`). It is also possible to use 0 for OFF, and 1 for ON when setting this variable. Thus, any of the following 4 statements can be used in the `mysql` client to turn on the Event Scheduler:

```sql
SET GLOBAL event_scheduler = ON;
SET @@global.event_scheduler = ON;
SET GLOBAL event_scheduler = 1;
SET @@global.event_scheduler = 1;
```

Similarly, any of these 4 statements can be used to turn off the Event Scheduler:

```sql
SET GLOBAL event_scheduler = OFF;
SET @@global.event_scheduler = OFF;
SET GLOBAL event_scheduler = 0;
SET @@global.event_scheduler = 0;
```

Although ON and OFF have numeric equivalents, the value displayed for `event_scheduler` by `SELECT` or `SHOW VARIABLES` is always one of OFF, ON, or DISABLED. DISABLED has no numeric equivalent. For this reason, ON and OFF are usually preferred over 1 and 0 when setting this variable.

Note that attempting to set `event_scheduler` without specifying it as a global variable causes an error:

```sql
mysql< SET @@event_scheduler = OFF;
ERROR 1229 (HY000): Variable 'event_scheduler' is a GLOBAL variable and should be set with SET GLOBAL
```

**Important**

It is possible to set the Event Scheduler to DISABLED only at server startup. If `event_scheduler` is ON or OFF, you cannot set it to DISABLED at runtime. Also, if the Event Scheduler is set to DISABLED at startup, you cannot change the value of `event_scheduler` at runtime.

To disable the event scheduler, use one of the following two methods:

- As a command-line option when starting the server:
  ```
  --event-scheduler=DISABLED
  ```

- In the server configuration file (`my.cnf`, or `my.ini` on Windows systems), include the line where it will be read by the server (for example, in a `[mysqld]` section):
To enable the Event Scheduler, restart the server without the `--event-scheduler=DISABLED` command-line option, or after removing or commenting out the line containing `event-scheduler=DISABLED` in the server configuration file, as appropriate. Alternatively, you can use **ON** (or 1) or **OFF** (or 0) in place of the **DISABLED** value when starting the server.

**Note**

You can issue event-manipulation statements when `event_scheduler` is set to **DISABLED**. No warnings or errors are generated in such cases (provided that the statements are themselves valid). However, scheduled events cannot execute until this variable is set to **ON** (or 1). Once this has been done, the event scheduler thread executes all events whose scheduling conditions are satisfied.

In MySQL 5.1.11, `event_scheduler` behaved as follows: this variable could take one of the values 0 (or **OFF**), 1 (or **ON**), or 2. Setting it to 0 turned event scheduling off, so that the event scheduler thread did not run; the `event_scheduler` variable could not be set to this value while the server was running. Setting it to 1 so that the event scheduler thread ran and executed scheduled events. In this state, the event scheduler thread appeared to be sleeping when viewed with `SHOW PROCESSLIST`. When `event_scheduler` was set to 2 (which was the default value), the Event Scheduler was considered to be “suspended”; the event scheduler thread ran and could be seen in the output of `SHOW PROCESSLIST` (where **Suspended** was displayed in the State column), but did not execute any scheduled events. The value of `event_scheduler` could be changed only between 1 (or **ON**) and 2 while the server was running. Setting it to 0 (or **OFF**) required a server restart, as did changing its value from 0 (or **OFF**) to 1 (or **ON**) or 2.

Prior to MySQL 5.1.11, `event_scheduler` could take one of only the 2 values 0 (**OFF**) or 1 (**ON**), and the default value was 0 (**OFF**). It was also possible to start and stop the event scheduler thread while the MySQL server was running.

For more information concerning the reasons for these changes in behavior, see Bug #17619.

Beginning with MySQL 5.1.17, starting the MySQL server with the `--skip-grant-tables` option causes `event_scheduler` to be set to **DISABLED**, overriding any other value set either on the command line or in the `my.cnf` or `my.ini` file (Bug #26807).

For SQL statements used to create, alter, and drop events, see Section 19.4.3, “Event Syntax”.

MySQL 5.1.6 and later provides an **EVENTS** table in the **INFORMATION_SCHEMA** database. This table can be queried to obtain information about scheduled events which have been defined on the server. See Section 19.4.4, “Event Metadata”, and Section 20.7, “The **INFORMATION_SCHEMA EVENTS Table**”, for more information.

For information regarding event scheduling and the MySQL privilege system, see Section 19.4.6, “The Event Scheduler and MySQL Privileges”.

### 19.4.3 Event Syntax

MySQL 5.1.6 and later provides several SQL statements for working with scheduled events:

- New events are defined using the **CREATE EVENT** statement. See Section 13.1.11, “CREATE EVENT Syntax”.

- The definition of an existing event can be changed by means of the **ALTER EVENT** statement. See Section 13.1.2, “ALTER EVENT Syntax”.

- When a scheduled event is no longer wanted or needed, it can be deleted from the server by its definer using the **DROP EVENT** statement. See Section 13.1.22, “DROP EVENT Syntax”. Whether an event persists past the end of its schedule also depends on its **ON COMPLETION** clause, if it has one. See Section 13.1.11, “CREATE EVENT Syntax”.
An event can be dropped by any user having the `EVENT` privilege for the database on which the event is defined. Prior to MySQL 5.1.12, a user other than the definer required privileges on the `mysql.event` table. See Section 19.4.6, “The Event Scheduler and MySQL Privileges”.

### 19.4.4 Event Metadata

Metadata about events can be obtained as follows:

- Query the `event` table of the `mysql` database.
- Query the `EVENTS` table of the `INFORMATION_SCHEMA` database. See Section 20.7, “The INFORMATION_SCHEMA EVENTS Table”.
- Use the `SHOW CREATE EVENT` statement. See Section 13.7.5.9, “SHOW CREATE EVENT Syntax”.
- Use the `SHOW EVENTS` statement. See Section 13.7.5.19, “SHOW EVENTS Syntax”.

### Event Scheduler Time Representation

Each session in MySQL has a session time zone (STZ). This is the session `time_zone` value that is initialized from the server's global `time_zone` value when the session begins but may be changed during the session.

The session time zone that is current when a `CREATE EVENT` or `ALTER EVENT` statement executes is used to interpret times specified in the event definition. This becomes the event time zone (ETZ); that is, the time zone that is used for event scheduling and is in effect within the event as it executes.

For representation of event information in the `mysql.event` table, the `execute_at`, `starts`, and `ends` times are converted to UTC and stored along with the event time zone. This enables event execution to proceed as defined regardless of any subsequent changes to the server time zone or daylight saving time effects. The `last_executed` time is also stored in UTC.

If you select information from `mysql.event`, the times just mentioned are retrieved as UTC values. These times can also be obtained by selecting from the `INFORMATION_SCHEMA.EVENTS` table or from `SHOW EVENTS`, but they are reported as ETZ values. Other times available from these sources indicate when an event was created or last altered; these are displayed as STZ values. The following table summarizes representation of event times.

<table>
<thead>
<tr>
<th>Value</th>
<th>mysql.event</th>
<th>INFORMATION_SCHEMA EVENTS</th>
<th>SHOW EVENTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execute at</td>
<td>UTC</td>
<td>ETZ</td>
<td>ETZ</td>
</tr>
<tr>
<td>Starts</td>
<td>UTC</td>
<td>ETZ</td>
<td>ETZ</td>
</tr>
<tr>
<td>Ends</td>
<td>UTC</td>
<td>ETZ</td>
<td>ETZ</td>
</tr>
<tr>
<td>Last executed</td>
<td>UTC</td>
<td>ETZ</td>
<td>n/a</td>
</tr>
<tr>
<td>Created</td>
<td>STZ</td>
<td>STZ</td>
<td>n/a</td>
</tr>
<tr>
<td>Last altered</td>
<td>STZ</td>
<td>STZ</td>
<td>n/a</td>
</tr>
</tbody>
</table>

The preceding table applies for MySQL 5.1.17 and up. Prior to MySQL 5.1.17, the event time zone is not stored in the `mysql.event` table or available from `INFORMATION_SCHEMA.EVENTS` or `SHOW EVENTS`. Times that are displayed using ETZ from 5.1.17 and up are displayed in UTC before 5.1.17, as shown in the following table.

<table>
<thead>
<tr>
<th>Value</th>
<th>mysql.event</th>
<th>INFORMATION_SCHEMA EVENTS</th>
<th>SHOW EVENTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execute at</td>
<td>UTC</td>
<td>UTC</td>
<td>UTC</td>
</tr>
<tr>
<td>Starts</td>
<td>UTC</td>
<td>UTC</td>
<td>UTC</td>
</tr>
<tr>
<td>Ends</td>
<td>UTC</td>
<td>UTC</td>
<td>UTC</td>
</tr>
<tr>
<td>Last executed</td>
<td>UTC</td>
<td>UTC</td>
<td>n/a</td>
</tr>
</tbody>
</table>
19.4.5 Event Scheduler Status

The Event Scheduler writes information about event execution that terminates with an error or warning to the MySQL Server's error log. See Section 19.4.6, “The Event Scheduler and MySQL Privileges” for an example. (Before MySQL 5.1.31, the Event Scheduler also logged messages when events started execution and terminated successfully.)

Information about the state of the Event Scheduler for debugging and troubleshooting purposes can be obtained as follows:

- In debugging builds of MySQL 5.1.11, you can use the SHOW SCHEDULER STATUS statement; see Section 13.7.5.34, “SHOW SCHEDULER STATUS Syntax”. This statement was removed in MySQL 5.1.12. We intend to implement an SQL statement providing similar functionality in a future MySQL release.

- Beginning with MySQL 5.1.12, event scheduler status information can be obtained by running mysqladmin debug (see Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”); after running this command, the server's error log contains output relating to the Event Scheduler, similar to what is shown here:

```
Events status:
   LLA = Last Locked At   LUA = Last Unlocked At
   WOC = Waiting On Condition   DL = Data Locked

  Event scheduler status:
   State    :  INITIALIZED
   Thread id:  0
   LLA       :  init_scheduler:313
   LUA       :  init_scheduler:318
   WOC       :  NO
   Workers   :  0
   Executed  :  0
   Data locked:  NO

  Event queue status:
   Element count :  1
   Data locked   :  NO
   Attempting lock:  NO
   LLA           :  init_queue:148
   LUA           :  init_queue:168
   WOC           :  NO
   Next activation :  0000-00-00 00:00:00
```

In statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log. For frequently executed events, it is possible for this to result in many logged messages. For example, for SELECT ... INTO var_list statements, if the query returns no rows, a warning with error code 1329 occurs (No data), and the variable values remain unchanged. If the query returns multiple rows, error 1172 occurs (Result consisted of more than one row). For either condition, you can avoid having the warnings be logged by declaring a condition handler; see Section 13.6.7.2, “DECLARE ... HANDLER Syntax”. For statements that may retrieve multiple rows, another strategy is to use LIMIT 1 to limit the result set to a single row.

19.4.6 The Event Scheduler and MySQL Privileges

To enable or disable the execution of scheduled events, it is necessary to set the value of the global event_scheduler system variable. This requires the SUPER privilege.
MySQL 5.1.6 introduces a privilege governing the creation, modification, and deletion of events, the **EVENT** privilege. This privilege can be bestowed using **GRANT**. For example, this **GRANT** statement confers the **EVENT** privilege for the schema named `myschema` on the user `jon@ghidora`:

```sql
GRANT EVENT ON myschema.* TO jon@ghidora;
```

(We assume that this user account already exists, and that we wish for it to remain unchanged otherwise.)

To grant this same user the **EVENT** privilege on all schemas, use the following statement:

```sql
GRANT EVENT ON *.* TO jon@ghidora;
```

The **EVENT** privilege has global or schema-level scope. Therefore, trying to grant it on a single table results in an error as shown:

```sql
mysql> GRANT EVENT ON myschema.mytable TO jon@ghidora;
ERROR 1144 (42000): Illegal GRANT/REVOKE command; please consult the manual to see which privileges can be used
```

It is important to understand that an event is executed with the privileges of its definer, and that it cannot perform any actions for which its definer does not have the requisite privileges. For example, suppose that `jon@ghidora` has the **EVENT** privilege for `myschema`. Suppose also that this user has the **SELECT** privilege for `myschema`, but no other privileges for this schema. It is possible for `jon@ghidora` to create a new event such as this one:

```sql
CREATE EVENT e_store_ts
ON SCHEDULE EVERY 10 SECOND
DO
    INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
```

The user waits for a minute or so, and then performs a `SELECT * FROM mytable;` query, expecting to see several new rows in the table. Instead, the table is empty. Since the user does not have the **INSERT** privilege for the table in question, the event has no effect.

If you inspect the MySQL error log (`hostname.err`), you can see that the event is executing, but the action it is attempting to perform fails, as indicated by `RetCode=0`:

```
060209 22:39:44 [Note]     EVEX EXECUTED event newdb.e  [EXPR:10]. RetCode=0
060209 22:39:54 [Note]     EVEX EXECUTING event newdb.e [EXPR:10]
060209 22:39:54 [Note]     EVEX EXECUTED event newdb.e  [EXPR:10]. RetCode=0
060209 22:40:04 [Note]     EVEX EXECUTING event newdb.e [EXPR:10]
060209 22:40:04 [Note]     EVEX EXECUTED event newdb.e  [EXPR:10]. RetCode=0
```

Since this user very likely does not have access to the error log, it is possible to verify whether the event's action statement is valid by executing it directly:

```sql
mysql> INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
ERROR 1142 (42000): INSERT command denied to user 'jon'@'ghidora' for table 'mytable'
```

Inspection of the **INFORMATION_SCHEMA.EVENTS** table shows that `e_store_ts` exists and is enabled, but its **LAST_EXECUTED** column is **NULL**:

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
    > WHERE EVENT_NAME='e_store_ts'
    > AND EVENT_SCHEMA='myschema';
```

**In summary,** the **EVENT** privilege is used to grant permissions to users to create, modify, and delete events. It operates at a global or schema level, and its execution is limited by the privileges of the user who owns the event. If a user attempts an action for which they do not have the requisite privileges, the event will not execute as intended. Additionally, inspecting the error log or the INFORMATION_SCHEMA<Event> table can provide insights into the execution of events and their associated permissions.
To rescind the EVENT privilege, use the REVOKE statement. In this example, the EVENT privilege on the schema myschema is removed from the jon@ghidora user account:

```
REVOKE EVENT ON myschema.* FROM jon@ghidora;
```

Important
Revoking the EVENT privilege from a user does not delete or disable any events that may have been created by that user.

An event is not migrated or dropped as a result of renaming or dropping the user who created it.

Suppose that the user jon@ghidora has been granted the EVENT and INSERT privileges on the myschema schema. This user then creates the following event:

```
CREATE EVENT e_insert
ON SCHEDULE
    EVERY 7 SECOND
DO
    INSERT INTO myschema.mytable;
```

After this event has been created, root revokes the EVENT privilege for jon@ghidora. However, e_insert continues to execute, inserting a new row into mytable each seven seconds. The same would be true if root had issued either of these statements:

• DROP USER jon@ghidora;

• RENAME USER jon@ghidora TO someotherguy@ghidora;

You can verify that this is true by examining the mysql.event table (discussed later in this section) or the INFORMATION_SCHEMA.EVENTS table (see Section 20.7, "The INFORMATION_SCHEMA EVENTS Table") before and after issuing a DROP USER or RENAME USER statement.

Event definitions are stored in the mysql.event table, which was added in MySQL 5.1.6. To drop an event created by another user account, the MySQL root user (or another user with the necessary

1 row in set (0.00 sec)
privileges) can delete rows from this table. For example, to remove the event e_insert shown previously, root can use the following statement:

```sql
DELETE FROM mysql.event
WHERE db = 'myschema'
    AND definer = 'jon@ghidora'
    AND name = 'e_insert';
```

It is very important to match the event name, database schema name, and user account when deleting rows from the mysql.event table. This is because the same user can create different events of the same name in different schemas.

**Note**

The namespace for scheduled events changed in MySQL 5.1.12. Prior to that MySQL version, different users could create different events having the same name in the same database; in MySQL 5.1.12 and later, that is no longer the case. When upgrading to MySQL 5.1.12 or later from MySQL 5.1.11 or earlier, it is extremely important to make sure that no events in the same database share the same name, prior to performing the upgrade.

Users’ EVENT privileges are stored in the Event_priv columns of the mysql.user and mysql.db tables. In both cases, this column holds one of the values ‘Y’ or ‘N’. ‘N’ is the default. mysql.user.Event_priv is set to ‘Y’ for a given user only if that user has the global EVENT privilege (that is, if the privilege was bestowed using GRANT EVENT ON *.*). For a schema-level EVENT privilege, GRANT creates a row in mysql.db and sets that row’s Db column to the name of the schema, the User column to the name of the user, and the Event_priv column to ‘Y’. There should never be any need to manipulate these tables directly, since the GRANT EVENT and REVOKE EVENT statements perform the required operations on them.

MySQL 5.1.6 introduces five status variables providing counts of event-related operations (but not of statements executed by events; see Section C.1, “Restrictions on Stored Programs”). These are:

- **Com_create_event**: The number of CREATE EVENT statements executed since the last server restart.
- **Com_alter_event**: The number of ALTER EVENT statements executed since the last server restart.
- **Com_drop_event**: The number of DROP EVENT statements executed since the last server restart.
- **Com_show_create_event**: The number of SHOW CREATE EVENT statements executed since the last server restart.
- **Com_show_events**: The number of SHOW EVENTS statements executed since the last server restart.

You can view current values for all of these at one time by running the statement `SHOW STATUS LIKE '%event%';`.

### 19.5 Using Views

MySQL supports views, including updatable views. Views are stored queries that when invoked produce a result set. A view acts as a virtual table.

To use views if you have upgraded to MySQL 5.1 from an older release that did not support views, you should upgrade your grant tables so that they contain the view-related privileges. See Section 4.4.8, "mysql_upgrade — Check and Upgrade MySQL Tables".

The following discussion describes the syntax for creating and dropping views, and shows some examples of how to use them.
Additional Resources

- You may find the Views User Forum of use when working with views.
- For answers to some commonly asked questions regarding views in MySQL, see Section A.6, “MySQL 5.1 FAQ: Views”.
- There are some restrictions on the use of views; see Section C.4, “Restrictions on Views”.

19.5.1 View Syntax

The `CREATE VIEW` statement creates a new view (see Section 13.1.20, “CREATE VIEW Syntax”). To alter the definition of a view or drop a view, use `ALTER VIEW` (see Section 13.1.9, “ALTER VIEW Syntax”), or `DROP VIEW` (see Section 13.1.31, “DROP VIEW Syntax”).

A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables. The following example defines a view that selects two columns from another table, as well as an expression calculated from those columns:

```sql
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50), (5, 60);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+------+-------+-------+
<table>
<thead>
<tr>
<th>qty</th>
<th>price</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>50</td>
<td>150</td>
</tr>
<tr>
<td>5</td>
<td>60</td>
<td>300</td>
</tr>
<tr>
<td>------</td>
<td>-------</td>
<td>-------</td>
</tr>
</tbody>
</table>
```

19.5.2 View Processing Algorithms

The optional `ALGORITHM` clause for `CREATE VIEW` or `ALTER VIEW` is a MySQL extension to standard SQL. It affects how MySQL processes the view. `ALGORITHM` takes three values: `MERGE`, `TEMPTABLE`, or `UNDEFINED`.

- For `MERGE`, the text of a statement that refers to the view and the view definition are merged such that parts of the view definition replace corresponding parts of the statement.
- For `TEMPTABLE`, the results from the view are retrieved into a temporary table, which then is used to execute the statement.
- For `UNDEFINED`, MySQL chooses which algorithm to use. It prefers `MERGE` over `TEMPTABLE` if possible, because `MERGE` is usually more efficient and because a view cannot be updatable if a temporary table is used.
- If no `ALGORITHM` clause is present, `UNDEFINED` is the default algorithm.

A reason to specify `TEMPTABLE` explicitly is that locks can be released on underlying tables after the temporary table has been created and before it is used to finish processing the statement. This might result in quicker lock release than the `MERGE` algorithm so that other clients that use the view are not blocked as long.

A view algorithm can be `UNDEFINED` for three reasons:

- No `ALGORITHM` clause is present in the `CREATE VIEW` statement.
• The `CREATE VIEW` statement has an explicit `ALGORITHM = UNDEFINED` clause.

• `ALGORITHM = MERGE` is specified for a view that can be processed only with a temporary table. In this case, MySQL generates a warning and sets the algorithm to `UNDEFINED`.

As mentioned earlier, `MERGE` is handled by merging corresponding parts of a view definition into the statement that refers to the view. The following examples briefly illustrate how the `MERGE` algorithm works. The examples assume that there is a view `v_merge` that has this definition:

```
CREATE ALGORITHM = MERGE VIEW v_merge (vc1, vc2) AS
    SELECT c1, c2 FROM t WHERE c3 > 100;
```

**Example 1:** Suppose that we issue this statement:

```
SELECT * FROM v_merge;
```

MySQL handles the statement as follows:

• `v_merge` becomes `t`

• `*` becomes `vc1, vc2`, which corresponds to `c1, c2`

• The view `WHERE` clause is added

The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE c3 > 100;
```

**Example 2:** Suppose that we issue this statement:

```
SELECT * FROM v_merge WHERE vc1 < 100;
```

This statement is handled similarly to the previous one, except that `vc1 < 100` becomes `c1 < 100` and the view `WHERE` clause is added to the statement `WHERE` clause using an `AND` connective (and parentheses are added to make sure the parts of the clause are executed with correct precedence). The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE (c3 > 100) AND (c1 < 100);
```

Effectively, the statement to be executed has a `WHERE` clause of this form:

```
WHERE (select WHERE) AND (view WHERE)
```

If the `MERGE` algorithm cannot be used, a temporary table must be used instead. `MERGE` cannot be used if the view contains any of the following constructs:

• Aggregate functions (`SUM()`, `MIN()`, `MAX()`, `COUNT()`, and so forth)

• `DISTINCT`

• `GROUP BY`

• `HAVING`

• `LIMIT`

• `UNION` or `UNION ALL`

• Subquery in the select list

• Assignment to user variables

• Refers only to literal values (in this case, there is no underlying table)
19.5.3 Updatable and Insertable Views

Some views are updatable and references to them can be used to specify tables to be updated in data change statements. That is, you can use them in statements such as **UPDATE**, **DELETE**, or **INSERT** to update the contents of the underlying table.

For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view nonupdatable. To be more specific, a view is not updatable if it contains any of the following:

- Aggregate functions (**SUM()**, **MIN()**, **MAX()**, **COUNT()**, and so forth)
- **DISTINCT**
- **GROUP BY**
- **HAVING**
- **UNION** or **UNION ALL**
- Subquery in the select list
- Certain joins (see additional join discussion later in this section)
- Reference to nonupdatable view in the **FROM** clause
- Subquery in the **WHERE** clause that refers to a table in the **FROM** clause
- Refers only to literal values (in this case, there is no underlying table to update)
- **ALGORITHM = TEMPTABLE** (use of a temporary table always makes a view nonupdatable)
- Multiple references to any column of a base table

It is sometimes possible for a multiple-table view to be updatable, assuming that it can be processed with the **MERGE** algorithm. For this to work, the view must use an inner join (not an outer join or a **UNION**). Also, only a single table in the view definition can be updated, so the **SET** clause must name only columns from one of the tables in the view. Views that use **UNION ALL** are not permitted even though they might be theoretically updatable.

With respect to insertability (being updatable with **INSERT** statements), an updatable view is insertable if it also satisfies these additional requirements for the view columns:

- There must be no duplicate view column names.
- The view must contain all columns in the base table that do not have a default value.
- The view columns must be simple column references. They must not be expressions or composite expressions, such as these:

  ```
  3.14159
  col1 + 3
  UPPER(col2)
  col3 / col4
  (subquery)
  ```

MySQL sets a flag, called the view updatability flag, at **CREATE VIEW** time. The flag is set to **YES** (true) if **UPDATE** and **DELETE** (and similar operations) are legal for the view. Otherwise, the flag is set to **NO** (false). The **IS_UPDATABLE** column in the **INFORMATION_SCHEMA.VIEWS** table displays the status of this flag. It means that the server always knows whether a view is updatable.

If a view is not updatable, statements such **UPDATE**, **DELETE**, and **INSERT** are illegal and are rejected. (Note that even if a view is updatable, it might not be possible to insert into it, as described elsewhere in this section.)
The updatability of views may be affected by the value of the `updatable_views_with_limit` system variable. See Section 5.1.4, “Server System Variables”.

Earlier discussion in this section pointed out that a view is not insertable if not all columns are simple column references (for example, if it contains columns that are expressions or composite expressions). Although such a view is not insertable, it can be updatable if you update only columns that are not expressions. Consider this view:

```sql
CREATE VIEW v AS SELECT col1, 1 AS col2 FROM t;
```

This view is not insertable because `col2` is an expression. But it is updatable if the update does not try to update `col2`. This update is permissible:

```sql
UPDATE v SET col1 = 0;
```

This update is not permissible because it attempts to update an expression column:

```sql
UPDATE v SET col2 = 0;
```

For a multiple-table updatable view, `INSERT` can work if it inserts into a single table. `DELETE` is not supported.

`INSERT DELAYED` is not supported for views.

If a table contains an `AUTO_INCREMENT` column, inserting into an insertable view on the table that does not include the `AUTO_INCREMENT` column does not change the value of `LAST_INSERT_ID()`, because the side effects of inserting default values into columns not part of the view should not be visible.

### 19.5.4 The View WITH CHECK OPTION Clause

The `WITH CHECK OPTION` clause can be given for an updatable view to prevent inserts to rows for which the `WHERE` clause in the `select_statement` is not true. It also prevents updates to rows for which the `WHERE` clause is true but the update would cause it to be not true (in other words, it prevents visible rows from being updated to nonvisible rows).

In a `WITH CHECK OPTION` clause for an updatable view, the `LOCAL` and `CASCADED` keywords determine the scope of check testing when the view is defined in terms of another view. When neither keyword is given, the default is `CASCADED`. The `LOCAL` keyword restricts the `CHECK OPTION` only to the view being defined. `CASCADED` causes the checks for underlying views to be evaluated as well.

Consider the definitions for the following table and set of views:

```sql
CREATE TABLE t1 (a INT);
CREATE VIEW v1 AS SELECT * FROM t1 WHERE a < 2
WITH CHECK OPTION;
CREATE VIEW v2 AS SELECT * FROM v1 WHERE a > 0
WITH LOCAL CHECK OPTION;
CREATE VIEW v3 AS SELECT * FROM v1 WHERE a > 0
WITH CASCADED CHECK OPTION;
```

Here the `v2` and `v3` views are defined in terms of another view, `v1`. `v2` has a `LOCAL` check option, so inserts are tested only against the `v2` check. `v3` has a `CASCADED` check option, so inserts are tested not only against its own check, but against those of underlying views. The following statements illustrate these differences:

```sql
mysql> INSERT INTO v2 VALUES (2);
Query OK, 1 row affected (0.00 sec)
mysql> INSERT INTO v3 VALUES (2);
ERROR 1369 (HY000): CHECK OPTION failed 'test.v3'
```
19.5.5 View Metadata

Metadata about views can be obtained as follows:

- Query the VIEWS table of the INFORMATION_SCHEMA database. See Section 20.25, “The INFORMATION_SCHEMA VIEWS Table”.
- Use the SHOW CREATE VIEW statement. See Section 13.7.5.14, “SHOW CREATE VIEW Syntax”.

19.6 Access Control for Stored Programs and Views

Stored programs and views are defined prior to use and, when referenced, execute within a security context that determines their privileges. These privileges are controlled by their DEFINER attribute, and, if there is one, their SQL SECURITY characteristic.

All stored programs (procedures, functions, triggers, and events) and views can have a DEFINER attribute that names a MySQL account. If the DEFINER attribute is omitted from a stored program or view definition, the default account is the user who creates the object.

In addition, stored routines (procedures and functions) and views can have a SQL SECURITY characteristic with a value of DEFINER or INVOKER to specify whether the object executes in definer or invoker context. If the SQL SECURITY characteristic is omitted, the default is definer context.

Triggers and events have no SQL SECURITY characteristic and always execute in definer context. The server invokes these objects automatically as necessary, so there is no invoking user.

Definer and invoker security contexts differ as follows:

- A stored program or view that executes in definer security context executes with the privileges of the account named by its DEFINER attribute. These privileges may be entirely different from those of the invoking user. The invoker must have appropriate privileges to reference the object (for example, EXECUTE to call a stored procedure or SELECT to select from a view), but when the object executes, the invoker's privileges are ignored and only the DEFINER account privileges matter. If this account has few privileges, the object is correspondingly limited in the operations it can perform. If the DEFINER account is highly privileged (such as a root account), the object can perform powerful operations no matter who invokes it.

- A stored routine or view that executes in invoker security context can perform only operations for which the invoker has privileges. The DEFINER attribute can be specified but has no effect for objects that execute in invoker context.

Consider the following stored procedure:

```sql
CREATE DEFINER = 'admin'@'localhost' PROCEDURE p1()
SQL SECURITY DEFINER
BEGIN
  UPDATE t1 SET counter = counter + 1;
END;
```

Any user who has the EXECUTE privilege for `p1` can invoke it with a CALL statement. However, when `p1` executes, it does so in DEFINER security context and thus executes with the privileges of 'admin'@'localhost', the account named in the DEFINER attribute. This account must have the EXECUTE privilege for `p1` as well as the UPDATE privilege for the table `t1`. Otherwise, the procedure fails.

Now consider this stored procedure, which is identical to `p1` except that its SQL SECURITY characteristic is INVOKER:

```sql
CREATE DEFINER = 'admin'@'localhost' PROCEDURE p2()
SQL SECURITY INVOKER
```
BEGIN
    UPDATE t1 SET counter = counter + 1;
END;

p2, unlike p1, executes in INVOKER security context. The DEFINER attribute is irrelevant and p2 executes with the privileges of the invoking user. p2 fails if the invoker lacks the EXECUTE privilege for p2 or the UPDATE privilege for the table t1.

MySQL uses the following rules to control which accounts a user can specify in an object DEFINER attribute:

- You can specify a DEFINER value other than your own account only if you have the SUPER privilege.
- If you do not have the SUPER privilege, the only legal user value is your own account, either specified literally or by using CURRENT_USER. You cannot set the definer to some other account.

To minimize the risk potential for stored program and view creation and use, follow these guidelines:

- For a stored routine or view, use SQL SECURITY INVOKER in the object definition when possible so that it can be used only by users with permissions appropriate for the operations performed by the object.
- If you create definer-context stored programs or views while using an account that has the SUPER privilege, specify an explicit DEFINER attribute that names an account possessing only the privileges required for the operations performed by the object. Specify a highly privileged DEFINER account only when absolutely necessary.
- Administrators can prevent users from specifying highly privileged DEFINER accounts by not granting them the SUPER privilege.
- Definer-context objects should be written keeping in mind that they may be able to access data for which the invoking user has no privileges. In some cases, you can prevent reference to these objects by not granting unauthorized users particular privileges:
  - A stored procedure or function cannot be referenced by a user who does not have the EXECUTE privilege for it.
  - A view cannot be referenced by a user who does not have the appropriate privilege for it (SELECT to select from it, INSERT to insert into it, and so forth).

However, no such control exists for triggers because users do not reference them directly. A trigger always executes in DEFINER context and is activated by access to the table with which it is associated, even ordinary table accesses by users with no special privileges. If the DEFINER account is highly privileged, the trigger can perform sensitive or dangerous operations. This remains true if the SUPER and TRIGGER privileges needed to create the trigger are revoked from the account of the user who created it. Administrators should be especially careful about granting users that combination of privileges.

19.7 Binary Logging of Stored Programs

The binary log contains information about SQL statements that modify database contents. This information is stored in the form of “events” that describe the modifications. The binary log has two important purposes:

- For replication, the binary log is used on master replication servers as a record of the statements to be sent to slave servers. The master server sends the events contained in its binary log to its slaves, which execute those events to make the same data changes that were made on the master. See Section 16.2, “Replication Implementation”.
- Certain data recovery operations require use of the binary log. After a backup file has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These
events bring databases up to date from the point of the backup. See Section 7.3.2, “Using Backups for Recovery”.

However, there are certain binary logging issues that apply with respect to stored programs (stored procedures and functions, triggers, and events), if logging occurs at the statement level:

- In some cases, it is possible that a statement will affect different sets of rows on a master and a slave.

- Replicated statements executed on a slave are processed by the slave SQL thread, which has full privileges. It is possible for a procedure to follow different execution paths on master and slave servers, so a user can write a routine containing a dangerous statement that will execute only on the slave where it is processed by a thread that has full privileges.

- If a stored program that modifies data is nondeterministic, it is not repeatable. This can result in different data on a master and slave, or cause restored data to differ from the original data.

This section describes how MySQL 5.1 handles binary logging for stored programs. It states the current conditions that the implementation places on the use of stored programs, and what you can do to avoid problems. It also provides additional information about the reasons for these conditions.

In general, the issues described here result when binary logging occurs at the SQL statement level. If you use row-based binary logging, the log contains changes made to individual rows as a result of executing SQL statements. When routines or triggers execute, row changes are logged, not the statements that make the changes. For stored procedures, this means that the CALL statement is not logged. For stored functions, row changes made within the function are logged, not the function invocation. For triggers, row changes made by the trigger are logged. On the slave side, only the row changes are seen, not the stored program invocation. For general information about row-based logging, see Section 16.1.2, “Replication Formats”.

Unless noted otherwise, the remarks here assume that you have enabled binary logging by starting the server with the --log-bin option. (See Section 5.4.4, “The Binary Log”.) If the binary log is not enabled, replication is not possible, nor is the binary log available for data recovery.

The current conditions on the use of stored functions in MySQL 5.1 can be summarized as follows. These conditions do not apply to stored procedures or Event Scheduler events and they do not apply unless binary logging is enabled.

- To create or alter a stored function, you must have the SUPER privilege, in addition to the CREATE ROUTINE or ALTER ROUTINE privilege that is normally required. (Depending on the DEFINER value in the function definition, SUPER might be required regardless of whether binary logging is enabled. See Section 13.1.15, “CREATE PROCEDURE and CREATE FUNCTION Syntax”.)

- When you create a stored function, you must declare either that it is deterministic or that it does not modify data. Otherwise, it may be unsafe for data recovery or replication.

By default, for a CREATE FUNCTION statement to be accepted, at least one of DETERMINISTIC, NO SQL, or READS SQL DATA must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL, or READS SQL DATA in its declaration and binary logging is enabled
(you "might" want to use the less safe log_bin_trust_function_creators variable)
```

This function is deterministic (and does not modify data), so it is safe:

```
CREATE FUNCTION f1(i INT)
RETURNS INT
DETERMINISTIC
READS SQL DATA
BEGIN
```
RETURN i;
END;

This function uses `UUID()`, which is not deterministic, so the function also is not deterministic and is not safe:

```sql
CREATE FUNCTION f2()
RETURNS CHAR(36) CHARACTER SET utf8
BEGIN
  RETURN UUID();
END;
```

This function modifies data, so it may not be safe:

```sql
CREATE FUNCTION f3(p_id INT)
RETURNS INT
BEGIN
  UPDATE t SET modtime = NOW() WHERE id = p_id;
  RETURN ROW_COUNT();
END;
```

Assessment of the nature of a function is based on the “honesty” of the creator: MySQL does not check that a function declared `DETERMINISTIC` is free of statements that produce nondeterministic results.

- Although it is possible to create a deterministic stored function without specifying `DETERMINISTIC`, you cannot as of MySQL 5.1.15 execute this function using statement-based binary logging. To execute such a function, you must use row-based or mixed binary logging. Alternatively, if you explicitly specify `DETERMINISTIC` in the function definition, you can use any kind of logging, including statement-based logging.

- To relax the preceding conditions on function creation (that you must have the `SUPER` privilege and that a function must be declared deterministic or to not modify data), set the global `log_bin_trust_function_creators` system variable to 1. By default, this variable has a value of 0, but you can change it like this:

  ```sql
  mysql> SET GLOBAL log_bin_trust_function_creators = 1;
  ```

  You can also set this variable by using the `--log-bin-trust-function-creators=1` option when starting the server.

  If binary logging is not enabled, `log_bin_trust_function_creators` does not apply. `SUPER` is not required for function creation unless, as described previously, the `DEFINER` value in the function definition requires it.

- For information about built-in functions that may be unsafe for replication (and thus cause stored functions that use them to be unsafe as well), see Section 16.4.1, “Replication Features and Issues”.

Triggers are similar to stored functions, so the preceding remarks regarding functions also apply to triggers with the following exception: `CREATE TRIGGER` does not have an optional `DETERMINISTIC` characteristic, so triggers are assumed to be always deterministic. However, this assumption might in some cases be invalid. For example, the `UUID()` function is nondeterministic (and does not replicate). You should be careful about using such functions in triggers.

Triggers can update tables, so error messages similar to those for stored functions occur with `CREATE TRIGGER` if you do not have the required privileges. On the slave side, the slave uses the trigger `DEFINER` attribute to determine which user is considered to be the creator of the trigger.

The rest of this section provides additional detail about the logging implementation and its implications. You need not read it unless you are interested in the background on the rationale for the current logging-related conditions on stored routine use. This discussion applies only for statement-based
Binary Logging of Stored Programs

logging, and not for row-based logging, with the exception of the first item: CREATE and DROP statements are logged as statements regardless of the logging mode.

- The server writes CREATE EVENT, CREATE PROCEDURE, CREATE FUNCTION, ALTER EVENT, ALTER PROCEDURE, ALTER FUNCTION, DROP EVENT, DROP PROCEDURE, and DROP FUNCTION statements to the binary log.

- A stored function invocation is logged as a SELECT statement if the function changes data and occurs within a statement that would not otherwise be logged. This prevents nonreplication of data changes that result from use of stored functions in nonlogged statements. For example, SELECT statements are not written to the binary log, but a SELECT might invoke a stored function that makes changes. To handle this, a SELECT func_name() statement is written to the binary log when the given function makes a change. Suppose that the following statements are executed on the master:

```sql
CREATE FUNCTION f1(a INT) RETURNS INT
BEGIN
  IF (a < 3) THEN
    INSERT INTO t2 VALUES (a);
  END IF;
  RETURN 0;
END;
CREATE TABLE t1 (a INT);
INSERT INTO t1 VALUES (1),(2),(3);
SELECT f1(a) FROM t1;
```

When the SELECT statement executes, the function f1() is invoked three times. Two of those invocations insert a row, and MySQL logs a SELECT statement for each of them. That is, MySQL writes the following statements to the binary log:

```sql
SELECT f1(1);
SELECT f1(2);
```

The server also logs a SELECT statement for a stored function invocation when the function invokes a stored procedure that causes an error. In this case, the server writes the SELECT statement to the log along with the expected error code. On the slave, if the same error occurs, that is the expected result and replication continues. Otherwise, replication stops.

Note: Before MySQL 5.1.7, you will see these SELECT func_name() statements logged as DO func_name(). The change to SELECT was made because use of DO was found to yield insufficient control over error code checking.

- Logging stored function invocations rather than the statements executed by a function has a security implication for replication, which arises from two factors:
  - It is possible for a function to follow different execution paths on master and slave servers.
  - Statements executed on a slave are processed by the slave SQL thread which has full privileges.

The implication is that although a user must have the CREATE ROUTINE privilege to create a function, the user can write a function containing a dangerous statement that will execute only on the slave where it is processed by a thread that has full privileges. For example, if the master and slave servers have server ID values of 1 and 2, respectively, a user on the master server could create and invoke an unsafe function unsafe_func() as follows:

```sql
mysql> delimiter //
mysql> CREATE FUNCTION unsafe_func () RETURNS INT
| BEGIN |
| IF @@server_id=2 THEN dangerous_statement; END IF;
| RETURN 1; |
| END;
```
The `CREATE FUNCTION` and `INSERT` statements are written to the binary log, so the slave will execute them. Because the slave SQL thread has full privileges, it will execute the dangerous statement. Thus, the function invocation has different effects on the master and slave and is not replication-safe.

To guard against this danger for servers that have binary logging enabled, stored function creators must have the `SUPER` privilege, in addition to the usual `CREATE ROUTINE` privilege that is required. Similarly, to use `ALTER FUNCTION`, you must have the `SUPER` privilege in addition to the `ALTER ROUTINE` privilege. Without the `SUPER` privilege, an error will occur:

```
ERROR 1419 (HY000): You do not have the SUPER privilege and
binary logging is enabled (you *might* want to use the less safe
log_bin_trust_function_creators variable)
```

If you do not want to require function creators to have the `SUPER` privilege (for example, if all users with the `CREATE ROUTINE` privilege on your system are experienced application developers), set the global `log_bin_trust_function_creators` system variable to 1. You can also set this variable by using the `--log-bin-trust-function-creators=1` option when starting the server. If binary logging is not enabled, `log_bin_trust_function_creators` does not apply. `SUPER` is not required for function creation unless, as described previously, the `DEFINER` value in the function definition requires it.

- If a function that performs updates is nondeterministic, it is not repeatable. This can have two undesirable effects:
  - It will make a slave different from the master.
  - Restored data will be different from the original data.

To deal with these problems, MySQL enforces the following requirement: On a master server, creation and alteration of a function is refused unless you declare the function to be deterministic or to not modify data. Two sets of function characteristics apply here:

- The `DETERMINISTIC` and `NOT DETERMINISTIC` characteristics indicate whether a function always produces the same result for given inputs. The default is `NOT DETERMINISTIC` if neither characteristic is given. To declare that a function is deterministic, you must specify `DETERMINISTIC` explicitly.

- The `CONTAINS SQL`, `NO SQL`, `READS SQL DATA`, and `MODIFIES SQL DATA` characteristics provide information about whether the function reads or writes data. Either `NO SQL` or `READS SQL DATA` indicates that a function does not change data, but you must specify one of these explicitly because the default is `CONTAINS SQL` if no characteristic is given.

By default, for a `CREATE FUNCTION` statement to be accepted, at least one of `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL, or READS SQL DATA in its declaration and binary logging is enabled
(you *might* want to use the less safe log_bin_trust_functionCreators variable)
```

If you set `log_bin_trust_functionCreators` to 1, the requirement that functions be deterministic or not modify data is dropped.

- Stored procedure calls are logged at the statement level rather than at the `CALL` level. That is, the server does not log the `CALL` statement, it logs those statements within the procedure that actually execute. As a result, the same changes that occur on the master will be observed on slave servers.
This prevents problems that could result from a procedure having different execution paths on different machines.

In general, statements executed within a stored procedure are written to the binary log using the same rules that would apply were the statements to be executed in standalone fashion. Some special care is taken when logging procedure statements because statement execution within procedures is not quite the same as in nonprocedure context:

- A statement to be logged might contain references to local procedure variables. These variables do not exist outside of stored procedure context, so a statement that refers to such a variable cannot be logged literally. Instead, each reference to a local variable is replaced by this construct for logging purposes:

  \[
  \text{NAME\_CONST}(\text{var\_name}, \text{var\_value})
  \]

  \text{var\_name} is the local variable name, and \text{var\_value} is a constant indicating the value that the variable has at the time the statement is logged. \text{NAME\_CONST()} has a value of \text{var\_value}, and a “name” of \text{var\_name}. Thus, if you invoke this function directly, you get a result like this:

  \[
  \text{mysql> SELECT NAME\_CONST('myname', 14);}
  \]

<table>
<thead>
<tr>
<th>myname</th>
</tr>
</thead>
<tbody>
<tr>
<td>14</td>
</tr>
</tbody>
</table>

  \text{NAME\_CONST()} enables a logged standalone statement to be executed on a slave with the same effect as the original statement that was executed on the master within a stored procedure.

  The use of \text{NAME\_CONST()} can result in a problem for \text{CREATE TABLE ... SELECT} statements when the source column expressions refer to local variables. Converting these references to \text{NAME\_CONST()} expressions can result in column names that are different on the master and slave servers, or names that are too long to be legal column identifiers. A workaround is to supply aliases for columns that refer to local variables. Consider this statement when \text{myvar} has a value of 1:

  \[
  \text{CREATE TABLE t1 SELECT myvar;}
  \]

  That will be rewritten as follows:

  \[
  \text{CREATE TABLE t1 SELECT NAME\_CONST(myvar, 1);}
  \]

  To ensure that the master and slave tables have the same column names, write the statement like this:

  \[
  \text{CREATE TABLE t1 SELECT myvar AS myvar;}
  \]

  The rewritten statement becomes:

  \[
  \text{CREATE TABLE t1 SELECT NAME\_CONST(myvar, 1) AS myvar;}
  \]

- A statement to be logged might contain references to user-defined variables. To handle this, MySQL writes a \text{SET} statement to the binary log to make sure that the variable exists on the slave with the same value as on the master. For example, if a statement refers to a variable \text{@my\_var}, that statement will be preceded in the binary log by the following statement, where \text{value} is the value of \text{@my\_var} on the master:
• Procedure calls can occur within a committed or rolled-back transaction. Transactional context is accounted for so that the transactional aspects of procedure execution are replicated correctly. That is, the server logs those statements within the procedure that actually execute and modify data, and also logs `BEGIN`, `COMMIT`, and `ROLLBACK` statements as necessary. For example, if a procedure updates only transactional tables and is executed within a transaction that is rolled back, those updates are not logged. If the procedure occurs within a committed transaction, `BEGIN` and `COMMIT` statements are logged with the updates. For a procedure that executes within a rolled-back transaction, its statements are logged using the same rules that would apply if the statements were executed in standalone fashion:

• Updates to transactional tables are not logged.

• Updates to nontransactional tables are logged because rollback does not cancel them.

• Updates to a mix of transactional and nontransactional tables are logged surrounded by `BEGIN` and `ROLLBACK` so that slaves will make the same changes and rollbacks as on the master.

• A stored procedure call is *not* written to the binary log at the statement level if the procedure is invoked from within a stored function. In that case, the only thing logged is the statement that invokes the function (if it occurs within a statement that is logged) or a `DO` statement (if it occurs within a statement that is not logged). For this reason, care should be exercised in the use of stored functions that invoke a procedure, even if the procedure is otherwise safe in itself.
Chapter 20 INFORMATION_SCHEMA Tables

INFORMATION_SCHEMA provides access to database metadata, information about the MySQL server such as the name of a database or table, the data type of a column, or access privileges. Other terms that are sometimes used for this information are data dictionary and system catalog.

INFORMATION_SCHEMA Usage Notes

INFORMATION_SCHEMA is a database within each MySQL instance, the place that stores information about all the other databases that the MySQL server maintains. The INFORMATION_SCHEMA database contains several read-only tables. They are actually views, not base tables, so there are no files associated with them, and you cannot set triggers on them. Also, there is no database directory with that name.

Although you can select INFORMATION_SCHEMA as the default database with a USE statement, you can only read the contents of tables, not perform INSERT, UPDATE, or DELETE operations on them.

Example

Here is an example of a statement that retrieves information from INFORMATION_SCHEMA:

```sql
mysql> SELECT table_name, table_type, engine
        -> FROM information_schema.tables
        -> WHERE table_schema = 'db5'
        -> ORDER BY table_name;
```

2347
Character Set Considerations

The definition for character columns (for example, \texttt{TABLES.TABLE_NAME}) is generally \texttt{VARCHAR(\textit{N}) CHARACTER SET utf8} where \textit{N} is at least 64. MySQL uses the default collation for this character set (\texttt{utf8_general_ci}) for all searches, sorts, comparisons, and other string operations on such columns.

Because some MySQL objects are represented as files, searches in \texttt{INFORMATION_SCHEMA} string columns can be affected by file system case sensitivity. For more information, see Section 10.1.7.9, “Collation and \texttt{INFORMATION_SCHEMA} Searches”.

\textbf{INFORMATION_SCHEMA as Alternative to SHOW Statements}

The \texttt{SELECT \ldots FROM INFORMATION_SCHEMA} statement is intended as a more consistent way to provide access to the information provided by the various \texttt{SHOW} statements that MySQL supports (\texttt{SHOW DATABASES}, \texttt{SHOW TABLES}, and so forth). Using \texttt{SELECT} has these advantages, compared to \texttt{SHOW}:

\begin{itemize}
  \item It conforms to Codd's rules, because all access is done on tables.
  \item You can use the familiar syntax of the \texttt{SELECT} statement, and only need to learn some table and column names.
  \item The implementor need not worry about adding keywords.
  \item You can filter, sort, concatenate, and transform the results from \texttt{INFORMATION_SCHEMA} queries into whatever format your application needs, such as a data structure or a text representation to parse.
  \item This technique is more interoperable with other database systems. For example, Oracle Database users are familiar with querying tables in the Oracle data dictionary.
\end{itemize}

Because \texttt{SHOW} is familiar and widely used, the \texttt{SHOW} statements remain as an alternative. In fact, along with the implementation of \texttt{INFORMATION_SCHEMA}, there are enhancements to \texttt{SHOW} as described in Section 20.27, “Extensions to SHOW Statements”.

\textbf{Privileges}

Each MySQL user has the right to access these tables, but can see only the rows in the tables that correspond to objects for which the user has the proper access privileges. In some cases (for example,
the ROUTINE_DEFINITION column in the INFORMATION_SCHEMA.ROUTINES table), users who have insufficient privileges see NULL. These restrictions do not apply for InnoDB tables; you can see them with only the PROCESS privilege.

The same privileges apply to selecting information from INFORMATION_SCHEMA and viewing the same information through SHOW statements. In either case, you must have some privilege on an object to see information about it.

**Performance Considerations**

INFORMATION_SCHEMA queries that search for information from more than one database might take a long time and impact performance. To check the efficiency of a query, you can use EXPLAIN. For information about using EXPLAIN output to tune INFORMATION_SCHEMA queries, see Section 8.2.4, “INFORMATION_SCHEMA Optimization”.

**Standards Considerations**

The implementation for the INFORMATION_SCHEMA table structures in MySQL follows the ANSI/ISO SQL:2003 standard Part 11 Schemata. Our intent is approximate compliance with SQL:2003 core feature F021 Basic information schema.

Users of SQL Server 2000 (which also follows the standard) may notice a strong similarity. However, MySQL has omitted many columns that are not relevant for our implementation, and added columns that are MySQL-specific. One such column is the ENGINE column in the INFORMATION_SCHEMA.TABLES table.

To avoid using any name that is reserved in the standard or in DB2, SQL Server, or Oracle, we changed the names of some columns marked “MySQL extension”. (For example, we changed COLLATION to TABLE_COLLATION in the TABLES table.) See the list of reserved words near the end of this article: https://web.archive.org/web/20070428032454/http://www.dbazine.com/db2/db2-disarticles/gulutzan5.

**Conventions in the INFORMATION_SCHEMA Reference Sections**

The following sections describe each of the tables and columns in INFORMATION_SCHEMA. For each column, there are three pieces of information:

- “INFORMATION_SCHEMA Name” indicates the name for the column in the INFORMATION_SCHEMA table. This corresponds to the standard SQL name unless the “Remarks” field says “MySQL extension.”

- “SHOW Name” indicates the equivalent field name in the closest SHOW statement, if there is one.

- “Remarks” provides additional information where applicable. If this field is NULL, it means that the value of the column is always NULL. If this field says “MySQL extension,” the column is a MySQL extension to standard SQL.

Many sections indicate what SHOW statement is equivalent to a SELECT that retrieves information from INFORMATION_SCHEMA. For SHOW statements that display information for the default database if you omit a FROM db_name clause, you can often select information for the default database by adding an AND TABLE_SCHEMA = SCHEMA() condition to the WHERE clause of a query that retrieves information from an INFORMATION_SCHEMA table.

For information about INFORMATION_SCHEMA tables specific to the NDB storage engine (MySQL Cluster), see Section 20.26, “INFORMATION_SCHEMA Tables for MySQL Cluster”.

For answers to questions that are often asked concerning the INFORMATION_SCHEMA database, see Section A.7, “MySQL 5.1 FAQ: INFORMATION_SCHEMA”.

**20.1 The INFORMATION_SCHEMA CHARACTER_SETS Table**

The CHARACTER_SETS table provides information about available character sets.
### 20.2 The INFORMATION_SCHEMA COLLATIONS Table

The **COLLATIONS** table provides information about collations for each character set.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHARACTER_SET_NAME</td>
<td>Charset</td>
<td></td>
</tr>
<tr>
<td>DEFAULT_COLLATE_NAME</td>
<td>Default collation</td>
<td></td>
</tr>
<tr>
<td>DESCRIPTION</td>
<td>Description</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>MAXLEN</td>
<td>Maxlen</td>
<td>MySQL extension</td>
</tr>
</tbody>
</table>

The following statements are equivalent:

```sql
SELECT * FROM INFORMATION_SCHEMA.CHARACTER_SETS
WHERE CHARACTER_SET_NAME LIKE 'wild'

SHOW CHARACTER SET
LIKE 'wild'
```

## 20.3 The INFORMATION_SCHEMA COLLATION_CHARACTER_SET_APPLICABILITY Table

The **COLLATION_CHARACTER_SET_APPLICABILITY** table indicates what character set is applicable for what collation. The columns are equivalent to the first two display fields that we get from **SHOW COLLATION**.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>COLLATION_NAME</td>
<td>Collation</td>
<td></td>
</tr>
</tbody>
</table>

**COLLATION_NAME** is the collation name.

**CHARACTER_SET_NAME** is the name of the character set with which the collation is associated.

**ID** is the collation ID.

**IS_DEFAULT** indicates whether the collation is the default for its character set.

**IS_COMPILED** indicates whether the character set is compiled into the server.

**SORTLEN** is related to the amount of memory required to sort strings expressed in the character set.

Collation information is also available from the **SHOW COLLATION** statement. The following statements are equivalent:

```sql
SELECT COLLATION_NAME FROM INFORMATION_SCHEMA.COLLATIONS
WHERE COLLATION_NAME LIKE 'wild'

SHOW COLLATION
LIKE 'wild'
```
20.4 The INFORMATION_SCHEMA COLUMNS Table

The COLUMNS table provides information about columns in tables.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_CATALOG</td>
<td>NULL</td>
<td></td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td></td>
<td></td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td></td>
<td></td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td>Field</td>
<td></td>
</tr>
<tr>
<td>ORDINAL_POSITION</td>
<td>Default</td>
<td>see notes</td>
</tr>
<tr>
<td>COLUMN_DEFAULT</td>
<td>Default</td>
<td></td>
</tr>
<tr>
<td>IS_NULLABLE</td>
<td>Null</td>
<td></td>
</tr>
<tr>
<td>DATA_TYPE</td>
<td>Type</td>
<td></td>
</tr>
<tr>
<td>CHARACTER_MAXIMUM_LENGTH</td>
<td>Type</td>
<td></td>
</tr>
<tr>
<td>CHARACTER_OCTET_LENGTH</td>
<td>Type</td>
<td></td>
</tr>
<tr>
<td>NUMERIC_PRECISION</td>
<td>Type</td>
<td></td>
</tr>
<tr>
<td>NUMERIC_SCALE</td>
<td>Type</td>
<td></td>
</tr>
<tr>
<td>CHARACTER_SET_NAME</td>
<td></td>
<td></td>
</tr>
<tr>
<td>COLLATION_NAME</td>
<td>Collation</td>
<td></td>
</tr>
<tr>
<td>COLUMN_TYPE</td>
<td>Type</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>COLUMN_KEY</td>
<td>Key</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>EXTRA</td>
<td>Extra</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>PRIVILEGES</td>
<td>Privileges</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>COLUMN_COMMENT</td>
<td>Comment</td>
<td>MySQL extension</td>
</tr>
</tbody>
</table>

Notes:

- In SHOW, the Type display includes values from several different COLUMNS columns.
- ORDINAL_POSITION is necessary because you might want to say ORDER BY ORDINAL_POSITION. Unlike SHOW, SELECT does not have automatic ordering.
- CHARACTER_OCTET_LENGTH should be the same as CHARACTER_MAXIMUM_LENGTH, except for multibyte character sets.
- CHARACTER_SET_NAME can be derived from Collation. For example, if you say SHOW FULL COLUMNS FROM t, and you see in the Collation column a value of latin1_swedish_ci, the character set is what is before the first underscore: latin1.

The following statements are nearly equivalent:

```sql
SELECT COLUMN_NAME, DATA_TYPE, IS_NULLABLE, COLUMN_DEFAULT
FROM INFORMATION_SCHEMA.COLUMNS
WHERE table_name = 'tbl_name'
[AND table_schema = 'db_name']
[AND column_name LIKE 'wild']

SHOW COLUMNS
FROM tbl_name
[FROM db_name]
```
20.5 The INFORMATION_SCHEMA COLUMN_PRIVILEGES Table

The COLUMN_PRIVILEGES table provides information about column privileges. This information comes from the mysql.columns_priv grant table.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRANTEE</td>
<td>'user_name'@'host_name' value</td>
<td></td>
</tr>
<tr>
<td>TABLE_CATALOG</td>
<td>NULL</td>
<td></td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td></td>
<td></td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td></td>
<td></td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td></td>
<td></td>
</tr>
<tr>
<td>PRIVILEGE_TYPE</td>
<td></td>
<td></td>
</tr>
<tr>
<td>IS_GRANTABLE</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Notes:

- In the output from SHOW FULL COLUMNS, the privileges are all in one field and in lowercase, for example, select, insert, update, references. In COLUMN_PRIVILEGES, there is one privilege per row, in uppercase.

- PRIVILEGE_TYPE can contain one (and only one) of these values: SELECT, INSERT, UPDATE, REFERENCES.

- If the user has GRANT OPTION privilege, IS_GRANTABLE should be YES. Otherwise, IS_GRANTABLE should be NO. The output does not list GRANT OPTION as a separate privilege.

The following statements are not equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.COLUMN_PRIVILEGES
SHOW GRANTS ...
```

20.6 The INFORMATION_SCHEMA ENGINES Table

The ENGINES table provides information about storage engines.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENGINE</td>
<td>Engine</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>SUPPORT</td>
<td>Support</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>COMMENT</td>
<td>Comment</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>TRANSACTIONS</td>
<td>Transactions</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>XA</td>
<td>XA</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>SAVEPOINTS</td>
<td>Savepoints</td>
<td>MySQL extension</td>
</tr>
</tbody>
</table>

Notes:

- The ENGINES table is a nonstandard table. It was added in MySQL 5.1.5. Its contents correspond to the columns of the SHOW ENGINES statement. For descriptions of its columns, see Section 13.7.5.17, “SHOW ENGINES Syntax”.

See also Section 13.7.5.17, “SHOW ENGINES Syntax”.

20.7 The INFORMATION_SCHEMA EVENTS Table
The `INFORMATION_SCHEMA EVENTS` Table

The `EVENTS` table provides information about scheduled events, which are discussed in Section 19.4, “Using the Event Scheduler”. The `SHOW` `Name` values correspond to column names of the `SHOW EVENTS` statement.

<table>
<thead>
<tr>
<th><code>INFORMATION_SCHEMA Name</code></th>
<th><code>SHOW Name</code></th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>EVENT_CATALOG</td>
<td>NULL</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>EVENT_SCHEMA</td>
<td>Db</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>EVENT_NAME</td>
<td>Name</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>DEFINER</td>
<td>Definer</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>TIME_ZONE</td>
<td>Time zone</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>EVENT_BODY</td>
<td></td>
<td>MySQL extension</td>
</tr>
<tr>
<td>EVENT_DEFINITION</td>
<td></td>
<td>MySQL extension</td>
</tr>
<tr>
<td>EVENT_TYPE</td>
<td>Type</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>EXECUTE_AT</td>
<td>Execute at</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>INTERVAL_VALUE</td>
<td>Interval value</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>INTERVAL_FIELD</td>
<td>Interval field</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>SQL_MODE</td>
<td></td>
<td>MySQL extension</td>
</tr>
<tr>
<td>STARTS</td>
<td>Starts</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>ENDS</td>
<td>Ends</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>STATUS</td>
<td>Status</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>ON_COMPLETION</td>
<td></td>
<td>MySQL extension</td>
</tr>
<tr>
<td>CREATED</td>
<td></td>
<td>MySQL extension</td>
</tr>
<tr>
<td>LAST_ALTERED</td>
<td></td>
<td>MySQL extension</td>
</tr>
<tr>
<td>LAST_EXECUTED</td>
<td></td>
<td>MySQL extension</td>
</tr>
<tr>
<td>EVENT_COMMENT</td>
<td></td>
<td>MySQL extension</td>
</tr>
<tr>
<td>ORIGINATOR</td>
<td>Originator</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>CHARACTER_SET_CLIENT</td>
<td>character_set_client</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>COLLATION_CONNECTION</td>
<td>collation_connection</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>DATABASE_COLLATION</td>
<td>Database Collation</td>
<td>MySQL extension</td>
</tr>
</tbody>
</table>

Notes:

- The `EVENTS` table is a nonstandard table. It was added in MySQL 5.1.6.
- `EVENT_CATALOG`: The value of this column is always `NULL`.
- `EVENT_SCHEMA`: The name of the schema (database) to which this event belongs.
- `EVENT_NAME`: The name of the event.
- `DEFINER`: The account of the user who created the event, in `user_name'@'host_name'` format.
- `TIME_ZONE`: The event time zone, which is the time zone used for scheduling the event and that is in effect within the event as it executes. The default value is `SYSTEM`.

This column was added in MySQL 5.1.17. See Release Notes for MySQL 5.1.17 for important information if you are using the Event Scheduler and are upgrading to MySQL 5.1.17 or later from an earlier version.

- `EVENT_BODY`: The language used for the statements in the event's `DO` clause; in MySQL 5.1, this is always `SQL`.

Notes:

- The `EVENTS` table is a nonstandard table. It was added in MySQL 5.1.6.
- `EVENT_CATALOG`: The value of this column is always `NULL`.
- `EVENT_SCHEMA`: The name of the schema (database) to which this event belongs.
- `EVENT_NAME`: The name of the event.
- `DEFINER`: The account of the user who created the event, in `user_name'@'host_name'` format.
- `TIME_ZONE`: The event time zone, which is the time zone used for scheduling the event and that is in effect within the event as it executes. The default value is `SYSTEM`.

This column was added in MySQL 5.1.17. See Release Notes for MySQL 5.1.17 for important information if you are using the Event Scheduler and are upgrading to MySQL 5.1.17 or later from an earlier version.

- `EVENT_BODY`: The language used for the statements in the event's `DO` clause; in MySQL 5.1, this is always `SQL`.
This column was added in MySQL 5.1.12. It is not to be confused with the column of the same name (now named EVENT_DEFINITION) that existed in earlier MySQL versions.

- **EVENT_DEFINITION**: The text of the SQL statement making up the event's DO clause; in other words, the statement executed by this event.

  ![Note]
  Prior to MySQL 5.1.12, this column was named EVENT_BODY.

- **EVENT_TYPE**: The event repetition type, either ONE TIME (transient) or RECURRING (repeating).

- **EXECUTE_AT**: For a one-time event, this is the DATETIME value specified in the AT clause of the CREATE EVENT statement used to create the event, or of the last ALTER EVENT statement that modified the event. The value shown in this column reflects the addition or subtraction of any INTERVAL value included in the event's AT clause. For example, if an event is created using ON SCHEDULE AT CURRENT_TIMESTAMP + '1:6' DAY_HOUR, and the event was created at 2006-02-09 14:05:30, the value shown in this column would be '2006-02-10 20:05:30'.

  If the event's timing is determined by an EVERY clause instead of an AT clause (that is, if the event is recurring), the value of this column is NULL.

- **INTERVAL_VALUE**: For recurring events, this column contains the numeric portion of the event's EVERY clause.

  For a one-time event (that is, an event whose timing is determined by an AT clause), this column is NULL.

- **INTERVAL_FIELD**: For recurring events, this column contains the units portion of the EVERY clause governing the timing of the event. Thus, this column contains a value such as 'YEAR', 'QUARTER', 'DAY', and so on.

  ![Note]
  In early MySQL 5.1 releases, this value was prefixed with 'INTERVAL_', and was displayed as 'INTERVAL_YEAR', 'INTERVAL_QUARTER', 'INTERVAL_DAY', and so on.

  For a one-time event (that is, an event whose timing is determined by an AT clause), this column is NULL.

- **SQL_MODE**: The SQL mode in effect when the event was created or altered, and under which the event executes. For the permitted values, see Section 5.1.7, “Server SQL Modes”.

- **STARTS**: For a recurring event whose definition includes a STARTS clause, this column contains the corresponding DATETIME value. As with the EXECUTE_AT column, this value resolves any expressions used.

  If there is no STARTS clause affecting the timing of the event, this column is NULL. (Prior to MySQL 5.1.8, it contained 0000-00-00 00:00:00 in such cases.)

- **ENDS**: For a recurring event whose definition includes a ENDS clause, this column contains the corresponding DATETIME value. As with the EXECUTE_AT column, this value resolves any expressions used.

  If there is no ENDS clause affecting the timing of the event, this column is NULL.

- **STATUS**: One of the three values ENABLED, DISABLED, or SLAVESIDE_DISABLED.

  SLAVESIDE_DISABLED was added to the list of possible values for this column in MySQL 5.1.18. This value indicates that the creation of the event occurred on another MySQL server acting as a
The INFORMATION_SCHEMA EVENTS Table

replication master and was replicated to the current MySQL server which is acting as a slave, but the event is not presently being executed on the slave. See Section 16.4.1.12, “Replication of Invoked Features”, for more information.

- **ON_COMPLETION**: One of the two values PRESERVE or NOT PRESERVE.

- **CREATED**: The date and time when the event was created. This is a TIMESTAMP value.

- **LAST_ALTERED**: The date and time when the event was last modified. This is a TIMESTAMP value. If the event has not been modified since its creation, this column holds the same value as the CREATED column.

- **LAST_EXECUTED**: The date and time when the event last executed. A DATETIME value. If the event has never executed, this column is NULL.

Before MySQL 5.1.23, LAST_EXECUTED indicates when event finished executing. As of 5.1.23, LAST_EXECUTED instead indicates when the event started. As a result, the ENDS column is never less than LAST_EXECUTED.

- **EVENT_COMMENT**: The text of a comment, if the event has one. If not, the value of this column is an empty string.

- **ORIGINATOR**: The server ID of the MySQL server on which the event was created; used in replication. The default value is 0. This column was added in MySQL 5.1.18.

- **CHARACTER_SET_CLIENT**: The session value of the character_set_client system variable when the event was created. This column was added in MySQL 5.1.21.

- **COLLATION_CONNECTION**: The session value of the collation_connection system variable when the event was created. This column was added in MySQL 5.1.21.

- **DATABASE_COLLATION**: The collation of the database with which the event is associated. This column was added in MySQL 5.1.21.

**Example**: Suppose that the user jon@ghidora creates an event named e_daily, and then modifies it a few minutes later using an ALTER EVENT statement, as shown here:

```
DELIMITER |

CREATE EVENT e_daily
  ON SCHEDULE
    EVERY 1 DAY
  COMMENT 'Saves total number of sessions then clears the table each day'
  DO
    BEGIN
      INSERT INTO site_activity.totals (time, total)
      SELECT CURRENT_TIMESTAMP, COUNT(*)
      FROM site_activity.sessions;
      DELETE FROM site_activity.sessions;
    END |

ALTER EVENT e_daily
  ENABLE;
```

(Note that comments can span multiple lines.)

This user can then run the following SELECT statement, and obtain the output shown:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
  > WHERE EVENT_NAME = 'e_daily'
  > AND EVENT_SCHEMA = 'myschema'
G
*************************** 1. row ***************************
```
The INFORMATION_SCHEMA GLOBAL_STATUS and SESSION_STATUS Tables

The INFORMATION_SCHEMA GLOBAL_STATUS and SESSION_STATUS tables provide information about server status variables. Their contents correspond to the information produced by the SHOW GLOBAL STATUS and SHOW SESSION STATUS statements (see Section 13.7.5.37, "SHOW STATUS Syntax").

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>VARIABLE_NAME</td>
<td>Variable_name</td>
<td></td>
</tr>
<tr>
<td>VARIABLE_VALUE</td>
<td>Value</td>
<td></td>
</tr>
</tbody>
</table>

Notes:

- The GLOBAL_STATUS and SESSION_STATUS tables were added in MySQL 5.1.12.

- The VARIABLE_VALUE column for each of these tables is defined as VARCHAR(1024). Previously, this column had the data type DECIMAL(22,7), but was changed to VARCHAR(20480) in 5.1.19 to avoid loss of data when working with status variables whose values were strings, and shortened to VARCHAR(1024) in 5.1.31 to improve performance.

20.9 The INFORMATION_SCHEMA GLOBAL_VARIABLES and SESSION_VARIABLES Tables

The GLOBAL_VARIABLES and SESSION_VARIABLES tables provide information about server status variables. Their contents correspond to the information produced by the SHOW GLOBAL VARIABLES and SHOW SESSION VARIABLES statements (see Section 13.7.5.41, "SHOW VARIABLES Syntax").
20.10 The INFORMATION_SCHEMA KEY_COLUMN_USAGE Table

The KEY_COLUMN_USAGE table describes which key columns have constraints.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONSTRAINT_CATALOG</td>
<td></td>
<td>NULL</td>
</tr>
<tr>
<td>CONSTRAINT_SCHEMA</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CONSTRAINT_NAME</td>
<td></td>
<td></td>
</tr>
<tr>
<td>TABLE_CATALOG</td>
<td></td>
<td></td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td></td>
<td></td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td></td>
<td></td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ORDINAL_POSITION</td>
<td></td>
<td></td>
</tr>
<tr>
<td>POSITION_IN_UNIQUE_CONSTRAINT</td>
<td></td>
<td></td>
</tr>
<tr>
<td>REFERENCED_TABLE_SCHEMA</td>
<td></td>
<td></td>
</tr>
<tr>
<td>REFERENCED_TABLE_NAME</td>
<td></td>
<td></td>
</tr>
<tr>
<td>REFERENCED_COLUMN_NAME</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Notes:

- If the constraint is a foreign key, then this is the column of the foreign key, not the column that the foreign key references.
- The value of ORDINAL_POSITION is the column's position within the constraint, not the column's position within the table. Column positions are numbered beginning with 1.
- The value of POSITION_IN_UNIQUE_CONSTRAINT is NULL for unique and primary-key constraints. For foreign-key constraints, it is the ordinal position in key of the table that is being referenced.

Suppose that there are two tables name t1 and t3 that have the following definitions:

```sql
CREATE TABLE t1
(
    s1 INT,
```
CREATE TABLE t3
(
  s1 INT,
  s2 INT,
  s3 INT,
  PRIMARY KEY(s3),
  KEY(s1),
  CONSTRAINT CO FOREIGN KEY (s2) REFERENCES t1(s3)
) ENGINE=InnoDB;

For those two tables, the `KEY_COLUMN_USAGE` table has two rows:

- One row with `CONSTRAINT_NAME = 'PRIMARY’, TABLE_NAME = 't1’, COLUMN_NAME = 's3’, ORDINAL_POSITION = 1, POSITION_IN_UNIQUE_CONSTRAINT = NULL.

- One row with `CONSTRAINT_NAME = 'CO’, TABLE_NAME = 't3’, COLUMN_NAME = 's2’, ORDINAL_POSITION = 1, POSITION_IN_UNIQUE_CONSTRAINT = 1.

### 20.11 The INFORMATION_SCHEMA PARTITIONS Table

The `PARTITIONS` table provides information about table partitions. See Chapter 18, `Partitioning`, for more information about partitioning tables.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_CATALOG</td>
<td></td>
<td>MySQL extension</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td></td>
<td>MySQL extension</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td></td>
<td>MySQL extension</td>
</tr>
<tr>
<td>PARTITION_NAME</td>
<td></td>
<td>MySQL extension</td>
</tr>
<tr>
<td>SUBPARTITION_NAME</td>
<td></td>
<td>MySQL extension</td>
</tr>
<tr>
<td>PARTITION_ORDINAL_POSITION</td>
<td></td>
<td>MySQL extension</td>
</tr>
<tr>
<td>SUBPARTITION_ORDINAL_POSITION</td>
<td></td>
<td>MySQL extension</td>
</tr>
<tr>
<td>PARTITION_METHOD</td>
<td></td>
<td>MySQL extension</td>
</tr>
<tr>
<td>SUBPARTITION_METHOD</td>
<td></td>
<td>MySQL extension</td>
</tr>
<tr>
<td>PARTITION_EXPRESSION</td>
<td></td>
<td>MySQL extension</td>
</tr>
<tr>
<td>SUBPARTITION_EXPRESSION</td>
<td></td>
<td>MySQL extension</td>
</tr>
<tr>
<td>PARTITION_DESCRIPTION</td>
<td></td>
<td>MySQL extension</td>
</tr>
<tr>
<td>TABLE_ROWS</td>
<td></td>
<td>MySQL extension</td>
</tr>
<tr>

<td></td>
<td>MySQL extension</td>
</tr>
<tr>
<td>UPDATE_TIME</td>
<td></td>
<td>MySQL extension</td>
</tr>
<tr>
<td>CHECK_TIME</td>
<td></td>
<td>MySQL extension</td>
</tr>
<tr>
<td>CHECKSUM</td>
<td></td>
<td>MySQL extension</td>
</tr>
<tr>
<td>PARTITION_COMMENT</td>
<td></td>
<td>MySQL extension</td>
</tr>
<tr>
<td>NODEGROUP</td>
<td></td>
<td>MySQL extension</td>
</tr>
</tbody>
</table>
The INFORMATION_SCHEMA PARTITIONS Table

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLESPACE_NAME</td>
<td></td>
<td>MySQL extension</td>
</tr>
</tbody>
</table>

Notes:

- The PARTITIONS table is a nonstandard table. It was added in MySQL 5.1.6. Each record in this table corresponds to an individual partition or subpartition of a partitioned table.

- TABLE_CATALOG: This column is always NULL.

- TABLE_SCHEMA: This column contains the name of the database to which the table belongs.

- TABLE_NAME: This column contains the name of the table containing the partition.

- PARTITION_NAME: The name of the partition.

- SUBPARTITION_NAME: If the PARTITIONS table record represents a subpartition, then this column contains the name of subpartition; otherwise it is NULL.

- PARTITION_ORDINAL_POSITION: All partitions are indexed in the same order as they are defined, with 1 being the number assigned to the first partition. The indexing can change as partitions are added, dropped, and reorganized; the number shown is this column reflects the current order, taking into account any indexing changes.

- SUBPARTITION_ORDINAL_POSITION: Subpartitions within a given partition are also indexed and reindexed in the same manner as partitions are indexed within a table.

- PARTITION_METHOD: One of the values RANGE, LIST, HASH, LINEAR HASH, KEY, or LINEAR KEY; that is, one of the available partitioning types as discussed in Section 18.2, “Partitioning Types”.

- SUBPARTITION_METHOD: One of the values HASH, LINEAR HASH, KEY, or LINEAR KEY; that is, one of the available subpartitioning types as discussed in Section 18.2.5, “Subpartitioning”.

- PARTITION_EXPRESSION: This is the expression for the partitioning function used in the CREATE TABLE or ALTER TABLE statement that created the table’s current partitioning scheme.

  For example, consider a partitioned table created in the test database using this statement:

  ```sql
  CREATE TABLE tp (
      c1 INT,
      c2 INT,
      c3 VARCHAR(25)
  )
  PARTITION BY HASH(c1 + c2)
  PARTITIONS 4;
  
  The PARTITION_EXPRESSION column in a PARTITIONS table record for a partition from this table displays c1 + c2, as shown here:
  
  mysql> SELECT DISTINCT PARTITION_EXPRESSION
  > FROM INFORMATION_SCHEMA.PARTITIONS
  > WHERE TABLE_NAME='tp' AND TABLE_SCHEMA='test';
  +----------------------+
  | PARTITION_EXPRESSION |
  +----------------------+
  | c1 + c2              |
  +----------------------+
  1 row in set (0.09 sec)
  
  - SUBPARTITION_EXPRESSION: This works in the same fashion for the subpartitioning expression that defines the subpartitioning for a table as PARTITION_EXPRESSION does for the partitioning expression used to define a table’s partitioning.
If the table has no subpartitions, then this column is NULL.

- **PARTITION_DESCRIPTION**: This column is used for RANGE and LIST partitions. For a RANGE partition, it contains the value set in the partition's VALUES LESS THAN clause, which can be either an integer or MAXVALUE. For a LIST partition, this column contains the values defined in the partition's VALUES IN clause, which is a comma-separated list of integer values.

For partitions whose **PARTITION_METHOD** is other than RANGE or LIST, this column is always NULL.

- **TABLE_ROWS**: The number of table rows in the partition.

For partitioned InnoDB tables, the row count given in the **TABLE_ROWS** column is only an estimated value used in SQL optimization, and may not always be exact.

Beginning with MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11, **TABLE_ROWS** shows correct information for NDB tables. Previously, for partitions of NDB tables, the **TABLE_ROWS** column value was always 0.

For NDB tables, you can also obtain this information using the `ndb_desc` utility.

- **AVG_ROW_LENGTH**: The average length of the rows stored in this partition or subpartition, in bytes.

  This is the same as **DATA_LENGTH** divided by **TABLE_ROWS**.

Beginning with MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11, **AVG_ROW_LENGTH** includes statistics for partitions of NDB tables, whether the tables use implicit or explicit partitioning. (Previously the value of this column was always 0 for partitions of NDB tables.)

You can also obtain equivalent information using the `ndb_desc` utility.

- **DATA_LENGTH**: The total length of all rows stored in this partition or subpartition, in bytes—that is, the total number of bytes stored in the partition or subpartition.

Beginning with MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11, **DATA_LENGTH** shows correct information for in-memory data in NDB tables. Previously, for partitions of NDB tables, the **DATA_LENGTH** column value was always 0.

For NDB tables, you can also obtain this information using the `ndb_desc` utility.

- **MAX_DATA_LENGTH**: The maximum number of bytes that can be stored in this partition or subpartition.

Beginning with MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11, **MAX_DATA_LENGTH** shows the space allocated for the disk part of a MySQL Cluster Disk Data table or fragment. (Previously, for partitions of NDB tables, the **MAX_DATA_LENGTH** column value was always NULL.)

For NDB tables, you can also obtain this information using the `ndb_desc` utility.

- **INDEX_LENGTH**: The length of the index file for this partition or subpartition, in bytes.

For partitions of NDB tables, whether the tables use implicit or explicit partitioning, the **INDEX_LENGTH** column value is always 0. However, you can obtain equivalent information using the `ndb_desc` utility.

- **DATA_FREE**: The number of bytes allocated to the partition or subpartition but not used.

For MySQL Cluster Disk Data tables, beginning with MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11, **DATA_FREE** shows the space allocated on disk for, but not used by, a Disk Data table or fragment on disk. (Previously, for partitions of NDB tables, the value of this column was always 0.)

For NDB tables, you can also obtain this information using the `ndb_desc` utility.
• **CREATE_TIME:** The time of the partition's or subpartition's creation.
  
  For partitioned InnoDB tables, this column is always **NULL**.

• **UPDATE_TIME:** The time that the partition or subpartition was last modified.
  
  For partitioned InnoDB tables, this column is always **NULL**.

• **CHECK_TIME:** The last time that the table to which this partition or subpartition belongs was checked.
  
  For partitioned InnoDB tables, this column is always **NULL**.

• **CHECKSUM:** The checksum value, if any; otherwise, this column is **NULL**.

• **PARTITION_COMMENT:** This column contains the text of any comment made for the partition.
  
  In MySQL 5.1, the display width of this column is 80 characters, and partition comments which exceed this length are truncated to fit. This issue is fixed in MySQL 5.6. (Bug #11748924, Bug #37728)
  
  The default value for this column is an empty string.

• **NODEGROUP:** This is the nodegroup to which the partition belongs. This is relevant only to MySQL Cluster tables; otherwise the value of this column is always **0**.

• **TABLESPACE_NAME:** This column contains the name of the tablespace to which the partition belongs. The value of this column is always **DEFAULT**.

• **Important**
  
  If any partitioned tables created in a MySQL version prior to MySQL 5.1.6 are present following an upgrade to MySQL 5.1.6 or later, it is not possible to **SELECT** from, **SHOW**, or **DESCRIBE** the **PARTITIONS** table. See the **Release Notes** for MySQL 5.1.6 **before** upgrading from MySQL 5.1.5 or earlier to MySQL 5.1.6 or later.

• A nonpartitioned table has one record in **INFORMATION_SCHEMA.PARTITIONS**; however, the values of the **PARTITION_NAME**, **SUBPARTITION_NAME**, **PARTITION_ORDINAL_POSITION**, **SUBPARTITION_ORDINAL_POSITION**, **PARTITION_METHOD**, **SUBPARTITION_METHOD**, **PARTITION_EXPRESSION**, **SUBPARTITION_EXPRESSION**, and **PARTITION_DESCRIPTION** columns are all **NULL**. (The **PARTITION_COMMENT** column in this case is blank.)
  
  In MySQL 5.1, there is also only one record in the **PARTITIONS** table for a table using the **NDBCLUSTER** storage engine. The same columns are also **NULL** (or empty) as for a nonpartitioned table.

20.12 The INFORMATION_SCHEMA PLUGINS Table

The **PLUGINS** table provides information about server plugins.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>PLUGIN_NAME</td>
<td>Name</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>PLUGIN_VERSION</td>
<td></td>
<td>MySQL extension</td>
</tr>
<tr>
<td>PLUGIN_STATUS</td>
<td>Status</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>PLUGIN_TYPE</td>
<td>Type</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>PLUGIN_TYPE_VERSION</td>
<td></td>
<td>MySQL extension</td>
</tr>
<tr>
<td>PLUGIN_LIBRARY</td>
<td>Library</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>PLUGIN_LIBRARY_VERSION</td>
<td></td>
<td>MySQL extension</td>
</tr>
</tbody>
</table>
The INFORMATION_SCHEMA PROCESSLIST Table

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>PLUGIN_AUTHOR</td>
<td>MySQL</td>
<td>extension</td>
</tr>
<tr>
<td>PLUGIN_DESCRIPTION</td>
<td>MySQL</td>
<td>extension</td>
</tr>
<tr>
<td>PLUGIN_LICENSE</td>
<td>MySQL</td>
<td>extension</td>
</tr>
</tbody>
</table>

Notes:

- The PLUGINS table is a nonstandard table. It was added in MySQL 5.1.5.
- PLUGIN_NAME is the name used to refer to the plugin in statements such as INSTALL PLUGIN and UNINSTALL PLUGIN.
- PLUGIN_VERSION is the version from the plugin's general type descriptor.
- PLUGIN_STATUS indicates the plugin status, one of ACTIVE, INACTIVE, DISABLED, or_DELETED.
- PLUGIN_TYPE indicates the type of plugin, such as STORAGE ENGINE or INFORMATION_SCHEMA.
- PLUGIN_TYPE_VERSION is the version from the plugin's type-specific descriptor.
- PLUGIN_LIBRARY is the name of the plugin shared object file. This is the name used to refer to the plugin file in statements such as INSTALL PLUGIN and UNINSTALL PLUGIN. This file is located in the directory named by the plugin_dir system variable. If the library name is NULL, the plugin is compiled in and cannot be uninstalled with UNINSTALL PLUGIN.
- PLUGIN_LIBRARY_VERSION indicates the plugin API interface version.
- PLUGIN_AUTHOR names the plugin author.
- PLUGIN_DESCRIPTION provides a short description of the plugin.
- PLUGIN_LICENSE indicates how the plugin is licensed; for example, GPL. This column was added in MySQL 5.1.12.

For plugins installed with INSTALL PLUGIN, the PLUGIN_NAME and PLUGIN_LIBRARY values are also registered in the mysql.plugin table.

These statements are equivalent:

```sql
SELECT
  PLUGIN_NAME, PLUGIN_STATUS, PLUGIN_TYPE,
  PLUGIN_LIBRARY, PLUGIN_LICENSE
FROM INFORMATION_SCHEMA.PLUGINS;

SHOW PLUGINS;
```

For information about plugin data structures that form the basis of the information in the PLUGINS table, see Section 22.2, "The MySQL Plugin API".

Plugin information is also available using the SHOW PLUGINS statement. See Section 13.7.5.27, "SHOW PLUGINS Syntax".

20.13 The INFORMATION_SCHEMA PROCESSLIST Table

The PROCESSLIST table provides information about which threads are running.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>Id</td>
<td>MySQL</td>
</tr>
<tr>
<td>USER</td>
<td>User</td>
<td>MySQL</td>
</tr>
<tr>
<td>HOST</td>
<td>Host</td>
<td>MySQL</td>
</tr>
<tr>
<td>DB</td>
<td>db</td>
<td>MySQL</td>
</tr>
</tbody>
</table>
The INFORMATION_SCHEMA PROFILING Table

For an extensive description of the table columns, see Section 13.7.5.31, “SHOW PROCESSLIST Syntax”.

Notes:

• The PROCESSLIST table is a nonstandard table. It was added in MySQL 5.1.7.

• Like the output from the corresponding SHOW statement, the PROCESSLIST table will only show information about your own threads, unless you have the PROCESS privilege, in which case you will see information about other threads, too. As an anonymous user, you cannot see any rows at all.

• If an SQL statement refers to INFORMATION_SCHEMA.PROCESSLIST, MySQL populates the entire table once, when statement execution begins, so there is read consistency during the statement. There is no read consistency for a multi-statement transaction, though.

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST
SHOW FULL PROCESSLIST
```

20.14 The INFORMATION_SCHEMA PROFILING Table

The PROFILING table provides statement profiling information. Its contents correspond to the information produced by the SHOW PROFILES and SHOW PROFILE statements (see Section 13.7.5.33, “SHOW PROFILES Syntax”). The table is empty unless the profiling session variable is set to 1.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>QUERY_ID</td>
<td>Query_ID</td>
<td></td>
</tr>
<tr>
<td>SEQ</td>
<td>Status</td>
<td></td>
</tr>
<tr>
<td>STATE</td>
<td>Status</td>
<td></td>
</tr>
<tr>
<td>DURATION</td>
<td>Duration</td>
<td></td>
</tr>
<tr>
<td>CPU_USER</td>
<td>CPU_user</td>
<td></td>
</tr>
<tr>
<td>CPU_SYSTEM</td>
<td>CPU_system</td>
<td></td>
</tr>
<tr>
<td>CONTEXT_VOLUNTARY</td>
<td>Context_voluntary</td>
<td></td>
</tr>
<tr>
<td>CONTEXT_INVOLUNTARY</td>
<td>Context_involuntary</td>
<td></td>
</tr>
<tr>
<td>BLOCK_OPS_IN</td>
<td>Block_ops_in</td>
<td></td>
</tr>
<tr>
<td>BLOCK_OPS_OUT</td>
<td>Block_ops_out</td>
<td></td>
</tr>
<tr>
<td>MESSAGES_SENT</td>
<td>Messages_sent</td>
<td></td>
</tr>
<tr>
<td>MESSAGES_RECEIVED</td>
<td>Messages_released</td>
<td></td>
</tr>
<tr>
<td>PAGE_FAULTS_MAJOR</td>
<td>Page_faults_major</td>
<td></td>
</tr>
<tr>
<td>PAGE_FAULTS_MINOR</td>
<td>Page_faults_minor</td>
<td></td>
</tr>
<tr>
<td>SWAPS</td>
<td>Swaps</td>
<td></td>
</tr>
<tr>
<td>SOURCE_FUNCTION</td>
<td>Source_function</td>
<td></td>
</tr>
<tr>
<td>SOURCE_FILE</td>
<td>Source_file</td>
<td></td>
</tr>
</tbody>
</table>
The INFORMATION_SCHEMA REFERENTIALCONSTRAINTS Table

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>SOURCE_LINE</td>
<td>Source_line</td>
<td></td>
</tr>
</tbody>
</table>

Notes:

- The PROFILING table was added in MySQL 5.1.24 but contains no information unless the SHOW PROFILE feature is enabled. The SHOW PROFILE feature is not included in binary distributions by default until MySQL 5.1.28.
- QUERY_ID is a numeric statement identifier.
- SEQ is a sequence number indicating the display order for rows with the same QUERY_ID value.
- STATE is the profiling state to which the row measurements apply.
- DURATION indicates how long statement execution remained in the given state, in seconds.
- CPU_USER and CPU_SYSTEM indicate user and system CPU use, in seconds.
- CONTEXT_VOLUNTARY and CONTEXT_INVOLUNTARY indicate how many voluntary and involuntary context switches occurred.
- BLOCK_OPS_IN and BLOCK_OPS_OUT indicate the number of block input and output operations.
- MESSAGES_SENT and MESSAGES_RECEIVED indicate the number of communication messages sent and received.
- PAGE_FAULTS_MAJOR and PAGE_FAULTS_MINOR indicate the number of major and minor page faults.
- SWAPS indicates how many swaps occurred.
- SOURCE_FUNCTION, SOURCE_FILE, and SOURCE_LINE provide information indicating where in the source code the profiled state executes.

20.15 The INFORMATION_SCHEMA REFERENTIALCONSTRAINTS Table

The REFERENTIALCONSTRAINTS table provides information about foreign keys.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONSTRAINT_CATALOG</td>
<td></td>
<td>NULL</td>
</tr>
<tr>
<td>CONSTRAINT_SCHEMA</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CONSTRAINT_NAME</td>
<td></td>
<td></td>
</tr>
<tr>
<td>UNIQUE_CONSTRAINT_CATALOG</td>
<td></td>
<td>NULL</td>
</tr>
<tr>
<td>UNIQUE_CONSTRAINT_SCHEMA</td>
<td></td>
<td></td>
</tr>
<tr>
<td>UNIQUE_CONSTRAINT_NAME</td>
<td></td>
<td></td>
</tr>
<tr>
<td>MATCH_OPTION</td>
<td></td>
<td></td>
</tr>
<tr>
<td>UPDATE_RULE</td>
<td></td>
<td></td>
</tr>
<tr>
<td>DELETE_RULE</td>
<td></td>
<td></td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td></td>
<td></td>
</tr>
<tr>
<td>REFERENCED_TABLE_NAME</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Notes:

- The REFERENTIALCONSTRAINTS table was added in MySQL 5.1.10. The REFERENCED_TABLE_NAME column was added in MySQL 5.1.16.
• **TABLE_NAME** has the same value as **TABLE_NAME** in INFORMATION_SCHEMA.TABLE_CONSTRAINTS.

• **CONSTRAINT_SCHEMA** and **CONSTRAINT_NAME** identify the foreign key.

• **UNIQUE_CONSTRAINT_SCHEMA**, **UNIQUE_CONSTRAINT_NAME**, and **REFERENCED_TABLE_NAME** identify the referenced key. (Note: Before MySQL 5.1.16, **UNIQUE_CONSTRAINT_NAME** incorrectly named the referenced table, not the constraint.)

• The only valid value at this time for **MATCH_OPTION** is **NONE**.

• The possible values for **UPDATE_RULE** or **DELETE_RULE** are **CASCADE**, **SET NULL**, **SET DEFAULT**, **RESTRICT**, **NO ACTION**.

### 20.16 The INFORMATION_SCHEMA ROUTINES Table

The **ROUTINES** table provides information about stored routines (both procedures and functions). The **ROUTINES** table does not include user-defined functions (UDFs).

The column named "**mysql.proc name**" indicates the mysql.proc table column that corresponds to the INFORMATION_SCHEMA.ROUTINES table column, if any.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>mysql.proc Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPECIFIC_NAME</td>
<td>specific_name</td>
<td></td>
</tr>
<tr>
<td>ROUTINE_CATALOG</td>
<td></td>
<td>NULL</td>
</tr>
<tr>
<td>ROUTINE_SCHEMA</td>
<td>db</td>
<td></td>
</tr>
<tr>
<td>ROUTINE_NAME</td>
<td>name</td>
<td></td>
</tr>
<tr>
<td>ROUTINE_TYPE</td>
<td>type</td>
<td>(PROCEDURE</td>
</tr>
<tr>
<td>DTD_IDENTIFIER</td>
<td></td>
<td>data type descriptor</td>
</tr>
<tr>
<td>ROUTINE_BODY</td>
<td>SQL</td>
<td></td>
</tr>
<tr>
<td>ROUTINE_DEFINITION</td>
<td>body or body_utf8</td>
<td>see Notes</td>
</tr>
<tr>
<td>EXTERNAL_NAME</td>
<td></td>
<td>NULL</td>
</tr>
<tr>
<td>EXTERNAL_LANGUAGE</td>
<td>language</td>
<td>NULL</td>
</tr>
<tr>
<td>PARAMETER_STYLE</td>
<td>SQL</td>
<td></td>
</tr>
<tr>
<td>IS_DETERMINISTIC</td>
<td>is_deterministic</td>
<td></td>
</tr>
<tr>
<td>SQL_DATA_ACCESS</td>
<td>sql_data_access</td>
<td></td>
</tr>
<tr>
<td>SQL_PATH</td>
<td></td>
<td>NULL</td>
</tr>
<tr>
<td>SECURITY_TYPE</td>
<td>security_type</td>
<td></td>
</tr>
<tr>
<td>CREATED</td>
<td>created</td>
<td></td>
</tr>
<tr>
<td>LAST_ALTERED</td>
<td>modified</td>
<td></td>
</tr>
<tr>
<td>SQL_MODE</td>
<td>sql_mode</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>ROUTINE_COMMENT</td>
<td>comment</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>DEFINER</td>
<td>definer</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>CHARACTER_SET_CLIENT</td>
<td></td>
<td>MySQL extension</td>
</tr>
<tr>
<td>COLLATION_CONNECTION</td>
<td></td>
<td>MySQL extension</td>
</tr>
<tr>
<td>DATABASE_COLLATION</td>
<td></td>
<td>MySQL extension</td>
</tr>
</tbody>
</table>

**Notes:**

• MySQL calculates **EXTERNAL_LANGUAGE** thus:
  • If **mysql.proc.language='SQL'**, **EXTERNAL_LANGUAGE** is **NULL**
• Otherwise, `EXTERNAL_LANGUAGE` is what is in `mysql.proc.language`. However, we do not have external languages yet, so it is always `NULL`.

• `ROUTINE_DEFINITION` is what is in `mysql.proc.body_utf8` as of MySQL 5.1.21, `mysql.proc.body` before 5.1.21.

• `CREATED`: The date and time when the routine was created. This is a `TIMESTAMP` value.

• `LAST_ALTERED`: The date and time when the routine was last modified. This is a `TIMESTAMP` value. If the routine has not been modified since its creation, this column holds the same value as the `CREATED` column.

• `SQL_MODE`: The SQL mode in effect when the routine was created or altered, and under which the routine executes. For the permitted values, see Section 5.1.7, “Server SQL Modes”.

• `CHARACTER_SET_CLIENT`: The session value of the `character_set_client` system variable when the routine was created. This column was added in MySQL 5.1.21.

• `COLLATION_CONNECTION`: The session value of the `collation_connection` system variable when the routine was created. This column was added in MySQL 5.1.21.

• `DATABASE_COLLATION`: The collation of the database with which the routine is associated. This column was added in MySQL 5.1.21.

20.17 The INFORMATION_SCHEMA SCHEMATA Table

A schema is a database, so the `SCHEMATA` table provides information about databases.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>CATALOG_NAME</td>
<td></td>
<td>NULL</td>
</tr>
<tr>
<td>SCHEMA_NAME</td>
<td>Database</td>
<td></td>
</tr>
<tr>
<td>DEFAULT_CHARACTER_SET_NAME</td>
<td></td>
<td></td>
</tr>
<tr>
<td>DEFAULT_COLLATION_NAME</td>
<td></td>
<td></td>
</tr>
<tr>
<td>SQL_PATH</td>
<td>NULL</td>
<td></td>
</tr>
</tbody>
</table>

The following statements are equivalent:

```
SELECT SCHEMA_NAME AS `Database`
FROM INFORMATION_SCHEMA.SCHEMATA
WHERE SCHEMA_NAME LIKE 'wild'

SHOW DATABASES LIKE 'wild'
```

20.18 The INFORMATION_SCHEMA SCHEMA_PRIVILEGES Table

The `SCHEMA_PRIVILEGES` table provides information about schema (database) privileges. This information comes from the `mysql.db` grant table.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRANTEE</td>
<td></td>
<td>'user_name'@'host_name' value, MySQL extension</td>
</tr>
<tr>
<td>TABLE_CATALOG</td>
<td></td>
<td>NULL, MySQL extension</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td></td>
<td>MySQL extension</td>
</tr>
<tr>
<td>PRIVILEGE_TYPE</td>
<td></td>
<td>MySQL extension</td>
</tr>
<tr>
<td>IS_GRANTABLE</td>
<td></td>
<td>MySQL extension</td>
</tr>
</tbody>
</table>
The INFORMATION_SCHEMA STATISTICS Table

Notes:

• This is a nonstandard table. It takes its values from the mysql.db table.

20.19 The INFORMATION_SCHEMA STATISTICS Table

The STATISTICS table provides information about table indexes.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_CATALOG</td>
<td>NULL</td>
<td></td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td>= Database</td>
<td></td>

</tbody>
</table>

Notes:

• There is no standard table for indexes. The preceding list is similar to what SQL Server 2000 returns for sp_statistics, except that we replaced the name QUALIFIER with CATALOG and we replaced the name OWNER with SCHEMA.

Clearly, the preceding table and the output from SHOW INDEX are derived from the same parent. So the correlation is already close.

The following statements are equivalent:

```sql
SELECT * FROM INFORMATION_SCHEMA.STATISTICS
WHERE table_name = 'tbl_name'
AND table_schema = 'db_name'
```

SHOW INDEX
FROM tbl_name
FROM db_name

20.20 The INFORMATION_SCHEMA TABLES Table

The TABLES table provides information about tables in databases.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_CATALOG</td>
<td>NULL</td>
<td></td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td>Table_...</td>
<td></td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>Table_...</td>
<td></td>
</tr>
</tbody>
</table>
### The INFORMATION_SCHEMA TABLES Table

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_TYPE</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ENGINE</td>
<td>Engine</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>VERSION</td>
<td>Version</td>
<td>The version number of the table's .frm file, MySQL extension</td>
</tr>
<tr>
<td>ROW_FORMAT</td>

</tr>
<tr>
<td>TABLE_COLLATION</td>
<td>Collation</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>CHECKSUM</td>
<td>Checksum</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>CREATE_OPTIONS</td>
<td>Create_options</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>TABLE_COMMENT</td>
<td>Comment</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>INDEX_COMMENT</td>
<td>Index_comment</td>
<td>MySQL extension</td>
</tr>
</tbody>
</table>

**Notes:**

- Refer to SHOW TABLE STATUS for field descriptions.
- TABLE_SCHEMA and TABLE_NAME are a single field in a SHOW display, for example Table_in_db1.
- TABLE_TYPE should be BASE TABLE or VIEW. The TABLES table does not list TEMPORARY tables.
- For partitioned tables, beginning with MySQL 5.1.9, the ENGINE column shows the name of the storage engine used by all partitions. (Previously, this column showed PARTITION for such tables.)
- The TABLE_ROWS column is NULL if the table is in the INFORMATION_SCHEMA database.
  
  For InnoDB tables, the row count is only a rough estimate used in SQL optimization. (This is also true if the InnoDB table is partitioned.)

Prior to MySQL 5.1.12, MySQL Cluster allocated storage for variable-width columns in 10-page extents of 32 kilobytes each; thus, the DATA_LENGTH for such columns was reported in increments of 320 KB. Beginning with MySQL 5.1.12, the DATA_LENGTH column reflects the true amount of storage for variable-width columns of NDB tables. (Bug #18413)

For NDB tables, DATA_LENGTH includes data stored in main memory only; the MAX_DATA_LENGTH and DATA_FREE columns apply to Disk Data.

- Beginning with MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11, for MySQL Cluster Disk Data tables, MAX_DATA_LENGTH shows the space allocated for the disk part of a Disk Data table or fragment. (In-memory data resource usage is reported by the DATA_LENGTH column.)
- Beginning with MySQL 5.1.28, the DATA_FREE column shows the free space in bytes for InnoDB tables.
Beginning with MySQL Cluster NDB 7.0.22 and MySQL Cluster NDB 7.1.11, `DATA_FREE` shows the space allocated on disk for, but not used by, a Disk Data table or fragment on disk. (In-memory data resource usage is reported by the `DATA_LENGTH` column.)

- For partitioned InnoDB tables, the `CREATE_TIME`, `UPDATE_TIME`, and `CHECK_TIME` columns are always `NULL`.
- We have nothing for the table’s default character set. `TABLE_COLLATION` is close, because collation names begin with a character set name.
- Beginning with MySQL 5.1.9, the `CREATE_OPTIONS` column shows `partitioned` if the table is partitioned.

The following statements are equivalent:

```sql
SELECT table_name FROM INFORMATION_SCHEMA.TABLES
WHERE table_schema = 'db_name'
[AND table_name LIKE 'wild']
SHOW TABLES
FROM 'db_name'
[LIKE 'wild']
```

### 20.21 The INFORMATION_SCHEMA TABLE_CONSTRAINTS Table

The `TABLE_CONSTRAINTS` table describes which tables have constraints.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONSTRAINT_CATALOG</td>
<td></td>
<td>NULL</td>
</tr>
<tr>
<td>CONSTRAINT_SCHEMA</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CONSTRAINT_NAME</td>
<td></td>
<td></td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td></td>
<td></td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CONSTRAINT_TYPE</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Notes:**

- The `CONSTRAINT_TYPE` value can be `UNIQUE`, `PRIMARY_KEY`, or `FOREIGN_KEY`.
- The `UNIQUE` and `PRIMARY_KEY` information is about the same as what you get from the `Key_name` field in the output from `SHOW_INDEX` when the `Non_unique` field is `0`.
- The `CONSTRAINT_TYPE` column can contain one of these values: `UNIQUE`, `PRIMARY_KEY`, `FOREIGN_KEY`, `CHECK`. This is a `CHAR` (not `ENUM`) column. The `CHECK` value is not available until we support `CHECK`.

### 20.22 The INFORMATION_SCHEMA TABLE_PRIVILEGES Table

The `TABLE_PRIVILEGES` table provides information about table privileges. This information comes from the `mysql.tables_priv` grant table.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRANTEE</td>
<td></td>
<td>'user_name'@'host_name' value</td>
</tr>
<tr>
<td>TABLE_CATALOG</td>
<td></td>
<td>NULL</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### The INFORMATION_SCHEMA TRIGGERS Table

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_NAME</td>
<td></td>
<td></td>
</tr>
<tr>
<td>PRIVILEGE_TYPE</td>
<td></td>
<td></td>
</tr>
<tr>
<td>IS_GRANTABLE</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Notes:**

- PRIVILEGE_TYPE can contain one (and only one) of these values: SELECT, INSERT, UPDATE, REFERENCES, ALTER, INDEX, DROP, CREATE VIEW.

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.TABLE_PRIVILEGES
SHOW GRANTS ...
```

### 20.23 The INFORMATION_SCHEMA TRIGGERS Table

The TRIGGERS table provides information about triggers. To see information about a table's triggers, you must have the TRIGGER privilege for the table (prior to MySQL 5.1.23, you must have the SUPER privilege).

