In this case, the locator `a/b` resolves to `/a/b`.

Relative locators are also supported within predicates. In the following example, `d[../@c="1"]` is resolved as `/a/b[@c="1"]/d`:

```sql
mysql> SELECT ExtractValue('‐<a>‐<b c="1">X</b><d>X</d></b>‐<b c="2">X</b><d>X</d></b>‐<a>', 'a/b/d[../@c="1"]') AS result;
+--------+
| result |
| X      |
+--------+
1 row in set (0.00 sec)
```

- Locators prefixed with expressions that evaluate as scalar values—including variable references, literals, numbers, and scalar function calls—are not permitted, and their use results in an error.
- The `::` operator is not supported in combination with node types such as the following:
  - `axis::comment()`
  - `axis::text()`
  - `axis::processing-instructions()`
  - `axis::node()`

However, name tests (such as `axis::name` and `axis::*`) are supported, as shown in these examples:

```sql
mysql> SELECT ExtractValue('<a><b>x</b><c>y</c></a>','/a/child::b');
+-------------------------------------------------------+
| ExtractValue('<a><b>x</b><c>y</c></a>','/a/child::b') |
| x                                                     |
+-------------------------------------------------------+
1 row in set (0.02 sec)
mysql> SELECT ExtractValue('<a><b>x</b><c>y</c></a>','/a/child::*');
+-------------------------------------------------------+
| ExtractValue('<a><b>x</b><c>y</c></a>','/a/child::*') |
+-------------------------------------------------------+
```

1420
• “Up-and-down” navigation is not supported in cases where the path would lead “above” the root element. That is, you cannot use expressions which match on descendants of ancestors of a given element, where one or more of the ancestors of the current element is also an ancestor of the root element (see Bug #16321).

• The following XPath functions are not supported, or have known issues as indicated:
  - id()
  - lang()
  - local-name()
  - name()
  - namespace-uri()
  - normalize-space()
  - starts-with()
  - string()
  - substring-after()
  - substring-before()
  - translate()

• The following axes are not supported:
  - following-sibling
  - following
  - preceding-sibling
  - preceding

XPath expressions passed as arguments to ExtractValue() and UpdateXML() may contain the colon character (:) in element selectors, which enables their use with markup employing XML namespaces notation. For example:

```sql
mysql> SET @xml = '<a>111<b:c>222</d>333</d><e:f>444</e:f></b:c></a>'; Query OK, 0 rows affected (0.00 sec)

mysql> SELECT ExtractValue(@xml, '//e:f');
+-----------------------------+
| ExtractValue(@xml, '//e:f') |
+-----------------------------+
| 444                         |
+-----------------------------+

mysql> SELECT UpdateXML(@xml, '//b:c', '<g:h>555</g:h>');
+--------------------------------------------+
| UpdateXML(@xml, '//b:c', '<g:h>555</g:h>') |
| <a>111<g:h>555</g:h></a>                   |
+--------------------------------------------+
```

1 row in set (0.00 sec)
This is similar in some respects to what is permitted by Apache Xalan and some other parsers, and
is much simpler than requiring namespace declarations or the use of the namespace-uri() and
local-name() functions.

**Error handling.** For both ExtractValue() and UpdateXML(), the XPath locator used must be
valid and the XML to be searched must consist of elements which are properly nested and closed. If
the locator is invalid, an error is generated:

```sql
mysql> SELECT ExtractValue('<a>c</a><b/>', '/&a');
ERROR 1105 (HY000): XPATH syntax error: '&a'
```

If xml_frag does not consist of elements which are properly nested and closed, NULL is returned and
a warning is generated, as shown in this example:

```sql
mysql> SELECT ExtractValue('<a>c</a><b>', '//a');
+-----------------------------------+
| ExtractValue('<a>c</a><b>', '//a') |
+-----------------------------------+
| NULL                              |
+-----------------------------------+
1 row in set, 1 warning (0.00 sec)
```

```sql
mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Warning
Code: 1525
Message: Incorrect XML value: 'parse error at line 1 pos 11:
END-OF-INPUT unexpected ('>' wanted)'
1 row in set (0.00 sec)
```

The replacement XML used as the third argument to UpdateXML() is not
checked to determine whether it consists solely of elements which are properly
nested and closed.

**XPath Injection.** Code injection occurs when malicious code is introduced into the system to gain
unauthorized access to privileges and data. It is based on exploiting assumptions made by developers
about the type and content of data input from users. XPath is no exception in this regard.

A common scenario in which this can happen is the case of application which handles authorization
by matching the combination of a login name and password with those found in an XML file, using an
XPath expression like this one:

```
//user[login/text()='neapolitan' and password/text()='1c3cr34m']/attribute::id
```

This is the XPath equivalent of an SQL statement like this one:

```
SELECT id FROM users WHERE login='neapolitan' AND password='1c3cr34m';
```

A PHP application employing XPath might handle the login process like this:

```php
<?php
    $file = "users.xml";
    $login = $POST["login"]; $password = $POST["password"]; $xpath = "/user[login/text()='$login' and password/text()='$password']/attribute::id";
```
No checks are performed on the input. This means that a malevolent user can “short-circuit” the test by entering ' or 1=1 for both the login name and password, resulting in $xpath being evaluated as shown here:

//user[login/text()='' or 1=1 and password/text()='' or 1=1]/attribute::id

Since the expression inside the square brackets always evaluates as true, it is effectively the same as this one, which matches the id attribute of every user element in the XML document:

//user/attribute::id

One way in which this particular attack can be circumvented is simply by quoting the variable names to be interpolated in the definition of $xpath, forcing the values passed from a Web form to be converted to strings:

$xmlpath = "//user[login/text()='$login' and password/text()='$password']/attribute::id";

This is the same strategy that is often recommended for preventing SQL injection attacks. In general, the practices you should follow for preventing XPath injection attacks are the same as for preventing SQL injection:

• Never accepted untested data from users in your application.

• Check all user-submitted data for type; reject or convert data that is of the wrong type

• Test numeric data for out of range values; truncate, round, or reject values that are out of range. Test strings for illegal characters and either strip them out or reject input containing them.

• Do not output explicit error messages that might provide an unauthorized user with clues that could be used to compromise the system; log these to a file or database table instead.

Just as SQL injection attacks can be used to obtain information about database schemas, so can XPath injection be used to traverse XML files to uncover their structure, as discussed in Amit Klein's paper Blind XPath Injection (PDF file, 46KB).

It is also important to check the output being sent back to the client. Consider what can happen when we use the MySQL ExtractValue() function:

Because ExtractValue() returns multiple matches as a single space-delimited string, this injection attack provides every valid ID contained within users.xml to the user as a single row of output. As an extra safeguard, you should also test output before returning it to the user. Here is a simple example:
Bit Functions and Operators

MySQL>
SELECT @id = ExtractValue(
  LOAD_FILE('users.xml'),
  '//user[login/text()="" or l=1 and password/text()="" or l=1]/attribute::id'
);  
Query OK, 0 rows affected (0.00 sec)

MySQL>
SELECT IF(
  INSTR(@id, ' ') = 0,
  @id,
  'Unable to retrieve user ID'
) AS singleID;  
+----------------------------+
<table>
<thead>
<tr>
<th>singleID</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unable to retrieve user ID</td>
</tr>
</tbody>
</table>
+----------------------------+
1 row in set (0.00 sec)

In general, the guidelines for returning data to users securely are the same as for accepting user input. These can be summed up as:

- Always test outgoing data for type and permissible values.
- Never permit unauthorized users to view error messages that might provide information about the application that could be used to exploit it.

### 12.13 Bit Functions and Operators

Table 12.17 Bit Functions and Operators

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&amp;</td>
<td>Bitwise AND</td>
</tr>
<tr>
<td>&gt;&gt;</td>
<td>Right shift</td>
</tr>
<tr>
<td>&lt;&lt;</td>
<td>Left shift</td>
</tr>
<tr>
<td>^</td>
<td>Bitwise XOR</td>
</tr>
<tr>
<td>BIT_COUNT()</td>
<td>Return the number of bits that are set</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>~</td>
<td>Bitwise inversion</td>
</tr>
</tbody>
</table>

Bit functions and operators comprise `BIT_COUNT()`, `BIT_AND()`, `BIT_OR()`, `BIT_XOR()`, `&`, `|`, `^`, `~`, `<<`, and `>>`. (`BIT_AND()`, `BIT_OR()`, and `BIT_XOR()` are aggregate functions described at Section 12.19.1. “Aggregate Function Descriptions”.) Bit functions and operators require `BIGINT` (64-bit integer) arguments and return `BIGINT` values, so they have a maximum range of 64 bits. Arguments of other types (such as the `BINARY` and `VARBINARY` binary string types) are converted to `BIGINT` and truncation might occur.

The following list describes available bit functions and operators:

- `|`
  Bitwise OR.

  The result is an unsigned 64-bit integer.

MySQL>
SELECT 29 | 15;  
-> 31

- `&`
  Bitwise AND.
The result is an unsigned 64-bit integer.

```
mysql> SELECT 29 & 15;
  -> 13
```

• ^

Bitwise XOR.

The result is an unsigned 64-bit integer.

```
mysql> SELECT 1 ^ 1;
  -> 0
mysql> SELECT 1 ^ 0;
  -> 1
mysql> SELECT 11 ^ 3;
  -> 8
```

• <<

Shifts a longlong (BIGINT) number to the left.

The result is an unsigned 64-bit integer. The value is truncated to 64 bits. In particular, if the shift count is greater or equal to the width of an unsigned 64-bit number, the result is zero.

```
mysql> SELECT 1 << 2;
  -> 4
```

• >>

Shifts a longlong (BIGINT) number to the right.

The result is an unsigned 64-bit integer. The value is truncated to 64 bits. In particular, if the shift count is greater or equal to the width of an unsigned 64-bit number, the result is zero.

```
mysql> SELECT 4 >> 2;
  -> 1
```

• ~

Invert all bits.

The result is an unsigned 64-bit integer.

```
mysql> SELECT 5 & ~1;
  -> 4
```

• BIT_COUNT(N)

Returns the number of bits that are set in the argument N as an unsigned 64-bit integer, or NULL if the argument is NULL.

```
mysql> SELECT BIT_COUNT(29), BIT_COUNT(b'101010');
  -> 4, 3
```

### 12.14 Encryption and Compression Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AES_DECRYPT()</td>
<td>Decrypt using AES</td>
</tr>
<tr>
<td>AES_ENCRYPT()</td>
<td>Encrypt using AES</td>
</tr>
<tr>
<td>COMPRESS()</td>
<td>Return result as a binary string</td>
</tr>
</tbody>
</table>
Many encryption and compression functions return strings for which the result might contain arbitrary byte values. If you want to store these results, use a column with a `VARBINARY` or `BLOB` binary string data type. This will avoid potential problems with trailing space removal or character set conversion that would change data values, such as may occur if you use a nonbinary string data type (`CHAR`, `VARCHAR`, `TEXT`).

Some encryption functions return strings of ASCII characters: `MD5()`, `OLD_PASSWORD()`, `PASSWORD()`, `SHA()`, `SHA1()`, `SHA2()`. Their return value is a string that has a character set and collation determined by the `character_set_connection` and `collation_connection` system variables. This is a nonbinary string unless the character set is `binary`.

If an application stores values from a function such as `MD5()` or `SHA1()` that returns a string of hex digits, more efficient storage and comparisons can be obtained by converting the hex representation to binary using `UNHEX()` and storing the result in a `BINARY(N)` column. Each pair of hexadecimal digits requires one byte in binary form, so the value of `N` depends on the length of the hex string. `N` is 16 for an `MD5()` value and 20 for a `SHA1()` value. For `SHA2()`, `N` ranges from 28 to 32 depending on the argument specifying the desired bit length of the result.

The size penalty for storing the hex string in a `CHAR` column is at least two times, up to eight times if the value is stored in a column that uses the `utf8` character set (where each character uses 4 bytes). Storing the string also results in slower comparisons because of the larger values and the need to take character set collation rules into account.

Suppose that an application stores `MD5()` string values in a `CHAR(32)` column:

```sql
CREATE TABLE md5_tbl (md5_val CHAR(32), ...);
INSERT INTO md5_tbl (md5_val, ...) VALUES(MD5('abcdef'), ...);
```

To convert hex strings to more compact form, modify the application to use `UNHEX()` and `BINARY(16)` instead as follows:

```sql
CREATE TABLE md5_tbl (md5_val BINARY(16), ...);
INSERT INTO md5_tbl (md5_val, ...) VALUES(UNHEX(MD5('abcdef')), ...);
```

Applications should be prepared to handle the very rare case that a hashing function produces the same value for two different input values. One way to make collisions detectable is to make the hash column a primary key.
Note
Exploits for the MD5 and SHA-1 algorithms have become known. You may wish to consider using another one-way encryption function described in this section instead, such as SHA2().

Caution
Passwords or other sensitive values supplied as arguments to encryption functions are sent as cleartext to the MySQL server unless an SSL connection is used. Also, such values will appear in any MySQL logs to which they are written. To avoid these types of exposure, applications can encrypt sensitive values on the client side before sending them to the server. The same considerations apply to encryption keys. To avoid exposing these, applications can use stored procedures to encrypt and decrypt values on the server side.

- **AES_DECRYPT(crypt_str, key_str[, init_vector])**

  This function decrypts data using the official AES (Advanced Encryption Standard) algorithm. For more information, see the description of AES_ENCRYPT().

  The optional initialization vector argument, *init_vector*, is available as of MySQL 5.6.17. As of that version, statements that use AES_DECRYPT() are unsafe for statement-based replication and cannot be stored in the query cache.

- **AES_ENCRYPT(str, key_str[, init_vector])**

  AES_ENCRYPT() and AES_DECRYPT() implement encryption and decryption of data using the official AES (Advanced Encryption Standard) algorithm, previously known as “Rijndael.” The AES standard permits various key lengths. By default these functions implement AES with a 128-bit key length. As of MySQL 5.6.17, key lengths of 192 or 256 bits can be used, as described later. The key length is a trade off between performance and security.

  AES_ENCRYPT() encrypts the string *str* using the key string *key_str* and returns a binary string containing the encrypted output. AES_DECRYPT() decrypts the encrypted string *crypt_str* using the key string *key_str* and returns the original plaintext string. If either function argument is NULL, the function returns NULL.

  The *str* and *crypt_str* arguments can be any length, and padding is automatically added to *str* so it is a multiple of a block as required by block-based algorithms such as AES. This padding is automatically removed by the AES_DECRYPT() function. The length of *crypt_str* can be calculated using this formula:

  \[
  16 \times (\text{trunc}(\text{string length} / 16) + 1)
  \]

  For a key length of 128 bits, the most secure way to pass a key to the *key_str* argument is to create a truly random 128-bit value and pass it as a binary value. For example:

  ```sql
  INSERT INTO t
  VALUES (1, AES_ENCRYPT('text', UNHEX('F3229A0B371ED2D9441B830D21A390C3')));
  ```

  A passphrase can be used to generate an AES key by hashing the passphrase. For example:

  ```sql
  INSERT INTO t
  VALUES (1, AES_ENCRYPT('text', UNHEX(SHA2('My secret passphrase', 512))));
  ```

  Do not pass a password or passphrase directly to *crypt_str*, hash it first. Previous versions of this documentation suggested the former approach, but it is no longer recommended as the examples shown here are more secure.
If `AES_DECRYPT()` detects invalid data or incorrect padding, it returns `NULL`. However, it is possible for `AES_DECRYPT()` to return a non-`NULL` value (possibly garbage) if the input data or the key is invalid.

As of MySQL 5.6.17, `AES_ENCRYPT()` and `AES_DECRYPT()` permit control of the block encryption mode and take an optional `init_vector` initialization vector argument:

- The `block_encryption_mode` system variable controls the mode for block-based encryption algorithms. Its default value is `aes-128-ecb`, which signifies encryption using a key length of 128 bits and ECB mode. For a description of the permitted values of this variable, see Section 5.1.7, “Server System Variables”.

- The optional `init_vector` argument provides an initialization vector for block encryption modes that require it.

For modes that require the optional `init_vector` argument, it must be 16 bytes or longer (bytes in excess of 16 are ignored). An error occurs if `init_vector` is missing.

For modes that do not require `init_vector`, it is ignored and a warning is generated if it is specified.

A random string of bytes to use for the initialization vector can be produced by calling `RANDOM_BYTES(16)`. For encryption modes that require an initialization vector, the same vector must be used for encryption and decryption.

```
mysql> SET block_encryption_mode = 'aes-256-cbc';
mysql> SET @key_str = SHA2('My secret passphrase',512);
mysql> SET @init_vector = RANDOM_BYTES(16);
mysql> SET @crypt_str = AES_ENCRYPT('text',@key_str,@init_vector);
mysql> SELECT AES_DECRYPT(@crypt_str,@key_str,@init_vector);
+-----------------------------------------------+
| AES_DECRYPT(@crypt_str,@key_str,@init_vector) |
| text                                          |
+-----------------------------------------------+
```

The following table lists each permitted block encryption mode, the SSL libraries that support it, and whether the initialization vector argument is required.

<table>
<thead>
<tr>
<th>Block Encryption Mode</th>
<th>SSL Libraries that Support Mode</th>
<th>Initialization Vector Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>ECB</td>
<td>OpenSSL, yaSSL</td>
<td>No</td>
</tr>
<tr>
<td>CBC</td>
<td>OpenSSL, yaSSL</td>
<td>Yes</td>
</tr>
<tr>
<td>CFB1</td>
<td>OpenSSL</td>
<td>Yes</td>
</tr>
<tr>
<td>CFB8</td>
<td>OpenSSL</td>
<td>Yes</td>
</tr>
<tr>
<td>CFB128</td>
<td>OpenSSL</td>
<td>Yes</td>
</tr>
<tr>
<td>OFB</td>
<td>OpenSSL</td>
<td>Yes</td>
</tr>
</tbody>
</table>

As of MySQL 5.6.17, statements that use `AES_ENCRYPT()` or `AES_DECRYPT()` are unsafe for statement-based replication and cannot be stored in the query cache.

- `COMPRESS(string_to_compress)`

Compresses a string and returns the result as a binary string. This function requires MySQL to have been compiled with a compression library such as `zlib`. Otherwise, the return value is always `NULL`. The compressed string can be uncompressed with `UNCOMPRESS()`.

```
mysql> SELECT LENGTH(COMPRESS(REPEAT('a',1000)));
-> 21
```
Encryption and Compression Functions

<table>
<thead>
<tr>
<th>mysql&gt; SELECT LENGTH(COMPRESS(''));</th>
</tr>
</thead>
<tbody>
<tr>
<td>-&gt; 0</td>
</tr>
<tr>
<td>mysql&gt; SELECT LENGTH(COMPRESS('a'));</td>
</tr>
<tr>
<td>-&gt; 13</td>
</tr>
<tr>
<td>mysql&gt; SELECT LENGTH(COMPRESS(REPEAT('a',16)));</td>
</tr>
<tr>
<td>-&gt; 15</td>
</tr>
</tbody>
</table>

The compressed string contents are stored the following way:

- Empty strings are stored as empty strings.
- Nonempty strings are stored as a 4-byte length of the uncompressed string (low byte first), followed by the compressed string. If the string ends with space, an extra character is added to avoid problems with endspace trimming should the result be stored in a `CHAR` or `VARCHAR` column. (However, use of nonbinary string data types such as `CHAR` or `VARCHAR` to store compressed strings is not recommended anyway because character set conversion may occur. Use a `VARBINARY` or `BLOB` binary string column instead.)

- `DECODE(crypt_str, pass_str)`
  Decrypts the encrypted string `crypt_str` using `pass_str` as the password. `crypt_str` should be a string returned from `ENCODE()`.

- `DES_DECRYPT(crypt_str[, key_str])`
  Decrypts a string encrypted with `DES_ENCRYPT()`. If an error occurs, this function returns `NULL`.

  This function works only if MySQL has been configured with SSL support. See Section 6.3, “Using Encrypted Connections”.

  If no `key_str` argument is given, `DES_DECRYPT()` examines the first byte of the encrypted string to determine the DES key number that was used to encrypt the original string, and then reads the key from the DES key file to decrypt the message. For this to work, the user must have the `SUPER` privilege. The key file can be specified with the `--des-key-file` server option.

  If you pass this function a `key_str` argument, that string is used as the key for decrypting the message.

  If the `crypt_str` argument does not appear to be an encrypted string, MySQL returns the given `crypt_str`.

- `DES_ENCRYPT(str[, {key_num | key_str}])`
  Encrypts the string with the given key using the Triple-DES algorithm.

  This function works only if MySQL has been configured with SSL support. See Section 6.3, “Using Encrypted Connections”.

  The encryption key to use is chosen based on the second argument to `DES_ENCRYPT()`, if one was given. With no argument, the first key from the DES key file is used. With a `key_num` argument, the
given key number (0 to 9) from the DES key file is used. With a `key_str` argument, the given key string is used to encrypt `str`.

The key file can be specified with the `--des-key-file` server option.

The return string is a binary string where the first character is `CHAR(128 | key_num)`. If an error occurs, `DES_ENCRYPT()` returns `NULL`.

The 128 is added to make it easier to recognize an encrypted key. If you use a string key, `key_num` is 127.

The string length for the result is given by this formula:

```
new_len = orig_len + (8 - (orig_len % 8)) + 1
```

Each line in the DES key file has the following format:

```
key_num des_key_str
```

Each `key_num` value must be a number in the range from 0 to 9. Lines in the file may be in any order. `des_key_str` is the string that is used to encrypt the message. There should be at least one space between the number and the key. The first key is the default key that is used if you do not specify any key argument to `DES_ENCRYPT()`.

You can tell MySQL to read new key values from the key file with the `FLUSH DES_KEY_FILE` statement. This requires the `RELOAD` privilege.

One benefit of having a set of default keys is that it gives applications a way to check for the existence of encrypted column values, without giving the end user the right to decrypt those values.

```
mysql> SELECT customer_address FROM customer_table
    > WHERE crypted_credit_card = DES_ENCRYPT('credit_card_number');
```

- **ENCODE**(str, pass_str)

Encrypt `str` using `pass_str` as the password. The result is a binary string of the same length as `str`. To decrypt the result, use `DECODE()`.

The `ENCODE()` function should no longer be used. If you still need to use `ENCODE()`, a salt value must be used with it to reduce risk. For example:

```
ENCODE('cleartext', CONCAT('my_random_salt','my_secret_password'))
```

A new random salt value must be used whenever a password is updated.

- **ENCRYPT**(str[, salt])

Encrypts `str` using the Unix `crypt()` system call and returns a binary string. The `salt` argument must be a string with at least two characters or the result will be `NULL`. If no `salt` argument is given, a random value is used.

```
mysql> SELECT ENCRYPT('hello');
    > 'VxuFAJXVARROc'
```

`ENCRYPT()` ignores all but the first eight characters of `str`, at least on some systems. This behavior is determined by the implementation of the underlying `crypt()` system call.

The use of `ENCRYPT()` with the `ucs2`, `utf16`, `utf16le`, or `utf32` multibyte character sets is not recommended because the system call expects a string terminated by a zero byte.

If `crypt()` is not available on your system (as is the case with Windows), `ENCRYPT()` always returns `NULL`. 

```
• **MD5(str)**

Calculates an MD5 128-bit checksum for the string. The value is returned as a string of 32 hexadecimal digits, or **NULL** if the argument was **NULL**. The return value can, for example, be used as a hash key. See the notes at the beginning of this section about storing hash values efficiently.

The return value is a string in the connection character set.

```sql
mysql> SELECT MD5('testing');
-> 'ae2b1fca515949e5d54fb22b8ed95575'
```

This is the “RSA Data Security, Inc. MD5 Message-Digest Algorithm.”

See the note regarding the MD5 algorithm at the beginning this section.

• **OLD_PASSWORD(str)**

**OLD_PASSWORD()** was added when the implementation of **PASSWORD()** was changed in MySQL 4.1 to improve security. **OLD_PASSWORD()** returns the value of the pre-4.1 implementation of **PASSWORD()** as a string, and is intended to permit you to reset passwords for any pre-4.1 clients that need to connect to your MySQL server without locking them out. See Section 6.1.2.4, “Password Hashing in MySQL”.

The return value is a string in the connection character set.

**Note**

Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords are deprecated and support for them will be removed in a future MySQL release. Consequently, **OLD_PASSWORD()** is also deprecated.

• **PASSWORD(str)**

Returns a hashed password string calculated from the cleartext password **str**. The return value is a string in the connection character set, or **NULL** if the argument is **NULL**. This function is the SQL interface to the algorithm used by the server to encrypt MySQL passwords for storage in the **mysql.user** grant table.

The **old_passwords** system variable controls the password hashing method used by the **PASSWORD()** function. It also influences password hashing performed by **CREATE USER** and **GRANT** statements that specify a password using an **IDENTIFIED BY** clause.

The following table shows, for each password hashing method, the permitted value of **old_passwords** and which authentication plugins use the hashing method.

<table>
<thead>
<tr>
<th>Password Hashing Method</th>
<th>old_passwords Value</th>
<th>Associated Authentication Plugin</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 4.1 native hashing</td>
<td>0</td>
<td><strong>mysql_native_password</strong></td>
</tr>
<tr>
<td>Pre-4.1 (“old”) hashing</td>
<td>1</td>
<td><strong>mysql_old_password</strong></td>
</tr>
<tr>
<td>SHA-256 hashing</td>
<td>2</td>
<td><strong>sha256_password</strong></td>
</tr>
</tbody>
</table>

**Note**

Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords are deprecated and support for them will be removed in a future MySQL release. Consequently, **old_passwords=1**, which causes **PASSWORD()** to generate pre-4.1 password hashes, is also
Encryption and Compression Functions

deprecated. For account upgrade instructions, see Section 6.4.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql_old_password Plugin”.

If `old_passwords=1`, `PASSWORD(str)` returns the same value as `OLD_PASSWORD(str)`. The latter function is not affected by the value of `old_passwords`.

```sql
mysql> SET old_passwords = 0;
mysql> SELECT PASSWORD('mypass'), OLD_PASSWORD('mypass');
+-------------------------------------------+------------------------+
| PASSWORD('mypass')                        | OLD_PASSWORD('mypass')  |
| *6C8988936EAF75BB670AD8EA7A7FC1176A95CEF4 | 6f8c114b58f2ce9e        |
+-------------------------------------------+------------------------+
mysql> SET old_passwords = 1;
mysql> SELECT PASSWORD('mypass'), OLD_PASSWORD('mypass');
+--------------------+------------------------+
| PASSWORD('mypass') | OLD_PASSWORD('mypass')  |
| 6f8c114b58f2ce9e   | 6f8c114b58f2ce9e        |
+--------------------+------------------------+
```

SHA-256 password hashing (`old_passwords=2`) uses a random salt value, which makes the result from `PASSWORD()` nondeterministic. Consequently, statements that use this function are not safe for statement-based replication and cannot be stored in the query cache.

Encryption performed by `PASSWORD()` is one-way (not reversible). It is not the same type of encryption as used for Unix passwords; for that, use `ENCRYPT()`.

**Note**

`PASSWORD()` is used by the authentication system in MySQL Server; you should not use it in your own applications. For that purpose, consider a more secure function such as `AES_ENCRYPT()` or `SHA2()` instead. Also see RFC 2195, section 2 (Challenge-Response Authentication Mechanism (CRAM)), for more information about handling passwords and authentication securely in your applications.

**Caution**

Under some circumstances, statements that invoke `PASSWORD()` may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see Section 6.1.2.3, “Passwords and Logging”. For similar information about client-side logging, see Section 4.5.1.3, “mysql Client Logging”.

**• RANDOM_BYTES(len)**

This function returns a binary string of `len` random bytes generated using the random number generator of the SSL library. Permitted values of `len` range from 1 to 1024. For values outside that range, an error occurs.

`RANDOM_BYTES()` can be used to provide the initialization vector for the `AES_DECRYPT()` and `AES_ENCRYPT()` functions. For use in that context, `len` must be at least 16. Larger values are permitted, but bytes in excess of 16 are ignored.

`RANDOM_BYTES()` generates a random value, which makes its result nondeterministic. Consequently, statements that use this function are unsafe for statement-based replication and cannot be stored in the query cache.

This function is available as of MySQL 5.6.17.
• SHA1(str), SHA(str)

Calculates an SHA-1 160-bit checksum for the string, as described in RFC 3174 (Secure Hash Algorithm). The value is returned as a string of 40 hexadecimal digits, or NULL if the argument was NULL. One of the possible uses for this function is as a hash key. See the notes at the beginning of this section about storing hash values efficiently. SHA() is synonymous with SHA1().

The return value is a string in the connection character set.

```sql
mysql> SELECT SHA1('abc');
-> 'a9993e364706816aba3e25717850c26c9cd0d89d'
```

SHA1() can be considered a cryptographically more secure equivalent of MD5(). However, see the note regarding the MD5 and SHA-1 algorithms at the beginning this section.

• SHA2(str, hash_length)

Calculates the SHA-2 family of hash functions (SHA-224, SHA-256, SHA-384, and SHA-512). The first argument is the plaintext string to be hashed. The second argument indicates the desired bit length of the result, which must have a value of 224, 256, 384, 512, or 0 (which is equivalent to 256). If either argument is NULL or the hash length is not one of the permitted values, the return value is NULL. Otherwise, the function result is a hash value containing the desired number of bits. See the notes at the beginning of this section about storing hash values efficiently.

The return value is a string in the connection character set.

```sql
mysql> SELECT SHA2('abc', 224);
-> '23097d223405d8228642a477bda255b32adbcfe4bda0b3f7e36c9da7'
```

This function works only if MySQL has been configured with SSL support. See Section 6.3, “Using Encrypted Connections”.

SHA2() can be considered cryptographically more secure than MD5() or SHA1().

• UNCOMPRESS(string_to_uncompress)

Uncompresses a string compressed by the COMPRESS() function. If the argument is not a compressed value, the result is NULL. This function requires MySQL to have been compiled with a compression library such as zlib. Otherwise, the return value is always NULL.

```sql
mysql> SELECT UNCOMPRESS(COMPRESS('any string'));
-> 'any string'
mysql> SELECT UNCOMPRESS('any string');
-> NULL
```

• UNCOMPRESSED_LENGTH(compressed_string)

Returns the length that the compressed string had before being compressed.

```sql
mysql> SELECT UNCOMPRESSED_LENGTH(COMPRESS(REPEAT('a',30)));
-> 30
```

• VALIDATE_PASSWORD_STRENGTH(str)

Given an argument representing a plaintext password, this function returns an integer to indicate how strong the password is. The return value ranges from 0 (weak) to 100 (strong).

Password assessment by VALIDATE_PASSWORD_STRENGTH() is done by the validate_password plugin. If that plugin is not installed, the function always returns 0. For information about installing validate_password, see Section 6.4.3, “The Password Validation Plugin”. To examine or configure the parameters that affect password testing, check or set the
system variables implemented by `validate_password`. See Section 6.4.3.2, “Password Validation
Plugin Options and Variables”.

The password is subjected to increasingly strict tests and the return value reflects which tests were satisfied, as shown in the following table.

<table>
<thead>
<tr>
<th>Password Test</th>
<th>Return Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Length &lt; 4</td>
<td>0</td>
</tr>
<tr>
<td>Length ≥ 4 and &lt; <code>validate_password_length</code></td>
<td>25</td>
</tr>
<tr>
<td>Satisfies policy 1 (LOW)</td>
<td>50</td>
</tr>
<tr>
<td>Satisfies policy 2 (MEDIUM)</td>
<td>75</td>
</tr>
<tr>
<td>Satisfies policy 3 (STRONG)</td>
<td>100</td>
</tr>
</tbody>
</table>

### 12.15 Locking Functions

This section describes functions used to manipulate user-level locks.

**Table 12.19 Locking Functions**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET_LOCK()</td>
<td>Get a named lock</td>
</tr>
<tr>
<td>IS_FREE_LOCK()</td>
<td>Whether the named lock is free</td>
</tr>
<tr>
<td>IS_USED_LOCK()</td>
<td>Whether the named lock is in use; return connection identifier if true</td>
</tr>
<tr>
<td>RELEASE_LOCK()</td>
<td>Release the named lock</td>
</tr>
</tbody>
</table>

- **GET_LOCK(str,timeout)**

  Tries to obtain a lock with a name given by the string `str`, using a timeout of `timeout` seconds. A negative `timeout` value means infinite timeout. The lock is exclusive. While held by one session, other sessions cannot obtain a lock of the same name.

  Returns 1 if the lock was obtained successfully, 0 if the attempt timed out (for example, because another client has previously locked the name), or NULL if an error occurred (such as running out of memory or the thread was killed with `mysqladmin kill`).

  A lock obtained with `GET_LOCK()` is released explicitly by executing `RELEASE_LOCK()` or implicitly when your session terminates (either normally or abnormally). Locks obtained with `GET_LOCK()` are not released when transactions commit or roll back.

**Important**

The behavior of `GET_LOCK()` changes in MySQL 5.7. In consideration of future upgrades, limit the `str` value to 64 characters or less and do not rely on subsequent calls to `GET_LOCK()` releasing previous locks.

`GET_LOCK()` can be used to implement application locks or to simulate record locks. Names are locked on a server-wide basis. If a name has been locked within one session, `GET_LOCK()` blocks any request by another session for a lock with the same name. This enables clients that agree on a given lock name to use the name to perform cooperative advisory locking. But be aware that it also enables a client that is not among the set of cooperating clients to lock a name, either inadvertently or deliberately, and thus prevent any of the cooperating clients from locking that name. One way to reduce the likelihood of this is to use lock names that are database-specific or application-specific. For example, use lock names of the form `db_name.str` or `app_name.str`.

```sql
mysql> SELECT GET_LOCK('lock1',10);
```

1434
The second `RELEASE_LOCK()` call returns `NULL` because the lock 'lock1' was automatically released by the second `GET_LOCK()` call.

If multiple clients are waiting for a lock, the order in which they will acquire it is undefined. Applications should not assume that clients will acquire the lock in the same order that they issued the lock requests.

`GET_LOCK()` is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- **IS_FREE_LOCK(str)**

  Checks whether the lock named `str` is free to use (that is, not locked). Returns 1 if the lock is free (no one is using the lock), 0 if the lock is in use, and `NULL` if an error occurs (such as an incorrect argument).

  This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- **IS_USED_LOCK(str)**

  Checks whether the lock named `str` is in use (that is, locked). If so, it returns the connection identifier of the client session that holds the lock. Otherwise, it returns `NULL`.

  This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- **RELEASE_LOCK(str)**

  Releases the lock named by the string `str` that was obtained with `GET_LOCK()`. Returns 1 if the lock was released, 0 if the lock was not established by this thread (in which case the lock is not released), and `NULL` if the named lock did not exist. The lock does not exist if it was never obtained by a call to `GET_LOCK()` or if it has previously been released.

  The `DO` statement is convenient to use with `RELEASE_LOCK()`. See Section 13.2.3, “DO Statement”.

  This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

### 12.16 Information Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>BENCHMARK()</strong></td>
<td>Repeatedly execute an expression</td>
</tr>
<tr>
<td><strong>CHARSET()</strong></td>
<td>Return the character set of the argument</td>
</tr>
<tr>
<td><strong>COERCIBILITY()</strong></td>
<td>Return the collation coercibility value of the string argument</td>
</tr>
<tr>
<td><strong>COLLATION()</strong></td>
<td>Return the collation of the string argument</td>
</tr>
<tr>
<td><strong>CONNECTION_ID()</strong></td>
<td>Return the connection ID (thread ID) for the connection</td>
</tr>
<tr>
<td><strong>CURRENT_USER(), CURRENT_USER</strong></td>
<td>The authenticated user name and host name</td>
</tr>
</tbody>
</table>
Information Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATABASE()</td>
<td>Return the default (current) database name</td>
</tr>
<tr>
<td>FOUND_ROWS()</td>
<td>For a SELECT with a LIMIT clause, the number of rows that would be returned were there no LIMIT clause</td>
</tr>
<tr>
<td>LAST_INSERT_ID()</td>
<td>Value of the AUTOINCREMENT column for the last INSERT</td>
</tr>
<tr>
<td>ROW_COUNT()</td>
<td>The number of rows updated</td>
</tr>
<tr>
<td>SCHEMA()</td>
<td>Synonym for DATABASE()</td>
</tr>
<tr>
<td>SESSION_USER()</td>
<td>Synonym for USER()</td>
</tr>
<tr>
<td>SYSTEM_USER()</td>
<td>Synonym for USER()</td>
</tr>
<tr>
<td>USER()</td>
<td>The user name and host name provided by the client</td>
</tr>
<tr>
<td>VERSION()</td>
<td>Return a string that indicates the MySQL server version</td>
</tr>
</tbody>
</table>

- **BENCHMARK**(count, expr)

The `BENCHMARK()` function executes the expression `expr` repeatedly `count` times. It may be used to time how quickly MySQL processes the expression. The result value is 0, or NULL for inappropriate arguments such as a NULL or negative repeat count.

The intended use is from within the `mysql` client, which reports query execution times:

```sql
mysql> SELECT BENCHMARK(1000000, AES_ENCRYPT('hello', 'goodbye'));
+---------------------------------------------------+
| BENCHMARK(1000000, AES_ENCRYPT('hello', 'goodbye')) |
+---------------------------------------------------+
|                                                 0 |
+---------------------------------------------------+
1 row in set (4.74 sec)
```

The time reported is elapsed time on the client end, not CPU time on the server end. It is advisable to execute `BENCHMARK()` several times, and to interpret the result with regard to how heavily loaded the server machine is.

`BENCHMARK()` is intended for measuring the runtime performance of scalar expressions, which has some significant implications for the way that you use it and interpret the results:

- Only scalar expressions can be used. Although the expression can be a subquery, it must return a single column and at most a single row. For example, `BENCHMARK(10, (SELECT * FROM t))` will fail if the table `t` has more than one column or more than one row.

- Executing a `SELECT expr` statement `N` times differs from executing `SELECT BENCHMARK(N, expr)` in terms of the amount of overhead involved. The two have very different execution profiles and you should not expect them to take the same amount of time. The former involves the parser, optimizer, table locking, and runtime evaluation `N` times each. The latter involves only runtime evaluation `N` times, and all the other components just once. Memory structures already allocated are reused, and runtime optimizations such as local caching of results already evaluated for aggregate functions can alter the results. Use of `BENCHMARK()` thus measures performance of the runtime component by giving more weight to that component and removing the “noise” introduced by the network, parser, optimizer, and so forth.

- **CHARSET**(str)

Returns the character set of the string argument.

```sql
mysql> SELECT CHARSET('abc');
-> 'latin1'
mysql> SELECT CHARSET(CONVERT('abc' USING utf8));
-> 'utf8'
mysql> SELECT CHARSET(USER());
-> 'utf8'
```
• **COERCIBILITY**(str)

Returns the collation coercibility value of the string argument.

```sql
mysql> SELECT COERCIBILITY('abc' COLLATE latin1_swedish_ci);
-> 0
mysql> SELECT COERCIBILITY(USER());
-> 3
mysql> SELECT COERCIBILITY('abc');
-> 4
mysql> SELECT COERCIBILITY(1000);
-> 5
```

The return values have the meanings shown in the following table. Lower values have higher precedence.

<table>
<thead>
<tr>
<th>Coercibility</th>
<th>Meaning</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Explicit collation</td>
<td>Value with <code>COLLATE</code> clause</td>
</tr>
<tr>
<td>1</td>
<td>No collation</td>
<td>Concatenation of strings with different collations</td>
</tr>
<tr>
<td>2</td>
<td>Implicit collation</td>
<td>Column value, stored routine parameter or local variable</td>
</tr>
<tr>
<td>3</td>
<td>System constant</td>
<td><code>USER()</code> return value</td>
</tr>
<tr>
<td>4</td>
<td>Coercible</td>
<td>Literal string</td>
</tr>
<tr>
<td>5</td>
<td>Numeric</td>
<td>Numeric or temporal value</td>
</tr>
<tr>
<td>5</td>
<td>Ignorable</td>
<td><code>NULL</code> or an expression derived from <code>NULL</code></td>
</tr>
</tbody>
</table>

For more information, see Section 10.8.4, “Collation Coercibility in Expressions”.

• **COLLATION**(str)

Returns the collation of the string argument.

```sql
mysql> SELECT COLLATION('abc');
-> 'latin1_swedish_ci'
mysql> SELECT COLLATION(_utf8'abc');
-> 'utf8_general_ci'
```

• **CONNECTION_ID()**

Returns the connection ID (thread ID) for the connection. Every connection has an ID that is unique among the set of currently connected clients.

The value returned by `CONNECTION_ID()` is the same type of value as displayed in the `ID` column of the `INFORMATION_SCHEMA.PROCESSLIST` table, the `Id` column of `SHOW PROCESSLIST` output, and the `PROCESSLIST_ID` column of the Performance Schema `threads` table.

```sql
mysql> SELECT CONNECTION_ID();
-> 23786
```

**Warning**

Changing the session value of the `pseudo_thread_id` system variable changes the value returned by the `CONNECTION_ID()` function.

• **CURRENT_USER, CURRENT_USER()**

Returns the user name and host name combination for the MySQL account that the server used to authenticate the current client. This account determines your access privileges. The return value is a string in the `utf8` character set.
The value of `CURRENT_USER()` can differ from the value of `USER()`.

```sql
mysql> SELECT USER();
-> 'davida@localhost'
mysql> SELECT * FROM mysql.user;
ERROR 1044: Access denied for user ''@'localhost' to database 'mysql'
mysql> SELECT CURRENT_USER();
-> '@localhost'
```

The example illustrates that although the client specified a user name of `davida` (as indicated by the value of the `USER()` function), the server authenticated the client using an anonymous user account (as seen by the empty user name part of the `CURRENT_USER()` value). One way this might occur is that there is no account listed in the grant tables for `davida`.

Within a stored program or view, `CURRENT_USER()` returns the account for the user who defined the object (as given by its `DEFINER` value) unless defined with the `SQL SECURITY INVOKER` characteristic. In the latter case, `CURRENT_USER()` returns the object's invoker.

Triggers and events have no option to define the `SQL SECURITY` characteristic, so for these objects, `CURRENT_USER()` returns the account for the user who defined the object. To return the invoker, use `USER()` or `SESSION_USER()`.

The following statements support use of the `CURRENT_USER()` function to take the place of the name of (and, possibly, a host for) an affected user or a definer; in such cases, `CURRENT_USER()` is expanded where and as needed:

- `DROP USER`
- `RENAME USER`
- `GRANT`
- `REVOKE`
- `CREATE FUNCTION`
- `CREATE PROCEDURE`
- `CREATE TRIGGER`
- `CREATE EVENT`
- `CREATE VIEW`
- `ALTER EVENT`
- `ALTER VIEW`
- `SET PASSWORD`

For information about the implications that this expansion of `CURRENT_USER()` has for replication, see Section 17.4.1.8, “Replication of CURRENT_USER()”.

- `DATABASE()`

Returns the default (current) database name as a string in the `utf8` character set. If there is no default database, `DATABASE()` returns `NULL`. Within a stored routine, the default database is the database that the routine is associated with, which is not necessarily the same as the database that is the default in the calling context.

```sql
mysql> SELECT DATABASE();
```
Information Functions

- 'test'

If there is no default database, `DATABASE()` returns `NULL`.

- **FOUND_ROWS()**

  A `SELECT` statement may include a `LIMIT` clause to restrict the number of rows the server returns to the client. In some cases, it is desirable to know how many rows the statement would have returned without the `LIMIT`, but without running the statement again. To obtain this row count, include an `SQL_CALC_FOUND_ROWS` option in the `SELECT` statement, and then invoke `FOUND_ROWS()` afterward:

  ```sql
  mysql> SELECT SQL_CALC_FOUND_ROWS * FROM tbl_name
           -> WHERE id > 100 LIMIT 10;
  mysql> SELECT FOUND_ROWS();
  
  The second `SELECT` returns a number indicating how many rows the first `SELECT` would have returned had it been written without the `LIMIT` clause.

  In the absence of the `SQL_CALC_FOUND_ROWS` option in the most recent successful `SELECT` statement, `FOUND_ROWS()` returns the number of rows in the result set returned by that statement. If the statement includes a `LIMIT` clause, `FOUND_ROWS()` returns the number of rows up to the limit. For example, `FOUND_ROWS()` returns 10 or 60, respectively, if the statement includes `LIMIT 10` or `LIMIT 50, 10`.

  The row count available through `FOUND_ROWS()` is transient and not intended to be available past the statement following the `SELECT SQL_CALC_FOUND_ROWS` statement. If you need to refer to the value later, save it:

  ```sql
  mysql> SELECT SQL_CALC_FOUND_ROWS * FROM ... ;
  mysql> SET @rows = FOUND_ROWS();
  
  If you are using `SELECT SQL_CALC_FOUND_ROWS`, MySQL must calculate how many rows are in the full result set. However, this is faster than running the query again without `LIMIT`, because the result set need not be sent to the client.

  `SQL_CALC_FOUND_ROWS` and `FOUND_ROWS()` can be useful in situations when you want to restrict the number of rows that a query returns, but also determine the number of rows in the full result set without running the query again. An example is a Web script that presents a paged display...
containing links to the pages that show other sections of a search result. Using `FOUND_ROWS()` enables you to determine how many other pages are needed for the rest of the result.

The use of `SQL_CALC_FOUND_ROWS` and `FOUND_ROWS()` is more complex for `UNION` statements than for simple `SELECT` statements, because `LIMIT` may occur at multiple places in a `UNION`. It may be applied to individual `SELECT` statements in the `UNION`, or global to the `UNION` result as a whole.

The intent of `SQL_CALC_FOUND_ROWS` for `UNION` is that it should return the row count that would be returned without a global `LIMIT`. The conditions for use of `SQL_CALC_FOUND_ROWS` with `UNION` are:

- The `SQL_CALC_FOUND_ROWS` keyword must appear in the first `SELECT` of the `UNION`.
- The value of `FOUND_ROWS()` is exact only if `UNION ALL` is used. If `UNION` without `ALL` is used, duplicate removal occurs and the value of `FOUND_ROWS()` is only approximate.
- If no `LIMIT` is present in the `UNION`, `SQL_CALC_FOUND_ROWS` is ignored and returns the number of rows in the temporary table that is created to process the `UNION`.

Beyond the cases described here, the behavior of `FOUND_ROWS()` is undefined (for example, its value following a `SELECT` statement that fails with an error).

---

Important

`FOUND_ROWS()` is not replicated reliably using statement-based replication. This function is automatically replicated using row-based replication.

• `LAST_INSERT_ID()`, `LAST_INSERT_ID(expr)`

With no argument, `LAST_INSERT_ID()` returns a 64-bit value representing the first automatically generated value successfully inserted for an `AUTO_INCREMENT` column as a result of the most recently executed `INSERT` statement. The value of `LAST_INSERT_ID()` remains unchanged if no rows are successfully inserted.

With an argument, `LAST_INSERT_ID()` returns an unsigned integer.

For example, after inserting a row that generates an `AUTO_INCREMENT` value, you can get the value like this:

```sql
mysql> SELECT LAST_INSERT_ID();
-> 195
```

The currently executing statement does not affect the value of `LAST_INSERT_ID()`. Suppose that you generate an `AUTO_INCREMENT` value with one statement, and then refer to `LAST_INSERT_ID()` in a multiple-row `INSERT` statement that inserts rows into a table with its own `AUTO_INCREMENT` column. The value of `LAST_INSERT_ID()` will remain stable in the second statement; its value for the second and later rows is not affected by the earlier row insertions. (However, if you mix references to `LAST_INSERT_ID()` and `LAST_INSERT_ID(expr)`, the effect is undefined.)

If the previous statement returned an error, the value of `LAST_INSERT_ID()` is undefined. For transactional tables, if the statement is rolled back due to an error, the value of `LAST_INSERT_ID()` is left undefined. For manual `ROLLBACK`, the value of `LAST_INSERT_ID()` is not restored to that before the transaction; it remains as it was at the point of the `ROLLBACK`.

Prior to MySQL 5.6.15, this function was not replicated correctly if replication filtering rules were in use. (Bug #17234370, Bug #69861)

Within the body of a stored routine (procedure or function) or a trigger, the value of `LAST_INSERT_ID()` changes the same way as for statements executed outside the body of these
kinds of objects. The effect of a stored routine or trigger upon the value of `LAST_INSERT_ID()` that is seen by following statements depends on the kind of routine:

- If a stored procedure executes statements that change the value of `LAST_INSERT_ID()`, the changed value is seen by statements that follow the procedure call.

- For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so following statements will not see a changed value.

The ID that was generated is maintained in the server on a *per-connection basis*. This means that the value returned by the function to a given client is the first `AUTO_INCREMENT` value generated for most recent statement affecting an `AUTO_INCREMENT` column by that client. This value cannot be affected by other clients, even if they generate `AUTO_INCREMENT` values of their own. This behavior ensures that each client can retrieve its own ID without concern for the activity of other clients, and without the need for locks or transactions.

The value of `LAST_INSERT_ID()` is not changed if you set the `AUTO_INCREMENT` column of a row to a non-“magic” value (that is, a value that is not `NULL` and not `0`).

**Important**

If you insert multiple rows using a single `INSERT` statement, `LAST_INSERT_ID()` returns the value generated for the *first* inserted row only. The reason for this is to make it possible to reproduce easily the same `INSERT` statement against some other server.

For example:

```sql
mysql> USE test;

mysql> CREATE TABLE t (
    | id INT AUTO_INCREMENT NOT NULL PRIMARY KEY, |
    | name VARCHAR(10) NOT NULL |
);

mysql> INSERT INTO t VALUES (NULL, 'Bob');

mysql> SELECT * FROM t;
+----+------+
| id | name |
+----+------+
|  1 | Bob  |
+----+------+

mysql> SELECT LAST_INSERT_ID();
+------------------+
| LAST_INSERT_ID() |
+------------------+
|                1 |
+------------------+

mysql> INSERT INTO t VALUES (NULL, 'Mary'), (NULL, 'Jane'), (NULL, 'Lisa');

mysql> SELECT * FROM t;
+----+------+
<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Bob</td>
</tr>
<tr>
<td>2</td>
<td>Mary</td>
</tr>
<tr>
<td>3</td>
<td>Jane</td>
</tr>
<tr>
<td>4</td>
<td>Lisa</td>
</tr>
</tbody>
</table>
+----+------+

mysql> SELECT LAST_INSERT_ID();
+------------------+
| LAST_INSERT_ID() |
+------------------+
|  1441            |
+------------------+
```
Although the second `INSERT` statement inserted three new rows into `t`, the ID generated for the first of these rows was 2, and it is this value that is returned by `LAST_INSERT_ID()` for the following `SELECT` statement.

If you use `INSERT IGNORE` and the row is ignored, the `LAST_INSERT_ID()` remains unchanged from the current value (or 0 is returned if the connection has not yet performed a successful `INSERT`) and, for non-transactional tables, the `AUTO_INCREMENT` counter is not incremented. For InnoDB tables, the `AUTO_INCREMENT` counter is incremented if `innodb_autoinc_lock_mode` is set to 1 or 2, as demonstrated in the following example:

```sql
mysql> USE test;

mysql> SELECT @@innodb_autoinc_lock_mode;
+------------------+
| @@innodb_autoinc_lock_mode |
+------------------+
| 1                  |
+------------------+

mysql> CREATE TABLE `t` (
  `id` INT(11) NOT NULL AUTO_INCREMENT,
  `val` INT(11) DEFAULT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `i1` (`val`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1;

# Insert two rows
mysql> INSERT INTO t (val) VALUES (1),(2);
# With auto_increment_offset=1, the inserted rows result in an AUTO_INCREMENT value of 3
mysql> SHOW CREATE TABLE t
*************************** 1. row ***************************
Table: t
Create Table: CREATE TABLE `t` (`id` int(11) NOT NULL AUTO_INCREMENT, `val` int(11) DEFAULT NULL, PRIMARY KEY (`id`), UNIQUE KEY `i1` (`val`)) ENGINE=InnoDB AUTO_INCREMENT=3 DEFAULT CHARSET=latin1

mysql> SELECT LAST_INSERT_ID();
+------------------+
| LAST_INSERT_ID() |
+------------------+
| 1                |
+------------------+

# The attempted insertion of duplicate rows fail but errors are ignored
mysql> INSERT IGNORE INTO t (val) VALUES (1),(2);
Query OK, 0 rows affected (0.00 sec)
Records: 2  Duplicates: 2  Warnings: 0

mysql> SHOW CREATE TABLE t
*************************** 1. row ***************************
Table: t

# With innodb_autoinc_lock_mode=1, the AUTO_INCREMENT counter is incremented for the ignored rows
mysql> SHOW CREATE TABLE t
*************************** 1. row ***************************
Table: t
Create Table: CREATE TABLE `t` (`id` int(11) NOT NULL AUTO_INCREMENT, `val` int(11) DEFAULT NULL, PRIMARY KEY (`id`), UNIQUE KEY `i1` (`val`)) ENGINE=InnoDB AUTO_INCREMENT=3 DEFAULT CHARSET=latin1
```
For more information, see Section 14.6.1.6, “AUTO_INCREMENT Handling in InnoDB”.

If `expr` is given as an argument to `LAST_INSERT_ID()`, the value of the argument is returned by the function and is remembered as the next value to be returned by `LAST_INSERT_ID()`. This can be used to simulate sequences:

1. Create a table to hold the sequence counter and initialize it:

   ```sql
   mysql> CREATE TABLE sequence (id INT NOT NULL);
   mysql> INSERT INTO sequence VALUES (0);
   ```

2. Use the table to generate sequence numbers like this:

   ```sql
   mysql> UPDATE sequence SET id=LAST_INSERT_ID(id+1);
   mysql> SELECT LAST_INSERT_ID();
   ```

   The `UPDATE` statement increments the sequence counter and causes the next call to `LAST_INSERT_ID()` to return the updated value. The `SELECT` statement retrieves that value. The `mysql_insert_id()` C API function can also be used to get the value. See `mysql_insert_id()`.

You can generate sequences without calling `LAST_INSERT_ID()`, but the utility of using the function this way is that the ID value is maintained in the server as the last automatically generated value. It is multi-user safe because multiple clients can issue the `UPDATE` statement and get their own sequence value with the `SELECT` statement (or `mysql_insert_id()`), without affecting or being affected by other clients that generate their own sequence values.

The `mysql_insert_id()` function is only updated after the `INSERT` and `UPDATE` statements, so you cannot use the C API function to retrieve the value for `LAST_INSERT_ID(expr)` after executing other SQL statements like `SELECT` or `SET`.

- **ROW_COUNT()**

  `ROW_COUNT()` returns a value as follows:

  - DDL statements: 0. This applies to statements such as `CREATE TABLE` or `DROP TABLE`.
  
  - DML statements other than `SELECT`: The number of affected rows. This applies to statements such as `UPDATE`, `INSERT`, or `DELETE` (as before), but now also to statements such as `ALTER TABLE` and `LOAD DATA`.
  
  - `SELECT`: -1 if the statement returns a result set, or the number of rows “affected” if it does not. For example, for `SELECT * FROM t1,ROW_COUNT()` returns -1. For `SELECT * FROM t1 INTO OUTFILE 'file_name'`, `ROW_COUNT()` returns the number of rows written to the file.
  
  - `SIGNAL` statements: 0.

For `UPDATE` statements, the affected-rows value by default is the number of rows actually changed. If you specify the `CLIENT_FOUND_ROWS` flag to `mysql_real_connect()` when connecting to
mysqld, the affected-rows value is the number of rows “found”; that is, matched by the `WHERE` clause.

For `REPLACE` statements, the affected-rows value is 2 if the new row replaced an old row, because in this case, one row was inserted after the duplicate was deleted.

For `INSERT ... ON DUPLICATE KEY UPDATE` statements, the affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the `CLIENT_FOUND_ROWS` flag, the affected-rows value is 1 (not 0) if an existing row is set to its current values.

The `ROW_COUNT()` value is similar to the value from the `mysql_affected_rows()` C API function and the row count that the `mysql` client displays following statement execution.

```sql
mysql> INSERT INTO t VALUES(1),(2),(3);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT ROW_COUNT();
+-------------+
<table>
<thead>
<tr>
<th>ROW_COUNT()</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
</tr>
</tbody>
</table>
+-------------+
1 row in set (0.00 sec)

mysql> DELETE FROM t WHERE i IN(1,2);
Query OK, 2 rows affected (0.00 sec)

mysql> SELECT ROW_COUNT();
+-------------+
<table>
<thead>
<tr>
<th>ROW_COUNT()</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
</tr>
</tbody>
</table>
+-------------+
1 row in set (0.00 sec)
```

### Important

`ROW_COUNT()` is not replicated reliably using statement-based replication. This function is automatically replicated using row-based replication.

- `SCHEMA()`

  This function is a synonym for `DATABASE()`.

- `SESSION_USER()`

  `SESSION_USER()` is a synonym for `USER()`.

- `SYSTEM_USER()`

  `SYSTEM_USER()` is a synonym for `USER()`.

- `USER()`

  Returns the current MySQL user name and host name as a string in the `utf8` character set.

  ```sql
  mysql> SELECT USER();
  -> 'davida@localhost'
  ```

  The value indicates the user name you specified when connecting to the server, and the client host from which you connected. The value can be different from that of `CURRENT_USER()`. 
Spatial Analysis Functions

- **VERSION()**

Returns a string that indicates the MySQL server version. The string uses the `utf8` character set. The value might have a suffix in addition to the version number. See the description of the `version` system variable in Section 5.1.7, “Server System Variables”.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

```
mysql> SELECT VERSION();
-> '5.6.51-standard'
```

### 12.17 Spatial Analysis Functions

MySQL provides functions to perform various operations on spatial data. These functions can be grouped into several major categories according to the type of operation they perform:

- Functions that create geometries in various formats (WKT, WKB, internal)
- Functions that convert geometries between formats
- Functions that access qualitative or quantitative properties of a geometry
- Functions that describe relations between two geometries
- Functions that create new geometries from existing ones

For general background about MySQL support for using spatial data, see Section 11.4, “Spatial Data Types”.

#### 12.17.1 Spatial Function Reference

The following table lists each spatial function and provides a short description of each one.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Area()</td>
<td>Return Polygon or MultiPolygon area</td>
</tr>
<tr>
<td>AsBinary(), AsWKB()</td>
<td>Convert from internal geometry format to WKB</td>
</tr>
<tr>
<td>AsText(), AsWKT()</td>
<td>Convert from internal geometry format to WKT</td>
</tr>
<tr>
<td>Buffer()</td>
<td>Return geometry of points within given distance from geometry</td>
</tr>
<tr>
<td>Centroid()</td>
<td>Return centroid as a point</td>
</tr>
<tr>
<td>Contains()</td>
<td>Whether MBR of one geometry contains MBR of another</td>
</tr>
<tr>
<td>Crosses()</td>
<td>Whether one geometry crosses another</td>
</tr>
<tr>
<td>Dimension()</td>
<td>Dimension of geometry</td>
</tr>
<tr>
<td>Disjoint()</td>
<td>Whether MBRs of two geometries are disjoint</td>
</tr>
<tr>
<td>EndPoint()</td>
<td>End Point of LineString</td>
</tr>
<tr>
<td>Envelope()</td>
<td>Return MBR of geometry</td>
</tr>
<tr>
<td>Equals()</td>
<td>Whether MBRs of two geometries are equal</td>
</tr>
<tr>
<td>ExteriorRing()</td>
<td>Return exterior ring of Polygon</td>
</tr>
<tr>
<td>GeomCollFromText(),</td>
<td>Return geometry collection from WKT</td>
</tr>
<tr>
<td>GeometryCollectionFromText()</td>
<td></td>
</tr>
<tr>
<td>GeomCollFromWKB(),</td>
<td>Return geometry collection from WKB</td>
</tr>
<tr>
<td>GeometryCollectionFromWKB()</td>
<td></td>
</tr>
<tr>
<td>GeometryCollection()</td>
<td>Construct geometry collection from geometries</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>------------------------------------------------</td>
</tr>
<tr>
<td>GeometryN()</td>
<td>Return N-th geometry from geometry collection</td>
</tr>
<tr>
<td>GeometryType()</td>
<td>Return name of geometry type</td>
</tr>
<tr>
<td>GeomFromText(), GeometryFromText()</td>
<td>Return geometry from WKT</td>
</tr>
<tr>
<td>GeomFromWKB(), GeometryFromWKB()</td>
<td>Return geometry from WKB</td>
</tr>
<tr>
<td>GLength()</td>
<td>Return length of LineString</td>
</tr>
<tr>
<td>InteriorRingN()</td>
<td>Return N-th interior ring of Polygon</td>
</tr>
<tr>
<td>Intersects()</td>
<td>Whether MBRs of two geometries intersect</td>
</tr>
<tr>
<td>IsClosed()</td>
<td>Whether a geometry is closed and simple</td>
</tr>
<tr>
<td>IsEmpty()</td>
<td>Whether a geometry is empty</td>
</tr>
<tr>
<td>IsSimple()</td>
<td>Whether a geometry is simple</td>
</tr>
<tr>
<td>LineFromText(), LineStringFromText()</td>
<td>Construct LineString from WKT</td>
</tr>
<tr>
<td>LineFromWKB(), LineStringFromWKB()</td>
<td>Construct LineString from WKB</td>
</tr>
<tr>
<td>LineString()</td>
<td>Construct LineString from Point values</td>
</tr>
<tr>
<td>MBRContains()</td>
<td>Whether MBR of one geometry contains MBR of another</td>
</tr>
<tr>
<td>MBRDisjoint()</td>
<td>Whether MBRs of two geometries are disjoint</td>
</tr>
<tr>
<td>MBREqual()</td>
<td>Whether MBRs of two geometries are equal</td>
</tr>
<tr>
<td>MBRIntersects()</td>
<td>Whether MBRs of two geometries intersect</td>
</tr>
<tr>
<td>MBROverlaps()</td>
<td>Whether MBRs of two geometries overlap</td>
</tr>
<tr>
<td>MBRTouches()</td>
<td>Whether MBRs of two geometries touch</td>
</tr>
<tr>
<td>MBRWithin()</td>
<td>Whether MBR of one geometry is within MBR of another</td>
</tr>
<tr>
<td>MLineFromText(), MultiLineStringFromText()</td>
<td>Construct MultiLineString from WKT</td>
</tr>
<tr>
<td>MLineFromWKB(), MultiLineStringFromWKB()</td>
<td>Construct MultiLineString from WKB</td>
</tr>
<tr>
<td>MPointFromText(), MultiPointFromText()</td>
<td>Construct MultiPoint from WKT</td>
</tr>
<tr>
<td>MPointFromWKB(), MultiPointFromWKB()</td>
<td>Construct MultiPoint from WKB</td>
</tr>
<tr>
<td>MPolyFromText(), MultiPolygonFromText()</td>
<td>Construct MultiPolygon from WKT</td>
</tr>
<tr>
<td>MPolyFromWKB(), MultiPolygonFromWKB()</td>
<td>Construct MultiPolygon from WKB</td>
</tr>
<tr>
<td>MultiLineString()</td>
<td>Construct MultiLineString from LineString values</td>
</tr>
<tr>
<td>MultiPoint()</td>
<td>Construct MultiPoint from Point values</td>
</tr>
<tr>
<td>MultiPolygon()</td>
<td>Construct MultiPolygon from Polygon values</td>
</tr>
<tr>
<td>NumGeometries()</td>
<td>Return number of geometries in geometry collection</td>
</tr>
<tr>
<td>NumInteriorRings()</td>
<td>Return number of interior rings in Polygon</td>
</tr>
<tr>
<td>NumPoints()</td>
<td>Return number of points in LineString</td>
</tr>
<tr>
<td>Overlaps()</td>
<td>Whether MBRs of two geometries overlap</td>
</tr>
<tr>
<td>Point()</td>
<td>Construct Point from coordinates</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>---------------------------------------</td>
</tr>
<tr>
<td>PointFromText()</td>
<td>Construct Point from WKT</td>
</tr>
<tr>
<td>PointFromWKB()</td>
<td>Construct Point from WKB</td>
</tr>
<tr>
<td>PointN()</td>
<td>Return N-th point from LineString</td>
</tr>
<tr>
<td>PolyFromText(), PolygonFromText()</td>
<td>Construct Polygon from WKT</td>
</tr>
<tr>
<td>PolyFromWKB(), PolygonFromWKB()</td>
<td>Construct Polygon from WKB</td>
</tr>
<tr>
<td>Polygon()</td>
<td>Construct Polygon from LineString arguments</td>
</tr>
<tr>
<td>SRID()</td>
<td>Return spatial reference system ID for geometry</td>
</tr>
<tr>
<td>ST_Area()</td>
<td>Return Polygon or MultiPolygon area</td>
</tr>
<tr>
<td>ST_AsBinary(), ST_AsWKB()</td>
<td>Convert from internal geometry format to WKB</td>
</tr>
<tr>
<td>ST_AsText(), ST_AsWKT()</td>
<td>Convert from internal geometry format to WKT</td>
</tr>
<tr>
<td>ST_Buffer()</td>
<td>Return geometry of points within given distance from geometry</td>
</tr>
<tr>
<td>ST_Centroid()</td>
<td>Return centroid as a point</td>
</tr>
<tr>
<td>ST_Contains()</td>
<td>Whether one geometry contains another</td>
</tr>
<tr>
<td>ST_Crosses()</td>
<td>Whether one geometry crosses another</td>
</tr>
<tr>
<td>ST_Difference()</td>
<td>Return point set difference of two geometries</td>
</tr>
<tr>
<td>ST_Dimension()</td>
<td>Dimension of geometry</td>
</tr>
<tr>
<td>ST_Disjoint()</td>
<td>Whether one geometry is disjoint from another</td>
</tr>
<tr>
<td>ST_Distance()</td>
<td>The distance of one geometry from another</td>
</tr>
<tr>
<td>ST_EndPoint()</td>
<td>End Point of LineString</td>
</tr>
<tr>
<td>ST_Envelope()</td>
<td>Return MBR of geometry</td>
</tr>
<tr>
<td>ST_Equals()</td>
<td>Whether one geometry is equal to another</td>
</tr>
<tr>
<td>ST_ExteriorRing()</td>
<td>Return exterior ring of Polygon</td>
</tr>
<tr>
<td>ST_GeomCollFromText(), ST_GeometryCollectionFromText(), ST_GeomCollFromTxt()</td>
<td>Return geometry collection from WKT</td>
</tr>
<tr>
<td>ST_GeomCollFromWKB(), ST_GeometryCollectionFromWKB()</td>
<td>Return geometry collection from WKB</td>
</tr>
<tr>
<td>ST_GeometryN()</td>
<td>Return N-th geometry from geometry collection</td>
</tr>
<tr>
<td>ST_GeometryType()</td>
<td>Return name of geometry type</td>
</tr>
<tr>
<td>ST_GeomFromText(), ST_GeometryFromText()</td>
<td>Return geometry from WKT</td>
</tr>
<tr>
<td>ST_GeomFromWKB(), ST_GeometryFromWKB()</td>
<td>Return geometry from WKB</td>
</tr>
<tr>
<td>ST_InteriorRingN()</td>
<td>Return N-th interior ring of Polygon</td>
</tr>
<tr>
<td>ST_Intersection()</td>
<td>Return point set intersection of two geometries</td>
</tr>
<tr>
<td>ST_Intersects()</td>
<td>Whether one geometry intersects another</td>
</tr>
<tr>
<td>ST_IsClosed()</td>
<td>Whether a geometry is closed and simple</td>
</tr>
<tr>

<tr>
<td>ST_PointN()</td>
<td>Return N-th point from LineString</td>
</tr>
<tr>
<td>ST_PolyFromText(),</td>
<td>Construct Polygon from WKT</td>
</tr>
<tr>
<td>ST_PolygonFromText()</td>
<td></td>
</tr>
<tr>
<td>ST_PolyFromWKB(),</td>
<td>Construct Polygon from WKB</td>
</tr>
<tr>
<td>ST_PolygonFromWKB()</td>
<td></td>
</tr>
<tr>
<td>ST_SRID()</td>
<td>Return spatial reference system ID for geometry</td>
</tr>
<tr>
<td>ST_StartPoint()</td>
<td>Start Point of LineString</td>
</tr>
<tr>
<td>ST_SymDifference()</td>
<td>Return point set symmetric difference of two geometries</td>
</tr>
<tr>
<td>ST_Touches()</td>
<td>Whether one geometry touches another</td>
</tr>
<tr>
<td>ST_Union()</td>
<td>Return point set union of two geometries</td>
</tr>
<tr>
<td>ST_Within()</td>
<td>Whether one geometry is within another</td>
</tr>
<tr>
<td>ST_X()</td>
<td>Return X coordinate of Point</td>
</tr>
<tr>
<td>ST_Y()</td>
<td>Return Y coordinate of Point</td>
</tr>
<tr>
<td>StartPoint()</td>
<td>Start Point of LineString</td>
</tr>
<tr>
<td>Touches()</td>
<td>Whether one geometry touches another</td>
</tr>
<tr>
<td>Within()</td>
<td>Whether MBR of one geometry is within MBR of another</td>
</tr>
<tr>
<td>X()</td>
<td>Return X coordinate of Point</td>
</tr>
<tr>
<td>Y()</td>
<td>Return Y coordinate of Point</td>
</tr>
</tbody>
</table>

12.17.2 Argument Handling by Spatial Functions

Spatial values, or geometries, have the properties described in Section 11.4.2.2, “Geometry Class”. The following discussion lists general spatial function argument-handling characteristics. Specific functions or groups of functions may have additional or different argument-handling characteristics, as discussed in the sections where those function descriptions occur. Where that is true, those descriptions take precedence over the general discussion here.

Spatial functions are defined only for valid geometry values. If an invalid geometry is passed to a spatial function, the result is undefined.

The spatial reference identifier (SRID) of a geometry identifies the coordinate space in which the geometry is defined. In MySQL, the SRID value is an integer associated with the geometry value. The maximum usable SRID value is 2^{32}−1. If a larger value is given, only the lower 32 bits are used.

Geometry values produced by any spatial function inherit the SRID of the geometry arguments.
12.17.3 Functions That Create Geometry Values from WKT Values

These functions take as arguments a Well-Known Text (WKT) representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry.

`GeomFromText()` and `ST_GeomFromText()` accept a WKT value of any geometry type as their first argument. Other functions provide type-specific construction functions for construction of geometry values of each geometry type.

For a description of WKT format, see Well-Known Text (WKT) Format.

- `GeomCollFromText(wkt[, srid]), GeometryCollectionFromText(wkt[, srid])`
  `ST_GeomCollFromText(), ST_GeometryCollectionFromText(), and GeometryCollectionFromText()` are synonyms. For more information, see the description of `ST_GeomCollFromText()`.

- `GeomFromText(wkt[, srid]), GeometryFromText(wkt[, srid])`
  `ST_GeomFromText(), ST_GeometryFromText(), GeomFromText(), and GeometryFromText()` are synonyms. For more information, see the description of `ST_GeomFromText()`.

- `LineFromText(wkt[, srid]), LineStringFromText(wkt[, srid])`
  `ST_LineFromText(), ST_LineStringFromText(), LineFromText(), and LineStringFromText()` are synonyms. For more information, see the description of `ST_LineFromText()`.

- `MLineFromText(wkt[, srid]), MultiLineStringFromText(wkt[, srid])`
  Constructs a MultiLineString value using its WKT representation and SRID.
  The result is `NULL` if the geometry argument is `NULL` or not a syntactically well-formed geometry.

- `MPointFromText(wkt[, srid]), MultiPointFromText(wkt[, srid])`
  Constructs a MultiPoint value using its WKT representation and SRID.
  The result is `NULL` if the geometry argument is `NULL` or not a syntactically well-formed geometry.

- `MPolyFromText(wkt[, srid]), MultiPolygonFromText(wkt[, srid])`
  Constructs a MultiPolygon value using its WKT representation and SRID.
  The result is `NULL` if the geometry argument is `NULL` or not a syntactically well-formed geometry.

- `PointFromText(wkt[, srid])`
  `ST_PointFromText()` and `PointFromText()` are synonyms. For more information, see the description of `ST_PointFromText()`.

- `PolyFromText(wkt[, srid]), PolygonFromText(wkt[, srid])`
  `ST_PolyFromText(), ST_PolygonFromText(), PolyFromText(), and PolygonFromText()` are synonyms. For more information, see the description of `ST_PolyFromText()`.

- `ST_GeomCollFromText(wkt[, srid]), ST_GeometryCollectionFromText(wkt[, srid])`
  Constructs a GeometryCollection value using its WKT representation and SRID.
  The result is `NULL` if the geometry argument is `NULL` or not a syntactically well-formed geometry.
Functions That Create Geometry Values from WKB Values

12.17.4 Functions That Create Geometry Values from WKB Values

These functions take as arguments a BLOB containing a Well-Known Binary (WKB) representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry.

GeomFromWKB() and ST_GeomFromWKB() accept a WKB value of any geometry type as their first argument. Other functions provide type-specific construction functions for construction of geometry values of each geometry type.

These functions also accept geometry objects as returned by the functions in Section 12.17.5, “MySQL-Specific Functions That Create Geometry Values”. Thus, those functions may be used to provide the first argument to the functions in this section.

For a description of WKB format, see Well-Known Binary (WKB) Format.
Functions That Create Geometry Values from WKB Values

ST_GeomCollFromWKB(), ST_GeometryCollectionFromWKB(), GeomCollFromWKB(), and GeometryCollectionFromWKB() are synonyms. For more information, see the description of ST_GeomCollFromWKB().

- GeomFromWKB(wkb[, srid]), GeometryFromWKB(wkb[, srid])
  
  ST_GeomFromWKB(), ST_GeometryFromWKB(), GeomFromWKB(), and GeometryFromWKB() are synonyms. For more information, see the description of ST_GeomFromWKB().

- LineFromWKB(wkb[, srid]), LineStringFromWKB(wkb[, srid])
  
  ST_LineFromWKB(), ST_LineStringFromWKB(), LineFromWKB(), and LineStringFromWKB() are synonyms. For more information, see the description of ST_LineFromWKB().

- MLineFromWKB(wkb[, srid]), MultiLineStringFromWKB(wkb[, srid])
  Constructs a MultiLineString value using its WKB representation and SRID.
  The result is NULL if the WKB or SRID argument is NULL.

- MPointFromWKB(wkb[, srid]), MultiPointFromWKB(wkb[, srid])
  Constructs a MultiPoint value using its WKB representation and SRID.
  The result is NULL if the WKB or SRID argument is NULL.

- MPolyFromWKB(wkb[, srid]), MultiPolygonFromWKB(wkb[, srid])
  Constructs a MultiPolygon value using its WKB representation and SRID.
  The result is NULL if the WKB or SRID argument is NULL.

- PointFromWKB(wkb[, srid])
  ST_PointFromWKB() and PointFromWKB() are synonyms. For more information, see the description of ST_PointFromWKB().

- PolyFromWKB(wkb[, srid]), PolygonFromWKB(wkb[, srid])
  ST_PolyFromWKB(), ST_PolygonFromWKB(), PolyFromWKB(), and PolygonFromWKB() are synonyms. For more information, see the description of ST_PolyFromWKB().

- ST_GeomCollFromWKB(wkb[, srid]), ST_GeometryCollectionFromWKB(wkb[, srid])
  Constructs a GeometryCollection value using its WKB representation and SRID.
  The result is NULL if the WKB or SRID argument is NULL.

ST_GeomCollFromWKB(), ST_GeometryCollectionFromWKB(), GeomCollFromWKB(), and GeometryCollectionFromWKB() are synonyms.

- ST_GeomFromWKB(wkb[, srid]), ST_GeometryFromWKB(wkb[, srid])
  Constructs a geometry value of any type using its WKB representation and SRID.
  The result is NULL if the WKB or SRID argument is NULL.

ST_GeomFromWKB(), ST_GeometryFromWKB(), GeomFromWKB(), and GeometryFromWKB() are synonyms.

- ST_LineFromWKB(wkb[, srid]), ST_LineStringFromWKB(wkb[, srid])
Constructs a `LineString` value using its WKB representation and SRID.

The result is `NULL` if the WKB or SRID argument is `NULL`.

`ST_LineFromWKB()`, `ST_LineStringFromWKB()`, `LineFromWKB()`, and `LineStringFromWKB()` are synonyms.

- `ST_PointFromWKB(wkb[, srid])`

Constructs a `Point` value using its WKB representation and SRID.

The result is `NULL` if the WKB or SRID argument is `NULL`.

`ST_PointFromWKB()` and `PointFromWKB()` are synonyms.

- `ST_PolyFromWKB(wkb[, srid]), ST_PolygonFromWKB(wkb[, srid])`

Constructs a `Polygon` value using its WKB representation and SRID.

The result is `NULL` if the WKB or SRID argument is `NULL`.

`ST_PolyFromWKB()`, `ST_PolygonFromWKB()`, `PolyFromWKB()`, and `PolygonFromWKB()` are synonyms.

### 12.17.5 MySQL-Specific Functions That Create Geometry Values

MySQL provides a set of useful nonstandard functions for creating geometry values. The functions described in this section are MySQL extensions to the OpenGIS specification.

These functions produce geometry objects from either WKB values or geometry objects as arguments. If any argument is not a proper WKB or geometry representation of the proper object type, the return value is `NULL`.

For example, you can insert the geometry return value from `Point()` directly into a `POINT` column:

```
INSERT INTO t1 (pt_col) VALUES(Point(1,2));
```

- `GeometryCollection(g [, g] ...)`

Constructs a `GeometryCollection` value from the geometry arguments.

If an argument contains a nonsupported geometry, the return value is `NULL`.

- `LineString(pt [, pt] ...)`

Constructs a `LineString` value from a number of `Point` or WKB `Point` arguments. If the number of arguments is less than two, the return value is `NULL`.

- `MultiLineString(ls [, ls] ...)`

Constructs a `MultiLineString` value using `LineString` or WKB `LineString` arguments.

- `MultiPoint(pt [, pt2] ...)`

Constructs a `MultiPoint` value using `Point` or WKB `Point` arguments.

- `MultiPolygon(poly [, poly] ...)`

Constructs a `MultiPolygon` value from a set of `Polygon` or WKB `Polygon` arguments.

- `Point(x, y)`

Constructs a `Point` using its coordinates.
• **Polygon(ls [, ls] ...)**

Constructs a **Polygon** value from a number of **LineString** or WKB **LineString** arguments. If any argument does not represent a **LinearRing** (that is, not a closed and simple **LineString**), the return value is **NULL**.

### 12.17.6 Geometry Format Conversion Functions

MySQL supports the functions listed in this section for converting geometry values from internal geometry format to WKT or WKB format.

There are also functions to convert a string from WKT or WKB format to internal geometry format. See Section 12.17.3, “Functions That Create Geometry Values from WKT Values”, and Section 12.17.4, “Functions That Create Geometry Values from WKB Values”.

• **AsBinary(g), AsWKB(g)**

  - **ST_AsBinary(), ST_AsWKB(), AsBinary(), and AsWKB()** are synonyms. For more information, see the description of **ST_AsBinary()**.

• **AsText(g), AsWKT(g)**

  - **ST_AsText(), ST_AsWKT(), AsText(), and AsWKT()** are synonyms. For more information, see the description of **ST_AsText()**.

• **ST_AsBinary(g), ST_AsWKB(g)**

  Converts a value in internal geometry format to its WKB representation and returns the binary result. The result is **NULL** if the geometry argument is **NULL** or not a syntactically well-formed geometry.

  ```sql
  SELECT ST_AsBinary(g) FROM geom;
  ``

  **ST_AsBinary(), ST_AsWKB(), AsBinary(), and AsWKB()** are synonyms.

• **ST_AsText(g), ST_AsWKT(g)**

  Converts a value in internal geometry format to its WKT representation and returns the string result. The result is **NULL** if the geometry argument is **NULL** or not a syntactically well-formed geometry.

  ```sql
  mysql> SET @g = 'LineString(1 1,2 2,3 3)';
  mysql> SELECT ST_AsText(ST_GeomFromText(@g));
  +--------------------------------+
  | ST_AsText(ST_GeomFromText(@g)) |
  +--------------------------------+
  | LINESTRING(1 1,2 2,3 3)        |
  +--------------------------------+
  ``

  **ST_AsText(), ST_AsWKT(), AsText(), and AsWKT()** are synonyms.

### 12.17.7 Geometry Property Functions

Each function that belongs to this group takes a geometry value as its argument and returns some quantitative or qualitative property of the geometry. Some functions restrict their argument type. Such functions return **NULL** if the argument is of an incorrect geometry type. For example, the **ST_Area()** polygon function returns **NULL** if the object type is neither **Polygon** nor **MultiPolygon**.

#### 12.17.7.1 General Geometry Property Functions

The functions listed in this section do not restrict their argument and accept a geometry value of any type.

• **Dimension(g)**
ST_Dimension() and Dimension() are synonyms. For more information, see the description of ST_Dimension().

• Envelope(g)

ST_Envelope() and Envelope() are synonyms. For more information, see the description of ST_Envelope().

• GeometryType(g)

ST_GeometryType() and GeometryType() are synonyms. For more information, see the description of ST_GeometryType().

• IsEmpty(g)

ST_IsEmpty() and IsEmpty() are synonyms. For more information, see the description of ST_IsEmpty().

• IsSimple(g)

ST_IsSimple() and IsSimple() are synonyms. For more information, see the description of ST_IsSimple().

• SRID(g)

ST_SRID() and SRID() are synonyms. For more information, see the description of ST_SRID().

• ST_Dimension(g)

Returns the inherent dimension of the geometry value g, or NULL if the argument is NULL. The dimension can be −1, 0, 1, or 2. The meaning of these values is given in Section 11.4.2.2, “Geometry Class”.

```sql
mysql> SELECT ST_Dimension(ST_GeomFromText('LineString(1 1,2 2)'));
+------------------------------------------------------+
| ST_Dimension(ST_GeomFromText('LineString(1 1,2 2)')) |
+------------------------------------------------------+
|                                                    1 |
+------------------------------------------------------+
```

ST_Dimension() and Dimension() are synonyms.

• ST_Envelope(g)

Returns the minimum bounding rectangle (MBR) for the geometry value g, or NULL if the argument is NULL. The result is returned as a Polygon value that is defined by the corner points of the bounding box:

```
POLYGON((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))
```

```sql
mysql> SELECT ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,2 2)')));
+----------------------------------------------------------------+
| ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,2 2)'))) |
+----------------------------------------------------------------+
| POLYGON((1 1,2 1,2 2,1 2,1 1))                                 |
+----------------------------------------------------------------+
```

ST_Envelope() and Envelope() are synonyms.

• ST_GeometryType(g)

Returns a binary string indicating the name of the geometry type of which the geometry instance g is a member, or NULL if the argument is NULL. The name corresponds to one of the instantiable Geometry subclasses.
ST_GeometryType() and GeometryType() are synonyms.

- **ST_IsEmpty(g)**
  
  This function is a placeholder that returns 0 for any valid geometry value, 1 for any invalid geometry value, or NULL if the argument is NULL.

MySQL does not support GIS EMPTY values such as POINT EMPTY.

ST_IsEmpty() and IsEmpty() are synonyms.

- **ST_IsSimple(g)**

  Returns 1 if the geometry value g has no anomalous geometric points, such as self-intersection or self-tangency. ST_IsSimple() returns 0 if the argument is not simple, and NULL if the argument is NULL.

  The descriptions of the instantiable geometric classes given under Section 11.4.2, “The OpenGIS Geometry Model” includes the specific conditions that cause class instances to be classified as not simple.

ST_IsSimple() and IsSimple() are synonyms.

- **ST_SRID(g)**

  Returns an integer indicating the spatial reference system ID associated with the geometry value g, or NULL if the argument is NULL.

12.17.7.2 Point Property Functions

A Point consists of X and Y coordinates, which may be obtained using the following functions:

- **ST_X(p)**

  Returns the X-coordinate value for the Point object p as a double-precision number.

1455
ST_X() and Y() are synonyms.

- \( X(p) \)
  
  ST_X() and X() are synonyms. For more information, see the description of ST_X().

- \( Y(p) \)
  
  ST_Y() and Y() are synonyms. For more information, see the description of ST_Y().

### 12.17.7.3 LineString and MultiLineString Property Functions

A LineString consists of Point values. You can extract particular points of a LineString, count the number of points that it contains, or obtain its length.

Some functions in this section also work for MultiLineString values.

- **EndPoint(ls)**
  
  ST_EndPoint() and EndPoint() are synonyms. For more information, see the description of ST_EndPoint().

- **GLength(ls)**
  
  Returns a double-precision number indicating the length of the LineString or MultiLineString value \( ls \) in its associated spatial reference. The length of a MultiLineString value is equal to the sum of the lengths of its elements. If the argument is NULL or an empty geometry, the return value is NULL.

```sql
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT GLength(GeomFromText(@ls));
+----------------------------+
| GLength(GeomFromText(@ls)) |
+----------------------------+
|         2.8284271247461903 |
+----------------------------+

mysql> SET @mls = 'MultiLineString((1 1,2 2,3 3),(4 4,5 5))';
mysql> SELECT GLength(GeomFromText(@mls));
+-----------------------------+
| GLength(GeomFromText(@mls)) |
+-----------------------------+
|           4.242640687119286 |
+-----------------------------+
```

GLength() is a nonstandard name. It corresponds to the OpenGIS Length() function. (There is an existing SQL function Length() that calculates the length of string values.)

- **IsClosed(ls)**
  
  ST_IsClosed() and IsClosed() are synonyms. For more information, see the description of ST_IsClosed().

- **NumPoints(ls)**
  
  ST_NumPoints() and NumPoints() are synonyms. For more information, see the description of ST_NumPoints().

- **PointN(ls, N)***
Geometry Property Functions

**ST_PointN() and PointN()** are synonyms. For more information, see the description of ST_PointN().

- **ST_EndPoint(ls)**

  Returns the Point that is the endpoint of the LineString value `ls`. If the argument is NULL or an empty geometry, the return value is NULL.

  ```
  mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
  mysql> SELECT ST_AsText(ST_EndPoint(ST_GeomFromText(@ls)));
  +----------------------------------------------+
  | ST_AsText(ST_EndPoint(ST_GeomFromText(@ls))) |
  +----------------------------------------------+
  | POINT(3 3)                                   |
  +----------------------------------------------+
  
  ST_EndPoint() and EndPoint() are synonyms.

- **ST_IsClosed(ls)**

  For a LineString value `ls`, ST_IsClosed() returns 1 if `ls` is closed (that is, its ST_StartPoint() and ST_EndPoint() values are the same). If the argument is NULL or an empty geometry, the return value is NULL.

  For a MultiLineString value `ls`, ST_IsClosed() returns 1 if `ls` is closed (that is, the ST_StartPoint() and ST_EndPoint() values are the same for each LineString in `ls`).

  ```
  mysql> SET @ls1 = 'LineString(1 1,2 2,3 3,2 2)';
  mysql> SET @ls2 = 'LineString(1 1,2 2,3 3,1 1)';
  mysql> SELECT ST_IsClosed(ST_GeomFromText(@ls1));
  +------------------------------------+
  | ST_IsClosed(ST_GeomFromText(@ls1)) |
  +------------------------------------+
  |                                  0 |
  +------------------------------------+
  
  mysql> SELECT ST_IsClosed(ST_GeomFromText(@ls2));
  +------------------------------------+
  | ST_IsClosed(ST_GeomFromText(@ls2)) |
  +------------------------------------+
  |                                  1 |
  +------------------------------------+
  
  mysql> SET @ls3 = 'MultiLineString((1 1,2 2,3 3),(4 4,5 5))';
  mysql> SELECT ST_IsClosed(ST_GeomFromText(@ls3));
  +------------------------------------+
  | ST_IsClosed(ST_GeomFromText(@ls3)) |
  +------------------------------------+
  |                                  0 |
  +------------------------------------+
  
  ST_IsClosed() and IsClosed() are synonyms.

- **ST_NumPoints(ls)**

  Returns the number of Point objects in the LineString value `ls`. If the argument is NULL or an empty geometry, the return value is NULL.

  ```
  mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
  mysql> SELECT ST_NumPoints(ST_GeomFromText(@ls));
  +------------------------------------+
  | ST_NumPoints(ST_GeomFromText(@ls)) |
  +------------------------------------+
  |                                  3 |
  +------------------------------------+
  ```
Geometry Property Functions

<table>
<thead>
<tr>
<th>3</th>
</tr>
</thead>
</table>

**ST_NumPoints()** and **NumPoints()** are synonyms.

- **ST_PointN(ls, N)**

  Returns the N-th Point in the LineString value *ls*. Points are numbered beginning with 1. If any argument is NULL or the geometry argument is an empty geometry, the return value is NULL.

  ```sql
  mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
  mysql> SELECT ST_AsText(ST_PointN(ST_GeomFromText(@ls),2));
  +----------------------------------------------+
  | ST_AsText(ST_PointN(ST_GeomFromText(@ls),2)) |
  +----------------------------------------------+
  | POINT(2 2)                                   |
  +----------------------------------------------+
  ```

**ST_PointN()** and **PointN()** are synonyms.

- **ST_StartPoint(ls)**

  Returns the Point that is the start point of the LineString value *ls*. If the argument is NULL or an empty geometry, the return value is NULL.

  ```sql
  mysql> SET @ls = 'LineString(1,2,3)';
  mysql> SELECT ST_AsText(ST_StartPoint(ST_GeomFromText(@ls)));;
  +------------------------------------------------+
  | ST_AsText(ST_StartPoint(ST_GeomFromText(@ls))) |
  +------------------------------------------------+
  | POINT(1 1)                                     |
  +------------------------------------------------+
  ```

**ST_StartPoint()** and **StartPoint()** are synonyms. For more information, see the description of **ST_StartPoint()**.

12.17.7.4 Polygon and MultiPolygon Property Functions

Functions in this section return properties of Polygon or MultiPolygon values.

- **Area({poly|mpoly})**

  **ST_Area()** and **Area()** are synonyms. For more information, see the description of **ST_Area()**.

- **Centroid({poly|mpoly})**

  **ST_Centroid()** and **Centroid()** are synonyms. For more information, see the description of **ST_Centroid()**.

- **ExteriorRing(poly)**

  **ST_ExteriorRing()** and **ExteriorRing()** are synonyms. For more information, see the description of **ST_ExteriorRing()**.

- **InteriorRingN(poly, N)**

  **ST_InteriorRingN()** and **InteriorRingN()** are synonyms. For more information, see the description of **ST_InteriorRingN()**.

- **NumInteriorRings(poly)**
**ST_NumInteriorRings()** and **NumInteriorRings()** are synonyms. For more information, see the description of **ST_NumInteriorRings()**.

- **ST_Area({poly|mpoly})**

Returns a double-precision number indicating the area of the **Polygon** or **MultiPolygon** argument, as measured in its spatial reference system. For arguments of dimension 0 or 1, the result is 0. If the argument is an empty geometry the return value is 0. If the argument is **NULL** the return value is **NULL**.

```sql
mysql> SET @poly = 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 1,1 1))';
mysql> SELECT ST_Area(ST_GeomFromText(@poly));
+---------------------------------+
| ST_Area(ST_GeomFromText(@poly)) |
+---------------------------------+
|                               4 |
+---------------------------------+

mysql> SET @mpoly = 'MultiPolygon(((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1)))';
mysql> SELECT ST_Area(ST_GeomFromText(@mpoly));
+----------------------------------+
| ST_Area(ST_GeomFromText(@mpoly)) |
+----------------------------------+
|                                8 |
+----------------------------------+
```

**ST_Area()** and **Area()** are synonyms.

- **ST_Centroid({poly|mpoly})**

Returns the mathematical centroid for the **Polygon** or **MultiPolygon** argument as a **Point**. The result is not guaranteed to be on the **MultiPolygon**. If the argument is **NULL** or an empty geometry, the return value is **NULL**.

```sql
mysql> SET @poly = ST_GeomFromText('POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7,5 5))');
mysql> SELECT GeometryType(@poly),ST_AsText(ST_Centroid(@poly));
+---------------------+--------------------------------------------+
| GeometryType(@poly) | ST_AsText(ST_Centroid(@poly))              |
+---------------------+--------------------------------------------+
| POLYGON             | POINT(4.958333333333333 4.958333333333333) |
+---------------------+--------------------------------------------+
```

**ST_Centroid()** and **Centroid()** are synonyms.

- **ST_ExteriorRing(poly)**

Returns the exterior ring of the **Polygon** value **poly** as a **LineString**. If the argument is **NULL** or an empty geometry, the return value is **NULL**.

```sql
mysql> SET @poly = ST_GeomFromText('POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7,5 5))');
mysql> SELECT ST_AsText(ST_ExteriorRing(ST_GeomFromText(@poly)));
+----------------------------------------------------+
| ST_AsText(ST_ExteriorRing(ST_GeomFromText(@poly))) |
+----------------------------------------------------+
| LINESTRING(0 0,0 3,3 3,3 0,0 0)                    |
+----------------------------------------------------+
```

**ST_ExteriorRing()** and **ExteriorRing()** are synonyms.
Geometry Property Functions

- **ST_InteriorRingN(poly, N)**

  Returns the \( N \)-th interior ring for the Polygon value \( poly \) as a LineString. Rings are numbered beginning with 1. If the argument is NULL or an empty geometry, the return value is NULL.

  ```
  mysql> SET @poly = 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,2 2,2 1,1 1))';
  mysql> SELECT ST_AsText(ST_InteriorRingN(ST_GeomFromText(@poly),1));
  +-------------------------------------------------------+
  | ST_AsText(ST_InteriorRingN(ST_GeomFromText(@poly),1)) |
  | LINESTRING(1 1,1 2,2 2,2 1,1 1)                        |
  +-------------------------------------------------------+
  
  ST_InteriorRingN() and InteriorRingN() are synonyms.

- **ST_NumInteriorRings(poly)**

  Returns the number of interior rings in the Polygon value \( poly \). If the argument is NULL or an empty geometry, the return value is NULL.

  ```
  mysql> SET @poly = 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,2 2,2 1,1 1))';
  mysql> SELECT ST_NumInteriorRings(ST_GeomFromText(@poly));
  +---------------------------------------------+
  | ST_NumInteriorRings(ST_GeomFromText(@poly))  |
  |                                           1 |
  +---------------------------------------------+
  
  ST_NumInteriorRings() and NumInteriorRings() are synonyms.

12.17.7.5 GeometryCollection Property Functions

These functions return properties of GeometryCollection values.

- **GeometryN(gc, N)**

  ST_GeometryN() and GeometryN() are synonyms. For more information, see the description of ST_GeometryN().

- **NumGeometries(gc)**

  ST_NumGeometries() and NumGeometries() are synonyms. For more information, see the description of ST_NumGeometries().

- **ST_GeometryN(gc, N)**

  Returns the \( N \)-th geometry in the GeometryCollection value \( gc \). Geometries are numbered beginning with 1. If any argument is NULL or the geometry argument is an empty geometry, the return value is NULL.

  ```
  mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
  mysql> SELECT ST_AsText(ST_GeometryN(ST_GeomFromText(@gc),1));
  +-------------------------------------------------+
  | ST_AsText(ST_GeometryN(ST_GeomFromText(@gc),1)) |
  | POINT(1 1)                                      |
  +-------------------------------------------------+
  
  ST_GeometryN() and GeometryN() are synonyms.

- **ST_NumGeometries(gc)**

  Returns the number of geometries in the GeometryCollection value \( gc \). If the argument is NULL or an empty geometry, the return value is NULL.
Spatial Operator Functions

12.17.8 Spatial Operator Functions

OpenGIS proposes a number of functions that can produce geometries. They are designed to implement spatial operators.

- **Buffer\((g, d)\)**
  
  ST_Buffer() and Buffer() are synonyms. For more information, see the description of ST_Buffer().

- **ST_Buffer\((g, d)\)**
  
  Returns a geometry that represents all points whose distance from the geometry value \(g\) is less than or equal to a distance of \(d\), or NULL if any argument is NULL.

  ST_Buffer() supports negative distances for polygons, multipolygons, and geometry collections containing polygons or multipolygons. For point, multipoint, linestring, multilinestring, and geometry collections not containing any polygons or multipolygons, ST_Buffer() with a negative distance returns NULL.

  ST_Buffer() and Buffer() are synonyms.

- **ST_Difference\((g1, g2)\)**
  
  Returns a geometry that represents the point set difference of the geometry values \(g1\) and \(g2\). If any argument is NULL, the return value is NULL.

- **ST_Intersection\((g1, g2)\)**
  
  Returns a geometry that represents the point set intersection of the geometry values \(g1\) and \(g2\). If any argument is NULL, the return value is NULL.

- **ST_SymDifference\((g1, g2)\)**
  
  Returns a geometry that represents the point set symmetric difference of the geometry values \(g1\) and \(g2\), which is defined as:

  \[ g1 \text{ symdifference } g2 := (g1 \text{ union } g2) \text{ difference } (g1 \text{ intersection } g2) \]
Functions That Test Spatial Relations Between Geometry Objects

Or, in function call notation:

\[
\text{ST\_SymDifference}(g_1, g_2) = \text{ST\_Difference}(\text{ST\_Union}(g_1, g_2), \text{ST\_Intersection}(g_1, g_2))
\]

If any argument is \texttt{NULL}, the return value is \texttt{NULL}.

mysql> \texttt{SET @g1 = Point(1,1), @g2 = Point(2,2);}
mysql> \texttt{SELECT ST\_AsText(ST\_SymDifference(@g1, @g2));}
+---------------------------------------+
<table>
<thead>
<tr>
<th>ST_AsText(ST_SymDifference(@g1, @g2))</th>
</tr>
</thead>
<tbody>
<tr>
<td>MULTIPOINT(1 1, 2 2)</td>
</tr>
</tbody>
</table>
+---------------------------------------+

\* \texttt{ST\_Union}(g_1, g_2)

Returns a geometry that represents the point set union of the geometry values \textit{g1} and \textit{g2}. If any argument is \texttt{NULL}, the return value is \texttt{NULL}.

mysql> \texttt{SET @g1 = ST\_GeomFromText('LineString(1 1, 3 3)');}
mysql> \texttt{SET @g2 = ST\_GeomFromText('LineString(1 3, 3 1)');}
mysql> \texttt{SELECT ST\_AsText(ST\_Union(@g1, @g2));}
+--------------------------------------+
<table>
<thead>
<tr>
<th>ST_AsText(ST_Union(@g1, @g2))</th>
</tr>
</thead>
<tbody>
<tr>
<td>MULTILINESTRING((1 1, 3 3), (3 1, 1 3))</td>
</tr>
</tbody>
</table>
+--------------------------------------+

In addition, Section 12.17.7, “Geometry Property Functions”, discusses several functions that construct new geometries from existing ones. See that section for descriptions of these functions:

\* \texttt{ST\_Envelope}(g)

\* \texttt{StartPoint}(ls)

\* \texttt{ST\_EndPoint}(ls)

\* \texttt{ST\_PointN}(ls, N)

\* \texttt{ST\_ExteriorRing}(poly)

\* \texttt{ST\_InteriorRingN}(poly, N)

\* \texttt{ST\_GeometryN}(gc, N)

### 12.17.9 Functions That Test Spatial Relations Between Geometry Objects

The functions described in this section take two geometries as arguments and return a qualitative or quantitative relation between them.

MySQL implements two sets of functions using function names defined by the OpenGIS specification. One set tests the relationship between two geometry values using precise object shapes, the other set uses object minimum bounding rectangles (MBRs).

There is also a MySQL-specific set of MBR-based functions available to test the relationship between two geometry values.

#### 12.17.9.1 Spatial Relation Functions That Use Object Shapes

The OpenGIS specification defines the following functions to test the relationship between two geometry values \textit{g1} and \textit{g2}, using precise object shapes. The return values 1 and 0 indicate true and false, respectively, except for \texttt{ST\_Distance()}, which returns distance values.

\* \texttt{ST\_Contains}(g1, g2)
Functions That Test Spatial Relations Between Geometry Objects

Returns 1 or 0 to indicate whether $g_1$ completely contains $g_2$. This tests the opposite relationship as `ST_Within()`.

- **Crosses($g_1$, $g_2$)**

  `ST_Crosses()` and `Crosses()` are synonyms. For more information, see the description of `ST_Crosses()`.

- **`ST_Crosses($g_1$, $g_2$)`**

  The term *spatially crosses* denotes a spatial relation between two given geometries that has the following properties:
  
  - The two geometries intersect.
  
  - Their intersection results in a geometry that has a dimension that is one less than the maximum dimension of the two given geometries.
  
  - Their intersection is not equal to either of the two given geometries.

  This function returns 1 or 0 to indicate whether $g_1$ spatially crosses $g_2$. If $g_1$ is a *Polygon* or a *MultiPolygon*, or if $g_2$ is a *Point* or a *MultiPoint*, the return value is `NULL`.

  `ST_Crosses()` and `Crosses()` are synonyms.

- **`ST_Disjoint($g_1$, $g_2$)`**

  Returns 1 or 0 to indicate whether $g_1$ is spatially disjoint from (does not intersect) $g_2$.

- **`ST_Distance($g_1$, $g_2$)`**

  Returns the distance between $g_1$ and $g_2$.

  ```
  mysql> SET @g1 = Point(1,1);
  mysql> SET @g2 = Point(2,2);
  mysql> SELECT ST_Distance(@g1, @g2);
  +-----------------------+
  | ST_Distance(@g1, @g2) |
  +-----------------------+
  |    1.4142135623730951 |
  +-----------------------+
  ```

- **`ST_Equals($g_1$, $g_2$)`**

  Returns 1 or 0 to indicate whether $g_1$ is spatially equal to $g_2$.

  ```
  mysql> SET @g1 = Point(1,1), @g2 = Point(2,2);
  mysql> SELECT ST_Equals(@g1, @g1), ST_Equals(@g1, @g2);
  +---------------------+---------------------+
  | ST_Equals(@g1, @g1) | ST_Equals(@g1, @g2) |
  +---------------------+---------------------+
  |                   1 |                   0 |
  +---------------------+---------------------+
  ```

- **`ST_Intersects($g_1$, $g_2$)`**

  Returns 1 or 0 to indicate whether $g_1$ spatially intersects $g_2$.

- **`ST_Overlaps($g_1$, $g_2$)`**

  Two geometries *spatially overlap* if they intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

  This function returns 1 or 0 to indicate whether $g_1$ spatially overlaps $g_2$. 

1463
Functions That Test Spatial Relations Between Geometry Objects

- **ST_Touches**(g1, g2)
  
  Two geometries spatially touch if their interiors do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

  This function returns 1 or 0 to indicate whether g1 spatially touches g2.

  **ST_Touches()** and **Touches()** are synonyms.

- **ST_Within**(g1, g2)
  
  Returns 1 or 0 to indicate whether g1 is spatially within g2. This tests the opposite relationship as **ST_Contains()**.

- **Touches**(g1, g2)
  
  **ST_Touches()** and **Touches()** are synonyms. For more information, see the description of **ST_Touches()**.

12.17.9.2 Spatial Relation Functions That Use Minimum Bounding Rectangles

MySQL provides several MySQL-specific functions that test the relationship between minimum bounding rectangles (MBRs) of two geometries g1 and g2. The return values 1 and 0 indicate true and false, respectively.

A corresponding set of MBR functions defined according to the OpenGIS specification is described later in this section.

- **MBRContains**(g1, g2)
  
  Returns 1 or 0 to indicate whether the minimum bounding rectangle of g1 contains the minimum bounding rectangle of g2. This tests the opposite relationship as **MBRWithin()**.

```
mysql> SET @g1 = ST_GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
mysql> SET @g2 = ST_GeomFromText('Point(1 1)');
mysql> SELECT MBRContains(@g1, @g2), MBRWithin(@g2, @g1);
```

<table>
<thead>
<tr>
<th>MBRContains(@g1, @g2)</th>
<th>MBRWithin(@g2, @g1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

**MBRContains()** and **Contains()** are synonyms.

- **MBRDisjoint**(g1, g2)
  
  Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries g1 and g2 are disjoint (do not intersect).

  **MBRDisjoint()** and **Disjoint()** are synonyms.

- **MBREqual**(g1, g2)
  
  Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries g1 and g2 are the same.

- **MBRIntersects**(g1, g2)
  
  Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries g1 and g2 intersect.

  **MBRIntersects()** and **Intersects()** are synonyms.

- **MBROverlaps**(g1, g2)
Two geometries *spatially overlap* if they intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

This function returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries $g_1$ and $g_2$ overlap.

$MBROverlaps()$ and $Overlaps()$ are synonyms.

- $MBRTouches(g_1, g_2)$

Two geometries *spatially touch* if their interiors do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

This function returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries $g_1$ and $g_2$ touch.

- $MBRWithin(g_1, g_2)$

Returns 1 or 0 to indicate whether the minimum bounding rectangle of $g_1$ is within the minimum bounding rectangle of $g_2$. This tests the opposite relationship as $MBRContains()$.

```
mysql> SET @g1 = ST_GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
mysql> SET @g2 = ST_GeomFromText('Polygon((0 0,0 5,5 5,5 0,0 0))');
mysql> SELECT MBRWithin(@g1,@g2), MBRWithin(@g2,@g1);
+--------------------+--------------------+
| MBRWithin(@g1,@g2) | MBRWithin(@g2,@g1) |
+--------------------+--------------------+
|                  1 |                  0 |
+--------------------+--------------------+
```

$MBRWithin()$ and $Within()$ are synonyms.

The OpenGIS specification defines the following functions that test the relationship between two geometry values $g_1$ and $g_2$. The MySQL implementation uses minimum bounding rectangles, so these functions return the same result as the corresponding MBR-based functions described earlier in this section. The return values 1 and 0 indicate true and false, respectively.

- $Contains(g_1, g_2)$

$MBRContains()$ and $Contains()$ are synonyms. For more information, see the description of $MBRContains()$.

- $Disjoint(g_1, g_2)$

$MBRDisjoint()$ and $Disjoint()$ are synonyms. For more information, see the description of $MBRDisjoint()$.

- $Equals(g_1, g_2)$

Returns 1 or 0 to indicate whether $g_1$ is spatially equal to $g_2$.

- $Intersects(g_1, g_2)$

$MBRIntersects()$ and $Intersects()$ are synonyms. For more information, see the description of $MBRIntersects()$.

- $Overlaps(g_1, g_2)$

$MBROverlaps()$ and $Overlaps()$ are synonyms. For more information, see the description of $MBROverlaps()$.

- $Within(g_1, g_2)$

Functions Used with Global Transaction IDs

12.18 Functions Used with Global Transaction IDs

The functions described in this section are used with GTID-based replication. It is important to keep in mind that all of these functions take string representations of GTID sets as arguments—as such, the GTID sets must always be quoted when used with them.

The union of two GTID sets is simply their representations as strings, joined together with an interposed comma. In other words, you can define a very simple function for obtaining the union of two GTID sets, similar to that created here:

```sql
CREATE FUNCTION GTID_UNION(g1 TEXT, g2 TEXT)
RETURNS TEXT DETERMINISTIC
RETURN CONCAT(g1,',',g2);
```

For more information about GTIDs and how these GTID functions are used in practice, see Section 17.1.3, "Replication with Global Transaction Identifiers".

Table 12.22 GTID Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GTID_SUBSET()</td>
<td>Return true if all GTIDs in subset are also in set; otherwise false.</td>
</tr>
<tr>
<td>GTID_SUBTRACT()</td>
<td>Return all GTIDs in set that are not in subset.</td>
</tr>
<tr>
<td>SQL_THREAD_WAIT_AFTER_GTIDS()</td>
<td>Obsolete. Use WAIT_FOR_EXECUTED_GTID_SET().</td>
</tr>
<tr>
<td>(deprecated)</td>
<td></td>
</tr>
<tr>
<td>WAIT_UNTIL_SQL_THREAD_WAIT_AFTER_GTIDS()</td>
<td>Use WAIT_FOR_EXECUTED_GTID_SET().</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- **GTID_SUBSET(subset, set)**

Given two sets of global transaction IDs `subset` and `set`, returns true (1) if all GTIDs in `subset` are also in `set`. Returns false (0) otherwise.

The GTID sets used with this function are represented as strings, as shown in the following examples:

```sql
mysql> SELECT GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:23',
                         '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57')
       -> CONCAT('3E11FA47-71CA-11E1-9E33-C80AA9429562:23',
                 '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57');
+--------------------------------------------------------------------------------------------------+
| GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:23', '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57'): 1  |
| 1 row in set (0.00 sec)  |

mysql> SELECT GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:23-25',
                         '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57')
       -> CONCAT('3E11FA47-71CA-11E1-9E33-C80AA9429562:23-25',
                 '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57');
+--------------------------------------------------------------------------------------------------+
| 1 row in set (0.00 sec)  |

mysql> SELECT GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:20-25',
                         '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57')
       -> CONCAT('3E11FA47-71CA-11E1-9E33-C80AA9429562:20-25',
                 '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57');
+--------------------------------------------------------------------------------------------------+
| 1 row in set (0.00 sec)  |
```

- **GTID_SUBTRACT(set, subset)**

Given two sets of global transaction IDs `subset` and `set`, returns only those GTIDs from `set` that are not in `subset`.  

**MBRWithin() and Within() are synonyms. For more information, see the description of MBRWithin().**
All GTID sets used with this function are represented as strings and must be quoted, as shown in these examples:

```sql
mysql> SELECT GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
-> '3E11FA47-71CA-11E1-9E33-C80AA9429562:21');
*************************** 1. row ***************************
GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
'3E11FA47-71CA-11E1-9E33-C80AA9429562:21'): 3e11fa47-71ca-11e1-9e33-c80aa9429562:22-57
1 row in set (0.00 sec)
```

```sql
mysql> SELECT GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
-> '3E11FA47-71CA-11E1-9E33-C80AA9429562:20-25');
*************************** 1. row ***************************
GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
1 row in set (0.00 sec)
```

```sql
mysql> SELECT GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
-> '3E11FA47-71CA-11E1-9E33-C80AA9429562:23-24');
*************************** 1. row ***************************
GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
1 row in set (0.01 sec)
```

- `SQL_THREAD_WAIT_AFTER_GTIDS(gtid_set[, timeout])`

  `SQL_THREAD_WAIT_AFTER_GTIDS()` was added in MySQL 5.6.5, and replaced by `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()` in MySQL 5.6.9. (Bug #14775984)

  For more information, see Section 17.1.3, “Replication with Global Transaction Identifiers”.

- `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS(gtid_set[, timeout])`

  Wait until the replica SQL thread has executed all of the transactions whose global transaction identifiers are contained in `gtid_set` (see Section 17.1.3.1, “GTID Concepts”, for a definition of “GTID sets”), or until `timeout` seconds have elapsed, whichever occurs first. `timeout` is optional; the default timeout is 0 seconds, in which case the source simply waits until all of the transactions in the GTID set have been executed.

  Prior to MySQL 5.6.9, `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()` was named `SQL_THREAD_WAIT_AFTER_GTIDS()` (Bug #14775984)

  For more information, see Section 17.1.3, “Replication with Global Transaction Identifiers”.

GTID sets used with this function are represented as strings and so must be quoted as shown in the following example:

```sql
mysql> SELECT WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS('3E11FA47-71CA-11E1-9E33-C80AA9429562:1-5');
-> 5
```

The return value is the number of transactional events that were executed. Prior to MySQL 5.6.8, this function behaved unpredictably if no timeout was set and it was invoked while GTID-based replication was not active; in MySQL 5.6.8 and later, the function returns `NULL` whenever `gtid_mode` is `OFF`. (Bug #14640065)

### 12.19 Aggregate Functions

Aggregate functions operate on sets of values. They are often used with a `GROUP BY` clause to group values into subsets.

#### 12.19.1 Aggregate Function Descriptions

This section describes aggregate functions that operate on sets of values. They are often used with a `GROUP BY` clause to group values into subsets.
### Table 12.23 Aggregate Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AVG()</td>
<td>Return the average value of the argument</td>
</tr>
<tr>
<td>BIT_AND()</td>
<td>Return bitwise AND</td>
</tr>
<tr>
<td>BIT_OR()</td>
<td>Return bitwise OR</td>
</tr>
<tr>
<td>BIT_XOR()</td>
<td>Return bitwise XOR</td>
</tr>
<tr>
<td>COUNT()</td>
<td>Return a count of the number of rows returned</td>
</tr>
<tr>
<td>COUNT(DISTINCT)</td>
<td>Return the count of a number of different values</td>
</tr>
<tr>
<td>GROUP_CONCAT()</td>
<td>Return a concatenated string</td>
</tr>
<tr>
<td>MAX()</td>
<td>Return the maximum value</td>
</tr>
<tr>
<td>MIN()</td>
<td>Return the minimum value</td>
</tr>
<tr>
<td>STD()</td>
<td>Return the population standard deviation</td>
</tr>
<tr>
<td>STDDEV()</td>
<td>Return the population standard deviation</td>
</tr>
<tr>
<td>STDDEV_POP()</td>
<td>Return the population standard deviation</td>
</tr>
<tr>
<td>STDDEV_SAMP()</td>
<td>Return the sample standard deviation</td>
</tr>
<tr>
<td>SUM()</td>
<td>Return the sum</td>
</tr>
<tr>
<td>VAR_POP()</td>
<td>Return the population standard variance</td>
</tr>
<tr>
<td>VAR_SAMP()</td>
<td>Return the sample variance</td>
</tr>
<tr>
<td>VARIANCE()</td>
<td>Return the population standard variance</td>
</tr>
</tbody>
</table>

Unless otherwise stated, aggregate functions ignore **NULL** values.

If you use an aggregate function in a statement containing no **GROUP BY** clause, it is equivalent to grouping on all rows. For more information, see Section 12.19.3, “MySQL Handling of GROUP BY”.

For numeric arguments, the variance and standard deviation functions return a **DOUBLE** value. The **SUM()** and **AVG()** functions return a **DECIMAL** value for exact-value arguments (integer or **DECIMAL**) and a **DOUBLE** value for approximate-value arguments (**FLOAT** or **DOUBLE**).

The **SUM()** and **AVG()** aggregate functions do not work with temporal values. (They convert the values to numbers, losing everything after the first nonnumeric character.) To work around this problem, convert to numeric units, perform the aggregate operation, and convert back to a temporal value.

Examples:

```sql
SELECT SEC_TO_TIME(SUM(TIME_TO_SEC(time_col))) FROM tbl_name;
SELECT FROM_DAYS(SUM(TO_DAYS(date_col))) FROM tbl_name;
```

Functions such as **SUM()** or **AVG()** that expect a numeric argument cast the argument to a number if necessary. For **SET** or **ENUM** values, the cast operation causes the underlying numeric value to be used.

The **BIT_AND()**, **BIT_OR()**, and **BIT_XOR()** aggregate functions perform bit operations. They require **BIGINT** (64-bit integer) arguments and return **BIGINT** values. Arguments of other types are converted to **BIGINT** and truncation might occur.

• **AVG([DISTINCT] expr)**

Returns the average value of **expr**. The **DISTINCT** option can be used to return the average of the distinct values of **expr**.

If there are no matching rows, **AVG()** returns **NULL**.
FROM student
GROUP BY student_name;

• **BIT_AND(expr)**

Returns the bitwise AND of all bits in `expr`. The calculation is performed with 64-bit (BIGINT) precision.

If there are no matching rows, **BIT_AND()** returns a neutral value (all bits set to 1).

• **BIT_OR(expr)**

Returns the bitwise OR of all bits in `expr`. The calculation is performed with 64-bit (BIGINT) precision.

If there are no matching rows, **BIT_OR()** returns a neutral value (all bits set to 0).

• **BIT_XOR(expr)**

Returns the bitwise XOR of all bits in `expr`. The calculation is performed with 64-bit (BIGINT) precision.

If there are no matching rows, **BIT_XOR()** returns a neutral value (all bits set to 0).

• **COUNT(expr)**

Returns a count of the number of non-NULL values of `expr` in the rows retrieved by a SELECT statement. The result is a BIGINT value.

If there are no matching rows, **COUNT()** returns 0.

```sql
SELECT student.student_name,COUNT(*)
FROM student,course
WHERE student.student_id=course.student_id
GROUP BY student_name;
```

**COUNT(*)** is somewhat different in that it returns a count of the number of rows retrieved, whether or not they contain NULL values.

For transactional storage engines such as InnoDB, storing an exact row count is problematic. Multiple transactions may be occurring at the same time, each of which may affect the count.

**InnoDB** does not keep an internal count of rows in a table because concurrent transactions might “see” different numbers of rows at the same time. Consequently, **SELECT COUNT(*)** statements only count rows visible to the current transaction.

To process a **SELECT COUNT(*)** statement, **InnoDB** scans an index of the table, which takes some time if the index is not entirely in the buffer pool. For a faster count, create a counter table and let your application update it according to the inserts and deletes it does. However, this method may not scale well in situations where thousands of concurrent transactions are initiating updates to the same counter table. If an approximate row count is sufficient, use **SHOW TABLE STATUS**.

**InnoDB** handles **SELECT COUNT(*)** and **SELECT COUNT(1)** operations in the same way. There is no performance difference.

For **MyISAM** tables, **COUNT(*)** is optimized to return very quickly if the **SELECT** retrieves from one table, no other columns are retrieved, and there is no **WHERE** clause. For example:

```sql
SELECT COUNT(*) FROM student;
```

This optimization only applies to **MyISAM** tables, because an exact row count is stored for this storage engine and can be accessed very quickly. **COUNT(1)** is only subject to the same optimization if the first column is defined as **NOT NULL**.
• **COUNT**(DISTINCT expr,[expr...])

Returns a count of the number of rows with different non-NULL expr values.

If there are no matching rows, **COUNT**(DISTINCT) returns 0.

mysql> SELECT COUNT(DISTINCT results) FROM student;

In MySQL, you can obtain the number of distinct expression combinations that do not contain NULL by giving a list of expressions. In standard SQL, you would have to do a concatenation of all expressions inside **COUNT**(DISTINCT ...).

• **GROUP_CONCAT**(expr)

This function returns a string result with the concatenated non-NULL values from a group. It returns NULL if there are no non-NULL values. The full syntax is as follows:

```sql
GROUP_CONCAT([DISTINCT] expr [,expr...] [ORDER BY {unsigned_integer | col_name | expr} [ASC | DESC] [,col_name ...]] [SEPARATOR str_val])
```

mysql> SELECT student_name, 
    GROUP_CONCAT(test_score) 
FROM student 
GROUP BY student_name;

Or:

mysql> SELECT student_name, 
    GROUP_CONCAT(DISTINCT test_score ORDER BY test_score DESC SEPARATOR '') 
FROM student 
GROUP BY student_name;

In MySQL, you can get the concatenated values of expression combinations. To eliminate duplicate values, use the **DISTINCT** clause. To sort values in the result, use the **ORDER BY** clause. To sort in reverse order, add the **DESC** (descending) keyword to the name of the column you are sorting by in the **ORDER BY** clause. The default is ascending order; this may be specified explicitly using the **ASC** keyword. The default separator between values in a group is comma (,). To specify a separator explicitly, use **SEPARATOR** followed by the string literal value that should be inserted between group values. To eliminate the separator altogether, specify **SEPARATOR ''**.

The result is truncated to the maximum length that is given by the **group_concat_max_len** system variable, which has a default value of 1024. The value can be set higher, although the effective maximum length of the return value is constrained by the value of **max_allowed_packet**. The syntax to change the value of **group_concat_max_len** at runtime is as follows, where **val** is an unsigned integer:

```sql
SET [GLOBAL | SESSION] group_concat_max_len = val;
```

The return value is a nonbinary or binary string, depending on whether the arguments are nonbinary or binary strings. The result type is **TEXT** or **BLOB** unless **group_concat_max_len** is less than or equal to 512, in which case the result type is **VARCHAR** or **VARBINARY**.

See also **CONCAT()** and **CONCAT_WS()**: Section 12.8, “String Functions and Operators”.

• **MAX**(DISTINCT expr)

Returns the maximum value of expr. **MAX()** may take a string argument; in such cases, it returns the maximum string value. See Section 8.3.1, “How MySQL Uses Indexes”. The **DISTINCT** keyword
can be used to find the maximum of the distinct values of \texttt{expr}, however, this produces the same result as omitting \texttt{DISTINCT}.

If there are no matching rows, \texttt{MAX()} returns \texttt{NULL}.

\begin{verbatim}
mysql> SELECT student_name, MIN(test_score), MAX(test_score)
     FROM student
     GROUP BY student_name;
\end{verbatim}

For \texttt{MAX()}, MySQL currently compares \texttt{ENUM} and \texttt{SET} columns by their string value rather than by the string's relative position in the set. This differs from how \texttt{ORDER BY} compares them.

\begin{itemize}
\item \texttt{MIN([DISTINCT] \texttt{expr})}
\end{itemize}

Returns the minimum value of \texttt{expr}. \texttt{MIN()} may take a string argument; in such cases, it returns the minimum string value. See Section 8.3.1, “How MySQL Uses Indexes”. The \texttt{DISTINCT} keyword can be used to find the minimum of the distinct values of \texttt{expr}, however, this produces the same result as omitting \texttt{DISTINCT}.

If there are no matching rows, \texttt{MIN()} returns \texttt{NULL}.

\begin{verbatim}
mysql> SELECT student_name, MIN(test_score), MAX(test_score)
     FROM student
     GROUP BY student_name;
\end{verbatim}

For \texttt{MIN()}, MySQL currently compares \texttt{ENUM} and \texttt{SET} columns by their string value rather than by the string's relative position in the set. This differs from how \texttt{ORDER BY} compares them.

\begin{itemize}
\item \texttt{STD(\texttt{expr})}
\end{itemize}

Returns the population standard deviation of \texttt{expr}. \texttt{STD()} is a synonym for the standard SQL function \texttt{STDDEV_POP()}, provided as a MySQL extension.

If there are no matching rows, \texttt{STD()} returns \texttt{NULL}.

\begin{itemize}
\item \texttt{STDDEV(\texttt{expr})}
\end{itemize}

Returns the population standard deviation of \texttt{expr}. \texttt{STDDEV()} is a synonym for the standard SQL function \texttt{STDDEV_POP()}, provided for compatibility with Oracle.

If there are no matching rows, \texttt{STDDEV()} returns \texttt{NULL}.

\begin{itemize}
\item \texttt{STDDEV_POP(\texttt{expr})}
\end{itemize}

Returns the population standard deviation of \texttt{expr} (the square root of \texttt{VAR_POP()}). You can also use \texttt{STD()} or \texttt{STDDEV()}, which are equivalent but not standard SQL.

If there are no matching rows, \texttt{STDDEV_POP()} returns \texttt{NULL}.

\begin{itemize}
\item \texttt{STDDEV_SAMP(\texttt{expr})}
\end{itemize}

Returns the sample standard deviation of \texttt{expr} (the square root of \texttt{VAR_SAMP}).

If there are no matching rows, \texttt{STDDEV_SAMP()} returns \texttt{NULL}.

\begin{itemize}
\item \texttt{SUM([DISTINCT] \texttt{expr})}
\end{itemize}

Returns the sum of \texttt{expr}. If the return set has no rows, \texttt{SUM()} returns \texttt{NULL}. The \texttt{DISTINCT} keyword can be used to sum only the distinct values of \texttt{expr}.

If there are no matching rows, \texttt{SUM()} returns \texttt{NULL}.
• **VAR_POP(expr)**

Returns the population standard variance of `expr`. It considers rows as the whole population, not as a sample, so it has the number of rows as the denominator. You can also use **VARIANCE()**, which is equivalent but is not standard SQL.

If there are no matching rows, **VAR_POP()** returns **NULL**.

• **VAR_SAMP(expr)**

Returns the sample variance of `expr`. That is, the denominator is the number of rows minus one.

If there are no matching rows, **VAR_SAMP()** returns **NULL**.

• **VARIANCE(expr)**

Returns the population standard variance of `expr`. **VARIANCE()** is a synonym for the standard SQL function **VAR_POP()**, provided as a MySQL extension.

If there are no matching rows, **VARIANCE()** returns **NULL**.

### 12.19.2 GROUP BY Modifiers

The **GROUP BY** clause permits a **WITH ROLLUP** modifier that causes summary output to include extra rows that represent higher-level (that is, super-aggregate) summary operations. **ROLLUP** thus enables you to answer questions at multiple levels of analysis with a single query. For example, **ROLLUP** can be used to provide support for OLAP (Online Analytical Processing) operations.

Suppose that a sales table has `year`, `country`, `product`, and `profit` columns for recording sales profitability:

```sql
CREATE TABLE sales
(
    year    INT,
    country VARCHAR(20),
    product VARCHAR(32),
    profit  INT
);
```

To summarize table contents per year, use a simple **GROUP BY** like this:

```sql
mysql> SELECT year, SUM(profit) AS profit
    FROM sales
    GROUP BY year;
```

<table>
<thead>
<tr>
<th>year</th>
<th>profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>4525</td>
</tr>
<tr>
<td>2001</td>
<td>3010</td>
</tr>
</tbody>
</table>

The output shows the total (aggregate) profit for each year. To also determine the total profit summed over all years, you must add up the individual values yourself or run an additional query. Or you can use **ROLLUP**, which provides both levels of analysis with a single query. Adding a **WITH ROLLUP** modifier to the **GROUP BY** clause causes the query to produce another (super-aggregate) row that shows the grand total over all year values:

```sql
mysql> SELECT year, SUM(profit) AS profit
    FROM sales
    GROUP BY year WITH ROLLUP;
```

<table>
<thead>
<tr>
<th>year</th>
<th>profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>4525</td>
</tr>
<tr>
<td>2001</td>
<td>3010</td>
</tr>
<tr>
<td>NULL</td>
<td>7535</td>
</tr>
</tbody>
</table>
The NULL value in the year column identifies the grand total super-aggregate line.

ROLLUP has a more complex effect when there are multiple GROUP BY columns. In this case, each time there is a change in value in any but the last grouping column, the query produces an extra super-aggregate summary row.

For example, without ROLLUP, a summary of the sales table based on year, country, and product might look like this, where the output indicates summary values only at the year/country/product level of analysis:

```
mysql> SELECT year, country, product, SUM(profit) AS profit
    FROM sales
    GROUP BY year, country, product;
```

```
+------+---------+------------+--------+
| year | country | product    | profit |
+------+---------+------------+--------+
| 2000 | Finland | Computer   |   1500 |
| 2000 | Finland | Phone      |    100 |
| 2000 | India   | Calculator |    150 |
| 2000 | India   | Computer   |  1200 |
| 2000 | USA     | Calculator |    75  |
| 2000 | USA     | Computer   |  1500 |
| 2001 | Finland | Phone      |     10 |
| 2001 | USA     | Calculator |    50  |
| 2001 | USA     | Computer   |  2700 |
| 2001 | USA     | TV         |    250 |
+------+---------+------------+--------+
```

With ROLLUP added, the query produces several extra rows:

```
mysql> SELECT year, country, product, SUM(profit) AS profit
    FROM sales
    GROUP BY year, country, product WITH ROLLUP;
```

```
+------+---------+------------+--------+
| year | country | product    | profit |
| 2000 | Finland | Computer   |   1500 |
| 2000 | Finland | Phone      |    100 |
| 2000 | Finland | NULL       |   1600 |
| 2000 | India   | Calculator |    150 |
| 2000 | India   | Computer   |  1200 |
| 2000 | India   | NULL       |  1350 |
| 2000 | USA     | Calculator |    75  |
| 2000 | USA     | Computer   |  1500 |
| 2000 | USA     | NULL       |  1575 |
| 2000 | NULL    | NULL       |  4525  |
| 2001 | Finland | Phone      |     10 |
| 2001 | Finland | NULL       |     10 |
| 2001 | USA     | Calculator |    50  |
| 2001 | USA     | Computer   |  2700 |
| 2001 | USA     | TV         |    250 |
| 2001 | USA     | NULL       |  3000  |
| 2001 | NULL    | NULL       |  3010  |
| NULL | NULL    | NULL       |  7535  |
+------+---------+------------+--------+
```

Now the output includes summary information at four levels of analysis, not just one:

- Following each set of product rows for a given year and country, an extra super-aggregate summary row appears showing the total for all products. These rows have the product column set to NULL.

- Following each set of rows for a given year, an extra super-aggregate summary row appears showing the total for all countries and products. These rows have the country and products columns set to NULL.

- Finally, following all other rows, an extra super-aggregate summary row appears showing the grand total for all years, countries, and products. This row has the year, country, and products columns set to NULL.
The **NULL** indicators in each super-aggregate row are produced when the row is sent to the client. The server looks at the columns named in the **GROUP BY** clause following the leftmost one that has changed value. For any column in the result set with a name that matches any of those names, its value is set to **NULL**. (If you specify grouping columns by column position, the server identifies which columns to set to **NULL** by position.)

Because the **NULL** values in the super-aggregate rows are placed into the result set at such a late stage in query processing, you can test them as **NULL** values only in the select list or **HAVING** clause. You cannot test them as **NULL** values in join conditions or the **WHERE** clause to determine which rows to select. For example, you cannot add **WHERE product IS NULL** to the query to eliminate from the output all but the super-aggregate rows.

The **NULL** values do appear as **NULL** on the client side and can be tested as such using any MySQL client programming interface. However, at this point, you cannot distinguish whether a **NULL** represents a regular grouped value or a super-aggregate value.

### Other Considerations When using ROLLUP

The following discussion lists some behaviors specific to the MySQL implementation of **ROLLUP**.

When you use **ROLLUP**, you cannot also use an **ORDER BY** clause to sort the results. In other words, **ROLLUP** and **ORDER BY** are mutually exclusive in MySQL. However, you still have some control over sort order. **GROUP BY** in MySQL implicitly sorts results by default (in the absence of **ASC** or **DESC** designators). However, implicit **GROUP BY** sorting in MySQL is deprecated. To achieve a specific sort order of grouped results:

- Use explicit **ASC** and **DESC** keywords with columns named in the **GROUP BY** list to specify sort order for individual columns. In this case, the super-aggregate summary rows added by **ROLLUP** still appear after the rows from which they are calculated, regardless of the sort order.

- To work around the restriction that prevents using **ROLLUP** with **ORDER BY**, generate the grouped result set as a derived table and apply **ORDER BY** to it. For example:

  ```sql
  mysql> SELECT * FROM
    | SELECT year, SUM(profit) AS profit
    | FROM sales GROUP BY year WITH ROLLUP) AS dt
    | ORDER BY year DESC;

  +------+--------+
  | year | profit |
  +------+--------+
  | 2001 | 3010   |
  | 2000 | 4525   |
  | NULL | 7535   |
  +------+--------+
  ``

In this case, the super-aggregate summary rows sort with the rows from which they are calculated, and their placement depends on sort order (at the beginning for ascending sort, at the end for descending sort).

**LIMIT** can be used to restrict the number of rows returned to the client. **LIMIT** is applied after **ROLLUP**, so the limit applies against the extra rows added by **ROLLUP**. For example:

```sql
mysql> SELECT year, country, product, SUM(profit) AS profit
  > FROM sales
  > GROUP BY year, country, product WITH ROLLUP
  > LIMIT 5;

+------ |--------- |------------+--------+
| year  | country  | product    | profit |
|-------|----------|------------|--------+
| 2000  | Finland  | Computer   | 1500   |
| 2000  | Finland  | Phone      | 100    |
| 2000  | Finland  | NULL       | 1600   |
| 2000  | India    | Calculator | 150    |
| 2000  | India    | Computer   | 1200   |
+------ |--------- |------------+--------+
```
MySQL Handling of GROUP BY

Using **LIMIT** with **ROLLUP** may produce results that are more difficult to interpret, because there is less context for understanding the super-aggregate rows.

A MySQL extension permits a column that does not appear in the **GROUP BY** list to be named in the select list. (For information about nonaggregated columns and **GROUP BY**, see Section 12.19.3, “MySQL Handling of GROUP BY”. In this case, the server is free to choose any value from this nonaggregated column in summary rows, and this includes the extra rows added by **WITH ROLLUP**. For example, in the following query, **country** is a nonaggregated column that does not appear in the **GROUP BY** list and values chosen for this column are nondeterministic:

```
mysql> SELECT year, country, SUM(profit) AS profit
    FROM sales
    GROUP BY year WITH ROLLUP;
```

```
+------+---------+--------+
<table>
<thead>
<tr>
<th>year</th>
<th>country</th>
<th>profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>India</td>
<td>4525</td>
</tr>
<tr>
<td>2001</td>
<td>USA</td>
<td>3010</td>
</tr>
<tr>
<td>NULL</td>
<td>USA</td>
<td>7535</td>
</tr>
</tbody>
</table>
+------+---------+--------+
```

This behavior is permitted when the **ONLY_FULL_GROUP_BY** SQL mode is not enabled. If that mode is enabled, the server rejects the query as illegal because **country** is not listed in the **GROUP BY** clause.

### 12.19.3 MySQL Handling of GROUP BY

In standard SQL, a query that includes a **GROUP BY** clause cannot refer to nonaggregated columns in the select list that are not named in the **GROUP BY** clause. For example, this query is illegal in standard SQL because the nonaggregated **name** column in the select list does not appear in the **GROUP BY**:

```
SELECT o.custid, c.name, MAX(o.payment)
FROM orders AS o, customers AS c
WHERE o.custid = c.custid
GROUP BY o.custid;
```

For the query to be legal, the **name** column must be omitted from the select list or named in the **GROUP BY** clause.

MySQL extends the standard SQL use of **GROUP BY** so that the select list can refer to nonaggregated columns not named in the **GROUP BY** clause. This means that the preceding query is legal in MySQL. You can use this feature to get better performance by avoiding unnecessary column sorting and grouping. However, this is useful primarily when all values in each nonaggregated column not named in the **GROUP BY** are the same for each group. The server is free to choose any value from each group, so unless they are the same, the values chosen are nondeterministic. Furthermore, the selection of values from each group cannot be influenced by adding an **ORDER BY** clause. Result set sorting occurs after values have been chosen, and **ORDER BY** does not affect which values within each group the server chooses.

A similar MySQL extension applies to the **HAVING** clause. In standard SQL, a query cannot refer to nonaggregated columns in the **HAVING** clause that are not named in the **GROUP BY** clause. To simplify calculations, a MySQL extension permits references to such columns. This extension assumes that the nongrouped columns have the same group-wise values. Otherwise, the result is nondeterministic.

To disable the MySQL **GROUP BY** extension and enable standard SQL behavior, enable the **ONLY_FULL_GROUP_BY** SQL mode. In this case, columns not named in the **GROUP BY** clause cannot be used in the select list or **HAVING** clause unless enclosed in an aggregate function.

The select list extension also applies to **ORDER BY**. That is, you can refer to nonaggregated columns in the **ORDER BY** clause that do not appear in the **GROUP BY** clause. (However, as mentioned previously, **ORDER BY** does not affect which values are chosen from nonaggregated columns; it only sorts them after they have been chosen.) This extension does not apply if the **ONLY_FULL_GROUP_BY** SQL mode is enabled.
If a query has aggregate functions and no GROUP BY clause, it cannot have nonaggregated columns in the select list, HAVING condition, or ORDER BY list with ONLY_FULL_GROUP_BY enabled:

```sql
mysql> SELECT name, MAX(age) FROM t;
ERROR 1140 (42000): Mixing of GROUP columns (MIN(),MAX(),COUNT(),...) with no GROUP columns is illegal if there is no GROUP BY clause
```

Without GROUP BY, there is a single group and it is nondeterministic which value to choose for the group.

Another MySQL extension to standard SQL permits references in the HAVING clause to aliased expressions in the select list. Enabling ONLY_FULL_GROUP_BY prevents this. For example, the following query returns name values that occur only once in table orders; the query is accepted regardless of whether ONLY_FULL_GROUP_BY is enabled:

```sql
SELECT name, COUNT(name) FROM orders
GROUP BY name
HAVING COUNT(name) = 1;
```

The following query is accepted only if ONLY_FULL_GROUP_BY is disabled.

```sql
SELECT name, COUNT(name) AS c FROM orders
GROUP BY name
HAVING c = 1;
```

If you are trying to follow standard SQL, you can use only column expressions in GROUP BY clauses. As a workaround, use an alias for the expression:

```sql
SELECT id, FLOOR(value/100) AS val
FROM tbl_name
GROUP BY id, val;
```

MySQL permits noncolumn expressions in GROUP BY clauses, so the alias is unnecessary:

```sql
SELECT id, FLOOR(value/100)
FROM tbl_name
GROUP BY id, FLOOR(value/100);
```

## 12.20 Miscellaneous Functions

### Table 12.24 Miscellaneous Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFAULT()</td>
<td>Return the default value for a table column</td>
</tr>
<tr>
<td>INET_ATON()</td>
<td>Return the numeric value of an IP address</td>
</tr>
<tr>
<td>INET_NTOA()</td>
<td>Return the IP address from a numeric value</td>
</tr>
<tr>
<td>INET6_ATON()</td>
<td>Return the numeric value of an IPv6 address</td>
</tr>
<tr>
<td>INET6_NTOA()</td>
<td>Return the IPv6 address from a numeric value</td>
</tr>
<tr>
<td>IS_IPV4()</td>
<td>Whether argument is an IPv4 address</td>
</tr>
<tr>
<td>IS_IPV4_COMPAT()</td>
<td>Whether argument is an IPv4-compatible address</td>
</tr>
<tr>
<td>IS_IPV4_MAPPED()</td>
<td>Whether argument is an IPv4-mapped address</td>
</tr>
<tr>
<td>IS_IPV6()</td>
<td>Whether argument is an IPv6 address</td>
</tr>
<tr>
<td>MASTER_POS_WAIT()</td>
<td>Block until the replica has read and applied all updates up to the specified position</td>
</tr>
<tr>
<td>NAME_CONST()</td>
<td>Cause the column to have the given name</td>
</tr>
<tr>
<td>SLEEP()</td>
<td>Sleep for a number of seconds</td>
</tr>
<tr>
<td>UUID()</td>
<td>Return a Universal Unique Identifier (UUID)</td>
</tr>
<tr>
<td>UUID_SHORT()</td>
<td>Return an integer-valued universal identifier</td>
</tr>
</tbody>
</table>
### Miscellaneous Functions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VALUES()</td>
<td>Define the values to be used during an INSERT</td>
</tr>
</tbody>
</table>

- **DEFAULT(col_name)**

Returns the default value for a table column. An error results if the column has no default value.

```sql
mysql> UPDATE t SET i = DEFAULT(i)+1 WHERE id < 100;
```

- **FORMAT(X,D)**

Formats the number \( X \) to a format like '#,###,###.##', rounded to \( D \) decimal places, and returns the result as a string. For details, see Section 12.8, “String Functions and Operators”.

- **INET_ATON(expr)**

Given the dotted-quad representation of an IPv4 network address as a string, returns an integer that represents the numeric value of the address in network byte order (big endian). \( \text{INET_ATON()} \) returns NULL if it does not understand its argument.

```sql
mysql> SELECT INET_ATON('10.0.5.9');
-> 167773449
```

For this example, the return value is calculated as \( 10 \times 256^3 + 0 \times 256^2 + 5 \times 256 + 9 \).

\( \text{INET_ATON()} \) may or may not return a non-NULL result for short-form IP addresses (such as '127.1' as a representation of '127.0.0.1'). Because of this, \( \text{INET_ATON()} \) a should not be used for such addresses.

**Note**

To store values generated by \( \text{INET_ATON()} \), use an \texttt{INT UNSIGNED} column rather than \texttt{INT}, which is signed. If you use a signed column, values corresponding to IP addresses for which the first octet is greater than 127 cannot be stored correctly. See Section 11.1.7, “Out-of-Range and Overflow Handling”.

- **INET_NTOA(expr)**

Given a numeric IPv4 network address in network byte order, returns the dotted-quad string representation of the address as a string in the connection character set. \( \text{INET_NTOA()} \) returns NULL if it does not understand its argument.

```sql
mysql> SELECT INET_NTOA(167773449);
-> '10.0.5.9'
```

- **INET6_ATON(expr)**

Given an IPv6 or IPv4 network address as a string, returns a binary string that represents the numeric value of the address in network byte order (big endian). Because numeric-format IPv6 addresses require more bytes than the largest integer type, the representation returned by this function has the \texttt{VARBINARY} data type: \texttt{VARBINARY (16)} for IPv6 addresses and \texttt{VARBINARY (4)} for IPv4 addresses. If the argument is not a valid address, \( \text{INET6_ATON()} \) returns NULL.

The following examples use \( \text{HEX()} \) to display the \( \text{INET6_ATON()} \) result in printable form:

```sql
mysql> SELECT HEX(INET6_ATON('fdfe::5a55:caff:fe6a:9089'));
-> 'FDFE000000000005A55C67FEEA9089'

mysql> SELECT HEX(INET6_ATON('10.0.5.9'));
-> '0A000509'
```

\( \text{INET6_ATON()} \) observes several constraints on valid arguments. These are given in the following list along with examples.
• A trailing zone ID is not permitted, as in fe80::3%1 or fe80::3%eth0.

• A trailing network mask is not permitted, as in 2001:45f:3::64 or 198.51.100.0/24.

• For values representing IPv4 addresses, only classless addresses are supported. Classful addresses such as 198.51.1 are rejected. A trailing port number is not permitted, as in 198.51.100.2:8080. Hexadecimal numbers in address components are not permitted, as in 198.0xa0.1.2. Octal numbers are not supported: 198.51.010.1 is treated as 198.51.101, not 198.51.8.1. These IPv4 constraints also apply to IPv6 addresses that have IPv4 address parts, such as IPv4-compatible or IPv4-mapped addresses.

To convert an IPv4 address `expr` represented in numeric form as an INT value to an IPv6 address represented in numeric form as a VARBINARY value, use this expression:

```
INET6_ATON(INET_NTOA(expr))
```

For example:

```
mysql> SELECT HEX(INET6_ATON(INET_NTOA(167773449)));
-> '0A000509'
```

• `INET6_NTOA(expr)`

Given an IPv6 or IPv4 network address represented in numeric form as a binary string, returns the string representation of the address as a string in the connection character set. If the argument is not a valid address, `INET6_NTOA()` returns NULL.

`INET6_NTOA()` has these properties:

• It does not use operating system functions to perform conversions, thus the output string is platform independent.

• The return string has a maximum length of 39 (4 x 8 + 7). Given this statement:

```
CREATE TABLE t AS SELECT INET6_NTOA(expr) AS c1;
```

The resulting table would have this definition:

```
CREATE TABLE t (c1 VARCHAR(39) CHARACTER SET utf8 DEFAULT NULL);
```

• The return string uses lowercase letters for IPv6 addresses.

```
mysql> SELECT INET6_NTOA(INET6_ATON('fdfe::5a55:caff:fefa:9089'));
-> 'fdfe::5a55:caff:fefa:9089'
mysql> SELECT INET6_NTOA(INET6_ATON('10.0.5.9'));
-> '10.0.5.9'
mysql> SELECT INET6_NTOA(UNHEX('FDFE0000000000A55CAFFFEFA9089'));
-> 'fdfe::5a55:caff:fefa:9089'
mysql> SELECT INET6_NTOA(UNHEX('0A000509'));
-> '10.0.5.9'
```

• `IS_IPV4(expr)`

Returns 1 if the argument is a valid IPv4 address specified as a string, 0 otherwise.

```
mysql> SELECT IS_IPV4('10.0.5.9'), IS_IPV4('10.0.5.256');
```
For a given argument, if IS_IPV4() returns 1, INET_ATON() (and INET6_ATON()) will return non-NULL. The converse statement is not true: In some cases, INET_ATON() returns non-NULL when IS_IPV4() returns 0.

As implied by the preceding remarks, IS_IPV4() is more strict than INET_ATON() about what constitutes a valid IPv4 address, so it may be useful for applications that need to perform strong checks against invalid values. Alternatively, use INET6_ATON() to convert IPv4 addresses to internal form and check for a NULL result (which indicates an invalid address). INET6_ATON() is equally strong as IS_IPV4() about checking IPv4 addresses.

- **IS_IPV4_COMPAT(expr)**

  This function takes an IPv6 address represented in numeric form as a binary string, as returned by INET6_ATON(). It returns 1 if the argument is a valid IPv4-compatible IPv6 address, 0 otherwise. IPv4-compatible addresses have the form ::ipv4_address.

  ```
  mysql> SELECT IS_IPV4_COMPAT(INET6_ATON('::10.0.5.9'));
  -> 1
  mysql> SELECT IS_IPV4_COMPAT(INET6_ATON('::ffff:10.0.5.9'));
  -> 0
  ```

  The IPv4 part of an IPv4-compatible address can also be represented using hexadecimal notation. For example, 198.51.100.1 has this raw hexadecimal value:

  ```
  mysql> SELECT HEX(INET6_ATON('198.51.100.1'));
  -> 'C6336401'
  ```

  Expressed in IPv4-compatible form, ::198.51.100.1 is equivalent to ::c0a8:0001 or (without leading zeros) ::c0a8:1

  ```
  mysql> SELECT IS_IPV4_COMPAT(INET6_ATON('::198.51.100.1')), IS_IPV4_COMPAT(INET6_ATON('::c0a8:0001')), IS_IPV4_COMPAT(INET6_ATON('::c0a8:1'));
  -> 1, 1, 1
  ```

- **IS_IPV4_MAPPED(expr)**

  This function takes an IPv6 address represented in numeric form as a binary string, as returned by INET6_ATON(). It returns 1 if the argument is a valid IPv4-mapped IPv6 address, 0 otherwise. IPv4-mapped addresses have the form ::ffff:ipv4_address.

  ```
  mysql> SELECT IS_IPV4_MAPPED(INET6_ATON('::10.0.5.9'));
  -> 0
  mysql> SELECT IS_IPV4_MAPPED(INET6_ATON('::ffff:10.0.5.9'));
  -> 1
  ```

  As with IS_IPV4_COMPAT() the IPv4 part of an IPv4-mapped address can also be represented using hexadecimal notation:

  ```
  mysql> SELECT IS_IPV4_MAPPED(INET6_ATON('::ffff:198.51.100.1')), IS_IPV4_MAPPED(INET6_ATON('::ffff:c0a8:0001')), IS_IPV4_MAPPED(INET6_ATON('::ffff:c0a8:1'));
  -> 1, 1, 1
  ```

- **IS_IPV6(expr)**

  Returns 1 if the argument is a valid IPv6 address specified as a string, 0 otherwise. This function does not consider IPv4 addresses to be valid IPv6 addresses.

  ```
  mysql> SELECT IS_IPV6('10.0.5.9'), IS_IPV6('::1');
  ```
For a given argument, if `IS_IPV6()` returns 1, `INET6_ATON()` will return non-NULL.

- **MASTER_POS_WAIT(log_name, log_pos[, timeout])**

  This function is useful for control of source/replica synchronization. It blocks until the replica has read and applied all updates up to the specified position in the source log. The return value is the number of log events the replica had to wait for to advance to the specified position. The function returns `NULL` if the replica SQL thread is not started, the replica's source information is not initialized, the arguments are incorrect, or an error occurs. It returns `-1` if the timeout has been exceeded. If the replica SQL thread stops while `MASTER_POS_WAIT()` is waiting, the function returns `NULL`. If the replica is past the specified position, the function returns immediately.

  On a multithreaded replica, the function waits until expiry of the limit set by the `slave_checkpoint_group` or `slave_checkpoint_period` system variable, when the checkpoint operation is called to update the status of the replica. Depending on the setting for the system variables, the function might therefore return some time after the specified position was reached.

  If a `timeout` value is specified, `MASTER_POS_WAIT()` stops waiting when `timeout` seconds have elapsed. `timeout` must be greater than 0; a zero or negative `timeout` means no timeout.

  This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- **NAME_CONST(name, value)**

  Returns the given value. When used to produce a result set column, `NAME_CONST()` causes the column to have the given name. The arguments should be constants.

  ```sql
  mysql> SELECT NAME_CONST('myname', 14);
  +--------+
  | myname |
  | 14     |
  +--------+
  1 row in set (0.00 sec)
  ```

  This function is for internal use only. The server uses it when writing statements from stored programs that contain references to local program variables, as described in Section 20.7, “Stored Program Binary Logging”. You might see this function in the output from `mysqlbinlog`.

  For your applications, you can obtain exactly the same result as in the example just shown by using simple aliasing, like this:

  ```sql
  mysql> SELECT 14 AS myname;
  +--------+
  | myname |
  | 14     |
  +--------+
  1 row in set (0.00 sec)
  ```

  See Section 13.2.9, “SELECT Statement”, for more information about column aliases.

- **SLEEP(duration)**

  Sleeps (pauses) for the number of seconds given by the `duration` argument, then returns 0. If `SLEEP()` is interrupted, it returns 1. The duration may have a fractional part.

  When sleep returns normally (without interruption), it returns 0:

  ```sql
  mysql> SELECT SLEEP(1000);
  +-------------------+
  | SLEEP(1000)       |
  +-------------------+
  1 row in set (0.00 sec)
  ```
### Miscellaneous Functions

<table>
<thead>
<tr>
<th>SLEEP(1000)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
<tr>
<td>+-----------</td>
</tr>
</tbody>
</table>

When `SLEEP()` is the only thing invoked by a query that is interrupted, it returns 1 and the query itself returns no error. This statement is interrupted using `KILL QUERY` from another session:

```sql
mysql> SELECT SLEEP(1000);
+-------------+
| SLEEP(1000) |
| 1           |
+-------------+
```

When `SLEEP()` is only part of a query that is interrupted, the query returns an error. This statement is interrupted using `KILL QUERY` from another session:

```sql
mysql> SELECT 1 FROM t1 WHERE SLEEP(1000);
ERROR 1317 (70100): Query execution was interrupted
```

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- **UUID()**

  Returns a Universal Unique Identifier (UUID) generated according to RFC 4122, “A Universally Unique IDentifier (UUID) URN Namespace” ([http://www.ietf.org/rfc/rfc4122.txt](http://www.ietf.org/rfc/rfc4122.txt)).

  A UUID is designed as a number that is globally unique in space and time. Two calls to `UUID()` are expected to generate two different values, even if these calls are performed on two separate devices not connected to each other.

  **Warning**

  Although `UUID()` values are intended to be unique, they are not necessarily unguessable or unpredictable. If unpredictability is required, UUID values should be generated some other way.

  `UUID()` returns a value that conforms to UUID version 1 as described in RFC 4122. The value is a 128-bit number represented as a `utf8` string of five hexadecimal numbers in `aaaaaaaa-bbbbcccc-dddd-eeeeeeeeeee` format:

  - The first three numbers are generated from the low, middle, and high parts of a timestamp. The high part also includes the UUID version number.
  - The fourth number preserves temporal uniqueness in case the timestamp value loses monotonicity (for example, due to daylight saving time).
  - The fifth number is an IEEE 802 node number that provides spatial uniqueness. A random number is substituted if the latter is not available (for example, because the host device has no Ethernet card, or it is unknown how to find the hardware address of an interface on the host operating system). In this case, spatial uniqueness cannot be guaranteed. Nevertheless, a collision should have very low probability.

    The MAC address of an interface is taken into account only on FreeBSD, Linux, and Windows. On other operating systems, MySQL uses a randomly generated 48-bit number.

    ```sql
    mysql> SELECT UUID();
    -> '6ccd780c-baba-1026-9564-5b8c656024db'
    ```

    This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

---

1481
• **UUID_SHORT()**

Returns a “short” universal identifier as a 64-bit unsigned integer. Values returned by **UUID_SHORT()** differ from the string-format 128-bit identifiers returned by the **UUID()** function and have different uniqueness properties. The value of **UUID_SHORT()** is guaranteed to be unique if the following conditions hold:

- The server_id value of the current server is between 0 and 255 and is unique among your set of source and replica servers
- You do not set back the system time for your server host between mysqld restarts
- You invoke **UUID_SHORT()** on average fewer than 16 million times per second between mysqld restarts

The **UUID_SHORT()** return value is constructed this way:

```
(server_id & 255) << 56
+ (server_startup_time_in_seconds << 24)
+ incremented_variable++;
```

```
mysql> SELECT UUID_SHORT();
-> 92395783831158784
```

**Note**

**UUID_SHORT()** does not work with statement-based replication.

• **VALUES(col_name)**

In an **INSERT ... ON DUPLICATE KEY UPDATE** statement, you can use the **VALUES(col_name)** function in the **UPDATE** clause to refer to column values from the **INSERT** portion of the statement. In other words, **VALUES(col_name)** in the **UPDATE** clause refers to the value of **col_name** that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The **VALUES()** function is meaningful only in the **ON DUPLICATE KEY UPDATE** clause of **INSERT** statements and returns **NULL** otherwise. See Section 13.2.5.2, “**INSERT ... ON DUPLICATE KEY UPDATE Statement**”.

```
mysql> INSERT INTO table (a,b,c) VALUES (1,2,3),(4,5,6)
-> ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

### 12.21 Precision Math

MySQL provides support for precision math: numeric value handling that results in extremely accurate results and a high degree control over invalid values. Precision math is based on these two features:

- SQL modes that control how strict the server is about accepting or rejecting invalid data.
- The MySQL library for fixed-point arithmetic.

These features have several implications for numeric operations and provide a high degree of compliance with standard SQL:

- **Precise calculations**: For exact-value numbers, calculations do not introduce floating-point errors. Instead, exact precision is used. For example, MySQL treats a number such as `.0001` as an exact value rather than as an approximation, and summing it 10,000 times produces a result of exactly 1, not a value that is merely “close” to 1.

- **Well-defined rounding behavior**: For exact-value numbers, the result of **ROUND()** depends on its argument, not on environmental factors such as how the underlying C library works.

- **Platform independence**: Operations on exact numeric values are the same across different platforms such as Windows and Unix.
Types of Numeric Values

• Control over handling of invalid values: Overflow and division by zero are detectable and can be treated as errors. For example, you can treat a value that is too large for a column as an error rather than having the value truncated to lie within the range of the column’s data type. Similarly, you can treat division by zero as an error rather than as an operation that produces a result of NULL. The choice of which approach to take is determined by the setting of the server SQL mode.

The following discussion covers several aspects of how precision math works, including possible incompatibilities with older applications. At the end, some examples are given that demonstrate how MySQL handles numeric operations precisely. For information about controlling the SQL mode, see Section 5.1.10, “Server SQL Modes”.

12.21.1 Types of Numeric Values

The scope of precision math for exact-value operations includes the exact-value data types (integer and DECIMAL types) and exact-value numeric literals. Approximate-value data types and numeric literals are handled as floating-point numbers.

Exact-value numeric literals have an integer part or fractional part, or both. They may be signed. Examples: 1, .2, 3.4, −5, −6.78, +9.10.

Approximate-value numeric literals are represented in scientific notation with a mantissa and exponent. Either or both parts may be signed. Examples: 1.2E3, 1.2E−3, −1.2E3, −1.2E−3.

Two numbers that look similar may be treated differently. For example, 2.34 is an exact-value (fixed-point) number, whereas 2.34E0 is an approximate-value (floating-point) number.

The DECIMAL data type is a fixed-point type and calculations are exact. In MySQL, the DECIMAL type has several synonyms: NUMERIC, DEC, FIXED. The integer types also are exact-value types.

The FLOAT and DOUBLE data types are floating-point types and calculations are approximate. In MySQL, types that are synonymous with FLOAT or DOUBLE are DOUBLE PRECISION and REAL.

12.21.2 DECIMAL Data Type Characteristics

This section discusses the characteristics of the DECIMAL data type (and its synonyms), with particular regard to the following topics:

• Maximum number of digits
• Storage format
• Storage requirements
• The nonstandard MySQL extension to the upper range of DECIMAL columns

The declaration syntax for a DECIMAL column is DECIMAL(M, D). The ranges of values for the arguments are as follows:

• M is the maximum number of digits (the precision). It has a range of 1 to 65.
• D is the number of digits to the right of the decimal point (the scale). It has a range of 0 to 30 and must be no larger than M.