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRIGGER_CATALOG</td>
<td></td>
<td>NULL</td>
</tr>
<tr>
<td>TRIGGER_SCHEMA</td>
<td></td>
<td>Trigger</td>
</tr>
<tr>
<td>TRIGGER_NAME</td>
<td>Trigger</td>
<td></td>
</tr>
<tr>
<td>EVENT_MANIPULATION</td>
<td>Event</td>
<td></td>
</tr>
<tr>
<td>EVENT_OBJECT_CATALOG</td>
<td></td>
<td>NULL</td>
</tr>
<tr>
<td>EVENT_OBJECT_SCHEMA</td>
<td></td>
<td></td>
</tr>
<tr>
<td>EVENT_OBJECT_TABLE</td>
<td>Table</td>
<td></td>
</tr>
<tr>
<td>ACTION_ORDER</td>
<td>0</td>
<td></td>
</tr>
<tr>
<td>ACTION_CONDITION</td>
<td></td>
<td>NULL</td>
</tr>
<tr>
<td>ACTION_STATEMENT</td>
<td>Statement</td>
<td></td>
</tr>
<tr>
<td>ACTION_ORIENTATION</td>
<td>ROW</td>
<td></td>
</tr>
<tr>
<td>ACTION_TIMING</td>
<td>Timing</td>
<td></td>
</tr>
<tr>
<td>ACTION_REFERENCE_OLD_TABLE</td>
<td></td>
<td>NULL</td>
</tr>
<tr>
<td>ACTION_REFERENCE_NEW_TABLE</td>
<td></td>
<td>NULL</td>
</tr>
<tr>
<td>ACTION_REFERENCE_OLD_ROW</td>
<td>OLD</td>
<td></td>
</tr>
<tr>
<td>ACTION_REFERENCE_NEW_ROW</td>
<td>NEW</td>
<td></td>
</tr>
<tr>
<td>CREATED</td>
<td>Created</td>
<td></td>
</tr>
<tr>
<td>SQL_MODE</td>
<td>sql_mode</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>DEFINER</td>
<td>Definer</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>CHARACTER_SET_CLIENT</td>
<td>character_set_client</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>COLLATION_CONNECTION</td>
<td>collation_connection</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>DATABASE_COLLATION</td>
<td>Database Collation</td>
<td>MySQL extension</td>
</tr>
</tbody>
</table>

**Notes:**

- The names in the "SHOW Name" column refer to the SHOW TRIGGERS statement, not SHOW CREATE TRIGGER. See Section 13.7.5.40, "SHOW TRIGGERS Syntax".
• **TRIGGER_SCHEMA** and **TRIGGER_NAME**: The name of the database in which the trigger occurs and the trigger name, respectively.

• **EVENT_MANIPULATION**: The trigger event. This is the type of operation on the associated table for which the trigger activates. The value is 'INSERT' (a row was inserted), 'DELETE' (a row was deleted), or 'UPDATE' (a row was modified).

• **EVENT_OBJECT_SCHEMA** and **EVENT_OBJECT_TABLE**: As noted in Section 19.3, “Using Triggers”, every trigger is associated with exactly one table. These columns indicate the database in which this table occurs, and the table name, respectively.

• **ACTION_ORDER**: The ordinal position of the trigger’s action within the list of all similar triggers on the same table. This value is always 0, because it is not possible to have more than one trigger with the same **EVENT_MANIPULATION** and **ACTION_TIMING** on the same table.

• **ACTION_STATEMENT**: The trigger body; that is, the statement executed when the trigger activates. This text uses UTF-8 encoding.

• **ACTION_ORIENTATION**: Always contains the value 'ROW'.

• **ACTION_TIMING**: Whether the trigger activates before or after the triggering event. The value is 'BEFORE' or 'AFTER'.

• **ACTION_REFERENCE_OLD_ROW** and **ACTION_REFERENCE_NEW_ROW**: The old and new column identifiers, respectively. This means that **ACTION_REFERENCE_OLD_ROW** always contains the value 'OLD' and **ACTION_REFERENCE_NEW_ROW** always contains the value 'NEW'.

• **SQL_MODE**: The SQL mode in effect when the trigger was created, and under which the trigger executes. For the permitted values, see Section 5.1.7, “Server SQL Modes”.

• **DEFINER**: The account of the user who created the trigger, in 'user_name'@'host_name' format. This column was added in MySQL 5.1.2.

• **CHARACTER_SET_CLIENT**: The session value of the character_set_client system variable when the trigger was created. This column was added in MySQL 5.1.21.

• **COLLATION_CONNECTION**: The session value of the collation_connection system variable when the trigger was created. This column was added in MySQL 5.1.21.

• **DATABASE_COLLATION**: The collation of the database with which the trigger is associated. This column was added in MySQL 5.1.21.

• The following columns currently always contain NULL: **TRIGGER_CATALOG**, **EVENT_OBJECT_CATALOG**, **ACTION_CONDITION**, **ACTION_REFERENCE_OLD_TABLE**, **ACTION_REFERENCE_NEW_TABLE**, and **CREATED**.

Example, using the *ins_sum* trigger defined in Section 19.3, “Using Triggers”:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.TRIGGERS
   -> WHERE TRIGGER_SCHEMA='test' AND TRIGGER_NAME='ins_sum'
G
*************************** 1. row ***************************
TRIGGER_CATALOG: def
TRIGGER_SCHEMA: test
TRIGGER_NAME: ins_sum
EVENT_MANIPULATION: INSERT
EVENT_OBJECT_CATALOG: def
EVENT_OBJECT_SCHEMA: test
EVENT_OBJECT_TABLE: account
ACTION_ORDER: 0
ACTION_CONDITION: NULL
ACTION_STATEMENT: SET @sum = @sum + NEW.amount
ACTION_ORIENTATION: ROW
ACTION_TIMING: BEFORE
ACTION_REFERENCE_OLD_TABLE: NULL
```
The INFORMATION_SCHEMA USER_PRIVILEGES Table

The `USER_PRIVILEGES` table provides information about global privileges. This information comes from the `mysql.user` grant table.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRANTEE</td>
<td>'user_name'@'host_name'</td>
<td>value, MySQL extension</td>
</tr>
<tr>
<td>TABLE_CATALOG</td>
<td>NULL</td>
<td>MySQL extension</td>
</tr>
<tr>
<td>PRIVILEGE_TYPE</td>
<td>MySQL extension</td>
<td></td>
</tr>
<tr>
<td>IS_GRANTABLE</td>
<td>MySQL extension</td>
<td></td>
</tr>
</tbody>
</table>

Notes:
- This is a nonstandard table. It takes its values from the `mysql.user` table.

20.25 The INFORMATION_SCHEMA VIEWS Table

The `VIEWS` table provides information about views in databases. You must have the `SHOW VIEW` privilege to access this table.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_CATALOG</td>
<td>NULL</td>
<td></td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td></td>
<td></td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td></td>
<td></td>
</tr>
<tr>
<td>VIEW_DEFINITION</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CHECK_OPTION</td>
<td></td>
<td></td>
</tr>
<tr>
<td>IS_UPDATABLE</td>
<td></td>
<td></td>
</tr>
<tr>
<td>DEFINER</td>
<td></td>
<td></td>
</tr>
<tr>
<td>SECURITY_TYPE</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CHARACTER_SET_CLIENT</td>
<td>MySQL extension</td>
<td></td>
</tr>
<tr>
<td>COLLATION_CONNECTION</td>
<td>MySQL extension</td>
<td></td>
</tr>
</tbody>
</table>

Notes:
- The `VIEW_DEFINITION` column has most of what you see in the `Create Table` field that `SHOW CREATE VIEW` produces. Skip the words before `SELECT` and skip the words `WITH CHECK OPTION`. Suppose that the original statement was:

```
CREATE VIEW v AS
SELECT s2, s1 FROM t
WHERE s1 > 5
ORDER BY s1
WITH CHECK OPTION;
```

Then the view definition looks like this:
SELECT s2, s1 FROM t WHERE s1 > 5 ORDER BY s1

- The **CHECK_OPTION** column has a value of **NONE, CASCADE, or LOCAL**.

- MySQL sets a flag, called the view updatability flag, at **CREATE VIEW** time. The flag is set to **YES** (true) if **UPDATE** and **DELETE** (and similar operations) are legal for the view. Otherwise, the flag is set to **NO** (false). The **IS_UPDATABLE** column in the **VIEWS** table displays the status of this flag. It means that the server always knows whether a view is updatable.

  If a view is not updatable, statements such as **UPDATE, DELETE, and INSERT** are illegal and will be rejected. (Note that even if a view is updatable, it might not be possible to insert into it; for details, refer to [Section 19.5.3, "Updatable and Insertable Views"]).

- **DEFINER**: The account of the user who created the view, in 'user_name'@'host_name' format. The **SECURITY_TYPE** has a value of **DEFINER** or **INVOKER**.

- **CHARACTER_SET_CLIENT**: The session value of the character_set_client system variable when the view was created. This column was added in MySQL 5.1.21.

- **COLLATION_CONNECTION**: The session value of the collation_connection system variable when the view was created. This column was added in MySQL 5.1.21.

MySQL lets you use different sql_mode settings to tell the server the type of SQL syntax to support. For example, you might use the **ANSI** SQL mode to ensure MySQL correctly interprets the standard SQL concatenation operator, the double bar (||), in your queries. If you then create a view that concatenates items, you might worry that changing the sql_mode setting to a value different from **ANSI** could cause the view to become invalid. But this is not the case. No matter how you write out a view definition, MySQL always stores it the same way, in a canonical form. Here is an example that shows how the server changes a double bar concatenation operator to a **CONCAT()** function:

```
mysql> SET sql_mode = 'ANSI';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE VIEW test.v AS SELECT 'a' || 'b' as col1;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT VIEW_DEFINITION FROM INFORMATION_SCHEMA.VIEWS
      -> WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME = 'v';
+----------------------------------+
| VIEW_DEFINITION                  |
| select concat('a','b') AS `col1` |
+----------------------------------+
1 row in set (0.00 sec)
```

The advantage of storing a view definition in canonical form is that changes made later to the value of sql_mode will not affect the results from the view. However an additional consequence is that comments prior to **SELECT** are stripped from the definition by the server.

20.26 INFORMATION_SCHEMA Tables for MySQL Cluster

The following sections provide information about **INFORMATION_SCHEMA** tables which are specific to MySQL Cluster. The **FILES** table was added in MySQL Server 5.1.6 as part of MySQL Cluster data-on-disk support (it is available in standard MySQL 5.5 but is not used there). The **ndb_transid_mysql_connection_map** table was added as part of additions made to MySQL Cluster's ndbinfo information database in MySQL Cluster NDB 7.1.17; it is implemented as an **INFORMATION_SCHEMA** plugin available only in MySQL Cluster binaries or source, and does not exist in MySQL Server 5.1.

Additional statistical and other data about MySQL Cluster transactions, operations, threads, blocks, and other aspects of performance can be obtained from the tables in the **ndbinfo** database.
20.26.1 The INFORMATION_SCHEMA FILES Table

The FILES table provides information about the files in which MySQL NDB Disk Data tables are stored.

**Note**

This table provides information about Disk Data files only; you cannot use it for determining disk space allocation or availability for individual NDB tables. However, beginning with MySQL Cluster NDB 6.3.27 and MySQL Cluster NDB 7.0.8, it is possible to see how much space is allocated for each NDB table having data stored on disk, as well as how much remains available for storage of data on disk for that table, using ndb_desc. For more information, see Section 17.4.10, “ndb_desc — Describe NDB Tables”.

</tr>
</tbody>
</table>

**Notes:**

- **FILE_ID** column values are auto-generated.
- **FILE_NAME** is the name of an UNDO log file created by CREATE LOGFILE GROUP or ALTER LOGFILE GROUP, or of a data file created by CREATE TABLESPACE or ALTER TABLESPACE.
- **FILE_TYPE** is one of the values UNDOFILE or DATAFILE.
  
  Beginning with MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.32, MySQL Cluster NDB 7.0.13, and MySQL Cluster NDB 7.1.2, this column can also have the value TABLESPACE.
- **TABLESPACE_NAME** is the name of the tablespace with which the file is associated.
- The value of the TABLESPACE_CATALOG column is always NULL.
- **TABLE_NAME** is the name of the Disk Data table with which the file is associated, if any.
- The LOGFILE_GROUP_NAME column gives the name of the log file group to which the log file or data file belongs.
- For an UNDO log file, the LOGFILE_GROUP_NUMBER contains the auto-generated ID number of the log file group to which the log file belongs.
- For a MySQL Cluster Disk Data log file or data file, the value of the ENGINE column is always NDB or NDBCLUSTER.
- For a MySQL Cluster Disk Data log file or data file, the value of the FULLTEXT_KEYS column is always empty.
- The **FREE EXTENTS** column displays the number of extents which have not yet been used by the file. The **TOTAL EXTENTS** column show the total number of extents allocated to the file.

The difference between these two columns is the number of extents currently in use by the file:

```sql
SELECT TOTAL_EXTENTS - FREE_EXTENTS AS extents_used
FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME = 'myfile.dat';
```

You can approximate the amount of disk space in use by the file by multiplying this difference by the value of the EXTENT_SIZE column, which gives the size of an extent for the file in bytes:

```sql
SELECT (TOTAL_EXTENTS - FREE_EXTENTS) * EXTENT_SIZE AS bytes_used
FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME = 'myfile.dat';
```

Similarly, you can estimate the amount of space that remains available in a given file by multiplying **FREE_EXTENTS** by **EXTENT_SIZE**.
The INFORMATION_SCHEMA FILES Table

Important

The byte values produced by the preceding queries are approximations only, and their precision is inversely proportional to the value of EXTENT_SIZE. That is, the larger EXTENT_SIZE becomes, the less accurate the approximations are.

It is also important to remember that once an extent is used, it cannot be freed again without dropping the data file of which it is a part. This means that deletes from a Disk Data table do not release disk space.

The extent size can be set in a CREATE TABLESPACE statement. See Section 13.1.18, "CREATE TABLESPACE Syntax", for more information.

• The INITIAL_SIZE column shows the size in bytes of the file. This is the same value that was used in the INITIAL_SIZE clause of the CREATE LOGFILE GROUP, ALTER LOGFILE GROUP, CREATE TABLESPACE, or ALTER TABLESPACE statement used to create the file.

For MySQL Cluster Disk Data files, the value of the MAXIMUM_SIZE column is always the same as INITIAL_SIZE, and the AUTOEXTEND_SIZE column is always empty.

• The CREATION_TIME column shows the date and time when the file was created. The LAST_UPDATE_TIME column displays the date and time when the file was last modified. The LAST_ACCESSED column provides the date and time when the file was last accessed by the server.

The values of these columns are as reported by the operating system, and are not supplied by the NDB storage engine. Where no value is provided by the operating system, these columns display 0000-00-00 00:00:00.

• For MySQL Cluster Disk Data files, the value of the RECOVER_TIME and TRANSACTION_COUNTER columns is always 0.

• For MySQL Cluster Disk Data files, the following columns are always NULL:
  • VERSION
  • ROW_FORMAT
  • TABLE_ROWS
  • AVG_ROW_LENGTH
  • DATA_LENGTH
  • MAX_DATA_LENGTH
  • INDEX_LENGTH
  • DATA_FREE
  • CREATE_TIME
  • UPDATE_TIME
  • CHECK_TIME
  • CHECKSUM
For MySQL Cluster Disk Data files, the value of the **STATUS** column is always **NORMAL**.

For MySQL Cluster Disk Data files, the **EXTRA** column shows which data node the file belongs to, as each data node has its own copy of the file. Suppose that you use this statement on a MySQL Cluster with four data nodes:

```sql
CREATE LOGFILE GROUP mygroup
   ADD UNDOFILE 'new_undo.dat'
   INITIAL_SIZE 2G
   ENGINE NDB;
```

After running the `CREATE LOGFILE GROUP` statement successfully, you should see a result similar to the one shown here for this query against the **FILES** table:

```sql
mysql> SELECT LOGFILE_GROUP_NAME, FILE_TYPE, EXTRA
   -> FROM INFORMATION_SCHEMA.FILES
   -> WHERE FILE_NAME = 'new_undo.dat';
```

```plaintext
+--------------------+-------------+----------------+
<table>
<thead>
<tr>
<th>LOGFILE_GROUP_NAME</th>

<tr>
<td>mygroup</td>
<td>UNDO FILE</td>
<td>CLUSTER_NODE=6</td>
</tr>
</tbody>
</table>
+--------------------+-------------+----------------+
```

The **FILES** table is a nonstandard table. It was added in MySQL 5.1.6.

Beginning with MySQL 5.1.14, an additional row is present in the **FILES** table following the creation of a logfile group. This row has **NULL** for the value of the **FILE_NAME** column. For this row, the value of the **FILE_ID** column is always **0**, that of the **FILE_TYPE** column is always **UNDO FILE**, and that of the **STATUS** column is always **NORMAL**. The value of the **ENGINE** column is always **NDBCLUSTER**.

The **FREE_EXTENTS** column in this row shows the total number of free extents available to all undo files belonging to a given log file group whose name and number are shown in the **LOGFILE_GROUP_NAME** and **LOGFILE_GROUP_NUMBER** columns, respectively.

Suppose there are no existing log file groups on your MySQL Cluster, and you create one using the following statement:

```sql
mysql> CREATE LOGFILE GROUP lg1
   -> ADD UNDOFILE 'undofile.dat'
   -> INITIAL_SIZE = 16M
   -> UNDO_BUFFER_SIZE = 1M
   -> ENGINE = NDB;
```

Query OK, 0 rows affected (3.81 sec)

You can now see this **NULL** row when you query the **FILES** table:

```sql
mysql> SELECT DISTINCT
   -> FILE_NAME AS File,
   -> FREE_EXTENTS AS Free,
   -> TOTAL_EXTENTS AS Total,
   -> EXTENT_SIZE AS Size,
   -> INITIAL_SIZE AS Initial
   -> FROM INFORMATION_SCHEMA.FILES;
```

```plaintext
+--------------+---------+---------+------+----------+
<table>
<thead>
<tr>
<th>File</th>
<th>Free</th>
<th>Total</th>
<th>Size</th>
<th>Initial</th>
</tr>
</thead>
<tbody>
<tr>
<td>undofile.dat</td>
<td>NULL</td>
<td>4194304</td>
<td>4</td>
<td>16777216</td>
</tr>
<tr>
<td>NULL</td>
<td>4184068</td>
<td>NULL</td>
<td>4</td>
<td>NULL</td>
</tr>
</tbody>
</table>
+--------------+---------+---------+------+----------+
```

2 rows in set (0.01 sec)
The total number of free extents available for undo logging is always somewhat less than the sum of the `TOTAL_EXTENTS` column values for all undo files in the log file group due to overhead required for maintaining the undo files. This can be seen by adding a second undo file to the log file group, then repeating the previous query against the `FILES` table:

```
mysql> ALTER LOGFILE GROUP lg1
    -> ADD UNDOFILE 'undofile02.dat'
    -> INITIAL_SIZE = 4M
    -> ENGINE = NDB;
Query OK, 0 rows affected (1.02 sec)

mysql> SELECT DISTINCT
    -> FILE_NAME AS File,
    -> FREE_EXTENTS AS Free,
    -> TOTAL_EXTENTS AS Total,
    -> EXTENT_SIZE AS Size,
    -> INITIAL_SIZE AS Initial
    -> FROM INFORMATION_SCHEMA.FILES;
```

```
+----------------+---------+---------+------+----------+
| File           | Free    | Total   | Size | Initial  |
+----------------+---------+---------+------+----------+
| undofile.dat   |    NULL | 4194304 |    4 | 16777216 |
| undofile02.dat |    NULL | 1048576 |    4 |  4194304 |
| NULL           | 5223944 |    NULL |    4 |     NULL |
+----------------+---------+---------+------+----------+
3 rows in set (0.01 sec)
```

The amount of free space in bytes which is available for undo logging by Disk Data tables using this log file group can be approximated by multiplying the number of free extents by the initial size:

```
mysql> SELECT
    -> FREE_EXTENTS AS 'Free Extents',
    -> FREE_EXTENTS * EXTENT_SIZE AS 'Free Bytes'
    -> FROM INFORMATION_SCHEMA.FILES
    -> WHERE LOGFILE_GROUP_NAME = 'lg1'
    -> AND FILE_NAME IS NULL;
```

```
+--------------+------------+
<table>
<thead>
<tr>
<th>Free Extents</th>
<th>Free Bytes</th>
</tr>
</thead>
<tbody>
<tr>
<td>5223944</td>
<td>20895776</td>
</tr>
</tbody>
</table>
+--------------+------------+
1 row in set (0.02 sec)
```

If you create a MySQL Cluster Disk Data table and then insert some rows into it, you can see approximately how much space remains for undo logging afterward, for example:

```
mysql> CREATE TABLESPACE ts1
    -> ADD DATAFILE 'data1.dat'
    -> USE LOGFILE GROUP lg1
    -> INITIAL_SIZE 512M
    -> ENGINE = NDB;
Query OK, 0 rows affected (8.71 sec)

mysql> CREATE TABLE dd (c1 INT NOT NULL PRIMARY KEY, c2 INT, c3 DATE)
    -> TABLESPACE ts1 STORAGE DISK
    -> ENGINE = NDB;
Query OK, 0 rows affected (2.11 sec)

mysql> INSERT INTO dd VALUES
    -> (NULL, 1234567890, '2007-02-02'),
    -> (NULL, 1126789005, '2007-02-03'),
    -> (NULL, 1357924680, '2007-02-04'),
```
• Beginning with MySQL Cluster NDB 6.2.19, MySQL Cluster NDB 6.3.32, MySQL Cluster NDB 7.0.13, and MySQL Cluster NDB 7.1.2, an additional row is present in the FILES table for any tablespace, whether or not any data files are associated with the tablespace. This row has NULL for the value of the FILE_NAME column. For this row, the value of the FILE_ID column is always 0, that of the FILE_TYPE column is always TABLESPACE, and that of the STATUS column is always NORMAL. The value of the ENGINE column is always NDBCLUSTER.

• There are no SHOW statements associated with the FILES table.

• For additional information, and examples of creating and dropping MySQL Cluster Disk Data objects, see Section 17.5.12, “MySQL Cluster Disk Data Tables”.

20.26.2 The INFORMATION_SCHEMA ndb_transid_mysql_connection_map Table

The ndb_transid_mysql_connection_map table provides a mapping between NDB transactions, NDB transaction coordinators, and MySQL Servers attached to a MySQL Cluster as API nodes. This information is used when populating the server_operations and server_transactions tables of the ndbinfo MySQL Cluster information database.

<table>
<thead>
<tr>
<th>INFORMATION_SCHEMA Name</th>
<th>SHOW Name</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql_connection_id</td>
<td></td>
<td>MySQL Server connection ID</td>
</tr>
<tr>
<td>node_id</td>
<td></td>
<td>Transaction coordinator node ID</td>
</tr>
<tr>
<td>ndb_transid</td>
<td></td>
<td>NDB transaction ID</td>
</tr>
</tbody>
</table>

The mysql_connection_id is the same as the connection or session ID shown in the output of SHOW PROCESSLIST.

There are no SHOW statements associated with this table.

This is a nonstandard table, added in MySQL Cluster NDB 7.1.17. It is implemented as an INFORMATION_SCHEMA plugin; you can verify that it is supported by checking the output of SHOW PLUGINS. If ndb_transid_mysql_connection_map support is enabled, the output from this statement includes a plugin having this name, of type INFORMATION_SCHEMA, and having status ACTIVE, as shown here (using emphasized text):

<table>
<thead>
<tr>
<th>Name</th>
<th>Status</th>
<th>Type</th>
<th>Library</th>
<th>License</th>
</tr>
</thead>
<tbody>
<tr>
<td>binlog</td>
<td>ACTIVE</td>
<td>STORAGE ENGINE</td>
<td>NULL</td>
<td>GPL</td>
</tr>
<tr>
<td>CSV</td>
<td>ACTIVE</td>
<td>STORAGE ENGINE</td>
<td>NULL</td>
<td>GPL</td>
</tr>
<tr>
<td>MEMORY</td>
<td>ACTIVE</td>
<td>STORAGE ENGINE</td>
<td>NULL</td>
<td>GPL</td>
</tr>
<tr>
<td>MRG_MYISAM</td>
<td>ACTIVE</td>
<td>STORAGE ENGINE</td>
<td>NULL</td>
<td>GPL</td>
</tr>
</tbody>
</table>
The plugin is enabled by default. You can disable it (or force the server not to run unless the plugin starts) by starting the server with the `--ndb-transid-mysql-connection-map` option. If the plugin is disabled, the status is shown by `SHOW PLUGINS` as `DISABLED`. The plugin cannot be enabled or disabled at runtime.

Although the names of this table and its columns are displayed using lowercase, you can use uppercase or lowercase when referring to them in SQL statements.

For this table to be created, the MySQL Server must be a binary that was supplied with the MySQL Cluster distribution, or one that was built from the MySQL Cluster sources with NDB storage engine support enabled. It is not available in the standard MySQL 5.1 Server.

### 20.27 Extensions to SHOW Statements

Some extensions to `SHOW` statements accompany the implementation of `INFORMATION_SCHEMA`:

- `SHOW` can be used to get information about the structure of `INFORMATION_SCHEMA` itself.
- Several `SHOW` statements accept a `WHERE` clause that provides more flexibility in specifying which rows to display.

`INFORMATION_SCHEMA` is an information database, so its name is included in the output from `SHOW DATABASES`. Similarly, `SHOW TABLES` can be used with `INFORMATION_SCHEMA` to obtain a list of its tables:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA;
+---------------------------------------+
| Tables_in_INFORMATION_SCHEMA          |
+---------------------------------------+
| CHARACTER_SETS                        |
| COLLATIONS                            |
| COLLATION_CHARACTER_SET_APPLICABILITY |
| COLUMNS                               |
| COLUMN_PRIVILEGES                     |
| ENGINES                               |
| EVENTS                                |
| FILES                                 |
| GLOBAL_STATUS                         |
| GLOBAL_VARIABLES                      |
| KEY_COLUMN_USAGE                      |
| PARTITIONS                            |
| PLUGINS                               |
| PROCESSLIST                           |
| REFERENTIAL_CONSTRAINTS               |
| ROUTINES                              |
| SCHEMATA                              |
| SCHEMA_PRIVILEGES                     |
| SESSION_STATUS                        |
```
Extensions to SHOW Statements

SHOW_COLUMNS and DESCRIBE can display information about the columns in individual INFORMATION_SCHEMA tables.

SHOW statements that accept a LIKE clause to limit the rows displayed also permit a WHERE clause that specifies more general conditions that selected rows must satisfy:

SHOW CHARACTER SET
SHOW COLLATION
SHOW COLUMNS
SHOW DATABASES
SHOW FUNCTION STATUS
SHOW INDEX
SHOW OPEN TABLES
SHOW PROCEDURE STATUS
SHOW STATUS
SHOW TABLE STATUS
SHOW TABLES
SHOW TRIGGERS
SHOW VARIABLES

The WHERE clause, if present, is evaluated against the column names displayed by the SHOW statement. For example, the SHOW CHARACTER SET statement produces these output columns:

```
mysql> SHOW CHARACTER SET;
+----------+-----------------------------+---------------------+--------+
| Charset  | Description                 | Default collation   | Maxlen |
|----------|-----------------------------+---------------------+--------+
| big5     | Big5 Traditional Chinese   | big5_chinese_ci     | 2      |
| dec8     | DEC West European           | dec8_swedish_ci     | 1      |
| cp850    | DOS West European           | cp850_general_ci    | 1      |
| hp8      | HP West European            | hp8_english_ci      | 1      |
| koi8r    | KOI8-R Relcom Russian       | koi8r_general_ci    | 1      |
| latin1   | cp1252 West European        | latin1_swedish_ci   | 1      |
| latin2   | ISO 8859-2 Central European | latin2_general_ci   | 1      |
|...       |                             |                     |        |
```

To use a WHERE clause with SHOW CHARACTER SET, you would refer to those column names. As an example, the following statement displays information about character sets for which the default collation contains the string 'japanese':

```
mysql> SHOW CHARACTER SET WHERE `Default collation` LIKE '%japanese%';
+---------+---------------------------+---------------------+--------+
| Charset | Description               | Default collation   | Maxlen |
|---------|---------------------------+---------------------+--------+
| ujis    | EUC-JP Japanese           | ujis_japanese_ci    | 3      |
| sjis    | Shift-JIS Japanese        | sjis_japanese_ci    | 2      |
| cp932   | SJIS for Windows Japanese | cp932_japanese_ci   | 2      |
| eucjps  | UJIS for Windows Japanese | eucjps_japanese_ci  | 3      |
```

This statement displays the multibyte character sets:

```
mysql> SHOW CHARACTER SET WHERE Maxlen > 1;
+---------+---------------------------+---------------------+--------+
| Charset | Description               | Default collation   | Maxlen |
|---------|---------------------------+---------------------+--------|
```
### Extensions to SHOW Statements

| big5    | Big5 Traditional Chinese | big5_chinese_ci | 2 |
| ujis    | EUC-JP Japanese          | ujis_japanese_ci | 3 |
| sjis    | Shift-JIS Japanese       | sjis_japanese_ci | 2 |
| euckr   | EUC-KR Korean            | euckr_korean_ci | 2 |
| gb2312  | GB2312 Simplified Chinese| gb2312_chinese_ci | 2 |
| gbk     | GBK Simplified Chinese   | gbk_chinese_ci | 2 |
| utf8    | UTF-8 Unicode            | utf8_general_ci | 3 |
| ucs2    | UCS-2 Unicode            | ucs2_general_ci | 2 |
| cp932   | SJIS for Windows Japanese| cp932_japanese_ci | 2 |
| eucjpms | UJIS for Windows Japanese| eucjpms_japanese_ci | 3 |

MySQL Connectors provide connectivity to the MySQL server for client programs. APIs provide low-level access to the MySQL protocol and MySQL resources. Both Connectors and the APIs enable you to connect and execute MySQL statements from another language or environment, including ODBC, Java (JDBC), Perl, Python, PHP, Ruby, and native C and embedded MySQL instances.

Note

Connector version numbers do not correlate with MySQL Server version numbers. See Table 21.2, “MySQL Connector Versions and MySQL Server Versions”.

2383
MySQL Connectors

Oracle develops a number of connectors:

- **Connector/ODBC** provides driver support for connecting to MySQL using the Open Database Connectivity (ODBC) API. Support is available for ODBC connectivity from Windows, Unix, and OS X platforms.

- **Connector/Net** enables developers to create .NET applications that connect to MySQL. Connector/Net implements a fully functional ADO.NET interface and provides support for use with ADO.NET aware tools. Applications that use Connector/Net can be written in any supported .NET language.

  The MySQL Visual Studio Plugin works with Connector/Net and Visual Studio 2005. The plugin is a MySQL DDEX Provider, which means that you can use the schema and data manipulation tools available in Visual Studio to create and edit objects within a MySQL database.

- **Connector/J** provides driver support for connecting to MySQL from Java applications using the standard Java Database Connectivity (JDBC) API.

- **Connector/Python** provides driver support for connecting to MySQL from Python applications using an API that is compliant with the Python DB API version 2.0. No additional Python modules or MySQL client libraries are required.

- **Connector/C++** enables C++ applications to connect to MySQL.

- **Connector/C** is a standalone replacement for the MySQL Client Library (`libmysqlclient`), to be used for C applications.

The MySQL C API

For direct access to using MySQL natively within a C application, there are two methods:

- The C API provides low-level access to the MySQL client/server protocol through the `libmysqlclient` client library. This is the primary method used to connect to an instance of the MySQL server, and is used both by MySQL command-line clients and many of the MySQL Connectors and third-party APIs detailed here.

  `libmysqlclient` is included in MySQL distributions and in Connector/C distributions.

- `libmysqld` is an embedded MySQL server library that enables you to embed an instance of the MySQL server into your C applications.

  `libmysqld` is included in MySQL distributions, but not in Connector/C distributions.

  See also Section 21.8.1, “MySQL C API Implementations”.

To access MySQL from a C application, or to build an interface to MySQL for a language not supported by the Connectors or APIs in this chapter, the C API is where to start. A number of programmer’s utilities are available to help with the process; see Section 4.7, “MySQL Program Development Utilities”.

Third-Party MySQL APIs

The remaining APIs described in this chapter provide an interface to MySQL from specific application languages. These third-party solutions are not developed or supported by Oracle. Basic information on their usage and abilities is provided here for reference purposes only.

All the third-party language APIs are developed using one of two methods, using `libmysqlclient` or by implementing a native driver. The two solutions offer different benefits:

- Using `libmysqlclient` offers complete compatibility with MySQL because it uses the same libraries as the MySQL client applications. However, the feature set is limited to the implementation
and interfaces exposed through `libmysqlclient` and the performance may be lower as data is copied between the native language, and the MySQL API components.

- **Native drivers** are an implementation of the MySQL network protocol entirely within the host language or environment. Native drivers are fast, as there is less copying of data between components, and they can offer advanced functionality not available through the standard MySQL API. Native drivers are also easier for end users to build and deploy because no copy of the MySQL client libraries is needed to build the native driver components.

Table 21.1, “MySQL APIs and Interfaces” lists many of the libraries and interfaces available for MySQL. Table 21.2, “MySQL Connector Versions and MySQL Server Versions” shows which MySQL Server versions each connector supports.

### 21.1 MySQL Connector/ODBC

The MySQL Connector/ODBC manual is now published in standalone form, not as part of the MySQL Reference Manual. For information, see these documents:
MySQL Connector/Net

• Main manual: MySQL Connector/ODBC Developer Guide
• Release notes: MySQL Connector/ODBC Release Notes

21.2 MySQL Connector/Net

The MySQL Connector/Net manual is now published in standalone form, not as part of the MySQL Reference Manual. For information, see these documents:

• Main manual: MySQL Connector/Net Developer Guide
• Release notes: MySQL Connector/Net Release Notes

21.3 MySQL Connector/J

The MySQL Connector/J manual is now published in standalone form, not as part of the MySQL Reference Manual. For information, see these documents:

• Main manual: MySQL Connector/J 5.1 Developer Guide
• Release notes: MySQL Connector/J Release Notes

21.4 MySQL Connector/C++

The MySQL Connector/C++ manual is now published in standalone form, not as part of the MySQL Reference Manual. For information, see these documents:

• Main manual: MySQL Connector/C++ Developer Guide
• Release notes: MySQL Connector/C++ Release Notes

21.5 MySQL Connector/C

The MySQL Connector/C manual is now published in standalone form, not as part of the MySQL Reference Manual. For information, see these documents:

• Main manual: MySQL Connector/C Developer Guide
• Release notes: MySQL Connector/C Release Notes

21.6 MySQL Connector/Python

The MySQL Connector/Python manual is now published in standalone form, not as part of the MySQL Reference Manual. For information, see these documents:

• Main manual: MySQL Connector/Python Developer Guide
• Release notes: MySQL Connector/Python Release Notes

21.7 libmysqld, the Embedded MySQL Server Library

The embedded MySQL server library makes it possible to run a full-featured MySQL server inside a client application. The main benefits are increased speed and more simple management for embedded applications.

The embedded server library is based on the client/server version of MySQL, which is written in C/C++. Consequently, the embedded server also is written in C/C++. There is no embedded server available in other languages.

The API is identical for the embedded MySQL version and the client/server version. To change an old threaded application to use the embedded library, you normally only have to add calls to the following functions.
### Compiling Programs with libmysqld

#### Table 21.3 MySQL Embedded Server Library Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>When to Call</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>mysql_library_init()</code></td>
<td>Call it before any other MySQL function is called, preferably early in the</td>
</tr>
<tr>
<td></td>
<td><code>main()</code> function.</td>
</tr>
<tr>
<td><code>mysql_library_end()</code></td>
<td>Call it before your program exits.</td>
</tr>
<tr>
<td><code>mysql_thread_init()</code></td>
<td>Call it in each thread you create that accesses MySQL.</td>
</tr>
<tr>
<td><code>mysql_thread_end()</code></td>
<td>Call it before calling <code>pthread_exit()</code>.</td>
</tr>
</tbody>
</table>

Then you must link your code with `libmysqld.a` instead of `libmysqlclient.a`. To ensure binary compatibility between your application and the server library, be sure to compile your application against headers for the same series of MySQL that was used to compile the server library. For example, if `libmysqld` was compiled against MySQL 5.0 headers, do not compile your application against MySQL 5.1 headers, or vice versa.

The `mysql_library_xxx()` functions are also included in `libmysqlclient.a` to enable you to change between the embedded and the client/server version by just linking your application with the right library. See Section 21.8.7.40, “`mysql_library_init()`”.

One difference between the embedded server and the standalone server is that for the embedded server, authentication for connections is disabled by default. To use authentication for the embedded server, specify the `--with-embedded-privilege-control` option when you invoke `configure` to configure your MySQL distribution.

### 21.7.1 Compiling Programs with libmysqld

In precompiled binary MySQL distributions that include `libmysqld`, the embedded server library, MySQL builds the library using the appropriate vendor compiler if there is one.

To get a `libmysqld` library if you build MySQL from source yourself, you should configure MySQL with the `--with-embedded-server` option. See Section 2.11.4, “MySQL Source-Configuration Options”.

When you link your program with `libmysqld`, you must also include the system-specific `pthread` libraries and some libraries that the MySQL server uses. You can get the full list of libraries by executing `mysql_config --libmysqld-libs`.

The correct flags for compiling and linking a threaded program must be used, even if you do not directly call any thread functions in your code.

To compile a C program to include the necessary files to embed the MySQL server library into an executable version of a program, the compiler will need to know where to find various files and need instructions on how to compile the program. The following example shows how a program could be compiled from the command line, assuming that you are using `gcc`, use the GNU C compiler:

```bash
gcc mysql_test.c -o mysql_test -lz \ 
'/usr/local/mysql/bin/mysql_config --include --libmysqld-libs'
```

Immediately following the `gcc` command is the name of the C program source file. After it, the `-o` option is given to indicate that the file name that follows is the name that the compiler is to give to the output file, the compiled program. The next line of code tells the compiler to obtain the location of the include files and libraries and other settings for the system on which it is compiled. Because of a problem with `mysql_config`, the option `-lz` (for compression) is added here. The `mysql_config` command is contained in backticks, not single quotation marks.

On some non-`gcc` platforms, the embedded library depends on C++ runtime libraries and linking against the embedded library might result in missing-symbol errors. To solve this, link using a C++ compiler or explicitly list the required libraries on the link command line.
21.7.2 Restrictions When Using the Embedded MySQL Server

The embedded server has the following limitations:

- No user-defined functions (UDFs).
- No stack trace on core dump.
- You cannot set this up as a master or a slave (no replication).
- Very large result sets may be unusable on low memory systems.
- You cannot connect to an embedded server from an outside process with sockets or TCP/IP. However, you can connect to an intermediate application, which in turn can connect to an embedded server on the behalf of a remote client or outside process.
- InnoDB is not reentrant in the embedded server and cannot be used for multiple connections, either successively or simultaneously.
- The Event Scheduler is not available. Because of this, the event_scheduler system variable is disabled.

Some of these limitations can be changed by editing the mysql_embed.h include file and recompiling MySQL.

21.7.3 Options with the Embedded Server

Any options that may be given with the mysqld server daemon, may be used with an embedded server library. Server options may be given in an array as an argument to the mysql_library_init(), which initializes the server. They also may be given in an option file like my.cnf. To specify an option file for a C program, use the --defaults-file option as one of the elements of the second argument of the mysql_library_init() function. See Section 21.8.7.40, "mysql_library_init()", for more information on the mysql_library_init() function.

Using option files can make it easier to switch between a client/server application and one where MySQL is embedded. Put common options under the [server] group. These are read by both MySQL versions. Client/server-specific options should go under the [mysqld] section. Put options specific to the embedded MySQL server library in the [embedded] section. Options specific to applications go under section labeled [ApplicationName_SERVER]. See Section 4.2.6, "Using Option Files".

21.7.4 Embedded Server Examples

These two example programs should work without any changes on a Linux or FreeBSD system. For other operating systems, minor changes are needed, mostly with file paths. These examples are designed to give enough details for you to understand the problem, without the clutter that is a necessary part of a real application. The first example is very straightforward. The second example is a little more advanced with some error checking. The first is followed by a command-line entry for compiling the program. The second is followed by a GNUmake file that may be used for compiling instead.

Example 1

test1_libmysqld.c

```c
#include <stdio.h>
#include <stdlib.h>
#include <stdarg.h>
#include "mysql.h"

MYSQL *mysql;
MYSQL_RES *results;
MYSQL_ROW record;
```
static char *server_options[] = { "mysql_test", "--defaults-file=my.cnf", NULL };  
int num_elements = (sizeof(server_options) / sizeof(char *)) - 1;

static char *server_groups[] = { "libmysqld_server",  
                                "libmysqld_client", NULL };  

int main(void)  
{  
   mysql_library_init(num_elements, server_options, server_groups);  
   mysql = mysql_init(NULL);  
   mysql_options(mysql, MYSQL_READ_DEFAULT_GROUP, "libmysqld_client");  
   mysql_options(mysql, MYSQL_OPT_USE_EMBEDDED_CONNECTION, NULL);  
   mysql_real_connect(mysql, NULL, NULL, NULL, "database1", 0, NULL, 0);  
   mysql_query(mysql, "SELECT column1, column2 FROM table1");  
   results = mysql_store_result(mysql);  
   while((record = mysql_fetch_row(results))) {  
      printf("%s - %s \n", record[0], record[1]);  
   }  
   mysql_free_result(results);  
   mysql_close(mysql);  
   mysql_library_end();  
   return 0;  
}

Here is the command line for compiling the above program:

gcc test1_libmysqld.c -o test1_libmysqld -lz  
`/usr/local/mysql/bin/mysql_config --include --libmysqld-libs`

Example 2

To try the example, create an test2_libmysqld directory at the same level as the MySQL source directory. Save the test2_libmysqld.c source and the GNUmakefile in the directory, and run GNU make from inside the test2_libmysqld directory.

test2_libmysqld.c

/*  
 * A simple example client, using the embedded MySQL server library  
 */

#include <mysql.h>  
#include <stdarg.h>  
#include <stdio.h>  
#include <stdlib.h>  

MYSQL *db_connect(const char *dbname);  
void db_disconnect(MYSQL *db);  
void db_do_query(MYSQL *db, const char *query);  

const char *server_groups[] = {  
   "test2_libmysqld_SERVER", "embedded", "server", NULL  
};  

int  
main(int argc, char **argv)  
{  
   MYSQL *one, *two;  

   /* mysql_library_init() must be called before any other mysql *  
    * functions. *  

* You can use `mysql_library_init(0, NULL, NULL)`, and it
  initializes the server using groups = {
  * "server", "embedded", NULL
  * }.
  *
  * In your `$HOME/.my.cnf` file, you probably want to put:

  [test2_libmysqld_SERVER]
  language = /path/to/source/of/mysql/sql/share/english

  * You could, of course, modify `argc` and `argv` before passing
    * them to this function. Or you could create new ones in any
    * way you like. But all of the arguments in `argv` (except for
    * `argv[0]`, which is the program name) should be valid options
    * for the MySQL server.
    *
    * If you link this client against the normal mysqlclient
    * library, this function is just a stub that does nothing.
    */
  mysql_library_init(argc, argv, (char **)server_groups);

  one = db_connect("test");
  two = db_connect(NULL);

  db_do_query(one, "SHOW TABLE STATUS");
  db_do_query(two, "SHOW DATABASES");

  mysql_close(two);
  mysql_close(one);

  /* This must be called after all other mysql functions */
  mysql_library_end();

  exit(EXIT_SUCCESS);
}

static void
die(MYSQL *db, char *fmt, ...)
{
  va_list ap;
  va_start(ap, fmt);
  vfprintf(stderr, fmt, ap);
  va_end(ap);
  (void)putc('\n', stderr);
  if (db)
    db_disconnect(db);
  exit(EXIT_FAILURE);
}

MYSQL *
db_connect(const char *dbname)
{
  MYSQL *db = mysql_init(NULL);
  if (!db)
    die(db, "mysql_init failed: no memory");
  /*
   * Notice that the client and server use separate group names.
   * This is critical, because the server does not accept the
   * client's options, and vice versa.
   */
  mysql_options(db, MYSQL_READ_DEFAULT_GROUP, "test2_libmysqld_CLIENT");
  if (!(mysql_real_connect(db, NULL, NULL, NULL, dbname, 0, NULL, 0))
    die(db, "mysql_real_connect failed: %s", mysql_error(db));

  return db;
}

void
db_disconnect(MYSQL *db)
{
  mysql_close(db);
}
void
db_do_query(MYSQL *db, const char *query)
{
    if (mysql_query(db, query) != 0)
        goto err;

    if (mysql_field_count(db) > 0)
    {
        MYSQL_RES   *res;
        MYSQL_ROW    row, end_row;
        int num_fields;

        if (!(res = mysql_store_result(db)))
            goto err;
        num_fields = mysql_num_fields(res);
        while ((row = mysql_fetch_row(res)))
        {
            (void)fputs(">> ", stdout);
            for (end_row = row + num_fields; row < end_row; ++row)
                (void)printf("%s\t", row ? (char*)*row : "NULL");
            (void)fputc('
', stdout);
        }
        (void)fputc('
', stdout);
        mysql_free_result(res);
    }
    else
        (void)printf("Affected rows: %lld\n", mysql_affected_rows(db));

    return;
}

err:
die(db, "db_do_query failed: %s [%s]", mysql_error(db), query);

GNUmakefile

# This assumes the MySQL software is installed in /usr/local/mysql
inc := /usr/local/mysql/include/mysql
lib := /usr/local/mysql/lib

# If you have not installed the MySQL software yet, try this instead
#inc := $(HOME)/mysql-5.1/include

**21.8 MySQL C API**

The C API provides low-level access to the MySQL client/server protocol and enables C programs to access database contents. The C API code is distributed with MySQL and implemented in the `libmysqlclient` library. See Section 21.8.1, “MySQL C API Implementations”.

Most client APIs use the `libmysqlclient` library to communicate with the MySQL server. (Exceptions are Connector/J and Connector/Net) This means that, for example, you can take advantage of many of the same environment variables that are used by other client programs because they are referenced from the library. For a list of these variables, see Section 4.1, “Overview of MySQL Programs”.

For instructions on building client programs using the C API, see Section 21.8.4.1, “Building C API Client Programs”. For programming with threads, see Section 21.8.4.2, “Writing C API Threaded Client Programs”. To create a standalone application which includes the "server" and "client" in the same program (and does not communicate with an external MySQL server), see Section 21.7, “libmysqld, the Embedded MySQL Server Library”.

**Note**

If, after an upgrade, you experience problems with compiled client programs, such as Commands out of sync or unexpected core dumps, the programs were probably compiled using old header or library files. In this case, check the date of the `mysql.h` file and `libmysqlclient.a` library used for compilation to verify that they are from the new MySQL distribution. If not, recompile the programs with the new headers and libraries. Recompilation might also be necessary for programs compiled against the shared client library if the library major version number has changed (for example, from `libmysqlclient.so.17` to `libmysqlclient.so.18`). For additional compatibility information, see Section 21.8.4.3, “Running C API Client Programs”.

Clients have a maximum communication buffer size. The size of the buffer that is allocated initially (16KB) is automatically increased up to the maximum size (16MB by default). Because buffer sizes are increased only as demand warrants, simply increasing the maximum limit does not in itself cause more resources to be used. This size check is mostly a precaution against erroneous statements and communication packets.

The communication buffer must be large enough to contain a single SQL statement (for client-to-server traffic) and one row of returned data (for server-to-client traffic). Each session's communication buffer is dynamically enlarged to handle any query or row up to the maximum limit. For example, if you have BLOB values that contain up to 16MB of data, you must have a communication buffer limit of at least 16MB (in both server and client). The default maximum built into the client library is 1GB, but the default maximum in the server is 1MB. You can increase this by changing the value of the `max_allowed_packet` parameter at server startup. See Section 8.12.2, “Tuning Server Parameters”.

The MySQL server shrinks each communication buffer to `net_buffer_length` bytes after each query. For clients, the size of the buffer associated with a connection is not decreased until the connection is closed, at which time client memory is reclaimed.

**21.8.1 MySQL C API Implementations**

The MySQL C API is a C-based API that client applications written in C can use to communicate with MySQL Server. Client programs refer to C API header files at compile time and link to a C API library file at link time. The library comes in two versions, depending on how the application is intended to communicate with the server:

- `libmysqlclient`: The client version of the library, used for applications that communicate over a network connection as a client of a standalone server process.
Simultaneous MySQL Server and Connector/C Installations

- **libmysqld**: The embedded server version of the library, used for applications intended to include an embedded MySQL server within the application itself. The application communicates with its own private server instance.

Both libraries have the same interface. In terms of C API calls, an application communicates with a standalone server the same way it communicates with an embedded server. A given client can be built to communicate with a standalone or embedded server, depending on whether it is linked against `libmysqlclient` or `libmysqld` at build time.

There are two ways to obtain the C API header and library files required to build C API client programs:

- Install a MySQL Server distribution. Server distributions include both `libmysqlclient` and `libmysqld`.
- Install a Connector/C distribution. Connector/C distributions include only `libmysqlclient`. They do not include `libmysqld`.

For both MySQL Server and Connector/C, you can install a binary distribution that contains the C API files pre-built, or you can use a source distribution and build the C API files yourself.

Normally, you install either a MySQL Server distribution or a Connector/C distribution, but not both. For information about issues involved with simultaneous MySQL Server and Connector/C installations, see Section 21.8.2, “Simultaneous MySQL Server and Connector/C Installations”.

The names of the library files to use when linking C API client applications depend on the library type and platform for which a distribution is built:

- On Unix (and Unix-like) systems, the static library is `libmysqlclient.a`. The dynamic library is `libmysqlclient.so` on most Unix systems and `libmysqlclient.dylib` on OS X.

  For distributions that include embedded server libraries, the corresponding library names begin with `libmysqld` rather than `libmysqlclient`.

- On Windows, the static library is `mysqlclient.lib` and the dynamic library is `libmysql.dll`. Windows distributions also include `libmysql.lib`, a static import library needed for using the dynamic library.

  For distributions that include embedded server libraries, the corresponding library names are `mysqserver.lib`, `libmysqld.dll`, and `libmysqld.lib`.

Windows distributions also include a set of debug libraries. These have the same names as the nondebug libraries, but are located in the `lib/debug` library. You must use the debug libraries when compiling clients built using the debug C runtime.

### 21.8.2 Simultaneous MySQL Server and Connector/C Installations

MySQL Server and Connector/C installation packages both provide the files needed to build and run MySQL C API client programs. This section discusses when it is possible to install both products on the same system. For some packaging formats, this is possible without conflict. For others, both products cannot be installed at the same time.

This discussion assumes the use of similar package types for both products (for example, RPM packages for both products). It does not try to describe coexistence between packaging types (for example, use of RPM packages for one product and a `tar` file package for the other). Nor does it describe coexistence of packages provided by Oracle and those provided by third-party vendors.

If you install both products, it may be necessary to adjust your development tools or runtime environment to choose one set of header files and libraries over the other. See Section 21.8.4.1, “Building C API Client Programs”, and Section 21.8.4.3, “Running C API Client Programs”.

2394
Example C API Client Programs

**tar** and Zip file packages install under the directory into which you unpack them. For example, you can unpack MySQL Server and Connector/C **tar** packages under `/usr/local` and they will unpack into distinct directory names without conflict.

Windows MSI installers use their own installation directory, so MySQL Server and Connector/C installers do not conflict.

OS X DMG packages install under the same parent directory but in a different subdirectory, so there is no conflict. For example:

```
/usr/local/mysql-5.6.11-osx10.7-x86_64/
/usr/local/mysql-connector-c-6.1.0-osx10.7-x86/
```

Solaris PKG packages install under the same parent directory but in a different subdirectory, so there is no conflict. For example:

```
/opt/mysql/mysql
/opt/mysql/connector-c
```

The Solaris Connector/C installer does not create any symlinks from system directories such as `/usr/bin` or `/usr/lib` into the installation directory. That must be done manually if desired after installation.

For RPM installations, there are several types of RPM packages. MySQL Server **shared** and **devel** RPM packages are similar to the corresponding Connector/C RPM packages. These RPM package types cannot coexist because the MySQL Server and Connector/C RPM packages use the same installation locations for the client library-related files. This means the following conditions hold:

- If MySQL Server **shared** and **devel** RPM packages are installed, they provide the C API headers and libraries, and there is no need to install the Connector/C RPM packages. To install the Connector/C packages anyway, you must first remove the corresponding MySQL Server packages.

- To install MySQL Server RPM packages if you already have Connector/C RPM packages installed, you must first remove the Connector/C RPM packages.

MySQL Server RPM packages other than **shared** and **devel** do not conflict with Connector/C packages and can be installed if Connector/C is installed. This includes the main server RPM that includes the **mysqld** server itself.

### 21.8.3 Example C API Client Programs

Many of the clients in MySQL source distributions are written in C, such as **mysql**, **mysqladmin**, and **mysqlshow**. If you are looking for examples that demonstrate how to use the C API, take a look at these clients: Obtain a source distribution and look in its **client** directory. See Section 2.1.2, “How to Get MySQL”.

### 21.8.4 Building and Running C API Client Programs

The following sections provide information on building client programs that use the C API. Topics include compiling and linking clients, writing threaded clients, and troubleshooting runtime problems.

#### 21.8.4.1 Building C API Client Programs

This section provides guidelines for compiling C programs that use the MySQL C API.

**Compiling MySQL Clients on Unix**

You may need to specify an **-I** option when you compile client programs that use MySQL header files, so that the compiler can find them. For example, if the header files are installed in `/usr/local/mysql/include`, use this option in the compile command:

```
```
MySQL clients must be linked using the `-lmysqlclient -lz` options in the link command. You may also need to specify a `-L` option to tell the linker where to find the library. For example, if the library is installed in `/usr/local/mysql/lib`, use these options in the link command:

```
-L/usr/local/mysql/lib -lmysqlclient -lz
```

The path names may differ on your system. Adjust the `-I` and `-L` options as necessary.

To make it simpler to compile MySQL programs on Unix, use the `mysql_config` script. See Section 4.7.2, "mysql_config — Display Options for Compiling Clients".

`mysql_config` displays the options needed for compiling or linking:

```
shell> mysql_config --cflags
shell> mysql_config --libs
```

You can run those commands to get the proper options and add them manually to compilation or link commands. Alternatively, include the output from `mysql_config` directly within command lines using backticks:

```
shell> gcc -c `mysql_config --cflags` progname.c
shell> gcc -o progname progname.o `mysql_config --libs`
```

### Compiling MySQL Clients on Microsoft Windows

To specify header and library file locations, use the facilities provided by your development environment.

On Windows, you can link your code with either the dynamic or static C client library. The static library is named `mysqlclient.lib` and the dynamic library is named `libmysql.dll`. In addition, the `libmysql.lib` static import library is needed for using the dynamic library.

If you link with the static library, failure can occur unless these conditions are satisfied:

- The client application must be compiled with the same version of Visual Studio used to compile the library.
- The client application should link the C runtime statically by using the `/MT` compiler option.

If the client application is built in debug mode and uses the static debug C runtime (`/MTd` compiler option), it can link to the `mysqlclient.lib` static library if that library was built using the same option. If the client application uses the dynamic C runtime (`/MD` option, or `/MDd` option in debug mode), it must be linked to the `libmysql.dll` dynamic library. It cannot link to the static client library.

The MSDN page describing the link options can be found here: http://msdn.microsoft.com/en-us/library/2kzt1wy3.aspx

### Troubleshooting Problems Linking to the MySQL Client Library

Linking with the single-threaded library (`libmysqlclient`) may lead to linker errors related to `pthread` symbols. When using the single-threaded library, please compile your client with `MYSQL_CLIENT_NO_THREADS` defined. This can be done on the command line by using the `-D` option to the compiler, or in your source code before including the MySQL header files. This define should not be used when building for use with the thread-safe client library (`libmysqlclient_r`).

If the linker cannot find the MySQL client library, you might get undefined-reference errors for symbols that start with `mysql_`, such as those shown here:

```
/tmp/ccFKsdPa.o: In function `main':
/tmp/ccFKsdPa.o(.text+0xb): undefined reference to `mysql_init'
```

```
/tmp/ccFKsdPa.o: In function `main':
/tmp/ccFKsdPa.o(.text+0xb): undefined reference to `mysql_init'
```
Building and Running C API Client Programs

You should be able to solve this problem by adding `-L` dir_path `-lmysqlclient` at the end of your link command, where dir_path represents the path name of the directory where the client library is located. To determine the correct directory, try this command:

```
shell> mysql_config --libs
```

The output from `mysql_config` might indicate other libraries that should be specified on the link command as well. You can include `mysql_config` output directly in your compile or link command using backticks. For example:

```
shell> gcc -o proname proname.o `mysql_config --libs`
```

If an error occurs at link time that the floor symbol is undefined, link to the math library by adding `-lm` to the end of the compile/link line.

If you get undefined reference errors for the uncompress or compress function, add `-lz` to the end of your link command and try again.

Similarly, if you get undefined-reference errors for other functions that should exist on your system, such as `connect()`, check the manual page for the function in question to determine which libraries you should add to the link command.

If you get undefined-reference errors such as the following for functions that do not exist on your system, it usually means that your MySQL client library was compiled on a system that is not 100% compatible with yours:

```
mf_format.o(.text+0x201): undefined reference to `__lxstat'
```

In this case, you should download the latest MySQL or Connector/C source distribution and compile the MySQL client library yourself. See Section 2.11, “Installing MySQL from Source”, and MySQL Connector/C Developer Guide.

21.8.4.2 Writing C API Threaded Client Programs

The client library is almost thread-safe. The biggest problem is that the subroutines in sql/net_serv.cc that read from sockets are not interrupt-safe. This was done with the thought that you might want to have your own alarm that can break a long read to a server. If you install interrupt handlers for the SIGPIPE interrupt, socket handling should be thread-safe.

To avoid aborting the program when a connection terminates, MySQL blocks SIGPIPE on the first call to `mysql_library_init()`, `mysql_init()`, or `mysql_connect()`. To use your own SIGPIPE handler, first call `mysql_library_init()`, then install your handler.

Current binary distributions should have both a normal client library, `libmysqlclient`, and a thread-safe library, `libmysqlclient_r`. For threaded clients, link against the latter library. If “undefined symbol” errors occur, in most cases this is because you have not included the thread libraries on the link/command.

The thread-safe client library, `libmysqlclient_r`, is thread-safe per connection. You can let two threads share the same connection with the following caveats:

- Multiple threads cannot send a query to the MySQL server at the same time on the same connection. In particular, you must ensure that between calls to `mysql_query()` and `mysql_store_result()` in one thread, no other thread uses the same connection. You must have a mutex lock around your pair of `mysql_query()` and `mysql_store_result()` calls. After `mysql_store_result()` returns, the lock can be released and other threads may query the same connection.
If you use POSIX threads, you can use `pthread_mutex_lock()` and `pthread_mutex_unlock()` to establish and release a mutex lock.

- Many threads can access different result sets that are retrieved with `mysql_store_result()`.
- To use `mysql_use_result()`, you must ensure that no other thread is using the same connection until the result set is closed. However, it really is best for threaded clients that share the same connection to use `mysql_store_result()`.

You need to know the following if you have a thread that did not create the connection to the MySQL database but is calling MySQL functions:

When you call `mysql_init()`, MySQL creates a thread-specific variable for the thread that is used by the debug library (among other things). If you call a MySQL function before the thread has called `mysql_init()`, the thread does not have the necessary thread-specific variables in place and you are likely to end up with a core dump sooner or later. To avoid problems, you must do the following:

1. Call `mysql_library_init()` before any other MySQL functions. It is not thread-safe, so call it before threads are created, or protect the call with a mutex.
2. Arrange for `mysql_thread_init()` to be called early in the thread handler before calling any MySQL function. If you call `mysql_init()`, it will call `mysql_thread_init()` for you.
3. In the thread, call `mysql_thread_end()` before calling `pthread_exit()`. This frees the memory used by MySQL thread-specific variables.

The preceding notes regarding `mysql_init()` also apply to `mysql_connect()`, which calls `mysql_init()`.

### 21.8.4.3 Running C API Client Programs

If, after an upgrade, you experience problems with compiled client programs, such as **Commands out of sync** or unexpected core dumps, the programs were probably compiled using old header or library files. In this case, check the date of the `mysql.h` file and `libmysqlclient.a` library used for compilation to verify that they are from the new MySQL distribution. If not, recompile the programs with the new headers and libraries. Recompilation might also be necessary for programs compiled against the shared client library if the library major version number has changed (for example, from `libmysqlclient.so.17` to `libmysqlclient.so.18`).

The major client library version determines compatibility. (For example, for `libmysqlclient.so.18.1.0`, the major version is 18.) For this reason, the libraries shipped with newer versions of MySQL are drop-in replacements for older versions that have the same major number. As long as the major library version is the same, you can upgrade the library and old applications should continue to work with it.

Undefined-reference errors might occur at runtime when you try to execute a MySQL program. If these errors specify symbols that start with `mysql_` or indicate that the `libmysqlclient` library cannot be found, it means that your system cannot find the shared `libmysqlclient.so` library. The solution to this problem is to tell your system to search for shared libraries in the directory where that library is located. Use whichever of the following methods is appropriate for your system:

- Add the path of the directory where `libmysqlclient.so` is located to the `LD_LIBRARY_PATH` or `LD_LIBRARY` environment variable.
- On OS X, add the path of the directory where `libmysqlclient.dylib` is located to the `DYLD_LIBRARY_PATH` environment variable.
- Copy the shared-library files (such as `libmysqlclient.so`) to some directory that is searched by your system, such as `/lib`, and update the shared library information by executing `ldconfig`. Be sure to copy all related files. A shared library might exist under several names, using symlinks to provide the alternate names.
Another way to solve this problem is by linking your program statically with the \texttt{-static} option, or by removing the dynamic MySQL libraries before linking your code. Before trying the second method, you should be sure that no other programs are using the dynamic libraries.

### 21.8.4.4 C API Server and Client Library Versions

The string and numeric forms of the MySQL server version are available at compile time as the values of the \texttt{MYSQL_SERVER_VERSION} and \texttt{MYSQL_VERSION_ID} macros, and at runtime as the values of the \texttt{mysql_get_server_info()} and \texttt{mysql_get_server_version()} functions.

The client library version is the MySQL version. For Connector/C, this is the MySQL version on which the Connector/C distribution is based. The string and numeric forms of this version are available at compile time as the values of the \texttt{MYSQL_SERVER_VERSION} and \texttt{MYSQL_VERSION_ID} macros, and at runtime as the values of the \texttt{mysql_get_client_info()} and \texttt{mysql_get_client_version()} functions.

### 21.8.5 C API Data Structures

This section describes C API data structures other than those used for prepared statements. For information about the latter, see Section 21.8.9, “C API Prepared Statement Data Structures”.

- **MYSQL**

  This structure represents a handle to one database connection. It is used for almost all MySQL functions. Do not try to make a copy of a \texttt{MYSQL} structure. There is no guarantee that such a copy will be usable.

- **MYSQL_RES**

  This structure represents the result of a query that returns rows (\texttt{SELECT}, \texttt{SHOW}, \texttt{DESCRIBE}, \texttt{EXPLAIN}). The information returned from a query is called the result set in the remainder of this section.

- **MYSQL_ROW**

  This is a type-safe representation of one row of data. It is currently implemented as an array of counted byte strings. (You cannot treat these as null-terminated strings if field values may contain binary data, because such values may contain null bytes internally.) Rows are obtained by calling \texttt{mysql_fetch_row()}.

- **MYSQL_FIELD**

  This structure contains metadata: information about a field, such as the field's name, type, and size. Its members are described in more detail later in this section. You may obtain the \texttt{MYSQL_FIELD} structures for each field by calling \texttt{mysql_fetch_field()} repeatedly. Field values are not part of this structure; they are contained in a \texttt{MYSQL_ROW} structure.

- **MYSQL_FIELD_OFFSET**

  This is a type-safe representation of an offset into a MySQL field list. (Used by \texttt{mysql_field_seek()}.) Offsets are field numbers within a row, beginning at zero.

- **my_ulonglong**

  The type used for the number of rows and for \texttt{mysql_affected_rows()}, \texttt{mysql_num_rows()}, and \texttt{mysql_insert_id()}. This type provides a range of \texttt{0} to \texttt{1.84e19}.

  Some functions that return a row count using this type return \texttt{-1} as an unsigned value to indicate an error or exceptional condition. You can check for \texttt{-1} by comparing the return value to \texttt{(my_ulonglong)-1} (or to \texttt{(my_ulonglong)-0}, which is equivalent).
On some systems, attempting to print a value of type `my_ulonglong` does not work. To print such a value, convert it to `unsigned long` and use a `%lu` print format. Example:

```c
printf("Number of rows: %lu\n",
    (unsigned long) mysql_num_rows(result));
```

- `my_bool`

  A boolean type, for values that are true (nonzero) or false (zero).

The `MYSQL_FIELD` structure contains the members described in the following list:

- `char * name`

  The name of the field, as a null-terminated string. If the field was given an alias with an `AS` clause, the value of `name` is the alias.

- `char * org_name`

  The name of the field, as a null-terminated string. Aliases are ignored. For expressions, the value is an empty string.

- `char * table`

  The name of the table containing this field, if it is not a calculated field. For calculated fields, the `table` value is an empty string. If the column is selected from a view, `table` names the view. If the table or view was given an alias with an `AS` clause, the value of `table` is the alias. For a `UNION`, the value is the empty string.

- `char * org_table`

  The name of the table, as a null-terminated string. Aliases are ignored. If the column is selected from a view, `org_table` names the view. For a `UNION`, the value is the empty string.

- `char * db`

  The name of the database that the field comes from, as a null-terminated string. If the field is a calculated field, `db` is an empty string. For a `UNION`, the value is the empty string.

- `char * catalog`

  The catalog name. This value is always "def".

- `char * def`

  The default value of this field, as a null-terminated string. This is set only if you use `mysql_list_fields()`.

- `unsigned long length`

  The width of the field. This corresponds to the display length, in bytes.

  The server determines the `length` value before it generates the result set, so this is the minimum length required for a data type capable of holding the largest possible value from the result column, without knowing in advance the actual values that will be produced by the query for the result set.

- `unsigned long max_length`

  The maximum width of the field for the result set (the length in bytes of the longest field value for the rows actually in the result set). If you use `mysql_store_result()` or `mysql_list_fields()`, this contains the maximum length for the field. If you use `mysql_use_result()`, the value of this variable is zero.
The value of `max_length` is the length of the string representation of the values in the result set. For example, if you retrieve a `FLOAT` column and the "widest" value is \(-12.345\), `max_length` is 7 (the length of `'-12.345'`).

If you are using prepared statements, `max_length` is not set by default because for the binary protocol the lengths of the values depend on the types of the values in the result set. (See Section 21.8.9, "C API Prepared Statement Data Structures".) If you want the `max_length` values anyway, enable the `STMT_ATTR_UPDATE_MAX_LENGTH` option with `mysql_stmt_attr_set()` and the lengths will be set when you call `mysql_stmt_store_result()`. (See Section 21.8.11.3, "mysql_stmt_attr_set()", and Section 21.8.11.27, "mysql_stmt_store_result()".)

- **unsigned int name_length**
  The length of `name`.

- **unsigned int org_name_length**
  The length of `org_name`.

- **unsigned int table_length**
  The length of `table`.

- **unsigned int org_table_length**
  The length of `org_table`.

- **unsigned int db_length**
  The length of `db`.

- **unsigned int catalog_length**
  The length of `catalog`.

- **unsigned int def_length**
  The length of `def`.

- **unsigned int flags**
  Bit-flags that describe the field. The `flags` value may have zero or more of the bits set that are shown in the following table.

<table>
<thead>
<tr>
<th>Flag Value</th>
<th>Flag Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NOT_NULL_FLAG</td>
<td>Field cannot be NULL</td>
</tr>
<tr>
<td>PRI_KEY_FLAG</td>
<td>Field is part of a primary key</td>
</tr>
<tr>
<td>UNIQUE_KEY_FLAG</td>
<td>Field is part of a unique key</td>
</tr>
<tr>
<td>MULTIPLE_KEY_FLAG</td>
<td>Field is part of a nonunique key</td>
</tr>
<tr>
<td>UNSIGNED_FLAG</td>
<td>Field has the <code>UNSIGNED</code> attribute</td>
</tr>
<tr>
<td>ZEROFILL_FLAG</td>
<td>Field has the <code>ZEROFILL</code> attribute</td>
</tr>
<tr>
<td>BINARY_FLAG</td>
<td>Field has the <code>BINARY</code> attribute</td>
</tr>
<tr>
<td>AUTO_INCREMENT_FLAG</td>
<td>Field has the <code>AUTO_INCREMENT</code> attribute</td>
</tr>
<tr>
<td>ENUM_FLAG</td>
<td>Field is an <code>ENUM</code></td>
</tr>
<tr>
<td>SET_FLAG</td>
<td>Field is a <code>SET</code></td>
</tr>
<tr>
<td>BLOB_FLAG</td>
<td>Field is a <code>BLOB</code> or <code>TEXT</code> (deprecated)</td>
</tr>
</tbody>
</table>
Flag Value       | Flag Description                                           |
-------------|-----------------------------------------------------------|
TIMESTAMP_FLAG | Field is a TIMESTAMP (deprecated)                          |
NUM_FLAG      | Field is numeric; see additional notes following table    |
NO_DEFAULT_VALUE_FLAG | Field has no default value; see additional notes following table |

Some of these flags indicate data type information and are superseded by or used in conjunction with the MYSQL_TYPE_xxx value in the field->type member described later:

- To check for BLOB or TIMESTAMP values, check whether type is MYSQL_TYPE_BLOB or MYSQL_TYPE_TIMESTAMP. (The BLOB_FLAG and TIMESTAMP_FLAG flags are unneeded.)
- ENUM and SET values are returned as strings. For these, check that the type value is MYSQL_TYPE_STRING and that the ENUM_FLAG or SET_FLAG flag is set in the flags value.

NUM_FLAG indicates that a column is numeric. This includes columns with a type of MYSQL_TYPE_DECIMAL, MYSQL_TYPE_TINY, MYSQL_TYPE_SHORT, MYSQL_TYPE_LONG, MYSQL_TYPE_FLOAT, MYSQL_TYPE_DOUBLE, MYSQL_TYPE_NULL, MYSQL_TYPE_LONGLONG, MYSQL_TYPE_INT24, and MYSQL_TYPE_YEAR.

NO_DEFAULT_VALUE_FLAG indicates that a column has no DEFAULT clause in its definition. This does not apply to NULL columns (because such columns have a default of NULL), or to AUTO_INCREMENT columns (which have an implied default value).

The following example illustrates a typical use of the flags value:

```c
if (field->flags & NOT_NULL_FLAG)
    printf("Field cannot be null\n");
```

You may use the convenience macros shown in the following table to determine the boolean status of the flags value.

| Flag Status       | Description                                           |
-------------------|-------------------------------------------------------|
IS_NOT_NULL(flags) | True if this field is defined as NOT NULL             |
IS_PRI_KEY(flags)  | True if this field is a primary key                   |
IS_BLOB(flags)     | True if this field is a BLOB or TEXT (deprecated; test field->type instead) |

- unsigned int decimals
  The number of decimals for numeric fields.
- unsigned int charsetnr
  An ID number that indicates the character set/collation pair for the field.

Normally, character values in result sets are converted to the character set indicated by the character_set_results system variable. In this case, charsetnr corresponds to the character set indicated by that variable. Character set conversion can be suppressed by setting character_set_results to NULL. In this case, charsetnr corresponds to the character set of the original table column or expression. See also Section 10.1.4, “Connection Character Sets and Collations”.

To distinguish between binary and nonbinary data for string data types, check whether the charsetnr value is 63. If so, the character set is binary, which indicates binary rather than nonbinary data. This enables you to distinguish BINARY from CHAR,VARBINARY from VARCHAR, and the BLOB types from the TEXT types.
charsetnr values are the same as those displayed in the `id` column of the `SHOW COLLATION` statement or the `id` column of the `INFORMATION_SCHEMA.COLLATIONS` table. You can use those information sources to see which character set and collation specific charsetnr values indicate:

```
<table>
<thead>
<tr>
<th>Collation</th>
<th>Charset</th>
<th>Id</th>
<th>Default</th>
<th>Compiled</th>
<th>Sortlen</th>
</tr>
</thead>
<tbody>
<tr>
<td>binary</td>
<td>binary</td>
<td>63</td>
<td>Yes</td>
<td>Yes</td>
<td>1</td>
</tr>
</tbody>
</table>
```

```
mysql> SELECT COLLATION_NAME, CHARACTER_SET_NAME
FROM INFORMATION_SCHEMA.COLLATIONS WHERE ID = 33;

<table>
<thead>
<tr>
<th>COLLATION_NAME</th>
<th>CHARACTER_SET_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>utf8_general_ci</td>
<td>utf8</td>
</tr>
</tbody>
</table>
```

- **enum enum_field_types type**

The type of the field. The type value may be one of the `MYSQL_TYPE_` symbols shown in the following table.

<table>
<thead>
<tr>
<th>Type Value</th>
<th>Type Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>MYSQL_TYPE_TINY</code></td>
<td>TINYINT field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_SHORT</code></td>
<td>SMALLINT field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_LONG</code></td>
<td>INTEGER field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_INT24</code></td>
<td>MEDIUMINT field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_LONGLONG</code></td>
<td>BIGINT field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_DECIMAL</code></td>
<td>DECIMAL or NUMERIC field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_NEWDECIMAL</code></td>
<td>Precision math DECIMAL or NUMERIC field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_FLOAT</code></td>
<td>FLOAT field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_DOUBLE</code></td>
<td>DOUBLE or REAL field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_BIT</code></td>
<td>BIT field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_TIMESTAMP</code></td>
<td>TIMESTAMP field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_DATE</code></td>
<td>DATE field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_TIME</code></td>
<td>TIME field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_DATETIME</code></td>
<td>DATETIME field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_YEAR</code></td>
<td>YEAR field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_STRING</code></td>
<td>CHAR or BINARY field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_VAR_STRING</code></td>
<td>VARCHAR or VARBINARY field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_BLOB</code></td>
<td>BLOB or TEXT field (use max_length to determine the maximum length)</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_SET</code></td>
<td>SET field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_ENUM</code></td>
<td>ENUM field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_GEOMETRY</code></td>
<td>Spatial field</td>
</tr>
<tr>
<td><code>MYSQL_TYPE_NULL</code></td>
<td>NULL-type field</td>
</tr>
</tbody>
</table>

You can use the `IS_NUM()` macro to test whether a field has a numeric type. Pass the `type` value to `IS_NUM()` and it evaluates to TRUE if the field is numeric.
if (IS_NUM(field->type))
    printf("Field is numeric\n");

**ENUM** and **SET** values are returned as strings. For these, check that the **type** value is **MYSQL_TYPE_STRING** and that the **ENUM_FLAG** or **SET_FLAG** flag is set in the **flags** value.

### 21.8.6 C API Function Overview

The functions available in the C API are summarized here and described in greater detail in a later section. See [Section 21.8.7, "C API Function Descriptions"](#).

**Table 21.4 C API Function Names and Descriptions**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>my_init()</td>
<td>Initialize global variables, and thread handler in thread-safe programs</td>
</tr>
<tr>
<td>mysql_affected_rows()</td>
<td>Returns the number of rows changed/deleted/inserted by the last <strong>UPDATE</strong>, <strong>DELETE</strong>, or <strong>INSERT</strong> query</td>
</tr>
<tr>
<td>mysql_autocommit()</td>
<td>Toggles autocommit mode on/off</td>
</tr>
<tr>
<td>mysql_change_user()</td>
<td>Changes user and database on an open connection</td>
</tr>
<tr>
<td>mysql_character_set_name()</td>
<td>Return default character set name for current connection</td>
</tr>
<tr>
<td>mysql_close()</td>
<td>Closes a server connection</td>
</tr>
<tr>
<td>mysql_commit()</td>
<td>Commits the transaction</td>
</tr>
<tr>
<td>mysql_connect()</td>
<td>Connects to a MySQL server (this function is deprecated; use mysql_real_connect() instead)</td>
</tr>
<tr>
<td>mysql_create_db()</td>
<td>Creates a database (this function is deprecated; use the SQL statement <strong>CREATE DATABASE</strong> instead)</td>
</tr>
<tr>
<td>mysql_data_seek()</td>
<td>Seeks to an arbitrary row number in a query result set</td>
</tr>
<tr>
<td>mysql_debug()</td>
<td>Does a <strong>DBG_PUSH</strong> with the given string</td>
</tr>
<tr>
<td>mysql_drop_db()</td>
<td>Drops a database (this function is deprecated; use the SQL statement <strong>DROP DATABASE</strong> instead)</td>
</tr>
<tr>
<td>mysql_dump_debug_info()</td>
<td>Makes the server write debug information to the log</td>
</tr>
<tr>
<td>mysql_eof()</td>
<td>Determines whether the last row of a result set has been read (this function is deprecated; mysql_errno() or mysql_error() may be used instead)</td>
</tr>
<tr>
<td>mysql_errno()</td>
<td>Returns the error number for the most recently invoked MySQL function</td>
</tr>
<tr>
<td>mysql_error()</td>
<td>Returns the error message for the most recently invoked MySQL function</td>
</tr>
<tr>
<td>mysql_escape_string()</td>
<td>Escapes special characters in a string for use in an SQL statement</td>
</tr>
<tr>
<td>mysql_fetch_field()</td>
<td>Returns the type of the next table field</td>
</tr>
<tr>
<td>mysql_fetch_field_direct()</td>
<td>Returns the type of a table field, given a field number</td>
</tr>
<tr>
<td>mysql_fetch_fields()</td>
<td>Returns an array of all field structures</td>
</tr>
<tr>
<td>mysql_fetch_lengths()</td>
<td>Returns the lengths of all columns in the current row</td>
</tr>
<tr>
<td>mysql_fetch_row()</td>
<td>Fetches the next row from the result set</td>
</tr>
<tr>
<td>mysql_field_count()</td>
<td>Returns the number of result columns for the most recent statement</td>
</tr>
<tr>
<td>mysql_field_seek()</td>
<td>Puts the column cursor on a specified column</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>mysql_field_tell()</code></td>
<td>Returns the position of the field cursor used for the last <code>mysql_fetch_field()</code></td>
</tr>
<tr>
<td><code>mysql_free_result()</code></td>
<td>Frees memory used by a result set</td>
</tr>
<tr>
<td><code>mysql_get_character_set_info()</code></td>
<td>Returns information about default character set</td>
</tr>
<tr>
<td><code>mysql_get_client_info()</code></td>
<td>Returns client version information as a string</td>
</tr>
<tr>
<td><code>mysql_get_client_version()</code></td>
<td>Returns client version information as an integer</td>
</tr>
<tr>
<td><code>mysql_get_host_info()</code></td>
<td>Returns a string describing the connection</td>
</tr>
<tr>
<td><code>mysql_get_proto_info()</code></td>
<td>Returns the protocol version used by the connection</td>
</tr>
<tr>
<td><code>mysql_get_server_info()</code></td>
<td>Returns the server version number</td>
</tr>
<tr>
<td><code>mysql_get_server_version()</code></td>
<td>Returns version number of server as an integer</td>
</tr>
<tr>
<td><code>mysql_get_ssl_cipher()</code></td>
<td>Return current SSL cipher</td>
</tr>
<tr>
<td><code>mysql_hex_string()</code></td>
<td>Encode string in hexadecimal format</td>
</tr>
<tr>
<td><code>mysql_info()</code></td>
<td>Returns information about the most recently executed query</td>
</tr>
<tr>
<td><code>mysql_init()</code></td>
<td>Gets or initializes a <code>MYSQL</code> structure</td>
</tr>
<tr>
<td><code>mysql_insert_id()</code></td>
<td>Returns the ID generated for an <code>AUTO_INCREMENT</code> column by the previous query</td>
</tr>
<tr>
<td><code>mysql_kill()</code></td>
<td>Kills a given thread</td>
</tr>
<tr>
<td><code>mysql_library_end()</code></td>
<td>Finalize the MySQL C API library</td>
</tr>
<tr>
<td><code>mysql_library_init()</code></td>
<td>Initialize the MySQL C API library</td>
</tr>
<tr>
<td><code>mysql_list_dbs()</code></td>
<td>Returns database names matching a simple regular expression</td>
</tr>
<tr>
<td><code>mysql_list_fields()</code></td>
<td>Returns field names matching a simple regular expression</td>
</tr>
<tr>
<td><code>mysql_list_processes()</code></td>
<td>Returns a list of the current server threads</td>
</tr>
<tr>
<td><code>mysql_list_tables()</code></td>
<td>Returns table names matching a simple regular expression</td>
</tr>
<tr>
<td><code>mysql_more_results()</code></td>
<td>Checks whether any more results exist</td>
</tr>
<tr>
<td><code>mysql_next_result()</code></td>
<td>Returns/initiates the next result in multiple-result executions</td>
</tr>
<tr>
<td><code>mysql_num_fields()</code></td>
<td>Returns the number of columns in a result set</td>
</tr>
<tr>
<td><code>mysql_num_rows()</code></td>
<td>Returns the number of rows in a result set</td>
</tr>
<tr>
<td><code>mysql_options()</code></td>
<td>Sets connect options for <code>mysql_real_connect()</code></td>
</tr>
<tr>
<td><code>mysql_ping()</code></td>
<td>Checks whether the connection to the server is working, reconnecting as necessary</td>
</tr>
<tr>
<td><code>mysql_query()</code></td>
<td>Executes an SQL query specified as a null-terminated string</td>
</tr>
<tr>
<td><code>mysql_real_connect()</code></td>
<td>Connects to a MySQL server</td>
</tr>
<tr>
<td><code>mysql_real_escape_string()</code></td>
<td>Escapes special characters in a string for use in an SQL statement, taking into account the current character set of the connection</td>
</tr>
<tr>
<td><code>mysql_real_query()</code></td>
<td>Executes an SQL query specified as a counted string</td>
</tr>
<tr>
<td><code>mysql_refresh()</code></td>
<td>Flush or reset tables and caches</td>
</tr>
<tr>
<td><code>mysql_reload()</code></td>
<td>Tells the server to reload the grant tables</td>
</tr>
<tr>
<td><code>mysql_rollback()</code></td>
<td>Rolls back the transaction</td>
</tr>
<tr>
<td><code>mysql_row_seek()</code></td>
<td>Seeks to a row offset in a result set, using value returned from <code>mysql_row_tell()</code></td>
</tr>
<tr>
<td><code>mysql_row_tell()</code></td>
<td>Returns the row cursor position</td>
</tr>
<tr>
<td><code>mysql_select_db()</code></td>
<td>Selects a database</td>
</tr>
</tbody>
</table>
### C API Function Overview

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>mysql_server_end()</code></td>
<td>Finalize the MySQL C API library</td>
</tr>
<tr>
<td><code>mysql_server_init()</code></td>
<td>Initialize the MySQL C API library</td>
</tr>
<tr>
<td><code>mysql_set_character_set()</code></td>
<td>Set default character set for current connection</td>
</tr>
<tr>
<td><code>mysql_set_local_infile()</code></td>
<td>Set the <code>LOAD DATA LOCAL INFILE</code> handler callbacks to their default values</td>
</tr>
<tr>
<td><code>mysql_set_local_infile_handler()</code></td>
<td>Install application-specific <code>LOAD DATA LOCAL INFILE</code> handler callbacks</td>
</tr>
<tr>
<td><code>mysql_set_server_option()</code></td>
<td>Sets an option for the connection (like <code>multi-statements</code>)</td>
</tr>
<tr>
<td><code>mysql_sqlstate()</code></td>
<td>Returns the SQLSTATE error code for the last error</td>
</tr>
<tr>
<td><code>mysql_shutdown()</code></td>
<td>Shuts down the database server</td>
</tr>
<tr>
<td><code>mysql_ssl_set()</code></td>
<td>Prepare to establish SSL connection to server</td>
</tr>
<tr>
<td><code>mysql_stat()</code></td>
<td>Returns the server status as a string</td>
</tr>
<tr>
<td><code>mysql_store_result()</code></td>
<td>Retrieves a complete result set to the client</td>
</tr>
<tr>
<td><code>mysql_thread_end()</code></td>
<td>Finalize thread handler</td>
</tr>
<tr>
<td><code>mysql_thread_id()</code></td>
<td>Returns the current thread ID</td>
</tr>
<tr>
<td><code>mysql_thread_init()</code></td>
<td>Initialize thread handler</td>
</tr>
<tr>
<td><code>mysql_thread_safe()</code></td>
<td>Returns 1 if the clients are compiled as thread-safe</td>
</tr>
<tr>
<td><code>mysql_use_result()</code></td>
<td>Initiates a row-by-row result set retrieval</td>
</tr>
<tr>
<td><code>mysql_warning_count()</code></td>
<td>Returns the warning count for the previous SQL statement</td>
</tr>
</tbody>
</table>

Application programs should use this general outline for interacting with MySQL:

1. Initialize the MySQL library by calling `mysql_library_init()`. This function exists in both the `libmysqlclient` C client library and the `libmysqld` embedded server library, so it is used whether you build a regular client program by linking with the `libmysqlclient` flag, or an embedded server application by linking with the `libmysqld` flag.

2. Initialize a connection handler by calling `mysql_init()` and connect to the server by calling `mysql_real_connect()`.

3. Issue SQL statements and process their results. (The following discussion provides more information about how to do this.)

4. Close the connection to the MySQL server by calling `mysql_close()`.

5. End use of the MySQL library by calling `mysql_library_end()`.

The purpose of calling `mysql_library_init()` and `mysql_library_end()` is to provide proper initialization and finalization of the MySQL library. For applications that are linked with the client library, they provide improved memory management. If you do not call `mysql_library_end()`, a block of memory remains allocated. (This does not increase the amount of memory used by the application, but some memory leak detectors will complain about it.) For applications that are linked with the embedded server, these calls start and stop the server.

In a nonmulti-threaded environment, the call to `mysql_library_init()` may be omitted, because `mysql_init()` will invoke it automatically as necessary. However, `mysql_library_init()` is not thread-safe in a multi-threaded environment, and thus neither is `mysql_init()`, which calls `mysql_library_init()`. You must either call `mysql_library_init()` prior to spawning any threads, or else use a mutex to protect the call, whether you invoke `mysql_library_init()` or indirectly through `mysql_init()`. This should be done prior to any other client library call.

To connect to the server, call `mysql_init()` to initialize a connection handler, then call `mysql_real_connect()` with that handler (along with other information such as the host name, user...
name, and password). Upon connection, mysql_real_connect() sets the reconnect flag (part of the MYSQL structure) to a value of 1 in versions of the API older than 5.0.3, or 0 in newer versions. A value of 1 for this flag indicates that if a statement cannot be performed because of a lost connection, to try reconnecting to the server before giving up. You can use the MYSQL_OPT_RECONNECT option to mysql_options() to control reconnection behavior. When you are done with the connection, call mysql_close() to terminate it.

While a connection is active, the client may send SQL statements to the server using mysql_query() or mysql_real_query(). The difference between the two is that mysql_query() expects the query to be specified as a null-terminated string whereas mysql_real_query() expects a counted string. If the string contains binary data (which may include null bytes), you must use mysql_real_query(). For each non-SELECT query (for example, INSERT, UPDATE, DELETE), you can find out how many rows were changed (affected) by calling mysql_affected_rows().

For SELECT queries, you retrieve the selected rows as a result set. (Note that some statements are SELECT-like in that they return rows. These include SHOW, DESCRIBE, and EXPLAIN. Treat these statements the same way as SELECT statements.)

There are two ways for a client to process result sets. One way is to retrieve the entire result set all at once by calling mysql_store_result(). This function acquires from the server all the rows returned by the query and stores them in the client. The second way is for the client to initiate a row-by-row result set retrieval by calling mysql_use_result(). This function initializes the retrieval, but does not actually get any rows from the server.

In both cases, you access rows by calling mysql_fetch_row(). With mysql_store_result(), mysql_fetch_row() accesses rows that have previously been fetched from the server. With mysql_use_result(), mysql_fetch_row() actually retrieves the row from the server. Information about the size of the data in each row is available by calling mysql_fetch_lengths().

After you are done with a result set, call mysql_free_result() to free the memory used for it.

The two retrieval mechanisms are complementary. Choose the approach that is most appropriate for each client application. In practice, clients tend to use mysql_store_result() more commonly.

An advantage of mysql_store_result() is that because the rows have all been fetched to the client, you not only can access rows sequentially, you can move back and forth in the result set using mysql_data_seek() or mysql_row_seek() to change the current row position within the result set. You can also find out how many rows there are by calling mysql_num_rows(). On the other hand, the memory requirements for mysql_store_result() may be very high for large result sets and you are more likely to encounter out-of-memory conditions.

An advantage of mysql_use_result() is that the client requires less memory for the result set because it maintains only one row at a time (and because there is less allocation overhead, mysql_use_result() can be faster). Disadvantages are that you must process each row quickly to avoid tying up the server, you do not have random access to rows within the result set (you can only access rows sequentially), and the number of rows in the result set is unknown until you have retrieved them all. Furthermore, you must retrieve all the rows even if you determine in mid-retrieval that you’ve found the information you were looking for.

The API makes it possible for clients to respond appropriately to statements (retrieving rows only as necessary) without knowing whether the statement is a SELECT. You can do this by calling mysql_store_result() after each mysql_query() (or mysql_real_query()). If the result set call succeeds, the statement was a SELECT and you can read the rows. If the result set call fails, call mysql_field_count() to determine whether a result was actually to be expected. If mysql_field_count() returns zero, the statement returned no data (indicating that it was an INSERT, UPDATE, DELETE, and so forth), and was not expected to return rows. If mysql_field_count() is nonzero, the statement should have returned rows, but did not. This indicates that the statement was a SELECT that failed. See the description for mysql_field_count() for an example of how this can be done.
Both `mysql_store_result()` and `mysql_use_result()` enable you to obtain information about the fields that make up the result set (the number of fields, their names and types, and so forth). You can access field information sequentially within the row by calling `mysql_fetch_field()` repeatedly, or by field number within the row by calling `mysql_fetch_field_direct()`. The current field cursor position may be changed by calling `mysql_field_seek()`. Setting the field cursor affects subsequent calls to `mysql_fetch_field()`. You can also get information for fields all at once by calling `mysql_fetch_fields()`.

For detecting and reporting errors, MySQL provides access to error information by means of the `mysql_errno()` and `mysql_error()` functions. These return the error code or error message for the most recently invoked function that can succeed or fail, enabling you to determine when an error occurred and what it was.

### 21.8.7 C API Function Descriptions

In the descriptions here, a parameter or return value of `NULL` means `NULL` in the sense of the C programming language, not a MySQL `NULL` value.

Functions that return a value generally return a pointer or an integer. Unless specified otherwise, functions returning a pointer return a non-`NULL` value to indicate success or a `NULL` value to indicate an error, and functions returning an integer return zero to indicate success or nonzero to indicate an error. Note that “nonzero” means just that. Unless the function description says otherwise, do not test against a value other than zero:

```c
if (result)                   /* correct */
   ... error ...
if (result < 0)               /* incorrect */
   ... error ...
if (result == -1)             /* incorrect */
   ... error ...
```

When a function returns an error, the **Errors** subsection of the function description lists the possible types of errors. You can find out which of these occurred by calling `mysql_errno()`. A string representation of the error may be obtained by calling `mysql_error()`.

#### 21.8.7.1 mysql_affected_rows()

```c
my_ulonglong mysql_affected_rows(MYSQL *mysql)
```

**Description**

`mysql_affected_rows()` may be called immediately after executing a statement with `mysql_query()` or `mysql_real_query()`. It returns the number of rows changed, deleted, or inserted by the last statement if it was an `UPDATE`, `DELETE`, or `INSERT`. For `SELECT` statements, `mysql_affected_rows()` works like `mysql_num_rows()`.

For `UPDATE` statements, the affected-rows value by default is the number of rows actually changed. If you specify the `CLIENT_FOUND_ROWS` flag to `mysql_real_connect()` when connecting to `mysqld`, the affected-rows value is the number of rows “found”; that is, matched by the `WHERE` clause.

For `REPLACE` statements, the affected-rows value is 2 if the new row replaced an old row, because in this case, one row was inserted after the duplicate was deleted.

For `INSERT ... ON DUPLICATE KEY UPDATE` statements, the affected-rows value is 1 if the row is inserted as a new row and 2 if an existing row is updated.

Following a `CALL` statement for a stored procedure, `mysql_affected_rows()` returns the value that it would return for the last statement executed within the procedure, or 0 if that statement would
return -1. Within the procedure, you can use **ROW_COUNT**() at the SQL level to obtain the affected-rows value for individual statements.

### Return Values

An integer greater than zero indicates the number of rows affected or retrieved. Zero indicates that no records were updated for an **UPDATE** statement, no rows matched the **WHERE** clause in the query or that no query has yet been executed. -1 indicates that the query returned an error or that, for a **SELECT** query, **mysql_affected_rows**() was called prior to calling **mysql_store_result**().

Because **mysql_affected_rows**() returns an unsigned value, you can check for -1 by comparing the return value to (my_ulonglong)-1 (or to (my_ulonglong)~0, which is equivalent).

### Errors

None.

### Example

```c
char *stmt = "UPDATE products SET cost=cost*1.25
WHERE group=10";
mysql_query(&mysql,stmt);
printf("%ld products updated",
(long) mysql_affected_rows(&mysql));
```

### 21.8.7.2 mysql_autocommit()

```c
my_bool mysql_autocommit(MYSQL *mysql, my_bool mode)
```

### Description

Sets autocommit mode on if **mode** is 1, off if **mode** is 0.

### Return Values

Zero for success. Nonzero if an error occurred.

### Errors

None.

### 21.8.7.3 mysql_change_user()

```c
my_bool mysql_change_user(MYSQL *mysql, const char *user, const char *password, const char *db)
```

### Description

Changes the user and causes the database specified by **db** to become the default (current) database on the connection specified by **mysql**. In subsequent queries, this database is the default for table references that include no explicit database specifier.

**mysql_change_user**() fails if the connected user cannot be authenticated or does not have permission to use the database. In this case, the user and database are not changed.

Pass a **db** parameter of NULL if you do not want to have a default database.

This function resets the session state as if one had done a new connect and reauthenticate. (See **Section 21.8.15, “Controlling Automatic Reconnection Behavior”**.) It always performs a **ROLLBACK** of any active transactions, closes and drops all temporary tables, and unlocks all locked tables. Session system variables are reset to the values of the corresponding global system variables. Prepared
statements are released and **HANDLER** variables are closed. Locks acquired with **GET_LOCK()** are released. These effects occur even if the user did not change.

**Return Values**

Zero for success. Nonzero if an error occurred.

**Errors**

The same that you can get from **mysql_real_connect()**, plus:

- **CR_COMMANDS_OUT_OF_SYNC**
  
  Commands were executed in an improper order.

- **CR_SERVER_GONE_ERROR**
  
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  
  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  
  An unknown error occurred.

- **ER_UNKNOWN_COM_ERROR**
  
  The MySQL server does not implement this command (probably an old server).

- **ER_ACCESS_DENIED_ERROR**
  
  The user or password was wrong.

- **ER_BAD_DB_ERROR**
  
  The database did not exist.

- **ER_DBACCESS_DENIED_ERROR**
  
  The user did not have access rights to the database.

- **ER_WRONG_DB_NAME**
  
  The database name was too long.

**Example**

```c
if (mysql_change_user(&mysql, "user", "password", "new_database"))
{
    fprintf(stderr, "Failed to change user. Error: %s\n", mysql_error(&mysql));
}
```

**21.8.7.4 mysql_character_set_name()**

```c
const char *mysql_character_set_name(MYSQL *mysql)
```

**Description**

Returns the default character set name for the current connection.
Return Values
The default character set name

Errors
None.

21.8.7.5 mysql_close()

```c
void mysql_close(MYSQL *mysql)
```

Description
Closes a previously opened connection. `mysql_close()` also deallocates the connection handle pointed to by `mysql` if the handle was allocated automatically by `mysql_init()` or `mysql_connect()`.

Return Values
None.

Errors
None.

21.8.7.6 mysql_commit()

```c
my_bool mysql_commit(MYSQL *mysql)
```

Description
Commits the current transaction.

The action of this function is subject to the value of the `completion_type` system variable. In particular, if the value of `completion_type` is 2, the server performs a release after terminating a transaction and closes the client connection. The client program should call `mysql_close()` to close the connection from the client side.

Return Values
Zero for success. Nonzero if an error occurred.

Errors
None.

21.8.7.7 mysql_connect()

```c
MYSQL *mysql_connect(MYSQL *mysql, const char *host, const char *user, const char *passwd)
```

Description
This function is deprecated. Use `mysql_real_connect()` instead.

`mysql_connect()` attempts to establish a connection to a MySQL database engine running on `host`. `mysql_connect()` must complete successfully before you can execute any of the other API functions, with the exception of `mysql_get_client_info()`.

The meanings of the parameters are the same as for the corresponding parameters for `mysql_real_connect()` with the difference that the connection parameter may be `NULL`. In this

---

2411
case, the C API allocates memory for the connection structure automatically and frees it when you call `mysql_close()`. The disadvantage of this approach is that you cannot retrieve an error message if the connection fails. (To get error information from `mysql_errno()` or `mysql_error()`, you must provide a valid `MYSQL` pointer.)

**Return Values**

Same as for `mysql_real_connect()`.

**Errors**

Same as for `mysql_real_connect()`.

### 21.8.7.8 `mysql_create_db()`

```c
int mysql_create_db(MYSQL *mysql, const char *db)
```

**Description**

Creates the database named by the `db` parameter.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL `CREATE DATABASE` statement instead.

**Return Values**

Zero for success. Nonzero if an error occurred.

**Errors**

- **CR_COMMANDS_OUT_OF_SYNC**
  
  Commands were executed in an improper order.

- **CR_SERVER_GONE_ERROR**
  
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  
  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  
  An unknown error occurred.

**Example**

```c
if(mysql_create_db(&mysql, "my_database"))
{
    fprintf(stderr, "Failed to create new database. Error: %s\n", mysql_error(&mysql));
}
```

### 21.8.7.9 `mysql_data_seek()`

```c
void mysql_data_seek(MYSQL_RES *result, my_ulonglong offset)
```

**Description**

Seeks to an arbitrary row in a query result set. The `offset` value is a row number. Specify a value in the range from 0 to `mysql_num_rows(result)-1`. 
This function requires that the result set structure contains the entire result of the query, so `mysql_data_seek()` may be used only in conjunction with `mysql_store_result()`, not with `mysql_use_result()`.

### Return Values

None.

### Errors

None.

#### 21.8.7.10 mysql_debug()

```c
void mysql_debug(const char *debug)
```

**Description**

Does a `DEBUG_PUSH` with the given string. `mysql_debug()` uses the Fred Fish debug library. To use this function, you must compile the client library to support debugging. See Section 22.4.3, "The DBUG Package".

**Return Values**

None.

**Errors**

None.

**Example**

The call shown here causes the client library to generate a trace file in `/tmp/client.trace` on the client machine:

```c
mysql_debug("d:t:O,/tmp/client.trace");
```

#### 21.8.7.11 mysql_drop_db()

```c
int mysql_drop_db(MYSQL *mysql, const char *db)
```

**Description**

Drops the database named by the `db` parameter.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL `DROP DATABASE` statement instead.

**Return Values**

Zero for success. Nonzero if an error occurred.

**Errors**

- **CR_COMMANDS_OUT_OF_SYNC**
  
  Commands were executed in an improper order.

- **CR_SERVER_GONE_ERROR**
  
  The MySQL server has gone away.
21.8.7.12 mysql_dump_debug_info()

int mysql_dump_debug_info(MYSQL *mysql)

Description

Instructs the server to write debugging information to the error log. The connected user must have the super privilege.

Return Values

Zero for success. Nonzero if an error occurred.

Errors

• CR_COMMANDS_OUT_OF_SYNC

Commands were executed in an improper order.

• CR_SERVER_GONE_ERROR

The MySQL server has gone away.

• CR_SERVER_LOST

The connection to the server was lost during the query.

• CR_UNKNOWN_ERROR

An unknown error occurred.

21.8.7.13 mysql_eof()

my_bool mysql_eof(MYSQL_RES *result)

Description

This function is deprecated. mysql_errno() or mysql_error() may be used instead.

mysql_eof() determines whether the last row of a result set has been read.

If you acquire a result set from a successful call to mysql_store_result(), the client receives the entire set in one operation. In this case, a NULL return from mysql_fetch_row() always means the end of the result set has been reached and it is unnecessary to call mysql_eof(). When used with mysql_store_result(), mysql_eof() always returns true.

On the other hand, if you use mysql_use_result() to initiate a result set retrieval, the rows of the set are obtained from the server one by one as you call mysql_fetch_row() repeatedly. Because an error may occur on the connection during this process, a NULL return value from
mysql_fetch_row() does not necessarily mean the end of the result set was reached normally. In this case, you can use mysql_eof() to determine what happened. mysql_eof() returns a nonzero value if the end of the result set was reached and zero if an error occurred.

Historically, mysql_eof() predates the standard MySQL error functions mysql_errno() and mysql_error(). Because those error functions provide the same information, their use is preferred over mysql_eof(), which is deprecated. (In fact, they provide more information, because mysql_eof() returns only a boolean value whereas the error functions indicate a reason for the error when one occurs.)

Return Values

Zero for success. Nonzero if the end of the result set has been reached.

Errors

None.

Example

The following example shows how you might use mysql_eof():

```c
mysql_query(&mysql,"SELECT * FROM some_table");
result = mysql_use_result(&mysql);
while((row = mysql_fetch_row(result)))
{
    // do something with data
}
if(!mysql_eof(result)) // mysql_fetch_row() failed due to an error
{
    fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
}
```

However, you can achieve the same effect with the standard MySQL error functions:

```c
mysql_query(&mysql,"SELECT * FROM some_table");
result = mysql_use_result(&mysql);
while((row = mysql_fetch_row(result)))
{
    // do something with data
}
if(mysql_errno(&mysql)) // mysql_fetch_row() failed due to an error
{
    fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
}
```

21.8.7.14 mysql_errno()

```c
unsigned int mysql_errno(MYSQL *mysql)
```

Description

For the connection specified by mysql, mysql_errno() returns the error code for the most recently invoked API function that can succeed or fail. A return value of zero means that no error occurred. Client error message numbers are listed in the MySQL errmsg.h header file. Server error message numbers are listed in mysqld_error.h. Errors also are listed at Appendix B, Errors, Error Codes, and Common Problems.

Note

Some functions such as mysql_fetch_row() do not set mysql_errno() if they succeed. A rule of thumb is that all functions that have to ask the server for information reset mysql_errno() if they succeed.
MySQL-specific error numbers returned by `mysql_errno()` differ from SQLSTATE values returned by `mysql_sqlstate()`. For example, the `mysql` client program displays errors using the following format, where `1146` is the `mysql_errno()` value and `'42S02'` is the corresponding `mysql_sqlstate()` value:

```
shell> SELECT * FROM no_such_table;
ERROR 1146 (42S02): Table 'test.no_such_table' doesn't exist
```

**Return Values**

An error code value for the last `mysql_xxx()` call, if it failed. Zero means no error occurred.

**Errors**

None.

### 21.8.7.15 `mysql_error()`

```c
const char *mysql_error(MYSQL *mysql)
```

**Description**

For the connection specified by `mysql`, `mysql_error()` returns a null-terminated string containing the error message for the most recently invoked API function that failed. If a function did not fail, the return value of `mysql_error()` may be the previous error or an empty string to indicate no error.

A rule of thumb is that all functions that have to ask the server for information reset `mysql_error()` if they succeed.

For functions that reset `mysql_error()`, either of these two tests can be used to check for an error:

```c
if(*mysql_error(&mysql))
{
  // an error occurred
}
if(mysql_error(&mysql)[0])
{
  // an error occurred
}
```

The language of the client error messages may be changed by recompiling the MySQL client library. You can choose error messages in several different languages. See Section 10.2, “Setting the Error Message Language”.

**Return Values**

A null-terminated character string that describes the error. An empty string if no error occurred.

**Errors**

None.

### 21.8.7.16 `mysql_escape_string()`

**Note**

This function should not be used. Use `mysql_real_escape_string()` instead.

`mysql_escape_string()` is identical to `mysql_real_escape_string()` except that `mysql_real_escape_string()` takes a connection handler as its first argument and escapes the
string according to the current character set. mysql_escape_string() does not take a connection argument and does not respect the current character set.

### 21.8.7.17 mysql_fetch_field()

`MYSQL_FIELD *mysql_fetch_field(MYSQL_RES *result)`

**Description**

Returns the definition of one column of a result set as a `MYSQL_FIELD` structure. Call this function repeatedly to retrieve information about all columns in the result set. `mysql_fetch_field()` returns `NULL` when no more fields are left.

`mysql_fetch_field()` is reset to return information about the first field each time you execute a new `SELECT` query. The field returned by `mysql_fetch_field()` is also affected by calls to `mysql_field_seek()`.