If D is omitted, the default is 0. If M is omitted, the default is 10.

The maximum value of 65 for M means that calculations on DECIMAL values are accurate up to 65 digits. This limit of 65 digits of precision also applies to exact-value numeric literals, so the maximum range of such literals differs from before. (There is also a limit on how long the text of DECIMAL literals can be; see Section 12.21.3, “Expression Handling”.)

Values for DECIMAL columns are stored using a binary format that packs nine decimal digits into 4 bytes. The storage requirements for the integer and fractional parts of each value are determined
separately. Each multiple of nine digits requires 4 bytes, and any remaining digits left over require some fraction of 4 bytes. The storage required for remaining digits is given by the following table.

<table>
<thead>
<tr>
<th>Leftover Digits</th>
<th>Number of Bytes</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1–2</td>
<td>1</td>
</tr>
<tr>
<td>3–4</td>
<td>2</td>
</tr>
<tr>
<td>5–6</td>
<td>3</td>
</tr>
<tr>
<td>7–9</td>
<td>4</td>
</tr>
</tbody>
</table>

For example, a `DECIMAL(18,9)` column has nine digits on either side of the decimal point, so the integer part and the fractional part each require 4 bytes. A `DECIMAL(20,6)` column has fourteen integer digits and six fractional digits. The integer digits require four bytes for nine of the digits and 3 bytes for the remaining five digits. The six fractional digits require 3 bytes.

`DECIMAL` columns do not store a leading `+` character or `–` character or leading `0` digits. If you insert `+0003.1` into a `DECIMAL(5,1)` column, it is stored as `3.1`. For negative numbers, a literal `–` character is not stored.

`DECIMAL` columns do not permit values larger than the range implied by the column definition. For example, a `DECIMAL(3,0)` column supports a range of `–999` to `999`. A `DECIMAL(M,D)` column permits up to `M - D` digits to the left of the decimal point.

The SQL standard requires that the precision of `NUMERIC(M,D)` be exactly `N` digits. For `DECIMAL(M,D)`, the standard requires a precision of at least `M` digits but permits more. In MySQL, `DECIMAL(M,D)` and `NUMERIC(M,D)` are the same, and both have a precision of exactly `M` digits.

For a full explanation of the internal format of `DECIMAL` values, see the file `strings/decimal.c` in a MySQL source distribution. The format is explained (with an example) in the `decimal2bin()` function.

### 12.21.3 Expression Handling

With precision math, exact-value numbers are used as given whenever possible. For example, numbers in comparisons are used exactly as given without a change in value. In strict SQL mode, for INSERT into a column with an exact data type (`DECIMAL` or integer), a number is inserted with its exact value if it is within the column range. When retrieved, the value should be the same as what was inserted. (If strict SQL mode is not enabled, truncation for INSERT is permissible.)

Handling of a numeric expression depends on what kind of values the expression contains:

- If any approximate values are present, the expression is approximate and is evaluated using floating-point arithmetic.
- If no approximate values are present, the expression contains only exact values. If any exact value contains a fractional part (a value following the decimal point), the expression is evaluated using `DECIMAL` exact arithmetic and has a precision of 65 digits. The term “exact” is subject to the limits of what can be represented in binary. For example, `1.0/3.0` can be approximated in decimal notation as `.333...`, but not written as an exact number, so `(1.0/3.0)*3.0` does not evaluate to exactly `1.0`.
- Otherwise, the expression contains only integer values. The expression is exact and is evaluated using integer arithmetic and has a precision the same as `BIGINT` (64 bits).

If a numeric expression contains any strings, they are converted to double-precision floating-point values and the expression is approximate.

Inserts into numeric columns are affected by the SQL mode, which is controlled by the `sql_mode` system variable. (See Section 5.1.10, “Server SQL Modes”.) The following discussion mentions
strict mode (selected by the STRICT_ALL_TABLES or STRICT_TRANS_TABLES mode values) and ERROR_FOR_DIVISION_BY_ZERO. To turn on all restrictions, you can simply use TRADITIONAL mode, which includes both strict mode values and ERROR_FOR_DIVISION_BY_ZERO:

```sql
SET sql_mode='TRADITIONAL';
```

If a number is inserted into an exact type column (DECIMAL or integer), it is inserted with its exact value if it is within the column range and precision.

If the value has too many digits in the fractional part, rounding occurs and a note is generated. Rounding is done as described in Section 12.21.4, “Rounding Behavior”. Truncation due to rounding of the fractional part is not an error, even in strict mode.

If the value has too many digits in the integer part, it is too large (out of range) and is handled as follows:

- If strict mode is not enabled, the value is truncated to the nearest legal value and a warning is generated.
- If strict mode is enabled, an overflow error occurs.

For DECIMAL literals, in addition to the precision limit of 65 digits, there is a limit on how long the text of the literal can be. If the value exceeds approximately 80 characters, unexpected results can occur. For example:

```sql
mysql> SELECT CAST('0000000000000000000000000000000000000000000000000000000000000000000000000000000020.01' AS DECIMAL(15,2)) as val;
+------------------+
| val              |
+------------------+
| 9999999999999.99 |
+------------------+
1 row in set, 2 warnings (0.00 sec)
```

```sql
mysql> SHOW WARNINGS;
+---------+------+----------------------------------------------+
<table>
<thead>
<tr>
<th>Level</th>
<th>Code</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>Warning</td>
<td>1292</td>
<td>Truncated incorrect DECIMAL value: ''</td>
</tr>
<tr>
<td>Warning</td>
<td>1264</td>
<td>Out of range value for column 'val' at row 1</td>
</tr>
</tbody>
</table>
+---------+------+----------------------------------------------+
2 rows in set (0.00 sec)
```

Underflow is not detected, so underflow handling is undefined.

For inserts of strings into numeric columns, conversion from string to number is handled as follows if the string has nonnumeric contents:

- A string that does not begin with a number cannot be used as a number and produces an error in strict mode, or a warning otherwise. This includes the empty string.
- A string that begins with a number can be converted, but the trailing nonnumeric portion is truncated. If the truncated portion contains anything other than spaces, this produces an error in strict mode, or a warning otherwise.

By default, division by zero produces a result of NULL and no warning. By setting the SQL mode appropriately, division by zero can be restricted.

With the ERROR_FOR_DIVISION_BY_ZERO SQL mode enabled, MySQL handles division by zero differently:

- If strict mode is not enabled, a warning occurs.
- If strict mode is enabled, inserts and updates involving division by zero are prohibited, and an error occurs.
In other words, inserts and updates involving expressions that perform division by zero can be treated as errors, but this requires `ERROR_FOR_DIVISION_BY_ZERO` in addition to strict mode.

Suppose that we have this statement:

```
INSERT INTO t SET i = 1/0;
```

This is what happens for combinations of strict and `ERROR_FOR_DIVISION_BY_ZERO` modes.

<table>
<thead>
<tr>
<th>sql_mode Value</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>'' (Default)</td>
<td>No warning, no error; i is set to NULL.</td>
</tr>
<tr>
<td>strict</td>
<td>No warning, no error; i is set to NULL.</td>
</tr>
<tr>
<td>ERROR_FOR_DIVISION_BY_ZERO</td>
<td>Warning, no error; i is set to NULL.</td>
</tr>
<tr>
<td>strict, ERROR_FOR_DIVISION_BY_ZERO</td>
<td>Error condition; no row is inserted.</td>
</tr>
</tbody>
</table>

### 12.21.4 Rounding Behavior

This section discusses precision math rounding for the `ROUND()` function and for inserts into columns with exact-value types (`DECIMAL` and integer).

The `ROUND()` function rounds differently depending on whether its argument is exact or approximate:

- For exact-value numbers, `ROUND()` uses the “round half up” rule: A value with a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negative. (In other words, it is rounded away from zero.) A value with a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative. (In other words, it is rounded toward zero.)

- For approximate-value numbers, the result depends on the C library. On many systems, this means that `ROUND()` uses the “round to nearest even” rule: A value with a fractional part exactly half way between two integers is rounded to the nearest even integer.

The following example shows how rounding differs for exact and approximate values:

```sql
mysql> SELECT ROUND(2.5), ROUND(25E-1);
+------------+--------------+
| ROUND(2.5) | ROUND(25E-1) |
+------------+--------------+
| 3          |            2 |
+------------+--------------+
```

For inserts into a `DECIMAL` or integer column, the target is an exact data type, so rounding uses “round half away from zero,” regardless of whether the value to be inserted is exact or approximate:

```sql
mysql> CREATE TABLE t (d DECIMAL(10,0));
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO t VALUES(2.5),(2.5E0);
Query OK, 2 rows affected, 2 warnings (0.00 sec)
Records: 2  Duplicates: 0  Warnings: 2
mysql> SHOW WARNINGS;
+-------+------+----------------------------------------+
| Level | Code | Message                                |
|-------+------|----------------------------------------|
| Note  | 1265 | Data truncated for column 'd' at row 1 |
| Note  | 1265 | Data truncated for column 'd' at row 2 |
+-------+------|----------------------------------------+
2 rows in set (0.00 sec)
mysql> SELECT d FROM t;
+------+
| d    |
+------+
```
### 12.21.5 Precision Math Examples

This section provides some examples that show precision math query results in MySQL. These examples demonstrate the principles described in Section 12.21.3, “Expression Handling”, and Section 12.21.4, “Rounding Behavior”.

**Example 1.** Numbers are used with their exact value as given when possible:

```sql
mysql> SELECT (.1 + .2) = .3;
+----------------+
| (.1 + .2) = .3 |
+----------------+
|              1 |
+----------------+
```

For floating-point values, results are inexact:

```sql
mysql> SELECT (.1E0 + .2E0) = .3E0;
+----------------------+
| (.1E0 + .2E0) = .3E0 |
+----------------------+
|                    0 |
+----------------------+
```

Another way to see the difference in exact and approximate value handling is to add a small number to a sum many times. Consider the following stored procedure, which adds 0.0001 to a variable 1,000 times.

```sql
CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 0;
  DECLARE d DECIMAL(10,4) DEFAULT 0;
  DECLARE f FLOAT DEFAULT 0;
  WHILE i < 10000 DO
    SET d = d + .0001;
    SET f = f + .0001E0;
    SET i = i + 1;
  END WHILE;
  SELECT d, f;
END;
```

The sum for both `d` and `f` logically should be 1, but that is true only for the decimal calculation. The floating-point calculation introduces small errors:

```sql
+--------+------------------+
| d      | f                |
+--------+------------------+
| 1.0000 | 0.99999999999991 |
+--------+------------------+
```

**Example 2.** Multiplication is performed with the scale required by standard SQL. That is, for two numbers `X1` and `X2` that have scale `S1` and `S2`, the scale of the result is `S1 + S2`:

```sql
mysql> SELECT .01 * .01;
+-----------+
| .01 * .01 |
+-----------+
```
Example 3. Rounding behavior for exact-value numbers is well-defined:

Rounding behavior (for example, with the `ROUND()` function) is independent of the implementation of the underlying C library, which means that results are consistent from platform to platform.

- Rounding for exact-value columns (`DECIMAL` and integer) and exact-valued numbers uses the “round half away from zero” rule. A value with a fractional part of .5 or greater is rounded away from zero to the nearest integer, as shown here:

  ```
  mysql> SELECT ROUND(2.5), ROUND(-2.5);
  +------------+-------------+
  | ROUND(2.5) | ROUND(-2.5) |
  +------------+-------------+
  | 3          | -3          |
  +------------+-------------+
  ```

- Rounding for floating-point values uses the C library, which on many systems uses the “round to nearest even” rule. A value with a fractional part exactly half way between two integers is rounded to the nearest even integer:

  ```
  mysql> SELECT ROUND(2.5E0), ROUND(-2.5E0);
  +--------------+---------------+
  | ROUND(2.5E0) | ROUND(-2.5E0) |
  +--------------+---------------+
  | 2            | -2            |
  +--------------+---------------+
  ```

Example 4. In strict mode, inserting a value that is out of range for a column causes an error, rather than truncation to a legal value.

When MySQL is not running in strict mode, truncation to a legal value occurs:

```
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t SET i = 128;
Query OK, 1 row affected, 1 warning (0.00 sec)

mysql> SELECT i FROM t;
+------+
| i    |
+------+
|  127 |
1 row in set (0.00 sec)
```

However, an error occurs if strict mode is in effect:

```
mysql> SET sql_mode='STRICT_ALL_TABLES';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 128;
ERROR 1264 (22003): Out of range value adjusted for column 'i' at row 1

mysql> SELECT i FROM t;
Empty set (0.00 sec)
```

Example 5: In strict mode and with `ERROR_FOR_DIVISION_BY_ZERO` set, division by zero causes an error, not a result of `NULL`.  

1488
In nonstrict mode, division by zero has a result of \texttt{NULL}:

```
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.01 sec)
mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO t SET i = 1 / 0;
Query OK, 1 row affected (0.00 sec)
mysql> SELECT i FROM t;
+-----+
| i    |
+-----+
| NULL |
+-----+
1 row in set (0.03 sec)
```

However, division by zero is an error if the proper SQL modes are in effect:

```
mysql> SET sql_mode='STRICT_ALL_TABLES,ERROR_FOR_DIVISION_BY_ZERO';
Query OK, 0 rows affected (0.00 sec)
mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO t SET i = 1 / 0;
ERROR 1365 (22012): Division by 0
mysql> SELECT i FROM t;
Empty set (0.01 sec)
```

Example 6. Exact-value literals are evaluated as exact values.

Approximate-value literals are evaluated using floating point, but exact-value literals are handled as \texttt{DECIMAL}:

```
mysql> CREATE TABLE t SELECT 2.5 AS a, 25E-1 AS b;
Query OK, 1 row affected (0.01 sec)
Records: 1  Duplicates: 0  Warnings: 0
mysql> DESCRIBE t;
+-------+-----------------------+------+-----+---------+-------+
| Field | Type                  | Null | Key | Default | Extra |
+-------+-----------------------+------+-----+---------+-------+
| a     | decimal(2,1) unsigned | NO   |     | 0.0     |       |
| b     | double                | NO   |     | 0       |       |
+-------+-----------------------+------+-----+---------+-------+
2 rows in set (0.01 sec)
```

Example 7. If the argument to an aggregate function is an exact numeric type, the result is also an exact numeric type, with a scale at least that of the argument.

Consider these statements:

```
mysql> CREATE TABLE t (i INT, d DECIMAL, f FLOAT);
mysql> INSERT INTO t VALUES(1,1,1);
mysql> CREATE TABLE y SELECT AVG(i), AVG(d), AVG(f) FROM t;
```

The result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type:

```
mysql> DESCRIBE y;
+--------+---------------+------+-----+---------+-------+
| Field  | Type          | Null | Key | Default | Extra |
+--------+---------------+------+-----+---------+-------+
| AVG(i) | decimal(14,4) | YES  | NULL| NULL    |       |
| AVG(d) | decimal(14,4) | YES  | NULL|         |       |
| AVG(f) | double        | YES  | NULL|         |       |
+--------+---------------+------+-----+---------+-------+
```
The result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type.

13.1 Data Definition Statements

13.1.1 ALTER DATABASE Statement

```
ALTER (DATABASE | SCHEMA) [db_name]
  alter_option ...

ALTER DATABASE db_name
  UPGRADE DATA DIRECTORY NAME
```

The `ALTER DATABASE` statement allows you to change the overall characteristics of a database. These characteristics are stored in the `db.opt` file in the database directory. This statement requires the `ALTER` privilege on the database. `ALTER DATABASE` is a synonym for `ALTER SCHEMA`.

The database name can be omitted from the first syntax, in which case the statement applies to the default database. An error occurs if there is no default database.

- Character Set and Collation Options
- Upgrading from Versions Older than MySQL 5.1

Character Set and Collation Options

The `CHARACTER_SET` clause changes the default database character set. The `COLLATE` clause changes the default database collation. For information about character set and collation names, see Chapter 10, `Character Sets, Collations, Unicode`.

This chapter describes the syntax for the SQL statements supported by MySQL.
To see the available character sets and collations, use the SHOW CHARACTER SET and SHOW COLLATION statements, respectively. See Section 13.7.5.4, “SHOW CHARACTER SET Statement”, and Section 13.7.5.5, “SHOW COLLATION Statement”.

A stored routine that uses the database defaults when the routine is created includes those defaults as part of its definition. (In a stored routine, variables with character data types use the database defaults if the character set or collation are not specified explicitly. See Section 13.1.15, “CREATE PROCEDURE and CREATE FUNCTION Statements”.) If you change the default character set or collation for a database, any stored routines that are to use the new defaults must be dropped and recreated.

Upgrading from Versions Older than MySQL 5.1

The syntax that includes the UPGRADE DATA DIRECTORY NAME clause updates the name of the directory associated with the database to use the encoding implemented in MySQL 5.1 for mapping database names to database directory names (see Section 9.2.4, “Mapping of Identifiers to File Names”). This clause is for use under these conditions:

- It is intended when upgrading MySQL to 5.1 or later from older versions.
- It is intended to update a database directory name to the current encoding format if the name contains special characters that need encoding.
- The statement is used by mysqlcheck (as invoked by mysql_upgrade).

For example, if a database in MySQL 5.0 has the name a-b-c, the name contains instances of the - (dash) character. In MySQL 5.0, the database directory is also named a-b-c, which is not necessarily safe for all file systems. In MySQL 5.1 and later, the same database name is encoded as a@002db@002dc to produce a file system-neutral directory name.

When a MySQL installation is upgraded to MySQL 5.1 or later from an older version, the server displays a name such as a-b-c (which is in the old format) as #mysql50#a-b-c, and you must refer to the name using the #mysql50# prefix. Use UPGRADE DATA DIRECTORY NAME in this case to explicitly tell the server to re-encode the database directory name to the current encoding format:

```sql
ALTER DATABASE '#mysql50#a-b-c' UPGRADE DATA DIRECTORY NAME;
```

After executing this statement, you can refer to the database as a-b-c without the special #mysql50# prefix.

### 13.1.2 ALTER EVENT Statement

```sql
ALTER [DEFINER = user]
  EVENT event_name
  [ON SCHEDULE schedule]
  [ON COMPLETION [NOT] PRESERVE]
  [RENAME TO new_event_name]
  [ENABLE | DISABLE | DISABLE ON SLAVE]
  [COMMENT 'string']
  [DO event_body]
```

The ALTER EVENT statement changes one or more of the characteristics of an existing event without the need to drop and recreate it. The syntax for each of the DEFINER, ON SCHEDULE, ON COMPLETION, COMMENT, ENABLE / DISABLE, and DO clauses is exactly the same as when used with CREATE EVENT. (See Section 13.1.11, “CREATE EVENT Statement”.)

Any user can alter an event defined on a database for which that user has the EVENT privilege. When a user executes a successful ALTER EVENT statement, that user becomes the definer for the affected event.

ALTER EVENT works only with an existing event:
ALTER EVENT Statement

In each of the following examples, assume that the event named `myevent` is defined as shown here:

```sql
CREATE EVENT myevent
ON SCHEDULE EVERY 6 HOUR
COMMENT 'A sample comment.'
DO
  UPDATE myschema.mytable SET mycol = mycol + 1;
```

The following statement changes the schedule for `myevent` from once every six hours starting immediately to once every twelve hours, starting four hours from the time the statement is run:

```sql
ALTER EVENT myevent
ON SCHEDULE EVERY 12 HOUR
STARTS CURRENT_TIMESTAMP + INTERVAL 4 HOUR;
```

It is possible to change multiple characteristics of an event in a single statement. This example changes the SQL statement executed by `myevent` to one that deletes all records from `mytable`; it also changes the schedule for the event such that it executes once, one day after this `ALTER EVENT` statement is run.

```sql
ALTER EVENT myevent
ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
DO TRUNCATE TABLE myschema.mytable;
```

Specify the options in an `ALTER EVENT` statement only for those characteristics that you want to change; omitted options keep their existing values. This includes any default values for `CREATE EVENT` such as `ENABLE`.

To disable `myevent`, use this `ALTER EVENT` statement:

```sql
ALTER EVENT myevent
DISABLE;
```

The `ON SCHEDULE` clause may use expressions involving built-in MySQL functions and user variables to obtain any of the `timestamp` or `interval` values which it contains. You cannot use stored routines or user-defined functions in such expressions, and you cannot use any table references; however, you can use `SELECT FROM DUAL`. This is true for both `ALTER EVENT` and `CREATE EVENT` statements. References to stored routines, user-defined functions, and tables in such cases are specifically not permitted, and fail with an error (see Bug #22830).

Although an `ALTER EVENT` statement that contains another `ALTER EVENT` statement in its `DO` clause appears to succeed, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

To rename an event, use the `ALTER EVENT` statement's `RENAME TO` clause. This statement renames the event `myevent` to `yourevent`:

```sql
ALTER EVENT myevent
RENAME TO yourevent;
```

You can also move an event to a different database using `ALTER EVENT ... RENAME TO ...` and `db_name.event_name` notation, as shown here:

```sql
ALTER EVENT olddb.myevent
RENAME TO newdb.myevent;
```
To execute the previous statement, the user executing it must have the EVENT privilege on both the olddb and newdb databases.

**Note**

There is no RENAME EVENT statement.

The value DISABLE ON SLAVE is used on a replica instead of ENABLE or DISABLE to indicate an event that was created on the source and replicated to the replica, but that is not executed on the replica. Normally, DISABLE ON SLAVE is set automatically as required; however, there are some circumstances under which you may want or need to change it manually. See Section 17.4.1.16, “Replication of Invoked Features”, for more information.

### 13.1.3 ALTER FUNCTION Statement

```sql
ALTER FUNCTION func_name [characteristic ...]
characteristic: {
    COMMENT 'string'
    | LANGUAGE SQL
    | { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
    | SQL SECURITY { DEFINER | INVOKER }
}
```

This statement can be used to change the characteristics of a stored function. More than one change may be specified in an ALTER FUNCTION statement. However, you cannot change the parameters or body of a stored function using this statement; to make such changes, you must drop and re-create the function using DROP FUNCTION and CREATE FUNCTION.

You must have the ALTER ROUTINE privilege for the function. (That privilege is granted automatically to the function creator.) If binary logging is enabled, the ALTER FUNCTION statement might also require the SUPER privilege, as described in Section 20.7, “Stored Program Binary Logging”.

### 13.1.4 ALTER LOGFILE GROUP Statement

```sql
ALTER LOGFILE GROUP logfile_group
    ADD UNDOFILE 'file_name'
    [INITIAL_SIZE [=] size]
    [WAIT]
    ENGINE [=] engine_name
```

This statement adds an UNDO file named 'file_name' to an existing log file group logfile_group. An ALTER LOGFILE GROUP statement has one and only one ADD UNDOFILE clause. No DROP UNDOFILE clause is currently supported.

**Note**

All NDB Cluster Disk Data objects share the same namespace. This means that each Disk Data object must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and an undo log file with the same name, or an undo log file and a data file with the same name.

The optional INITIAL_SIZE parameter sets the UNDO file’s initial size in bytes; if not specified, the initial size defaults to 134217728 (128 MB). Prior to MySQL NDB Cluster 7.3.2, this value was required to be specified using digits; in MySQL NDB Cluster 7.3.2 and later, you may optionally follow size with a one-letter abbreviation for an order of magnitude, similar to those used in my.cnf. Generally, this is one of the letters M (megabytes) or G (gigabytes). (Bug #13116514, Bug #16104705, Bug #62858)

On 32-bit systems, the maximum supported value for INITIAL_SIZE is 4294967296 (4 GB). (Bug #29186)

The minimum allowed value for INITIAL_SIZE is 1048576 (1 MB). (Bug #29574)
The `ENGINE` parameter (required) determines the storage engine which is used by this log file group, with `engine_name` being the name of the storage engine. Currently, the only accepted values for `engine_name` are "NDBCLUSTER" and "NDB". The two values are equivalent.

Here is an example, which assumes that the log file group `lg_3` has already been created using `CREATE LOGFILE GROUP` (see Section 13.1.14, “CREATE LOGFILE GROUP Statement”):

```sql
ALTER LOGFILE GROUP lg_3
  ADD UNDOFILE 'undo_10.dat'
  INITIAL_SIZE=32M
  ENGINE=NDBCLUSTER;
```

When `ALTER LOGFILE GROUP` is used with `ENGINE = NDBCLUSTER` (alternatively, `ENGINE = NDB`), an UNDO log file is created on each NDB Cluster data node. You can verify that the UNDO files were created and obtain information about them by querying the `INFORMATION_SCHEMA.FILES` table. For example:

```sql
mysql> SELECT FILE_NAME, LOGFILE_GROUP_NUMBER, EXTRA
    -> FROM INFORMATION_SCHEMA.FILES
    -> WHERE LOGFILE_GROUP_NAME = 'lg_3';
+-------------+----------------------+----------------+
<table>
<thead>
<tr>
<th>FILE_NAME</th>
<th>LOGFILE_GROUP_NUMBER</th>
<th>EXTRA</th>
</tr>
</thead>
<tbody>
<tr>
<td>newdata.dat</td>
<td>0</td>
<td>CLUSTER_NODE=3</td>
</tr>
<tr>
<td>newdata.dat</td>
<td>0</td>
<td>CLUSTER_NODE=4</td>
</tr>
<tr>
<td>undo_10.dat</td>
<td>11</td>
<td>CLUSTER_NODE=3</td>
</tr>
<tr>
<td>undo_10.dat</td>
<td>11</td>
<td>CLUSTER_NODE=4</td>
</tr>
</tbody>
</table>
+-------------+----------------------+----------------+
4 rows in set (0.01 sec)
```

(See Section 21.31.1, “The INFORMATION_SCHEMA.FILES Table”.)

Memory used for `UNDO_BUFFER_SIZE` comes from the global pool whose size is determined by the value of the `SharedGlobalMemory` data node configuration parameter. This includes any default value implied for this option by the setting of the `InitialLogFileGroup` data node configuration parameter.

`ALTER LOGFILE GROUP` is useful only with Disk Data storage for NDB Cluster. For more information, see Section 18.5.10, “NDB Cluster Disk Data Tables”.

### 13.1.5 ALTER PROCEDURE Statement

```sql
ALTER PROCEDURE proc_name [characteristic ...]
characteristic: |
    COMMENT 'string'
    | LANGUAGE SQL
    | { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
    | SQL SECURITY { DEFINER | INVOKER }
}]
```

This statement can be used to change the characteristics of a stored procedure. More than one change may be specified in an `ALTER PROCEDURE` statement. However, you cannot change the parameters or body of a stored procedure using this statement; to make such changes, you must drop and re-create the procedure using `DROP PROCEDURE` and `CREATE PROCEDURE`.

You must have the `ALTER ROUTINE` privilege for the procedure. By default, that privilege is granted automatically to the procedure creator. This behavior can be changed by disabling the `automatic_sp_privileges` system variable. See Section 20.2.2, “Stored Routines and MySQL Privileges”.

1496
13.1.6 ALTER SERVER Statement

```
ALTER SERVER server_name
    OPTIONS (option [, option] ...)
```

Alters the server information for `server_name`, adjusting any of the options permitted in the `CREATE SERVER` statement. The corresponding fields in the `mysql.servers` table are updated accordingly. This statement requires the `SUPER` privilege.

For example, to update the `USER` option:

```
ALTER Server s OPTIONS (USER 'sally');
```

`ALTER_SERVER` causes an implicit commit. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

`ALTER_SERVER` is not written to the binary log, regardless of the logging format that is in use.

In MySQL 5.6.11 only, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. (Bug #16062608, Bug #16715809, Bug #69045)

13.1.7 ALTER TABLE Statement

```
ALTER [ONLINE | OFFLINE] [IGNORE] TABLE tbl_name
    [alter_option [, alter_option] ...]
    [partition_options]
```

```
alter_option: {
    table_options
    | ADD [COLUMN] col_name column_definition
    | ADD [INDEX | KEY] [index_name] [index_type] (key_part,...) [index_option] ...
    | ADD [FULLTEXT | SPATIAL] [INDEX | KEY] [index_name]
    | ADD {INDEX | KEY} [index_name] [index_type] (key_part,...) [index_option] ...  
    | ADD [CONSTRAINT [symbol]] PRIMARY KEY
    | ADD [CONSTRAINT [symbol]] UNIQUE [INDEX | KEY]
    | ADD [CONSTRAINT [symbol]] FOREIGN KEY
    | ADD CHECK (expr)
    | ALGORITHM [=] {DEFAULT | INPLACE | COPY}
    | ALTER [COLUMN] col_name {SET DEFAULT literal | DROP DEFAULT}
    | CHANGE [COLUMN] old_col_name new_col_name column_definition
    | ORDER BY col_name [, col_name] ...
    | RENAME [TO | AS] new_tbl_name}
```

```
partition_options: {
    partition_option [partition_option] ...
```

```
partition_option: {
```
ALTER TABLE Statement

| ADD PARTITION (partition_definition) |
| DROP PARTITION partition_names |
| TRUNCATE PARTITION (partition_names | ALL) |
| COALESCE PARTITION number |
| REORGANIZE PARTITION partition_names INTO (partition_definitions) |
| EXCHANGE PARTITION partition_name WITH TABLE tbl_name |
| ANALYZE PARTITION (partition_names | ALL) |
| CHECK PARTITION (partition_names | ALL) |
| OPTIMIZE PARTITION (partition_names | ALL) |
| REBUILD PARTITION (partition_names | ALL) |
| REPAIR PARTITION (partition_names | ALL) |
| REMOVE PARTITIONING |

key_part:
- col_name [{(length)}] [ASC | DESC]

index_type:
- USING {BTREE | HASH}

index_option:
- [KEY_BLOCK_SIZE [=] value
- | index_type
- WITH PARSER parser_name
- | COMMENT 'string'

Table options:
- [table_option [[,] table_option] ...]

Table option:
- [AUTO_INCREMENT [=] value
- | AVG_ROW_LENGTH [=] value
- | [DEFAULT] CHARACTER SET [=] charset_name
- | CHECKSUM [=] {0 | 1}
- | [DEFAULT] COLLATE [=] collation_name
- | COMMENT [=] 'string'
- | CONNECTION [=] 'connect_string'
- | {DATA | INDEX} DIRECTORY [=] 'absolute path to directory'
- | DELAY_KEY_WRITE [=] {0 | 1}
- | ENGINE [=] engine_name
- | INSERT_METHOD [=] { NO | FIRST | LAST }
- | KEY_BLOCK_SIZE [=] value
- | MAX_ROWS [=] value
- | MIN_ROWS [=] value
- | PACK_KEYS [=] {0 | 1 | DEFAULT}
- | PASSWORD [=] 'string'
- | ROW_FORMAT [=] {DEFAULT | DYNAMIC | FIXED | COMPRESSED | REDUNDANT | COMPACT}
- | STATS_AUTO_RECALC [=] {DEFAULT | 0 | 1}
- | STATS_PERSISTENT [=] {DEFAULT | 0 | 1}
- | STATS_SAMPLE_PAGES [=] value
- | TABLESPACE tablespace_name [STORAGE {DISK | MEMORY}]
- | UNION [=] (tbl_name[, tbl_name]...)

**ALTER TABLE** changes the structure of a table. For example, you can add or delete columns, create or destroy indexes, change the type of existing columns, or rename columns or the table itself. You can also change characteristics such as the storage engine used for the table or the table comment.

- To use **ALTER TABLE**, you need **ALTER**, **CREATE**, and **INSERT** privileges for the table. Renaming a table requires **ALTER** and **DROP** on the old table, **ALTER**, **CREATE**, and **INSERT** on the new table.

- Following the table name, specify the alterations to be made. If none are given, **ALTER TABLE** does nothing.

- The syntax for many of the permissible alterations is similar to clauses of the **CREATE TABLE** statement. **column_definition** clauses use the same syntax for **ADD** and **CHANGE** as for **CREATE TABLE**. For more information, see Section 13.1.17, “CREATE TABLE Statement”.

- The word **COLUMN** is optional and can be omitted.
• Multiple **ADD**, **ALTER**, **DROP**, and **CHANGE** clauses are permitted in a single **ALTER TABLE** statement, separated by commas. This is a MySQL extension to standard SQL, which permits only one of each clause per **ALTER TABLE** statement. For example, to drop multiple columns in a single statement, do this:

```
ALTER TABLE t2 DROP COLUMN c, DROP COLUMN d;
```

• If a storage engine does not support an attempted **ALTER TABLE** operation, a warning may result. Such warnings can be displayed with **SHOW WARNINGS**. See Section 13.7.5.41, “SHOW WARNINGS Statement”. For information on troubleshooting **ALTER TABLE**, see Section B.3.6.1, “Problems with **ALTER TABLE**”.

• For usage examples, see Section 13.1.7.2, “**ALTER TABLE** Examples”.

• With the `mysql_info()` C API function, you can find out how many rows were copied by **ALTER TABLE**, and (when **IGNORE** is used) how many rows were deleted due to duplication of unique key values. See `mysql_info()`.

There are several additional aspects to the **ALTER TABLE** statement, described under the following topics in this section:

- **Table Options**
- **Performance and Space Requirements**
- **Concurrency Control**
- **Adding and Dropping Columns**
- **Renaming, Redefining, and Reordering Columns**
- **Primary Keys and Indexes**
- **Foreign Keys and Other Constraints**
- **Changing the Character Set**
- **Discarding and Importing InnoDB Tablespaces**
- **Row Order for MyISAM Tables**
- **Partitioning Options**

### Table Options

`table_options` signifies table options of the kind that can be used in the **CREATE TABLE** statement, such as **ENGINE**, **AUTO_INCREMENT**, **AVG_ROW_LENGTH**, **MAX_ROWS**, or **ROW_FORMAT**.

For descriptions of all table options, see Section 13.1.17, “**CREATE TABLE** Statement”. However, **ALTER TABLE** ignores **DATA DIRECTORY** and **INDEX DIRECTORY** when given as table options. **ALTER TABLE** permits them only as partitioning options, and, as of MySQL 5.6.35, requires that you have the **FILE** privilege.

Use of table options with **ALTER TABLE** provides a convenient way of altering single table characteristics. For example:

• If `t1` is currently not an **InnoDB** table, this statement changes its storage engine to **InnoDB**:

```
ALTER TABLE t1 ENGINE = InnoDB;
```

• See Section 14.6.1.5, “Converting Tables from MyISAM to InnoDB” for considerations when switching tables to the **InnoDB** storage engine.

• When you specify an **ENGINE** clause, **ALTER TABLE** rebuilds the table. This is true even if the table already has the specified storage engine.
• Running `ALTER TABLE tbl_name ENGINE=INNODB` on an existing InnoDB table performs a "null" ALTER TABLE operation, which can be used to defragment an InnoDB table, as described in Section 14.12.4, “Defragmenting a Table”. Running `ALTER TABLE tbl_name FORCE` on an InnoDB table performs the same function.

• As of MySQL 5.6.17, `ALTER TABLE tbl_name ENGINE=INNODB` and `ALTER TABLE tbl_name FORCE` use online DDL. For more information, see Section 14.13, “InnoDB and Online DDL”.

• The outcome of attempting to change the storage engine of a table is affected by whether the desired storage engine is available and the setting of the NO_ENGINE_SUBSTITUTION SQL mode, as described in Section 5.1.10, “Server SQL Modes”.

• To prevent inadvertent loss of data, `ALTER TABLE` cannot be used to change the storage engine of a table to MERGE or BLACKHOLE.

• To change the InnoDB table to use compressed row-storage format:

```
ALTER TABLE t1 ROW_FORMAT = COMPRESSED;
```

• To reset the current auto-increment value:

```
ALTER TABLE t1 AUTO_INCREMENT = 13;
```

You cannot reset the counter to a value less than or equal to the value that is currently in use. For both InnoDB and MyISAM, if the value is less than or equal to the maximum value currently in the AUTO_INCREMENT column, the value is reset to the current maximum AUTO_INCREMENT column value plus one.

• To change the default table character set:

```
ALTER TABLE t1 CHARACTER SET = utf8;
```

See also Changing the Character Set.

• To add (or change) a table comment:

```
ALTER TABLE t1 COMMENT = 'New table comment';
```

To verify that the table options were changed as intended, use `SHOW CREATE TABLE`, or query the INFORMATION_SCHEMA.TABLES table.

### Performance and Space Requirements

`ALTER TABLE` operations are processed using one of the following algorithms:

• **COPY**: Operations are performed on a copy of the original table, and table data is copied from the original table to the new table row by row. Concurrent DML is not permitted.

• **INPLACE**: Operations avoid copying table data but may rebuild the table in place. An exclusive metadata lock on the table may be taken briefly during preparation and execution phases of the operation. Typically, concurrent DML is supported.

The `ALGORITHM` clause is optional. If the `ALGORITHM` clause is omitted (or if you specify `ALGORITHM=DEFAULT`), MySQL uses `ALGORITHM=INPLACE` for storage engines and `ALTER TABLE` clauses that support it. Otherwise, `ALGORITHM=COPY` is used.

Note

`ALGORITHM=DEFAULT`, `ALGORITHM=INPLACE`, and `ALGORITHM=COPY` are not supported for `ALTER TABLE` operations on partitioned tables. MySQL 5.6.11 and later supports `ALGORITHM=1` and `ALGORITHM=2` for use with upgrades and

1500
downgrades; see Section 13.1.7.1, “ALTER TABLE Partition Operations”, for more information.

Specifying an \texttt{ALGORITHM} clause requires the operation to use the specified algorithm for clauses and storage engines that support it, or fail with an error otherwise. Specifying \texttt{ALGORITHM=DEFAULT} is the same as omitting the \texttt{ALGORITHM} clause.

\texttt{ALTER TABLE} operations that use the \texttt{COPY} algorithm wait for other operations that are modifying the table to complete. After alterations are applied to the table copy, data is copied over, the original table is deleted, and the table copy is renamed to the name of the original table. While the \texttt{ALTER TABLE} operation executes, the original table is readable by other sessions (with the exception noted shortly). Updates and writes to the table started after the \texttt{ALTER TABLE} operation begins are stalled until the new table is ready, then are automatically redirected to the new table. The temporary copy of the table is created in the database directory of the original table unless it is a \texttt{RENAME TO} operation that moves the table to a database that resides in a different directory.

The exception referred to earlier is that \texttt{ALTER TABLE} blocks reads (not just writes) at the point where it is ready to install a new version of the table \texttt{.frm} file, discard the old file, and clear outdated table structures from the table and table definition caches. At this point, it must acquire an exclusive lock. To do so, it waits for current readers to finish, and blocks new reads and writes.

An \texttt{ALTER TABLE} operation that uses the \texttt{COPY} algorithm prevents concurrent DML operations. Concurrent queries are still allowed. That is, a table-copying operation always includes at least the concurrency restrictions of \texttt{LOCK=SHARED} (allow queries but not DML). You can further restrict concurrency for operations that support the \texttt{LOCK} clause by specifying \texttt{LOCK=EXCLUSIVE}, which prevents DML and queries. For more information, see Concurrency Control.

\begin{note}

In MySQL 5.6, \texttt{LOCK} is not supported for \texttt{ALTER TABLE} operations on partitioned tables.

\end{note}

To force use of the \texttt{COPY} algorithm for an \texttt{ALTER TABLE} operation that would otherwise not use it, enable the \texttt{old_alter_table} system variable or specify \texttt{ALGORITHM=COPY}. If there is a conflict between the \texttt{old_alter_table} setting and an \texttt{ALGORITHM} clause with a value other than \texttt{DEFAULT}, the \texttt{ALGORITHM} clause takes precedence.

For InnoDB tables, an \texttt{ALTER TABLE} operation that uses the \texttt{COPY} algorithm on a table that resides in a shared tablespace such as the \texttt{system tablespace} can increase the amount of space used by the tablespace. Such operations require as much additional space as the data in the table plus indexes. For a table residing in a shared tablespace, the additional space used during the operation is not released back to the operating system as it is for a table that resides in a file-per-table tablespace.

For information about space requirements for online DDL operations, see Section 14.13.3, “Online DDL Space Requirements”.

\texttt{ALTER TABLE} operations that use the \texttt{INPLACE} algorithm include:

\begin{itemize}
  \item \texttt{ALTER TABLE} operations supported by the InnoDB online DDL feature. See Section 14.13.1, “Online DDL Operations”.
  \item Renaming a table. MySQL renames files that correspond to the table \texttt{tbl_name} without making a copy. (You can also use the \texttt{RENAME TABLE} statement to rename tables. See Section 13.1.32, “RENAME TABLE Statement”.) Privileges granted specifically for the renamed table are not migrated to the new name. They must be changed manually.
  \item Operations that only modify table metadata. These operations are immediate because the server only alters the table \texttt{.frm} file, not touch table contents. Metadata-only operations include:
    \begin{itemize}
      \item Renaming a column.
    \end{itemize}
\end{itemize}
• Changing the default value of a column (except for NDB tables; see Limitations of NDB online operations).

• Modifying the definition of an ENUM or SET column by adding new enumeration or set members to the end of the list of valid member values, as long as the storage size of the data type does not change. For example, adding a member to a SET column that has 8 members changes the required storage per value from 1 byte to 2 bytes; this requires a table copy. Adding members in the middle of the list causes renumbering of existing members, which requires a table copy.

• Adding or dropping a secondary index, for InnoDB and NDB tables. See Section 14.13, “InnoDB and Online DDL”.

• For NDB tables, operations that add and drop indexes on variable-width columns. These operations occur online, without table copying and without blocking concurrent DML actions for most of their duration. See Section 18.5.11, “Online Operations with ALTER TABLE in NDB Cluster”.

As of MySQL 5.6.16, ALTER TABLE upgrades MySQL 5.5 temporal columns to 5.6 format for ADD COLUMN, CHANGE COLUMN, MODIFY COLUMN, ADD INDEX, and FORCE operations. This conversion cannot be done using the INPLACE algorithm because the table must be rebuilt, so specifying ALGORITHM=INPLACE in these cases results in an error. Specify ALGORITHM=COPY if necessary.

NDB Cluster supports online ALTER TABLE operations using the ALGORITHM=INPLACE syntax in MySQL NDB Cluster 7.3 and later. NDB Cluster also supports an older syntax specific to NDB that uses the ONLINE and OFFLINE keywords. These keywords are deprecated beginning with MySQL NDB Cluster 7.4, but are subject to removal in a future version of NDB Cluster. See Section 18.5.11, “Online Operations with ALTER TABLE in NDB Cluster”, for the exact syntax and other particulars.

If an ALTER TABLE operation on a multicolumn index used to partition a table by KEY changes the order of the columns, it can only be performed using ALGORITHM=COPY.

MySQL NDB Cluster 7.3 (and later) supports online operations using the same ALGORITHM=INPLACE syntax used with the standard MySQL Server. NDB Cluster 7.3 and 7.4 also continue to support online ALTER TABLE operations using the ONLINE and OFFLINE keywords for backwards compatibility, but these keywords are deprecated in NDB 7.3 and 7.4, and no longer supported as of NDB 7.5. NDB does not support changing a tablespace online. See Section 18.5.11, “Online Operations with ALTER TABLE in NDB Cluster”, for more information.

ALTER TABLE with ADD PARTITION, DROP PARTITION, COALESCE PARTITION, REBUILD PARTITION, or REORGANIZE PARTITION does not create temporary tables (except when used with NDB tables); however, these operations can and do create temporary partition files.

ADD or DROP operations for RANGE or LIST partitions are immediate operations or nearly so. ADD or COALESCE operations for HASH or KEY partitions copy data between all partitions, unless LINEAR HASH or LINEAR KEY was used; this is effectively the same as creating a new table, although the ADD or COALESCE operation is performed partition by partition. REORGANIZE operations copy only changed partitions and do not touch unchanged ones.

For MyISAM tables, you can speed up index re-creation (the slowest part of the alteration process) by setting the myisam_sort_buffer_size system variable to a high value.

Concurrency Control

For ALTER TABLE operations that support it, you can use the LOCK clause to control the level of concurrent reads and writes on a table while it is being altered. Specifying a non-default value for this clause enables you to require a certain amount of concurrent access or exclusivity during the alter operation, and halts the operation if the requested degree of locking is not available. The parameters for the LOCK clause are:

• LOCK = DEFAULT
Maximum level of concurrency for the given `ALGORITHM` clause (if any) and `ALTER TABLE` operation: Permit concurrent reads and writes if supported. If not, permit concurrent reads if supported. If not, enforce exclusive access.

- **LOCK = NONE**
  
  If supported, permit concurrent reads and writes. Otherwise, an error occurs.

- **LOCK = SHARED**
  
  If supported, permit concurrent reads but block writes. Writes are blocked even if concurrent writes are supported by the storage engine for the given `ALGORITHM` clause (if any) and `ALTER TABLE` operation. If concurrent reads are not supported, an error occurs.

- **LOCK = EXCLUSIVE**
  
  Enforce exclusive access. This is done even if concurrent reads/writes are supported by the storage engine for the given `ALGORITHM` clause (if any) and `ALTER TABLE` operation.

**Note**

Pending `INSERT DELAYED` statements are lost if a table is write locked and `ALTER TABLE` is used to modify the table structure.

### Adding and Dropping Columns

Use `ADD` to add new columns to a table, and `DROP` to remove existing columns. `DROP col_name` is a MySQL extension to standard SQL.

To add a column at a specific position within a table row, use `FIRST` or `AFTER col_name`. The default is to add the column last.

If a table contains only one column, the column cannot be dropped. If what you intend is to remove the table, use the `DROP TABLE` statement instead.

If columns are dropped from a table, the columns are also removed from any index of which they are a part. If all columns that make up an index are dropped, the index is dropped as well.

### Renaming, Redefining, and Reordering Columns

The `CHANGE`, `MODIFY`, and `ALTER` clauses enable the names and definitions of existing columns to be altered. They have these comparative characteristics:

- **CHANGE**:
  
  - Can rename a column and change its definition, or both.
  
  - Has more capability than `MODIFY`, but at the expense of convenience for some operations. `CHANGE` requires naming the column twice if not renaming it.

  - With `FIRST` or `AFTER`, can reorder columns.

- **MODIFY**:
  
  - Can change a column definition but not its name.
  
  - More convenient than `CHANGE` to change a column definition without renaming it.

  - With `FIRST` or `AFTER`, can reorder columns.

- **ALTER**: Used only to change a column default value.
**CHANGE** is a MySQL extension to standard SQL. **MODIFY** is a MySQL extension for Oracle compatibility.

To alter a column to change both its name and definition, use **CHANGE**, specifying the old and new names and the new definition. For example, to rename an INT NOT NULL column from `a` to `b` and change its definition to use the **BIGINT** data type while retaining the NOT NULL attribute, do this:

```
ALTER TABLE t1 CHANGE a b BIGINT NOT NULL;
```

To change a column definition but not its name, use **CHANGE** or **MODIFY**. With **CHANGE**, the syntax requires two column names, so you must specify the same name twice to leave the name unchanged. For example, to change the definition of column `b`, do this:

```
ALTER TABLE t1 CHANGE b b INT NOT NULL;
```

**MODIFY** is more convenient to change the definition without changing the name because it requires the column name only once:

```
ALTER TABLE t1 MODIFY b INT NOT NULL;
```

To change a column name but not its definition, use **CHANGE**. The syntax requires a column definition, so to leave the definition unchanged, you must respecify the definition the column currently has. For example, to rename an INT NOT NULL column from `b` to `a`, do this:

```
ALTER TABLE t1 CHANGE b a INT NOT NULL;
```

For column definition changes using **CHANGE** or **MODIFY**, the definition must include the data type and all attributes that should apply to the new column, other than index attributes such as **PRIMARY KEY** or **UNIQUE**. Attributes present in the original definition but not specified for the new definition are not carried forward. Suppose that a column `col1` is defined as `INT UNSIGNED DEFAULT 1 COMMENT 'my column'` and you modify the column as follows, intending to change only `INT` to **BIGINT**:

```
ALTER TABLE t1 MODIFY col1 BIGINT;
```

That statement changes the data type from **INT** to **BIGINT**, but it also drops the `UNSIGNED`, `DEFAULT`, and **COMMENT** attributes. To retain them, the statement must include them explicitly:

```
ALTER TABLE t1 MODIFY col1 BIGINT UNSIGNED DEFAULT 1 COMMENT 'my column';
```

For data type changes using **CHANGE** or **MODIFY**, MySQL tries to convert existing column values to the new type as well as possible.

![Warning](image)

This conversion may result in alteration of data. For example, if you shorten a string column, values may be truncated. To prevent the operation from succeeding if conversions to the new data type would result in loss of data, enable strict SQL mode before using **ALTER TABLE** (see Section 5.1.10, "Server SQL Modes").

If you use **CHANGE** or **MODIFY** to shorten a column for which an index exists on the column, and the resulting column length is less than the index length, MySQL shortens the index automatically.

For columns renamed by **CHANGE**, MySQL automatically renames these references to the renamed column:

- Indexes that refer to the old column, including indexes and disabled **MyISAM** indexes.
- Foreign keys that refer to the old column.

For columns renamed by **CHANGE**, MySQL does not automatically rename these references to the renamed column:

- Partition expressions that refer to the renamed column. You must use **CHANGE** to redefine such expressions in the same **ALTER TABLE** statement as the one that renames the column.
• Views and stored programs that refer to the renamed column. You must manually alter the definition of these objects to refer to the new column name.

To reorder columns within a table, use FIRST and AFTER in CHANGE or MODIFY operations.

`ALTER ... SET DEFAULT` or `ALTER ... DROP DEFAULT` specify a new default value for a column or remove the old default value, respectively. If the old default is removed and the column can be NULL, the new default is NULL. If the column cannot be NULL, MySQL assigns a default value as described in Section 11.5, “Data Type Default Values”.

### Primary Keys and Indexes

`DROP PRIMARY KEY` drops the primary key. If there is no primary key, an error occurs. For information about the performance characteristics of primary keys, especially for InnoDB tables, see Section 8.3.2, “Primary Key Optimization”.

If you add a UNIQUE INDEX or PRIMARY KEY to a table, MySQL stores it before any nonunique index to permit detection of duplicate keys as early as possible.

`IGNORE` is a MySQL extension to standard SQL. It controls how `ALTER TABLE` works if there are duplicates on unique keys in the new table or if warnings occur when strict mode is enabled. If `IGNORE` is not specified, the copy is aborted and rolled back if duplicate-key errors occur. If `IGNORE` is specified, only one row is used of rows with duplicates on a unique key. The other conflicting rows are deleted. Incorrect values are truncated to the closest matching acceptable value.

As of MySQL 5.6.17, the `IGNORE` clause is deprecated and its use generates a warning. `IGNORE` is removed in MySQL 5.7.

`DROP INDEX` removes an index. This is a MySQL extension to standard SQL. See Section 13.1.24, “DROP INDEX Statement”. To determine index names, use `SHOW INDEX FROM tbl_name`.

Some storage engines permit you to specify an index type when creating an index. The syntax for the `index_type` specifier is `USING type_name`. For details about `USING`, see Section 13.1.13, “CREATE INDEX Statement”. The preferred position is after the column list. Support for use of the option before the column list will be removed in a future MySQL release.

`index_option` values specify additional options for an index. For details about permissible `index_option` values, see Section 13.1.13, “CREATE INDEX Statement”.

If you use `ALTER TABLE` on a MyISAM table, all nonunique indexes are created in a separate batch (as for `REPAIR TABLE`). This should make `ALTER TABLE` much faster when you have many indexes.

For MyISAM tables, key updating can be controlled explicitly. Use `ALTER TABLE ... DISABLE KEYS` to tell MySQL to stop updating nonunique indexes. Then use `ALTER TABLE ... ENABLE KEYS` to re-create missing indexes. MyISAM does this with a special algorithm that is much faster than inserting keys one by one, so disabling keys before performing bulk insert operations should give a considerable speedup. Using `ALTER TABLE ... DISABLE KEYS` requires the INDEX privilege in addition to the privileges mentioned earlier.

While the nonunique indexes are disabled, they are ignored for statements such as `SELECT` and `EXPLAIN` that otherwise would use them.

After an `ALTER TABLE` statement, it may be necessary to run `ANALYZE TABLE` to update index cardinality information. See Section 13.7.5.23, “SHOW INDEX Statement”.

### Foreign Keys and Other Constraints

The FOREIGN KEY and REFERENCES clauses are supported by the InnoDB and NDB storage engines, which implement `ADD [CONSTRAINT [symbol]] FOREIGN KEY [index_name] (...) REFERENCES ... (...).` See Section 13.1.17.5, “FOREIGN KEY Constraints”. For other storage engines, the clauses are parsed but ignored.
The CHECK constraint clause is parsed but ignored by all storage engines. See Section 13.1.17, “CREATE TABLE Statement”. The reason for accepting but ignoring syntax clauses is for compatibility, to make it easier to port code from other SQL servers, and to run applications that create tables with references. See Section 1.7.2, “MySQL Differences from Standard SQL”.

For ALTER TABLE, unlike CREATE TABLE, ADD FOREIGN KEY ignores index_name if given and uses an automatically generated foreign key name. As a workaround, include the CONSTRAINT clause to specify the foreign key name:

```
ADD CONSTRAINT name FOREIGN KEY (...) ...
```

Important
MySQL silently ignores inline REFERENCES specifications, where the references are defined as part of the column specification. MySQL accepts only REFERENCES clauses defined as part of a separate FOREIGN KEY specification.

Note
Partitioned InnoDB tables do not support foreign keys. This restriction does not apply to NDB tables, including those explicitly partitioned by [LINEAR] KEY. For more information, see Section 19.6.2, “Partitioning Limitations Relating to Storage Engines”.

The InnoDB and NDB storage engines support the use of ALTER TABLE to drop foreign keys:

```
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```

Adding and dropping a foreign key in the same ALTER TABLE statement is supported for ALTER TABLE ... ALGORITHM=INPLACE but not for ALTER TABLE ... ALGORITHM=COPY.

The server prohibits changes to foreign key columns that have the potential to cause loss of referential integrity. A workaround is to use ALTER TABLE ... DROP FOREIGN KEY before changing the column definition and ALTER TABLE ... ADD FOREIGN KEY afterward. Examples of prohibited changes include:

- Changes to the data type of foreign key columns that may be unsafe. For example, changing VARCHAR(20) to VARCHAR(30) is permitted, but changing it to VARCHAR(1024) is not because that alters the number of length bytes required to store individual values.

- Changing a NULL column to NOT NULL in non-strict mode is prohibited to prevent converting NULL values to default non-NULL values, for which there are no corresponding values in the referenced table. The operation is permitted in strict mode, but an error is returned if any such conversion is required.

```
ALTER TABLE tbl_name RENAME new_tbl_name changes internally generated foreign key constraint names and user-defined foreign key constraint names that begin with the string “tbl_name_ibfk_” to reflect the new table name. InnoDB interprets foreign key constraint names that begin with the string “tbl_name_ibfk_” as internally generated names.
```

### Changing the Character Set

To change the table default character set and all character columns (CHAR, VARCHAR, TEXT) to a new character set, use a statement like this:

```
ALTER TABLE tbl_name
CONVERT TO CHARACTER SET charset_name [COLLATE collation_name];
```

The statement also changes the collation of all character columns. If you specify no COLLATE clause to indicate which collation to use, the statement uses default collation for the character set. If this collation is inappropriate for the intended table use (for example, if it would change from a case-sensitive collation to a case-insensitive collation), specify a collation explicitly.
For a column that has a data type of VARCHAR or one of the TEXT types, CONVERT TO CHARACTER SET changes the data type as necessary to ensure that the new column is long enough to store as many characters as the original column. For example, a TEXT column has two length bytes, which store the byte-length of values in the column, up to a maximum of 65,535. For a latin1 TEXT column, each character requires a single byte, so the column can store up to 65,535 characters. If the column is converted to utf8, each character might require up to three bytes, for a maximum possible length of $3 \times 65,535 = 196,605$ bytes. That length does not fit in a TEXT column's length bytes, so MySQL converts the data type to MEDIUMTEXT, which is the smallest string type for which the length bytes can record a value of 196,605. Similarly, a VARCHAR column might be converted to MEDIUMTEXT.

To avoid data type changes of the type just described, do not use CONVERT TO CHARACTER SET. Instead, use MODIFY to change individual columns. For example:

```
ALTER TABLE t MODIFY latin1_text_col TEXT CHARACTER SET utf8;
ALTER TABLE t MODIFY latin1_varchar_col VARCHAR(M) CHARACTER SET utf8;
```

If you specify CONVERT TO CHARACTER SET binary, the CHAR, VARCHAR, and TEXT columns are converted to their corresponding binary string types (BINARY, VARBINARY, BLOB). This means that the columns no longer will have a character set and a subsequent CONVERT TO operation will not apply to them.

If charset_name is DEFAULT in a CONVERT TO CHARACTER SET operation, the character set named by the character_set_database system variable is used.

**Warning**

The CONVERT TO operation converts column values between the original and named character sets. This is *not* what you want if you have a column in one character set (like latin1) but the stored values actually use some other, incompatible character set (like utf8). In this case, you have to do the following for each such column:

```
ALTER TABLE t1 CHANGE c1 c1 BLOB;
ALTER TABLE t1 CHANGE c1 c1 TEXT CHARACTER SET utf8;
```

The reason this works is that there is no conversion when you convert to or from BLOB columns.

To change only the *default* character set for a table, use this statement:

```
ALTER TABLE tbl_name DEFAULT CHARACTER SET charset_name;
```

The word DEFAULT is optional. The default character set is the character set that is used if you do not specify the character set for columns that you add to a table later (for example, with ALTER TABLE ... ADD column).

When the foreign_key_checks system variable is enabled, which is the default setting, character set conversion is not permitted on tables that include a character string column used in a foreign key constraint. The workaround is to disable foreign_key_checks before performing the character set conversion. You must perform the conversion on both tables involved in the foreign key constraint before re-enabling foreign_key_checks. If you re-enable foreign_key_checks after converting only one of the tables, an ON DELETE CASCADE or ON UPDATE CASCADE operation could corrupt data in the referencing table due to implicit conversion that occurs during these operations (Bug #45290, Bug #74816).

**Discarding and Importing InnoDB Tablespaces**

An InnoDB table created in its own file-per-table tablespace can be imported from a backup or from another MySQL server instance using the DISCARD TABLESPACE and IMPORT TABLESPACE clauses. See Section 14.6.1.3, “Importing InnoDB Tables”.

**Row Order for MyISAM Tables**
**ORDER BY** enables you to create the new table with the rows in a specific order. This option is useful primarily when you know that you query the rows in a certain order most of the time. By using this option after major changes to the table, you might be able to get higher performance. In some cases, it might make sorting easier for MySQL if the table is in order by the column that you want to order it by later.

**Note**

The table does not remain in the specified order after inserts and deletes.

**ORDER BY** syntax permits one or more column names to be specified for sorting, each of which optionally can be followed by **ASC** or **DESC** to indicate ascending or descending sort order, respectively. The default is ascending order. Only column names are permitted as sort criteria; arbitrary expressions are not permitted. This clause should be given last after any other clauses.

**ORDER BY** does not make sense for InnoDB tables because InnoDB always orders table rows according to the clustered index.

When used on a partitioned table, **ALTER TABLE ... ORDER BY** orders rows within each partition only.

**Partitioning Options**

**partition_options** signifies options that can be used with partitioned tables for repartitioning, to add, drop, discard, merge, and split partitions, and to perform partitioning maintenance.

It is possible for an **ALTER TABLE** statement to contain a **PARTITION BY** or **REMOVE PARTITIONING** clause in an addition to other alter specifications, but the **PARTITION BY** or **REMOVE PARTITIONING** clause must be specified last after any other specifications. The **ADD PARTITION**, **DROP PARTITION**, **COALESCE PARTITION**, **REORGANIZE PARTITION**, **EXCHANGE PARTITION**, **ANALYZE PARTITION**, **CHECK PARTITION**, and **REPAIR PARTITION** options cannot be combined with other alter specifications in a single **ALTER TABLE**, since the options just listed act on individual partitions.

For more information about partition options, see Section 13.1.17, “CREATE TABLE Statement”, and Section 13.1.7.1, “ALTER TABLE Partition Operations”. For information about and examples of **ALTER TABLE ... EXCHANGE PARTITION** statements, see Section 19.3.3, “Exchanging Partitions and Subpartitions with Tables”.

### 13.1.7.1 ALTER TABLE Partition Operations

Partitioning-related clauses for **ALTER TABLE** can be used with partitioned tables for repartitioning, to add, drop, discard, merge, and split partitions, and to perform partitioning maintenance.

- Simply using a **partition_options** clause with **ALTER TABLE** on a partitioned table repartitions the table according to the partitioning scheme defined by the **partition_options**. This clause always begins with **PARTITION BY**, and follows the same syntax and other rules as apply to the **partition_options** clause for **CREATE TABLE** (for more detailed information, see Section 13.1.17, “CREATE TABLE Statement”), and can also be used to partition an existing table that is not already partitioned. For example, consider a (nonpartitioned) table defined as shown here:

```sql
CREATE TABLE t1 {
    id INT,
    year_col INT
};
```

This table can be partitioned by **HASH**, using the **id** column as the partitioning key, into 8 partitions by means of this statement:

```sql
ALTER TABLE t1
    PARTITION BY HASH(id)
    PARTITIONS 8;
```
MySQL 5.6.11 and later supports an `ALGORITHM` option with `PARTITION BY [LINEAR] KEY`. `ALGORITHM=1` causes the server to use the same key-hashing functions as MySQL 5.1 when computing the placement of rows in partitions; `ALGORITHM=2` means that the server employs the key-hashing functions implemented and used by default for new `KEY` partitioned tables in MySQL 5.5 and later. (Partitioned tables created with the key-hashing functions employed in MySQL 5.5 and later cannot be used by a MySQL 5.1 server.) Not specifying the option has the same effect as using `ALGORITHM=2`. This option is intended for use chiefly when upgrading or downgrading `KEY` partitioned tables between MySQL 5.1 and later MySQL versions, or for creating tables partitioned by `KEY` or `LINEAR KEY` on a MySQL 5.5 or later server which can be used on a MySQL 5.1 server.

To upgrade a `KEY` partitioned table that was created in MySQL 5.1, first execute `SHOW CREATE TABLE` and note the exact columns and number of partitions shown. Now execute an `ALTER TABLE` statement using exactly the same column list and number of partitions as in the `CREATE TABLE` statement, while adding `ALGORITHM=2` immediately following the `PARTITION BY` keywords. (You should also include the `LINEAR` keyword if it was used for the original table definition.) An example from a session in the `mysql` client is shown here:

```
mysql> SHOW CREATE TABLE p\G
*************************** 1. row ***************************
Table: p
Create Table: CREATE TABLE `p` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `cd` datetime NOT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
/*!50100 PARTITION BY LINEAR KEY (id)
PARTITIONS 32 */
1 row in set (0.00 sec)
mysql> ALTER TABLE p PARTITION BY LINEAR KEY ALGORITHM=2 (id) PARTITIONS 32;
Query OK, 0 rows affected (5.34 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> SHOW CREATE TABLE p\G
*************************** 1. row ***************************
Table: p
Create Table: CREATE TABLE `p` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `cd` datetime NOT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
/*!50100 PARTITION BY LINEAR KEY (id)
PARTITIONS 32 */
1 row in set (0.00 sec)
```

Downgrading a table created using the default key-hashing used in MySQL 5.5 and later to enable its use by a MySQL 5.1 server is similar, except in this case you should use `ALGORITHM=1` to force the table's partitions to be rebuilt using the MySQL 5.1 key-hashing functions. It is recommended that you not do this except when necessary for compatibility with a MySQL 5.1 server, as the improved `KEY` hashing functions used by default in MySQL 5.5 and later provide fixes for a number of issues found in the older implementation.

**Note**

A table upgraded by means of `ALTER TABLE ... PARTITION BY ALGORITHM=2 [LINEAR] KEY ...` can no longer be used by a MySQL 5.1 server. (Such a table would need to be downgraded with `ALTER TABLE ... PARTITION BY ALGORITHM=1 [LINEAR] KEY ...` before it could be used again by a MySQL 5.1 server.)

The table that results from using an `ALTER TABLE ... PARTITION BY` statement must follow the same rules as one created using `CREATE TABLE ... PARTITION BY`. This includes the rules...
ALTER TABLE Statement

governing the relationship between any unique keys (including any primary key) that the table might have, and the column or columns used in the partitioning expression, as discussed in Section 19.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”. The CREATE TABLE ... PARTITION BY rules for specifying the number of partitions also apply to ALTER TABLE ... PARTITION BY.

The partition_definition clause for ALTER TABLE ADD PARTITION supports the same options as the clause of the same name for the CREATE TABLE statement. (See Section 13.1.17, “CREATE TABLE Statement”, for the syntax and description.) Suppose that you have the partitioned table created as shown here:

```
CREATE TABLE t1 (
   id INT,
   year_col INT
)
PARTITION BY RANGE (year_col) {
   PARTITION p0 VALUES LESS THAN (1991),
   PARTITION p1 VALUES LESS THAN (1995),
   PARTITION p2 VALUES LESS THAN (1999)
};
```

You can add a new partition p3 to this table for storing values less than 2002 as follows:

```
ALTER TABLE t1 ADD PARTITION (PARTITION p3 VALUES LESS THAN (2002));
```

DROP PARTITION can be used to drop one or more RANGE or LIST partitions. This statement cannot be used with HASH or KEY partitions; instead, use COALESCE PARTITION (see below). Any data that was stored in the dropped partitions named in the partition_names list is discarded. For example, given the table t1 defined previously, you can drop the partitions named p0 and p1 as shown here:

```
ALTER TABLE t1 DROP PARTITION p0, p1;
```

Note

DROP PARTITION does not work with tables that use the NDB storage engine. See Section 19.3.1, “Management of RANGE and LIST Partitions”, and Section 18.1.7, “Known Limitations of NDB Cluster”.

ADD PARTITION and DROP PARTITION do not currently support IF [NOT] EXISTS.

Renames of partitioned tables are supported. You can rename individual partitions indirectly using ALTER TABLE ... REORGANIZE PARTITION; however, this operation copies the partition’s data.

To delete rows from selected partitions, use the TRUNCATE PARTITION option. This option takes a list of one or more comma-separated partition names. For example, consider the table t1 as defined here:

```
CREATE TABLE t1 (
   id INT,
   year_col INT
)
PARTITION BY RANGE (year_col) {
   PARTITION p0 VALUES LESS THAN (1991),
   PARTITION p1 VALUES LESS THAN (1995),
   PARTITION p2 VALUES LESS THAN (1999),
   PARTITION p3 VALUES LESS THAN (2003),
   PARTITION p4 VALUES LESS THAN (2007)
};
```

1510
ALTER TABLE Statement

To delete all rows from partition \texttt{p0}, use the following statement:

\begin{verbatim}
ALTER TABLE t1 TRUNCATE PARTITION p0;
\end{verbatim}

The statement just shown has the same effect as the following \texttt{DELETE} statement:

\begin{verbatim}
DELETE FROM t1 WHERE year_col < 1991;
\end{verbatim}

When truncating multiple partitions, the partitions do not have to be contiguous: This can greatly simplify delete operations on partitioned tables that would otherwise require very complex \texttt{WHERE} conditions if done with \texttt{DELETE} statements. For example, this statement deletes all rows from partitions \texttt{p1} and \texttt{p3}:

\begin{verbatim}
ALTER TABLE t1 TRUNCATE PARTITION p1, p3;
\end{verbatim}

An equivalent \texttt{DELETE} statement is shown here:

\begin{verbatim}
DELETE FROM t1 WHERE (year_col >= 1991 AND year_col < 1995) OR (year_col >= 2003 AND year_col < 2007);
\end{verbatim}

If you use the \texttt{ALL} keyword in place of the list of partition names, the statement acts on all table partitions.

\texttt{TRUNCATE PARTITION} merely deletes rows; it does not alter the definition of the table itself, or of any of its partitions.

\begin{itemize}
\item \textbf{Note} \texttt{TRUNCATE PARTITION} does not work with subpartitions.
\end{itemize}

To verify that the rows were dropped, check the \texttt{INFORMATION_SCHEMA.PARTITIONS} table, using a query such as this one:

\begin{verbatim}
SELECT PARTITION_NAME, TABLE_ROWS
FROM INFORMATION_SCHEMA.PARTITIONS
WHERE TABLE_NAME = 't1';
\end{verbatim}

\texttt{TRUNCATE PARTITION} is supported only for partitioned tables that use the \texttt{MyISAM}, \texttt{InnoDB}, or \texttt{MEMORY} storage engine. It also works on \texttt{BLACKHOLE} tables (but has no effect). It is not supported for \texttt{ARCHIVE} tables.

\texttt{COALESCE PARTITION} can be used with a table that is partitioned by \texttt{HASH} or \texttt{KEY} to reduce the number of partitions by \texttt{number}. Suppose that you have created table \texttt{t2} as follows:

\begin{verbatim}
CREATE TABLE t2 (
    name VARCHAR (30),
    started DATE
) PARTITION BY HASH (YEAR(started))
\end{verbatim}
ALTER TABLE Statement

PARTITIONS 6;

To reduce the number of partitions used by `t2` from 6 to 4, use the following statement:

```
ALTER TABLE t2 COALESCE PARTITION 2;
```

The data contained in the last `number` partitions will be merged into the remaining partitions. In this case, partitions 4 and 5 will be merged into the first 4 partitions (the partitions numbered 0, 1, 2, and 3).

To change some but not all the partitions used by a partitioned table, you can use `REORGANIZE PARTITION`. This statement can be used in several ways:

- To merge a set of partitions into a single partition. This is done by naming several partitions in the `partition_names` list and supplying a single definition for `partition_definition`.
- To split an existing partition into several partitions. Accomplish this by naming a single partition for `partition_names` and providing multiple `partition_definitions`.
- To change the ranges for a subset of partitions defined using `VALUES LESS THAN` or the value lists for a subset of partitions defined using `VALUES IN`.
- This statement may also be used without the `partition_names INTO (partition_definitions)` option on tables that are automatically partitioned using `HASH` partitioning to force redistribution of data. (Currently, only `NDB` tables are automatically partitioned in this way.) This is useful in NDB Cluster where, after you have added new NDB Cluster data nodes online to an existing NDB Cluster, you wish to redistribute existing NDB Cluster table data to the new data nodes. In such cases, you should invoke the statement with the `ONLINE` option; in other words, as shown here:

```
ALTER ONLINE TABLE table REORGANIZE PARTITION;
```

You cannot perform other DDL concurrently with online table reorganization—that is, no other DDL statements can be issued while an `ALTER ONLINE TABLE ... REORGANIZE PARTITION` statement is executing. For more information about adding NDB Cluster data nodes online, see Section 18.5.7, “Adding NDB Cluster Data Nodes Online”.

`ALTER ONLINE TABLE ... REORGANIZE PARTITION` does not work with tables which were created using the `MAX_ROWS` option, because it uses the constant `MAX_ROWS` value specified in the original `CREATE TABLE` statement to determine the number of partitions required, so no new partitions are created. Instead, you can use `ALTER ONLINE TABLE ... MAX_ROWS=rows` to increase the maximum number of rows for such a table; in this case, `ALTER ONLINE TABLE ... REORGANIZE PARTITION` is not needed (and causes an error if executed). The value of `rows` must be greater than the value specified for `MAX_ROWS` in the original `CREATE TABLE` statement for this to work.

Attempting to use `REORGANIZE PARTITION` without the `partition_names INTO (partition_definitions)` option on explicitly partitioned tables results in the error `REORGANIZE PARTITION without parameters can only be used on auto-partitioned tables using HASH partitioning`.

Note

For partitions that have not been explicitly named, MySQL automatically provides the default names `p0, p1, p2`, and so on. The same is true with regard to subpartitions.

For more detailed information about and examples of `ALTER TABLE ... REORGANIZE PARTITION` statements, see Section 19.3.1, “Management of RANGE and LIST Partitions”.
To exchange a table partition or subpartition with a table, use the `ALTER TABLE ... EXCHANGE PARTITION` statement—that is, to move any existing rows in the partition or subpartition to the nonpartitioned table, and any existing rows in the nonpartitioned table to the table partition or subpartition.

For usage information and examples, see Section 19.3.3, “Exchanging Partitions and Subpartitions with Tables”.

Several options provide partition maintenance and repair functionality analogous to that implemented for nonpartitioned tables by statements such as `CHECK TABLE` and `REPAIR TABLE` (which are also supported for partitioned tables; for more information, see Section 13.7.2, “Table Maintenance Statements”). These include `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, `REBUILD PARTITION`, and `REPAIR PARTITION`. Each of these options takes a `partition_names` clause consisting of one or more names of partitions, separated by commas. The partitions must already exist in the table to be altered. You can also use the `ALL` keyword in place of `partition_names`, in which case the statement acts on all table partitions. For more information and examples, see Section 19.3.4, “Maintenance of Partitions”.

Some MySQL storage engines, such as InnoDB, do not support per-partition optimization. For a partitioned table using such a storage engine, `ALTER TABLE ... OPTIMIZE PARTITION` causes the entire table to be rebuilt and analyzed, and an appropriate warning to be issued. (Bug #11751825, Bug #42822)

To work around this problem, use the statements `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION` instead.

The `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, and `REPAIR PARTITION` options are not permitted for tables which are not partitioned.

`REMOVE PARTITIONING` enables you to remove a table’s partitioning without otherwise affecting the table or its data. This option can be combined with other `ALTER TABLE` options such as those used to add, drop, or rename columns or indexes.

Using the `ENGINE` option with `ALTER TABLE` changes the storage engine used by the table without affecting the partitioning.

When `ALTER TABLE ... EXCHANGE PARTITION` or `ALTER TABLE ... TRUNCATE PARTITION` is run against a partitioned table that uses MyISAM (or another storage engine that makes use of table-level locking), only those partitions that are actually read from are locked. (This does not apply to partitioned tables using a storage enginethat employs row-level locking, such as InnoDB.) See Section 19.6.4, “Partitioning and Locking”.

It is possible for an `ALTER TABLE` statement to contain a `PARTITION BY` or `REMOVE PARTITIONING` clause in an addition to other alter specifications, but the `PARTITION BY` or `REMOVE PARTITIONING` clause must be specified last after any other specifications.

The `ADD PARTITION`, `DROP PARTITION`, `COALESCE PARTITION`, `REORGANIZE PARTITION`, `ANALYZE PARTITION`, `CHECK PARTITION`, and `REPAIR PARTITION` options cannot be combined with other alter specifications in a single `ALTER TABLE`, since the options just listed act on individual partitions. For more information, see Section 13.1.7.1, “ALTER TABLE Partition Operations”.

Only a single instance of any one of the following options can be used in a given `ALTER TABLE` statement: `PARTITION BY`, `ADD PARTITION`, `DROP PARTITION`, `TRUNCATE PARTITION`, `EXCHANGE PARTITION`, `REORGANIZE PARTITION`, or `COALESCE PARTITION`, `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, `REBUILD PARTITION`, `REMOVE PARTITIONING`.

For example, the following two statements are invalid:

```sql
ALTER TABLE t1 ANALYZE PARTITION p1, ANALYZE PARTITION p2;
```
ALTER TABLE Statement

ALTER TABLE t1 ANALYZE PARTITION p1, CHECK PARTITION p2;

In the first case, you can analyze partitions p1 and p2 of table t1 concurrently using a single statement with a single ANALYZE PARTITION option that lists both of the partitions to be analyzed, like this:

ALTER TABLE t1 ANALYZE PARTITION p1, p2;

In the second case, it is not possible to perform ANALYZE and CHECK operations on different partitions of the same table concurrently. Instead, you must issue two separate statements, like this:

ALTER TABLE t1 ANALYZE PARTITION p1;
ALTER TABLE t1 CHECK PARTITION p2;

ANALYZE, CHECK, OPTIMIZE, REBUILD, REPAIR, and TRUNCATE operations are not supported for subpartitions.

13.1.7.2 ALTER TABLE Examples

Begin with a table t1 created as shown here:

CREATE TABLE t1 (a INTEGER, b CHAR(10));

To rename the table from t1 to t2:

ALTER TABLE t1 RENAME t2;

To change column a from INTEGER to TINYINT NOT NULL (leaving the name the same), and to change column b from CHAR(10) to CHAR(20) as well as renaming it from b to c:

ALTER TABLE t2 MODIFY a TINYINT NOT NULL, CHANGE b c CHAR(20);

To add a new TIMESTAMP column named d:

ALTER TABLE t2 ADD d TIMESTAMP;

To add an index on column d and a UNIQUE index on column a:

ALTER TABLE t2 ADD INDEX (d), ADD UNIQUE (a);

To remove column c:

ALTER TABLE t2 DROP COLUMN c;

To add a new AUTO_INCREMENT integer column named c:

ALTER TABLE t2 ADD c INT UNSIGNED NOT NULL AUTO_INCREMENT, ADD PRIMARY KEY (c);

We indexed c (as a PRIMARY KEY) because AUTO_INCREMENT columns must be indexed, and we declare c as NOT NULL because primary key columns cannot be NULL.

For NDB tables, it is also possible to change the storage type used for a table or column. For example, consider an NDB table created as shown here:

mysql> CREATE TABLE t1 (c1 INT) TABLESPACE ts_1 ENGINE NDB;
Query OK, 0 rows affected (1.27 sec)

To convert this table to disk-based storage, you can use the following ALTER TABLE statement:

mysql> ALTER TABLE t1 TABLESPACE ts_1 STORAGE DISK;
Query OK, 0 rows affected (2.99 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> SHOW CREATE TABLE t1\G
*************************** 1. row ***************************
Table: t1
Create Table: CREATE TABLE `t1` (c1 int(11) DEFAULT NULL)
/*!50100 TABLESPACE ts_1 STORAGE DISK */
It is not necessary that the tablespace was referenced when the table was originally created; however, the tablespace must be referenced by the `ALTER TABLE`:

```sql
cREATE TABLE t2 (c1 INT) ts_1 ENGINE NDB;
```

Query OK, 0 rows affected (1.00 sec)

```sql
ALTER TABLE t2 STORAGE DISK;
```

ERROR 1005 (HY000): Can't create table 'c.#sql-1750_3' (errno: 140)

```sql
ALTER TABLE t2 TABLESPACE ts_1 STORAGE DISK;
```

Query OK, 0 rows affected (3.42 sec)

To change the storage type of an individual column, you can use `ALTER TABLE ... MODIFY [COLUMN]`. For example, suppose you create an NDB Cluster Disk Data table with two columns, using this `CREATE TABLE` statement:

```sql
CREATE TABLE t3 (c1 INT, c2 INT)
-> TABLESPACE ts_1 STORAGE DISK ENGINE NDB;
```

Query OK, 0 rows affected (1.34 sec)

To change column `c2` from disk-based to in-memory storage, include a `STORAGE MEMORY` clause in the column definition used by the `ALTER TABLE` statement, as shown here:

```sql
ALTER TABLE t3 MODIFY c2 INT STORAGE MEMORY;
```

Query OK, 0 rows affected (3.14 sec)

You can make an in-memory column into a disk-based column by using `STORAGE DISK` in a similar fashion.

Column `c1` uses disk-based storage, since this is the default for the table (determined by the table-level `STORAGE DISK` clause in the `CREATE TABLE` statement). However, column `c2` uses in-memory storage, as can be seen here in the output of `SHOW CREATE TABLE`:

```sql
SHOW CREATE TABLE t3;
```

When you add an `AUTO_INCREMENT` column, column values are filled in with sequence numbers automatically. For `MyISAM` tables, you can set the first sequence number by executing `SET INSERT_ID=value` before `ALTER TABLE` or by using the `AUTO_INCREMENT=value` table option.

With `MyISAM` tables, if you do not change the `AUTO_INCREMENT` column, the sequence number is not affected. If you drop an `AUTO_INCREMENT` column and then add another `AUTO_INCREMENT` column, the numbers are resequenced beginning with 1.

When replication is used, adding an `AUTO_INCREMENT` column to a table might not produce the same ordering of the rows on the replica and the source. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the source and replica, the rows must be ordered before assigning an `AUTO_INCREMENT` number. Assuming that you want to add an
**ALTER TABLESPACE Statement**

**AUTO_INCREMENT** column to the table `t1`, the following statements produce a new table `t2` identical to `t1` but with an **AUTO_INCREMENT** column:

```sql
CREATE TABLE t2 (id INT AUTO_INCREMENT PRIMARY KEY)
SELECT * FROM t1 ORDER BY col1, col2;
```

This assumes that the table `t1` has columns `col1` and `col2`.

This set of statements will also produce a new table `t2` identical to `t1`, with the addition of an `AUTO_INCREMENT` column:

```sql
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

---

**Important**

To guarantee the same ordering on both source and replica, all columns of `t1` must be referenced in the `ORDER BY` clause.

Regardless of the method used to create and populate the copy having the **AUTO_INCREMENT** column, the final step is to drop the original table and then rename the copy:

```sql
DROP TABLE t1;
ALTER TABLE t2 RENAME t1;
```

### 13.1.8 ALTER TABLESPACE Statement

**ALTER TABLESPACE** `tablespace_name`

```sql
{ADD | DROP} DATAFILE 'file_name'
[INITIAL_SIZE [=] size]
[WAIT]
ENGINE [=] engine_name
```

This statement is used either to add a new data file, or to drop a data file from a tablespace.

The **ADD DATAFILE** variant enables you to specify an initial size using an **INITIAL_SIZE** clause, where `size` is measured in bytes; the default value is 134217728 (128 MB). Prior to MySQL NDB Cluster 7.3.2, this value was required to be specified using digits (Bug #13116514, Bug #16104705, Bug #62858); in MySQL NDB Cluster 7.3.2 and later, you may optionally follow `size` with a one-letter abbreviation for an order of magnitude, similar to those used in `my.cnf`. Generally, this is one of the letters `M` (megabytes) or `G` (gigabytes).

**Note**

All NDB Cluster Disk Data objects share the same namespace. This means that each Disk Data object must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a data file with the same name, or an undo log file and a tablespace with the same name.

On 32-bit systems, the maximum supported value for **INITIAL_SIZE** is 4294967296 (4 GB). (Bug #29186)

**INITIAL_SIZE** is rounded, explicitly, as for **CREATE TABLESPACE**.

Once a data file has been created, its size cannot be changed; however, you can add more data files to the tablespace using additional **ALTER TABLESPACE** ... **ADD DATAFILE** statements.

Using **DROP DATAFILE** with **ALTER TABLESPACE** drops the data file `file_name` from the tablespace. You cannot drop a data file from a tablespace which is in use by any table; in other words, the data file must be empty (no extents used). See Section 18.5.10.1, “NDB Cluster Disk Data Objects”. In addition, any data file to be dropped must previously have been added to the tablespace with **CREATE TABLESPACE** or **ALTER TABLESPACE**.
Both `ALTER TABLESPACE ... ADD DATAFILE` and `ALTER TABLESPACE ... DROP DATAFILE` require an `ENGINE` clause which specifies the storage engine used by the tablespace. Currently, the only accepted values for `engine_name` are `NDB` and `NDBCLUSTER`.

`WAIT` is parsed but otherwise ignored, and so has no effect in MySQL 5.6. It is intended for future expansion.

When `ALTER TABLESPACE ... ADD DATAFILE` is used with `ENGINE = NDB`, a data file is created on each Cluster data node. You can verify that the data files were created and obtain information about them by querying the `INFORMATION_SCHEMA.FILES` table. For example, the following query shows all data files belonging to the tablespace named `newts`:

```
mysql> SELECT LOGFILE_GROUP_NAME, FILE_NAME, EXTRA
    FROM INFORMATION_SCHEMA.FILES
    WHERE TABLESPACE_NAME = 'newts' AND FILE_TYPE = 'DATAFILE';
```

```
+--------------------+--------------+----------------+
| LOGFILE_GROUP_NAME | FILE_NAME    | EXTRA          |
|--------------------+--------------+----------------|
| lg_3               | newdata.dat  | CLUSTER_NODE=3 |
| lg_3               | newdata.dat  | CLUSTER_NODE=4 |
| lg_3               | newdata2.dat | CLUSTER_NODE=3 |
| lg_3               | newdata2.dat | CLUSTER_NODE=4 |
+--------------------+--------------+----------------+
```

2 rows in set (0.03 sec)

See Section 21.31.1, “The INFORMATION_SCHEMA.FILES Table”.

`ALTER TABLESPACE` is useful only with Disk Data storage for NDB Cluster. See Section 18.5.10, “NDB Cluster Disk Data Tables”.

### 13.1.9 ALTER VIEW Statement

```
ALTER
    [ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
    [DEFINER = user]
    [SQL SECURITY { DEFINER | INVOKER }]
    VIEW view_name [(column_list)]
    AS select_statement
    [WITH [CASCADED | LOCAL] CHECK OPTION]
```

This statement changes the definition of a view, which must exist. The syntax is similar to that for `CREATE VIEW` (see Section 13.1.20, “CREATE VIEW Statement”). This statement requires the `CREATE VIEW` and `DROP` privileges for the view, and some privilege for each column referred to in the `SELECT` statement. `ALTER VIEW` is permitted only to the definer or users with the `SUPER` privilege.

### 13.1.10 CREATE DATABASE Statement

```
CREATE {DATABASE | SCHEMA} [IF NOT EXISTS] db_name
    [create_option] ...
```

```
create_option: [DEFAULT] {
    CHARACTER SET [=] charset_name
    | COLLATE [=] collation_name
}
```

`CREATE DATABASE` creates a database with the given name. To use this statement, you need the `CREATE` privilege for the database. `CREATE SCHEMA` is a synonym for `CREATE DATABASE`.

An error occurs if the database exists and you did not specify `IF NOT EXISTS`.

`CREATE DATABASE` is not permitted within a session that has an active `LOCK TABLES` statement.

Each `create_option` specifies a database characteristic. Database characteristics are stored in the `db.opt` file in the database directory. The `CHARACTER SET` option specifies the default database character set. The `COLLATE` option specifies the default database collation. For information about character set and collation names, see Chapter 10, Character Sets, Collations, Unicode.
To see the available character sets and collations, use the `SHOW CHARACTER SET` and `SHOW COLLATION` statements, respectively. See Section 13.7.5.4, “SHOW CHARACTER SET Statement”, and Section 13.7.5.5, “SHOW COLLATION Statement”.

A database in MySQL is implemented as a directory containing files that correspond to tables in the database. Because there are no tables in a database when it is initially created, the `CREATE DATABASE` statement creates only a directory under the MySQL data directory and the `db.opt` file. Rules for permissible database names are given in Section 9.2, “Schema Object Names”. If a database name contains special characters, the name for the database directory contains encoded versions of those characters as described in Section 9.2.4, “Mapping of Identifiers to File Names”.

If you manually create a directory under the data directory (for example, with `mkdir`), the server considers it a database directory and it shows up in the output of `SHOW DATABASES`.

When you create a database, let the server manage the directory and the files in it. Manipulating database directories and files directly can cause inconsistencies and unexpected results.

MySQL has no limit on the number of databases. The underlying file system may have a limit on the number of directories.

You can also use the `mysqladmin` program to create databases. See Section 4.5.2, “mysqladmin — A MySQL Server Administration Program”.

### 13.1.11 CREATE EVENT Statement

```
CREATE
  [DEFINER = user]
EVENT
  [IF NOT EXISTS]
  event_name
ON SCHEDULE schedule
  [ON COMPLETION [NOT] PRESERVE]
  [ENABLE | DISABLE | DISABLE ON SLAVE]
  [COMMENT 'string']
DO event_body;
```

This statement creates and schedules a new event. The event will not run unless the Event Scheduler is enabled. For information about checking Event Scheduler status and enabling it if necessary, see Section 20.4.2, “Event Scheduler Configuration”.

`CREATE EVENT` requires the `EVENT` privilege for the schema in which the event is to be created. If the `DEFINER` clause is present, the privileges required depend on the `user` value, as discussed in Section 20.6, “Stored Object Access Control”.

The minimum requirements for a valid `CREATE EVENT` statement are as follows:

- The keywords `CREATE EVENT` plus an event name, which uniquely identifies the event in a database schema.
- An `ON SCHEDULE` clause, which determines when and how often the event executes.
- A `DO` clause, which contains the SQL statement to be executed by an event.

This is an example of a minimal `CREATE EVENT` statement:
CREATE EVENT myevent
  ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
  DO
    UPDATE myschema.mytable SET mycol = mycol + 1;

The previous statement creates an event named `myevent`. This event executes once—one hour following its creation—by running an SQL statement that increments the value of the `myschema.mytable` table's `mycol` column by 1.

The `event_name` must be a valid MySQL identifier with a maximum length of 64 characters. Event names are not case-sensitive, so you cannot have two events named `myevent` and `MyEvent` in the same schema. In general, the rules governing event names are the same as those for names of stored routines. See Section 9.2, “Schema Object Names”.

An event is associated with a schema. If no schema is indicated as part of `event_name`, the default (current) schema is assumed. To create an event in a specific schema, qualify the event name with a schema using `schema_name.event_name` syntax.

The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at event execution time. If the `DEFINER` clause is present, the `user` value should be a MySQL account specified as `'user_name'@'host_name'`, `CURRENT_USER`, or `CURRENT_USER()`. The permitted `user` values depend on the privileges you hold, as discussed in Section 20.6, “Stored Object Access Control”. Also see that section for additional information about event security.

If the `DEFINER` clause is omitted, the default definer is the user who executes the `CREATE EVENT` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

Within an event body, the `CURRENT_USER` function returns the account used to check privileges at event execution time, which is the `DEFINER` user. For information about user auditing within events, see Section 6.2.15, “SQL-Based Account Activity Auditing”.

`IF NOT EXISTS` has the same meaning for `CREATE EVENT` as for `CREATE TABLE`: If an event named `event_name` already exists in the same schema, no action is taken, and no error results. (However, a warning is generated in such cases.)

The `ON SCHEDULE` clause determines when, how often, and for how long the `event_body` defined for the event repeats. This clause takes one of two forms:

- **AT timestamp** is used for a one-time event. It specifies that the event executes one time only at the date and time given by `timestamp`, which must include both the date and time, or must be an expression that resolves to a datetime value. You may use a value of either the `DATETIME` or `TIMESTAMP` type for this purpose. If the date is in the past, a warning occurs, as shown here:

```
mysql> SELECT NOW();
+---------------------+
| NOW()               |
+---------------------+
| 2006-02-10 23:59:01 |
+---------------------+
1 row in set (0.04 sec)

mysql> CREATE EVENT e_totals
    -> ON SCHEDULE AT '2006-02-10 23:59:00'
    -> DO INSERT INTO test.totals VALUES (NOW());
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS
*************************** 1. row ***************************
Level: Note
Code: 1588
Message: Event execution time is in the past and ON COMPLETION NOT PRESERVE is set. The event was dropped immediately after creation.
```

`CREATE EVENT` statements which are themselves invalid—for whatever reason—fail with an error.
CREATE EVENT Statement

You may use `CURRENT_TIMESTAMP` to specify the current date and time. In such a case, the event acts as soon as it is created.

To create an event which occurs at some point in the future relative to the current date and time—such as that expressed by the phrase “three weeks from now”—you can use the optional clause `+ INTERVAL interval`. The `interval` portion consists of two parts, a quantity and a unit of time, and follows the syntax rules described in Temporal Intervals, except that you cannot use any units keywords that involving microseconds when defining an event. With some interval types, complex time units may be used. For example, “two minutes and ten seconds” can be expressed as `+ INTERVAL '2:10' MINUTE_SECOND`.

You can also combine intervals. For example, `AT CURRENT_TIMESTAMP + INTERVAL 3 WEEK + INTERVAL 2 DAY` is equivalent to “three weeks and two days from now”. Each portion of such a clause must begin with `+ INTERVAL`.

- To repeat actions at a regular interval, use an `EVERY` clause. The `EVERY` keyword is followed by an `interval` as described in the previous discussion of the `AT` keyword. (`+ INTERVAL` is not used with `EVERY`). For example, `EVERY 6 WEEK` means “every six weeks”.

Although `+ INTERVAL` clauses are not permitted in an `EVERY` clause, you can use the same complex time units permitted in a `+ INTERVAL`.

An `EVERY` clause may contain an optional `STARTS` clause. `STARTS` is followed by a `timestamp` value that indicates when the action should begin repeating, and may also use `+ INTERVAL interval` to specify an amount of time “from now”. For example, `EVERY 3 MONTH STARTS CURRENT_TIMESTAMP + INTERVAL 1 WEEK` means “every three months, beginning one week from now”. Similarly, you can express “every two weeks, beginning six hours and fifteen minutes from now” as `EVERY 2 WEEK STARTS CURRENT_TIMESTAMP + INTERVAL '6:15' HOUR_MINUTE`. Not specifying `STARTS` is the same as using `STARTS CURRENT_TIMESTAMP`—that is, the action specified for the event begins repeating immediately upon creation of the event.

An `EVERY` clause may contain an optional `ENDS` clause. The `ENDS` keyword is followed by a `timestamp` value that tells MySQL when the event should stop repeating. You may also use `+ INTERVAL interval` with `ENDS`; for instance, `EVERY 12 HOUR STARTS CURRENT_TIMESTAMP + INTERVAL 30 MINUTE ENDS CURRENT_TIMESTAMP + INTERVAL 4 WEEK` is equivalent to “every twelve hours, beginning thirty minutes from now, and ending four weeks from now”. Not using `ENDS` means that the event continues executing indefinitely.

`ENDS` supports the same syntax for complex time units as `STARTS` does.

You may use `STARTS`, `ENDS`, both, or neither in an `EVERY` clause.

If a repeating event does not terminate within its scheduling interval, the result may be multiple instances of the event executing simultaneously. If this is undesirable, you should institute a mechanism to prevent simultaneous instances. For example, you could use the `GET_LOCK()` function, or row or table locking.

The `ON SCHEDULE` clause may use expressions involving built-in MySQL functions and user variables to obtain any of the `timestamp` or `interval` values which it contains. You may not use stored functions or user-defined functions in such expressions, nor may you use any table references; however, you may use `SELECT FROM DUAL`. This is true for both `CREATE EVENT` and `ALTER EVENT` statements. References to stored functions, user-defined functions, and tables in such cases are specifically not permitted, and fail with an error (see Bug #22830).

Times in the `ON SCHEDULE` clause are interpreted using the current session `time_zone` value. This becomes the event time zone; that is, the time zone that is used for event scheduling and is in effect within the event as it executes. These times are converted to UTC and stored along with the event time zone in the `mysql.event` table. This enables event execution to proceed as defined regardless of any subsequent changes to the server time zone or daylight saving time effects. For additional information
CREATE EVENT Statement

about representation of event times, see Section 20.4.4, “Event Metadata”. See also Section 13.7.5.19, “SHOW EVENTS Statement”, and Section 21.8, “The INFORMATION_SCHEMA EVENTS Table”.

Normally, once an event has expired, it is immediately dropped. You can override this behavior by specifying **ON COMPLETION PRESERVE**. Using **ON COMPLETION NOT PRESERVE** merely makes the default nonpersistent behavior explicit.

You can create an event but prevent it from being active using the **DISABLE** keyword. Alternatively, you can use **ENABLE** to make explicit the default status, which is active. This is most useful in conjunction with **ALTER EVENT** (see Section 13.1.2, “ALTER EVENT Statement”).

A third value may also appear in place of **ENABLE** or **DISABLE**; **DISABLE ON SLAVE** is set for the status of an event on a replica to indicate that the event was created on the source and replicated to the replica, but is not executed on the replica. See Section 17.4.1.16, “Replication of Invoked Features”.

You may supply a comment for an event using a **COMMENT** clause. **comment** may be any string of up to 64 characters that you wish to use for describing the event. The comment text, being a string literal, must be surrounded by quotation marks.

The **DO** clause specifies an action carried by the event, and consists of an SQL statement. Nearly any valid MySQL statement that can be used in a stored routine can also be used as the action statement for a scheduled event. (See Section 20.8, “Restrictions on Stored Programs”.) For example, the following event **e_hourly** deletes all rows from the **sessions** table once per hour, where this table is part of the **site_activity** schema:

```sql
CREATE EVENT e_hourly
  ON SCHEDULE EVERY 1 HOUR
  COMMENT 'Clears out sessions table each hour.'
  DO
    DELETE FROM site_activity.sessions;
```

MySQL stores the **sql_mode** system variable setting in effect when an event is created or altered, and always executes the event with this setting in force, regardless of the current server SQL mode when the event begins executing.

A **CREATE EVENT** statement that contains an **ALTER EVENT** statement in its **DO** clause appears to succeed; however, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

**Note**

Statements such as **SELECT** or **SHOW** that merely return a result set have no effect when used in an event; the output from these is not sent to the MySQL Monitor, nor is it stored anywhere. However, you can use statements such as **SELECT ... INTO** and **INSERT INTO ... SELECT** that store a result. (See the next example in this section for an instance of the latter.)

The schema to which an event belongs is the default schema for table references in the **DO** clause. Any references to tables in other schemas must be qualified with the proper schema name.

As with stored routines, you can use compound-statement syntax in the **DO** clause by using the **BEGIN** and **END** keywords, as shown here:

```sql
CREATE EVENT e_daily
  ON SCHEDULE EVERY 1 DAY
  COMMENT 'Saves total number of sessions then clears the table each day'
  DO
    BEGIN
      INSERT INTO site_activity.totals (time, total)
      SELECT CURRENT_TIMESTAMP, COUNT(*)
    END
```
This example uses the `delimiter` command to change the statement delimiter. See Section 20.1, “Defining Stored Programs”.

More complex compound statements, such as those used in stored routines, are possible in an event. This example uses local variables, an error handler, and a flow control construct:

```sql
CREATE EVENT e
ON SCHEDULE
EVERY 5 SECOND
DO
BEGIN
DECLARE v INTEGER;
DECLARE CONTINUE HANDLER FOR SQLEXCEPTION BEGIN END;
SET v = 0;
WHILE v < 5 DO
  INSERT INTO t1 VALUES (0);
  UPDATE t2 SET s1 = s1 + 1;
  SET v = v + 1;
END WHILE;
END |
```

There is no way to pass parameters directly to or from events; however, it is possible to invoke a stored routine with parameters within an event:

```sql
CREATE EVENT e_call_myproc
ON SCHEDULE
AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
DO CALL myproc(5, 27);
```

If an event’s definer has privileges sufficient to set global system variables (see Section 5.1.8.1, “System Variable Privileges”), the event can read and write global variables. As granting such privileges entails a potential for abuse, extreme care must be taken in doing so.

Generally, any statements that are valid in stored routines may be used for action statements executed by events. For more information about statements permitted within stored routines, see Section 20.2.1, “Stored Routine Syntax”. You can create an event as part of a stored routine, but an event cannot be created by another event.

### 13.1.12 CREATE FUNCTION Statement

The `CREATE FUNCTION` statement is used to create stored functions and user-defined functions (UDFs):

- For information about creating stored functions, see Section 13.1.15, “CREATE PROCEDURE and CREATE FUNCTION Statements”.
- For information about creating user-defined functions, see Section 13.7.3.1, “CREATE FUNCTION Statement for User-Defined Functions”.

### 13.1.13 CREATE INDEX Statement

```sql
CREATE [ONLINE | OFFLINE] [UNIQUE | FULLTEXT | SPATIAL] INDEX index_name
[index_type]
ON tbl_name (key_part,...)
[index_option]
[algorithm_option | lock_option] ...
```
CREATE INDEX Statement

key_part:
   col_name [(length)] [ASC | DESC]

index_option: {
   KEY_BLOCK_SIZE [=] value
   | index_type
   | WITH PARSER parser_name
   | COMMENT 'string'
}

index_type:
   USING {BTREE | HASH}

algorithm_option:
   ALGORITHM [=] {DEFAULT | INPLACE | COPY}

lock_option:
   LOCK [=] {DEFAULT | NONE | SHARED | EXCLUSIVE}

Normally, you create all indexes on a table at the time the table itself is created with CREATE TABLE. See Section 13.1.17, “CREATE TABLE Statement”. This guideline is especially important for InnoDB tables, where the primary key determines the physical layout of rows in the data file. CREATE INDEX enables you to add indexes to existing tables.

CREATE INDEX is mapped to an ALTER TABLE statement to create indexes. See Section 13.1.7, “ALTER TABLE Statement”. CREATE INDEX cannot be used to create a PRIMARY KEY; use ALTER TABLE instead. For more information about indexes, see Section 8.3.1, “How MySQL Uses Indexes”.

When the innodb_stats_persistent setting is enabled, run the ANALYZE TABLE statement for an InnoDB table after creating an index on that table.

An index specification of the form (key_part1, key_part2, ...) creates an index with multiple key parts. Index key values are formed by concatenating the values of the given key parts. For example (col1, col2, col3) specifies a multiple-column index with index keys consisting of values from col1, col2, and col3.

A key_part specification can end with ASC or DESC. These keywords are permitted for future extensions for specifying ascending or descending index value storage. Currently, they are parsed but ignored; index values are always stored in ascending order.

The following sections describe different aspects of the CREATE_INDEX statement:

• Column Prefix Key Parts
• Unique Indexes
• Full-Text Indexes
• Spatial Indexes
• Index Options
• Table Copying and Locking Options

Column Prefix Key Parts

For string columns, indexes can be created that use only the leading part of column values, using col_name(length) syntax to specify an index prefix length:

• Prefixes can be specified for CHAR, VARCHAR, BINARY, and VARBINARY key parts.
• Prefixes must be specified for BLOB and TEXT key parts. Additionally, BLOB and TEXT columns can be indexed only for InnoDB, MyISAM, and BLACKHOLE tables.
• Prefix limits are measured in bytes. However, prefix lengths for index specifications in CREATE TABLE, ALTER TABLE, and CREATE_INDEX statements are interpreted as number of characters for
CREATE INDEX Statement

nonbinary string types (CHAR, VARCHAR, TEXT) and number of bytes for binary string types (BINARY, VARBINARY, BLOB). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

Prefix support and lengths of prefixes (where supported) are storage engine dependent. For example, a prefix can be up to 767 bytes long for InnoDB tables or 3072 bytes if the innodb_large_prefix option is enabled. For MyISAM tables, the prefix length limit is 1000 bytes. The NDB storage engine does not support prefixes (see Section 18.1.7.6, “Unsupported or Missing Features in NDB Cluster”).

The statement shown here creates an index using the first 10 characters of the name column (assuming that name has a nonbinary string type):

```
CREATE INDEX part_of_name ON customer (name(10));
```

If names in the column usually differ in the first 10 characters, lookups performed using this index should not be much slower than using an index created from the entire name column. Also, using column prefixes for indexes can make the index file much smaller, which could save a lot of disk space and might also speed up INSERT operations.

Unique Indexes

A UNIQUE index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. If you specify a prefix value for a column in a UNIQUE index, the column values must be unique within the prefix length. A UNIQUE index permits multiple NULL values for columns that can contain NULL.

If a table has a PRIMARY KEY or UNIQUE NOT NULL index that consists of a single column that has an integer type, you can use _rowid to refer to the indexed column in SELECT statements, as follows:

- _rowid refers to the PRIMARY KEY column if there is a PRIMARY KEY consisting of a single integer column. If there is a PRIMARY KEY but it does not consist of a single integer column, _rowid cannot be used.
- Otherwise, _rowid refers to the column in the first UNIQUE NOT NULL index if that index consists of a single integer column. If the first UNIQUE NOT NULL index does not consist of a single integer column, _rowid cannot be used.

Full-Text Indexes

FULLTEXT indexes are supported only for InnoDB and MyISAM tables and can include only CHAR, VARCHAR, and TEXT columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See Section 12.10, “Full-Text Search Functions”, for details of operation.

Spatial Indexes

The MyISAM, InnoDB, NDB, and ARCHIVE storage engines support spatial columns such as POINT and GEOMETRY. (Section 11.4, “Spatial Data Types”, describes the spatial data types.) However, support for spatial column indexing varies among engines. Spatial and nonspatial indexes on spatial columns are available according to the following rules.

Spatial indexes on spatial columns (created using SPATIAL INDEX) have these characteristics:

- Available only for MyISAM tables. Specifying SPATIAL INDEX for other storage engines results in an error.
- Indexed columns must be NOT NULL.
- Column prefix lengths are prohibited. The full width of each column is indexed.

Nonspatial indexes on spatial columns (created with INDEX, UNIQUE, or PRIMARY KEY) have these characteristics:
CREATE INDEX Statement

- Permitted for any storage engine that supports spatial columns except ARCHIVE.
- Columns can be NULL unless the index is a primary key.
- For each spatial column in a non-SPATIAL index except POINT columns, a column prefix length must be specified. (This is the same requirement as for indexed BLOB columns.) The prefix length is given in bytes.
- The index type for a non-SPATIAL index depends on the storage engine. Currently, B-tree is used.
- Permitted for a column that can have NULL values only for InnoDB, MyISAM, and MEMORY tables.

Index Options

Following the key part list, index options can be given. An index_option value can be any of the following:

- key_block_size [=] value

  For MyISAM tables, key_block_size optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A key_block_size value specified for an individual index definition overrides a table-level key_block_size value.

  key_block_size is not supported at the index level for InnoDB tables. See Section 13.1.17, “CREATE TABLE Statement”.

- index_type

Some storage engines permit you to specify an index type when creating an index. For example:

```
CREATE TABLE lookup (id INT) ENGINE = MEMORY;
CREATE INDEX id_index ON lookup (id) USING BTREE;
```

Table 13.1, “Index Types Per Storage Engine” shows the permissible index type values supported by different storage engines. Where multiple index types are listed, the first one is the default when no index type specifier is given. Storage engines not listed in the table do not support an index_type clause in index definitions.

<table>
<thead>
<tr>
<th>Storage Engine</th>
<th>Permissible Index Types</th>
</tr>
</thead>
<tbody>
<tr>
<td>InnoDB</td>
<td>BTREE</td>
</tr>
<tr>
<td>MyISAM</td>
<td>BTREE</td>
</tr>
<tr>
<td>MEMORY/HEAP</td>
<td>HASH, BTREE</td>
</tr>
<tr>
<td>NDB</td>
<td>HASH, BTREE (see note in text)</td>
</tr>
</tbody>
</table>

The index_type clause cannot be used for FULLTEXT_INDEX or SPATIAL_INDEX specifications. Full-text index implementation is storage engine dependent. Spatial indexes are implemented as R-tree indexes.

BTREE indexes are implemented by the NDB storage engine as T-tree indexes.

Note

For indexes on NDB table columns, the USING option can be specified only for a unique index or primary key. USING HASH prevents the creation of an ordered index; otherwise, creating a unique index or primary key on an NDB table automatically results in the creation of both an ordered index and a hash index, each of which indexes the same set of columns.
For unique indexes that include one or more NULL columns of an NDB table, the hash index can be used only to look up literal values, which means that IS [NOT] NULL conditions require a full scan of the table. One workaround is to make sure that a unique index using one or more NULL columns on such a table is always created in such a way that it includes the ordered index; that is, avoid employing USING HASH when creating the index.

If you specify an index type that is not valid for a given storage engine, but another index type is available that the engine can use without affecting query results, the engine uses the available type. The parser recognizes RTREE as a type name, but currently this cannot be specified for any storage engine.

Note
Use of the index_type option before the ON tbl_name clause is deprecated; support for use of the option in this position will be removed in a future MySQL release. If an index_type option is given in both the earlier and later positions, the final option applies.

TYPE type_name is recognized as a synonym for USING type_name. However, USING is the preferred form.

The following tables show index characteristics for the storage engines that support the index_type option.

Table 13.2 InnoDB Storage Engine Index Characteristics

<table>
<thead>
<tr>

</tbody>
</table>

Table note:

1. If **USING HASH** is specified that prevents creation of an implicit ordered index.

- **WITH PARSER parser_name**
  
  This option can be used only with **FULLTEXT** indexes. It associates a parser plugin with the index if full-text indexing and searching operations need special handling. See [The MySQL Plugin API](#), for details on creating plugins.

- **COMMENT 'string'**
  
  Index definitions can include an optional comment of up to 1024 characters.

### Table Copying and Locking Options

**ALGORITHM** and **LOCK** clauses may be given to influence the table copying method and level of concurrency for reading and writing the table while its indexes are being modified. They have the same meaning as for the **ALTER TABLE** statement. For more information, see Section 13.1.7, “ALTER TABLE Statement”

Indexes on variable-width columns of **NDBCLUSTER** tables are created online; that is, without any table copying. The table is not locked against access from other NDB Cluster API nodes, although it is locked against other operations on the same API node for the duration of the operation. This is done automatically by the server whenever it determines that it is possible to do so; you do not have to use any special SQL syntax or server options to cause it to happen.

In standard MySQL 5.6 releases, it is not possible to override the server when it determines that an index is to be created without table copying. In NDB Cluster, you can create indexes offline (which causes the table to be locked to all API nodes in the cluster) using the **OFFLINE** keyword. The rules and limitations governing **CREATE OFFLINE INDEX** and **CREATE ONLINE INDEX** are the same as for **ALTER OFFLINE TABLE ... ADD INDEX** and **ALTER ONLINE TABLE ... ADD INDEX**. You cannot cause the noncopying creation of an index that would normally be created offline by using the **ONLINE** keyword: If it is not possible to perform the **CREATE INDEX** operation without table copying, the server ignores the **ONLINE** keyword. For more information, see Section 18.5.11, “Online Operations with ALTER TABLE in NDB Cluster”.

The **ONLINE** and **OFFLINE** keywords are available only in NDB Cluster; attempting to use these keywords in standard MySQL Server 5.6 releases results in a syntax error. The **ONLINE** and **OFFLINE** keywords are deprecated in MySQL NDB Cluster 7.3; they continue to be supported in MySQL NDB Cluster 7.4, but they are subject to removal in a future NDB Cluster release.

13.1.14 CREATE LOGFILE GROUP Statement
CREATE LOGFILE GROUP `logfile_group`
  ADD UNDOFILE 'undo_file'
  [INITIAL_SIZE [=] initial_size]
  [UNDO_BUFFER_SIZE [=] undo_buffer_size]
  [REDO_BUFFER_SIZE [=] redo_buffer_size]
  [NODEGROUP [=] nodegroup_id]
  [WAIT]
  [COMMENT [=] 'string']
  ENGINE [=] engine_name

This statement creates a new log file group named `logfile_group` having a single UNDO file named `undo_file`. A CREATE LOGFILE GROUP statement has one and only one ADD UNDOFILE clause. For rules covering the naming of log file groups, see Section 9.2, “Schema Object Names”.

Note

All NDB Cluster Disk Data objects share the same namespace. This means that each Disk Data object must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group with the same name, or a tablespace and a data file with the same name.

In MySQL NDB Cluster 7.3 and later, you can have only one log file group per Cluster at any given time. (See Bug #16386)

The optional INITIAL_SIZE parameter sets the UNDO file's initial size; if not specified, it defaults to 128M (128 megabytes). The optional UNDO_BUFFER_SIZE parameter sets the size used by the UNDO buffer for the log file group; The default value for UNDO_BUFFER_SIZE is 8M (eight megabytes); this value cannot exceed the amount of system memory available. Both of these parameters are specified in bytes. In MySQL NDB Cluster 7.3.2 and later, you may optionally follow either or both of these with a one-letter abbreviation for an order of magnitude, similar to those used in my.cnf. Generally, this is one of the letters M (for megabytes) or G (for gigabytes). Prior to MySQL NDB Cluster 7.3.2, the values for these options could only be specified using digits. (Bug #13116514, Bug #16104705, Bug #62858)

Memory used for UNDO_BUFFER_SIZE comes from the global pool whose size is determined by the value of the SharedGlobalMemory data node configuration parameter. This includes any default value implied for this option by the setting of the InitialLogFileGroup data node configuration parameter.

The maximum permitted for UNDO_BUFFER_SIZE is 629145600 (600 MB).

On 32-bit systems, the maximum supported value for INITIAL_SIZE is 4294967296 (4 GB). (Bug #29186)

The minimum allowed value for INITIAL_SIZE is 1048576 (1 MB).

The ENGINE option determines the storage engine to be used by this log file group, with engine_name being the name of the storage engine. In MySQL 5.6, this must be NDB (or NDBCLUSTER). If ENGINE is not set, MySQL tries to use the engine specified by the default_storage_engine server system variable (formerly storage_engine). In any case, if the engine is not specified as NDB or NDBCLUSTER, the CREATE LOGFILE GROUP statement appears to succeed but actually fails to create the log file group, as shown here:

```
mysql> CREATE LOGFILE GROUP lg1
    -> ADD UNDOFILE 'undo.dat' INITIAL_SIZE = 10M;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+----+-----+------------------------------------------------------------------------+
|    |     | Table storage engine 'InnoDB' does not support the create option 'TABLESPACE or LOGFILE GROUP'
|    |     |+++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++
| Error | 1478 | Table storage engine 'InnoDB' does not support the create option 'TABLESPACE or LOGFILE GROUP'
+----+-----+------------------------------------------------------------------------+
1 row in set (0.00 sec)
```
CREATE LOGFILE GROUP lg1 ENGINE = NDB;
ERROR 1529 (HY000): Failed to drop LOGFILE GROUP

mysql> CREATE LOGFILE GROUP lg1
  -> ADD UNDOFILE 'undo.dat' INITIAL_SIZE = 10M
  -> ENGINE = NDB;
Query OK, 0 rows affected (2.97 sec)

The fact that the CREATE LOGFILE GROUP statement does not actually return an error when a non-NDB storage engine is named, but rather appears to succeed, is a known issue which we hope to address in a future release of NDB Cluster.

REDO_BUFFER_SIZE, NODEGROUP, WAIT, and COMMENT are parsed but ignored, and so have no effect in MySQL 5.6. These options are intended for future expansion.

When used with ENGINE [=] NDB, a log file group and associated UNDO log file are created on each Cluster data node. You can verify that the UNDO files were created and obtain information about them by querying the INFORMATION_SCHEMA.FILES table. For example:

mysql> SELECT LOGFILE_GROUP_NAME, LOGFILE_GROUP_NUMBER, EXTRA
  -> FROM INFORMATION_SCHEMA.FILES
  -> WHERE FILE_NAME = 'undo_10.dat';
+--------------------+----------------------+----------------+
<table>
<thead>
<tr>
<th>LOGFILE_GROUP_NAME</th>
<th>LOGFILE_GROUP_NUMBER</th>
<th>EXTRA</th>
</tr>
</thead>
<tbody>
<tr>
<td>lg_3</td>
<td>11</td>
<td>CLUSTER_NODE=3</td>
</tr>
<tr>
<td>lg_3</td>
<td>11</td>
<td>CLUSTER_NODE=4</td>
</tr>
</tbody>
</table>
+--------------------+----------------------+----------------+
2 rows in set (0.06 sec)

CREATE LOGFILE GROUP is useful only with Disk Data storage for NDB Cluster. See Section 18.5.10, “NDB Cluster Disk Data Tables”.

13.1.15 CREATE PROCEDURE and CREATE FUNCTION Statements

CREATE
  [DEFINER = user]
  PROCEDURE sp_name ([proc_parameter[, ...]])
  [characteristic ...] routine_body

CREATE
  [DEFINER = user]
  FUNCTION sp_name ([func_parameter[, ...]])
  RETURNS type
  [characteristic ...] routine_body

proc_parameter:
  [ IN | OUT | INOUT ] param_name type

func_parameter:
  param_name type

type:
  Any valid MySQL data type

characteristic:
  { COMMENT 'string'
    | LANGUAGE SQL
    | [NOT] DETERMINISTIC
    | [ CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA ]
    | SQL SECURITY { DEFINER | INVOKER }
  }

routine_body:
  Valid SQL routine statement

These statements are used to create a stored routine (a stored procedure or function). That is, the specified routine becomes known to the server. By default, a stored routine is associated with the
CREATE PROCEDURE and CREATE FUNCTION Statements

default database. To associate the routine explicitly with a given database, specify the name as
\texttt{db_name.sp_name} when you create it.

The \texttt{CREATE FUNCTION} statement is also used in MySQL to support UDFs (user-defined functions). See Section 13.7.3.1, “CREATE FUNCTION Statement for User-Defined Functions”. A UDF can be regarded as an external stored function. Stored functions share their namespace with UDFs. See Section 9.2.5, “Function Name Parsing and Resolution”, for the rules describing how the server interprets references to different kinds of functions.

To invoke a stored procedure, use the \texttt{CALL} statement (see Section 13.2.1, “CALL Statement”). To invoke a stored function, refer to it in an expression. The function returns a value during expression evaluation.

\texttt{CREATE PROCEDURE} and \texttt{CREATE FUNCTION} require the \texttt{CREATE ROUTINE} privilege. If the \texttt{DEFINER} clause is present, the privileges required depend on the \texttt{user} value, as discussed in Section 20.6, “Stored Object Access Control”. If binary logging is enabled, \texttt{CREATE FUNCTION} might require the \texttt{SUPER} privilege, as discussed in Section 20.7, “Stored Program Binary Logging”.

By default, MySQL automatically grants the \texttt{ALTER ROUTINE} and \texttt{EXECUTE} privileges to the routine creator. This behavior can be changed by disabling the \texttt{automatic_sp_privileges} system variable. See Section 20.2.2, “Stored Routines and MySQL Privileges”.

The \texttt{DEFINER} and \texttt{SQL SECURITY} clauses specify the security context to be used when checking access privileges at routine execution time, as described later in this section.

If the routine name is the same as the name of a built-in SQL function, a syntax error occurs unless you use a space between the name and the following parenthesis when defining the routine or invoking it later. For this reason, avoid using the names of existing SQL functions for your own stored routines.

The \texttt{IGNORE_SPACE} SQL mode applies to built-in functions, not to stored routines. It is always permissible to have spaces after a stored routine name, regardless of whether \texttt{IGNORE_SPACE} is enabled.

The parameter list enclosed within parentheses must always be present. If there are no parameters, an empty parameter list of () should be used. Parameter names are not case-sensitive.

Each parameter is an \texttt{IN} parameter by default. To specify otherwise for a parameter, use the keyword \texttt{OUT} or \texttt{INOUT} before the parameter name.

\begin{itemize}
  \item \textbf{Note}
  \end{itemize}

Specifying a parameter as \texttt{IN}, \texttt{OUT}, or \texttt{INOUT} is valid only for a \texttt{PROCEDURE}. For a \texttt{FUNCTION}, parameters are always regarded as \texttt{IN} parameters.

An \texttt{IN} parameter passes a value into a procedure. The procedure might modify the value, but the modification is not visible to the caller when the procedure returns. An \texttt{OUT} parameter passes a value from the procedure back to the caller. Its initial value is \texttt{NULL} within the procedure, and its value is visible to the caller when the procedure returns. An \texttt{INOUT} parameter is initialized by the caller, can be modified by the procedure, and any change made by the procedure is visible to the caller when the procedure returns.

For each \texttt{OUT} or \texttt{INOUT} parameter, pass a user-defined variable in the \texttt{CALL} statement that invokes the procedure so that you can obtain its value when the procedure returns. If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an \texttt{OUT} or \texttt{INOUT} parameter. If you are calling the procedure from within a trigger, you can also pass \texttt{NEW.col_name} as an \texttt{OUT} or \texttt{INOUT} parameter.

For information about the effect of unhandled conditions on procedure parameters, see Section 13.6.7.8, “Condition Handling and OUT or INOUT Parameters”.

Routine parameters cannot be referenced in statements prepared within the routine; see Section 20.8, “Restrictions on Stored Programs”.

1530
The following example shows a simple stored procedure that, given a country code, counts the number of cities for that country that appear in the city table of the world database. The country code is passed using a IN parameter, and the city count is returned using an OUT parameter:

```sql
mysql> delimiter //
mysql> CREATE PROCEDURE citycount (IN country CHAR(3), OUT cities INT)
    BEGIN
        SELECT COUNT(*) INTO cities FROM world.city
        WHERE CountryCode = country;
    END//
Query OK, 0 rows affected (0.01 sec)
mysql> delimiter ;
mysql> CALL citycount('JPN', @cities); -- cities in Japan
Query OK, 1 row affected (0.00 sec)

mysql> SELECT @cities;
+---------+
| @cities |
+---------+
|     248 |
+---------+
1 row in set (0.00 sec)

mysql> CALL citycount('FRA', @cities); -- cities in France
Query OK, 1 row affected (0.00 sec)

mysql> SELECT @cities;
+---------+
| @cities |
+---------+
|      40 |
+---------+
1 row in set (0.00 sec)
```

The example uses the mysql client delimiter command to change the statement delimiter from ; to // while the procedure is being defined. This enables the ; delimiter used in the procedure body to be passed through to the server rather than being interpreted by mysql itself. See Section 20.1, “Defining Stored Programs”.

The RETURNS clause may be specified only for a FUNCTION, for which it is mandatory. It indicates the return type of the function, and the function body must contain a RETURN value statement. If the RETURN statement returns a value of a different type, the value is coerced to the proper type. For example, if a function specifies an ENUM or SET value in the RETURNS clause, but the RETURN statement returns an integer, the value returned from the function is the string for the corresponding ENUM member of a set of SET members.

The following example function takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use delimiter because the function definition contains no internal ; statement delimiters:

```sql
mysql> CREATE FUNCTION hello (s CHAR(20))
    RETURNS CHAR(50) DETERMINISTIC
    RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT hello('world');
+----------------+
| hello('world') |
+----------------+
| Hello, world! |
+----------------+
1 row in set (0.00 sec)
```

Parameter types and function return types can be declared to use any valid data type. The COLLATE attribute can be used if preceded by a CHARACTER_SET specification.
CREATE PROCEDURE and CREATE FUNCTION Statements

The *routine_body* consists of a valid SQL routine statement. This can be a simple statement such as `SELECT` or `INSERT`, or a compound statement written using `BEGIN` and `END`. Compound statements can contain declarations, loops, and other control structure statements. The syntax for these statements is described in Section 13.6, “Compound Statements”. In practice, stored functions tend to use compound statements, unless the body consists of a single `RETURN` statement.

MySQL permits routines to contain DDL statements, such as `CREATE` and `DROP`. MySQL also permits stored procedures (but not stored functions) to contain SQL transaction statements such as `COMMIT`. Stored functions may not contain statements that perform explicit or implicit commit or rollback. Support for these statements is not required by the SQL standard, which states that each DBMS vendor may decide whether to permit them.

Statements that return a result set can be used within a stored procedure but not within a stored function. This prohibition includes `SELECT` statements that do not have an `INTO var_list` clause and other statements such as `SHOW`, `EXPLAIN`, and `CHECK TABLE`. For statements that can be determined at function definition time to return a result set, a `Not allowed to return a result set from a function` error occurs (ER_SP_NO_RETSET). For statements that can be determined only at runtime to return a result set, a `PROCEDURE %s can't return a result set in the given context` error occurs (ER_SP_BADSELECT).

`USE` statements within stored routines are not permitted. When a routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). The causes the routine to have the given default database while it executes. References to objects in databases other than the routine default database should be qualified with the appropriate database name.

For additional information about statements that are not permitted in stored routines, see Section 20.8, “Restrictions on Stored Programs”.

For information about invoking stored procedures from within programs written in a language that has a MySQL interface, see Section 13.2.1, “CALL Statement”.

MySQL stores the `sql_mode` system variable setting in effect when a routine is created or altered, and always executes the routine with this setting in force, regardless of the current server SQL mode when the routine begins executing.

The switch from the SQL mode of the invoker to that of the routine occurs after evaluation of arguments and assignment of the resulting values to routine parameters. If you define a routine in strict SQL mode but invoke it in nonstrict mode, assignment of arguments to routine parameters does not take place in strict mode. If you require that expressions passed to a routine be assigned in strict SQL mode, you should invoke the routine with strict mode in effect.

The `COMMENT` characteristic is a MySQL extension, and may be used to describe the stored routine. This information is displayed by the `SHOW CREATE PROCEDURE` and `SHOW CREATE FUNCTION` statements.

The `LANGUAGE` characteristic indicates the language in which the routine is written. The server ignores this characteristic; only SQL routines are supported.

A routine is considered “deterministic” if it always produces the same result for the same input parameters, and “not deterministic” otherwise. If neither `DETERMINISTIC` nor `NOT DETERMINISTIC` is given in the routine definition, the default is `NOT DETERMINISTIC`. To declare that a function is deterministic, you must specify `DETERMINISTIC` explicitly.

Assessment of the nature of a routine is based on the “honesty” of the creator: MySQL does not check that a routine declared `DETERMINISTIC` is free of statements that produce nondeterministic results. However, misdeclaring a routine might affect results or affect performance. Declaring a nondeterministic routine as `DETERMINISTIC` might lead to unexpected results by causing the optimizer to make incorrect execution plan choices. Declaring a deterministic routine as `NONDETERMINISTIC` might diminish performance by causing available optimizations not to be used.

If binary logging is enabled, the `DETERMINISTIC` characteristic affects which routine definitions MySQL accepts. See Section 20.7, “Stored Program Binary Logging”.
A routine that contains the `NOW()` function (or its synonyms) or `RAND()` is nondeterministic, but it might still be replication-safe. For `NOW()`, the binary log includes the timestamp and replicates correctly. `RAND()` also replicates correctly as long as it is called only a single time during the execution of a routine. (You can consider the routine execution timestamp and random number seed as implicit inputs that are identical on the source and replica.)

Several characteristics provide information about the nature of data use by the routine. In MySQL, these characteristics are advisory only. The server does not use them to constrain what kinds of statements a routine will be permitted to execute.

- **CONTAINS SQL** indicates that the routine does not contain statements that read or write data. This is the default if none of these characteristics is given explicitly. Examples of such statements are `SET @x = 1` or `DO RELEASE_LOCK('abc')`, which execute but neither read nor write data.

- **NO SQL** indicates that the routine contains no SQL statements.

- **READS SQL DATA** indicates that the routine contains statements that read data (for example, `SELECT`), but not statements that write data.

- **MODIFIES SQL DATA** indicates that the routine contains statements that may write data (for example, `INSERT` or `DELETE`).

The **SQL SECURITY** characteristic can be **DEFINER** or **INVOKER** to specify the security context; that is, whether the routine executes using the privileges of the account named in the routine `DEFINER` clause or the user who invokes it. This account must have permission to access the database with which the routine is associated. The default value is `DEFINER`. The user who invokes the routine must have the `EXECUTE` privilege for it, as must the `DEFINER` account if the routine executes in definer security context.

The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at routine execution time for routines that have the **SQL SECURITY DEFINER** characteristic.

If the `DEFINER` clause is present, the `user` value should be a MySQL account specified as `'user_name'@'host_name'`, `CURRENT_USER`, or `CURRENT_USER()`. The permitted `user` values depend on the privileges you hold, as discussed in Section 20.6, “Stored Object Access Control”. Also see that section for additional information about stored routine security.

If the `DEFINER` clause is omitted, the default definer is the user who executes the `CREATE PROCEDURE` or `CREATE FUNCTION` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

Within the body of a stored routine that is defined with the **SQL SECURITY DEFINER** characteristic, the `CURRENT_USER` function returns the routine's `DEFINER` value. For information about user auditing within stored routines, see Section 6.2.15, “SQL-Based Account Activity Auditing”.

Consider the following procedure, which displays a count of the number of MySQL accounts listed in the `mysql.user` system table:

```sql
CREATE DEFINER = 'admin'@'localhost' PROCEDURE account_count()
BEGIN
  SELECT 'Number of accounts:', COUNT(*) FROM mysql.user;
END;
```

The procedure is assigned a `DEFINER` account of `'admin'@'localhost'` no matter which user defines it. It executes with the privileges of that account no matter which user invokes it (because the default security characteristic is `DEFINER`). The procedure succeeds or fails depending on whether the invoker has the `EXECUTE` privilege for it and `'admin'@'localhost'` has the `SELECT` privilege for the `mysql.user` system table.

Now suppose that the procedure is defined with the **SQL SECURITY INVOKER** characteristic:

```sql
CREATE DEFINER = 'admin'@'localhost' PROCEDURE account_count()
SQL SECURITY INVOKER
```

1533
The procedure still has a DEFINER of 'admin'@'localhost', but in this case, it executes with the privileges of the invoking user. Thus, the procedure succeeds or fails depending on whether the invoker has the EXECUTE privilege for it and the SELECT privilege for the mysql.user table.

The server handles the data type of a routine parameter, local routine variable created with DECLARE, or function return value as follows:

- Assignments are checked for data type mismatches and overflow. Conversion and overflow problems result in warnings, or errors in strict SQL mode.
- Only scalar values can be assigned. For example, a statement such as `SET x = (SELECT 1, 2)` is invalid.
- For character data types, if CHARACTER SET is included in the declaration, the specified character set and its default collation is used. If the COLLATE attribute is also present, that collation is used rather than the default collation.

If CHARACTER SET and COLLATE are not present, the database character set and collation in effect at routine creation time are used. To avoid having the server use the database character set and collation, provide an explicit CHARACTER SET and a COLLATE attribute for character data parameters.

If you alter the database default character set or collation, stored routines that are to use the new database defaults must be dropped and recreated.

The database character set and collation are given by the value of the character_set_database and collation_database system variables. For more information, see Section 10.3.3, "Database Character Set and Collation".

### 13.1.16 CREATE SERVER Statement

This statement creates the definition of a server for use with the FEDERATED storage engine. The CREATE SERVER statement creates a new row in the servers table in the mysql database. This statement requires the SUPER privilege.

The server_name should be a unique reference to the server. Server definitions are global within the scope of the server, it is not possible to qualify the server definition to a specific database. server_name has a maximum length of 64 characters (names longer than 64 characters are silently truncated), and is case-insensitive. You may specify the name as a quoted string.

The wrapper_name is an identifier and may be quoted with single quotation marks.

For each option you must specify either a character literal or numeric literal. Character literals are UTF-8, support a maximum length of 64 characters and default to a blank (empty) string. String literals are silently truncated to 64 characters. Numeric literals must be a number between 0 and 9999, default value is 0.
The `CREATE SERVER` statement creates an entry in the `mysql.servers` table that can later be used with the `CREATE TABLE` statement when creating a `FEDERATED` table. The options that you specify will be used to populate the columns in the `mysql.servers` table. The table columns are `Server_name`, `Host`, `Db`, `Username`, `Password`, `Port` and `Socket`.

For example:

```sql
CREATE SERVER s
FOREIGN DATA WRAPPER mysql
OPTIONS (USER 'Remote', HOST '198.51.100.106', DATABASE 'test');
```

Be sure to specify all options necessary to establish a connection to the server. The user name, host name, and database name are mandatory. Other options might be required as well, such as password.

The data stored in the table can be used when creating a connection to a `FEDERATED` table:

```sql
CREATE TABLE t (s1 INT) ENGINE=FEDERATED CONNECTION='s';
```

For more information, see Section 15.8, "The FEDERATED Storage Engine".

`CREATE SERVER` causes an implicit commit. See Section 13.3.3, "Statements That Cause an Implicit Commit".

`CREATE SERVER` is not written to the binary log, regardless of the logging format that is in use.

In MySQL 5.6.11 only, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. (Bug #16062608, Bug #16715809, Bug #69045)

### 13.1.17 CREATE TABLE Statement

```sql
CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
    (create_definition,...)
    [table_options]
    [partition_options]
CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
    [(create_definition,...)]
    [table_options]
    [partition_options]
    [IGNORE | REPLACE]
    [AS] query_expression
CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
    { LIKE old_tbl_name | (LIKE old_tbl_name) }
create_definition: {
    col_name column_definition
    | {INDEX | KEY} [index_name] [index_type] (key_part,...)
    | [index_option] ...
    | {FULLTEXT | SPATIAL} [INDEX | KEY] [index_name] (key_part,...)
    | [index_option] ...
    | [CONSTRAINT [symbol]] PRIMARY KEY
    | [index_type] (key_part,...)
    | [index_option] ...
    | [CONSTRAINT [symbol]] UNIQUE [INDEX | KEY]
    | [index_name] [index_type] (key_part,...)
    | [index_option] ...
    | [CONSTRAINT [symbol]] FOREIGN KEY
    | [index_name] (col_name,...)
    | reference_definition
    | CHECK (expr)
}
column_definition:
```

1535
### CREATE TABLE Statement

| PARTITIONS num
| SUBPARTITION BY
| [LINEAR] HASH(expr)
| [LINEAR] KEY [ALGORITHM={1 | 2}] (column_list) }
| [SUBPARTITIONS num]
CREATE TABLE creates a table with the given name. You must have the CREATE privilege for the table.

By default, tables are created in the default database, using the InnoDB storage engine. An error occurs if the table exists, if there is no default database, or if the database does not exist.

MySQL has no limit on the number of tables. The underlying file system may have a limit on the number of files that represent tables. Individual storage engines may impose engine-specific constraints. InnoDB permits up to 4 billion tables.

For information about the physical representation of a table, see Section 13.1.17.1, “Files Created by CREATE TABLE”.

There are several aspects to the CREATE TABLE statement, described under the following topics in this section:

- Table Name
- Temporary Tables
- Table Cloning and Copying
- Column Data Types and Attributes
- Indexes and Foreign Keys
- Table Options
- Table Partitioning

**Table Name**

- `tbl_name`

The table name can be specified as `db_name.tbl_name` to create the table in a specific database. This works regardless of whether there is a default database, assuming that the database exists.
CREATE TABLE Statement

If you use quoted identifiers, quote the database and table names separately. For example, write `mydb`.`mytbl`, not `mydb.mytbl`.

Rules for permissible table names are given in Section 9.2, “Schema Object Names”.

• IF NOT EXISTS

Prevents an error from occurring if the table exists. However, there is no verification that the existing table has a structure identical to that indicated by the CREATE TABLE statement.

Temporary Tables

You can use the TEMPORARY keyword when creating a table. A TEMPORARY table is visible only within the current session, and is dropped automatically when the session is closed. For more information, see Section 13.1.17.2, “CREATE TEMPORARY TABLE Statement”.

Table Cloning and Copying

• LIKE

Use CREATE TABLE ... LIKE to create an empty table based on the definition of another table, including any column attributes and indexes defined in the original table:

```
CREATE TABLE new_tbl LIKE orig_tbl;
```

For more information, see Section 13.1.17.3, “CREATE TABLE ... LIKE Statement”.

• [AS] query_expression

To create one table from another, add a SELECT statement at the end of the CREATE TABLE statement:

```
CREATE TABLE new_tbl AS SELECT * FROM orig_tbl;
```

For more information, see Section 13.1.17.4, “CREATE TABLE ... SELECT Statement”.

• IGNORE | REPLACE

The IGNORE and REPLACE options indicate how to handle rows that duplicate unique key values when copying a table using a SELECT statement.

For more information, see Section 13.1.17.4, “CREATE TABLE ... SELECT Statement”.

Column Data Types and Attributes

There is a hard limit of 4096 columns per table, but the effective maximum may be less for a given table and depends on the factors discussed in Section 8.4.7, “Limits on Table Column Count and Row Size”.

• data_type

data_type represents the data type in a column definition. For a full description of the syntax available for specifying column data types, as well as information about the properties of each type, see Chapter 11, Data Types.

• Some attributes do not apply to all data types. AUTO_INCREMENT applies only to integer and floating-point types. DEFAULT does not apply to the BLOB or TEXT types.

• Character data types (CHAR, VARCHAR, the TEXT types, ENUM, SET, and any synonyms) can include CHARACTER SET to specify the character set for the column. CHARSET is a synonym for CHARACTER SET. A collation for the character set can be specified with the COLLATE attribute, along with any other attributes. For details, see Chapter 10, Character Sets, Collations, Unicode. Example:
CREATE TABLE t (c CHAR(20) CHARACTER SET utf8 COLLATE utf8_bin);

MySQL 5.6 interprets length specifications in character column definitions in characters. Lengths for BINARY and VARBINARY are in bytes.

- For CHAR, VARCHAR, BINARY, and VARBINARY columns, indexes can be created that use only the leading part of column values, using `col_name(length)` syntax to specify an index prefix length. BLOB and TEXT columns also can be indexed, but a prefix length must be given. Prefix lengths are given in characters for nonbinary string types and in bytes for binary string types. That is, index entries consist of the first `length` characters of each column value for CHAR, VARCHAR, and TEXT columns, and the first `length` bytes of each column value for BINARY, VARBINARY, and BLOB columns. Indexing only a prefix of column values like this can make the index file much smaller. For additional information about index prefixes, see Section 13.1.13, “CREATE INDEX Statement”.

Only the InnoDB and MyISAM storage engines support indexing on BLOB and TEXT columns. For example:

```sql
CREATE TABLE test (blob_col BLOB, INDEX(blob_col(10)));
```

### NOT NULL | NULL

If neither NULL nor NOT NULL is specified, the column is treated as though NULL had been specified.

In MySQL 5.6, only the InnoDB, MyISAM, and MEMORY storage engines support indexes on columns that can have NULL values. In other cases, you must declare indexed columns as NOT NULL or an error results.

### DEFAULT

Specifies a default value for a column. For more information about default value handling, including the case that a column definition includes no explicit DEFAULT value, see Section 11.5, “Data Type Default Values”.

If the NO_ZERO_DATE or NO_ZERO_IN_DATE SQL mode is enabled and a date-valued default is not correct according to that mode, CREATE TABLE produces a warning if strict SQL mode is not enabled and an error if strict mode is enabled. For example, with NO_ZERO_IN_DATE enabled, `c1 DATE DEFAULT '2010-00-00'` produces a warning.

### AUTO_INCREMENT

An integer or floating-point column can have the additional attribute AUTO_INCREMENT. When you insert a value of NULL (recommended) or 0 into an indexed AUTO_INCREMENT column, the column is set to the next sequence value. Typically this is `value+1`, where `value` is the largest value for the column currently in the table. AUTO_INCREMENT sequences begin with 1.

To retrieve an AUTO_INCREMENT value after inserting a row, use the `LAST_INSERT_ID()` SQL function or the `mysql_insert_id()` C API function. See Section 12.16, “Information Functions”, and `mysql_insert_id()`.

If the NO_AUTO_VALUE_ON_ZERO SQL mode is enabled, you can store 0 in AUTO_INCREMENT columns as 0 without generating a new sequence value. See Section 5.1.10, “Server SQL Modes”.

There can be only one AUTO_INCREMENT column per table, it must be indexed, and it cannot have a DEFAULT value. An AUTO_INCREMENT column works properly only if it contains only positive values. Inserting a negative number is regarded as inserting a very large positive number. This is done to
avoid precision problems when numbers “wrap” over from positive to negative and also to ensure that you do not accidentally get an AUTO_INCREMENT column that contains 0.

For MyISAM tables, you can specify an AUTO_INCREMENT secondary column in a multiple-column key. See Section 3.6.9, “Using AUTO_INCREMENT”.

To make MySQL compatible with some ODBC applications, you can find the AUTO_INCREMENT value for the last inserted row with the following query:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

This method requires that sql_auto_is_null variable is not set to 0. See Section 5.1.7, “Server System Variables”.

For information about InnoDB and AUTO_INCREMENT, see Section 14.6.1.6, “AUTO_INCREMENT Handling in InnoDB”. For information about AUTO_INCREMENT and MySQL Replication, see Section 17.4.1.1, “Replication and AUTO_INCREMENT”.

- **COMMENT**

A comment for a column can be specified with the COMMENT option, up to 1024 characters long. The comment is displayed by the SHOW CREATE TABLE and SHOW FULL COLUMNS statements.

- **COLUMN_FORMAT**

In NDB Cluster, it is also possible to specify a data storage format for individual columns of NDB tables using COLUMN_FORMAT. Permissible column formats are FIXED, DYNAMIC, and DEFAULT. FIXED is used to specify fixed-width storage, DYNAMIC permits the column to be variable-width, and DEFAULT causes the column to use fixed-width or variable-width storage as determined by the column’s data type (possibly overridden by a ROW_FORMAT specifier).

For NDB tables, the default value for COLUMN_FORMAT is DEFAULT.

In NDB Cluster, the maximum possible offset for a column defined with COLUMN_FORMAT=FIXED is 8188 bytes. For more information and possible workarounds, see Section 18.1.7.5, “Limits Associated with Database Objects in NDB Cluster”.

COLUMN_FORMAT currently has no effect on columns of tables using storage engines other than NDB. In MySQL 5.6 and later, COLUMN_FORMAT is silently ignored.

- **STORAGE**

For NDB tables, it is possible to specify whether the column is stored on disk or in memory by using a STORAGE clause. STORAGE_DISK causes the column to be stored on disk, and STORAGE_MEMORY causes in-memory storage to be used. The CREATE TABLE statement used must still include a TABLESPACE clause:

```
CREATE TABLE t1 (
    c1 INT STORAGE DISK,
    c2 INT STORAGE MEMORY
) ENGINE NDB;
```

ERROR 1005 (HY000): Can't create table 'c.t1' (errno: 140)

```
CREATE TABLE t1 (
    c1 INT STORAGE DISK,
    c2 INT STORAGE MEMORY
) TABLESPACE ts_1 ENGINE NDB;
```

Query OK, 0 rows affected (1.06 sec)

For NDB tables, STORAGE_DEFAULT is equivalent to STORAGE_MEMORY.

The STORAGE clause has no effect on tables using storage engines other than NDB. The STORAGE keyword is supported only in the build of mysql that is supplied with NDB Cluster; it is not
recognized in any other version of MySQL, where any attempt to use the STORAGE keyword causes a syntax error.

Indexes and Foreign Keys

Several keywords apply to creation of indexes and foreign keys. For general background in addition to the following descriptions, see Section 13.1.13, “CREATE INDEX Statement”, and Section 13.1.17.5, “FOREIGN KEY Constraints”.

- CONSTRAINT symbol

The CONSTRAINT symbol clause may be given to name a constraint. If the clause is not given, or a symbol is not included following the CONSTRAINT keyword, MySQL automatically generates a constraint name. The symbol value, if used, must be unique per schema (database), per constraint type. A duplicate symbol results in an error. See also the discussion about length limits of generated constraint identifiers at Section 9.2.1, “Identifier Length Limits”.

The SQL standard specifies that all types of constraints (primary key, unique index, foreign key, check) belong to the same namespace. In MySQL, each constraint type has its own namespace per schema. Consequently, names for each type of constraint must be unique per schema.

- PRIMARY KEY

A unique index where all key columns must be defined as NOT NULL. If they are not explicitly declared as NOT NULL, MySQL declares them so implicitly (and silently). A table can have only one PRIMARY KEY. The name of a PRIMARY KEY is always PRIMARY, which thus cannot be used as the name for any other kind of index.

If you do not have a PRIMARY KEY and an application asks for the PRIMARY KEY in your tables, MySQL returns the first UNIQUE index that has no NULL columns as the PRIMARY KEY.

In InnoDB tables, keep the PRIMARY KEY short to minimize storage overhead for secondary indexes. Each secondary index entry contains a copy of the primary key columns for the corresponding row. (See Section 14.6.2.1, “Clustered and Secondary Indexes”.)

In the created table, a PRIMARY KEY is placed first, followed by all UNIQUE indexes, and then the nonunique indexes. This helps the MySQL optimizer to prioritize which index to use and also more quickly to detect duplicated UNIQUE keys.

A PRIMARY KEY can be a multiple-column index. However, you cannot create a multiple-column index using the PRIMARY KEY key attribute in a column specification. Doing so only marks that single column as primary. You must use a separate PRIMARY KEY(key_part, ...) clause.

If a table has a PRIMARY KEY or UNIQUE NOT NULL index that consists of a single column that has an integer type, you can use _rowid to refer to the indexed column in SELECT statements, as described in Unique Indexes.

In MySQL, the name of a PRIMARY KEY is PRIMARY. For other indexes, if you do not assign a name, the index is assigned the same name as the first indexed column, with an optional suffix (_2, _3, ...) to make it unique. You can see index names for a table using SHOW INDEX FROM tbl_name. See Section 13.7.5.23, “SHOW INDEX Statement”.

- KEY | INDEX

KEY is normally a synonym for INDEX. The key attribute PRIMARY KEY can also be specified as just KEY when given in a column definition. This was implemented for compatibility with other database systems.

- UNIQUE
A `UNIQUE` index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. For all engines, a `UNIQUE` index permits multiple `NULL` values for columns that can contain `NULL`. If you specify a prefix value for a column in a `UNIQUE` index, the column values must be unique within the prefix length.

If a table has a `PRIMARY KEY` or `UNIQUE NOT NULL` index that consists of a single column that has an integer type, you can use `_rowid` to refer to the indexed column in `SELECT` statements, as described in *Unique Indexes*.

- **FULLTEXT**

A `FULLTEXT` index is a special type of index used for full-text searches. Only the InnoDB and MyISAM storage engines support `FULLTEXT` indexes. They can be created only from `CHAR`, `VARCHAR`, and `TEXT` columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See Section 12.10, “Full-Text Search Functions”, for details of operation. A `WITH PARSER` clause can be specified as an `index_option` value to associate a parser plugin with the index if full-text indexing and searching operations need special handling. This clause is valid only for `FULLTEXT` indexes. See The MySQL Plugin API, for details on creating plugins.

- **SPATIAL**

You can create `SPATIAL` indexes on spatial data types. Spatial types are supported only for MyISAM tables and indexed columns must be declared as `NOT NULL`. See Section 11.4, “Spatial Data Types”.

- **FOREIGN KEY**

MySQL supports foreign keys, which let you cross-reference related data across tables, and foreign key constraints, which help keep this spread-out data consistent. For definition and option information, see `reference_definition`, and `reference_option`.

Partitioned tables employing the InnoDB storage engine do not support foreign keys. See Section 19.6, “Restrictions and Limitations on Partitioning”, for more information.

- **CHECK**

The `CHECK` clause is parsed but ignored by all storage engines.

- **key_part**

  A `key_part` specification can end with `ASC` or `DESC`. These keywords are permitted for future extensions for specifying ascending or descending index value storage. Currently, they are parsed but ignored; index values are always stored in ascending order.

  Prefixes, defined by the `length` attribute, can be up to 767 bytes long for InnoDB tables or 3072 bytes if the `innodb_large_prefix` option is enabled. For MyISAM tables, the prefix length limit is 1000 bytes.

  Prefix limits are measured in bytes. However, prefix lengths for index specifications in `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements are interpreted as number of characters for nonbinary string types (`CHAR`, `VARCHAR`, `TEXT`) and number of bytes for binary string types (`BINARY`, `VARBINARY`, `BLOB`). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

- **index_type**

  Some storage engines permit you to specify an index type when creating an index. The syntax for the `index_type` specifier is `USING type_name`.
Example:

```sql
CREATE TABLE lookup
  (id INT, INDEX USING BTREE (id))
ENGINE = MEMORY;
```

The preferred position for `USING` is after the index column list. It can be given before the column list, but support for use of the option in that position is deprecated and will be removed in a future MySQL release.

- **index_option**

  `index_option` values specify additional options for an index.

- **KEY_BLOCK_SIZE**

  For **MyISAM** tables, `KEY_BLOCK_SIZE` optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A `KEY_BLOCK_SIZE` value specified for an individual index definition overrides the table-level `KEY_BLOCK_SIZE` value.

  For information about the table-level `KEY_BLOCK_SIZE` attribute, see Table Options.

- **WITH PARSER**

  A `WITH PARSER` clause can be specified as an `index_option` value to associate a parser plugin with the index if full-text indexing and searching operations need special handling. This clause is valid only for `FULLTEXT` indexes. See The MySQL Plugin API, for details on creating plugins.

- **COMMENT**

  In MySQL 5.6, index definitions can include an optional comment of up to 1024 characters.

  For more information about permissible `index_option` values, see Section 13.1.13, “CREATE INDEX Statement”. For more information about indexes, see Section 8.3.1, “How MySQL Uses Indexes”.

- **reference_definition**

  For `reference_definition` syntax details and examples, see Section 13.1.17.5, “FOREIGN KEY Constraints”.

  **InnoDB** and **NDB** tables support checking of foreign key constraints. The columns of the referenced table must always be explicitly named. Both `ON DELETE` and `ON UPDATE` actions on foreign keys are supported. For more detailed information and examples, see Section 13.1.17.5, “FOREIGN KEY Constraints”.

  For other storage engines, MySQL Server parses and ignores the `FOREIGN KEY` and `REFERENCES` syntax in `CREATE TABLE` statements. See Section 1.7.2.3, “FOREIGN KEY Constraint Differences”.

---

**Important**

For users familiar with the ANSI/ISO SQL Standard, please note that no storage engine, including **InnoDB**, recognizes or enforces the `MATCH` clause used in referential integrity constraint definitions. Use of an explicit `MATCH` clause will not have the specified effect, and also causes `ON DELETE` and `ON UPDATE` clauses to be ignored. For these reasons, specifying `MATCH` should be avoided.

The `MATCH` clause in the SQL standard controls how **NULL** values in a composite (multiple-column) foreign key are handled when comparing to a
CREATE TABLE Statement

primary key. InnoDB essentially implements the semantics defined by MATCH SIMPLE, which permit a foreign key to be all or partially NULL. In that case, the (child table) row containing such a foreign key is permitted to be inserted, and does not match any row in the referenced (parent) table. It is possible to implement other semantics using triggers.

Additionally, MySQL requires that the referenced columns be indexed for performance. However, it does not enforce any requirement that the referenced columns be declared UNIQUE or NOT NULL. The handling of foreign key references to nonunique keys or keys that contain NULL values is not well defined for operations such as UPDATE or DELETE CASCADE. You are advised to use foreign keys that reference only keys that are both UNIQUE (or PRIMARY) and NOT NULL.

MySQL parses but ignores “inline REFERENCES specifications” (as defined in the SQL standard) where the references are defined as part of the column specification. MySQL accepts REFERENCES clauses only when specified as part of a separate FOREIGN KEY specification.

- reference_option

For information about the RESTRICT, CASCADE, SET NULL, NO ACTION, and SET DEFAULT options, see Section 13.1.17.5, “FOREIGN KEY Constraints”.

Table Options

Table options are used to optimize the behavior of the table. In most cases, you do not have to specify any of them. These options apply to all storage engines unless otherwise indicated. Options that do not apply to a given storage engine may be accepted and remembered as part of the table definition. Such options then apply if you later use ALTER TABLE to convert the table to use a different storage engine.

- ENGINE

Specifies the storage engine for the table, using one of the names shown in the following table. The engine name can be unquoted or quoted. The quoted name 'DEFAULT' is recognized but ignored.

<table>
<thead>
<tr>
<th>Storage Engine</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>InnoDB</td>
<td>Transaction-safe tables with row locking and foreign keys. The default storage engine for new tables. See Chapter 14, The InnoDB Storage Engine, and in particular Section 14.1, “Introduction to InnoDB” if you have MySQL experience but are new to InnoDB.</td>
</tr>
<tr>
<td>MyISAM</td>
<td>The binary portable storage engine that is primarily used for read-only or read-mostly workloads. See Section 15.2, “The MyISAM Storage Engine”.</td>
</tr>
<tr>
<td>MEMORY</td>
<td>The data for this storage engine is stored only in memory. See Section 15.3, “The MEMORY Storage Engine”.</td>
</tr>
<tr>
<td>CSV</td>
<td>Tables that store rows in comma-separated values format. See Section 15.4, “The CSV Storage Engine”.</td>
</tr>
<tr>
<td>ARCHIVE</td>
<td>The archiving storage engine. See Section 15.5, “The ARCHIVE Storage Engine”.</td>
</tr>
<tr>
<td>EXAMPLE</td>
<td>An example engine. See Section 15.9, “The EXAMPLE Storage Engine”.</td>
</tr>
<tr>
<td>FEDERATED</td>
<td>Storage engine that accesses remote tables. See Section 15.8, “The FEDERATED Storage Engine”.</td>
</tr>
<tr>
<td>HEAP</td>
<td>This is a synonym for MEMORY.</td>
</tr>
</tbody>
</table>
### CREATE TABLE Statement

<table>
<thead>
<tr>
<th>Storage Engine</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MERGE</td>
<td>A collection of MyISAM tables used as one table. Also known as <strong>MRG_MyISAM</strong>. See Section 15.7, “The MERGE Storage Engine”.</td>
</tr>
<tr>
<td>NDB</td>
<td>Clustered, fault-tolerant, memory-based tables, supporting transactions and foreign keys. Also known as <strong>NDBCluster</strong>. See Chapter 18, <strong>MySQL NDB Cluster 7.3 and NDB Cluster 7.4</strong>.</td>
</tr>
</tbody>
</table>

If a storage engine is specified that is not available, MySQL uses the default engine instead. Normally, this is **MyISAM**. For example, if a table definition includes the ENGINE=INNODB option but the MySQL server does not support INNODB tables, the table is created as a MyISAM table. This makes it possible to have a replication setup where you have transactional tables on the source but tables created on the replica are nontransactional (to get more speed). In MySQL 5.6, a warning occurs if the storage engine specification is not honored.

Engine substitution can be controlled by the setting of the **NO_ENGINE_SUBSTITUTION** SQL mode, as described in Section 5.1.10, “Server SQL Modes”.

**Note**

The older **TYPE** option that was synonymous with **ENGINE** was removed in MySQL 5.5. **When upgrading to MySQL 5.5 or later, you must convert existing applications that rely on **TYPE** to use **ENGINE** instead.**

- **AUTO_INCREMENT**

  The initial **AUTO_INCREMENT** value for the table. In MySQL 5.6, this works for **MyISAM**, **MEMORY**, **InnoDB**, and **ARCHIVE** tables. To set the first auto-increment value for engines that do not support the **AUTO_INCREMENT** table option, insert a “dummy” row with a value one less than the desired value after creating the table, and then delete the dummy row.

  For engines that support the **AUTO_INCREMENT** table option in **CREATE TABLE** statements, you can also use **ALTER TABLE tbl_name AUTO_INCREMENT = N** to reset the **AUTO_INCREMENT** value. The value cannot be set lower than the maximum value currently in the column.

- **AVG_ROW_LENGTH**

  An approximation of the average row length for your table. You need to set this only for large tables with variable-size rows.

  When you create a **MyISAM** table, MySQL uses the product of the **MAX_ROWS** and **AVG_ROW_LENGTH** options to decide how big the resulting table is. If you don't specify either option, the maximum size for **MyISAM** data and index files is 256TB by default. (If your operating system does not support files that large, table sizes are constrained by the file size limit.) If you want to keep down the pointer sizes to make the index smaller and faster and you don't really need big files, you can decrease the default pointer size by setting the **myisam_data_pointer_size** system variable. (See Section 5.1.7, “Server System Variables”.) If you want all your tables to be able to grow above the default limit and are willing to have your tables slightly slower and larger than necessary, you can increase the default pointer size by setting this variable. Setting the value to 7 permits table sizes up to 65,536TB.

- **[DEFAULT] CHARACTER SET**

  Specifies a default character set for the table. **CHARSET** is a synonym for **CHARACTER SET**. If the character set name is **DEFAULT**, the database character set is used.

- **CHECKSUM**

  Set this to 1 if you want MySQL to maintain a live checksum for all rows (that is, a checksum that MySQL updates automatically as the table changes). This makes the table a little slower to update,
but also makes it easier to find corrupted tables. The `CHECKSUM TABLE` statement reports the checksum. (MyISAM only.)

- **[DEFAULT] COLLATE**
  Specifies a default collation for the table.

- **COMMENT**
  A comment for the table, up to 2048 characters long.

- **CONNECTION**
  The connection string for a FEDERATED table.

  Note
  Older versions of MySQL used a `COMMENT` option for the connection string.

- **DATA DIRECTORY, INDEX DIRECTORY**
  For InnoDB, the `DATA DIRECTORY='directory'` clause permits creating a table outside of the data directory. The `innodb_file_per_table` variable must be enabled to use the `DATA DIRECTORY` clause. The full directory path must be specified. For more information, see Section 14.6.1.2, “Creating Tables Externally”.

  When creating MyISAM tables, you can use the `DATA DIRECTORY='directory'` clause, the `INDEX DIRECTORY='directory'` clause, or both. They specify where to put a MyISAM table’s data file and index file, respectively. Unlike InnoDB tables, MySQL does not create subdirectories that correspond to the database name when creating a MyISAM table with a `DATA DIRECTORY` or `INDEX DIRECTORY` option. Files are created in the directory that is specified.