If you've called `mysql_query()` to perform a `SELECT` on a table but have not called `mysql_store_result()`, MySQL returns the default blob length (8KB) if you call `mysql_fetch_field()` to ask for the length of a `BLOB` field. (The 8KB size is chosen because MySQL does not know the maximum length for the `BLOB`. This should be made configurable sometime.) Once you've retrieved the result set, `field->max_length` contains the length of the largest value for this column in the specific query.

**Return Values**

The `MYSQL_FIELD` structure for the current column. `NULL` if no columns are left.

**Errors**

None.

**Example**

```c
MYSQL_FIELD *field;
while((field = mysql_fetch_field(result)))
{
    printf("field name %s\n", field->name);
}
```

### 21.8.7.18 mysql_fetch_field_direct()

`MYSQL_FIELD *mysql_fetch_field_direct(MYSQL_RES *result, unsigned int fieldnr)`

**Description**

Given a field number `fieldnr` for a column within a result set, returns that column's field definition as a `MYSQL_FIELD` structure. Use this function to retrieve the definition for an arbitrary column. Specify a value for `fieldnr` in the range from 0 to `mysql_num_fields(result) - 1`.

**Return Values**

The `MYSQL_FIELD` structure for the specified column.

**Errors**

None.

**Example**
21.8.7.19 mysql_fetch_fields()

MySQL_FIELD *mysql_fetch_fields(MYSQL_RES *result)

Description

Returns an array of all MYSQL_FIELD structures for a result set. Each structure provides the field definition for one column of the result set.

Return Values

An array of MYSQL_FIELD structures for all columns of a result set.

Errors

None.

Example

unsigned int num_fields;
unsigned int i;
MYSQL_FIELD *fields;

num_fields = mysql_num_fields(result);
fields = mysql_fetch_fields(result);
for(i = 0; i < num_fields; i++)
{
    printf("Field %u is %s\n", i, fields[i].name);
}

21.8.7.20 mysql_fetch_lengths()

unsigned long *mysql_fetch_lengths(MYSQL_RES *result)

Description

Returns the lengths of the columns of the current row within a result set. If you plan to copy field values, this length information is also useful for optimization, because you can avoid calling strlen(). In addition, if the result set contains binary data, you must use this function to determine the size of the data, because strlen() returns incorrect results for any field containing null characters.

The length for empty columns and for columns containing NULL values is zero. To see how to distinguish these two cases, see the description for mysql_fetch_row().

Return Values

An array of unsigned long integers representing the size of each column (not including any terminating null bytes). NULL if an error occurred.

Errors

mysql_fetch_lengths() is valid only for the current row of the result set. It returns NULL if you call it before calling mysql_fetch_row() or after retrieving all rows in the result.
Example

```c
MYSQL_ROW row;
unsigned long *lengths;
unsigned int num_fields;
unsigned int i;
row = mysql_fetch_row(result);
if (row)
{
    num_fields = mysql_num_fields(result);
    lengths = mysql_fetch_lengths(result);
    for(i = 0; i < num_fields; i++)
    {
        printf("Column %u is %lu bytes in length.\n", i, lengths[i]);
    }
}
```

21.8.7.21 mysql_fetch_row()

```c
MYSQL_ROW mysql_fetch_row(MYSQL_RES *result)
```

Description

Retrieves the next row of a result set. When used after `mysql_store_result()`, `mysql_fetch_row()` returns `NULL` when there are no more rows to retrieve. When used after `mysql_use_result()`, `mysql_fetch_row()` returns `NULL` when there are no more rows to retrieve or if an error occurred.

The number of values in the row is given by `mysql_num_fields(result)`. If `row` holds the return value from a call to `mysql_fetch_row()`, pointers to the values are accessed as `row[0]` to `row[mysql_num_fields(result)-1]`. NULL values in the row are indicated by NULL pointers.

The lengths of the field values in the row may be obtained by calling `mysql_fetch_lengths()`. Empty fields and fields containing NULL both have length 0; you can distinguish these by checking the pointer for the field value. If the pointer is NULL, the field is NULL; otherwise, the field is empty.

Return Values

A `MYSQL_ROW` structure for the next row. `NULL` if there are no more rows to retrieve or if an error occurred.

Errors

Errors are not reset between calls to `mysql_fetch_row()`

- **CR_SERVER_LOST**

  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**

  An unknown error occurred.

Example

```c
MYSQL_ROW row;
unsigned int num_fields;
unsigned int i;
num_fields = mysql_num_fields(result);
```
while ((row = mysql_fetch_row(result)))
{
    unsigned long *lengths;
    lengths = mysql_fetch_lengths(result);
    for (i = 0; i < num_fields; i++)
    {
        printf("[%.*s] ", (int) lengths[i],
            row[i] ? row[i] : "NULL");
    }
    printf("\n");
}

21.8.7.22 mysql_field_count()

unsigned int mysql_field_count(MYSQL *mysql)

Description

Returns the number of columns for the most recent query on the connection.

The normal use of this function is when mysql_store_result() returned NULL (and thus you have no result set pointer). In this case, you can call mysql_field_count() to determine whether mysql_store_result() should have produced a nonempty result. This enables the client program to take proper action without knowing whether the query was a SELECT (or SELECT-like) statement. The example shown here illustrates how this may be done.

Return Values

An unsigned integer representing the number of columns in a result set.

Errors

None.

Example

MYSQL_RES *result;
unsigned int num_fields;
unsigned int num_rows;

if (mysql_query(&mysql,query_string))
{
    // error
} else // query succeeded, process any data returned by it
{
    result = mysql_store_result(&mysql);
    if (result) // there are rows
    {
        num_fields = mysql_num_fields(result);
        // retrieve rows, then call mysql_free_result(result)
    } else // mysql_store_result() returned nothing; should it have?
    {
        if (mysql_field_count(&mysql) == 0)
        {
            // query does not return data
            // (it was not a SELECT)
            num_rows = mysql_affected_rows(&mysql);
        } else // mysql_store_result() should have returned data
        {
            fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
        }
    } else // query succeeded, process any data returned by it
    {
        result = mysql_store_result(&mysql);
        if (result) // there are rows
        {
            num_fields = mysql_num_fields(result);
            // retrieve rows, then call mysql_free_result(result)
        } else // mysql_store_result() returned nothing; should it have?
        {
            if (mysql_field_count(&mysql) == 0)
            {
                // query does not return data
                // (it was not a SELECT)
                num_rows = mysql_affected_rows(&mysql);
            } else // mysql_store_result() should have returned data
            {
                fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
            }
        }
    }
}
An alternative is to replace the `mysql_field_count(&mysql)` call with `mysql_errno(&mysql)`. In this case, you are checking directly for an error from `mysql_store_result()` rather than inferring from the value of `mysql_field_count()` whether the statement was a SELECT.

### 21.8.7.23 `mysql_field_seek()`

```c
MYSQL_FIELD_OFFSET mysql_field_seek(MYSQL_RES *result, MYSQL_FIELD_OFFSET offset)
```

**Description**

Sets the field cursor to the given offset. The next call to `mysql_fetch_field()` retrieves the field definition of the column associated with that offset.

To seek to the beginning of a row, pass an `offset` value of zero.

**Return Values**

The previous value of the field cursor.

**Errors**

None.

### 21.8.7.24 `mysql_field_tell()`

```c
MYSQL_FIELD_OFFSET mysql_field_tell(MYSQL_RES *result)
```

**Description**

Returns the position of the field cursor used for the last `mysql_fetch_field()`. This value can be used as an argument to `mysql_field_seek()`.

**Return Values**

The current offset of the field cursor.

**Errors**

None.

### 21.8.7.25 `mysql_free_result()`

```c
void mysql_free_result(MYSQL_RES *result)
```

**Description**

Frees the memory allocated for a result set by `mysql_store_result()`, `mysql_use_result()`, `mysql_list_dbs()`, and so forth. When you are done with a result set, you must free the memory it uses by calling `mysql_free_result()`.

Do not attempt to access a result set after freeing it.

**Return Values**

None.
C API Function Descriptions

Errors

None.

21.8.7.26 mysql_get_character_set_info()

```c
void mysql_get_character_set_info(MYSQL *mysql, MY_CHARSET_INFO *cs)
```

Description

This function provides information about the default client character set. The default character set may be changed with the `mysql_set_character_set()` function.

Example

This example shows the fields that are available in the `MY_CHARSET_INFO` structure:

```c
if (!mysql_set_character_set(&mysql, "utf8"))
{
    MY_CHARSET_INFO cs;
    mysql_get_character_set_info(&mysql, &cs);
    printf("character set information:

collation name: %s
", cs.csname);
}
```

21.8.7.27 mysql_get_client_info()

```c
const char *mysql_get_client_info(void)
```

Description

Returns a string that represents the MySQL client library version; for example, "5.1.73".

The function value is the MySQL version. For Connector/C, this is the MySQL version on which the Connector/C distribution is based. For more information, see Section 21.8.4.4, "C API Server and Client Library Versions".

Return Values

A character string that represents the MySQL client library version.

Errors

None.

21.8.7.28 mysql_get_client_version()

```c
unsigned long mysql_get_client_version(void)
```

Description

Returns an integer that represents the MySQL client library version. The value has the format `XYYZZ` where `X` is the major version, `YY` is the release level (or minor version), and `ZZ` is the sub-version within the release level:
For example, "5.1.73" is returned as 50173.

The function value is the MySQL version. For Connector/C, this is the MySQL version on which the Connector/C distribution is based. For more information, see Section 21.8.4.4, "C API Server and Client Library Versions".

**Return Values**

An integer that represents the MySQL client library version.

**Errors**

None.

### 21.8.7.29 mysql_get_host_info()

```c
const char *mysql_get_host_info(MYSQL *mysql)
```

**Description**

Returns a string describing the type of connection in use, including the server host name.

**Return Values**

A character string representing the server host name and the connection type.

**Errors**

None.

### 21.8.7.30 mysql_get_proto_info()

```c
unsigned int mysql_get_proto_info(MYSQL *mysql)
```

**Description**

Returns the protocol version used by current connection.

**Return Values**

An unsigned integer representing the protocol version used by the current connection.

**Errors**

None.

### 21.8.7.31 mysql_get_server_info()

```c
const char *mysql_get_server_info(MYSQL *mysql)
```

**Description**

Returns a string that represents the MySQL server version; for example, "5.1.73".

**Return Values**

A character string that represents the MySQL server version.
Errors

None.

21.8.7.32 mysql_get_server_version()

`unsigned long mysql_get_server_version(MYSQL *mysql)`

**Description**

Returns an integer that represents the MySQL server version. The value has the format `XYYZZ` where `X` is the major version, `YY` is the release level (or minor version), and `ZZ` is the sub-version within the release level:

`major_version*10000 + release_level*100 + sub_version`

For example, "5.1.73" is returned as `50173`.

This function is useful in client programs for determining whether some version-specific server capability exists.

**Return Values**

An integer that represents the MySQL server version.

Errors

None.

21.8.7.33 mysql_get_ssl_cipher()

`const char *mysql_get_ssl_cipher(MYSQL *mysql)`

**Description**

`mysql_get_ssl_cipher()` returns the encryption cipher used for the given connection to the server. `mysql` is the connection handler returned from `mysql_init()`.

This function was added in MySQL 5.1.11.

**Return Values**

A string naming the encryption cipher used for the connection, or `NULL` if no cipher is being used.

21.8.7.34 mysql_hex_string()

`unsigned long mysql_hex_string(char *to, const char *from, unsigned long length)`

**Description**

This function creates a legal SQL string for use in an SQL statement. See Section 9.1.1, “String Literals”.

The string in the `from` argument is encoded in hexadecimal format, with each character encoded as two hexadecimal digits. The result is placed in the `to` argument, followed by a terminating null byte.

The string pointed to by `from` must be `length` bytes long. You must allocate the `to` buffer to be at least `length*2+1` bytes long. When `mysql_hex_string()` returns, the contents of `to` is a null-
terminated string. The return value is the length of the encoded string, not including the terminating null byte.

The return value can be placed into an SQL statement using either \texttt{X'value'} or \texttt{0xvalue} format. However, the return value does not include the \texttt{X'...'} or \texttt{0x}. The caller must supply whichever of those is desired.

\textbf{Example}

```
char query[1000],*end;
end = strmov(query,"INSERT INTO test_table values(");
end = strmov(end,"X'");
end += mysql_hex_string(end,"What is this",12);
end = strmov(end,"',X'");
end += mysql_hex_string(end,"binary data: \\n",16);
end = strmov(end,"')");
if (mysql_real_query(&mysql,query,(unsigned int) (end - query)))
{
    fprintf(stderr, "Failed to insert row, Error: %s\n", mysql_error(&mysql));
}
```

The \texttt{strmov()} function used in the example is included in the \texttt{libmysqlclient} library and works like \texttt{strcpy()} but returns a pointer to the terminating null of the first parameter.

\textbf{Return Values}

The length of the encoded string that is placed into \texttt{to}, not including the terminating null character.

\textbf{Errors}

None.

\textbf{21.8.7.35 mysql_info()}

```
const char *mysql_info(MYSQL *mysql)
```

\textbf{Description}

Retrieves a string providing information about the most recently executed statement, but only for the statements listed here. For other statements, \texttt{mysql_info()} returns NULL. The format of the string varies depending on the type of statement, as described here. The numbers are illustrative only; the string contains values appropriate for the statement.

\begin{itemize}
  \item \textbf{INSERT INTO ... SELECT ...}
    \textbf{String format:} Records: 100 Duplicates: 0 Warnings: 0
  \item \textbf{INSERT INTO ... VALUES (...),(...)...}
    \textbf{String format:} Records: 3 Duplicates: 0 Warnings: 0
  \item \textbf{LOAD DATA INFILE ...}
    \textbf{String format:} Records: 3 Deleted: 0 Skipped: 0 Warnings: 0
  \item \textbf{ALTER TABLE}
    \textbf{String format:} Records: 3 Duplicates: 0 Warnings: 0
  \item \textbf{UPDATE}
\end{itemize}
String format: Rows matched: 40 Changed: 40 Warnings: 0

`mysql_info()` returns a non-NULL value for `INSERT ... VALUES` only for the multiple-row form of the statement (that is, only if multiple value lists are specified).

**Return Values**

A character string representing additional information about the most recently executed statement. `NULL` if no information is available for the statement.

**Errors**

None.

**21.8.7.36 mysql_init()**

```c
MYSQL *mysql_init(MYSQL *mysql)
```

**Description**

Allocates or initializes a `MYSQL` object suitable for `mysql_real_connect()`. If `mysql` is a `NULL` pointer, the function allocates, initializes, and returns a new object. Otherwise, the object is initialized and the address of the object is returned. If `mysql_init()` allocates a new object, it is freed when `mysql_close()` is called to close the connection.

In a nonmulti-threaded environment, `mysql_init()` invokes `mysql_library_init()` automatically as necessary. However, `mysql_library_init()` is not thread-safe in a multi-threaded environment, and thus neither is `mysql_init()`. Before calling `mysql_init()`, either call `mysql_library_init()` prior to spawning any threads, or use a mutex to protect the `mysql_library_init()` call. This should be done prior to any other client library call.

**Return Values**

An initialized `MYSQL*` handle. `NULL` if there was insufficient memory to allocate a new object.

**Errors**

In case of insufficient memory, `NULL` is returned.

**21.8.7.37 mysql_insert_id()**

```c
my_ulonglong mysql_insert_id(MYSQL *mysql)
```

**Description**

Returns the value generated for an `AUTO_INCREMENT` column by the previous `INSERT` or `UPDATE` statement. Use this function after you have performed an `INSERT` statement into a table that contains an `AUTO_INCREMENT` field, or have used `INSERT` or `UPDATE` to set a column value with `LAST_INSERT_ID(expr)`.

The return value of `mysql_insert_id()` is always zero unless explicitly updated under one of the following conditions:

- `INSERT` statements that store a value into an `AUTO_INCREMENT` column. This is true whether the value is automatically generated by storing the special values `NULL` or `0` into the column, or is an explicit nonspecial value.
- In the case of a multiple-row `INSERT` statement, the return value of `mysql_insert_id()` depends on the MySQL server version.
In MySQL 5.1.12 and later, \texttt{mysql_insert_id()} returns the first automatically generated \texttt{AUTO_INCREMENT} value that was successfully inserted. In MySQL 5.1.11 and earlier, \texttt{mysql_insert_id()} returns the first automatically generated \texttt{AUTO_INCREMENT} value, regardless of whether insertion of that value was successful.

If no rows are successfully inserted, \texttt{mysql_insert_id()} returns 0.

- Starting in MySQL 5.1.12, if an \texttt{INSERT ... SELECT} statement is executed, and no automatically generated value is successfully inserted, \texttt{mysql_insert_id()} returns the ID of the last inserted row.

- Starting in MySQL 5.1.12, if an \texttt{INSERT ... SELECT} statement uses \texttt{LAST_INSERT_ID(expr)}, \texttt{mysql_insert_id()} returns \texttt{expr}.

- \texttt{INSERT} statements that generate an \texttt{AUTO_INCREMENT} value by inserting \texttt{LAST_INSERT_ID(expr)} into any column or by updating any column to \texttt{LAST_INSERT_ID(expr)}.

- If the previous statement returned an error, the value of \texttt{mysql_insert_id()} is undefined.

For 5.1.12 and later, the return value of \texttt{mysql_insert_id()} can be simplified to the following sequence:

1. If there is an \texttt{AUTO_INCREMENT} column, and an automatically generated value was successfully inserted, return the first such value.

2. If \texttt{LAST_INSERT_ID(expr)} occurred in the statement, return \texttt{expr}, even if there was an \texttt{AUTO_INCREMENT} column in the affected table.

3. The return value varies depending on the statement used. When called after an \texttt{INSERT} statement:
   - If there is an \texttt{AUTO_INCREMENT} column in the table, and there were some explicit values for this column that were successfully inserted into the table, return the last of the explicit values.

When called after an \texttt{INSERT ... ON DUPLICATE KEY UPDATE} statement:

   - If there is an \texttt{AUTO_INCREMENT} column in the table and there were some explicit successfully inserted values or some updated values, return the last of the inserted or updated values.

\texttt{mysql_insert_id()} returns 0 if the previous statement does not use an \texttt{AUTO_INCREMENT} value. If you need to save the value for later, be sure to call \texttt{mysql_insert_id()} immediately after the statement that generates the value.

The value of \texttt{mysql_insert_id()} is affected only by statements issued within the current client connection. It is not affected by statements issued by other clients.

The \texttt{LAST_INSERT_ID()} SQL function returns the value of the first automatically generated value that was successfully inserted (starting from 5.1.12) or the first automatically generated value if any rows were successfully inserted (before 5.1.12). \texttt{LAST_INSERT_ID()} is not reset between statements because the value of that function is maintained in the server. Another difference from \texttt{mysql_insert_id()} is that \texttt{LAST_INSERT_ID()} is not updated if you set an \texttt{AUTO_INCREMENT} column to a specific nonspecial value. See Section 12.14, “Information Functions”.

\texttt{mysql_insert_id()} returns 0 following a \texttt{CALL} statement for a stored procedure that generates an \texttt{AUTO_INCREMENT} value because in this case \texttt{mysql_insert_id()} applies to \texttt{CALL} and not the statement within the procedure. Within the procedure, you can use \texttt{LAST_INSERT_ID()} at the SQL level to obtain the \texttt{AUTO_INCREMENT} value.

The reason for the differences between \texttt{LAST_INSERT_ID()} and \texttt{mysql_insert_id()} is that \texttt{LAST_INSERT_ID()} is made easy to use in scripts while \texttt{mysql_insert_id()} tries to provide more exact information about what happens to the \texttt{AUTO_INCREMENT} column.
Return Values

Described in the preceding discussion.

Errors

None.

21.8.7.38 mysql_kill()

```c
int mysql_kill(MYSQL *mysql, unsigned long pid)
```

Description

Asks the server to kill the thread specified by `pid`.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL KILL statement instead.

Return Values

Zero for success. Nonzero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
  Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`
  The MySQL server has gone away.
- `CR_SERVER_LOST`
  The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`
  An unknown error occurred.

21.8.7.39 mysql_library_end()

```c
void mysql_library_end(void)
```

Description

This function finalizes the MySQL library. Call it when you are done using the library (for example, after disconnecting from the server). The action taken by the call depends on whether your application is linked to the MySQL client library or the MySQL embedded server library. For a client program linked against the libmysqlclient library by using the `-lmysqlclient` flag, `mysql_library_end()` performs some memory management to clean up. For an embedded server application linked against the libmysqld library by using the `-lmysqld` flag, `mysql_library_end()` shuts down the embedded server and then cleans up.

For usage information, see Section 21.8.6, "C API Function Overview", and Section 21.8.7.40, "mysql_library_init()".

21.8.7.40 mysql_library_init()

```c
int mysql_library_init(int argc, char **argv, char **groups)
```
C API Function Descriptions

Description

Call this function to initialize the MySQL library before you call any other MySQL function, whether your application is a regular client program or uses the embedded server. If the application uses the embedded server, this call starts the server and initializes any subsystems (mysys, InnoDB, and so forth) that the server uses.

After your application is done using the MySQL library, call `mysql_library_end()` to clean up. See Section 21.8.7.39, "mysql_library_end()".

The choice of whether the application operates as a regular client or uses the embedded server depends on whether you use the libmysqlclient or libmysqld library at link time to produce the final executable. For additional information, see Section 21.8.6, "C API Function Overview".

In a nonmulti-threaded environment, the call to `mysql_library_init()` may be omitted, because `mysql_init()` will invoke it automatically as necessary. However, `mysql_library_init()` is not thread-safe in a multi-threaded environment, and thus neither is `mysql_init()`, which calls `mysql_library_init()`. You must either call `mysql_library_init()` prior to spawning any threads, or else use a mutex to protect the call, whether you invoke `mysql_library_init()` or indirectly through `mysql_init()`. Do this prior to any other client library call.

The `argc` and `argv` arguments are analogous to the arguments to `main()`, and enable passing of options to the embedded server. For convenience, `argc` may be 0 (zero) if there are no command-line arguments for the server. This is the usual case for applications intended for use only as regular (nonembedded) clients, and the call typically is written as `mysql_library_init(0, NULL, NULL).

```
#include <mysql.h>
#include <stdlib.h>

int main(void) {
  if (mysql_library_init(0, NULL, NULL)) {
    fprintf(stderr, "could not initialize MySQL library\n");
    exit(1);
  }
  /* Use any MySQL API functions here */
  mysql_library_end();
  return EXIT_SUCCESS;
}
```

When arguments are to be passed (`argc` is greater than 0), the first element of `argv` is ignored (it typically contains the program name). `mysql_library_init()` makes a copy of the arguments so it is safe to destroy `argv` or `groups` after the call.

For embedded applications, if you want to connect to an external server without starting the embedded server, you have to specify a negative value for `argc`.

The `groups` argument is an array of strings that indicate the groups in option files from which to read options. See Section 4.2.6, "Using Option Files". Make the final entry in the array `NULL`. For convenience, if the `groups` argument itself is `NULL`, the `[server]` and `[embedded]` groups are used by default.

```
#include <mysql.h>
#include <stdlib.h>

static char *server_args[] = {
  "this_program",       /* this string is not used */
  "--datadir=.",
  "--key_buffer_size=32M"
};
static char *server_groups[] = {
  "embedded",
```

2429
"server",
"this_program_SERVER",
(char *)NULL
};

int main(void) {
    if (mysql_library_init(sizeof(server_args) / sizeof(char *),
                           server_args, server_groups)) {
        fprintf(stderr, "could not initialize MySQL library\n");
        exit(1);
    }
/* Use any MySQL API functions here */
mysql_library_end();
return EXIT_SUCCESS;
}

Return Values
Zero for success. Nonzero if an error occurred.

21.8.7.41 mysql_list_dbs()

MYSQL_RES *mysql_list_dbs(MYSQL *mysql, const char *wild)

Description
Returns a result set consisting of database names on the server that match the simple regular
expression specified by the wild parameter. wild may contain the wildcard characters "%" or ".", or
may be a NULL pointer to match all databases. Calling mysql_list_dbs() is similar to executing the
query SHOW DATABASES [LIKE wild].

You must free the result set with mysql_free_result().

Return Values
A MYSQL_RES result set for success. NULL if an error occurred.

Errors
• CR_COMMANDS_OUT_OF_SYNC
  Commands were executed in an improper order.
• CR_OUT_OF_MEMORY
  Out of memory.
• CR_SERVER_GONE_ERROR
  The MySQL server has gone away.
• CR_SERVER_LOST
  The connection to the server was lost during the query.
• CR_UNKNOWN_ERROR
  An unknown error occurred.

21.8.7.42 mysql_list_fields()

MYSQL_RES *mysql_list_fields(MYSQL *mysql, const char *table, const char *
wild)
C API Function Descriptions

Description

Returns an empty result set for which the metadata provides information about the columns in the
given table that match the simple regular expression specified by the \texttt{wild} parameter. \texttt{wild} may
contain the wildcard characters "\%" or "\_", or may be a \texttt{NULL} pointer to match all fields. Calling
\texttt{mysql_list_fields()} is similar to executing the query \texttt{SHOW COLUMNS FROM tbl_name [LIKE \texttt{wild}]}.

It is preferable to use \texttt{SHOW COLUMNS FROM tbl_name} instead of \texttt{mysql_list_fields()}.

You must free the result set with \texttt{mysql_free_result()}. 

Return Values

\texttt{MYSQL_RES} result set for success. \texttt{NULL} if an error occurred.

Errors

- \texttt{CR_COMMANDS_OUT_OF_SYNC}

  Commands were executed in an improper order.

- \texttt{CR_SERVER_GONE_ERROR}

  The MySQL server has gone away.

- \texttt{CR_SERVER_LOST}

  The connection to the server was lost during the query.

- \texttt{CR_UNKNOWN_ERROR}

  An unknown error occurred.

Example

```c
int i;
MYSQL_RES *tbl_cols = mysql_list_fields(mysql, "mytbl", "f%")
unsigned int field_cnt = mysql_num_fields(tbl_cols);
printf("Number of columns: %d\n", field_cnt);
for (i=0; i < field_cnt; ++i)
{
  /* col describes i-th column of the table */
  MYSQL_FIELD *col = mysql_fetch_field_direct(tbl_cols, i);
  printf("Column %d: %s\n", i, col->name);
}
mysql_free_result(tbl_cols);
```

21.8.7.43 \texttt{mysql_list_processes()}

\texttt{MYSQL_RES *mysql_list_processes(MYSQL *mysql)}

Description

Returns a result set describing the current server threads. This is the same kind of information as that
reported by \texttt{mysqladmin processlist} or a \texttt{SHOW PROCESSLIST} query.

You must free the result set with \texttt{mysql_free_result()}. 

Return Values

\texttt{MYSQL_RES} result set for success. \texttt{NULL} if an error occurred.
Errors

- **CR_COMMANDS_OUT_OF_SYNC**
  Commands were executed in an improper order.
- **CR_SERVER_GONE_ERROR**
  The MySQL server has gone away.
- **CR_SERVER_LOST**
  The connection to the server was lost during the query.
- **CR_UNKNOWN_ERROR**
  An unknown error occurred.

### 21.8.7.44 mysql_list_tables()

```c
MYSQL_RES *mysql_list_tables(MYSQL *mysql, const char *wild)
```

**Description**

Returns a result set consisting of table names in the current database that match the simple regular expression specified by the `wild` parameter. `wild` may contain the wildcard characters "%" or "_", or may be a NULL pointer to match all tables. Calling `mysql_list_tables()` is similar to executing the query `SHOW TABLES [LIKE wild]`.

You must free the result set with `mysql_free_result()`.

**Return Values**

A `MYSQL_RES` result set for success. `NULL` if an error occurred.

**Errors**

- **CR_COMMANDS_OUT_OF_SYNC**
  Commands were executed in an improper order.
- **CR_SERVER_GONE_ERROR**
  The MySQL server has gone away.
- **CR_SERVER_LOST**
  The connection to the server was lost during the query.
- **CR_UNKNOWN_ERROR**
  An unknown error occurred.

### 21.8.7.45 mysql_more_results()

```c
my_bool mysql_more_results(MYSQL *mysql)
```

**Description**

This function is used when you execute multiple statements specified as a single statement string, or when you execute `CALL` statements, which can return multiple result sets.

`mysql_more_results()` returns `true` if more results exist from the currently executed statement, in which case the application must call `mysql_next_result()` to fetch the results.
Return Values

TRUE (1) if more results exist. FALSE (0) if no more results exist.

In most cases, you can call `mysql_next_result()` instead to test whether more results exist and initiate retrieval if so.

See Section 21.8.16, “C API Support for Multiple Statement Execution”, and Section 21.8.7.46, “mysql_next_result()”.

Errors

None.

21.8.7.46 mysql_next_result()

```c
int mysql_next_result(MYSQL *mysql)
```

Description

This function is used when you execute multiple statements specified as a single statement string, or when you use CALL statements to execute stored procedures, which can return multiple result sets.

`mysql_next_result()` reads the next statement result and returns a status to indicate whether more results exist. If `mysql_next_result()` returns an error, there are no more results.

Before each call to `mysql_next_result()`, you must call `mysql_free_result()` for the current statement if it is a statement that returned a result set (rather than just a result status).

After calling `mysql_next_result()` the state of the connection is as if you had called `mysql_real_query()` or `mysql_query()` for the next statement. This means that you can call `mysql_store_result()`, `mysql_warning_count()`, `mysql_affected_rows()`, and so forth.

If your program uses CALL statements to execute stored procedures, the CLIENT_MULTI_RESULTS flag must be enabled. This is because each CALL returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure. Because CALL can return multiple results, process them using a loop that calls `mysql_next_result()` to determine whether there are more results.

`CLIENT_MULTI_RESULTS` can be enabled when you call `mysql_real_connect()`, either explicitly by passing the `CLIENT_MULTI_RESULTS` flag itself, or implicitly by passing `CLIENT_MULTI_STATEMENTS` (which also enables `CLIENT_MULTI_RESULTS`).

It is also possible to test whether there are more results by calling `mysql_more_results()`. However, this function does not change the connection state, so if it returns true, you must still call `mysql_next_result()` to advance to the next result.

For an example that shows how to use `mysql_next_result()`, see Section 21.8.16, “C API Support for Multiple Statement Execution”.

Return Values

<table>
<thead>

</tr>
</tbody>
</table>

Errors

- CR_COMMANDS_OUT_OF_SYNC
Commands were executed in an improper order. For example, if you did not call `mysql_use_result()` for a previous result set.

- **CR_SERVER_GONE_ERROR**
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  An unknown error occurred.

### 21.8.7.47 mysql_num_fields()

```c
unsigned int mysql_num_fields(MYSQL_RES *result)
```

To pass a `MYSQL*` argument instead, use `unsigned int mysql_field_count(MYSQL *mysql)`.

**Description**

Returns the number of columns in a result set.

You can get the number of columns either from a pointer to a result set or to a connection handle. You would use the connection handle if `mysql_store_result()` or `mysql_use_result()` returned `NULL` (and thus you have no result set pointer). In this case, you can call `mysql_field_count()` to determine whether `mysql_store_result()` should have produced a nonempty result. This enables the client program to take proper action without knowing whether the query was a `SELECT` (or `SELECT-like`) statement. The example shown here illustrates how this may be done.

**Return Values**

An unsigned integer representing the number of columns in a result set.

**Errors**

None.

**Example**

```c
MYSQL_RES *result;
unsigned int num_fields;
unsigned int num_rows;

if (mysql_query(&mysql,query_string))
{
    // error
}
else // query succeeded, process any data returned by it
{
    result = mysql_store_result(&mysql);
    if (result) // there are rows
    {
        num_fields = mysql_num_fields(result);
        // retrieve rows, then call mysql_free_result(result)
    }
    else // mysql_store_result() returned nothing; should it have?
    {
```
An alternative (if you know that your query should have returned a result set) is to replace the `mysql_errno(&mysql)` call with a check whether `mysql_field_count(&mysql)` returns 0. This happens only if something went wrong.

21.8.7.48 mysql_num_rows()

```c
my_ulonglong mysql_num_rows(MYSQL_RES *result)
```

**Description**

Returns the number of rows in the result set.

The use of `mysql_num_rows()` depends on whether you use `mysql_store_result()` or `mysql_use_result()` to return the result set. If you use `mysql_store_result()`, `mysql_num_rows()` may be called immediately. If you use `mysql_use_result()`, `mysql_num_rows()` does not return the correct value until all the rows in the result set have been retrieved.

`mysql_num_rows()` is intended for use with statements that return a result set, such as `SELECT`. For statements such as `INSERT`, `UPDATE`, or `DELETE`, the number of affected rows can be obtained with `mysql_affected_rows()`.

**Return Values**

The number of rows in the result set.

**Errors**

None.

21.8.7.49 mysql_options()

```c
int mysql_options(MYSQL *mysql, enum mysql_option option, const void *arg)
```

**Description**

Can be used to set extra connect options and affect behavior for a connection. This function may be called multiple times to set several options.

Call `mysql_options()` after `mysql_init()` and before `mysql_connect()` or `mysql_real_connect()`.

The `option` argument is the option that you want to set; the `arg` argument is the value for the option. If the option is an integer, specify a pointer to the value of the integer as the `arg` argument.

The following list describes the possible options, their effect, and how `arg` is used for each option. Several of the options apply only when the application is linked against the `libmysqld` embedded server library and are unused for applications linked against the `libmysqlclient` client library. For option descriptions that indicate `arg` is unused, its value is irrelevant; it is conventional to pass 0.
C API Function Descriptions

- **MYSQL_INIT_COMMAND** (argument type: `char *`)
  SQL statement to execute when connecting to the MySQL server. Automatically re-executed if reconnection occurs.

- **MYSQL_OPT_COMPRESS** (argument: not used)
  Use the compressed client/server protocol.

- **MYSQL_OPT_CONNECT_TIMEOUT** (argument type: `unsigned int *`)
  The connect timeout in seconds.

- **MYSQL_OPT_GUESS_CONNECTION** (argument: not used)
  For an application linked against the `libmysqld` embedded server library, this enables the library to guess whether to use the embedded server or a remote server. "Guess" means that if the host name is set and is not `localhost`, it uses a remote server. This behavior is the default. `MYSQL_OPT_USE_EMBEDDED_CONNECTION` and `MYSQL_OPT_USE_REMOTE_CONNECTION` can be used to override it. This option is ignored for applications linked against the `libmysqlclient` client library.

- **MYSQL_OPT_LOCAL_INFILE** (argument type: optional pointer to `unsigned int`)
  If no pointer is given or if pointer points to an `unsigned int` that has a nonzero value, the `LOAD DATA LOCAL INFILE` statement is enabled.

- **MYSQL_OPT_NAMED_PIPE** (argument: not used)
  Use a named pipe to connect to the MySQL server on Windows, if the server permits named-pipe connections.

- **MYSQL_OPT_PROTOCOL** (argument type: `unsigned int *`)
  Type of protocol to use. Specify one of the enum values of `mysql_protocol_type` defined in `mysql.h`.

- **MYSQL_OPT_READ_TIMEOUT** (argument type: `unsigned int *`)
  The timeout in seconds for each attempt to read from the server. There are retries if necessary, so the total effective timeout value is three times the option value. You can set the value so that a lost connection can be detected earlier than the TCP/IP `Close_Wait_Timeout` value of 10 minutes. Before MySQL 5.1.41, this option applies only to TCP/IP connections and, prior to MySQL 5.1.12, only for Windows. Implementation of this timeout uses mechanisms that may not be available on all platforms. On such a platform, a client that issues a read call might under certain circumstances wait without timing out. For example, a client might not time out if the server is not responding because it is waiting for a "disk full" condition to clear.

- **MYSQL_OPT_RECONNECT** (argument type: `my_bool *`)
  Enable or disable automatic reconnection to the server if the connection is found to have been lost. Reconnect is off by default; this option provides a way to set reconnection behavior explicitly.
  **Note:** `mysql_real_connect()` incorrectly reset the `MYSQL_OPT_RECONNECT` option to its default value before MySQL 5.1.6. Therefore, prior to that version, if you want reconnect to be enabled for each connection, you must call `mysql_options()` with the `MYSQL_OPT_RECONNECT` option after each call to `mysql_real_connect()`. This is not necessary as of 5.1.6: Call `mysql_options()` only before `mysql_real_connect()` as usual.

- **MYSQL_OPT_SSL_VERIFY_SERVER_CERT** (argument type: `my_bool *`
Enable or disable verification of the server's Common Name value in its certificate against the host name used when connecting to the server. The connection is rejected if there is a mismatch. For encrypted connections, this feature can be used to prevent man-in-the-middle attacks. Verification is disabled by default. Added in MySQL 5.1.11.

- **MYSQL_OPT_USE_EMBEDDED_CONNECTION** (argument: not used)

  For an application linked against the `libmysqld` embedded server library, this forces the use of the embedded server for the connection. This option is ignored for applications linked against the `libmysqlclient` client library.

- **MYSQL_OPT_USE_REMOTE_CONNECTION** (argument: not used)

  For an application linked against the `libmysqld` embedded server library, this forces the use of a remote server for the connection. This option is ignored for applications linked against the `libmysqlclient` client library.

- **MYSQL_OPT_USE_RESULT** (argument: not used)

  This option is unused.

- **MYSQL_OPT_WRITE_TIMEOUT** (argument type: unsigned int *)

  The timeout in seconds for each attempt to write to the server. There is a retry if necessary, so the total effective timeout value is two times the option value. Before MySQL 5.1.41, this option applies only to TCP/IP connections and, prior to MySQL 5.1.12, only for Windows.

- **MYSQL_READ_DEFAULT_FILE** (argument type: char *)

  Read options from the named option file instead of from `my.cnf`.

- **MYSQL_READ_DEFAULT_GROUP** (argument type: char *)

  Read options from the named group from `my.cnf` or the file specified with `MYSQL_READ_DEFAULT_FILE`.

- **MYSQL_REPORT_DATA_TRUNCATION** (argument type: my_bool *)

  Enable or disable reporting of data truncation errors for prepared statements using the `error` member of `MYSQL_BIND` structures. (Default: enabled.)

- **MYSQL_SECURE_AUTH** (argument type: my_bool *)

  Whether to connect to a server that does not support the password hashing used in MySQL 4.1.1 and later.

- **MYSQL_SET_CHARSET_DIR** (argument type: char *)

  The path name to the directory that contains character set definition files.

- **MYSQL_SET_CHARSET_NAME** (argument type: char *)

  The name of the character set to use as the default character set.

- **MYSQL_SET_CLIENT_IP** (argument type: char *)

  For an application linked against the `libmysqld` embedded server library (when `libmysqld` is compiled with authentication support), this means that the user is considered to have connected from the specified IP address (specified as a string) for authentication purposes. This option is ignored for applications linked against the `libmysqlclient` client library.

- **MYSQL_SHARED_MEMORY_BASE_NAME** (argument type: char *)
The name of the shared-memory object for communication to the server on Windows, if the server supports shared-memory connections. Specify the same value as the \texttt{--shared-memory-base-name} option used for the \texttt{mysqld} server you want to connect to.

The client group is always read if you use \texttt{MYSQL_READ_DEFAULT_FILE} or \texttt{MYSQL_READ_DEFAULT_GROUP}.

The specified group in the option file may contain the following options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{character-sets-dir=dir_name}</td>
<td>The directory where character sets are installed.</td>
</tr>
<tr>
<td>\texttt{compress}</td>
<td>Use the compressed client/server protocol.</td>
</tr>
<tr>
<td>\texttt{connect-timeout=seconds}</td>
<td>The connect timeout in seconds. On Linux this timeout is also used for waiting for the first answer from the server.</td>
</tr>
<tr>
<td>\texttt{database=db_name}</td>
<td>Connect to this database if no database was specified in the connect command.</td>
</tr>
<tr>
<td>\texttt{debug}</td>
<td>Debug options.</td>

<td>1]}</td>
</tr>
<tr>
<td>\texttt{max_allowed_packet=bytes}</td>
<td>Maximum size of packet that client can read from server.</td>
</tr>
<tr>
<td>\texttt{multi-queries,multi-results}</td>
<td>Enable multiple result sets from multiple-statement executions or stored procedures.</td>
</tr>
<tr>
<td>\texttt{multi-statements}</td>
<td>Enable the client to send multiple statements in a single string (separated by ; characters).</td>
</tr>
<tr>
<td>\texttt{password=password}</td>
<td>Default password.</td>
</tr>
<tr>
<td>\texttt{pipe}</td>
<td>Use named pipes to connect to a MySQL server on Windows.</td>
</tr>
<tr>
<td>\texttt{port=port_num}</td>
<td>Default port number.</td>
</tr>
<tr>
<td>\texttt{protocol={TCP</td>
<td>SOCKET</td>
</tr>
<tr>
<td>\texttt{return-found-rows}</td>
<td>Tell mysql_info() to return found rows instead of updated rows when using UPDATE.</td>
</tr>
<tr>
<td>\texttt{shared-memory-base-name=name}</td>
<td>Shared-memory name to use to connect to server.</td>
</tr>
<tr>
<td>\texttt{socket={file_name</td>
<td>pipe_name}}</td>
</tr>
<tr>
<td>\texttt{ssl-ca=file_name}</td>
<td>Certificate Authority file.</td>
</tr>
<tr>
<td>\texttt{ssl-capath=dir_name}</td>
<td>Certificate Authority directory.</td>
</tr>
<tr>
<td>\texttt{ssl-cert=file_name}</td>
<td>Certificate file.</td>
</tr>
<tr>
<td>\texttt{ssl-cipher=cipher_list}</td>
<td>Permissible SSL ciphers.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>------------------------------------</td>
</tr>
<tr>
<td>ssl-key=file_name</td>
<td>Key file.</td>
</tr>
<tr>
<td>timeout=seconds</td>
<td>Like connect-timeout.</td>
</tr>
<tr>
<td>user</td>
<td>Default user.</td>
</tr>
</tbody>
</table>

**Option**

`timeout` has been replaced by `connect-timeout`, but `timeout` is still supported for backward compatibility.

For more information about option files used by MySQL programs, see Section 4.2.6, “Using Option Files”.

Before MySQL 5.1.18, the `arg` argument was declared as `char *`.

**Return Values**

Zero for success. Nonzero if you specify an unknown option.

**Example**

The following `mysql_options()` calls request the use of compression in the client/server protocol, cause options to be read from the `[odbc]` group of option files, and disable transaction autocommit mode:

```c
MYSQL mysql;
mysql_init(&mysql);
mysql_options(&mysql, MYSQL_OPT_COMPRESS, 0);
mysql_options(&mysql, MYSQL_READ_DEFAULT_GROUP, "odbc");
mysql_options(&mysql, MYSQL_INIT_COMMAND, "SET autocommit=0");
if (!mysql_real_connect(&mysql, "host", "user", "passwd", "database", 0, NULL, 0))
{
    fprintf(stderr, "Failed to connect to database: Error: %s\n",
            mysql_error(&mysql));
}
```

This code requests that the client use the compressed client/server protocol and read the additional options from the `odbc` section in the `my.cnf` file.

### 21.8.7.50 mysql_ping()

**int mysql_ping(MYSQL *mysql)**

**Description**

Checks whether the connection to the server is working. If the connection has gone down and auto-reconnect is enabled an attempt to reconnect is made. If the connection is down and auto-reconnect is disabled, `mysql_ping()` returns an error.

Auto-reconnect is disabled by default. To enable it, call `mysql_options()` with the `MYSQL_OPT_RECONNECT` option. For details, see Section 21.8.7.49, “mysql_options()”.

`mysql_ping()` can be used by clients that remain idle for a long while, to check whether the server has closed the connection and reconnect if necessary.

If `mysql_ping()` does cause a reconnect, there is no explicit indication of it. To determine whether a reconnect occurs, call `mysql_thread_id()` to get the original connection identifier before calling `mysql_ping()`, then call `mysql_thread_id()` again to see whether the identifier has changed.

If reconnect occurs, some characteristics of the connection will have been reset. For details about these characteristics, see Section 21.8.15, “Controlling Automatic Reconnection Behavior”.
Return Values

Zero if the connection to the server is active. Nonzero if an error occurred. A nonzero return does not indicate whether the MySQL server itself is down; the connection might be broken for other reasons such as network problems.

Errors

- CR_COMMANDS_OUT_OF_SYNC
  Commands were executed in an improper order.
- CR_SERVER_GONE_ERROR
  The MySQL server has gone away.
- CR_UNKNOWN_ERROR
  An unknown error occurred.

21.8.7.51 mysql_query()

```c
int mysql_query(MYSQL *mysql, const char *stmt_str)
```

Description

Executes the SQL statement pointed to by the null-terminated string `stmt_str`. Normally, the string must consist of a single SQL statement without a terminating semicolon (`;`) or \g. If multiple-statement execution has been enabled, the string can contain several statements separated by semicolons. See Section 21.8.16, “C API Support for Multiple Statement Execution”.

`mysql_query()` cannot be used for statements that contain binary data; you must use `mysql_real_query()` instead. (Binary data may contain the “\0” character, which `mysql_query()` interprets as the end of the statement string.)

If you want to know whether the statement should return a result set, you can use `mysql_field_count()` to check for this. See Section 21.8.7.22, “mysql_field_count()”.

Return Values

Zero for success. Nonzero if an error occurred.

Errors

- CR_COMMANDS_OUT_OF_SYNC
  Commands were executed in an improper order.
- CR_SERVER_GONE_ERROR
  The MySQL server has gone away.
- CR_SERVER_LOST
  The connection to the server was lost during the query.
- CR_UNKNOWN_ERROR
  An unknown error occurred.

21.8.7.52 mysql_real_connect()
**Description**

`mysql_real_connect()` attempts to establish a connection to a MySQL database engine running on `host`. `mysql_real_connect()` must complete successfully before you can execute any other API functions that require a valid `MYSQL` connection handle structure.

The parameters are specified as follows:

- For the first parameter, specify the address of an existing `MYSQL` structure. Before calling `mysql_real_connect()`, call `mysql_init()` to initialize the `MYSQL` structure. You can change a lot of connect options with the `mysql_options()` call. See Section 21.8.7.49, "mysql_options()".

- The value of `host` may be either a host name or an IP address. If `host` is `NULL` or the string "localhost", a connection to the local host is assumed. For Windows, the client connects using a shared-memory connection, if the server has shared-memory connections enabled. Otherwise, TCP/IP is used. For Unix, the client connects using a Unix socket file. For local connections, you can also influence the type of connection to use with the `MYSQL_OPT_PROTOCOL` or `MYSQL_OPT_NAMED_PIPE` options to `mysql_options()`. The type of connection must be supported by the server. For a `host` value of "." on Windows, the client connects using a named pipe, if the server has named-pipe connections enabled. If named-pipe connections are not enabled, an error occurs.

- The `user` parameter contains the user's MySQL login ID. If `user` is `NULL` or the empty string ",", the current user is assumed. Under Unix, this is the current login name. Under Windows ODBC, the current user name must be specified explicitly. See the Connector/ODBC section of Chapter 21, Connectors and APIs.

- The `passwd` parameter contains the password for `user`. If `passwd` is `NULL`, only entries in the `user` table for the user that have a blank (empty) password field are checked for a match. This enables the database administrator to set up the MySQL privilege system in such a way that users get different privileges depending on whether they have specified a password.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>Do not attempt to encrypt the password before calling <code>mysql_real_connect()</code>; password encryption is handled automatically by the client API.</td>
</tr>
</tbody>
</table>

- The `user` and `passwd` parameters use whatever character set has been configured for the `MYSQL` object. By default, this is `latin1`, but can be changed by calling `mysql_options(mysql, MYSQL_SET_CHARSET_NAME, "charset_name")` prior to connecting.

- `db` is the database name. If `db` is not `NULL`, the connection sets the default database to this value.

- If `port` is not 0, the value is used as the port number for the TCP/IP connection. Note that the `host` parameter determines the type of the connection.

- If `unix_socket` is not `NULL`, the string specifies the socket or named pipe to use. Note that the `host` parameter determines the type of the connection.

- The value of `client_flag` is usually 0, but can be set to a combination of the following flags to enable certain features.

<table>
<thead>
<tr>
<th>Flag Name</th>
<th>Flag Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLIENT_COMPRESS</td>
<td>Use compression in the client/server protocol.</td>
</tr>
<tr>
<td>CLIENT_FOUND_ROWS</td>
<td>Return the number of found (matched) rows, not the number of changed rows.</td>
</tr>
<tr>
<td>Flag Name</td>
<td>Flag Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>CLIENT_IGNORE_SIGPIPE</td>
<td>Prevents the client library from installing a \texttt{SIGPIPE} signal handler. This can be used to avoid conflicts with a handler that the application has already installed.</td>
</tr>
<tr>
<td>CLIENT_IGNORE_SPACE</td>
<td>Permit spaces after function names. Makes all functions names reserved words.</td>
</tr>
<tr>
<td>CLIENT_INTERACTIVE</td>
<td>Permit \texttt{interactive_timeout} seconds of inactivity (rather than \texttt{wait_timeout} seconds) before closing the connection. The client's session \texttt{wait_timeout} variable is set to the value of the session \texttt{interactive_timeout} variable.</td>
</tr>
<tr>
<td>CLIENT_LOCAL_FILES</td>
<td>Enable \texttt{LOAD DATA LOCAL} handling.</td>
</tr>
<tr>
<td>CLIENT_MULTI_RESULTS</td>
<td>Tell the server that the client can handle multiple result sets from multiple-statement executions or stored procedures. This flag is automatically enabled if CLIENT_MULTI_STATEMENTS is enabled. See the note following this table for more information about this flag.</td>
</tr>
<tr>
<td>CLIENT_MULTI_STATEMENTS</td>
<td>Tell the server that the client may send multiple statements in a single string (separated by ; characters). If this flag is not set, multiple-statement execution is disabled. See the note following this table for more information about this flag.</td>
</tr>
<tr>
<td>CLIENT_NO_SCHEMA</td>
<td>Do not permit \texttt{db_name.tbl_name.col_name} syntax. This is for ODBC. It causes the parser to generate an error if you use that syntax, which is useful for trapping bugs in some ODBC programs.</td>
</tr>
<tr>
<td>CLIENT_ODBC</td>
<td>Unused.</td>
</tr>
<tr>
<td>CLIENT_SSL</td>
<td>Use SSL (encrypted protocol). Do not set this option within an application program; it is set internally in the client library. Instead, use \texttt{mysql_ssl_set()} before calling \texttt{mysql_real_connect()}.</td>
</tr>
<tr>
<td>CLIENT_REMEMBER_OPTIONS</td>
<td>Remember options specified by calls to \texttt{mysql_options()}. Without this option, if \texttt{mysql_real_connect()} fails, you must repeat the \texttt{mysql_options()} calls before trying to connect again. With this option, the \texttt{mysql_options()} calls need not be repeated.</td>
</tr>
</tbody>
</table>

If your program uses \texttt{CALL} statements to execute stored procedures, the CLIENT_MULTI_RESULTS flag must be enabled. This is because each \texttt{CALL} returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure. Because \texttt{CALL} can return multiple results, process them using a loop that calls \texttt{mysql_next_result()} to determine whether there are more results.

CLIENT_MULTI_RESULTS can be enabled when you call \texttt{mysql_real_connect()}, either explicitly by passing the CLIENT_MULTI_RESULTS flag itself, or implicitly by passing CLIENT_MULTI_STATEMENTS (which also enables CLIENT_MULTI_RESULTS).

If you enable CLIENT_MULTI_STATEMENTS or CLIENT_MULTI_RESULTS, you should process the result for every call to \texttt{mysql_query()} or \texttt{mysql_real_query()} by using a loop that calls \texttt{mysql_next_result()} to determine whether there are more results. For an example, see Section 21.8.16, “C API Support for Multiple Statement Execution”.

For some parameters, it is possible to have the value taken from an option file rather than from an explicit value in the \texttt{mysql_real_connect()} call. To do this, call \texttt{mysql_options()} with the MYSQL_READ_DEFAULT_FILE or MYSQL_READ_DEFAULT_GROUP option before calling \texttt{mysql_real_connect()}. Then, in the \texttt{mysql_real_connect()} call, specify the “no-value” value for each parameter to be read from an option file:
• For host, specify a value of NULL or the empty string (""").

• For user, specify a value of NULL or the empty string.

• For passwd, specify a value of NULL. (For the password, a value of the empty string in the mysql_real_connect() call cannot be overridden in an option file, because the empty string indicates explicitly that the MySQL account must have an empty password.)

• For db, specify a value of NULL or the empty string.

• For port, specify a value of 0.

• For unix_socket, specify a value of NULL.

If no value is found in an option file for a parameter, its default value is used as indicated in the descriptions given earlier in this section.

**Return Values**

A MYSQL* connection handle if the connection was successful, NULL if the connection was unsuccessful. For a successful connection, the return value is the same as the value of the first parameter.

**Errors**

• CR_CONN_HOST_ERROR
  Failed to connect to the MySQL server.

• CR_CONNECTION_ERROR
  Failed to connect to the local MySQL server.

• CR_IPSOCK_ERROR
  Failed to create an IP socket.

• CR_OUT_OF_MEMORY
  Out of memory.

• CR_SOCKET_CREATE_ERROR
  Failed to create a Unix socket.

• CR_UNKNOWN_HOST
  Failed to find the IP address for the host name.

• CR_VERSION_ERROR
  A protocol mismatch resulted from attempting to connect to a server with a client library that uses a different protocol version.

• CR_NAMEDPIPEOPEN_ERROR
  Failed to create a named pipe on Windows.

• CR_NAMEDPIPEWAIT_ERROR
  Failed to wait for a named pipe on Windows.

• CR_NAMEDPIPESETSTATE_ERROR
Failed to get a pipe handler on Windows.

- **CR_SERVER_LOST**
  
  If `connect_timeout` > 0 and it took longer than `connect_timeout` seconds to connect to the server or if the server died while executing the `init-command`.

**Example**

```c
MYSQL mysql;
mysql_init(&mysql);
mysql_options(&mysql,MYSQL_READ_DEFAULT_GROUP,"your_prog_name");
if (!mysql_real_connect(&mysql,"host","user","passwd","database",0,NULL,0))
{
    fprintf(stderr, "Failed to connect to database: Error: %s\n",
            mysql_error(&mysql));
}
```

By using `mysql_options()` the MySQL library reads the [client] and [your_prog_name] sections in the `my.cnf` file which ensures that your program works, even if someone has set up MySQL in some nonstandard way.

Upon connection, `mysql_real_connect()` sets the `reconnect` flag (part of the `MYSQL` structure) to a value of 1 in versions of the API older than 5.0.3, or 0 in newer versions. A value of 1 for this flag indicates that if a statement cannot be performed because of a lost connection, to try reconnecting to the server before giving up. You can use the `MYSQL_OPT_RECONNECT` option to `mysql_options()` to control reconnection behavior.

### 21.8.7.53 mysql_real_escape_string()

**Description**

This function creates a legal SQL string for use in an SQL statement. See Section 9.1.1, “String Literals”.

The `mysql` argument must be a valid, open connection because character escaping depends on the character set in use by the server.

The string in the `from` argument is encoded to produce an escaped SQL string, taking into account the current character set of the connection. The result is placed in the `to` argument, followed by a terminating null byte.

Characters encoded are “\”, “\”, “\”, “\”, NUL (ASCII 0), “\n”, “\r”, and Control+Z. Strictly speaking, MySQL requires only that backslash and the quote character used to quote the string in the query be escaped. `mysql_real_escape_string()` quotes the other characters to make them easier to read in log files. For comparison, see the quoting rules for literal strings and the `QUOTE()` SQL function in Section 9.1.1, “String Literals”, and Section 12.5, “String Functions”.

The string pointed to by `from` must be `length` bytes long. You must allocate the `to` buffer to be at least `length*2+1` bytes long. (In the worst case, each character may need to be encoded as using two bytes, and there must be room for the terminating null byte.) When `mysql_real_escape_string()` returns, the contents of `to` is a null-terminated string. The return value is the length of the encoded string, not including the terminating null byte.

If you must change the character set of the connection, use the `mysql_set_character_set()` function rather than executing a `SET NAMES` (or `SET CHARACTER_SET`) statement. `mysql_set_character_set()` works like `SET NAMES` but also affects the character set used by `mysql_real_escape_string()`, which `SET NAMES` does not.
Example

The following example inserts two escaped strings into an `INSERT` statement, each within single quote characters:

```c
char query[1000], *end;
end = strmov(query, "INSERT INTO test_table VALUES("");
*end++ = '\';
end += mysql_real_escape_string(&mysql, end, "What is this", 12);
*end++ = '\';
*end++ = ',';
*end++ = '\';
end += mysql_real_escape_string(&mysql, end, "binary data: \0\r\n", 16);
*end++ = '\';
*end++ = ');
if (mysql_real_query(&mysql, query, (unsigned int) (end - query)))
{
    fprintf(stderr, "Failed to insert row, Error: %s\n",
            mysql_error(&mysql));
}
```

The `strmov()` function used in the example is included in the `libmysqlclient` library and works like `strcpy()` but returns a pointer to the terminating null of the first parameter.

Return Values

The length of the encoded string that is placed into the `to` argument, not including the terminating null character.

Errors

None.

21.8.7.54 `mysql_real_query()`

```c
int mysql_real_query(MYSQL *mysql, const char *stmt_str, unsigned long length)
```

Description

Executes the SQL statement pointed to by `stmt_str`, a string `length` bytes long. Normally, the string must consist of a single SQL statement without a terminating semicolon (";") or `\g`. If multiple-statement execution has been enabled, the string can contain several statements separated by semicolons. See Section 21.8.16, “C API Support for Multiple Statement Execution”.

`mysql_query()` cannot be used for statements that contain binary data; you must use `mysql_real_query()` instead. (Binary data may contain the “\0” character, which `mysql_query()` interprets as the end of the statement string.) In addition, `mysql_real_query()` is faster than `mysql_query()` because it does not call `strlen()` on the statement string.

If you want to know whether the statement should return a result set, you can use `mysql_field_count()` to check for this. See Section 21.8.7.22, “`mysql_field_count()`”.

Return Values

Zero for success. Nonzero if an error occurred.

Errors

- `CR_COMMANDS_OUT_OF_SYNC`
Commands were executed in an improper order.

- **CR_SERVER_GONE_ERROR**
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  An unknown error occurred.

### 21.8.7.55 mysql_refresh()

```c
int mysql_refresh(MYSQL *mysql, unsigned int options)
```

**Description**

This function flushes tables or caches, or resets replication server information. The connected user must have the `RELOAD` privilege.

The `options` argument is a bit mask composed from any combination of the following values. Multiple values can be OR'ed together to perform multiple operations with a single call.

- **REFRESH_GRANT**
  Refresh the grant tables, like `FLUSH PRIVILEGES`.

- **REFRESH_LOG**
  Flush the logs, like `FLUSH LOGS`.

- **REFRESH_TABLES**
  Flush the table cache, like `FLUSH TABLES`.

- **REFRESH_HOSTS**
  Flush the host cache, like `FLUSH HOSTS`.

- **REFRESH_STATUS**
  Reset status variables, like `FLUSH STATUS`.

- **REFRESH_THREADS**
  Flush the thread cache.

- **REFRESH_SLAVE**
  On a slave replication server, reset the master server information and restart the slave, like `RESET SLAVE`.

- **REFRESH_MASTER**
  On a master replication server, remove the binary log files listed in the binary log index and truncate the index file, like `RESET MASTER`.

**Return Values**

Zero for success. Nonzero if an error occurred.
Errors

- **CR_COMMANDS_OUT_OF_SYNC**
  Commands were executed in an improper order.

- **CR_SERVER_GONE_ERROR**
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  An unknown error occurred.

21.8.7.56 mysql_reload()

```c
int mysql_reload(MYSQL *mysql)
```

**Description**

Asks the MySQL server to reload the grant tables. The connected user must have the **RELOAD** privilege.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL **FLUSH PRIVILEGES** statement instead.

**Return Values**

Zero for success. Nonzero if an error occurred.

Errors

- **CR_COMMANDS_OUT_OF_SYNC**
  Commands were executed in an improper order.

- **CR_SERVER_GONE_ERROR**
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  An unknown error occurred.

21.8.7.57 mysql_rollback()

```c
my_bool mysql_rollback(MYSQL *mysql)
```

**Description**

Rolls back the current transaction.

The action of this function is subject to the value of the **completion_type** system variable. In particular, if the value of **completion_type** is 2, the server performs a release after terminating a transaction and closes the client connection. The client program should call `mysql_close()` to close the connection from the client side.
C API Function Descriptions

Return Values

Zero for success. Nonzero if an error occurred.

Errors

None.

21.8.7.58 mysql_row_seek()

MYSQL_ROW_OFFSET mysql_row_seek(MYSQL_RES *result, MYSQL_ROW_OFFSET offset)

Description

Sets the row cursor to an arbitrary row in a query result set. The offset value is a row offset, typically a value returned from mysql_row_tell() or from mysql_row_seek(). This value is not a row number; to seek to a row within a result set by number, use mysql_data_seek() instead.

This function requires that the result set structure contains the entire result of the query, so mysql_row_seek() may be used only in conjunction with mysql_store_result(), not with mysql_use_result().

Return Values

The previous value of the row cursor. This value may be passed to a subsequent call to mysql_row_seek().

Errors

None.

21.8.7.59 mysql_row_tell()

MYSQL_ROW_OFFSET mysql_row_tell(MYSQL_RES *result)

Description

Returns the current position of the row cursor for the last mysql_fetch_row(). This value can be used as an argument to mysql_row_seek().

Use mysql_row_tell() only after mysql_store_result(), not after mysql_use_result().

Return Values

The current offset of the row cursor.

Errors

None.

21.8.7.60 mysql_select_db()

int mysql_select_db(MYSQL *mysql, const char *db)

Description

Causes the database specified by db to become the default (current) database on the connection specified by mysql. In subsequent queries, this database is the default for table references that include no explicit database specifier.

mysql_select_db() fails unless the connected user can be authenticated as having permission to use the database.
Return Values

Zero for success. Nonzero if an error occurred.

Errors

- **CR_COMMANDS_OUT_OF_SYNC**
  
  Commands were executed in an improper order.

- **CR_SERVER_GONE_ERROR**
  
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  
  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  
  An unknown error occurred.

21.8.7.61 mysql_set_character_set()

```c
int mysql_set_character_set(MYSQL *mysql, const char *csname)
```

Description

This function is used to set the default character set for the current connection. The string `csname` specifies a valid character set name. The connection collation becomes the default collation of the character set. This function works like the `SET NAMES` statement, but also sets the value of `mysql->charset`, and thus affects the character set used by `mysql_real_escape_string()`.

Return Values

Zero for success. Nonzero if an error occurred.

Example

```c
MYSQL mysql;
mysql_init(&mysql);
if (!mysql_real_connect(&mysql,"host","user","passwd","database",0,NULL,0))
{
    fprintf(stderr, "Failed to connect to database: Error: %s\n",
            mysql_error(&mysql));
}
if (!mysql_set_character_set(&mysql, "utf8"))
{
    printf("New client character set: \n",
            mysql_character_set_name(&mysql));
}
```

21.8.7.62 mysql_set_local_infile_default()

```c
void mysql_set_local_infile_default(MYSQL *mysql);
```

Description

Sets the `LOAD DATA LOCAL INFILE` callback functions to the defaults used internally by the C client library. The library calls this function automatically if `mysql_set_local_infile_handler()` has not been called or does not supply valid functions for each of its callbacks.
2450

Return Values

None.

Errors

None.

21.8.7.63 mysql_set_local_infile_handler()

```c
void mysql_set_local_infile_handler(MYSQL *mysql, int (*local_infile_init)(void **, const char *, void *), int (*local_infile_read)(void *, char *, unsigned int), void (*local_infile_end)(void *), int (*local_infile_error)(void *, char*, unsigned int), void *userdata);
```

Description

This function installs callbacks to be used during the execution of `LOAD DATA LOCAL INFILE` statements. It enables application programs to exert control over local (client-side) data file reading. The arguments are the connection handler, a set of pointers to callback functions, and a pointer to a data area that the callbacks can use to share information.

To use `mysql_set_local_infile_handler()`, you must write the following callback functions:

```c
int local_infile_init(void **ptr, const char *filename, void *userdata);
```

The initialization function. This is called once to do any setup necessary, open the data file, allocate data structures, and so forth. The first `void**` argument is a pointer to a pointer. You can set the pointer (that is, `*ptr`) to a value that will be passed to each of the other callbacks (as a `void*`). The callbacks can use this pointed-to value to maintain state information. The `userdata` argument is the same value that is passed to `mysql_set_local_infile_handler()`.

The initialization function should return zero for success, nonzero for an error.

```c
int local_infile_read(void *ptr, char *buf, unsigned int buf_len);
```

The data-reading function. This is called repeatedly to read the data file. `buf` points to the buffer where the read data is stored, and `buf_len` is the maximum number of bytes that the callback can read and store in the buffer. (It can read fewer bytes, but should not read more.)

The return value is the number of bytes read, or zero when no more data could be read (this indicates EOF). Return a value less than zero if an error occurs.

```c
void local_infile_end(void *ptr)
```

The termination function. This is called once after `local_infile_read()` has returned zero (EOF) or an error. Within this function, deallocate any memory allocated by `local_infile_init()` and perform any other cleanup necessary. It is invoked even if the initialization function returns an error.

```c
int local_infile_error(void *ptr, 
        char *error_msg, 
        unsigned int error_msg_len);
```

The error-handling function. This is called to get a textual error message to return to the user in case any of your other functions returns an error. `error_msg` points to the buffer into which the message is
written, and `error_msg_len` is the length of the buffer. Write the message as a null-terminated string, at most `error_msg_len`−1 bytes long.

The return value is the error number.

Typically, the other callbacks store the error message in the data structure pointed to by `ptr`, so that `local_infile_error()` can copy the message from there into `error_msg`.

After calling `mysql_set_local_infile_handler()` in your C code and passing pointers to your callback functions, you can then issue a `LOAD DATA LOCAL INFILE` statement (for example, by using `mysql_query()`). The client library automatically invokes your callbacks. The file name specified in `LOAD DATA LOCAL INFILE` will be passed as the second parameter to the `local_infile_init()` callback.

Return Values

None.

Errors

None.

### 21.8.7.64 `mysql_set_server_option()`

```c
int mysql_set_server_option(MYSQL *mysql, enum enum_mysql_set_option option)
```

**Description**

Enables or disables an option for the connection. `option` can have one of the following values.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>MYSQL_OPTION_MULTI_STATEMENTS_ON</code></td>
<td>Enable multiple-statement support</td>
</tr>
<tr>
<td><code>MYSQL_OPTION_MULTI_STATEMENTS_OFF</code></td>
<td>Disable multiple-statement support</td>
</tr>
</tbody>
</table>

If you enable multiple-statement support, you should retrieve results from calls to `mysql_query()` or `mysql_real_query()` by using a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see Section 21.8.16, “C API Support for Multiple Statement Execution”.

Enabling multiple-statement support with `MYSQL_OPTION_MULTI_STATEMENTS_ON` does not have quite the same effect as enabling it by passing the `CLIENT_MULTI_STATEMENTS` flag to `mysql_real_connect()`: `CLIENT_MULTI_STATEMENTS` also enables `CLIENT_MULTI_RESULTS`.

If you are using the `CALL SQL` statement in your programs, multiple-result support must be enabled; this means that `MYSQL_OPTION_MULTI_STATEMENTS_ON` by itself is insufficient to permit the use of `CALL`.

Return Values

Zero for success. Nonzero if an error occurred.

Errors

- **CR_COMMANDS_OUT_OF_SYNC**
  
  Commands were executed in an improper order.

- **CR_SERVER_GONE_ERROR**
  
  The MySQL server has gone away.
• **CR_SERVER_LOST**

  The connection to the server was lost during the query.

• **ER_UNKNOWN_COM_ERROR**

  The server did not support `mysql_set_server_option()` (which is the case that the server is older than 4.1.1) or the server did not support the option one tried to set.

### 21.8.7.65 `mysql_shutdown()`

```c
int mysql_shutdown(MYSQL *mysql, enum mysql_enum_shutdown_level shutdown_level)
```

**Description**

Asks the database server to shut down. The connected user must have the `SHUTDOWN` privilege. MySQL servers support only one type of shutdown; `shutdown_level` must be equal to `SHUTDOWN_DEFAULT`. Dynamically linked executables which have been compiled with older versions of the `libmysqlclient` headers and call `mysql_shutdown()` need to be used with the old `libmysqlclient` dynamic library.

The shutdown process is described in Section 5.1.11, "The Server Shutdown Process".

**Return Values**

Zero for success. Nonzero if an error occurred.

**Errors**

• **CR_COMMANDS_OUT_OF_SYNC**

  Commands were executed in an improper order.

• **CR_SERVER_GONE_ERROR**

  The MySQL server has gone away.

• **CR_SERVER_LOST**

  The connection to the server was lost during the query.

• **CR_UNKNOWN_ERROR**

  An unknown error occurred.

### 21.8.7.66 `mysql_sqlstate()`

```c
const char *mysql_sqlstate(MYSQL *mysql)
```

**Description**

Returns a null-terminated string containing the SQLSTATE error code for the most recently executed SQL statement. The error code consists of five characters. '00000' means "no error." The values are specified by ANSI SQL and ODBC. For a list of possible values, see Appendix B, Errors, Error Codes, and Common Problems.

SQLSTATE values returned by `mysql_sqlstate()` differ from MySQL-specific error numbers returned by `mysql_errno()`. For example, the `mysql` client program displays errors using the following format, where 1146 is the `mysql_errno()` value and '42S02' is the corresponding `mysql_sqlstate()` value:
SELECT * FROM no_such_table;
ERROR 1146 (42S02): Table 'test.no_such_table' doesn't exist

Not all MySQL error numbers are mapped to SQLSTATE error codes. The value 'HY000' (general error) is used for unmapped error numbers.

If you call `mysql_sqlstate()` after `mysql_real_connect()` fails, `mysql_sqlstate()` might not return a useful value. For example, this happens if a host is blocked by the server and the connection is closed without any SQLSTATE value being sent to the client.

**Return Values**

A null-terminated character string containing the SQLSTATE error code.

**See Also**

See Section 21.8.7.14, "mysql_errno()", Section 21.8.7.15, "mysql_error()", and Section 21.8.11.26, "mysql_stmt_sqlstate()".

**21.8.7.67 mysql_ssl_set()**

```c
my_bool mysql_ssl_set(MYSQL *mysql, const char *key, const char *cert, const char *ca, const char *capath, const char *cipher)
```

**Description**

`mysql_ssl_set()` is used for establishing secure connections using SSL. It must be called before `mysql_real_connect()`.

`mysql_ssl_set()` does nothing unless SSL support is enabled in the client library.

`mysql` is the connection handler returned from `mysql_init()`. The other parameters are specified as follows:

- `key` is the path name to the key file.
- `cert` is the path name to the certificate file.
- `ca` is the path name to the certificate authority file.
- `capath` is the path name to a directory that contains trusted SSL CA certificates in PEM format.
- `cipher` is a list of permissible ciphers to use for SSL encryption.

Any unused SSL parameters may be given as NULL.

**Return Values**

This function always returns 0. If SSL setup is incorrect, `mysql_real_connect()` returns an error when you attempt to connect.

**21.8.7.68 mysql_stat()**

```c
const char *mysql_stat(MYSQL *mysql)
```

**Description**

Returns a character string containing information similar to that provided by the `mysqladmin status` command. This includes uptime in seconds and the number of running threads, questions, reloads, and open tables.
Return Values

A character string describing the server status. **NULL** if an error occurred.

Errors

- **CR_COMMANDS_OUT_OF_SYNC**
  Commands were executed in an improper order.

- **CR_SERVER_GONE_ERROR**
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  An unknown error occurred.

### 21.8.7.69 mysql_store_result()

```c
MYSQL_RES *mysql_store_result(MYSQL *mysql)
```

**Description**

After invoking `mysql_query()` or `mysql_real_query()`, you must call `mysql_store_result()` or `mysql_use_result()` for every statement that successfully produces a result set (SELECT, SHOW, DESCRIBE, EXPLAIN, CHECK TABLE, and so forth). You must also call `mysql_free_result()` after you are done with the result set.

You need not call `mysql_store_result()` or `mysql_use_result()` for other statements, but it does not do any harm or cause any notable performance degradation if you call `mysql_store_result()` in all cases. You can detect whether the statement has a result set by checking whether `mysql_store_result()` returns a nonzero value (more about this later).

If you enable multiple-statement support, you should retrieve results from calls to `mysql_query()` or `mysql_real_query()` by using a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see Section 21.8.16, "C API Support for Multiple Statement Execution".

If you want to know whether a statement should return a result set, you can use `mysql_field_count()` to check for this. See Section 21.8.7.22, "mysql_field_count()".

`mysql_store_result()` reads the entire result of a query to the client, allocates a `MYSQL_RES` structure, and places the result into this structure.

`mysql_store_result()` returns a null pointer if the statement did not return a result set (for example, if it was an INSERT statement).

`mysql_store_result()` also returns a null pointer if reading of the result set failed. You can check whether an error occurred by checking whether `mysql_error()` returns a nonempty string, `mysql_errno()` returns nonzero, or `mysql_field_count()` returns zero.

An empty result set is returned if there are no rows returned. (An empty result set differs from a null pointer as a return value.)

After you have called `mysql_store_result()` and gotten back a result that is not a null pointer, you can call `mysql_num_rows()` to find out how many rows are in the result set.
You can call `mysql_fetch_row()` to fetch rows from the result set, or `mysql_row_seek()` and `mysql_row_tell()` to obtain or set the current row position within the result set.

**Return Values**

A `MYSQL_RES` result structure with the results. NULL (0) if an error occurred.

**Errors**

`mysql_store_result()` resets `mysql_error()` and `mysql_errno()` if it succeeds.

- **CR_COMMANDS_OUT_OF_SYNC**
  Commands were executed in an improper order.

- **CR_OUT_OF_MEMORY**
  Out of memory.

- **CR_SERVER_GONE_ERROR**
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  An unknown error occurred.

### 21.8.7.70 mysql_thread_id()

```c
unsigned long mysql_thread_id(MYSQL *mysql)
```

**Description**

Returns the thread ID of the current connection. This value can be used as an argument to `mysql_kill()` to kill the thread.

If the connection is lost and you reconnect with `mysql_ping()`, the thread ID changes. This means you should not get the thread ID and store it for later. You should get it when you need it.

**Note**

This function does not work correctly if thread IDs become larger than 32 bits, which can occur on some systems. To avoid problems with `mysql_thread_id()`, do not use it. To get the connection ID, execute a `SELECT CONNECTION_ID()` query and retrieve the result.

**Return Values**

The thread ID of the current connection.

**Errors**

None.

### 21.8.7.71 mysql_use_result()
MYSQL_RES *mysql_use_result(MYSQL *mysql)

**Description**

After invoking `mysql_query()` or `mysql_real_query()`, you must call `mysql_store_result()` or `mysql_use_result()` for every statement that successfully produces a result set (SELECT, SHOW, DESCRIBE, EXPLAIN, CHECK TABLE, and so forth). You must also call `mysql_free_result()` after you are done with the result set.

`mysql_use_result()` initiates a result set retrieval but does not actually read the result set into the client like `mysql_store_result()` does. Instead, each row must be retrieved individually by making calls to `mysql_fetch_row()`. This reads the result of a query directly from the server without storing it in a temporary table or local buffer, which is somewhat faster and uses much less memory than `mysql_store_result()`. The client allocates memory only for the current row and a communication buffer that may grow up to `max_allowed_packet` bytes.

On the other hand, you should not use `mysql_use_result()` for locking reads if you are doing a lot of processing for each row on the client side, or if the output is sent to a screen on which the user may type a `^S` (stop scroll). This ties up the server and prevent other threads from updating any tables from which the data is being fetched.

When using `mysql_use_result()`, you must execute `mysql_fetch_row()` until a `NULL` value is returned, otherwise, the unfetched rows are returned as part of the result set for your next query. The C API gives the error `Commands out of sync; you can't run this command now` if you forget to do this!

You may not use `mysql_data_seek()`, `mysql_row_seek()`, `mysql_row_tell()`, `mysql_num_rows()`, or `mysql_affected_rows()` with a result returned from `mysql_use_result()`, nor may you issue other queries until `mysql_use_result()` has finished. (However, after you have fetched all the rows, `mysql_num_rows()` accurately returns the number of rows fetched.)

You must call `mysql_free_result()` once you are done with the result set.

When using the `libmysqld` embedded server, the memory benefits are essentially lost because memory usage incrementally increases with each row retrieved until `mysql_free_result()` is called.

**Return Values**

A `MYSQL_RES` result structure. `NULL` if an error occurred.

**Errors**

`mysql_use_result()` resets `mysql_error()` and `mysql_errno()` if it succeeds.

- **CR_COMMANDS_OUT_OF_SYNC**
  
  Commands were executed in an improper order.

- **CR_OUT_OF_MEMORY**
  
  Out of memory.

- **CR_SERVER_GONE_ERROR**
  
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  
  The connection to the server was lost during the query.
21.8.7.72 mysql_warning_count()

unsigned int mysql_warning_count(MYSQL *mysql)

Description

Returns the number of errors, warnings, and notes generated during execution of the previous SQL statement.

Return Values

The warning count.

Errors

None.

21.8.8 C API Prepared Statements

The MySQL client/server protocol provides for the use of prepared statements. This capability uses the `MYSQL_STMT` statement handler data structure returned by the `mysql_stmt_init()` initialization function. Prepared execution is an efficient way to execute a statement more than once. The statement is first parsed to prepare it for execution. Then it is executed one or more times at a later time, using the statement handle returned by the initialization function.

Prepared execution is faster than direct execution for statements executed more than once, primarily because the query is parsed only once. In the case of direct execution, the query is parsed every time it is executed. Prepared execution also can provide a reduction of network traffic because for each execution of the prepared statement, it is necessary only to send the data for the parameters.

Prepared statements might not provide a performance increase in some situations. For best results, test your application both with prepared and nonprepared statements and choose whichever yields best performance.

Another advantage of prepared statements is that it uses a binary protocol that makes data transfer between client and server more efficient.

For a list of SQL statements that can be used as prepared statements, see Section 13.5, “SQL Syntax for Prepared Statements”.

As of MySQL 5.1.25, metadata changes to tables or views referred to by prepared statements are detected and cause automatic repreparation of the statement when it is next executed. For more information, see Section 13.5.4, “Automatic Prepared Statement Repreparation”.

21.8.9 C API Prepared Statement Data Structures

Prepared statements use several data structures:

- To obtain a statement handle, pass a `MYSQL` connection handler to `mysql_stmt_init()`, which returns a pointer to a `MYSQL_STMT` data structure. This structure is used for further operations with the statement. To specify the statement to prepare, pass the `MYSQL_STMT` pointer and the statement string to `mysql_stmt_prepare()`.

- To provide input parameters for a prepared statement, set up `MYSQL_BIND` structures and pass them to `mysql_stmt_bind_param()`. To receive output column values, set up `MYSQL_BIND` structures and pass them to `mysql_stmt_bind_result()`.
• The **MYSQL_TIME** structure is used to transfer temporal data in both directions.

The following discussion describes the prepared statement data types in detail. For examples that show how to use them, see Section 21.8.11.10, "mysql_stmt_execute()", and Section 21.8.11.11, "mysql_stmt_fetch()".

• **MYSQL_STMT**

This structure is a handle for a prepared statement. A handle is created by calling `mysql_stmt_init()`, which returns a pointer to a `MYSQL_STMT`. The handle is used for all subsequent operations with the statement until you close it with `mysql_stmt_close()`, at which point the handle becomes invalid.

The `MYSQL_STMT` structure has no members intended for application use. Applications should not try to copy a `MYSQL_STMT` structure. There is no guarantee that such a copy will be usable.

Multiple statement handles can be associated with a single connection. The limit on the number of handles depends on the available system resources.

• **MYSQL_BIND**

This structure is used both for statement input (data values sent to the server) and output (result values returned from the server):

• For input, use `MYSQL_BIND` structures with `mysql_stmt_bind_param()` to bind parameter data values to buffers for use by `mysql_stmt_execute()`.

• For output, use `MYSQL_BIND` structures with `mysql_stmt_bind_result()` to bind buffers to result set columns, for use in fetching rows with `mysql_stmt_fetch()`.

To use a `MYSQL_BIND` structure, zero its contents to initialize it, then set its members appropriately. For example, to declare and initialize an array of three `MYSQL_BIND` structures, use this code:

```c
MYSQL_BIND bind[3];
memset(bind, 0, sizeof(bind));
```

The `MYSQL_BIND` structure contains the following members for use by application programs. For several of the members, the manner of use depends on whether the structure is used for input or output.

• **enum enum_field_types buffer_type**

The type of the buffer. This member indicates the data type of the C language variable bound to a statement parameter or result set column. For input, `buffer_type` indicates the type of the variable containing the value to be sent to the server. For output, it indicates the type of the variable into which a value received from the server should be stored. For permissible `buffer_type` values, see Section 21.8.9.1, “C API Prepared Statement Type Codes”.

• **void *buffer**

A pointer to the buffer to be used for data transfer. This is the address of a C language variable.

For input, `buffer` is a pointer to the variable in which you store the data value for a statement parameter. When you call `mysql_stmt_execute()`, MySQL use the value stored in the variable in place of the corresponding parameter marker in the statement (specified with ? in the statement string).

For output, `buffer` is a pointer to the variable in which to return a result set column value. When you call `mysql_stmt_fetch()`, MySQL stores a column value from the current row of the result set in this variable. You can access the value when the call returns.
To minimize the need for MySQL to perform type conversions between C language values on the client side and SQL values on the server side, use C variables that have types similar to those of the corresponding SQL values:

- For numeric data types, `buffer` should point to a variable of the proper numeric C type. For integer variables (which can be `char` for single-byte values or an integer type for larger values), you should also indicate whether the variable has the `unsigned` attribute by setting the `is_unsigned` member, described later.

- For character (nonbinary) and binary string data types, `buffer` should point to a character buffer.

- For date and time data types, `buffer` should point to a `MYSQL_TIME` structure.

For guidelines about mapping between C types and SQL types and notes about type conversions, see Section 21.8.9.1, "C API Prepared Statement Type Codes", and Section 21.8.9.2, "C API Prepared Statement Type Conversions".

- `unsigned long buffer_length`

  The actual size of `*buffer` in bytes. This indicates the maximum amount of data that can be stored in the buffer. For character and binary C data, the `buffer_length` value specifies the length of `*buffer` when used with `mysql_stmt_bind_param()` to specify input values, or the maximum number of output data bytes that can be fetched into the buffer when used with `mysql_stmt_bind_result()`.

- `unsigned long *length`

  A pointer to an `unsigned long` variable that indicates the actual number of bytes of data stored in `*buffer`. This is used for character or binary C data.

  For input parameter data binding, set `*length` to indicate the actual length of the parameter value stored in `*buffer`. This is used by `mysql_stmt_execute()`.

  For output value binding, MySQL sets `*length` when you call `mysql_stmt_fetch()`. The `mysql_stmt_fetch()` return value determines how to interpret the length:

  - If the return value is 0, `*length` indicates the actual length of the parameter value.
  - If the return value is `MYSQL_DATA_TRUNCATED`, `*length` indicates the nontruncated length of the parameter value. In this case, the minimum of `*length` and `buffer_length` indicates the actual length of the value.

  `length` is ignored for numeric and temporal data types because the `buffer_type` value determines the length of the data value.

  If you must determine the length of a returned value before fetching it, see Section 21.8.11.11, "mysql_stmt_fetch()", for some strategies.

- `my_bool *is_null`

  This member points to a `my_bool` variable that is true if a value is `NULL`, false if it is not `NULL`. For input, set `*is_null` to true to indicate that you are passing a `NULL` value as a statement parameter.

  `is_null` is a `pointer` to a boolean scalar, not a boolean scalar, to provide flexibility in how you specify `NULL` values:

  - If your data values are always `NULL`, use `MYSQL_TYPE_NULL` as the `buffer_type` value when you bind the column. The other `MYSQL_BIND` members, including `is_null`, do not matter.
• If your data values are always NOT NULL, set `is_null = (my_bool*) 0`, and set the other members appropriately for the variable you are binding.

• In all other cases, set the other members appropriately and set `is_null` to the address of a `my_bool` variable. Set that variable’s value to true or false appropriately between executions to indicate whether the corresponding data value is NULL or NOT NULL, respectively.

For output, when you fetch a row, MySQL sets the value pointed to by `is_null` to true or false according to whether the result set column value returned from the statement is or is not NULL.

• `my_bool is_unsigned`

This member applies for C variables with data types that can be `unsigned` (`char, short int, int, long long int`). Set `is_unsigned` to true if the variable pointed to by `buffer` is unsigned and false otherwise. For example, if you bind a `signed char` variable to `buffer`, specify a type code of `MYSQL_TYPE_TINY` and set `is_unsigned` to false. If you bind an `unsigned char` instead, the type code is the same but `is_unsigned` should be true. (For `char`, it is not defined whether it is signed or unsigned, so it is best to be explicit about signedness by using `signed char` or `unsigned char`.)

`is_unsigned` applies only to the C language variable on the client side. It indicates nothing about the signedness of the corresponding SQL value on the server side. For example, if you use an `int` variable to supply a value for a `BIGINT UNSIGNED` column, `is_unsigned` should be false because `int` is a signed type. If you use an `unsigned int` variable to supply a value for a `BIGINT` column, `is_unsigned` should be true because `unsigned int` is an unsigned type. MySQL performs the proper conversion between signed and unsigned values in both directions, although a warning occurs if truncation results.

• `my_bool *error`

For output, set this member to point to a `my_bool` variable to have truncation information for the parameter stored there after a row fetching operation. When truncation reporting is enabled, `mysql_stmt_fetch()` returns `MYSQL_DATA_TRUNCATED` and `*error` is true in the `MYSQL_BIND` structures for parameters in which truncation occurred. Truncation indicates loss of sign or significant digits, or that a string was too long to fit in a column. Truncation reporting is enabled by default, but can be controlled by calling `mysql_options()` with the `MYSQL_REPORT_DATA_TRUNCATION` option.

• `MYSQL_TIME`

This structure is used to send and receive `DATE, TIME, DATETIME,` and `TIMESTAMP` data directly to and from the server. Set the `buffer` member to point to a `MYSQL_TIME` structure, and set the `buffer_type` member of a `MYSQL_BIND` structure to one of the temporal types (`MYSQL_TYPE_TIME, MYSQL_TYPE_DATE, MYSQL_TYPE_DATETIME, MYSQL_TYPE_TIMESTAMP`).

The `MYSQL_TIME` structure contains the members listed in the following table.

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>unsigned int year</td>
<td>The year</td>
</tr>
<tr>
<td>unsigned int month</td>
<td>The month of the year</td>
</tr>
<tr>
<td>unsigned int day</td>
<td>The day of the month</td>
</tr>
<tr>
<td>unsigned int hour</td>
<td>The hour of the day</td>
</tr>
<tr>
<td>unsigned int minute</td>
<td>The minute of the hour</td>
</tr>
<tr>
<td>unsigned int second</td>
<td>The second of the minute</td>
</tr>
<tr>
<td>my_bool neg</td>
<td>A boolean flag indicating whether the time is negative</td>
</tr>
</tbody>
</table>
Only those parts of a `MYSQL_TIME` structure that apply to a given type of temporal value are used. The `year`, `month`, and `day` elements are used for `DATE`, `DATETIME`, and `TIMESTAMP` values. The `hour`, `minute`, and `second` elements are used for `TIME`, `DATETIME`, and `TIMESTAMP` values. See Section 21.8.18, “C API Prepared Statement Handling of Date and Time Values”.

### 21.8.9.1 C API Prepared Statement Type Codes

The `buffer_type` member of `MYSQL_BIND` structures indicates the data type of the C language variable bound to a statement parameter or result set column. For input, `buffer_type` indicates the type of the variable containing the value to be sent to the server. For output, it indicates the type of the variable into which a value received from the server should be stored.

The following table shows the permissible values for the `buffer_type` member of `MYSQL_BIND` structures for input values sent to the server. The table shows the C variable types that you can use, the corresponding type codes, and the SQL data types for which the supplied value can be used without conversion. Choose the `buffer_type` value according to the data type of the C language variable that you are binding. For the integer types, you should also set the `is_unsigned` member to indicate whether the variable is signed or unsigned.

<table>
<thead>
<tr>
<th>Input Variable C Type</th>
<th>buffer_type Value</th>
<th>SQL Type of Destination Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>signed char</td>
<td>MYSQL_TYPE_TINY</td>
<td>TINYINT</td>
</tr>
<tr>
<td>short int</td>
<td>MYSQL_TYPE_SHORT</td>
<td>SMALLINT</td>
</tr>
<tr>
<td>int</td>
<td>MYSQL_TYPE_LONG</td>
<td>INT</td>
</tr>
<tr>
<td>long long int</td>
<td>MYSQL_TYPE_LONGLONG</td>
<td>BIGINT</td>
</tr>
<tr>
<td>float</td>
<td>MYSQL_TYPE_FLOAT</td>
<td>DOUBLE</td>
</tr>
<tr>
<td>double</td>
<td>MYSQL_TYPE_DOUBLE</td>
<td>TIME</td>
</tr>
<tr>
<td><code>MYSQL_TIME</code></td>
<td>MYSQL_TYPE_TIME</td>
<td>DATE</td>
</tr>
<tr>
<td><code>MYSQL_TIME</code></td>
<td>MYSQL_TYPE_DATE</td>
<td>DATETIME</td>
</tr>
<tr>
<td><code>MYSQL_TIME</code></td>
<td>MYSQL_TYPE_DATETIME</td>
<td>TIMESTAMP</td>
</tr>
<tr>
<td><code>MYSQL_TIME</code></td>
<td>MYSQL_TYPE_TIMESTAMP</td>
<td>TIMESTAMP</td>
</tr>
<tr>
<td>char[]</td>
<td>MYSQL_TYPE_STRING</td>
<td>TEXT, CHAR, VARCHAR</td>
</tr>
<tr>
<td>char[]</td>
<td>MYSQL_TYPE_BLOB</td>
<td>BLOB, BINARY, VARBINARY</td>
</tr>
<tr>
<td><code>MYSQL_TIME</code></td>
<td>MYSQL_TYPE_NULL</td>
<td>NULL</td>
</tr>
</tbody>
</table>

Use `MYSQL_TYPE_NULL` as indicated in the description for the `is_null` member in Section 21.8.9, “C API Prepared Statement Data Structures”.

For input string data, use `MYSQL_TYPE_STRING` or `MYSQL_TYPE_BLOB` depending on whether the value is a character (nonbinary) or binary string:

- `MYSQL_TYPE_STRING` indicates character input string data. The value is assumed to be in the character set indicated by the `character_set_client` system variable. If the server stores the value into a column with a different character set, it converts the value to that character set.

- `MYSQL_TYPE_BLOB` indicates binary input string data. The value is treated as having the `binary` character set. That is, it is treated as a byte string and no conversion occurs.

The following table shows the permissible values for the `buffer_type` member of `MYSQL_BIND` structures for output values received from the server. The table shows the SQL types of received values, the corresponding type codes that such values have in result set metadata, and the
recommended C language data types to bind to the `MYSQL_BIND` structure to receive the SQL values without conversion. Choose the `buffer_type` value according to the data type of the C language variable that you are binding. For the integer types, you should also set the `is_unsigned` member to indicate whether the variable is signed or unsigned.

<table>
<thead>
<tr>
<th>SQL Type of Received Value</th>
<th><code>buffer_type</code> Value</th>
<th>Output Variable C Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>TINYINT</td>
<td>MYSQL_TYPE_TINY</td>
<td>signed char</td>
</tr>
<tr>
<td>SMALLINT</td>
<td>MYSQL_TYPE_SHORT</td>
<td>short int</td>
</tr>
<tr>

<td>MYSQL_TYPE_NEWDECIMAL</td>
<td>char[]</td>
</tr>
<tr>
<td>YEAR</td>
<td>MYSQL_TYPE_SHORT</td>
<td>short int</td>
</tr>
<tr>
<td>TIME</td>
<td>MYSQL_TYPE_TIME</td>
<td>MYSQL_TIME</td>
</tr>
<tr>
<td>DATE</td>
<td>MYSQL_TYPE_DATE</td>
<td>MYSQL_TIME</td>
</tr>
<tr>
<td>DATETIME</td>
<td>MYSQL_TYPE_DATE_TIME</td>
<td>MYSQL_TIME</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>MYSQL_TYPE_TIMESTAMP</td>
<td>MYSQL_TIME</td>
</tr>
<tr>
<td>CHAR, BINARY</td>
<td>MYSQL_TYPE_STRING</td>
<td>char[]</td>
</tr>
<tr>
<td>VARCHAR, VARBINARY</td>
<td>MYSQL_TYPE_VAR_STRING</td>
<td>char[]</td>
</tr>
<tr>
<td>TINYBLOB, TINYTEXT</td>
<td>MYSQL_TYPE_TINY_BLOB</td>
<td>char[]</td>
</tr>
<tr>
<td>BLOB, TEXT</td>
<td>MYSQL_TYPE_BLOB</td>
<td>char[]</td>
</tr>
<tr>
<td>MEDIUMBLOB, MEDIUMTEXT</td>
<td>MYSQL_TYPE_MEDIUM_BLOB</td>
<td>char[]</td>
</tr>
<tr>
<td>LONGBLOB, LONGTEXT</td>
<td>MYSQL_TYPE_LONG_BLOB</td>
<td>char[]</td>
</tr>
<tr>
<td>BIT</td>
<td>MYSQL_TYPE_BIT</td>
<td>char[]</td>
</tr>
</tbody>
</table>

### 21.8.9.2 C API Prepared Statement Type Conversions

Prepared statements transmit data between the client and server using C language variables on the client side that correspond to SQL values on the server side. If there is a mismatch between the C variable type on the client side and the corresponding SQL value type on the server side, MySQL performs implicit type conversions in both directions.

MySQL knows the type code for the SQL value on the server side. The `buffer_type` value in the `MYSQL_BIND` structure indicates the type code of the C variable that holds the value on the client side. The two codes together tell MySQL what conversion must be performed, if any. Here are some examples:

- If you use `MYSQL_TYPE_LONG` with an `int` variable to pass an integer value to the server that is to be stored into a `FLOAT` column, MySQL converts the value to floating-point format before storing it.
- If you fetch an SQL `MEDIUMINT` column value, but specify a `buffer_type` value of `MYSQL_TYPE_LONGLONG` and use a C variable of type `long long int` as the destination buffer, MySQL converts the `MEDIUMINT` value (which requires less than 8 bytes) for storage into the `long long int` (an 8-byte variable).
- If you fetch a numeric column with a value of 255 into a `char[4]` character array and specify a `buffer_type` value of `MYSQL_TYPE_STRING`, the resulting value in the array is a 4-byte string `'255\0'`. 

2462
MySQL returns DECIMAL values as the string representation of the original server-side value, which is why the corresponding C type is char[]. For example, 12.345 is returned to the client as '12.345'. If you specify MYSQL_TYPE_NEWDECIMAL and bind a string buffer to the MYSQL_BIND structure, mysql_stmt_fetch() stores the value in the buffer as a string without conversion. If instead you specify a numeric variable and type code, mysql_stmt_fetch() converts the string-formal DECIMAL value to numeric form.

For the MYSQL_TYPE_BIT type code, BIT values are returned into a string buffer, which is why the corresponding C type is char[]. The value represents a bit string that requires interpretation on the client side. To return the value as a type that is easier to deal with, you can cause the value to be cast to integer using either of the following types of expressions:

```
SELECT bit_col + 0 FROM t
SELECT CAST(bit_col AS UNSIGNED) FROM t
```

To retrieve the value, bind an integer variable large enough to hold the value and specify the appropriate corresponding integer type code.

Before binding variables to the MYSQL_BIND structures that are to be used for fetching column values, you can check the type codes for each column of the result set. This might be desirable if you want to determine which variable types would be best to use to avoid type conversions. To get the type codes, call mysql_stmt_result_metadata() after executing the prepared statement with mysql_stmt_execute(). The metadata provides access to the type codes for the result set as described in Section 21.8.11.22, “mysql_stmt_result_metadata()”, and Section 21.8.5, “C API Data Structures”.

To determine whether output string values in a result set returned from the server contain binary or nonbinary data, check whether the charsetnr value of the result set metadata is 63 (see Section 21.8.5, “C API Data Structures”). If so, the character set is binary, which indicates binary rather than nonbinary data. This enables you to distinguish BINARY from CHAR, VARBINARY from VARCHAR, and the BLOB types from the TEXT types.

If you cause the max_length member of the MYSQL_FIELD column metadata structures to be set (by calling mysql_stmt_attr_set()), be aware that the max_length values for the result set indicate the lengths of the longest string representation of the result values, not the lengths of the binary representation. That is, max_length does not necessarily correspond to the size of the buffers needed to fetch the values with the binary protocol used for prepared statements. Choose the size of the buffers according to the types of the variables into which you fetch the values. For example, a TINYINT column containing the value -128 might have a max_length value of 4. But the binary representation of any TINYINT value requires only 1 byte for storage, so you can supply a signed char variable in which to store the value and set is_unsigned to indicate that values are signed.

As of MySQL 5.1.25, metadata changes to tables or views referred to by prepared statements are detected and cause automatic repreparation of the statement when it is next executed. For more information, see Section 13.5.4, “Automatic Prepared Statement Repreparation”.

### 21.8.10 C API Prepared Statement Function Overview

The functions available for prepared statement processing are summarized here and described in greater detail in a later section. See Section 21.8.11, “C API Prepared Statement Function Descriptions”.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql_stmt_affected_rows()</td>
<td>Returns the number of rows changed, deleted, or inserted by prepared UPDATE, DELETE, or INSERT statement</td>
</tr>
<tr>
<td>mysql_stmt_attr_get()</td>
<td>Gets value of an attribute for a prepared statement</td>
</tr>
<tr>
<td>mysql_stmt_attr_set()</td>
<td>Sets an attribute for a prepared statement</td>
</tr>
</tbody>
</table>
### C API Prepared Statement Function Overview

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql_stmt_bind_param()</td>
<td>Associates application data buffers with the parameter markers in a prepared SQL statement</td>
</tr>
<tr>
<td>mysql_stmt_bind_result()</td>
<td>Associates application data buffers with columns in a result set</td>
</tr>
<tr>
<td>mysql_stmt_close()</td>
<td>Frees memory used by a prepared statement</td>
</tr>
<tr>
<td>mysql_stmt_data_seek()</td>
<td>Seeks to an arbitrary row number in a statement result set</td>
</tr>
<tr>
<td>mysql_stmt_errno()</td>
<td>Returns the error number for the last statement execution</td>
</tr>
<tr>
<td>mysql_stmt_error()</td>
<td>Returns the error message for the last statement execution</td>
</tr>
<tr>
<td>mysql_stmt_execute()</td>
<td>Executes a prepared statement</td>
</tr>
<tr>
<td>mysql_stmt_fetch()</td>
<td>Fetches the next row of data from a result set and returns data for all bound columns</td>
</tr>
<tr>
<td>mysql_stmt_fetch_column()</td>
<td>Fetch data for one column of the current row of a result set</td>
</tr>
<tr>
<td>mysql_stmt_field_count()</td>
<td>Returns the number of result columns for the most recent statement</td>
</tr>
<tr>
<td>mysql_stmt_free_result()</td>
<td>Free the resources allocated to a statement handle</td>
</tr>
<tr>
<td>mysql_stmt_init()</td>
<td>Allocates memory for a MYSQL_STMT structure and initializes it</td>
</tr>
<tr>
<td>mysql_stmt_insert_id()</td>
<td>Returns the ID generated for an AUTO_INCREMENT column by a prepared statement</td>
</tr>
<tr>
<td>mysql_stmt_num_rows()</td>
<td>Returns the row count from a buffered statement result set</td>
</tr>
<tr>
<td>mysql_stmt_param_count()</td>
<td>Returns the number of parameters in a prepared statement</td>
</tr>
<tr>
<td>mysql_stmt_param_metadata()</td>
<td>(Return parameter metadata in the form of a result set) This function does nothing</td>
</tr>
<tr>
<td>mysql_stmt_prepare()</td>
<td>Prepares an SQL statement string for execution</td>
</tr>
<tr>
<td>mysql_stmt_reset()</td>
<td>Resets the statement buffers in the server</td>
</tr>
<tr>
<td>mysql_stmt_result_metadata()</td>
<td>Returns prepared statement metadata in the form of a result set</td>
</tr>
<tr>
<td>mysql_stmt_row_seek()</td>
<td>Seeks to a row offset in a statement result set, using value returned from mysql_stmt_row_tell()</td>
</tr>
<tr>
<td>mysql_stmt_row_tell()</td>
<td>Returns the statement row cursor position</td>
</tr>
<tr>
<td>mysql_stmt_send_long_data()</td>
<td>Sends long data in chunks to server</td>
</tr>
<tr>
<td>mysql_stmt_sqlstate()</td>
<td>Returns the SQLSTATE error code for the last statement execution</td>
</tr>
<tr>
<td>mysql_stmt_store_result()</td>
<td>Retrieves a complete result set to the client</td>
</tr>
</tbody>
</table>

Call `mysql_stmt_init()` to create a statement handle, then `mysql_stmt_prepare()` to prepare the statement string, `mysql_stmt_bind_param()` to supply the parameter data, and `mysql_stmt_execute()` to execute the statement. You can repeat the `mysql_stmt_execute()` by changing parameter values in the respective buffers supplied through `mysql_stmt_bind_param()`.

You can send text or binary data in chunks to server using `mysql_stmt_send_long_data()`. See Section 21.8.11.25, “mysql_stmt_send_long_data()”.

If the statement is a `SELECT` or any other statement that produces a result set, `mysql_stmt_prepare()` also returns the result set metadata information in the form of a MYSQL_RES result set through `mysql_stmt_result_metadata()`.

You can supply the result buffers using `mysql_stmt_bind_result()`, so that the `mysql_stmt_fetch()` automatically returns data to these buffers. This is row-by-row fetching.

When statement execution has been completed, close the statement handle using `mysql_stmt_close()` so that all resources associated with it can be freed.
If you obtained a `SELECT` statement's result set metadata by calling `mysql_stmt_result_metadata()`, you should also free the metadata using `mysql_free_result()`.

**Execution Steps**

To prepare and execute a statement, an application follows these steps:

1. Create a prepared statement handle with `mysql_stmt_init()`. To prepare the statement on the server, call `mysql_stmt_prepare()` and pass it a string containing the SQL statement.

2. If the statement will produce a result set, call `mysql_stmt_result_metadata()` to obtain the result set metadata. This metadata is itself in the form of result set, albeit a separate one from the one that contains the rows returned by the query. The metadata result set indicates how many columns are in the result and contains information about each column.

3. Set the values of any parameters using `mysql_stmt_bind_param()`. All parameters must be set. Otherwise, statement execution returns an error or produces unexpected results.

4. Call `mysql_stmt_execute()` to execute the statement.

5. If the statement produces a result set, bind the data buffers to use for retrieving the row values by calling `mysql_stmt_bind_result()`.

6. Fetch the data into the buffers row by row by calling `mysql_stmt_fetch()` repeatedly until no more rows are found.

7. Repeat steps 3 through 6 as necessary, by changing the parameter values and re-executing the statement.

When `mysql_stmt_prepare()` is called, the MySQL client/server protocol performs these actions:

- The server parses the statement and sends the okay status back to the client by assigning a statement ID. It also sends total number of parameters, a column count, and its metadata if it is a result set oriented statement. All syntax and semantics of the statement are checked by the server during this call.

- The client uses this statement ID for the further operations, so that the server can identify the statement from among its pool of statements.

When `mysql_stmt_execute()` is called, the MySQL client/server protocol performs these actions:

- The client uses the statement handle and sends the parameter data to the server.

- The server identifies the statement using the ID provided by the client, replaces the parameter markers with the newly supplied data, and executes the statement. If the statement produces a result set, the server sends the data back to the client. Otherwise, it sends an okay status and the number of rows changed, deleted, or inserted.

When `mysql_stmt_fetch()` is called, the MySQL client/server protocol performs these actions:

- The client reads the data from the current row of the result set and places it into the application data buffers by doing the necessary conversions. If the application buffer type is same as that of the field type returned from the server, the conversions are straightforward.

If an error occurs, you can get the statement error number, error message, and SQLSTATE code using `mysql_stmt_errno()`, `mysql_stmt_error()`, and `mysql_stmt_sqlstate()`, respectively.

**Prepared Statement Logging**

For prepared statements that are executed with the `mysql_stmt_prepare()` and `mysql_stmt_execute()` C API functions, the server writes `Prepare` and `Execute` lines to the general query log so that you can tell when statements are prepared and executed.
Suppose that you prepare and execute a statement as follows:

1. Call `mysql_stmt_prepare()` to prepare the statement string "SELECT ?".
2. Call `mysql_stmt_bind_param()` to bind the value 3 to the parameter in the prepared statement.
3. Call `mysql_stmt_execute()` to execute the prepared statement.

As a result of the preceding calls, the server writes the following lines to the general query log:

<table>
<thead>
<tr>
<th>Prepare</th>
<th>Execute</th>
</tr>
</thead>
</table>

Each `Prepare` and `Execute` line in the log is tagged with a `[N]` statement identifier so that you can keep track of which prepared statement is being logged. N is a positive integer. If there are multiple prepared statements active simultaneously for the client, N may be greater than 1. Each `Execute` line shows a prepared statement after substitution of data values for ? parameters.

### 21.8.11 C API Prepared Statement Function Descriptions

To prepare and execute queries, use the functions described in detail in the following sections.

All functions that operate with a `MYSQL_STMT` structure begin with the prefix `mysql_stmt_`.

To create a `MYSQL_STMT` handle, use the `mysql_stmt_init()` function.

#### 21.8.11.1 `mysql_stmt_affected_rows()`

```c
my_ulonglong mysql_stmt_affected_rows(MYSQL_STMT *stmt)
```

**Description**

`mysql_stmt_affected_rows()` may be called immediately after executing a statement with `mysql_stmt_execute()`. It is like `mysql_affected_rows()` but for prepared statements. For a description of what the affected-rows value returned by this function means, see Section 21.8.7.1, "mysql_affected_rows()".

**Errors**

None.

**Example**

See the Example in Section 21.8.11.10, "mysql_stmt_execute()".

#### 21.8.11.2 `mysql_stmt_attr_get()`

```c
my_bool mysql_stmt_attr_get(MYSQL_STMT *stmt, enum enum_stmt_attr_type option, void *arg)
```

**Description**

Can be used to get the current value for a statement attribute.

The `option` argument is the option that you want to get; the `arg` should point to a variable that should contain the option value. If the option is an integer, `arg` should point to the value of the integer.

See Section 21.8.11.3, “mysql_stmt_attr_set()”, for a list of options and option types.

**Note**

In MySQL 5.1, `mysql_stmt_attr_get()` originally used `unsigned long *`, not `my_bool *`, for `STMT_ATTR_UPDATE_MAX_LENGTH`. This was corrected in MySQL 5.1.7.
Return Values
Zero for success. Nonzero if `option` is unknown.

Errors
None.

21.8.11.3 `mysql_stmt_attr_set()`

```c
my_bool mysql_stmt_attr_set(MYSQL_STMT *stmt, enum enum_stmt_attr_type option, const void *arg)
```

Description
Can be used to affect behavior for a prepared statement. This function may be called multiple times to set several options.

The `option` argument is the option that you want to set. The `arg` argument is the value for the option. `arg` should point to a variable that is set to the desired attribute value. The variable type is as indicated in the following table.

The following table shows the possible `option` values.

<table>
<thead>
<tr>
<th>Option</th>
<th>Argument Type</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>STMT_ATTR_UPDATE_MAX_LENGTH</td>
<td>my_bool</td>
<td>If set to 1, causes <code>mysql_stmt_store_result()</code> to update the metadata <code>MYSQL_FIELD-&gt;max_length</code> value.</td>
</tr>
<tr>
<td>STMT_ATTR_CURSOR_TYPE</td>
<td>unsigned long</td>
<td>Type of cursor to open for statement when <code>mysql_stmt_execute()</code> is invoked. *arg can be <code>CURSOR_TYPE_NO_CURSOR</code> (the default) or <code>CURSOR_TYPE_READ_ONLY</code>.</td>
</tr>
<tr>
<td>STMT_ATTR_PREFETCH_ROWS</td>
<td>unsigned long</td>
<td>Number of rows to fetch from server at a time when using a cursor. *arg can be in the range from 1 to the maximum value of <code>unsigned long</code>. The default is 1.</td>
</tr>
</tbody>
</table>

If you use the `STMT_ATTR_CURSOR_TYPE` option with `CURSOR_TYPE_READ_ONLY`, a cursor is opened for the statement when you invoke `mysql_stmt_execute()`. If there is already an open cursor from a previous `mysql_stmt_execute()` call, it closes the cursor before opening a new one. `mysql_stmt_reset()` also closes any open cursor before preparing the statement for re-execution. `mysql_stmt_free_result()` closes any open cursor.

If you open a cursor for a prepared statement, `mysql_stmt_store_result()` is unnecessary, because that function causes the result set to be buffered on the client side.

Return Values
Zero for success. Nonzero if `option` is unknown.

Errors
None.

Example
The following example opens a cursor for a prepared statement and sets the number of rows to fetch at a time to 5:
21.8.11.4 mysql_stmt_bind_param()

my_bool mysql_stmt_bind_param(MYSQL_STMT *stmt, MYSQL_BIND *bind)

Description

mysql_stmt_bind_param() is used to bind input data for the parameter markers in the SQL statement that was passed to mysql_stmt_prepare(). It uses MYSQL_BIND structures to supply the data. bind is the address of an array of MYSQL_BIND structures. The client library expects the array to contain one element for each ? parameter marker that is present in the query.

Suppose that you prepare the following statement:

```
INSERT INTO mytbl VALUES(?,?,?)
```

When you bind the parameters, the array of MYSQL_BIND structures must contain three elements, and can be declared like this:

```
MYSQL_BIND bind[3];
```

Section 21.8.9, "C API Prepared Statement Data Structures", describes the members of each MYSQL_BIND element and how they should be set to provide input values.

Return Values

Zero for success. Nonzero if an error occurred.

Errors

- **CR_UNSUPPORTED_PARAM_TYPE**
  The conversion is not supported. Possibly the buffer_type value is invalid or is not one of the supported types.

- **CR_OUT_OF_MEMORY**
  Out of memory.

- **CR_UNKNOWN_ERROR**
  An unknown error occurred.

Example

See the Example in Section 21.8.11.10, "mysql_stmt_execute()".

21.8.11.5 mysql_stmt_bind_result()
**Description**

`mysql_stmt_bind_result()` is used to associate (that is, bind) output columns in the result set to data buffers and length buffers. When `mysql_stmt_fetch()` is called to fetch data, the MySQL client/server protocol places the data for the bound columns into the specified buffers.

All columns must be bound to buffers prior to calling `mysql_stmt_fetch()`. `bind` is the address of an array of `MYSQL_BIND` structures. The client library expects the array to contain one element for each column of the result set. If you do not bind columns to `MYSQL_BIND` structures, `mysql_stmt_fetch()` simply ignores the data fetch. The buffers should be large enough to hold the data values, because the protocol does not return data values in chunks.

A column can be bound or rebound at any time, even after a result set has been partially retrieved. The new binding takes effect the next time `mysql_stmt_fetch()` is called. Suppose that an application binds the columns in a result set and calls `mysql_stmt_fetch()`. The client/server protocol returns data in the bound buffers. Then suppose that the application binds the columns to a different set of buffers. The protocol places data into the newly bound buffers when the next call to `mysql_stmt_fetch()` occurs.

To bind a column, an application calls `mysql_stmt_bind_result()` and passes the type, address, and length of the output buffer into which the value should be stored. Section 21.8.9, “C API Prepared Statement Data Structures”, describes the members of each `MYSQL_BIND` element and how they should be set to receive output values.

**Return Values**

Zero for success. Nonzero if an error occurred.

**Errors**

- **CR_UNSUPPORTED_PARAM_TYPE**
  
  The conversion is not supported. Possibly the `buffer_type` value is invalid or is not one of the supported types.

- **CR_OUT_OF_MEMORY**
  
  Out of memory.

- **CR_UNKNOWN_ERROR**
  
  An unknown error occurred.

**Example**

See the Example in Section 21.8.11.11, “mysql_stmt_fetch()”.

**21.8.11.6 mysql_stmt_close()**

```c
my_bool mysql_stmt_close(MYSQL_STMT *)
```

**Description**

Closes the prepared statement. `mysql_stmt_close()` also deallocates the statement handle pointed to by `stmt`.

If the current statement has pending or unread results, this function cancels them so that the next query can be executed.

**Return Values**

Zero for success. Nonzero if an error occurred.
Errors

- **CR_SERVER_GONE_ERROR**
  The MySQL server has gone away.
- **CR_UNKNOWN_ERROR**
  An unknown error occurred.

Example

See the Example in Section 21.8.11.10, "mysql_stmt_execute()".

21.8.11.7 mysql_stmt_data_seek()

```c
void mysql_stmt_data_seek(MYSQL_STMT *stmt, my_ulonglong offset)
```

Description

Seeks to an arbitrary row in a statement result set. The `offset` value is a row number and should be in the range from 0 to `mysql_stmt_num_rows(stmt)-1`.

This function requires that the statement result set structure contains the entire result of the last executed query, so `mysql_stmt_data_seek()` may be used only in conjunction with `mysql_stmt_store_result()`.

Return Values

- None.

Errors

- None.

21.8.11.8 mysql_stmt_errno()

```c
unsigned int mysql_stmt_errno(MYSQL_STMT *stmt)
```

Description

For the statement specified by `stmt`, `mysql_stmt_errno()` returns the error code for the most recently invoked statement API function that can succeed or fail. A return value of zero means that no error occurred. Client error message numbers are listed in the MySQL `errmsg.h` header file. Server error message numbers are listed in `mysqld_error.h`. Errors also are listed at Appendix B, Errors, Error Codes, and Common Problems.

Return Values

- An error code value. Zero if no error occurred.

Errors

- None.

21.8.11.9 mysql_stmt_error()

```c
const char *mysql_stmt_error(MYSQL_STMT *stmt)
```

Description

For the statement specified by `stmt`, `mysql_stmt_error()` returns a null-terminated string containing the error message for the most recently invoked statement API function that can succeed or fail. An empty string (""") is returned if no error occurred. Either of these two tests can be used to check for an error:
if(*mysql_stmt_errno(stmt))
{
    // an error occurred
}
if (mysql_stmt_error(stmt)[0])
{
    // an error occurred
}

The language of the client error messages may be changed by recompiling the MySQL client library. You can choose error messages in several different languages.

Return Values
A character string that describes the error. An empty string if no error occurred.

Errors
None.

21.8.11.10 mysql_stmt_execute()

    int mysql_stmt_execute(MYSQL_STMT *stmt)

Description

mysql_stmt_execute() executes the prepared query associated with the statement handle. The currently bound parameter marker values are sent to server during this call, and the server replaces the markers with this newly supplied data.

Statement processing following mysql_stmt_execute() depends on the type of statement:

• For an UPDATE, DELETE, or INSERT, the number of changed, deleted, or inserted rows can be found by calling mysql_stmt_affected_rows().

• For a statement such as SELECT that generates a result set, you must call mysql_stmt_fetch() to fetch the data prior to calling any other functions that result in query processing. For more information on how to fetch the results, refer to Section 21.8.11.11, “mysql_stmt_fetch()”.

Do not following invocation of mysql_stmt_execute() with a call to mysql_store_result() or mysql_use_result(). Those functions are not intended for processing results from prepared statements.

For statements that generate a result set, you can request that mysql_stmt_execute() open a cursor for the statement by calling mysql_stmt_attr_set() before executing the statement. If you execute a statement multiple times, mysql_stmt_execute() closes any open cursor before opening a new one.

As ofMySQL 5.1.25, metadata changes to tables or views referred to by prepared statements are detected and cause automatic repreparation of the statement when it is next executed. For more information, see Section 13.5.4, “Automatic Prepared Statement Repreparation”.

Return Values
Zero for success. Nonzero if an error occurred.

Errors

• CR_COMMANDS_OUT_OF_SYNC

  Commands were executed in an improper order.

• CR_OUT_OF_MEMORY
Out of memory.

- **CR_SERVER_GONE_ERROR**
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  An unknown error occurred.

**Example**

The following example demonstrates how to create and populate a table using `mysql_stmt_init()`, `mysql_stmt_prepare()`, `mysql_stmt_param_count()`, `mysql_stmt_bind_param()`, `mysql_stmt_execute()`, and `mysql_stmt_affected_rows()`. The `mysql` variable is assumed to be a valid connection handle. For an example that shows how to retrieve data, see Section 21.8.11.11, “mysql_stmt_fetch()”.

```c
#define STRING_SIZE 50
#define DROP_SAMPLE_TABLE "DROP TABLE IF EXISTS test_table"
#define CREATE_SAMPLE_TABLE "CREATE TABLE test_table(col1 INT,\n    col2 VARCHAR(40),\n    col3 SMALLINT,\n    col4 TIMESTAMP)"
#define INSERT_SAMPLE "INSERT INTO \n    test_table(col1,col2,col3) \n    VALUES(?,?,?)"

MYSQL_STMT *stmt;
MYSQL_BIND bind[3];
my_ulonglong affected_rows;
int param_count;
short small_data;
uint int_data;
char str_data[STRING_SIZE];
unsigned long str_length;
my_bool is_null;

if (mysql_query(mysql, DROP_SAMPLE_TABLE))
{
    fprintf(stderr, " DROP TABLE failed\n");
    fprintf(stderr, " %s\n", mysql_error(mysql));
    exit(0);
}

if (mysql_query(mysql, CREATE_SAMPLE_TABLE))
{
    fprintf(stderr, " CREATE TABLE failed\n");
    fprintf(stderr, " %s\n", mysql_error(mysql));
    exit(0);
}

/* Prepare an INSERT query with 3 parameters */
/* (the TIMESTAMP column is not named; the server */
/*  sets it to the current date and time) */
stmt = mysql_stmt_init(mysql);
if (!stmt)
{
    fprintf(stderr, " mysql_stmt_init(), out of memory\n");
    exit(0);
}
if (mysql_stmt_prepare(stmt, INSERT_SAMPLE, strlen(INSERT_SAMPLE)))
{
```

    fprintf(stderr, " mysql_stmt_execute() failed\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

/* Get the number of affected rows */
affected_rows= mysql_stmt_affected_rows(stmt);
fprintf(stdout, " total affected rows(insert 1): %lu\n",
(unsigned long) affected_rows);
if (affected_rows != 1) /* validate affected rows */
{
Note

For complete examples on the use of prepared statement functions, refer to the file `tests/mysql_client_test.c`. This file can be obtained from a MySQL source distribution or from the source repository (see Section 2.11, “Installing MySQL from Source”).

21.8.11.11 mysql_stmt_fetch()

```c
int mysql_stmt_fetch(MYSQL_STMT *stmt)
```

Description

`mysql_stmt_fetch()` returns the next row in the result set. It can be called only while the result set exists; that is, after a call to `mysql_stmt_execute()` for a statement such as `SELECT` that produces a result set.

`mysql_stmt_fetch()` returns row data using the buffers bound by `mysql_stmt_bind_result()`. It returns the data in those buffers for all the columns in the current row set and the lengths are returned to the `length` pointer. All columns must be bound by the application before it calls `mysql_stmt_fetch()`.

By default, result sets are fetched unbuffered a row at a time from the server. To buffer the entire result set on the client, call `mysql_stmt_store_result()` after binding the data buffers and before calling `mysql_stmt_fetch()`.
If a fetched data value is a `NULL` value, the `*is_null` value of the corresponding `MYSQL_BIND` structure contains TRUE (1). Otherwise, the data and its length are returned in the `*buffer` and `*length` elements based on the buffer type specified by the application. Each numeric and temporal type has a fixed length, as listed in the following table. The length of the string types depends on the length of the actual data value, as indicated by `data_length`.

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>MYSQL_TYPE_TINY</td>
<td>1</td>
</tr>
<tr>
<td>MYSQL_TYPE_SHORT</td>
<td>2</td>
</tr>
<tr>
<td>MYSQL_TYPE_LONG</td>
<td>4</td>
</tr>
<tr>
<td>MYSQL_TYPE_LONGLONG</td>
<td>8</td>
</tr>
<tr>
<td>MYSQL_TYPE_FLOAT</td>
<td>4</td>
</tr>
<tr>
<td>MYSQL_TYPE_DOUBLE</td>
<td>8</td>
</tr>
<tr>
<td>MYSQL_TYPE_TIME</td>
<td><code>sizeof(MYSQL_TIME)</code></td>
</tr>
<tr>
<td>MYSQL_TYPE_DATE</td>
<td><code>sizeof(MYSQL_TIME)</code></td>
</tr>
<tr>
<td>MYSQL_TYPE_DATETIME</td>
<td><code>sizeof(MYSQL_TIME)</code></td>
</tr>
<tr>
<td>MYSQL_TYPE_STRING</td>
<td><code>data_length</code></td>
</tr>
<tr>
<td>MYSQL_TYPE_BLOB</td>
<td><code>data_length</code></td>
</tr>
</tbody>
</table>

In some cases you might want to determine the length of a column value before fetching it with `mysql_stmt_fetch()`. For example, the value might be a long string or a `BLOB` value for which you want to know how much space must be allocated. To accomplish this, you can use these strategies:

- Before invoking `mysql_stmt_fetch()` to retrieve individual rows, pass `STMT_ATTR_UPDATE_MAX_LENGTH` to `mysql_stmt_attr_set()`, then invoke `mysql_stmt_store_result()` to buffer the entire result on the client side. Setting the `STMT_ATTR_UPDATE_MAX_LENGTH` attribute causes the maximal length of column values to be indicated by the `max_length` member of the result set metadata returned by `mysql_stmt_result_metadata()`.

- Invoke `mysql_stmt_fetch()` with a zero-length buffer for the column in question and a pointer in which the real length can be stored. Then use the real length with `mysql_stmt_fetch_column()`.

```c
real_length= 0;
bind[0].buffer= 0;
bind[0].buffer_length= 0;
bind[0].length= &real_length
mysql_stmt_bind_result(stmt, bind);
mysql_stmt_fetch(stmt);
if (real_length > 0)
{
    data= malloc(real_length);
    bind[0].buffer= data;
    bind[0].buffer_length= real_length;
    mysql_stmt_fetch_column(stmt, bind, 0, 0);
}
```

### Return Values

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Successful, the data has been fetched to application data buffers.</td>
</tr>
<tr>
<td>1</td>
<td>Error occurred. Error code and message can be obtained by calling <code>mysql_stmt_errno()</code> and <code>mysql_stmt_error()</code>.</td>
</tr>
<tr>
<td>MYSQL_NO_DATA</td>
<td>No more rows/data exists</td>
</tr>
</tbody>
</table>
Return Value | Description
--- | ---
MySQL_DATA_TRUNCATED | Data truncation occurred

**MySQL_DATA_TRUNCATED** is returned when truncation reporting is enabled. To determine which column values were truncated when this value is returned, check the error members of the MySQL_BIND structures used for fetching values. Truncation reporting is enabled by default, but can be controlled by calling mysql_options() with the MYSQL_REPORT_DATA_TRUNCATION option.

**Errors**

- **CR_COMMANDS_OUT_OF_SYNC**
  Commands were executed in an improper order.

- **CR_OUT_OF_MEMORY**
  Out of memory.

- **CR_SERVER_GONE_ERROR**
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  An unknown error occurred.

- **CR_UNSUPPORTED_PARAM_TYPE**
  The buffer type is MYSQL_TYPE_DATE, MYSQL_TYPE_TIME, MYSQL_TYPE_DATETIME, or MYSQL_TYPE_TIMESTAMP, but the data type is not DATE, TIME, DATETIME, or TIMESTAMP.

  All other unsupported conversion errors are returned from mysql_stmt_bind_result().

**Example**

The following example demonstrates how to fetch data from a table using mysql_stmt_result_metadata(), mysql_stmt_bind_result(), and mysql_stmt_fetch().

(This example expects to retrieve the two rows inserted by the example shown in Section 21.8.11.10, “mysql_stmt_execute().”) The mysql variable is assumed to be a valid connection handle.

```c
#define STRING_SIZE 50
#define SELECT_SAMPLE "SELECT col1, col2, col3, col4 \ FROM test_table"

MYSQL_STMT *stmt;
MYSQL_BIND bind[4];
MYSQL_RES *prepare_meta_result;
MYSQL_TIME ts;
unsigned long length[4];
int param_count, column_count, row_count;
short small_data;
int int_data;
char str_data[STRING_SIZE];
my_bool is_null[4];
my_bool error[4];

/* Prepare a SELECT query to fetch data from test_table */
stmt = mysql_stmt_init(mysql);
if (!stmt)
{
```
fprintf(stderr, " mysql_stmt_init(), out of memory\n");
exit(0);
}
if (mysql_stmt_prepare(stmt, SELECT_SAMPLE, strlen(SELECT_SAMPLE)))
{
 fprintf(stderr, " mysql_stmt_prepare(), SELECT failed\n");
 fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
 exit(0);
}
fprintf(stdout, " prepare, SELECT successful\n");
/* Get the parameter count from the statement */
param_count = mysql_stmt_param_count(stmt);
fprintf(stdout, " total parameters in SELECT: %d\n", param_count);
if (param_count != 0) /* validate parameter count */
{
 fprintf(stderr, " invalid parameter count returned by MySQL\n");
 exit(0);
}
/* Fetch result set meta information */
prepare_meta_result = mysql_stmt_result_metadata(stmt);
if (!prepare_meta_result)
{
 fprintf(stderr,
 " mysql_stmt_result_metadata(), \n returned no meta information\n\n";
 fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
 exit(0);
}
/* Get total columns in the query */
column_count = mysql_num_fields(prepare_meta_result);
fprintf(stdout,
 " total columns in SELECT statement: %d\n",
 column_count);
if (column_count != 4) /* validate column count */
{
 fprintf(stderr, " invalid column count returned by MySQL\n");
 exit(0);
}
/* Execute the SELECT query */
if (mysql_stmt_execute(stmt))
{
 fprintf(stderr, " mysql_stmt_execute(), failed\n");
 fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
 exit(0);
}
/* Bind the result buffers for all 4 columns before fetching them */
memset(bind, 0, sizeof(bind));

/* INTEGER COLUMN */

    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

/* Now buffer all results to client (optional step) */
if (mysql_stmt_store_result(stmt))
{
    fprintf(stderr, " mysql_stmt_store_result() failed\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

/* Fetch all rows */
row_count= 0;
fprintf(stdout, "Fetching results ...
");
while (!mysql_stmt_fetch(stmt))
{
    row_count++;
    fprintf(stdout, " row %d\n", row_count);

    /* column 1 */
    if (is_null[0])
    {
        fprintf(stdout, " NULL\n");
    }
    else
    {
        fprintf(stdout, " %d(%ld)\n", int_data, length[0]);
    }

    /* column 2 */
    if (is_null[1])
    {
        fprintf(stdout, " NULL\n");
    }
    else
    {
        fprintf(stdout, " %s(%ld)\n", str_data, length[1]);
    }

    /* column 3 */
    if (is_null[2])
    {
        fprintf(stdout, " NULL\n");
    }
    else
    {
        fprintf(stdout, " %d(%ld)\n", small_data, length[2]);
    }

    /* column 4 */
    if (is_null[3])
    {
        fprintf(stdout, " NULL\n");
    }
    else
    {
        fprintf(stdout, " %04d-%02d-%02d %02d:%02d:%02d (%ld)\n",
            ts.year, ts.month, ts.day,
            ts.hour, ts.minute, ts.second,
            length[3]);
        fprintf(stdout, "\n");
    }

    /* Validate rows fetched */
    fprintf(stdout, " total rows fetched: %d\n", row_count);
if (row_count != 2)
{
    fprintf(stderr, " MySQL failed to return all rows\n");
    exit(0);
}

/* Free the prepared result metadata */
mysql_free_result(prepare_meta_result);

/* Close the statement */
if (mysql_stmt_close(stmt))
{
    fprintf(stderr, " failed while closing the statement\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

21.8.11.12 mysql_stmt_fetch_column()

int mysql_stmt_fetch_column(MYSQL_STMT *stmt, MYSQL_BIND *bind, unsigned int column, unsigned long offset)

Description

Fetch one column from the current result set row. bind provides the buffer where data should be placed. It should be set up the same way as for mysql_stmt_bind_result(). column indicates which column to fetch. The first column is numbered 0. offset is the offset within the data value at which to begin retrieving data. This can be used for fetching the data value in pieces. The beginning of the value is offset 0.

Return Values

Zero for success. Nonzero if an error occurred.

Errors

• CR_INVALID_PARAMETER_NO
  Invalid column number.

• CR_NO_DATA
  The end of the result set has already been reached.

21.8.11.13 mysql_stmt_field_count()

unsigned int mysql_stmt_field_count(MYSQL_STMT *stmt)

Description

Returns the number of columns for the most recent statement for the statement handler. This value is zero for statements such as INSERT or DELETE that do not produce result sets.

mysql_stmt_field_count() can be called after you have prepared a statement by invoking mysql_stmt_prepare().

Return Values

An unsigned integer representing the number of columns in a result set.

Errors

None.
21.8.11.14 mysql_stmt_free_result()

my_bool mysql_stmt_free_result(MYSQL_STMT *stmt)

Description

Releases memory associated with the result set produced by execution of the prepared statement. If there is a cursor open for the statement, mysql_stmt_free_result() closes it.

Return Values

Zero for success. Nonzero if an error occurred.

Errors

21.8.11.15 mysql_stmt_init()

MYSQL_STMT *mysql_stmt_init(MYSQL *mysql)

Description

Create a MYSQL_STMT handle. The handle should be freed with mysql_stmt_close(MYSQL_STMT *).

See also Section 21.8.9, “C API Prepared Statement Data Structures”, for more information.

Return Values

A pointer to a MYSQL_STMT structure in case of success. NULL if out of memory.

Errors

• CR_OUT_OF_MEMORY

Out of memory.

21.8.11.16 mysql_stmt_insert_id()

my_ulonglong mysql_stmt_insert_id(MYSQL_STMT *stmt)

Description

Returns the value generated for an AUTO_INCREMENT column by the prepared INSERT or UPDATE statement. Use this function after you have executed a prepared INSERT statement on a table which contains an AUTO_INCREMENT field.

See Section 21.8.7.37, “mysql_insert_id()”, for more information.

Return Values

Value for AUTO_INCREMENT column which was automatically generated or explicitly set during execution of prepared statement, or value generated by LAST_INSERT_ID(expr) function. Return value is undefined if statement does not set AUTO_INCREMENT value.

Errors

None.

21.8.11.17 mysql_stmt_num_rows()
my_ulonglong mysql_stmt_num_rows(MYSQL_STMT *stmt)

**Description**

Returns the number of rows in the result set.

The use of `mysql_stmt_num_rows()` depends on whether you used
`mysql_stmt_store_result()` to buffer the entire result set in the statement handle. If you use
`mysql_stmt_store_result()`, `mysql_stmt_num_rows()` may be called immediately. Otherwise,
the row count is unavailable unless you count the rows as you fetch them.

`mysql_stmt_num_rows()` is intended for use with statements that return a result set, such as
`SELECT`. For statements such as `INSERT`, `UPDATE`, or `DELETE`, the number of affected rows can be
obtained with `mysql_stmt_affected_rows()`.

**Return Values**

The number of rows in the result set.

**Errors**

None.

21.8.11.18 mysql_stmt_param_count()

unsigned long mysql_stmt_param_count(MYSQL_STMT *stmt)

**Description**

Returns the number of parameter markers present in the prepared statement.

**Return Values**

An unsigned long integer representing the number of parameters in a statement.

**Errors**

None.

21.8.11.19 mysql_stmt_param_metadata()

MYSQL_RES *mysql_stmt_param_metadata(MYSQL_STMT *stmt)

This function currently does nothing.

**Description**

**Return Values**

**Errors**

21.8.11.20 mysql_stmt_prepare()
Description

Given the statement handle returned by `mysql_stmt_init()`, prepares the SQL statement pointed to by the string `stmt_str` and returns a status value. The string length should be given by the `length` argument. The string must consist of a single SQL statement. You should not add a terminating semicolon (`;`) or `\g` to the statement.

The application can include one or more parameter markers in the SQL statement by embedding question mark (`) characters into the SQL string at the appropriate positions.

The markers are legal only in certain places in SQL statements. For example, they are permitted in the `VALUES()` list of an `INSERT` statement (to specify column values for a row), or in a comparison with a column in a `WHERE` clause to specify a comparison value. However, they are not permitted for identifiers (such as table or column names), or to specify both operands of a binary operator such as the `=` equal sign. The latter restriction is necessary because it would be impossible to determine the parameter type. In general, parameters are legal only in Data Manipulation Language (DML) statements, and not in Data Definition Language (DDL) statements.

The parameter markers must be bound to application variables using `mysql_stmt_bind_param()` before executing the statement.

Return Values

Zero for success. Nonzero if an error occurred.

Errors

- **CR_COMMANDS_OUT_OF_SYNC**
  
  Commands were executed in an improper order.

- **CR_OUT_OF_MEMORY**
  
  Out of memory.

- **CR_SERVER_GONE_ERROR**
  
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  
  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  
  An unknown error occurred.

If the prepare operation was unsuccessful (that is, `mysql_stmt_prepare()` returns nonzero), the error message can be obtained by calling `mysql_stmt_error()`.

Example

See the Example in Section 21.8.11.10, "mysql_stmt_execute()".

21.8.11.21 mysql_stmt_reset()

```c
my_bool mysql_stmt_reset(MYSQL_STMT *stmt)
```

Description

Resets a prepared statement on client and server to state after prepare. It resets the statement on the server, data sent using `mysql_stmt_send_long_data()`, unbuffered result sets and current errors.
It does not clear bindings or stored result sets. Stored result sets will be cleared when executing the prepared statement (or closing it).

To re-prepare the statement with another query, use `mysql_stmt_prepare()`.

**Return Values**

Zero for success. Nonzero if an error occurred.

**Errors**

- **CR_COMMANDS_OUT_OF_SYNC**
  
  Commands were executed in an improper order.

- **CR_SERVER_GONE_ERROR**
  
  The MySQL server has gone away.

- **CR_SERVER_LOST**
  
  The connection to the server was lost during the query.

- **CR_UNKNOWN_ERROR**
  
  An unknown error occurred.

**21.8.11.22 mysql_stmt_result_metadata()**

```c
MYSQL_RES *mysql_stmt_result_metadata(MYSQL_STMT *stmt)
```

**Description**

If a statement passed to `mysql_stmt_prepare()` is one that produces a result set, `mysql_stmt_result_metadata()` returns the result set metadata in the form of a pointer to a `MYSQL_RES` structure that can be used to process the meta information such as number of fields and individual field information. This result set pointer can be passed as an argument to any of the field-based API functions that process result set metadata, such as:

- `mysql_num_fields`
- `mysql_fetch_field`
- `mysql_fetch_field_direct`
- `mysql_fetch_fields`
- `mysql_field_count`
- `mysql_field_seek`
- `mysql_field_tell`
- `mysql_free_result`

The result set structure should be freed when you are done with it, which you can do by passing it to `mysql_free_result()`. This is similar to the way you free a result set obtained from a call to `mysql_store_result()`.

The result set returned by `mysql_stmt_result_metadata()` contains only metadata. It does not contain any row results. The rows are obtained by using the statement handle with `mysql_stmt_fetch()`.
Return Values

A MYSQL_RES result structure. NULL if no meta information exists for the prepared query.

Errors

- CR_OUT_OF_MEMORY
  Out of memory.

- CR_UNKNOWN_ERROR
  An unknown error occurred.

Example

See the Example in Section 21.8.11, “mysql_stmt_fetch()”.

21.8.11.23 mysql_stmt_row_seek()

MYSQL_ROW_OFFSET mysql_stmt_row_seek(MYSQL_STMT *stmt, MYSQL_ROW_OFFSET offset)

Description

Sets the row cursor to an arbitrary row in a statement result set. The offset value is a row offset that should be a value returned from mysql_stmt_row_tell() or from mysql_stmt_row_seek(). This value is not a row number; if you want to seek to a row within a result set by number, use mysql_stmt_data_seek() instead.

This function requires that the result set structure contains the entire result of the query, so mysql_stmt_row_seek() may be used only in conjunction with mysql_stmt_store_result().

Return Values

The previous value of the row cursor. This value may be passed to a subsequent call to mysql_stmt_row_seek().

Errors

None.

21.8.11.24 mysql_stmt_row_tell()

MYSQL_ROW_OFFSET mysql_stmt_row_tell(MYSQL_STMT *stmt)

Description

Returns the current position of the row cursor for the last mysql_stmt_fetch(). This value can be used as an argument to mysql_stmt_row_seek().

You should use mysql_stmt_row_tell() only after mysql_stmt_store_result().

Return Values

The current offset of the row cursor.

Errors

None.

21.8.11.25 mysql_stmt_send_long_data()
my_bool mysql_stmt_send_long_data(MYSQL_STMT *stmt, unsigned int parameter_number, const char *data, unsigned long length)

Description

Enables an application to send parameter data to the server in pieces (or “chunks”). Call this function after mysql_stmt_bind_param() and before mysql_stmt_execute(). It can be called multiple times to send the parts of a character or binary data value for a column, which must be one of the TEXT or BLOB data types.

parameter_number indicates which parameter to associate the data with. Parameters are numbered beginning with 0. data is a pointer to a buffer containing data to be sent, and length indicates the number of bytes in the buffer.

Note

The next mysql_stmt_execute() call ignores the bind buffer for all parameters that have been used with mysql_stmt_send_long_data() since last mysql_stmt_execute() or mysql_stmt_reset().

If you want to reset/forget the sent data, you can do it with mysql_stmt_reset(). See Section 21.8.11.21, “mysql_stmt_reset()”.

As of MySQL 5.1.57, the max_long_data_size system variable controls the maximum size of parameter values that can be sent with mysql_stmt_send_long_data(). If this variable not set at server startup, the default is the value of the max_allowed_packet system variable. max_long_data_size is deprecated. In MySQL 5.6, it is removed and the maximum parameter size is controlled by max_allowed_packet.

Return Values

Zero for success. Nonzero if an error occurred.

Errors

• CR_INVALID_BUFFER_USE
  The parameter does not have a string or binary type.

• CR_COMMANDS_OUT_OF_SYNC
  Commands were executed in an improper order.

• CR_SERVER_GONE_ERROR
  The MySQL server has gone away.

• CR_OUT_OF_MEMORY
  Out of memory.

• CR_UNKNOWN_ERROR
  An unknown error occurred.

Example

The following example demonstrates how to send the data for a TEXT column in chunks. It inserts the data value 'MySQL - The most popular Open Source database' into the text_column column. The mysql variable is assumed to be a valid connection handle.
#define INSERT_QUERY "INSERT INTO \n    test_long_data(text_column) VALUES(?)"

MYSQL_BIND bind[1];
long length;

stmt = mysql_stmt_init(mysql);
if (!stmt)
{
    fprintf(stderr, " mysql_stmt_init(), out of memory\n");
    exit(0);
}
if (mysql_stmt_prepare(stmt, INSERT_QUERY, strlen(INSERT_QUERY)))
{
    fprintf(stderr, "\n mysql_stmt_prepare(), INSERT failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}
memset(bind, 0, sizeof(bind));
bind[0].buffer_type= MYSQL_TYPE_STRING;
bind[0].length= &length;
bind[0].is_null= 0;

/* Bind the buffers */
if (mysql_stmt_bind_param(stmt, bind))
{
    fprintf(stderr, "\n param bind failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}

/* Supply data in chunks to server */
if (mysql_stmt_send_long_data(stmt,0,"MySQL",5))
{
    fprintf(stderr, "\n send_long_data failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}

/* Supply the next piece of data */
if (mysql_stmt_send_long_data(stmt,0,
    " - The most popular Open Source database",40))
{
    fprintf(stderr, "\n send_long_data failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}

/* Now, execute the query */
if (mysql_stmt_execute(stmt))
{
    fprintf(stderr, "\n mysql_stmt_execute failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}

21.8.11.26 mysql_stmt_sqlstate()

const char *mysql_stmt_sqlstate(MYSQL_STMT *stmt)

Description

For the statement specified by stmt, mysql_stmt_sqlstate() returns a null-terminated string containing the SQLSTATE error code for the most recently invoked prepared statement API function that can succeed or fail. The error code consists of five characters. "00000" means "no error." The values are specified by ANSI SQL and ODBC. For a list of possible values, see Appendix B, Errors, Error Codes, and Common Problems.

Not all MySQL errors are mapped to SQLSTATE codes. The value "HY000" (general error) is used for unmapped errors.
Return Values

A null-terminated character string containing the SQLSTATE error code.

21.8.11.27 mysql_stmt_store_result()

```c
int mysql_stmt_store_result(MYSQL_STMT *stmt)
```

Description

Result sets are produced by calling `mysql_stmt_execute()` to executed prepared statements for SQL statements such as `SELECT`, `SHOW`, `DESCRIBE`, and `EXPLAIN`. By default, result sets for successfully executed prepared statements are not buffered on the client and `mysql_stmt_fetch()` fetches them one at a time from the server. To cause the complete result set to be buffered on the client, call `mysql_stmt_store_result()` after binding data buffers with `mysql_stmt_bind_result()` and before calling `mysql_stmt_fetch()` to fetch rows. (For an example, see Section 21.8.11.11, "mysql_stmt_fetch()".)

`mysql_stmt_store_result()` is optional for result set processing, unless you will call `mysql_stmt_data_seek()`, `mysql_stmt_row_seek()`, or `mysql_stmt_row_tell()`. Those functions require a seekable result set.

It is unnecessary to call `mysql_stmt_store_result()` after executing an SQL statement that does not produce a result set, but if you do, it does not harm or cause any notable performance problem. You can detect whether the statement produced a result set by checking if `mysql_stmt_result_metadata()` returns `NULL`. For more information, refer to Section 21.8.11.22, "mysql_stmt_result_metadata()".

Note

MySQL does not by default calculate `MYSQL_FIELD->max_length` for all columns in `mysql_stmt_store_result()` because calculating this would slow down `mysql_stmt_store_result()` considerably and most applications do not need `max_length`. If you want `max_length` to be updated, you can call `mysql_stmt_attr_set(MYSQL_STMT, STMATR_ATTR_UPDATE_MAX_LENGTH, &flag)` to enable this. See Section 21.8.11.3, "mysql_stmt_attr_set()".

Return Values

Zero for success. Nonzero if an error occurred.

Errors

- **CR_COMMANDS_OUT_OF_SYNC**
  Commands were executed in an improper order.
- **CR_OUT_OF_MEMORY**
  Out of memory.
- **CR_SERVER_GONE_ERROR**
  The MySQL server has gone away.
- **CR_SERVER_LOST**
  The connection to the server was lost during the query.
- **CR_UNKNOWN_ERROR**
An unknown error occurred.

If the application is linked to the embedded server library, runtime error messages will indicate the `libmysqld` rather than `libmysqlclient` library, but the solution to the problem is the same as just described.

21.8.12 C API Threaded Function Descriptions

To create a threaded client, use the functions described in the following sections. See also Section 21.8.4.2, “Writing C API Threaded Client Programs”.

21.8.12.1 my_init()

```c
void my_init(void)
```

**Description**

`my_init()` initializes some global variables that MySQL needs. If you are using a thread-safe client library, it also calls `mysql_thread_init()` for this thread.

It is necessary for `my_init()` to be called early in the initialization phase of a program’s use of the MySQL library. However, `my_init()` is automatically called by `mysql_init()`, `mysql_library_init()`, `mysql_server_init()`, and `mysql_connect()`. If you ensure that your program invokes one of those functions before any other MySQL calls, there is no need to invoke `my_init()` explicitly.

To access the prototype for `my_init()`, your program should include these header files:

```c
#include <my_global.h>
#include <my_sys.h>
```

**Return Values**

None.

21.8.12.2 mysql_thread_end()

```c
void mysql_thread_end(void)
```

**Description**

This function needs to be called before calling `pthread_exit()` to free memory allocated by `mysql_thread_init()`.

`mysql_thread_end()` *is not invoked automatically by the client library*. It must be called explicitly to avoid a memory leak.

**Return Values**

None.

21.8.12.3 mysql_thread_init()

```c
my_bool mysql_thread_init(void)
```

**Description**

This function must be called early within each created thread to initialize thread-specific variables. However, you may not necessarily need to invoke it explicitly: `mysql_thread_init()` is
automatically called by \texttt{my_init()}, which itself is automatically called by \texttt{mysql_init()}, \texttt{mysql_library_init()}, \texttt{mysql_server_init()}, and \texttt{mysql_connect()}. If you invoke any of those functions, \texttt{mysql_thread_init()} will be called for you.

Return Values

Zero for success. Nonzero if an error occurred.

21.8.12.4 \texttt{mysql_thread_safe()}

\begin{verbatim}
unsigned int mysql_thread_safe(void)
\end{verbatim}

Description

This function indicates whether the client library is compiled as thread-safe.

Return Values

1 if the client library is thread-safe, 0 otherwise.

21.8.13 C API Embedded Server Function Descriptions

MySQL applications can be written to use an embedded server. See Section 21.7, "libmysqld, the Embedded MySQL Server Library". To write such an application, you must link it against the \texttt{libmysqld} library by using the \texttt{-lmysqld} flag rather than linking it against the \texttt{libmysqlclient} client library by using the \texttt{-lmysqlclient} flag. However, the calls to initialize and finalize the library are the same whether you write a client application or one that uses the embedded server: Call \texttt{mysql_library_init()} to initialize the library and \texttt{mysql_library_end()} when you are done with it. See Section 21.8.6, "C API Function Overview".

21.8.13.1 \texttt{mysql_server_init()}

\begin{verbatim}
int mysql_server_init(int argc, char **argv, char **groups)
\end{verbatim}

Description

This function initializes the MySQL library, which must be done before you call any other MySQL function. However, \texttt{mysql_server_init()} is deprecated and you should call \texttt{mysql_library_init()} instead. See Section 21.8.40, "mysql_library_init()".

Return Values

Zero for success. Nonzero if an error occurred.

21.8.13.2 \texttt{mysql_server_end()}

\begin{verbatim}
void mysql_server_end(void)
\end{verbatim}

Description

This function finalizes the MySQL library, which should be done when you are done using the library. However, \texttt{mysql_server_end()} is deprecated and \texttt{mysql_library_end()} should be used instead. See Section 21.8.39, "mysql_library_end()".

Return Values

None.

21.8.14 Common Questions and Problems When Using the C API

It is possible for `mysql_store_result()` to return NULL following a successful call to `mysql_query()`. When this happens, it means one of the following conditions occurred:

- There was a `malloc()` failure (for example, if the result set was too large).
- The data could not be read (an error occurred on the connection).
- The query returned no data (for example, it was an `INSERT`, `UPDATE`, or `DELETE`).

You can always check whether the statement should have produced a nonempty result by calling `mysql_field_count()`. If `mysql_field_count()` returns zero, the result is empty and the last query was a statement that does not return values (for example, an `INSERT` or a `DELETE`). If `mysql_field_count()` returns a nonzero value, the statement should have produced a nonempty result. See the description of the `mysql_field_count()` function for an example.

You can test for an error by calling `mysql_error()` or `mysql_errno()`.

21.8.14.2 What Results You Can Get from a Query

In addition to the result set returned by a query, you can also get the following information:

- `mysql_affected_rows()` returns the number of rows affected by the last query when doing an `INSERT`, `UPDATE`, or `DELETE`.
  For a fast re-create, use `TRUNCATE TABLE`.

- `mysql_num_rows()` returns the number of rows in a result set. With `mysql_store_result()`, `mysql_num_rows()` may be called as soon as `mysql_store_result()` returns. With `mysql_use_result()`, `mysql_num_rows()` may be called only after you have fetched all the rows with `mysql_fetch_row()`.

- `mysql_insert_id()` returns the ID generated by the last query that inserted a row into a table with an `AUTO_INCREMENT` index. See Section 21.8.7.37, “mysql_insert_id()”.

- Some queries (`LOAD DATA INFILE ...`, `INSERT INTO ... SELECT ...`, `UPDATE`) return additional information. The result is returned by `mysql_info()`. See the description for `mysql_info()` for the format of the string that it returns. `mysql_info()` returns a NULL pointer if there is no additional information.

21.8.14.3 How to Get the Unique ID for the Last Inserted Row

If you insert a record into a table that contains an `AUTO_INCREMENT` column, you can obtain the value stored into that column by calling the `mysql_insert_id()` function.

You can check from your C applications whether a value was stored in an `AUTO_INCREMENT` column by executing the following code (which assumes that you've checked that the statement succeeded). It determines whether the query was an `INSERT` with an `AUTO_INCREMENT` index:

```c
if ((result = mysql_store_result(&mysql)) == 0 &&
    mysql_field_count(&mysql) == 0 &&
    mysql_insert_id(&mysql) != 0)
{
    used_id = mysql_insert_id(&mysql);
}
```

When a new `AUTO_INCREMENT` value has been generated, you can also obtain it by executing a `SELECT LAST_INSERT_ID()` statement with `mysql_query()` and retrieving the value from the result set returned by the statement.
When inserting multiple values, the last automatically incremented value is returned.

For `LAST_INSERT_ID()` , the most recently generated ID is maintained in the server on a per-connection basis. It is not changed by another client. It is not even changed if you update another `AUTO_INCREMENT` column with a nonmagic value (that is, a value that is not `NULL` and not `0`). Using `LAST_INSERT_ID()` and `AUTO_INCREMENT` columns simultaneously from multiple clients is perfectly valid. Each client will receive the last inserted ID for the last statement that client executed.

If you want to use the ID that was generated for one table and insert it into a second table, you can use SQL statements like this:

```sql
INSERT INTO foo (auto,text) VALUES(NULL,'text');         # generate ID by inserting NULL
INSERT INTO foo2 (id,text) VALUES(LAST_INSERT_ID(),'text');  # use ID in second table
```

`mysql_insert_id()` returns the value stored into an `AUTO_INCREMENT` column, whether that value is automatically generated by storing `NULL` or `0` or was specified as an explicit value. `LAST_INSERT_ID()` returns only automatically generated `AUTO_INCREMENT` values. If you store an explicit value other than `NULL` or `0`, it does not affect the value returned by `LAST_INSERT_ID()`.

For more information on obtaining the last ID in an `AUTO_INCREMENT` column:

- For information on `LAST_INSERT_ID()` , which can be used within an SQL statement, see Section 12.14, “Information Functions”.
- For information on `mysql_insert_id()` , the function you use from within the C API, see Section 21.8.7.37, “mysql_insert_id()”.
- For information on obtaining the auto-incremented value when using Connector/J, see Retrieving `AUTO_INCREMENT` Column Values through JDBC.
- For information on obtaining the auto-incremented value when using Connector/ODBC, see Obtaining Auto-Increment Values.

### 21.8.15 Controlling Automatic Reconnection Behavior

The MySQL client library can perform an automatic reconnection to the server if it finds that the connection is down when you attempt to send a statement to the server to be executed. If auto-reconnect is enabled, the library tries once to reconnect to the server and send the statement again.

Auto-reconnect is disabled by default.

If it is important for your application to know that the connection has been dropped (so that it can exit or take action to adjust for the loss of state information), be sure that auto-reconnect is disabled. To ensure this, call `mysql_options()` with the `MYSQL_OPT_RECONNECT` option:

```c
my_bool reconnect = 0;
mysql_options(&mysql, MYSQL_OPT_RECONNECT, &reconnect);
```

If the connection has gone down, the effect of `mysql_ping()` depends on the auto-reconnect state. If auto-reconnect is enabled, `mysql_ping()` performs a reconnect. Otherwise, it returns an error.

Some client programs might provide the capability of controlling automatic reconnection. For example, `mysql` reconnects by default, but the `--skip-reconnect` option can be used to suppress this behavior.

If an automatic reconnection does occur (for example, as a result of calling `mysql_ping()`), there is no explicit indication of it. To check for reconnection, call `mysql_thread_id()` to get the original connection identifier before calling `mysql_ping()`, then call `mysql_thread_id()` again to see whether the identifier changed.
Automatic reconnection can be convenient because you need not implement your own reconnect code, but if a reconnection does occur, several aspects of the connection state are reset on the server side and your application will not be notified.

The connection-related state is affected as follows:

- Any active transactions are rolled back and autocommit mode is reset.
- All table locks are released.
- All `TEMPORARY` tables are closed (and dropped).
- Session system variables are reinitialized to the values of the corresponding global system variables, including system variables that are set implicitly by statements such as `SET NAMES`.
- User variable settings are lost.
- Prepared statements are released.
- `HANDLER` variables are closed.
- The value of `LAST_INSERT_ID()` is reset to 0.
- Locks acquired with `GET_LOCK()` are released.

If the connection drops, it is possible that the session associated with the connection on the server side will still be running if the server has not yet detected that the client is no longer connected. In this case, any locks held by the original connection still belong to that session, so you may want to kill it by calling `mysql_kill()`.

### 21.8.16 C API Support for Multiple Statement Execution

By default, `mysql_query()` and `mysql_real_query()` interpret their statement string argument as a single statement to be executed, and you process the result according to whether the statement produces a result set (a set of rows, as for `SELECT`) or an affected-rows count (as for `INSERT`, `UPDATE`, and so forth).

MySQL also supports the execution of a string containing multiple statements separated by semicolon (`;`) characters. This capability is enabled by special options that are specified either when you connect to the server with `mysql_real_connect()` or after connecting by calling `mysql_set_server_option()`.

Executing a multiple-statement string can produce multiple result sets or row-count indicators. Processing these results involves a different approach than for the single-statement case: After handling the result from the first statement, it is necessary to check whether more results exist and process them in turn if so. To support multiple-result processing, the C API includes the `mysql_more_results()` and `mysql_next_result()` functions. These functions are used at the end of a loop that iterates as long as more results are available. *Failure to process the result this way may result in a dropped connection to the server.*

Multiple-result processing also is required if you execute `CALL` statements for stored procedures. Results from a stored procedure have these characteristics:

- Statements within the procedure may produce result sets (for example, if it executes `SELECT` statements). These result sets are returned in the order that they are produced as the procedure executes.

In general, the caller cannot know how many result sets a procedure will return. Procedure execution may depend on loops or conditional statements that cause the execution path to differ from one call to the next. Therefore, you must be prepared to retrieve multiple results.
The final result from the procedure is a status result that includes no result set. The status indicates whether the procedure succeeded or an error occurred.

The multiple statement and result capabilities can be used only with `mysql_query()` or `mysql_real_query()`. They cannot be used with the prepared statement interface. Prepared statement handles are defined to work only with strings that contain a single statement. See Section 21.8.8, “C API Prepared Statements”.

To enable multiple-statement execution and result processing, the following options may be used:

- The `mysql_real_connect()` function has a `flags` argument for which two option values are relevant:
  - `CLIENT_MULTI_RESULTS` enables the client program to process multiple results. This option must be enabled if you execute `CALL` statements for stored procedures that produce result sets. Otherwise, such procedures result in an error `Error 1312 (0A000): PROCEDURE proc_name can't return a result set in the given context.`
  - `CLIENT_MULTI_STATEMENTS` enables `mysql_query()` and `mysql_real_query()` to execute statement strings containing multiple statements separated by semicolons. This option also enables `CLIENT_MULTI_RESULTS` implicitly, so a `flags` argument of `CLIENT_MULTI_STATEMENTS` to `mysql_real_connect()` is equivalent to an argument of `CLIENT_MULTI_STATEMENTS | CLIENT_MULTI_RESULTS`. That is, `CLIENT_MULTI_STATEMENTS` is sufficient to enable multiple-statement execution and all multiple-result processing.

- After the connection to the server has been established, you can use the `mysql_set_server_option()` function to enable or disable multiple-statement execution by passing it an argument of `MYSQL_OPTION_MULTI_STATEMENTS_ON` or `MYSQL_OPTION_MULTI_STATEMENTS_OFF`. Enabling multiple-statement execution with this function also enables processing of “simple” results for a multiple-statement string where each statement produces a single result, but is not sufficient to permit processing of stored procedures that produce result sets.

The following procedure outlines a suggested strategy for handling multiple statements:

1. Pass `CLIENT_MULTI_STATEMENTS` to `mysql_real_connect()`, to fully enable multiple-statement execution and multiple-result processing.
2. After calling `mysql_query()` or `mysql_real_query()` and verifying that it succeeds, enter a loop within which you process statement results.
3. For each iteration of the loop, handle the current statement result, retrieving either a result set or an affected-rows count. If an error occurs, exit the loop.
4. At the end of the loop, call `mysql_next_result()` to check whether another result exists and initiate retrieval for it if so. If no more results are available, exit the loop.

One possible implementation of the preceding strategy is shown following. The final part of the loop can be reduced to a simple test of whether `mysql_next_result()` returns nonzero. The code as written distinguishes between no more results and an error, which enables a message to be printed for the latter occurrence.

```c
/* connect to server with the CLIENT_MULTI_STATEMENTS option */
if (mysql_real_connect (mysql, host_name, user_name, password,
    db_name, port_num, socket_name, CLIENT_MULTI_STATEMENTS) == NULL)
{
    printf("mysql_real_connect() failed\n");
    mysql_close(mysql);
    exit(1);
}
```
C API Prepared Statement Problems

Here follows a list of the currently known problems with prepared statements:

- **TIME, TIMESTAMP, and DATETIME** do not support parts of seconds (for example, from `DATE_FORMAT()`).

- When converting an integer to string, **ZERO_FILL** is honored with prepared statements in some cases where the MySQL server does not print the leading zeros. (For example, with `MIN(number-with-zero-fill)`).

- When converting a floating-point number to a string in the client, the rightmost digits of the converted value may differ slightly from those of the original value.

- Before MySQL 5.1.17, prepared statements do not use the query cache. As of 5.1.17, prepared statements use the query cache under the conditions described in Section 8.10.3.1, “How the Query Cache Operates”.

- Prepared statements do not support multi-statements (that is, multiple statements within a single string separated by ; characters).

- In MySQL 5.1, prepared **CALL** statements cannot invoke stored procedures that return result sets because prepared statements do not support multiple result sets. Nor can the calling application
access a stored procedure’s **OUT** or **INOUT** parameters when the procedure returns. These capabilities are supported beginning with MySQL 5.5.

## 21.8.18 C API Prepared Statement Handling of Date and Time Values

The binary (prepared statement) protocol enables you to send and receive date and time values (**DATE**, **TIME**, **DATETIME**, and **TIMESTAMP**), using the **MYSQL_TIME** structure. The members of this structure are described in Section 21.8.9, “C API Prepared Statement Data Structures”.

To send temporal data values, create a prepared statement using `mysql_stmt_prepare()`. Then, before calling `mysql_stmt_execute()` to execute the statement, use the following procedure to set up each temporal parameter:

1. In the **MYSQL_BIND** structure associated with the data value, set the `buffer_type` member to the type that indicates what kind of temporal value you’re sending. For **DATE**, **TIME**, **DATETIME**, or **TIMESTAMP** values, set `buffer_type` to `MYSQL_TYPE_DATE`, `MYSQL_TYPE_TIME`, `MYSQL_TYPE_DATETIME`, or `MYSQL_TYPE_TIMESTAMP`, respectively.

2. Set the `buffer` member of the **MYSQL_BIND** structure to the address of the **MYSQL_TIME** structure in which you pass the temporal value.

3. Fill in the members of the **MYSQL_TIME** structure that are appropriate for the type of temporal value to pass.

Use `mysql_stmt_bind_param()` to bind the parameter data to the statement. Then you can call `mysql_stmt_execute()`.

To retrieve temporal values, the procedure is similar, except that you set the `buffer_type` member to the type of value you expect to receive, and the `buffer` member to the address of a **MYSQL_TIME** structure into which the returned value should be placed. Use `mysql_stmt_bind_result()` to bind the buffers to the statement after calling `mysql_stmt_execute()` and before fetching the results.

Here is a simple example that inserts **DATE**, **TIME**, and **TIMESTAMP** data. The `mysql` variable is assumed to be a valid connection handle.

```c
MYSQL_TIME ts;
MYSQL_BIND bind[3];
MYSQL_STMT *stmt;

strmov(query, "INSERT INTO test_table(date_field, time_field, \t timestamp_field) VALUES(?,?,?);

stmt = mysql_stmt_init(mysql);
if (!stmt)
    { fprintf(stderr, " mysql_stmt_init(), out of memory\n");
      exit(0);
    }
if (mysql_stmt_prepare(mysql, query, strlen(query)))
    { fprintf(stderr, "mysql_stmt_prepare(), INSERT failed\n"); fprintf(stderr, "%s", mysql_stmt_error(stmt));
      exit(0);
    }

/* set up input buffers for all 3 parameters */
bind[0].buffer_type= MYSQL_TYPE_DATE;
bind[0].buffer= (char *)&ts;
bind[0].is_null= 0;
bind[0].length= 0;
... 
bind[1]= bind[2]= bind[0];
... 
```
```c
mysql_stmt_bind_param(stmt, bind);
/* supply the data to be sent in the ts structure */
ts.year= 2002;
ts.month= 02;
ts.day= 03;

ts.hour= 10;
ts.minute= 45;
ts.second= 20;

mysql_stmt_execute(stmt);
```

21.8.19 C API Support for Prepared CALL Statements

In MySQL 5.1, prepared CALL statements can be used only for stored procedures that produce at most one result set. Nor can the calling application use placeholders for OUT or INOUT parameters.

MySQL 5.5 expands prepared CALL statement support for stored procedures that produce multiple result sets and to provide placeholder access to OUT and INOUT parameters.

21.9 MySQL PHP API

The MySQL PHP API manual is now published in standalone form, not as part of the MySQL Reference Manual. See MySQL and PHP.

21.10 MySQL Perl API

The Perl DBI module provides a generic interface for database access. You can write a DBI script that works with many different database engines without change. To use DBI with MySQL, install the following:

1. The DBI module.
2. The DBD::mysql module. This is the DataBase Driver (DBD) module for Perl.
3. Optionally, the DBD module for any other type of database server you want to access.

Perl DBI is the recommended Perl interface. It replaces an older interface called mysqlperl, which should be considered obsolete.

These sections contain information about using Perl with MySQL and writing MySQL applications in Perl:

- For installation instructions for Perl DBI support, see Section 2.15, “Perl Installation Notes”.
- For an example of reading options from option files, see Section 5.5.4, “Using Client Programs in a Multiple-Server Environment”.
- For secure coding tips, see Section 6.1.1, “Security Guidelines”.
- For debugging tips, see Section 22.4.1.4, “Debugging mysqld under gdb”.
- For some Perl-specific environment variables, see Section 2.14, “Environment Variables”.
- For considerations for running on OS X, see Section 2.4, “Installing MySQL on OS X”.
- For ways to quote string literals, see Section 9.1.1, “String Literals”.

DBI information is available at the command line, online, or in printed form:
• Once you have the DBI and DBD::mysql modules installed, you can get information about them at the command line with the perldoc command:

```
shell> perldoc DBI
shell> perldoc DBI::FAQ
shell> perldoc DBD::mysql
```

You can also use pod2man, pod2html, and so on to translate this information into other formats.

• For online information about Perl DBI, visit the DBI Web site, http://dbi.perl.org/. That site hosts a general DBI mailing list. Oracle Corporation hosts a list specifically about DBD::mysql; see Section 1.6.1, “MySQL Mailing Lists”.

21.11 MySQL Python API

MySQLdb is a third-party driver that provides MySQL support for Python, compliant with the Python DB API version 2.0. It can be found at http://sourceforge.net/projects/mysql-python/.

The new MySQL Connector/Python component provides an interface to the same Python API, and is built into the MySQL Server and supported by Oracle. See MySQL Connector/Python Developer Guide for details on the Connector, as well as coding guidelines for Python applications and sample Python code.

21.12 MySQL Ruby APIs

Two APIs are available for Ruby programmers developing MySQL applications:

• The MySQL/Ruby API is based on the libmysqlclient API library. For information on installing and using the MySQL/Ruby API, see Section 21.12.1, “The MySQL/Ruby API”.

• The Ruby/MySQL API is written to use the native MySQL network protocol (a native driver). For information on installing and using the Ruby/MySQL API, see Section 21.12.2, “The Ruby/MySQL API”.

For background and syntax information about the Ruby language, see Ruby Programming Language.

21.12.1 The MySQL/Ruby API

The MySQL/Ruby module provides access to MySQL databases using Ruby through libmysqlclient.

For information on installing the module, and the functions exposed, see MySQL/Ruby.

21.12.2 The Ruby/MySQL API

The Ruby/MySQL module provides access to MySQL databases using Ruby through a native driver interface using the MySQL network protocol.

For information on installing the module, and the functions exposed, see Ruby/MySQL.

21.13 MySQL Tcl API
**MySQL Eiffel Wrapper**

*MySQLtcl* is a simple API for accessing a MySQL database server from the Tcl programming language. It can be found at [http://www.xdobry.de/mysqltcl/](http://www.xdobry.de/mysqltcl/).

### 21.14 MySQL Eiffel Wrapper

Eiffel MySQL is an interface to the MySQL database server using the Eiffel programming language, written by Michael Ravits. It can be found at [http://efsa.sourceforge.net/archive/ravits/mysql.htm](http://efsa.sourceforge.net/archive/ravits/mysql.htm).

22.1 MySQL Internals

This chapter describes a lot of things that you need to know when working on the MySQL code. To track or contribute to MySQL development, follow the instructions in Section 2.11.3, “Installing MySQL Using a Development Source Tree”. If you are interested in MySQL internals, you should also subscribe to our internals mailing list. This list has relatively low traffic. For details on how to subscribe, please see Section 1.6.1, “MySQL Mailing Lists”. Many MySQL developers at Oracle Corporation are on the internals list and we help other people who are working on the MySQL code. Feel free to use this list both to ask questions about the code and to send patches that you would like to contribute to the MySQL project!

22.1.1 MySQL Threads

The MySQL server creates the following threads:

- Connection manager threads handle client connection requests on the network interfaces that the server listens to. On all platforms, one manager thread handles TCP/IP connection requests. On Unix, this manager thread also handles Unix socket file connection requests. On Windows, a manager thread handles shared-memory connection requests, and another handles named-pipe connection requests. The server does not create threads to handle interfaces that it does not listen to. For example, a Windows server that does not have support for named-pipe connections enabled does not create a thread to handle them.

- Connection manager threads associate each client connection with a thread dedicated to it that handles authentication and request processing for that connection. Manager threads create a new thread when necessary but try to avoid doing so by consulting the thread cache first to see whether it contains a thread that can be used for the connection. When a connection ends, its thread is returned to the thread cache if the cache is not full.

  For information about tuning the parameters that control thread resources, see Section 8.12.6.1, “How MySQL Uses Threads for Client Connections”.

- On a master replication server, connections from slave servers are handled like client connections: There is one thread per connected slave.
• On a slave replication server, an I/O thread is started to connect to the master server and read updates from it. An SQL thread is started to apply updates read from the master. These two threads run independently and can be started and stopped independently.

• A signal thread handles all signals. This thread also normally handles alarms and calls process_alarm() to force timeouts on connections that have been idle too long.

• If InnoDB is used, there will be 4 additional threads by default. Those are file I/O threads, controlled by the innodb_file_io_threads parameter. See Section 14.6.8, "InnoDB Startup Options and System Variables".

• If mysqld is compiled with -DUSE_ALARM_THREAD, a dedicated thread that handles alarms is created. This is only used on some systems where there are problems with sigwait() or if you want to use the thr_alarm() code in your application without a dedicated signal handling thread.

• If the server is started with the --flush_time=val option, a dedicated thread is created to flush all tables every val seconds.

• Each table for which INSERT DELAYED statements are issued gets its own thread. See Section 13.2.5.2, “INSERT DELAYED Syntax”.

• If the event scheduler is active, there is one thread for the scheduler, and a thread for each event currently running. See Section 19.4.1, “Event Scheduler Overview”.

mysqladmin processlist only shows the connection, INSERT DELAYED, replication, and event threads.

22.1.2 The MySQL Test Suite

The test system that is included in Unix source and binary distributions makes it possible for users and developers to perform regression tests on the MySQL code. These tests can be run on Unix.

You can also write your own test cases. For information about the MySQL Test Framework, including system requirements, see the manual available at http://dev.mysql.com/doc/mysqltest/2.0/en/.

The current set of test cases doesn't test everything in MySQL, but it should catch most obvious bugs in the SQL processing code, operating system or library issues, and is quite thorough in testing replication. Our goal is to have the tests cover 100% of the code. We welcome contributions to our test suite. You may especially want to contribute tests that examine the functionality critical to your system because this ensures that all future MySQL releases work well with your applications.

The test system consists of a test language interpreter (mysqltest), a Perl script to run all tests (mysql-test-run.pl), the actual test cases written in a special test language, and their expected results. To run the test suite on your system after a build, type make test from the source root directory, or change location to the mysql-test directory and type ./mysql-test-run.pl. If you have installed a binary distribution, change location to the mysql-test directory under the installation root directory (for example, /usr/local/mysql/mysql-test), and run ./mysql-test-run.pl. All tests should succeed. If any do not, feel free to try to find out why and report the problem if it indicates a bug in MySQL. See Section 1.7, “How to Report Bugs or Problems”.

If one test fails, you should run mysql-test-run.pl with the --force option to check whether any other tests fail.

If you have a copy of mysqld running on the machine where you want to run the test suite, you do not have to stop it, as long as it is not using ports 9306 or 9307. If either of those ports is taken, you should set the MTR_BUILD_THREAD environment variable to an appropriate value, and the test suite will use a different set of ports for master, slave, NDB, and Instance Manager). For example:

```
shell> export MTR_BUILD_THREAD=31
shell> ./mysql-test-run.pl [options] [test_name]
```
In the mysql-test directory, you can run an individual test case with ./mysql-test-run.pl test_name.

If you have a question about the test suite, or have a test case to contribute, send an email message to the MySQL internals mailing list. See Section 1.6.1, “MySQL Mailing Lists”.

22.2 The MySQL Plugin API

MySQL supports a plugin API that enables creation of server components. Plugins can be loaded at server startup, or loaded and unloaded at runtime without restarting the server. The API is generic and does not specify what plugins can do. The components supported by this interface include, but are not limited to, storage engines, full-text parser plugins, and server extensions.

For example, full-text parser plugins can be used to replace or augment the built-in full-text parser. A plugin can parse text into words using rules that differ from those used by the built-in parser. This can be useful if you need to parse text with characteristics different from those expected by the built-in parser.

The plugin interface is more general than the older user-defined function (UDF) interface.

The plugin interface uses the plugin table in the mysql database to record information about plugins that have been installed permanently with the INSTALL PLUGIN statement. This table is created as part of the MySQL installation process. (If you are upgrading from a version of MySQL older than 5.1, you should run the mysql_upgrade command to create this table. See Section 4.4.8, "mysql_upgrade — Check and Upgrade MySQL Tables"). Plugins can also be installed for a single server invocation with the --plugin-load option. Plugins installed this way are not recorded in the plugin table. See Section 5.1.8.1, “Installing and Uninstalling Plugins”.

Additional Resources

The book MySQL 5.1 Plugin Development by Sergei Golubchik and Andrew Hutchings provides a wealth of detail about the plugin API. Despite the fact that the book's title refers to MySQL Server 5.1, most of the information in it applies to later versions as well.

22.2.1 Types of Plugins

The plugin API enables creation of plugins that implement several capabilities:

• Storage engines
• Full-text parsers
• Daemons
• INFORMATION_SCHEMA tables

The following sections provide an overview of these plugin types.

Storage Engine Plugins

The pluggable storage engine architecture used by MySQL Server enables storage engines to be written as plugins and loaded into and unloaded from a running server. For a description of this architecture, see Section 14.4, “Overview of MySQL Storage Engine Architecture”.

For information on how to use the plugin API to write storage engines, see MySQL Internals: Writing a Custom Storage Engine.

Full-Text Parser Plugins

MySQL has a built-in parser that it uses by default for full-text operations (parsing text to be indexed, or parsing a query string to determine the terms to be used for a search). For full-text processing,
“parsing” means extracting words from text or a query string based on rules that define which character sequences make up a word and where word boundaries lie.

When parsing for indexing purposes, the parser passes each word to the server, which adds it to a full-text index. When parsing a query string, the parser passes each word to the server, which accumulates the words for use in a search.

The parsing properties of the built-in full-text parser are described in Section 12.9, “Full-Text Search Functions”. These properties include rules for determining how to extract words from text. The parser is influenced by certain system variables such as `ft_min_word_len` and `ft_max_word_len` that cause words shorter or longer to be excluded, and by the stopword list that identifies common words to be ignored.

The plugin API enables you to provide a full-text parser of your own so that you have control over the basic duties of a parser. A parser plugin can operate in either of two roles:

- The plugin can replace the built-in parser. In this role, the plugin reads the input to be parsed, splits it up into words, and passes the words to the server (either for indexing or for word accumulation).

  One reason to use a parser this way is that you need to use different rules from those of the built-in parser for determining how to split up input into words. For example, the built-in parser considers the text “case-sensitive” to consist of two words “case” and “sensitive,” whereas an application might need to treat the text as a single word.

- The plugin can act in conjunction with the built-in parser by serving as a front end for it. In this role, the plugin extracts text from the input and passes the text to the parser, which splits up the text into words using its normal parsing rules. In particular, this parsing will be affected by the `ft_` system variables and the stopword list.

  One reason to use a parser this way is that you need to index content such as PDF documents, XML documents, or `.doc` files. The built-in parser is not intended for those types of input but a plugin can pull out the text from these input sources and pass it to the built-in parser.

It is also possible for a parser plugin to operate in both roles. That is, it could extract text from noncleartext input (the front end role), and also parse the text into words (thus replacing the built-in parser).

A full-text plugin is associated with full-text indexes on a per-index basis. That is, when you install a parser plugin initially, that does not cause it to be used for any full-text operations. It simply becomes available. For example, a full-text parser plugin becomes available to be named in a `WITH PARSER` clause when creating individual `FULLTEXT` indexes. To create such an index at table-creation time, do this:

```sql
CREATE TABLE t
(
  doc CHAR(255),
  FULLTEXT INDEX (doc) WITH PARSER my_parser
) ENGINE=MyISAM;
```

Or you can add the index after the table has been created:

```sql
ALTER TABLE t ADD FULLTEXT INDEX (doc) WITH PARSER my_parser;
```

The only SQL change for associating the parser with the index is the `WITH PARSER` clause. Searches are specified as before, with no changes needed for queries.

When you associate a parser plugin with a `FULLTEXT` index, the plugin is required for using the index. If the parser plugin is dropped, any index associated with it becomes unusable. Any attempt to use a table for which a plugin is not available results in an error, although `DROP TABLE` is still possible.

For more information about full-text plugins, see Section 22.2.4.4, “Writing Full-Text Parser Plugins”. MySQL 5.1 only supports full-text plugins with `MyISAM`.
### Daemon Plugins

A daemon plugin is a simple type of plugin used for code that should be run by the server but that does not communicate with it. MySQL distributions include an example daemon plugin that writes periodic heartbeat messages to a file.

For more information about daemon plugins, see Section 22.2.4.5, “Writing Daemon Plugins”.

### INFORMATION_SCHEMA Plugins

INFORMATION_SCHEMA plugins enable the creation of tables containing server metadata that are exposed to users through the INFORMATION_SCHEMA database. For example, InnoDB uses INFORMATION_SCHEMA plugins to provide tables that contain information about current transactions and locks.

For more information about INFORMATION_SCHEMA plugins, see Section 22.2.4.6, “Writing INFORMATION_SCHEMA Plugins”.

### 22.2.2 Plugin API Characteristics

The server plugin API has these characteristics:

- **All plugins have several things in common.**
  
  Each plugin has a name that it can be referred to in SQL statements, as well as other metadata such as an author and a description that provide other information. This information can be examined in the INFORMATION_SCHEMA.PLUGINS table or using the SHOW PLUGINS statement.

- **The plugin framework is extendable to accommodate different kinds of plugins.**
  
  Although some aspects of the plugin API are common to all types of plugins, the API also permits type-specific interface elements so that different types of plugins can be created. A plugin with one purpose can have an interface most appropriate to its own requirements and not the requirements of some other plugin type.

  Interfaces for several types of plugins exist, such as storage engines, full-text parser, and INFORMATION_SCHEMA tables. Others can be added.

- **Plugins can expose information to users.**
  
  A plugin can implement system and status variables that are available through the SHOW VARIABLES and SHOW STATUS statements.

- **The plugin API includes versioning information.**
  
  The version information included in the plugin API enables a plugin library and each plugin that it contains to be self-identifying with respect to the API version that was used to build the library. If the API changes over time, the version numbers will change, but a server can examine a given plugin library's version information to determine whether it supports the plugins in the library.

  There are two types of version numbers. The first is the version for the general plugin framework itself. Each plugin library includes this kind of version number. The second type of version applies to individual plugins. Each specific type of plugin has a version for its interface, so each plugin in a library has a type-specific version number. For example, a library containing a full-text parser plugin has a general plugin API version number, and the plugin has a version number specific to the full-text plugin interface.

- **The plugin API implements security restrictions.**
  
  A plugin library must be installed in a specific dedicated directory for which the location is controlled by the server and cannot be changed at runtime. Also, the library must contain specific symbols that
identify it as a plugin library. The server will not load something as a plugin if it was not built as a plugin.

In some respects, the server plugin API is similar to the older user-defined function (UDF) API that it supersedes, but the plugin API has several advantages over the older interface. For example, UDFs had no versioning information. Also, the newer plugin interface eliminates the security issues of the older UDF interface. The older interface for writing nonplugin UDFs permitted libraries to be loaded from any directory searched by the system's dynamic linker, and the symbols that identified the UDF library were relatively nonspecific.

22.2.3 Plugin API Components

The server plugin implementation comprises several components.

SQL statements:

- **INSTALL PLUGIN** registers a plugin in the `mysql.plugin` table and loads the plugin code.
- **UNINSTALL PLUGIN** unregisters a plugin from the `mysql.plugin` table and unloads the plugin code.
- The **WITH PARSER** clause for full-text index creation associates a full-text parser plugin with a given **FULLTEXT** index.
- **SHOW PLUGINS** displays information about server plugins.

Command-line options and system variables:

- The **--plugin-load** option enables plugins to be loaded at server startup time.
- The **plugin_dir** system variable indicates the location of the directory where all plugins must be installed. The value of this variable can be specified at server startup with a **--plugin_dir=dir_name** option. **mysql_config --plugindir** displays the default plugin directory path name.

For additional information about plugin loading, see Section 5.1.8.1, “Installing and Uninstalling Plugins”.

Plugin-related tables:

- The **INFORMATION_SCHEMA.PLUGINS** table contains plugin information.
- The **mysql.plugin** table lists each plugin that was installed with **INSTALL PLUGIN** and is required for plugin use. For new MySQL installations, this table is created during the installation process. If you are upgrading from a version of MySQL older than 5.1, you should run **mysql_upgrade** to update your system tables and create the **plugin** table (see Section 4.4.8, "mysql_upgrade — Check and Upgrade MySQL Tables").

Source files (the locations indicate where the files are found in MySQL source distributions):

- In the **include/mysql** directory, **plugin.h** exposes the public plugin API. This file should be examined by anyone who wants to write a plug-in library. **plugin_XXX.h** files provide additional information that pertains to specific types of plugins.
- In the **sql** directory, **sql_plugin.h** and **sql_plugin.cc** comprise the internal plugin implementation. These files need not be consulted by plugin developers. They may be of interest for those who want to know more about how the server handles plugins.

22.2.4 Writing Plugins

To create a plugin library, you must provide the required descriptor information that indicates what plugins the library file contains, and write the interface functions for each plugin.
Writing Plugins

Every server plugin must have a general descriptor that provides information to the plugin API, and a type-specific descriptor that provides information about the plugin interface for a given type of plugin. The structure of the general descriptor is the same for all plugin types. The structure of the type-specific descriptor varies among plugin types and is determined by the requirements of what the plugin needs to do. The server plugin interface also enables plugins to expose status and system variables. These variables become visible through the `SHOW STATUS` and `SHOW VARIABLES` statements and the corresponding `INFORMATION_SCHEMA` tables.

You can write plugins in C or C++ (or another language that can use C calling conventions). Plugins are loaded and unloaded dynamically, so your operating system must support dynamic loading and you must have compiled `mysqld` dynamically (not statically).

A server plugin contains code that becomes part of the running server, so when you write the plugin, you are bound by any and all constraints that otherwise apply to writing server code. For example, you may have problems if you attempt to use functions from the `libstdc++` library. These constraints may change in future versions of the server, so it is possible that server upgrades will require revisions to plugins originally written for older servers. For information about these constraints, see Section 2.11.4, “MySQL Source-Configuration Options”, and Section 2.11.5, “Dealing with Problems Compiling MySQL”.

### 22.2.4.1 Overview of Plugin Writing

The following procedure provides an overview of the steps needed to create a plugin library. The next sections provide additional details on setting plugin data structures and writing specific types of plugins.

1. In the plugin source file, include the header files that the plugin library needs. The `plugin.h` file is required, and the library might require other files as well. For example:

   ```
   #include <stdlib.h>
   #include <ctype.h>
   #include <mysql/plugin.h>
   ```

2. Set up the descriptor information for the plugin library file. This descriptor must contain the general plugin descriptor for each server plugin in the file. For more information, see Library and Plugin Descriptors. In addition, set up the type-specific descriptor for each server plugin in the library. Each plugin's general descriptor points to its type-specific descriptor.

3. Write the plugin interface functions for each plugin. Each plugin's general plugin descriptor points to the initialization and deinitialization functions that the server should invoke when it loads and unloads the plugin. The plugin's type-specific description may also point to interface functions.

4. Set up the status and system variables, if there are any.

5. Compile the plugin library as a shared library and install it in the plugin directory. For more information, see Section 22.2.4.3, “Compiling and Installing Plugin Libraries”.

6. Register the plugin with the server. For more information, see Section 5.1.8.1, “Installing and Uninstalling Plugins”.

7. Test the plugin to verify that it works properly.

### 22.2.4.2 Plugin Data Structures

A plugin library file includes descriptor information to indicate what plugins it contains. The plugin library must include the following descriptor information:

- A library descriptor indicates the general server plugin API version number used by the library and contains a general plugin descriptor for each server plugin in the library. To provide the framework for this descriptor, invoke two macros from the `plugin.h` header file:
Writing Plugins

mysql_declare_plugin(name)
... one or more server plugin descriptors here ...
mysql_declare_plugin_end;

The macros expand to provide a declaration for the API version automatically. You must provide the
plugin descriptors.

• Within the library descriptor, each general server plugin is described by a st_mysql_plugin
structure. This plugin descriptor structure contains information that is common to every type of server
plugin: A value that indicates the plugin type; the plugin name, author, description, and license type;
pointers to the initialization and deinitialization functions that the server invokes when it loads and
unloads the plugin, and pointers to any status or system variables the plugin implements.

• Each general server plugin descriptor within the library descriptor also contains a pointer to a type-
specific plugin descriptor. The structure of the type-specific descriptors varies from one plugin type to
another because each type of plugin can have its own API. A type-specific plugin descriptor contains
a type-specific API version number and pointers to the functions that are needed to implement that
plugin type. For example, a full-text parser plugin has initialization and deinitialization functions, and
a main parsing function. The server invokes these functions when it uses the plugin to parse text.

The plugin library also contains the interface functions that are referenced by the general and type-
specific descriptors for each plugin in the library.

Library and Plugin Descriptors

Every plugin library must include a library descriptor that contains the general plugin descriptor for
each server plugin in the file. This section discusses how to write the library and general descriptors for
server plugins.

The library descriptor must define two symbols:

• _mysql_plugin_interface_version_ specifies the version number of the general plugin
framework. This is given by the MYSQL_PLUGIN_INTERFACE_VERSION symbol, which is defined in
the plugin.h file.

• _mysql_plugin_declarations_ defines an array of plugin declarations, terminated by a
declaration with all members set to 0. Each declaration is an instance of the st_mysql_plugin
structure (also defined in plugin.h). There must be one of these for each server plugin in the
library.

If the server does not find those two symbols in a library, it does not accept it as a legal plugin library
and rejects it with an error. This prevents use of a library for plugin purposes unless it was built
specifically as a plugin library.

The conventional way to define the two required symbols is by using the mysql_declare_plugin() and
mysql_declare_plugin_end macros from the plugin.h file:

mysql_declare_plugin(name)
... one or more server plugin descriptors here ...
mysql_declare_plugin_end;

Each server plugin must have a general descriptor that provides information to the server plugin API.
The general descriptor has the same structure for all plugin types. The st_mysql_plugin structure in
the plugin.h file defines this descriptor:

```c
struct st_mysql_plugin
{
  int type;          /* the plugin type (a MYSQL_XXX_PLUGIN value) */
  void *info;        /* pointer to type-specific plugin descriptor */
  const char *name;  /* plugin name */
  const char *author; /* plugin author (for I_S.PLUGINS) */
  const char *descr; /* general descriptive text (for I_S.PLUGINS) */
  int license;       /* the plugin license (PLUGIN_LICENSE_XXX) */
};
```
Writing Plugins

```c
int (*init)(void *); /* the function to invoke when plugin is loaded */
int (*deinit)(void *); /* the function to invoke when plugin is unloaded */
unsigned int version; /* plugin version (for I_S.PLUGINS) */
struct st_mysql_show_var *status_vars;
struct st_mysql_sys_var **system_vars;
void __reserved1; /* reserved for dependency checking */
};
```

The `st_mysql_plugin` descriptor structure members are used as follows. *char* members should be specified as null-terminated strings.

- **type**: The plugin type. This must be one of the plugin-type values from `plugin.h`:

```c
/*
 * The allowable types of plugins
 */
#define MYSQL_UDF_PLUGIN             0  /* User-defined function */
#define MYSQL_STORAGE_ENGINE_PLUGIN  1  /* Storage Engine */
#define MYSQL_FTPARSER_PLUGIN        2  /* Full-text parser plugin */
#define MYSQL_DAEMON_PLUGIN          3  /* The daemon/raw plugin type */
#define MYSQL_INFORMATION_SCHEMA_PLUGIN  4  /* The I_S plugin type */
...```

For example, for a full-text parser plugin, the **type** value is `MYSQL_FTPARSER_PLUGIN`.

- **info**: A pointer to the type-specific descriptor for the plugin. This descriptor’s structure depends on the particular type of plugin, unlike that of the general plugin descriptor structure. For version-control purposes, the first member of the type-specific descriptor for every plugin type is expected to be the interface version for the type. This enables the server to check the type-specific version for every plugin no matter its type. Following the version number, the descriptor includes any other members needed, such as callback functions and other information needed by the server to invoke the plugin properly. Later sections on writing particular types of server plugins describe the structure of their type-specific descriptors.

- **name**: A string that gives the plugin name. This is the name that will be listed in the `mysql.plugin` table and by which you refer to the plugin in SQL statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`, or with the `--plugin-load` option. The name is also visible in the `INFORMATION_SCHEMA.PLUGINS` table or the output from `SHOW PLUGINS`.

The plugin name should not begin with the name of any server option. If it does, the server will fail to initialize it. For example, the server has a `--socket` option, so you should not use a plugin name such as `socket`, `socket_plugin`, and so forth.

- **author**: A string naming the plugin author. This can be whatever you like.

- **desc**: A string that provides a general description of the plugin. This can be whatever you like.

- **license**: The plugin license type. The value can be one of `PLUGIN_LICENSE_PROPRIETARY`, `PLUGIN_LICENSE_GPL`, or `PLUGIN_LICENSE_BSD`.

- **init**: A once-only initialization function, or `NULL` if there is no such function. The server executes this function when it loads the plugin, which happens for `INSTALL PLUGIN` or, for plugins listed in the `mysql.plugin` table, at server startup. The function takes one argument that points to the internal structure used to identify the plugin. It returns zero for success and nonzero for failure.

- **deinit**: A once-only deinitialization function, or `NULL` if there is no such function. The server executes this function when it unloads the plugin, which happens for `UNINSTALL PLUGIN` or, for plugins listed in the `mysql.plugin` table, at server shutdown. The function takes one argument that points to the internal structure used to identify the plugin. It returns zero for success and nonzero for failure.

- **version**: The plugin version number. When the plugin is installed, this value can be retrieved from the `INFORMATION_SCHEMA.PLUGINS` table. The value includes major and minor numbers. If you
write the value as a hex constant, the format is 0xMMNN, where MM and NN are the major and minor numbers, respectively. For example, 0x0302 represents version 3.2.

- **status_vars**: A pointer to a structure for status variables associated with the plugin, or NULL if there are no such variables. When the plugin is installed, these variables are displayed in the output of the SHOW STATUS statement.

The status_vars member, if not NULL, points to an array of st_mysql_show_var structures that describe status variables. See Plugin Status and System Variables.

- **system_vars**: A pointer to a structure for system variables associated with the plugin, or NULL if there are no such variables. These options and system variables can be used to help initialize variables within the plugin.

The system_vars member, if not NULL, points to an array of st_mysql_sys_var structures that describe system variables. See Plugin Status and System Variables.

- **__reserved1**: A placeholder for the future. It should be set to NULL.

The server invokes the init and deinit functions in the general plugin descriptor only when loading and unloading the plugin. They have nothing to do with use of the plugin such as happens when an SQL statement causes the plugin to be invoked.

For example, the descriptor information for a library that contains a single full-text parser plugin named simple_parser looks like this:

```c
mysql_declare_plugin(ftexample)
{
  MYSQL_FTPARSER_PLUGIN,      /* type                            */
  &simple_parser_descriptor,  /* descriptor                      */
  "simple_parser",            /* name                            */
  "Oracle Corporation",       /* author                          */
  "Simple Full-Text Parser",  /* description                     */
  PLUGIN_LICENSE_GPL,         /* plugin license                  */
  simple_parser_plugin_init,  /* init function (when loaded)     */
  simple_parser_plugin_deinit,/* deinit function (when unloaded) */
  0x0001,                     /* version                         */
  simple_status,              /* status variables                */
  simple_system_variables,    /* system variables                */
  NULL
}
mysql_declare_plugin_end;
```

For a full-text parser plugin, the type must be MYSQL_FTPARSER_PLUGIN. This is the value that identifies the plugin as being legal for use in a WITH PARSER clause when creating a FULLTEXT index. (No other plugin type is legal for this clause.)

`plugin.h` defines the mysql_declare_plugin() and mysql_declare_plugin_end macros like this:

```c
#ifndef MYSQL_DYNAMIC_PLUGIN
#define __MYSQL_DECLARE_PLUGIN(NAME, VERSION, PSIZE, DECLS)
  int VERSION= MYSQL_PLUGIN_INTERFACE_VERSION;                           
  int PSIZE= sizeof(struct st_mysql_plugin);                             
  struct st_mysql_plugin DECLS[]= {                                 
#endif
#define mysql_declare_plugin(NAME) 
  __MYSQL_DECLARE_PLUGIN(NAME, builtin_ ## NAME ## _plugin_interface_version, 
```

2508
Writing Plugins

Note

Those declarations define the `__mysql_plugin_interface_version__` symbol only if the `MYSQL_DYNAMIC_PLUGIN` symbol is defined. This means that `-DMYSQL_DYNAMIC_PLUGIN` must be provided as part of the compilation command to build the plugin as a shared library.

When the macros are used as just shown, they expand to the following code, which defines both of the required symbols (`__mysql_plugin_interface_version__` and `__mysql_plugin_declarations__`):

```c
int __mysql_plugin_interface_version__ = MYSQL_PLUGIN_INTERFACE_VERSION;
int __mysql_sizeof_struct_st_plugin__ = sizeof(struct st_mysql_plugin);
struct st_mysql_plugin __mysql_plugin_declarations__[] = {
    {MYSQL_FTPARSER_PLUGIN, /* type */
     &simple_parser_descriptor, /* descriptor */
     "simple_parser", /* name */
     "Oracle Corporation", /* author */
     "Simple Full-Text Parser", /* description */
     PLUGIN_LICENSE_GPL, /* plugin license */
     simple_parser_plugin_init, /* init function (when loaded) */
     simple_parser_plugin_deinit, /* deinit function (when unloaded) */
     0x0001, /* version */
     simple_status, /* status variables */
     simple_system_variables, /* system variables */
     NULL
    },{0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0}
};
```

The preceding example declares a single plugin in the general descriptor, but it is possible to declare multiple plugins. List the declarations one after the other between `mysql_declare_plugin()` and `mysql_declare_plugin_end`, separated by commas.

MySQL server plugins can be written in C or C++ (or another language that can use C calling conventions). If you write a C++ plugin, one C++ feature that you should not use is nonconstant variables to initialize global structures. Members of structures such as the `st_mysql_plugin` structure should be initialized only with constant variables. The `simple_parser` descriptor shown earlier is permissible in a C++ plugin because it satisfies that requirement:

```c
mysql_declare_plugin(ftexample)
{
    MYSQL_FTPARSER_PLUGIN, /* type */
    &simple_parser_descriptor, /* descriptor */
    "simple_parser", /* name */
    "Oracle Corporation", /* author */
    "Simple Full-Text Parser", /* description */
    PLUGIN_LICENSE_GPL, /* plugin license */
    simple_parser_plugin_init, /* init function (when loaded) */
    simple_parser_plugin_deinit, /* deinit function (when unloaded) */
    0x0001, /* version */
    simple_status, /* status variables */
    simple_system_variables, /* system variables */
    NULL
}
mysql_declare_plugin_end;
```

Here is another valid way to write the general descriptor. It uses constant variables to indicate the plugin name, author, and description:
const char *simple_parser_name = "simple_parser";
const char *simple_parser_author = "Oracle Corporation";
const char *simple_parser_description = "Simple Full-Text Parser";

mysql_declare_plugin(ftexample)
{
  MYSQL_FTPARSER_PLUGIN,      /* type                            */
  &simple_parser_descriptor,  /* descriptor                      */
  simple_parser_name,         /* name                            */
  simple_parser_author,       /* author                          */
  simple_parser_description,  /* description                     */
  PLUGIN_LICENSE_GPL,         /* plugin license                  */
  simple_parser_plugin_init,  /* init function (when loaded)     */
  simple_parser_plugin_deinit,/* deinit function (when unloaded) */
  0x0001,                     /* version                         */
  NULL
}
mysql_declare_plugin_end;

However, the following general descriptor is invalid. It uses structure members to indicate the plugin name, author, and description, but structures are not considered constant initializers in C++:

typedef struct
{
  const char *name;
  const char *author;
  const char *description;
} plugin_info;

plugin_info parser_info = {
  "simple_parser",
  "Oracle Corporation",
  "Simple Full-Text Parser"
};

mysql_declare_plugin(ftexample)
{
  MYSQL_FTPARSER_PLUGIN,      /* type                            */
  &simple_parser_descriptor,  /* descriptor                      */
  parser_info.name,           /* name                            */
  parser_info.author,         /* author                          */
  parser_info.description,    /* description                     */
  PLUGIN_LICENSE_GPL,         /* plugin license                  */
  simple_parser_plugin_init,  /* init function (when loaded)     */
  simple_parser_plugin_deinit,/* deinit function (when unloaded) */
  0x0001,                     /* version                         */
  NULL
}
mysql_declare_plugin_end;

Plugin Status and System Variables

The server plugin interface enables plugins to expose status and system variables using the status_vars and system_vars members of the general plugin descriptor.

The status_vars member of the general plugin descriptor, if not 0, points to an array of st_mysql_show_var structures, each of which describes one status variable, followed by a structure with all members set to 0. The st_mysql_show_var structure has this definition:

struct st_mysql_show_var {
  const char *name;
  char *value;
  enum enum_mysql_show_type type;
};
When the plugin is installed, the plugin name and the name value are joined with an underscore to form the name displayed by `SHOW STATUS`.

The following table shows the permissible status variable type values and what the corresponding variable should be.

### Table 22.1 Server Plugin Status Variable Types

<table>
<thead>
<tr>
<th>Variable Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>SHOW_BOOL</td>
<td>Pointer to a boolean variable</td>
</tr>
<tr>
<td>SHOW_INT</td>
<td>Pointer to an integer variable</td>
</tr>
<tr>
<td>SHOW_LONG</td>
<td>Pointer to a long integer variable</td>
</tr>
<tr>
<td>SHOW_LONGLONG</td>
<td>Pointer to a longlong integer variable</td>
</tr>
<tr>
<td>SHOW_CHAR</td>
<td>A string</td>
</tr>
<tr>
<td>SHOW_CHAR_PTR</td>
<td>Pointer to a string</td>
</tr>
<tr>
<td>SHOW_ARRAY</td>
<td>Pointer to another <code>st_mysql_show_var</code> array</td>
</tr>
<tr>
<td>SHOW_FUNC</td>
<td>Pointer to a function</td>
</tr>
<tr>
<td>SHOW_DOUBLE</td>
<td>Pointer to a double</td>
</tr>
</tbody>
</table>

For the SHOW_FUNC type, the function is called and fills in its out parameter, which then provides information about the variable to be displayed. The function has this signature:

```c
#define SHOW_VAR_FUNC_BUFF_SIZE 1024
typedef int (*mysql_show_var_func) (void *thd,
    struct st_mysql_show_var *out,
    char *buf);
```

The system_vars member, if not 0, points to an array of `st_mysql_sys_var` structures, each of which describes one system variable (which can also be set from the command-line or configuration file), followed by a structure with all members set to 0. The `st_mysql_sys_var` structure is defined as follows:

```c
struct st_mysql_sys_var {
    int flags;
    const char *name, *comment;
    int (*check)(THD*, struct st_mysql_sys_var *, void*, st_mysql_value*);
    void (*update)(THD*, struct st_mysql_sys_var *, void*, const void*);
};
```

Additional fields are appended as required depending upon the flags.

For convenience, a number of macros are defined that make creating new system variables within a plugin much simpler.

Throughout the macros, the following fields are available:

- **name**: An unquoted identifier for the system variable.
- **varname**: The identifier for the static variable. Where not available, it is the same as the name field.
- **opt**: Additional use flags for the system variable. The following table shows the permissible flags.

### Table 22.2 Server Plugin System Variable Flags

<table>
<thead>
<tr>
<th>Flag Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PLUGIN_VAR_READONLY</td>
<td>The system variable is read only</td>
</tr>
<tr>
<td>PLUGIN_VAR_NOSYVAR</td>
<td>The system variable is not user visible at runtime</td>
</tr>
<tr>
<td>Flag Value</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-------------</td>
</tr>
<tr>
<td>PLUGIN_VAR_NOCMDARG</td>
<td>The system variable is not configurable from the command line</td>
</tr>
<tr>
<td>PLUGIN_VAR_NOCMDARG</td>
<td>No argument is required at the command line (typically used for boolean variables)</td>
</tr>
<tr>
<td>PLUGIN_VAR_RQCMDARG</td>
<td>An argument is required at the command line (this is the default)</td>
</tr>
<tr>
<td>PLUGIN_VAR_OPCMDARG</td>
<td>An argument is optional at the command line</td>
</tr>
<tr>
<td>PLUGIN_VAR_MEMALLOC</td>
<td>Used for string variables; indicates that memory is to be allocated for storage of the string</td>
</tr>
</tbody>
</table>

- **comment**: A descriptive comment to be displayed in the server help message. NULL if this variable is to be hidden.
- **check**: The check function, NULL for default.
- **update**: The update function, NULL for default.
- **default**: The variable default value.
- **minimum**: The variable minimum value.
- **maximum**: The variable maximum value.
- **blocksize**: The variable block size. When the value is set, it is rounded to the nearest multiple of blocksize.

A system variable may be accessed either by using the static variable directly or by using the SYSVAR() accessor macro. The SYSVAR() macro is provided for completeness. Usually it should be used only when the code cannot directly access the underlying variable.

For example:

```c
static int my_foo;
static MYSQL_SYSVAR_INT(foo_var, my_foo,
    PLUGIN_VAR_RQCMDARG, "foo comment",
    NULL, NULL, 0, 0, INT_MAX, 0);
...
    SYSVAR(foo_var)= value;
    value= SYSVAR(foo_var);
    my_foo= value;
    value= my_foo;
```

Session variables may be accessed only through the THDVAR() accessor macro. For example:

```c
static MYSQL_THDVAR_BOOL(some_flag, PLUGIN_VAR_NOCMDARG, "flag comment",
    NULL, NULL, FALSE);
...
    if (THDVAR(thd, some_flag))
    {
        do_something();
        THDVAR(thd, some_flag)= FALSE;
    }
```

All global and session system variables must be published to mysqld before use. This is done by constructing a NULL-terminated array of the variables and linking to it in the plugin public interface. For example:

```c
static struct st_mysql_sys_var *my_plugin_vars[] = {
    MYSQL_SYSVAR(foo_var),
    MYSQL_SYSVAR(some_flag),
    NULL
};
```
Writing Plugins

```c
mysql_declare_plugin(fooplug)
{
    MYSQL__PLUGIN,
    &plugin_data,
    "fooplug",
    "foo author",
    PLUGIN_LICENSE_GPL,
    foo_init,
    foo_fini,
    0x0001,
    NULL,
    my_plugin_vars,
    NULL
}
mysql_declare_plugin_end;
```

The following convenience macros enable you to declare different types of system variables:

- **Boolean system variables of type** `my_bool`, which is a 1-byte boolean. (0 = FALSE, 1 = TRUE)
  ```c
  MYSQL_THDVAR_BOOL(name, opt, comment, check, update, default)
  MYSQL_SYSVAR_BOOL(name, varname, opt, comment, check, update, default)
  ```

- **String system variables of type** `char*`, which is a pointer to a null-terminated string.
  ```c
  MYSQL_THDVAR_STR(name, opt, comment, check, update, default)
  MYSQL_SYSVAR_STR(name, varname, opt, comment, check, update, default)
  ```

- **Integer system variables, of which there are several varieties.**
  
  - **An** `int` **system variable**, which is typically a 4-byte signed word.
    ```c
    MYSQL_THDVAR_INT(name, opt, comment, check, update, default, min, max, blk)
    MYSQL_SYSVAR_INT(name, varname, opt, comment, check, update, default,
                      minimum, maximum, blocksize)
    ```

  - **An** `unsigned int` **system variable**, which is typically a 4-byte unsigned word.
    ```c
    MYSQL_THDVAR_UINT(name, opt, comment, check, update, default, min, max, blk)
    MYSQL_SYSVAR_UINT(name, varname, opt, comment, check, update, default,
                       minimum, maximum, blocksize)
    ```

  - **A** `long` **system variable**, which is typically either a 4- or 8-byte signed word.
    ```c
    MYSQL_THDVAR_LONG(name, opt, comment, check, update, default, min, max, blk)
    MYSQL_SYSVAR_LONG(name, varname, opt, comment, check, update, default,
                       minimum, maximum, blocksize)
    ```

  - **An** `unsigned long` **system variable**, which is typically either a 4- or 8-byte unsigned word.
    ```c
    MYSQL_THDVAR_ULONG(name, opt, comment, check, update, default, min, max, blk)
    MYSQL_SYSVAR_ULONG(name, varname, opt, comment, check, update, default,
                        minimum, maximum, blocksize)
    ```

  - **A** `long long` **system variable**, which is typically an 8-byte signed word.
    ```c
    MYSQL_THDVAR_LONGLONG(name, opt, comment, check, update,
                          default, minimum, maximum, blocksize)
    MYSQL_SYSVAR_LONGLONG(name, varname, opt, comment, check, update,
                           default, minimum, maximum, blocksize)
    ```

  - **An** `unsigned long long` **system variable**, which is typically an 8-byte unsigned word.
    ```c
    MYSQL_THDVAR_LONGLONG(name, opt, comment, check, update,
                          default, minimum, maximum, blocksize)
    MYSQL_SYSVAR_LONGLONG(name, varname, opt, comment, check, update,
                          default, minimum, maximum, blocksize)
    ```
Writing Plugins

MySQL_THDVAR_ULONGLONG(name, opt, comment, check, update, default, minimum, maximum, blocksize)
MySQL_SYSVAR_ULONGLONG(name, varname, opt, comment, check, update, default, minimum, maximum, blocksize)

• An unsigned long system variable, which is typically either a 4- or 8-byte unsigned word. The range of possible values is an ordinal of the number of elements in the typelib, starting from 0.

MySQL_THDVAR_ENUM(name, opt, comment, check, update, default, typelib)
MySQL_SYSVAR_ENUM(name, varname, opt, comment, check, update, default, typelib)

• An unsigned long long system variable, which is typically an 8-byte unsigned word. Each bit represents an element in the typelib.

MySQL_THDVAR_SET(name, opt, comment, check, update, default, typelib)
MySQL_SYSVAR_SET(name, varname, opt, comment, check, update, default, typelib)

Internally, all mutable and plugin system variables are stored in a HASH structure.

Display of the server command-line help text is handled by compiling a DYNAMIC_ARRAY of all variables relevant to command-line options, sorting them, and then iterating through them to display each option.

When a command-line option has been handled, it is then removed from the argv by the handle_option() function (my_getopt.c); in effect, it is consumed.

The server processes command-line options during the plugin installation process, immediately after the plugin has been successfully loaded but before the plugin initialization function has been called.

Plugins loaded at runtime do not benefit from any configuration options and must have usable defaults. Once they are installed, they are loaded at mysqld initialization time and configuration options can be set at the command line or within my.cnf.

Plugins should consider the thd parameter to be read only.

22.2.4.3 Compiling and Installing Plugin Libraries

After your plugin is written, you must compile it and install it. The procedure for compiling shared objects varies from system to system. If you build your library using the GNU autotools, libtool should be able to generate the correct compilation commands for your system. If the library is named somepluglib, you should end up with a shared object file that has a name something like somepluglib.so. (The .so file name suffix might differ on your system.)

To use the autotools, you’ll need to make a few changes to the configuration files at this point to enable the plugin to be compiled and installed. Assume that your MySQL distribution is installed at a base directory of /usr/local/mysql and that its header files are located in the include directory under the base directory.

Edit Makefile.am, which should look something like this:

```makefile
#Makefile.am example for a plugin
pkgplugindir=$(libdir)/mysql/plugin
INCLUDES= -I$(top_builddir)/include -I$(top_srcdir)/include
#noinst_LTLIBRARIES= somepluglib.la
pkgpluglib_LTLIBRARIES= somepluglib.la
somepluglib_la_SOURCES= plugin_example.c
somepluglib_la_LDFLAGS= -module -rpath $(pkgplugindir)
somepluglib_la_CFLAGS= -DMYSQL_DYNAMIC_PLUGIN
```
As mentioned in Library and Plugin Descriptors, be sure to specify `DMYSQL_DYNAMIC_PLUGIN` as part of the compilation command when you build the plugin. The `somedebugger_la_CFLAGS` line takes care of this.

Adjust the `INCLUDES` line to specify the path name to the installed MySQL header files. Edit it to look like this:

```
INCLUDES= -I/usr/local/mysql/include
```

Make sure that the `noinst_LTLIBRARIES` line is commented out or remove it. Make sure that the `pkglib_LTLIBRARIES` line is not commented out; it enables the `make install` command.

Set up the files needed for the `configure` command, invoke it, and run `make`:

```
shell> autoreconf --force --install --symlink
shell> ./configure --prefix=/usr/local/mysql
shell> make
```

The `--prefix` option to `configure` indicates the MySQL base directory under which the plugin should be installed. You can see what value to use for this option with `SHOW VARIABLES`:

```
mysql> SHOW VARIABLES LIKE 'basedir';
+---------------+------------------+
| Variable_name | Value            |
+---------------+------------------+
| base          | /usr/local/mysql |
+---------------+------------------+
```

The location of the plugin directory where you should install the library is given by the `plugin_dir` system variable. For example:

```
mysql> SHOW VARIABLES LIKE 'plugin_dir';
+---------------+-----------------------------------+
| Variable_name | Value                             |
+---------------+-----------------------------------+
| plugin_dir    | /usr/local/mysql/lib/mysql/plugin |
+---------------+-----------------------------------+
```

To install the plugin library, use `make`:

```
shell> make install
```

Verify that `make install` installed the plugin library in the proper directory. After installing it, make sure that the library permissions permit it to be executed by the server.

### 22.2.4.4 Writing Full-Text Parser Plugins

MySQL supports server-side full-text parser plugins only with `MyISAM`. For introductory information about full-text parser plugins, see Full-Text Parser Plugins.

A full-text parser plugin can be used to replace or modify the built-in full-text parser. This section describes how to write a full-text parser plugin named `simple_parser`. This plugin performs parsing based on simpler rules than those used by the MySQL built-in full-text parser: Words are nonempty runs of whitespace characters.

The instructions use the source code in the `plugin/fulltext` directory of MySQL source distributions, so change location into that directory. The following procedure describes how the plugin library is created:
Writing Plugins

1. To write a full-text parser plugin, include the following header file in the plugin source file. Other MySQL or general header files might also be needed, depending on the plugin capabilities and requirements.