  As of MySQL 5.6.35, you must have the `FILE` privilege to use the `DATA DIRECTORY` or `INDEX DIRECTORY` table option.

  Important
  Table-level `DATA DIRECTORY` and `INDEX DIRECTORY` options are ignored for partitioned tables. (Bug #32091)

  These options work only when you are not using the `--skip-symbolic-links` option. Your operating system must also have a working, thread-safe `realpath()` call. See Section 8.12.3.2, “Using Symbolic Links for MyISAM Tables on Unix”, for more complete information.

  If a MyISAM table is created with no `DATA DIRECTORY` option, the `.MYD` file is created in the database directory. By default, if MyISAM finds an existing `.MYD` file in this case, it overwrites it. The same applies to `.MYI` files for tables created with no `INDEX DIRECTORY` option. To suppress this behavior, start the server with the `--keep_files_on_create` option, in which case MyISAM will not overwrite existing files and returns an error instead.

  If a MyISAM table is created with a `DATA DIRECTORY` or `INDEX DIRECTORY` option and an existing `.MYD` or `.MYI` file is found, MyISAM always returns an error. It will not overwrite a file in the specified directory.

  Important
  You cannot use path names that contain the MySQL data directory with `DATA DIRECTORY` or `INDEX DIRECTORY`. This includes partitioned tables and individual table partitions. (See Bug #32167.)

- **DELAY_KEY_WRITE**
Set this to 1 if you want to delay key updates for the table until the table is closed. See the
description of the `delay_key_write` system variable in Section 5.1.7, “Server System Variables”.
(MyISAM only.)

• **INSERT_METHOD**

If you want to insert data into a `MERGE` table, you must specify with `INSERT_METHOD` the table into
which the row should be inserted. `INSERT_METHOD` is an option useful for `MERGE` tables only. Use a
value of `FIRST` or `LAST` to have inserts go to the first or last table, or a value of `NO` to prevent inserts.
See Section 15.7, “The MERGE Storage Engine”.

• **KEY_BLOCK_SIZE**

For **MyISAM** tables, `KEY_BLOCK_SIZE` optionally specifies the size in bytes to use for index
key blocks. The value is treated as a hint; a different size could be used if necessary. A
`KEY_BLOCK_SIZE` value specified for an individual index definition overrides the table-level
`KEY_BLOCK_SIZE` value.

For **InnoDB** tables, `KEY_BLOCK_SIZE` specifies the page size in kilobytes to use for compressed
InnoDB tables. The `KEY_BLOCK_SIZE` value is treated as a hint; a different size could
be used by InnoDB if necessary. `KEY_BLOCK_SIZE` can only be less than or equal to the
`innodb_page_size` value. A value of 0 represents the default compressed page size, which is half
of the `innodb_page_size` value. Depending on `innodb_page_size`, possible `KEY_BLOCK_SIZE`
values include 0, 1, 2, 4, 8, and 16. See InnoDB Table Compression for more information.

Oracle recommends enabling `innodb_strict_mode` when specifying `KEY_BLOCK_SIZE` for
InnoDB tables. When `innodb_strict_mode` is enabled, specifying an invalid `KEY_BLOCK_SIZE`
value returns an error. If `innodb_strict_mode` is disabled, an invalid `KEY_BLOCK_SIZE` value
results in a warning, and the `KEY_BLOCK_SIZE` option is ignored.

The `Create_options` column in response to `SHOW TABLE STATUS` reports the originally specified
`KEY_BLOCK_SIZE` option, as does `SHOW CREATE TABLE`.

**InnoDB** only supports `KEY_BLOCK_SIZE` at the table level.

• **MAX_ROWS**

The maximum number of rows you plan to store in the table. This is not a hard limit, but rather a hint
to the storage engine that the table must be able to store at least this many rows.

The **NDB** storage engine treats this value as a maximum. If you plan to create very large NDB Cluster
tables (containing millions of rows), you should use this option to insures that **NDB** allocates sufficient
number of index slots in the hash table used for storing hashes of the table's primary keys by setting
`MAX_ROWS = 2 * rows`, where `rows` is the number of rows that you expect to insert into the table.

The maximum `MAX_ROWS` value is 4294967295; larger values are truncated to this limit.

• **MIN_ROWS**

The minimum number of rows you plan to store in the table. The **MEMORY** storage engine uses this
option as a hint about memory use.

• **PACK_KEYS**

Takes effect only with **MyISAM** tables. Set this option to 1 if you want to have smaller indexes.
This usually makes updates slower and reads faster. Setting the option to 0 disables all packing of
keys. Setting it to `DEFAULT` tells the storage engine to pack only long `CHAR`, `VARCHAR`, `BINARY`, or `VARBINARY` columns.

If you do not use `PACK_KEYS`, the default is to pack strings, but not numbers. If you use `PACK_KEYS=1`, numbers are packed as well.

When packing binary number keys, MySQL uses prefix compression:

- Every key needs one extra byte to indicate how many bytes of the previous key are the same for the next key.
- The pointer to the row is stored in high-byte-first order directly after the key, to improve compression.

This means that if you have many equal keys on two consecutive rows, all following “same” keys usually only take two bytes (including the pointer to the row). Compare this to the ordinary case where the following keys takes `storage_size_for_key + pointer_size` (where the pointer size is usually 4). Conversely, you get a significant benefit from prefix compression only if you have many numbers that are the same. If all keys are totally different, you use one byte more per key, if the key is not a key that can have `NULL` values. (In this case, the packed key length is stored in the same byte that is used to mark if a key is `NULL`.)

- **PASSWORD**

  This option is unused. If you have a need to scramble your `.frm` files and make them unusable to any other MySQL server, please contact our sales department.

- **ROW_FORMAT**

  Defines the physical format in which the rows are stored.

  When creating a table with `strict mode` disabled, the storage engine's default row format is used if the specified row format is not supported. The actual row format of the table is reported in the `Row_format` column in response to `SHOW TABLE STATUS`. The `Create_options` column shows the row format that was specified in the `CREATE TABLE` statement, as does `SHOW CREATE TABLE`.

  Row format choices differ depending on the storage engine used for the table.

  For **InnoDB** tables:

  - Rows are stored in compact format (`ROW_FORMAT=COMPACT`) by default.
  - The noncompact format used in older versions of MySQL can still be requested by specifying `ROW_FORMAT=REDUNDANT`.
  - To enable compression for **InnoDB** tables, specify `ROW_FORMAT=COMPRESSED` and follow the procedures in Section 14.9, “InnoDB Table Compression”.
  - For more efficient **InnoDB** storage of data types, especially `BLOB` types, specify `ROW_FORMAT=DYNAMIC` and follow the procedures in DYNAMIC Row Format. Both the `COMPRESSED` and `DYNAMIC` row formats require creating the table with the configuration settings `innodb_file_per_table=1` and `innodb_file_format=barracuda`.
  - When you specify a non-default `ROW_FORMAT` clause, consider also enabling the `innodb_strict_mode` configuration option.
  - `ROW_FORMAT=FIXED` is not supported. If `ROW_FORMAT=FIXED` is specified while `innodb_strict_mode` is disabled, **InnoDB** issues a warning and assumes...
ROW_FORMAT=COMPACT. If ROW_FORMAT=FIXED is specified while innodb_strict_mode is enabled, InnoDB returns an error.

- For additional information about InnoDB row formats, see Section 14.11, “InnoDB Row Formats”.

For MyISAM tables, the option value can be FIXED or DYNAMIC for static or variable-length row format. myisampack sets the type to COMPRESSED. See Section 15.2.3, “MyISAM Table Storage Formats”.

- STATS_AUTO_RECALC

Specifies whether to automatically recalculate persistent statistics for an InnoDB table. The value DEFAULT causes the persistent statistics setting for the table to be determined by the innodb_stats_auto_recalc configuration option. The value 1 causes statistics to be recalculated when 10% of the data in the table has changed. The value 0 prevents automatic recalculation for this table; with this setting, issue an ANALYZE TABLE statement to recalculate the statistics after making substantial changes to the table. For more information about the persistent statistics feature, see Section 14.8.11.1, “Configuring Persistent Optimizer Statistics Parameters”.

- STATS_PERSISTENT

Specifies whether to enable persistent statistics for an InnoDB table. The value DEFAULT causes the persistent statistics setting for the table to be determined by the innodb_stats_persistent configuration option. The value 1 enables persistent statistics for the table, while the value 0 turns off this feature. After enabling persistent statistics through a CREATE TABLE or ALTER TABLE statement, issue an ANALYZE TABLE statement to calculate the statistics, after loading representative data into the table. For more information about the persistent statistics feature, see Section 14.8.11.1, “Configuring Persistent Optimizer Statistics Parameters”.

- STATS_SAMPLE_PAGES

The number of index pages to sample when estimating cardinality and other statistics for an indexed column, such as those calculated by ANALYZE TABLE. For more information, see Section 14.8.11.1, “Configuring Persistent Optimizer Statistics Parameters”.

- TABLESPACE

The TABLESPACE and STORAGE table options are employed only with NDB tables. The tablespace named tablespace_name must already have been created using CREATE TABLESPACE. STORAGE determines the type of storage used (disk or memory), and can be either DISK or MEMORY.

TABLESPACE ... STORAGE DISK assigns a table to an NDB Cluster Disk Data tablespace. See Section 18.5.10, “NDB Cluster Disk Data Tables”, for more information.

Important

A STORAGE clause cannot be used in a CREATE TABLE statement without a TABLESPACE clause.

- UNION

Used to access a collection of identical MyISAM tables as one. This works only with MERGE tables. See Section 15.7, “The MERGE Storage Engine”.

You must have SELECT, UPDATE, and DELETE privileges for the tables you map to a MERGE table.

Note

Formerly, all tables used had to be in the same database as the MERGE table itself. This restriction no longer applies.
CREATE TABLE Statement

Table Partitioning

partition_options can be used to control partitioning of the table created with CREATE TABLE.

Not all options shown in the syntax for partition_options at the beginning of this section are available for all partitioning types. Please see the listings for the following individual types for information specific to each type, and see Chapter 19, Partitioning, for more complete information about the workings of and uses for partitioning in MySQL, as well as additional examples of table creation and other statements relating to MySQL partitioning.

Partitions can be modified, merged, added to tables, and dropped from tables. For basic information about the MySQL statements to accomplish these tasks, see Section 13.1.7, “ALTER TABLE Statement”. For more detailed descriptions and examples, see Section 19.3, “Partition Management”.

• PARTITION BY

If used, a partition_options clause begins with PARTITION BY. This clause contains the function that is used to determine the partition; the function returns an integer value ranging from 1 to num, where num is the number of partitions. (The maximum number of user-defined partitions which a table may contain is 1024; the number of subpartitions—discussed later in this section—is included in this maximum.)

Note

The expression (expr) used in a PARTITION BY clause cannot refer to any columns not in the table being created; such references are specifically not permitted and cause the statement to fail with an error. (Bug #29444)

• HASH(expr)

Hashes one or more columns to create a key for placing and locating rows. expr is an expression using one or more table columns. This can be any valid MySQL expression (including MySQL functions) that yields a single integer value. For example, these are both valid CREATE TABLE statements using PARTITION BY HASH:

```sql
CREATE TABLE t1 (col1 INT, col2 CHAR(5))
PARTITION BY HASH (col1);

CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATETIME)
PARTITION BY HASH (YEAR(col3));
```

You may not use either VALUES LESS THAN or VALUES IN clauses with PARTITION BY HASH.

PARTITION BY HASH uses the remainder of expr divided by the number of partitions (that is, the modulus). For examples and additional information, see Section 19.2.4, “HASH Partitioning”.

The LINEAR keyword entails a somewhat different algorithm. In this case, the number of the partition in which a row is stored is calculated as the result of one or more logical AND operations. For discussion and examples of linear hashing, see Section 19.2.4.1, “LINEAR HASH Partitioning”.

• KEY(column_list)

This is similar to HASH, except that MySQL supplies the hashing function so as to guarantee an even data distribution. The column_list argument is simply a list of 1 or more table columns (maximum: 16). This example shows a simple table partitioned by key, with 4 partitions:

```sql
CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY KEY(col3)
PARTITIONS 4;
```

For tables that are partitioned by key, you can employ linear partitioning by using the LINEAR keyword. This has the same effect as with tables that are partitioned by HASH. That is, the partition number is found using the & operator rather than the modulus (see Section 19.2.4.1, “LINEAR
create table tk (col1 int, col2 char(5), col3 date)
partition by linear key(col3)
partitions 5;

the algorithm={1 | 2} option is supported with [sub]partition by [linear] key
beginning with mysql 5.6.11. algorithm=1 causes the server to use the same key-hashing
functions as mysql 5.1; algorithm=2 means that the server employs the key-hashing functions
implemented and used by default for new key partitioned tables in mysql 5.5 and later. (partitioned
tables created with the key-hashing functions employed in mysql 5.5 and later cannot be used
by a mysql 5.1 server.) not specifying the option has the same effect as using algorithm=2.
this option is intended for use chiefly when upgrading or downgrading [linear] key partitioned
tables between mysql 5.1 and later mysql versions, or for creating tables partitioned by key or
linear key on a mysql 5.5 or later server which can be used on a mysql 5.1 server. for more
information, see section 13.1.7.1, “alter table partition operations”.

mysql dump in mysql 5.6.11 and later writes this option encased in versioned comments, like this:

create table t1 (a int)
/*!50100 partition by key */ /*!50611 algorithm = 1 */ /*!50100 ()
partitions 3 */

this causes mysql 5.6.10 and earlier servers to ignore the option, which would otherwise cause a
syntax error in those versions. if you plan to load a dump made on a mysql 5.5.31 or later mysql
5.5 server where you use tables that are partitioned or subpartitioned by key into a mysql 5.6
server previous to version 5.6.11, be sure to consult section 2.11.3, “changes in mysql 5.6”, before
proceeding. (the information found there also applies if you are loading a dump containing key
partitioned or subpartitioned tables made from a mysql 5.6.11 or later server into a mysql 5.5.30 or
earlier server.)

also in mysql 5.6.11 and later, algorithm=1 is shown when necessary in the output of show
create table using versioned comments in the same manner as mysql dump. algorithm=2 is
always omitted from show create table output, even if this option was specified when creating
the original table.

you may not use either values less than or values in clauses with partition by key.

• range(expr)

in this case, expr shows a range of values using a set of values less than operators. when
using range partitioning, you must define at least one partition using values less than. you
cannot use values in with range partitioning.

note

for tables partitioned by range, values less than must be used with
either an integer literal value or an expression that evaluates to a single
integer value. in mysql 5.6, you can overcome this limitation in a table that
is defined using partition by range columns, as described later in this
section.

suppose that you have a table that you wish to partition on a column containing year values,
according to the following scheme.

<table>
<thead>
<tr>
<th>partition number:</th>
<th>years range:</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1990 and earlier</td>
</tr>
<tr>
<td>1</td>
<td>1991 to 1994</td>
</tr>
<tr>
<td>2</td>
<td>1995 to 1998</td>
</tr>
</tbody>
</table>
A table implementing such a partitioning scheme can be realized by the `CREATE TABLE` statement shown here:

```sql
CREATE TABLE t1 (
    year_col  INT,
    some_data INT
) PARTITION BY RANGE (year_col) (
    PARTITION p0 VALUES LESS THAN (1991),
    PARTITION p1 VALUES LESS THAN (1995),
    PARTITION p2 VALUES LESS THAN (1999),
    PARTITION p3 VALUES LESS THAN (2002),
    PARTITION p4 VALUES LESS THAN (2006),
    PARTITION p5 VALUES LESS THAN MAXVALUE
);
```

`PARTITION ... VALUES LESS THAN ...` statements work in a consecutive fashion. `VALUES LESS THAN MAXVALUE` works to specify “leftover” values that are greater than the maximum value otherwise specified.

`VALUES LESS THAN` clauses work sequentially in a manner similar to that of the `case` portions of a `switch ... case` block (as found in many programming languages such as C, Java, and PHP). That is, the clauses must be arranged in such a way that the upper limit specified in each successive `VALUES LESS THAN` is greater than that of the previous one, with the one referencing `MAXVALUE` coming last of all in the list.

- **RANGE COLUMNS(column_list)**

  This variant on `RANGE` facilitates partition pruning for queries using range conditions on multiple columns (that is, having conditions such as `WHERE a = 1 AND b < 10` or `WHERE a = 1 AND b = 10 AND c < 10`). It enables you to specify value ranges in multiple columns by using a list of columns in the `COLUMNS` clause and a set of column values in each `PARTITION ... VALUES LESS THAN (value_list)` partition definition clause. (In the simplest case, this set consists of a single column.) The maximum number of columns that can be referenced in the `column_list` and `value_list` is 16.

  The `column_list` used in the `COLUMNS` clause may contain only names of columns; each column in the list must be one of the following MySQL data types: the integer types; the string types; and time or date column types. Columns using `BLOB`, `TEXT`, `SET`, `ENUM`, `BIT`, or spatial data types are not permitted; columns that use floating-point number types are also not permitted. You also may not use functions or arithmetic expressions in the `COLUMNS` clause.

  The `VALUES LESS THAN` clause used in a partition definition must specify a literal value for each column that appears in the `COLUMNS()` clause; that is, the list of values used for each `VALUES LESS THAN` clause must contain the same number of values as there are columns listed in the `COLUMNS` clause. An attempt to use more or fewer values in a `VALUES LESS THAN` clause than there are in the `COLUMNS` clause causes the statement to fail with the error `Inconsistency in usage of column lists for partitioning...` You cannot use `NULL` for any value appearing in `VALUES LESS THAN`. It is possible to use `MAXVALUE` more than once for a given column other than the first, as shown in this example:

```sql
CREATE TABLE rc (
    a INT NOT NULL,
    b INT NOT NULL
) PARTITION BY RANGE COLUMNS(a,b) (
    PARTITION p0 VALUES LESS THAN (10,5),
```

1552
CREATE TABLE Statement
PARTITION p1 VALUES LESS THAN (20,10),
PARTITION p2 VALUES LESS THAN (50,MAXVALUE),
PARTITION p3 VALUES LESS THAN (65,MAXVALUE),
PARTITION p4 VALUES LESS THAN (MAXVALUE,MAXVALUE);

Each value used in a VALUES LESS THAN value list must match the type of the corresponding column exactly; no conversion is made. For example, you cannot use the string ‘1’ for a value that matches a column that uses an integer type (you must use the numeral 1 instead), nor can you use the numeral 1 for a value that matches a column that uses a string type (in such a case, you must use a quoted string: ‘1’).

For more information, see Section 19.2.1, “RANGE Partitioning”, and Section 19.4, “Partition Pruning”.

• LIST(expr)

This is useful when assigning partitions based on a table column with a restricted set of possible values, such as a state or country code. In such a case, all rows pertaining to a certain state or country can be assigned to a single partition, or a partition can be reserved for a certain set of states or countries. It is similar to RANGE, except that only VALUES IN may be used to specify permissible values for each partition.

VALUES IN is used with a list of values to be matched. For instance, you could create a partitioning scheme such as the following:

```
CREATE TABLE client_firms (id INT, name VARCHAR(35))
PARTITION BY LIST (id) (
    PARTITION r0 VALUES IN (1, 5, 9, 13, 17, 21),
    PARTITION r1 VALUES IN (2, 6, 10, 14, 18, 22),
    PARTITION r2 VALUES IN (3, 7, 11, 15, 19, 23),
    PARTITION r3 VALUES IN (4, 8, 12, 16, 20, 24)
);
```

When using list partitioning, you must define at least one partition using VALUES IN. You cannot use VALUES LESS THAN with PARTITION BY LIST.

Note

For tables partitioned by LIST, the value list used with VALUES IN must consist of integer values only. In MySQL 5.6, you can overcome this limitation using partitioning by LIST COLUMNS, which is described later in this section.

• LIST COLUMNS(column_list)

This variant on LIST facilitates partition pruning for queries using comparison conditions on multiple columns (that is, having conditions such as WHERE a = 5 AND b = 5 or WHERE a = 1 AND b = 10 AND c = 5). It enables you to specify values in multiple columns by using a list of columns in the COLUMNS clause and a set of column values in each PARTITION ... VALUES IN(value_list) partition definition clause.

The rules governing regarding data types for the column list used in LIST COLUMNS(column_list) and the value list used in VALUES IN(value_list) are the same as those for the column list used in RANGE COLUMNS(column_list) and the value list used in VALUES LESS THAN(value_list), respectively, except that in the VALUES IN clause, MAXVALUE is not permitted, and you may use NULL.

There is one important difference between the list of values used for VALUES IN with PARTITION BY LIST COLUMNS as opposed to when it is used with PARTITION BY LIST. When used with PARTITION BY LIST COLUMNS, each element in the VALUES IN clause must be a set of column
values; the number of values in each set must be the same as the number of columns used in the
COLUMNS clause, and the data types of these values must match those of the columns (and occur in
the same order). In the simplest case, the set consists of a single column. The maximum number of
columns that can be used in the column_list and in the elements making up the value_list is
16.

The table defined by the following CREATE TABLE statement provides an example of a table using
LIST COLUMNS partitioning:

```sql
CREATE TABLE lc (
    a INT NULL,
    b INT NULL
) PARTITION BY LIST COLUMNS(a,b) (
    PARTITION p0 VALUES IN( (0,0), (NULL,NULL) ),
    PARTITION p1 VALUES IN( (0,1), (0,2), (0,3), (1,1), (1,2) ),
    PARTITION p2 VALUES IN( (1,0), (2,0), (2,1), (3,0), (3,1) ),
    PARTITION p3 VALUES IN( (1,3), (2,2), (2,3), (3,2), (3,3) )
);
```

- **PARTITIONS num**

The number of partitions may optionally be specified with a PARTITIONS num clause, where num
is the number of partitions. If both this clause and any PARTITION clauses are used, num must be
equal to the total number of any partitions that are declared using PARTITION clauses.

**Note**

Whether or not you use a PARTITIONS clause in creating a table that is
partitioned by RANGE or LIST, you must still include at least one PARTITION
VALUES clause in the table definition (see below).

- **SUBPARTITION BY**

A partition may optionally be divided into a number of subpartitions. This can be indicated by using
the optional SUBPARTITION BY clause. Subpartitioning may be done by HASH or KEY. Either of
these may be LINEAR. These work in the same way as previously described for the equivalent
partitioning types. (It is not possible to subpartition by LIST or RANGE.)

The number of subpartitions can be indicated using the SUBPARTITIONS keyword followed by an
integer value.

- Rigorous checking of the value used in PARTITIONS or SUBPARTITIONS clauses is applied and this
value must adhere to the following rules:
  - The value must be a positive, nonzero integer.
  - No leading zeros are permitted.
  - The value must be an integer literal, and cannot not be an expression. For example, PARTITIONS
    0.2E+01 is not permitted, even though 0.2E+01 evaluates to 2. (Bug #15890)
CREATE TABLE Statement

• **partition_definition**

Each partition may be individually defined using a *partition_definition* clause. The individual parts making up this clause are as follows:

• **PARTITION partition_name**

  Specifies a logical name for the partition.

• **VALUES**

  For range partitioning, each partition must include a *VALUES LESS THAN* clause; for list partitioning, you must specify a *VALUES IN* clause for each partition. This is used to determine which rows are to be stored in this partition. See the discussions of partitioning types in Chapter 19, *Partitioning*, for syntax examples.

• **[STORAGE] ENGINE**

  The partitioning handler accepts a [STORAGE] ENGINE option for both PARTITION and SUBPARTITION. Currently, the only way in which this can be used is to set all partitions or all subpartitions to the same storage engine, and an attempt to set different storage engines for partitions or subpartitions in the same table will give rise to the error ERROR 1469 (HY000): The mix of handlers in the partitions is not permitted in this version of MySQL. We expect to lift this restriction on partitioning in a future MySQL release.

• **COMMENT**

  An optional COMMENT clause may be used to specify a string that describes the partition. Example:

  ```
  COMMENT = 'Data for the years previous to 1999'
  ```

  The maximum length for a partition comment is 1024 characters.

• **DATA DIRECTORY and INDEX DIRECTORY**

  DATA DIRECTORY and INDEX DIRECTORY may be used to indicate the directory where, respectively, the data and indexes for this partition are to be stored. Both the *data_dir* and the *index_dir* must be absolute system path names.

  As of MySQL 5.6.35, you must have the FILE privilege to use the DATA DIRECTORY or INDEX DIRECTORY partition option.

Example:

```sql
CREATE TABLE th (id INT, name VARCHAR(30), adate DATE)
PARTITION BY LIST(YEAR(adate))
(
      DATA DIRECTORY = '/var/appdata/95/data'
      INDEX DIRECTORY = '/var/appdata/95/idx',
      DATA DIRECTORY = '/var/appdata/96/data'
      INDEX DIRECTORY = '/var/appdata/96/idx',
      DATA DIRECTORY = '/var/appdata/97/data'
      INDEX DIRECTORY = '/var/appdata/97/idx',
      DATA DIRECTORY = '/var/appdata/98/data'
      INDEX DIRECTORY = '/var/appdata/98/idx'
)
CREATE TABLE Statement

DATA DIRECTORY and INDEX DIRECTORY behave in the same way as in the CREATE TABLE statement's table_option clause as used for MyISAM tables.

One data directory and one index directory may be specified per partition. If left unspecified, the data and indexes are stored by default in the table's database directory.

On Windows, the DATA DIRECTORY and INDEX DIRECTORY options are not supported for individual partitions or subpartitions of MyISAM tables, and the INDEX DIRECTORY option is not supported for individual partitions or subpartitions of InnoDB tables. These options are ignored on Windows, except that a warning is generated. (Bug #30459)

Note
The DATA DIRECTORY and INDEX DIRECTORY options are ignored for creating partitioned tables if NO_DIR_IN_CREATE is in effect. (Bug #24633)

• MAX_ROWS and MIN_ROWS

May be used to specify, respectively, the maximum and minimum number of rows to be stored in the partition. The values for max_number_of_rows and min_number_of_rows must be positive integers. As with the table-level options with the same names, these act only as "suggestions" to the server and are not hard limits.

• TABLESPACE

May be used to designate a tablespace for the partition. Used for NDB Cluster only.

• subpartition_definition

The partition definition may optionally contain one or more subpartition_definition clauses. Each of these consists at a minimum of the SUBPARTITION name, where name is an identifier for the subpartition. Except for the replacement of the PARTITION keyword with SUBPARTITION, the syntax for a subpartition definition is identical to that for a partition definition.

Subpartitioning must be done by HASH or KEY, and can be done only on RANGE or LIST partitions. See Section 19.2.6, "Subpartitioning".

13.1.17.1 Files Created by CREATE TABLE

MySQL represents each table by an .frm table format (definition) file in the database directory. The storage engine for the table might create other files as well.

For InnoDB tables, the file storage is controlled by the innodb_file_per_table configuration option. For each InnoDB table created when this option is turned on, the table data and all associated indexes are stored in a .ibd file located inside the database directory. When this option is turned off, all InnoDB tables and indexes are stored in the system tablespace, represented by one or more ibdata* files.

For MyISAM tables, the storage engine creates data and index files. Thus, for each MyISAM table tbl_name, there are three disk files.

<table>
<thead>
<tr>
<th>File</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>tbl_name.frm</td>
<td>Table format (definition) file</td>
</tr>
<tr>
<td>tbl_name.MYD</td>
<td>Data file</td>
</tr>
<tr>
<td>tbl_name.MYI</td>
<td>Index file</td>
</tr>
</tbody>
</table>
Chapter 15, Alternative Storage Engines, describes what files each storage engine creates to represent tables. If a table name contains special characters, the names for the table files contain encoded versions of those characters as described in Section 9.2.4, “Mapping of Identifiers to File Names”.

Limits Imposed by .frm File Structure

As described previously, each table has an .frm file that contains the table definition. The server uses the following expression to check some of the table information stored in the file against an upper limit of 64KB:

```sql
if (info_length+(ulong) create_fields.elements*FCOMP+288+
    n_length+int_length+com_length > 65535L || int_count > 255)
```

The portion of the information stored in the .frm file that is checked against the expression cannot grow beyond the 64KB limit, so if the table definition reaches this size, no more columns can be added.

The relevant factors in the expression are:

- `info_length` is space needed for “screens.” This is related to MySQL’s Unireg heritage.
- `create_fields.elements` is the number of columns.
- `FCOMP` is 17.
- `n_length` is the total length of all column names, including one byte per name as a separator.
- `int_length` is related to the list of values for ENUM and SET columns. In this context, “int” does not mean “integer.” It means “interval,” a term that refers collectively to ENUM and SET columns.
- `int_count` is the number of unique ENUM and SET definitions.
- `com_length` is the total length of column comments.

The expression just described has several implications for permitted table definitions:

- Using long column names can reduce the maximum number of columns, as can the inclusion of ENUM or SET columns, or use of column comments.
- A table can have no more than 255 unique ENUM and SET definitions. Columns with identical element lists are considered the same against this limit. For example, if a table contains these two columns, they count as one (not two) toward this limit because the definitions are identical:

  ```sql
  e1 ENUM('a','b','c')
  e2 ENUM('a','b','c')
  ```

- The sum of the length of element names in the unique ENUM and SET definitions counts toward the 64KB limit, so although the theoretical limit on number of elements in a given ENUM column is 65,535, the practical limit is less than 3000.

13.1.17.2 CREATE TEMPORARY TABLE Statement

You can use the TEMPORARY keyword when creating a table. A TEMPORARY table is visible only within the current session, and is dropped automatically when the session is closed. This means that two different sessions can use the same temporary table name without conflicting with each other or with an existing non-TEMPORARY table of the same name. (The existing table is hidden until the temporary table is dropped.)

CREATE_TABLE causes an implicit commit, except when used with the TEMPORARY keyword. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

TEMPORARY tables have a very loose relationship with databases (schemas). Dropping a database does not automatically drop any TEMPORARY tables created within that database. Also, you can create
a `TEMPORARY` table in a nonexistent database if you qualify the table name with the database name in the `CREATE TABLE` statement. In this case, all subsequent references to the table must be qualified with the database name.

To create a temporary table, you must have the `CREATE TEMPORARY TABLES` privilege. After a session has created a temporary table, the server performs no further privilege checks on the table. The creating session can perform any operation on the table, such as `DROP TABLE`, `INSERT`, `UPDATE`, or `SELECT`.

One implication of this behavior is that a session can manipulate its temporary tables even if the current user has no privilege to create them. Suppose that the current user does not have the `CREATE TEMPORARY TABLES` privilege but is able to execute a definer-context stored procedure that executes with the privileges of a user who does have `CREATE TEMPORARY TABLES` and that creates a temporary table. While the procedure executes, the session uses the privileges of the defining user. After the procedure returns, the effective privileges revert to those of the current user, which can still see the temporary table and perform any operation on it.

### 13.1.17.3 CREATE TABLE ... LIKE Statement

Use `CREATE TABLE ... LIKE` to create an empty table based on the definition of another table, including any column attributes and indexes defined in the original table:

```
CREATE TABLE new_tbl LIKE orig_tbl;
```

The copy is created using the same version of the table storage format as the original table. The `SELECT` privilege is required on the original table.

`LIKE` works only for base tables, not for views.

**Important**

You cannot execute `CREATE TABLE` or `CREATE TABLE ... LIKE` while a `LOCK TABLES` statement is in effect.

`CREATE TABLE ... LIKE` makes the same checks as `CREATE TABLE` and does not just copy the `.frm` file. This means that if the current SQL mode is different from the mode in effect when the original table was created, the table definition might be considered invalid for the new mode and the statement will fail.

`CREATE TABLE ... LIKE` does not preserve any `DATA DIRECTORY` or `INDEX DIRECTORY` table options that were specified for the original table, or any foreign key definitions.

If the original table is a `TEMPORARY` table, `CREATE TABLE ... LIKE` does not preserve `TEMPORARY`. To create a `TEMPORARY` destination table, use `CREATE TEMPORARY TABLE ... LIKE`.

### 13.1.17.4 CREATE TABLE ... SELECT Statement

You can create one table from another by adding a `SELECT` statement at the end of the `CREATE TABLE` statement:

```
CREATE TABLE new_tbl [AS] SELECT * FROM orig_tbl;
```

MySQL creates new columns for all elements in the `SELECT`. For example:

```
mysql> CREATE TABLE test (a INT NOT NULL AUTO_INCREMENT, -> PRIMARY KEY (a), KEY (b)) -> ENGINE=MyISAM SELECT b,c FROM test2;
```

This creates a `MyISAM` table with three columns, `a`, `b`, and `c`. The `ENGINE` option is part of the `CREATE TABLE` statement, and should not be used following the `SELECT`; this would result in a syntax error. The same is true for other `CREATE TABLE` options such as `CHARSET`.

1558
Notice that the columns from the \texttt{SELECT} statement are appended to the right side of the table, not overlapped onto it. Take the following example:

\begin{verbatim}
mysql> SELECT * FROM foo;
+---+
| n |
+---+
| 1 |
+---+
mysql> CREATE TABLE bar (m INT) SELECT n FROM foo;
Query OK, 1 row affected (0.02 sec)
Records: 1  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM bar;
+------+---+
| m    | n |
+------+---+
| NULL | 1 |
+------+---+
1 row in set (0.00 sec)
\end{verbatim}

For each row in table \texttt{foo}, a row is inserted in \texttt{bar} with the values from \texttt{foo} and default values for the new columns.

In a table resulting from \texttt{CREATE TABLE \ldots SELECT}, columns named only in the \texttt{CREATE TABLE} part come first. Columns named in both parts or only in the \texttt{SELECT} part come after that. The data type of \texttt{SELECT} columns can be overridden by also specifying the column in the \texttt{CREATE TABLE} part.

If any errors occur while copying the data to the table, it is automatically dropped and not created.

You can precede the \texttt{SELECT} by \texttt{IGNORE} or \texttt{REPLACE} to indicate how to handle rows that duplicate unique key values. With \texttt{IGNORE}, rows that duplicate an existing row on a unique key value are discarded. With \texttt{REPLACE}, new rows replace rows that have the same unique key value. If neither \texttt{IGNORE} nor \texttt{REPLACE} is specified, duplicate unique key values result in an error.

Because the ordering of the rows in the underlying \texttt{SELECT} statements cannot always be determined, \texttt{CREATE TABLE \ldots IGNORE SELECT} and \texttt{CREATE TABLE \ldots REPLACE SELECT} statements are flagged as unsafe for statement-based replication. Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using \texttt{MIXED} mode. See also Section 17.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

\texttt{CREATE TABLE \ldots SELECT} does not automatically create any indexes for you. This is done intentionally to make the statement as flexible as possible. If you want to have indexes in the created table, you should specify these before the \texttt{SELECT} statement:

\begin{verbatim}
mysql> CREATE TABLE bar (UNIQUE (n)) SELECT n FROM foo;
\end{verbatim}

Some conversion of data types might occur. For example, the \texttt{AUTO_INCREMENT} attribute is not preserved, and \texttt{VARCHAR} columns can become \texttt{CHAR} columns. Retrained attributes are \texttt{NULL} (or \texttt{NOT NULL}) and, for those columns that have them, \texttt{CHARACTER SET}, \texttt{COLLATION}, \texttt{COMMENT}, and the \texttt{DEFAULT} clause.

When creating a table with \texttt{CREATE TABLE \ldots SELECT}, make sure to alias any function calls or expressions in the query. If you do not, the \texttt{CREATE} statement might fail or result in undesirable column names.

\begin{verbatim}
CREATE TABLE artists_and_works
    SELECT artist.name, COUNT(work.artist_id) AS number_of_works
    FROM artist LEFT JOIN work ON artist.id = work.artist_id
    GROUP BY artist.id;
\end{verbatim}

You can also explicitly specify the data type for a column in the created table:
CREATE TABLE foo (a TINYINT NOT NULL) SELECT b+1 AS a FROM bar;

For CREATE TABLE ... SELECT, if IF NOT EXISTS is given and the destination table already exists, the result is version dependent. Before MySQL 5.5.6, MySQL handles the statement as follows:

- The table definition given in the CREATE TABLE part is ignored. No error occurs, even if the definition does not match that of the existing table. MySQL attempts to insert the rows from the SELECT part anyway.

- If there is a mismatch between the number of columns in the table and the number of columns produced by the SELECT part, the selected values are assigned to the rightmost columns. For example, if the table contains n columns and the SELECT produces m columns, where m < n, the selected values are assigned to the m rightmost columns in the table. Each of the initial n - m columns is assigned its default value, either that specified explicitly in the column definition or the implicit column data type default if the definition contains no default. If the SELECT part produces too many columns (m > n), an error occurs.

- If strict SQL mode is enabled and any of these initial columns do not have an explicit default value, the statement fails with an error.

The following example illustrates IF NOT EXISTS handling:

```sql
mysql> CREATE TABLE t1 (i1 INT DEFAULT 0, i2 INT, i3 INT, i4 INT);
Query OK, 0 rows affected (0.05 sec)

mysql> CREATE TABLE IF NOT EXISTS t1 (c1 CHAR(10)) SELECT 1, 2;
Query OK, 1 row affected, 1 warning (0.01 sec)
Records: 1  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM t1;
+------+------+------+------+
<table>
<thead>
<tr>
<th>i1</th>
<th>i2</th>
<th>i3</th>
<th>i4</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>NULL</td>
<td>1</td>
<td>2</td>
</tr>
</tbody>
</table>
+------+------+------+------+
1 row in set (0.00 sec)
```

As of MySQL 5.5.6, handling of CREATE TABLE IF NOT EXISTS ... SELECT statements was changed for the case that the destination table already exists. This change also involves a change in MySQL 5.1 beginning with 5.1.51.

- Previously, for CREATE TABLE IF NOT EXISTS ... SELECT, MySQL produced a warning that the table exists, but inserted the rows and wrote the statement to the binary log anyway. By contrast, CREATE TABLE ... SELECT (without IF NOT EXISTS) failed with an error, but MySQL inserted no rows and did not write the statement to the binary log.

- MySQL now handles both statements the same way when the destination table exists, in that neither statement inserts rows or is written to the binary log. The difference between them is that MySQL produces a warning when IF NOT EXISTS is present and an error when it is not.

This change means that, for the preceding example, the CREATE TABLE IF NOT EXISTS ... SELECT statement inserts nothing into the destination table as of MySQL 5.5.6.

This change in handling of IF NOT EXISTS results in an incompatibility for statement-based replication from a MySQL 5.1 source with the original behavior and a MySQL 5.5 replica with the new behavior. Suppose that CREATE TABLE IF NOT EXISTS ... SELECT is executed on the source and the destination table exists. The result is that rows are inserted on the source but not on the replica. (Row-based replication does not have this problem.)

To address this issue, statement-based binary logging for CREATE TABLE IF NOT EXISTS ... SELECT is changed in MySQL 5.1 as of 5.1.51:

- If the destination table does not exist, there is no change: The statement is logged as is.
• If the destination table does exist, the statement is logged as the equivalent pair of `CREATE TABLE IF NOT EXISTS` and `INSERT ... SELECT` statements. (If the `SELECT` in the original statement is preceded by `IGNORE` or `REPLACE`, the `INSERT` becomes `INSERT IGNORE` or `REPLACE`, respectively.)

This change provides forward compatibility for statement-based replication from MySQL 5.1 to 5.5 because when the destination table exists, the rows will be inserted on both the source and replica. To take advantage of this compatibility measure, the 5.1 server must be at least 5.1.51 and the 5.5 server must be at least 5.5.6.

To upgrade an existing 5.1-to-5.5 replication scenario, upgrade the source first to 5.1.51 or higher. Note that this differs from the usual replication upgrade advice of upgrading the replica first.

A workaround for applications that wish to achieve the original effect (rows inserted regardless of whether the destination table exists) is to use `CREATE TABLE IF NOT EXISTS` and `INSERT ... SELECT` statements rather than `CREATE TABLE IF NOT EXISTS ... SELECT` statements.

Along with the change just described, the following related change was made: Previously, if an existing view was named as the destination table for `CREATE TABLE IF NOT EXISTS ... SELECT`, rows were inserted into the underlying base table and the statement was written to the binary log. As of MySQL 5.1.51 and 5.5.6, nothing is inserted or logged.

To ensure that the binary log can be used to re-create the original tables, MySQL does not permit concurrent inserts during `CREATE TABLE ... SELECT`.

**Important**

You cannot use `FOR UPDATE` as part of the `SELECT` in a statement such as `CREATE TABLE new_table SELECT ... FROM old_table ...`. If you attempt to do so, the statement fails. This represents a change in behavior from MySQL 5.5 and earlier, which permitted `CREATE TABLE ... SELECT` statements to make changes in tables other than the table being created.

This change can also have implications for statement-based replication from an older source to a MySQL 5.6 or higher replica. See Section 17.4.1.7, “Replication of CREATE TABLE ... SELECT Statements”, for more information.

### 13.1.17.5 FOREIGN KEY Constraints

MySQL supports foreign keys, which permit cross-referencing related data across tables, and foreign key constraints, which help keep the related data consistent.

A foreign key relationship involves a parent table that holds the initial column values, and a child table with column values that reference the parent column values. A foreign key constraint is defined on the child table.

The essential syntax for a defining a foreign key constraint in a `CREATE TABLE` or `ALTER TABLE` statement includes the following:

```sql
[CONSTRAINT [symbol]] FOREIGN KEY
    [index_name] (col_name, ...)
    REFERENCES tbl_name (col_name, ...)
    [ON DELETE reference_option]
    [ON UPDATE reference_option]

reference_option:
    RESTRICT | CASCADE | SET NULL | NO ACTION | SET DEFAULT
```

Foreign key constraint usage is described under the following topics in this section:

- Identifiers
- Conditions and Restrictions
CREATE TABLE Statement

- Referential Actions
- Foreign Key Constraint Examples
- Adding Foreign Key Constraints
- Dropping Foreign Key Constraints
- Foreign Key Checks
- Foreign Key Definitions and Metadata
- Foreign Key Errors

**Identifiers**

Foreign key constraint naming is governed by the following rules:

- The `CONSTRAINT symbol` value is used, if defined.
- If the `CONSTRAINT symbol` clause is not defined, or a symbol is not included following the `CONSTRAINT` keyword:
  - For InnoDB tables, a constraint name is generated automatically.
  - For NDB tables, the `FOREIGN KEY index_name` value is used, if defined. Otherwise, a constraint name is generated automatically.
- The `CONSTRAINT symbol` value, if defined, must be unique in the database. A duplicate symbol results in an error similar to: `ERROR 1005 (HY000): Can't create table 'test.fk1' (errno: 121).

Table and column identifiers in a `FOREIGN KEY ... REFERENCES` clause can be quoted within backticks (`). Alternatively, double quotation marks (") can be used if the `ANSI_QUOTES` SQL mode is enabled. The `lower_case_table_names` system variable setting is also taken into account.

**Conditions and Restrictions**

Foreign key constraints are subject to the following conditions and restrictions:

- Parent and child tables must use the same storage engine, and they cannot be defined as temporary tables.
- Creating a foreign key constraint requires at least one of the `SELECT`, `INSERT`, `UPDATE`, `DELETE`, or `REFERENCES` privileges on the parent table as of 5.6.22.
- Corresponding columns in the foreign key and the referenced key must have similar data types. The size and sign of integer types must be the same. The length of string types need not be the same. For nonbinary (character) string columns, the character set and collation must be the same.
- MySQL supports foreign key references between one column and another within a table. (A column cannot have a foreign key reference to itself.) In these cases, a "child table record" refers to a dependent record within the same table.
- MySQL requires indexes on foreign keys and referenced keys so that foreign key checks can be fast and not require a table scan. In the referencing table, there must be an index where the foreign key columns are listed as the first columns in the same order. Such an index is created on the referencing table automatically if it does not exist. This index might be silently dropped later if you create another index that can be used to enforce the foreign key constraint. `index_name`, if given, is used as described previously.
- InnoDB permits a foreign key to reference any index column or group of columns. However, in the referenced table, there must be an index where the referenced columns are the first columns.
CREATE TABLE Statement

in the same order. Hidden columns that InnoDB adds to an index are also considered (see Section 14.6.2.1, “Clustered and Secondary Indexes”).

NDB requires an explicit unique key (or primary key) on any column referenced as a foreign key. InnoDB does not, which is an extension of standard SQL.

• Index prefixes on foreign key columns are not supported. Consequently, BLOB and TEXT columns cannot be included in a foreign key because indexes on those columns must always include a prefix length.

• InnoDB does not currently support foreign keys for tables with user-defined partitioning. This includes both parent and child tables.

This restriction does not apply for NDB tables that are partitioned by KEY or LINEAR KEY (the only user partitioning types supported by the NDB storage engine); these may have foreign key references or be the targets of such references.

• A table in a foreign key relationship cannot be altered to use another storage engine. To change the storage engine, you must drop any foreign key constraints first.

For information about how the MySQL implementation of foreign key constraints differs from the SQL standard, see Section 1.7.2.3, “FOREIGN KEY Constraint Differences”.

Referential Actions

When an UPDATE or DELETE operation affects a key value in the parent table that has matching rows in the child table, the result depends on the referential action specified by ON UPDATE and ON DELETE subclauses of the FOREIGN KEY clause. Referential actions include:

• CASCADE: Delete or update the row from the parent table and automatically delete or update the matching rows in the child table. Both ON DELETE CASCADE and ON UPDATE CASCADE are supported. Between two tables, do not define several ON UPDATE CASCADE clauses that act on the same column in the parent table or in the child table.

Note
Cascaded foreign key actions do not activate triggers.

• SET NULL: Delete or update the row from the parent table and set the foreign key column or columns in the child table to NULL. Both ON DELETE SET NULL and ON UPDATE SET NULL clauses are supported.

If you specify a SET NULL action, make sure that you have not declared the columns in the child table as NOT NULL.

• RESTRICT: Rejects the delete or update operation for the parent table. Specifying RESTRICT (or NO ACTION) is the same as omitting the ON DELETE or ON UPDATE clause.

• NO ACTION: A keyword from standard SQL. In MySQL, equivalent to RESTRICT. The MySQL Server rejects the delete or update operation for the parent table if there is a related foreign key value in the referenced table. Some database systems have deferred checks, and NO ACTION is a deferred check. In MySQL, foreign key constraints are checked immediately, so NO ACTION is the same as RESTRICT.

• SET DEFAULT: This action is recognized by the MySQL parser, but both InnoDB and NDB reject table definitions containing ON DELETE SET DEFAULT or ON UPDATE SET DEFAULT clauses.

For storage engines that support foreign keys, MySQL rejects any INSERT or UPDATE operation that attempts to create a foreign key value in a child table if there is no matching candidate key value in the parent table.
CREATE TABLE Statement

For an ON DELETE or ON UPDATE that is not specified, the default action is always RESTRICT.

For NDB tables, ON UPDATE CASCADE is not supported where the reference is to the parent table's primary key.

As of NDB 7.3.25 and NDB 7.4.24: For NDB tables, ON DELETE CASCADE is not supported where the child table contains one or more columns of any of the TEXT or BLOB types. (Bug #89511, Bug #27484882)

InnoDB performs cascading operations using a depth-first search algorithm on the records of the index that corresponds to the foreign key constraint.

Foreign Key Constraint Examples

This simple example relates parent and child tables through a single-column foreign key:

```
CREATE TABLE parent {
  id INT NOT NULL,
  PRIMARY KEY (id)
} ENGINE=INNODB;

CREATE TABLE child {
  id INT,
  parent_id INT,
  INDEX par_ind (parent_id),
  FOREIGN KEY (parent_id)
    REFERENCES parent(id)
    ON DELETE CASCADE
} ENGINE=INNODB;
```

This is a more complex example in which a product_order table has foreign keys for two other tables. One foreign key references a two-column index in the product table. The other references a single-column index in the customer table:

```
CREATE TABLE product {
  category INT NOT NULL, id INT NOT NULL,
  price DECIMAL,
  PRIMARY KEY(category, id)
} ENGINE=INNODB;

CREATE TABLE customer {
  id INT NOT NULL,
  PRIMARY KEY (id)
} ENGINE=INNODB;

CREATE TABLE product_order {
  no INT NOT NULL AUTO_INCREMENT,
  product_category INT NOT NULL,
  product_id INT NOT NULL,
  customer_id INT NOT NULL,
  PRIMARY KEY(no),
  INDEX (product_category, product_id),
  INDEX (customer_id),
  FOREIGN KEY (product_category, product_id)
    REFERENCES product(category, id)
    ON UPDATE CASCADE ON DELETE RESTRICT,
  FOREIGN KEY (customer_id)
    REFERENCES customer(id)
} ENGINE=INNODB;
```

Adding Foreign Key Constraints

You can add a foreign key constraint to an existing table using the following ALTER TABLE syntax:

```
ALTER TABLE tbl_name
```
The foreign key can be self referential (referring to the same table). When you add a foreign key constraint to a table using `ALTER TABLE`, remember to first create an index on the column(s) referenced by the foreign key.

### Dropping Foreign Key Constraints

You can drop a foreign key constraint using the following `ALTER TABLE` syntax:

```
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```

If the `FOREIGN KEY` clause defined a `CONSTRAINT` name when you created the constraint, you can refer to that name to drop the foreign key constraint. Otherwise, a constraint name was generated internally, and you must use that value. To determine the foreign key constraint name, use `SHOW CREATE TABLE`:

```
mysql> SHOW CREATE TABLE child\G
*************************** 1. row ***************************
Table: child
Create Table: CREATE TABLE `child` (
  `id` int(11) DEFAULT NULL,
  `parent_id` int(11) DEFAULT NULL,
  KEY `par_ind` (`parent_id`),
  CONSTRAINT `child_ibfk_1` FOREIGN KEY (`parent_id`)
    REFERENCES `parent` (`id`) ON DELETE CASCADE
) ENGINE=InnoDB DEFAULT CHARSET=latin1
mysql> ALTER TABLE child DROP FOREIGN KEY `child_ibfk_1`;
```

Adding and dropping a foreign key in the same `ALTER TABLE` statement is supported for `ALTER TABLE ... ALGORITHM=INPLACE`. It is not supported for `ALTER TABLE ... ALGORITHM=COPY`.

### Foreign Key Checks

Foreign key checking is controlled by the `foreign_key_checks` variable, which is enabled by default. Typically, you leave this variable enabled during normal operation to enforce referential integrity. Beginning with MySQL NDB Cluster 7.3.2, the `foreign_key_checks` variable has the same effect on NDB tables as it does for InnoDB tables. Previously, the setting was ignored for NDB tables and all such checks were enforced (Bug #14095855).

The `foreign_key_checks` variable is dynamic and supports both global and session scopes. For information about using system variables, see Section 5.1.8, “Using System Variables”.

Disabling foreign key checking is useful when:

- Dropping a table that is referenced by a foreign key constraint. A referenced table can only be dropped after `foreign_key_checks` is disabled. When you drop a table, constraints defined on the table are also dropped.

- Reloading tables in different order than required by their foreign key relationships. For example, `mysqldump` produces correct definitions of tables in the dump file, including foreign key constraints for child tables. To make it easier to reload dump files for tables with foreign key relationships, `mysqldump` automatically includes a statement in the dump output that disables `foreign_key_checks`. This enables you to import the tables in any order in case the dump file contains tables that are not correctly ordered for foreign keys. Disabling `foreign_key_checks` also speeds up the import operation by avoiding foreign key checks.

- Executing `LOAD DATA` operations, to avoid foreign key checking.
CREATE TABLE Statement

• Performing an `ALTER TABLE` operation on a table that has a foreign key relationship.

When `foreign_key_checks` is disabled, foreign key constraints are ignored, with the following exceptions:

• Recreating a table that was previously dropped returns an error if the table definition does not
  conform to the foreign key constraints that reference the table. The table must have the correct
  column names and types. It must also have indexes on the referenced keys. If these requirements
  are not satisfied, MySQL returns Error 1005 that refers to errno: 150 in the error message, which
  means that a foreign key constraint was not correctly formed.

• Altering a table returns an error (errno: 150) if a foreign key definition is incorrectly formed for the
  altered table.

• Dropping an index required by a foreign key constraint. The foreign key constraint must be removed
  before dropping the index.

• Creating a foreign key constraint where a column references a nonmatching column type.

Disabling `foreign_key_checks` has these additional implications:

• It is permitted to drop a database that contains tables with foreign keys that are referenced by tables
  outside the database.

• It is permitted to drop a table with foreign keys referenced by other tables.

• Enabling `foreign_key_checks` does not trigger a scan of table data, which means that rows
  added to a table while `foreign_key_checks` is disabled are not checked for consistency when
  `foreign_key_checks` is re-enabled.

Foreign Key Definitions and Metadata

To view a foreign key definition, use `SHOW CREATE TABLE`:

```
mysql> SHOW CREATE TABLE child\G
*************************** 1. row ***************************
 Table: child
 Create Table: CREATE TABLE `child` (  `id` int(11) DEFAULT NULL,
 `parent_id` int(11) DEFAULT NULL,
 KEY `par_ind` (`parent_id`),
 CONSTRAINT `child_ibfk_1` FOREIGN KEY (`parent_id`)
 REFERENCES `parent` (`id`) ON DELETE CASCADE
 ) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

You can obtain information about foreign keys from the `INFORMATION_SCHEMA.KEY_COLUMN_USAGE`
table. An example of a query against this table is shown here:

```
mysql> SELECT TABLE_SCHEMA, TABLE_NAME, COLUMN_NAME, CONSTRAINT_NAME
 FROM INFORMATION_SCHEMA.KEY_COLUMN_USAGE
 WHERE REFERENCED_TABLE_SCHEMA IS NOT NULL;
+--------------+------------+-------------+-----------------+
<table>
<thead>
<tr>
<th>TABLE_SCHEMA</th>
<th>TABLE_NAME</th>
<th>COLUMN_NAME</th>
<th>CONSTRAINT_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>test</td>
<td>child</td>
<td>parent_id</td>
<td>child_ibfk_1</td>
</tr>
</tbody>
</table>
+--------------+------------+-------------+-----------------+
```

You can obtain information specific to InnoDB foreign keys from the `INNODB_SYS_FOREIGN` and
`INNODB_SYS_FOREIGN_COLS` tables. Example queries are show here:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN \G
*************************** 1. row ***************************
 ID: test/child_ibfk_1
 FOR_NAME: test/child
 REF_NAME: test/parent
```
CREATE TABLE Statement
N_COLS: 1
TYPE: 1
mysql>
SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN_COLS
G
*************************** 1. row ***************************
ID: test/child_ibfk_1
FOR_COL_NAME: parent_id
REF_COL_NAME: id
POS: 0

Foreign Key Errors

In the event of a foreign key error involving InnoDB tables (usually Error 150 in the MySQL Server), information about the latest foreign key error can be obtained by checking SHOW ENGINE INNODB STATUS output.

mysql> SHOW ENGINE INNODB STATUS\G
...

### 13.1.17.6 Silent Column Specification Changes

In some cases, MySQL silently changes column specifications from those given in a `CREATE TABLE` or `ALTER TABLE` statement. These might be changes to a data type, to attributes associated with a data type, or to an index specification.

All changes are subject to the internal row-size limit of 65,535 bytes, which may cause some attempts at data type changes to fail. See Section 8.4.7, “Limits on Table Column Count and Row Size”.

- Columns that are part of a `PRIMARY KEY` are made `NOT NULL` even if not declared that way.
- Trailing spaces are automatically deleted from `ENUM` and `SET` member values when the table is created.
- MySQL maps certain data types used by other SQL database vendors to MySQL types. See Section 11.8, “Using Data Types from Other Database Engines”.
- If you include a `USING` clause to specify an index type that is not permitted for a given storage engine, but there is another index type available that the engine can use without affecting query results, the engine uses the available type.
- If strict SQL mode is not enabled, a `VARCHAR` column with a length specification greater than 65535 is converted to `TEXT`, and a `VARBINARY` column with a length specification greater than 65535 is converted to `BLOB`. Otherwise, an error occurs in either of these cases.
- Specifying the `CHARACTER SET binary` attribute for a character data type causes the column to be created as the corresponding binary data type: `CHAR` becomes `BINARY`, `VARCHAR` becomes `VARBINARY`, and `TEXT` becomes `BLOB`. For the `ENUM` and `SET` data types, this does not occur; they are created as declared. Suppose that you specify a table using this definition:

```sql
CREATE TABLE t
  (  
c1 VARCHAR(10) CHARACTER SET binary,
  c2 TEXT CHARACTER SET binary,
  c3 ENUM('a','b','c') CHARACTER SET binary
 );
```

The resulting table has this definition:

```sql
CREATE TABLE t
  (  
c1 VARBINARY(10),
  c2 BLOB,
  c3 ENUM('a','b','c') CHARACTER SET binary
 );
```

To see whether MySQL used a data type other than the one you specified, issue a `DESCRIBE` or `SHOW CREATE TABLE` statement after creating or altering the table.

Certain other data type changes can occur if you compress a table using `myisampack`. See Section 15.2.3.3, “Compressed Table Characteristics”.

### 13.1.18 CREATE TABLESPACE Statement

```sql
CREATE TABLESPACE tablespace_name
  ADD DATAFILE 'file_name'
```
CREATE TABLESPACE Statement

USE LOGFILE GROUP logfile_group
[EXTENT_SIZE [=] extent_size]
[INITIAL_SIZE [=] initial_size]
[AUTOEXTEND_SIZE [=] autoextend_size]
[MAX_SIZE [=] max_size]
[NODEGROUP [=] nodegroup_id]
[WAIT]
[COMMENT [=] comment_text]
ENGINE [=] engine_name

This statement is used to create a tablespace, which can contain one or more data files, providing storage space for tables. One data file is created and added to the tablespace using this statement. Additional data files may be added to the tablespace by using the ALTER TABLESPACE statement (see Section 13.1.8, “ALTER TABLESPACE Statement”). For rules covering the naming of tablespaces, see Section 9.2, “Schema Object Names”.

Note

All NDB Cluster Disk Data objects share the same namespace. This means that each Disk Data object must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group with the same name, or a tablespace and a data file with the same name.

A log file group of one or more UNDO log files must be assigned to the tablespace to be created with the USE LOGFILE GROUP clause. logfile_group must be an existing log file group created with CREATE LOGFILE GROUP (see Section 13.1.14, “CREATE LOGFILE GROUP Statement”). Multiple tablespaces may use the same log file group for UNDO logging.

The EXTENT_SIZE sets the size, in bytes, of the extents used by any files belonging to the tablespace. The default value is 1M. The minimum size is 32K, and theoretical maximum is 2G, although the practical maximum size depends on a number of factors. In most cases, changing the extent size does not have any measurable effect on performance, and the default value is recommended for all but the most unusual situations.

An extent is a unit of disk space allocation. One extent is filled with as much data as that extent can contain before another extent is used. In theory, up to 65,535 (64K) extents may be used per data file; however, the recommended maximum is 32,768 (32K). The recommended maximum size for a single data file is 32G—that is, 32K extents × 1 MB per extent. In addition, once an extent is allocated to a given partition, it cannot be used to store data from a different partition; an extent cannot store data from more than one partition. This means, for example that a tablespace having a single datafile whose INITIAL_SIZE is 256 MB and whose EXTENT_SIZE is 128M has just two extents, and so can be used to store data from at most two different disk data table partitions.

You can see how many extents remain free in a given data file by querying the INFORMATION_SCHEMA.FILES table, and so derive an estimate for how much space remains free in the file. For further discussion and examples, see Section 21.31.1, “The INFORMATION_SCHEMA FILES Table”.

The INITIAL_SIZE parameter sets the data file’s total size in bytes. Once the file has been created, its size cannot be changed; however, you can add more data files to the tablespace using ALTER TABLESPACE ... ADD DATAFILE. See Section 13.1.8, “ALTER TABLESPACE Statement”.

INITIAL_SIZE is optional; its default value is 134217728 (128 MB).

On 32-bit systems, the maximum supported value for INITIAL_SIZE is 4294967296 (4 GB). (Bug #29186)

When setting EXTENT_SIZE, you may optionally follow the number with a one-letter abbreviation for an order of magnitude, similar to those used in my.cnf. Generally, this is one of the letters M (for megabytes) or G (for gigabytes). In MySQL NDB Cluster 7.3.2 and later, these abbreviations are also supported when specifying INITIAL_SIZE as well. (Bug #13116514, Bug #16104705, Bug #62858)
CREATE TRIGGER Statement

INITIAL_SIZE, EXTENT_SIZE, and UNDO_BUFFER_SIZE are subject to rounding as follows:

- EXTENT_SIZE and UNDO_BUFFER_SIZE are each rounded up to the nearest whole multiple of 32K.
- INITIAL_SIZE is rounded down to the nearest whole multiple of 32K.

For data files, INITIAL_SIZE is subject to further rounding; the result just obtained is rounded up to the nearest whole multiple of EXTENT_SIZE (after any rounding).

The rounding just described is done explicitly, and a warning is issued by the MySQL Server when any such rounding is performed. The rounded values are also used by the NDB kernel for calculating INFORMATION_SCHEMA.FILES column values and other purposes. However, to avoid an unexpected result, we suggest that you always use whole multiples of 32K in specifying these options.

AUTOEXTEND_SIZE, MAX_SIZE, NODEGROUP, WAIT, and COMMENT are parsed but ignored, and so currently have no effect. These options are intended for future expansion.

The ENGINE parameter determines the storage engine which uses this tablespace, with engine_name being the name of the storage engine. Currently, engine_name must be one of the values NDB or NDBCLUSTER.

When CREATE TABLESPACE is used with ENGINE = NDB, a tablespace and associated data file are created on each Cluster data node. You can verify that the data files were created and obtain information about them by querying the INFORMATION_SCHEMA.FILES table. For example:

```sql
mysql> SELECT LOGFILE_GROUP_NAME, FILE_NAME, EXTRA
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE TABLESPACE_NAME = 'newts' AND FILE_TYPE = 'DATAFILE';
+--------------------+-------------+----------------+
| LOGFILE_GROUP_NAME | FILE_NAME   | EXTRA          |
| lg_3               | newdata.dat | CLUSTER_NODE=3 |
| lg_3               | newdata.dat | CLUSTER_NODE=4 |
+--------------------+-------------+----------------+
2 rows in set (0.01 sec)
```

(See Section 21.31.1, “The INFORMATION_SCHEMA FILES Table”.)

CREATE TABLESPACE is useful only with Disk Data storage for NDB Cluster. See Section 18.5.10, “NDB Cluster Disk Data Tables”.

13.1.19 CREATE TRIGGER Statement

```sql
CREATE [DEFINER = user]
TRIGGER trigger_name
trigger_time trigger_event
ON tbl_name FOR EACH ROW
trigger_body
```

trigger_time: { BEFORE | AFTER }

trigger_event: { INSERT | UPDATE | DELETE }

This statement creates a new trigger. A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. The trigger becomes associated with the table named tbl_name, which must refer to a permanent table. You cannot associate a trigger with a TEMPORARY table or a view.

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

This section describes CREATE TRIGGER syntax. For additional discussion, see Section 20.3.1, “Trigger Syntax and Examples”.

1570
CREATE TRIGGER requires the TRIGGER privilege for the table associated with the trigger. If the DEFINER clause is present, the privileges required depend on the user value, as discussed in Section 20.6, “Stored Object Access Control”. If binary logging is enabled, CREATE TRIGGER might require the SUPER privilege, as discussed in Section 20.7, “Stored Program Binary Logging”.

The DEFINER clause determines the security context to be used when checking access privileges at trigger activation time, as described later in this section.

trigger_time is the trigger action time. It can be BEFORE or AFTER to indicate that the trigger activates before or after each row to be modified.

Basic column value checks occur prior to trigger activation, so you cannot use BEFORE triggers to convert values inappropriate for the column type to valid values.

trigger_event indicates the kind of operation that activates the trigger. These trigger_event values are permitted:

- **INSERT**: The trigger activates whenever a new row is inserted into the table (for example, through INSERT, LOAD DATA, and REPLACE statements).
- **UPDATE**: The trigger activates whenever a row is modified (for example, through UPDATE statements).
- **DELETE**: The trigger activates whenever a row is deleted from the table (for example, through DELETE and REPLACE statements). DROP TABLE and TRUNCATE TABLE statements on the table do not activate this trigger, because they do not use DELETE. Dropping a partition does not activate DELETE triggers, either.

The trigger_event does not represent a literal type of SQL statement that activates the trigger so much as it represents a type of table operation. For example, an INSERT trigger activates not only for INSERT statements but also LOAD DATA statements because both statements insert rows into a table.

A potentially confusing example of this is the INSERT INTO … ON DUPLICATE KEY UPDATE … syntax: a BEFORE INSERT trigger activates for every row, followed by either an AFTER INSERT trigger or both the BEFORE UPDATE and AFTER UPDATE triggers, depending on whether there was a duplicate key for the row.

**Note**

Cascaded foreign key actions do not activate triggers.

There cannot be multiple triggers for a given table that have the same trigger event and action time. For example, you cannot have two BEFORE UPDATE triggers for a table. But you can have a BEFORE UPDATE and a BEFORE INSERT trigger, or a BEFORE UPDATE and an AFTER UPDATE trigger.

trigger_body is the statement to execute when the trigger activates. To execute multiple statements, use the BEGIN ... END compound statement construct. This also enables you to use the same statements that are permissible within stored routines. See Section 13.6.1, “BEGIN ... END Compound Statement”. Some statements are not permitted in triggers; see Section 20.8, “Restrictions on Stored Programs”.

Within the trigger body, you can refer to columns in the subject table (the table associated with the trigger) by using the aliases OLD and NEW. OLD.col_name refers to a column of an existing row before it is updated or deleted. NEW.col_name refers to the column of a new row to be inserted or an existing row after it is updated.

MySQL stores the sql_mode system variable setting in effect when a trigger is created, and always executes the trigger body with this setting in force, regardless of the current server SQL mode when the trigger begins executing.
The **DEFINER** clause specifies the MySQL account to be used when checking access privileges at trigger activation time. If the **DEFINER** clause is present, the *user* value should be a MySQL account specified as `'user_name'@'host_name'`, `CURRENT_USER`, or `CURRENT_USER()`. The permitted *user* values depend on the privileges you hold, as discussed in Section 20.6, “Stored Object Access Control”. Also see that section for additional information about trigger security.

If the **DEFINER** clause is omitted, the default definer is the user who executes the CREATE TRIGGER statement. This is the same as specifying **DEFINER = CURRENT_USER** explicitly.

MySQL takes the **DEFINER** user into account when checking trigger privileges as follows:

- At **CREATE TRIGGER** time, the user who issues the statement must have the **TRIGGER** privilege.
- At trigger activation time, privileges are checked against the **DEFINER** user. This user must have these privileges:
  - The **TRIGGER** privilege for the subject table.
  - The **SELECT** privilege for the subject table if references to table columns occur using `OLD.col_name` or `NEW.col_name` in the trigger body.
  - The **UPDATE** privilege for the subject table if table columns are targets of `SET NEW.col_name = value` assignments in the trigger body.
  - Whatever other privileges normally are required for the statements executed by the trigger.

Within a trigger body, the **CURRENT_USER** function returns the account used to check privileges at trigger activation time. This is the **DEFINER** user, not the user whose actions caused the trigger to be activated. For information about user auditing within triggers, see Section 6.2.15, “SQL-Based Account Activity Auditing”.

If you use **LOCK TABLES** to lock a table that has triggers, the tables used within the trigger are also locked, as described in **LOCK TABLES and Triggers**.

For additional discussion of trigger use, see Section 20.3.1, “Trigger Syntax and Examples”.

### 13.1.20 CREATE VIEW Statement

```
CREATE [OR REPLACE]
[ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
[DEFINER = user]
[SQL SECURITY { DEFINER | INVOKER }]
VIEW view_name [(column_list)]
AS select_statement
[WITH [CASCADED | LOCAL] CHECK OPTION]
```

The **CREATE VIEW** statement creates a new view, or replaces an existing view if the **OR REPLACE** clause is given. If the view does not exist, **CREATE OR REPLACE VIEW** is the same as **CREATE VIEW**. If the view does exist, **CREATE OR REPLACE VIEW** replaces it.

For information about restrictions on view use, see Section 20.9, “Restrictions on Views”.

The **select_statement** is a **SELECT** statement that provides the definition of the view. (Selecting from the view selects, in effect, using the **SELECT** statement.) The **select_statement** can select from base tables or other views.

The view definition is “frozen” at creation time and is not affected by subsequent changes to the definitions of the underlying tables. For example, if a view is defined as **SELECT * on a table**, new columns added to the table later do not become part of the view, and columns dropped from the table will result in an error when selecting from the view.
CREATE VIEW Statement

The `ALGORITHM` clause affects how MySQL processes the view. The `DEFINER` and `SQL SECURITY` clauses specify the security context to be used when checking access privileges at view invocation time. The `WITH CHECK OPTION` clause can be given to constrain inserts or updates to rows in tables referenced by the view. These clauses are described later in this section.

The `CREATE VIEW` statement requires the `CREATE VIEW` privilege for the view, and some privilege for each column selected by the `SELECT` statement. For columns used elsewhere in the `SELECT` statement, you must have the `SELECT` privilege. If the `OR REPLACE` clause is present, you must also have the `DROP` privilege for the view. If the `DEFINER` clause is present, the privileges required depend on the `user` value, as discussed in Section 20.6, “Stored Object Access Control”.

When a view is referenced, privilege checking occurs as described later in this section.

A view belongs to a database. By default, a new view is created in the default database. To create the view explicitly in a given database, use `db_name.view_name` syntax to qualify the view name with the database name:

```
CREATE VIEW test.v AS SELECT * FROM t;
```

Unqualified table or view names in the `SELECT` statement are also interpreted with respect to the default database. A view can refer to tables or views in other databases by qualifying the table or view name with the appropriate database name.

Within a database, base tables and views share the same namespace, so a base table and a view cannot have the same name.

Columns retrieved by the `SELECT` statement can be simple references to table columns, or expressions that use functions, constant values, operators, and so forth.

A view must have unique column names with no duplicates, just like a base table. By default, the names of the columns retrieved by the `SELECT` statement are used for the view column names. To define explicit names for the view columns, specify the optional `column_list` clause as a list of comma-separated identifiers. The number of names in `column_list` must be the same as the number of columns retrieved by the `SELECT` statement.

A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables:

```
CREATE VIEW v_today (today) AS SELECT CURRENT_DATE;
```

The following example defines a view that selects two columns from another table as well as an expression calculated from those columns:

```
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+-----+-------+-------+
<table>
<thead>
<tr>
<th>qty</th>
<th>price</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>50</td>
<td>150</td>
</tr>
</tbody>
</table>
```

A view definition is subject to the following restrictions:

- The `SELECT` statement cannot contain a subquery in the `FROM` clause.
- The `SELECT` statement cannot refer to system variables or user-defined variables.
- Within a stored program, the `SELECT` statement cannot refer to program parameters or local variables.
- The `SELECT` statement cannot refer to prepared statement parameters.
CREATE VIEW Statement

- Any table or view referred to in the definition must exist. If, after the view has been created, a table or view that the definition refers to is dropped, use of the view results in an error. To check a view definition for problems of this kind, use the `CHECK TABLE` statement.

- The definition cannot refer to a `TEMPORARY` table, and you cannot create a `TEMPORARY` view.

- You cannot associate a trigger with a view.

- Aliases for column names in the `SELECT` statement are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters).

`ORDER BY` is permitted in a view definition, but it is ignored if you select from a view using a statement that has its own `ORDER BY` or filtering or grouping. When `ORDER BY` is combined with `LIMIT` or `OFFSET` in a view definition, the ordering is always enforced before the query result is used by the outer query, but it does not guarantee that the same ordering is used in the end result. As a workaround, add an `ORDER BY` clause to the outer query.

For other options or clauses in the definition, they are added to the options or clauses of the statement that references the view, but the effect is undefined. For example, if a view definition includes a `LIMIT` clause, and you select from the view using a statement that has its own `LIMIT` clause, it is undefined which limit applies. This same principle applies to options such as `ALL`, `DISTINCT`, or `SQL_SMALL_RESULT` that follow the `SELECT` keyword, and to clauses such as `INTO`, `FOR UPDATE`, `LOCK IN SHARE MODE`, and `PROCEDURE`.

The results obtained from a view may be affected if you change the query processing environment by changing system variables:

```sql
mysql> CREATE VIEW v (mycol) AS SELECT 'abc';
Query OK, 0 rows affected (0.01 sec)

mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT "mycol" FROM v;
+-------+
| mycol |
+-------+
1 row in set (0.01 sec)

mysql> SET sql_mode = 'ANSI_QUOTES';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT "mycol" FROM v;
+-------+
| abc   |
+-------+
1 row in set (0.00 sec)
```

The `DEFINER` and `SQL SECURITY` clauses determine which MySQL account to use when checking access privileges for the view when a statement is executed that references the view. The valid `SQL SECURITY` characteristic values are `DEFINER` (the default) and `INVOKER`. These indicate that the required privileges must be held by the user who defined or invoked the view, respectively.

If the `DEFINER` clause is present, the `user` value should be a MySQL account specified as `user_name@host_name`, `CURRENT_USER`, or `CURRENT_USER()`. The permitted `user` values depend on the privileges you hold, as discussed in Section 20.6, “Stored Object Access Control”. Also see that section for additional information about view security.

If the `DEFINER` clause is omitted, the default definer is the user who executes the `CREATE VIEW` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.
Within a view definition, the CURRENT_USER function returns the view's DEFINER value by default. For views defined with the SQL SECURITY INVOKER characteristic, CURRENT_USER returns the account for the view's invoker. For information about user auditing within views, see Section 6.2.15, “SQL-Based Account Activity Auditing”.

Within a stored routine that is defined with the SQL SECURITY DEFINER characteristic, CURRENT_USER returns the routine's DEFINER value. This also affects a view defined within such a routine, if the view definition contains a DEFINER value of CURRENT_USER.

MySQL checks view privileges like this:

- At view definition time, the view creator must have the privileges needed to use the top-level objects accessed by the view. For example, if the view definition refers to table columns, the creator must have some privilege for each column in the select list of the definition, and the SELECT privilege for each column used elsewhere in the definition. If the definition refers to a stored function, only the privileges needed to invoke the function can be checked. The privileges required at function invocation time can be checked only as it executes: For different invocations, different execution paths within the function might be taken.

- The user who references a view must have appropriate privileges to access it (SELECT to select from it, INSERT to insert into it, and so forth.)

- When a view has been referenced, privileges for objects accessed by the view are checked against the privileges held by the view DEFINER account or invoker, depending on whether the SQL SECURITY characteristic is DEFINER or INVOKER, respectively.

- If reference to a view causes execution of a stored function, privilege checking for statements executed within the function depend on whether the function SQL SECURITY characteristic is DEFINER or INVOKER. If the security characteristic is DEFINER, the function runs with the privileges determined by the view's SQL SECURITY characteristic.

Example: A view might depend on a stored function, and that function might invoke other stored routines. For example, the following view invokes a stored function f():

```
CREATE VIEW v AS SELECT * FROM t WHERE t.id = f(t.name);
```

Suppose that f() contains a statement such as this:

```sql
IF name IS NULL then
    CALL p1();
ELSE
    CALL p2();
END IF;
```

The privileges required for executing statements within f() need to be checked when f() executes. This might mean that privileges are needed for p1() or p2(), depending on the execution path within f(). Those privileges must be checked at runtime, and the user who must possess the privileges is determined by the SQL SECURITY values of the view v and the function f().

The DEFINER and SQL SECURITY clauses for views are extensions to standard SQL. In standard SQL, views are handled using the rules for SQL SECURITY DEFINER. The standard says that the definer of the view, which is the same as the owner of the view's schema, gets applicable privileges on the view (for example, SELECT) and may grant them. MySQL has no concept of a schema “owner”, so MySQL adds a clause to identify the definer. The DEFINER clause is an extension where the intent is to have what the standard has; that is, a permanent record of who defined the view. This is why the default DEFINER value is the account of the view creator.

The optional ALGORITHM clause is a MySQL extension to standard SQL. It affects how MySQL processes the view. ALGORITHM takes three values: MERGE, TEMPTABLE, or UNDEFINED. The default algorithm is UNDEFINED if no ALGORITHM clause is present. For more information, see Section 20.5.2, “View Processing Algorithms”, as well as Section 8.2.2.4, “Optimizing Derived Tables”.

1575
Some views are updatable. That is, you can use them in statements such as UPDATE, DELETE, or INSERT to update the contents of the underlying table. For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view nonupdatable.

The WITH CHECK OPTION clause can be given for an updatable view to prevent inserts or updates to rows except those for which the WHERE clause in the select_statement is true.

In a WITH CHECK OPTION clause for an updatable view, the LOCAL and CASCADED keywords determine the scope of check testing when the view is defined in terms of another view. The LOCAL keyword restricts the CHECK OPTION only to the view being defined. CASCADED causes the checks for underlying views to be evaluated as well. When neither keyword is given, the default is CASCADED.

For more information about updatable views and the WITH CHECK OPTION clause, see Section 20.5.3, “Updatable and Insertable Views”, and Section 20.5.4, “The View WITH CHECK OPTION Clause”.

13.1.21 DROP DATABASE Statement

```
DROP {DATABASE | SCHEMA} [IF EXISTS] db_name
```

DROP DATABASE drops all tables in the database and deletes the database. Be very careful with this statement! To use DROP DATABASE, you need the DROP privilege on the database. DROP SCHEMA is a synonym for DROP DATABASE.

Important

When a database is dropped, privileges granted specifically for the database are not automatically dropped. They must be dropped manually. See Section 13.7.1.4, “GRANT Statement”.

IF EXISTS is used to prevent an error from occurring if the database does not exist.

If the default database is dropped, the default database is unset (the DATABASE() function returns NULL).

If you use DROP DATABASE on a symbolically linked database, both the link and the original database are deleted.

DROP DATABASE returns the number of tables that were removed. This corresponds to the number of .frm files removed.

The DROP DATABASE statement removes from the given database directory those files and directories that MySQL itself may create during normal operation:

- All files with the following extensions:
  - .frm
  - .BAK
  - .DAT
  - .HSH
  - .MRG
  - .MYD
  - .MYI
  - .TRG
DROP EVENT Statement

- `.TRN`
- `.db`
- `.ibd`
- `.ndb`
- `.par`
- The `db.opt` file, if it exists.

If other files or directories remain in the database directory after MySQL removes those just listed, the database directory cannot be removed. In this case, you must remove any remaining files or directories manually and issue the `DROP DATABASE` statement again.

Dropping a database does not remove any `TEMPORARY` tables that were created in that database. `TEMPORARY` tables are automatically removed when the session that created them ends. See Section 13.1.17.2, “CREATE TEMPORARY TABLE Statement”.

You can also drop databases with `mysqladmin`. See Section 4.5.2, “mysqladmin — A MySQL Server Administration Program”.

13.1.22 DROP EVENT Statement

```sql
DROP EVENT [IF EXISTS] event_name
```

This statement drops the event named `event_name`. The event immediately ceases being active, and is deleted completely from the server.

If the event does not exist, the error `ERROR 1517 (HY000): Unknown event 'event_name'` results. You can override this and cause the statement to generate a warning for nonexistent events instead using `IF EXISTS`.

This statement requires the `EVENT` privilege for the schema to which the event to be dropped belongs.

13.1.23 DROP FUNCTION Statement

The `DROP FUNCTION` statement is used to drop stored functions and user-defined functions (UDFs):

- For information about dropping stored functions, see Section 13.1.26, “DROP PROCEDURE and DROP FUNCTION Statements”.
- For information about dropping user-defined functions, see Section 13.7.3.2, “DROP FUNCTION Statement for User-Defined Functions”.

13.1.24 DROP INDEX Statement

```sql
DROP INDEX [ONLINE | OFFLINE] index_name ON tbl_name
   [algorithm_option | lock_option] ... 
```

- `algorithm_option`:
  - `ALGORITHM [=] {DEFAULT | INPLACE | COPY}`

- `lock_option`:
  - `LOCK [=] {DEFAULT | NONE | SHARED | EXCLUSIVE}`

`DROP INDEX` drops the index named `index_name` from the table `tbl_name`. This statement is mapped to an `ALTER TABLE` statement to drop the index. See Section 13.1.7, “ALTER TABLE Statement”.
To drop a primary key, the index name is always `PRIMARY`, which must be specified as a quoted identifier because `PRIMARY` is a reserved word:

```
DROP INDEX 'PRIMARY' ON t;
```

Indexes on variable-width columns of NDB tables are dropped online; that is, without any table copying. The table is not locked against access from other NDB Cluster API nodes, although it is locked against other operations on the same API node for the duration of the operation. This is done automatically by the server whenever it determines that it is possible to do so; you do not have to use any special SQL syntax or server options to cause it to happen.

In NDB Cluster, you can drop indexes offline (which causes the table to be locked for all API nodes in the cluster) using the `OFFLINE` keyword. The rules and limitations governing `DROP OFFLINE INDEX` and `DROP ONLINE INDEX` are the same as for `ALTER OFFLINE TABLE ... DROP INDEX` and `ALTER ONLINE TABLE ... DROP INDEX`. You cannot cause the noncopying dropping of an index that would normally be dropped offline by using the `ONLINE` keyword: If it is not possible to perform the `DROP` operation without table copying, the server ignores the `ONLINE` keyword. For more information, see Section 18.5.11, “Online Operations with ALTER TABLE in NDB Cluster”.

The `ONLINE` and `OFFLINE` keywords are available only in NDB Cluster; attempting to use these keywords in standard MySQL Server 5.6 releases results in a syntax error. The `ONLINE` and `OFFLINE` keywords are deprecated in MySQL NDB Cluster 7.4; they continue to be supported in MySQL NDB Cluster 7.3, but are scheduled for removal in a future NDB Cluster release.

`ALGORITHM` and `LOCK` clauses may be given to influence the table copying method and level of concurrency for reading and writing the table while its indexes are being modified. They have the same meaning as for the `ALTER TABLE` statement. For more information, see Section 13.1.7, “ALTER TABLE Statement”

### 13.1.25 DROP LOGFILE GROUP Statement

```
DROP LOGFILE GROUP logfile_group
    ENGINE [=] engine_name
```

This statement drops the log file group named `logfile_group`. The log file group must already exist or an error results. (For information on creating log file groups, see Section 13.1.14, “CREATE LOGFILE GROUP Statement”.)

**Important**

Before dropping a log file group, you must drop all tablespaces that use that log file group for UNDO logging.

The required `ENGINE` clause provides the name of the storage engine used by the log file group to be dropped. Currently, the only permitted values for `engine_name` are `NDB` and `NDBCLUSTER`.

`DROP LOGFILE GROUP` is useful only with Disk Data storage for NDB Cluster. See Section 18.5.10, “NDB Cluster Disk Data Tables”.

### 13.1.26 DROP PROCEDURE and DROP FUNCTION Statements

```
DROP {PROCEDURE | FUNCTION} [IF EXISTS] sp_name
```

These statements are used to drop a stored routine (a stored procedure or function). That is, the specified routine is removed from the server. (`DROP FUNCTION` is also used to drop user-defined functions; see Section 13.7.3.2, “DROP FUNCTION Statement for User-Defined Functions”.)

To drop a stored routine, you must have the `ALTER ROUTINE` privilege for it. (If the `automatic_sp_privileges` system variable is enabled, that privilege and `EXECUTE` are granted automatically to the routine creator when the routine is created and dropped from the creator when the routine is dropped. See Section 20.2.2, “Stored Routines and MySQL Privileges”.)
The `IF EXISTS` clause is a MySQL extension. It prevents an error from occurring if the procedure or function does not exist. A warning is produced that can be viewed with `SHOW WARNINGS`.

`DROP FUNCTION` is also used to drop user-defined functions (see Section 13.7.3.2, “DROP FUNCTION Statement for User-Defined Functions”).

### 13.1.27 DROP SERVER Statement

```sql
DROP SERVER [ IF EXISTS ] server_name
```

Drops the server definition for the server named `server_name`. The corresponding row in the `mysql.servers` table is deleted. This statement requires the `SUPER` privilege.

Dropping a server for a table does not affect any `FEDERATED` tables that used this connection information when they were created. See Section 13.1.16, “CREATE SERVER Statement”.

`DROP SERVER` causes an implicit commit. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

`DROP SERVER` is not written to the binary log, regardless of the logging format that is in use.

In MySQL 5.6.11 only, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. (Bug #16062608, Bug #16715809, Bug #69045)

### 13.1.28 DROP TABLE Statement

```sql
DROP [TEMPORARY] TABLE [IF EXISTS] tbl_name [, tbl_name] ...
[RESTRIC | CASCADE]
```

`DROP TABLE` removes one or more tables. You must have the `DROP` privilege for each table.

*Be careful* with this statement! For each table, it removes the table definition and all table data. If the table is partitioned, the statement removes the table definition, all its partitions, all data stored in those partitions, and all partition definitions associated with the dropped table.

Dropping a table also drops any triggers for the table.

`DROP TABLE` causes an implicit commit, except when used with the `TEMPORARY` keyword. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

---

**Important**

When a table is dropped, privileges granted specifically for the table are *not* automatically dropped. They must be dropped manually. See Section 13.7.1.4, “GRANT Statement”.

If any tables named in the argument list do not exist, `DROP TABLE` behavior depends on whether the `IF EXISTS` clause is given:

- Without `IF EXISTS`, the statement drops all named tables that do exist, and returns an error indicating which nonexisting tables it was unable to drop.

- With `IF EXISTS`, no error occurs for nonexisting tables. The statement drops all named tables that do exist, and generates a `NOTE` diagnostic for each nonexistent table. These notes can be displayed with `SHOW WARNINGS`. See Section 13.7.5.41, “SHOW WARNINGS Statement”.

`IF EXISTS` can also be useful for dropping tables in unusual circumstances under which there is an `.frm` file but no table managed by the storage engine. (For example, if an abnormal server exit occurs after removal of the table from the storage engine but before `.frm` file removal.)

The `TEMPORARY` keyword has the following effects:
• The statement drops only **TEMPORARY** tables.

• The statement does not cause an implicit commit.

• No access rights are checked. A **TEMPORARY** table is visible only with the session that created it, so no check is necessary.

Including the **TEMPORARY** keyword is a good way to prevent accidentally dropping non-**TEMPORARY** tables.

The **RESTRICT** and **CASCADE** keywords do nothing. They are permitted to make porting easier from other database systems.

**DROP TABLE** is not supported with all **innodb_force_recovery** settings. See Section 14.21.2, “Forcing InnoDB Recovery”.

### 13.1.29 DROP TABLESPACE Statement

```sql
DROP TABLESPACE tablespace_name
  ENGINE [=] engine_name
```

This statement drops a tablespace that was previously created using **CREATE TABLESPACE** (see Section 13.1.18, “CREATE TABLESPACE Statement”).

**Important**

The tablespace to be dropped must not contain any data files; in other words, before you can drop a tablespace, you must first drop each of its data files using **ALTER TABLESPACE ... DROP DATAFILE** (see Section 13.1.8, “ALTER TABLESPACE Statement”).

The **ENGINE** clause (required) specifies the storage engine used by the tablespace. Currently, the only accepted values for **engine_name** are **NDB** and **NDBCLUSTER**.

**DROP TABLESPACE** is useful only with Disk Data storage for NDB Cluster. See Section 18.5.10, “NDB Cluster Disk Data Tables”.

### 13.1.30 DROP TRIGGER Statement

```sql
DROP TRIGGER [IF EXISTS] [schema_name.]trigger_name
```

This statement drops a trigger. The schema (database) name is optional. If the schema is omitted, the trigger is dropped from the default schema. **DROP TRIGGER** requires the **TRIGGER** privilege for the table associated with the trigger.

Use **IF EXISTS** to prevent an error from occurring for a trigger that does not exist. A **NOTE** is generated for a nonexistent trigger when using **IF EXISTS**. See Section 13.7.5.41, “SHOW WARNINGS Statement”.

Triggers for a table are also dropped if you drop the table.

### 13.1.31 DROP VIEW Statement

```sql
DROP VIEW [IF EXISTS] [view_name [, view_name] ...]
  [RESTRICT | CASCADE]
```

**DROP VIEW** removes one or more views. You must have the **DROP** privilege for each view.

If any views named in the argument list do not exist, the statement returns an error indicating by name which nonexisting views it was unable to drop, but also drops all views in the list that do exist.
The `IF EXISTS` clause prevents an error from occurring for views that don't exist. When this clause is given, a **NOTE** is generated for each nonexistent view. See Section 13.7.5.41, "SHOW WARNINGS Statement".

RESTRICT and CASCADE, if given, are parsed and ignored.

### 13.1.32 RENAME TABLE Statement

```
RENAME TABLE
  tbl_name TO new_tbl_name
  [, tbl_name2 TO new_tbl_name2] ...
```

`RENAME TABLE` renames one or more tables. You must have **ALTER** and **DROP** privileges for the original table, and **CREATE** and **INSERT** privileges for the new table.

For example, to rename a table named `old_table` to `new_table`, use this statement:

```
RENAME TABLE old_table TO new_table;
```

That statement is equivalent to the following **ALTER TABLE** statement:

```
ALTER TABLE old_table RENAME new_table;
```

`RENAME TABLE`, unlike **ALTER TABLE**, can rename multiple tables within a single statement:

```
RENAME TABLE old_table1 TO new_table1,
  old_table2 TO new_table2,
  old_table3 TO new_table3;
```

Renaming operations are performed left to right. Thus, to swap two table names, do this (assuming that a table with the intermediary name `tmp_table` does not already exist):

```
RENAME TABLE old_table TO tmp_table,
  new_table TO old_table,
  tmp_table TO new_table;
```

metadata locks on tables are acquired in name order, which in some cases can make a difference in operation outcome when multiple transactions execute concurrently. See Section 8.11.4, "Metadata Locking".

To execute `RENAME TABLE`, there must be no active transactions or tables locked with **LOCK TABLES**. With the transaction table locking conditions satisfied, the rename operation is done atomically; no other session can access any of the tables while the rename is in progress.

If any errors occur during a `RENAME TABLE`, the statement fails and no changes are made.

You can use `RENAME TABLE` to move a table from one database to another:

```
RENAME TABLE current_db.tbl_name TO other_db.tbl_name;
```

Using this method to move all tables from one database to a different one in effect renames the database (an operation for which MySQL has no single statement), except that the original database continues to exist, albeit with no tables.

Like `RENAME TABLE`, **ALTER TABLE ... RENAME** can also be used to move a table to a different database. Regardless of the statement used, if the rename operation would move the table to a database located on a different file system, the success of the outcome is platform specific and depends on the underlying operating system calls used to move table files.

If a table has triggers, attempts to rename the table into a different database fail with a **Trigger in wrong schema (ER_TRG_IN_WRONG_SCHEMA)** error.
To rename TEMPORARY tables, RENAME TABLE does not work. Use ALTER TABLE instead.

RENAME TABLE works for views, except that views cannot be renamed into a different database.

Any privileges granted specifically for a renamed table or view are not migrated to the new name. They must be changed manually.

RENAME TABLE tbl_name TO new_tbl_name changes internally generated foreign key constraint names and user-defined foreign key constraint names that begin with the string "tbl_name_ibfk_" to reflect the new table name. InnoDB interprets foreign key constraint names that begin with the string "tbl_name_ibfk_" as internally generated names.

Foreign key constraint names that point to the renamed table are automatically updated unless there is a conflict, in which case the statement fails with an error. A conflict occurs if the renamed constraint name already exists. In such cases, you must drop and re-create the foreign keys for them to function properly.

13.1.33 TRUNCATE TABLE Statement

TRUNCATE [TABLE] tbl_name

TRUNCATE TABLE empties a table completely. It requires the DROP privilege.

Logically, TRUNCATE TABLE is similar to a DELETE statement that deletes all rows, or a sequence of DROP TABLE and CREATE TABLE statements. To achieve high performance, it bypasses the DML method of deleting data. Thus, it cannot be rolled back, it does not cause ON DELETE triggers to fire, and it cannot be performed for InnoDB tables with parent-child foreign key relationships.

Although TRUNCATE TABLE is similar to DELETE, it is classified as a DDL statement rather than a DML statement. It differs from DELETE in the following ways:

• Truncate operations drop and re-create the table, which is much faster than deleting rows one by one, particularly for large tables.

• Truncate operations cause an implicit commit, and so cannot be rolled back. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

• Truncation operations cannot be performed if the session holds an active table lock.

• TRUNCATE TABLE fails for an InnoDB table or NDB table if there are any FOREIGN KEY constraints from other tables that reference the table. Foreign key constraints between columns of the same table are permitted.

• Truncation operations do not return a meaningful value for the number of deleted rows. The usual result is “0 rows affected,” which should be interpreted as “no information.”

• As long as the table format file tbl_name.frm is valid, the table can be re-created as an empty table with TRUNCATE TABLE, even if the data or index files have become corrupted.

• Any AUTO_INCREMENT value is reset to its start value. This is true even for MyISAM and InnoDB, which normally do not reuse sequence values.

• When used with partitioned tables, TRUNCATE TABLE preserves the partitioning; that is, the data and index files are dropped and re-created, while the partition definitions (.par) file is unaffected.

• The TRUNCATE TABLE statement does not invoke ON DELETE triggers.

TRUNCATE TABLE for a table closes all handlers for the table that were opened with HANDLER OPEN.

TRUNCATE TABLE is treated for purposes of binary logging and replication as DROP TABLE followed by CREATE TABLE—that is, as DDL rather than DML. This is due to the fact that, when using
InnoDB and other transactional storage engines where the transaction isolation level does not permit statement-based logging (READ COMMITTED or READ UNCOMMITTED), the statement was not logged and replicated when using STATEMENT or MIXED logging mode. (Bug #36763) However, it is still applied on replicas using InnoDB in the manner described previously.

On a system with a large InnoDB buffer pool and innodb_adaptive_hash_index enabled, TRUNCATE TABLE operations may cause a temporary drop in system performance due to an LRU scan that occurs when removing an InnoDB table’s adaptive hash index entries. The problem was addressed for DROP TABLE in MySQL 5.5.23 (Bug #13704145, Bug #64284) but remains a known issue for TRUNCATE TABLE (Bug #68184).

TRUNCATE TABLE can be used with Performance Schema summary tables, but the effect is to reset the summary columns to 0 or NULL, not to remove rows. See Section 22.12.9, “Performance Schema Summary Tables”.

13.2 Data Manipulation Statements

13.2.1 CALL Statement

CALL sp_name([parameter[,...]])
CALL sp_name()

The CALL statement invokes a stored procedure that was defined previously with CREATE PROCEDURE.

Stored procedures that take no arguments can be invoked without parentheses. That is, CALL p() and CALL p are equivalent.

CALL can pass back values to its caller using parameters that are declared as OUT or INOUT parameters. When the procedure returns, a client program can also obtain the number of rows affected for the final statement executed within the routine: At the SQL level, call the ROW_COUNT() function; from the C API, call the mysql_affected_rows() function.

For information about the effect of unhandled conditions on procedure parameters, see Section 13.6.7.8, “Condition Handling and OUT or INOUT Parameters”.

To get back a value from a procedure using an OUT or INOUT parameter, pass the parameter by means of a user variable, and then check the value of the variable after the procedure returns. (If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an IN or INOUT parameter.) For an INOUT parameter, initialize its value before passing it to the procedure. The following procedure has an OUT parameter that the procedure sets to the current server version, and an INOUT value that the procedure increments by one from its current value:

```
CREATE PROCEDURE p (OUT ver_param VARCHAR(25), INOUT incr_param INT)
BEGIN
    # Set value of OUT parameter
    SELECT VERSION() INTO ver_param;
    # Increment value of INOUT parameter
    SET incr_param = incr_param + 1;
END;
```

Before calling the procedure, initialize the variable to be passed as the INOUT parameter. After calling the procedure, the values of the two variables will have been set or modified:

```
mysql> SET @increment = 10;
mysql> CALL p(@version, @increment);
mysql> SELECT @version, @increment;
+------------------+------------+
| @version         | @increment |
|------------------+------------+
| 5.6.38-debug-log |         11 |
```
In prepared CALL statements used with PREPARE and EXECUTE, placeholders can be used for IN parameters, OUT, and INOUT parameters. These types of parameters can be used as follows:

```
mysql> SET @increment = 10;
mysql> PREPARE s FROM 'CALL p(? , ?)';
mysql> EXECUTE s USING @version, @increment;
```

```
+------------+------------+
| @version   | @increment |
| 5.6.38-debug-log | 11 |
```

To write C programs that use the CALL SQL statement to execute stored procedures that produce result sets, the CLIENT_MULTI_RESULTS flag must be enabled. This is because each CALL returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure. CLIENT_MULTI_RESULTS must also be enabled if CALL is used to execute any stored procedure that contains prepared statements. It cannot be determined when such a procedure is loaded whether those statements will produce result sets, so it is necessary to assume that they will.

CLIENT_MULTI_RESULTS can be enabled when you call mysql_real_connect(), either explicitly by passing the CLIENT_MULTI_RESULTS flag itself, or implicitly by passing CLIENT_MULTI_STATEMENTS (which also enables CLIENT_MULTI_RESULTS).

CLIENT_MULTI_RESULTS is enabled by default.

To process the result of a CALL statement executed using mysql_query() or mysql_real_query(), use a loop that calls mysql_next_result() to determine whether there are more results. For an example, see C API Multiple Statement Execution Support.

C programs can use the prepared-statement interface to execute CALL statements and access OUT and INOUT parameters. This is done by processing the result of a CALL statement using a loop that calls mysql_stmt_next_result() to determine whether there are more results. For an example, see C API Prepared CALL Statement Support. Languages that provide a MySQL interface can use prepared CALL statements to directly retrieve OUT and INOUT procedure parameters.

Metadata changes to objects referred to by stored programs are detected and cause automatic reparsing of the affected statements when the program is next executed. For more information, see Section 8.10.4, “Caching of Prepared Statements and Stored Programs”.

### 13.2.2 DELETE Statement

**DELETE** is a DML statement that removes rows from a table.

#### Single-Table Syntax

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE] FROM tbl_name
    [PARTITION (partition_name [, partition_name] ...)]
    [WHERE where_condition]
    [ORDER BY ...]
    [LIMIT row_count]
```

The **DELETE** statement deletes rows from **tbl_name** and returns the number of deleted rows. To check the number of deleted rows, call the **ROW_COUNT()** function described in Section 12.16, “Information Functions”.

#### Main Clauses

The conditions in the optional **WHERE** clause identify which rows to delete. With no **WHERE** clause, all rows are deleted.
**DELETE Statement**

*where_conditions* is an expression that evaluates to true for each row to be deleted. It is specified as described in Section 13.2.9, “SELECT Statement”.

If the **ORDER BY** clause is specified, the rows are deleted in the order that is specified. The **LIMIT** clause places a limit on the number of rows that can be deleted. These clauses apply to single-table deletes, but not multi-table deletes.

**Multiple-Table Syntax**

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
  tbl_name[./*] [, tbl_name[./*]] ... 
  FROM table_references
  [WHERE where_condition]

DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
  FROM tbl_name[./*] [, tbl_name[./*]] ... 
  USING table_references
  [WHERE where_condition]
```

**Privileges**

You need the **DELETE** privilege on a table to delete rows from it. You need only the **SELECT** privilege for any columns that are only read, such as those named in the **WHERE** clause.

**Performance**

When you do not need to know the number of deleted rows, the **TRUNCATE TABLE** statement is a faster way to empty a table than a **DELETE** statement with no **WHERE** clause. Unlike **DELETE**, **TRUNCATE TABLE** cannot be used within a transaction or if you have a lock on the table. See Section 13.1.33, “TRUNCATE TABLE Statement” and Section 13.3.5, “LOCK TABLES and UNLOCK TABLES Statements”.

The speed of delete operations may also be affected by factors discussed in Section 8.2.4.3, “Optimizing DELETE Statements”.

To ensure that a given **DELETE** statement does not take too much time, the MySQL-specific **LIMIT row_count** clause for **DELETE** specifies the maximum number of rows to be deleted. If the number of rows to delete is larger than the limit, repeat the **DELETE** statement until the number of affected rows is less than the **LIMIT** value.

**Subqueries**

You cannot delete from a table and select from the same table in a subquery.

**Partitioned Table Support**

**DELETE** supports explicit partition selection using the **PARTITION** option, which takes a list of the comma-separated names of one or more partitions or subpartitions (or both) from which to select rows to be dropped. Partitions not included in the list are ignored. Given a partitioned table `t` with a partition named `p0`, executing the statement **DELETE FROM t PARTITION (p0)** has the same effect on the table as executing **ALTER TABLE t TRUNCATE PARTITION (p0)**; in both cases, all rows in partition `p0` are dropped.

**PARTITION** can be used along with a **WHERE** condition, in which case the condition is tested only on rows in the listed partitions. For example, **DELETE FROM t PARTITION (p0) WHERE c < 5** deletes rows only from partition `p0` for which the condition `c < 5` is true; rows in any other partitions are not checked and thus not affected by the **DELETE**.

The **PARTITION** option can also be used in multiple-table **DELETE** statements. You can use up to one such option per table named in the **FROM** option.

For more information and examples, see Section 19.5, “Partition Selection”.

1585
DELETE Statement

Auto-Increment Columns

If you delete the row containing the maximum value for an `AUTO_INCREMENT` column, the value is not reused for a `MyISAM` or InnoDB table. If you delete all rows in the table with `DELETE FROM tbl_name` (without a `WHERE` clause) in autocommit mode, the sequence starts over for all storage engines except InnoDB and MyISAM. There are some exceptions to this behavior for InnoDB tables, as discussed in Section 14.6.1.6, "AUTO_INCREMENT Handling in InnoDB".

For MyISAM tables, you can specify an `AUTO_INCREMENT` secondary column in a multiple-column key. In this case, reuse of values deleted from the top of the sequence occurs even for MyISAM tables. See Section 3.6.9, "Using AUTO_INCREMENT".

Modifers

The `DELETE` statement supports the following modifiers:

- If you specify the `LOW_PRIORITY` modifier, the server delays execution of the `DELETE` until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as MyISAM, MEMORY, and MERGE).

- For MyISAM tables, if you use the `QUICK` modifier, the storage engine does not merge index leaves during delete, which may speed up some kinds of delete operations.

- The `IGNORE` modifier causes MySQL to ignore errors during the process of deleting rows. (Errors encountered during the parsing stage are processed in the usual manner.) Errors that are ignored due to the use of `IGNORE` are returned as warnings.

Order of Deletion

If the `DELETE` statement includes an `ORDER BY` clause, rows are deleted in the order specified by the clause. This is useful primarily in conjunction with `LIMIT`. For example, the following statement finds rows matching the `WHERE` clause, sorts them by `timestamp_column`, and deletes the first (oldest) one:

```
DELETE FROM somelog WHERE user = 'jcole'
ORDER BY timestamp_column LIMIT 1;
```

`ORDER BY` also helps to delete rows in an order required to avoid referential integrity violations.

InnoDB Tables

If you are deleting many rows from a large table, you may exceed the lock table size for an InnoDB table. To avoid this problem, or simply to minimize the time that the table remains locked, the following strategy (which does not use `DELETE` at all) might be helpful:

1. Select the rows not to be deleted into an empty table that has the same structure as the original table:

   ```sql
   INSERT INTO t_copy SELECT * FROM t WHERE ... ;
   ```

2. Use `RENAME TABLE` to atomically move the original table out of the way and rename the copy to the original name:

   ```sql
   RENAME TABLE t TO t_old, t_copy TO t;
   ```

3. Drop the original table:

   ```sql
   DROP TABLE t_old;
   ```

No other sessions can access the tables involved while `RENAME TABLE` executes, so the rename operation is not subject to concurrency problems. See Section 13.1.32, "RENAME TABLE Statement".
MyISAM Tables

In MyISAM tables, deleted rows are maintained in a linked list and subsequent INSERT operations reuse old row positions. To reclaim unused space and reduce file sizes, use the OPTIMIZE TABLE statement or the myisamchk utility to reorganize tables. OPTIMIZE TABLE is easier to use, but myisamchk is faster. See Section 13.7.2.4, “OPTIMIZE TABLE Statement”, and Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”.

The QUICK modifier affects whether index leaves are merged for delete operations. DELETE QUICK is most useful for applications where index values for deleted rows are replaced by similar index values from rows inserted later. In this case, the holes left by deleted values are reused.

DELETE QUICK is not useful when deleted values lead to underfilled index blocks spanning a range of index values for which new inserts occur again. In this case, use of QUICK can lead to wasted space in the index that remains unreclaimed. Here is an example of such a scenario:

1. Create a table that contains an indexed AUTO_INCREMENT column.
2. Insert many rows into the table. Each insert results in an index value that is added to the high end of the index.
3. Delete a block of rows at the low end of the column range using DELETE QUICK.

In this scenario, the index blocks associated with the deleted index values become underfilled but are not merged with other index blocks due to the use of QUICK. They remain underfilled when new inserts occur, because new rows do not have index values in the deleted range. Furthermore, they remain underfilled even if you later use DELETE without QUICK, unless some of the deleted index values happen to lie in index blocks within or adjacent to the underfilled blocks. To reclaim unused index space under these circumstances, use OPTIMIZE TABLE.

If you are going to delete many rows from a table, it might be faster to use DELETE QUICK followed by OPTIMIZE TABLE. This rebuilds the index rather than performing many index block merge operations.

Multi-Table Deletes

You can specify multiple tables in a DELETE statement to delete rows from one or more tables depending on the condition in the WHERE clause. You cannot use ORDER BY or LIMIT in a multiple-table DELETE. The table_references clause lists the tables involved in the join, as described in Section 13.2.9.2, “JOIN Clause”.

For the first multiple-table syntax, only matching rows from the tables listed before the FROM clause are deleted. For the second multiple-table syntax, only matching rows from the tables listed in the FROM clause (before the USING clause) are deleted. The effect is that you can delete rows from many tables at the same time and have additional tables that are used only for searching:

```
DELETE t1, t2 FROM t1 INNER JOIN t2 INNER JOIN t3
WHERE t1.id=t2.id AND t2.id=t3.id;
```

Or:

```
DELETE FROM t1, t2 USING t1 INNER JOIN t2 INNER JOIN t3
WHERE t1.id=t2.id AND t2.id=t3.id;
```

These statements use all three tables when searching for rows to delete, but delete matching rows only from tables t1 and t2.

The preceding examples use INNER JOIN, but multiple-table DELETE statements can use other types of join permitted in SELECT statements, such as LEFT JOIN. For example, to delete rows that exist in t1 that have no match in t2, use a LEFT JOIN:

```
DELETE t1 FROM t1 LEFT JOIN t2 ON t1.id=t2.id WHERE t2.id IS NULL;
```
The syntax permits .* after each tbl_name for compatibility with Access.

If you use a multiple-table DELETE statement involving InnoDB tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, you should delete from a single table and rely on the ON DELETE capabilities that InnoDB provides to cause the other tables to be modified accordingly.

**Note**

If you declare an alias for a table, you must use the alias when referring to the table:

```sql
DELETE t1 FROM test AS t1, test2 WHERE ...
```

Table aliases in a multiple-table DELETE should be declared only in the table_references part of the statement. Elsewhere, alias references are permitted but not alias declarations.

**Correct:**

```sql
DELETE a1, a2 FROM t1 AS a1 INNER JOIN t2 AS a2
WHERE a1.id=a2.id;
```

```sql
DELETE FROM a1, a2 USING t1 AS a1 INNER JOIN t2 AS a2
WHERE a1.id=a2.id;
```

**Incorrect:**

```sql
DELETE t1 AS a1, t2 AS a2 FROM t1 INNER JOIN t2
WHERE a1.id=a2.id;
```

```sql
DELETE FROM t1 AS a1, t2 AS a2 USING t1 INNER JOIN t2
WHERE a1.id=a2.id;
```

### 13.2.3 DO Statement

**DO expr [, expr] ...**

**DO** executes the expressions but does not return any results. In most respects, **DO** is shorthand for **SELECT expr, ...**, but has the advantage that it is slightly faster when you do not care about the result.

**DO** is useful primarily with functions that have side effects, such as `RELEASE_LOCK()`.

**Example:** This **SELECT** statement pauses, but also produces a result set:

```sql
mysql> SELECT SLEEP(5);
+----------+
| SLEEP(5) |
+----------+
|        0 |
+----------+
1 row in set (5.02 sec)
```

**DO**, on the other hand, pauses without producing a result set:

```sql
mysql> DO SLEEP(5);
Query OK, 0 rows affected (4.99 sec)
```

This could be useful, for example in a stored function or trigger, which prohibit statements that produce result sets.

**DO** only executes expressions. It cannot be used in all cases where **SELECT** can be used. For example, **DO id FROM t1** is invalid because it references a table.
13.2.4 HANDLER Statement

```
HANDLER tbl_name OPEN [ [AS] alias]
HANDLER tbl_name READ index_name { = | <= | >= | < | > } (value1,value2,...)
   [ WHERE where_condition ] [LIMIT ...]
HANDLER tbl_name READ index_name { FIRST | NEXT | PREV | LAST }
   [ WHERE where_condition ] [LIMIT ...]
HANDLER tbl_name READ { FIRST | NEXT }
   [ WHERE where_condition ] [LIMIT ...]
HANDLER tbl_name CLOSE
```

The HANDLER statement provides direct access to table storage engine interfaces. It is available for InnoDB and MyISAM tables.

The HANDLER ... OPEN statement opens a table, making it accessible using subsequent HANDLER ... READ statements. This table object is not shared by other sessions and is not closed until the session calls HANDLER ... CLOSE or the session terminates.

If you open the table using an alias, further references to the open table with other HANDLER statements must use the alias rather than the table name. If you do not use an alias, but open the table using a table name qualified by the database name, further references must use the unqualified table name. For example, for a table opened using `mydb.mytable`, further references must use `mytable`.

The first HANDLER ... READ syntax fetches a row where the index specified satisfies the given values and the WHERE condition is met. If you have a multiple-column index, specify the index column values as a comma-separated list. Either specify values for all the columns in the index, or specify values for a leftmost prefix of the index columns. Suppose that an index `my_idx` includes three columns named `col_a`, `col_b`, and `col_c`, in that order. The HANDLER statement can specify values for all three columns in the index, or for the columns in a leftmost prefix. For example:

```
HANDLER ... READ my_idx = (col_a_val,col_b_val,col_c_val) ...
HANDLER ... READ my_idx = (col_a_val,col_b_val) ...
HANDLER ... READ my_idx = (col_a_val) ...
```

To employ the HANDLER interface to refer to a table's PRIMARY KEY, use the quoted identifier `"PRIMARY"`:

```
HANDLER tbl_name READ "PRIMARY" ...
```

The second HANDLER ... READ syntax fetches a row from the table in index order that matches the WHERE condition.

The third HANDLER ... READ syntax fetches a row from the table in natural row order that matches the WHERE condition. It is faster than HANDLER tbl_name READ index_name when a full table scan is desired. Natural row order is the order in which rows are stored in a MyISAM table data file. This statement works for InnoDB tables as well, but there is no such concept because there is no separate data file.

Without a LIMIT clause, all forms of HANDLER ... READ fetch a single row if one is available. To return a specific number of rows, include a LIMIT clause. It has the same syntax as for the SELECT statement. See Section 13.2.9, “SELECT Statement”.

HANDLER ... CLOSE closes a table that was opened with HANDLER ... OPEN.

There are several reasons to use the HANDLER interface instead of normal SELECT statements:

- HANDLER is faster than SELECT:
  - A designated storage engine handler object is allocated for the HANDLER ... OPEN. The object is reused for subsequent HANDLER statements for that table; it need not be reinitialized for each one.
• There is less parsing involved.

• There is no optimizer or query-checking overhead.

• The handler interface does not have to provide a consistent look of the data (for example, dirty reads are permitted), so the storage engine can use optimizations that `SELECT` does not normally permit.

• `HANDLER` makes it easier to port to MySQL applications that use a low-level `ISAM`-like interface. (See Section 14.20, “InnoDB memcached Plugin” for an alternative way to adapt applications that use the key-value store paradigm.)

• `HANDLER` enables you to traverse a database in a manner that is difficult (or even impossible) to accomplish with `SELECT`. The `HANDLER` interface is a more natural way to look at data when working with applications that provide an interactive user interface to the database.

`HANDLER` is a somewhat low-level statement. For example, it does not provide consistency. That is, `HANDLER ... OPEN` does not take a snapshot of the table, and does not lock the table. This means that after a `HANDLER ... OPEN` statement is issued, table data can be modified (by the current session or other sessions) and these modifications might be only partially visible to `HANDLER ... NEXT` or `HANDLER ... PREV` scans.

An open handler can be closed and marked for reopen, in which case the handler loses its position in the table. This occurs when both of the following circumstances are true:

• Any session executes `FLUSH TABLES` or DDL statements on the handler’s table.

• The session in which the handler is open executes non-`HANDLER` statements that use tables.

`TRUNCATE TABLE` for a table closes all handlers for the table that were opened with `HANDLER OPEN`.

If a table is flushed with `FLUSH TABLES tbl_name WITH READ LOCK` was opened with `HANDLER`, the handler is implicitly flushed and loses its position.

`HANDLER` is not supported with partitioned tables.

### 13.2.5 INSERT Statement

```sql
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name
[PARTITION (partition_name [, partition_name] ...)]
[VALUES | VALUE] (value_list) [, (value_list)] ...
[ON DUPLICATE KEY UPDATE assignment_list]
```

```sql
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name
[PARTITION (partition_name [, partition_name] ...)]
SET assignment_list
[ON DUPLICATE KEY UPDATE assignment_list]
```

```sql
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
[INTO] tbl_name
[PARTITION (partition_name [, partition_name] ...)]
[VALUES | VALUE] (value_list) ...
SELECT ...
[ON DUPLICATE KEY UPDATE assignment_list]
```

```
value:
 {expr | DEFAULT}

value_list:
 value [, value] ...
```
**INSERT Statement**

<table>
<thead>
<tr>
<th>assignment:</th>
</tr>
</thead>
<tbody>
<tr>
<td>col_name = value</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>assignment_list:</th>
</tr>
</thead>
<tbody>
<tr>
<td>assignment [, assignment] ...</td>
</tr>
</tbody>
</table>

The `INSERT` statement inserts new rows into an existing table. The `INSERT ... VALUES` and `INSERT ... SET` forms of the statement insert rows based on explicitly specified values. The `INSERT ... SELECT` form inserts rows selected from another table or tables. `INSERT` with an `ON DUPLICATE KEY UPDATE` clause enables existing rows to be updated if a row to be inserted would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`.

For additional information about `INSERT ... SELECT` and `INSERT ... ON DUPLICATE KEY UPDATE`, see Section 13.2.5.1, “INSERT ... SELECT Statement”, and Section 13.2.5.2, “INSERT ... ON DUPLICATE KEY UPDATE Statement”.

Inserting into a table requires the `INSERT` privilege for the table. If the `ON DUPLICATE KEY UPDATE` clause is used and a duplicate key causes an `UPDATE` to be performed instead, the statement requires the `UPDATE` privilege for the columns to be updated. For columns that are read but not modified you need only the `SELECT` privilege (such as for a column referenced only on the right hand side of an `col_name=expr` assignment in an `ON DUPLICATE KEY UPDATE` clause).

When inserting into a partitioned table, you can control which partitions and subpartitions accept new rows. The `PARTITION` option takes a list of the comma-separated names of one or more partitions or subpartitions (or both) of the table. If any of the rows to be inserted by a given `INSERT` statement do not match one of the partitions listed, the `INSERT` statement fails with the error `Found a row not matching the given partition set`. For more information and examples, see Section 19.5, “Partition Selection”.

You can use `REPLACE` instead of `INSERT` to overwrite old rows. `REPLACE` is the counterpart to `INSERT IGNORE` in the treatment of new rows that contain unique key values that duplicate old rows: The new rows replace the old rows rather than being discarded. See Section 13.2.8, “REPLACE Statement”.

`tbl_name` is the table into which rows should be inserted. Specify the columns for which the statement provides values as follows:

- Provide a parenthesized list of comma-separated column names following the table name. In this case, a value for each named column must be provided by the `VALUES` list or the `SELECT` statement.

- If you do not specify a list of column names for `INSERT ... VALUES` or `INSERT ... SELECT`, values for every column in the table must be provided by the `VALUES` list or the `SELECT` statement. If you do not know the order of the columns in the table, use `DESCRIBE tbl_name` to find out.

- A `SET` clause indicates columns explicitly by name, together with the value to assign each one.

Column values can be given in several ways:

- If strict SQL mode is not enabled, any column not explicitly given a value is set to its default (explicit or implicit) value. For example, if you specify a column list that does not name all the columns in the table, unnamed columns are set to their default values. Default value assignment is described in Section 11.5, “Data Type Default Values”. See also Section 1.7.3.3, “Constraints on Invalid Data”.

- If strict SQL mode is enabled, an `INSERT` statement generates an error if it does not specify an explicit value for every column that has no default value. See Section 5.1.10, “Server SQL Modes”.

- If both the column list and the `VALUES` list are empty, `INSERT` creates a row with each column set to its default value:

```sql
INSERT INTO tbl_name () VALUES();
```

If strict mode is not enabled, MySQL uses the implicit default value for any column that has no explicitly defined default. If strict mode is enabled, an error occurs if any column has no default value.
• Use the keyword `DEFAULT` to set a column explicitly to its default value. This makes it easier to write `INSERT` statements that assign values to all but a few columns, because it enables you to avoid writing an incomplete `VALUES` list that does not include a value for each column in the table. Otherwise, you must provide the list of column names corresponding to each value in the `VALUES` list.

• In expressions, you can use `DEFAULT(col_name)` to produce the default value for column `col_name`.

• Type conversion of an expression `expr` that provides a column value might occur if the expression data type does not match the column data type. Conversion of a given value can result in different inserted values depending on the column type. For example, inserting the string '1999.0e-2' into an `INT`, `FLOAT`, `DECIMAL(10,6)`, or `YEAR` column inserts the value 1999, 19.9921, 19.992100, or 1999, respectively. The value stored in the `INT` and `YEAR` columns is 1999 because the string-to-number conversion looks only at as much of the initial part of the string as may be considered a valid integer or year. For the `FLOAT` and `DECIMAL` columns, the string-to-number conversion considers the entire string a valid numeric value.

• An expression `expr` can refer to any column that was set earlier in a value list. For example, you can do this because the value for `col2` refers to `col1`, which has previously been assigned:

```
INSERT INTO tbl_name (col1,col2) VALUES(15,col1*2);
```

But the following is not legal, because the value for `col1` refers to `col2`, which is assigned after `col1`:

```
INSERT INTO tbl_name (col1,col2) VALUES(col2*2,15);
```

An exception occurs for columns that contain `AUTO_INCREMENT` values. Because `AUTO_INCREMENT` values are generated after other value assignments, any reference to an `AUTO_INCREMENT` column in the assignment returns a 0.

`INSERT` statements that use `VALUES` syntax can insert multiple rows. To do this, include multiple lists of comma-separated column values, with lists enclosed within parentheses and separated by commas.

Example:

```
INSERT INTO tbl_name (a,b,c) VALUES(1,2,3),(4,5,6),(7,8,9);
```

Each values list must contain exactly as many values as are to be inserted per row. The following statement is invalid because it contains one list of nine values, rather than three lists of three values each:

```
INSERT INTO tbl_name (a,b,c) VALUES(1,2,3,4,5,6,7,8,9);
```

`VALUE` is a synonym for `VALUES` in this context. Neither implies anything about the number of values lists, nor about the number of values per list. Either may be used whether there is a single values list or multiple lists, and regardless of the number of values per list.

The affected-rows value for an `INSERT` can be obtained using the `ROW_COUNT()` SQL function or the `mysql_affected_rows()` C API function. See Section 12.16, "Information Functions", and `mysql_affected_rows()`.

If you use an `INSERT ... VALUES` statement with multiple value lists or `INSERT ... SELECT`, the statement returns an information string in this format:

```
Records: N1 Duplicates: N2 Warnings: N3
```

If you are using the C API, the information string can be obtained by invoking the `mysql_info()` function. See `mysql_info()`.

`Records` indicates the number of rows processed by the statement. (This is not necessarily the number of rows actually inserted because `Duplicates` can be nonzero.) `Duplicates` indicates the
number of rows that could not be inserted because they would duplicate some existing unique index value. Warnings indicates the number of attempts to insert column values that were problematic in some way. Warnings can occur under any of the following conditions:

- Inserting NULL into a column that has been declared NOT NULL. For multiple-row INSERT statements or INSERT INTO ... SELECT statements, the column is set to the implicit default value for the column data type. This is 0 for numeric types, the empty string ("") for string types, and the “zero” value for date and time types. INSERT INTO ... SELECT statements are handled the same way as multiple-row inserts because the server does not examine the result set from the SELECT to see whether it returns a single row. (For a single-row INSERT, no warning occurs when NULL is inserted into a NOT NULL column. Instead, the statement fails with an error.)

- Setting a numeric column to a value that lies outside the column's range. The value is clipped to the closest endpoint of the range.

- Assigning a value such as '10.34 a' to a numeric column. The trailing nonnumeric text is stripped off and the remaining numeric part is inserted. If the string value has no leading numeric part, the column is set to 0.

- Inserting a string into a string column (CHAR, VARCHAR, TEXT, or BLOB) that exceeds the column's maximum length. The value is truncated to the column's maximum length.

- Inserting a value into a date or time column that is illegal for the data type. The column is set to the appropriate zero value for the type.

- For INSERT examples involving AUTO_INCREMENT column values, see Section 3.6.9, “Using AUTO_INCREMENT”.

If INSERT inserts a row into a table that has an AUTO_INCREMENT column, you can find the value used for that column by using the LAST_INSERT_ID() SQL function or the mysql_insert_id() C API function.

### Note

These two functions do not always behave identically. The behavior of INSERT statements with respect to AUTO_INCREMENT columns is discussed further in Section 12.16, “Information Functions”, and mysql_insert_id().

The INSERT statement supports the following modifiers:

- If you use the DELAYED modifier, the server puts the row or rows to be inserted into a buffer, and the client issuing the INSERT DELAYED statement can then continue immediately. If the table is in use, the server holds the rows. When the table is free, the server begins inserting rows, checking periodically to see whether there are any new read requests for the table. If there are, the delayed row queue is suspended until the table becomes free again. See Section 13.2.5.3, “INSERT DELAYED Statement”.

  DELAYED is ignored with INSERT ... SELECT or INSERT ... ON DUPLICATE KEY UPDATE.

  DELAYED is also disregarded for an INSERT that uses functions accessing tables or triggers, or that is called from a function or a trigger.

### Note

As of MySQL 5.6.6, INSERT DELAYED is deprecated, and will be removed in a future release. Use INSERT (without DELAYED) instead.

- If you use the LOW_PRIORITY modifier, execution of the INSERT is delayed until no other clients are reading from the table. This includes other clients that began reading while existing clients are reading, and while the INSERT LOW_PRIORITY statement is waiting. It is possible, therefore, for a client that issues an INSERT LOW_PRIORITY statement to wait for a very long time (or even
forever) in a read-heavy environment. (This is in contrast to INSERT DELAYED, which lets the client continue at once.)

LOW_PRIORITY affects only storage engines that use only table-level locking (such as MyISAM, MEMORY, and MERGE).

Note

LOW_PRIORITY should normally not be used with MyISAM tables because doing so disables concurrent inserts. See Section 8.11.3, “Concurrent Inserts”.

- If you specify HIGH_PRIORITY, it overrides the effect of the --low-priority-updates option if the server was started with that option. It also causes concurrent inserts not to be used. See Section 8.11.3, “Concurrent Inserts”.

HIGH_PRIORITY affects only storage engines that use only table-level locking (such as MyISAM, MEMORY, and MERGE).

- If you use the IGNORE modifier, errors that occur while executing the INSERT statement are ignored. For example, without IGNORE, a row that duplicates an existing UNIQUE index or PRIMARY KEY value in the table causes a duplicate-key error and the statement is aborted. With IGNORE, the row is discarded and no error occurs. Ignored errors may generate warnings instead, although duplicate-key errors do not.

IGNORE has a similar effect on inserts into partitioned tables where no partition matching a given value is found. Without IGNORE, such INSERT statements are aborted with an error. When INSERT IGNORE is used, the insert operation fails silently for rows containing the unmatched value, but inserts rows that are matched. For an example, see Section 19.2.2, “LIST Partitioning”.

Data conversions that would trigger errors abort the statement if IGNORE is not specified. With IGNORE, invalid values are adjusted to the closest values and inserted; warnings are produced but the statement does not abort. You can determine with the mysql_info() C API function how many rows were actually inserted into the table.

- If you specify ON DUPLICATE KEY UPDATE, and a row is inserted that would cause a duplicate value in a UNIQUE index or PRIMARY KEY, an UPDATE of the old row occurs. The affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the CLIENT_FOUND_ROWS flag to the mysql_real_connect() C API function when connecting to mysqld, the affected-rows value is 1 (not 0) if an existing row is set to its current values. See Section 13.2.5.2, “INSERT ... ON DUPLICATE KEY UPDATE Statement”.

An INSERT statement affecting a partitioned table using a storage engine such as MyISAM that employs table-level locks locks only those partitions into which rows are actually inserted. (For storage engines such as InnoDB that employ row-level locking, no locking of partitions takes place.) For more information, see Section 19.6.4, “Partitioning and Locking”.

13.2.5.1 INSERT ... SELECT Statement

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
INTO tbl_name
[PARTITION (partition_name [, partition_name] ...)]
[([col_name [, col_name] ...])]
SELECT ...
[ON DUPLICATE KEY UPDATE assignment_list]
value:
{expr | DEFAULT}
assignment:
col_name = value
```
With **INSERT ... SELECT**, you can quickly insert many rows into a table from the result of a **SELECT** statement, which can select from one or many tables. For example:

```sql
INSERT INTO tbl_temp2 (fld_id) 
SELECT tbl_temp1.fld_order_id 
FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

The following conditions hold for **INSERT ... SELECT** statements:

- Specify **IGNORE** to ignore rows that would cause duplicate-key violations.

- **DELAYED** is ignored with **INSERT ... SELECT**.

- The target table of the **INSERT** statement may appear in the **FROM** clause of the **SELECT** part of the query. However, you cannot insert into a table and select from the same table in a subquery.

When selecting from and inserting into the same table, MySQL creates an internal temporary table to hold the rows from the **SELECT** and then inserts those rows into the target table. However, you cannot use **INSERT INTO t ... SELECT ... FROM t** when **t** is a **TEMPORARY** table, because **TEMPORARY** tables cannot be referred to twice in the same statement. See Section 8.4.4, “Internal Temporary Table Use in MySQL”, and Section B.3.6.2, “TEMPORARY Table Problems”.

- **AUTO_INCREMENT** columns work as usual.

- To ensure that the binary log can be used to re-create the original tables, MySQL does not permit concurrent inserts for **INSERT ... SELECT** statements (see Section 8.11.3, “Concurrent Inserts”).

- To avoid ambiguous column reference problems when the **SELECT** and the **INSERT** refer to the same table, provide a unique alias for each table used in the **SELECT** part, and qualify column names in that part with the appropriate alias.

You can explicitly select which partitions or subpartitions (or both) are to be used with a **PARTITION** option following the name of the table. When **PARTITION** is used with the name of the source table in the **SELECT** portion of the statement, rows are selected only from the partitions or subpartitions named in its partition list. When **PARTITION** is used with the name of the target table for the **INSERT** portion of the statement, it must be possible to insert all rows selected into the partitions or subpartitions named in the partition list following the option. Otherwise, the **INSERT ... SELECT** statement fails. For more information and examples, see Section 19.5, “Partition Selection”.

For **INSERT ... SELECT** statements, see Section 13.2.5.2, “**INSERT ... ON DUPLICATE KEY UPDATE Statement**” for conditions under which the **SELECT** columns can be referred to in an **ON DUPLICATE KEY UPDATE** clause.

The order in which a **SELECT** statement with no **ORDER BY** clause returns rows is nondeterministic. This means that, when using replication, there is no guarantee that such a **SELECT** returns rows in the same order on the source and the replica, which can lead to inconsistencies between them. To prevent this from occurring, always write **INSERT ... SELECT** statements that are to be replicated using an **ORDER BY** clause that produces the same row order on the source and the replica. See also Section 17.4.1.17, “Replication and LIMIT”.

Due to this issue, **INSERT ... SELECT ON DUPLICATE KEY UPDATE** and **INSERT IGNORE ... SELECT** statements are flagged as unsafe for statement-based replication. Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using **MIXED** mode. (Bug #11758262, Bug #50439)

See also Section 17.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

---

**assignment_list:**

```sql
    assignment [, assignment] ...
```
An `INSERT ... SELECT` statement affecting partitioned tables using a storage engine such as `MyISAM` that employs table-level locks locks all partitions of the target table; however, only those partitions that are actually read from the source table are locked. (This does not occur with tables using storage engines such as `InnoDB` that employ row-level locking.) For more information, see Section 19.6.4, “Partitioning and Locking”.

### 13.2.5.2 INSERT ... ON DUPLICATE KEY UPDATE Statement

If you specify an `ON DUPLICATE KEY UPDATE` clause and a row to be inserted would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`, an `UPDATE` of the old row occurs. For example, if column `a` is declared as `UNIQUE` and contains the value 1, the following two statements have similar effect:

```sql
INSERT INTO t1 (a,b,c) VALUES (1,2,3)
ON DUPLICATE KEY UPDATE c=c+1;
UPDATE t1 SET c=c+1 WHERE a=1;
```

(The effects are not identical for an `InnoDB` table where `a` is an auto-increment column. With an auto-increment column, an `INSERT` statement increases the auto-increment value but `UPDATE` does not.)

If column `b` is also unique, the `INSERT` is equivalent to this `UPDATE` statement instead:

```sql
UPDATE t1 SET c=c+1 WHERE a=1 OR b=2 LIMIT 1;
```

If `a=1 OR b=2` matches several rows, only one row is updated. In general, you should try to avoid using an `ON DUPLICATE KEY UPDATE` clause on tables with multiple unique indexes.

With `ON DUPLICATE KEY UPDATE`, the affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the `CLIENT_FOUND_ROWS` flag to the `mysql_real_connect()` C API function when connecting to `mysqld`, the affected-rows value is 1 (not 0) if an existing row is set to its current values.

If a table contains an `AUTO_INCREMENT` column and `INSERT ... ON DUPLICATE KEY UPDATE` inserts or updates a row, the `LAST_INSERT_ID()` function returns the `AUTO_INCREMENT` value.

The `ON DUPLICATE KEY UPDATE` clause can contain multiple column assignments, separated by commas.

In assignment value expressions in the `ON DUPLICATE KEY UPDATE` clause, you can use the `VALUES(col_name)` function to refer to column values from the `INSERT` portion of the `INSERT ... ON DUPLICATE KEY UPDATE` statement. In other words, `VALUES(col_name)` in the `ON DUPLICATE KEY UPDATE` clause refers to the value of `col_name` that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The `VALUES()` function is meaningful only in the `ON DUPLICATE KEY UPDATE` clause or `INSERT` statements and returns `NULL` otherwise. Example:

```sql
INSERT INTO t1 (a,b,c) VALUES (1,2,3),(4,5,6)
ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

That statement is identical to the following two statements:

```sql
INSERT INTO t1 (a,b,c) VALUES (1,2,3)
ON DUPLICATE KEY UPDATE c=3;
INSERT INTO t1 (a,b,c) VALUES (4,5,6)
ON DUPLICATE KEY UPDATE c=9;
```

The `DELAYED` option is ignored when you use `ON DUPLICATE KEY UPDATE`.

For `INSERT ... SELECT` statements, these rules apply regarding acceptable forms of `SELECT` query expressions that you can refer to in an `ON DUPLICATE KEY UPDATE` clause:
• References to columns from queries on a single table, which may be a derived table.

• References to columns from queries on a join over multiple tables.

• References to columns from `DISTINCT` queries.

• References to columns in other tables, as long as the `SELECT` does not use `GROUP BY`. One side effect is that you must qualify references to nonunique column names.

References to columns from a `UNION` do not work reliably. To work around this restriction, rewrite the `UNION` as a derived table so that its rows can be treated as a single-table result set. For example, this statement can produce incorrect results:

```
INSERT INTO t1 (a, b)
SELECT c, d FROM t2
UNION
SELECT e, f FROM t3
ON DUPLICATE KEY UPDATE b = b + c;
```

Instead, use an equivalent statement that rewrites the `UNION` as a derived table:

```
INSERT INTO t1 (a, b)
SELECT * FROM
  (SELECT c, d FROM t2
   UNION
   SELECT e, f FROM t3) AS dt
ON DUPLICATE KEY UPDATE b = b + c;
```

The technique of rewriting a query as a derived table also enables references to columns from `GROUP BY` queries.

Because the results of `INSERT ... SELECT` statements depend on the ordering of rows from the `SELECT` and this order cannot always be guaranteed, it is possible when logging `INSERT ... SELECT` statements for the source and the replica to diverge. Thus, `INSERT ... SELECT` statements are flagged as unsafe for statement-based replication. Such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using `MIXED` mode. An `INSERT ... ON DUPLICATE KEY UPDATE` statement against a table having more than one unique or primary key is also marked as unsafe. (Bug #11765650, Bug #58637)

See also Section 17.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

An `INSERT ... ON DUPLICATE KEY UPDATE` on a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks any partitions of the table in which a partitioning key column is updated. (This does not occur with tables using storage engines such as `InnoDB` that employ row-level locking.) For more information, see Section 19.6.4, “Partitioning and Locking”.

### 13.2.5.3 INSERT DELAYED Statement

```
INSERT DELAYED ...
```

The `DELAYED` option for the `INSERT` statement is a MySQL extension to standard SQL that can be used for certain kinds of tables (such as `MyISAM`). When a client uses `INSERT DELAYED`, it gets an okay from the server at once, and the row is queued to be inserted when the table is not in use by any other thread.

**Note**

`INSERT DELAYED` is slower than a normal `INSERT` if the table is not otherwise in use. There is also the additional overhead for the server to handle a separate thread for each table for which there are delayed rows. This means that you should use `INSERT DELAYED` only when you are really sure that you need it.
As of MySQL 5.6.6, `INSERT DELAYED` is deprecated, and will be removed in a future release. Use `INSERT` (without `DELAYED`) instead.

The queued rows are held only in memory until they are inserted into the table. This means that if you terminate `mysqld` forcibly (for example, with `kill -9`) or if `mysqld` dies unexpectedly, any queued rows that have not been written to disk are lost.

There are some constraints on the use of `DELAYED`:

- `INSERT DELAYED` works only with `MyISAM`, `MEMORY`, `ARCHIVE`, and `BLACKHOLE` tables. For engines that do not support `DELAYED`, an error occurs.

- An error occurs for `INSERT DELAYED` if used with a table that has been locked with `LOCK TABLES` because the insert must be handled by a separate thread, not by the session that holds the lock.

- For `MyISAM` tables, if there are no free blocks in the middle of the data file, concurrent `SELECT` and `INSERT` statements are supported. Under these circumstances, you very seldom need to use `INSERT DELAYED` with `MyISAM`.

- `INSERT DELAYED` should be used only for `INSERT` statements that specify value lists. The server ignores `DELAYED` for `INSERT ... SELECT` or `INSERT ... ON DUPLICATE KEY UPDATE` statements.

- Because the `INSERT DELAYED` statement returns immediately, before the rows are inserted, you cannot use `LAST_INSERT_ID()` to get the `AUTO_INCREMENT` value that the statement might generate.

- `DELAYED` rows are not visible to `SELECT` statements until they actually have been inserted.

- `INSERT DELAYED` is handled as a simple `INSERT` (that is, without the `DELAYED` option) whenever the value of `binlog_format` is `STATEMENT` or `MIXED`. (In the latter case, the statement does not trigger a switch to row-based logging, and so is logged using the statement-based format.) This does not apply when using row-based binary logging mode (`binlog_format` set to `ROW`), in which `INSERT DELAYED` statements are always executed using the `DELAYED` option as specified, and logged as row-update events.

- `DELAYED` is ignored on replica servers, so that `INSERT DELAYED` is treated as a normal `INSERT` on replicas. This is because `DELAYED` could cause the slave to have different data than the source.

- Pending `INSERT DELAYED` statements are lost if a table is write locked and `ALTER TABLE` is used to modify the table structure.

- `INSERT DELAYED` is not supported for views.

- `INSERT DELAYED` is not supported for partitioned tables.

The following describes in detail what happens when you use the `DELAYED` option to `INSERT` or `REPLACE`. In this description, the “thread” is the thread that received an `INSERT DELAYED` statement and “handler” is the thread that handles all `INSERT DELAYED` statements for a particular table.

- When a thread executes a `DELAYED` statement for a table, a handler thread is created to process all `DELAYED` statements for the table, if no such handler already exists.

- The thread checks whether the handler has previously acquired a `DELAYED` lock; if not, it tells the handler thread to do so. The `DELAYED` lock can be obtained even if other threads have a `READ` or `WRITE` lock on the table. However, the handler waits for all `ALTER TABLE` locks or `FLUSH TABLES` statements to finish, to ensure that the table structure is up to date.

- The thread executes the `INSERT` statement, but instead of writing the row to the table, it puts a copy of the final row into a queue that is managed by the handler thread. Any syntax errors are noticed by the thread and reported to the client program.
LOAD DATA Statement

- The client cannot obtain from the server the number of duplicate rows or the AUTO_INCREMENT value for the resulting row, because the INSERT returns before the insert operation has been completed. (If you use the C API, the mysql_info() function does not return anything meaningful, for the same reason.)

- The binary log is updated by the handler thread when the row is inserted into the table. In case of multiple-row inserts, the binary log is updated when the first row is inserted.

- Each time that delayed_insert_limit rows are written, the handler checks whether any SELECT statements are still pending. If so, it permits these to execute before continuing.

- When the handler has no more rows in its queue, the table is unlocked. If no new INSERT DELAYED statements are received within delayed_insert_timeout seconds, the handler terminates.

- If more than delayed_queue_size rows are pending in a specific handler queue, the thread requesting INSERT DELAYED waits until there is room in the queue. This is done to ensure that mysqld does not use all memory for the delayed memory queue.

- The handler thread shows up in the MySQL process list with delayed_insert in the Command column. It is killed if you execute a FLUSH TABLES statement or kill it with KILL thread_id. However, before exiting, it first stores all queued rows into the table. During this time it does not accept any new INSERT statements from other threads. If you execute an INSERT DELAYED statement after this, a new handler thread is created.

This means that INSERT DELAYED statements have higher priority than normal INSERT statements if there is an INSERT DELAYED handler running. Other update statements have to wait until the INSERT DELAYED queue is empty, someone terminates the handler thread (with KILL thread_id), or someone executes a FLUSH TABLES.

- The following status variables provide information about INSERT DELAYED statements.

<table>
<thead>
<tr>
<th>Status Variable</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delayed_insert_threads</td>
<td>Number of handler threads</td>
</tr>
<tr>
<td>Delayed_writes</td>
<td>Number of rows written with INSERT DELAYED</td>
</tr>
<tr>
<td>Not_flushed_delayed_rows</td>
<td>Number of rows waiting to be written</td>
</tr>
</tbody>
</table>

You can view these variables by issuing a SHOW STATUS statement or by executing a mysqladmin extended-status command.

13.2.6 LOAD DATA Statement

```sql
LOAD DATA
[LOW_PRIORITY | CONCURRENT] [LOCAL]
INFILE 'file_name'
[REPLACE | IGNORE]
INTO TABLE tbl_name
[PARTITION (partition_name [, partition_name] ...)]
[CHARACTER SET charset_name]
[{FIELDS | COLUMNS}
[Terminated BY 'string']
[[OPTIONALLY] ENCLOSED BY 'char']
[ESCAPED BY 'char']
]}
[LINES
[STARTING BY 'string']
[TERMINATED BY 'string']
]
[IGNORE number (LINES | ROWS)]
[(col_name_or_user_var
 [, col_name_or_user_var] ...)]
[SET col_name={expr | DEFAULT}]
```
The `LOAD DATA` statement reads rows from a text file into a table at a very high speed. `LOAD DATA` is the complement of `SELECT ... INTO OUTFILE`. (See Section 13.2.9.1, “SELECT ... INTO Statement”.) To write data from a table to a file, use `SELECT ... INTO OUTFILE`. To read the file back into a table, use `LOAD DATA`. The syntax of the `FIELDS` and `LINES` clauses is the same for both statements.

You can also load data files by using the `mysqlimport` utility; see Section 4.5.5, “mysqlimport — A Data Import Program”. `mysqlimport` operates by sending a `LOAD DATA` statement to the server.

For more information about the efficiency of `INSERT` versus `LOAD DATA` and speeding up `LOAD DATA`, see Section 8.2.4.1, “Optimizing INSERT Statements”.

- Partitioned Table Support
- Input File Name, Location, and Content Interpretation
- Concurrency Considerations
- Duplicate-Key Handling
- Index Handling
- Field and Line Handling
- Column List Specification
- Input Preprocessing
- Statement Result Information
- Miscellaneous Topics

**Partitioned Table Support**

`LOAD DATA` supports explicit partition selection using the `PARTITION` option with a list of one or more comma-separated names of partitions, subpartitions, or both. When this option is used, if any rows from the file cannot be inserted into any of the partitions or subpartitions named in the list, the statement fails with the error `Found a row not matching the given partition set`. For more information and examples, see Section 19.5, “Partition Selection”.

For partitioned tables using storage engines that employ table locks, such as MyISAM, `LOAD DATA` cannot prune any partition locks. This does not apply to tables using storage engines that employ row-level locking, such as InnoDB. For more information, see Section 19.6.4, “Partitioning and Locking”.

**Input File Name, Location, and Content Interpretation**

The file name must be given as a literal string. On Windows, specify backslashes in path names as forward slashes or doubled backslashes. The `character_set_filesystem` system variable controls the interpretation of the file name character set.

The server uses the character set indicated by the `character_set_database` system variable to interpret the information in the file. `SET NAMES` and the setting of `character_set_client` do not affect interpretation of input. If the contents of the input file use a character set that differs from the default, it is usually preferable to specify the character set of the file by using the `CHARACTER SET` clause. A character set of `binary` specifies “no conversion.”

`LOAD DATA` interprets all fields in the file as having the same character set, regardless of the data types of the columns into which field values are loaded. For proper interpretation of file contents, you must ensure that it was written with the correct character set. For example, if you write a data file with
LOAD DATA Statement

mysqldump -T or by issuing a SELECT ... INTO OUTFILE statement in mysql, be sure to use a
--default-character-set option so that output is written in the character set to be used when the
file is loaded with LOAD DATA.

Note
It is not possible to load data files that use the ucs2, utf16, utf16le, or
utf32 character set.

The LOCAL modifier affects expected location of the file and error handling, as described later. LOCAL
works only if your server and your client both have been configured to permit it. For example, if
mysqld was started with the local_infile system variable disabled, LOCAL does not work. See
Section 6.1.6, “Security Considerations for LOAD DATA LOCAL”.

The LOCAL modifier affects where the file is expected to be found:

• If LOCAL is specified, the file is read by the client program on the client host and sent to the server.
The file can be given as a full path name to specify its exact location. If given as a relative path
name, the name is interpreted relative to the directory in which the client program was started.

When using LOCAL with LOAD DATA, a copy of the file is created in the directory where the MySQL
server stores temporary files. See Section B.3.3.5, “Where MySQL Stores Temporary Files”. Lack of
sufficient space for the copy in this directory can cause the LOAD DATA LOCAL statement to fail.

• If LOCAL is not specified, the file must be located on the server host and is read directly by the
server. The server uses the following rules to locate the file:

  • If the file name is an absolute path name, the server uses it as given.
  • If the file name is a relative path name with one or more leading components, the server searches
    for the file relative to the server's data directory.
  • If a file name with no leading components is given, the server looks for the file in the database
directory of the default database.

In the non-LOCAL case, these rules mean that a file named as ./myfile.txt is read from the
server's data directory, whereas the file named as myfile.txt is read from the database directory of
the default database. For example, if db1 is the default database, the following LOAD DATA statement
reads the file data.txt from the database directory for db1, even though the statement explicitly
loads the file into a table in the db2 database:

```sql
LOAD DATA INFILE 'data.txt' INTO TABLE db2.my_table;
```

Non-LOCAL load operations read text files located on the server. For security reasons, such operations
require that you have the FILE privilege. See Section 6.2.2, “Privileges Provided by MySQL”. Also,
non-LOCAL load operations are subject to the secure_file_priv system variable setting. If the
variable value is a nonempty directory name, the file to be loaded must be located in that directory. If
the variable value is empty (which is insecure), the file need only be readable by the server.

Using LOCAL is a bit slower than letting the server access the files directly, because the file contents
must be sent over the connection by the client to the server. On the other hand, you do not need the
FILE privilege to load local files.

LOCAL also affects error handling:

• With LOAD DATA, data-interpretation and duplicate-key errors terminate the operation.

• With LOAD DATA LOCAL, data-interpretation and duplicate-key errors become warnings and the
operation continues because the server has no way to stop transmission of the file in the middle
of the operation. For duplicate-key errors, this is the same as if IGNORE is specified. IGNORE is
explained further later in this section.
Concurrency Considerations

If you use the LOW_PRIORITY modifier, execution of the LOAD DATA statement is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as MyISAM, MEMORY, and MERGE).

If you specify the CONCURRENT modifier with a MyISAM table that satisfies the condition for concurrent inserts (that is, it contains no free blocks in the middle), other threads can retrieve data from the table while LOAD DATA is executing. This modifier affects the performance of LOAD DATA a bit, even if no other thread is using the table at the same time.

For information about LOAD DATA in relation to replication, see Section 17.4.1.18, “Replication and LOAD DATA”.

Duplicate-Key Handling

The REPLACE and IGNORE modifiers control handling of input rows that duplicate existing rows on unique key values:

- If you specify REPLACE, input rows replace existing rows. In other words, rows that have the same value for a primary key or unique index as an existing row. See Section 13.2.8, “REPLACE Statement”.

- If you specify IGNORE, rows that duplicate an existing row on a unique key value are discarded.

- If you do not specify either modifier, the behavior depends on whether the LOCAL modifier is specified. Without LOCAL, an error occurs when a duplicate key value is found, and the rest of the text file is ignored. With LOCAL, the default behavior is the same as if IGNORE is specified; this is because the server has no way to stop transmission of the file in the middle of the operation.

Index Handling

To ignore foreign key constraints during the load operation, execute a SET foreign_key_checks = 0 statement before executing LOAD DATA.

If you use LOAD DATA on an empty MyISAM table, all nonunique indexes are created in a separate batch (as for REPAIR TABLE). Normally, this makes LOAD DATA much faster when you have many indexes. In some extreme cases, you can create the indexes even faster by turning them off with ALTER TABLE ... DISABLE KEYS before loading the file into the table and using ALTER TABLE ... ENABLE KEYS to re-create the indexes after loading the file. See Section 8.2.4.1, “Optimizing INSERT Statements”.

Field and Line Handling

For both the LOAD DATA and SELECT ... INTO OUTFILE statements, the syntax of the FIELDS and LINES clauses is the same. Both clauses are optional, but FIELDS must precede LINES if both are specified.

If you specify a FIELDS clause, each of its subclauses (TERMINATED BY, [OPTIONALLY] ENCLOSED BY, and ESCAPED BY) is also optional, except that you must specify at least one of them. Arguments to these clauses are permitted to contain only ASCII characters.

If you specify no FIELDS or LINES clause, the defaults are the same as if you had written this:

FIELDS TERMINATED BY '\t' ENCLOSED BY '' ESCAPED BY '\\'
LINES TERMINATED BY '\n' STARTING BY ''

Backslash is the MySQL escape character within strings in SQL statements. Thus, to specify a literal backslash, you must specify two backslashes for the value to be interpreted as a single backslash. The escape sequences '\t' and '\n' specify tab and newline characters, respectively.

In other words, the defaults cause LOAD DATA to act as follows when reading input:
LOAD DATA Statement

• Look for line boundaries at newlines.
• Do not skip any line prefix.
• Break lines into fields at tabs.
• Do not expect fields to be enclosed within any quoting characters.
• Interpret characters preceded by the escape character \ as escape sequences. For example, \t, \n, and \ signify tab, newline, and backslash, respectively. See the discussion of FIELDS ESCAPED BY later for the full list of escape sequences.

Conversely, the defaults cause SELECT ... INTO OUTFILE to act as follows when writing output:
• Write tabs between fields.
• Do not enclose fields within any quoting characters.
• Use \ to escape instances of tab, newline, or \ that occur within field values.
• Write newlines at the ends of lines.

Note
For a text file generated on a Windows system, proper file reading might require LINES TERMINATED BY '\r\n' because Windows programs typically use two characters as a line terminator. Some programs, such as WordPad, might use \r as a line terminator when writing files. To read such files, use LINES TERMINATED BY '\r'.

If all the input lines have a common prefix that you want to ignore, you can use LINES STARTING BY 'prefix_string' to skip the prefix and anything before it. If a line does not include the prefix, the entire line is skipped. Suppose that you issue the following statement:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test
FIELDS TERMINATED BY ',' LINES STARTING BY 'xxx';
```

If the data file looks like this:

```
xxx"abc",1
something xxx"def",2
"ghi",3
```

The resulting rows will be ("abc",1) and ("def",2). The third row in the file is skipped because it does not contain the prefix.

The IGNORE number LINES option can be used to ignore lines at the start of the file. For example, you can use IGNORE 1 LINES to skip an initial header line containing column names:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test IGNORE 1 LINES;
```

When you use SELECT ... INTO OUTFILE in tandem with LOAD DATA to write data from a database into a file and then read the file back into the database later, the field- and line-handling options for both statements must match. Otherwise, LOAD DATA will not interpret the contents of the file properly. Suppose that you use SELECT ... INTO OUTFILE to write a file with fields delimited by commas:

```
SELECT * INTO OUTFILE 'data.txt'
FIELDS TERMINATED BY ','
FROM table2;
```

To read the comma-delimited file, the correct statement would be:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
```
LOAD DATA Statement

LOAD DATA INFILE 'data.txt' INTO TABLE table2
FIELDS TERMINATED BY ','
LINES TERMINATED BY '\r\n'
IGNORE 1 LINES;

If the input values are not necessarily enclosed within quotation marks, use **OPTIONALLY** before the **ENCLOSED BY** option.

Any of the field- or line-handling options can specify an empty string ("'"'). If not empty, the **FIELDS [OPTIONALLY] ENCLOSED BY** and **FIELDS ESCAPED BY** values must be a single character. The **FIELDS TERMINATED BY**, **LINES STARTING BY**, and **LINES TERMINATED BY** values can be more than one character. For example, to write lines that are terminated by carriage return/linefeed pairs, or to read a file containing such lines, specify a **LINES TERMINATED BY \'\r\n'** clause.

To read a file containing jokes that are separated by lines consisting of %%

CREATE TABLE jokes
(a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  joke TEXT NOT NULL);
LOAD DATA INFILE '/tmp/jokes.txt' INTO TABLE jokes
FIELDS TERMINATED BY ''
LINES TERMINATED BY '\n%%
' (joke);

**FIELDS [OPTIONALLY] ENCLOSED BY** controls quoting of fields. For output (**SELECT ... INTO OUTFILE**), if you omit the word **OPTIONALLY**, all fields are enclosed by the **ENCLOSED BY** character. An example of such output (using a comma as the field delimiter) is shown here:

"1", "a string", 100.20
"2", "a string containing a , comma", 102.20
"3", "a string containing a " quote", 102.20
"4", "a string containing a ", quote and comma", 102.20

If you specify **OPTIONALLY**, the **ENCLOSED BY** character is used only to enclose values from columns that have a string data type (such as **CHAR**, **BINARY**, **TEXT**, or **ENUM**):

1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a " quote",102.20
4,"a string containing a ", quote and comma",102.20

**ESCAPED BY** character within a field value are escaped by prefixing them with the **ESCAPED BY** character. Also, if you specify an empty **ESCAPED BY** value, it is possible to inadvertently generate output that cannot be read properly by **LOAD DATA**. For example, the preceding output just shown would appear as follows if the escape character is empty. Observe that the second field in the fourth line contains a comma following the quote, which (erroneously) appears to terminate the field:

1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a * quote",102.20
4,"a string containing a *, quote and comma",102.20
For input, the **ENCLOSED BY** character, if present, is stripped from the ends of field values. (This is true regardless of whether **OPTIONALLY** is specified; **OPTIONALLY** has no effect on input interpretation.) Occurrences of the **ENCLOSED BY** character preceded by the **ESCAPED BY** character are interpreted as part of the current field value.

If the field begins with the **ENCLOSED BY** character, instances of that character are recognized as terminating a field value only if followed by the field or line **TERMINATED BY** sequence. To avoid ambiguity, occurrences of the **ENCLOSED BY** character within a field value can be doubled and are interpreted as a single instance of the character. For example, if **ENCLOSED BY '*'** is specified, quotation marks are handled as shown here:

```
"The ""BIG"" boss"  -> The "BIG" boss
The "BIG" boss      -> The "BIG" boss
The ""BIG"" boss    -> The ""BIG"" boss
```

**FIELDS ESCAPED BY** controls how to read or write special characters:

- For input, if the **FIELDS ESCAPED BY** character is not empty, occurrences of that character are stripped and the following character is taken literally as part of a field value. Some two-character sequences that are exceptions, where the first character is the escape character. These sequences are shown in the following table (using \\ for the escape character). The rules for **NULL** handling are described later in this section.

<table>
<thead>
<tr>
<th>Character</th>
<th>Escape Sequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>\0</td>
<td>An ASCII NUL (X'00') character</td>
</tr>
<tr>
<td>\b</td>
<td>A backspace character</td>
</tr>
<tr>
<td>\n</td>
<td>A newline (linefeed) character</td>
</tr>
<tr>
<td>\r</td>
<td>A carriage return character</td>
</tr>
<tr>
<td>\t</td>
<td>A tab character.</td>
</tr>
<tr>
<td>\Z</td>
<td>ASCII 26 (Control+Z)</td>
</tr>
<tr>
<td>\N</td>
<td><strong>NULL</strong></td>
</tr>
</tbody>
</table>

For more information about \\-escape syntax, see Section 9.1.1, “String Literals”.

If the **FIELDS ESCAPED BY** character is empty, escape-sequence interpretation does not occur.

- For output, if the **FIELDS ESCAPED BY** character is not empty, it is used to prefix the following characters on output:
  - The **FIELDS ESCAPED BY** character.
  - The **FIELDS [OPTIONALLY] ENCLOSED BY** character.
  - The first character of the **FIELDS TERMINATED BY** and **LINES TERMINATED BY** values, if the **ENCLOSED BY** character is empty or unspecified.
  - ASCII 0 (what is actually written following the escape character is ASCII 0, not a zero-valued byte).

If the **FIELDS ESCAPED BY** character is empty, no characters are escaped and **NULL** is output as **NULL**, not **\N**. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

In certain cases, field- and line-handling options interact:

- **If **LINES TERMINATED BY** is an empty string and **FIELDS TERMINATED BY** is nonempty, lines are also terminated with **FIELDS TERMINATED BY**.**

- **If the **FIELDS TERMINATED BY** and **FIELDS ENCLOSED BY** values are both empty (**''**), a fixed-row (nondelimited) format is used. With fixed-row format, no delimiters are used between fields.**
LOAD DATA Statement

(but you can still have a line terminator). Instead, column values are read and written using a field width wide enough to hold all values in the field. For TINYINT, SMALLINT, MEDIUMINT, INT, and BIGINT, the field widths are 4, 6, 8, 11, and 20, respectively, no matter what the declared display width is.

LINES TERMINATED BY is still used to separate lines. If a line does not contain all fields, the rest of the columns are set to their default values. If you do not have a line terminator, you should set this to "". In this case, the text file must contain all fields for each row.