```
#include <mysql/plugin.h>
```

`plugin.h` defines the `MYSQL_FTPARSER_PLUGIN` server plugin type and the data structures needed to declare the plugin.

2. Set up the library descriptor for the plugin library file.

This descriptor contains the general plugin descriptor for the server plugin. For a full-text parser plugin, the type must be `MYSQL_FTPARSER_PLUGIN`. This is the value that identifies the plugin as being legal for use in a `WITH PARSER` clause when creating a `FULLTEXT` index. (No other plugin type is legal for this clause.)

For example, the library descriptor for a library that contains a single full-text parser plugin named `simple_parser` looks like this:

```
mysql_declare_plugin(ftexample)
{
  MYSQL_FTPARSER_PLUGIN,  /* type                            */
  &simple_parser_descriptor,  /* descriptor                      */
  "simple_parser",            /* name                            */
  "Oracle Corporation",       /* author                          */
  "Simple Full-Text Parser",  /* description                     */
  PLUGIN_LICENSE_GPL,         /* plugin license                  */
  simple_parser_plugin_init,  /* init function (when loaded)     */
  simple_parser_plugin_deinit,/* deinit function (when unloaded) */
  0x0001,                     /* version                         */
  NULL
}
```

The `name` member (`simple_parser`) indicates the name to use for references to the plugin in statements such as `INSTALL PLUGIN` or `UNINSTALL PLUGIN`. This is also the name displayed by `SHOW PLUGINS` or `INFORMATION_SCHEMA.PLUGINS`.

For more information, see Library and Plugin Descriptors.

3. Set up the type-specific plugin descriptor.

Each general plugin descriptor in the library descriptor points to a type-specific descriptor. For a full-text parser plugin, the type-specific descriptor is an instance of the `st_mysql_ftparser` structure in the `plugin.h` file:

```
struct st_mysql_ftparser
{
  int interface_version;
  int (*parse)(MYSQL_FTPARSER_PARAM *param);
  int (*init)(MYSQL_FTPARSER_PARAM *param);
  int (*deinit)(MYSQL_FTPARSER_PARAM *param);
};
```

As shown by the structure definition, the descriptor has an interface version number and contains pointers to three functions.

The interface version number is specified using a symbol, which is in the form: `MYSQL_xxx_INTERFACE_VERSION`. For full-text parser plugins, the symbol is `MYSQL_FTPARSER_INTERFACE_VERSION`. In the source code, you will find the actual interface version number for the full-text parser plugin defined in `include/mysql/plugin.h`.
The \texttt{init} and \texttt{deinit} members should point to a function or be set to 0 if the function is not needed. The \texttt{parse} member must point to the function that performs the parsing.

In the \texttt{simple_parser} declaration, that descriptor is indicated by \texttt{&simple_parser_descriptor}. The descriptor specifies the version number for the full-text plugin interface (as given by \texttt{MYSQL_FTPARSER_INTERFACE_VERSION}), and the plugin’s parsing, initialization, and deinitialization functions:

```c
static struct st_mysql_ftparser simple_parser_descriptor=
{
    MYSQL_FTPARSER_INTERFACE_VERSION, /* interface version */
    simple_parser_parse,              /* parsing function */
    simple_parser_init,               /* parser init function */
    simple_parser_deinit              /* parser deinit function */
};
```

A full-text parser plugin is used in two different contexts, indexing and searching. In both contexts, the server calls the initialization and deinitialization functions at the beginning and end of processing each SQL statement that causes the plugin to be invoked. However, during statement processing, the server calls the main parsing function in context-specific fashion:

- For indexing, the server calls the parser for each column value to be indexed.
- For searching, the server calls the parser to parse the search string. The parser might also be called for rows processed by the statement. In natural language mode, there is no need for the server to call the parser. For boolean mode phrase searches or natural language searches with query expansion, the parser is used to parse column values for information that is not in the index. Also, if a boolean mode search is done for a column that has no \texttt{FULLTEXT} index, the built-in parser will be called. (Plugins are associated with specific indexes. If there is no index, no plugin is used.)

The plugin declaration in the general plugin descriptor has \texttt{init} and \texttt{deinit} members that point initialization and deinitialization functions, and so does the type-specific plugin descriptor to which it points. However, these pairs of functions have different purposes and are invoked for different reasons:

- For the plugin declaration in the general plugin descriptor, the initialization and deinitialization functions are invoked when the plugin is loaded and unloaded.
- For the type-specific plugin descriptor, the initialization and deinitialization functions are invoked per SQL statement for which the plugin is used.

Each interface function named in the plugin descriptor should return zero for success or nonzero for failure, and each of them receives an argument that points to a \texttt{MYSQL_FTPARSER_PARAM} structure containing the parsing context. The structure has this definition:

```c
typedef struct st_mysql_ftparser_param
{
    int (*mysql_parse)(struct st_mysql_ftparser_param *,
                       char *doc, int doc_len);
    int (*mysql_add_word)(struct st_mysql_ftparser_param *,
                          char *word, int word_len,
                          MYSQL_FTPARSER_BOOLEAN_INFO *boolean_info);
    void *ftp_parser_state;
    void *mysql_ftparam;
    struct charset_info_st *cs;
    char *doc;
    int length;
    int flags;
    enum enum_ftparser_mode mode;
} MYSQL_FTPARSER_PARAM;
```
Note

The definition shown is current as of MySQL 5.1.12. It is incompatible with versions of MySQL older than 5.1.12.

The structure members are used as follows:

- **mysql_parse**: A pointer to a callback function that invokes the server's built-in parser. Use this callback when the plugin acts as a front end to the built-in parser. That is, when the plugin parsing function is called, it should process the input to extract the text and pass the text to the *mysql_parse* callback.

  The first parameter for this callback function should be the *param* value itself:

  ```
  param->mysql_parse(param, ...);
  ```

  A front end plugin can extract text and pass it all at once to the built-in parser, or it can extract and pass text to the built-in parser a piece at a time. However, in this case, the built-in parser treats the pieces of text as though there are implicit word breaks between them.

- **mysql_add_word**: A pointer to a callback function that adds a word to a full-text index or to the list of search terms. Use this callback when the parser plugin replaces the built-in parser. That is, when the plugin parsing function is called, it should parse the input into words and invoke the *mysql_add_word* callback for each word.

  The first parameter for this callback function should be the *param* value itself:

  ```
  param->mysql_add_word(param, ...);
  ```

- **ftparser_state**: This is a generic pointer. The plugin can set it to point to information to be used internally for its own purposes.

- **mysql_ftparam**: This is set by the server. It is passed as the first argument to the *mysql_parse* or *mysql_add_word* callback.

- **cs**: A pointer to information about the character set of the text, or 0 if no information is available.

- **doc**: A pointer to the text to be parsed.

- **length**: The length of the text to be parsed, in bytes.

- **flags**: Parser flags. This is zero if there are no special flags. The only nonzero flag is *MYSQL_FTFLAGS_NEED_COPY*, which means that *mysql_add_word()* must save a copy of the word (that is, it cannot use a pointer to the word because the word is in a buffer that will be overwritten.) This member was added in MySQL 5.1.12.

  This flag might be set or reset by MySQL before calling the parser plugin, by the parser plugin itself, or by the *mysql_parse()* function.

- **mode**: The parsing mode. This value will be one of the following constants:

  - **MYSQL_FTPARSER_SIMPLE_MODE**: Parse in fast and simple mode, which is used for indexing and for natural language queries. The parser should pass to the server only those words that should be indexed. If the parser uses length limits or a stopword list to determine which words to ignore, it should not pass such words to the server.

  - **MYSQL_FTPARSER_WITH_STOPWORDS**: Parse in stopword mode. This is used in boolean searches for phrase matching. The parser should pass all words to the server, even stopwords or words that are outside any normal length limits.
• MySQL_FTPARSER_FULL_BOOLEAN_INFO: Parse in boolean mode. This is used for parsing boolean query strings. The parser should recognize not only words but also boolean-mode operators and pass them to the server as tokens using the mysql_add_word callback. To tell the server what kind of token is being passed, the plugin needs to fill in a MySQL_FTPARSER_BOOLEAN_INFO structure and pass a pointer to it.

If the parser is called in boolean mode, the param->mode value will be MySQL_FTPARSER_FULL_BOOLEAN_INFO. The MySQL_FTPARSER_BOOLEAN_INFO structure that the parser uses for passing token information to the server looks like this:

```c
typedef struct st_mysql_ftparser_boolean_info
{
  enum enum_ft_token_type type;
  int yesno;
  int weight_adjust;
  char wasign;
  char trunc;
  /* These are parser state and must be removed. */
  char *prev;
  char *quot;
} MYSQL_FTPARSER_BOOLEAN_INFO;
```

The parser should fill in the structure members as follows:

• **type**: The token type. The following table shows the permissible types.

<table>
<thead>
<tr>
<th>Token Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>FT_TOKEN_EOF</td>
<td>End of data</td>
</tr>
<tr>
<td>FT_TOKEN_WORD</td>
<td>A regular word</td>
</tr>
<tr>
<td>FT_TOKEN_LEFT_PAREN</td>
<td>The beginning of a group or subexpression</td>
</tr>
<tr>
<td>FT_TOKEN_RIGHT_PAREN</td>
<td>The end of a group or subexpression</td>
</tr>
<tr>
<td>FT_TOKEN_STOPWORD</td>
<td>A stopword</td>
</tr>
</tbody>
</table>

• **yesno**: Whether the word must be present for a match to occur. 0 means that the word is optional but increases the match relevance if it is present. Values larger than 0 mean that the word must be present. Values smaller than 0 mean that the word must not be present.

• **weight_adjust**: A weighting factor that determines how much a match for the word counts. It can be used to increase or decrease the word's importance in relevance calculations. A value of zero indicates no weight adjustment. Values greater than or less than zero mean higher or lower weight, respectively. The examples at Section 12.9.2, “Boolean Full-Text Searches”, that use the < and > operators illustrate how weighting works.

• **wasign**: The sign of the weighting factor. A negative value acts like the ~ boolean-search operator, which causes the word's contribution to the relevance to be negative.

• **trunc**: Whether matching should be done as if the boolean-mode * truncation operator had been given.

Plugins should not use the prev and quot members of the MySQL_FTPARSER_BOOLEAN_INFO structure.

**Note**

The plugin parser framework does not support:

• The @distance boolean operator.
• A leading plus sign (+) or minus sign (−) boolean operator followed by a
  space and then a word ('+ apple' or '- apple'). The leading plus or
  minus sign must be directly adjacent to the word, for example: '+apple'
  or '-apple'.

For information about boolean full-text search operators, see Section 12.9.2,
“Boolean Full-Text Searches”.

4. Set up the plugin interface functions.

The general plugin descriptor in the library descriptor names the initialization and deinitialization
functions that the server should invoke when it loads and unloads the plugin. For simple_parser,
these functions do nothing but return zero to indicate that they succeeded:

```c
static int simple_parser_plugin_init(void *arg __attribute__((unused)))
{
    return(0);
}

static int simple_parser_plugin_deinit(void *arg __attribute__((unused)))
{
    return(0);
}
```

Because those functions do not actually do anything, you could omit them and specify 0 for each of
them in the plugin declaration.

The type-specific plugin descriptor for simple_parser names the initialization, deinitialization,
and parsing functions that the server invokes when the plugin is used. For simple_parser, the
initialization and deinitialization functions do nothing:

```c
static int simple_parser_init(MYSQL_FTPARSER_PARAM *param
    __attribute__((unused)))
{
    return(0);
}

static int simple_parser_deinit(MYSQL_FTPARSER_PARAM *param
    __attribute__((unused)))
{
    return(0);
}
```

Here too, because those functions do nothing, you could omit them and specify 0 for each of them
in the plugin descriptor.

The main parsing function, simple_parser_parse(), acts as a replacement for the built-in
full-text parser, so it needs to split text into words and pass each word to the server. The parsing
function's first argument is a pointer to a structure that contains the parsing context. This structure
has a doc member that points to the text to be parsed, and a length member that indicates how
long the text is. The simple parsing done by the plugin considers nonempty runs of whitespace
characters to be words, so it identifies words like this:

```c
static int simple_parser_parse(MYSQL_FTPARSER_PARAM *param)
{
    char *end, *start, *docend= param->doc + param->length;
    for (end= start= param->doc;; end++)
    {
        if (end == docend)
        {
            if (end > start)
As the parser finds each word, it invokes a function `add_word()` to pass the word to the server. `add_word()` is a helper function only; it is not part of the plugin interface. The parser passes the parsing context pointer to `add_word()`, as well as a pointer to the word and a length value:

```c
static void add_word(MYSQL_FTPARSER_PARAM *param, char *word, size_t len)
{
    MYSQL_FTPARSER_BOOLEAN_INFO bool_info=
    { FT_TOKEN_WORD, 0, 0, 0, 0, ' ', 0 };
    param->mysql_add_word(param, word, len, &bool_info);
}
```

For boolean-mode parsing, `add_word()` fills in the members of the `bool_info` structure as described earlier in the discussion of the `st_mysql_ftparser_boolean_info` structure.

5. Set up the status variables. For the `simple_parser` plugin, the following status variable array sets up one status variable with a value that is static text, and another with a value that is stored in a long integer variable:

```c
long number_of_calls= 0;
struct st_mysql_show_var simple_status[] =
{
    {"static", (char *)"just a static text", SHOW_CHAR},
    {"called", (char *)&number_of_calls,     SHOW_LONG},
};
```

When the plugin is installed, the plugin name and the `name` value are joined with an underscore to form the name displayed by `SHOW STATUS`. For the array just shown, the resulting status variable names are `simple_parser_static` and `simple_parser_called`. This convention means that you can easily display the variables for a plugin using its name:

```
mysql> SHOW STATUS LIKE 'simple_parser%';
+----------------------+--------------------+
| Variable_name        | Value              |
+----------------------+--------------------+
| simple_parser_static | just a static text |
| simple_parser_called | 0                  |
+----------------------+--------------------+
```

6. To compile and install a plugin library object file, use the instructions in Section 22.2.4.3, “Compiling and Installing Plugin Libraries”. To make the library file available for use, install it in the plugin directory (the directory named by the `plugin_dir` system variable). For the `simple_parser` plugin, it is compiled and installed when you build MySQL from source. It is also included in binary distributions. The build process produces a shared object library with a name of `mypluglib.so` (the `.so` suffix might differ depending on your platform).

7. To use the plugin, register it with the server. For example, to register the plugin at runtime, use this statement (changing the suffix as necessary):

```sql
Writing Plugins
```
Writing Plugins

mysql> INSTALL PLUGIN simple_parser SONAME 'mypluglib.so';

For additional information about plugin loading, see Section 5.1.8.1, “Installing and Uninstalling Plugins”.

8. To verify plugin installation, examine the INFORMATION_SCHEMA.PLUGINS table or use the SHOW PLUGINS statement. See Section 5.1.8.2, “Obtaining Server Plugin Information”.

9. Test the plugin to verify that it works properly.

Create a table that contains a string column and associate the parser plugin with a FULLTEXT index on the column:

mysql> CREATE TABLE t (c VARCHAR(255),
                      ->   FULLTEXT (c) WITH PARSER simple_parser
                      -> ) ENGINE=MyISAM;

Query OK, 0 rows affected (0.01 sec)

Insert some text into the table and try some searches. These should verify that the parser plugin treats all nonwhitespace characters as word characters:

mysql> INSERT INTO t VALUES
        -> ('latin1_general_cs is a case-sensitive collation'),
        -> ('I'd like a case of oranges'),
        -> ('this is sensitive information'),
        -> ('another row'),
        -> ('yet another row');

Query OK, 5 rows affected (0.02 sec)
Records: 5  Duplicates: 0  Warnings: 0

mysql> SELECT c FROM t;

+-------------------------------------------------+
| c                                               |
+-------------------------------------------------+
| latin1_general_cs is a case-sensitive collation  |
| I'd like a case of oranges                      |
| this is sensitive information                   |
| another row                                     |
| yet another row                                 |
+-------------------------------------------------+
5 rows in set (0.00 sec)

mysql> SELECT MATCH(c) AGAINST('case') FROM t;

+--------------------------+
| MATCH(c) AGAINST('case') |
+--------------------------+
|                        0  |
|          1.2968142032623 |
|                        0  |
|                        0  |
|                        0  |
+--------------------------+
5 rows in set (0.00 sec)

mysql> SELECT MATCH(c) AGAINST('sensitive') FROM t;

+-------------------------------+
| MATCH(c) AGAINST('sensitive') |
+-------------------------------+
|                             0 |
|                             0 |
|               1.3253291845322 |
|                             0 |
|                             0 |
+-------------------------------+
5 rows in set (0.00 sec)
Neither “case” nor “insensitive” match “case-insensitive” the way that they would for the built-in parser.

22.2.4.5 Writing Daemon Plugins

A daemon plugin is a simple type of plugin used for code that should be run by the server but that does not communicate with it. This section describes how to write a daemon server plugin, using the example plugin found in the plugin/daemon_example directory of MySQL source distributions. That directory contains the daemon_example.cc source file for a daemon plugin named daemon_example that writes a heartbeat string at regular intervals to a file named mysql-heartbeat.log in the data directory.

To write a daemon plugin, include the following header file in the plugin source file. Other MySQL or general header files might also be needed, depending on the plugin capabilities and requirements.

```c
#include <mysql/plugin.h>
```

plugin.h defines the MYSQL_DAEMON_PLUGIN server plugin type and the data structures needed to declare the plugin.

The daemon_example.cc file sets up the library descriptor as follows. The library descriptor includes a single general server plugin descriptor.

```c
#include <mysql/plugin.h>

#include "mysql/plugin.h"

plugin.h defines the MYSQL_DAEMON_PLUGIN server plugin type and the data structures needed to declare the plugin.

The daemon_example.cc file sets up the library descriptor as follows. The library descriptor includes a single general server plugin descriptor.

```c

mysql_declare_plugin(daemon_example)
{
  MYSQL_DAEMON_PLUGIN,
  daemon_example_plugin,
  "daemon_example",
  "Brian Aker",
  "Daemon example, creates a heartbeat file in mysql-heartbeat.log",
  PLUGIN_LICENSE_GPL,
  daemon_example_plugin_init, /* Plugin Init */
  daemon_example_plugin_deinit, /* Plugin Deinit */
  0x0100 /* 1.0 */,
  NULL, /* status variables */
  NULL, /* system variables */
  NULL /* config options */
}

mysql_declare_plugin_end;
```

The name member (daemon_example) indicates the name to use for references to the plugin in statements such as INSTALL PLUGIN or UNINSTALL PLUGIN. This is also the name displayed by SHOW PLUGINS or INFORMATION_SCHEMA.PLUGINS.
The second member of the plugin descriptor, `daemon_example_plugin`, points to the type-specific daemon plugin descriptor. This structure consists only of the type-specific API version number:

```
struct st_mysql_daemon daemon_example_plugin =
{ MYSQL_DAEMON_INTERFACE_VERSION  };
```

The type-specific structure has no interface functions. There is no communication between the server and the plugin, except that the server calls the initialization and deinitialization functions from the general plugin descriptor to start and stop the plugin:

- `daemon_example_plugin_init()` opens the heartbeat file and spawns a thread that wakes up periodically and writes the next message to the file.
- `daemon_example_plugin_deinit()` closes the file and performs other cleanup.

To compile and install a plugin library object file, use the instructions in Section 22.2.4.3, “Compiling and Installing Plugin Libraries”. To make the library file available for use, install it in the plugin directory (the directory named by the `plugin_dir` system variable). For the `daemon_example` plugin, it is compiled and installed when you build MySQL from source. It is also included in binary distributions. The build process produces a shared object library with a name of `libdaemon_example.so` (the `.so` suffix might differ depending on your platform).

To use the plugin, register it with the server. For example, to register the plugin at runtime, use this statement (change the suffix as necessary):

```
mysql> INSTALL PLUGIN daemon_example SONAME 'libdaemon_example.so';
```

For additional information about plugin loading, see Section 5.1.8.1, “Installing and Uninstalling Plugins”.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement. See Section 5.1.8.2, “Obtaining Server Plugin Information”.

While the plugin is loaded, it writes a heartbeat string at regular intervals to a file named `mysql-heartbeat.log` in the data directory. This file grows without limit, so after you have satisfied yourself that the plugin operates correctly, unload it:

```
mysql> UNINSTALL PLUGIN daemon_example;
```

### 22.2.4.6 Writing INFORMATION_SCHEMA Plugins

This section describes how to write a server-side `INFORMATION_SCHEMA` table plugin. For example code that implements such plugins, see the `sql/sql_show.cc` file of a MySQL source distribution. You can also look at the example plugins found in the InnoDB source. See the `handler/i_s.cc` and `handler/ha_innodb.cc` files within the InnoDB source tree (in the `storage/innodb_plugin` directory).

To write an `INFORMATION_SCHEMA` table plugin, include the following header files in the plugin source file. Other MySQL or general header files might also be needed, depending on the plugin capabilities and requirements.

```
#include <sql_class.h>
#include <table.h>
```

These header files are located in the `sql` directory of MySQL source distributions. They contain C++ structures, so the source file for an `INFORMATION_SCHEMA` plugin must be compiled as C++ (not C) code.
The source file for the example plugin developed here is named `simple_i_s_table.cc`. It creates a simple `INFORMATION_SCHEMA` table named `SIMPLE_I_S_TABLE` that has two columns named `NAME` and `VALUE`. The general descriptor for a plugin library that implements the table looks like this:

```c
mysql_declare_plugin(simple_i_s_library)
{
  MYSQL_INFORMATION_SCHEMA_PLUGIN,
  &simple_table_info,               /* type-specific descriptor */
  "SIMPLE_I_S_TABLE",               /* table name */
  "Author Name",                     /* author */
  "Simple INFORMATION_SCHEMA table", /* description */
  PLUGIN_LICENSE_GPL,                /* license type */
  simple_table_init,                 /* init function */
  NULL,                              /* version = 1.0 */
  NULL,                              /* no status variables */
  NULL,                              /* no system variables */
  NULL                               /* no reserved information */
} mysql_declare_plugin_end;
```

The `name` member (`SIMPLE_I_S_TABLE`) indicates the name to use for references to the plugin in statements such as `INSTALL PLUGIN` or `UNINSTALL PLUGIN`. This is also the name displayed by `SHOW PLUGINS` or `INFORMATION_SCHEMA.PLUGINS`.

The `simple_table_info` member of the general descriptor points to the type-specific descriptor, which consists only of the type-specific API version number:

```c
static struct st_mysql_information_schema simple_table_info =
{ MYSQL_INFORMATION_SCHEMA_INTERFACE_VERSION};
```

The general descriptor points to the initialization and deinitialization functions:

- The initialization function provides information about the table structure and a function that populates the table.
- The deinitialization function performs any required cleanup. If no cleanup is needed, this descriptor member can be `NULL` (as in the example shown).

The initialization function should return 0 for success, 1 if an error occurs. The function receives a generic pointer, which it should interpret as a pointer to the table structure:

```c
static int table_init(void *ptr)
{
  ST_SCHEMA_TABLE *schema_table= (ST_SCHEMA_TABLE*)ptr;
  schema_table->fields_info= simple_table_fields;
  schema_table->fill_table= simple_fill_table;
  return 0;
}
```

The function should set these two members of the table structure:

- `fields_info`: An array of `ST_FIELD_INFO` structures that contain information about each column.
- `fill_table`: A function that populates the table.

The array pointed to by `fields_info` should contain one element per column of the `INFORMATION_SCHEMA` plus a terminating element. The following `simple_table_fields` array for the example plugin indicates that `SIMPLE_I_S_TABLE` has two columns. `NAME` is string-valued with a length of 10 and `VALUE` is integer-valued with a display width of 20. The last structure marks the end of the array.
For more information about the column information structure, see the definition of `ST_FIELD_INFO` in the `table.h` header file. The permissible `MYSQL_TYPE_xxx` type values are those used in the C API; see Section 21.8.5, “C API Data Structures”.

The `fill_table` member should be set to a function that populates the table and returns 0 for success, 1 if an error occurs. For the example plugin, the `simple_fill_table()` function looks like this:

```c
static int simple_fill_table(THD *thd, TABLE_LIST *tables, COND *cond)
{
    TABLE *table= tables->table;
    table->field[0]->store("Name 1", 6, system_charset_info);
    table->field[1]->store(1);
    if (schema_table_store_record(thd, table))
        return 1;
    table->field[0]->store("Name 2", 6, system_charset_info);
    table->field[1]->store(2);
    if (schema_table_store_record(thd, table))
        return 1;
    return 0;
}
```

For each row of the `INFORMATION_SCHEMA` table, this function initializes each column, then calls `schema_table_store_record()` to install the row. The `store()` method arguments depend on the type of value to be stored. For column 0 (`NAME`, a string), `store()` takes a pointer to a string, its length, and information about the character set of the string:

```c
store(const char *to, uint length, CHARSET_INFO *cs);
```

For column 1 (`VALUE`, an integer), `store()` takes the value and a flag indicating whether it is unsigned:

```c
store(longlong nr, bool unsigned_value);
```

For other examples of how to populate `INFORMATION_SCHEMA` tables, search for instances of `schema_table_store_record()` in `sql_show.cc`.

To compile and install a plugin library object file, use the instructions in Section 22.2.4.3, “Compiling and Installing Plugin Libraries”. To make the library file available for use, install it in the plugin directory (the directory named by the `plugin_dir` system variable).

To test the plugin, install it:

```sql
mysql> INSTALL PLUGIN SIMPLE_I_S_TABLE SONAME 'simple_i_s_table.so';
```

Verify that the table is present:

```sql
mysql> SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
    -> WHERE TABLE_NAME = 'SIMPLE_I_S_TABLE';
+------------------+
| TABLE_NAME       |
+------------------+
| SIMPLE_I_S_TABLE |
+------------------+
```
### 22.3 Adding New Functions to MySQL

There are three ways to add new functions to MySQL:

- You can add functions through the user-defined function (UDF) interface. User-defined functions are compiled as object files and then added to and removed from the server dynamically using the `CREATE FUNCTION` and `DROP FUNCTION` statements. See Section 13.7.3.1, “CREATE FUNCTION Syntax for User-Defined Functions”.

- You can add functions as native (built-in) MySQL functions. Native functions are compiled into the `mysqld` server and become available on a permanent basis.

- Another way to add functions is by creating stored functions. These are written using SQL statements rather than by compiling object code. The syntax for writing stored functions is not covered here. See Section 19.2, “Using Stored Routines (Procedures and Functions)”.  

Each method of creating compiled functions has advantages and disadvantages:

- If you write user-defined functions, you must install object files in addition to the server itself. If you compile your function into the server, you don’t need to do that.

- Native functions require you to modify a source distribution. UDFs do not. You can add UDFs to a binary MySQL distribution. No access to MySQL source is necessary.

- If you upgrade your MySQL distribution, you can continue to use your previously installed UDFs, unless you upgrade to a newer version for which the UDF interface changes. For native functions, you must repeat your modifications each time you upgrade.

Whichever method you use to add new functions, they can be invoked in SQL statements just like native functions such as `ABS()` or `SOUNDEX()`.

See Section 9.2.4, “Function Name Parsing and Resolution”, for the rules describing how the server interprets references to different kinds of functions.

The following sections describe features of the UDF interface, provide instructions for writing UDFs, discuss security precautions that MySQL takes to prevent UDF misuse, and describe how to add native MySQL functions.

For example source code that illustrates how to write UDFs, take a look at the `sql/udf_example.c` file that is provided in MySQL source distributions.

### 22.3.1 Features of the User-Defined Function Interface

The MySQL interface for user-defined functions provides the following features and capabilities:

- Functions can return string, integer, or real values and can accept arguments of those same types.
• You can define simple functions that operate on a single row at a time, or aggregate functions that operate on groups of rows.

• Information is provided to functions that enables them to check the number, types, and names of the arguments passed to them.

• You can tell MySQL to coerce arguments to a given type before passing them to a function.

• You can indicate that a function returns NULL or that an error occurred.

### 22.3.2 Adding a New User-Defined Function

For the UDF mechanism to work, functions must be written in C or C++ and your operating system must support dynamic loading. MySQL source distributions include a file `sql/udf_example.c` that defines five UDF functions. Consult this file to see how UDF calling conventions work. The `include/mysql_com.h` header file defines UDF-related symbols and data structures, although you need not include this header file directly; it is included by `mysql.h`.

A UDF contains code that becomes part of the running server, so when you write a UDF, you are bound by any and all constraints that apply to writing server code. For example, you may have problems if you attempt to use functions from the `libstdc++` library. These constraints may change in future versions of the server, so it is possible that server upgrades will require revisions to UDFs that were originally written for older servers. For information about these constraints, see Section 2.11.4, “MySQL Source-Configuration Options”, and Section 2.11.5, “Dealing with Problems Compiling MySQL”.

To be able to use UDFs, you must link `mysqld` dynamically. Don't configure MySQL using `--with-mysqld-ldflags=-all-static`. If you want to use a UDF that needs to access symbols from `mysqld` (for example, the `metaphone` function in `sql/udf_example.c` uses `default_charset_info`), you must link the program with `-rdynamic` (see `man dlopen`). If you plan to use UDFs, the rule of thumb is to configure MySQL with `--with-mysqld-ldflags=-rdynamic` unless you have a very good reason not to.

For each function that you want to use in SQL statements, you should define corresponding C (or C++) functions. In the following discussion, the name “xxx” is used for an example function name. To distinguish between SQL and C/C++ usage, `XXX()` (uppercase) indicates an SQL function call, and `xxx()` (lowercase) indicates a C/C++ function call.

#### Note

When using C++ you can encapsulate your C functions within:

```c
extern "C" {
...
}
```

This ensures that your C++ function names remain readable in the completed UDF.

The following list describes the C/C++ functions that you write to implement the interface for a function named `XXX()`. The main function, `xxx()`, is required. In addition, a UDF requires at least one of the other functions described here, for reasons discussed in Section 22.3.2.6, “UDF Security Precautions”.

- `xxx()`

  The main function. This is where the function result is computed. The correspondence between the SQL function data type and the return type of your C/C++ function is shown here.

<table>
<thead>
<tr>
<th>SQL Type</th>
<th>C/C++ Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>STRING</td>
<td><code>char *</code></td>
</tr>
<tr>
<td>INTEGER</td>
<td><code>long long</code></td>
</tr>
</tbody>
</table>
Adding a New User-Defined Function

<table>
<thead>
<tr>
<th>SQL Type</th>
<th>C/C++ Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>REAL</td>
<td>double</td>
</tr>
</tbody>
</table>

It is also possible to declare a DECIMAL function, but currently the value is returned as a string, so you should write the UDF as though it were a STRING function. ROW functions are not implemented.

- **xxx_init()**
  
  The initialization function for xxx(). If present, it can be used for the following purposes:
  
  - To check the number of arguments to XXX().
  - To verify that the arguments are of a required type or, alternatively, to tell MySQL to coerce arguments to the required types when the main function is called.
  - To allocate any memory required by the main function.
  - To specify the maximum length of the result.
  - To specify (for REAL functions) the maximum number of decimal places in the result.
  - To specify whether the result can be NULL.

- **xxx_deinit()**
  
  The deinitialization function for xxx(). If present, it should deallocate any memory allocated by the initialization function.

When an SQL statement invokes XXX(), MySQL calls the initialization function xxx_init() to let it perform any required setup, such as argument checking or memory allocation. If xxx_init() returns an error, MySQL aborts the SQL statement with an error message and does not call the main or deinitialization functions. Otherwise, MySQL calls the main function xxx() once for each row. After all rows have been processed, MySQL calls the deinitialization function xxx_deinit() so that it can perform any required cleanup.

For aggregate functions that work like SUM(), you must also provide the following functions:

- **xxx_clear()**
  
  Reset the current aggregate value but do not insert the argument as the initial aggregate value for a new group.

- **xxx_add()**
  
  Add the argument to the current aggregate value.

MySQL handles aggregate UDFs as follows:

1. Call xxx_init() to let the aggregate function allocate any memory it needs for storing results.
2. Sort the table according to the GROUP BY expression.
3. Call xxx_clear() for the first row in each new group.
4. Call xxx_add() for each row that belongs in the same group.
5. Call xxx() to get the result for the aggregate when the group changes or after the last row has been processed.
6. Repeat steps 3 to 5 until all rows have been processed
7. Call xxx_deinit() to let the UDF free any memory it has allocated.
Adding a New User-Defined Function

All functions must be thread-safe. This includes not just the main function, but the initialization and deinitialization functions as well, and also the additional functions required by aggregate functions. A consequence of this requirement is that you are not permitted to allocate any global or static variables that change! If you need memory, you should allocate it in `xxx_init()` and free it in `xxx_deinit()`.

### 22.3.2.1 UDF Calling Sequences for Simple Functions

This section describes the different functions that you need to define when you create a simple UDF. Section 22.3.2, “Adding a New User-Defined Function”, describes the order in which MySQL calls these functions.

The main `xxx()` function should be declared as shown in this section. Note that the return type and parameters differ, depending on whether you declare the SQL function `XXX()` to return `STRING`, `INTEGER`, or `REAL` in the `CREATE FUNCTION` statement:

For **STRING** functions:

```c
char *xxx(UDF_INIT *initid, UDF_ARGS *args,
          char *result, unsigned long *length,
          char *is_null, char *error);
```

For **INTEGER** functions:

```c
long long xxx(UDF_INIT *initid, UDF_ARGS *args,
              char *is_null, char *error);
```

For **REAL** functions:

```c
double xxx(UDF_INIT *initid, UDF_ARGS *args,
           char *is_null, char *error);
```

**DECIMAL** functions return string values and should be declared the same way as **STRING** functions. **ROW** functions are not implemented.

The initialization and deinitialization functions are declared like this:

```c
my_bool xxx_init(UDF_INIT *initid, UDF_ARGS *args, char *message);
void xxx_deinit(UDF_INIT *initid);
```

The `initid` parameter is passed to all three functions. It points to a **UDF_INIT** structure that is used to communicate information between functions. The **UDF_INIT** structure members follow. The initialization function should fill in any members that it wishes to change. (To use the default for a member, leave it unchanged.)

- **my_bool maybe_null**

  `xxx_init()` should set `maybe_null` to 1 if `xxx()` can return `NULL`. The default value is 1 if any of the arguments are declared `maybe_null`.

- **unsigned int decimals**

  The number of decimal digits to the right of the decimal point. The default value is the maximum number of decimal digits in the arguments passed to the main function. For example, if the function is passed `1.34`, `1.345`, and `1.3`, the default would be 3, because `1.345` has 3 decimal digits.

  For arguments that have no fixed number of decimals, the `decimals` value is set to 31, which is 1 more than the maximum number of decimals permitted for the **DECIMAL**, **FLOAT**, and **DOUBLE** data types.
Adding a New User-Defined Function

A **decimals** value of 31 is used for arguments in cases such as a FLOAT or DOUBLE column declared without an explicit number of decimals (for example, FLOAT rather than FLOAT(10,3)) and for floating-point constants such as 1345E-3. It is also used for string and other nonnumber arguments that might be converted within the function to numeric form.

The value to which the **decimals** member is initialized is only a default. It can be changed within the function to reflect the actual calculation performed. The default is determined such that the largest number of decimals of the arguments is used. If the number of decimals is 31 for even one of the arguments, that is the value used for **decimals**.

- **unsigned int max_length**

  The maximum length of the result. The default **max_length** value differs depending on the result type of the function. For string functions, the default is the length of the longest argument. For integer functions, the default is 21 digits. For real functions, the default is 13 plus the number of decimal digits indicated by `initid->decimals`. (For numeric functions, the length includes any sign or decimal point characters.)

  If you want to return a blob value, you can set **max_length** to 65KB or 16MB. This memory is not allocated, but the value is used to decide which data type to use if there is a need to temporarily store the data.

- **char *ptr**

  A pointer that the function can use for its own purposes. For example, functions can use `initid->ptr` to communicate allocated memory among themselves. `xxx_init()` should allocate the memory and assign it to this pointer:

  ```
  initid->ptr = allocated_memory;
  ```

  In `xxx()` and `xxx_deinit()`, refer to `initid->ptr` to use or deallocate the memory.

- **my_bool const_item**

  `xxx_init()` should set `const_item` to **1** if `xxx()` always returns the same value and to **0** otherwise.

### 22.3.2.2 UDF Calling Sequences for Aggregate Functions

This section describes the different functions that you need to define when you create an aggregate UDF. Section 22.3.2, “Adding a New User-Defined Function”, describes the order in which MySQL calls these functions.

- **xxx_reset()**

  This function is called when MySQL finds the first row in a new group. It should reset any internal summary variables and then use the given **UDF_ARGS** argument as the first value in your internal summary value for the group. Declare **xxx_reset()** as follows:

  ```
  void xxx_reset(UDF_INIT *initid, UDF_ARGS *args,
  char *is_null, char *error);
  ```

  **xxx_reset()** is not needed or used in MySQL 5.1, in which the UDF interface uses **xxx_clear()** instead. However, you can define both **xxx_reset()** and **xxx_clear()** if you want to have your UDF work with older versions of the server. (If you do include both functions, the **xxx_reset()** function in many cases can be implemented internally by calling **xxx_clear()** to reset all variables, and then calling **xxx_add()** to add the **UDF_ARGS** argument as the first value in the group.)

- **xxx_clear()**
Adding a New User-Defined Function

This function is called when MySQL needs to reset the summary results. It is called at the beginning for each new group but can also be called to reset the values for a query where there were no matching rows. Declare `xxx_clear()` as follows:

```c
void xxx_clear(UDF_INIT *initid, char *is_null, char *error);
```

*is_null* is set to point to `CHAR(0)` before calling `xxx_clear()`.

If something went wrong, you can store a value in the variable to which the *error* argument points. *error* points to a single-byte variable, not to a string buffer.

`xxx_clear()` is required by MySQL 5.1.

- **`xxx_add()`**

  This function is called for all rows that belong to the same group. You should use it to add the value in the `UDF_ARGS` argument to your internal summary variable.

  ```c
  void xxx_add(UDF_INIT *initid, UDF_ARGS *args, char *is_null, char *error);
  ```

  The `xxx()` function for an aggregate UDF should be declared the same way as for a nonaggregate UDF. See Section 22.3.2.1, “UDF Calling Sequences for Simple Functions”.

  For an aggregate UDF, MySQL calls the `xxx()` function after all rows in the group have been processed. You should normally never access its `UDF_ARGS` argument here but instead return a value based on your internal summary variables.

  Return value handling in `xxx()` should be done the same way as for a nonaggregate UDF. See Section 22.3.2.4, “UDF Return Values and Error Handling”.

  The `xxx_reset()` and `xxx_add()` functions handle their `UDF_ARGS` argument the same way as functions for nonaggregate UDFs. See Section 22.3.2.3, “UDF Argument Processing”.

  The pointer arguments to *is_null* and *error* are the same for all calls to `xxx_reset()`, `xxx_clear()`, `xxx_add()` and `xxx()`. You can use this to remember that you got an error or whether the `xxx()` function should return `NULL`. You should not store a string into `*error!error` points to a single-byte variable, not to a string buffer.

  `*is_null` is reset for each group (before calling `xxx_clear()`). *error* is never reset.

  If `*is_null` or *error* are set when `xxx()` returns, MySQL returns `NULL` as the result for the group function.

22.3.2.3 UDF Argument Processing

The `args` parameter points to a `UDF_ARGS` structure that has the members listed here:

- **unsigned int arg_count**

  The number of arguments. Check this value in the initialization function if you require your function to be called with a particular number of arguments. For example:

  ```c
  if (args->arg_count != 2) {
    strcpy(message,"XXX() requires two arguments");
    return 1;
  }
  ```
For other `UDF_ARGS` member values that are arrays, array references are zero-based. That is, refer to array members using index values from 0 to `args->arg_count - 1`.

- **enum Item_result *arg_type**

  A pointer to an array containing the types for each argument. The possible type values are `STRING_RESULT`, `INT_RESULT`, `REAL_RESULT`, and `DECIMAL_RESULT`.

  To make sure that arguments are of a given type and return an error if they are not, check the `arg_type` array in the initialization function. For example:

  ```c
  if (args->arg_type[0] != STRING_RESULT ||
      args->arg_type[1] != INT_RESULT)
  {
    strcpy(message, "XXX() requires a string and an integer");
    return 1;
  }
  ```

  Arguments of type `DECIMAL_RESULT` are passed as strings, so you should handle them the same way as `STRING_RESULT` values.

  As an alternative to requiring your function’s arguments to be of particular types, you can use the initialization function to set the `arg_type` elements to the types you want. This causes MySQL to coerce arguments to those types for each call to `xxx()`. For example, to specify that the first two arguments should be coerced to string and integer, respectively, do this in `xxx_init()`:

  ```c
  args->arg_type[0] = STRING_RESULT;
  args->arg_type[1] = INT_RESULT;
  ```

  Exact-value decimal arguments such as `1.3` or `DECIMAL` column values are passed with a type of `DECIMAL_RESULT`. However, the values are passed as strings. If you want to receive a number, use the initialization function to specify that the argument should be coerced to a `REAL_RESULT` value:

  ```c
  args->arg_type[2] = REAL_RESULT;
  ```

- **char **args**

  `args` communicates information to the initialization function about the general nature of the arguments passed to your function. For a constant argument `i`, `args->args[i]` points to the argument value. (See later for instructions on how to access the value properly.) For a nonconstant argument, `args->args[i]` is `0`. A constant argument is an expression that uses only constants, such as `3` or `4*7-2` or `SIN(3.14)`. A nonconstant argument is an expression that refers to values that may change from row to row, such as column names or functions that are called with nonconstant arguments.

  For each invocation of the main function, `args->args` contains the actual arguments that are passed for the row currently being processed.

  If argument `i` represents `NULL`, `args->args[i]` is a null pointer (`0`). If the argument is not `NULL`, functions can refer to it as follows:

  - An argument of type `STRING_RESULT` is given as a string pointer plus a length, to enable handling of binary data or data of arbitrary length. The string contents are available as `args->args[i]` and the string length is `args->lengths[i]`. Do not assume that the string is null-terminated.

  - For an argument of type `INT_RESULT`, you must cast `args->args[i]` to a `long long` value:

    ```c
    long long int_val;
    int_val = *((long long*) args->args[i]);
    ```
• For an argument of type `REAL_RESULT`, you must cast `args->args[i]` to a `double` value:

```c
double real_val;
real_val = *((double*) args->args[i]);
```

• For an argument of type `DECIMAL_RESULT`, the value is passed as a string and should be handled like a `STRING_RESULT` value.

• `ROW_RESULT` arguments are not implemented.

• `unsigned long *lengths`

For the initialization function, the `lengths` array indicates the maximum string length for each argument. You should not change these. For each invocation of the main function, `lengths` contains the actual lengths of any string arguments that are passed for the row currently being processed. For arguments of types `INT_RESULT` or `REAL_RESULT`, `lengths` still contains the maximum length of the argument (as for the initialization function).

• `char *maybe_null`

For the initialization function, the `maybe_null` array indicates for each argument whether the argument value might be null (0 if no, 1 if yes).

• `char **attributes`

`args->attributes` communicates information about the names of the UDF arguments. For argument `i`, the attribute name is available as a string in `args->attributes[i]` and the attribute length is `args->attribute_lengths[i]`. Do not assume that the string is null-terminated.

By default, the name of a UDF argument is the text of the expression used to specify the argument. For UDFs, an argument may also have an optional `[AS] alias_name` clause, in which case the argument name is `alias_name`. The `attributes` value for each argument thus depends on whether an alias was given.

Suppose that a UDF `my_udf()` is invoked as follows:

```sql
SELECT my_udf(expr1, expr2 AS alias1, expr3 alias2);
```

In this case, the `attributes` and `attribute_lengths` arrays will have these values:

```c
args->attributes[0] = "expr1"
args->attribute_lengths[0] = 5
args->attributes[1] = "alias1"
args->attribute_lengths[1] = 6
args->attributes[2] = "alias2"
args->attribute_lengths[2] = 6
```

• `unsigned long *attribute_lengths`

The `attribute_lengths` array indicates the length of each argument name.

### 22.3.2.4 UDF Return Values and Error Handling

The initialization function should return 0 if no error occurred and 1 otherwise. If an error occurs, `xxx_init()` should store a null-terminated error message in the `message` parameter. The message is returned to the client. The message buffer is `MYSQL_ERRMSG_SIZE` characters long, but you should try to keep the message to less than 80 characters so that it fits the width of a standard terminal screen.
The return value of the main function `xxx()` is the function value, for `long long` and `double` functions. A string function should return a pointer to the result and set `*length` to the length (in bytes) of the return value. For example:

```c
memcpy(result, "result string", 13);
*length = 13;
```

MySQL passes a buffer to the `xxx()` function using the `result` parameter. This buffer is sufficiently long to hold 255 characters, which can be multibyte characters. The `xxx()` function can store the result in this buffer if it fits, in which case the return value should be a pointer to the buffer. If the function stores the result in a different buffer, it should return a pointer to that buffer.

If your string function does not use the supplied buffer (for example, if it needs to return a string longer than 255 characters), you must allocate the space for your own buffer with `malloc()` in your `xxx_init()` function or your `xxx()` function and free it in your `xxx_deinit()` function. You can store the allocated memory in the `ptr` slot in the `UDF_INIT` structure for reuse by future `xxx()` calls. See Section 22.3.2.1, “UDF Calling Sequences for Simple Functions”.

To indicate a return value of `NULL` in the main function, set `*is_null` to 1:

```c
*is_null = 1;
```

To indicate an error return in the main function, set `*error` to 1:

```c
*error = 1;
```

If `xxx()` sets `*error` to 1 for any row, the function value is `NULL` for the current row and for any subsequent rows processed by the statement in which `XXX()` was invoked. (`xxx()` is not even called for subsequent rows.)

### 22.3.2.5 UDF Compiling and Installing

Files implementing UDFs must be compiled and installed on the host where the server runs. This process is described below for the example UDF file `sql/udf_example.c` that is included in MySQL source distributions.

If a UDF will be referred to in statements that will be replicated to slave servers, you must ensure that every slave also has the function available. Otherwise, replication will fail on the slaves when they attempt to invoke the function.

The immediately following instructions are for Unix. Instructions for Windows are given later in this section.

The `udf_example.c` file contains the following functions:

- `metaphon()` returns a metaphon string of the string argument. This is something like a soundex string, but it is more tuned for English.
- `myfunc_double()` returns the sum of the ASCII values of the characters in its arguments, divided by the sum of the length of its arguments.
- `myfunc_int()` returns the sum of the length of its arguments.
- `sequence(const int)` returns a sequence starting from the given number or 1 if no number has been given.
- `lookup()` returns the IP address for a host name.
- `reverse_lookup()` returns the host name for an IP address. The function may be called either with a single string argument of the form `"xxx.xxx.xxx.xxx"` or with four numbers.
Adding a New User-Defined Function

• **avgcost()** returns an average cost. This is an aggregate function.

A dynamically loadable file should be compiled as a sharable object file, using a command something like this:

```
shell> gcc -shared -o udf_example.so udf_example.c
```

If you are using gcc with configure and libtool (which is how MySQL is configured), you should be able to create **udf_example.so** with a simpler command:

```
shell> make udf_example.la
```

After you compile a shared object containing UDFs, you must install it and tell MySQL about it. Compiling a shared object from **udf_example.c** using gcc directly produces a file named **udf_example.so**. Compiling the shared object using make produces a file named something like **udf_example.so.0.0.0** in the .libs directory (the exact name may vary from platform to platform). Copy the shared object to the server's plugin directory and name it **udf_example.so**. This directory is given by the value of the **plugin_dir** system variable.

**Note**

This is a change in MySQL 5.1. For earlier versions of MySQL, the shared object can be located in any directory that is searched by your system's dynamic linker.

On some systems, the **ldconfig** program that configures the dynamic linker does not recognize a shared object unless its name begins with **lib**. In this case you should rename a file such as **udf_example.so** to **libudf_example.so**.

On Windows, you can compile user-defined functions by using the following procedure:

1. Obtain the development source for MySQL 5.1. See Section 2.1.2, “How to Get MySQL”.
2. Obtain the **CMake** build utility, if necessary, from http://www.cmake.org. (Version 2.6 or later is required).
3. In the source tree, look in the **sql** directory. There are files named **udf_example.def** and **udf_example.c** there. Copy both files from this directory to your working directory.
4. Create a **CMake makefile** (**CMakeLists.txt**) with these contents:

   ```
   PROJECT(udf_example)
   # Path for MySQL include directory
   INCLUDE_DIRECTORIES("c:/mysql/include")
   ADD_DEFINITIONS("-DHAVE_DLOPEN")
   ADD_LIBRARY(udf_example MODULE udf_example.c udf_example.def)
   TARGET_LINK_LIBRARIES(udf_example wsock32)
   ```
5. Create the VC project and solution files:

   ```
   cmake -G "<Generator>"
   ```

   Invoking cmake --help shows you a list of valid Generators.
6. Create **udf_example.dll**:

   ```
   devenv udf_example.sln /build Release
   ```
After the shared object file has been installed, notify `mysqld` about the new functions with the following statements. If object files have a suffix different from `.so` on your system, substitute the correct suffix throughout (for example, `.dll` on Windows).

```sql
cREATE FUNCTION metaphon RETURNS STRING SONAME 'udf_example.so';
cREATE FUNCTION myfunc_double RETURNS REAL SONAME 'udf_example.so';
cREATE FUNCTION myfunc_int RETURNS INTEGER SONAME 'udf_example.so';
cREATE FUNCTION sequence RETURNS INTEGER SONAME 'udf_example.so';
cREATE FUNCTION lookup RETURNS STRING SONAME 'udf_example.so';
cREATE FUNCTION reverse_lookup RETURNS STRING SONAME 'udf_example.so';
cREATE AGGREGATE FUNCTION avgcost RETURNS REAL SONAME 'udf_example.so';
```

Once installed, a function remains installed until it is uninstalled.

To delete functions, use `DROP FUNCTION`:

```sql
DROP FUNCTION metaphon;
DROP FUNCTION myfunc_double;
DROP FUNCTION myfunc_int;
DROP FUNCTION sequence;
DROP FUNCTION lookup;
DROP FUNCTION reverse_lookup;
DROP FUNCTION avgcost;
```

The `CREATE FUNCTION` and `DROP FUNCTION` statements update the `func` system table in the `mysql` database. The function's name, type and shared library name are saved in the table. You must have the `INSERT` or `DELETE` privilege for the `mysql` database to create or drop functions, respectively.

You should not use `CREATE FUNCTION` to add a function that has previously been created. If you need to reinstall a function, you should remove it with `DROP FUNCTION` and then reinstall it with `CREATE FUNCTION`. You would need to do this, for example, if you recompile a new version of your function, so that `mysqld` gets the new version. Otherwise, the server continues to use the old version.

An active function is one that has been loaded with `CREATE FUNCTION` and not removed with `DROP FUNCTION`. All active functions are reloaded each time the server starts, unless you start `mysqld` with the `--skip-grant-tables` option. In this case, UDF initialization is skipped and UDFs are unavailable.

### 22.3.2.6 UDF Security Precautions

MySQL takes several measures to prevent misuse of user-defined functions.

UDF object files cannot be placed in arbitrary directories. They must be located in the server's plugin directory. This directory is given by the value of the `plugin_dir` system variable.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>This is a change in MySQL 5.1. For earlier versions of MySQL, the shared object can be located in any directory that is searched by your system's dynamic linker.</td>
</tr>
</tbody>
</table>

To use `CREATE FUNCTION` or `DROP FUNCTION`, you must have the `INSERT` or `DELETE` privilege, respectively, for the `mysql` database. This is necessary because those statements add and delete rows from the `mysql.func` table.

UDFs should have at least one symbol defined in addition to the `xxx` symbol that corresponds to the main `xxx()` function. These auxiliary symbols correspond to the `xxx_init()`, `xxx_deinit()`, `xxx_reset()`, `xxx_clear()`, and `xxx_add()` functions. `mysqld` also supports an `--allow-suspicious-udfs` option that controls whether UDFs that have only an `xxx` symbol can be loaded.
By default, the option is off, to prevent attempts at loading functions from shared object files other than those containing legitimate UDFs. If you have older UDFs that contain only the xxx symbol and that cannot be recompiled to include an auxiliary symbol, it may be necessary to specify the --allow-suspicious-udfs option. Otherwise, you should avoid enabling this capability.

### 22.3.3 Adding a New Native Function

To add a new native MySQL function, use the procedure described here, which requires that you use a source distribution. You cannot add native functions to a binary distribution because it is necessary to modify MySQL source code and compile MySQL from the modified source. If you migrate to another version of MySQL (for example, when a new version is released), you must repeat the procedure with the new version.

If the new native function will be referred to in statements that will be replicated to slave servers, you must ensure that every slave server also has the function available. Otherwise, replication will fail on the slaves when they attempt to invoke the function.

To add a new native function, follow these steps to modify source files in the sql directory. For MySQL 5.1, the first two steps apply only as of 5.1.13. For older versions, see the instructions in the corresponding section of the MySQL 5.0 manual.

1. Create a subclass for the function in item_create.cc:
   - If the function takes a fixed number of arguments, create a subclass of Create_func_arg0, Create_func_arg1, Create_func_arg2, or Create_func_arg3, respectively, depending on whether the function takes zero, one, two, or three arguments. For examples, see the Create_func_uuid, Create_func_abs, Create_func_pow, and Create_func_lpad classes.
   - If the function takes a variable number of arguments, create a subclass of Create_native_func. For an example, see Create_func_concat.

2. To provide a name by which the function can be referred to in SQL statements, register the name in item_create.cc by adding a line to this array:

   ```
   static Native_func_registry func_array[]
   ```

   You can register several names for the same function. For example, see the lines for "LCASE" and "LOWER", which are aliases for Create_func_lcase.

3. In item_func.h, declare a class inheriting from Item_num_func or Item_str_func, depending on whether your function returns a number or a string.

4. In item_func.cc, add one of the following declarations, depending on whether you are defining a numeric or string function:

   ```
   double Item_func_newname::val()
   longlong Item_func_newname::val_int()
   String *Item_func_newname::Str(String *str)
   ```

   If you inherit your object from any of the standard items (like Item_num_func), you probably only have to define one of these functions and let the parent object take care of the other functions. For example, the Item_str_func class defines a val() function that executes atof() on the value returned by ::str().

5. If the function is nondeterministic, include the following statement in the item constructor to indicate that function results should not be cached:

   ```
   current_thd->lex->safe_to_cache_query=0;
   ```
A function is nondeterministic if, given fixed values for its arguments, it can return different results for different invocations.

6. You should probably also define the following object function:

```c
void Item_func_newname::fix_length_and_dec()
```

This function should at least calculate `max_length` based on the given arguments. `max_length` is the maximum number of characters the function may return. This function should also set `maybe_null = 0` if the main function can't return a `NULL` value. The function can check whether any of the function arguments can return `NULL` by checking the arguments' `maybe_null` variable. Look at `Item_func_mod::fix_length_and_dec` for a typical example of how to do this.

All functions must be thread-safe. In other words, do not use any global or static variables in the functions without protecting them with mutexes.

If you want to return `NULL` from `::val()`, `::val_int()`, or `::str()`, you should set `null_value` to 1 and return 0.

For `::str()` object functions, there are additional considerations to be aware of:

- The `String *str` argument provides a string buffer that may be used to hold the result. (For more information about the `String` type, take a look at the `sql_string.h` file.)
- The `::str()` function should return the string that holds the result, or `(char*) 0` if the result is `NULL`.
- All current string functions try to avoid allocating any memory unless absolutely necessary!

**22.4 Debugging and Porting MySQL**

This section helps you port MySQL to other operating systems. Do check the list of currently supported operating systems first. See Section 2.1, “General Installation Guidance”. If you have created a new port of MySQL, please let us know so that we can list it here and on our Web site (http://www.mysql.com/), recommending it to other users.

- **Note**
  If you create a new port of MySQL, you are free to copy and distribute it under the GPL license, but it does not make you a copyright holder of MySQL.

A working POSIX thread library is needed for the server.

Both the server and the client need a working C++ compiler. We use `gcc` on many platforms. Other compilers that are known to work are Sun Studio, HP-UX `aCC`, IBM AIX `xlc_r`), Intel `ecc/icc`. With previous versions on the respective platforms, we also used Irix `cc` and Compaq `cxx`.

- **Important**
  If you are trying to build MySQL 5.1 with `icc` on the IA64 platform, and need support for MySQL Cluster, you should first ensure that you are using `icc` version 9.1.043 or later. (For details, see Bug #21875.)

To compile only the client, use `./configure --without-server`.

If you want or need to change any `Makefile` or the `configure` script, you also need GNU Automake and Autoconf. See Section 2.11.3, “Installing MySQL Using a Development Source Tree”.

All steps needed to remake everything from the most basic files.
Debugging a MySQL Server

If you run into problems with a new port, you may have to do some debugging of MySQL! See Section 22.4.1, “Debugging a MySQL Server”.

Note
Before you start debugging mysqld, first get the test programs mysys/thr_alarm and mysys/thr_lock to work. This ensures that your thread installation has even a remote chance to work!

22.4.1 Debugging a MySQL Server

If you are using some functionality that is very new in MySQL, you can try to run mysqld with the --skip-new (which disables all new, potentially unsafe functionality). See Section B.5.3.3, “What to Do If MySQL Keeps Crashing”.

Binary distributions of MySQL server from Oracle include a specific debug binary, mysqld-debug. This is a build including the debugging information and is built in the same way as the debug build format described in Section 22.4.1.1, “Compiling MySQL for Debugging”. You should use this build when debugging the MySQL server.

If mysqld doesn't want to start, you should verify that you don't have any my.cnf files that interfere with your setup! You can check your my.cnf arguments with mysqld --print-defaults and avoid using them by starting with mysqld --no-defaults ....

If mysqld starts to eat up CPU or memory or if it “hangs,” you can use mysqladmin processlist status to find out if someone is executing a query that takes a long time. It may be a good idea to run mysqladmin -i10 processlist status in some window if you are experiencing performance problems or problems when new clients can't connect.

The command mysqladmin debug dumps some information about locks in use, used memory and query usage to the MySQL log file. This may help solve some problems. This command also provides some useful information even if you haven’t compiled MySQL for debugging!

If the problem is that some tables are getting slower and slower you should try to optimize the table with OPTIMIZE TABLE or myisamchk. See Chapter 5, MySQL Server Administration. You should also check the slow queries with EXPLAIN.

You should also read the OS-specific section in this manual for problems that may be unique to your environment. See Section 2.1, “General Installation Guidance”.

22.4.1.1 Compiling MySQL for Debugging

If you have some very specific problem, you can always try to debug MySQL. To do this you must configure MySQL with the --with-debug or the --with-debug=full option. You can check whether MySQL was compiled with debugging by doing: mysqld --help. If the --debug flag is listed with the options then you have debugging enabled. mysqladmin ver also lists the mysqld version as mysql ... --debug in this case.

If you are using gcc, the recommended configure line is:
This avoids problems with the *libstdc++* library and with C++ exceptions (many compilers have problems with C++ exceptions in threaded code) and compile a MySQL version with support for all character sets.

If you suspect a memory overrun error, you can configure MySQL with `--with-debug=full`, which installs a memory allocation (*SAFEMALLOC*) checker. However, running with *SAFEMALLOC* is quite slow, so if you get performance problems you should start *mysqld* with the `--skip-safemalloc` option. This disables the memory overrun checks for each call to `malloc()` and `free()`.

If *mysqld* stops crashing when you compile it with `--with-debug`, you probably have found a compiler bug or a timing bug within MySQL. In this case, you can try to add `-g` to the CFLAGS and CXXFLAGS variables above and not use `--with-debug`. If *mysqld* dies, you can at least attach to it with *gdb* or use *gdb* on the core file to find out what happened.

When you configure MySQL for debugging you automatically enable a lot of extra safety check functions that monitor the health of *mysqld*. If they find something "unexpected," an entry is written to *stderr*, which *mysqld_safe* directs to the error log! This also means that if you are having some unexpected problems with MySQL and are using a source distribution, the first thing you should do is to configure MySQL for debugging! (The second thing is to send mail to a MySQL mailing list and ask for help. See Section 1.6.1, "MySQL Mailing Lists". If you believe that you have found a bug, please use the instructions at Section 1.7, "How to Report Bugs or Problems".

In the Windows MySQL distribution, *mysqld.exe* is by default compiled with support for trace files.

### 22.4.1.2 Creating Trace Files

If the *mysql* server doesn’t start or if you can cause it to crash quickly, you can try to create a trace file to find the problem.

To do this, you must have a *mysqld* that has been compiled with debugging support. You can check this by executing `mysqld --V`. If the version number ends with `--debug`, it is compiled with support for trace files. (On Windows, the debugging server is named *mysqld-debug* rather than *mysqld*.)

Start the *mysqld* server with a trace log in `/tmp/mysqld.trace` on Unix or `$mysqld.trace` on Windows:

```
shell> mysqld --debug
```

On Windows, you should also use the `--standalone` flag to not start *mysqld* as a service. In a console window, use this command:

```
C:\> mysqld-debug --debug --standalone
```

After this, you can use the *mysql.exe* command-line tool in a second console window to reproduce the problem. You can stop the *mysqld* server with `mysqladmin shutdown`.

The trace file can become very large! To generate a smaller trace file, you can use debugging options something like this:

```
mysqld --debug=d,info,error,query,general,where:0,/tmp/mysqld.trace
```

This only prints information with the most interesting tags to the trace file.

If you make a bug report about this, please only send the lines from the trace file to the appropriate mailing list where something seems to go wrong! If you can't locate the wrong place, you can open a
bug report and upload the trace file to the report, so that a MySQL developer can take a look at it. For instructions, see Section 1.7, “How to Report Bugs or Problems”.

The trace file is made with the DBUG package by Fred Fish. See Section 22.4.3, “The DBUG Package”.

22.4.1.3 Using pdb to create a Windows crashdump

Starting with MySQL 5.1.12 the Program Database files (extension pdb) are included in the Noinstall distribution of MySQL. These files provide information for debugging your MySQL installation in the event of a problem.

The PDB file contains more detailed information about mysqld and other tools that enables more detailed trace and dump files to be created. You can use these with Dr Watson, WinDbg and Visual Studio to debug mysqld.

For more information on PDB files, see Microsoft Knowledge Base Article 121366. For more information on the debugging options available, see Debugging Tools for Windows.

Dr Watson is installed with all Windows distributions, but if you have installed Windows development tools, Dr Watson may have been replaced with WinDbg, the debugger included with Visual Studio, or the debugging tools provided with Borland or Delphi.

To generate a crash file using Dr Watson, follow these steps:

1. Start Dr Watson by running drwtsn32.exe interactively using the -i option:

   C:\> drwtsn32 -i

2. Set the Log File Path to the directory where you want to store trace files.

3. Make sure Dump All Thread Contexts and Append To Existing Log File.

4. Uncheck Dump Symbol Table, Visual Notification, Sound Notification and Create Crash Dump File.

5. Set the Number of Instructions to a suitable value to capture enough calls in the stacktrace. A value of at 25 should be enough.

Note that the file generated can become very large.

22.4.1.4 Debugging mysqld under gdb

On most systems you can also start mysqld from gdb to get more information if mysqld crashes.

With some older gdb versions on Linux you must use run --one-thread if you want to be able to debug mysqld threads. In this case, you can only have one thread active at a time. It is best to upgrade to gdb 5.1 because thread debugging works much better with this version!

NPTL threads (the new thread library on Linux) may cause problems while running mysqld under gdb. Some symptoms are:

- mysqld hangs during startup (before it writes ready for connections).
- mysqld crashes during a pthread_mutex_lock() or pthread_mutex_unlock() call.

In this case, you should set the following environment variable in the shell before starting gdb:

LD_ASSUME_KERNEL=2.4.1
export LD_ASSUME_KERNEL
When running `mysqld` under `gdb`, you should disable the stack trace with `--skip-stack-trace` to be able to catch segfaults within `gdb`.

Use the `--gdb` option to `mysqld` to install an interrupt handler for SIGINT (needed to stop `mysqld` with `^C` to set breakpoints) and disable stack tracing and core file handling.

It is very hard to debug MySQL under `gdb` if you do a lot of new connections the whole time as `gdb` doesn't free the memory for old threads. You can avoid this problem by starting `mysqld` with `thread_cache_size` set to a value equal to `max_connections + 1`. In most cases just using `--thread_cache_size=5` helps a lot!

If you want to get a core dump on Linux if `mysqld` dies with a SIGSEGV signal, you can start `mysqld` with the `--core-file` option. This core file can be used to make a backtrace that may help you find out why `mysqld` died:

```
shell> gdb mysqld core
gdb> backtrace full
```

See Section B.5.3.3, “What to Do If MySQL Keeps Crashing”.

If you are using `gdb` 4.17.x or above on Linux, you should install a `.gdb` file, with the following information, in your current directory:

```
set print sevenbit off
handle SIGUSR1 nostop nprint
handle SIGUSR2 nostop nprint
handle SIGWAITING nostop nprint
handle SIGLWP nostop nprint
handle SIGPIPE nostop
handle SIGALRM nostop
handle SIGHUP nostop
handle SIGTERM nostop nprint
```

If you have problems debugging threads with `gdb`, you should download gdb 5.x and try this instead. The new `gdb` version has very improved thread handling!

Here is an example how to debug `mysqld`:

```
shell> gdb /usr/local/libexec/mysqld
gdb> run
... 
backtrace full # Do this when mysqld crashes
```

Include the preceding output in a bug report, which you can file using the instructions in Section 1.7, “How to Report Bugs or Problems”.

If `mysqld` hangs, you can try to use some system tools like `strace` or `/usr/proc/bin/pstack` to examine where `mysqld` has hung.

```
strace /tmp/log libexec/mysqld
```

If you are using the Perl DBI interface, you can turn on debugging information by using the `trace` method or by setting the `DBI_TRACE` environment variable.

### 22.4.1.5 Using a Stack Trace

On some operating systems, the error log contains a stack trace if `mysqld` dies unexpectedly. You can use this to find out where (and maybe why) `mysqld` died. See Section 5.4.2, “The Error Log”. To get
Debugging a MySQL Server

A stack trace in the error log looks something like this:

```
mysqld got signal 11;
Attempting backtrace. You can use the following information
to find out where mysqld died. If you see no messages after
this, something went terribly wrong...

stack_bottom = 0x41fd0110 thread_stack 0x400000
mysqld(my_print_stacktrace+0x32)[0x9da402]
mysqld(handle_segment+0x28a)[0x6648e9]
/lib/ld64.so.1[0x7f1a5af000f0]
/lib/libc.so.6([0x7f1a5a10f0f2]
mysqld(_ZN17check_change_passwordP3THDPCks2_Pcj+0x7c)[0x7412cb]
mysqld(_ZN17check_change_passwordP3THDPCks2_Pcj+0x7c)[0x7412cb]
/mylib/libpthread.so.0[0x7f1a5af000f0]
/mylib/libc.so.6([0x7f1a5a10f0f2]
mysqld(_ZN16set_var_password5checkEP3THD+0x68)[0x688494]
mysqld(_ZN16set_var_password5checkEP3THD+0x68)[0x688494]
```

If resolution of function names for the trace fails, the trace contains less information:

```
mysqld got signal 11;
Attempting backtrace. You can use the following information
to find out where mysqld died. If you see no messages after
this, something went terribly wrong...

stack_bottom = 0x41fd0110 thread_stack 0x400000
[0x9da402]
[0x6648e9]
[0x7f1a5af000f0]
[0x7f1a5a10f0f2]
[0x7412cb]
[0x688354]
[0x688494]
[0x67a170]
[0x67f0ad]
[0x6811b6]
[0x66e05e]
```

In the latter case, you can use the `resolve_stack_dump` utility to determine where `mysqld` died by using the following procedure:

1. Copy the numbers from the stack trace to a file, for example `mysqld.stack`. The numbers should not include the surrounding square brackets:

```
0x9da402
0x6648e9
0x7f1a5af000f0
0x7f1a5a10f0f2
0x7412cb
0x688354
0x688494
0x67a170
0x67f0ad
0x6811b6
0x66e05e
```

2. Make a symbol file for the `mysqld` server:
Debugging a MySQL Server

shell> nm -n libexec/mysqld > /tmp/mysqld.sym

If mysqld is not linked statically, use the following command instead:

shell> nm -D -n libexec/mysqld > /tmp/mysqld.sym

If you want to decode C++ symbols, use the --demangle, if available, to nm. If your version of nm does not have this option, you will need to use the c++filt command after the stack dump has been produced to demangle the C++ names.

3. Execute the following command:

shell> resolve_stack_dump -s /tmp/mysqld.sym -n mysqld.stack

If you were not able to include demangled C++ names in your symbol file, process the resolve_stack_dump output using c++filt:

shell> resolve_stack_dump -s /tmp/mysqld.sym -n mysqld.stack | c++filt

This prints out where mysqld died. If that does not help you find out why mysqld died, you should create a bug report and include the output from the preceding command with the bug report.

However, in most cases it does not help us to have just a stack trace to find the reason for the problem. To be able to locate the bug or provide a workaround, in most cases we need to know the statement that killed mysqld and preferably a test case so that we can repeat the problem! See Section 1.7, "How to Report Bugs or Problems".

22.4.1.6 Using Server Logs to Find Causes of Errors in mysqld

Note that before starting mysqld with the general query log enabled, you should check all your tables with myisamchk. See Chapter 5, MySQL Server Administration.

If mysqld dies or hangs, you should start mysqld with the general query log enabled. See Section 5.4.3, "The General Query Log". When mysqld dies again, you can examine the end of the log file for the query that killed mysqld.

If you use the default general query log file, the log is stored in the database directory as host_name.log In most cases it is the last query in the log file that killed mysqld, but if possible you should verify this by restarting mysqld and executing the found query from the mysql command-line tools. If this works, you should also test all complicated queries that didn't complete.

You can also try the command EXPLAIN on all SELECT statements that takes a long time to ensure that mysqld is using indexes properly. See Section 13.8.2, "EXPLAIN Syntax".

You can find the queries that take a long time to execute by starting mysqld with the slow query log enabled. See Section 5.4.5, "The Slow Query Log".

If you find the text mysqld restarted in the error log file (normally named hostname.err) you probably have found a query that causes mysqld to fail. If this happens, you should check all your tables with myisamchk (see Chapter 5, MySQL Server Administration), and test the queries in the MySQL log files to see whether one fails. If you find such a query, try first upgrading to the newest MySQL version. If this doesn't help and you can't find anything in the mysql mail archive, you should report the bug to a MySQL mailing list. The mailing lists are described at http://lists.mysql.com/, which also has links to online list archives.

If you have started mysqld with --myisam-recover, MySQL automatically checks and tries to repair MyISAM tables if they are marked as 'not closed properly' or 'crashed'. If this happens, MySQL writes an entry in the hostname.err file 'Warning: Checking table ...' which is followed by Warning: Repairing table if the table needs to be repaired. If you get a lot of these errors,
without `mysqld` having died unexpectedly just before, then something is wrong and needs to be investigated further. See Section 5.1.3, “Server Command Options”.

It is not a good sign if `mysqld` did die unexpectedly, but in this case, you should not investigate the Checking table... messages, but instead try to find out why `mysqld` died.

### 22.4.1.7 Making a Test Case If You Experience Table Corruption

The following procedure applies to MyISAM tables. For information about steps to take when encountering InnoDB table corruption, see Section 1.7, “How to Report Bugs or Problems”.

If you encounter corrupted MyISAM tables or if `mysqld` always fails after some update statements, you can test whether the issue is reproducible by doing the following:

1. Stop the MySQL daemon with `mysqladmin shutdown`.
2. Make a backup of the tables to guard against the very unlikely case that the repair does something bad.
3. Check all tables with `myisamchk -s database/*.MYI`. Repair any corrupted tables with `myisamchk -r database/table.MYI`.
4. Make a second backup of the tables.
5. Remove (or move away) any old log files from the MySQL data directory if you need more space.
6. Start `mysqld` with the binary log enabled. If you want to find a statement that crashes `mysqld`, you should start the server with the general query log enabled as well. See Section 5.4.3, “The General Query Log”, and Section 5.4.4, “The Binary Log”.
7. When you have gotten a crashed table, stop the `mysqld` server.
8. Restart the backup.
9. Restart the `mysqld` server without the binary log enabled.
10. Re-execute the statements with `mysqlbinlog binary-log-file | mysql`. The binary log is saved in the MySQL database directory with the name `hostname-bin.NNNNNN`.
11. If the tables are corrupted again or you can get `mysqld` to die with the above command, you have found a reproducible bug. FTP the tables and the binary log to our bugs database using the instructions given in Section 1.7, “How to Report Bugs or Problems”. If you are a support customer, you can use the MySQL Customer Support Center (http://www.mysql.com/support/) to alert the MySQL team about the problem and have it fixed as soon as possible.

You can also use the script `mysql_find_rows` to just execute some of the update statements if you want to narrow down the problem.

### 22.4.2 Debugging a MySQL Client

To be able to debug a MySQL client with the integrated debug package, you should configure MySQL with `--with-debug` or `--with-debug=full`. See Section 2.11.4, “MySQL Source-Configuration Options”.

Before running a client, you should set the `MYSQL_DEBUG` environment variable:

```bash
shell> export MYSQL_DEBUG=d:t:O,/tmp/client.trace
shell> export MYSQL_DEBUG
```

This causes clients to generate a trace file in `/tmp/client.trace`. 
If you have problems with your own client code, you should attempt to connect to the server and run your query using a client that is known to work. Do this by running `mysql` in debugging mode (assuming that you have compiled MySQL with debugging on):

```
shell> mysql --debug=d:t:O,/tmp/client.trace
```

This provides useful information in case you mail a bug report. See Section 1.7, “How to Report Bugs or Problems”.

If your client crashes at some ‘legal’ looking code, you should check that your `mysql.h` include file matches your MySQL library file. A very common mistake is to use an old `mysql.h` file from an old MySQL installation with new MySQL library.

### 22.4.3 The DBUG Package

The MySQL server and most MySQL clients are compiled with the DBUG package originally created by Fred Fish. When you have configured MySQL for debugging, this package makes it possible to get a trace file of what the program is doing. See Section 22.4.1.2, “Creating Trace Files”.

This section summarizes the argument values that you can specify in debug options on the command line for MySQL programs that have been built with debugging support. For more information about programming with the DBUG package, see the DBUG manual in the `dbug` directory of MySQL source distributions. It’s best to use a recent distribution to get the most updated DBUG manual.

The DBUG package can be used by invoking a program with the `--debug[=debug_options]` or `--# [debug_options]` option. If you specify the `--debug` or `--#` option without a `debug_options` value, most MySQL programs use a default value. The server default is `d:t:i:o,/tmp/mysqld.trace` on Unix and `d:t:i:O,\mysqld.trace` on Windows. The effect of this default is:

- **d**: Enable output for all debug macros
- **t**: Trace function calls and exits
- **i**: Add PID to output lines
- **o,/tmp/mysqld.trace, O,\mysqld.trace**: Set the debug output file.

Most client programs use a default `debug_options` value of `d:t:o,/tmp/program_name.trace`, regardless of platform.

Here are some example debug control strings as they might be specified on a shell command line:

```
--debug=d:t
--debug=d:f,main,subr1:F:L:t,20
--debug=d,input,output,files:n
--debug=d:t:i:O,\mysqld.trace
```

For `mysqld`, it is also possible to change DBUG settings at runtime by setting the `debug` system variable. This variable has global and session values:

```
mysql> SET GLOBAL debug = 'debug_options';
mysql> SET SESSION debug = 'debug_options';
```

Changes at runtime require the `SUPER` privilege, even for the session value.

The `debug_options` value is a sequence of colon-separated fields:

```
field_1:field_2:...:field_N
```

Each field within the value consists of a mandatory flag character, optionally preceded by a `+` or `-` character, and optionally followed by a comma-delimited list of modifiers:
The following table describes the permitted flag characters. Unrecognized flag characters are silently ignored.

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>d</td>
<td>Enable output from DBUG_XXX macros for the current state. May be followed by a list of keywords, which enables output only for the DBUG macros with that keyword. An empty list of keywords enables output for all macros. In MySQL, common debug macro keywords to enable are enter, exit, error, warning, info, and loop.</td>
</tr>
<tr>
<td>D</td>
<td>Delay after each debugger output line. The argument is the delay, in tenths of seconds, subject to machine capabilities. For example, D,20 specifies a delay of two seconds.</td>
</tr>
<tr>
<td>f</td>
<td>Limit debugging, tracing, and profiling to the list of named functions. An empty list enables all functions. The appropriate d or t flags must still be given; this flag only limits their actions if they are enabled.</td>
</tr>
<tr>
<td>P</td>
<td>Identify the source file name for each line of debug or trace output.</td>
</tr>
<tr>
<td>i</td>
<td>Identify the process with the PID or thread ID for each line of debug or trace output.</td>
</tr>
<tr>
<td>L</td>
<td>Identify the source file line number for each line of debug or trace output.</td>
</tr>
<tr>
<td>n</td>
<td>Print the current function nesting depth for each line of debug or trace output.</td>
</tr>
<tr>
<td>N</td>
<td>Number each line of debug output.</td>
</tr>
<tr>
<td>o</td>
<td>Redirect the debugger output stream to the specified file. The default output is stderr.</td>
</tr>
<tr>
<td>O</td>
<td>Like o, but the file is really flushed between each write. When needed, the file is closed and reopened between each write.</td>
</tr>
<tr>
<td>p</td>
<td>Limit debugger actions to specified processes. A process must be identified with the DBUG_PROCESS macro and match one in the list for debugger actions to occur.</td>
</tr>
<tr>
<td>P</td>
<td>Print the current process name for each line of debug or trace output.</td>
</tr>
<tr>
<td>r</td>
<td>When pushing a new state, do not inherit the previous state's function nesting level. Useful when the output is to start at the left margin.</td>
</tr>
<tr>
<td>S</td>
<td>Do function _sanity(<em>file</em>,<em>line</em>) at each debugged function until _sanity() returns something that differs from 0. (Mostly used with safemalloc to find memory leaks.)</td>
</tr>
<tr>
<td>t</td>
<td>Enable function call/exit trace lines. May be followed by a list (containing only one modifier) giving a numeric maximum trace level, beyond which no output occurs for either debugging or tracing macros. The default is a compile time option.</td>
</tr>
</tbody>
</table>

The leading + or - character and trailing list of modifiers are used for flag characters such as d or f that can enable a debug operation for all applicable modifiers or just some of them:

- With no leading + or -, the flag value is set to exactly the modifier list as given.
- With a leading + or -, the modifiers in the list are added to or subtracted from the current modifier list.

The following examples show how this works for the d flag. An empty d list enabled output for all debug macros. A nonempty list enables output only for the macro keywords in the list.

These statements set the d value to the modifier list as given:

```sql
mysql> SET debug = 'd';
mysql> SELECT @@debug;
+---------+
| @@debug |
+---------+
```
A leading `+` or `-` adds to or subtracts from the current `d` value:

```sql
mysql> SET debug = 'd,error,warning';
mysql> SELECT @@debug;
+-----------------+
| @@debug         |
+-----------------+
| d,error,warning |
+-----------------+
```

```sql
mysql> SET debug = '+d,loop';
mysql> SELECT @@debug;
+-------------------+
| @@debug           |
+-------------------+
| d,error,warning,loop |
+-------------------+
```

```sql
mysql> SET debug = '-d,error,loop';
mysql> SELECT @@debug;
+----------+
| @@debug  |
+----------+
| d,warning |
+----------+
```

Adding to “all macros enabled” results in no change:

```sql
mysql> SET debug = 'd';
mysql> SELECT @@debug;
+---------+
| @@debug |
+---------+
| d       |
+---------+
```

```sql
mysql> SET debug = '+d,loop';
mysql> SELECT @@debug;
+---------+
| @@debug |
+---------+
| d       |
+---------+
```

Disabling all enabled macros disables the `d` flag entirely:

```sql
mysql> SET debug = 'd,error,loop';
mysql> SELECT @@debug;
+-------------------+
| @@debug           |
+-------------------+
| d,error,loop      |
+-------------------+
```

```sql
mysql> SET debug = '-d,error,loop';
mysql> SELECT @@debug;
+----------+
| @@debug  |
+----------+
|         |
+----------+
```

**Note**

The `+` and `-` modifiers are not always handled correctly and can leave a flag value in an incorrect state. Verify your `debug`-setting sequence in advance or set it without using `+` or `-.`
Chapter 23 MySQL Enterprise Edition

23.6 MySQL Enterprise Firewall Overview ............................................................. 2553
23.7 MySQL Enterprise Thread Pool Overview ....................................................... 2554

MySQL Enterprise Edition is a commercial product. Like MySQL Community Edition, MySQL Enterprise Edition includes MySQL Server, a fully integrated transaction-safe, ACID-compliant database with full commit, rollback, crash-recovery, and row-level locking capabilities. In addition, MySQL Enterprise Edition includes the following components designed to provide monitoring and online backup, as well as improved security and scalability:

The following sections briefly discuss each of these components and indicate where to find more detailed information. To learn more about commercial products, see http://www.mysql.com/products/.

- MySQL Enterprise Monitor
- MySQL Enterprise Backup
- MySQL Enterprise Security
- MySQL Enterprise Encryption
- MySQL Enterprise Audit
- MySQL Enterprise Firewall
- MySQL Enterprise Thread Pool

23.1 MySQL Enterprise Monitor Overview

MySQL Enterprise Monitor is an enterprise monitoring system for MySQL that keeps an eye on your MySQL servers, notifies you of potential issues and problems, and advises you how to fix the issues. MySQL Enterprise Monitor can monitor all kinds of configurations, from a single MySQL server that is important to your business, all the way up to a huge farm of MySQL servers powering a busy web site.

The following discussion briefly summarizes the basic components that make up the MySQL Enterprise Monitor product. For more information, see the MySQL Enterprise Monitor manual, available at http://dev.mysql.com/doc/mysql-monitor/en/.

MySQL Enterprise Monitor components can be installed in various configurations depending on your database and network topology, to give you the best combination of reliable and responsive monitoring data, with minimal overhead on the database server machines. A typical MySQL Enterprise Monitor installation consists of:

- One or more MySQL servers to monitor. MySQL Enterprise Monitor can monitor both Community and Enterprise MySQL server releases.
- A MySQL Enterprise Monitor Agent for each monitored host.
- A single MySQL Enterprise Service Manager, which collates information from the agents and provides the user interface to the collected data.
MySQL Enterprise Monitor is designed to monitor one or more MySQL servers. The monitoring information is collected by using an agent, MySQL Enterprise Monitor Agent. The agent communicates with the hosts and MySQL servers that it monitors, collecting variables, status and health information, and sending this information to the MySQL Enterprise Service Manager.

The information collected by the agent about each MySQL server and host you are monitoring is sent to the MySQL Enterprise Service Manager. This server collates all of the information from the agents. As it collates the information sent by the agents, the MySQL Enterprise Service Manager continually tests the collected data, comparing the status of the server to reasonable values. When thresholds are reached, the server can trigger an event (including an alarm and notification) to highlight a potential issue, such as low memory, high CPU usage, or more complex conditions such insufficient buffer sizes and status information. We call each test, with its associated threshold value, a rule.

These rules, and the alarms and notifications, are each known as a MySQL Enterprise Advisors. Advisors form a critical part of the MySQL Enterprise Service Manager, as they provide warning information and troubleshooting advice about potential problems.

The MySQL Enterprise Service Manager includes a web server, and you interact with it through any web browser. This interface, the MySQL Enterprise Monitor User Interface, displays all of the information collected by the agents, and lets you view all of your servers and their current status as a group or individually. You control and configure all aspects of the service using the MySQL Enterprise Monitor User Interface.

The information supplied by the MySQL Enterprise Monitor Agent processes also includes statistical and query information, which you can view in the form of graphs. For example, you can view aspects such as server load, query numbers, or index usage information as a graph over time. The graph lets you pinpoint problems or potential issues on your server, and can help diagnose the impact from database or external problems (such as external system or network failure) by examining the data from a specific time interval.

The MySQL Enterprise Monitor Agent can also be configured to collect detailed information about the queries executed on your server, including the row counts and performance times for executing each query. You can correlate the detailed query data with the graphical information to identify which queries were executing when you experienced a particularly high load, index or other issue. The query data is supported by a system called Query Analyzer, and the data can be presented in different ways depending on your needs.

### 23.2 MySQL Enterprise Backup Overview

MySQL Enterprise Backup performs hot backup operations for MySQL databases. The product is architected for efficient and reliable backups of tables created by the InnoDB storage engine. For completeness, it can also back up tables from MyISAM and other storage engines.

Hot backups are performed while the database is running and applications are reading and writing to it. This type of backup does not block normal database operations, and it captures even changes that occur while the backup is happening. For these reasons, hot backups are desirable when your database “grows up” -- when the data is large enough that the backup takes significant time, and when your data is important enough to your business that you must capture every last change, without taking your application, web site, or web service offline.

MySQL Enterprise Backup does a hot backup of all tables that use the InnoDB storage engine. For tables using MyISAM or other non-InnoDB storage engines, it does a “warm” backup, where the database continues to run, but those tables cannot be modified while being backed up. For efficient backup operations, you can designate InnoDB as the default storage engine for new tables, or convert existing tables to use the InnoDB storage engine.

### 23.3 MySQL Enterprise Security Overview
MySQL Enterprise Edition provides plugins that implement authentication using external services:

- MySQL Enterprise Edition includes an authentication plugin that enables MySQL Server to use PAM (Pluggable Authentication Modules) to authenticate MySQL users. PAM enables a system to use a standard interface to access various kinds of authentication methods, such as Unix passwords or an LDAP directory. For more information, see The PAM Authentication Plugin.

- MySQL Enterprise Edition includes an authentication plugin that performs external authentication on Windows, enabling MySQL Server to use native Windows services to authenticate client connections. Users who have logged in to Windows can connect from MySQL client programs to the server based on the information in their environment without specifying an additional password. For more information, see The Windows Native Authentication Plugin.

- MySQL Enterprise Edition includes a keyring plugin that uses Oracle Key Vault for keyring backend storage. For more information, see The MySQL Keyring.

For other related Enterprise security features, see Section 23.4, “MySQL Enterprise Encryption Overview”.

23.4 MySQL Enterprise Encryption Overview

MySQL Enterprise Edition includes a set of encryption functions based on the OpenSSL library that expose OpenSSL capabilities at the SQL level. These functions enable Enterprise applications to perform the following operations:

- Implement added data protection using public-key asymmetric cryptography
- Create public and private keys and digital signatures
- Perform asymmetric encryption and decryption
- Use cryptographic hashing for digital signing and data verification and validation

For more information, see MySQL Enterprise Encryption Functions.

For other related Enterprise security features, see Section 23.3, “MySQL Enterprise Security Overview”.

23.5 MySQL Enterprise Audit Overview

MySQL Enterprise Edition includes MySQL Enterprise Audit, implemented using a server plugin. MySQL Enterprise Audit uses the open MySQL Audit API to enable standard, policy-based monitoring and logging of connection and query activity executed on specific MySQL servers. Designed to meet the Oracle audit specification, MySQL Enterprise Audit provides an out of box, easy to use auditing and compliance solution for applications that are governed by both internal and external regulatory guidelines.

When installed, the audit plugin enables MySQL Server to produce a log file containing an audit record of server activity. The log contents include when clients connect and disconnect, and what actions they perform while connected, such as which databases and tables they access.

For more information, see MySQL Enterprise Audit.

23.6 MySQL Enterprise Firewall Overview

MySQL Enterprise Edition includes MySQL Enterprise Firewall, an application-level firewall that enables database administrators to permit or deny SQL statement execution based on matching against whitelists of accepted statement patterns. This helps harden MySQL Server against attacks such as SQL injection or attempts to exploit applications by using them outside of their legitimate query workload characteristics.
Each MySQL account registered with the firewall has its own statement whitelist, enabling protection to be tailored per account. For a given account, the firewall can operate in recording or protecting mode, for training in the accepted statement patterns or protection against unacceptable statements.

For more information, see MySQL Enterprise Firewall.

23.7 MySQL Enterprise Thread Pool Overview

MySQL Enterprise Edition includes MySQL Enterprise Thread Pool, implemented using a server plugin. The default thread-handling model in MySQL Server executes statements using one thread per client connection. As more clients connect to the server and execute statements, overall performance degrades. In MySQL Enterprise Edition, a thread pool plugin provides an alternative thread-handling model designed to reduce overhead and improve performance. The plugin implements a thread pool that increases server performance by efficiently managing statement execution threads for large numbers of client connections.

For more information, see MySQL Enterprise Thread Pool.
Chapter 24 MySQL Workbench

MySQL Workbench provides a graphical tool for working with MySQL servers and databases. MySQL Workbench fully supports MySQL versions 5.1 and above.

The following discussion briefly describes MySQL Workbench capabilities. For more information, see the MySQL Workbench manual, available at http://dev.mysql.com/doc/workbench/en/.

MySQL Workbench provides five main areas of functionality:

- **SQL Development**: Enables you to create and manage connections to database servers. As well as enabling you to configure connection parameters, MySQL Workbench provides the capability to execute SQL queries on the database connections using the built-in SQL Editor. This functionality replaces that previously provided by the Query Browser standalone application.

- **Data Modeling**: Enables you to create models of your database schema graphically, reverse and forward engineer between a schema and a live database, and edit all aspects of your database using the comprehensive Table Editor. The Table Editor provides easy-to-use facilities for editing Tables, Columns, Indexes, Triggers, Partitioning, Options, Inserts and Privileges, Routines and Views.

- **Server Administration**: Enables you to create and administer server instances.

- **Data Migration**: Allows you to migrate from Microsoft SQL Server, Sybase ASE, SQLite, SQL Anywhere, PostreSQL, and other RDBMS tables, objects and data to MySQL. Migration also supports migrating from earlier versions of MySQL to the latest releases.

- **MySQL Enterprise Support**: Support for Enterprise products such as MySQL Enterprise Backup and MySQL Audit.

MySQL Workbench is available in two editions, the Community Edition and the Commercial Edition. The Community Edition is available free of charge. The Commercial Edition provides additional Enterprise features, such as database documentation generation, at low cost.
Appendix A MySQL 5.1 Frequently Asked Questions

Table of Contents

A.1 MySQL 5.1 FAQ: General .......................................................... 2557

A.11 MySQL 5.1 FAQ: MySQL Chinese, Japanese, and Korean Character Sets ........................................... 2582
A.12 MySQL 5.1 FAQ: Connectors & APIs ....................................... 2594
A.13 MySQL 5.1 FAQ: Replication ................................................ 2594

A.1 MySQL 5.1 FAQ: General

A.1.1 Which version of MySQL is production-ready (GA)? .................. 2557
A.1.2 What is the state of development (non-GA) versions? ............... 2557
A.1.3 Can MySQL 5.1 do subqueries? ............................................ 2558
A.1.4 Can MySQL 5.1 perform multiple-table inserts, updates, and deletes? ........................................... 2558
A.1.5 Does MySQL 5.1 have a Query Cache? Does it work on Server, Instance or Database? .................. 2558
A.1.6 Does MySQL 5.1 have Sequences? ....................................... 2558
A.1.7 Does MySQL 5.1 have a NOW() function with fractions of seconds? ........................................... 2558
A.1.8 Does MySQL 5.1 work with multi-core processors? ................ 2558
A.1.9 Why do I see multiple processes for mysqld? .......................... 2558
A.1.10 Can MySQL 5.1 perform ACID transactions? ......................... 2558

A.1.1. Which version of MySQL is production-ready (GA)?

MySQL 5.7 and MySQL 5.6 are supported for production use.

MySQL 5.7 achieved General Availability (GA) status with MySQL 5.7.9, which was released for production use on 21 October 2015.

MySQL 5.6 achieved General Availability (GA) status with MySQL 5.6.10, which was released for production use on 5 February 2013.

MySQL 5.5 achieved General Availability (GA) status with MySQL 5.5.8, which was released for production use on 3 December 2010. The MySQL 5.5 series is no longer current, but still supported in production.

MySQL 5.1 achieved General Availability (GA) status with MySQL 5.1.30, which was released for production use on 14 November 2008. Active development for MySQL 5.1 has ended.

MySQL 5.0 achieved General Availability (GA) status with MySQL 5.0.15, which was released for production use on 19 October 2005. Active development for MySQL 5.0 has ended.

A.1.2. What is the state of development (non-GA) versions?

MySQL follows a milestone release model that introduces pre-production-quality features and stabilizes them to release quality (see http://dev.mysql.com/doc/mysql-development-cycle/en/index.html). This process then repeats, so releases cycle between pre-production and release quality status. Please check the change logs to identify the status of a given release.

MySQL 5.4 was a development series. Work on this series has ceased.
A successor to MySQL 5.7 is being actively developed using the milestone release methodology described above.

A.1.3. Can MySQL 5.1 do subqueries?

Yes. See Section 13.2.9, “Subquery Syntax”.

A.1.4. Can MySQL 5.1 perform multiple-table inserts, updates, and deletes?

Yes. For the syntax required to perform multiple-table updates, see Section 13.2.10, “UPDATE Syntax”; for that required to perform multiple-table deletes, see Section 13.2.2, “DELETE Syntax”.

A multiple-table insert can be accomplished using a trigger whose FOR EACH ROW clause contains multiple INSERT statements within a BEGIN ... END block. See Section 19.3, “Using Triggers”.

A.1.5. Does MySQL 5.1 have a Query Cache? Does it work on Server, Instance or Database?

Yes. The query cache operates on the server level, caching complete result sets matched with the original query string. If an exactly identical query is made (which often happens, particularly in web applications), no parsing or execution is necessary; the result is sent directly from the cache. Various tuning options are available. See Section 8.10.3, “The MySQL Query Cache”.

A.1.6. Does MySQL 5.1 have Sequences?

No. However, MySQL has an AUTO_INCREMENT system, which in MySQL 5.1 can also handle inserts in a multi-master replication setup. With the auto_increment_increment and auto_increment_offset system variables, you can set each server to generate auto-increment values that don't conflict with other servers. The auto_increment_increment value should be greater than the number of servers, and each server should have a unique offset.

A.1.7. Does MySQL 5.1 have a NOW() function with fractions of seconds?

No, but support was added in 5.6.4.

Also, MySQL does parse time strings with a fractional component. See Section 11.3.2, “The TIME Type”.

A.1.8. Does MySQL 5.1 work with multi-core processors?

Yes. MySQL is fully multi-threaded, and will make use of multiple CPUs, provided that the operating system supports them.

A.1.9. Why do I see multiple processes for mysqld?

When using LinuxThreads, you should see a minimum of three mysqld processes running. These are in fact threads. There is one thread for the LinuxThreads manager, one thread to handle connections, and one thread to handle alarms and signals.

A.1.10 Can MySQL 5.1 perform ACID transactions?

Yes. All current MySQL versions support transactions. The InnoDB storage engine offers full ACID transactions with row-level locking, multi-versioning, nonlocking repeatable reads, and all four SQL standard isolation levels.

The NDB storage engine supports the READ COMMITTED transaction isolation level only.

A.2 MySQL 5.1 FAQ: Storage Engines

A.2.1 Where can I obtain complete documentation for MySQL storage engines and the pluggable storage engine architecture?
A.2.2 Are there any new storage engines in MySQL 5.1? ................................. 2559
A.2.3 Have any storage engines been removed in MySQL 5.1? ......................... 2559
A.2.4 What are the unique benefits of the **ARCHIVE** storage engine? .......... 2559
A.2.5 Do the new features in MySQL 5.1 apply to all storage engines? ............ 2559

### A.2.1. Where can I obtain complete documentation for MySQL storage engines and the pluggable storage engine architecture?

### A.2.2. Are there any new storage engines in MySQL 5.1?

Yes:

- The **InnoDB Plugin** is available as an alternative to the built-in version of the InnoDB storage engine. It includes a number of features such as the Barracuda file format, table compression, and new configuration options for performance. As you upgrade to MySQL 5.5 and higher, these features become core features of the MySQL server, and InnoDB becomes the default storage engine for new tables.

- There have been significant improvements in existing storage engines, in particular for the NDB storage engine that forms the basis for MySQL Cluster.

- The **IBMDB2I** storage engine is included in the IBM i5/OS (TAR packages) and IBM i5/OS (SAVF packages).

### A.2.3. Have any storage engines been removed in MySQL 5.1?

Yes. MySQL 5.1 no longer supports the BDB storage engine. Any existing BDB tables should be converted to another storage engine before upgrading to MySQL 5.1.

### A.2.4. What are the unique benefits of the **ARCHIVE** storage engine?

The **ARCHIVE** storage engine is ideally suited for storing large amounts of data without indexes; it has a very small footprint, and performs selects using table scans. See Section 14.12, "The **ARCHIVE** Storage Engine", for details.

### A.2.5. Do the new features in MySQL 5.1 apply to all storage engines?

The general new features such as views, stored procedures, triggers, **INFORMATION_SCHEMA**, precision math (DECIMAL column type), and the BIT column type, apply to all storage engines. There are also additions and changes for specific storage engines.

#### A.3 MySQL 5.1 FAQ: Server SQL Mode

### A.3.1 What are server SQL modes? ................................................................. 2559
### A.3.2 How many server SQL modes are there? ........................................... 2559
### A.3.3 How do you determine the server SQL mode? .................................... 2560
### A.3.4 Is the mode dependent on the database or connection? ...................... 2560
### A.3.5 Can the rules for strict mode be extended? ....................................... 2560
### A.3.6 Does strict mode impact performance? ............................................. 2560
### A.3.7 What is the default server SQL mode when MySQL 5.1 is installed? ...... 2560

### A.3.1. What are server SQL modes?

Server SQL modes define what SQL syntax MySQL should support and what kind of data validation checks it should perform. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers. The MySQL Server apply these modes individually to different clients. For more information, see Section 5.1.7, “Server SQL Modes”.

### A.3.2. How many server SQL modes are there?
Each mode can be independently switched on and off. See Section 5.1.7, “Server SQL Modes”, for a complete list of available modes.

A.3.3. How do you determine the server SQL mode?

You can set the default SQL mode (for mysql startup) with the --sql-mode option. Using the statement `SET [GLOBAL|SESSION] sql_mode='modes'`, you can change the settings from within a connection, either locally to the connection, or to take effect globally. You can retrieve the current mode by issuing a `SELECT @@sql_mode` statement.

A.3.4. Is the mode dependent on the database or connection?

A mode is not linked to a particular database. Modes can be set locally to the session (connection), or globally for the server. You can change these settings using `SET [GLOBAL|SESSION] sql_mode='modes'`.

A.3.5. Can the rules for strict mode be extended?

When we refer to strict mode, we mean a mode where at least one of the modes TRADITIONAL, STRICT_TRANS_TABLES, or STRICT_ALL_TABLES is enabled. Options can be combined, so you can add restrictions to a mode. See Section 5.1.7, “Server SQL Modes”, for more information.

A.3.6. Does strict mode impact performance?

The intensive validation of input data that some settings requires more time than if the validation is not done. While the performance impact is not that great, if you do not require such validation (perhaps your application already handles all of this), then MySQL gives you the option of leaving strict mode disabled. However—if you do require it—strict mode can provide such validation.

A.3.7. What is the default server SQL mode when MySQL 5.1 is installed?

By default, no special modes are enabled. For information about all available modes and MySQL’s default behavior, see Section 5.1.7, “Server SQL Modes”.

A.4 MySQL 5.1 FAQ: Stored Procedures and Functions

A.4.1 Does MySQL 5.1 support stored procedures and functions? .................................................. 2561
A.4.2 Where can I find documentation for MySQL stored procedures and stored functions? .... 2561
A.4.3 Is there a discussion forum for MySQL stored procedures? .............................................. 2561
A.4.4 Where can I find the ANSI SQL 2003 specification for stored procedures? .................. 2561
A.4.5 How do you manage stored routines? ................................................................. 2561
A.4.6 Is there a way to view all stored procedures and stored functions in a given database? .... 2561
A.4.7 Where are stored procedures stored? .................................................................. 2561
A.4.8 Is it possible to group stored procedures or stored functions into packages? .............. 2562
A.4.9 Can a stored procedure call another stored procedure? ...................................................... 2562
A.4.10 Can a stored procedure call a trigger? .............................................................. 2562
A.4.11 Can a stored procedure access tables? ............................................................... 2562
A.4.12 Do stored procedures have a statement for raising application errors? ...................... 2562
A.4.13 Do stored procedures provide exception handling? .............................................. 2562
A.4.14 Can MySQL 5.1 stored routines return result sets? .................................................... 2562
A.4.15 Is WITH RECOMPILE supported for stored procedures? ........................................... 2562
A.4.16 Is there a MySQL equivalent to using mod_plsql as a gateway on Apache to talk directly to a stored procedure in the database? ................................................................ 2562
A.4.17 Can I pass an array as input to a stored procedure? ................................................... 2562
A.4.18 Can I pass a cursor as an IN parameter to a stored procedure? ................................. 2562
A.4.19 Can I return a cursor as an OUT parameter from a stored procedure? ..................... 2562
A.4.20 Can I print out a variable’s value within a stored routine for debugging purposes? ...... 2562
A.4.21 Can I commit or roll back transactions inside a stored procedure? ............................ 2562
A.4.22 Do MySQL 5.1 stored procedures and functions work with replication? ..................... 2563
A.4.23 Are stored procedures and functions created on a master server replicated to a slave?  
A.4.24 How are actions that take place inside stored procedures and functions replicated?  
A.4.25 Are there special security requirements for using stored procedures and functions together with replication?  
A.4.26 What limitations exist for replicating stored procedure and function actions?  
A.4.27 Do the preceding limitations affect MySQL’s ability to do point-in-time recovery?  
A.4.28 What is being done to correct the aforementioned limitations?  

A.4.1. Does MySQL 5.1 support stored procedures and functions?  
Yes. MySQL 5.1 supports two types of stored routines—stored procedures and stored functions.  

A.4.2. Where can I find documentation for MySQL stored procedures and stored functions?  
See Section 19.2, “Using Stored Routines (Procedures and Functions)”.  

A.4.3. Is there a discussion forum for MySQL stored procedures?  

A.4.4. Where can I find the ANSI SQL 2003 specification for stored procedures?  
Unfortunately, the official specifications are not freely available (ANSI makes them available for purchase). However, there are books—such as SQL-99 Complete, Really by Peter Gulutzan and Trudy Pelzer—which give a comprehensive overview of the standard, including coverage of stored procedures.  

A.4.5. How do you manage stored routines?  
It is always good practice to use a clear naming scheme for your stored routines. You can manage stored procedures with `CREATE [FUNCTION|PROCEDURE]`, `ALTER [FUNCTION|PROCEDURE]`, `DROP [FUNCTION|PROCEDURE]`, and `SHOW CREATE [FUNCTION|PROCEDURE]`. You can obtain information about existing stored procedures using the `ROUTINES` table in the `INFORMATION_SCHEMA` database (see Section 20.16, “The INFORMATION_SCHEMA ROUTINES Table”).  

A.4.6. Is there a way to view all stored procedures and stored functions in a given database?  
Yes. For a database named `dbname`, use this query on the `INFORMATION_SCHEMA.ROUTINES` table:  