Fixed-row format also affects handling of NULL values, as described later.

Note
Fixed-size format does not work if you are using a multibyte character set.

Handling of NULL values varies according to the FIELDS and LINES options in use:

- For the default FIELDS and LINES values, NULL is written as a field value of \N for output, and a field value of \N is read as NULL for input (assuming that the ESCAPED BY character is \).
- If FIELDS ENCLOSED BY is not empty, a field containing the literal word NULL as its value is read as a NULL value. This differs from the word NULL enclosed within FIELDS ENCLOSED BY characters, which is read as the string 'NULL'.
- If FIELDS ESCAPED BY is empty, NULL is written as the word NULL.
- With fixed-row format (which is used when FIELDS TERMINATED BY and FIELDS ENCLOSED BY are both empty), NULL is written as an empty string. This causes both NULL values and empty strings in the table to be indistinguishable when written to the file because both are written as empty strings. If you need to be able to tell the two apart when reading the file back in, you should not use fixed-row format.

An attempt to load NULL into a NOT NULL column causes assignment of the implicit default value for the column's data type and a warning, or an error in strict SQL mode. Implicit default values are discussed in Section 11.5, “Data Type Default Values”.

Some cases are not supported by LOAD DATA:

- Fixed-size rows (FIELDS TERMINATED BY and FIELDS ENCLOSED BY both empty) and BLOB or TEXT columns.
- If you specify one separator that is the same as or a prefix of another, LOAD DATA cannot interpret the input properly. For example, the following FIELDS clause would cause problems:

  FIELDS TERMINATED BY ' ' ENCLOSED BY ' ':

- If FIELDS ESCAPED BY is empty, a field value that contains an occurrence of FIELDS ENCLOSED BY or LINES TERMINATED BY followed by the FIELDS TERMINATED BY value causes LOAD DATA to stop reading a field or line too early. This happens because LOAD DATA cannot properly determine where the field or line value ends.

Column List Specification

The following example loads all columns of the persondata table:

```sql
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata;
```

By default, when no column list is provided at the end of the LOAD DATA statement, input lines are expected to contain a field for each table column. If you want to load only some of a table's columns, specify a column list:

```sql
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata
col_name_or_user_var [, col_name_or_user_var] ...);
```
You must also specify a column list if the order of the fields in the input file differs from the order of the columns in the table. Otherwise, MySQL cannot tell how to match input fields with table columns.

**Input Preprocessing**

Each `col_name_or_user_var` value is either a column name or a user variable. With user variables, the `SET` clause enables you to perform preprocessing transformations on their values before assigning the result to columns.

User variables in the `SET` clause can be used in several ways. The following example uses the first input column directly for the value of `t1.column1`, and assigns the second input column to a user variable that is subjected to a division operation before being used for the value of `t1.column2`:

```sql
LOAD DATA INFILE 'file.txt'
INTO TABLE t1
(column1, @var1)
SET column2 = @var1/100;
```

The `SET` clause can be used to supply values not derived from the input file. The following statement sets `column3` to the current date and time:

```sql
LOAD DATA INFILE 'file.txt'
INTO TABLE t1
(column1, column2)
SET column3 = CURRENT_TIMESTAMP;
```

You can also discard an input value by assigning it to a user variable and not assigning the variable to a table column:

```sql
LOAD DATA INFILE 'file.txt'
INTO TABLE t1
(column1, @dummy, column2, @dummy, column3);
```

Use of the column/variable list and `SET` clause is subject to the following restrictions:

- Assignments in the `SET` clause should have only column names on the left hand side of assignment operators.

- You can use subqueries in the right hand side of `SET` assignments. A subquery that returns a value to be assigned to a column may be a scalar subquery only. Also, you cannot use a subquery to select from the table that is being loaded.

- Lines ignored by an `IGNORE` clause are not processed for the column/variable list or `SET` clause.

- User variables cannot be used when loading data with fixed-row format because user variables do not have a display width.

When processing an input line, `LOAD DATA` splits it into fields and uses the values according to the column/variable list and the `SET` clause, if they are present. Then the resulting row is inserted into the table. If there are `BEFORE INSERT` or `AFTER INSERT` triggers for the table, they are activated before or after inserting the row, respectively.

If an input line has too many fields, the extra fields are ignored and the number of warnings is incremented.

If an input line has too few fields, the table columns for which input fields are missing are set to their default values. Default value assignment is described in Section 11.5, “Data Type Default Values”.

An empty field value is interpreted different from a missing field:

- For string types, the column is set to the empty string.

- For numeric types, the column is set to 0.

- For date and time types, the column is set to the appropriate “zero” value for the type. See Section 11.2, “Date and Time Data Types”.

1607
These are the same values that result if you assign an empty string explicitly to a string, numeric, or date or time type explicitly in an `INSERT` or `UPDATE` statement.

Treatment of empty or incorrect field values differs from that just described if the SQL mode is set to a restrictive value. For example, if `sql_mode` is set to `TRADITIONAL`, conversion of an empty value or a value such as `'x'` for a numeric column results in an error, not conversion to 0. (With `LOCAL` or `IGNORE`, warnings occur rather than errors, even with a restrictive `sql_mode` value, and the row is inserted using the same closest-value behavior used for nonrestrictive SQL modes. This occurs because the server has no way to stop transmission of the file in the middle of the operation.)

`TIMESTAMP` columns are set to the current date and time only if there is a `NULL` value for the column (that is, `\N`) and the column is not declared to permit `NULL` values, or if the `TIMESTAMP` column's default value is the current timestamp and it is omitted from the field list when a field list is specified.

`LOAD DATA` regards all input as strings, so you cannot use numeric values for `ENUM` or `SET` columns the way you can with `INSERT` statements. All `ENUM` and `SET` values must be specified as strings.

`BIT` values cannot be loaded directly using binary notation (for example, `b'011010'`). To work around this, use the `SET` clause to strip off the leading `b`' and trailing ` ' and perform a base-2 to base-10 conversion so that MySQL loads the values into the `BIT` column properly:

```sql
shell> cat /tmp/bit_test.txt
b'10'
b'1111111'
shell> mysql test
mysql>
mysql> LOAD DATA INFILE '/tmp/bit_test.txt'
INTO TABLE bit_test (@var1)
SET b = CAST(CONV(MID(@var1, 3, LENGTH(@var1)-3), 2, 10) AS UNSIGNED);
Query OK, 2 rows affected (0.00 sec)
Records: 2 Deleted: 0 Skipped: 0 Warnings: 0
mysql>
SELECT BIN(b+0) FROM bit_test;
```

```
+----------+
| BIN(b+0) |
+----------+
| 10       |
| 1111111  |
+----------+
2 rows in set (0.00 sec)
```

For `BIT` values in `0b` binary notation (for example, `0b011010`), use this `SET` clause instead to strip off the leading `0b`:

```sql
SET b = CAST(CONV(MID(@var1, 3, LENGTH(@var1)-2), 2, 10) AS UNSIGNED)
```

**Statement Result Information**

When the `LOAD DATA` statement finishes, it returns an information string in the following format:

```
Records: 1 Deleted: 0 Skipped: 0 Warnings: 0
```

Warnings occur under the same circumstances as when values are inserted using the `INSERT` statement (see Section 13.2.5, “INSERT Statement”), except that `LOAD DATA` also generates warnings when there are too few or too many fields in the input row.

You can use `SHOW WARNINGS` to get a list of the first `max_error_count` warnings as information about what went wrong. See Section 13.7.5.41, “SHOW WARNINGS Statement”.

If you are using the C API, you can get information about the statement by calling the `mysql_info()` function. See `mysql_info()`.

**Miscellaneous Topics**

On Unix, if you need `LOAD DATA` to read from a pipe, you can use the following technique (the example loads a listing of the `/` directory into the table `db1.t1`):
Here you must run the command that generates the data to be loaded and the `mysql` commands either on separate terminals, or run the data generation process in the background (as shown in the preceding example). If you do not do this, the pipe will block until data is read by the `mysql` process.

**13.2.7 LOAD XML Statement**

The `LOAD XML` statement reads data from an XML file into a table. The `file_name` must be given as a literal string. The `tagname` in the optional `ROWS IDENTIFIED BY` clause must also be given as a literal string, and must be surrounded by angle brackets (`<` and `>`).

```
LOAD XML
  [LOW_PRIORITY | CONCURRENT] [LOCAL]
  INFILE 'file_name'
  [REPLACE | IGNORE]
  INTO TABLE [db_name.]tbl_name
  [CHARACTER SET charset_name]
  [ROWS IDENTIFIED BY '<tagname>']
  [IGNORE number {LINES | ROWS}]
  [(field_name_or_user_var
      , field_name_or_user_var
      ) ...]
  [SET col_name={expr | DEFAULT},
      , col_name={expr | DEFAULT}]
```

This statement supports three different XML formats:

- **Column names as attributes and column values as attribute values:**

```
<row column1="value1" column2="value2" .../>
```

- **Column names as tags and column values as the content of these tags:**

```
<row>
  <column1>value1</column1>
  <column2>value2</column2>
</row>
```

- **Column names are the `name` attributes of `<field>` tags, and values are the contents of these tags:**

```
<row>
  <field name='column1'>value1</field>
  <field name='column2'>value2</field>
</row>
```

This is the format used by other MySQL tools, such as `mysqldump`.

All three formats can be used in the same XML file; the import routine automatically detects the format for each row and interprets it correctly. Tags are matched based on the tag or attribute name and the column name.

Prior to MySQL 5.6.27, `LOAD XML` did not handle empty XML elements in the form `<element/>` correctly. (Bug #67542, Bug #16171518)
In MySQL 5.6, `LOAD XML` does not support `CDATA` sections in the source XML. This limitation is removed in MySQL 8.0. (Bug #30753708, Bug #981999)

The following clauses work essentially the same way for `LOAD XML` as they do for `LOAD DATA`:

- `LOW_PRIORITY` or `CONCURRENT`
- `LOCAL`
- `REPLACE` or `IGNORE`
- `CHARACTER SET`
- `SET`

See Section 13.2.6, “LOAD DATA Statement”, for more information about these clauses.

`(<field_name_or_user_var>, ...)` is a list of one or more comma-separated XML fields or user variables. The name of a user variable used for this purpose must match the name of a field from the XML file, prefixed with `@`. You can use field names to select only desired fields. User variables can be employed to store the corresponding field values for subsequent re-use.

The `IGNORE number LINES` or `IGNORE number ROWS` clause causes the first `number` rows in the XML file to be skipped. It is analogous to the `LOAD DATA` statement's `IGNORE ... LINES` clause.

Suppose that we have a table named `person`, created as shown here:

```sql
USE test;
CREATE TABLE person (
    person_id INT NOT NULL PRIMARY KEY,
    fname VARCHAR(40) NULL,
    lname VARCHAR(40) NULL,
    created TIMESTAMP
);
```

Suppose further that this table is initially empty.

Now suppose that we have a simple XML file `person.xml`, whose contents are as shown here:

```xml
<list>
    <person person_id="1" fname="Kapek" lname="Sainnouine"/>
    <person person_id="2" fname="Sajon" lname="Rondela"/>
    <person person_id="3" fname="Likame" lname="Örrtmons"/>...
</list>
```

Each of the permissible XML formats discussed previously is represented in this example file.

To import the data in `person.xml` into the `person` table, you can use this statement:

```sql
mysql> LOAD XML LOCAL INFILE 'person.xml'
    -> INTO TABLE person
    -> ROWS IDENTIFIED BY '<person>';
Query OK, 8 rows affected (0.00 sec)
Records: 8  Deleted: 0  Skipped: 0  Warnings: 0
```

Here, we assume that `person.xml` is located in the MySQL data directory. If the file cannot be found, the following error results:

```sql
ERROR 2 (HY000): File '/person.xml' not found (Errcode: 2)
```
The `ROWS IDENTIFIED BY `<person>'` clause means that each `<person>` element in the XML file is considered equivalent to a row in the table into which the data is to be imported. In this case, this is the `person` table in the `test` database.

As can be seen by the response from the server, 8 rows were imported into the `test.person` table. This can be verified by a simple `SELECT` statement:

```
mysql> SELECT * FROM person;
+-----------+--------+------------+---------------------+
| person_id | fname  | lname      | created             |
|-----------+--------+------------+---------------------|
|         1 | Kapek  | Sainnouine | 2007-07-13 16:18:47 |
|         2 | Sajon  | Rondela    | 2007-07-13 16:18:47 |
|         3 | Likame | Örrtmons   | 2007-07-13 16:18:47 |
|         4 | Slar   | Manlanth   | 2007-07-13 16:18:47 |
|         5 | Stoma  | Nilu       | 2007-07-13 16:18:47 |
|         6 | Nirtam | Sklöd      | 2007-07-13 16:18:47 |
|         7 | Sungam | Dulbåd     | 2007-07-13 16:18:47 |
|         8 | Sreraf | Encmelt    | 2007-07-13 16:18:47 |
+-----------+--------+------------+---------------------+
8 rows in set (0.00 sec)
```

This shows, as stated earlier in this section, that any or all of the 3 permitted XML formats may appear in a single file and be read using `LOAD XML`.

The inverse of the import operation just shown—that is, dumping MySQL table data into an XML file—can be accomplished using the `mysql` client from the system shell, as shown here:

```
shell> mysql --xml -e "SELECT * FROM test.person" > person-dump.xml
shell> cat person-dump.xml
<?xml version="1.0"?>
<resultset statement="SELECT * FROM test.person" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
    <row>
        <field name="person_id">1</field>
        <field name="fname">Kapek</field>
        <field name="lname">Sainnouine</field>
    </row>
    <row>
        <field name="person_id">2</field>
        <field name="fname">Sajon</field>
        <field name="lname">Rondela</field>
    </row>
    <row>
        <field name="person_id">3</field>
        <field name="fname">Likame</field>
        <field name="lname">Örrtmons</field>
    </row>
    <row>
        <field name="person_id">4</field>
        <field name="fname">Slar</field>
        <field name="lname">Manlanth</field>
    </row>
    <row>
        <field name="person_id">5</field>
        <field name="fname">Stoma</field>
        <field name="lname">Nilu</field>
    </row>
    <row>
        <field name="person_id">6</field>
        <field name="fname">Nirtam</field>
        <field name="lname">Sklöd</field>
    </row>
    <row>
        <field name="person_id">7</field>
        <field name="fname">Sungam</field>
        <field name="lname">Dulbåd</field>
    </row>
    <row>
        <field name="person_id">8</field>
        <field name="fname">Sreraf</field>
        <field name="lname">Encmelt</field>
    </row>
</resultset>
```
Note

The --xml option causes the mysql client to use XML formatting for its output; the -e option causes the client to execute the SQL statement immediately following the option. See Section 4.5.1, "mysql — The MySQL Command-Line Client".

You can verify that the dump is valid by creating a copy of the person table and importing the dump file into the new table, like this:

```sql
mysql> USE test;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE person2 LIKE person;
Query OK, 0 rows affected (0.00 sec)

mysql> LOAD XML LOCAL INFILE 'person-dump.xml' INTO TABLE person2;
Query OK, 8 rows affected (0.01 sec)
Records: 8  Deleted: 0  Skipped: 0  Warnings: 0

mysql> SELECT * FROM person2;
+-----------+--------+------------+---------------------+
| person_id | fname  | lname      | created             |
+-----------+--------+------------+---------------------+
|         1 | Kapek  | Sainnouine | 2007-07-13 16:18:47 |
|         2 | Sajon  | Rondela    | 2007-07-13 16:18:47 |
|         3 | Likema | Örrtmons   | 2007-07-13 16:18:47 |
|         4 | Slar   | Manlanth   | 2007-07-13 16:18:47 |
|         5 | Stoma  | Nulu       | 2007-07-13 16:18:47 |
|         6 | Nirtam | Sklöd      | 2007-07-13 16:18:47 |
|         7 | Sungam | Dulbåd     | 2007-07-13 16:18:47 |
|         8 | Sreraf | Encmelt    | 2007-07-13 16:18:47 |
+-----------+--------+------------+---------------------+
8 rows in set (0.00 sec)
```

There is no requirement that every field in the XML file be matched with a column in the corresponding table. Fields which have no corresponding columns are skipped. You can see this by first emptying the person2 table and dropping the created column, then using the same LOAD XML statement we just employed previously, like this:

```sql
mysql> TRUNCATE person2;
Query OK, 8 rows affected (0.26 sec)

mysql> ALTER TABLE person2 DROP COLUMN created;
Query OK, 0 rows affected (0.52 sec)
Records: 0  Duplicates: 0  Warnings: 0

mysql> SHOW CREATE TABLE person2\G
*************************** 1. row ***************************
Table: person2
Create Table: CREATE TABLE `person2` (  `person_id` int(11) NOT NULL,  `fname` varchar(40) DEFAULT NULL,  `lname` varchar(40) DEFAULT NULL,  PRIMARY KEY (`person_id`) ) ENGINE=InnoDB DEFAULT CHARSET=utf8
1 row in set (0.00 sec)

mysql> LOAD XML LOCAL INFILE `person-dump.xml`
```
The order in which the fields are given within each row of the XML file does not affect the operation of `LOAD XML`; the field order can vary from row to row, and is not required to be in the same order as the corresponding columns in the table.

As mentioned previously, you can use a `(field_name_or_user_var, ...)` list of one or more XML fields (to select desired fields only) or user variables (to store the corresponding field values for later use). User variables can be especially useful when you want to insert data from an XML file into table columns whose names do not match those of the XML fields. To see how this works, we first create a table named `individual` whose structure matches that of the `person` table, but whose columns are named differently:

```sql
mysql> CREATE TABLE individual (individual_id INT NOT NULL PRIMARY KEY, name1 VARCHAR(40) NULL, name2 VARCHAR(40) NULL, made TIMESTAMP);
Query OK, 0 rows affected (0.42 sec)
```

In this case, you cannot simply load the XML file directly into the table, because the field and column names do not match:

```sql
mysql> LOAD XML INFILE '../bin/person-dump.xml' INTO TABLE test.individual;
ERROR 1263 (22004): Column set to default value; NULL supplied to NOT NULL column 'individual_id' at row 1
```

This happens because the MySQL server looks for field names matching the column names of the target table. You can work around this problem by selecting the field values into user variables, then setting the target table’s columns equal to the values of those variables using `SET`. You can perform both of these operations in a single statement, as shown here:

```sql
mysql> LOAD XML INFILE '../bin/person-dump.xml'
    -> INTO TABLE test.individual (@person_id, @fname, @lname, @created)
    -> SET individual_id=@person_id, name1=@fname, name2=@lname, made=@created;
Query OK, 8 rows affected (0.05 sec)
```

This results in:

```sql
+---------------+--------+------------+---------------------+
| individual_id | name1  | name2      | made                |
+---------------+--------+------------+---------------------+
|             1 | Kapek  | Sainnouine | 2007-07-13 16:18:47 |
|             2 | Sajon  | Rondela    | 2007-07-13 16:18:47 |
|             3 | Likema | Örrtmons   | 2007-07-13 16:18:47 |
|             4 | Slar   | Manlanth   | 2007-07-13 16:18:47 |
|             5 | Stoma  | Nilu       | 2007-07-13 16:18:47 |
|             6 | Nirtam | Sklöd      | 2007-07-13 16:18:47 |
|             7 | Sungam | Dulbåd     | 2007-07-13 16:18:47 |
|             8 | Srraf  | Encmelt    | 2007-07-13 16:18:47 |
+---------------+--------+------------+---------------------+
8 rows in set (0.00 sec)
```
The names of the user variables must match those of the corresponding fields from the XML file, with the addition of the required @ prefix to indicate that they are variables. The user variables need not be listed or assigned in the same order as the corresponding fields.

Using a ROWS IDENTIFIED BY '<tagname>' clause, it is possible to import data from the same XML file into database tables with different definitions. For this example, suppose that you have a file named address.xml which contains the following XML:

```xml
<?xml version="1.0"?>
<list>
  <person person_id="1">
    <fname>Robert</fname>
    <lname>Jones</lname>
    <address address_id="1" street="Mill Creek Road" zip="45365" city="Sidney"/>
    <address address_id="2" street="Main Street" zip="28681" city="Taylorsville"/>
  </person>
  <person person_id="2">
    <fname>Mary</fname>
    <lname>Smith</lname>
    <address address_id="3" street="River Road" zip="80239" city="Denver"/>
    <!-- <address address_id="4" street="North Street" zip="37920" city="Knoxville"/> -->
  </person>
</list>
```

You can again use the test.person table as defined previously in this section, after clearing all the existing records from the table and then showing its structure as shown here:

```
mysql> TRUNCATE person;
Query OK, 0 rows affected (0.04 sec)

mysql> SHOW CREATE TABLE person\G
*************************** 1. row ***************************
Table: person
Create Table: CREATE TABLE `person` (  `person_id` int(11) NOT NULL,  `fname` varchar(40) DEFAULT NULL,  `lname` varchar(40) DEFAULT NULL,  `created` timestamp NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,  PRIMARY KEY (`person_id`)) ENGINE=MyISAM DEFAULT CHARSET=latin1
1 row in set (0.00 sec)
```

Now create an address table in the test database using the following CREATE TABLE statement:

```
CREATE TABLE address (  address_id INT NOT NULL PRIMARY KEY,  person_id INT NULL,  street VARCHAR(40) NULL,  zip INT NULL,  city VARCHAR(40) NULL,  created TIMESTAMP);
```

To import the data from the XML file into the person table, execute the following LOAD XML statement, which specifies that rows are to be specified by the <person> element, as shown here:

```
mysql> LOAD XML LOCAL INFILE 'address.xml'  -> INTO TABLE person  -> ROWS IDENTIFIED BY '<person>';  Query OK, 2 rows affected (0.00 sec)  Records: 2  Deleted: 0  Skipped: 0  Warnings: 0
```

You can verify that the records were imported using a SELECT statement:

```
mysql> SELECT * FROM person;
| person_id | fname  | lname | created |
+-----------+--------+-------+---------|
```

1614
Since the `<address>` elements in the XML file have no corresponding columns in the `person` table, they are skipped.

To import the data from the `<address>` elements into the `address` table, use the `LOAD XML` statement shown here:

```sql
mysql> LOAD XML LOCAL INFILE 'address.xml'
    -> INTO TABLE address
    -> ROWS IDENTIFIED BY '<address>';
Query OK, 3 rows affected (0.00 sec)
Records: 3 Deleted: 0 Skipped: 0 Warnings: 0
```

You can see that the data was imported using a `SELECT` statement such as this one:

```sql
mysql> SELECT * FROM address;
```

The data from the `<address>` element that is enclosed in XML comments is not imported. However, since there is a `person_id` column in the `address` table, the value of the `person_id` attribute from the parent `<person>` element for each `<address>` is imported into the `address` table.

**Security Considerations.** As with the `LOAD DATA` statement, the transfer of the XML file from the client host to the server host is initiated by the MySQL server. In theory, a patched server could be built that would tell the client program to transfer a file of the server's choosing rather than the file named by the client in the `LOAD XML` statement. Such a server could access any file on the client host to which the user has read access.

In a Web environment, clients usually connect to MySQL from a Web server. A user that can run any command against the MySQL server can use `LOAD XML LOCAL` to read any files to which the Web server process has read access. In this environment, the client with respect to the MySQL server is actually the Web server, not the remote program being run by the user who connects to the Web server.

You can disable loading of XML files from clients by starting the server with `--local-infile=0` or `--local-infile=OFF`. This option can also be used when starting the `mysql` client to disable `LOAD XML` for the duration of the client session.

To prevent a client from loading XML files from the server, do not grant the `FILE` privilege to the corresponding MySQL user account, or revoke this privilege if the client user account already has it.

---

### Important

Revoking the `FILE` privilege (or not granting it in the first place) keeps the user only from executing the `LOAD XML` statement (as well as the `LOAD_FILE()` function); it does not prevent the user from executing `LOAD XML LOCAL`. To disallow this statement, you must start the server or the client with `--local-infile=OFF`.

In other words, the `FILE` privilege affects only whether the client can read files on the server; it has no bearing on whether the client can read files on the local file system.
For partitioned tables using storage engines that employ table locks, such as MyISAM, any locks caused by LOAD XML perform locks on all partitions of the table. This does not apply to tables using storage engines which employ row-level locking, such as InnoDB. For more information, see Section 19.6.4, “Partitioning and Locking”.

13.2.8 REPLACE Statement

REPLACE [LOW_PRIORITY | DELAYED]
[INTO] tbl_name
[PARTITION (partition_name [, partition_name] ...)]
[({col_name [, col_name] ...})]
[VALUES | VALUE] (value_list) [, (value_list)] ...

REPLACE [LOW_PRIORITY | DELAYED]
[INTO] tbl_name
[PARTITION (partition_name [, partition_name] ...)]
SET assignment_list

REPLACE [LOW_PRIORITY | DELAYED]
[INTO] tbl_name
[PARTITION (partition_name [, partition_name] ...)]
[({col_name [, col_name] ...})]
SELECT ...

value:
    {expr | DEFAULT}

value_list:
    value [, value] ...

assignment:
    col_name = value

assignment_list:
    assignment [, assignment] ...

REPLACE works exactly like INSERT, except that if an old row in the table has the same value as a new row for a PRIMARY KEY or a UNIQUE index, the old row is deleted before the new row is inserted. See Section 13.2.5, “INSERT Statement”.

REPLACE is a MySQL extension to the SQL standard. It either inserts, or deletes and inserts. For another MySQL extension to standard SQL—that either inserts or updates—see Section 13.2.5.2, “INSERT ... ON DUPLICATE KEY UPDATE Statement”.

Note

REPLACE makes sense only if a table has a PRIMARY KEY or UNIQUE index. Otherwise, it becomes equivalent to INSERT, because there is no index to be used to determine whether a new row duplicates another.

Values for all columns are taken from the values specified in the REPLACE statement. Any missing columns are set to their default values, just as happens for INSERT. You cannot refer to values from the current row and use them in the new row. If you use an assignment such as SET col_name = col_name + 1, the reference to the column name on the right hand side is treated as DEFAULT(col_name), so the assignment is equivalent to SET col_name = DEFAULT(col_name) + 1.

To use REPLACE, you must have both the INSERT and DELETE privileges for the table.

REPLACE supports explicit partition selection using the PARTITION keyword with a list of comma-separated names of partitions, subpartitions, or both. As with INSERT, if it is not possible to insert the new row into any of these partitions or subpartitions, the REPLACE statement fails with the error Found a row not matching the given partition set. For more information and examples, see Section 19.5, “Partition Selection”.
The `REPLACE` statement returns a count to indicate the number of rows affected. This is the sum of the rows deleted and inserted. If the count is 1 for a single-row `REPLACE`, a row was inserted and no rows were deleted. If the count is greater than 1, one or more old rows were deleted before the new row was inserted. It is possible for a single row to replace more than one old row if the table contains multiple unique indexes and the new row duplicates values for different old rows in different unique indexes.

The affected-rows count makes it easy to determine whether `REPLACE` only added a row or whether it also replaced any rows: Check whether the count is 1 (added) or greater (replaced).

If you are using the C API, the affected-rows count can be obtained using the `mysql_affected_rows()` function.

You cannot replace into a table and select from the same table in a subquery.

MySQL uses the following algorithm for `REPLACE` (and `LOAD DATA ... REPLACE`):

1. Try to insert the new row into the table
2. While the insertion fails because a duplicate-key error occurs for a primary key or unique index:
   a. Delete from the table the conflicting row that has the duplicate key value
   b. Try again to insert the new row into the table

It is possible that in the case of a duplicate-key error, a storage engine may perform the `REPLACE` as an update rather than a delete plus insert, but the semantics are the same. There are no user-visible effects other than a possible difference in how the storage engine increments `Handler_xxx` status variables.

Because the results of `REPLACE ... SELECT` statements depend on the ordering of rows from the `SELECT` and this order cannot always be guaranteed, it is possible when logging these statements for the source and the slave to diverge. For this reason, `REPLACE ... SELECT` statements are flagged as unsafe for statement-based replication. such statements produce a warning in the error log when using statement-based mode and are written to the binary log using the row-based format when using `MIXED` mode. See also Section 17.1.2.1, "Advantages and Disadvantages of Statement-Based and Row-Based Replication".

When modifying an existing table that is not partitioned to accommodate partitioning, or, when modifying the partitioning of an already partitioned table, you may consider altering the table's primary key (see Section 19.6.1, "Partitioning Keys, Primary Keys, and Unique Keys"). You should be aware that, if you do this, the results of `REPLACE` statements may be affected, just as they would be if you modified the primary key of a nonpartitioned table. Consider the table created by the following `CREATE TABLE` statement:

```sql
CREATE TABLE test (
    id INT UNSIGNED NOT NULL AUTO_INCREMENT,
    data VARCHAR(64) DEFAULT NULL,
    ts TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
    PRIMARY KEY (id)
);
```

When we create this table and run the statements shown in the `mysql` client, the result is as follows:

```sql
mysql> REPLACE INTO test VALUES (1, 'Old', '2014-08-20 18:47:00');
Query OK, 1 row affected (0.04 sec)

mysql> REPLACE INTO test VALUES (1, 'New', '2014-08-20 18:47:42');
Query OK, 2 rows affected (0.04 sec)

mysql> SELECT * FROM test;
+----+------+---------------------+
<table>
<thead>
<tr>
<th>id</th>
<th>data</th>
<th>ts</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>New</td>
<td>2014-08-20 18:47:42</td>
</tr>
</tbody>
</table>
+----+------+---------------------+
```

1617
Now we create a second table almost identical to the first, except that the primary key now covers 2 columns, as shown here (emphasized text):

```sql
CREATE TABLE test2 (    id INT UNSIGNED NOT NULL AUTO_INCREMENT,    data VARCHAR(64) DEFAULT NULL,    ts TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,    PRIMARY KEY (id, ts) );
```

When we run on `test2` the same two `REPLACE` statements as we did on the original `test` table, we obtain a different result:

```sql
mysql> REPLACE INTO test2 VALUES (1, 'Old', '2014-08-20 18:47:00'); Query OK, 1 row affected (0.05 sec)
mysql> REPLACE INTO test2 VALUES (1, 'New', '2014-08-20 18:47:42'); Query OK, 1 row affected (0.06 sec)
mysql> SELECT * FROM test2;
+----+------+---------------------+    | id | data | ts                  |    +----+------+---------------------+    |  1 | Old  | 2014-08-20 18:47:00 |    |  1 | New  | 2014-08-20 18:47:42 |    +----+------+---------------------+    2 rows in set (0.00 sec)
```

This is due to the fact that, when run on `test2`, both the `id` and `ts` column values must match those of an existing row for the row to be replaced; otherwise, a row is inserted.

A `REPLACE` statement affecting a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks only those partitions containing rows that match the `REPLACE` statement `WHERE` clause, as long as none of the table partitioning columns are updated; otherwise the entire table is locked. (For storage engines such as InnoDB that employ row-level locking, no locking of partitions takes place.) For more information, see Section 19.6.4, “Partitioning and Locking”.

### SELECT Statement

```sql
SELECT
   [ALL | DISTINCT | DISTINCTROW ]
   [HIGH_PRIORITY]
   [STRAIGHT_JOIN]
   [SQL_SMALL_RESULT] [SQL_BIG_RESULT] [SQL_BUFFER_RESULT]
   [SQL_CACHE | SQL_NO_CACHE]
   [SQL_CALC_FOUND_ROWS]
   select_expr [ , select_expr ] ...
   [into_option]
   [FROM table_references
      [PARTITION partition_list]]
   [WHERE where_condition]
   [GROUP BY {col_name | expr | position]
      [ASC | DESC], ... [WITH ROLLUP]]
   [HAVING where_condition]
   [ORDER BY {col_name | expr | position]
      [ASC | DESC], ...]
   [LIMIT { [offset,] row_count | row_count OFFSET offset}]
   [PROCEDURE procedure_name(argument_list)]
   [into_option]
   [FOR UPDATE | LOCK IN SHARE MODE]
   into_option: {
      INTO OUTFILE 'file_name'
      [CHARACTER SET charset_name]
      export_options
      INTO DUMPFILE 'file_name'
      INTO var_name [, var_name] ...
   }
```
**SELECT Statement**

**SELECT** is used to retrieve rows selected from one or more tables, and can include **UNION** statements and subqueries. See Section 13.2.9.3, “UNION Clause”, and Section 13.2.10, “Subqueries”.

The most commonly used clauses of **SELECT** statements are these:

- Each **select_expr** indicates a column that you want to retrieve. There must be at least one **select_expr**.

- **table_references** indicates the table or tables from which to retrieve rows. Its syntax is described in Section 13.2.9.2, “JOIN Clause”.

- **SELECT** supports explicit partition selection using the **PARTITION** keyword with a list of partitions or subpartitions (or both) following the name of the table in a **table_reference** (see Section 13.2.9.2, “JOIN Clause”). In this case, rows are selected only from the partitions listed, and any other partitions of the table are ignored. For more information and examples, see Section 19.5, “Partition Selection”.

**SELECT ... PARTITION** from tables using storage engines such as **MyISAM** that perform table-level locks (and thus partition locks) lock only the partitions or subpartitions named by the **PARTITION** option.

For more information, see Section 19.6.4, “Partitioning and Locking”.

- The **WHERE** clause, if given, indicates the condition or conditions that rows must satisfy to be selected. **where_condition** is an expression that evaluates to true for each row to be selected. The statement selects all rows if there is no **WHERE** clause.

In the **WHERE** expression, you can use any of the functions and operators that MySQL supports, except for aggregate (group) functions. See Section 9.5, “Expressions”, and Chapter 12, Functions and Operators.

**SELECT** can also be used to retrieve rows computed without reference to any table.

For example:

```
mysql> SELECT 1 + 1;
-> 2
```

You are permitted to specify **DUAL** as a dummy table name in situations where no tables are referenced:

```
mysql> SELECT 1 + 1 FROM DUAL;
-> 2
```

**DUAL** is purely for the convenience of people who require that all **SELECT** statements should have **FROM** and possibly other clauses. MySQL may ignore the clauses. MySQL does not require **FROM** **DUAL** if no tables are referenced.

In general, clauses used must be given in exactly the order shown in the syntax description. For example, a **HAVING** clause must come after any **GROUP BY** clause and before any **ORDER BY** clause. The **INTO** clause, if present, can appear in any position indicated by the syntax description, but within a given statement can appear only once, not in multiple positions. For more information about **INTO**, see Section 13.2.9.1, “SELECT ... INTO Statement”.

The list of **select_expr** terms comprises the select list that indicates which columns to retrieve. Terms specify a column or expression or can use *** -shorthand**:

- A select list consisting only of a single unqualified *** can be used as shorthand to select all columns from all tables:

  ```
  SELECT * FROM t1 INNER JOIN t2 ...
  ```

- **tbl_name.** can be used as a qualified shorthand to select all columns from the named table:

  ```
  SELECT t1.*, t2.* FROM t1 INNER JOIN t2 ...
  ```
**SELECT Statement**

- Use of an unqualified * with other items in the select list may produce a parse error. To avoid this problem, use a qualified `tbl_name`.* reference

```sql
SELECT AVG(score), t1.* FROM t1 ...
```

The following list provides additional information about other `SELECT` clauses:

- A `select_expr` can be given an alias using `AS alias_name`. The alias is used as the expression’s column name and can be used in `GROUP BY`, `ORDER BY`, or `HAVING` clauses. For example:

```sql
SELECT CONCAT(last_name,', ',first_name) AS full_name
    FROM mytable ORDER BY full_name;
```

The `AS` keyword is optional when aliasing a `select_expr` with an identifier. The preceding example could have been written like this:

```sql
SELECT CONCAT(last_name,', ',first_name) full_name
    FROM mytable ORDER BY full_name;
```

However, because the `AS` is optional, a subtle problem can occur if you forget the comma between two `select_expr` expressions: MySQL interprets the second as an alias name. For example, in the following statement, `columnb` is treated as an alias name:

```sql
SELECT columna columnb FROM mytable;
```

For this reason, it is good practice to be in the habit of using `AS` explicitly when specifying column aliases.

- It is not permissible to refer to a column alias in a `WHERE` clause, because the column value might not yet be determined when the `WHERE` clause is executed. See Section B.3.4.4, “Problems with Column Aliases”.

- The `FROM table_references` clause indicates the table or tables from which to retrieve rows. If you name more than one table, you are performing a join. For information on join syntax, see Section 13.2.9.2, “JOIN Clause”. For each table specified, you can optionally specify an alias.

```sql
tbl_name [{AS} alias] [index_hint]
```

The use of index hints provides the optimizer with information about how to choose indexes during query processing. For a description of the syntax for specifying these hints, see Section 8.9.3, “Index Hints”.

You can use `SET max_seeks_for_key=value` as an alternative way to force MySQL to prefer key scans instead of table scans. See Section 5.1.7, “Server System Variables”.

- You can refer to a table within the default database as `tbl_name`, or as `db_name.tbl_name` to specify a database explicitly. You can refer to a column as `col_name`, `tbl_name.col_name`, or `db_name.tbl_name.col_name`. You need not specify a `tbl_name` or `db_name` prefix for a column reference unless the reference would be ambiguous. See Section 9.2.2, “Identifier Qualifiers”, for examples of ambiguity that require the more explicit column reference forms.

```sql
SELECT t1.name, t2.salary FROM employee AS t1, info AS t2
    WHERE t1.name = t2.name;
```

- A table reference can be aliased using `tbl_name AS alias_name` or `tbl_name alias_name`. These statements are equivalent:

```sql
SELECT t1.name, t2.salary FROM employee AS t1, info AS t2
    WHERE t1.name = t2.name;
SELECT t1.name, t2.salary FROM employee t1, info t2
    WHERE t1.name = t2.name;
```

- Columns selected for output can be referred to in `ORDER BY` and `GROUP BY` clauses using column names, column aliases, or column positions. Column positions are integers and begin with 1:
SELECT college, region, seed FROM tournament
ORDER BY region, seed;

SELECT college, region AS r, seed AS s FROM tournament
ORDER BY r, s;

SELECT college, region, seed FROM tournament
ORDER BY 2, 3;

To sort in reverse order, add the `DESC` (descending) keyword to the name of the column in the `ORDER BY` clause that you are sorting by. The default is ascending order; this can be specified explicitly using the `ASC` keyword.

If `ORDER BY` occurs within a parenthesized query expression and also is applied in the outer query, the results are undefined and may change in a future MySQL version.

Use of column positions is deprecated because the syntax has been removed from the SQL standard.

- MySQL extends the `GROUP BY` clause so that you can also specify `ASC` and `DESC` after columns named in the clause:

  ```sql
  SELECT a, COUNT(b) FROM test_table GROUP BY a DESC;
  ```

- If you use `GROUP BY`, output rows are sorted according to the `GROUP BY` columns as if you had an `ORDER BY` for the same columns. To avoid the overhead of sorting that `GROUP BY` produces, add `ORDER BY NULL`:

  ```sql
  SELECT a, COUNT(b) FROM test_table GROUP BY a ORDER BY NULL;
  ```

Relying on implicit `GROUP BY` sorting (that is, sorting in the absence of `ASC` or `DESC` designators) is deprecated. To produce a given sort order, use explicit `ASC` or `DESC` designators for `GROUP BY` columns or provide an `ORDER BY` clause.

- When you use `ORDER BY` or `GROUP BY` to sort a column in a `SELECT`, the server sorts values using only the initial number of bytes indicated by the `max_sort_length` system variable.

- MySQL extends the use of `GROUP BY` to permit selecting fields that are not mentioned in the `GROUP BY` clause. If you are not getting the results that you expect from your query, please read the description of `GROUP BY` found in Section 12.19, “Aggregate Functions”.

- `GROUP BY` permits a `WITH ROLLUP` modifier. See Section 12.19.2, “GROUP BY Modifiers”.

- The `HAVING` clause is applied nearly last, just before items are sent to the client, with no optimization. (`LIMIT` is applied after `HAVING`.)

The SQL standard requires that `HAVING` must reference only columns in the `GROUP BY` clause or columns used in aggregate functions. However, MySQL supports an extension to this behavior, and permits `HAVING` to refer to columns in the `SELECT` list and columns in outer subqueries as well.

If the `HAVING` clause refers to a column that is ambiguous, a warning occurs. In the following statement, `col12` is ambiguous because it is used as both an alias and a column name:

```sql
SELECT COUNT(col1) AS col12 FROM t GROUP BY col12 HAVING col12 = 2;
```

Preference is given to standard SQL behavior, so if a `HAVING` column name is used both in `GROUP BY` and as an aliased column in the output column list, preference is given to the column in the `GROUP BY` column.

- Do not use `HAVING` for items that should be in the `WHERE` clause. For example, do not write the following:

  ```sql
  SELECT col_name FROM tbl_name HAVING col_name > 0;
  ```
Write this instead:

```
SELECT col_name FROM tbl_name WHERE col_name > 0;
```

- The **HAVING** clause can refer to aggregate functions, which the **WHERE** clause cannot:

```
SELECT user, MAX(salary) FROM users
  GROUP BY user HAVING MAX(salary) > 10;
```

(This did not work in some older versions of MySQL.)

- MySQL permits duplicate column names. That is, there can be more than one `select_expr` with the same name. This is an extension to standard SQL. Because MySQL also permits `GROUP BY` and `HAVING` to refer to `select_expr` values, this can result in an ambiguity:

```
SELECT 12 AS a, a FROM t GROUP BY a;
```

In that statement, both columns have the name `a`. To ensure that the correct column is used for grouping, use different names for each `select_expr`.

- MySQL resolves unqualified column or alias references in `ORDER BY` clauses by searching in the `select_expr` values, then in the columns of the tables in the `FROM` clause. For `GROUP BY` or `HAVING` clauses, it searches the `FROM` clause before searching in the `select_expr` values. (For `GROUP BY` and `HAVING`, this differs from the pre-MySQL 5.0 behavior that used the same rules as for `ORDER BY`.)

- The **LIMIT** clause can be used to constrain the number of rows returned by the **SELECT** statement. **LIMIT** takes one or two numeric arguments, which must both be nonnegative integer constants, with these exceptions:

  - Within prepared statements, **LIMIT** parameters can be specified using `?` placeholder markers.
  - Within stored programs, **LIMIT** parameters can be specified using integer-valued routine parameters or local variables.

  With two arguments, the first argument specifies the offset of the first row to return, and the second specifies the maximum number of rows to return. The offset of the initial row is 0 (not 1):

```
SELECT * FROM tbl LIMIT 5,10;  # Retrieve rows 6-15
```

To retrieve all rows from a certain offset up to the end of the result set, you can use some large number for the second parameter. This statement retrieves all rows from the 96th row to the last:

```
SELECT * FROM tbl LIMIT 95,18446744073709551615;
```

With one argument, the value specifies the number of rows to return from the beginning of the result set:

```
SELECT * FROM tbl LIMIT 5;     # Retrieve first 5 rows
```

In other words, `LIMIT row_count` is equivalent to `LIMIT 0, row_count`.

For prepared statements, you can use placeholders. The following statements will return one row from the `tbl` table:

```
SET @a=1;
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?';
EXECUTE STMT USING @a;
```

The following statements will return the second to sixth row from the `tbl` table:

```
SET @skip=1; SET @numrows=5;
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?, ?';
EXECUTE STMT USING @skip, @numrows;
```
For compatibility with PostgreSQL, MySQL also supports the `LIMIT` row_count OFFSET offset syntax.

If `LIMIT` occurs within a parenthesized query expression and also is applied in the outer query, the results are undefined and may change in a future MySQL version.

- A `PROCEDURE` clause names a procedure that should process the data in the result set. For an example, see Section 8.4.2.4, “Using PROCEDURE ANALYSE”, which describes `ANALYSE`, a procedure that can be used to obtain suggestions for optimal column data types that may help reduce table sizes.

  A `PROCEDURE` clause is not permitted in a `UNION` statement.

- The `SELECT ... INTO` form of `SELECT` enables the query result to be written to a file or stored in variables. For more information, see Section 13.2.9.1, “SELECT ... INTO Statement”.

- If you use `FOR UPDATE` with a storage engine that uses page or row locks, rows examined by the query are write-locked until the end of the current transaction. Using `LOCK IN SHARE MODE` sets a shared lock that permits other transactions to read the examined rows but not to update or delete them. See Section 14.7.2.4, “Locking Reads”.

  In addition, you cannot use `FOR UPDATE` as part of the `SELECT` in a statement such as `CREATE TABLE new_table SELECT ... FROM old_table ....` (If you attempt to do so, the statement is rejected with the error Can't update table 'old_table' while 'new_table' is being created.) This is a change in behavior from MySQL 5.5 and earlier, which permitted `CREATE TABLE ... SELECT` statements to make changes in tables other than the table being created.

Following the `SELECT` keyword, you can use a number of modifiers that affect the operation of the statement. `HIGH_PRIORITY`, `STRAIGHT_JOIN`, and modifiers beginning with `SQL_` are MySQL extensions to standard SQL.

- The `ALL` and `DISTINCT` modifiers specify whether duplicate rows should be returned. `ALL` (the default) specifies that all matching rows should be returned, including duplicates. `DISTINCT` specifies removal of duplicate rows from the result set. It is an error to specify both modifiers. `DISTINCTROW` is a synonym for `DISTINCT`.

- `HIGH_PRIORITY` gives the `SELECT` higher priority than a statement that updates a table. You should use this only for queries that are very fast and must be done at once. A `SELECT HIGH_PRIORITY` query that is issued while the table is locked for reading runs even if there is an update statement waiting for the table to be free. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

  `HIGH_PRIORITY` cannot be used with `SELECT` statements that are part of a `UNION`.

- `STRAIGHT_JOIN` forces the optimizer to join the tables in the order in which they are listed in the `FROM` clause. You can use this to speed up a query if the optimizer joins the tables in nonoptimal order. `STRAIGHT_JOIN` also can be used in the `table_references` list. See Section 13.2.9.2, “JOIN Clause”.

  `STRAIGHT_JOIN` does not apply to any table that the optimizer treats as a `const` or `system` table. Such a table produces a single row, is read during the optimization phase of query execution, and references to its columns are replaced with the appropriate column values before query execution proceeds. These tables will appear first in the query plan displayed by `EXPLAIN`. See Section 8.8.1, “Optimizing Queries with EXPLAIN”. This exception may not apply to `const` or `system` tables that are used on the NULL-complemented side of an outer join (that is, the right-side table of a `LEFT JOIN` or the left-side table of a `RIGHT JOIN`.

- `SQL_BIG_RESULT` or `SQL_SMALL_RESULT` can be used with `GROUP BY` or `DISTINCT` to tell the optimizer that the result set has many rows or is small, respectively. For `SQL_BIG_RESULT`,...
SELECT Statement

MySQL directly uses disk-based temporary tables if they are created, and prefers sorting to using a temporary table with a key on the GROUP BY elements. For SQL_SMALL_RESULT, MySQL uses in-memory temporary tables to store the resulting table instead of using sorting. This should not normally be needed.

- SQL_BUFFER_RESULT forces the result to be put into a temporary table. This helps MySQL free the table locks early and helps in cases where it takes a long time to send the result set to the client. This modifier can be used only for top-level SELECT statements, not for subqueries or following UNION.

- SQL_CALC_FOUND_ROWS tells MySQL to calculate how many rows there would be in the result set, disregarding any LIMIT clause. The number of rows can then be retrieved with SELECT FOUND_ROWS(). See Section 12.16, “Information Functions”.

- The SQL_CACHE and SQL_NO_CACHE modifiers affect caching of query results in the query cache (see Section 8.10.3, “The MySQL Query Cache”). SQL_CACHE tells MySQL to store the result in the query cache if it is cacheable and the value of the query_cache_type system variable is 2 or DEMAND. With SQL_NO_CACHE, the server does not use the query cache. It neither checks the query cache to see whether the result is already cached, nor does it cache the query result. (Due to a limitation in the parser, a space character must precede and follow the SQL_NO_CACHE keyword; a nonspace such as a newline causes the server to check the query cache to see whether the result is already cached.)

These two modifiers are mutually exclusive and an error occurs if they are both specified. Also, these modifiers are not permitted in subqueries (including subqueries in the FROM clause), and SELECT statements in unions other than the first SELECT.

For views, SQL_NO_CACHE applies if it appears in any SELECT in the query. For a cacheable query, SQL_CACHE applies if it appears in the first SELECT of a view referred to by the query.

A SELECT from a partitioned table using a storage engine such as MyISAM that employs table-level locks locks only those partitions containing rows that match the SELECT statement WHERE clause. (This does not occur with storage engines such as InnoDB that employ row-level locking.) For more information, see Section 19.6.4, “Partitioning and Locking”.

13.2.9.1 SELECT ... INTO Statement

The SELECT ... INTO form of SELECT enables a query result to be stored in variables or written to a file:

- SELECT ... INTO var_list selects column values and stores them into variables.

- SELECT ... INTO OUTFILE writes the selected rows to a file. Column and line terminators can be specified to produce a specific output format.

- SELECT ... INTO DUMPFILE writes a single row to a file without any formatting.

A given SELECT statement can contain at most one INTO clause, although as shown by the SELECT syntax description (see Section 13.2.9, “SELECT Statement”), the INTO can appear in different positions:

- Before FROM. Example:

  SELECT * INTO @myvar FROM t1;

- Before a trailing locking clause. Example:

  SELECT * FROM t1 INTO @myvar FOR UPDATE;

An INTO clause should not be used in a nested SELECT because such a SELECT must return its result to the outer context. There are also constraints on the use of INTO within UNION statements; see Section 13.2.9.3, “UNION Clause”.

1624
For the `INTO var_list` variant:

- `var_list` names a list of one or more variables, each of which can be a user-defined variable, stored procedure or function parameter, or stored program local variable. (Within a prepared `SELECT ... INTO var_list` statement, only user-defined variables are permitted; see Section 13.6.4.2, “Local Variable Scope and Resolution”.)

- The selected values are assigned to the variables. The number of variables must match the number of columns. The query should return a single row. If the query returns no rows, a warning with error code 1329 occurs (No data), and the variable values remain unchanged. If the query returns multiple rows, error 1172 occurs (Result consisted of more than one row). If it is possible that the statement may retrieve multiple rows, you can use `LIMIT 1` to limit the result set to a single row.

```
SELECT id, data INTO @x, @y FROM test.t1 LIMIT 1;
```

User variable names are not case-sensitive. See Section 9.4, “User-Defined Variables”.

The `SELECT ... INTO OUTFILE 'file_name'` form of `SELECT` writes the selected rows to a file. The file is created on the server host, so you must have the `FILE` privilege to use this syntax. `file_name` cannot be an existing file, which among other things prevents files such as `/etc/passwd` and database tables from being modified. The `character_set_filesystem` system variable controls the interpretation of the file name.

The `SELECT ... INTO OUTFILE` statement is intended to enable dumping a table to a text file on the server host. To create the resulting file on some other host, `SELECT ... INTO OUTFILE` normally is unsuitable because there is no way to write a path to the file relative to the server host file system, unless the location of the file on the remote host can be accessed using a network-mapped path on the server host file system.

Alternatively, if the MySQL client software is installed on the remote host, you can use a client command such as `mysql -e "SELECT ..." > file_name` to generate the file on that host.

`SELECT ... INTO OUTFILE` is the complement of `LOAD DATA`. Column values are written converted to the character set specified in the `CHARACTER SET` clause. If no such clause is present, values are dumped using the binary character set. In effect, there is no character set conversion. If a result set contains columns in several character sets, so will the output data file and it may not be possible to reload the file correctly.

The syntax for the `export_options` part of the statement consists of the same `FIELDS` and `LINES` clauses that are used with the `LOAD DATA` statement. For information about the `FIELDS` and `LINES` clauses, including their default values and permissible values, see Section 13.2.6, “LOAD DATA Statement”.

`FIELDS ESCAPED BY` controls how to write special characters. If the `FIELDS ESCAPED BY` character is not empty, it is used when necessary to avoid ambiguity as a prefix that precedes following characters on output:

- The `FIELDS ESCAPED BY` character
- The `FIELDS [OPTIONALLY] ENCLOSED BY` character
- The first character of the `FIELDS TERMINATED BY` and `LINES TERMINATED BY` values
- ASCII NUL (the zero-valued byte; what is actually written following the escape character is ASCII 0, not a zero-valued byte)

The `FIELDS TERMINATED BY, ENCLOSED BY, ESCAPED BY, or LINES TERMINATED BY` characters must be escaped so that you can read the file back in reliably. ASCII NUL is escaped to make it easier to view with some pagers.

The resulting file need not conform to SQL syntax, so nothing else need be escaped.
If the `FIELDS ESCAPED BY` character is empty, no characters are escaped and `NULL` is output as `NULL`, not `\N`. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

Here is an example that produces a file in the comma-separated values (CSV) format used by many programs:

```sql
SELECT a, b, a+b INTO OUTFILE '/tmp/result.txt'
FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"'
LINES TERMINATED BY '\n'
FROM test_table;
```

If you use `INTO DUMPFILE` instead of `INTO OUTFILE`, MySQL writes only one row into the file, without any column or line termination and without performing any escape processing. This is useful for selecting a `BLOB` value and storing it in a file.

**Note**

Any file created by `INTO OUTFILE` or `INTO DUMPFILE` is writable by all users on the server host. The reason for this is that the MySQL server cannot create a file that is owned by anyone other than the user under whose account it is running. (You should *never* run `mysqld` as `root` for this and other reasons.)

The file thus must be world-writable so that you can manipulate its contents.

If the `secure_file_priv` system variable is set to a nonempty directory name, the file to be written must be located in that directory.

In the context of `SELECT ... INTO` statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log. For additional information, see Section 20.4.5, “Event Scheduler Status”.

### 13.2.9.2 JOIN Clause

MySQL supports the following `JOIN` syntax for the `table_references` part of `SELECT` statements and multiple-table `DELETE` and `UPDATE` statements:

```
SELECT a, b, a+b INTO OUTFILE '/tmp/result.txt'
FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"'
LINES TERMINATED BY '\n'
FROM test_table;
```

If you use `INTO DUMPFILE` instead of `INTO OUTFILE`, MySQL writes only one row into the file, without any column or line termination and without performing any escape processing. This is useful for selecting a `BLOB` value and storing it in a file.

**Note**

Any file created by `INTO OUTFILE` or `INTO DUMPFILE` is writable by all users on the server host. The reason for this is that the MySQL server cannot create a file that is owned by anyone other than the user under whose account it is running. (You should *never* run `mysqld` as `root` for this and other reasons.)

The file thus must be world-writable so that you can manipulate its contents.

If the `secure_file_priv` system variable is set to a nonempty directory name, the file to be written must be located in that directory.

In the context of `SELECT ... INTO` statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log. For additional information, see Section 20.4.5, “Event Scheduler Status”.

### 13.2.9.2 JOIN Clause

MySQL supports the following `JOIN` syntax for the `table_references` part of `SELECT` statements and multiple-table `DELETE` and `UPDATE` statements:

```
table_references: 
    escaped_table_reference [ , escaped_table_reference ] ...  

escaped_table_reference: { 
    table_reference 
    | { OJ table_reference } 
} 

table_reference: { 
    table_factor 
    | joined_table 
} 

table_factor: { 
    tbl_name [PARTITION (partition_names)] 
    | [AS] alias] [index_hint_list] 
    | table_subquery [AS] alias 
    | ( table_references ) 
} 

joined_table: { 
    table_reference [INNER | CROSS] JOIN table_factor [join_specification] 
    | table_reference STRAIGHT_JOIN table_factor 
    | table_reference STRAIGHT_JOIN table_factor ON search_condition 
    | table_reference (LEFT|RIGHT) [OUTER] JOIN table_reference join_specification 
    | table_reference NATURAL ([LEFT|RIGHT] [OUTER]) JOIN table_factor 
} 

join_specification: { 
```
A table reference is also known as a join expression.

A table reference (when it refers to a partitioned table) may contain a PARTITION option, including a list of comma-separated partitions, subpartitions, or both. This option follows the name of the table and precedes any alias declaration. The effect of this option is that rows are selected only from the listed partitions or subpartitions. Any partitions or subpartitions not named in the list are ignored. For more information and examples, see Section 19.5, “Partition Selection”.

The syntax of table_factor is extended in MySQL in comparison with standard SQL. The standard accepts only table_reference, not a list of them inside a pair of parentheses.

This is a conservative extension if each comma in a list of table_reference items is considered as equivalent to an inner join. For example:

```
SELECT * FROM t1 LEFT JOIN (t2, t3, t4)
ON (t2.a = t1.a AND t3.b = t1.b AND t4.c = t1.c)
```

is equivalent to:

```
SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4)
ON (t2.a = t1.a AND t3.b = t1.b AND t4.c = t1.c)
```

In MySQL, JOIN, CROSS JOIN, and INNER JOIN are syntactic equivalents (they can replace each other). In standard SQL, they are not equivalent. INNER JOIN is used with an ON clause, CROSS JOIN is used otherwise.

In general, parentheses can be ignored in join expressions containing only inner join operations. MySQL also supports nested joins. See Section 8.2.1.7, “Nested Join Optimization”.

Index hints can be specified to affect how the MySQL optimizer makes use of indexes. For more information, see Section 8.9.3, “Index Hints”. The optimizer_switch system variable is another way to influence optimizer use of indexes. See Section 8.9.2, “Switchable Optimizations”.

The following list describes general factors to take into account when writing joins:

- A table reference can be aliased using tbl_name AS alias_name or tbl_name alias_name:

```
SELECT t1.name, t2.salary
FROM employee AS t1 INNER JOIN info AS t2 ON t1.name = t2.name;
```

```
SELECT t1.name, t2.salary
FROM employee t1 INNER JOIN info t2 ON t1.name = t2.name;
```

- A table_subquery is also known as a derived table or subquery in the FROM clause. See Section 13.2.10.8, “Derived Tables”. Such subqueries must include an alias to give the subquery result a table name. A trivial example follows:
SELECT * FROM (SELECT 1, 2, 3) AS t1;

- The maximum number of tables that can be referenced in a single join is 61.

- **INNER JOIN** and `,` (comma) are semantically equivalent in the absence of a join condition: both produce a Cartesian product between the specified tables (that is, each and every row in the first table is joined to each and every row in the second table).

However, the precedence of the comma operator is less than that of **INNER JOIN**, **CROSS JOIN**, **LEFT JOIN**, and so on. If you mix comma joins with the other join types when there is a join condition, an error of the form Unknown column 'col_name' in 'on clause' may occur. Information about dealing with this problem is given later in this section.

- The **search_condition** used with **ON** is any conditional expression of the form that can be used in a **WHERE** clause. Generally, the **ON** clause serves for conditions that specify how to join tables, and the **WHERE** clause restricts which rows to include in the result set.

- If there is no matching row for the right table in the **ON** or **USING** part in a **LEFT JOIN**, a row with all columns set to **NULL** is used for the right table. You can use this fact to find rows in a table that have no counterpart in another table:

```sql
SELECT left_tbl.*
FROM left_tbl LEFT JOIN right_tbl ON left_tbl.id = right_tbl.id
WHERE right_tbl.id IS NULL;
```

This example finds all rows in `left_tbl` with an `id` value that is not present in `right_tbl` (that is, all rows in `left_tbl` with no corresponding row in `right_tbl`). See Section 8.2.1.8, “Outer Join Optimization”.

- The **USING**(`join_column_list`) clause names a list of columns that must exist in both tables. If tables `a` and `b` both contain columns `c1, c2,` and `c3`, the following join compares corresponding columns from the two tables:

```sql
a LEFT JOIN b USING (c1, c2, c3)
```

- The **NATURAL [LEFT] JOIN** of two tables is defined to be semantically equivalent to an **INNER JOIN** or a **LEFT JOIN** with a **USING** clause that names all columns that exist in both tables.

- **RIGHT JOIN** works analogously to **LEFT JOIN**. To keep code portable across databases, it is recommended that you use **LEFT JOIN** instead of **RIGHT JOIN**.

- The `{ OJ ... }` syntax shown in the join syntax description exists only for compatibility with ODBC. The curly braces in the syntax should be written literally; they are not metasyntax as used elsewhere in syntax descriptions.

```sql
SELECT left_tbl.*
FROM { OJ left_tbl LEFT OUTER JOIN right_tbl
    ON left_tbl.id = right_tbl.id };
```

You can use other types of joins within `{ OJ ... }`, such as **INNER JOIN** or **RIGHT OUTER JOIN**. This helps with compatibility with some third-party applications, but is not official ODBC syntax.

- **STRAIGHT_JOIN** is similar to **JOIN**, except that the left table is always read before the right table. This can be used for those (few) cases for which the join optimizer processes the tables in a suboptimal order.

Some join examples:

```sql
SELECT * FROM table1, table2;
SELECT * FROM table1 INNER JOIN table2 ON table1.id = table2.id;
```
Natural joins and joins with **USING**, including outer join variants, are processed according to the SQL:2003 standard:

- Redundant columns of a **NATURAL** join do not appear. Consider this set of statements:

```sql
CREATE TABLE t1 (i INT, j INT);
CREATE TABLE t2 (k INT, j INT);
INSERT INTO t1 VALUES(1, 1);
INSERT INTO t2 VALUES(1, 1);
SELECT * FROM t1 NATURAL JOIN t2;
SELECT * FROM t1 JOIN t2 USING (j);
```

In the first `SELECT` statement, column `j` appears in both tables and thus becomes a join column, so, according to standard SQL, it should appear only once in the output, not twice. Similarly, in the second `SELECT` statement, column `j` is named in the `USING` clause and should appear only once in the output, not twice.

Thus, the statements produce this output:

```
+------+------+------+
| j    | i    | k    |
+------+------+------+
|    1 |    1 |    1 |
+------+------+------+
```

Redundant column elimination and column ordering occurs according to standard SQL, producing this display order:

- First, coalesced common columns of the two joined tables, in the order in which they occur in the first table
- Second, columns unique to the first table, in order in which they occur in that table
- Third, columns unique to the second table, in order in which they occur in that table

The single result column that replaces two common columns is defined using the coalesce operation. That is, for two `t1.a` and `t2.a` the resulting single join column `a` is defined as `a = COALESCE(t1.a, t2.a)`, where:

```
COALESCE(x, y) = (CASE WHEN x IS NOT NULL THEN x ELSE y END)
```

If the join operation is any other join, the result columns of the join consist of the concatenation of all columns of the joined tables.

A consequence of the definition of coalesced columns is that, for outer joins, the concatenated column contains the value of the non-**NULL** column if one of the two columns is always **NULL**. If neither or both columns are **NULL**, both common columns have the same value, so it doesn't matter which one is chosen as the value of the coalesced column. A simple way to interpret this is to consider that a coalesced column of an outer join is represented by the common column of the inner table of a **JOIN**. Suppose that the tables `t1(a, b)` and `t2(a, c)` have the following contents:

```
t1    t2
----    ----
```

```sql
SELECT * FROM table1 LEFT JOIN table2 ON table1.id = table2.id;
SELECT * FROM table1 LEFT JOIN table2 USING (id);
SELECT * FROM table1 LEFT JOIN table2 ON table1.id = table2.id
  LEFT JOIN table3 ON table2.id = table3.id;
```
SELECT Statement

Then, for this join, column a contains the values of t1.a:

```
mysql> SELECT * FROM t1 NATURAL LEFT JOIN t2;
+------+------+------+
| a    | b    | c    |
+------+------+------+
|    1 | x    | NULL |
|    2 | y    | z    |
+------+------+------+
```

By contrast, for this join, column a contains the values of t2.a.

```
mysql> SELECT * FROM t1 NATURAL RIGHT JOIN t2;
+------+------+------+
| a    | c    | b    |
+------+------+------+
|    2 | z    | y    |
|    3 | w    | NULL |
+------+------+------+
```

Compare those results to the otherwise equivalent queries with JOIN ... ON:

```
mysql> SELECT * FROM t1 LEFT JOIN t2 ON (t1.a = t2.a);
+------+------+------+
| a    | b    | a    | c    |
+------+------+------+
|    1 | x    | NULL | NULL |
|    2 | y    | 2    | z    |
+------+------+------+
```

```
mysql> SELECT * FROM t1 RIGHT JOIN t2 ON (t1.a = t2.a);
+------+------+------+
| a    | b    | a    | c    |
+------+------+------+
|    2 | y    | 2    | z    |
| NULL | NULL | 3    | w    |
+------+------+------+
```

- A USING clause can be rewritten as an ON clause that compares corresponding columns. However, although USING and ON are similar, they are not quite the same. Consider the following two queries:

  a LEFT JOIN b USING (c1, c2, c3)
  a LEFT JOIN b ON a.c1 = b.c1 AND a.c2 = b.c2 AND a.c3 = b.c3

  With respect to determining which rows satisfy the join condition, both joins are semantically identical.

  With respect to determining which columns to display for SELECT * expansion, the two joins are not semantically identical. The USING join selects the coalesced value of corresponding columns, whereas the ON join selects all columns from all tables. For the USING join, SELECT * selects these values:

  COALESCE(a.c1, b.c1), COALESCE(a.c2, b.c2), COALESCE(a.c3, b.c3)

  For the ON join, SELECT * selects these values:

  a.c1, a.c2, a.c3, b.c1, b.c2, b.c3

  With an inner join, COALESCE(a.c1, b.c1) is the same as either a.c1 or b.c1 because both columns will have the same value. With an outer join (such as LEFT JOIN), one of the two columns can be NULL. That column is omitted from the result.

- An ON clause can refer only to its operands.

  Example:
CREATE TABLE t1 (i1 INT);
CREATE TABLE t2 (i2 INT);
CREATE TABLE t3 (i3 INT);
SELECT * FROM t1 JOIN t2 ON (i1 = i3) JOIN t3;

The statement fails with an Unknown column 'i3' in 'on clause' error because i3 is a column in t3, which is not an operand of the ON clause. To enable the join to be processed, rewrite the statement as follows:

SELECT * FROM t1 JOIN t2 JOIN t3 ON (i1 = i3);

• JOIN has higher precedence than the comma operator (,), so the join expression t1, t2 JOIN t3 is interpreted as (t1, (t2 JOIN t3)), not as ((t1, t2) JOIN t3). This affects statements that use an ON clause because that clause can refer only to columns in the operands of the join, and the precedence affects interpretation of what those operands are.

Example:

CREATE TABLE t1 (i1 INT, j1 INT);
CREATE TABLE t2 (i2 INT, j2 INT);
CREATE TABLE t3 (i3 INT, j3 INT);
INSERT INTO t1 VALUES(1, 1);
INSERT INTO t2 VALUES(1, 1);
INSERT INTO t3 VALUES(1, 1);
SELECT * FROM t1, t2 JOIN t3 ON (t1.i1 = t3.i3);

The JOIN takes precedence over the comma operator, so the operands for the ON clause are t2 and t3. Because t1.i1 is not a column in either of the operands, the result is an Unknown column 't1.i1' in 'on clause' error.

To enable the join to be processed, use either of these strategies:

• Group the first two tables explicitly with parentheses so that the operands for the ON clause are (t1, t2) and t3:

SELECT * FROM (t1, t2) JOIN t3 ON (t1.i1 = t3.i3);

• Avoid the use of the comma operator and use JOIN instead:

SELECT * FROM t1 JOIN t2 JOIN t3 ON (t1.i1 = t3.i3);

The same precedence interpretation also applies to statements that mix the comma operator with INNER JOIN, CROSS JOIN, LEFT JOIN, and RIGHT JOIN, all of which have higher precedence than the comma operator.

• A MySQL extension compared to the SQL:2003 standard is that MySQL permits you to qualify the common (coalesced) columns of NATURAL or USING joins, whereas the standard disallows that.

13.2.9.3 UNION Clause

SELECT ... 
UNION [ALL | DISTINCT] SELECT ... 
[UNION [ALL | DISTINCT] SELECT ...]

UNION combines the result from multiple SELECT statements into a single result set.

• Result Set Column Names and Data Types
• UNION DISTINCT and UNION ALL
• ORDER BY and LIMIT in Unions
• UNION Restrictions
**Result Set Column Names and Data Types**

The result set column names are taken from the column names of the first `SELECT` statement.

Selected columns listed in corresponding positions of each `SELECT` statement should have the same data type. For example, the first column selected by the first statement should have the same type as the first column selected by the other statements. If the data types of corresponding `SELECT` columns do not match, the types and lengths of the columns in the `UNION` result take into account the values retrieved by all the `SELECT` statements. For example, consider the following, where the column length is not constrained to the length of the value from the first `SELECT`:

```
mysql> SELECT REPEAT('a',1) UNION SELECT REPEAT('b',20);
+----------------------+
| REPEAT('a',1)        |
| a                    |
| bbbbbbbbbbbbbbbbbbbb |
+----------------------+
```

**UNION DISTINCT and UNION ALL**

By default, duplicate rows are removed from `UNION` results. The optional `DISTINCT` keyword has the same effect but makes it explicit. With the optional `ALL` keyword, duplicate-row removal does not occur and the result includes all matching rows from all the `SELECT` statements.

You can mix `UNION ALL` and `UNION DISTINCT` in the same query. Mixed `UNION` types are treated such that a `DISTINCT` union overrides any `ALL` union to its left. A `DISTINCT` union can be produced explicitly by using `UNION DISTINCT` or implicitly by using `UNION` with no following `DISTINCT` or `ALL` keyword.

**ORDER BY and LIMIT in Unions**

To apply an `ORDER BY` or `LIMIT` clause to an individual `SELECT`, parenthesize the `SELECT` and place the clause inside the parentheses:

```
(SELECT a FROM t1 WHERE a=10 AND B=1 ORDER BY a LIMIT 10)
UNION
(SELECT a FROM t2 WHERE a=11 AND B=2 ORDER BY a LIMIT 10);
```

Use of `ORDER BY` for individual `SELECT` statements implies nothing about the order in which the rows appear in the final result because `UNION` by default produces an unordered set of rows. Therefore, `ORDER BY` in this context typically is used in conjunction with `LIMIT`, to determine the subset of the selected rows to retrieve for the `SELECT`, even though it does not necessarily affect the order of those rows in the final `UNION` result. If `ORDER BY` appears without `LIMIT` in a `SELECT`, it is optimized away because it will have no effect, anyway.

To use an `ORDER BY` or `LIMIT` clause to sort or limit the entire `UNION` result, parenthesize the individual `SELECT` statements and place the `ORDER BY` or `LIMIT` after the last one:

```
(SELECT a FROM t1 WHERE a=10 AND B=1)
UNION
(SELECT a FROM t2 WHERE a=11 AND B=2)
ORDER BY a LIMIT 10;
```

A statement without parentheses is equivalent to one parenthesized as just shown.

This kind of `ORDER BY` cannot use column references that include a table name (that is, names in `tbl_name.col_name` format). Instead, provide a column alias in the first `SELECT` statement and refer to the alias in the `ORDER BY`. (Alternatively, refer to the column in the `ORDER BY` using its column position. However, use of column positions is deprecated.)

Also, if a column to be sorted is aliased, the `ORDER BY` clause must refer to the alias, not the column name. The first of the following statements is permitted, but the second fails with an `Unknown column 'a' in 'order clause'` error:
To cause rows in a `UNION` result to consist of the sets of rows retrieved by each `SELECT` one after the other, select an additional column in each `SELECT` to use as a sort column and add an `ORDER BY` that sorts on that column following the last `SELECT`:

```
(SELECT 1 AS sort_col, col1a, col1b, ... FROM t1)
UNION
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col;
```

To additionally maintain sort order within individual `SELECT` results, add a secondary column to the `ORDER BY` clause:

```
(SELECT 1 AS sort_col, col1a, col1b, ... FROM t1)
UNION
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col, col1a;
```

Use of an additional column also enables you to determine which `SELECT` each row comes from. Extra columns can provide other identifying information as well, such as a string that indicates a table name.

**UNION Restrictions**

In a `UNION`, the `SELECT` statements are normal select statements, but with the following restrictions:

- `HIGH_PRIORITY` in the first `SELECT` has no effect. `HIGH_PRIORITY` in any subsequent `SELECT` produces a syntax error.
- Only the last `SELECT` statement can use an `INTO` clause. However, the entire `UNION` result is written to the `INTO` output destination.

### 13.2.10 Subqueries

A subquery is a `SELECT` statement within another statement.

All subquery forms and operations that the SQL standard requires are supported, as well as a few features that are MySQL-specific.

Here is an example of a subquery:

```
SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
```

In this example, `SELECT * FROM t1` ... is the *outer query* (or *outer statement*), and `(SELECT column1 FROM t2)` is the *subquery*. We say that the subquery is *nested* within the outer query, and in fact it is possible to nest subqueries within other subqueries, to a considerable depth. A subquery must always appear within parentheses.

The main advantages of subqueries are:

- They allow queries that are *structured* so that it is possible to isolate each part of a statement.
- They provide alternative ways to perform operations that would otherwise require complex joins and unions.
- Many people find subqueries more readable than complex joins or unions. Indeed, it was the innovation of subqueries that gave people the original idea of calling the early SQL “Structured Query Language.”

Here is an example statement that shows the major points about subquery syntax as specified by the SQL standard and supported in MySQL:

```
DELETE FROM t1
```
WHERE s11 > ANY
(SELECT COUNT(*) /* no hint */ FROM t2
WHERE NOT EXISTS
(SELECT * FROM t3
WHERE ROW(5*t2.s1,77)=(SELECT 50,11*s1 FROM t4 UNION SELECT 50,77 FROM
(SELECT * FROM t5) AS t5)))

A subquery can return a scalar (a single value), a single row, a single column, or a table (one or more rows of one or more columns). These are called scalar, column, row, and table subqueries. Subqueries that return a particular kind of result often can be used only in certain contexts, as described in the following sections.

There are few restrictions on the type of statements in which subqueries can be used. A subquery can contain many of the keywords or clauses that an ordinary SELECT can contain: DISTINCT, GROUP BY, ORDER BY, LIMIT, joins, index hints, UNION constructs, comments, functions, and so on.

A subquery's outer statement can be any one of: SELECT, INSERT, UPDATE, DELETE, SET, or DO.

In MySQL, you cannot modify a table and select from the same table in a subquery. This applies to statements such as DELETE, INSERT, REPLACE, UPDATE, and (because subqueries can be used in the SET clause) LOAD DATA.

For information about how the optimizer handles subqueries, see Section 8.2.2, "Optimizing Subqueries and Derived Tables". For a discussion of restrictions on subquery use, including performance issues for certain forms of subquery syntax, see Section 13.2.10.12, "Restrictions on Subqueries".

### 13.2.10.1 The Subquery as Scalar Operand

In its simplest form, a subquery is a scalar subquery that returns a single value. A scalar subquery is a simple operand, and you can use it almost anywhere a single column value or literal is legal, and you can expect it to have those characteristics that all operands have: a data type, a length, an indication that it can be NULL, and so on. For example:

```sql
CREATE TABLE t1 (s1 INT, s2 CHAR(5) NOT NULL);
INSERT INTO t1 VALUES(100, 'abcde');
SELECT (SELECT s2 FROM t1);
```

The subquery in this SELECT returns a single value ('abcde') that has a data type of CHAR, a length of 5, a character set and collation equal to the defaults in effect at CREATE TABLE time, and an indication that the value in the column can be NULL. Nullability of the value selected by a scalar subquery is not copied because if the subquery result is empty, the result is NULL. For the subquery just shown, if `t1` were empty, the result would be NULL even though `s2` is NOT NULL.

There are a few contexts in which a scalar subquery cannot be used. If a statement permits only a literal value, you cannot use a subquery. For example, LIMIT requires literal integer arguments, and LOAD DATA requires a literal string file name. You cannot use subqueries to supply these values.

When you see examples in the following sections that contain the rather spartan construct `(SELECT column1 FROM t1)`, imagine that your own code contains much more diverse and complex constructions.

Suppose that we make two tables:

```sql
CREATE TABLE t1 (s1 INT);
INSERT INTO t1 VALUES (1);
CREATE TABLE t2 (s1 INT);
INSERT INTO t2 VALUES (2);
```

Then perform a SELECT:

```sql
SELECT (SELECT s1 FROM t2) FROM t1;
```
The result is 2 because there is a row in \( t_2 \) containing a column \( s_1 \) that has a value of 2.

A scalar subquery can be part of an expression, but remember the parentheses, even if the subquery is an operand that provides an argument for a function. For example:

```
SELECT UPPER((SELECT s1 FROM t1)) FROM t2;
```

### 13.2.10.2 Comparisons Using Subqueries

The most common use of a subquery is in the form:

```
non_subquery_operand comparison_operator (subquery)
```

Where \( \text{comparison_operator} \) is one of these operators:

- \( = \)
- \( < \)
- \( <= \)
- \( >= \)
- \( <> \)
- \( != \)
- \( <=> \)

For example:

```
... WHERE 'a' = (SELECT column1 FROM t1)
```

MySQL also permits this construct:

```
non_subquery_operand LIKE (subquery)
```

At one time the only legal place for a subquery was on the right side of a comparison, and you might still find some old DBMSs that insist on this.

Here is an example of a common-form subquery comparison that you cannot do with a join. It finds all the rows in table \( t_1 \) for which the \( \text{column1} \) value is equal to a maximum value in table \( t_2 \):

```
SELECT * FROM t1
WHERE column1 = (SELECT MAX(column2) FROM t2);
```

Here is another example, which again is impossible with a join because it involves aggregating for one of the tables. It finds all rows in table \( t_1 \) containing a value that occurs twice in a given column:

```
SELECT * FROM t1 AS t
WHERE 2 = (SELECT COUNT(*) FROM t1 WHERE t1.id = t.id);
```

For a comparison of the subquery to a scalar, the subquery must return a scalar. For a comparison of the subquery to a row constructor, the subquery must be a row subquery that returns a row with the same number of values as the row constructor. See Section 13.2.10.5, “Row Subqueries”.