```
SELECT ROUTINE_TYPE, ROUTINE_NAME  
FROM INFORMATION_SCHEMA.ROUTINES  
WHERE ROUTINE_SCHEMA = 'dbname';
```

For more information, see Section 20.16, “The INFORMATION_SCHEMA ROUTINES Table”.  

The body of a stored routine can be viewed using `SHOW CREATE FUNCTION` (for a stored function) or `SHOW CREATE PROCEDURE` (for a stored procedure). See Section 13.7.5.11, “SHOW CREATE PROCEDURE Syntax”, for more information.  

A.4.7. Where are stored procedures stored?  
In the `proc` table of the `mysql` system database. However, you should not access the tables in the system database directly. Instead, use `SHOW CREATE FUNCTION` to obtain information about stored functions, and `SHOW CREATE PROCEDURE` to obtain information about stored procedures. See Section 13.7.5.11, “SHOW CREATE PROCEDURE Syntax”, for more information about these statements.  

You can also query the `ROUTINES` table in the `INFORMATION_SCHEMA` database—see Section 20.16, “The INFORMATION_SCHEMA ROUTINES Table”, for information about this table.
A.4.8. Is it possible to group stored procedures or stored functions into packages?
   No. This is not supported in MySQL 5.1.

A.4.9. Can a stored procedure call another stored procedure?
   Yes.

A.4.10 Can a stored procedure call a trigger?
   A stored procedure can execute an SQL statement, such as an \texttt{UPDATE}, that causes a trigger to activate.

A.4.11 Can a stored procedure access tables?
   Yes. A stored procedure can access one or more tables as required.

A.4.12 Do stored procedures have a statement for raising application errors?
   Not in MySQL 5.1. The SQL standard \texttt{SIGNAL} and \texttt{RESIGNAL} statements are implemented in MySQL 5.5.

A.4.13 Do stored procedures provide exception handling?
   MySQL implements \texttt{HANDLER} definitions according to the SQL standard. See Section 13.6.7.2, “DECLARE ... HANDLER Syntax”, for details.

A.4.14 Can MySQL 5.1 stored routines return result sets?
   Stored procedures can, but stored functions cannot. If you perform an ordinary \texttt{SELECT} inside a stored procedure, the result set is returned directly to the client. You need to use the MySQL 4.1 (or above) client/server protocol for this to work. This means that—for instance—in PHP, you need to use the \texttt{mysqli} extension rather than the old \texttt{mysql} extension.

A.4.15 Is \texttt{WITH RECOMPILE} supported for stored procedures?
   Not in MySQL 5.1.

A.4.16 Is there a MySQL equivalent to using \texttt{mod_plsql} as a gateway on Apache to talk directly to a stored procedure in the database?
   There is no equivalent in MySQL 5.1.

A.4.17 Can I pass an array as input to a stored procedure?
   Not in MySQL 5.1.

A.4.18 Can I pass a cursor as an \texttt{IN} parameter to a stored procedure?
   In MySQL 5.1, cursors are available inside stored procedures only.

A.4.19 Can I return a cursor as an \texttt{OUT} parameter from a stored procedure?
   In MySQL 5.1, cursors are available inside stored procedures only. However, if you do not open a cursor on a \texttt{SELECT}, the result will be sent directly to the client. You can also \texttt{SELECT INTO} variables. See Section 13.2.8, “SELECT Syntax”.

A.4.20 Can I print out a variable’s value within a stored routine for debugging purposes?
   Yes, you can do this in a \texttt{stored procedure}, but not in a stored function. If you perform an ordinary \texttt{SELECT} inside a stored procedure, the result set is returned directly to the client. You will need to use the MySQL 4.1 (or above) client/server protocol for this to work. This means that—for instance—in PHP, you need to use the \texttt{mysqli} extension rather than the old \texttt{mysql} extension.

A.4.21 Can I commit or roll back transactions inside a stored procedure?
Yes. However, you cannot perform transactional operations within a stored function.

A.4.22 Do MySQL 5.1 stored procedures and functions work with replication?
Yes, standard actions carried out in stored procedures and functions are replicated from a master MySQL server to a slave server. There are a few limitations that are described in detail in Section 19.7, “Binary Logging of Stored Programs”.

A.4.23 Are stored procedures and functions created on a master server replicated to a slave?
Yes, creation of stored procedures and functions carried out through normal DDL statements on a master server are replicated to a slave, so the objects will exist on both servers. ALTER and DROP statements for stored procedures and functions are also replicated.

A.4.24 How are actions that take place inside stored procedures and functions replicated?
MySQL records each DML event that occurs in a stored procedure and replicates those individual actions to a slave server. The actual calls made to execute stored procedures are not replicated.

Stored functions that change data are logged as function invocations, not as the DML events that occur inside each function.

A.4.25 Are there special security requirements for using stored procedures and functions together with replication?
Yes. Because a slave server has authority to execute any statement read from a master's binary log, special security constraints exist for using stored functions with replication. If replication or binary logging in general (for the purpose of point-in-time recovery) is active, then MySQL DBAs have two security options open to them:

1. Any user wishing to create stored functions must be granted the SUPER privilege.

2. Alternatively, a DBA can set the log_bin_trust_function_creators system variable to 1, which enables anyone with the standard CREATE ROUTINE privilege to create stored functions.

A.4.26 What limitations exist for replicating stored procedure and function actions?
Nondeterministic (random) or time-based actions embedded in stored procedures may not replicate properly. By their very nature, randomly produced results are not predictable and cannot be exactly reproduced, and therefore, random actions replicated to a slave will not mirror those performed on a master. Declaring stored functions to be DETERMINISTIC or setting the log_bin_trust_function_creators system variable to 0 will not allow random-valued operations to be invoked.

In addition, time-based actions cannot be reproduced on a slave because the timing of such actions in a stored procedure is not reproducible through the binary log used for replication. It records only DML events and does not factor in timing constraints.

Finally, nontransactional tables for which errors occur during large DML actions (such as bulk inserts) may experience replication issues in that a master may be partially updated from DML activity, but no updates are done to the slave because of the errors that occurred. A workaround is for a function's DML actions to be carried out with the IGNORE keyword so that updates on the master that cause errors are ignored and updates that do not cause errors are replicated to the slave.

A.4.27 Do the preceding limitations affect MySQL's ability to do point-in-time recovery?
The same limitations that affect replication do affect point-in-time recovery.

A.4.28 What is being done to correct the aforementioned limitations?
As of MySQL 5.1.5, you can choose either statement-based replication or row-based replication. The original replication implementation is based on statement-based binary logging. Row-based binary logging resolves the limitations mentioned earlier.

Beginning with MySQL 5.1.8, mixed replication is also available (by starting the server with `--binlog-format=mixed`). This hybrid, "smart" form of replication "knows" whether statement-level replication can safely be used, or row-level replication is required.

For additional information, see Section 16.1.2, "Replication Formats".

A.5 MySQL 5.1 FAQ: Triggers

A.5.1 Where can I find the documentation for MySQL 5.1 triggers?

See Section 19.3, "Using Triggers".

A.5.2 Is there a discussion forum for MySQL Triggers?

A.5.3 Does MySQL 5.1 have statement-level or row-level triggers?

In MySQL 5.1, all triggers are **FOR EACH ROW**—that is, the trigger is activated for each row that is inserted, updated, or deleted. MySQL 5.1 does not support triggers using **FOR EACH STATEMENT**.

A.5.4 Are there any default triggers?

Not explicitly. MySQL does have specific special behavior for some **TIMESTAMP** columns, as well as for columns which are defined using **AUTO_INCREMENT**.

A.5.5 How are triggers managed in MySQL?

In MySQL 5.1, triggers can be created using the `CREATE TRIGGER` statement, and dropped using `DROP TRIGGER`. See Section 13.1.19, "CREATE TRIGGER Syntax", and Section 13.1.30, "DROP TRIGGER Syntax", for more about these statements.

Information about triggers can be obtained by querying the **INFORMATION_SCHEMA.TRIGGERS** table. See Section 20.23, "The INFORMATION_SCHEMA TRIGGERS Table".

A.5.6 Is there a way to view all triggers in a given database?

Yes. You can obtain a listing of all triggers defined on database `dbname` using a query on the **INFORMATION_SCHEMA.TRIGGERS** table such as the one shown here:

```
SELECT TRIGGER_NAME, EVENT_MANIPULATION, EVENT_OBJECT_TABLE, ACTION_STATEMENT
```
MySQL 5.1 FAQ: Triggers

For more information about this table, see Section 20.23, “The INFORMATION_SCHEMA TRIGGERS Table”.

A.5.7. Where are triggers stored?

Triggers are stored in .TRG files, with one such file one per table.

A.5.8. Can a trigger call a stored procedure?

Yes.

A.5.9. Can triggers access tables?

A trigger can access both old and new data in its own table. A trigger can also affect other tables, but it is not permitted to modify a table that is already being used (for reading or writing) by the statement that invoked the function or trigger.

A.5.10. Can a table have multiple triggers with the same trigger event and action time?

In MySQL 5.1, there cannot be multiple triggers for a given table that have the same trigger event and action time. For example, you cannot have two BEFORE UPDATE triggers for a table. This limitation is lifted in MySQL 5.7.

A.5.11. Can triggers call an external application through a UDF?

Yes. For example, a trigger could invoke the sys_exec() UDF.

A.5.12. Is it possible for a trigger to update tables on a remote server?

Yes. A table on a remote server could be updated using the FEDERATED storage engine. (See Section 14.11, “The FEDERATED Storage Engine”).

A.5.13. Do triggers work with replication?

Yes. However, the way in which they work depends whether you are using MySQL’s “classic” statement-based replication available in all versions of MySQL, or the row-based replication format introduced in MySQL 5.1.

When using statement-based replication, triggers on the slave are executed by statements that are executed on the master (and replicated to the slave).

When using row-based replication, triggers are not executed on the slave due to statements that were run on the master and then replicated to the slave. Instead, when using row-based replication, the changes caused by executing the trigger on the master are applied on the slave.

For more information, see Section 16.4.1.36, “Replication and Triggers”.

A.5.14. How are actions carried out through triggers on a master replicated to a slave?

Again, this depends on whether you are using statement-based or row-based replication.

**Statement-based replication.** First, the triggers that exist on a master must be re-created on the slave server. Once this is done, the replication flow works as any other standard DML statement that participates in replication. For example, consider a table EMP that has an AFTER insert trigger, which exists on a master MySQL server. The same EMP table and AFTER insert trigger exist on the slave server as well. The replication flow would be:

1. An INSERT statement is made to EMP.
2. The **AFTER** trigger on **EMP** activates.
3. The **INSERT** statement is written to the binary log.
4. The replication slave picks up the **INSERT** statement to **EMP** and executes it.
5. The **AFTER** trigger on **EMP** that exists on the slave activates.

**Row-based replication.** When you use row-based replication, the changes caused by executing the trigger on the master are applied on the slave. However, the triggers themselves are not actually executed on the slave under row-based replication. This is because, if both the master and the slave applied the changes from the master and—in addition—the trigger causing these changes were applied on the slave, the changes would in effect be applied twice on the slave, leading to different data on the master and the slave.

In most cases, the outcome is the same for both row-based and statement-based replication. However, if you use different triggers on the master and slave, you cannot use row-based replication. (This is because the row-based format replicates the changes made by triggers executing on the master to the slaves, rather than the statements that caused the triggers to execute, and the corresponding triggers on the slave are not executed.) Instead, any statements causing such triggers to be executed must be replicated using statement-based replication.

For more information, see Section 16.4.1.36, “Replication and Triggers”.

### A.6 MySQL 5.1 FAQ: Views

**A.6.1.** Where can I find documentation covering MySQL Views?

See Section 19.5, “Using Views”.

**A.6.2.** Is there a discussion forum for MySQL Views?

**A.6.3.** What happens to a view if an underlying table is dropped or renamed?

After a view has been created, it is possible to drop or alter a table or view to which the definition refers. To check a view definition for problems of this kind, use the **CHECK TABLE** statement. (See Section 13.7.2.3, “CHECK TABLE Syntax”.)

**A.6.4.** Does MySQL 5.1 have table snapshots?

No.

**A.6.5.** Does MySQL 5.1 have materialized views?

No.

**A.6.6.** Can you insert into views that are based on joins?

It is possible, provided that your **INSERT** statement has a column list that makes it clear there is only one table involved.

You **cannot** insert into multiple tables with a single insert on a view.
A.7 MySQL 5.1 FAQ: INFORMATION_SCHEMA

A.7.1 Where can I find documentation for the MySQL INFORMATION_SCHEMA database? ........... 2567
A.7.2 Is there a discussion forum for INFORMATION_SCHEMA? .................................................. 2567
A.7.3 Where can I find the ANSI SQL 2003 specification for INFORMATION_SCHEMA? ........... 2567
A.7.4 What is the difference between the Oracle Data Dictionary and MySQL's INFORMATION_SCHEMA? ........................................................................................................................................ 2567
A.7.5 Can I add to or otherwise modify the tables found in the INFORMATION_SCHEMA database? 2567

A.7.1. Where can I find documentation for the MySQL INFORMATION_SCHEMA database?

See Chapter 20, INFORMATION_SCHEMA Tables

A.7.2. Is there a discussion forum for INFORMATION_SCHEMA?

A.7.3. Where can I find the ANSI SQL 2003 specification for INFORMATION_SCHEMA?

Unfortunately, the official specifications are not freely available. (ANSI makes them available for purchase.) However, there are books available—such as SQL-99 Complete, Really by Peter Gulutzan and Trudy Pelzer—which give a comprehensive overview of the standard, including INFORMATION_SCHEMA.

A.7.4. What is the difference between the Oracle Data Dictionary and MySQL's INFORMATION_SCHEMA?

Both Oracle and MySQL provide metadata in tables. However, Oracle and MySQL use different table names and column names. MySQL's implementation is more similar to those found in DB2 and SQL Server, which also support INFORMATION_SCHEMA as defined in the SQL standard.

A.7.5. Can I add to or otherwise modify the tables found in the INFORMATION_SCHEMA database?

No. Since applications may rely on a certain standard structure, this should not be modified. For this reason, we cannot support bugs or other issues which result from modifying INFORMATION_SCHEMA tables or data.

A.8 MySQL 5.1 FAQ: Migration

A.8.1 Where can I find information on how to migrate from MySQL 5.0 to MySQL 5.1? ............... 2567
A.8.2 How has storage engine (table type) support changed in MySQL 5.1 from previous versions? .................................................................................................................................................... 2567

A.8.1. Where can I find information on how to migrate from MySQL 5.0 to MySQL 5.1?

For detailed upgrade information, see Section 2.13.1, “Upgrading MySQL”. Do not skip a major version when upgrading, but rather complete the process in steps, upgrading from one major version to the next in each step. This may seem more complicated, but it will save time and trouble—if you encounter problems during the upgrade, their origin will be easier to identify, either by you or—if you have a MySQL Enterprise subscription—by MySQL support.

A.8.2. How has storage engine (table type) support changed in MySQL 5.1 from previous versions?

Storage engine support has changed as follows:

- Support for ISAM tables was removed in MySQL 5.0 and you should now use the MyISAM storage engine in place of ISAM. To convert a table $tblname$ from ISAM to MyISAM, simply issue a statement such as this one:

  ```sql
  ALTER TABLE $tblname$ ENGINE=MYISAM;
  ```

- Internal RAID for MyISAM tables was also removed in MySQL 5.0. This was formerly used to allow large tables in file systems that did not support file sizes greater than 2GB. All modern
file systems allow for larger tables; in addition, there are now other solutions such as `MERGE` tables and views.

- The `VARCHAR` column type now retains trailing spaces in all storage engines.
- `MEMORY` tables (formerly known as `HEAP` tables) can also contain `VARCHAR` columns.

## A.9 MySQL 5.1 FAQ: Security

### A.9.1 Where can I find documentation that addresses security issues for MySQL?

The best place to start is Chapter 6, `Security`.

Other portions of the MySQL Documentation which you may find useful with regard to specific security concerns include the following:

- Section 6.1.1, “Security Guidelines”.
- Section 6.1.3, “Making MySQL Secure Against Attackers”.
- Section B.5.3.2, “How to Reset the Root Password”.
- Section 6.1.5, “How to Run MySQL as a Normal User”.
- Section 22.3.2.6, “UDF Security Precautions”.
- Section 6.1.4, “Security-Related `mysqld` Options and Variables”.
- Section 6.1.6, “Security Issues with LOAD DATA LOCAL”.
- Section 2.12, “Postinstallation Setup and Testing”.
- Section 6.4, “Using Secure Connections”.

### A.9.2 Does MySQL 5.1 have native support for SSL?

Most 5.1 binaries have support for SSL connections between the client and server. See Section 6.4, “Using Secure Connections”.

You can also tunnel a connection using SSH, if (for example) the client application does not support SSL connections. For an example, see Section 6.4.7, “Connecting to MySQL Remotely from Windows with SSH”.

### A.9.3 Is SSL support built into MySQL binaries, or must I recompile the binary myself to enable it?

Most 5.1 binaries have SSL enabled for client/server connections that are secured, authenticated, or both. See Section 6.4, “Using Secure Connections”.

### A.9.4 Does MySQL 5.1 have built-in authentication against LDAP directories?

No.

As of MySQL 5.5.16, the Enterprise edition includes a PAM Authentication Plugin that supports authentication against an LDAP directory.

### A.9.5 Does MySQL 5.1 include support for Roles Based Access Control (RBAC)?

No.
A.10 MySQL 5.1 FAQ: MySQL Cluster

In the following section, we answer questions that are frequently asked about MySQL Cluster and the NDBCLUSTER storage engine.

A.10.1 Which versions of the MySQL software support Cluster? Do I have to compile from source? ............................................................... 2570
A.10.2 What happened to MySQL Cluster NDB 6.4? .............................................................. 2570
A.10.3 What do “NDB” and “NDBCLUSTER” mean? ............................................................... 2570
A.10.4 What is the difference between using MySQL Cluster versus using MySQL Replication? ... 2571
A.10.5 Do I need any special networking to run MySQL Cluster? How do computers in a cluster communicate? ............................................................... 2571
A.10.6 How many computers do I need to run a MySQL Cluster, and why? .............................. 2571
A.10.7 What do the different computers do in a MySQL Cluster? ............................................. 2571
A.10.8 When I run the SHOW command in the MySQL Cluster management client, I see a line of output that looks like this: ............................................................... 2572
A.10.9 With which operating systems can I use MySQL Cluster? ............................................ 2572
A.10.10 What are the hardware requirements for running MySQL Cluster? ............................. 2573
A.10.11 How much RAM do I need to use MySQL Cluster? Is it possible to use disk memory at all? ........................................................................................................ 2573
A.10.12 What file systems can I use with MySQL Cluster? What about network file systems or network shares? ............................................................... 2574
A.10.13 Can I run MySQL Cluster nodes inside virtual machines (such as those created by VMWare, Parallels, or Xen)? .................................................. 2574
A.10.14 I am trying to populate a MySQL Cluster database. The loading process terminates prematurely and I get an error message like this one: .................................................. 2574
A.10.15 MySQL Cluster uses TCP/IP. Does this mean that I can run it over the Internet, with one or more nodes in remote locations? ............................................................... 2575
A.10.16 Do I have to learn a new programming or query language to use MySQL Cluster? .......... 2575
A.10.17 What programming languages and APIs are supported by MySQL Cluster? ............... 2575
A.10.18 Does MySQL Cluster include any management tools? ............................................. 2576
A.10.19 How do I find out what an error or warning message means when using MySQL Cluster? 2576
A.10.20 Is MySQL Cluster transaction-safe? What isolation levels are supported? .................... 2576
A.10.21 What storage engines are supported by MySQL Cluster? ........................................ 2576
A.10.22 In the event of a catastrophic failure—say, for instance, the whole city loses power and my UPS fails—would I lose all my data? ............................................................... 2576
A.10.23 Is it possible to use FULLTEXT indexes with MySQL Cluster? ..................................... 2576
A.10.24 Can I run multiple nodes on a single computer? .......................................................... 2576
A.10.25 Can I add data nodes to a MySQL Cluster without restarting it? ................................ 2577
A.10.26 Are there any limitations that I should be aware of when using MySQL Cluster? ........ 2577
A.10.27 Does MySQL Cluster support foreign keys? ............................................................... 2578
A.10.28 How do I import an existing MySQL database into a MySQL Cluster? ....................... 2578
A.10.29 How do MySQL Cluster nodes communicate with one another? ............................... 2578
A.10.30 What is an arbitrator? ................................................................................................. 2578
A.10.31 What data types are supported by MySQL Cluster? .................................................... 2579
A.10.32 How do I start and stop MySQL Cluster? ..................................................................... 2579
A.10.33 What happens to MySQL Cluster data when the MySQL Cluster is shut down? ........ 2580
A.10.34 Is it a good idea to have more than one management node for a MySQL Cluster? .... 2580
A.10.35 Can I mix different kinds of hardware and operating systems in one MySQL Cluster? ... 2580
A.10.36 Can I run two data nodes on a single host? Two SQL nodes? ........................................ 2580
A.10.37 Can I use host names with MySQL Cluster? ............................................................... 2580
A.10.38 Does MySQL Cluster support IPv6? ............................................................................ 2580
A.10.39 How do I handle MySQL users in a MySQL Cluster having multiple MySQL servers? ... 2581
A.10.40 How do I continue to send queries in the event that one of the SQL nodes fails? ...... 2581
A.10.41 How do I back up and restore a MySQL Cluster? ....................................................... 2581
A.10.42 What is an “angel process”? ....................................................................................... 2581
A.10.1. Which versions of the MySQL software support Cluster? Do I have to compile from source?

MySQL Cluster is not supported in standard MySQL Server 5.1 releases. Instead, MySQL Cluster is provided as a separate product. Currently, the following MySQL Cluster release series are available for production use:

- **MySQL Cluster NDB 7.2.** This series is a previous General Availability (GA) version of MySQL Cluster, still available for production, although we recommend that new deployments use the latest MySQL Cluster NDB 7.4 release. The most recent MySQL Cluster NDB 7.2 release can be obtained from [http://dev.mysql.com/downloads/cluster/](http://dev.mysql.com/downloads/cluster/).

- **MySQL Cluster NDB 7.3.** This series is a General Availability (GA) version of MySQL Cluster, still available for production, although we recommend that new deployments use the latest MySQL Cluster NDB 7.4 release. The most recent MySQL Cluster NDB 7.3 release can be obtained from [http://dev.mysql.com/downloads/cluster/](http://dev.mysql.com/downloads/cluster/).

- **MySQL Cluster NDB 7.4.** This series is the latest Generally Available (GA) version of MySQL Cluster, based on version 7.4 of the NDB storage engine and MySQL Server 5.6. New deployments should use the latest release in this series. The most recent MySQL Cluster NDB 7.4 release can be obtained from [http://dev.mysql.com/downloads/cluster/](http://dev.mysql.com/downloads/cluster/).

For an overview of improvements made in MySQL Cluster NDB 7.4, see What is New in MySQL Cluster NDB 7.4.

- **MySQL Cluster NDB 7.5.** This series is the latest development version of MySQL Cluster, based on version 7.5 of the NDB storage engine and MySQL Server 5.7. MySQL Cluster NDB 7.5 is available for testing and previewing of new features, but is not yet considered ready for production use; new deployments intended for production should continue to use the latest GA release in this series, which is currently MySQL Cluster NDB 7.4. The most recent MySQL Cluster NDB 7.4 and 7.5 releases can be obtained from [http://dev.mysql.com/downloads/cluster/](http://dev.mysql.com/downloads/cluster/).

For an overview of improvements made in MySQL Cluster NDB 7.5, see What is New in MySQL Cluster NDB 7.5.

You should use MySQL Cluster NDB 7.3 or MySQL Cluster NDB 7.4 for any new deployments; if you are using an older version of MySQL Cluster, you should upgrade to one of these soon as possible. For an overview of improvements made in MySQL Cluster NDB 7.4, see What is New in MySQL Cluster NDB 7.4; for information about improvements made in MySQL Cluster NDB 7.3, see What is New in MySQL Cluster NDB 7.3.

You can determine whether your MySQL Server has NDB support using one of the statements `SHOW VARIABLES LIKE 'have_%'`, `SHOW ENGINES`, or `SHOW PLUGINS`.

A.10.2. What happened to MySQL Cluster NDB 6.4?

Because of the number and impact of new features introduced into MySQL Cluster following the General Availability of MySQL Cluster NDB 6.3, it was decided that the following release series represented a “major” new release series rather than a “minor” one, and should be known as MySQL Cluster 7.0.

The earliest development versions of MySQL Cluster NDB 7.0 were originally designated “MySQL Cluster 6.4”, and the first four releases in this series were identified as MySQL Cluster NDB 6.4.0 through NDB 6.4.3. MySQL Cluster NDB 7.0.4 was the fifth MySQL Cluster NDB 7.0 release; it was the successor to MySQL Cluster NDB 6.4.3.

For more information about MySQL Cluster NDB 7.0, see Section 17.1.4.3, “What is New in MySQL Cluster NDB 7.0”, and [http://dev.mysql.com/doc/refman/5.6/en/mysql-cluster-news-7-0.html](http://dev.mysql.com/doc/refman/5.6/en/mysql-cluster-news-7-0.html).

A.10.3. What do “NDB” and “NDBCLUSTER” mean?
“NDB” stands for “Network Database”. NDB and NDBCLUSTER are both names for the storage engine that enables clustering support with MySQL. NDB is preferred, but either name is correct.

A.10.4 What is the difference between using MySQL Cluster versus using MySQL Replication?

In traditional MySQL replication, a master MySQL server updates one or more slaves. Transactions are committed sequentially, and a slow transaction can cause the slave to lag behind the master. This means that if the master fails, it is possible that the slave might not have recorded the last few transactions. If a transaction-safe engine such as InnoDB is being used, a transaction will either be complete on the slave or not applied at all, but replication does not guarantee that all data on the master and the slave will be consistent at all times. In MySQL Cluster, all data nodes are kept in synchrony, and a transaction committed by any one data node is committed for all data nodes. In the event of a data node failure, all remaining data nodes remain in a consistent state.

In short, whereas standard MySQL replication is asynchronous, MySQL Cluster is synchronous.

Asynchronous replication for MySQL Cluster is available in MySQL 5.1 and later. MySQL Cluster Replication (also sometimes known as “geo-replication”) includes the capability to replicate both between two MySQL Clusters, and from a MySQL Cluster to a non-Cluster MySQL server. See Section 17.6, “MySQL Cluster Replication”.

A.10.5 Do I need any special networking to run MySQL Cluster? How do computers in a cluster communicate?

MySQL Cluster is intended to be used in a high-bandwidth environment, with computers connecting using TCP/IP. Its performance depends directly upon the connection speed between the cluster's computers. The minimum connectivity requirements for MySQL Cluster include a typical 100-megabit Ethernet network or the equivalent. We recommend you use gigabit Ethernet whenever available.

A.10.6 How many computers do I need to run a MySQL Cluster, and why?

A minimum of three computers is required to run a viable cluster. However, the minimum recommended number of computers in a MySQL Cluster is four: one each to run the management and SQL nodes, and two computers to serve as data nodes. The purpose of the two data nodes is to provide redundancy; the management node must run on a separate machine to guarantee continued arbitration services in the event that one of the data nodes fails.

To provide increased throughput and high availability, you should use multiple SQL nodes (MySQL Servers connected to the cluster). It is also possible (although not strictly necessary) to run multiple management servers.

A.10.7 What do the different computers do in a MySQL Cluster?

A MySQL Cluster has both a physical and logical organization, with computers being the physical elements. The logical or functional elements of a cluster are referred to as nodes, and a computer housing a cluster node is sometimes referred to as a cluster host. There are three types of nodes, each corresponding to a specific role within the cluster. These are:

• Management node. This node provides management services for the cluster as a whole, including startup, shutdown, backups, and configuration data for the other nodes. The management node server is implemented as the application ndb_mgmd; the management client used to control MySQL Cluster is ndb_mgm. See Section 17.4.4, “ndb_mgmd — The MySQL Cluster Management Server Daemon”, and Section 17.4.5, “ndb_mgm — The MySQL Cluster Management Client”, for information about these programs.

• Data node. This type of node stores and replicates data. Data node functionality is handled by instances of the NDB data node process ndbd. For more information, see Section 17.4.1, “ndbd — The MySQL Cluster Data Node Daemon”.

2571
• **SQL node.** This is simply an instance of MySQL Server (mysqld) that is built with support for the NDBCLUSTER storage engine and started with the --ndb-cluster option to enable the engine and the --ndb-connectstring option to enable it to connect to a MySQL Cluster management server. For more about these options, see MySQL Server Options for MySQL Cluster.

---

**Note**

An API node is any application that makes direct use of Cluster data nodes for data storage and retrieval. An SQL node can thus be considered a type of API node that uses a MySQL Server to provide an SQL interface to the Cluster. You can write such applications (that do not depend on a MySQL Server) using the NDB API, which supplies a direct, object-oriented transaction and scanning interface to MySQL Cluster data; see MySQL Cluster API Overview: The NDB API, for more information.

---

**A.10.8** When I run the `SHOW` command in the MySQL Cluster management client, I see a line of output that looks like this:

```
 id=2    @10.100.10.32  (Version: 5.6.32-ndb-7.3.15 Nodegroup: 0, *)
```

What does the * mean? How is this node different from the others?

The simplest answer is, “It’s not something you can control, and it’s nothing that you need to worry about in any case, unless you’re a software engineer writing or analyzing the MySQL Cluster source code”.

If you don’t find that answer satisfactory, here’s a longer and more technical version:

A number of mechanisms in MySQL Cluster require distributed coordination among the data nodes. These distributed algorithms and protocols include global checkpointing, DDL (schema) changes, and node restart handling. To make this coordination simpler, the data nodes “elect” one of their number to act as leader. (This node was once referred to as a “master”, but this terminology was dropped to avoid confusion with master server in MySQL Replication.) There is no user-facing mechanism for influencing this selection, which is completely automatic; the fact that it is automatic is a key part of MySQL Cluster’s internal architecture.

When a node acts as the “leader” for any of these mechanisms, it is usually the point of coordination for the activity, and the other nodes act as “followers”, carrying out their parts of the activity as directed by the leader. If the node acting as leader fails, then the remaining nodes elect a new leader. Tasks in progress that were being coordinated by the old leader may either fail or be continued by the new leader, depending on the actual mechanism involved.

It is possible for some of these different mechanisms and protocols to have different leader nodes, but in general the same leader is chosen for all of them. The node indicated as the leader in the output of `SHOW` in the management client is known internally as the DICT manager (see The DBDICT Block, in the MySQL Cluster API Developer Guide, for more information), responsible for coordinating DDL and metadata activity.

MySQL Cluster is designed in such a way that the choice of leader has no discernible effect outside the cluster itself. For example, the current leader does not have significantly higher CPU or resource usage than the other data nodes, and failure of the leader should not have a significantly different impact on the cluster than the failure of any other data node.

**A.10.9** With which operating systems can I use MySQL Cluster?
MySQL Cluster is supported on most Unix-like operating systems. Beginning with MySQL Cluster NDB 7.1.3, MySQL Cluster is also supported in production on Microsoft Windows operating systems.

For more detailed information concerning the level of support which is offered for MySQL Cluster on various operating system versions, operating system distributions, and hardware platforms, please refer to http://www.mysql.com/support/supportedplatforms/cluster.html.

**A.10.10. What are the hardware requirements for running MySQL Cluster?**

MySQL Cluster should run on any platform for which NDB-enabled binaries are available. For data nodes and API nodes, faster CPUs and more memory are likely to improve performance, and 64-bit CPUs are likely to be more effective than 32-bit processors. There must be sufficient memory on machines used for data nodes to hold each node’s share of the database (see *How much RAM do I Need?* for more information). For a computer which is used only for running the MySQL Cluster management server, the requirements are minimal; a common desktop PC (or the equivalent) is generally sufficient for this task. Nodes can communicate through the standard TCP/IP network and hardware. They can also use the high-speed SCI protocol; however, special networking hardware and software are required to use SCI (see Section 17.3.4, “Using High-Speed Interconnects with MySQL Cluster”).

**A.10.11. How much RAM do I need to use MySQL Cluster? Is it possible to use disk memory at all?**

Formerly MySQL Cluster was in-memory only. MySQL 5.1 and later also provide the ability to store MySQL Cluster on disk. (Note that we have no plans to backport this capability to previous releases.) See Section 17.5.12, “MySQL Cluster Disk Data Tables”, for more information.

For in-memory NDB tables, you can use the following formula for obtaining a rough estimate of how much RAM is needed for each data node in the cluster:

\[
(\text{Size of Database} \times \text{Number of Replicas} \times 1.1) \div \text{Number of Data Nodes}
\]

To calculate the memory requirements more exactly requires determining, for each table in the cluster database, the storage space required per row (see Section 11.7, “Data Type Storage Requirements”, for details), and multiplying this by the number of rows. You must also remember to account for any column indexes as follows:

- Each primary key or hash index created for an NDBCLUSTER table requires 21–25 bytes per record. These indexes use IndexMemory.
- Each ordered index requires 10 bytes storage per record, using DataMemory.
- Creating a primary key or unique index also creates an ordered index, unless this index is created with USING HASH. In other words:
  - A primary key or unique index on a Cluster table normally takes up 31 to 35 bytes per record.
  - However, if the primary key or unique index is created with USING HASH, then it requires only 21 to 25 bytes per record.

Creating MySQL Cluster tables with USING HASH for all primary keys and unique indexes will generally cause table updates to run more quickly—in some cases by a much as 20 to 30 percent faster than updates on tables where USING HASH was not used in creating primary and unique keys. This is due to the fact that less memory is required (because no ordered indexes are created), and that less CPU must be utilized (because fewer indexes must be read and possibly updated). However, it also means that queries that could otherwise use range scans must be satisfied by other means, which can result in slower selects.
When calculating Cluster memory requirements, you may find useful the \texttt{ndb\_size.pl} utility which is available in recent MySQL 5.1 releases. This Perl script connects to a current (non-Cluster) MySQL database and creates a report on how much space that database would require if it used the \texttt{NDBCLUSTER} storage engine. For more information, see Section 17.4.24, "\texttt{ndb\_size.pl} — NDBCLUSTER Size Requirement Estimator".

It is especially important to keep in mind that every MySQL Cluster table must have a primary key. The \texttt{NDB} storage engine creates a primary key automatically if none is defined; this primary key is created without \texttt{USING HASH}.

You can determine how much memory is being used for storage of MySQL Cluster data and indexes at any given time using the \texttt{REPORT MEMORYUSAGE} command in the \texttt{ndb\_mgm} client; see Section 17.5.2, "Commands in the MySQL Cluster Management Client", for more information. In addition, warnings are written to the cluster log when 80\% of available \texttt{DataMemory} or \texttt{IndexMemory} is in use, and again when usage reaches 85\%, 90\%, and so on.

A.10.12 What file systems can I use with MySQL Cluster? What about network file systems or network shares?

Generally, any file system that is native to the host operating system should work well with MySQL Cluster. If you find that a given file system works particularly well (or not so especially well) with MySQL Cluster, we invite you to discuss your findings in the MySQL Cluster Forums.

For Windows, we recommend that you use \texttt{NTFS} file systems for MySQL Cluster, just as we do for standard MySQL. We do not test MySQL Cluster with \texttt{FAT} or \texttt{VFAT} file systems. Because of this, we do not recommend their use with MySQL or MySQL Cluster.

MySQL Cluster is implemented as a shared-nothing solution; the idea behind this is that the failure of a single piece of hardware should not cause the failure of multiple cluster nodes, or possibly even the failure of the cluster as a whole. For this reason, the use of network shares or network file systems is not supported for MySQL Cluster. This also applies to shared storage devices such as SANs.

A.10.13 Can I run MySQL Cluster nodes inside virtual machines (such as those created by VMWare, Parallels, or Xen)?

This is possible but not recommended for a production environment with MySQL Cluster versions prior to MySQL Cluster NDB 7.2.

For deployment in virtualized environments, you should use MySQL Cluster NDB 7.2 or later.

A.10.14 I am trying to populate a MySQL Cluster database. The loading process terminates prematurely and I get an error message like this one:

\texttt{ERROR 1114: The table 'my\_cluster\_table' is full}

Why is this happening?

The cause is very likely to be that your setup does not provide sufficient RAM for all table data and all indexes, \textit{including the primary key required by the NDB storage engine and automatically created in the event that the table definition does not include the definition of a primary key}.

It is also worth noting that all data nodes should have the same amount of RAM, since no data node in a cluster can use more memory than the least amount available to any individual data node. For example, if there are four computers hosting Cluster data nodes, and three of these have 3GB of RAM available to store Cluster data while the remaining data node has only 1GB RAM, then each data node can devote at most 1GB to MySQL Cluster data and indexes.

In some cases it is possible to get \textit{Table is full} errors in MySQL client applications even when \texttt{ndb\_mgm -e "ALL REPORT MEMORYUSAGE"} shows significant free \texttt{DataMemory}. You
can force NDB to create extra partitions for MySQL Cluster tables and thus have more memory available for hash indexes by using the \texttt{MAX\_ROWS} option for \texttt{CREATE TABLE}. In general, setting \texttt{MAX\_ROWS} to twice the number of rows that you expect to store in the table should be sufficient.

For similar reasons, you can also sometimes encounter problems with data node restarts on nodes that are heavily loaded with data. In MySQL Cluster NDB 7.1 and later, the addition of the \texttt{MinFreePct} parameter helps with this issue by reserving a portion (5\% by default) of \texttt{DataMemory} and \texttt{IndexMemory} for use in restarts. This reserved memory is not available for storing NDB tables or data.

A.10.15 MySQL Cluster uses TCP/IP. Does this mean that I can run it over the Internet, with one or more nodes in remote locations?

It is very unlikely that a cluster would perform reliably under such conditions, as MySQL Cluster was designed and implemented with the assumption that it would be run under conditions guaranteeing dedicated high-speed connectivity such as that found in a LAN setting using 100 Mbps or gigabit Ethernet—preferably the latter. We neither test nor warrant its performance using anything slower than this.

Also, it is extremely important to keep in mind that communications between the nodes in a MySQL Cluster are not secure; they are neither encrypted nor safeguarded by any other protective mechanism. The most secure configuration for a cluster is in a private network behind a firewall, with no direct access to any Cluster data or management nodes from outside. (For SQL nodes, you should take the same precautions as you would with any other instance of the MySQL server.) For more information, see Section 17.5.11, “MySQL Cluster Security Issues”.

A.10.16 Do I have to learn a new programming or query language to use MySQL Cluster?

\textit{No}. Although some specialized commands are used to manage and configure the cluster itself, only standard (My)SQL statements are required for the following operations:

- Creating, altering, and dropping tables
- Inserting, updating, and deleting table data
- Creating, changing, and dropping primary and unique indexes

Some specialized configuration parameters and files are required to set up a MySQL Cluster—see Section 17.3.3, “MySQL Cluster Configuration Files”, for information about these.

A few simple commands are used in the MySQL Cluster management client (\texttt{ndb\_mgm}) for tasks such as starting and stopping cluster nodes. See Section 17.5.2, “Commands in the MySQL Cluster Management Client”.

A.10.17 What programming languages and APIs are supported by MySQL Cluster?

MySQL Cluster 5.1 and later support the same programming APIs and languages as the standard MySQL Server, including ODBC, .Net, the MySQL C API, and numerous drivers for popular scripting languages such as PHP, Perl, and Python. MySQL Cluster applications written using these APIs behave similarly to other MySQL applications; they transmit SQL statements to a MySQL Server (in the case of MySQL Cluster, an SQL node), and receive responses containing rows of data. For more information about these APIs, see Chapter 21, Connectors and APIs.

MySQL Cluster 5.1 and later also support application programming using the NDB API, which provides a low-level C++ interface to MySQL Cluster data without needing to go through a MySQL Server. See The NDB API. In addition, many NDBCLUSTER management functions are exposed by the C-language MGM API; see The MGM API, for more information.
MySQL Cluster NDB 7.1 and later also support Java application programming using ClusterJ, which supports a domain object model of data using sessions and transactions. See Java and MySQL Cluster, for more information.

A.10.18 Does MySQL Cluster include any management tools?

MySQL Cluster includes a command line client for performing basic management functions. See Section 17.4.5, "ndb_mgm — The MySQL Cluster Management Client", and Section 17.5.2, "Commands in the MySQL Cluster Management Client".

MySQL Cluster NDB 7.0 and later is also supported by MySQL Cluster Manager, a separate product providing an advanced command line interface that can automate many MySQL Cluster management tasks such as rolling restarts and configuration changes. For more information about MySQL Cluster Manager, see MySQL™ Cluster Manager 1.3.6 User Manual.

A.10.19 How do I find out what an error or warning message means when using MySQL Cluster?

There are two ways in which this can be done:

- From within the mysql client, use SHOW ERRORS or SHOW WARNINGS immediately upon being notified of the error or warning condition.
- From a system shell prompt, use perror --ndb error_code.

A.10.20 MySQL Cluster transaction-safe? What isolation levels are supported?

Yes. For tables created with the NDB storage engine, transactions are supported. Currently, MySQL Cluster supports only the READ COMMITTED transaction isolation level.

A.10.21 What storage engines are supported by MySQL Cluster?

Clustering with MySQL is supported only by the NDB storage engine. That is, in order for a table to be shared between nodes in a MySQL Cluster, the table must be created using ENGINE=NDB (or the equivalent option ENGINE=NDBCLUSTER).

It is possible to create tables using other storage engines (such as InnoDB or MyISAM) on a MySQL server being used with a MySQL Cluster, but since these tables do not use NDB, they do not participate in clustering; each such table is strictly local to the individual MySQL server instance on which it is created.

A.10.22 In the event of a catastrophic failure—say, for instance, the whole city loses power and my UPS fails—would I lose all my data?

All committed transactions are logged. Therefore, although it is possible that some data could be lost in the event of a catastrophe, this should be quite limited. Data loss can be further reduced by minimizing the number of operations per transaction. (It is not a good idea to perform large numbers of operations per transaction in any case.)

A.10.23 Is it possible to use FULLTEXT indexes with MySQL Cluster?

FULLTEXT indexing is currently supported only by the MyISAM storage engine. See Section 12.9, “Full-Text Search Functions”, for more information.

A.10.24 Can I run multiple nodes on a single computer?

It is possible but not always advisable. One of the chief reasons to run a cluster is to provide redundancy. To obtain the full benefits of this redundancy, each node should reside on a separate machine. If you place multiple nodes on a single machine and that machine fails, you lose all of those nodes. For this reason, if you do run multiple data nodes on a single machine, it is extremely important that they be set up in such a way that the failure of this machine does not cause the loss of all the data nodes in a given node group.
Given that MySQL Cluster can be run on commodity hardware loaded with a low-cost (or even no-cost) operating system, the expense of an extra machine or two is well worth it to safeguard mission-critical data. It also worth noting that the requirements for a cluster host running a management node are minimal. This task can be accomplished with a 300 MHz Pentium or equivalent CPU and sufficient RAM for the operating system, plus a small amount of overhead for the ndb_mgmd and ndb_mgm processes.

It is acceptable to run multiple cluster data nodes on a single host that has multiple CPUs, cores, or both. MySQL Cluster NDB 7.0 and later also provide a multi-threaded version of the data node binary intended for use on such systems. For more information, see Section 17.4.3, "ndbmtd — The MySQL Cluster Data Node Daemon (Multi-Threaded)".

It is also possible in some cases to run data nodes and SQL nodes concurrently on the same machine; how well such an arrangement performs is dependent on a number of factors such as number of cores and CPUs as well as the amount of disk and memory available to the data node and SQL node processes, and you must take these factors into account when planning such a configuration.

A.10.25: Can I add data nodes to a MySQL Cluster without restarting it?

In MySQL Cluster NDB 7.0 and later, it is possible to add new data nodes to a running MySQL Cluster without taking it offline. For more information, see Section 17.5.13, “Adding MySQL Cluster Data Nodes Online”.

For other types of MySQL Cluster nodes, a rolling restart is all that is required (see Section 17.5.5, “Performing a Rolling Restart of a MySQL Cluster”).

(In MySQL Cluster NDB 6.3 and earlier releases, it was not possible to add new data nodes without shutting down and restarting the MySQL Cluster.)

A.10.26: Are there any limitations that I should be aware of when using MySQL Cluster?

Limitations on NDB tables in MySQL NDB 6.3, MySQL Cluster NDB 7.0, and MySQL Cluster NDB 7.1 include the following:

- Temporary tables are not supported; a CREATE TEMPORARY TABLE statement using ENGINE=NDB or ENGINE=NDBCLUSTER fails with an error.
- The only types of user-defined partitioning supported for NDBCLUSTER tables are KEY and LINEAR KEY. Trying to create an NDB table using any other partitioning type fails with an error.
- FULLTEXT indexes are not supported.
- Index prefixes are not supported. Only complete columns may be indexed.
- Spatial indexes are not supported (although spatial columns can be used). See Section 11.5, “Extensions for Spatial Data”.
- Prior to MySQL Cluster NDB 6.3.19, the NDBCLUSTER storage engine did not support partial transactions or partial rollbacks of transactions. Beginning with MySQL Cluster NDB 6.3.19, this limitation has been removed, and the behavior of NDBCLUSTER is now in line with that of other transactional storage engines (such as InnoDB) that can roll back individual statements.
- Prior to MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4, the maximum number of attributes allowed per table was 128; beginning with MySQL Cluster NDB 7.0.15 and MySQL Cluster NDB 7.1.4, this limit is increased to 512. Attribute names cannot be any longer than 31 characters. For each table, the maximum combined length of the table and database names is 122 characters.
• Previous to MySQL Cluster NDB 7.0, the maximum size for a table row was 8 kilobytes, not counting BLOB values. MySQL Cluster NDB 7.0 and later support a maximum row length of 14 KB (also not including BLOB values).

There is no set limit for the number of rows per NDB table. Limits on table size depend on a number of factors, in particular on the amount of RAM available to each data node.

• The NDBCLUSTER engine does not support foreign key constraints. As with MyISAM tables, if these are specified in a CREATE TABLE or ALTER TABLE statement, they are ignored.

For a complete listing of limitations in MySQL Cluster, see Section 17.1.6, “Known Limitations of MySQL Cluster”. See also Section 17.1.6.11, “Previous MySQL Cluster Issues Resolved in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x”.

A.10.27. Does MySQL Cluster support foreign keys?

MySQL Cluster NDB 7.1 and earlier MySQL Cluster releases do not support foreign key constraints, and ignore foreign keys in CREATE TABLE statements (similarly to how MyISAM treats foreign key syntax).

Foreign key support comparable to that found in the InnoDB storage engine is provided by NDB beginning with MySQL Cluster NDB 7.3. Applications requiring foreign support key should use MySQL Cluster NDB 7.3 or later.

A.10.28. How do I import an existing MySQL database into a MySQL Cluster?

You can import databases into MySQL Cluster much as you would with any other version of MySQL. Other than the limitations mentioned elsewhere in this FAQ, the only other special requirement is that any tables to be included in the cluster must use the NDB storage engine. This means that the tables must be created with ENGINE=NDB or ENGINE=NDBCLUSTER.

It is also possible to convert existing tables that use other storage engines to NDBCLUSTER using one or more ALTER TABLE statement. However, the definition of the table must be compatible with the NDBCLUSTER storage engine prior to making the conversion. In MySQL 5.1, an additional workaround is also required; see Section 17.1.6, “Known Limitations of MySQL Cluster”, for details.

A.10.29. How do MySQL Cluster nodes communicate with one another?

Cluster nodes can communicate through any of three different transport mechanisms: TCP/IP, SHM (shared memory), and SCI (Scalable Coherent Interface). Where available, SHM is used by default between nodes residing on the same cluster host; however, this is considered experimental. SCI is a high-speed (1 gigabit per second and higher), high-availability protocol used in building scalable multi-processor systems; it requires special hardware and drivers. See Section 17.3.4, “Using High-Speed Interconnects with MySQL Cluster”, for more about using SCI as a transport mechanism for MySQL Cluster.

A.10.30. What is an arbitrator?

If one or more data nodes in a cluster fail, it is possible that not all cluster data nodes will be able to “see” one another. In fact, it is possible that two sets of data nodes might become isolated from one another in a network partitioning, also known as a “split-brain” scenario. This type of situation is undesirable because each set of data nodes tries to behave as though it is the entire cluster. An arbitrator is required to decide between the competing sets of data nodes.

When all data nodes in at least one node group are alive, network partitioning is not an issue, because no single subset of the cluster can form a functional cluster on its own. The real problem arises when no single node group has all its nodes alive, in which case network partitioning (the “split-brain” scenario) becomes possible. Then an arbitrator is required. All cluster nodes recognize the same node as the arbitrator, which is normally the management
server; however, it is possible to configure any of the MySQL Servers in the cluster to act as the arbitrator instead. The arbitrator accepts the first set of cluster nodes to contact it, and tells the remaining set to shut down. Arbiter selection is controlled by the `ArbitrationRank` configuration parameter for MySQL Server and management server nodes. In MySQL Cluster NDB 7.0.7 and later, you can also use the `ArbitrationRank` configuration parameter to control the arbiter selection process. For more information about these parameters, see Section 17.3.3.5, “Defining a MySQL Cluster Management Server”.

The role of arbiter does not in and of itself impose any heavy demands upon the host so designated, and thus the arbiter host does not need to be particularly fast or to have extra memory especially for this purpose.

### A.10.31. What data types are supported by MySQL Cluster?

MySQL Cluster supports all of the usual MySQL data types, including those associated with MySQL's spatial extensions; however, the NDB storage engine does not support spatial indexes. (Spatial indexes are supported only by MyISAM; see Section 11.5, “Extensions for Spatial Data”, for more information.) In addition, there are some differences with regard to indexes when used with NDB tables.

**Note**

MySQL Cluster Disk Data tables (that is, tables created with `TABLESPACE ... STORAGE DISK ENGINE=NDB` or `TABLESPACE ... STORAGE DISK ENGINE=NDBCLUSTER`) have only fixed-width rows. This means that (for example) each Disk Data table record containing a `VARCHAR(255)` column requires space for 255 characters (as required for the character set and collation being used for the table), regardless of the actual number of characters stored therein.

See Section 17.1.6, “Known Limitations of MySQL Cluster”, for more information about these issues.

### A.10.32. How do I start and stop MySQL Cluster?

It is necessary to start each node in the cluster separately, in the following order:

1. Start the management node, using the `ndb_mgmd` command.

   You must include the `-f` or `--config-file` option to tell the management node where its configuration file can be found.

2. Start each data node with the `ndbd` command.

   Each data node must be started with the `-c` or `--ndb-connectstring` option so that the data node knows how to connect to the management server.

3. Start each MySQL Server (SQL node) using your preferred startup script, such as `mysqld_safe`.

   Each MySQL Server must be started with the `--ndbcluster` and `--ndb-connectstring` options. These options cause `mysqld` to enable NDBCLUSTER storage engine support and how to connect to the management server.

Each of these commands must be run from a system shell on the machine housing the affected node. (You do not have to be physically present at the machine—a remote login shell can be used for this purpose.) You can verify that the cluster is running by starting the NDB management client `ndb_mgm` on the machine housing the management node and issuing the `SHOW` or `ALL STATUS` command.
To shut down a running cluster, issue the command **SHUTDOWN** in the management client. Alternatively, you may enter the following command in a system shell:

```
shell> ndb_mgm -e "SHUTDOWN"
```

(The quotation marks in this example are optional, since there are no spaces in the command string following the `-e` option; in addition, the **SHUTDOWN** command, like other management client commands, is not case-sensitive.)

 Either of these commands causes the `ndb_mgm`, `ndb_mgm`, and any `ndbd` processes to terminate gracefully. MySQL servers running as SQL nodes can be stopped using `mysqladmin`. For more information, see Section 17.5.2, “Commands in the MySQL Cluster Management Client”, and Section 17.2.6, “Safe Shutdown and Restart of MySQL Cluster”.

**A.10.33.** What happens to MySQL Cluster data when the MySQL Cluster is shut down?

The data that was held in memory by the cluster’s data nodes is written to disk, and is reloaded into memory the next time that the cluster is started.

**A.10.34.** Is it a good idea to have more than one management node for a MySQL Cluster?

It can be helpful as a fail-safe. Only one management node controls the cluster at any given time, but it is possible to configure one management node as primary, and one or more additional management nodes to take over in the event that the primary management node fails. See Section 17.3.3, “MySQL Cluster Configuration Files”, for information on how to configure MySQL Cluster management nodes.

**A.10.35.** Can I mix different kinds of hardware and operating systems in one MySQL Cluster?

Yes, as long as all machines and operating systems have the same “endianness” (all big-endian or all little-endian).

It is also possible to use software from different MySQL Cluster releases on different nodes. However, we support this only as part of a rolling upgrade procedure (see Section 17.5.5, “Performing a Rolling Restart of a MySQL Cluster”).

**A.10.36.** Can I run two data nodes on a single host? Two SQL nodes?

Yes, it is possible to do this. In the case of multiple data nodes, it is advisable (but not required) for each node to use a different data directory. If you want to run multiple SQL nodes on one machine, each instance of `mysqld` must use a different TCP/IP port. However, in MySQL 5.1, running more than one cluster node of a given type per machine is generally not encouraged or supported for production use.

We also advise against running data nodes and SQL nodes together on the same host, since the `ndbd` and `mysqld` processes may compete for memory.

**A.10.37.** Can I use host names with MySQL Cluster?

Yes, it is possible to use DNS and DHCP for cluster hosts. However, if your application requires “five nines” availability, you should use fixed (numeric) IP addresses, since making communication between Cluster hosts dependent on services such as DNS and DHCP introduces additional potential points of failure.

**A.10.38.** Does MySQL Cluster support IPv6?

MySQL Cluster NDB 7.0 and later support IPv6 for connections between SQL nodes (MySQL servers). However, connections between all other types of nodes must use IPv4.
In practical terms, this means that you can use IPv6 for replication between MySQL Clusters, but connections between nodes in the same MySQL Cluster must use IPv4. For more information, see Section 17.6.3, “Known Issues in MySQL Cluster Replication”.

**A.10.39** How do I handle MySQL users in a MySQL Cluster having multiple MySQL servers?

MySQL user accounts and privileges are *not* automatically propagated between different MySQL servers accessing the same MySQL Cluster. Therefore, you must make sure that these are copied between the SQL nodes yourself. You can do this manually, or automate the task with scripts.

**Warning**

Do not attempt to work around this issue by converting the MySQL system tables to use the *NDBCLUSTER* storage engine. Only the *MyISAM* storage engine is supported for these tables.

**A.10.40** How do I continue to send queries in the event that one of the SQL nodes fails?

MySQL Cluster does not provide any sort of automatic failover between SQL nodes. Your application must be prepared to handle the loss of SQL nodes and to fail over between them.

**A.10.41** How do I back up and restore a MySQL Cluster?

You can use the NDB native backup and restore functionality in the MySQL Cluster management client and the *ndb_restore* program. See Section 17.5.3, “Online Backup of MySQL Cluster”, and Section 17.4.20, “*ndb_restore* — Restore a MySQL Cluster Backup”.

You can also use the traditional functionality provided for this purpose in *mysqldump* and the MySQL server. See Section 4.5.4, “*mysqldump* — A Database Backup Program”, for more information.

**A.10.42** What is an “angel process”?

This process monitors and, if necessary, attempts to restart the data node process. If you check the list of active processes on your system after starting *ndbd*, you can see that there are actually 2 processes running by that name, as shown here (we omit the output from *ndb_mgmd* and *ndbd* for brevity):

```shell
shell> ./ndb_mgmd
```

```shell
shell> ps aux | grep ndb
me 23002  0.0  0.0 122948  3104 ?      Ssl  14:14   0:00 ./ndb_mgmd

```

The *ndbd* process showing 0 memory and CPU usage is the angel process. It actually does use a very small amount of each, of course. It simply checks to see if the main *ndbd* process (the primary data node process that actually handles the data) is running. If permitted to do so (for example, if the StopOnError configuration parameter is set to false—see Section 17.3.2.1, “MySQL Cluster Data Node Configuration Parameters”), the angel process tries to restart the primary data node process.
## A.11 MySQL 5.1 FAQ: MySQL Chinese, Japanese, and Korean Character Sets

This set of Frequently Asked Questions derives from the experience of MySQL's Support and Development groups in handling many inquiries about CJK (Chinese-Japanese-Korean) issues.

### A.11.1 What CJK character sets are available in MySQL?

The list of CJK character sets may vary depending on your MySQL version. For example, the gb18030 character set was not supported prior to MySQL 5.7.4. However, since the name of the applicable language appears in the DESCRIPTION column for every entry in the INFORMATION_SCHEMA.CHARACTER_SETS table, you can obtain a current list of all the non-Unicode CJK character sets using this query:

```sql
SELECT CHARACTER_SET_NAME, DESCRIPTION
FROM INFORMATION_SCHEMA.CHARACTER_SETS
WHERE DESCRIPTION LIKE '%Chinese%' OR DESCRIPTION LIKE '%Japanese%' OR DESCRIPTION LIKE '%Korean%';
```

<table>
<thead>
<tr>
<th>CHARACTER_SET_NAME</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>big5</td>
<td>Big5 Traditional Chinese</td>
</tr>
<tr>
<td>cp932</td>
<td>SJIS for Windows Japanese</td>
</tr>
<tr>
<td>eucjps</td>
<td>UJIS for Windows Japanese</td>
</tr>
<tr>
<td>eucker</td>
<td>EUC-KR Korean</td>
</tr>
<tr>
<td>gb18030</td>
<td>China National Standard GB18030</td>
</tr>
<tr>
<td>gb2312</td>
<td>GB2312 Simplified Chinese</td>
</tr>
<tr>
<td>gbk</td>
<td>GBK Simplified Chinese</td>
</tr>
<tr>
<td>sjis</td>
<td>Shift-JIS Japanese</td>
</tr>
<tr>
<td>ujis</td>
<td>EUC-JP Japanese</td>
</tr>
</tbody>
</table>
```

9 rows in set (0.01 sec)
MySQL supports three variants of the GB (Guojia Biaozhun, or National Standard, or Simplified Chinese) character sets which are official in the People’s Republic of China: gb2312, gbk, and gb18030 (added in MySQL 5.7.4).

Sometimes people try to insert gbk characters into gb2312, and it works most of the time because gbk is a superset of gb2312—but eventually they try to insert a rarer Chinese character and it doesn't work. (See Bug #16072 for an example).

Here, we try to clarify exactly what characters are legitimate in gb2312 or gbk, with reference to the official documents. Please check these references before reporting gb2312 or gbk bugs.

- For a complete listing of the gb2312 characters, ordered according to the gb2312_chinese_ci collation: gb2312
- MySQL's gbk is in reality “Microsoft code page 936”. This differs from the official gbk for characters A1A4 (middle dot), A1AA (em dash), A6E0–A6F5, and A8BB–A8C0.
- For a listing of gbk/Unicode mappings, see http://www.unicode.org/Public/MAPPINGS/VENDORS/MICSFT/WINDOWS/CP936.TXT.
- For MySQL's listing of gbk characters, see gbk.

A.11.2 I have inserted CJK characters into my table. Why does SELECT display them as “?” characters?

This problem is usually due to a setting in MySQL that doesn't match the settings for the application program or the operating system. Here are some common steps for correcting these types of issues:

- Be certain of what MySQL version you are using.

Use the statement SELECT VERSION(); to determine this.

- Make sure that the database is actually using the desired character set.

People often think that the client character set is always the same as either the server character set or the character set used for display purposes. However, both of these are false assumptions. You can make sure by checking the result of SHOW CREATE TABLE tablename or—better yet—by using this statement:

```sql
SELECT character_set_name, collation_name
FROM information_schema.columns
WHERE table_schema = your_database_name
AND table_name = your_table_name
AND column_name = your_column_name;
```

- Determine the hexadecimal value of the character or characters that are not being displayed correctly.

You can obtain this information for a column column_name in the table table_name using the following query:

```sql
SELECT HEX(column_name)
FROM table_name;
```

3F is the encoding for the ? character; this means that ? is the character actually stored in the column. This most often happens because of a problem converting a particular character from your client character set to the target character set.
• Make sure that a round trip possible—that is, when you select literal (or _introducer hexadecimal-value), you obtain literal as a result.

For example, the Japanese Katakana character Pe (ペ) exists in all CJK character sets, and has the code point value (hexadecimal coding) 0x30da. To test a round trip for this character, use this query:

```
SELECT 'ペ' AS 'ペ';         /* or SELECT _ucs2 0x30da; */
```

If the result is not also ペ, then the round trip has failed.

For bug reports regarding such failures, we might ask you to follow up with `SELECT HEX('ペ');`. Then we can determine whether the client encoding is correct.

• Make sure that the problem is not with the browser or other application, rather than with MySQL.

Use the `mysql` client program (on Windows: `mysql.exe`) to accomplish this task. If `mysql` displays correctly but your application doesn't, then your problem is probably due to system settings.

To find out what your settings are, use the `SHOW VARIABLES` statement, whose output should resemble what is shown here:

```
mysql> SHOW VARIABLES LIKE 'char%';
+--------------------------+----------------------------------------+
| Variable_name            | Value                                  |
+--------------------------+----------------------------------------+
| character_set_client     | utf8                                   |
| character_set_connection | utf8                                   |
| character_set_database   | latin1                                 |
| character_set_filesystem | binary                                 |
| character_set_results    | utf8                                   |
| character_set_server     | latin1                                 |
| character_set_system     | utf8                                   |
| character_sets_dir       | /usr/local/mysql/share/mysql/charsets/  |
+--------------------------+----------------------------------------+
8 rows in set (0.03 sec)
```

These are typical character-set settings for an international-oriented client (notice the use of utf8 Unicode) connected to a server in the West (latin1 is a West Europe character set and a default for MySQL).

Although Unicode (usually the utf8 variant on Unix, and the ucs2 variant on Windows) is preferable to Latin, it is often not what your operating system utilities support best. Many Windows users find that a Microsoft character set, such as cp932 for Japanese Windows, is suitable.

If you cannot control the server settings, and you have no idea what your underlying computer is, then try changing to a common character set for the country that you're in (euckr = Korea; gb18030, gb2312 or gbk = People's Republic of China; big5 = Taiwan; sjis, ujis, cp932, or eucjpms = Japan; ucs2 or utf8 = anywhere). Usually it is necessary to change only the client and connection and results settings. There is a simple statement which changes all three at once: `SET NAMES`. For example:

```
SET NAMES 'big5';
```

Once the setting is correct, you can make it permanent by editing `my.cnf` or `my.ini`. For example you might add lines looking like these:
It is also possible that there are issues with the API configuration setting being used in your application; see Why does my GUI front end or browser not display CJK characters correctly...? for more information.

A.11.3 What problems should I be aware of when working with the Big5 Chinese character set?

MySQL supports the Big5 character set which is common in Hong Kong and Taiwan (Republic of China). MySQL’s big5 is in reality Microsoft code page 950, which is very similar to the original big5 character set. We changed to this character set starting with MySQL version 4.1.16 / 5.0.16 (as a result of Bug #12476). For example, the following statements work in current versions of MySQL, but not in old versions:

```
mysql> CREATE TABLE big5 (BIG5 CHAR(1) CHARACTER SET BIG5);
Query OK, 0 rows affected (0.13 sec)

mysql> INSERT INTO big5 VALUES (0xf9dc);
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM big5;
+------+
| big5 |
+------+
| 嫝 |
+------+
1 row in set (0.02 sec)
```

A feature request for adding HKSCS extensions has been filed. People who need this extension may find the suggested patch for Bug #13577 to be of interest.

A.11.4 Why do Japanese character set conversions fail?

MySQL supports the sjis, ujis, cp932, and eucjpms character sets, as well as Unicode. A common need is to convert between character sets. For example, there might be a Unix server (typically with sjis or ujis) and a Windows client (typically with cp932).

In the following conversion table, the ucs2 column represents the source, and the sjis, cp932, ujis, and eucjpms columns represent the destinations—that is, the last 4 columns provide the hexadecimal result when we use CONVERT(ucs2) or we assign a ucs2 column containing the value to an sjis, cp932, ujis, or eucjpms column.

<table>
<thead>
<tr>
<th>Character Name</th>
<th>ucs2</th>
<th>sjis</th>
<th>cp932</th>

<td>3F</td>
</tr>
<tr>
<td>FULLWIDTH NOT SIGN</td>
<td>FFE2</td>
<td>3F</td>
<td>81CA</td>
<td>3F</td>
<td>A2CC</td>
</tr>
</tbody>
</table>

This means that MySQL converts the NOT SIGN (Unicode U+00AC) to sjis code point 0x81CA and to cp932 code point 3F. (3F is the question mark (“?”)—this is what is always used when the conversion cannot be performed.

A.11.5 What should I do if I want to convert SJIS 81CA to cp932?

Our answer is: “?”. There are serious complaints about this: many people would prefer a “loose” conversion, so that 81CA (NOT SIGN) in sjis becomes 81CA (FULLWIDTH NOT SIGN) in cp932. We are considering a change to this behavior.

A.11.6 How does MySQL represent the Yen (¥) sign?

A problem arises because some versions of Japanese character sets (both sjis and euc) treat 5C as a reverse solidus (\—also known as a backslash), and others treat it as a yen sign (¥).

MySQL follows only one version of the JIS (Japanese Industrial Standards) standard description. In MySQL, 5C is always the reverse solidus (\).

A.11.7 Does MySQL plan to make a separate character set where 5C is the Yen sign, as at least one other major DBMS does?

This is one possible solution to the Yen sign issue; however, this will not happen in MySQL 5.1 or 6.0.

A.11.8 Of what issues should I be aware when working with Korean character sets in MySQL?

In theory, while there have been several versions of the euckr (Extended Unix Code Korea) character set, only one problem has been noted.

We use the “ASCII” variant of EUC-KR, in which the code point 0x5C is REVERSE SOLIDUS, that is \, instead of the “KS-Roman” variant of EUC-KR, in which the code point 0x5C is WON SIGN(₩). This means that you cannot convert Unicode U+20A9 to euckr:

```
mysql> SELECT
    -> CONV('₩' USING euckr) AS euckr;
```

2586
MySQL's graphic Korean chart is here: euckr.

A.11.9 Why do I get Incorrect string value error messages?

For illustration, we'll create a table with one Unicode (ucs2) column and one Chinese (gb2312) column.

mysql> CREATE TABLE ch
    -> (ucs2 CHAR(3) CHARACTER SET ucs2,
    -> gb2312 CHAR(3) CHARACTER SET gb2312);
Query OK, 0 rows affected (0.05 sec)

We'll try to place the rare character 汌 in both columns.

mysql> INSERT INTO ch VALUES ('A汌B','A汌B');
Query OK, 1 row affected, 1 warning (0.00 sec)

Ah, there is a warning. Use the following statement to see what it is:

mysql> SHOW WARNINGS
*************************** 1. row ***************************
  Level: Warning
  Code: 1366
  Message: Incorrect string value: '\xE6\xB1\x8CB' for column 'gb2312' at row 1
1 row in set (0.00 sec)

So it is a warning about the gb2312 column only.

mysql> SELECT ucs2,HEX(ucs2),gb2312,HEX(gb2312) FROM ch;
+-------+--------------+--------+-------------+
<table>
<thead>
<tr>
<th>ucs2</th>
<th>HEX(ucs2)</th>
<th>gb2312</th>
<th>HEX(gb2312)</th>
</tr>
</thead>
<tbody>
<tr>
<td>A汌B</td>
<td>00416C4C0042</td>
<td>A?B</td>
<td>413F42</td>
</tr>
</tbody>
</table>
+-------+--------------+--------+-------------+
1 row in set (0.00 sec)

Several things need explanation here:

1. The fact that it is a “warning” rather than an “error” is characteristic of MySQL. We like to try
to do what we can, to get the best fit, rather than give up.
2. The 汌 character is not in the gb2312 character set. We described that problem earlier.
3. If you are using an old version of MySQL, you will probably see a different message.
4. With sql_mode=TRADITIONAL, there would be an error message, rather than a warning.

A.11.10 Why does my GUI front end or browser not display CJK characters correctly in my application
using Access, PHP, or another API?

Obtain a direct connection to the server using the mysql client (Windows: mysql.exe), and try
the same query there. If mysql responds correctly, then the trouble may be that your application
interface requires initialization. Use mysql to tell you what character set or sets it uses with the
statement SHOW VARIABLES LIKE 'char%';. If you are using Access, then you are most
likely connecting with Connector/ODBC. In this case, you should check Configuring Connector/
ODBC. If, for instance, you use big5, you would enter `SET NAMES 'big5'`. (Note that no `;` is required in this case). If you are using ASP, you might need to add `SET NAMES` in the code. Here is an example that has worked in the past:

```html
<%
Session.CodePage=0
Dim strConnection
Dim Conn
strConnection="driver={MySQL ODBC 3.51 Driver};server=server;uid=username;" \\
& "pwd=password;database=database;stmt=SET NAMES 'big5';"
Set Conn = Server.CreateObject("ADODB.Connection")
Conn.Open strConnection
%
```

In much the same way, if you are using any character set other than `latin1` with Connector/Net, then you must specify the character set in the connection string. See Connecting to MySQL Using Connector/Net, for more information.

If you are using PHP, try this:

```php
<?php
$link = new mysqli($host, $usr, $pwd, $db);
if( mysqli_connect_errno() ) {
    printf("Connect failed: %s
", mysqli_connect_error());
    exit();
}
$link->query("SET NAMES 'utf8'");
?>
```

In this case, we used `SET NAMES` to change `character_set_client` and `character_set_connection` and `character_set_results`.

Another issue often encountered in PHP applications has to do with assumptions made by the browser. Sometimes adding or changing a `<meta>` tag suffices to correct the problem: for example, to insure that the user agent interprets page content as UTF-8, you should include `<meta http-equiv="Content-Type" content="text/html; charset=utf-8">` in the `<head>` of the HTML page.

If you are using Connector/J, see Using Character Sets and Unicode.

**A.11.1** I've upgraded to MySQL 5.1. How can I revert to behavior like that in MySQL 4.0 with regard to character sets?

In MySQL Version 4.0, there was a single “global” character set for both server and client, and the decision as to which character to use was made by the server administrator. This changed starting with MySQL Version 4.1. What happens now is a “handshake”, as described in Section 10.1.4, “Connection Character Sets and Collations”:

When a client connects, it sends to the server the name of the character set that it wants to use. The server uses the name to set the `character_set_client`, `character_set_results`, and `character_set_connection` system variables. In effect, the server performs a `SET NAMES` operation using the character set name.

The effect of this is that you cannot control the client character set by starting `mysqld` with `--character-set-server=utf8`. However, some of our Asian customers have said that they prefer the MySQL 4.0 behavior. To make it possible to retain this behavior, we added a `mysqld` switch, `--character-set-client-handshake`, which can be turned off with `--skip-character-set-client-handshake`. If you start `mysqld` with `--skip-character-
set-client-handshake, then, when a client connects, it sends to the server the name of the character set that it wants to use—however, the server ignores this request from the client.

By way of example, suppose that your favorite server character set is latin1 (unlikely in a CJK area, but this is the default value). Suppose further that the client uses utf8 because this is what the client’s operating system supports. Now, start the server with latin1 as its default character set:

```bash
mysqld --character-set-server=latin1
```

And then start the client with the default character set utf8:

```bash
mysql --default-character-set=utf8
```

The current settings can be seen by viewing the output of `SHOW VARIABLES`:

```
mysql> SHOW VARIABLES LIKE 'char%';
+--------------------------+----------------------------------------+
| Variable_name            | Value                                  |
+--------------------------+----------------------------------------+
| character_set_client     | utf8                                   |
| character_set_connection | utf8                                   |
| character_set_database   | latin1                                 |
| character_set_filesystem | binary                                 |
| character_set_results    | utf8                                   |
| character_set_server     | latin1                                 |
| character_set_system     | utf8                                   |
| character_sets_dir       | /usr/local/mysql/share/mysql/charsets/ |
+--------------------------+----------------------------------------+
8 rows in set (0.01 sec)
```

Now stop the client, and then stop the server using `mysqladmin`. Then start the server again, but this time tell it to skip the handshake like so:

```bash
mysqld --character-set-server=utf8 --skip-character-set-client-handshake
```

Start the client with utf8 once again as the default character set, then display the current settings:

```
mysql> SHOW VARIABLES LIKE 'char%';
+--------------------------+----------------------------------------+
| Variable_name            | Value                                  |
+--------------------------+----------------------------------------+
| character_set_client     | latin1                                 |
| character_set_connection | latin1                                 |
| character_set_database   | latin1                                 |
| character_set_filesystem | binary                                 |
| character_set_results    | latin1                                 |
| character_set_server     | latin1                                 |
| character_set_system     | utf8                                   |
| character_sets_dir       | /usr/local/mysql/share/mysql/charsets/ |
+--------------------------+----------------------------------------+
8 rows in set (0.01 sec)
```

As you can see by comparing the differing results from `SHOW VARIABLES`, the server ignores the client’s initial settings if the `--skip-character-set-client-handshake` is used.

A.11.12 Why do some LIKE and FULLTEXT searches with CJK characters fail?

There is a very simple problem with LIKE searches on BINARY and BLOB columns: we need to know the end of a character. With multibyte character sets, different characters might have
different octet lengths. For example, in \texttt{utf8}, \texttt{A} requires one byte but \texttt{ carácter} requires three bytes, as shown here:

\begin{verbatim}
| OCTET_LENGTH(_utf8 'A') | OCTET_LENGTH(_utf8 ' carácter') |
|-------------------------+--------------------------------|
| 1                       | 3                             |
\end{verbatim}

If we don't know where the first character ends, then we don't know where the second character begins, in which case even very simple searches such as \texttt{LIKE '_A%'} fail. The solution is to use a regular CJK character set in the first place, or to convert to a CJK character set before comparing.

This is one reason why MySQL cannot allow encodings of nonexistent characters. If it is not strict about rejecting bad input, then it has no way of knowing where characters end.

For \texttt{FULLTEXT} searches, we need to know where words begin and end. With Western languages, this is rarely a problem because most (if not all) of these use an easy-to-identify word boundary—the space character. However, this is not usually the case with Asian writing. We could use arbitrary halfway measures, like assuming that all Han characters represent words, or (for Japanese) depending on changes from Katakana to Hiragana due to grammatical endings. However, the only sure solution requires a comprehensive word list, which means that we would have to include a dictionary in the server for each Asian language supported. This is simply not feasible.

\textbf{A.11.13} How do I know whether character \texttt{X} is available in all character sets?

The majority of simplified Chinese and basic nonhalfwidth Japanese Kana characters appear in all CJK character sets. This stored procedure accepts a \texttt{UCS-2} Unicode character, converts it to all other character sets, and displays the results in hexadecimal.

```
DELIMITER //

CREATE PROCEDURE p_convert(ucs2_char CHAR(1) CHARACTER SET ucs2)
BEGIN

CREATE TABLE tj
(ucs2 CHAR(1) character set ucs2,
 utf8 CHAR(1) character set utf8,
 big5 CHAR(1) character set big5,
 cp932 CHAR(1) character set cp932,
 eucjpms CHAR(1) character set eucjpms,
 euckr CHAR(1) character set euckr,
 gb2312 CHAR(1) character set gb2312,
 gbk CHAR(1) character set gbk,
 sjis CHAR(1) character set sjis,
 ujis CHAR(1) character set ujis);

INSERT INTO tj (ucs2) VALUES (ucs2_char);

UPDATE tj SET utf8=ucs2,
 big5=ucs2,
 cp932=ucs2,
 eucjpms=ucs2,
 euckr=ucs2,
 gb2312=ucs2,
 gbk=ucs2,
 sjis=ucs2,
 ujis=ucs2;

/* If there is a conversion problem, UPDATE will produce a warning. */

SELECT hex(ucs2) AS ucs2,
```

2590
The input can be any single \texttt{ucs2} character, or it can be the code point value (hexadecimal representation) of that character. For example, from Unicode’s list of \texttt{ucs2} encodings and names (http://www.unicode.org/Public/UNIDATA/UnicodeData.txt), we know that the Katakana character \texttt{Pe} appears in all CJK character sets, and that its code point value is \texttt{0x30da}. If we use this value as the argument to \texttt{p_convert()}, the result is as shown here:

\begin{verbatim}
CALL p_convert(0x30da)//
<table>
<thead>
<tr>
<th>ucs2</th>
<th>utf8</th>
<th>big5</th>
<th>cp932</th>
<th>eucjpms</th>
<th>euckr</th>
<th>gb2312</th>
<th>gbk</th>
<th>sjis</th>
<th>ujis</th>
</tr>
</thead>
<tbody>
<tr>
<td>30DA</td>
<td>E3839A</td>
<td>C772</td>
<td>8379</td>
<td>A5DA</td>
<td>ABDA</td>
<td>A5DA</td>
<td>A5DA</td>
<td>8379</td>
<td>A5DA</td>
</tr>
</tbody>
</table>
\end{verbatim}

Since none of the column values is \texttt{3F}—that is, the question mark character (\texttt{?})—we know that every conversion worked.

A.11.1 Why do CJK strings sort incorrectly in Unicode? (I)

Sometimes people observe that the result of a \texttt{utf8_unicode_ci} or \texttt{ucs2_unicode_ci} search, or of an \texttt{ORDER BY} sort is not what they think a native would expect. Although we never rule out the possibility that there is a bug, we have found in the past that many people do not read correctly the standard table of weights for the Unicode Collation Algorithm. MySQL uses the table found at http://www.unicode.org/Public/UCA/4.0.0/allkeys-4.0.0.txt. This is not the first table you will find by navigating from the unicode.org home page, because MySQL uses the older 4.0.0 ‘allkeys’ table, rather than the more recent 4.1.0 table. (The newer ‘520’ collations in MySQL 5.6 use the 5.2 “allkeys” table.) This is because we are very wary about changing ordering which affects indexes, lest we bring about situations such as that reported in Bug #16526, illustrated as follows:

\begin{verbatim}
CREATE TABLE tj (s1 CHAR(1) CHARACTER SET utf8 COLLATE utf8_unicode_ci);
Query OK, 0 rows affected (0.05 sec)

INSERT INTO tj VALUES (’が’),(’か’);
Query OK, 2 rows affected (0.00 sec)
Records: 2  Duplicates: 0  Warnings: 0

SELECT * FROM tj WHERE s1 = ’が’;

+-----+
| s1   |
+-----+
| が   |
| か   |
+-----+
2 rows in set (0.00 sec)
\end{verbatim}

The character in the first result row is not the one that we searched for. Why did MySQL retrieve it? First we look for the Unicode code point value, which is possible by reading the hexadecimal number for the \texttt{ucs2} version of the characters:
MySQL 5.1 FAQ: MySQL Chinese, Japanese, and Korean Character Sets

mysql> SELECT s1, HEX(CONVERT(s1 USING ucs2)) FROM tj;
<table>
<thead>
<tr>
<th>s1</th>
<th>HEX(CONVERT(s1 USING ucs2))</th>
</tr>
</thead>
<tbody>
<tr>
<td>が</td>
<td>304C</td>
</tr>
<tr>
<td>か</td>
<td>304B</td>
</tr>
</tbody>
</table>
+------+-----------------------------+
2 rows in set (0.03 sec)

Now we search for 304B and 304C in the 4.0.0 allkeys table, and find these lines:

```
304B  ; [.1E57.0020.000E.304B] # HIRAGANA LETTER KA
304C  ; [.1E57.0020.000E.304B][.0000.0140.0002.3099] # HIRAGANA LETTER GA; QQCM
```

The official Unicode names (following the "#" mark) tell us the Japanese syllabary (Hiragana), the informal classification (letter, digit, or punctuation mark), and the Western identifier (KA or GA, which happen to be voiced and unvoiced components of the same letter pair). More importantly, the primary weight (the first hexadecimal number inside the square brackets) is 1E57 on both lines. For comparisons in both searching and sorting, MySQL pays attention to the primary weight only, ignoring all the other numbers. This means that we are sorting が and か correctly according to the Unicode specification. If we wanted to distinguish them, we’d have to use a non-UCA (Unicode Collation Algorithm) collation (utf8_bin or utf8_general_ci), or to compare the HEX() values, or use ORDER BY CONVERT(s1 USING sjis). Being correct “according to Unicode” isn’t enough, of course: the person who submitted the bug was equally correct. We plan to add another collation for Japanese according to the JIS X 4061 standard, in which voiced/unvoiced letter pairs like KA/GA are distinguishable for ordering purposes.

A.11.15. Why do CJK strings sort incorrectly in Unicode? (II)

If you are using Unicode (ucs2 or utf8), and you know what the Unicode sort order is (see Section A.11, “MySQL 5.1 FAQ: MySQL Chinese, Japanese, and Korean Character Sets”), but MySQL still seems to sort your table incorrectly, then you should first verify the table character set:

mysql> SHOW CREATE TABLE t;

```
Table: t
Create Table: CREATE TABLE `t` (
  `s1` char(1) CHARACTER SET ucs2 DEFAULT NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
```

Since the character set appears to be correct, let’s see what information the INFORMATION_SCHEMA.COLUMNS table can provide about this column:

```
mysql> SELECT COLUMN_NAME, CHARACTER_SET_NAME, COLLATION_NAME
    -> FROM INFORMATION_SCHEMA.COLUMNS
    -> WHERE COLUMN_NAME = 's1'
    -> AND TABLE_NAME = 't';
```

```
<table>
<thead>
<tr>
<th>COLUMN_NAME</th>
<th>CHARACTER_SET_NAME</th>
<th>COLLATION_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>s1</td>
<td>ucs2</td>
<td>ucs2_general_ci</td>
</tr>
</tbody>
</table>
+-------------+--------------------+-----------------+
```

(See Section 20.4, “The INFORMATION_SCHEMA COLUMNS Table”, for more information.)

You can see that the collation is ucs2_general_ci instead of ucs2_unicode_ci. The reason why this is so can be found using SHOW CHARSET, as shown here:
mysql> SHOW CHARSET LIKE 'ucs2%';
+---------+---------------+-------------------+--------+
<table>
<thead>
<tr>
<th>Charset</th>
<th>Description</th>
<th>Default collation</th>
<th>Maxlen</th>
</tr>
</thead>
<tbody>
<tr>
<td>ucs2</td>
<td>UCS-2 Unicode</td>
<td>ucs2_general_ci</td>
<td>2</td>
</tr>
</tbody>
</table>
+---------+---------------+-------------------+--------+
1 row in set (0.00 sec)

For ucs2 and utf8, the default collation is "general". To specify a Unicode collation, use COLLATE ucs2_unicode_ci.

**A.11.16** Why are my supplementary characters rejected by MySQL?

Before MySQL 5.5.3, MySQL does not support supplementary characters—that is, characters which need more than 3 bytes—for UTF-8. We support only what Unicode calls the Basic Multilingual Plane / Plane 0. Only a few very rare Han characters are supplementary; support for them is uncommon. This has led to reports such as that found in Bug #12600, which we rejected as "not a bug". With utf8, we must truncate an input string when we encounter bytes that we don’t understand. Otherwise, we wouldn’t know how long the bad multibyte character is.

One possible workaround is to use ucs2 instead of utf8, in which case the “bad” characters are changed to question marks; however, no truncation takes place. You can also change the data type to BLOB or BINARY, which perform no validity checking.

As of MySQL 5.5.3, Unicode support is extended to include supplementary characters by means of additional Unicode character sets: utf16, utf32, and 4-byte utf8mb4. These character sets support supplementary Unicode characters outside the Basic Multilingual Plane (BMP).

**A.11.17** Shouldn’t it be “CJKV”?

No. The term “CJKV” (Chinese Japanese Korean Vietnamese) refers to Vietnamese character sets which contain Han (originally Chinese) characters. MySQL has no plan to support the old Vietnamese script using Han characters. MySQL does of course support the modern Vietnamese script with Western characters.

As of MySQL 5.6, there are Vietnamese collations for Unicode character sets, as described in Section 10.1.13.1, “Unicode Character Sets”.

**A.11.18** Does MySQL allow CJK characters to be used in database and table names?

This issue is fixed in MySQL 5.1, by automatically rewriting the names of the corresponding directories and files.

For example, if you create a database named 楮 on a server whose operating system does not support CJK in directory names, MySQL creates a directory named @0w@00a5@00ae, which is just a fancy way of encoding E6A5AE—that is, the Unicode hexadecimal representation for the 楘 character. However, if you run a SHOW DATABASES statement, you can see that the database is listed as 楘.

**A.11.19** Where can I find translations of the MySQL Manual into Chinese, Japanese, and Korean?

The Japanese translation of the MySQL 5.6 manual can be downloaded from http://dev.mysql.com/doc/.

**A.11.20** Where can I get help with CJK and related issues in MySQL?

The following resources are available:

- A listing of MySQL user groups can be found at https://wikis.oracle.com/display/mysql/List+of+MySQL+User+Groups.
- View feature requests relating to character set issues at http://tinyurl.com/y6xcuf.
For common questions, issues, and answers relating to the MySQL Connectors and other APIs, see the following areas of the Manual:

- Section 21.8.14, “Common Questions and Problems When Using the C API”
- Common Problems with MySQL and PHP
- Connector/ODBC Notes and Tips
- Connector/Net Programming
- MySQL Connector/J 5.1 Developer Guide

In the following section, we provide answers to questions that are most frequently asked about MySQL Replication.

A.13.1 Must the slave be connected to the master all the time? .................................................. 2594
A.13.2 Must I enable networking on my master and slave to enable replication? .......................... 2594

A.13.10 How do I tell whether a master server is using statement-based or row-based binary logging format? .................................................................................................................. 2597
A.13.11 How do I tell a slave to use row-based replication? .............................................................. 2597
A.13.12 How do I prevent GRANT and REVOKE statements from replicating to slave machines? .... 2597
A.13.13 Does replication work on mixed operating systems (for example, the master runs on Linux while slaves run on OS X and Windows)? ................................................................. 2597
A.13.14 Does replication work on mixed hardware architectures (for example, the master runs on a 64-bit machine while slaves run on 32-bit machines)? ................................................ 2597

A.13.1 Must the slave be connected to the master all the time?

No, it does not. The slave can go down or stay disconnected for hours or even days, and then reconnect and catch up on updates. For example, you can set up a master/slave relationship over a dial-up link where the link is up only sporadically and for short periods of time. The implication of this is that, at any given time, the slave is not guaranteed to be in synchrony with the master unless you take some special measures.

To ensure that catchup can occur for a slave that has been disconnected, you must not remove binary log files from the master that contain information that has not yet been replicated to the slaves. Asynchronous replication can work only if the slave is able to continue reading the binary log from the point where it last read events.

A.13.2 Must I enable networking on my master and slave to enable replication?

Yes, networking must be enabled on the master and slave. If networking is not enabled, the slave cannot connect to the master and transfer the binary log. Check that the skip-networking option has not been enabled in the configuration file for either server.
A.13.3 How do I know how late a slave is compared to the master? In other words, how do I know the date of the last statement replicated by the slave?

Check the Seconds_Behind_Master column in the output from SHOW SLAVE STATUS. See Section 16.1.4.1, "Checking Replication Status".

When the slave SQL thread executes an event read from the master, it modifies its own time to the event timestamp. (This is why TIMESTAMP is well replicated.) In the Time column in the output of SHOW PROCESSLIST, the number of seconds displayed for the slave SQL thread is the number of seconds between the timestamp of the last replicated event and the real time of the slave machine. You can use this to determine the date of the last replicated event. Note that if your slave has been disconnected from the master for one hour, and then reconnects, you may immediately see large Time values such as 3600 for the slave SQL thread in SHOW PROCESSLIST. This is because the slave is executing statements that are one hour old. See Section 16.2.1, "Replication Implementation Details".

A.13.4 How do I force the master to block updates until the slave catches up?

Use the following procedure:

1. On the master, execute these statements:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SHOW MASTER STATUS;
```

Record the replication coordinates (the current binary log file name and position) from the output of the SHOW statement.

2. On the slave, issue the following statement, where the arguments to the MASTER_POS_WAIT() function are the replication coordinate values obtained in the previous step:

```
mysql> SELECT MASTER_POS_WAIT('log_name', log_pos);
```

The SELECT statement blocks until the slave reaches the specified log file and position. At that point, the slave is in synchrony with the master and the statement returns.

3. On the master, issue the following statement to enable the master to begin processing updates again:

```
mysql> UNLOCK TABLES;
```

A.13.5 What issues should I be aware of when setting up two-way replication?

MySQL replication currently does not support any locking protocol between master and slave to guarantee the atomicity of a distributed (cross-server) update. In other words, it is possible for client A to make an update to co-master 1, and in the meantime, before it propagates to co-master 2, client B could make an update to co-master 2 that makes the update of client A work differently than it did on co-master 1. Thus, when the update of client A makes it to co-master 2, it produces tables that are different from what you have on co-master 1, even after all the updates from co-master 2 have also propagated. This means that you should not chain two servers together in a two-way replication relationship unless you are sure that your updates can safely happen in any order, or unless you take care of mis-ordered updates somehow in the client code.

You should also realize that two-way replication actually does not improve performance very much (if at all) as far as updates are concerned. Each server must do the same number of updates, just as you would have a single server do. The only difference is that there is a little
less lock contention because the updates originating on another server are serialized in one
slave thread. Even this benefit might be offset by network delays.

A.13.6 How can I use replication to improve performance of my system?

Set up one server as the master and direct all writes to it. Then configure as many slaves as you
have the budget and rackspace for, and distribute the reads among the master and the slaves.
You can also start the slaves with the `--skip-innodb`, `--low-priority-updates`, and `--
delay-key-write=ALL` options to get speed improvements on the slave end. In this case,
the slave uses nontransactional MyISAM tables instead of InnoDB tables to get more speed by
eliminating transactional overhead.

A.13.7 What should I do to prepare client code in my own applications to use performance-enhancing
replication?

See the guide to using replication as a scale-out solution, Section 16.3.3, “Using Replication for
Scale-Out”.

A.13.8 When and how much can MySQL replication improve the performance of my system?

MySQL replication is most beneficial for a system that processes frequent reads and infrequent
writes. In theory, by using a single-master/multiple-slave setup, you can scale the system by
adding more slaves until you either run out of network bandwidth, or your update load grows to
the point that the master cannot handle it.

To determine how many slaves you can use before the added benefits begin to level out, and
how much you can improve performance of your site, you must know your query patterns, and
determine empirically by benchmarking the relationship between the throughput for reads and
writes on a typical master and a typical slave. The example here shows a rather simplified
calculation of what you can get with replication for a hypothetical system. Let reads and
writes denote the number of reads and writes per second, respectively.

Let's say that system load consists of 10% writes and 90% reads, and we have determined
by benchmarking that reads is $1200 - 2 \times \text{writes}$. In other words, the system can do 1,200
reads per second with no writes, the average write is twice as slow as the average read, and the
relationship is linear. Suppose that the master and each slave have the same capacity, and that
we have one master and $N$ slaves. Then we have for each server (master or slave):

$$\text{reads} = 1200 - 2 \times \text{writes}$$

$$\text{reads} = 9 \times \text{writes} / (N + 1) \text{ (reads are split, but writes replicated to all slaves)}$$

$$9 \times \text{writes} / (N + 1) + 2 \times \text{writes} = 1200$$

$$\text{writes} = 1200 / (2 + 9/(N + 1))$$

The last equation indicates the maximum number of writes for $N$ slaves, given a maximum
possible read rate of 1,200 per second and a ratio of nine reads per write.

This analysis yields the following conclusions:

- If $N = 0$ (which means we have no replication), our system can handle about $1200/11 = 109$
  writes per second.
- If $N = 1$, we get up to 184 writes per second.
- If $N = 8$, we get up to 400 writes per second.
- If $N = 17$, we get up to 480 writes per second.
Eventually, as $N$ approaches infinity (and our budget negative infinity), we can get very close to 600 writes per second, increasing system throughput about 5.5 times. However, with only eight servers, we increase it nearly four times.

These computations assume infinite network bandwidth and neglect several other factors that could be significant on your system. In many cases, you may not be able to perform a computation similar to the one just shown that accurately predicts what will happen on your system if you add $N$ replication slaves. However, answering the following questions should help you decide whether and by how much replication will improve the performance of your system:

- What is the read/write ratio on your system?
- How much more write load can one server handle if you reduce the reads?
- For how many slaves do you have bandwidth available on your network?

**A.13.9 How can I use replication to provide redundancy or high availability?**

How you implement redundancy is entirely dependent on your application and circumstances. High-availability solutions (with automatic failover) require active monitoring and either custom scripts or third party tools to provide the failover support from the original MySQL server to the slave.

To handle the process manually, you should be able to switch from a failed master to a pre-configured slave by altering your application to talk to the new server or by adjusting the DNS for the MySQL server from the failed server to the new server.

For more information and some example solutions, see Section 16.3.6, “Switching Masters During Failover”.

**A.13.10 How do I tell whether a master server is using statement-based or row-based binary logging format?**

Check the value of the `binlog_format` system variable:

```bash
mysql> SHOW VARIABLES LIKE 'binlog_format';
```

The value shown will be one of `STATEMENT`, `ROW`, or `MIXED`. For `MIXED` mode, statement-based logging is used by default but replication switches automatically to row-based logging under certain conditions, such as unsafe statements. For information about when this may occur, see Section 5.4.4.3, “Mixed Binary Logging Format”.

**A.13.11 How do I tell a slave to use row-based replication?**

Slaves automatically know which format to use.

**A.13.12 How do I prevent `GRANT` and `REVOKE` statements from replicating to slave machines?**

Start the server with the `--replicate-wild-ignore-table=mysql.%` option to ignore replication for tables in the `mysql` database.

**A.13.13 Does replication work on mixed operating systems (for example, the master runs on Linux while slaves run on OS X and Windows)?**

Yes.

**A.13.14 Does replication work on mixed hardware architectures (for example, the master runs on a 64-bit machine while slaves run on 32-bit machines)?**

Yes.

This appendix lists common problems and errors that may occur and potential resolutions, in addition to listing the errors that may appear when you call MySQL from any host language. The first section covers problems and resolutions. Detailed information on errors is provided: One list displays server error messages. Another list displays client program messages.

B.1 Sources of Error Information

There are several sources of error information in MySQL:

- Each SQL statement executed results in an error code, an SQLSTATE value, and an error message, as described in Section B.2, “Types of Error Values”. These errors are returned from the server side; see Section B.3, “Server Error Codes and Messages”.

- Errors can occur on the client side, usually involving problems communicating with the server; see Section B.4, “Client Error Codes and Messages”.

- SQL statement warning and error information is available through the \texttt{SHOW WARNINGS} and \texttt{SHOW ERRORS} statements. The \texttt{warning_count} system variable indicates the number of errors, warnings, and notes. The \texttt{error_count} system variable indicates the number of errors. Its value excludes warnings and notes.

- \texttt{SHOW SLAVE STATUS} statement output includes information about replication errors occurring on the slave side.

- \texttt{SHOW ENGINE INNODB STATUS} statement output includes information about the most recent foreign key error if a \texttt{CREATE TABLE} statement for an InnoDB table fails.

- The \texttt{perror} program provides information from the command line about error numbers. See Section 4.8.1, “perror — Explain Error Codes”.

Descriptions of server and client errors are provided later in this Appendix. For information about errors related to InnoDB, see Section 14.6.12.4, “InnoDB Error Handling”.

B.2 Types of Error Values

When an error occurs in MySQL, the server returns two types of error values:

- A MySQL-specific error code. This value is numeric. It is not portable to other database systems.

- An SQLSTATE value. The value is a five-character string (for example, '42S02'). The values are taken from ANSI SQL and ODBC and are more standardized.
A message string that provides a textual description of the error is also available.

When an error occurs, the MySQL error code, SQLSTATE value, and message string are available using C API functions:

- MySQL error code: Call `mysql_errno()`
- SQLSTATE value: Call `mysql_sqlstate()`
- Error message: Call `mysql_error()`

For prepared statements, the corresponding error functions are `mysql_stmt_errno()`, `mysql_stmt_sqlstate()`, and `mysql_stmt_error()`. All error functions are described in Section 21.8, “MySQL C API”.

The number of errors, warnings, and notes for the previous statement can be obtained by calling `mysql_warning_count()`. See Section 21.8.7.72, “mysql_warning_count()”.

The first two characters of an SQLSTATE value indicate the error class:

- Class = '00' indicates success.
- Class = '01' indicates a warning.
- Class = '02' indicates “not found.” This is relevant within the context of cursors and is used to control what happens when a cursor reaches the end of a data set. This condition also occurs for `SELECT ... INTO var_list` statements that retrieve no rows.
- Class > '02' indicates an exception.

B.3 Server Error Codes and Messages

MySQL programs have access to several types of error information when the server returns an error. For example, the `mysql` client program displays errors using the following format:

```
shell> SELECT * FROM no_such_table;
ERROR 1146 (42S02): Table 'test.no_such_table' doesn't exist
```

The message displayed contains three types of information:

- A numeric error code (1146). This number is MySQL-specific and is not portable to other database systems.
- A five-character SQLSTATE value ('42S02'). The values are taken from ANSI SQL and ODBC and are more standardized. Not all MySQL error numbers have corresponding SQLSTATE values. In these cases, 'HY000' (general error) is used.
- A message string that provides a textual description of the error.

For error checking, use error codes, not error messages. Error messages do not change often, but it is possible. Also if the database administrator changes the language setting, that affects the language of error messages.

Error codes are stable across GA releases of a given MySQL series. Before a series reaches GA status, new codes may still be under development and subject to change.

Server error information comes from the following source files. For details about the way that error information is defined, see the MySQL Internals Manual.

- Error message information is listed in the `share/errmsg.txt` file. %d and %s represent numbers and strings, respectively, that are substituted into the Message values when they are displayed.
The Error values listed in `share/errmsg.txt` are used to generate the definitions in the `include/mysqld_error.h` and `include/mysqld_ename.h` MySQL source files.

The SQLSTATE values listed in `share/errmsg.txt` are used to generate the definitions in the `include/sql_state.h` MySQL source file.

Because updates are frequent, it is possible that those files will contain additional error information not listed here.

• **Error:** 1000 SQLSTATE: HY000 (ER_HASHCHK)
  
  Message: hashchk
  Unused.

• **Error:** 1001 SQLSTATE: HY000 (ER_NISAMCHK)
  
  Message: isamchk
  Unused.

• **Error:** 1002 SQLSTATE: HY000 (ER_NO)
  
  Message: NO
  Used in the construction of other messages.

• **Error:** 1003 SQLSTATE: HY000 (ER_YES)
  
  Message: YES
  Used in the construction of other messages.
  
  Extended EXPLAIN format generates Note messages. ER_YES is used in the Code column for these messages in subsequent SHOW WARNINGS output.

• **Error:** 1004 SQLSTATE: HY000 (ER_CANT_CREATE_FILE)
  
  Message: Can't create file '%s' (errno: %d)
  Occurs for failure to copy an .frm file to a new location, during execution of a CREATE TABLE dst LIKE src statement when the server tries to copy the source table .frm file to the destination table .frm file.
  
  Possible causes: Permissions problem for source .frm file; destination .frm file already exists but is not writeable.

• **Error:** 1005 SQLSTATE: HY000 (ER_CANT_CREATE_TABLE)
  
  Message: Can't create table '%s' (errno: %d)
  InnoDB reports this error when a table cannot be created. If the error message refers to error 150, table creation failed because a foreign key constraint was not correctly formed. If the error message refers to error −1, table creation probably failed because the table includes a column name that matched the name of an internal InnoDB table.

• **Error:** 1006 SQLSTATE: HY000 (ER_CANT_CREATE_DB)
  
  Message: Can't create database '%s' (errno: %d)

• **Error:** 1007 SQLSTATE: HY000 (ER_DB_CREATE_EXISTS)
  
  Message: Can't create database '%s'; database exists
An attempt to create a database failed because the database already exists.

Drop the database first if you really want to replace an existing database, or add an `IF NOT EXISTS` clause to the `CREATE DATABASE` statement if to retain an existing database without having the statement produce an error.

- **Error:** 1008 SQLSTATE: HY000 (`ER_DB_DROP_EXISTS`)  
  Message: Can't drop database '%s'; database doesn't exist

- **Error:** 1009 SQLSTATE: HY000 (`ER_DB_DROP_DELETE`)  
  Message: Error dropping database (can't delete '%s', errno: %d)

- **Error:** 1010 SQLSTATE: HY000 (`ER_DB_DROP_RMDIR`)  
  Message: Error dropping database (can't rmdir '%s', errno: %d)

- **Error:** 1011 SQLSTATE: HY000 (`ER_CANT_DELETE_FILE`)  
  Message: Error on delete of '%s' (errno: %d)

- **Error:** 1012 SQLSTATE: HY000 (`ER_CANT_FIND_SYSTEM_REC`)  
  Message: Can't read record in system table

  Returned by InnoDB for attempts to access InnoDB INFORMATION_SCHEMA tables when InnoDB is unavailable.

- **Error:** 1013 SQLSTATE: HY000 (`ER_CANT_GET_STAT`)  
  Message: Can't get status of '%s' (errno: %d)

- **Error:** 1014 SQLSTATE: HY000 (`ER_CANT_GET_WD`)  
  Message: Can't get working directory (errno: %d)

- **Error:** 1015 SQLSTATE: HY000 (`ER_CANT_LOCK`)  
  Message: Can't lock file (errno: %d)

- **Error:** 1016 SQLSTATE: HY000 (`ER_CANT_OPEN_FILE`)  
  Message: Can't open file: '%s' (errno: %d)

  InnoDB reports this error when the table from the InnoDB data files cannot be found, even though the .frm file for the table exists. See Section 14.6.12.3, “Troubleshooting InnoDB Data Dictionary Operations”.

- **Error:** 1017 SQLSTATE: HY000 (`ER_FILE_NOT_FOUND`)  
  Message: Can't find file: '%s' (errno: %d)

- **Error:** 1018 SQLSTATE: HY000 (`ER_CANT_READ_DIR`)  
  Message: Can't read dir of '%s' (errno: %d)

- **Error:** 1019 SQLSTATE: HY000 (`ER_CANT_SET_WD`)  
  Message: Can't change dir to '%s' (errno: %d)

- **Error:** 1020 SQLSTATE: HY000 (`ER_CHECKREAD`)
Message: Record has changed since last read in table '%s'

• Error: **1021** SQLSTATE: **HY000 (ER_DISK_FULL)**
  Message: Disk full (%s); waiting for someone to free some space...

• Error: **1022** SQLSTATE: **23000 (ER_DUP_KEY)**
  Message: Can't write; duplicate key in table '%s'

• Error: **1023** SQLSTATE: **HY000 (ER_ERROR_ON_CLOSE)**
  Message: Error on close of '%s' (errno: %d)

• Error: **1024** SQLSTATE: **HY000 (ER_ERROR_ON_READ)**
  Message: Error reading file '%s' (errno: %d)

• Error: **1025** SQLSTATE: **HY000 (ER_ERROR_ON_RENAME)**
  Message: Error on rename of '%s' to '%s' (errno: %d)

  *InnoDB* reports this error if you attempt to drop the last index that can enforce a particular referential constraint. As of MySQL 5.5, this error message is replaced by ERROR 1553.

• Error: **1026** SQLSTATE: **HY000 (ER_ERROR_ON_WRITE)**
  Message: Error writing file '%s' (errno: %d)

• Error: **1027** SQLSTATE: **HY000 (ER_FILE_USED)**
  Message: '%s' is locked against change

• Error: **1028** SQLSTATE: **HY000 (ER_FILSORT_ABORT)**
  Message: Sort aborted

• Error: **1029** SQLSTATE: **HY000 (ER_FORM_NOT_FOUND)**
  Message: View '%s' doesn't exist for '%s'

• Error: **1030** SQLSTATE: **HY000 (ER_GET_ERRNO)**
  Message: Got error %d from storage engine

  Check the %d value to see what the OS error means. For example, 28 indicates that you have run out of disk space.

• Error: **1031** SQLSTATE: **HY000 (ER_ILLEGAL_HA)**
  Message: Table storage engine for '%s' doesn't have this option

• Error: **1032** SQLSTATE: **HY000 (ER_KEY_NOT_FOUND)**
  Message: Can't find record in '%s'

• Error: **1033** SQLSTATE: **HY000 (ER_NOT_FORM_FILE)**
  Message: Incorrect information in file: '%s'

• Error: **1034** SQLSTATE: **HY000 (ER_NOT_KEYFILE)**
  Message: Incorrect key file for table '%s'; try to repair it
Server Error Codes and Messages

- Error: **1035** SQLSTATE: **HY000** (**ER_OLD_KEYFILE**)
  Message: Old key file for table '%s'; repair it!

- Error: **1036** SQLSTATE: **HY000** (**ER_OPEN_AS_READONLY**)
  Message: Table '%s' is read only

- Error: **1037** SQLSTATE: **HY001** (**ER_OUTOFMEMORY**)
  Message: Out of memory; restart server and try again (needed %d bytes)

- Error: **1038** SQLSTATE: **HY001** (**ER_OUT_OF_SORTMEMORY**)
  Message: Out of sort memory; increase server sort buffer size

- Error: **1039** SQLSTATE: **HY000** (**ER_UNEXPECTED_EOF**)
  Message: Unexpected EOF found when reading file '%s' (errno: %d)

- Error: **1040** SQLSTATE: **08004** (**ER_CON_COUNT_ERROR**)
  Message: Too many connections

- Error: **1041** SQLSTATE: **HY000** (**ER_OUT_OF_RESOURCES**)
  Message: Out of memory; check if mysqld or some other process uses all available memory; if not, you may have to use 'ulimit' to allow mysqld to use more memory or you can add more swap space

- Error: **1042** SQLSTATE: **08S01** (**ER_BAD_HOST_ERROR**)
  Message: Can't get hostname for your address

- Error: **1043** SQLSTATE: **08S01** (**ER_HANDSHAKE_ERROR**)
  Message: Bad handshake

- Error: **1044** SQLSTATE: **42000** (**ER_DBACCESS_DENIED_ERROR**)
  Message: Access denied for user '%s'@'%s' to database '%s'

- Error: **1045** SQLSTATE: **28000** (**ER_ACCESS_DENIED_ERROR**)
  Message: Access denied for user '%s'@'%s' (using password: %s)

- Error: **1046** SQLSTATE: **3D000** (**ER_NO_DB_ERROR**)
  Message: No database selected

- Error: **1047** SQLSTATE: **08S01** (**ER_UNKNOWN_COM_ERROR**)
  Message: Unknown command

- Error: **1048** SQLSTATE: **23000** (**ER_BAD_NULL_ERROR**)
  Message: Column '%s' cannot be null

- Error: **1049** SQLSTATE: **42000** (**ER_BAD_DB_ERROR**)
  Message: Unknown database '%s'

- Error: **1050** SQLSTATE: **42S01** (**ER_TABLE_EXISTS_ERROR**)
  Message: Table '%s' already exists

- Error: **1051** SQLSTATE: **42S02** (**ER_BAD_TABLE_ERROR**)
Server Error Codes and Messages

Message: Unknown table '%s'

- **Error:** 1052 SQLSTATE: 23000 (ER_NON_UNIQ_ERROR)

Message: Column '%s' in %s is ambiguous

| %s = column name |
| %s = location of column (for example, "field list") |

Likely cause: A column appears in a query without appropriate qualification, such as in a select list or ON clause.

Examples:

```sql
mysql> SELECT i FROM t INNER JOIN t AS t2;
ERROR 1052 (23000): Column 'i' in field list is ambiguous
```

```sql
mysql> SELECT * FROM t LEFT JOIN t AS t2 ON i = i;
ERROR 1052 (23000): Column 'i' in on clause is ambiguous
```

Resolution:

- Qualify the column with the appropriate table name:

```sql
mysql> SELECT t2.i FROM t INNER JOIN t AS t2;
```

- Modify the query to avoid the need for qualification:

```sql
mysql> SELECT * FROM t LEFT JOIN t AS t2 USING (i);
```

- **Error:** 1053 SQLSTATE: 08S01 (ER_SERVER_SHUTDOWN)

Message: Server shutdown in progress

- **Error:** 1054 SQLSTATE: 42S22 (ER_BAD_FIELD_ERROR)

Message: Unknown column '%s' in '%s'

- **Error:** 1055 SQLSTATE: 42000 (ER_WRONG_FIELD_WITH_GROUP)

Message: '%s' isn't in GROUP BY

- **Error:** 1056 SQLSTATE: 42000 (ER_WRONG_GROUP_FIELD)

Message: Can't group on '%s'

- **Error:** 1057 SQLSTATE: 42000 (ER_WRONG_SUM_SELECT)

Message: Statement has sum functions and columns in same statement

- **Error:** 1058 SQLSTATE: 21S01 (ER_WRONG_VALUE_COUNT)

Message: Column count doesn't match value count

- **Error:** 1059 SQLSTATE: 42000 (ER_TOO_LONG_IDENT)

Message: Identifier name '%s' is too long

- **Error:** 1060 SQLSTATE: 42S21 (ER_DUP_FIELDNAME)

Message: Duplicate column name '%s'
• Error: 1061 SQLSTATE: 42000 (ER_DUP_KEYNAME)
  Message: Duplicate key name '%s'
• Error: 1062 SQLSTATE: 23000 (ER_DUP_ENTRY)
  Message: Duplicate entry '%s' for key %d
  From 5.1.20: The message returned with this error uses the format string for
  ER_DUP_ENTRY_WITH_KEY_NAME.
• Error: 1063 SQLSTATE: 42000 (ER_WRONG_FIELD_SPEC)
  Message: Incorrect column specifier for column '%s'
• Error: 1064 SQLSTATE: 42000 (ER_PARSE_ERROR)
  Message: %s near '%s' at line %d
• Error: 1065 SQLSTATE: 42000 (ER_EMPTY_QUERY)
  Message: Query was empty
• Error: 1066 SQLSTATE: 42000 (ER_NONUNIQ_TABLE)
  Message: Not unique table/alias: '%s'
• Error: 1067 SQLSTATE: 42000 (ER_INVALID_DEFAULT)
  Message: Invalid default value for '%s'
• Error: 1068 SQLSTATE: 42000 (ER_MULTIPLE_PRI_KEY)
  Message: Multiple primary key defined
• Error: 1069 SQLSTATE: 42000 (ER_TOO_MANY_KEYS)
  Message: Too many keys specified; max %d keys allowed
• Error: 1070 SQLSTATE: 42000 (ER_TOO_MANY_KEY_PARTS)
  Message: Too many key parts specified; max %d parts allowed
• Error: 1071 SQLSTATE: 42000 (ER_TOO_LONG_KEY)
  Message: Specified key was too long; max key length is %d bytes
• Error: 1072 SQLSTATE: 42000 (ER_KEY_COLUMN_DOES_NOT_EXITS)
  Message: Key column '%s' doesn't exist in table
• Error: 1073 SQLSTATE: 42000 (ER_BLOB_USED_AS_KEY)
  Message: BLOB column '%s' can't be used in key specification with the used table type
• Error: 1074 SQLSTATE: 42000 (ER_TOO_BIG_FIELDLENGTH)
  Message: Column length too big for column '%s' (max = %lu); use BLOB or TEXT instead
• Error: 1075 SQLSTATE: 42000 (ER_WRONG_AUTO_KEY)
  Message: Incorrect table definition; there can be only one auto column and it must be defined as a key
• Error: 1076 SQLSTATE: HY000 (ER_READY)
Message: %s: ready for connections. Version: '%s' socket: '%s' port: %d
•   Error: 1077 SQLSTATE: HY000 (ER_NORMAL_SHUTDOWN)
  Message: %s: Normal shutdown
•   Error: 1078 SQLSTATE: HY000 (ER_GOT_SIGNAL)
  Message: %s: Got signal %d. Aborting!
•   Error: 1079 SQLSTATE: HY000 (ER_SHUTDOWN_COMPLETE)
  Message: %s: Shutdown complete
•   Error: 1080 SQLSTATE: 08S01 (ER_FORCING_CLOSE)
  Message: %s: Forcing close of thread %ld user: '%s'
•   Error: 1081 SQLSTATE: 08S01 (ER_IPSOCK_ERROR)
  Message: Can't create IP socket
•   Error: 1082 SQLSTATE: 42S12 (ER_NO_SUCH_INDEX)
  Message: Table %s' has no index like the one used in CREATE INDEX; recreate the table
•   Error: 1083 SQLSTATE: 42000 (ER_WRONG_FIELD_TERMINATORS)
  Message: Field separator argument is not what is expected; check the manual
•   Error: 1084 SQLSTATE: 42000 (ER_BLOBS_AND_NO_TERMINATED)
  Message: You can't use fixed rowlength with BLOBs; please use 'fields terminated by'
•   Error: 1085 SQLSTATE: HY000 (ER_TEXTFILE_NOT_READABLE)
  Message: The file '%s' must be in the database directory or be readable by all
•   Error: 1086 SQLSTATE: HY000 (ER_FILE_EXISTS_ERROR)
  Message: File '%s' already exists
•   Error: 1087 SQLSTATE: HY000 (ER_LOAD_INFO)
  Message: Records: %ld Deleted: %ld Skipped: %ld Warnings: %ld
•   Error: 1088 SQLSTATE: HY000 (ER_ALTER_INFO)
  Message: Records: %ld Duplicates: %ld
•   Error: 1089 SQLSTATE: HY000 (ER_WRONG_SUB_KEY)
  Message: Incorrect prefix key; the used key part isn't a string, the used length is longer than the key part, or the storage engine doesn't support unique prefix keys
•   Error: 1090 SQLSTATE: 42000 (ER_CANT_REMOVE_ALL_FIELDS)
  Message: You can't delete all columns with ALTER TABLE; use DROP TABLE instead
•   Error: 1091 SQLSTATE: 42000 (ER_CANT_DROP_FIELD_OR_KEY)
  Message: Can't DROP '%s'; check that column/key exists
•   Error: 1092 SQLSTATE: HY000 (ER_INSERT_INFO)
Server Error Codes and Messages

Message: Records: %ld Duplicates: %ld Warnings: %ld

•   Error: 1093 SQLSTATE: HY000 (ER_UPDATE_TABLE_USED)
    Message: You can't specify target table '%s' for update in FROM clause
    This error occurs for attempts to select from and modify the same table within a single statement.

•   Error: 1094 SQLSTATE: HY000 (ER_NO_SUCH_THREAD)
    Message: Unknown thread id: %lu

•   Error: 1095 SQLSTATE: HY000 (ER_KILL_DENIED_ERROR)
    Message: You are not owner of thread %lu

•   Error: 1096 SQLSTATE: HY000 (ER_NO_TABLES_USED)
    Message: No tables used

•   Error: 1097 SQLSTATE: HY000 (ER_TOO_BIG_SET)
    Message: Too many strings for column %s and SET

•   Error: 1098 SQLSTATE: HY000 (ER_NO_UNIQUE_LOGFILE)
    Message: Can't generate a unique log-filename %s.(1-999)

•   Error: 1099 SQLSTATE: HY000 (ER_TABLE_NOT_LOCKED_FOR_WRITE)
    Message: Table '%s' was locked with a READ lock and can't be updated

•   Error: 1100 SQLSTATE: HY000 (ER_TABLE_NOT_LOCKED)
    Message: Table '%s' was not locked with LOCK TABLES

•   Error: 1101 SQLSTATE: 42000 (ER_BLOB_CANT_HAVE_DEFAULT)
    Message: BLOB/TEXT column '%s' can't have a default value

•   Error: 1102 SQLSTATE: 42000 (ER_WRONG_DB_NAME)
    Message: Incorrect database name '%s'

•   Error: 1103 SQLSTATE: 42000 (ER_WRONG_TABLE_NAME)
    Message: Incorrect table name '%s'

•   Error: 1104 SQLSTATE: 42000 (ER_TOO_BIG_SELECT)
    Message: The SELECT would examine more than MAX_JOIN_SIZE rows; check your WHERE and use SET SQL_BIG_SELECTS=1 or SET MAX_JOIN_SIZE=# if the SELECT is okay

•   Error: 1105 SQLSTATE: HY000 (ER_UNKNOWN_ERROR)
    Message: Unknown error

•   Error: 1106 SQLSTATE: 42000 (ER_UNKNOWN_PROCEDURE)
    Message: Unknown procedure '%s'

•   Error: 1107 SQLSTATE: 42000 (ER_WRONG_PARAMCOUNT_TO_PROCEDURE)
    Message: Incorrect parameter count to procedure '%s'
Server Error Codes and Messages

• Error: **1108** SQLSTATE: **HY000 (ER_WRONG_PARAMETERS_TO_PROCEDURE)**
  Message: Incorrect parameters to procedure '%s'

• Error: **1109** SQLSTATE: **42S02 (ER_UNKNOWN_TABLE)**
  Message: Unknown table '%s' in %s

• Error: **1110** SQLSTATE: **42000 (ER_FIELD_SPECIFIED_TWICE)**
  Message: Column '%s' specified twice

• Error: **1111** SQLSTATE: **HY000 (ER_INVALID_GROUP_FUNC_USE)**
  Message: Invalid use of group function

• Error: **1112** SQLSTATE: **42000 (ER_UNSUPPORTED_EXTENSION)**
  Message: Table '%s' uses an extension that doesn't exist in this MySQL version

• Error: **1113** SQLSTATE: **42000 (ER_TABLE_MUST_HAVE_COLUMNS)**
  Message: A table must have at least 1 column

• Error: **1114** SQLSTATE: **HY000 (ER_RECORD_FILE_FULL)**
  Message: The table '%s' is full
  InnoDB reports this error when the system tablespace runs out of free space. Reconfigure the system tablespace to add a new data file.

• Error: **1115** SQLSTATE: **42000 (ER_UNKNOWN_CHARACTER_SET)**
  Message: Unknown character set: '%s'

• Error: **1116** SQLSTATE: **HY000 (ER_TOO_MANY_TABLES)**
  Message: Too many tables; MySQL can only use %d tables in a join

• Error: **1117** SQLSTATE: **HY000 (ER_TOO_MANY_FIELDS)**
  Message: Too many columns

• Error: **1118** SQLSTATE: **42000 (ER_TOO_BIG_ROWSIZE)**
  Message: Row size too large. The maximum row size for the used table type, not counting BLOBs, is %ld. You have to change some columns to TEXT or BLOBs

• Error: **1119** SQLSTATE: **HY000 (ER_STACK_OVERRUN)**
  Message: Thread stack overrun: Used: %ld of a %ld stack. Use 'mysqld -O thread_stack=#' to specify a bigger stack if needed

• Error: **1120** SQLSTATE: **42000 (ER_WRONG_OUTER_JOIN)**
  Message: Cross dependency found in OUTER JOIN; examine your ON conditions

• Error: **1121** SQLSTATE: **42000 (ER_NULL_COLUMN_IN_INDEX)**
  Message: Table handler doesn't support NULL in given index. Please change column '%s' to be NOT NULL or use another handler

• Error: **1122** SQLSTATE: **HY000 (ER_CANT_FIND_UDF)**
  Message: Can't load function '%s'
Server Error Codes and Messages

- **Error:** 1123 SQLSTATE: HY000 (ER_CANT_INITIALIZE_UDF)
  
  Message: Can't initialize function '%s'; %s

- **Error:** 1124 SQLSTATE: HY000 (ER_UDF_NO_PATHS)
  
  Message: No paths allowed for shared library

- **Error:** 1125 SQLSTATE: HY000 (ER_UDF_EXISTS)
  
  Message: Function '%s' already exists

- **Error:** 1126 SQLSTATE: HY000 (ER_CANT_OPEN_LIBRARY)
  
  Message: Can't open shared library '%s' (errno: %d %s)

- **Error:** 1127 SQLSTATE: HY000 (ER_CANT_FIND_DL_ENTRY)
  
  Message: Can't find symbol '%s' in library

- **Error:** 1128 SQLSTATE: HY000 (ER_FUNCTION_NOT_DEFINED)
  
  Message: Function '%s' is not defined

- **Error:** 1129 SQLSTATE: HY000 (ER_HOST_IS_BLOCKED)
  
  Message: Host '%s' is blocked because of many connection errors; unblock with 'mysqladmin flush-hosts'

- **Error:** 1130 SQLSTATE: HY000 (ER_HOST_NOT_PRIVILEGED)
  
  Message: Host '%s' is not allowed to connect to this MySQL server

- **Error:** 1131 SQLSTATE: 42000 (ER_PASSWORD_ANONYMOUS_USER)
  
  Message: You are using MySQL as an anonymous user and anonymous users are not allowed to change passwords

- **Error:** 1132 SQLSTATE: 42000 (ER_PASSWORD_NOT_ALLOWED)
  
  Message: You must have privileges to update tables in the mysql database to be able to change passwords for others

- **Error:** 1133 SQLSTATE: 42000 (ER_PASSWORD_NO_MATCH)
  
  Message: Can't find any matching row in the user table

- **Error:** 1134 SQLSTATE: HY000 (ER_UPDATE_INFO)
  
  Message: Rows matched: %ld Changed: %ld Warnings: %ld

- **Error:** 1135 SQLSTATE: HY000 (ER_CANT_CREATE_THREAD)
  
  Message: Can't create a new thread (errno %d); if you are not out of available memory, you can consult the manual for a possible OS-dependent bug

- **Error:** 1136 SQLSTATE: 21S01 (ER_WRONG_VALUE_COUNT_ON_ROW)
  
  Message: Column count doesn't match value count at row %ld

- **Error:** 1137 SQLSTATE: HY000 (ER_CANT_REOPEN_TABLE)
  
  Message: Can't reopen table: '%s'

- **Error:** 1138 SQLSTATE: 22004 (ER_INVALID_USE_OF_NULL)
Server Error Codes and Messages

Message: Invalid use of NULL value

•   Error: 1139 SQLSTATE: 42000 (ER_REGEXP_ERROR)
Message: Got error '%s' from regexp

•   Error: 1140 SQLSTATE: 42000 (ER_MIX_OF_GROUP_FUNC_AND_FIELDS)
Message: Mixing of GROUP columns (MIN(),MAX(),COUNT(),...) with no GROUP columns is illegal if there is no GROUP BY clause

•   Error: 1141 SQLSTATE: 42000 (ER_NONEXISTING_GRANT)
Message: There is no such grant defined for user '%s' on host '%s'

•   Error: 1142 SQLSTATE: 42000 (ER_TABLEACCESS_DENIED_ERROR)
Message: %s command denied to user '%s'@'%s' for table '%s'

•   Error: 1143 SQLSTATE: 42000 (ER_COLUMNACCESS_DENIED_ERROR)
Message: %s command denied to user '%s'@'%s' for column '%s' in table '%s'

•   Error: 1144 SQLSTATE: 42000 (ER_ILLEGAL_GRANT_FOR_TABLE)
Message: Illegal GRANT/REVOKE command; please consult the manual to see which privileges can be used

•   Error: 1145 SQLSTATE: 42000 (ER_GRANT_WRONG_HOST_OR_USER)
Message: The host or user argument to GRANT is too long

•   Error: 1146 SQLSTATE: 42S02 (ER_NO_SUCH_TABLE)
Message: Table '%s.%s' doesn't exist

•   Error: 1147 SQLSTATE: 42000 (ER_NONEXISTING_TABLE_GRANT)
Message: There is no such grant defined for user '%s' on host '%s' on table '%s'

•   Error: 1148 SQLSTATE: 42000 (ER_NOT_ALLOWED_COMMAND)
Message: The used command is not allowed with this MySQL version

•   Error: 1149 SQLSTATE: 42000 (ER_SYNTAX_ERROR)
Message: You have an error in your SQL syntax; check the manual that corresponds to your MySQL server version for the right syntax to use

•   Error: 1150 SQLSTATE: HY000 (ER_DELAYED_CANT_CHANGE_LOCK)
Message: Delayed insert thread couldn't get requested lock for table %s

•   Error: 1151 SQLSTATE: HY000 (ER_TOO_MANY_DELAYED_THREADS)
Message: Too many delayed threads in use

•   Error: 1152 SQLSTATE: 08S01 (ER_ABORTING_CONNECTION)
Message: Aborted connection %ld to db: '%s' user: '%s' (%s)

•   Error: 1153 SQLSTATE: 08S01 (ER_NET_PACKET_TOO_LARGE)
Message: Got a packet bigger than 'max_allowed_packet' bytes
Server Error Codes and Messages

- **Error: 1154 SQLSTATE: 08S01 (ER_NET_READ_ERROR_FROM_PIPE)**
  
  Message: Got a read error from the connection pipe

- **Error: 1155 SQLSTATE: 08S01 (ER_NET_FCNTL_ERROR)**
  
  Message: Got an error from fcntl()

- **Error: 1156 SQLSTATE: 08S01 (ER_NET_PACKETS_OUT_OF_ORDER)**
  
  Message: Got packets out of order

- **Error: 1157 SQLSTATE: 08S01 (ER_NET_UNCOMPRESS_ERROR)**
  
  Message: Couldn't uncompress communication packet

- **Error: 1158 SQLSTATE: 08S01 (ER_NET_READ_ERROR)**
  
  Message: Got an error reading communication packets

- **Error: 1159 SQLSTATE: 08S01 (ER_NET_READ_INTERRUPTED)**
  
  Message: Got timeout reading communication packets

- **Error: 1160 SQLSTATE: 08S01 (ER_NET_ERROR_ON_WRITE)**
  
  Message: Got an error writing communication packets

- **Error: 1161 SQLSTATE: 08S01 (ER_NET_WRITE_INTERRUPTED)**
  
  Message: Got timeout writing communication packets

- **Error: 1169 SQLSTATE: 23000 (ER_DUP_UNIQUE)**
  
  Message: Can't write, because of unique constraint, to table '%s'
Server Error Codes and Messages

- **Error: 1170** SQLSTATE: 42000 (ER_BLOB_KEY_WITHOUT_LENGTH)
  Message: BLOB/TEXT column '%s' used in key specification without a key length

- **Error: 1171** SQLSTATE: 42000 (ER_PRIMARY_CANT_HAVE_NULL)
  Message: All parts of a PRIMARY KEY must be NOT NULL; if you need NULL in a key, use UNIQUE instead

- **Error: 1172** SQLSTATE: 42000 (ER_TOO_MANY_ROWS)
  Message: Result consisted of more than one row

- **Error: 1173** SQLSTATE: 42000 (ER_REQUIRES_PRIMARY_KEY)
  Message: This table type requires a primary key

  *InnoDB* reports this error when you attempt to drop an implicit clustered index (the first UNIQUE NOT NULL index) if the table did not contain a PRIMARY KEY.

  *InnoDB* should no longer report this error as of MySQL 5.5. For tables without an explicit PRIMARY KEY, *InnoDB* creates an implicit clustered index using the first columns of the table that are declared UNIQUE and NOT NULL. When you drop such an index, *InnoDB* now automatically copies the table and rebuilds the index using a different UNIQUE NOT NULL group of columns or a system-generated key. Since this operation changes the primary key, it uses the slow method of copying the table and re-creating the index, rather than the Fast Index Creation technique from Implementation Details of Fast Index Creation.

- **Error: 1174** SQLSTATE: HY000 (ER_NO_RAID_COMPILED)
  Message: This version of MySQL is not compiled with RAID support

- **Error: 1175** SQLSTATE: HY000 (ER_UPDATE_WITHOUT_KEY_IN_SAFE_MODE)

- Error: 1198 SQLSTATE: HY000 (ER_SLAVE_MUST_STOP)
  Message: This operation cannot be performed with a running slave; run STOP SLAVE first
• Error: **1199** SQLSTATE: **HY000 (ER_SLAVE_NOT_RUNNING)**
Message: This operation requires a running slave; configure slave and do START SLAVE

• Error: **1200** SQLSTATE: **HY000 (ER_BAD_SLAVE)**
Message: The server is not configured as slave; fix in config file or with CHANGE MASTER TO

• Error: **1201** SQLSTATE: **HY000 (ER_MASTER_INFO)**
Message: Could not initialize master info structure; more error messages can be found in the MySQL error log

• Error: **1202** SQLSTATE: **HY000 (ER_SLAVE_THREAD)**
Message: Could not create slave thread; check system resources

• Error: **1203** SQLSTATE: **42000 (ER_TOO_MANY_USER_CONNECTIONS)**
Message: User %s already has more than 'max_user_connections' active connections

• Error: **1204** SQLSTATE: **HY000 (ER_SET_CONSTANTS_ONLY)**
Message: You may only use constant expressions with SET

• Error: **1205** SQLSTATE: **HY000 (ER_LOCK_WAIT_TIMEOUT)**
Message: Lock wait timeout exceeded; try restarting transaction

  *InnoDB* reports this error when lock wait timeout expires. The statement that waited too long was rolled back (not the entire transaction). You can increase the value of the `innodb_lock_wait_timeout` configuration option if SQL statements should wait longer for other transactions to complete, or decrease it if too many long-running transactions are causing locking problems and reducing concurrency on a busy system.

• Error: **1206** SQLSTATE: **HY000 (ER_LOCK_TABLE_FULL)**
Message: The total number of locks exceeds the lock table size

  *InnoDB* reports this error when the total number of locks exceeds the amount of memory devoted to managing locks. To avoid this error, increase the value of `innodb_buffer_pool_size`. Within an individual application, a workaround may be to break a large operation into smaller pieces. For example, if the error occurs for a large `INSERT`, perform several smaller `INSERT` operations.

• Error: **1207** SQLSTATE: **25000 (ER_READ_ONLY_TRANSACTION)**
Message: Update locks cannot be acquired during a READ UNCOMMITTED transaction

• Error: **1208** SQLSTATE: **HY000 (ER_DROP_DB_WITH_READ_LOCK)**
Message: DROP DATABASE not allowed while thread is holding global read lock

• Error: **1209** SQLSTATE: **HY000 (ER_CREATE_DB_WITH_READ_LOCK)**
Message: CREATE DATABASE not allowed while thread is holding global read lock

• Error: **1210** SQLSTATE: **HY000 (ER_WRONG_ARGUMENTS)**
Message: Incorrect arguments to %s

• Error: **1211** SQLSTATE: **42000 (ER_NO_PERMISSION_TO_CREATE_USER)**
Message: '%s'@'%s' is not allowed to create new users
Server Error Codes and Messages

- **Error:** 1212 SQLSTATE: HY000 (ER_UNION_TABLES_IN_DIFFERENT_DIR)
  Message: Incorrect table definition; all MERGE tables must be in the same database

- **Error:** 1213 SQLSTATE: 40001 (ER_LOCK_DEADLOCK)
  Message: Deadlock found when trying to get lock; try restarting transaction

  **InnoDB** reports this error when a transaction encounters a deadlock and is automatically rolled back so that your application can take corrective action. To recover from this error, run all the operations in this transaction again. A deadlock occurs when requests for locks arrive in inconsistent order between transactions. The transaction that was rolled back released all its locks, and the other transaction can now get all the locks it requested. Thus, when you re-run the transaction that was rolled back, it might have to wait for other transactions to complete, but typically the deadlock does not recur. If you encounter frequent deadlocks, make the sequence of locking operations (LOCK TABLES, SELECT ... FOR UPDATE, and so on) consistent between the different transactions or applications that experience the issue. See Section 14.6.4.9, “How to Cope with Deadlocks” for details.

- **Error:** 1214 SQLSTATE: HY000 (ER_TABLE_CANT_HANDLE_FT)
  Message: The used table type doesn't support FULLTEXT indexes

- **Error:** 1215 SQLSTATE: HY000 (ER_CANNOT_ADD_FOREIGN)
  Message: Cannot add foreign key constraint

- **Error:** 1216 SQLSTATE: 23000 (ER_NO_REFERENCED_ROW)
  Message: Cannot add or update a child row: a foreign key constraint fails

  **InnoDB** reports this error when you try to add a row but there is no parent row, and a foreign key constraint fails. Add the parent row first.

- **Error:** 1217 SQLSTATE: 23000 (ER_ROW_IS_REFERENCED)
  Message: Cannot delete or update a parent row: a foreign key constraint fails

  **InnoDB** reports this error when you try to delete a parent row that has children, and a foreign key constraint fails. Delete the children first.

  Message: You are not allowed to create a user with GRANT

- Error: **1411** SQLSTATE: HY000 (**ER_WRONG_VALUE_FOR_TYPE**)  
  Message: Incorrect `%s` value: `%s` for function `%s`
Server Error Codes and Messages

- **Error: 1412 SQLSTATE: HY000 (ER_TABLE_DEF_CHANGED)**
  
  Message: Table definition has changed, please retry transaction

- **Error: 1413 SQLSTATE: 42000 (ER_SP_DUP_HANDLER)**

  Message: Duplicate handler declared in the same block

- **Error: 1414 SQLSTATE: 42000 (ER_SP_NOT_VAR_ARG)**

  Message: OUT or INOUT argument %d for routine %s is not a variable or NEW pseudo-variable in BEFORE trigger

- **Error: 1415 SQLSTATE: 0A000 (ER_SP_NO_RETSET)**

  Message: Not allowed to return a result set from a %s

- **Error: 1416 SQLSTATE: 22003 (ER_CANT_CREATE_GEOMETRY_OBJECT)**

  Message: Cannot get geometry object from data you send to the GEOMETRY field

- **Error: 1417 SQLSTATE: HY000 (ER_FAILED_ROUTINE_BREAK_BINLOG)**

  Message: A routine failed and has neither NO SQL nor READS SQL DATA in its declaration and binary logging is enabled; if non-transactional tables were updated, the binary log will miss their changes

- **Error: 1418 SQLSTATE: HY000 (ER_BINLOG_UNSAFE_ROUTINE)**

  Message: This function has none of DETERMINISTIC, NO SQL, or READS SQL DATA in its declaration and binary logging is enabled (you "might" want to use the less safe log_bin_trust_function_creators variable)

- **Error: 1419 SQLSTATE: HY000 (ER_BINLOG_CREATE_ROUTINE_NEED_SUPER)**

  Message: You do not have the SUPER privilege and binary logging is enabled (you "might" want to use the less safe log_bin_trust_function_creators variable)

- **Error: 1420 SQLSTATE: HY000 (ER_EXEC_STMT_WITH_OPEN_CURSOR)**

  Message: You can't execute a prepared statement which has an open cursor associated with it. Reset the statement to re-execute it.

- **Error: 1421 SQLSTATE: HY000 (ER_STMT_HAS_NO_OPEN_CURSOR)**

  Message: The statement (%lu) has no open cursor.

- **Error: 1422 SQLSTATE: HY000 (ER_COMMIT_NOT_ALLOWED_IN_SF_OR_TRG)**

  Message: Explicit or implicit commit is not allowed in stored function or trigger.

- **Error: 1423 SQLSTATE: HY000 (ER_NO_DEFAULT_FOR_VIEW_FIELD)**

  Message: Field of view '%s.%s' underlying table doesn't have a default value

- **Error: 1424 SQLSTATE: HY000 (ER_SP_NO_RECURSION)**

  Message: Recursive stored functions and triggers are not allowed.

- **Error: 1425 SQLSTATE: 42000 (ER_TOO_BIG_SCALE)**

  Message: Too big scale %d specified for column '%s'. Maximum is %lu.

- **Error: 1426 SQLSTATE: 42000 (ER_TOO_BIG_PRECISION)**
Server Error Codes and Messages

Message: Too big precision %d specified for column '%s'. Maximum is %lu.

•   Error: 1427 SQLSTATE: 42000 (ER_M_BIGGER_THAN_D)
Message: For float(M,D), double(M,D) or decimal(M,D), M must be >= D (column '%s').

•   Error: 1428 SQLSTATE: HY000 (ER_WRONG_LOCK_OF_SYSTEM_TABLE)
Message: You can't combine write-locking of system tables with other tables or lock types

•   Error: 1429 SQLSTATE: HY000 (ER_CONNECT_TO_FOREIGN_DATA_SOURCE)
Message: Unable to connect to foreign data source: %s

•   Error: 1430 SQLSTATE: HY000 (ER_QUERY_ON_FOREIGN_DATA_SOURCE)
Message: There was a problem processing the query on the foreign data source. Data source error: %s

•   Error: 1431 SQLSTATE: HY000 (ER_FOREIGN_DATA_SOURCE_DOESNT_EXIST)
Message: The foreign data source you are trying to reference does not exist. Data source error: %s

•   Error: 1432 SQLSTATE: HY000 (ER_FOREIGN_DATA_STRING_INVALID_CANT_CREATE)
Message: Can't create federated table. The data source connection string '%s' is not in the correct format

•   Error: 1433 SQLSTATE: HY000 (ER_FOREIGN_DATA_STRING_INVALID)
Message: The data source connection string '%s' is not in the correct format

•   Error: 1434 SQLSTATE: HY000 (ER_CANT_CREATE_FEDERATED_TABLE)
Message: Can't create federated table. Foreign data src error: %s

•   Error: 1435 SQLSTATE: HY000 (ER_TRG_IN_WRONG_SCHEMA)
Message: Trigger in wrong schema

•   Error: 1436 SQLSTATE: HY000 (ER_STACK_OVERRUN_NEED_MORE)
Message: Thread stack overrun: %ld bytes used of a %ld byte stack, and %ld bytes needed. Use 'mysqld -O thread_stack=#' to specify a bigger stack.

•   Error: 1437 SQLSTATE: 42000 (ER_TOO_LONG_BODY)
Message: Routine body for '%s' is too long

•   Error: 1438 SQLSTATE: HY000 (ER_WARN_CANT_DROP_DEFAULT_KEYCACHE)
Message: Cannot drop default keycache

•   Error: 1439 SQLSTATE: 42000 (ER_TOO_BIG_DISPLAYWIDTH)
Message: Display width out of range for column '%s' (max = %lu)

•   Error: 1440 SQLSTATE: XAE08 (ER_XAER_DUPLICATED)
Message: XAER_DUPLICATED: The XID already exists

•   Error: 1441 SQLSTATE: 22008 (ER_DATETIME_FUNCTION_OVERFLOW)
Message: Datetime function: %s field overflow
Server Error Codes and Messages

• Error: **1442 SQLSTATE: HY000 (ER_CANT_UPDATE_USED_TABLE_IN_SF_OR_TRG)**
  Message: Can't update table '%s' in stored function/trigger because it is already used by statement which invoked this stored function/trigger.

• Error: **1443 SQLSTATE: HY000 (ER_VIEW_PREVENT_UPDATE)**
  Message: The definition of table '%s' prevents operation %s on table '%s'.

• Error: **1444 SQLSTATE: HY000 (ER_PS_NO_RECURSION)**
  Message: The prepared statement contains a stored routine call that refers to that same statement. It's not allowed to execute a prepared statement in such a recursive manner.

• Error: **1445 SQLSTATE: HY000 (ER_SP_CANT_SET_AUTOCOMMIT)**
  Message: Not allowed to set autocommit from a stored function or trigger.

• Error: **1446 SQLSTATE: HY000 (ER_MALFORMED_DEFENER)**
  Message: Definer is not fully qualified.

• Error: **1447 SQLSTATE: HY000 (ER_VIEW_FRM_NO_USER)**
  Message: View '%s'.'%s' has no definer information (old table format). Current user is used as definer. Please recreate the view!

• Error: **1448 SQLSTATE: HY000 (ER_VIEW_OTHER_USER)**
  Message: You need the SUPER privilege for creation view with '%s'@'%s' definer.

• Error: **1449 SQLSTATE: HY000 (ER_NO_SUCH_USER)**
  Message: The user specified as a definer ('%s'@'%s') does not exist.

• Error: **1450 SQLSTATE: HY000 (ER_TRG_NO_DEFINER)**
  Message: No definer attribute for trigger '%s'.'%s'. The trigger will be activated under the authorization of the invoker, which may have insufficient privileges. Please recreate the trigger.

• Error: **1451 SQLSTATE: 23000 (ER_ROW_IS_REFERENCED_2)**
  Message: Cannot delete or update a parent row: a foreign key constraint fails (%s)

• Error: **1452 SQLSTATE: 23000 (ER_NO_REFERENCED_ROW_2)**
  Message: Cannot add or update a child row: a foreign key constraint fails (%s)

• Error: **1453 SQLSTATE: 42000 (ER_SP_BAD_VAR_SHADOW)**
  Message: Variable '%s' must be quoted with `...`, or renamed.

• Error: **1454 SQLSTATE: HY000 (ER_TRG_NO_DEFINER)**
  Message: No definer attribute for trigger '%s'.'%s'. The trigger will be activated under the authorization of the invoker, which may have insufficient privileges. Please recreate the trigger.

• Error: **1455 SQLSTATE: HY000 (ER_OLD_FILE_FORMAT)**
  Message: '%s' has an old format, you should re-create the '%s' object(s).

• Error: **1456 SQLSTATE: HY000 (ER_SP_RECURSION_LIMIT)**
  Message: Recursive limit %d (as set by the max_sp_recursion_depth variable) was exceeded for routine %s.
• Error: 1457 SQLSTATE: HY000 (ER_SP_PROC_TABLE_CORRUPT)
  Message: Failed to load routine %s. The table mysql.proc is missing, corrupt, or contains bad data (internal code %d)
  
  ER_SP_PROC_TABLE_CORRUPT was added in 5.1.4.
• Error: 1458 SQLSTATE: 42000 (ER_SP_WRONG_NAME)
  Message: Incorrect routine name '%s'
  
  ER_SP_WRONG_NAME was added in 5.1.7.
• Error: 1459 SQLSTATE: HY000 (ER_TABLE_NEEDS_UPGRADE)
  Message: Table upgrade required. Please do "REPAIR TABLE `%s`" or dump/reload to fix it!
  
  ER_TABLE_NEEDS_UPGRADE was added in 5.1.7.
• Error: 1460 SQLSTATE: 42000 (ER_SP_NO_AGGREGATE)
  Message: AGGREGATE is not supported for stored functions
  
  ER_SP_NO_AGGREGATE was added in 5.1.9.
• Error: 1461 SQLSTATE: 42000 (ER_MAX_PREPARED_STMT_COUNT_REACHED)
  Message: Can't create more than max_prepared_stmt_count statements (current value: %lu)
  
  ER_MAX_PREPARED_STMT_COUNT_REACHED was added in 5.1.11.
• Error: 1462 SQLSTATE: HY000 (ER_VIEW_RECURSIVE)
  Message: `%s`.`%s` contains view recursion
  
  ER_VIEW_RECURSIVE was added in 5.1.11.
• Error: 1463 SQLSTATE: 42000 (ER_NON_GROUPING_FIELD_USED)
  Message: non-grouping field '%s' is used in %s clause
  
  ER_NON_GROUPING_FIELD_USED was added in 5.1.11.
• Error: 1464 SQLSTATE: HY000 (ER_TABLE_CANT_HANDLE_SPKEYS)
  Message: The used table type doesn't support SPATIAL indexes
  
  ER_TABLE_CANT_HANDLE_SPKEYS was added in 5.1.11.
• Error: 1465 SQLSTATE: HY000 (ER_NO_TRIGGERS_ON_SYSTEM_SCHEMA)
  Message: Triggers can not be created on system tables
  
  ER_NO_TRIGGERS_ON_SYSTEM_SCHEMA was added in 5.1.12.
• Error: 1466 SQLSTATE: HY000 (ER_REMOVED_SPACES)
  Message: Leading spaces are removed from name '%s'
  
  ER_REMOVED_SPACES was added in 5.1.12.
• Error: 1467 SQLSTATE: HY000 (ER_AUTOINC_READ_FAILED)
  Message: Failed to read auto-increment value from storage engine
Server Error Codes and Messages

`ER_AUTOINC_READ_FAILED` was added in 5.1.12.

- Error: 1468 SQLSTATE: HY000 (ER_USERNAME)
  Message: user name
  `ER_USERNAME` was added in 5.1.12.

- Error: 1469 SQLSTATE: HY000 (ER_HOSTNAME)
  Message: host name
  `ER_HOSTNAME` was added in 5.1.12.

- Error: 1470 SQLSTATE: HY000 (ER_WRONG_STRING_LENGTH)
  Message: String '%s' is too long for %s (should be no longer than %d)
  `ER_WRONG_STRING_LENGTH` was added in 5.1.12.

- Error: 1471 SQLSTATE: HY000 (ER_NON_INSERTABLE_TABLE)
  Message: The target table %s of the %s is not insertable-into
  `ER_NON_INSERTABLE_TABLE` was added in 5.1.12.

- Error: 1472 SQLSTATE: HY000 (ER_ADMIN_WRONG_MRG_TABLE)
  Message: Table '%s' is differently defined or of non-MyISAM type or doesn't exist
  `ER_ADMIN_WRONG_MRG_TABLE` was added in 5.1.20.

- Error: 1473 SQLSTATE: HY000 (ER_TOO_HIGH_LEVEL_OF_NESTING_FOR_SELECT)
  Message: Too high level of nesting for select
  `ER_TOO_HIGH_LEVEL_OF_NESTING_FOR_SELECT` was added in 5.1.23.

- Error: 1474 SQLSTATE: HY000 (ER_NAME_BECOMES_EMPTY)
  Message: Name '%s' has become "
  `ER_NAME_BECOMES_EMPTY` was added in 5.1.23.

- Error: 1475 SQLSTATE: HY000 (ER_AMBIGUOUS_FIELD_TERM)
  Message: First character of the FIELDS TERMINATED string is ambiguous; please use non-optional and non-empty FIELDS ENCLOSED BY
  `ER_AMBIGUOUS_FIELD_TERM` was added in 5.1.23.

- Error: 1476 SQLSTATE: HY000 (ER_FOREIGN_SERVER_EXISTS)
  Message: The foreign server, %s, you are trying to create already exists.
  `ER_FOREIGN_SERVER_EXISTS` was added in 5.1.15.

- Error: 1477 SQLSTATE: HY000 (ER_FOREIGN_SERVER_DOESNT_EXIST)
  Message: The foreign server name you are trying to reference does not exist. Data source error: %s
  `ER_FOREIGN_SERVER_DOESNT_EXIST` was added in 5.1.15.

- Error: 1478 SQLSTATE: HY000 (ER_ILLEGAL_HA_CREATE_OPTION)
Message: Table storage engine '%s' does not support the create option '%s'

**ER_ILLEGAL_HA_CREATE_OPTION** was added in 5.1.7.

- **Error:** 1479 SQLSTATE: HY000 (**ER_PARTITION.Requires_VALUES_ERROR**)
  Message: Syntax error: %s PARTITIONING requires definition of VALUES %s for each partition

- **Error:** 1480 SQLSTATE: HY000 (**ER_PARTITION_WRONG_VALUES_ERROR**)
  Message: Only %s PARTITIONING can use VALUES %s in partition definition

- **Error:** 1481 SQLSTATE: HY000 (**ER_Char_SET_IN_PART_FIELD_ERROR**)
  Message: VARCHAT only allowed if binary collation for partition functions
  **ER_Char_SET_IN_PART_FIELD_ERROR** was removed after 5.1.5.

- **Error:** 1481 SQLSTATE: HY000 (**ER_PARTITION_MAXVALUE_ERROR**)
  Message: MAXVALUE can only be used in last partition definition

- **Error:** 1482 SQLSTATE: HY000 (**ER_PARTITION_SUBPARTITION_ERROR**)
  Message: Subpartitions can only be hash partitions and by key

- **Error:** 1483 SQLSTATE: HY000 (**ER_PARTITION_SUBPART_MIX_ERROR**)
  Message: Must define subpartitions on all partitions if on one partition
  **ER_PARTITION_SUBPART_MIX_ERROR** was added in 5.1.9.

- **Error:** 1484 SQLSTATE: HY000 (**ER_PARTITION_WRONG_NO_PART_ERROR**)
  Message: Wrong number of partitions defined, mismatch with previous setting

- **Error:** 1485 SQLSTATE: HY000 (**ER_PARTITION_WRONG_NO_SUBPART_ERROR**)
  Message: Wrong number of subpartitions defined, mismatch with previous setting

- **Error:** 1486 SQLSTATE: HY000 (**ER_CONST_EXPR_IN_PARTITION_FUNC_ERROR**)
  Message: Constant/Random expression in (sub)partitioning function is not allowed

  In 5.1.43: **ER_CONST_EXPR_IN_PARTITION_FUNC_ERROR** was renamed to **ER_WRONG_EXPR_IN_PARTITION_FUNC_ERROR**.

  **ER_CONST_EXPR_IN_PARTITION_FUNC_ERROR** was removed after 5.1.42.

- **Error:** 1486 SQLSTATE: HY000 (**ER_WRONG_EXPR_IN_PARTITION_FUNC_ERROR**)
  Message: Constant, random or timezone-dependent expressions in (sub)partitioning function are not allowed

  In 5.1.43: **ER_CONST_EXPR_IN_PARTITION_FUNC_ERROR** was renamed to **ER_WRONG_EXPR_IN_PARTITION_FUNC_ERROR**.

  **ER_WRONG_EXPR_IN_PARTITION_FUNC_ERROR** was added in 5.1.43.

- **Error:** 1487 SQLSTATE: HY000 (**ER_NO_CONST_EXPR_IN_RANGE_OR_LIST_ERROR**)
  Message: Expression in RANGE/LIST VALUES must be constant

- **Error:** 1488 SQLSTATE: HY000 (**ER_FIELD_NOT_FOUND_PART_ERROR**)
Message: Field in list of fields for partition function not found in table

• Error: 1489 SQLSTATE: HY000 (ER_LIST_OF_FIELDS_ONLY_IN_HASH_ERROR)
  Message: List of fields is only allowed in KEY partitions

• Error: 1490 SQLSTATE: HY000 (ER_INCONSISTENT_PARTITION_INFO_ERROR)
  Message: The partition info in the frm file is not consistent with what can be written into the frm file

• Error: 1491 SQLSTATE: HY000 (ER_PARTITION_FUNC_NOT_ALLOWED_ERROR)
  Message: The %s function returns the wrong type

• Error: 1492 SQLSTATE: HY000 (ER_PARTITIONS_MUST_BE_DEFINED_ERROR)
  Message: For %s partitions each partition must be defined

• Error: 1493 SQLSTATE: HY000 (ER_RANGE_NOT_INCREASING_ERROR)
  Message: VALUES LESS THAN value must be strictly increasing for each partition

• Error: 1494 SQLSTATE: HY000 (ER_INCONSISTENT_TYPE_OF_FUNCTIONS_ERROR)
  Message: VALUES value must be of same type as partition function

• Error: 1495 SQLSTATE: HY000 (ER_MULTIPLE_DEF_CONST_IN_LIST_PART_ERROR)
  Message: Multiple definition of same constant in list partitioning

• Error: 1496 SQLSTATE: HY000 (ER_DROP_PARTITION_FAILURE)
  Message: Drop partition not supported in this version for this handler
  ER_DROP_PARTITION_FAILURE was removed after 5.1.5.

• Error: 1496 SQLSTATE: HY000 (ER_PARTITION_ENTRY_ERROR)
  Message: Partitioning can not be used stand-alone in query

• Error: 1497 SQLSTATE: HY000 (ER_DROP_PARTITION_WHEN_FK_DEFINED)
  Message: Cannot drop a partition when a foreign key constraint is defined on the table
  ER_DROP_PARTITION_WHEN_FK_DEFINED was removed after 5.1.5.

• Error: 1497 SQLSTATE: HY000 (ER_MIX_HANDLER_ERROR)
  Message: The mix of handlers in the partitions is not allowed in this version of MySQL

• Error: 1498 SQLSTATE: HY000 (ER_PARTITION_NOT_DEFINED_ERROR)
  Message: For the partitioned engine it is necessary to define all %s

• Error: 1499 SQLSTATE: HY000 (ER_TOO_MANY_PARTITIONS_ERROR)
  Message: Too many partitions (including subpartitions) were defined

• Error: 1500 SQLSTATE: HY000 (ER_SUBPARTITION_ERROR)
  Message: It is only possible to mix RANGE/LIST partitioning with HASH/KEY partitioning for subpartitioning

• Error: 1501 SQLSTATE: HY000 (ER_CANT_CREATE_HANDLER_FILE)
Server Error Codes and Messages

Message: Failed to create specific handler file

• Error: 1502 SQLSTATE: HY000 (ER_BLOB_FIELD_IN_PART_FUNC_ERROR)
  Message: A BLOB field is not allowed in partition function

• Error: 1503 SQLSTATE: HY000 (ER_UNIQUE_KEY_NEED_ALL_FIELDS_IN_PF)
  Message: A %s must include all columns in the table’s partitioning function

• Error: 1504 SQLSTATE: HY000 (ER_NO_PARTS_ERROR)
  Message: Number of %s = 0 is not an allowed value

• Error: 1505 SQLSTATE: HY000 (ER_TABLESPACE_OPTION_ONLY_ONCE)
  Message: It is not allowed to specify %s more than once

  ER_TABLESPACE_OPTION_ONLY_ONCE was added in 5.1.6, removed after 5.1.6.

• Error: 1505 SQLSTATE: HY000 (ER_PARTITION_MGMT_ON_NONPARTITIONED)
  Message: Partition management on a not partitioned table is not possible

• Error: 1506 SQLSTATE: HY000 (ER_CREATE_TABLESPACE_FAILED)
  Message: Failed to create %s

  ER_CREATE_TABLESPACE_FAILED was added in 5.1.6, removed after 5.1.6.

• Error: 1506 SQLSTATE: HY000 (ER_FOREIGN_KEY_ON_PARTITIONED)
  Message: Foreign key clause is not yet supported in conjunction with partitioning

  ER_FOREIGN_KEY_ON_PARTITIONED was added in 5.1.6.

• Error: 1507 SQLSTATE: HY000 (ER_DROP_TABLESPACE_FAILED)
  Message: Failed to drop %s

  ER_DROP_TABLESPACE_FAILED was added in 5.1.6, removed after 5.1.6.

• Error: 1507 SQLSTATE: HY000 (ER_DROP_PARTITION_NON_EXISTENT)
  Message: Error in list of partitions to %s

• Error: 1508 SQLSTATE: HY000 (ER_DROP_LAST_PARTITION)
  Message: Cannot remove all partitions, use DROP TABLE instead

• Error: 1509 SQLSTATE: HY000 (ER_COALESCE_ONLY_ON_HASH_PARTITION)
  Message: COALESCE PARTITION can only be used on HASH/KEY partitions

• Error: 1510 SQLSTATE: HY000 (ER_REORG_HASH_ONLY_ONSAME_NO)
  Message: REORGANIZE PARTITION can only be used to reorganize partitions not to change their numbers

  ER_REORG_HASH_ONLY_ONSAME_NO was added in 5.1.6.

• Error: 1511 SQLSTATE: HY000 (ER_ALTER_TABLESPACE_FAILED)
  Message: Failed to alter: %s
**ER_ALTER_TABLESPACE_FAILED** was added in 5.1.6, removed after 5.1.6.

- **Error:** 1511 SQLSTATE: HY000 (**ER_REORG_NO_PARAM_ERROR**)  
  Message: REORGANIZE PARTITION without parameters can only be used on auto-partitioned tables using HASH PARTITIONS  
  **ER_REORG_NO_PARAM_ERROR** was added in 5.1.6.

- **Error:** 1512 SQLSTATE: HY000 (**ER_ONLY_ON_RANGE_LIST_PARTITION**)  
  Message: %s PARTITION can only be used on RANGE/LIST partitions

- **Error:** 1513 SQLSTATE: HY000 (**ER_ADD_PARTITION_SUBPART_ERROR**)  
  Message: Trying to Add partition(s) with wrong number of subpartitions

- **Error:** 1514 SQLSTATE: HY000 (**ER_ADD_PARTITION_NO_NEW_PARTITION**)  
  Message: At least one partition must be added

- **Error:** 1515 SQLSTATE: HY000 (**ER_COALESCE_PARTITION_NO_PARTITION**)  
  Message: At least one partition must be coalesced

- **Error:** 1516 SQLSTATE: HY000 (**ER_REORG_PARTITION_NOT_EXIST**)  
  Message: More partitions to reorganize than there are partitions

- **Error:** 1517 SQLSTATE: HY000 (**ERSAME_NAME_PARTITION**)  
  Message: Duplicate partition name %s

- **Error:** 1518 SQLSTATE: HY000 (**ER_NO_BINLOG_ERROR**)  
  Message: It is not allowed to shut off binlog on this command  
  **ER_NO_BINLOG_ERROR** was added in 5.1.6.

- **Error:** 1519 SQLSTATE: HY000 (**ER_CONSECUTIVE_REORG_PARTITIONS**)  
  Message: When reorganizing a set of partitions they must be in consecutive order

- **Error:** 1520 SQLSTATE: HY000 (**ER_REORG_OUTSIDE_RANGE**)  
  Message: Reorganize of range partitions cannot change total ranges except for last partition where it can extend the range

- **Error:** 1521 SQLSTATE: HY000 (**ER_PARTITION_FUNCTION_FAILURE**)  
  Message: Partition function not supported in this version for this handler  
  **ER_PARTITION_FUNCTION_FAILURE** was added in 5.1.6.

- **Error:** 1522 SQLSTATE: HY000 (**ER_PART_STATE_ERROR**)  
  Message: Partition state cannot be defined from CREATE/ALTER TABLE  
  **ER_PART_STATE_ERROR** was added in 5.1.6.

- **Error:** 1523 SQLSTATE: HY000 (**ER_LIMITED_PART_RANGE**)  
  Message: The %s handler only supports 32 bit integers in VALUES
**ER_LIMITED_PART_RANGE** was added in 5.1.6.

- **Error:** 1524 SQLSTATE: HY000 *(ER_PLUGIN_IS_NOT_LOADED)*
  
  Message: Plugin '%%s' is not loaded

- **Error:** 1525 SQLSTATE: HY000 *(ER_EVENT_COL_COUNT_DOESNT_MATCH)*
  
  Message: Column count of '%%s.%%s' is wrong. Table probably corrupted
  
  **ER_EVENT_COL_COUNT_DOESNT_MATCH** was added in 5.1.6, removed after 5.1.6.

- **Error:** 1525 SQLSTATE: HY000 *(ER_WRONG_VALUE)*
  
  Message: Incorrect '%%s' value: '%%s'
  
  **ER_WRONG_VALUE** was added in 5.1.4.

- **Error:** 1526 SQLSTATE: HY000 *(ER_EVENT_CANNOT_LOAD_FROM_TABLE)*
  
  Message: Cannot load from mysql.%%s. Table probably corrupted. See error log.
  
  **ER_EVENT_CANNOT_LOAD_FROM_TABLE** was added in 5.1.6, removed after 5.1.7.

- **Error:** 1526 SQLSTATE: HY000 *(ER_NO_PARTITION_FOR_GIVEN_VALUE)*
  
  Message: Table has no partition for value '%%s'
  
  **ER_NO_PARTITION_FOR_GIVEN_VALUE** was added in 5.1.4.

- **Error:** 1527 SQLSTATE: HY000 *(ER_FILEGROUP_OPTION_ONLY_ONCE)*
  
  Message: It is not allowed to specify '%%s' more than once
  
  **ER_FILEGROUP_OPTION_ONLY_ONCE** was added in 5.1.7.

- **Error:** 1528 SQLSTATE: HY000 *(ER_CREATE_FILEGROUP_FAILED)*
  
  Message: Failed to create '%%s'
  
  **ER_CREATE_FILEGROUP_FAILED** was added in 5.1.7.

- **Error:** 1529 SQLSTATE: HY000 *(ER_DROP_FILEGROUP_FAILED)*
  
  Message: Failed to drop '%%s'
  
  **ER_DROP_FILEGROUP_FAILED** was added in 5.1.7.

- **Error:** 1530 SQLSTATE: HY000 *(ER_TABLESPACE_AUTO_EXTEND_ERROR)*
  
  Message: The handler doesn't support autoextend of tablespaces
  
  **ER_TABLESPACE_AUTO_EXTEND_ERROR** was added in 5.1.6.

- **Error:** 1531 SQLSTATE: HY000 *(ER_WRONG_SIZE_NUMBER)*
  
  Message: A size parameter was incorrectly specified, either number or on the form 10M
  
  **ER_WRONG_SIZE_NUMBER** was added in 5.1.6.

- **Error:** 1532 SQLSTATE: HY000 *(ER_SIZE_OVERFLOW_ERROR)*
  
  Message: The size number was correct but we don't allow the digit part to be more than 2 billion
**ER_SIZE_OVERFLOW_ERROR was added in 5.1.6.**

- **Error:** 1533 SQLSTATE: HY000 (ER_ALTER_FILEGROUP_FAILED)
  
  Message: Failed to alter: %s

  **ER_ALTER_FILEGROUP_FAILED was added in 5.1.7.**

- **Error:** 1534 SQLSTATE: HY000 (ER_BINLOG_ROW_LOGGING_FAILED)
  
  Message: Writing one row to the row-based binary log failed

  **ER_BINLOG_ROW_LOGGING_FAILED was added in 5.1.5.**

- **Error:** 1535 SQLSTATE: HY000 (ER_BINLOG_ROW_WRONG_TABLE_DEF)
  
  Message: Table definition on master and slave does not match: %s

  **ER_BINLOG_ROW_WRONG_TABLE_DEF was added in 5.1.5.**

- **Error:** 1536 SQLSTATE: HY000 (ER_BINLOG_ROW_RBR_TO_SBR)
  
  Message: Slave running with --log-slave-updates must use row-based binary logging to be able to replicate row-based binary log events

  **ER_BINLOG_ROW_RBR_TO_SBR was added in 5.1.5.**

- **Error:** 1537 SQLSTATE: HY000 (ER_EVENT_ALREADY_EXISTS)
  
  Message: Event '%s' already exists

  **ER_EVENT_ALREADY_EXISTS was added in 5.1.6.**

- **Error:** 1538 SQLSTATE: HY000 (ER_EVENT_STORE_FAILED)
  
  Message: Failed to store event %s. Error code %d from storage engine.

  **ER_EVENT_STORE_FAILED was added in 5.1.6.**

- **Error:** 1539 SQLSTATE: HY000 (ER_EVENT_DOES_NOT_EXIST)
  
  Message: Unknown event '%s'

  **ER_EVENT_DOES_NOT_EXIST was added in 5.1.6.**

- **Error:** 1540 SQLSTATE: HY000 (ER_WARN_DEPRECATED_STATEMENT)
  
  Message: The '%s' statement is deprecated and will be removed in MySQL %s. Please use client programs (e.g. %s) instead.

  **ER_WARN_DEPRECATED_STATEMENT was added in 5.1.7, removed after 5.1.7.**

- **Error:** 1540 SQLSTATE: HY000 (ER_EVENT_CANT_ALTER)
  
  Message: Failed to alter event '%s'

  **ER_EVENT_CANT_ALTER was added in 5.1.6.**

- **Error:** 1541 SQLSTATE: HY000 (ER_WARN_DEPRECATED)
  
  Message: The syntax '%s' is deprecated and will be removed in MySQL %s. Please use %s instead.

  **ER_WARN_DEPRECATED was added in 5.1.9, removed after 5.1.9.**
Server Error Codes and Messages

- **Error:** 1541 SQLSTATE: HY000 (**ER_EVENT_DROP_FAILED**)
  
  Message: Failed to drop %s
  
  **ER_EVENT_DROP_FAILED** was added in 5.1.6.

- **Error:** 1542 SQLSTATE: HY000 (**ER_EVENT_INTERVAL_NOT_POSITIVE_OR_TOO_BIG**)
  
  Message: INTERVAL is either not positive or too big
  
  **ER_EVENT_INTERVAL_NOT_POSITIVE_OR_TOO_BIG** was added in 5.1.6.

- **Error:** 1543 SQLSTATE: HY000 (**ER_EVENT_ENDS_BEFORE_STARTS**)
  
  Message: ENDS is either invalid or before STARTS
  
  **ER_EVENT_ENDS_BEFORE_STARTS** was added in 5.1.6.

- **Error:** 1544 SQLSTATE: HY000 (**ER_EVENT_EXEC_TIME_IN_THE_PAST**)
  
  Message: Event execution time is in the past. Event has been disabled
  
  **ER_EVENT_EXEC_TIME_IN_THE_PAST** was added in 5.1.6.

- **Error:** 1545 SQLSTATE: HY000 (**ER_EVENT_OPEN_TABLE_FAILED**)
  
  Message: Failed to open mysql.event
  
  **ER_EVENT_OPEN_TABLE_FAILED** was added in 5.1.6.

- **Error:** 1546 SQLSTATE: HY000 (**ER_EVENT_NEITHER_M_EXPR_NOR_M_AT**)
  
  Message: No datetime expression provided
  
  **ER_EVENT_NEITHER_M_EXPR_NOR_M_AT** was added in 5.1.6.

- **Error:** 1547 SQLSTATE: HY000 (**ER_COL_COUNT_DOESNT_MATCH_CORRUPTED**)
  
  Message: Column count of mysql.%s is wrong. Expected %d, found %d. The table is probably corrupted
  
  **ER_COL_COUNT_DOESNT_MATCH_CORRUPTED** was added in 5.1.7.

- **Error:** 1548 SQLSTATE: HY000 (**ER_CANNOT_LOAD_FROM_TABLE**)
  
  Message: Cannot load from mysql.%s. The table is probably corrupted
  
  **ER_CANNOT_LOAD_FROM_TABLE** was added in 5.1.9.

- **Error:** 1549 SQLSTATE: HY000 (**ER_EVENT_CANNOT_DELETE**)
  
  Message: Failed to delete the event from mysql.event
  
  **ER_EVENT_CANNOT_DELETE** was added in 5.1.6.

- **Error:** 1550 SQLSTATE: HY000 (**ER_EVENT_COMPILE_ERROR**)
  
  Message: Error during compilation of event's body
  
  **ER_EVENT_COMPILE_ERROR** was added in 5.1.6.

- **Error:** 1551 SQLSTATE: HY000 (**ER_EVENTSAME_NAME**)
  
  Message: Same old and new event name
Server Error Codes and Messages

ER_EVENT_SAME_NAME was added in 5.1.6.

- **Error:** 1552 SQLSTATE: HY000 (ER_EVENT_DATA_TOO_LONG)
  
  Message: Data for column '%s' too long
  
  ER_EVENT_DATA_TOO_LONG was added in 5.1.6.

- **Error:** 1553 SQLSTATE: HY000 (ER_CANT_READ_LOCK_LOG_TABLE)
  
  Message: You can’t use usual read lock with log tables. Try READ LOCAL instead
  
  ER_CANT_READ_LOCK_LOG_TABLE was added in 5.1.6, removed after 5.1.20.

- **Error:** 1553 SQLSTATE: HY000 (ER_DROP_INDEX_FK)
  
  Message: Cannot drop index '%s': needed in a foreign key constraint
  
  InnoDB reports this error when you attempt to drop the last index that can enforce a particular referential constraint.

  For optimal performance with DML statements, InnoDB requires an index to exist on foreign key columns, so that UPDATE and DELETE operations on a parent table can easily check whether corresponding rows exist in the child table. MySQL creates or drops such indexes automatically when needed, as a side-effect of CREATE TABLE, CREATE INDEX, and ALTER TABLE statements.

  When you drop an index, InnoDB checks if the index is used for checking a foreign key constraint. It is still OK to drop the index if there is another index that can be used to enforce the same constraint. InnoDB prevents you from dropping the last index that can enforce a particular referential constraint.

  ER_DROP_INDEX_FK was added in 5.1.6.

- **Error:** 1554 SQLSTATE: HY000 (ER_WARN_DEPRECATED_SYNTAX_WITH_VER)
  
  Message: The syntax '%s' is deprecated and will be removed in MySQL %s. Please use %s instead
  
  ER_WARN_DEPRECATED_SYNTAX_WITH_VER was added in 5.1.20.

- **Error:** 1555 SQLSTATE: HY000 (ER_CANT_WRITE_LOCK_LOG_TABLE)
  
  Message: You can’t write-lock a log table. Only read access is possible
  
  ER_CANT_WRITE_LOCK_LOG_TABLE was added in 5.1.6.

- **Error:** 1556 SQLSTATE: HY000 (ER_CANT_LOCK_LOG_TABLE)
  
  Message: You can’t use locks with log tables.
  
  ER_CANT_LOCK_LOG_TABLE was added in 5.1.21.

- **Error:** 1557 SQLSTATE: 23000 (ER_FOREIGN_DUPLICATE_KEY)
  
  Message: Upholding foreign key constraints for table '%s', entry '%s', key %d would lead to a duplicate entry
  
  ER_FOREIGN_DUPLICATE_KEY was added in 5.1.7.

- **Error:** 1558 SQLSTATE: HY000 (ER_COL_COUNT_DOESNT_MATCH_PLEASE_UPDATE)
  
  Message: Column count of mysql.%s is wrong. Expected %d, found %d. Created with MySQL %d, now running %d. Please use mysql_upgrade to fix this error.
  
  ER_COL_COUNT_DOESNT_MATCH_PLEASE_UPDATE was added in 5.1.7.
• Error: 1559 SQLSTATE: HY000 (ER_TEMP_TABLE_PREVENTS_SWITCH_OUT_OF_RBR)
  Message: Cannot switch out of the row-based binary log format when the session has open temporary tables
  ER_TEMP_TABLE_PREVENTS_SWITCH_OUT_OF_RBR was added in 5.1.9.

• Error: 1560 SQLSTATE: HY000 (ER_STORED_FUNCTION_PREVENTS_SWITCH_BINLOG_FORMAT)
  Message: Cannot change the binary logging format inside a stored function or trigger
  ER_STORED_FUNCTION_PREVENTS_SWITCH_BINLOG_FORMAT was added in 5.1.9.

• Error: 1561 SQLSTATE: HY000 (ER_NDB_CANT_SWITCH_BINLOG_FORMAT)
  Message: The NDB cluster engine does not support changing the binlog format on the fly yet
  ER_NDB_CANT_SWITCH_BINLOG_FORMAT was added in 5.1.9.

• Error: 1562 SQLSTATE: HY000 (ER_PARTITION_NO_TEMPORARY)
  Message: Cannot create temporary table with partitions
  ER_PARTITION_NO_TEMPORARY was added in 5.1.9.

• Error: 1563 SQLSTATE: HY000 (ER_PARTITION_CONST_DOMAIN_ERROR)
  Message: Partition constant is out of partition function domain
  ER_PARTITION_CONST_DOMAIN_ERROR was added in 5.1.12.

• Error: 1564 SQLSTATE: HY000 (ER_PARTITION_FUNCTION_IS_NOT_ALLOWED)
  Message: This partition function is not allowed
  ER_PARTITION_FUNCTION_IS_NOT_ALLOWED was added in 5.1.12.

• Error: 1565 SQLSTATE: HY000 (ER_DDL_LOG_ERROR)
  Message: Error in DDL log
  ER_DDL_LOG_ERROR was added in 5.1.11.

• Error: 1566 SQLSTATE: HY000 (ER_NULL_IN_VALUES_LESS_THAN)
  Message: Not allowed to use NULL value in VALUES LESS THAN
  ER_NULL_IN_VALUES_LESS_THAN was added in 5.1.11.

• Error: 1567 SQLSTATE: HY000 (ER_EVENT_RECURSIVITY_FORBIDDEN)
  Message: Recursivity of EVENT DDL statements is forbidden when body is present
  ER_EVENT_RECURSIVITY_FORBIDDEN was added in 5.1.12, removed after 5.1.17.

• Error: 1567 SQLSTATE: HY000 (ER_WRONG_PARTITION_NAME)
  Message: Incorrect partition name
  ER_WRONG_PARTITION_NAME was added in 5.1.11.

• Error: 1568 SQLSTATE: 25001 (ER_CANT_CHANGE_TX_ISOLATION)
  Message: Transaction isolation level can't be changed while a transaction is in progress
Server Error Codes and Messages

**ER_CANT_CHANGE_TX_ISOLATION** was added in 5.1.7.

- **Error: 1569 SQLSTATE: HY000 (ER_DUP_ENTRY_AUTOINCREMENT_CASE)**
  
  Message: ALTER TABLE causes auto_increment resequencing, resulting in duplicate entry '%s' for key '%s'

  **ER_DUP_ENTRY_AUTOINCREMENT_CASE** was added in 5.1.12.

- **Error: 1570 SQLSTATE: HY000 (ER_EVENT_MODIFY_QUEUE_ERROR)**
  
  Message: Internal scheduler error %d

  **ER_EVENT_MODIFY_QUEUE_ERROR** was added in 5.1.11.

- **Error: 1571 SQLSTATE: HY000 (ER_EVENT_SET_VAR_ERROR)**
  
  Message: Error during starting/stopping of the scheduler. Error code %u

  **ER_EVENT_SET_VAR_ERROR** was added in 5.1.11.

- **Error: 1572 SQLSTATE: HY000 (ER_PARTITION_MERGE_ERROR)**
  
  Message: Engine cannot be used in partitioned tables

  **ER_PARTITION_MERGE_ERROR** was added in 5.1.12.

- **Error: 1573 SQLSTATE: HY000 (ER_CANT_ACTIVATE_LOG)**
  
  Message: Cannot activate '%s' log

  **ER_CANT_ACTIVATE_LOG** was added in 5.1.12.

- **Error: 1574 SQLSTATE: HY000 (ER_RBR_NOT_AVAILABLE)**
  
  Message: The server was not built with row-based replication

  **ER_RBR_NOT_AVAILABLE** was added in 5.1.12.

- **Error: 1575 SQLSTATE: HY000 (ER_BASE64_DECODE_ERROR)**
  
  Message: Decoding of base64 string failed

  **ER_BASE64_DECODE_ERROR** was added in 5.1.12.

- **Error: 1576 SQLSTATE: HY000 (ER_EVENT_RECURSION_FORBIDDEN)**
  
  Message: Recursion of EVENT DDL statements is forbidden when body is present

  **ER_EVENT_RECURSION_FORBIDDEN** was added in 5.1.18.

- **Error: 1577 SQLSTATE: HY000 (ER_EVENTS_DB_ERROR)**
  
  Message: Cannot proceed because system tables used by Event Scheduler were found damaged at server start

  To address this issue, try running `mysql_upgrade`.

  **ER_EVENTS_DB_ERROR** was added in 5.1.12.

- **Error: 1578 SQLSTATE: HY000 (ER_ONLY_INTEGERS_ALLOWED)**
  
  Message: Only integers allowed as number here
**Server Error Codes and Messages**

**ER_ONLY_INTEGERS_ALLOWED** was added in 5.1.12.

- **Error:** 1579 SQLSTATE: HY000 (ER_UNSUPORTED_LOG_ENGINE)
  Message: This storage engine cannot be used for log tables
  
  **ER_UNSUPORTED_LOG_ENGINE** was added in 5.1.12.

- **Error:** 1580 SQLSTATE: HY000 (ER_BAD_LOG_STATEMENT)
  Message: You cannot '%s' a log table if logging is enabled
  
  **ER_BAD_LOG_STATEMENT** was added in 5.1.12.

- **Error:** 1581 SQLSTATE: HY000 (ER_CANT_RENAME_LOG_TABLE)
  Message: Cannot rename '%s'. When logging enabled, rename to/from log table must rename two tables: the log table to an archive table and another table back to '%s
  
  **ER_CANT_RENAME_LOG_TABLE** was added in 5.1.13.

- **Error:** 1582 SQLSTATE: 42000 (ER_WRONG_PARAMCOUNT_TO_NATIVE_FCT)
  Message: Incorrect parameter count in the call to native function '%s'
  
  **ER_WRONG_PARAMCOUNT_TO_NATIVE_FCT** was added in 5.1.13.

- **Error:** 1583 SQLSTATE: 42000 (ER_WRONG_PARAMETERS_TO_NATIVE_FCT)
  Message: Incorrect parameters in the call to native function '%s'
  
  **ER_WRONG_PARAMETERS_TO_NATIVE_FCT** was added in 5.1.13.

- **Error:** 1584 SQLSTATE: 42000 (ER_WRONG_PARAMETERS_TO_STORED_FCT)
  Message: Incorrect parameters in the call to stored function '%s'
  
  **ER_WRONG_PARAMETERS_TO_STORED_FCT** was added in 5.1.14.

- **Error:** 1585 SQLSTATE: HY000 (ER_NATIVE_FCT_NAME_COLLISION)
  Message: This function '%s' has the same name as a native function
  
  **ER_NATIVE_FCT_NAME_COLLISION** was added in 5.1.14.

- **Error:** 1586 SQLSTATE: 23000 (ER_DUP_ENTRY_WITH_KEY_NAME)
  Message: Duplicate entry '%s' for key '%s'
  
  From 5.1.20: The format string for this error is also used with **ER_DUP_ENTRY**.
  
  **ER_DUP_ENTRY_WITH_KEY_NAME** was added in 5.1.15.

- **Error:** 1587 SQLSTATE: HY000 (ER_BINLOG_PURGE_EMFILE)
  Message: Too many files opened, please execute the command again
  
  **ER_BINLOG_PURGE_EMFILE** was added in 5.1.14.

- **Error:** 1588 SQLSTATE: HY000 (ER_EVENT_CANNOT_CREATE_IN_THE_PAST)
  Message: Event execution time is in the past and ON COMPLETION NOT PRESERVE is set. The event was dropped immediately after creation.
Server Error Codes and Messages

- **ER_EVENT_CANNOT_CREATE_IN_THE_PAST** was added in 5.1.17.
  - Error: 1589 SQLSTATE: HY000 (ER_EVENT_CANNOT_ALTER_IN_THE_PAST)
    - Message: Event execution time is in the past and ON COMPLETION NOT PRESERVE is set. The event was dropped immediately after creation.

- **ER_EVENT_CANNOT_ALTER_IN_THE_PAST** was added in 5.1.17.
  - Error: 1590 SQLSTATE: HY000 (ER_SLAVE_INCIDENT)
    - Message: The incident %s occurred on the master. Message: %s
      - **ER_SLAVE_INCIDENT** was added in 5.1.18.

- **ER_SLAVE_INCIDENT** was added in 5.1.18.
  - Error: 1591 SQLSTATE: HY000 (ER_NO_PARTITION_FOR_GIVEN_VALUE_SILENT)
    - Message: Table has no partition for some existing values
      - **ER_NO_PARTITION_FOR_GIVEN_VALUE_SILENT** was added in 5.1.18.

- **ER_NO_PARTITION_FOR_GIVEN_VALUE_SILENT** was added in 5.1.18.
  - Error: 1592 SQLSTATE: HY000 (ER_BINLOG_UNSAFE_STATEMENT)
    - Message: Statement may not be safe to log in statement format.
      - **ER_BINLOG_UNSAFE_STATEMENT** was added in 5.1.20.

- **ER_BINLOG_UNSAFE_STATEMENT** was added in 5.1.20.
  - Error: 1593 SQLSTATE: HY000 (ER_SLAVE_FATAL_ERROR)
    - Message: Fatal error: %s
      - **ER_SLAVE_FATAL_ERROR** was added in 5.1.20.

  **ER_RENAMED_NAME** was added in 5.1.36.

- **Error:** 1637 SQLSTATE: HY000 (ER_TOO_MANY_CONCURRENT_TRXS)
  
  Message: Too many active concurrent transactions  
  
  **ER_TOO_MANY_CONCURRENT_TRXS** was added in 5.1.38.

- **Error:** 1638 SQLSTATE: HY000 (WARN_NON_ASCII_SEPARATOR_NOT_IMPLEMENTED)
  
  Message: Non-ASCII separator arguments are not fully supported  
  
  **WARN_NON_ASCII_SEPARATOR_NOT_IMPLEMENTED** was added in 5.1.38.

- **Error:** 1639 SQLSTATE: HY000 (ER_DEBUG_SYNC_TIMEOUT)
  
  Message: debug sync point wait timed out  
  
  **ER_DEBUG_SYNC_TIMEOUT** was added in 5.1.40.

- **Error:** 1640 SQLSTATE: HY000 (ER_DEBUG_SYNC_HIT_LIMIT)
  
  Message: debug sync point hit limit reached  
  
  **ER_DEBUG_SYNC_HIT_LIMIT** was added in 5.1.40.
B.4 Client Error Codes and Messages

Client error information comes from the following source files:

- The Error values and the symbols in parentheses correspond to definitions in the include/errmsg.h MySQL source file.
- The Message values correspond to the error messages that are listed in the libmysql/errmsg.c file. $d and $s represent numbers and strings, respectively, that are substituted into the messages when they are displayed.

Because updates are frequent, it is possible that those files will contain additional error information not listed here.

- **Error:** 2000 (CR_UNKNOWN_ERROR)
  
  Message: Unknown MySQL error

- **Error:** 2001 (CR_SOCKET_CREATE_ERROR)
  
  Message: Can't create UNIX socket (%d)

- **Error:** 2002 (CR_CONNECTION_ERROR)
  
  Message: Can't connect to local MySQL server through socket "%s" (%d)

- **Error:** 2003 (CR_CONN_HOST_ERROR)
  
  Message: Can't connect to MySQL server on '%s' (%d)

- **Error:** 2004 (CR_IPSOCK_ERROR)
  
  Message: Can't create TCP/IP socket (%d)

- **Error:** 2005 (CR_UNKNOWN_HOST)
  
  Message: Unknown MySQL server host '%s' (%d)

- **Error:** 2006 (CR_SERVER_GONE_ERROR)
  
  Message: MySQL server has gone away

- **Error:** 2007 (CR_VERSION_ERROR)
  
  Message: Protocol mismatch; server version = %d, client version = %d

- **Error:** 2008 (CR_OUT_OF_MEMORY)
  
  Message: MySQL client ran out of memory

- **Error:** 2009 (CR_WRONG_HOST_INFO)
  
  Message: Wrong host info

- **Error:** 2010 (CR_LOCALHOST_CONNECTION)
  
  Message: Localhost via UNIX socket

- **Error:** 2011 (CR_TCP_CONNECTION)
  
  Message: %s via TCP/IP

- **Error:** 2012 (CR_SERVER_HANDSHAKE_ERR)
  
  Message: Error in server handshake
Client Error Codes and Messages

- **Error**: 2013 ([CR_SERVER_LOST](#))
  
  Message: Lost connection to MySQL server during query

- **Error**: 2014 ([CR_COMMANDS_OUT_OF_SYNC](#))
  
  Message: Commands out of sync; you can't run this command now

  Message: Error connecting to slave:

- **Error**: 2025 ([CR_PROBE_MASTER_CONNECT](#))
  
  Message: Error connecting to master:

- **Error**: 2026 ([CR_SSL_CONNECTION_ERROR](#))
  
  Message: SSL connection error

- **Error**: 2027 ([CR_MALFORMED_PACKET](#))
  
  Message: Malformed packet

- **Error**: 2028 ([CR_WRONG_LICENSE](#))
  
  Message: This client library is licensed only for use with MySQL servers having '%s' license

- **Error**: 2029 ([CR_NULL_POINTER](#))
Message: Invalid use of null pointer

- Error: 2030 (CR_NO_PREPARE_STMT)

Message: Statement not prepared

- Error: 2031 (CR_PARAMS_NOT_BOUND)

Message: No data supplied for parameters in prepared statement

- Error: 2032 (CR_DATA_TRUNCATED)

Message: Data truncated

- Error: 2033 (CR_NO_PARAMETERS_EXISTS)

Message: No parameters exist in the statement

- Error: 2034 (CR_INVALID_PARAMETER_NO)

Message: Invalid parameter number

The column number for mysql_stmt_fetch_column() was invalid.
The parameter number for mysql_stmt_send_long_data() was invalid.

- Error: 2035 (CR_INVALID_BUFFER_USE)

Message: Can't send long data for non-string/non-binary data types (parameter: %d)

- Error: 2036 (CR_UNSUPPORTED_PARAM_TYPE)

Message: Using unsupported buffer type: %d (parameter: %d)

- Error: 2037 (CR_SHARED_MEMORY_CONNECTION)

Message: Shared memory: %s

- Error: 2038 (CR_SHARED_MEMORY_CONNECT_REQUEST_ERROR)

Message: Can't open shared memory; client could not create request event (%lu)

- Error: 2039 (CR_SHARED_MEMORY_CONNECT_ANSWER_ERROR)

Message: Can't open shared memory; no answer event received from server (%lu)

- Error: 2040 (CR_SHARED_MEMORY_CONNECT_FILE_MAP_ERROR)

Message: Can't open shared memory; server could not allocate file mapping (%lu)

- Error: 2041 (CR_SHARED_MEMORY_CONNECT_MAP_ERROR)

Message: Can't open shared memory; server could not get pointer to file mapping (%lu)

- Error: 2042 (CR_SHARED_MEMORY_FILE_MAP_ERROR)

Message: Can't open shared memory; client could not allocate file mapping (%lu)

- Error: 2043 (CR_SHARED_MEMORY_MAP_ERROR)

Message: Can't open shared memory; client could not get pointer to file mapping (%lu)

- Error: 2044 (CR_SHARED_MEMORY_EVENT_ERROR)
Problems and Common Errors

Message: Can't open shared memory; client could not create %s event (%lu)
•   Error: 2045 (CR_SHARED_MEMORY_CONNECT_ABANDONED_ERROR)

Message: Can't open shared memory; no answer from server (%lu)
•   Error: 2046 (CR_SHARED_MEMORY_CONNECT_SET_ERROR)

Message: Can't open shared memory; cannot send request event to server (%lu)
•   Error: 2047 (CR_CONN_UNKNOWN_PROTOCOL)

Message: Wrong or unknown protocol
•   Error: 2048 (CR_INVALID_CONN_HANDLE)

Message: Invalid connection handle
•   Error: 2049 (CR_SECURE_AUTH)

Message: Connection using old (pre-4.1.1) authentication protocol refused (client option 'secure_auth' enabled)
•   Error: 2050 (CR_FETCH_CANCELED)

Message: Row retrieval was canceled by mysql_stmt_close() call
•   Error: 2051 (CR_NO_DATA)

Message: Attempt to read column without prior row fetch
•   Error: 2052 (CR_NO_STMT_METADATA)

Message: Prepared statement contains no metadata
•   Error: 2053 (CR_NO_RESULT_SET)

Message: Attempt to read a row while there is no result set associated with the statement
•   Error: 2054 (CR_NOT_IMPLEMENTED)

Message: This feature is not implemented yet
•   Error: 2055 (CR_SERVER_LOST_EXTENDED)

Message: Lost connection to MySQL server at '%s', system error: %d
CR_SERVER_LOST_EXTENDED was added in 5.1.14.
•   Error: 2056 (CR_STMT_CLOSED)

Message: Statement closed indirectly because of a preceding %s() call
CR_STMT_CLOSED was added in 5.1.18.
•   Error: 2057 (CR_NEW_STMT_METADATA)

Message: The number of columns in the result set differs from the number of bound buffers. You must reset the statement, rebind the result set columns, and execute the statement again
CR_NEW_STMT_METADATA was added in 5.1.25.

B.5 Problems and Common Errors
How to Determine What Is Causing a Problem

This section lists some common problems and error messages that you may encounter. It describes how to determine the causes of the problems and what to do to solve them.

B.5.1 How to Determine What Is Causing a Problem

When you run into a problem, the first thing you should do is to find out which program or piece of equipment is causing it:

- If you have one of the following symptoms, then it is probably a hardware problem (such as memory, motherboard, CPU, or hard disk) or kernel problem:
  - The keyboard does not work. This can normally be checked by pressing the Caps Lock key. If the Caps Lock light does not change, you have to replace your keyboard. (Before doing this, you should try to restart your computer and check all cables to the keyboard.)
  - The mouse pointer does not move.
  - The machine does not answer to a remote machine's pings.
  - Other programs that are not related to MySQL do not behave correctly.
  - Your system restarted unexpectedly. (A faulty user-level program should never be able to take down your system.)

In this case, you should start by checking all your cables and run some diagnostic tool to check your hardware! You should also check whether there are any patches, updates, or service packs for your operating system that could likely solve your problem. Check also that all your libraries (such as glibc) are up to date.

It is always good to use a machine with ECC memory to discover memory problems early.

- If your keyboard is locked up, you may be able to recover by logging in to your machine from another machine and executing `kbd_mode -a`.

- Please examine your system log file (`/var/log/messages` or similar) for reasons for your problem. If you think the problem is in MySQL, you should also examine MySQL’s log files. See Section 5.4, “MySQL Server Logs”.

- If you do not think you have hardware problems, you should try to find out which program is causing problems. Try using `top`, `ps`, Task Manager, or some similar program, to check which program is taking all CPU or is locking the machine.

- Use `top`, `df`, or a similar program to check whether you are out of memory, disk space, file descriptors, or some other critical resource.

- If the problem is some runaway process, you can always try to kill it. If it does not want to die, there is probably a bug in the operating system.

If after you have examined all other possibilities and you have concluded that the MySQL server or a MySQL client is causing the problem, it is time to create a bug report for our mailing list or our support team. In the bug report, try to give a very detailed description of how the system is behaving and what you think is happening. You should also state why you think that MySQL is causing the problem. Take into consideration all the situations in this chapter. State any problems exactly how they appear when you examine your system. Use the “copy and paste” method for any output and error messages from programs and log files.

Try to describe in detail which program is not working and all symptoms you see. We have in the past received many bug reports that state only “the system does not work.” This provides us with no information about what could be the problem.

If a program fails, it is always useful to know the following information:
Common Errors When Using MySQL Programs

• Has the program in question made a segmentation fault (did it dump core)?

• Is the program taking up all available CPU time? Check with top. Let the program run for a while, it may simply be evaluating something computationally intensive.

• If the mysqld server is causing problems, can you get any response from it with mysqladmin -u root ping or mysqladmin -u root processlist?

• What does a client program say when you try to connect to the MySQL server? (Try with mysql, for example.) Does the client jam? Do you get any output from the program?

When sending a bug report, you should follow the outline described in Section 1.7, “How to Report Bugs or Problems”.

B.5.2 Common Errors When Using MySQL Programs

This section lists some errors that users frequently encounter when running MySQL programs. Although the problems show up when you try to run client programs, the solutions to many of the problems involves changing the configuration of the MySQL server.

B.5.2.1 Access denied

An Access denied error can have many causes. Often the problem is related to the MySQL accounts that the server permits client programs to use when connecting. See Section 6.2, “The MySQL Access Privilege System”, and Section 6.2.7, “Troubleshooting Problems Connecting to MySQL”.

B.5.2.2 Can't connect to [local] MySQL server

A MySQL client on Unix can connect to the mysqld server in two different ways: By using a Unix socket file to connect through a file in the file system (default /tmp/mysql.sock), or by using TCP/IP, which connects through a port number. A Unix socket file connection is faster than TCP/IP, but can be used only when connecting to a server on the same computer. A Unix socket file is used if you do not specify a host name or if you specify the special host name localhost.

If the MySQL server is running on Windows, you can connect using TCP/IP. If the server is started with the --enable-named-pipe option, you can also connect with named pipes if you run the client on the host where the server is running. The name of the named pipe is MySQL by default. If you do not give a host name when connecting to mysqld, a MySQL client first tries to connect to the named pipe. If that does not work, it connects to the TCP/IP port. You can force the use of named pipes on Windows by using . as the host name.

The error (2002) Can't connect to ... normally means that there is no MySQL server running on the system or that you are using an incorrect Unix socket file name or TCP/IP port number when trying to connect to the server. You should also check that the TCP/IP port you are using has not been blocked by a firewall or port blocking service.

The error (2003) Can't connect to MySQL server on 'server' (10061) indicates that the network connection has been refused. You should check that there is a MySQL server running, that it has network connections enabled, and that the network port you specified is the one configured on the server.

Start by checking whether there is a process named mysqld running on your server host. (Use ps xa | grep mysqld on Unix or the Task Manager on Windows.) If there is no such process, you should start the server. See Section 2.12.2, “Starting the Server”.

If a mysqld process is running, you can check it by trying the following commands. The port number or Unix socket file name might be different in your setup. host_ip represents the IP address of the machine where the server is running.
Note the use of backticks rather than forward quotation marks with the `hostname` command; these cause the output of `hostname` (that is, the current host name) to be substituted into the `mysqladmin` command. If you have no `hostname` command or are running on Windows, you can manually type the host name of your machine (without backticks) following the `-h` option. You can also try `-h 127.0.0.1` to connect with TCP/IP to the local host.

Make sure that the server has not been configured to ignore network connections or (if you are attempting to connect remotely) that it has not been configured to listen only locally on its network interfaces. If the server was started with `--skip-networking`, it will not accept TCP/IP connections at all. If the server was started with `--bind-address=127.0.0.1`, it will listen for TCP/IP connections only locally on the loopback interface and will not accept remote connections.

Check to make sure that there is no firewall blocking access to MySQL. Your firewall may be configured on the basis of the application being executed, or the port number used by MySQL for communication (3306 by default). Under Linux or Unix, check your IP tables (or similar) configuration to ensure that the port has not been blocked. Under Windows, applications such as ZoneAlarm or the Windows XP personal firewall may need to be configured not to block the MySQL port.

Here are some reasons the Can't connect to local MySQL server error might occur:

- `mysqld` is not running on the local host. Check your operating system's process list to ensure the `mysqld` process is present.

- You're running a MySQL server on Windows with many TCP/IP connections to it. If you're experiencing that quite often your clients get that error, you can find a workaround here: Connection to MySQL Server Failing on Windows.

- Someone has removed the Unix socket file that `mysqld` uses (`/tmp/mysql.sock` by default). For example, you might have a cron job that removes old files from the `/tmp` directory. You can always run `mysqladmin version` to check whether the Unix socket file that `mysqladmin` is trying to use really exists. The fix in this case is to change the cron job to not remove `mysql.sock` or to place the socket file somewhere else. See Section B.5.3.6, “How to Protect or Change the MySQL Unix Socket File”.

- You have started the `mysqld` server with the `--socket=/path/to/socket` option, but forgotten to tell client programs the new name of the socket file. If you change the socket path name for the server, you must also notify the MySQL clients. You can do this by providing the same `--socket` option when you run client programs. You also need to ensure that clients have permission to access the `mysql.sock` file. To find out where the socket file is, you can do:

  ```bash
  shell> netstat -ln | grep mysql
  ```

  See Section B.5.3.6, “How to Protect or Change the MySQL Unix Socket File”.

- You are using Linux and one server thread has died (dumped core). In this case, you must kill the other `mysqld` threads (for example, with `kill` or with the `mysql_zap` script) before you can restart the MySQL server. See Section B.5.3.3, “What to Do If MySQL Keeps Crashing”.

- The server or client program might not have the proper access privileges for the directory that holds the Unix socket file or the socket file itself. In this case, you must either change the access privileges for the directory or socket file so that the server and clients can access them, or restart `mysqld` with a `--socket` option that specifies a socket file name in a directory where the server can create it and where client programs can access it.
If you get the error message *Can't connect to MySQL server on some_host*, you can try the following things to find out what the problem is:

- Check whether the server is running on that host by executing `telnet some_host 3306` and pressing the Enter key a couple of times. (3306 is the default MySQL port number. Change the value if your server is listening to a different port.) If there is a MySQL server running and listening to the port, you should get a response that includes the server's version number. If you get an error such as `telnet: Unable to connect to remote host: Connection refused`, then there is no server running on the given port.

- If the server is running on the local host, try using `mysqladmin -h localhost variables` to connect using the Unix socket file. Verify the TCP/IP port number that the server is configured to listen to (it is the value of the `port` variable.)

- If you are running under Linux and Security-Enhanced Linux (SELinux) is enabled, make sure you have disabled SELinux protection for the `mysqld` process.

## Connection to MySQL Server Failing on Windows

When you're running a MySQL server on Windows with many TCP/IP connections to it, and you're experiencing that quite often your clients get a *Can't connect to MySQL server* error, the reason might be that Windows does not allow for enough ephemeral (short-lived) ports to serve those connections.

The purpose of `TIME_WAIT` is to keep a connection accepting packets even after the connection has been closed. This is because Internet routing can cause a packet to take a slow route to its destination and it may arrive after both sides have agreed to close. If the port is in use for a new connection, that packet from the old connection could break the protocol or compromise personal information from the original connection. The `TIME_WAIT` delay prevents this by ensuring that the port cannot be reused until after some time has been permitted for those delayed packets to arrive.

It is safe to reduce `TIME_WAIT` greatly on LAN connections because there is little chance of packets arriving at very long delays, as they could through the Internet with its comparatively large distances and latencies.

Windows permits ephemeral (short-lived) TCP ports to the user. After any port is closed it will remain in a `TIME_WAIT` status for 120 seconds. The port will not be available again until this time expires. The default range of port numbers depends on the version of Windows, with a more limited number of ports in older versions:

- Windows through Server 2003: Ports in range 1025–5000

With a small stack of available TCP ports (5000) and a high number of TCP ports being open and closed over a short period of time along with the `TIME_WAIT` status you have a good chance for running out of ports. There are two ways to address this problem:

- Reduce the number of TCP ports consumed quickly by investigating connection pooling or persistent connections where possible
- Tune some settings in the Windows registry (see below)

---

### Important

The following procedure involves modifying the Windows registry. Before you modify the registry, make sure to back it up and make sure that you understand how to restore it if a problem occurs. For information about how to back up, restore, and edit the registry, view the following article in the Microsoft Knowledge Base: [http://support.microsoft.com/kb/256986/EN-US/](http://support.microsoft.com/kb/256986/EN-US/).
1. Start Registry Editor (Regedit32.exe).

2. Locate the following key in the registry:

   HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters

3. On the Edit menu, click Add Value, and then add the following registry value:

   Value Name: MaxUserPort
   Data Type: REG_DWORD
   Value: 65534

   This sets the number of ephemeral ports available to any user. The valid range is between 5000 and 65534 (decimal). The default value is 0x1388 (5000 decimal).

4. On the Edit menu, click Add Value, and then add the following registry value:

   Value Name: TcpTimedWaitDelay
   Data Type: REG_DWORD
   Value: 30

   This sets the number of seconds to hold a TCP port connection in TIME_WAIT state before closing. The valid range is between 30 and 300 decimal, although you may wish to check with Microsoft for the latest permitted values. The default value is 0x78 (120 decimal).

5. Quit Registry Editor.

6. Reboot the machine.

   Note: Undoing the above should be as simple as deleting the registry entries you’ve created.

B.5.2.3 Lost connection to MySQL server

   There are three likely causes for this error message.

   Usually it indicates network connectivity trouble and you should check the condition of your network if this error occurs frequently. If the error message includes “during query,” this is probably the case you are experiencing.

   Sometimes the “during query” form happens when millions of rows are being sent as part of one or more queries. If you know that this is happening, you should try increasing net_read_timeout from its default of 30 seconds to 60 seconds or longer, sufficient for the data transfer to complete.

   More rarely, it can happen when the client is attempting the initial connection to the server. In this case, if your connect_timeout value is set to only a few seconds, you may be able to resolve the problem by increasing it to ten seconds, perhaps more if you have a very long distance or slow connection. You can determine whether you are experiencing this more uncommon cause by using SHOW GLOBAL STATUS LIKE 'Aborted_connects'. It will increase by one for each initial connection attempt that the server aborts. You may see “reading authorization packet” as part of the error message; if so, that also suggests that this is the solution that you need.

   If the cause is none of those just described, you may be experiencing a problem with BLOB values that are larger than max_allowed_packet, which can cause this error with some clients. Sometimes you may see an ER_NET_PACKET_TOO_LARGE error, and that confirms that you need to increase max_allowed_packet.

B.5.2.4 Client does not support authentication protocol

   The current implementation of the authentication protocol uses a password hashing algorithm that is incompatible with that used by older (pre-4.1) clients. Attempts to connect to a 4.1 or newer server with an older client may fail with the following message:
To deal with this problem, the preferred solution is to upgrade all client programs to use a 4.1.1 or newer client library. If that is not possible, use one of the following approaches:

- To connect to the server with a pre-4.1 client program, use an account that still has a pre-4.1-style password.

- Reset the password to pre-4.1 style for each user that needs to use a pre-4.1 client program. This can be done using the `SET PASSWORD` statement and the `OLD_PASSWORD()` function:

  ```shell
  mysql> SET PASSWORD FOR 'some_user'@'some_host' = OLD_PASSWORD('new_password');
  ```

  Substitute the password you want to use for "new_password" in the preceding example. MySQL cannot tell you what the original password was, so you'll need to pick a new one.

- Tell the server to use the older password hashing algorithm by default:
  1. Start `mysqld` with the `old_passwords` system variable set to 1.
  2. Assign an old-format password to each account that has had its password updated to the longer 4.1 format. You can identify these accounts with the following query:

  ```shell
  mysql> SELECT Host, User, Password FROM mysql.user
  -> WHERE LENGTH(Password) > 16;
  ```

  For each account record displayed by the query, use the `Host` and `User` values and assign a password using one of the methods described previously.

The `Client does not support authentication protocol` error also can occur if multiple versions of MySQL are installed but client programs are dynamically linked and link to an older library. Make sure that clients use the most recent library version with which they are compatible. The procedure to do this will depend on your system.

**Note**

The PHP `mysql` extension does not support the authentication protocol in MySQL 4.1.1 and higher. This is true regardless of the PHP version being used. If you wish to use the `mysql` extension with MySQL 4.1 or newer, you may need to follow one of the options discussed above for configuring MySQL to work with old clients. The `mysqli` extension (stands for "MySQL, Improved"; added in PHP 5) is compatible with the improved password hashing employed in MySQL 4.1 and higher, and no special configuration of MySQL need be done to use this MySQL client library. For more information about the `mysqli` extension, see [http://php.net/mysqli](http://php.net/mysqli).

For additional background on password hashing and authentication, see Section 6.1.2.4, “Password Hashing in MySQL”.

### B.5.2.5 Password Fails When Entered Interactively

MySQL client programs prompt for a password when invoked with a `--password` or `-p` option that has no following password value:

```shell
shell> mysql -u user_name -p
Enter password:
```
On some systems, you may find that your password works when specified in an option file or on the command line, but not when you enter it interactively at the Enter password: prompt. This occurs when the library provided by the system to read passwords limits password values to a small number of characters (typically eight). That is a problem with the system library, not with MySQL. To work around it, change your MySQL password to a value that is eight or fewer characters long, or put your password in an option file.

B.5.2.6 Host 'host_name' is blocked

If the following error occurs, it means that MySQL has received many connection requests from the given host that were interrupted in the middle:

```
Host 'host_name' is blocked because of many connection errors.
Unblock with 'mysqladmin flush-hosts'
```

The value of the `max_connect_errors` system variable determines how many successive interrupted connection requests are permitted. (See Section 5.1.4, “Server System Variables”.) After `max_connect_errors` failed requests without a successful connection, MySQL assumes that something is wrong (for example, that someone is trying to break in), and blocks the host from further connections until you issue a `FLUSH HOSTS` statement or execute a `mysqladmin flush-hosts` command.

By default, MySQL blocks a host after 10 connection errors. You can adjust the value by setting `max_connect_errors` at server startup:

```
shell> mysql_safe --max_connect_errors=10000 &
```

The value can also be set at runtime:

```
mysql> SET GLOBAL max_connect_errors=10000;
```

If you get the Host 'host_name' is blocked error message for a given host, you should first verify that there is nothing wrong with TCP/IP connections from that host. If you are having network problems, it does you no good to increase the value of the `max_connect_errors` variable.

B.5.2.7 Too many connections

If you get a Too many connections error when you try to connect to the MySQL server, this means that all available connections are in use by other clients.

The number of connections permitted is controlled by the `max_connections` system variable. Beginning with MySQL 5.1.15, its default value is 151 to improve performance when MySQL is used with the Apache Web server. (Previously, the default was 100.) If you need to support more connections, you should set a larger value for this variable.

MySQL actually permits `max_connections+1` clients to connect. The extra connection is reserved for use by accounts that have the SUPER privilege. By granting the SUPER privilege to administrators and not to normal users (who should not need it), an administrator can connect to the server and use SHOW PROCESSLIST to diagnose problems even if the maximum number of unprivileged clients are connected. See Section 13.7.5.31, “SHOW PROCESSLIST Syntax”.

The maximum number of connections MySQL supports depends on the quality of the thread library on a given platform, the amount of RAM available, how much RAM is used for each connection, the workload from each connection, and the desired response time. Linux or Solaris should be able to support at 500 to 1000 simultaneous connections routinely and as many as 10,000 connections if you have many gigabytes of RAM available and the workload from each is low or the response time target undemanding. Windows is limited to (open tables × 2 + open connections) < 2048 due to the Posix compatibility layer used on that platform.
Increasing open-files-limit may be necessary. Also see Section 2.5, “Installing MySQL on Linux”, for how to raise the operating system limit on how many handles can be used by MySQL.

### B.5.2.8 Out of memory

If you issue a query using the mysql client program and receive an error like the following one, it means that mysql does not have enough memory to store the entire query result:

```plaintext
cr: Out of memory at line 42, 'malloc.c'
cr: needed 8136 byte (8k), memory in use: 12481367 bytes (12189k)
ERROR 2008: MySQL client ran out of memory
```

To remedy the problem, first check whether your query is correct. Is it reasonable that it should return so many rows? If not, correct the query and try again. Otherwise, you can invoke mysql with the --quick option. This causes it to use the mysql_use_result() C API function to retrieve the result set, which places less of a load on the client (but more on the server).

### B.5.2.9 MySQL server has gone away

This section also covers the related Lost connection to server during query error.

The most common reason for the MySQL server has gone away error is that the server timed out and closed the connection. In this case, you normally get one of the following error codes (which one you get is operating system-dependent).

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CR_SERVER_GONE_ERROR</td>
<td>The client couldn't send a question to the server.</td>
</tr>
<tr>
<td>CR_SERVER_LOST</td>
<td>The client didn't get an error when writing to the server, but it didn't get a full answer (or any answer) to the question.</td>
</tr>
</tbody>
</table>

By default, the server closes the connection after eight hours if nothing has happened. You can change the time limit by setting the `wait_timeout` variable when you start mysqld. See Section 5.1.4, “Server System Variables”.

If you have a script, you just have to issue the query again for the client to do an automatic reconnection. This assumes that you have automatic reconnection in the client enabled (which is the default for the mysql command-line client).

Some other common reasons for the MySQL server has gone away error are:

- You (or the db administrator) has killed the running thread with a KILL statement or a mysqladmin kill command.
- You tried to run a query after closing the connection to the server. This indicates a logic error in the application that should be corrected.
- A client application running on a different host does not have the necessary privileges to connect to the MySQL server from that host.
- You got a timeout from the TCP/IP connection on the client side. This may happen if you have been using the commands: `mysql_options(..., MYSQL_OPT_READ_TIMEOUT,...)` or `mysql_options(..., MYSQL_OPT_WRITE_TIMEOUT,...)`. In this case increasing the timeout may help solve the problem.
- You have encountered a timeout on the server side and the automatic reconnection in the client is disabled (the reconnect flag in the MYSQL structure is equal to 0).
- You are using a Windows client and the server had dropped the connection (probably because wait_timeout expired) before the command was issued.
The problem on Windows is that in some cases MySQL does not get an error from the OS when writing to the TCP/IP connection to the server, but instead gets the error when trying to read the answer from the connection.

Prior to MySQL 5.1.8, even if the reconnect flag in the MYSQL structure is equal to 1, MySQL does not automatically reconnect and re-issue the query as it doesn’t know if the server did get the original query or not.

The solution to this is to either do a mysql_ping() on the connection if there has been a long time since the last query (this is what Connector/ODBC does) or set wait_timeout on the mysqld server so high that it in practice never times out.

• You can also get these errors if you send a query to the server that is incorrect or too large. If mysqld receives a packet that is too large or out of order, it assumes that something has gone wrong with the client and closes the connection. If you need big queries (for example, if you are working with big BLOB columns), you can increase the query limit by setting the server’s max_allowed_packet variable, which has a default value of 1MB. You may also need to increase the maximum packet size on the client end. More information on setting the packet size is given in Section B.5.2.10, “Packet Too Large”.

An INSERT or REPLACE statement that inserts a great many rows can also cause these sorts of errors. Either one of these statements sends a single request to the server irrespective of the number of rows to be inserted; thus, you can often avoid the error by reducing the number of rows sent per INSERT or REPLACE.

• You also get a lost connection if you are sending a packet 16MB or larger if your client is older than 4.0.8 and your server is 4.0.8 and above, or the other way around.

• It is also possible to see this error if host name lookups fail (for example, if the DNS server on which your server or network relies goes down). This is because MySQL is dependent on the host system for name resolution, but has no way of knowing whether it is working—from MySQL's point of view the problem is indistinguishable from any other network timeout.

You may also see the MySQL server has gone away error if MySQL is started with the --skip-networking option.

Another networking issue that can cause this error occurs if the MySQL port (default 3306) is blocked by your firewall, thus preventing any connections at all to the MySQL server.

• You can also encounter this error with applications that fork child processes, all of which try to use the same connection to the MySQL server. This can be avoided by using a separate connection for each child process.

• You have encountered a bug where the server died while executing the query.

You can check whether the MySQL server died and restarted by executing mysqladmin version and examining the server's uptime. If the client connection was broken because mysqld crashed and restarted, you should concentrate on finding the reason for the crash. Start by checking whether issuing the query again kills the server again. See Section B.5.3.3, “What to Do If MySQL Keeps Crashing”.

You can get more information about the lost connections by starting mysqld with the --log-warnings=2 option. This logs some of the disconnected errors in the hostname.err file. See Section 5.4.2, “The Error Log”.

If you want to create a bug report regarding this problem, be sure that you include the following information:

• Indicate whether the MySQL server died. You can find information about this in the server error log. See Section B.5.3.3, “What to Do If MySQL Keeps Crashing”.
• If a specific query kills `mysqld` and the tables involved were checked with `CHECK TABLE` before you ran the query, can you provide a reproducible test case? See Section 22.4, “Debugging and Porting MySQL”.

• What is the value of the `wait_timeout` system variable in the MySQL server? (`mysqladmin variables` gives you the value of this variable.)

• Have you tried to run `mysqld` with the general query log enabled to determine whether the problem query appears in the log? (See Section 5.4.3, “The General Query Log”.)

See also Section B.5.2.11, “Communication Errors and Aborted Connections”, and Section 1.7, “How to Report Bugs or Problems”.

B.5.2.10 Packet Too Large

A communication packet is a single SQL statement sent to the MySQL server, a single row that is sent to the client, or a binary log event sent from a master replication server to a slave.

The largest possible packet that can be transmitted to or from a MySQL 5.1 server or client is 1GB.

When a MySQL client or the `mysqld` server receives a packet bigger than `max_allowed_packet` bytes, it issues an `ER_NET_PACKET_TOO_LARGE` error and closes the connection. With some clients, you may also get a `Lost connection to MySQL server during query` error if the communication packet is too large.

Both the client and the server have their own `max_allowed_packet` variable, so if you want to handle big packets, you must increase this variable both in the client and in the server.

If you are using the `mysql` client program, its default `max_allowed_packet` variable is 16MB. To set a larger value, start `mysql` like this:

```
shell> mysql --max_allowed_packet=32M
```

That sets the packet size to 32MB.

The server's default `max_allowed_packet` value is 1MB. You can increase this if the server needs to handle big queries (for example, if you are working with big `BLOB` columns). For example, to set the variable to 16MB, start the server like this:

```
shell> mysqld --max_allowed_packet=16M
```

You can also use an option file to set `max_allowed_packet`. For example, to set the size for the server to 16MB, add the following lines in an option file:

```ini
[mysqld]
max_allowed_packet=16M
```

It is safe to increase the value of this variable because the extra memory is allocated only when needed. For example, `mysqld` allocates more memory only when you issue a long query or when `mysqld` must return a large result row. The small default value of the variable is a precaution to catch incorrect packets between the client and server and also to ensure that you do not run out of memory by using large packets accidentally.

You can also get strange problems with large packets if you are using large `BLOB` values but have not given `mysqld` access to enough memory to handle the query. If you suspect this is the case, try adding `ulimit -d 256000` to the beginning of the `mysqld_safe` script and restarting `mysqld`.

B.5.2.11 Communication Errors and Aborted Connections
If connection problems occur such as communication errors or aborted connections, use these sources of information to diagnose problems:

- The error log. See Section 5.4.2, “The Error Log”.
- The general query log. See Section 5.4.3, “The General Query Log”.
- The `Aborted_xxxx` status variables. See Section 5.1.6, “Server Status Variables”.

If you start the server with the `--log-warnings` option, you might find messages like this in your error log:

```
Aborted connection 854 to db: 'employees' user: 'josh'
```

If a client is unable even to connect, the server increments the `Aborted_connects` status variable. Unsuccessful connection attempts can occur for the following reasons:

- A client attempts to access a database but has no privileges for it.
- A client uses an incorrect password.
- A connection packet does not contain the right information.
- It takes more than `connect_timeout` seconds to obtain a connect packet. See Section 5.1.4, “Server System Variables”.

If these kinds of things happen, it might indicate that someone is trying to break into your server! If the general query log is enabled, messages for these types of problems are logged to it.

If a client successfully connects but later disconnects improperly or is terminated, the server increments the `Aborted_clients` status variable, and logs an `Aborted connection` message to the error log. The cause can be any of the following:

- The client program did not call `mysql_close()` before exiting.
- The client had been sleeping more than `wait_timeout` or `interactive_timeout` seconds without issuing any requests to the server. See Section 5.1.4, “Server System Variables”.
- The client program ended abruptly in the middle of a data transfer.

Other reasons for problems with aborted connections or aborted clients:

- The `max_allowed_packet` variable value is too small or queries require more memory than you have allocated for `mysqld`. See Section B.5.2.10, “Packet Too Large”.
- Use of Ethernet protocol with Linux, both half and full duplex. Some Linux Ethernet drivers have this bug. You should test for this bug by transferring a huge file using FTP between the client and server machines. If a transfer goes in burst-pause-burst-pause mode, you are experiencing a Linux duplex syndrome. Switch the duplex mode for both your network card and hub/switch to either full duplex or to half duplex and test the results to determine the best setting.
- A problem with the thread library that causes interrupts on reads.
- Badly configured TCP/IP.
- Faulty Ethertns, hubs, switches, cables, and so forth. This can be diagnosed properly only by replacing hardware.

See also Section B.5.2.9, “MySQL server has gone away”.

**B.5.2.12 The table is full**
If a table-full error occurs, it may be that the disk is full or that the table has reached its maximum size. The effective maximum table size for MySQL databases is usually determined by operating system constraints on file sizes, not by MySQL internal limits. See Section C.7.3, “Limits on Table Size”.

This error can occur sometimes for MySQL Cluster tables even when there appears to be more than sufficient data memory available. See the documentation for the DataMemory MySQL Cluster data node configuration parameter, as well as Section 17.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”, for more information.

B.5.2.13 Can't create/write to file

If you get an error of the following type for some queries, it means that MySQL cannot create a temporary file for the result set in the temporary directory:

```
Can't create/write to file '\sqla3fe_0.ism'.
```

The preceding error is a typical message for Windows; the Unix message is similar.

One fix is to start `mysqld` with the `--tmpdir` option or to add the option to the `{mysqld}` section of your option file. For example, to specify a directory of `C:\temp`, use these lines:

```
[mysqld]
tmpdir=C:/temp
```

The `C:\temp` directory must exist and have sufficient space for the MySQL server to write to. See Section 4.2.6, “Using Option Files”.

Another cause of this error can be permissions issues. Make sure that the MySQL server can write to the `tmpdir` directory.

Check also the error code that you get with `perror`. One reason the server cannot write to a table is that the file system is full:

```
shell> perror 28
OS error code  28:  No space left on device
```

If you get an error of the following type during startup, it indicates that the file system or directory used for storing data files is write protected. Provided that the write error is to a test file, the error is not serious and can be safely ignored.

```
Can't create test file /usr/local/mysql/data/master.lower-test
```

B.5.2.14 Commands out of sync

If you get `Commands out of sync; you can't run this command now` in your client code, you are calling client functions in the wrong order.

This can happen, for example, if you are using `mysql_use_result()` and try to execute a new query before you have called `mysql_free_result()`. It can also happen if you try to execute two queries that return data without calling `mysql_use_result()` or `mysql_store_result()` in between.

B.5.2.15 Ignoring user

If you get the following error, it means that when `mysqld` was started or when it reloaded the grant tables, it found an account in the `user` table that had an invalid password.

```
Found wrong password for user 'some_user'@'some_host'; ignoring user
```

As a result, the account is simply ignored by the permission system.
The following list indicates possible causes of and fixes for this problem:

- You may be running a new version of mysqld with an old user table. Check whether the Password column of that table is shorter than 16 characters. If so, correct this condition by running mysql_upgrade.

- The account has an old password (eight characters long). Update the account in the user table to have a new password.

- You have specified a password in the user table without using the PASSWORD() function. Use mysql to update the account in the user table with a new password, making sure to use the PASSWORD() function:

  ```
  mysql> UPDATE user SET Password=PASSWORD('new_password')
  WHERE User='some_user' AND Host='some_host';
  ```

B.5.2.16 Table 'tbl_name' doesn't exist

If you get either of the following errors, it usually means that no table exists in the default database with the given name:

```
Table 'tbl_name' doesn't exist
Can't find file: 'tbl_name' (errno: 2)
```

In some cases, it may be that the table does exist but that you are referring to it incorrectly:

- Because MySQL uses directories and files to store databases and tables, database and table names are case sensitive if they are located on a file system that has case-sensitive file names.

- Even for file systems that are not case sensitive, such as on Windows, all references to a given table within a query must use the same lettercase.

You can check which tables are in the default database with SHOW TABLES. See Section 13.7.5, “SHOW Syntax”.

B.5.2.17 Can't initialize character set

You might see an error like this if you have character set problems:

```
MySQL Connection Failed: Can't initialize character set charset_name
```

This error can have any of the following causes:

- The character set is a multibyte character set and you have no support for the character set in the client. In this case, you need to recompile the client by running configure with the --with-charset=charset_name or --with-extra-charsets=charset_name option. See Section 2.11.4, “MySQL Source-Configuration Options”.

  All standard MySQL binaries are compiled with --with-extra-charsets=complex or (for Windows) --with-extra-charsets=complex, which enables support for all multibyte character sets. See Section 2.11.4, “MySQL Source-Configuration Options”.

- The character set is a simple character set that is not compiled into mysqld, and the character set definition files are not in the place where the client expects to find them.

  In this case, you need to use one of the following methods to solve the problem:

  - Recompile the client with support for the character set. See Section 2.11.4, “MySQL Source-Configuration Options”. 

• Specify to the client the directory where the character set definition files are located. For many clients, you can do this with the `--character-sets-dir` option.

• Copy the character definition files to the path where the client expects them to be.

### B.5.2.18 File Not Found and Similar Errors

If you get `ERROR 'file_name' not found (errno: 23), Can't open file: file_name (errno: 24)`, or any other error with `errno 23` or `errno 24` from MySQL, it means that you have not allocated enough file descriptors for the MySQL server. You can use the `perror` utility to get a description of what the error number means:

```shell
shell> perror 23
OS error code 23: File table overflow
shell> perror 24
OS error code 24: Too many open files
shell> perror 11
OS error code 11: Resource temporarily unavailable
```

The problem here is that `mysqld` is trying to keep open too many files simultaneously. You can either tell `mysqld` not to open so many files at once or increase the number of file descriptors available to `mysqld`.

To tell `mysqld` to keep open fewer files at a time, you can make the table cache smaller by reducing the value of the `table_open_cache` system variable (the default value is 64). This may not entirely prevent running out of file descriptors because in some circumstances the server may attempt to extend the cache size temporarily, as described in Section 8.4.3.1, “How MySQL Opens and Closes Tables”. Reducing the value of `max_connections` also reduces the number of open files (the default value is 100).

To change the number of file descriptors available to `mysqld`, you can use the `--open-files-limit` option to `mysqld_safe` or set the `open_files_limit` system variable. See Section 5.1.4, “Server System Variables”. The easiest way to set these values is to add an option to your option file. See Section 4.2.6, “Using Option Files”. If you have an old version of `mysqld` that does not support setting the open files limit, you can edit the `mysqld_safe` script. There is a commented-out line `ulimit -n 256` in the script. You can remove the “#” character to uncomment this line, and change the number 256 to set the number of file descriptors to be made available to `mysqld`.

`--open-files-limit` and `ulimit` can increase the number of file descriptors, but only up to the limit imposed by the operating system. There is also a “hard” limit that can be overridden only if you start `mysqld_safe` or `mysqld` as `root` (just remember that you also need to start the server with the `--user` option in this case so that it does not continue to run as `root` after it starts up). If you need to increase the operating system limit on the number of file descriptors available to each process, consult the documentation for your system.

---

**Note**

If you run the `tcsh` shell, `ulimit` does not work! `tcsh` also reports incorrect values when you ask for the current limits. In this case, you should start `mysqld_safe` using `sh`.

### B.5.2.19 Table-Corruption Issues

If you have started `mysqld` with `--myisam-recover`, MySQL automatically checks and tries to repair MyISAM tables if they are marked as `not closed properly` or `crashed`. If this happens, MySQL writes an entry in the `hostname.err` file `Warning: Checking table ...` which is followed by `Warning: Repairing table` if the table needs to be repaired. If you get a lot of these errors, without `mysqld` having died unexpectedly just before, then something is wrong and needs to be investigated further.
See also Section 5.1.3, “Server Command Options”, and Section 22.4.1.7, “Making a Test Case If You Experience Table Corruption”.

B.5.3 Administration-Related Issues

B.5.3.1 Problems with File Permissions

If you have problems with file permissions, the `UMASK` or `UMASK_DIR` environment variable might be set incorrectly when `mysqld` starts. For example, MySQL might issue the following error message when you create a table:

```
ERROR: Can't find file: 'path/with/filename.frm' (Errcode: 13)
```

The default `UMASK` and `UMASK_DIR` values are `0660` and `0700`, respectively. MySQL assumes that the value for `UMASK` or `UMASK_DIR` is in octal if it starts with a zero. For example, setting `UMASK=0600` is equivalent to `UMASK=384` because 0600 octal is 384 decimal.

To change the default `UMASK` value, start `mysqld_safe` as follows:

```
shell> UMASK=384  # = 600 in octal
shell> export UMASK
shell> mysqld_safe &
```

By default, MySQL creates database directories with an access permission value of `0700`. To modify this behavior, set the `UMASK_DIR` variable. If you set its value, new directories are created with the combined `UMASK` and `UMASK_DIR` values. For example, to give group access to all new directories, start `mysqld_safe` as follows:

```
shell> UMASK_DIR=504  # = 770 in octal
shell> export UMASK_DIR
shell> mysqld_safe &
```

For additional details, see Section 2.14, “Environment Variables”.

B.5.3.2 How to Reset the Root Password

If you have never assigned a root password for MySQL, the server does not require a password at all for connecting as root. However, this is insecure. For instructions on assigning passwords, see Section 2.12.4, “Securing the Initial MySQL Accounts”.

If you know the root password and want to change it, see Section 13.7.1.6, “SET PASSWORD Syntax”.

If you assigned a root password previously but have forgotten it, you can assign a new password. The following sections provide instructions for Windows and Unix and Unix-like systems, as well as generic instructions that apply to any system.

Resetting the Root Password: Windows Systems

On Windows, use the following procedure to reset the password for the MySQL `root'@'localhost'` account. To change the password for a root account with a different host name part, modify the instructions to use that host name.

1. Log on to your system as Administrator.

2. Stop the MySQL server if it is running. For a server that is running as a Windows service, go to the Services manager: From the Start menu, select Control Panel, then Administrative Tools, then Services. Find the MySQL service in the list and stop it.

   If your server is not running as a service, you may need to use the Task Manager to force it to stop.
3. Create a text file containing the following statement on a single line. Replace the password with the password that you want to use.

```sql
SET PASSWORD FOR 'root'@'localhost' = PASSWORD('MyNewPass');
```

4. Save the file. This example assumes that you name the file `C:\mysql-init.txt`.

5. Open a console window to get to the command prompt: From the Start menu, select Run, then enter `cmd` as the command to be run.

6. Start the MySQL server with the special `--init-file` option (notice that the backslash in the option value is doubled):

```sql
C:\> cd "C:\Program Files\MySQL\MySQL Server 5.1\bin"
C:\> mysqld --init-file=C:\mysql-init.txt
```

If you installed MySQL to a different location, adjust the cd command accordingly.

The server executes the contents of the file named by the `--init-file` option at startup, changing the `root'@'localhost'` account password.

To have server output to appear in the console window rather than in a log file, add the `--console` option to the `mysqld` command.

If you installed MySQL using the MySQL Installation Wizard, you may need to specify a `--defaults-file` option. For example:

```sql
C:\> mysqld
    --defaults-file="C:\Program Files\MySQL\MySQL Server 5.1\my.ini"
    --init-file=C:\mysql-init.txt
```

The appropriate `--defaults-file` setting can be found using the Services Manager: From the Start menu, select Control Panel, then Administrative Tools, then Services. Find the MySQL service in the list, right-click it, and choose the Properties option. The Path to executable field contains the `--defaults-file` setting.

7. After the server has started successfully, delete `C:\mysql-init.txt`.

You should now be able to connect to the MySQL server as `root` using the new password. Stop the MySQL server and restart it normally. If you run the server as a service, start it from the Windows Services window. If you start the server manually, use whatever command you normally use.

**Resetting the Root Password: Unix and Unix-Like Systems**

On Unix, use the following procedure to reset the password for the MySQL `root'@'localhost'` account. To change the password for a `root` account with a different host name part, modify the instructions to use that host name.

The instructions assume that you will start the MySQL server from the Unix login account that you normally use for running it. For example, if you run the server using the `mysql` login account, you should log in as `mysql` before using the instructions. Alternatively, you can log in as `root`, but in this case you must start `mysqld` with the `--user=mysql` option. If you start the server as `root` without using `--user=mysql`, the server may create `root`-owned files in the data directory, such as log files, and these may cause permission-related problems for future server startups. If that happens, you will need to either change the ownership of the files to `mysql` or remove them.

1. Log on to your system as the Unix user that the MySQL server runs as (for example, `mysql`).

2. Stop the MySQL server if it is running. Locate the `.pid` file that contains the server's process ID. The exact location and name of this file depend on your distribution, host name, and configuration.
Common locations are /var/lib/mysql/, /var/run/mysqld/, and /usr/local/mysql/data/. Generally, the file name has an extension of .pid and begins with either mysqld or your system's host name.

Stop the MySQL server by sending a normal `kill` (not `kill -9`) to the mysqld process. Use the actual path name of the .pid file in the following command:

```
shell> kill `cat /mysql-data-directory/host_name.pid`
```

Use backticks (not forward quotation marks) with the `cat` command. These cause the output of `cat` to be substituted into the `kill` command.

3. Create a text file containing the following statement on a single line. Replace the password with the password that you want to use.

   ```
   SET PASSWORD FOR 'root'@'localhost' = PASSWORD('MyNewPass');
   ```

4. Save the file. This example assumes that you name the file /home/me/mysql-init. The file contains the password, so do not save it where it can be read by other users. If you are not logged in as mysql (the user the server runs as), make sure that the file has permissions that permit mysql to read it.

5. Start the MySQL server with the special `--init-file` option:

   ```
   shell> mysqld_safe --init-file=/home/me/mysql-init &
   ```

   The server executes the contents of the file named by the `--init-file` option at startup, changing the 'root'@'localhost' account password.

6. After the server has started successfully, delete /home/me/mysql-init.

   You should now be able to connect to the MySQL server as root using the new password. Stop the server and restart it normally.

**Resetting the Root Password: Generic Instructions**

The preceding sections provide password-resetting instructions specifically for Windows and Unix and Unix-like systems. Alternatively, on any platform, you can reset the password using the `mysql` client (but this approach is less secure):

1. Stop the MySQL server if necessary, then restart it with the `--skip-grant-tables` option. This enables anyone to connect without a password and with all privileges, and disables account-management statements such as `SET PASSWORD`. Because this is insecure, you might want to use `--skip-grant-tables` in conjunction with `--skip-networking` to prevent remote clients from connecting.

2. Connect to the MySQL server using the `mysql` client; no password is necessary because the server was started with `--skip-grant-tables`:

   ```
   shell> mysql
   ```

3. In the `mysql` client, tell the server to reload the grant tables so that account-management statements work:

   ```
   mysql> FLUSH PRIVILEGES;
   ```

   Then change the 'root'@'localhost' account password. Replace the password with the password that you want to use. To change the password for a root account with a different host name part, modify the instructions to use that host name.
mysql> SET PASSWORD FOR 'root'@'localhost' = PASSWORD('MyNewPass');

You should now be able to connect to the MySQL server as root using the new password. Stop the server and restart it normally (without the --skip-grant-tables and --skip-networking options).

B.5.3.3 What to Do If MySQL Keeps Crashing

Each MySQL version is tested on many platforms before it is released. This does not mean that there are no bugs in MySQL, but if there are bugs, they should be very few and can be hard to find. If you have a problem, it always helps if you try to find out exactly what crashes your system, because you have a much better chance of getting the problem fixed quickly.

First, you should try to find out whether the problem is that the mysqld server dies or whether your problem has to do with your client. You can check how long your mysqld server has been up by executing mysqladmin version. If mysqld has died and restarted, you may find the reason by looking in the server’s error log. See Section 5.4.2, “The Error Log”.

On some systems, you can find in the error log a stack trace of where mysqld died that you can resolve with the resolve_stack_dump program. See Section 22.4, “Debugging and Porting MySQL”. Note that the variable values written in the error log may not always be 100% correct.

Many server crashes are caused by corrupted data files or index files. MySQL updates the files on disk with the write() system call after every SQL statement and before the client is notified about the result. (This is not true if you are running with --delay-key-write, in which case data files are written but not index files.) This means that data file contents are safe even if mysqld crashes, because the operating system ensures that the unflushed data is written to disk. You can force MySQL to flush everything to disk after every SQL statement by starting mysqld with the --flush option.

The preceding means that normally you should not get corrupted tables unless one of the following happens:

- The MySQL server or the server host was killed in the middle of an update.
- You have found a bug in mysqld that caused it to die in the middle of an update.
- Some external program is manipulating data files or index files at the same time as mysqld without locking the table properly.
- You are running many mysqld servers using the same data directory on a system that does not support good file system locks (normally handled by the lockd lock manager), or you are running multiple servers with external locking disabled.
- You have a crashed data file or index file that contains very corrupt data that confused mysqld.
- You have found a bug in the data storage code. This isn’t likely, but it is at least possible. In this case, you can try to change the storage engine to another engine by using ALTER TABLE on a repaired copy of the table.

Because it is very difficult to know why something is crashing, first try to check whether things that work for others crash for you. Please try the following things:

- Stop the mysqld server with mysqladmin shutdown, run myisamchk --silent --force */*.MYI from the data directory to check all MyISAM tables, and restart mysqld. This ensures that you are running from a clean state. See Chapter 5, MySQL Server Administration.
- Start mysqld with the general query log enabled (see Section 5.4.3, “The General Query Log”). Then try to determine from the information written to the log whether some specific query kills the server. About 95% of all bugs are related to a particular query. Normally, this is one of the last queries in the log file just before the server restarts. See Section 5.4.3, “The General Query Log”.

2671
If you can repeatedly kill MySQL with a specific query, even when you have checked all tables just before issuing it, then you have been able to locate the bug and should submit a bug report for it. See Section 1.7, “How to Report Bugs or Problems”.

- Try to make a test case that we can use to repeat the problem. See Section 22.4, “Debugging and Porting MySQL”.

- Try running the tests in the mysql-test directory and the MySQL benchmarks. See Section 22.1.2, “The MySQL Test Suite”. They should test MySQL rather well. You can also add code to the benchmarks that simulates your application. The benchmarks can be found in the sql-bench directory in a source distribution or, for a binary distribution, in the sql-bench directory under your MySQL installation directory.

- Try the fork_big.pl script. (It is located in the tests directory of source distributions.)

- If you configure MySQL for debugging, it is much easier to gather information about possible errors if something goes wrong. Configuring MySQL for debugging causes a safe memory allocator to be included that can find some errors. It also provides a lot of output about what is happening. Reconfigure MySQL with the --with-debug or --with-debug=full option to configure and then recompile. See Section 22.4, “Debugging and Porting MySQL”.

- Make sure that you have applied the latest patches for your operating system.

- Use the --skip-external-locking option to mysqld. On some systems, the lockd lock manager does not work properly; the --skip-external-locking option tells mysqld not to use external locking. (This means that you cannot run two mysqld servers on the same data directory and that you must be careful if you use myisamchk. Nevertheless, it may be instructive to try the option as a test.)

- Have you tried mysqladmin -u root processlist when mysqld appears to be running but not responding? Sometimes mysqld is not comatose even though you might think so. The problem may be that all connections are in use, or there may be some internal lock problem. mysqladmin -u root processlist usually is able to make a connection even in these cases, and can provide useful information about the current number of connections and their status.

- Run the command mysqladmin -i 5 status or mysqladmin -i 5 -r status in a separate window to produce statistics while you run your other queries.

- Try the following:

  1. Start mysqld from gdb (or another debugger). See Section 22.4, “Debugging and Porting MySQL”.

  2. Run your test scripts.

  3. Print the backtrace and the local variables at the three lowest levels. In gdb, you can do this with the following commands when mysqld has crashed inside gdb:

      ```
      backtrace
      info local
      up
      info local
      up
      info local
      ```

      With gdb, you can also examine which threads exist with info threads and switch to a specific thread with thread N, where N is the thread ID.

  • Try to simulate your application with a Perl script to force MySQL to crash or misbehave.

  • Send a normal bug report. See Section 1.7, “How to Report Bugs or Problems”. Be even more detailed than usual. Because MySQL works for many people, it may be that the crash results from
something that exists only on your computer (for example, an error that is related to your particular system libraries).

- If you have a problem with tables containing dynamic-length rows and you are using only VARCHAR columns (not BLOB or TEXT columns), you can try to change all VARCHAR to CHAR with ALTER TABLE. This forces MySQL to use fixed-size rows. Fixed-size rows take a little extra space, but are much more tolerant to corruption.

The current dynamic row code has been in use for several years with very few problems, but dynamic-length rows are by nature more prone to errors, so it may be a good idea to try this strategy to see whether it helps.

- Do not rule out your server hardware when diagnosing problems. Defective hardware can be the cause of data corruption. Particular attention should be paid to your memory and disk subsystems when troubleshooting hardware.

B.5.3.4 How MySQL Handles a Full Disk

This section describes how MySQL responds to disk-full errors (such as “no space left on device”), and to quota-exceeded errors (such as “write failed” or “user block limit reached”).

This section is relevant for writes to MyISAM tables. It also applies for writes to binary log files and binary log index file, except that references to “row” and “record” should be understood to mean “event.”

When a disk-full condition occurs, MySQL does the following:

- It checks once every minute to see whether there is enough space to write the current row. If there is enough space, it continues as if nothing had happened.

- Every 10 minutes it writes an entry to the log file, warning about the disk-full condition.

To alleviate the problem, you can take the following actions:

- To continue, you only have to free enough disk space to insert all records.

- To abort the thread, you must use mysqladmin kill. The thread is aborted the next time it checks the disk (in one minute).

- Other threads might be waiting for the table that caused the disk-full condition. If you have several “locked” threads, killing the one thread that is waiting on the disk-full condition enables the other threads to continue.

Exceptions to the preceding behavior are when you use REPAIR TABLE or OPTIMIZE TABLE or when the indexes are created in a batch after LOAD DATA INFILE or after an ALTER TABLE statement. All of these statements may create large temporary files that, if left to themselves, would cause big problems for the rest of the system. If the disk becomes full while MySQL is doing any of these operations, it removes the big temporary files and mark the table as crashed. The exception is that for ALTER TABLE, the old table is left unchanged.

B.5.3.5 Where MySQL Stores Temporary Files

On Unix, MySQL uses the value of the TMPDIR environment variable as the path name of the directory in which to store temporary files. If TMPDIR is not set, MySQL uses the system default, which is usually /tmp, /var/tmp, or /usr/tmp.

On Windows, Netware and OS2, MySQL checks in order the values of the TMPDIR, TEMP, and TMP environment variables. For the first one found to be set, MySQL uses it and does not check those remaining. If none of TMPDIR, TEMP, or TMP are set, MySQL uses the Windows system default, which is usually C:\windows\temp\.
If the file system containing your temporary file directory is too small, you can use the `mysqld --tmpdir` option to specify a directory in a file system where you have enough space. On replication slaves, you can use `--slave-load-tmpdir` to specify a separate directory for holding temporary files when replicating `LOAD DATA INFILE` statements.

The `--tmpdir` option can be set to a list of several paths that are used in round-robin fashion. Paths should be separated by colon characters (":") on Unix and semicolon characters (";") on Windows, NetWare, and OS/2.

**Note**
To spread the load effectively, these paths should be located on different physical disks, not different partitions of the same disk.

If the MySQL server is acting as a replication slave, you should be sure to set `--slave-load-tmpdir` not to point to a directory that is on a memory-based file system or to a directory that is cleared when the server host restarts. A replication slave needs some of its temporary files to survive a machine restart so that it can replicate temporary tables or `LOAD DATA INFILE` operations. If files in the slave temporary file directory are lost when the server restarts, replication fails.

MySQL arranges that temporary files are removed if `mysqld` is terminated. On platforms that support it (such as Unix), this is done by unlinking the file after opening it. The disadvantage of this is that the name does not appear in directory listings and you do not see a big temporary file that fills up the file system in which the temporary file directory is located. (In such cases, `lsof +L1` may be helpful in identifying large files associated with `mysqld`.)

When sorting (`ORDER BY` or `GROUP BY`), MySQL normally uses one or two temporary files. The maximum disk space required is determined by the following expression:

\[
\text{(length of what is sorted + sizeof(row pointer))} \\
\times \text{number of matched rows} \\
\times 2
\]

The row pointer size is usually four bytes, but may grow in the future for really big tables.

For some `SELECT` queries, MySQL also creates temporary SQL tables. These are not hidden and have names of the form `SQL_*`.

`ALTER TABLE` creates a temporary copy of the original table in the same directory as the original table.

### B.5.3.6 How to Protect or Change the MySQL Unix Socket File

The default location for the Unix socket file that the server uses for communication with local clients is `/tmp/mysql.sock`. (For some distribution formats, the directory might be different, such as `/var/lib/mysql` for RPMs.)

On some versions of Unix, anyone can delete files in the `/tmp` directory or other similar directories used for temporary files. If the socket file is located in such a directory on your system, this might cause problems.

On most versions of Unix, you can protect your `/tmp` directory so that files can be deleted only by their owners or the superuser (`root`). To do this, set the `sticky` bit on the `/tmp` directory by logging in as `root` and using the following command:

```
shell> chmod +t /tmp
```

You can check whether the `sticky` bit is set by executing `ls -ld /tmp`. If the last permission character is `t`, the bit is set.

Another approach is to change the place where the server creates the Unix socket file. If you do this, you should also let client programs know the new location of the file. You can specify the file location in several ways:
• Specify the path in a global or local option file. For example, put the following lines in `/etc/my.cnf`:

```ini
[mysqld]
socket=/path/to/socket

[client]
socket=/path/to/socket
```

See Section 4.2.6, “Using Option Files”.

• Specify a `--socket` option on the command line to `mysqld_safe` and when you run client programs.

• Set the `MYSQL_UNIX_PORT` environment variable to the path of the Unix socket file.

• Recompile MySQL from source to use a different default Unix socket file location. Define the path to the file with the `--with-unix-socket-path` option when you run `configure`. See Section 2.11.4, “MySQL Source-Configuration Options”.

You can test whether the new socket location works by attempting to connect to the server with this command:

```shell
shell> mysqladmin --socket=/path/to/socket version
```

### B.5.3.7 Time Zone Problems

If you have a problem with `SELECT NOW()` returning values in UTC and not your local time, you have to tell the server your current time zone. The same applies if `UNIX_TIMESTAMP()` returns the wrong value. This should be done for the environment in which the server runs; for example, in `mysqld_safe` or `mysql.server`. See Section 2.14, “Environment Variables”.

You can set the time zone for the server with the `--timezone=timezone_name` option to `mysqld_safe`. You can also set it by setting the `TZ` environment variable before you start `mysqld`.

The permissible values for `--timezone` or `TZ` are system dependent. Consult your operating system documentation to see what values are acceptable.

### B.5.4 Query-Related Issues

#### B.5.4.1 Case Sensitivity in String Searches

For nonbinary strings (CHAR, VARCHAR, TEXT), string searches use the collation of the comparison operands. For binary strings (BINARY, VARBINARY, BLOB), comparisons use the numeric values of the bytes in the operands; this means that for alphabetic characters, comparisons will be case sensitive.

A comparison between a nonbinary string and binary string is treated as a comparison of binary strings.

Simple comparison operations (>=, >, =, <, <=, sorting, and grouping) are based on each character’s “sort value.” Characters with the same sort value are treated as the same character. For example, if “é” and “ê” have the same sort value in a given collation, they compare as equal.

The default character set and collation are latin1 and latin1_swedish_ci, so nonbinary string comparisons are case insensitive by default. This means that if you search with `col_name LIKE 'a%'`, you get all column values that start with A or a. To make this search case sensitive, make sure that one of the operands has a case sensitive or binary collation. For example, if you are comparing a column and a string that both have the latin1 character set, you can use the COLLATE operator to cause either operand to have the latin1_general_cs or latin1_bin collation:

```sql
col_name COLLATE latin1_general_cs LIKE 'a%'
col_name LIKE 'a%' COLLATE latin1_general_cs
```
If you want a column always to be treated in case-sensitive fashion, declare it with a case sensitive or binary collation. See Section 13.1.17, “CREATE TABLE Syntax”.

To cause a case-sensitive comparison of nonbinary strings to be case insensitive, use `COLLATE` to name a case-insensitive collation. The strings in the following example normally are case sensitive, but `COLLATE` changes the comparison to be case insensitive:

```sql
mysql> SET @s1 = 'MySQL' COLLATE latin1_bin,
    -> @s2 = 'mysql' COLLATE latin1_bin;
mysql> SELECT @s1 = @s2;
+-----------+
| @s1 = @s2 |
+-----------+
|         0 |
mysql> SELECT @s1 COLLATE latin1_swedish_ci = @s2;
+-------------------------------------+
| @s1 COLLATE latin1_swedish_ci = @s2 |
+-------------------------------------+
|                                   1 |
```

A binary string is case sensitive in comparisons. To compare the string as case insensitive, convert it to a nonbinary string and use `COLLATE` to name a case-insensitive collation:

```sql
mysql> SET @s = BINARY 'MySQL';
mysql> SELECT @s = 'mysql';
+--------------+
| @s = 'mysql' |
+--------------+
|            0 |
mysql> SELECT CONVERT(@s USING latin1) COLLATE latin1_swedish_ci = 'mysql';
+--------------------------------------------------------------+
| CONVERT(@s USING latin1) COLLATE latin1_swedish_ci = 'mysql' |
+--------------------------------------------------------------+
|                                                            1 |
```

To determine whether a value will compare as a nonbinary or binary string, use the `COLLATION()` function. This example shows that `VERSION()` returns a string that has a case-insensitive collation, so comparisons are case insensitive:

```sql
mysql> SELECT COLLATION(VERSION());
+----------------------+
| COLLATION(VERSION()) |
+----------------------+
| utf8_general_ci      |
```

For binary strings, the collation value is `binary`, so comparisons will be case sensitive. One context in which you will see `binary` is for compression and encryption functions, which return binary strings as a general rule: string:

```sql
mysql> SELECT COLLATION(ENCRYPT('x')), COLLATION(SHA1('x'));
+-------------------------+----------------------+
| COLLATION(ENCRYPT('x')) | COLLATION(SHA1('x')) |
+-------------------------+----------------------+
| binary                  | binary               |
```

### B.5.4.2 Problems Using DATE Columns
The format of a \texttt{DATE} value is \texttt{'YYYY-MM-DD'}. According to standard SQL, no other format is permitted. You should use this format in \texttt{UPDATE} expressions and in the \texttt{WHERE} clause of \texttt{SELECT} statements. For example:

\begin{verbatim}
SELECT * FROM t1 WHERE date >= '2003-05-05';
\end{verbatim}

As a convenience, MySQL automatically converts a date to a number if the date is used in a numeric context and vice versa. MySQL also permits a “relaxed” string format when updating and in a \texttt{WHERE} clause that compares a date to a \texttt{DATE}, \texttt{DATETIME}, or \texttt{TIMESTAMP} column. “Relaxed” format means that any punctuation character may be used as the separator between parts. For example, \texttt{'2004-08-15'} and \texttt{'2004#08#15'} are equivalent. MySQL can also convert a string containing no separators (such as \texttt{'20040815'}), provided it makes sense as a date.

When you compare a \texttt{DATE}, \texttt{TIME}, \texttt{DATETIME}, or \texttt{TIMESTAMP} to a constant string with the \texttt{<}, \texttt{<=}, \texttt{=}, \texttt{>=}, \texttt{>}, or \texttt{BETWEEN} operators, MySQL normally converts the string to an internal long integer for faster comparison (and also for a bit more “relaxed” string checking). However, this conversion is subject to the following exceptions:

- When you compare two columns
- When you compare a \texttt{DATE}, \texttt{TIME}, \texttt{DATETIME}, or \texttt{TIMESTAMP} column to an expression
- When you use any comparison method other than those just listed, such as \texttt{IN} or \texttt{STRCMP()}

For those exceptions, the comparison is done by converting the objects to strings and performing a string comparison.

To be on the safe side, assume that strings are compared as strings and use the appropriate string functions if you want to compare a temporal value to a string.

The special "zero" date \texttt{'0000-00-00'} can be stored and retrieved as \texttt{'0000-00-00'}. When a \texttt{'0000-00-00'} date is used through Connector/ODBC, it is automatically converted to \texttt{NULL} because ODBC cannot handle that kind of date.

Because MySQL performs the conversions just described, the following statements work (assume that \texttt{idate} is a \texttt{DATE} column):

\begin{verbatim}
INSERT INTO t1 (idate) VALUES (19970505);
INSERT INTO t1 (idate) VALUES ('19970505');
INSERT INTO t1 (idate) VALUES ('97-05-05');
INSERT INTO t1 (idate) VALUES ('1997.05.05');
INSERT INTO t1 (idate) VALUES ('1997 05 05');
INSERT INTO t1 (idate) VALUES ('0000-00-00');

SELECT idate FROM t1 WHERE idate >= '1997-05-05';
SELECT idate FROM t1 WHERE idate >= 19970505;
SELECT MOD(idate,100) FROM t1 WHERE idate >= 19970505;
SELECT idate FROM t1 WHERE idate >= '19970505';
\end{verbatim}

However, the following statement does not work:

\begin{verbatim}
SELECT idate FROM t1 WHERE STRCMP(idate,'20030505')=0;
\end{verbatim}

\texttt{STRCMP()} is a string function, so it converts \texttt{idate} to a string in \texttt{'YYYY-MM-DD'} format and performs a string comparison. It does not convert \texttt{'20030505'} to the date \texttt{'2003-05-05'} and perform a date comparison.

If you enable the \texttt{ALLOW_INVALID_DATES} SQL mode, MySQL permits you to store dates that are given only limited checking: MySQL requires only that the day is in the range from 1 to 31 and the month is in the range from 1 to 12. This makes MySQL very convenient for Web applications where
you obtain year, month, and day in three different fields and you want to store exactly what the user inserted (without date validation).

MySQL permits you to store dates where the day or month and day are zero. This is convenient if you want to store a birthdate in a DATE column and you know only part of the date. To disallow zero month or day parts in dates, enable the NO_ZERO_IN_DATE SQL mode.

MySQL permits you to store a “zero” value of '0000-00-00' as a “dummy date.” This is in some cases more convenient than using NULL values. If a date to be stored in a DATE column cannot be converted to any reasonable value, MySQL stores '0000-00-00'. To disallow '0000-00-00', enable the NO_ZERO_DATE SQL mode.

To have MySQL check all dates and accept only legal dates (unless overridden by IGNORE), set the sql_mode system variable to "NO_ZERO_IN_DATE,NO_ZERO_DATE".

### B.5.4.3 Problems with NULL Values

The concept of the NULL value is a common source of confusion for newcomers to SQL, who often think that NULL is the same thing as an empty string ''). This is not the case. For example, the following statements are completely different:

```sql
mysql> INSERT INTO my_table (phone) VALUES (NULL);
mysql> INSERT INTO my_table (phone) VALUES ('');
```

Both statements insert a value into the phone column, but the first inserts a NULL value and the second inserts an empty string. The meaning of the first can be regarded as “phone number is not known” and the meaning of the second can be regarded as “the person is known to have no phone, and thus no phone number.”

To help with NULL handling, you can use the IS NULL and IS NOT NULL operators and the IFNULL() function.

In SQL, the NULL value is never true in comparison to any other value, even NULL. An expression that contains NULL always produces a NULL value unless otherwise indicated in the documentation for the operators and functions involved in the expression. All columns in the following example return NULL:

```sql
mysql> SELECT NULL, 1+NULL, CONCAT('Invisible',NULL);
```

To search for column values that are NULL, you cannot use an expr = NULL test. The following statement returns no rows, because expr = NULL is never true for any expression:

```sql
mysql> SELECT * FROM my_table WHERE phone = NULL;
```

To look for NULL values, you must use the IS NULL test. The following statements show how to find the NULL phone number and the empty phone number:

```sql
mysql> SELECT * FROM my_table WHERE phone IS NULL;
mysql> SELECT * FROM my_table WHERE phone = '';
```

See Section 3.3.4.6, “Working with NULL Values”, for additional information and examples.

You can add an index on a column that can have NULL values if you are using the MyISAM, InnoDB, or MEMORY storage engine. Otherwise, you must declare an indexed column NOT NULL, and you cannot insert NULL into the column.

When reading data with LOAD DATA INFILE, empty or missing columns are updated with ''. To load a NULL value into a column, use \N in the data file. The literal word "NULL" may also be used under some circumstances. See Section 13.2.6, “LOAD DATA INFILE Syntax”.

When using DISTINCT, GROUP BY, or ORDER BY, all NULL values are regarded as equal.
When using `ORDER BY`, NULL values are presented first, or last if you specify `DESC` to sort in descending order.

Aggregate (summary) functions such as `COUNT()`, `MIN()`, and `SUM()` ignore NULL values. The exception to this is `COUNT(*)`, which counts rows and not individual column values. For example, the following statement produces two counts. The first is a count of the number of rows in the table, and the second is a count of the number of non-NULL values in the `age` column:

```sql
mysql> SELECT COUNT(*), COUNT(age) FROM person;
```

For some data types, MySQL handles NULL values specially. If you insert NULL into a `TIMESTAMP` column, the current date and time is inserted. If you insert NULL into an integer or floating-point column that has the `AUTO_INCREMENT` attribute, the next number in the sequence is inserted.

### B.5.4.4 Problems with Column Aliases

An alias can be used in a query select list to give a column a different name. You can use the alias in `GROUP BY`, `ORDER BY`, or `HAVING` clauses to refer to the column:

```sql
SELECT SQRT(a*b) AS root FROM tbl_name
GROUP BY root HAVING root > 0;
```

```sql
SELECT id, COUNT(*) AS cnt FROM tbl_name
GROUP BY id HAVING cnt > 0;
```

```sql
SELECT id AS 'Customer identity' FROM tbl_name;
```

Standard SQL disallows references to column aliases in a `WHERE` clause. This restriction is imposed because when the `WHERE` clause is evaluated, the column value may not yet have been determined. For example, the following query is illegal:

```sql
SELECT id, COUNT(*) AS cnt FROM tbl_name WHERE cnt > 0 GROUP BY id;
```

The `WHERE` clause determines which rows should be included in the `GROUP BY` clause, but it refers to the alias of a column value that is not known until after the rows have been selected, and grouped by the `GROUP BY`.

In the select list of a query, a quoted column alias can be specified using identifier or string quoting characters:

```sql
SELECT 1 AS `one`, 2 AS 'two';
```

Elsewhere in the statement, quoted references to the alias must use identifier quoting or the reference is treated as a string literal. For example, this statement groups by the values in column `id`, referenced using the alias `a`:

```sql
SELECT id AS 'a', COUNT(*) AS cnt FROM tbl_name GROUP BY `a`;
```

But this statement groups by the literal string `'a` and will not work as expected:

```sql
SELECT id AS 'a', COUNT(*) AS cnt FROM tbl_name GROUP BY 'a';
```

### B.5.4.5 Rollback Failure for Nontransactional Tables

If you receive the following message when trying to perform a `ROLLBACK`, it means that one or more of the tables you used in the transaction do not support transactions:
Warning: Some non-transactional changed tables couldn't be rolled back

These nontransactional tables are not affected by the ROLLBACK statement.

If you were not deliberately mixing transactional and nontransactional tables within the transaction, the most likely cause for this message is that a table you thought was transactional actually is not. This can happen if you try to create a table using a transactional storage engine that is not supported by your mysqld server (or that was disabled with a startup option). If mysqld does not support a storage engine, it instead creates the table as a MyISAM table, which is nontransactional.

You can check the storage engine for a table by using either of these statements:

```sql
SHOW TABLE STATUS LIKE 'tbl_name';
SHOW CREATE TABLE tbl_name;
```

See Section 13.7.5.38, “SHOW TABLE STATUS Syntax”, and Section 13.7.5.12, “SHOW CREATE TABLE Syntax”.

You can check which storage engines your mysqld server supports by using this statement:

```sql
SHOW ENGINES;
```

You can also use the following statement, and check the value of the variable that is associated with the storage engine in which you are interested:

```sql
SHOW VARIABLES LIKE 'have_\%';
```

For example, to determine whether the InnoDB storage engine is available, check the value of the have_innodb variable.

See Section 13.7.5.17, “SHOW ENGINES Syntax”, and Section 13.7.5.41, “SHOW VARIABLES Syntax”.

**B.5.4.6 Deleting Rows from Related Tables**

If the total length of the DELETE statement for related_table is more than 1MB (the default value of the max_allowed_packet system variable), you should split it into smaller parts and execute multiple DELETE statements. You probably get the fastest DELETE by specifying only 100 to 1,000 related_column values per statement if the related_column is indexed. If the related_column isn't indexed, the speed is independent of the number of arguments in the IN clause.

**B.5.4.7 Solving Problems with No Matching Rows**

If you have a complicated query that uses many tables but that returns no rows, you should use the following procedure to find out what is wrong:

1. Test the query with EXPLAIN to check whether you can find something that is obviously wrong. See Section 13.8.2, “EXPLAIN Syntax”.
2. Select only those columns that are used in the WHERE clause.
3. Remove one table at a time from the query until it returns some rows. If the tables are large, it is a good idea to use LIMIT 10 with the query.
4. Issue a SELECT for the column that should have matched a row against the table that was last removed from the query.
5. If you are comparing FLOAT or DOUBLE columns with numbers that have decimals, you cannot use equality (=) comparisons. This problem is common in most computer languages because not all
floating-point values can be stored with exact precision. In some cases, changing the `FLOAT` to a `DOUBLE` fixes this. See Section B.5.4.8, “Problems with Floating-Point Values”.

6. If you still cannot figure out what is wrong, create a minimal test that can be run with `mysql test < query.sql` that shows your problems. You can create a test file by dumping the tables with `mysqldump --quick db_name tbl_name_1 ... tbl_name_n > query.sql`. Open the file in an editor, remove some insert lines (if there are more than needed to demonstrate the problem), and add your `SELECT` statement at the end of the file.

Verify that the test file demonstrates the problem by executing these commands:

```
shell> mysqladmin create test2
shell> mysql test2 < query.sql
```

Attach the test file to a bug report, which you can file using the instructions in Section 1.7, “How to Report Bugs or Problems”.

### B.5.4.8 Problems with Floating-Point Values

Floating-point numbers sometimes cause confusion because they are approximate and not stored as exact values. A floating-point value as written in an SQL statement may not be the same as the value represented internally. Attempts to treat floating-point values as exact in comparisons may lead to problems. They are also subject to platform or implementation dependencies. The `FLOAT` and `DOUBLE` data types are subject to these issues. For `DECIMAL` columns, MySQL performs operations with a precision of 65 decimal digits, which should solve most common inaccuracy problems.

The following example uses `DOUBLE` to demonstrate how calculations that are done using floating-point operations are subject to floating-point error.

```
mysql> CREATE TABLE t1 (i INT, d1 DOUBLE, d2 DOUBLE);
mysql> INSERT INTO t1 VALUES (1, 101.40, 21.40), (1, -80.00, 0.00),
    -> (2, 0.00, 0.00), (2, -13.20, 0.00), (2, 59.60, 46.40),
    -> (3, 37.00, 7.40), (3, -29.60, 0.00),
    -> (4, 60.00, 15.40), (4, -10.60, 0.00), (4, -34.00, 0.00),
    -> (5, 33.00, 0.00), (5, -25.80, 0.00), (5, 0.00, 7.20),
    -> (6, 0.00, 0.00), (6, -51.40, 0.00);
mysql> SELECT i, SUM(d1) AS a, SUM(d2) AS b
    -> FROM t1 GROUP BY i HAVING a <> b;
```

<table>
<thead>
<tr>
<th>i</th>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>21.4</td>
<td>21.4</td>
</tr>
<tr>
<td>2</td>
<td>76.8</td>
<td>76.8</td>
</tr>
<tr>
<td>3</td>
<td>7.4</td>
<td>7.4</td>
</tr>
<tr>
<td>4</td>
<td>15.4</td>
<td>15.4</td>
</tr>
<tr>
<td>5</td>
<td>7.2</td>
<td>7.2</td>
</tr>
<tr>
<td>6</td>
<td>-51.4</td>
<td>0</td>
</tr>
</tbody>
</table>

The result is correct. Although the first five records look like they should not satisfy the comparison (the values of `a` and `b` do not appear to be different), they may do so because the difference between the numbers shows up around the tenth decimal or so, depending on factors such as computer architecture or the compiler version or optimization level. For example, different CPUs may evaluate floating-point numbers differently.

If columns `d1` and `d2` had been defined as `DECIMAL` rather than `DOUBLE`, the result of the `SELECT` query would have contained only one row—the last one shown above.

The correct way to do floating-point number comparison is to first decide on an acceptable tolerance for differences between the numbers and then do the comparison against the tolerance value. For example, if we agree that floating-point numbers should be regarded the same if they are same within
a precision of one in ten thousand (0.0001), the comparison should be written to find differences larger than the tolerance value:

```sql
mysql> SELECT i, SUM(d1) AS a, SUM(d2) AS b FROM t1
    -> GROUP BY i HAVING ABS(a - b) > 0.0001;
```

<table>
<thead>
<tr>
<th>i</th>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td>-51.4</td>
<td>0</td>
</tr>
</tbody>
</table>

1 row in set (0.00 sec)

Conversely, to get rows where the numbers are the same, the test should find differences within the tolerance value:

```sql
mysql> SELECT i, SUM(d1) AS a, SUM(d2) AS b FROM t1
    -> GROUP BY i HAVING ABS(a - b) <= 0.0001;
```

<table>
<thead>
<tr>
<th>i</th>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>21.4</td>
<td>21.4</td>
</tr>
<tr>
<td>2</td>
<td>76.8</td>
<td>76.8</td>
</tr>
<tr>
<td>3</td>
<td>7.4</td>
<td>7.4</td>
</tr>
<tr>
<td>4</td>
<td>15.4</td>
<td>15.4</td>
</tr>
<tr>
<td>5</td>
<td>7.2</td>
<td>7.2</td>
</tr>
</tbody>
</table>

5 rows in set (0.03 sec)

Floating-point values are subject to platform or implementation dependencies. Suppose that you execute the following statements:

```sql
CREATE TABLE t1(c1 FLOAT(53,0), c2 FLOAT(53,0));
INSERT INTO t1 VALUES('1e+52','-1e+52');
SELECT * FROM t1;
```

On some platforms, the `SELECT` statement returns `inf` and `-inf`. On others, it returns `0` and `-0`.

An implication of the preceding issues is that if you attempt to create a replication slave by dumping table contents with `mysqldump` on the master and reloading the dump file into the slave, tables containing floating-point columns might differ between the two hosts.

**B.5.5 Optimizer-Related Issues**

MySQL uses a cost-based optimizer to determine the best way to resolve a query. In many cases, MySQL can calculate the best possible query plan, but sometimes MySQL does not have enough information about the data at hand and has to make “educated” guesses about the data.

For the cases when MySQL does not do the “right” thing, tools that you have available to help MySQL are:

- Use the `EXPLAIN` statement to get information about how MySQL processes a query. To use it, just add the keyword `EXPLAIN` to the front of your `SELECT` statement:

```sql
mysql> EXPLAIN SELECT * FROM t1, t2 WHERE t1.i = t2.i;
```

`EXPLAIN` is discussed in more detail in Section 13.8.2, “EXPLAIN Syntax”.

- Use `ANALYZE TABLE tbl_name` to update the key distributions for the scanned table. See Section 13.7.2.1, “ANALYZE TABLE Syntax”.

- Use `FORCE INDEX` for the scanned table to tell MySQL that table scans are very expensive compared to using the given index:
B.5.6 Table Definition-Related Issues

B.5.6.1 Problems with ALTER TABLE

If you get a duplicate-key error when using `ALTER TABLE` to change the character set or collation of a character column, the cause is either that the new column collation maps two keys to the same value or that the table is corrupted. In the latter case, you should run `REPAIR TABLE` on the table.

If `ALTER TABLE` dies with the following error, the problem may be that MySQL crashed during an earlier `ALTER TABLE` operation and there is an old table named `A-xxx` or `B-xxx` lying around:

```
Error on rename of './database/name.frm' to './database/B-xxx.frm' (Errcode: 17)
```

In this case, go to the MySQL data directory and delete all files that have names starting with `A-` or `B-`.

(You may want to move them elsewhere instead of deleting them.)

`ALTER TABLE` works in the following way:

- Create a new table named `A-xxx` with the requested structural changes.
- Copy all rows from the original table to `A-xxx`.
- Rename the original table to `B-xxx`.
- Rename `A-xxx` to your original table name.
- Delete `B-xxx`.

If something goes wrong with the renaming operation, MySQL tries to undo the changes. If something goes seriously wrong (although this shouldn't happen), MySQL may leave the old table as `B-xxx`. A simple rename of the table files at the system level should get your data back.

If you use `ALTER TABLE` on a transactional table or if you are using Windows or OS/2, `ALTER TABLE` unlocks the table if you had done a `LOCK TABLE` on it. This is done because InnoDB and these operating systems cannot drop a table that is in use.

B.5.6.2 TEMPORARY Table Problems

The following list indicates limitations on the use of `TEMPORARY` tables:

- A `TEMPORARY` table can only be of type `MEMORY`, `MyISAM`, `MERGE`, or `InnoDB`.

  Temporary tables are not supported for MySQL Cluster.

- You cannot refer to a `TEMPORARY` table more than once in the same query. For example, the following does not work:
mysql> SELECT * FROM temp_table, temp_table AS t2;
ERROR 1137: Can't reopen table: 'temp_table'

This error also occurs if you refer to a temporary table multiple times in a stored function under different aliases, even if the references occur in different statements within the function.

• The SHOW TABLES statement does not list TEMPORARY tables.

• You cannot use RENAME to rename a TEMPORARY table. However, you can use ALTER TABLE instead:

mysql> ALTER TABLE orig_name RENAME new_name;

• There are known issues in using temporary tables with replication. See Section 16.4.1, “Replication Features and Issues”, for more information.

B.5.7 Known Issues in MySQL

This section lists known issues in recent versions of MySQL.

For information about platform-specific issues, see the installation and porting instructions in Section 2.1, “General Installation Guidance”, and Section 22.4, “Debugging and Porting MySQL”.

The following problems are known:

• Subquery optimization for IN is not as effective as for =.

• Even if you use lower_case_table_names=2 (which enables MySQL to remember the case used for databases and table names), MySQL does not remember the case used for database names for the function DATABASE() or within the various logs (on case-insensitive systems).

• Dropping a FOREIGN KEY constraint does not work in replication because the constraint may have another name on the slave.

• REPLACE (and LOAD DATA with the REPLACE option) does not trigger ON DELETE CASCADE.

• DISTINCT with ORDER BY does not work inside GROUP_CONCAT() if you do not use all and only those columns that are in the DISTINCT list.

• If one user has a long-running transaction and another user drops a table that is updated in the transaction, there is small chance that the binary log may contain the DROP TABLE statement before the table is used in the transaction itself.

• When inserting a big integer value (between 2^{63} and 2^{64}−1) into a decimal or string column, it is inserted as a negative value because the number is evaluated in a signed integer context.

• FLUSH TABLES WITH READ LOCK does not block COMMIT if the server is running without binary logging, which may cause a problem (of consistency between tables) when doing a full backup.

• ANALYZE TABLE, OPTIMIZE TABLE, and REPAIR TABLE may cause problems on tables for which you are using INSERT DELAYED.

• Performing LOCK TABLE ... and FLUSH TABLES does not guarantee that there isn't a half-finished transaction in progress on the table.

• With statement-based binary logging, the master writes the executed queries to the binary log. This is a very fast, compact, and efficient logging method that works perfectly in most cases. However, it is possible for the data on the master and slave to become different if a query is designed in such a way that the data modification is nondeterministic (generally not a recommended practice, even outside of replication).

For example:
• **CREATE TABLE ... SELECT** or **INSERT ... SELECT** statements that insert zero or **NULL** values into an **AUTO_INCREMENT** column.

• **DELETE** if you are deleting rows from a table that has foreign keys with **ON DELETE CASCADE** properties.

• **REPLACE ... SELECT, INSERT IGNORE ... SELECT** if you have duplicate key values in the inserted data.

If and only if the preceding queries have no **ORDER BY** clause guaranteeing a deterministic order.

For example, for **INSERT ... SELECT** with no **ORDER BY**, the **SELECT** may return rows in a different order (which results in a row having different ranks, hence getting a different number in the **AUTO_INCREMENT** column), depending on the choices made by the optimizers on the master and slave.

A query is optimized differently on the master and slave only if:

• The table is stored using a different storage engine on the master than on the slave. (It is possible to use different storage engines on the master and slave. For example, you can use **InnoDB** on the master, but **MyISAM** on the slave if the slave has less available disk space.)

• MySQL buffer sizes (**key_buffer_size**, and so on) are different on the master and slave.

• The master and slave run different MySQL versions, and the optimizer code differs between these versions.

This problem may also affect database restoration using **mysqlbinlog|mysql**.

The easiest way to avoid this problem is to add an **ORDER BY** clause to the aforementioned nondeterministic queries to ensure that the rows are always stored or modified in the same order. Using row-based or mixed logging format also avoids the problem.

• Log file names are based on the server host name if you do not specify a file name with the startup option. To retain the same log file names if you change your host name to something else, you must explicitly use options such as **--log-bin=old_host_name-bin**. See Section 5.1.3, “Server Command Options”. Alternatively, rename the old files to reflect your host name change. If these are binary logs, you must edit the binary log index file and fix the binary log file names there as well. (The same is true for the relay logs on a slave server.)

• **mysqlbinlog** does not delete temporary files left after a **LOAD DATA INFILE** statement. See Section 4.6.7, “**mysqlbinlog** — Utility for Processing Binary Log Files”.

• **RENAME** does not work with **TEMPORARY** tables or tables used in a **MERGE** table.

• Due to the way table format (.frm) files are stored, you cannot use character 255 (**CHAR(255)**) in table names, column names, or enumerations.

• When using **SET CHARACTER SET**, you cannot use translated characters in database, table, and column names.

• You cannot use “_” or “%” with **ESCAPE** in **LIKE ... ESCAPE**.

• The server uses only the first **max_sort_length** bytes when comparing data values. This means that values cannot reliably be used in **GROUP BY, ORDER BY, or DISTINCT** if they differ only after the first **max_sort_length** bytes. To work around this, increase the variable value. The default value of **max_sort_length** is 1024 and can be changed at server startup time or at runtime.

• Numeric calculations are done with **BIGINT** or **DOUBLE** (both are normally 64 bits long). Which precision you get depends on the function. The general rule is that bit functions are performed with
**BIGINT** precision, **IF()** and **ELT()** with **BIGINT** or **DOUBLE** precision, and the rest with **DOUBLE** precision. You should try to avoid using unsigned long long values if they resolve to be larger than 63 bits (9223372036854775807) for anything other than bit fields.

- You can have up to 255 **ENUM** and **SET** columns in one table.

- In **MIN()**, **MAX()**, and other aggregate functions, MySQL currently compares **ENUM** and **SET** columns by their string value rather than by the string's relative position in the set.

- In an **UPDATE** statement, columns are updated from left to right. If you refer to an updated column, you get the updated value instead of the original value. For example, the following statement increments **KEY** by 2, **not 1**:

  ```sql
  mysql> UPDATE tbl_name SET KEY=KEY+1,KEY=KEY+1;
  ```

- You can refer to multiple temporary tables in the same query, but you cannot refer to any given temporary table more than once. For example, the following does not work:

  ```sql
  mysql> SELECT * FROM temp_table, temp_table AS t2;
  ERROR 1137: Can't reopen table: 'temp_table'
  ```

- The optimizer may handle **DISTINCT** differently when you are using “hidden” columns in a join than when you are not. In a join, hidden columns are counted as part of the result (even if they are not shown), whereas in normal queries, hidden columns do not participate in the **DISTINCT** comparison.

  An example of this is:

  ```sql
  SELECT DISTINCT mp3id FROM band_downloads
  WHERE userid = 9 ORDER BY id DESC;
  ```

  and

  ```sql
  SELECT DISTINCT band_downloads.mp3id
  FROM band_downloads,band_mp3
  WHERE band_downloads.userid = 9
  AND band_mp3.id = band_downloads.mp3id
  ORDER BY band_downloads.id DESC;
  ```

  In the second case, using MySQL Server 3.23.x, you may get two identical rows in the result set (because the values in the hidden **id** column may differ).

  Note that this happens only for queries that do not have the **ORDER BY** columns in the result.

- If you execute a **PROCEDURE** on a query that returns an empty set, in some cases the **PROCEDURE** does not transform the columns.

- Creation of a table of type **MERGE** does not check whether the underlying tables are compatible types.

- If you use **ALTER TABLE** to add a **UNIQUE** index to a table used in a **MERGE** table and then add a normal index on the **MERGE** table, the key order is different for the tables if there was an old, non-**UNIQUE** key in the table. This is because **ALTER TABLE** puts **UNIQUE** indexes before normal indexes to be able to detect duplicate keys as early as possible.

The discussion here describes restrictions that apply to the use of MySQL features such as subqueries or views.

C.1 Restrictions on Stored Programs

These restrictions apply to the features described in Chapter 19, Stored Programs and Views.

Some of the restrictions noted here apply to all stored routines; that is, both to stored procedures and stored functions. There are also some restrictions specific to stored functions but not to stored procedures.

The restrictions for stored functions also apply to triggers. There are also some restrictions specific to triggers.

The restrictions for stored procedures also apply to the DO clause of Event Scheduler event definitions. There are also some restrictions specific to events.

SQL Statements Not Permitted in Stored Routines

Stored routines cannot contain arbitrary SQL statements. The following statements are not permitted:

- The locking statements LOCK TABLES and UNLOCK TABLES.
- ALTER VIEW. (Before MySQL 5.1.21, this restriction is enforced only for stored functions.)
- LOAD DATA and LOAD TABLE.
- SQL prepared statements (PREPARE, EXECUTE, DEALLOCATE PREPARE) can be used in stored procedures, but not stored functions or triggers. Thus, stored functions and triggers cannot use dynamic SQL (where you construct statements as strings and then execute them).
- Generally, statements not permitted in SQL prepared statements are also not permitted in stored programs. For a list of statements supported as prepared statements, see Section 13.5, “SQL Syntax for Prepared Statements”.
- Because local variables are in scope only during stored program execution, references to them are not permitted in prepared statements created within a stored program. Prepared statement scope is the current session, not the stored program, so the statement could be executed after the program ends, at which point the variables would no longer be in scope. For example, SELECT ... INTO local_var cannot be used as a prepared statement. This restriction also applies to stored procedure and function parameters. See Section 13.5.1, “PREPARE Syntax”.

2687
Restrictions for Stored Functions

- Inserts cannot be delayed. `INSERT DELAYED` syntax is accepted, but the statement is handled as a normal `INSERT`.

- Within all stored programs (stored procedures and functions, triggers, and events), the parser treats `BEGIN [WORK]` as the beginning of a `BEGIN ... END` block. To begin a transaction in this context, use `START TRANSACTION` instead.

Restrictions for Stored Functions

The following additional statements or operations are not permitted within stored functions. They are permitted within stored procedures, except stored procedures that are invoked from within a stored function or trigger. For example, if you use `FLUSH` in a stored procedure, that stored procedure cannot be called from a stored function or trigger.

- Statements that perform explicit or implicit commit or rollback. Support for these statements is not required by the SQL standard, which states that each DBMS vendor may decide whether to permit them.

- Statements that return a result set. This includes `SELECT` statements that do not have an `INTO var_list` clause and other statements such as `SHOW`, `EXPLAIN`, and `CHECK TABLE`. A function can process a result set either with `SELECT ... INTO var_list` or by using a cursor and `FETCH` statements. See Section 13.2.8.1, “SELECT ... INTO Syntax”, and Section 13.6.6, “Cursors”.

- `FLUSH` statements.

- Stored functions cannot be used recursively.

- A stored function or trigger cannot modify a table that is already being used (for reading or writing) by the statement that invoked the function or trigger.

- If you refer to a temporary table multiple times in a stored function under different aliases, a `Can't reopen table: 'tbl_name'` error occurs, even if the references occur in different statements within the function.

Restrictions for Triggers

For triggers, the following additional restrictions apply:

- Triggers are not activated by foreign key actions.

- When using row-based replication, triggers on the slave are not activated by statements originating on the master. The triggers on the slave are activated when using statement-based replication. For more information, see Section 16.4.1.36, “Replication and Triggers”.

- The `RETURN` statement is not permitted in triggers, which cannot return a value. To exit a trigger immediately, use the `LEAVE` statement.

- Triggers are not permitted on tables in the `mysql` database.

- The trigger cache does not detect when metadata of the underlying objects has changed. If a trigger uses a table and the table has changed since the trigger was loaded into the cache, the trigger operates using the outdated metadata.

Restrictions on Calling Stored Procedures

Before MySQL 5.1.4, `CALL` statements cannot be prepared, meaning that stored procedures cannot be called from dynamic SQL. This is true both for server-side prepared statements and for SQL prepared statements.

Name Conflicts within Stored Routines

The same identifier might be used for a routine parameter, a local variable, and a table column. Also, the same local variable name can be used in nested blocks. For example:
CREATE PROCEDURE p (i INT)
BEGIN
  DECLARE i INT DEFAULT 0;
  SELECT i FROM t;
BEGIN
  DECLARE i INT DEFAULT 1;
  SELECT i FROM t;
END;
END;

In such cases, the identifier is ambiguous and the following precedence rules apply:

- A local variable takes precedence over a routine parameter or table column.
- A routine parameter takes precedence over a table column.
- A local variable in an inner block takes precedence over a local variable in an outer block.

The behavior that variables take precedence over table columns is nonstandard.

**Replication Considerations**

Use of stored routines can cause replication problems. This issue is discussed further in Section 19.7, “Binary Logging of Stored Programs”.

The `--replicate-wild-do-table=db_name.tbl_name` option applies to tables, views, and triggers. It does not apply to stored procedures and functions, or events. To filter statements operating on the latter objects, use one or more of the `--replicate-*/-db` options.

**Introspection Considerations**

`INFORMATION_SCHEMA` does not have a `PARAMETERS` table until MySQL 5.5; this table enables stored routines or client applications to determine the names, types, and default values of parameters for stored routines. For releases without this `INFORMATION_SCHEMA.PARAMETERS` table, to examine these types of metadata, you must use workarounds such as parsing the output of `SHOW CREATE` statements or the `param_list` column of the `mysql.proc` table. `param_list` contents can be processed from within a stored routine, unlike the output from `SHOW`.

**Debugging Considerations**

There are no stored routine debugging facilities.

**Unsupported Syntax from the SQL:2003 Standard**

The MySQL stored routine syntax is based on the SQL:2003 standard. The following items from that standard are not currently supported:

- `UNDO` handlers
- `FOR` loops

**Concurrency Considerations**

To prevent problems of interaction between sessions, when a client issues a statement, the server uses a snapshot of routines and triggers available for execution of the statement. That is, the server calculates a list of procedures, functions, and triggers that may be used during execution of the statement, loads them, and then proceeds to execute the statement. While the statement executes, it does not see changes to routines performed by other sessions.

For maximum concurrency, stored functions should minimize their side-effects; in particular, updating a table within a stored function can reduce concurrent operations on that table. A stored function acquires table locks before executing, to avoid inconsistency in the binary log due to mismatch of the order in which statements execute and when they appear in the log. When statement-based binary
logging is used, statements that invoke a function are recorded rather than the statements executed within the function. Consequently, stored functions that update the same underlying tables do not execute in parallel. In contrast, stored procedures do not acquire table-level locks. All statements executed within stored procedures are written to the binary log, even for statement-based binary logging. See Section 19.7, “Binary Logging of Stored Programs”.

Event Scheduler Restrictions

The following limitations are specific to the Event Scheduler:

- In MySQL 5.1.6 only, any table referenced in an event's action statement must be fully qualified with the name of the schema in which it occurs (that is, as `schema_name.table_name`).

- Beginning with MySQL 5.1.8, event names are handled in case-insensitive fashion. For example, this means that you cannot have two events in the same database (and—prior to MySQL 5.1.12—with the same definer) with the names `anEvent` and `AnEvent`.

  ![Important]

  If you have events created in MySQL 5.1.7 or earlier which are assigned to the same database and have the same definer, and whose names differ only with respect to lettercase, then you must rename these events to respect case-sensitive handling before upgrading to MySQL 5.1.8 or later.

- An event may not be created, altered, or dropped by a stored routine, trigger, or another event. An event also may not create, alter, or drop stored routines or triggers. (Bug #16409, Bug #18896)

- Event timings using the intervals `YEAR`, `QUARTER`, `MONTH`, and `YEAR_MONTH` are resolved in months; those using any other interval are resolved in seconds. There is no way to cause events scheduled to occur at the same second to execute in a given order. In addition—due to rounding, the nature of threaded applications, and the fact that a nonzero length of time is required to create events and to signal their execution—events may be delayed by as much as 1 or 2 seconds. However, the time shown in the `INFORMATION_SCHEMA.EVENTS` table's `LAST_EXECUTED` column or the `mysql.event` table's `last_executed` column is always accurate to within one second of the actual event execution time. (See also Bug #16522.)

- Each execution of the statements contained in the body of an event takes place in a new connection; thus, these statements has no effect in a given user session on the server's statement counts such as `Com_select` and `Com_insert` that are displayed by `SHOW STATUS`. However, such counts are updated in the global scope. (Bug #16422)

- Prior to MySQL 5.1.12, you could not view another user's events in the `INFORMATION_SCHEMA.EVENTS` table. In other words, any query made against this table was treated as though it contained the condition `DEFINER = CURRENT_USER()` in the `WHERE` clause.

- Events do not support times later than the end of the Unix Epoch; this is approximately the beginning of the year 2038. Prior to MySQL 5.1.8, handling in scheduled events of dates later than this was buggy; starting with MySQL 5.1.8, such dates are specifically not permitted by the Event Scheduler. (Bug #16396)

- In MySQL 5.1.6, `INFORMATION_SCHEMA.EVENTS` shows `NULL` in the `SQL_MODE` column. Beginning with MySQL 5.1.7, the `SQL_MODE` displayed is that in effect when the event was created.

- In MySQL 5.1.6, the only way to drop or alter an event created by a user who was not the definer of that event was by manipulation of the `mysql.event` system table by the MySQL root user or by another user with privileges on this table. Beginning with MySQL 5.1.7, `DROP USER` drops all events for which that user was the definer; also beginning with MySQL 5.1.7 `DROP SCHEMA` drops all events associated with the dropped schema.

- References to stored functions, user-defined functions, and tables in the `ON SCHEDULE` clauses of `CREATE EVENT` and `ALTER EVENT` statements are not supported. Beginning with MySQL 5.1.13, these sorts of references are not permitted. (See Bug #22830 for more information.)
• Generally speaking, statements that are not permitted in stored routines or in SQL prepared statements are also not permitted in the body of an event. For more information, see Section 13.5, “SQL Syntax for Prepared Statements”.

• When upgrading to MySQL 5.1.18 or 5.1.19 from a previous MySQL version where scheduled events were in use, the upgrade utilities `mysql_upgrade` and `mysql_fix_privilege_tables` do not accommodate changes in system tables relating to the Event Scheduler. This issue was fixed in MySQL 5.1.20 (see Bug #28521).

**Stored routines and triggers in MySQL Cluster.** Stored procedures, stored functions, and triggers are all supported by tables using the NDB storage engine; however, it is important to keep in mind that they do not propagate automatically between MySQL Servers acting as Cluster SQL nodes. This is because of the following:

- Stored routine definitions are kept in tables in the `mysql` system database using the MyISAM storage engine, and so do not participate in clustering.
- The `.TRN` and `.TRG` files containing trigger definitions are not read by the NDB storage engine, and are not copied between Cluster nodes.

Any stored routine or trigger that interacts with MySQL Cluster tables must be re-created by running the appropriate `CREATE PROCEDURE`, `CREATE FUNCTION`, or `CREATE TRIGGER` statements on each MySQL Server that participates in the cluster where you wish to use the stored routine or trigger. Similarly, any changes to existing stored routines or triggers must be carried out explicitly on all Cluster SQL nodes, using the appropriate `ALTER` or `DROP` statements on each MySQL Server accessing the cluster.

**Warning**

Do not attempt to work around the issue described in the first item mentioned previously by converting any `mysql` database tables to use the NDB storage engine. *Altering the system tables in the mysql database is not supported and is very likely to produce undesirable results.*

### C.2 Restrictions on Server-Side Cursors

Server-side cursors are implemented in the C API using the `mysql_stmt_attr_set()` function. The same implementation is used for cursors in stored routines. A server-side cursor enables a result set to be generated on the server side, but not transferred to the client except for those rows that the client requests. For example, if a client executes a query but is only interested in the first row, the remaining rows are not transferred.

In MySQL, a server-side cursor is materialized into an internal temporary table. Initially, this is a MEMORY table, but is converted to a MyISAM table when its size exceeds the minimum value of the `max_heap_table_size` and `tmp_table_size` system variables. The same restrictions apply to internal temporary tables created to hold the result set for a cursor as for other uses of internal temporary tables. See Section 8.4.4, “Internal Temporary Table Use in MySQL”. One limitation of the implementation is that for a large result set, retrieving its rows through a cursor might be slow.

Cursors are read only; you cannot use a cursor to update rows.

`UPDATE WHERE CURRENT OF` and `DELETE WHERE CURRENT OF` are not implemented, because updatable cursors are not supported.

Cursors are nonholdable (not held open after a commit).  
Cursors are asensitive.  
Cursors are nonscrollable.  
Cursors are not named. The statement handler acts as the cursor ID.
You can have open only a single cursor per prepared statement. If you need several cursors, you must prepare several statements.

You cannot use a cursor for a statement that generates a result set if the statement is not supported in prepared mode. This includes statements such as `CHECK TABLE`, `HANDLER READ`, and `SHOW BINLOG EVENTS`.

### C.3 Restrictions on Subqueries

- In MySQL 5.1 before 5.1.16, if you compare a `NULL` value to a subquery using `ALL`, `ANY`, or `SOME`, and the subquery returns an empty result, the comparison might evaluate to the nonstandard result of `NULL` rather than to `TRUE` or `FALSE`. As of 5.1.16, the comparison evaluates to `TRUE` or `FALSE` except for subqueries inside `IS NULL`, such as this:

```
SELECT ... WHERE NULL IN (SELECT ...) IS NULL
```

As of 5.1.32, the `IS NULL` limitation is removed and the comparison evaluates to `TRUE` or `FALSE`.

- Subquery optimization for `IN` is not as effective as for the `=` operator or for the `IN(value_list)` operator.

A typical case for poor `IN` subquery performance is when the subquery returns a small number of rows but the outer query returns a large number of rows to be compared to the subquery result.

The problem is that, for a statement that uses an `IN` subquery, the optimizer rewrites it as a correlated subquery. Consider the following statement that uses an uncorrelated subquery:

```
SELECT ... FROM t1 WHERE t1.a IN (SELECT b FROM t2);
```

The optimizer rewrites the statement to a correlated subquery:

```
SELECT ... FROM t1 WHERE EXISTS (SELECT 1 FROM t2 WHERE t2.b = t1.a);
```

If the inner and outer queries return `M` and `N` rows, respectively, the execution time becomes on the order of `O(MN)`, rather than `O(M+N)` as it would be for an uncorrelated subquery.

An implication is that an `IN` subquery can be much slower than a query written using an `IN(value_list)` operator that lists the same values that the subquery would return.

- In general, you cannot modify a table and select from the same table in a subquery. For example, this limitation applies to statements of the following forms:

```
DELETE FROM t WHERE ... (SELECT ... FROM t ...);
UPDATE t ... WHERE col = (SELECT ... FROM t ...);
{INSERT|REPLACE} INTO t (SELECT ... FROM t ...);
```

Exception: The preceding prohibition does not apply if you are using a subquery for the modified table in the `FROM` clause. Example:

```
UPDATE t ... WHERE col = (SELECT * FROM (SELECT ... FROM t...) AS _t ...);
```

Here the result from the subquery in the `FROM` clause is stored as a temporary table, so the relevant rows in `t` have already been selected by the time the update to `t` takes place.

- Row comparison operations are only partially supported:

  - For `expr [NOT] IN subquery`, `expr` can be an `n`-tuple (specified using row constructor syntax) and the subquery can return rows of `n`-tuples. The permitted syntax is therefore more specifically expressed as `row_constructor [NOT] IN table_subquery`
Restrictions on Subqueries

- For \( expr \ op \{\text{ALL}|\text{ANY}|\text{SOME}\} \ subquery, \ expr \) must be a scalar value and the subquery must be a column subquery; it cannot return multiple-column rows.

In other words, for a subquery that returns rows of \( n \)-tuples, this is supported:

\[
\begin{align*}
(expr_1, \ldots, expr_n) \ [\text{NOT}] & \ \text{IN table_subquery} \\
\end{align*}
\]

But this is not supported:

\[
\begin{align*}
(expr_1, \ldots, expr_n) \ op \{\text{ALL}|\text{ANY}|\text{SOME}\} \ subquery \\
\end{align*}
\]

The reason for supporting row comparisons for IN but not for the others is that IN is implemented by rewriting it as a sequence of = comparisons and \text{AND} operations. This approach cannot be used for ALL, ANY, or SOME.

- Prior to MySQL 5.1.12, row constructors were not well optimized; of the following two equivalent expressions, only the second could be optimized:

\[
\begin{align*}
(col1, col2, \ldots) & = (val1, val2, \ldots) \\
\text{col1} & = \text{val1} \ \text{AND} \ \text{col2} = \text{val2} \ \text{AND} \ \ldots \\
\end{align*}
\]

In MySQL 5.1.12 and later, all row equalities are converted into conjunctions of equalities between row elements, and handled by the optimizer in the same way. (Bug #16081)

- Subqueries in the FROM clause cannot be correlated subqueries. They are materialized in whole (evaluated to produce a result set) before evaluating the outer query, so they cannot be evaluated per row of the outer query.

- MySQL does not support LIMIT in subqueries for certain subquery operators:

\[
\begin{align*}
\text{mysql} \geq & \ \text{SELECT * FROM t1} \\
\text{--> } & \ \text{WHERE s1 IN (SELECT s2 FROM t2 ORDER BY s1 LIMIT 1)}; \\
\text{ERROR 1235 (42000): This version of MySQL doesn't yet support} \\
\text{'LIMIT & IN/ALL/ANY/SOME subquery'} \\
\end{align*}
\]

- The optimizer is more mature for joins than for subqueries, so in many cases a statement that uses a subquery can be executed more efficiently if you rewrite it as a join.

An exception occurs for the case where an IN subquery can be rewritten as a SELECT DISTINCT join. Example:

\[
\begin{align*}
\text{SELECT col FROM t1 WHERE id_{col} IN (SELECT id_{col2} FROM t2 WHERE condition);} \\
\end{align*}
\]

That statement can be rewritten as follows:

\[
\begin{align*}
\text{SELECT DISTINCT col FROM t1, t2 WHERE t1.id_{col} = t2.id_{col} AND condition;}
\end{align*}
\]

But in this case, the join requires an extra DISTINCT operation and is not more efficient than the subquery.

- MySQL permits a subquery to refer to a stored function that has data-modifying side effects such as inserting rows into a table. For example, if \( f() \) inserts rows, the following query can modify data:

\[
\begin{align*}
\text{SELECT ... WHERE x IN (SELECT f() ...);} \\
\end{align*}
\]

This behavior is an extension to the SQL standard. In MySQL, it can produce indeterminate results because \( f() \) might be executed a different number of times for different executions of a given query depending on how the optimizer chooses to handle it.

2693
For statement-based or mixed-format replication, one implication of this indeterminism is that such a query can produce different results on the master and its slaves.

C.4 Restrictions on Views

View processing is not optimized:

- It is not possible to create an index on a view.
- Indexes can be used for views processed using the merge algorithm. However, a view that is processed with the temptable algorithm is unable to take advantage of indexes on its underlying tables (although indexes can be used during generation of the temporary tables).

Subqueries cannot be used in the \texttt{FROM} clause of a view.

There is a general principle that you cannot modify a table and select from the same table in a subquery. See Section C.3, “Restrictions on Subqueries”.

The same principle also applies if you select from a view that selects from the table, if the view selects from the table in a subquery and the view is evaluated using the merge algorithm. Example:

\begin{verbatim}
CREATE VIEW v1 AS
SELECT * FROM t2 WHERE EXISTS (SELECT 1 FROM t1 WHERE t1.a = t2.a);
UPDATE t1, v2 SET t1.a = 1 WHERE t1.b = v2.b;
\end{verbatim}

If the view is evaluated using a temporary table, you can select from the table in the view subquery and still modify that table in the outer query. In this case the view will be stored in a temporary table and thus you are not really selecting from the table in a subquery and modifying it “at the same time.” (This is another reason you might wish to force MySQL to use the temptable algorithm by specifying \texttt{ALGORITHM = TEMPTABLE} in the view definition.)

You can use \texttt{DROP TABLE} or \texttt{ALTER TABLE} to drop or alter a table that is used in a view definition. No warning results from the \texttt{DROP} or \texttt{ALTER} operation, even though this invalidates the view. Instead, an error occurs later, when the view is used. \texttt{CHECK TABLE} can be used to check for views that have been invalidated by \texttt{DROP} or \texttt{ALTER} operations.

A view definition is “frozen” by certain statements:

- If a statement prepared by \texttt{PREPARE} refers to a view, the view definition seen each time the statement is executed later will be the definition of the view at the time it was prepared. This is true even if the view definition is changed after the statement is prepared and before it is executed. Example:

\begin{verbatim}
CREATE VIEW v AS SELECT RAND();
PREPARE s FROM 'SELECT * FROM v';
ALTER VIEW v AS SELECT NOW();
EXECUTE s;
\end{verbatim}

The result returned by the \texttt{EXECUTE} statement is a random number, not the current date and time.

- If a statement in a stored routine refers to a view, the view definition seen by the statement are its definition the first time that statement is executed. For example, this means that if the statement is executed in a loop, further iterations of the statement see the same view definition, even if the definition is changed later in the loop. Example:

\begin{verbatim}
CREATE VIEW v AS SELECT 1;
delimiter //
CREATE PROCEDURE p ()
BEGIN
    DECLARE i INT DEFAULT 0;
\end{verbatim}
Restrictions on Views

```
WHILE i < 5 DO
    SELECT * FROM v;
    SET i = i + 1;
    ALTER VIEW v AS SELECT 2;
END WHILE;
```

When the procedure `p()` is called, the `SELECT` returns 1 each time through the loop, even though the view definition is changed within the loop.

As of MySQL 5.1.21, `ALTER VIEW` is prohibited within stored routines, so this restriction does not apply.

With regard to view updatability, the overall goal for views is that if any view is theoretically updatable, it should be updatable in practice. This includes views that have `UNION` in their definition. Not all views that are theoretically updatable can be updated. The initial view implementation was deliberately written this way to get usable, updatable views into MySQL as quickly as possible. Many theoretically updatable views can be updated now, but limitations still exist:

- Updatable views with subqueries anywhere other than in the `WHERE` clause. Some views that have subqueries in the `SELECT` list may be updatable.
- You cannot use `UPDATE` to update more than one underlying table of a view that is defined as a join.
- You cannot use `DELETE` to update a view that is defined as a join.

There exists a shortcoming with the current implementation of views. If a user is granted the basic privileges necessary to create a view (the `CREATE VIEW` and `SELECT` privileges), that user will be unable to call `SHOW CREATE VIEW` on that object unless the user is also granted the `SHOW VIEW` privilege.

That shortcoming can lead to problems backing up a database with `mysqldump`, which may fail due to insufficient privileges. This problem is described in Bug #22062.

The workaround to the problem is for the administrator to manually grant the `SHOW VIEW` privilege to users who are granted `CREATE VIEW`, since MySQL doesn't grant it implicitly when views are created.

Views do not have indexes, so index hints do not apply. Use of index hints when selecting from a view is not permitted.

`SHOW CREATE VIEW` displays view definitions using an `AS alias_name` clause for each column. If a column is created from an expression, the default alias is the expression text, which can be quite long. As of MySQL 5.1.23, aliases for column names in `CREATE VIEW` statements are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters). As a result, views created from the output of `SHOW CREATE VIEW` fail if any column alias exceeds 64 characters. This can cause problems in the following circumstances for views with too-long aliases:

- View definitions fail to replicate to newer slaves that enforce the column-length restriction.
- Dump files created with `mysqldump` cannot be loaded into servers that enforce the column-length restriction.

A workaround for either problem is to modify each problematic view definition to use aliases that provide shorter column names. Then the view will replicate properly, and can be dumped and reloaded without causing an error. To modify the definition, drop and create the view again with `DROP VIEW` and `CREATE VIEW`, or replace the definition with `CREATE OR REPLACE VIEW`.

For problems that occur when reloading view definitions in dump files, another workaround is to edit the dump file to modify its `CREATE VIEW` statements. However, this does not change the original view definitions, which may cause problems for subsequent dump operations.
C.5 Restrictions on XA Transactions

XA transaction support is limited to the InnoDB storage engine.

For “external XA,” a MySQL server acts as a Resource Manager and client programs act as Transaction Managers. For “internal XA,” storage engines within a MySQL server act as RMs, and the server itself acts as a TM. Internal XA support is limited by the capabilities of individual storage engines. Internal XA is required for handling XA transactions that involve more than one storage engine. The implementation of internal XA requires that a storage engine support two-phase commit at the table handler level, and currently this is true only for InnoDB.

For **XA START**, the **JOIN** and **RESUME** clauses are not supported.

For **XA END**, the **SUSPEND [FOR MIGRATE]** clause is not supported.

The requirement that the bqual part of the xid value be different for each XA transaction within a global transaction is a limitation of the current MySQL XA implementation. It is not part of the XA specification.

If an XA transaction has reached the PREPARED state and the MySQL server is killed (for example, with `kill -9` on Unix) or shuts down abnormally, the transaction can be continued after the server restarts. However, if the client reconnects and commits the transaction, the transaction will be absent from the binary log even though it has been committed. This means the data and the binary log have gone out of synchrony. An implication is that XA cannot be used safely together with replication.

It is possible that the server will roll back a pending XA transaction, even one that has reached the PREPARED state. This happens if a client connection terminates and the server continues to run, or if clients are connected and the server shuts down gracefully. (In the latter case, the server marks each connection to be terminated, and then rolls back the PREPARED XA transaction associated with it.) It should be possible to commit or roll back a PREPARED XA transaction, but this cannot be done without changes to the binary logging mechanism.

C.6 Restrictions on Character Sets

- Identifiers are stored in *mysql* database tables (user, db, and so forth) using utf8, but identifiers can contain only characters in the Basic Multilingual Plane (BMP). Supplementary characters are not permitted in identifiers.

- The *ucs2* character sets has the following restrictions:
  - It cannot be used as a client character set, which means that it does not work for **SET NAMES** or **SET CHARACTER SET**. (See Section 10.1.4, “Connection Character Sets and Collations”.)
  - It is currently not possible to use **LOAD DATA INFILE** to load data files that use this character set.
  - **FULLTEXT** indexes cannot be created on a column that this character set. However, you can perform **IN BOOLEAN MODE** searches on the column without an index.
  - The use of **encrypt()** with this character set is not recommended because the underlying system call expects a string terminated by a zero byte.
  - The **REGEXP** and **RLIKE** operators work in byte-wise fashion, so they are not multibyte safe and may produce unexpected results with multibyte character sets. In addition, these operators compare characters by their byte values and accented characters may not compare as equal even if a given collation treats them as equal.

C.7 Limits in MySQL

This section lists current limits in MySQL 5.1.
C.7.1 Limits on Joins

The maximum number of tables that can be referenced in a single join is 61. This also applies to the number of tables that can be referenced in the definition of a view.

C.7.2 Limits on Number of Databases and Tables

MySQL has no limit on the number of databases. The underlying file system may have a limit on the number of directories.

MySQL has no limit on the number of tables. The underlying file system may have a limit on the number of files that represent tables. Individual storage engines may impose engine-specific constraints. InnoDB permits up to 4 billion tables.

C.7.3 Limits on Table Size

The effective maximum table size for MySQL databases is usually determined by operating system constraints on file sizes, not by MySQL internal limits. The following table lists some examples of operating system file-size limits. This is only a rough guide and is not intended to be definitive. For the most up-to-date information, be sure to check the documentation specific to your operating system.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>File-size Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Win32 w/ FAT/FAT32</td>
<td>2GB/4GB</td>
</tr>
<tr>
<td>Win32 w/ NTFS</td>
<td>2TB (possibly larger)</td>
</tr>
<tr>
<td>Linux 2.2-Intel 32-bit</td>
<td>2GB (LFS: 4GB)</td>
</tr>
<tr>
<td>Linux 2.4+</td>
<td>(using ext3 file system) 4TB</td>
</tr>
<tr>
<td>Solaris 9/10</td>
<td>16TB</td>
</tr>
<tr>
<td>OS X w/ HFS+</td>
<td>2TB</td>
</tr>
<tr>
<td>NetWare w/NSS file system</td>
<td>8TB</td>
</tr>
</tbody>
</table>

Windows users, please note that FAT and VFAT (FAT32) are not considered suitable for production use with MySQL. Use NTFS instead.

On Linux 2.2, you can get MyISAM tables larger than 2GB in size by using the Large File Support (LFS) patch for the ext2 file system. Most current Linux distributions are based on kernel 2.4 or higher and include all the required LFS patches. On Linux 2.4, patches also exist for ReiserFS to get support for big files (up to 2TB). With JFS and XFS, petabyte and larger files are possible on Linux.

For a detailed overview about LFS in Linux, have a look at Andreas Jaeger's Large File Support in Linux page at http://www.suse.de/~aj/linux_lfs.html.

If you do encounter a full-table error, there are several reasons why it might have occurred:

- The disk might be full.
- The InnoDB storage engine maintains InnoDB tables within a tablespace that can be created from several files. This enables a table to exceed the maximum individual file size. The tablespace can include raw disk partitions, which permits extremely large tables. The maximum tablespace size is 64TB.

If you are using InnoDB tables and run out of room in the InnoDB tablespace. In this case, the solution is to extend the InnoDB tablespace. See Section 14.6.5.2, “Changing the Number or Size of InnoDB Redo Log Files”.

- You are using MyISAM tables on an operating system that supports files only up to 2GB in size and you have hit this limit for the data file or index file.
• You are using a MyISAM table and the space required for the table exceeds what is permitted by the internal pointer size. MyISAM permits data and index files to grow up to 256TB by default, but this limit can be changed up to the maximum permissible size of 65,536TB (256^7 − 1 bytes).

If you need a MyISAM table that is larger than the default limit and your operating system supports large files, the CREATE TABLE statement supports AVG_ROW_LENGTH and MAX_ROWS options. See Section 13.1.17, “CREATE TABLE Syntax”. The server uses these options to determine how large a table to permit.

If the pointer size is too small for an existing table, you can change the options with ALTER TABLE to increase a table's maximum permissible size. See Section 13.1.7, “ALTER TABLE Syntax”.

```
ALTER TABLE tbl_name MAX_ROWS=1000000000 AVG_ROW_LENGTH=nnn;
```

You have to specify AVG_ROW_LENGTH only for tables with BLOB or TEXT columns; in this case, MySQL can't optimize the space required based only on the number of rows.

To change the default size limit for MyISAM tables, set the myisam_data_pointer_size, which sets the number of bytes used for internal row pointers. The value is used to set the pointer size for new tables if you do not specify the MAX_ROWS option. The value of myisam_data_pointer_size can be from 2 to 7. A value of 4 permits tables up to 4GB; a value of 6 permits tables up to 256TB.

You can check the maximum data and index sizes by using this statement:

```
SHOW TABLE STATUS FROM db_name LIKE 'tbl_name';
```

You also can use myisamchk -dv /path/to/table-index-file. See Section 13.7.5, “SHOW Syntax”, or Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”.

Other ways to work around file-size limits for MyISAM tables are as follows:

• If your large table is read only, you can use myisampack to compress it. myisampack usually compresses a table by at least 50%, so you can have, in effect, much bigger tables. myisampack also can merge multiple tables into a single table. See Section 4.6.5, “myisampack — Generate Compressed, Read-Only MyISAM Tables”.

• MySQL includes a MERGE library that enables you to handle a collection of MyISAM tables that have identical structure as a single MERGE table. See Section 14.8, “The MERGE Storage Engine”.

• You are using the NDB storage engine, in which case you need to increase the values for the DataMemory and IndexMemory configuration parameters in your config.ini file. See Section 17.3.2.1, “MySQL Cluster Data Node Configuration Parameters”.

• You are using the MEMORY (HEAP) storage engine; in this case you need to increase the value of the max_heap_table_size system variable. See Section 5.1.4, “Server System Variables”.

### C.7.4 Limits on Table Column Count and Row Size

There is a hard limit of 4096 columns per table, but the effective maximum may be less for a given table. The exact limit depends on several interacting factors.

• Every table (regardless of storage engine) has a maximum row size of 65,535 bytes. Storage engines may place additional constraints on this limit, reducing the effective maximum row size.

The maximum row size constrains the number (and possibly size) of columns because the total length of all columns cannot exceed this size. For example, utf8 characters require up to three bytes per character, so for a CHAR(255) CHARACTER SET utf8 column, the server must allocate 255 × 3 = 765 bytes per value. Consequently, a table cannot contain more than 65,535 / 765 = 85 such columns.
Storage for variable-length columns includes length bytes, which are assessed against the row size. For example, a \texttt{VARCHAR(255) CHARACTER SET utf8} column takes two bytes to store the length of the value, so each value can take up to 767 bytes.

\texttt{BLOB} and \texttt{TEXT} columns count from one to four plus eight bytes each toward the row-size limit because their contents are stored separately from the rest of the row.

Declaring columns \texttt{NULL} can reduce the maximum number of columns permitted. For \texttt{MyISAM} tables, \texttt{NULL} columns require additional space in the row to record whether their values are \texttt{NULL}. Each \texttt{NULL} column takes one bit extra, rounded up to the nearest byte. The maximum row length in bytes can be calculated as follows:

\begin{equation}
\text{row length} = 1 + (\text{sum of column lengths}) + (\text{number of NULL columns} + \text{delete_flag} + 7)/8 + (\text{number of variable-length columns})
\end{equation}

\texttt{delete_flag} is 1 for tables with static row format. Static tables use a bit in the row record for a flag that indicates whether the row has been deleted. \texttt{delete_flag} is 0 for dynamic tables because the flag is stored in the dynamic row header. For information about \texttt{MyISAM} table formats, see Section 14.5.3, "MyISAM Table Storage Formats".

For \texttt{InnoDB} tables, storage size is the same for \texttt{NULL} and \texttt{NOT NULL} columns, so the preceding calculations do not apply.

The following statement to create table \texttt{t1} succeeds because the columns require 32,765 + 2 bytes and 32,766 + 2 bytes, which falls within the maximum row size of 65,535 bytes:

```sql
mysql> CREATE TABLE t1
      -> (c1 VARCHAR(32765) NOT NULL, c2 VARCHAR(32766) NOT NULL)
      -> ENGINE = MyISAM CHARACTER SET latin1;
Query OK, 0 rows affected (0.02 sec)
```

The following statement to create table \texttt{t2} fails because the columns are \texttt{NULL} and \texttt{MyISAM} requires additional space that causes the row size to exceed 65,535 bytes:

```sql
mysql> CREATE TABLE t2
      -> (c1 VARCHAR(32765) NULL, c2 VARCHAR(32766) NULL)
      -> ENGINE = MyISAM CHARACTER SET latin1;
ERROR 1118 (42000): Row size too large. The maximum row size for the used table type, not counting BLOBs, is 65535. You have to change some columns to TEXT or BLOBs
```

The following statement to create table \texttt{t3} fails because, although the column length is within the maximum length of 65,535 bytes, two additional bytes are required to record the length, which causes the row size to exceed 65,535 bytes:

```sql
mysql> CREATE TABLE t3
      -> (c1 VARCHAR(65535) NOT NULL)
      -> ENGINE = MyISAM CHARACTER SET latin1;
ERROR 1118 (42000): Row size too large. The maximum row size for the used table type, not counting BLOBs, is 65535. You have to change some columns to TEXT or BLOBs
```

Reducing the column length to 65,533 or less permits the statement to succeed.

- Individual storage engines might impose additional restrictions that limit table column count. Examples:
  - \texttt{InnoDB} permits up to 1000 columns.
InnoDB restricts row size to something less than half a database page (approximately 8000 bytes), not including VARBINARY, VARCHAR, BLOB, or TEXT columns. For more information, see Section 14.6.6.7, "Limits on InnoDB Tables".

Different InnoDB storage formats (COMPRESSED, REDUNDANT) use different amounts of page header and trailer data, which affects the amount of storage available for rows.

Each table has a .frm file that contains the table definition. The definition affects the content of this file in ways that may affect the number of columns permitted in the table. For more information, see Section C.7.5, "Limits Imposed by .frm File Structure".

C.7.5 Limits Imposed by .frm File Structure

Each table has a .frm file that contains the table definition. The server uses the following expression to check some of the table information stored in the file against an upper limit of 64KB:

```c
if (info_length+(ulong) create_fields.elements*FCOMP+288+
    n_length+int_length+com_length > 65535L || int_count > 255)
```

The portion of the information stored in the .frm file that is checked against the expression cannot grow beyond the 64KB limit, so if the table definition reaches this size, no more columns can be added.

The relevant factors in the expression are:

- **info_length** is space needed for “screens.” This is related to MySQL’s Unireg heritage.
- **create_fields.elements** is the number of columns.
- **FCOMP** is 17.
- **n_length** is the total length of all column names, including one byte per name as a separator.
- **int_length** is related to the list of values for ENUM and SET columns. In this context, “int” does not mean “integer.” It means “interval,” a term that refers collectively to ENUM and SET columns.
- **int_count** is the number of unique ENUM and SET definitions.
- **com_length** is the total length of column comments.

The expression just described has several implications for permitted table definitions:

- Using long column names can reduce the maximum number of columns, as can the inclusion of ENUM or SET columns, or use of column comments.
- A table can have no more than 255 unique ENUM and SET definitions. Columns with identical element lists are considered the same against this limit. For example, if a table contains these two columns, they count as one (not two) toward this limit because the definitions are identical:

  ```
  e1 ENUM('a','b','c')
  e2 ENUM('a','b','c')
  ```

- The sum of the length of element names in the unique ENUM and SET definitions counts toward the 64KB limit, so although the theoretical limit on number of elements in a given ENUM column is 65,535, the practical limit is less than 3000.

C.7.6 Windows Platform Limitations

The following limitations apply to use of MySQL on the Windows platform:
• **Number of file descriptors**

The number of open file descriptors on Windows is limited to a maximum of 2048, which may limit the ability to open a large number of tables simultaneously. This limit is due not to Windows but to C runtime library compatibility functions used to open files on Windows that use the POSIX compatibility layer.

This limitation will also cause problems if you try to set `open_files_limit` to a value greater than the 2048 file limit.

• **Process memory**

On Windows 32-bit platforms it is not possible by default to use more than 2GB of RAM within a single process, including MySQL. This is because the physical address limit on Windows 32-bit is 4GB and the default setting within Windows is to split the virtual address space between kernel (2GB) and user/applications (2GB).

Some versions of Windows have a boot time setting to enable larger applications by reducing the kernel application. Alternatively, to use more than 2GB, use a 64-bit version of Windows.

• **File system aliases**

When using MyISAM tables, you cannot use aliases within Windows link to the data files on another volume and then link back to the main MySQL `datadir` location.

This facility is often used to move the data and index files to a RAID or other fast solution, while retaining the main `.frm` files in the default data directory configured with the `datadir` option.

• **Limited number of ports**

Windows systems have about 4,000 ports available for client connections, and after a connection on a port closes, it takes two to four minutes before the port can be reused. In situations where clients connect to and disconnect from the server at a high rate, it is possible for all available ports to be used up before closed ports become available again. If this happens, the MySQL server appears to be unresponsive even though it is running. Ports may be used by other applications running on the machine as well, in which case the number of ports available to MySQL is lower.

For more information about this problem, see [http://support.microsoft.com/default.aspx?scid=kb;en-us;196271](http://support.microsoft.com/default.aspx?scid=kb;en-us;196271).

• **Concurrent reads**

MySQL depends on the `pread()` and `pwrite()` system calls to be able to mix `INSERT` and `SELECT`. We use mutexes to emulate `pread()` and `pwrite()`. We intend to replace the file level interface with a virtual interface in the future so that we can use the `readfile()/writefile()` interface to get more speed. The current implementation limits the number of open files that MySQL 5.1 can use to 2,048, which means that you cannot run as many concurrent threads on Windows as on Unix.

This problem is fixed in MySQL 5.5.

• **Blocking read**

Before MySQL 5.1.41, MySQL uses a blocking read for each connection. That has the following implications if named-pipe connections are enabled:

• A connection is not disconnected automatically after eight hours, as happens with the Unix version of MySQL.

• If a connection hangs, it is not possible to break it without killing MySQL.

• `mysqladmin kill` does not work on a sleeping connection.
Windows Platform Limitations

- `mysqladmin shutdown` cannot abort as long as there are sleeping connections.

- **DROP DATABASE**

  You cannot drop a database that is in use by another session.

- **Case-insensitive names**

  File names are not case sensitive on Windows, so MySQL database and table names are also not case sensitive on Windows. The only restriction is that database and table names must be specified using the same case throughout a given statement. See Section 9.2.2, “Identifier Case Sensitivity”.

- **Directory and file names**

  On Windows, MySQL Server supports only directory and file names that are compatible with the current ANSI code pages. For example, the following Japanese directory name will not work in the Western locale (code page 1252):

  ```
  datadir="C:/私たちのプロジェクトのデータ"
  ```

  The same limitation applies to directory and file names referred to in SQL statements, such as the data file path name in `LOAD DATA INFILE`.

- **The “\” path name separator character**

  Path name components in Windows are separated by the “\” character, which is also the escape character in MySQL. If you are using `LOAD DATA INFILE` or `SELECT ... INTO OUTFILE`, use Unix-style file names with “/” characters:

  ```
  mysql> LOAD DATA INFILE 'C:/tmp/skr.txt' INTO TABLE skr;
  mysql> SELECT * INTO OUTFILE 'C:/tmp/skr.txt' FROM skr;
  ```

  Alternatively, you must double the “\” character:

  ```
  mysql> LOAD DATA INFILE 'C:\tmp\skr.txt' INTO TABLE skr;
  mysql> SELECT * INTO OUTFILE 'C:\tmp\skr.txt' FROM skr;
  ```

- **Problems with pipes**

  Pipes do not work reliably from the Windows command-line prompt. If the pipe includes the character `^Z / CHAR(24)`, Windows thinks that it has encountered end-of-file and aborts the program.

  This is mainly a problem when you try to apply a binary log as follows:

  ```
  C:\> mysqlbinlog binary_log_file | mysql --user=root
  ```

  If you have a problem applying the log and suspect that it is because of a `^Z / CHAR(24)` character, you can use the following workaround:

  ```
  C:\> mysqlbinlog binary_log_file --result-file=/tmp/bin.sql
  C:\> mysql --user=root --execute "source /tmp/bin.sql"
  ```

  The latter command also can be used to reliably read in any SQL file that may contain binary data.