### 13.2.10.3 Subqueries with ANY, IN, or SOME

Syntax:

```
operand comparison_operator ANY (subquery)
operand IN (subquery)
operand comparison_operator SOME (subquery)
```

Where \( \text{comparison_operator} \) is one of these operators:

- \( = \)
- \( < \)
- \( >= \)
- \( <= \)
- \( <> \)
- \( != \)
- \( <=> \)

The ANY keyword, which must follow a comparison operator, means “return TRUE if the comparison is TRUE for ANY of the values in the column that the subquery returns.” For example:

```
SELECT s1 FROM t1 WHERE s1 > ANY (SELECT s1 FROM t2);
```

Suppose that there is a row in table \( t_1 \) containing \( 10 \). The expression is TRUE if table \( t_2 \) contains \( 21, 14, 7 \) because there is a value 7 in \( t_2 \) that is less than 10. The expression is FALSE if table
t2 contains (20,10), or if table t2 is empty. The expression is unknown (that is, NULL) if table t2 contains (NULL,NULL,NULL).

When used with a subquery, the word IN is an alias for = ANY. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 = ANY (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 IN (SELECT s1 FROM t2);
```

IN and = ANY are not synonyms when used with an expression list. IN can take an expression list, but = ANY cannot. See Section 12.4.2, “Comparison Functions and Operators”.

NOT IN is not an alias for <> ANY, but for <> ALL. See Section 13.2.10.4, “Subqueries with ALL”.

The word SOME is an alias for ANY. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 <> ANY (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 <> SOME (SELECT s1 FROM t2);
```

Use of the word SOME is rare, but this example shows why it might be useful. To most people, the English phrase “a is not equal to any b” means “there is no b which is equal to a,” but that is not what is meant by the SQL syntax. The syntax means “there is some b to which a is not equal.” Using <> SOME instead helps ensure that everyone understands the true meaning of the query.

### 13.2.10.4 Subqueries with ALL

**Syntax:**

```
operand comparison_operator ALL (subquery)
```

The word ALL, which must follow a comparison operator, means “return TRUE if the comparison is TRUE for ALL of the values in the column that the subquery returns.” For example:

```
SELECT s1 FROM t1 WHERE s1 > ALL (SELECT s1 FROM t2);
```

Suppose that there is a row in table t1 containing (10). The expression is TRUE if table t2 contains (-5, 0, +5) because 10 is greater than all three values in t2. The expression is FALSE if table t2 contains (12, 6, NULL, -100) because there is a single value 12 in table t2 that is greater than 10. The expression is unknown (that is, NULL) if table t2 contains (0, NULL, 1).

Finally, the expression is TRUE if table t2 is empty. So, the following expression is TRUE when table t2 is empty:

```
SELECT * FROM t1 WHERE 1 > ALL (SELECT s1 FROM t2);
```

But this expression is NULL when table t2 is empty:

```
SELECT * FROM t1 WHERE 1 > (SELECT s1 FROM t2);
```

In addition, the following expression is NULL when table t2 is empty:

```
SELECT * FROM t1 WHERE 1 > ALL (SELECT MAX(s1) FROM t2);
```

In general, tables containing NULL values and empty tables are “edge cases.” When writing subqueries, always consider whether you have taken those two possibilities into account.

NOT IN is an alias for <> ALL. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 <> ALL (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 NOT IN (SELECT s1 FROM t2);
```

### 13.2.10.5 Row Subqueries
Scalar or column subqueries return a single value or a column of values. A row subquery is a subquery variant that returns a single row and can thus return more than one column value. Legal operators for row subquery comparisons are:

=  >  <  >=  <=  <>  !=  <=>

Here are two examples:

```sql
SELECT * FROM t1
  WHERE (col1,col2) = (SELECT col3, col4 FROM t2 WHERE id = 10);
SELECT * FROM t1
  WHERE ROW(col1,col2) = (SELECT col3, col4 FROM t2 WHERE id = 10);
```

For both queries, if the table `t2` contains a single row with `id = 10`, the subquery returns a single row. If this row has `col1` and `col2` values equal to the `col1` and `col2` values of any rows in `t1`, the WHERE expression is TRUE and each query returns those `t1` rows. If the `t2` row `col1` and `col2` values are not equal the `col1` and `col2` values of any `t1` row, the expression is FALSE and the query returns an empty result set. The expression is unknown (that is, NULL) if the subquery produces no rows. An error occurs if the subquery produces multiple rows because a row subquery can return at most one row.

For information about how each operator works for row comparisons, see Section 12.4.2, “Comparison Functions and Operators”.

The expressions `(1,2)` and `ROW(1,2)` are sometimes called row constructors. The two are equivalent. The row constructor and the row returned by the subquery must contain the same number of values.

A row constructor is used for comparisons with subqueries that return two or more columns. When a subquery returns a single column, this is regarded as a scalar value and not as a row, so a row constructor cannot be used with a subquery that does not return at least two columns. Thus, the following query fails with a syntax error:

```sql
SELECT * FROM t1 WHERE ROW(1) = (SELECT column1 FROM t2)
```

Row constructors are legal in other contexts. For example, the following two statements are semantically equivalent (and are handled in the same way by the optimizer):

```sql
SELECT * FROM t1 WHERE (column1,column2) = (1,1);
SELECT * FROM t1 WHERE column1 = 1 AND column2 = 1;
```

The following query answers the request, “find all rows in table `t1` that also exist in table `t2`”:

```sql
SELECT column1,column2,column3
  FROM t1
  WHERE (column1,column2,column3) IN
    (SELECT column1,column2,column3 FROM t2);
```

For more information about the optimizer and row constructors, see Section 8.2.1.18, “Row Constructor Expression Optimization”

13.2.10.6 Subqueries with EXISTS or NOT EXISTS

If a subquery returns any rows at all, EXISTS subquery is TRUE, and NOT EXISTS subquery is FALSE. For example:

```sql
SELECT column1 FROM t1 WHERE EXISTS (SELECT * FROM t2);
```

Traditionally, an EXISTS subquery starts with SELECT *, but it could begin with SELECT 5 or SELECT column1 or anything at all. MySQL ignores the SELECT list in such a subquery, so it makes no difference.

For the preceding example, if `t2` contains any rows, even rows with nothing but NULL values, the EXISTS condition is TRUE. This is actually an unlikely example because a [NOT] EXISTS subquery almost always contains correlations. Here are some more realistic examples:
Subqueries

- What kind of store is present in one or more cities?

```sql
SELECT DISTINCT store_type FROM stores
WHERE EXISTS (SELECT * FROM cities_stores
WHERE cities_stores.store_type = stores.store_type);
```

- What kind of store is present in no cities?

```sql
SELECT DISTINCT store_type FROM stores
WHERE NOT EXISTS (SELECT * FROM cities_stores
WHERE cities_stores.store_type = stores.store_type);
```

- What kind of store is present in all cities?

```sql
SELECT DISTINCT store_type FROM stores s1
WHERE NOT EXISTS (
    SELECT * FROM cities WHERE NOT EXISTS (
        SELECT * FROM cities_stores
        WHERE cities_stores.city = cities.city
        AND cities_stores.store_type = stores.store_type));
```

The last example is a double-nested NOT EXISTS query. That is, it has a NOT EXISTS clause within a NOT EXISTS clause. Formally, it answers the question “does a city exist with a store that is not in Stores”? But it is easier to say that a nested NOT EXISTS answers the question “is x TRUE for all y?”

13.2.10.7 Correlated Subqueries

A correlated subquery is a subquery that contains a reference to a table that also appears in the outer query. For example:

```sql
SELECT * FROM t1
WHERE column1 = ANY (SELECT column1 FROM t2
WHERE t2.column2 = t1.column2);
```

Notice that the subquery contains a reference to a column of t1, even though the subquery’s FROM clause does not mention a table t1. So, MySQL looks outside the subquery, and finds t1 in the outer query.

Suppose that table t1 contains a row where column1 = 5 and column2 = 6; meanwhile, table t2 contains a row where column1 = 5 and column2 = 7. The simple expression ... WHERE column1 = ANY (SELECT column1 FROM t2) would be TRUE, but in this example, the WHERE clause within the subquery is FALSE (because (5,6) is not equal to (5,7)), so the expression as a whole is FALSE.

**Scoping rule:** MySQL evaluates from inside to outside. For example:

```sql
SELECT column1 FROM t1 AS x
WHERE x.column1 = (SELECT column1 FROM t2 AS x
WHERE x.column2 = t2.column2);
```

In this statement, x.column2 must be a column in table t2 because SELECT column1 FROM t2 AS x ... renames t2. It is not a column in table t1 because SELECT column1 FROM t1 ... is an outer query that is farther out.

For subqueries in HAVING or ORDER BY clauses, MySQL also looks for column names in the outer select list.

For certain cases, a correlated subquery is optimized. For example:

```sql
val IN (SELECT key_val FROM tbl_name WHERE correlated_condition)
```

Otherwise, they are inefficient and likely to be slow. Rewriting the query as a join might improve performance.
Aggregate functions in correlated subqueries may contain outer references, provided the function contains nothing but outer references, and provided the function is not contained in another function or expression.

### 13.2.10.8 Derived Tables

A derived table is an expression that generates a table within the scope of a query `FROM` clause. For example, a subquery in a `SELECT` statement `FROM` clause is a derived table:

```sql
SELECT ... FROM (subquery) [AS] tbl_name ...
```

The `[AS]` `tbl_name` clause is mandatory because every table in a `FROM` clause must have a name. Any columns in the derived table must have unique names.

For the sake of illustration, assume that you have this table:

```sql
CREATE TABLE t1 (s1 INT, s2 CHAR(5), s3 FLOAT);
```

Here is how to use a subquery in the `FROM` clause, using the example table:

```sql
INSERT INTO t1 VALUES (1,'1',1.0);
INSERT INTO t1 VALUES (2,'2',2.0);
SELECT sb1,sb2,sb3
FROM (SELECT s1 AS sb1, s2 AS sb2, s3*2 AS sb3 FROM t1) AS sb
WHERE sb1 > 1;
```

Result:

```
<table>
<thead>
<tr>
<th>sb1</th>
<th>sb2</th>
<th>sb3</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>2</td>
<td>4</td>
</tr>
</tbody>
</table>
```

Here is another example: Suppose that you want to know the average of a set of sums for a grouped table. This does not work:

```sql
SELECT AVG(SUM(column1)) FROM t1 GROUP BY column1;
```

However, this query provides the desired information:

```sql
SELECT AVG(sum_column1)
FROM (SELECT SUM(column1) AS sum_column1
     FROM t1 GROUP BY column1) AS t1;
```

Notice that the column name used within the subquery (`sum_column1`) is recognized in the outer query.

A derived table can return a scalar, column, row, or table.

Derived tables are subject to these restrictions:

- A derived table cannot be a correlated subquery.
- A derived table cannot contain references to other tables of the same `SELECT`.
- A derived table cannot contain outer references. This is a MySQL restriction, not a restriction of the SQL standard.

The optimizer determines information about derived tables in such a way that `EXPLAIN` does not need to materialize them. See Section 8.2.2.4, “Optimizing Derived Tables”.

It is possible under certain circumstances that using `EXPLAIN SELECT` will modify table data. This can occur if the outer query accesses any tables and an inner query invokes a stored function that changes one or more rows of a table. Suppose that there are two tables `t1` and `t2` in database `d1`, and a stored function `f1` that modifies `t2`, created as shown here:
CREATE DATABASE d1;
USE d1;
CREATE TABLE t1 (c1 INT);
CREATE TABLE t2 (c1 INT);
CREATE FUNCTION f1(p1 INT) RETURNS INT
BEGIN
    INSERT INTO t2 VALUES (p1);
    RETURN p1;
END;

Referencing the function directly in an `EXPLAIN SELECT` has no effect on `t2`, as shown here:

```sql
mysql> SELECT * FROM t2;
Empty set (0.02 sec)
```

```sql
mysql> EXPLAIN SELECT f1(5)\G
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: NULL
type: NULL
possible_keys: NULL
key: NULL
key_len: NULL
ref: NULL
rows: NULL
Extra: No tables used
1 row in set (0.01 sec)
```

```sql
mysql> SELECT * FROM t2;
Empty set (0.01 sec)
```

This is because the `SELECT` statement did not reference any tables, as can be seen in the `table` and `Extra` columns of the output. This is also true of the following nested `SELECT`:

```sql
mysql> EXPLAIN SELECT NOW() AS a1, (SELECT f1(5)) AS a2\G
*************************** 1. row ***************************
id: 1
select_type: SIMPLE
table: NULL
type: NULL
possible_keys: NULL
key: NULL
key_len: NULL
ref: NULL
rows: NULL
filtered: NULL
Extra: No tables used
1 row in set, 1 warning (0.00 sec)
```

```sql
mysql> SHOW WARNINGS;
+-------+------+------------------------------------------+
| Level | Code | Message                                  |
+-------+------+------------------------------------------+
| Note  | 1249 | Select 2 was reduced during optimization |
+-------+------+------------------------------------------+
1 row in set (0.00 sec)
```

```sql
mysql> SELECT * FROM t2;
Empty set (0.00 sec)
```

However, if the outer `SELECT` references any tables, the optimizer executes the statement in the subquery as well, with the result that `t2` is modified:

```sql
mysql> EXPLAIN SELECT * FROM t1 AS a1, (SELECT f1(5)) AS a2\G
*************************** 1. row ***************************
id: 1
select_type: PRIMARY
table: <derived2>
type: system
possible_keys: NULL
```
### 13.2.10.9 Subquery Errors

There are some errors that apply only to subqueries. This section describes them.

- **Unsupported subquery syntax:**

  ```
  ERROR 1235 (ER_NOT_SUPPORTED_YET)
  SQLSTATE = 42000
  Message = "This version of MySQL doesn't yet support 'LIMIT & IN/ALL/ANY/SOME subquery'"
  ```

  This means that MySQL does not support statements of the following form:

  ```
  SELECT * FROM t1 WHERE s1 IN (SELECT s2 FROM t2 ORDER BY s1 LIMIT 1)
  ```

- **Incorrect number of columns from subquery:**

  ```
  ERROR 1241 (ER_OPERAND_COL)
  SQLSTATE = 21000
  Message = "Operand should contain 1 column(s)"
  ```

  This error occurs in cases like this:

  ```
  SELECT (SELECT column1, column2 FROM t2) FROM t1;
  ```

  You may use a subquery that returns multiple columns, if the purpose is row comparison. In other contexts, the subquery must be a scalar operand. See Section 13.2.10.5, “Row Subqueries”. 

---

**Task 1:**

Use the `EXPLAIN` command to analyze the query execution plan for the following SQL statement:

```
SELECT * FROM t2;
```

**Task 2:**

Modify the query to return only the `c1` column from `t2`. Then, use the `EXPLAIN` command again to analyze the new execution plan.

**Task 3:**

Discuss the differences in the execution plans between the two queries.
Subqueries

- Incorrect number of rows from subquery:

  ERROR 1242 (ER_SUBSELECT_NO_1_ROW)
  SQLSTATE = 21000
  Message = "Subquery returns more than 1 row"

  This error occurs for statements where the subquery must return at most one row but returns multiple rows. Consider the following example:

  ```sql
  SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
  ```

  If `SELECT column1 FROM t2` returns just one row, the previous query will work. If the subquery returns more than one row, error 1242 will occur. In that case, the query should be rewritten as:

  ```sql
  SELECT * FROM t1 WHERE column1 = ANY (SELECT column1 FROM t2);
  ```

- Incorrectly used table in subquery:

  Error 1093 (ER_UPDATE_TABLE_USED)
  SQLSTATE = HY000
  Message = "You can't specify target table 'x' for update in FROM clause"

  This error occurs in cases such as the following, which attempts to modify a table and select from the same table in the subquery:

  ```sql
  UPDATE t1 SET column2 = (SELECT MAX(column1) FROM t1);
  ```

  You can use a subquery for assignment within an `UPDATE` statement because subqueries are legal in `UPDATE` and `DELETE` statements as well as in `SELECT` statements. However, you cannot use the same table (in this case, table `t1`) for both the subquery `FROM` clause and the update target.

For transactional storage engines, the failure of a subquery causes the entire statement to fail. For nontransactional storage engines, data modifications made before the error was encountered are preserved.

### 13.2.10.10 Optimizing Subqueries

Development is ongoing, so no optimization tip is reliable for the long term. The following list provides some interesting tricks that you might want to play with. See also Section 8.2.2, “Optimizing Subqueries and Derived Tables”.

- Use subquery clauses that affect the number or order of the rows in the subquery. For example:

  ```sql
  SELECT * FROM t1 WHERE t1.column1 IN
  (SELECT column1 FROM t2 ORDER BY column1);
  ```

- Replace a join with a subquery. For example, try this:

  ```sql
  SELECT DISTINCT column1 FROM t1 WHERE t1.column1 IN {
    SELECT column1 FROM t2;
  }
  ```

  Instead of this:

  ```sql
  SELECT DISTINCT t1.column1 FROM t1, t2
  WHERE t1.column1 = t2.column1;
  ```

- Some subqueries can be transformed to joins for compatibility with older versions of MySQL that do not support subqueries. However, in some cases, converting a subquery to a join may improve performance. See Section 13.2.10.11, “Rewriting Subqueries as Joins”.

- Move clauses from outside to inside the subquery. For example, use this query:
Subqueries

SELECT * FROM t1
  WHERE s1 IN (SELECT s1 FROM t1 UNION ALL SELECT s1 FROM t2);

Instead of this query:

SELECT * FROM t1
  WHERE s1 IN (SELECT s1 FROM t1) OR s1 IN (SELECT s1 FROM t2);

For another example, use this query:

SELECT (SELECT column1 + 5 FROM t1) FROM t2;

Instead of this query:

SELECT (SELECT column1 FROM t1) + 5 FROM t2;

• Use a row subquery instead of a correlated subquery. For example, use this query:

SELECT * FROM t1
  WHERE (column1,column2) IN (SELECT column1,column2 FROM t2);

Instead of this query:

SELECT * FROM t1
  WHERE EXISTS (SELECT * FROM t2 WHERE t2.column1=t1.column1
               AND t2.column2=t1.column2);

• Use NOT (a = ANY (...)) rather than a <> ALL (...).
• Use x = ANY (table containing (1,2)) rather than x=1 OR x=2.
• Use = ANY rather than EXISTS.
• For uncorrelated subqueries that always return one row, IN is always slower than =. For example, use this query:

SELECT * FROM t1
  WHERE t1.col_name = (SELECT a FROM t2 WHERE b = some_const);

Instead of this query:

SELECT * FROM t1
  WHERE t1.col_name IN (SELECT a FROM t2 WHERE b = some_const);

These tricks might cause programs to go faster or slower. Using MySQL facilities like the BENCHMARK() function, you can get an idea about what helps in your own situation. See Section 12.16, “Information Functions”.

Some optimizations that MySQL itself makes are:

• MySQL executes uncorrelated subqueries only once. Use EXPLAIN to make sure that a given subquery really is uncorrelated.

• MySQL rewrites IN, ALL, ANY, and SOME subqueries in an attempt to take advantage of the possibility that the select-list columns in the subquery are indexed.

• MySQL replaces subqueries of the following form with an index-lookup function, which EXPLAIN describes as a special join type (unique_subquery or index_subquery):

  ... IN (SELECT indexed_column FROM single_table ...)

• MySQL enhances expressions of the following form with an expression involving MIN() or MAX(), unless NULL values or empty sets are involved:

  value {ALL|ANY|SOME} {> | < | >= | <=} {uncorrelated subquery}
For example, this `WHERE` clause:

```
WHERE 5 > ALL (SELECT x FROM t)
```

might be treated by the optimizer like this:

```
WHERE 5 > (SELECT MAX(x) FROM t)
```

See also MySQL Internals: How MySQL Transforms Subqueries.

### 13.2.10.11 Rewriting Subqueries as Joins

Sometimes there are other ways to test membership in a set of values than by using a subquery. Also, on some occasions, it is not only possible to rewrite a query without a subquery, but it can be more efficient to make use of some of these techniques rather than to use subqueries. One of these is the `IN()` construct:

For example, this query:

```
SELECT * FROM t1 WHERE id IN (SELECT id FROM t2);
```

Can be rewritten as:

```
SELECT DISTINCT t1.* FROM t1, t2 WHERE t1.id=t2.id;
```

The queries:

```
SELECT * FROM t1 WHERE id NOT IN (SELECT id FROM t2);
SELECT * FROM t1 WHERE NOT EXISTS (SELECT id FROM t2 WHERE t1.id=t2.id);
```

Can be rewritten as:

```
SELECT table1.*
FROM table1 LEFT JOIN table2 ON table1.id=table2.id
WHERE table2.id IS NULL;
```

A **LEFT [OUTER] JOIN** can be faster than an equivalent subquery because the server might be able to optimize it better—a fact that is not specific to MySQL Server alone. Prior to SQL-92, outer joins did not exist, so subqueries were the only way to do certain things. Today, MySQL Server and many other modern database systems offer a wide range of outer join types.

MySQL Server supports multiple-table `DELETE` statements that can be used to efficiently delete rows based on information from one table or even from many tables at the same time. Multiple-table `UPDATE` statements are also supported. See Section 13.2.2, “DELETE Statement”, and Section 13.2.11, “UPDATE Statement”.

### 13.2.10.12 Restrictions on Subqueries

- In general, you cannot modify a table and select from the same table in a subquery. For example, this limitation applies to statements of the following forms:

```
DELETE FROM t WHERE ... (SELECT ... FROM t ...);
UPDATE t ... WHERE col = (SELECT ... FROM t ...);
{INSERT|REPLACE} INTO t (SELECT ... FROM t ...);
```

Exception: The preceding prohibition does not apply if for the modified table you are using a derived table and that derived table is materialized rather than merged into the outer query. Example:

```
UPDATE t ... WHERE col = (SELECT * FROM (SELECT ... FROM t...) AS _t ...);
```

Here the result from the derived table is materialized as a temporary table, so the relevant rows in `t` have already been selected by the time the update to `t` takes place.

- Row comparison operations are only partially supported:
UPDATE Statement

• For `expr [NOT] IN subquery`, `expr` can be an `n`-tuple (specified using row constructor syntax) and the subquery can return rows of `n`-tuples. The permitted syntax is therefore more specifically expressed as `row_constructor [NOT] IN table_subquery`

• For `expr op {ALL|ANY|SOME} subquery`, `expr` must be a scalar value and the subquery must be a column subquery; it cannot return multiple-column rows.

In other words, for a subquery that returns rows of `n`-tuples, this is supported:

```
(expr_1, ..., expr_n) [NOT] IN table_subquery
```

But this is not supported:

```
(expr_1, ..., expr_n) op {ALL|ANY|SOME} subquery
```

The reason for supporting row comparisons for `IN` but not for the others is that `IN` is implemented by rewriting it as a sequence of `=` comparisons and `AND` operations. This approach cannot be used for `ALL`, `ANY`, or `SOME`.

• Subqueries in the `FROM` clause cannot be correlated subqueries. They are materialized in whole (evaluated to produce a result set) during query execution, so they cannot be evaluated per row of the outer query. Before MySQL 5.6.3, materialization takes place before evaluation of the outer query. As of 5.6.3, the optimizer delays materialization until the result is needed, which may permit materialization to be avoided. See Section 8.2.2.4, “Optimizing Derived Tables”.

• MySQL does not support `LIMIT` in subqueries for certain subquery operators:

```
mysql> SELECT * FROM t1
    -> WHERE s1 IN (SELECT s2 FROM t2 ORDER BY s1 LIMIT 1);
ERROR 1235 (42000): This version of MySQL doesn't yet support
'LIMIT & IN/ALL/ANY/SOME subquery'
```

• MySQL permits a subquery to refer to a stored function that has data-modifying side effects such as inserting rows into a table. For example, if `f()` inserts rows, the following query can modify data:

```
SELECT ... WHERE x IN (SELECT f() ...);
```

This behavior is an extension to the SQL standard. In MySQL, it can produce nondeterministic results because `f()` might be executed a different number of times for different executions of a given query depending on how the optimizer chooses to handle it.

For statement-based or mixed-format replication, one implication of this indeterminism is that such a query can produce different results on the source and its slaves.

• Before MySQL 5.6.3, a subquery in the `FROM` clause is evaluated by materializing the result into a temporary table, and this table does not use indexes. As of 5.6.3, the optimizer creates an index on the materialized table if this will result in faster query execution. See Section 8.2.2.4, “Optimizing Derived Tables”.

13.2.11 UPDATE Statement

`UPDATE` is a DML statement that modifies rows in a table.

Single-table syntax:

```
UPDATE [LOW_PRIORITY] [IGNORE] table_reference
    SET assignment_list
    [WHERE where_condition]
    [ORDER BY ...]
    [LIMIT row_count]

value:
    {expr | DEFAULT}
```
UPDATE Statement

**Assignment:**

- `col_name = value`

**Assignment List:**

- `assignment [, assignment] ...`

**Multiple-table syntax:**

```
UPDATE [LOW_PRIORITY] [IGNORE] table_references
SET assignment_list
[WHERE where_condition]
```

For the single-table syntax, the `UPDATE` statement updates columns of existing rows in the named table with new values. The `SET` clause indicates which columns to modify and the values they should be given. Each value can be given as an expression, or the keyword `DEFAULT` to set a column explicitly to its default value. The `WHERE` clause, if given, specifies the conditions that identify which rows to update. With no `WHERE` clause, all rows are updated. If the `ORDER BY` clause is specified, the rows are updated in the order that is specified. The `LIMIT` clause places a limit on the number of rows that can be updated.

For the multiple-table syntax, `UPDATE` updates rows in each table named in `table_references` that satisfy the conditions. Each matching row is updated once, even if it matches the conditions multiple times. For multiple-table syntax, `ORDER BY` and `LIMIT` cannot be used.

For partitioned tables, both the single-single and multiple-table forms of this statement support the use of a `PARTITION` option as part of a table reference. This option takes a list of one or more partitions or subpartitions (or both). Only the partitions (or subpartitions) listed are checked for matches, and a row that is not in any of these partitions or subpartitions is not updated, whether it satisfies the `where_condition` or not.

**Note**

Unlike the case when using `PARTITION` with an `INSERT` or `REPLACE` statement, an otherwise valid `UPDATE ... PARTITION` statement is considered successful even if no rows in the listed partitions (or subpartitions) match the `where_condition`.

For more information and examples, see Section 19.5, “Partition Selection”.

`where_condition` is an expression that evaluates to true for each row to be updated. For expression syntax, see Section 9.5, “Expressions”.

`table_references` and `where_condition` are specified as described in Section 13.2.9, “SELECT Statement”.

You need the `UPDATE` privilege only for columns referenced in an `UPDATE` that are actually updated. You need only the `SELECT` privilege for any columns that are read but not modified.

The `UPDATE` statement supports the following modifiers:

- With the `LOW_PRIORITY` modifier, execution of the `UPDATE` is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

- With the `IGNORE` modifier, the update statement does not abort even if errors occur during the update. Rows for which duplicate-key conflicts occur on a unique key value are not updated. Rows updated to values that would cause data conversion errors are updated to the closest valid values instead.

`UPDATE IGNORE` statements, including those having an `ORDER BY` clause, are flagged as unsafe for statement-based replication. (This is because the order in which the rows are updated determines which rows are ignored.) Such statements produce a warning in the error log when using statement-
based mode and are written to the binary log using the row-based format when using MIXED mode. (Bug #11758262, Bug #50439) See Section 17.1.2.3, “Determination of Safe and Unsafe Statements in Binary Logging”, for more information.

If you access a column from the table to be updated in an expression, UPDATE uses the current value of the column. For example, the following statement sets `col1` to one more than its current value:

```
UPDATE t1 SET col1 = col1 + 1;
```

The second assignment in the following statement sets `col2` to the current (updated) `col1` value, not the original `col1` value. The result is that `col1` and `col2` have the same value. This behavior differs from standard SQL.

```
UPDATE t1 SET col1 = col1 + 1, col2 = col1;
```

Single-table UPDATE assignments are generally evaluated from left to right. For multiple-table updates, there is no guarantee that assignments are carried out in any particular order.

If you set a column to the value it currently has, MySQL notices this and does not update it.

If you update a column that has been declared NOT NULL by setting to NULL, an error occurs if strict SQL mode is enabled; otherwise, the column is set to the implicit default value for the column data type and the warning count is incremented. The implicit default value is 0 for numeric types, the empty string ("") for string types, and the “zero” value for date and time types. See Section 11.5, “Data Type Default Values”.

UPDATE returns the number of rows that were actually changed. The `mysql_info()` C API function returns the number of rows that were matched and updated and the number of warnings that occurred during the UPDATE.

You can use LIMIT `row_count` to restrict the scope of the UPDATE. A LIMIT clause is a rows-matched restriction. The statement stops as soon as it has found `row_count` rows that satisfy the WHERE clause, whether or not they actually were changed.

If an UPDATE statement includes an ORDER BY clause, the rows are updated in the order specified by the clause. This can be useful in certain situations that might otherwise result in an error. Suppose that a table `t` contains a column `id` that has a unique index. The following statement could fail with a duplicate-key error, depending on the order in which rows are updated:

```
UPDATE t SET id = id + 1;
```

For example, if the table contains 1 and 2 in the `id` column and 1 is updated to 2 before 2 is updated to 3, an error occurs. To avoid this problem, add an ORDER BY clause to cause the rows with larger `id` values to be updated before those with smaller values:

```
UPDATE t SET id = id + 1 ORDER BY id DESC;
```

You can also perform UPDATE operations covering multiple tables. However, you cannot use ORDER BY or LIMIT with a multiple-table UPDATE. The `table_references` clause lists the tables involved in the join. Its syntax is described in Section 13.2.9.2, “JOIN Clause”. Here is an example:

```
UPDATE items,month SET items.price=month.price
WHERE items.id=month.id;
```

The preceding example shows an inner join that uses the comma operator, but multiple-table UPDATE statements can use any type of join permitted in SELECT statements, such as LEFT JOIN.

If you use a multiple-table UPDATE statement involving InnoDB tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, update a single table and rely on the ON UPDATE capabilities that InnoDB provides to cause the other tables to be modified accordingly. See Section 13.1.17.5, “FOREIGN KEY Constraints”.

UPDATE Statement

You cannot update a table and select directly from the same table in a subquery. You can work around this by using a multi-table update in which one of the tables is derived from the table that you actually wish to update, and referring to the derived table using an alias. Suppose you wish to update a table named `items` which is defined using the statement shown here:

```sql
CREATE TABLE items (  
id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,  
wholesale DECIMAL(6,2) NOT NULL DEFAULT 0.00,  
retail DECIMAL(6,2) NOT NULL DEFAULT 0.00,  
quantity BIGINT NOT NULL DEFAULT 0
);
```

To reduce the retail price of any items for which the markup is 30% or greater and of which you have fewer than one hundred in stock, you might try to use an `UPDATE` statement such as the one following, which uses a subquery in the `WHERE` clause. As shown here, this statement does not work:

```sql
mysql> UPDATE items  
> SET retail = retail * 0.9  
> WHERE id IN  
> (SELECT id FROM items  
> WHERE retail / wholesale >= 1.3 AND quantity > 100);
ERROR 1093 (HY000): You can't specify target table 'items' for update in FROM clause
```

Instead, you can employ a multi-table update in which the subquery is moved into the list of tables to be updated, using an alias to reference it in the outermost `WHERE` clause, like this:

```sql
UPDATE items,  
(SELECT id FROM items  
WHERE id IN  
(SELECT id FROM items  
WHERE retail / wholesale >= 1.3 AND quantity < 100)) AS discounted  
SET items.retail = items.retail * 0.9  
WHERE items.id = discounted.id;
```

Because the optimizer tries by default to merge the derived table `discounted` into the outermost query block, this works only if you force materialization of the derived table. You can do this by setting the `derived_merge` flag of the `optimizer_switch` system variable to `off` before running the update, or by using the `NO_MERGE` optimizer hint, as shown here:

```sql
UPDATE /*!+ NO_MERGE(discounted) */ items,  
(SELECT id FROM items  
WHERE retail / wholesale >= 1.3 AND quantity < 100) AS discounted  
SET items.retail = items.retail * 0.9  
WHERE items.id = discounted.id;
```

The advantage of using the optimizer hint in such a case is that it applies only within the query block where it is used, so that it is not necessary to change the value of `optimizer_switch` again after executing the `UPDATE`.

Another possibility is to rewrite the subquery so that it does not use `IN` or `EXISTS`, like this:

```sql
UPDATE items,  
(SELECT id, retail / wholesale AS markup, quantity FROM items)  
AS discounted  
SET items.retail = items.retail * 0.9  
WHERE discounted.markup >= 1.3  
AND discounted.quantity < 100  
AND items.id = discounted.id;
```

In this case, the subquery is materialized by default rather than merged, so it is not necessary to disable merging of the derived table.

An `UPDATE` on a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks only those partitions containing rows that match the `UPDATE` statement `WHERE` clause, as long as none of the table partitioning columns are updated. (For storage engines such as
13.3 Transactional and Locking Statements

MySQL supports local transactions (within a given client session) through statements such as `SET autocommit`, `START TRANSACTION`, `COMMIT`, and `ROLLBACK`. See Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Statements”. XA transaction support enables MySQL to participate in distributed transactions as well. See Section 13.3.7, “XA Transactions”.

13.3.1 START TRANSACTION, COMMIT, and ROLLBACK Statements

```
START TRANSACTION
  [transaction_characteristic [, transaction_characteristic] ...]

transaction_characteristic: {
  WITH CONSISTENT SNAPSHOT
  | READ WRITE
  | READ ONLY
}

BEGIN [WORK]  
COMMIT [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
ROLLBACK [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
SET autocommit = {0 | 1}
```

These statements provide control over use of transactions:

- **START TRANSACTION** or **BEGIN** start a new transaction.
- **COMMIT** commits the current transaction, making its changes permanent.
- **ROLLBACK** rolls back the current transaction, canceling its changes.
- **SET autocommit** disables or enables the default autocommit mode for the current session.

By default, MySQL runs with **autocommit** mode enabled. This means that, when not otherwise inside a transaction, each statement is atomic, as if it were surrounded by **START TRANSACTION** and **COMMIT**. You cannot use **ROLLBACK** to undo the effect; however, if an error occurs during statement execution, the statement is rolled back.

To disable autocommit mode implicitly for a single series of statements, use the **START TRANSACTION** statement:

```
START TRANSACTION;
SELECT @A:=SUM(salary) FROM table1 WHERE type=1;
UPDATE table2 SET summary=@A WHERE type=1;
COMMIT;
```

With **START TRANSACTION**, autocommit remains disabled until you end the transaction with **COMMIT** or **ROLLBACK**. The autocommit mode then reverts to its previous state.

**START TRANSACTION** permits several modifiers that control transaction characteristics. To specify multiple modifiers, separate them by commas.

- **The WITH CONSISTENT SNAPSHOT** modifier starts a consistent read for storage engines that are capable of it. This applies only to **InnoDB**. The effect is the same as issuing a **START TRANSACTION** followed by a **SELECT** from any **InnoDB** table. See Section 14.7.2.3, “Consistent Nonlocking Reads”. The **WITH CONSISTENT SNAPSHOT** modifier does not change the current transaction isolation level, so it provides a consistent snapshot only if the current isolation level is one that permits a consistent read. The only isolation level that permits a consistent read is **REPEATABLE READ**. For all other isolation levels, the **WITH CONSISTENT SNAPSHOT** clause is ignored.
START TRANSACTION, COMMIT, and ROLLBACK Statements

- The **READ WRITE** and **READ ONLY** modifiers set the transaction access mode. They permit or prohibit changes to tables used in the transaction. The **READ ONLY** restriction prevents the transaction from modifying or locking both transactional and nontransactional tables that are visible to other transactions; the transaction can still modify or lock temporary tables. These modifiers are available as of MySQL 5.6.5.

MySQL enables extra optimizations for queries on **InnoDB** tables when the transaction is known to be read-only. Specifying **READ ONLY** ensures these optimizations are applied in cases where the read-only status cannot be determined automatically. See Section 8.5.3, “Optimizing InnoDB Read-Only Transactions” for more information.

If no access mode is specified, the default mode applies. Unless the default has been changed, it is read/write. It is not permitted to specify both **READ WRITE** and **READ ONLY** in the same statement.

In read-only mode, it remains possible to change tables created with the **TEMPORARY** keyword using DML statements. Changes made with DDL statements are not permitted, just as with permanent tables.

For additional information about transaction access mode, including ways to change the default mode, see Section 13.3.6, “SET TRANSACTION Statement”.

If the **read_only** system variable is enabled, explicitly starting a transaction with **START TRANSACTION READ WRITE** requires the **SUPER** privilege.

**Important**

Many APIs used for writing MySQL client applications (such as JDBC) provide their own methods for starting transactions that can (and sometimes should) be used instead of sending a **START TRANSACTION** statement from the client. See Chapter 23, Connectors and APIs, or the documentation for your API, for more information.

To disable autocommit mode explicitly, use the following statement:

```sql
SET autocommit=0;
```

After disabling autocommit mode by setting the **autocommit** variable to zero, changes to transaction-safe tables (such as those for **InnoDB** or **NDB**) are not made permanent immediately. You must use **COMMIT** to store your changes to disk or **ROLLBACK** to ignore the changes.

**autocommit** is a session variable and must be set for each session. To disable autocommit mode for each new connection, see the description of the **autocommit** system variable at Section 5.1.7, “Server System Variables”.

**BEGIN** and **BEGIN WORK** are supported as aliases of **START TRANSACTION** for initiating a transaction. **START TRANSACTION** is standard SQL syntax, is the recommended way to start an ad-hoc transaction, and permits modifiers that **BEGIN** does not.

The **BEGIN** statement differs from the use of the **BEGIN** keyword that starts a **BEGIN ... END** compound statement. The latter does not begin a transaction. See Section 13.6.1, “BEGIN ... END Compound Statement”.

**Note**

Within all stored programs (stored procedures and functions, triggers, and events), the parser treats **BEGIN [WORK]** as the beginning of a **BEGIN ... END** block. Begin a transaction in this context with **START TRANSACTION** instead.

The optional **WORK** keyword is supported for **COMMIT** and **ROLLBACK**, as are the **CHAIN** and **RELEASE** clauses. **CHAIN** and **RELEASE** can be used for additional control over transaction completion. The
value of the completion_type system variable determines the default completion behavior. See Section 5.1.7, “Server System Variables”.

The AND CHAIN clause causes a new transaction to begin as soon as the current one ends, and the new transaction has the same isolation level as the just-terminated transaction. The new transaction also uses the same access mode (READ WRITE or READ ONLY) as the just-terminated transaction. The RELEASE clause causes the server to disconnect the current client session after terminating the current transaction. Including the NO keyword suppresses CHAIN or RELEASE completion, which can be useful if the completion_type system variable is set to cause chaining or release completion by default.

Beginning a transaction causes any pending transaction to be committed. See Section 13.3.3, “Statements That Cause an Implicit Commit”, for more information.

Beginning a transaction also causes table locks acquired with LOCK TABLES to be released, as though you had executed UNLOCK TABLES. Beginning a transaction does not release a global read lock acquired with FLUSH TABLES WITH READ LOCK.

For best results, transactions should be performed using only tables managed by a single transaction-safe storage engine. Otherwise, the following problems can occur:

- If you use tables from more than one transaction-safe storage engine (such as InnoDB), and the transaction isolation level is not SERIALIZABLE, it is possible that when one transaction commits, another ongoing transaction that uses the same tables will see only some of the changes made by the first transaction. That is, the atomicity of transactions is not guaranteed with mixed engines and inconsistencies can result. (If mixed-engine transactions are infrequent, you can use SET TRANSACTION ISOLATION LEVEL to set the isolation level to SERIALIZABLE on a per-transaction basis as necessary.)
- If you use tables that are not transaction-safe within a transaction, changes to those tables are stored at once, regardless of the status of autocommit mode.
- If you issue a ROLLBACK statement after updating a nontransactional table within a transaction, an ER_WARNING_NOT_COMPLETE_ROLLBACK warning occurs. Changes to transaction-safe tables are rolled back, but not changes to nontransactional-safe tables.

Each transaction is stored in the binary log in one chunk, upon COMMIT. Transactions that are rolled back are not logged. (Exception: Modifications to nontransactional tables cannot be rolled back. If a transaction that is rolled back includes modifications to nontransactional tables, the entire transaction is logged with a ROLLBACK statement at the end to ensure that modifications to the nontransactional tables are replicated.) See Section 5.4.4, “The Binary Log”.

You can change the isolation level or access mode for transactions with the SET TRANSACTION statement. See Section 13.3.6, “SET TRANSACTION Statement”.

Rolling back can be a slow operation that may occur implicitly without the user having explicitly asked for it (for example, when an error occurs). Because of this, SHOW PROCESSLIST displays Rolling back in the State column for the session, not only for explicit rollbacks performed with the ROLLBACK statement but also for implicit rollbacks.

**Note**

In MySQL 5.6, BEGIN, COMMIT, and ROLLBACK are not affected by --replicate-do-db or --replicate-ignore-db rules.

When InnoDB performs a complete rollback of a transaction, all locks set by the transaction are released. If a single SQL statement within a transaction rolls back as a result of an error, such as a duplicate key error, locks set by the statement are preserved while the transaction remains active. This happens because InnoDB stores row locks in a format such that it cannot know afterward which lock was set by which statement.
If a `SELECT` statement within a transaction calls a stored function, and a statement within the stored function fails, that statement rolls back. If `ROLLBACK` is executed for the transaction subsequently, the entire transaction rolls back.

### 13.3.2 Statements That Cannot Be Rolled Back

Some statements cannot be rolled back. In general, these include data definition language (DDL) statements, such as those that create or drop databases, those that create, drop, or alter tables or stored routines.

You should design your transactions not to include such statements. If you issue a statement early in a transaction that cannot be rolled back, and then another statement later fails, the full effect of the transaction cannot be rolled back in such cases by issuing a `ROLLBACK` statement.

### 13.3.3 Statements That Cause an Implicit Commit

The statements listed in this section (and any synonyms for them) implicitly end any transaction active in the current session, as if you had done a `COMMIT` before executing the statement.

Most of these statements also cause an implicit commit after executing. The intent is to handle each such statement in its own special transaction because it cannot be rolled back anyway. Transaction-control and locking statements are exceptions: If an implicit commit occurs before execution, another does not occur after.

- **Data definition language (DDL) statements that define or modify database objects.** `ALTER DATABASE ... UPGRADE DATA DIRECTORY NAME, ALTER EVENT, ALTER PROCEDURE, ALTER SERVER, ALTER TABLE, ALTER VIEW, CREATE DATABASE, CREATE EVENT, CREATE INDEX, CREATE PROCEDURE, CREATE SERVER, CREATE TABLE, CREATE TRIGGER, CREATE VIEW, DROP DATABASE, DROP EVENT, DROP INDEX, DROP PROCEDURE, DROP SERVER, DROP TABLE, DROP TRIGGER, DROP VIEW, RENAME TABLE, TRUNCATE TABLE.`

  `ALTER FUNCTION, CREATE FUNCTION` and `DROP FUNCTION` also cause an implicit commit when used with stored functions, but not with user-defined functions. (`ALTER FUNCTION` can only be used with stored functions.)

  `CREATE TABLE` and `DROP TABLE` statements do not commit a transaction if the `TEMPORARY` keyword is used. (This does not apply to other operations on temporary tables such as `ALTER TABLE` and `CREATE INDEX`, which do cause a commit.) However, although no implicit commit occurs, neither can the statement be rolled back, which means that the use of such statements causes transactional atomicity to be violated. For example, if you use `CREATE TEMPORARY TABLE` and then roll back the transaction, the table remains in existence.

  The `CREATE TABLE` statement in InnoDB is processed as a single transaction. This means that a `ROLLBACK` from the user does not undo `CREATE TABLE` statements the user made during that transaction.

  `CREATE TABLE ... SELECT` causes an implicit commit before and after the statement is executed when you are creating nontemporary tables. (No commit occurs for `CREATE TEMPORARY TABLE ... SELECT`.)

- **Statements that implicitly use or modify tables in the `mysql` database.** `ALTER USER, CREATE USER, DROP USER, GRANT, RENAME USER, REVOKE, SET PASSWORD.`

- **Transaction-control and locking statements.** `BEGIN, LOCK TABLES, SET autocommit = 1` (if the value is not already 1), `START TRANSACTION, UNLOCK TABLES`.

  `UNLOCK TABLES` commits a transaction only if any tables currently have been locked with `LOCK TABLES` to acquire nontransactional table locks. A commit does not occur for `UNLOCK TABLES` following `FLUSH TABLES WITH READ LOCK` because the latter statement does not acquire table-level locks.
Transactions cannot be nested. This is a consequence of the implicit commit performed for any current transaction when you issue a `START TRANSACTION` statement or one of its synonyms.

Statements that cause an implicit commit cannot be used in an XA transaction while the transaction is in an `ACTIVE` state.

The `BEGIN` statement differs from the use of the `BEGIN` keyword that starts a `BEGIN ... END` compound statement. The latter does not cause an implicit commit. See Section 13.6.1, “BEGIN ... END Compound Statement”.

- **Data loading statements.** `LOAD DATA` causes an implicit commit only for tables using the NDB storage engine.
- **Administrative statements.** `ANALYZE TABLE, CACHE INDEX, CHECK TABLE, FLUSH, LOAD INDEX INTO CACHE, OPTIMIZE TABLE, REPAIR TABLE, RESET`.
- **Replication control statements.** `START SLAVE, STOP SLAVE, RESET SLAVE, CHANGE MASTER TO`.

### 13.3.4 SAVEPOINT, ROLLBACK TO SAVEPOINT, and RELEASE SAVEPOINT Statements

```sql
SAVEPOINT identifier
ROLLBACK [WORK] TO [SAVEPOINT] identifier
RELEASE SAVEPOINT identifier
```

InnoDB supports the SQL statements `SAVEPOINT, ROLLBACK TO SAVEPOINT, RELEASE SAVEPOINT` and the optional `WORK` keyword for `ROLLBACK`.

The `SAVEPOINT` statement sets a named transaction savepoint with a name of `identifier`. If the current transaction has a savepoint with the same name, the old savepoint is deleted and a new one is set.

The `ROLLBACK TO SAVEPOINT` statement rolls back a transaction to the named savepoint without terminating the transaction. Modifications that the current transaction made to rows after the savepoint was set are undone in the rollback, but InnoDB does not release the row locks that were stored in memory after the savepoint. (For a new inserted row, the lock information is carried by the transaction ID stored in the row; the lock is not separately stored in memory. In this case, the row lock is released in the undo.) Savepoints that were set at a later time than the named savepoint are deleted.

If the `ROLLBACK TO SAVEPOINT` statement returns the following error, it means that no savepoint with the specified name exists:

```sql
ERROR 1305 (42000): SAVEPOINT identifier does not exist
```

The `RELEASE SAVEPOINT` statement removes the named savepoint from the set of savepoints of the current transaction. No commit or rollback occurs. It is an error if the savepoint does not exist.

All savepoints of the current transaction are deleted if you execute a `COMMIT`, or a `ROLLBACK` that does not name a savepoint.

A new savepoint level is created when a stored function is invoked or a trigger is activated. The savepoints on previous levels become unavailable and thus do not conflict with savepoints on the new level. When the function or trigger terminates, any savepoints it created are released and the previous savepoint level is restored.

### 13.3.5 LOCK TABLES and UNLOCK TABLES Statements

```sql
LOCK TABLES
  tbl_name [[AS] alias] lock_type
[, tbl_name [[AS] alias] lock_type] ...
```

1653
LOCK TABLES and UNLOCK TABLES Statements

LOCK TABLES and UNLOCK TABLES Statements

MySQL enables client sessions to acquire table locks explicitly for the purpose of cooperating with other sessions for access to tables, or to prevent other sessions from modifying tables during periods when a session requires exclusive access to them. A session can acquire or release locks only for itself. One session cannot acquire locks for another session or release locks held by another session.

Locks may be used to emulate transactions or to get more speed when updating tables. This is explained in more detail in Table-Locking Restrictions and Conditions.

LOCK TABLES explicitly acquires table locks for the current client session. Table locks can be acquired for base tables or views. You must have the LOCK TABLES privilege, and the SELECT privilege for each object to be locked.

For view locking, LOCK TABLES adds all base tables used in the view to the set of tables to be locked and locks them automatically. As of MySQL 5.6.50, LOCK TABLES checks that the view definer has the proper privileges on the tables underlying the view.

If you lock a table explicitly with LOCK TABLES, any tables used in triggers are also locked implicitly, as described in LOCK TABLES and Triggers.

UNLOCK TABLES explicitly releases any table locks held by the current session. LOCK TABLES implicitly releases any table locks held by the current session before acquiring new locks.

Another use for UNLOCK TABLES is to release the global read lock acquired with the FLUSH TABLES WITH READ LOCK statement, which enables you to lock all tables in all databases. See Section 13.7.6.3, “FLUSH Statement”. (This is a very convenient way to get backups if you have a file system such as Veritas that can take snapshots in time.)

A table lock protects only against inappropriate reads or writes by other sessions. A session holding a WRITE lock can perform table-level operations such as DROP TABLE or TRUNCATE TABLE. For sessions holding a READ lock, DROP TABLE and TRUNCATE TABLE operations are not permitted.

The following discussion applies only to non-TEMPORARY tables. LOCK TABLES is permitted (but ignored) for a TEMPORARY table. The table can be accessed freely by the session within which it was created, regardless of what other locking may be in effect. No lock is necessary because no other session can see the table.

- **Table Lock Acquisition**
- **Table Lock Release**
- **Interaction of Table Locking and Transactions**
- **LOCK TABLES and Triggers**
- **Table-Locking Restrictions and Conditions**

**Table Lock Acquisition**

To acquire table locks within the current session, use the LOCK TABLES statement, which acquires metadata locks (see Section 8.11.4, “Metadata Locking”).

The following lock types are available:

READ [LOCAL] lock:

- The session that holds the lock can read the table (but not write it).
LOCK TABLES and UNLOCK TABLES Statements

• Multiple sessions can acquire a READ lock for the table at the same time.
• Other sessions can read the table without explicitly acquiring a READ lock.
• The LOCAL modifier enables nonconflicting INSERT statements (concurrent inserts) by other sessions to execute while the lock is held. (See Section 8.11.3, "Concurrent Inserts".) However, READ LOCAL cannot be used if you are going to manipulate the database using processes external to the server while you hold the lock. For InnoDB tables, READ LOCAL is the same as READ.

[LOW_PRIORITY] WRITE lock:
• The session that holds the lock can read and write the table.
• Only the session that holds the lock can access the table. No other session can access it until the lock is released.
• Lock requests for the table by other sessions block while the WRITE lock is held.
• The LOW_PRIORITY modifier has no effect. In previous versions of MySQL, it affected locking behavior, but this is no longer true. It is now deprecated and its use produces a warning. Use WRITE without LOW_PRIORITY instead.

WRITE locks normally have higher priority than READ locks to ensure that updates are processed as soon as possible. This means that if one session obtains a READ lock and then another session requests a WRITE lock, subsequent READ lock requests wait until the session that requested the WRITE lock has obtained the lock and released it. (An exception to this policy can occur for small values of the max_write_lock_count system variable; see Section 8.11.4, "Metadata Locking").

If the LOCK TABLES statement must wait due to locks held by other sessions on any of the tables, it blocks until all locks can be acquired.

A session that requires locks must acquire all the locks that it needs in a single LOCK TABLES statement. While the locks thus obtained are held, the session can access only the locked tables. For example, in the following sequence of statements, an error occurs for the attempt to access t2 because it was not locked in the LOCK TABLES statement:

```sql
mysql> LOCK TABLES t1 READ;
mysql> SELECT COUNT(*) FROM t1;
+----------+
| COUNT(*) |
+----------+
|        3 |
mysql> SELECT COUNT(*) FROM t2;
ERROR 1100 (HY000): Table 't2' was not locked with LOCK TABLES
```

Tables in the INFORMATION_SCHEMA database are an exception. They can be accessed without being locked explicitly even while a session holds table locks obtained with LOCK TABLES.

You cannot refer to a locked table multiple times in a single query using the same name. Use aliases instead, and obtain a separate lock for the table and each alias:

```sql
mysql> LOCK TABLE t WRITE, t AS t1 READ;
mysql> INSERT INTO t SELECT * FROM t;
ERROR 1100: Table 't' was not locked with LOCK TABLES
```

The error occurs for the first INSERT because there are two references to the same name for a locked table. The second INSERT succeeds because the references to the table use different names.

If your statements refer to a table by means of an alias, you must lock the table using that same alias. It does not work to lock the table without specifying the alias:

```sql
mysql> LOCK TABLE t READ;
mysql> SELECT * FROM t AS myalias;
```
LOCK TABLES and UNLOCK TABLES Statements

ERROR 1100: Table 'myalias' was not locked with LOCK TABLES

Conversely, if you lock a table using an alias, you must refer to it in your statements using that alias:

```
mysql> LOCK TABLE t AS myalias READ;
mysql> SELECT * FROM t;
ERROR 1100: Table 't' was not locked with LOCK TABLES
mysql> SELECT * FROM t AS myalias;
```

Note

LOCK TABLES or UNLOCK TABLES, when applied to a partitioned table, always locks or unlocks the entire table; these statements do not support partition lock pruning. See Section 19.6.4, “Partitioning and Locking”.

Table Lock Release

When the table locks held by a session are released, they are all released at the same time. A session can release its locks explicitly, or locks may be released implicitly under certain conditions.

- A session can release its locks explicitly with UNLOCK TABLES.
- If a session issues a LOCK TABLES statement to acquire a lock while already holding locks, its existing locks are released implicitly before the new locks are granted.
- If a session begins a transaction (for example, with START TRANSACTION), an implicit UNLOCK TABLES is performed, which causes existing locks to be released. (For additional information about the interaction between table locking and transactions, see Interaction of Table Locking and Transactions.)

If the connection for a client session terminates, whether normally or abnormally, the server implicitly releases all table locks held by the session (transactional and nontransactional). If the client reconnects, the locks will no longer be in effect. In addition, if the client had an active transaction, the server rolls back the transaction upon disconnect, and if reconnect occurs, the new session begins with autocommit enabled. For this reason, clients may wish to disable auto-reconnect. With auto-reconnect in effect, the client is not notified if reconnect occurs but any table locks or current transaction will have been lost. With auto-reconnect disabled, if the connection drops, an error occurs for the next statement issued. The client can detect the error and take appropriate action such as reacquiring the locks or redoing the transaction. See C API Automatic Reconnection Control.

Note

If you use ALTER TABLE on a locked table, it may become unlocked. For example, if you attempt a second ALTER TABLE operation, the result may be an error Table 'tbl_name' was not locked with LOCK TABLES. To handle this, lock the table again prior to the second alteration. See also Section B.3.6.1, “Problems with ALTER TABLE”.

Interaction of Table Locking and Transactions

LOCK TABLES and UNLOCK TABLES interact with the use of transactions as follows:

- LOCK TABLES is not transaction-safe and implicitly commits any active transaction before attempting to lock the tables.
- UNLOCK TABLES implicitly commits any active transaction, but only if LOCK TABLES has been used to acquire table locks. For example, in the following set of statements, UNLOCK TABLES releases the global read lock but does not commit the transaction because no table locks are in effect:

```
FLUSH TABLES WITH READ LOCK;
START TRANSACTION;
SELECT ... ;
UNLOCK TABLES;
```
• Beginning a transaction (for example, with `START TRANSACTION`) implicitly commits any current transaction and releases existing table locks.

• `FLUSH TABLES WITH READ LOCK` acquires a global read lock and not table locks, so it is not subject to the same behavior as `LOCK TABLES` and `UNLOCK TABLES` with respect to table locking and implicit commits. For example, `START TRANSACTION` does not release the global read lock. See Section 13.7.6.3, “FLUSH Statement”.

• Other statements that implicitly cause transactions to be committed do not release existing table locks. For a list of such statements, see Section 13.3.3, “Statements That Cause an Implicit Commit”.

• The correct way to use `LOCK TABLES` and `UNLOCK TABLES` with transactional tables, such as InnoDB tables, is to begin a transaction with `SET autocommit = 0` (not `START TRANSACTION`) followed by `LOCK TABLES`, and to not call `UNLOCK TABLES` until you commit the transaction explicitly. For example, if you need to write to table `t1` and read from table `t2`, you can do this:

```sql
SET autocommit=0;
LOCK TABLES t1 WRITE, t2 READ, ...;
... do something with tables t1 and t2 here ... 
COMMIT;
UNLOCK TABLES;
```

When you call `LOCK TABLES`, InnoDB internally takes its own table lock, and MySQL takes its own table lock. InnoDB releases its internal table lock at the next commit, but for MySQL to release its table lock, you have to call `UNLOCK TABLES`. You should not have `autocommit = 1`, because then InnoDB releases its internal table lock immediately after the call of `LOCK TABLES`, and deadlocks can very easily happen. InnoDB does not acquire the internal table lock at all if `autocommit = 1`, to help old applications avoid unnecessary deadlocks.

• `ROLLBACK` does not release table locks.

**LOCK TABLES and Triggers**

If you lock a table explicitly with `LOCK TABLES`, any tables used in triggers are also locked implicitly:

• The locks are taken as the same time as those acquired explicitly with the `LOCK TABLES` statement.

• The lock on a table used in a trigger depends on whether the table is used only for reading. If so, a read lock suffices. Otherwise, a write lock is used.

• If a table is locked explicitly for reading with `LOCK TABLES`, but needs to be locked for writing because it might be modified within a trigger, a write lock is taken rather than a read lock. (That is, an implicit write lock needed due to the table’s appearance within a trigger causes an explicit read lock request for the table to be converted to a write lock request.)

Suppose that you lock two tables, `t1` and `t2`, using this statement:

```sql
LOCK TABLES t1 WRITE, t2 READ;
```

If `t1` or `t2` have any triggers, tables used within the triggers will also be locked. Suppose that `t1` has a trigger defined like this:

```sql
CREATE TRIGGER t1_a_ins AFTER INSERT ON t1 FOR EACH ROW
BEGIN
    UPDATE t4 SET count = count+1
    WHERE id = NEW.id AND EXISTS (SELECT a FROM t3);
    INSERT INTO t2 VALUES(1, 2);
END;
```

The result of the `LOCK TABLES` statement is that `t1` and `t2` are locked because they appear in the statement, and `t3` and `t4` are locked because they are used within the trigger:

• `t1` is locked for writing per the `WRITE` lock request.
LOCK TABLES and UNLOCK TABLES Statements

• t2 is locked for writing, even though the request is for a READ lock. This occurs because t2 is inserted into within the trigger, so the READ request is converted to a WRITE request.

• t3 is locked for reading because it is only read from within the trigger.

• t4 is locked for writing because it might be updated within the trigger.

Table-Locking Restrictions and Conditions

You can safely use KILL to terminate a session that is waiting for a table lock. See Section 13.7.6.4, “KILL Statement”.

Do not lock any tables that you are using with INSERT DELAYED. An INSERT DELAYED in this case results in an error because the insert must be handled by a separate thread, not by the session which holds the lock.

LOCK TABLES and UNLOCK TABLES cannot be used within stored programs.

Tables in the performance_schema database cannot be locked with LOCK TABLES, except the setup_xxx tables.

The following statements are prohibited while a LOCK TABLES statement is in effect: CREATE TABLE, CREATE TABLE ... LIKE, CREATE VIEW, DROP VIEW, and DDL statements on stored functions and procedures and events.

For some operations, system tables in the mysql database must be accessed. For example, the HELP statement requires the contents of the server-side help tables, and CONVERT_TZ() might need to read the time zone tables. The server implicitly locks the system tables for reading as necessary so that you need not lock them explicitly. These tables are treated as just described:

- mysql.help_category
- mysql.help_keyword
- mysql.help_relation
- mysql.help_topic
- mysql.proc
- mysql.time_zone
- mysql.time_zone_leap_second
- mysql.time_zone_name
- mysql.time_zone_transition
- mysql.time_zone_transition_type

If you want to explicitly place a WRITE lock on any of those tables with a LOCK TABLES statement, the table must be the only one locked; no other table can be locked with the same statement.

Normally, you do not need to lock tables, because all single UPDATE statements are atomic; no other session can interfere with any other currently executing SQL statement. However, there are a few cases when locking tables may provide an advantage:

• If you are going to run many operations on a set of MyISAM tables, it is much faster to lock the tables you are going to use. Locking MyISAM tables speeds up inserting, updating, or deleting on them because MySQL does not flush the key cache for the locked tables until UNLOCK TABLES is called. Normally, the key cache is flushed after each SQL statement.

The downside to locking the tables is that no session can update a READ-locked table (including the one holding the lock) and no session can access a WRITE-locked table other than the one holding the lock.

• If you are using tables for a nontransactional storage engine, you must use LOCK TABLES if you want to ensure that no other session modifies the tables between a SELECT and an UPDATE. The example shown here requires LOCK TABLES to execute safely:

    LOCK TABLES trans READ, customer WRITE;
    SELECT SUM(value) FROM trans WHERE customer_id=some_id;
    UPDATE customer
    SET total_value=sum_from_previous_statement
SET TRANSACTION Statement

```sql
WHERE customer_id=some_id;
UNLOCK TABLES;
```

Without `LOCK TABLES`, it is possible that another session might insert a new row in the `trans` table between execution of the `SELECT` and `UPDATE` statements.

You can avoid using `LOCK TABLES` in many cases by using relative updates (`UPDATE customer 
SET value=value+new_value`) or the `LAST_INSERT_ID()` function.

You can also avoid locking tables in some cases by using the user-level advisory lock functions `GET_LOCK()` and `RELEASE_LOCK()`. These locks are saved in a hash table in the server and implemented with `pthread_mutex_lock()` and `pthread_mutex_unlock()` for high speed. See Section 12.15, “Locking Functions”.

See Section 8.11.1, “Internal Locking Methods”, for more information on locking policy.

13.3.6 SET TRANSACTION Statement

```sql
SET [GLOBAL | SESSION] TRANSACTION
  transaction_characteristic [, transaction_characteristic] ... 
```

Transaction Isolation Levels

To set the transaction isolation level, use an `ISOLATION LEVEL level` clause. It is not permitted to specify multiple `ISOLATION LEVEL level` clauses in the same `SET TRANSACTION` statement.

The default isolation level is `REPEATABLE READ`. Other permitted values are `READ COMMITTED`, `READ UNCOMMITTED`, and `SERIALIZABLE`. For information about these isolation levels, see Section 14.7.2.1, “Transaction Isolation Levels”.

Transaction Access Mode

To set the transaction access mode, use a `READ WRITE` or `READ ONLY` clause. It is not permitted to specify multiple access-mode clauses in the same `SET TRANSACTION` statement.
By default, a transaction takes place in read/write mode, with both reads and writes permitted to tables used in the transaction. This mode may be specified explicitly using `SET TRANSACTION` with an access mode of `READ WRITE`.

If the transaction access mode is set to `READ ONLY`, changes to tables are prohibited. This may enable storage engines to make performance improvements that are possible when writes are not permitted.

In read-only mode, it remains possible to change tables created with the `TEMPORARY` keyword using DML statements. Changes made with DDL statements are not permitted, just as with permanent tables.

The `READ WRITE` and `READ ONLY` access modes also may be specified for an individual transaction using the `START TRANSACTION` statement.

**Transaction Characteristic Scope**

You can set transaction characteristics globally, for the current session, or for the next transaction only:

- With the `GLOBAL` keyword:
  - The statement applies globally for all subsequent sessions.
  - Existing sessions are unaffected.

- With the `SESSION` keyword:
  - The statement applies to all subsequent transactions performed within the current session.
  - The statement is permitted within transactions, but does not affect the current ongoing transaction.
  - If executed between transactions, the statement overrides any preceding statement that sets the next-transaction value of the named characteristics.

- Without any `SESSION` or `GLOBAL` keyword:
  - The statement applies only to the next single transaction performed within the session.
  - Subsequent transactions revert to using the session value of the named characteristics.
  - The statement is not permitted within transactions:

```sql
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.02 sec)
mysql> SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;
ERROR 1568 (25001): Transaction characteristics can’t be changed while a transaction is in progress
```

A change to global transaction characteristics requires the `SUPER` privilege. Any session is free to change its session characteristics (even in the middle of a transaction), or the characteristics for its next transaction (prior to the start of that transaction).

To set the global isolation level at server startup, use the `--transaction-isolation=level` option on the command line or in an option file. Values of `level` for this option use dashes rather than spaces, so the permissible values are `READ-UNCOMMITTED`, `READ-COMMITTED`, `REPEATABLE-READ`, or `SERIALIZABLE`.

Similarly, to set the global transaction access mode at server startup, use the `--transaction-read-only` option. The default is `OFF` (read/write mode) but the value can be set to `ON` for a mode of read only.

For example, to set the isolation level to `REPEATABLE READ` and the access mode to `READ WRITE`, use these lines in the `[mysqld]` section of an option file:
At runtime, characteristics at the global, session, and next-transaction scope levels can be set indirectly using the `SET TRANSACTION` statement, as described previously. They can also be set directly using the `SET` statement to assign values to the `tx_isolation` and `tx_read_only` system variables:

- **SET TRANSACTION** permits optional `GLOBAL` and `SESSION` keywords for setting transaction characteristics at different scope levels.

- The `SET` statement for assigning values to the `tx_isolation` and `tx_read_only` system variables has syntaxes for setting these variables at different scope levels.

The following tables show the characteristic scope level set by each `SET TRANSACTION` and variable-assignment syntax.

**Table 13.6 SET TRANSACTION Syntax for Transaction Characteristics**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Affected Characteristic Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>SET GLOBAL TRANSACTION transaction_characteristic</td>
<td>Global</td>
</tr>
<tr>
<td>SET SESSION TRANSACTION transaction_characteristic</td>
<td>Session</td>
</tr>
<tr>
<td>SET TRANSACTION transaction_characteristic</td>
<td>Next transaction only</td>
</tr>
</tbody>
</table>

**Table 13.7 SET Syntax for Transaction Characteristics**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Affected Characteristic Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>SET GLOBAL var_name = value</td>
<td>Global</td>
</tr>
<tr>
<td>SET @@GLOBAL.var_name = value</td>
<td>Global</td>
</tr>
<tr>
<td>SET PERSIST var_name = value</td>
<td>Global</td>
</tr>
<tr>
<td>SET @@PERSIST.var_name = value</td>
<td>Global</td>
</tr>
<tr>
<td>SET PERSIST_ONLY var_name = value</td>
<td>No runtime effect</td>
</tr>
<tr>
<td>SET @@PERSIST_ONLY.var_name = value</td>
<td>No runtime effect</td>
</tr>
<tr>
<td>SET SESSION var_name = value</td>
<td>Session</td>
</tr>
<tr>
<td>SET @@SESSION.var_name = value</td>
<td>Session</td>
</tr>
<tr>
<td>SET var_name = value</td>
<td>Session</td>
</tr>
<tr>
<td>SET @@var_name = value</td>
<td>Next transaction only</td>
</tr>
</tbody>
</table>

It is possible to check the global and session values of transaction characteristics at runtime:

```sql
SELECT @@GLOBAL.tx_isolation, @@GLOBAL.tx_read_only;
SELECT @@SESSION.tx_isolation, @@SESSION.tx_read_only;
```

### 13.3.7 XA Transactions

Support for XA transactions is available for the InnoDB storage engine. The MySQL XA implementation is based on the X/Open CAE document *Distributed Transaction Processing: The XA Specification*. This document is published by The Open Group and available at [http://www.opengroup.org/public/pubs/catalog/c193.htm](http://www.opengroup.org/public/pubs/catalog/c193.htm). Limitations of the current XA implementation are described in Section 13.3.7.3, “Restrictions on XA Transactions”.

On the client side, there are no special requirements. The XA interface to a MySQL server consists of SQL statements that begin with the `XA` keyword. MySQL client programs must be able to send SQL
statements and to understand the semantics of the XA statement interface. They do not need to be linked against a recent client library. Older client libraries also will work.

Among the MySQL Connectors, MySQL Connector/J 5.0.0 and higher supports XA directly, by means of a class interface that handles the XA SQL statement interface for you.

XA supports distributed transactions, that is, the ability to permit multiple separate transactional resources to participate in a global transaction. Transactional resources often are RDBMSs but may be other kinds of resources.

A global transaction involves several actions that are transactional in themselves, but that all must either complete successfully as a group, or all be rolled back as a group. In essence, this extends ACID properties “up a level” so that multiple ACID transactions can be executed in concert as components of a global operation that also has ACID properties. (As with nondistributed transactions, SERIALIZABLE may be preferred if your applications are sensitive to read phenomena. REPEATABLE READ may not be sufficient for distributed transactions.)

Some examples of distributed transactions:

• An application may act as an integration tool that combines a messaging service with an RDBMS. The application makes sure that transactions dealing with message sending, retrieval, and processing that also involve a transactional database all happen in a global transaction. You can think of this as “transactional email.”

• An application performs actions that involve different database servers, such as a MySQL server and an Oracle server (or multiple MySQL servers), where actions that involve multiple servers must happen as part of a global transaction, rather than as separate transactions local to each server.

• A bank keeps account information in an RDBMS and distributes and receives money through automated teller machines (ATMs). It is necessary to ensure that ATM actions are correctly reflected in the accounts, but this cannot be done with the RDBMS alone. A global transaction manager integrates the ATM and database resources to ensure overall consistency of financial transactions.

Applications that use global transactions involve one or more Resource Managers and a Transaction Manager:

• A Resource Manager (RM) provides access to transactional resources. A database server is one kind of resource manager. It must be possible to either commit or roll back transactions managed by the RM.

• A Transaction Manager (TM) coordinates the transactions that are part of a global transaction. It communicates with the RMs that handle each of these transactions. The individual transactions within a global transaction are “branches” of the global transaction. Global transactions and their branches are identified by a naming scheme described later.

The MySQL implementation of XA enables a MySQL server to act as a Resource Manager that handles XA transactions within a global transaction. A client program that connects to the MySQL server acts as the Transaction Manager.

To carry out a global transaction, it is necessary to know which components are involved, and bring each component to a point when it can be committed or rolled back. Depending on what each component reports about its ability to succeed, they must all commit or roll back as an atomic group. That is, either all components must commit, or all components must roll back. To manage a global transaction, it is necessary to take into account that any component or the connecting network might fail.

The process for executing a global transaction uses two-phase commit (2PC). This takes place after the actions performed by the branches of the global transaction have been executed.

1. In the first phase, all branches are prepared. That is, they are told by the TM to get ready to commit. Typically, this means each RM that manages a branch records the actions for the branch in
stable storage. The branches indicate whether they are able to do this, and these results are used for the second phase.

2. In the second phase, the TM tells the RMs whether to commit or roll back. If all branches indicated when they were prepared that they will be able to commit, all branches are told to commit. If any branch indicated when it was prepared that it will not be able to commit, all branches are told to roll back.

In some cases, a global transaction might use one-phase commit (1PC). For example, when a Transaction Manager finds that a global transaction consists of only one transactional resource (that is, a single branch), that resource can be told to prepare and commit at the same time.

13.3.7.1 XA Transaction SQL Statements

To perform XA transactions in MySQL, use the following statements:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>XA START</td>
<td>XA [START</td>
</tr>
<tr>
<td>XA END</td>
<td>XA END xid [SUSPEND [FOR MIGRATE]]</td>
</tr>
<tr>
<td>XA PREPARE</td>
<td>XA COMMIT xid [ONE PHASE]</td>
</tr>
<tr>
<td>XA ROLLBACK</td>
<td>XA ROLLBACK xid</td>
</tr>
<tr>
<td>XA RECOVER</td>
<td>XA RECOVER</td>
</tr>
</tbody>
</table>

For **XA START**, the **JOIN** and **RESUME** clauses are recognized but have no effect.

For **XA END** the **SUSPEND [FOR MIGRATE]** clause is recognized but has no effect.

Each XA statement begins with the **XA** keyword, and most of them require an **xid** value. An **xid** is an XA transaction identifier. It indicates which transaction the statement applies to. **xid** values are supplied by the client, or generated by the MySQL server. An **xid** value has from one to three parts:

- **gtrid** is a global transaction identifier,
- **bqual** is a branch qualifier, and
- **formatID** is a number that identifies the format used by the **gtrid** and **bqual** values. As indicated by the syntax, **bqual** and **formatID** are optional. The default **bqual** value is ''' if not given. The default **formatID** value is 1 if not given.

- **gtrid** and **bqual** must be string literals, each up to 64 bytes (not characters) long. **gtrid** and **bqual** can be specified in several ways. You can use a quoted string ('ab'), hex string (X'6162', 0x6162), or bit value (b'nnnn').

- **formatID** is an unsigned integer.

The **gtrid** and **bqual** values are interpreted in bytes by the MySQL server's underlying XA support routines. However, while an SQL statement containing an XA statement is being parsed, the server works with some specific character set. To be safe, write **gtrid** and **bqual** as hex strings.

**xid** values typically are generated by the Transaction Manager. Values generated by one TM must be different from values generated by other TMs. A given TM must be able to recognize its own **xid** values in a list of values returned by the **XA RECOVER** statement.

**XA START xid** starts an XA transaction with the given **xid** value. Each XA transaction must have a unique **xid** value, so the value must not currently be used by another XA transaction. Uniqueness is assessed using the **gtrid** and **bqual** values. All following XA statements for the XA transaction must be specified using the same **xid** value as that given in the **XA START** statement. If you use any of those statements but specify an **xid** value that does not correspond to some existing XA transaction, an error occurs.
One or more XA transactions can be part of the same global transaction. All XA transactions within a given global transaction must use the same gtrid value in the xid value. For this reason, gtrid values must be globally unique so that there is no ambiguity about which global transaction a given XA transaction is part of. The bqual part of the xid value must be different for each XA transaction within a global transaction. (The requirement that bqual values be different is a limitation of the current MySQL XA implementation. It is not part of the XA specification.)

The XA RECOVER statement returns information for those XA transactions on the MySQL server that are in the PREPARED state. (See Section 13.3.7.2, ‘XA Transaction States’.) The output includes a row for each such XA transaction on the server, regardless of which client started it.

XA RECOVER output rows look like this (for an example xid value consisting of the parts 'abc', 'def', and 7):

```
mysql> XA RECOVER;
+----------+--------------+--------------+--------+
<table>
<thead>
<tr>
<th>formatID</th>
<th>gtrid_length</th>
<th>bqual_length</th>
<th>data</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>3</td>
<td>3</td>
<td>abcdef</td>
</tr>
</tbody>
</table>
+----------+--------------+--------------+--------+
```

The output columns have the following meanings:

- `formatID` is the formatID part of the transaction xid
- `gtrid_length` is the length in bytes of the gtrid part of the xid
- `bqual_length` is the length in bytes of the bqual part of the xid
- `data` is the concatenation of the gtrid and bqual parts of the xid

### 13.3.7.2 XA Transaction States

An XA transaction progresses through the following states:

1. Use XA START to start an XA transaction and put it in the ACTIVE state.

2. For an ACTIVE XA transaction, issue the SQL statements that make up the transaction, and then issue an XA END statement. XA END puts the transaction in the IDLE state.

3. For an IDLE XA transaction, you can issue either an XA PREPARE statement or an XA COMMIT ... ONE PHASE statement:

   - **XA PREPARE** puts the transaction in the PREPARED state. An XA RECOVER statement at this point will include the transaction’s xid value in its output, because XA RECOVER lists all XA transactions that are in the PREPARED state.

   - **XA COMMIT ... ONE PHASE** prepares and commits the transaction. The xid value will not be listed by XA RECOVER because the transaction terminates.

4. For a PREPARED XA transaction, you can issue an XA COMMIT statement to commit and terminate the transaction, or XA ROLLBACK to roll back and terminate the transaction.

Here is a simple XA transaction that inserts a row into a table as part of a global transaction:

```
mysql> XA START 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO mytable (i) VALUES(10);
Query OK, 1 row affected (0.04 sec)

mysql> XA END 'xatest';
Query OK, 0 rows affected (0.00 sec)
```
Within the context of a given client connection, XA transactions and local (non-XA) transactions are mutually exclusive. For example, if `XA START` has been issued to begin an XA transaction, a local transaction cannot be started until the XA transaction has been committed or rolled back. Conversely, if a local transaction has been started with `START TRANSACTION`, no XA statements can be used until the transaction has been committed or rolled back.

If an XA transaction is in the `ACTIVE` state, you cannot issue any statements that cause an implicit commit. That would violate the XA contract because you could not roll back the XA transaction. You will receive the following error if you try to execute such a statement:

```text
ERROR 1399 (XAE07): XAER_RMFAIL: The command cannot be executed when global transaction is in the ACTIVE state
```

Statements to which the preceding remark applies are listed at Section 13.3.3, “Statements That Cause an Implicit Commit”.

### 13.3.7.3 Restrictions on XA Transactions

XA transaction support is limited to the **InnoDB** storage engine.

For “external XA,” a MySQL server acts as a Resource Manager and client programs act as Transaction Managers. For “Internal XA”, storage engines within a MySQL server act as RMs, and the server itself acts as a TM. Internal XA support is limited by the capabilities of individual storage engines. Internal XA is required for handling XA transactions that involve more than one storage engine. The implementation of internal XA requires that a storage engine support two-phase commit at the table handler level, and currently this is true only for **InnoDB**.

For `XA START`, the `JOIN` and `RESUME` clauses are recognized but have no effect.

For `XA END` the `SUSPEND [FOR MIGRATE]` clause is recognized but has no effect.

The requirement that the `bqual` part of the `xid` value be different for each XA transaction within a global transaction is a limitation of the current MySQL XA implementation. It is not part of the XA specification.

If an XA transaction has reached the `PREPARED` state and the MySQL server is killed (for example, with `kill -9` on Unix) or shuts down abnormally, the transaction can be continued after the server restarts. However, if the client reconnects and commits the transaction, the transaction will be absent from the binary log even though it has been committed. This means the data and the binary log have gone out of synchrony. An implication is that XA cannot be used safely together with replication.

It is possible that the server will roll back a pending XA transaction, even one that has reached the `PREPARED` state. This happens if a client connection terminates and the server continues to run, or if clients are connected and the server shuts down gracefully. (In the latter case, the server marks each connection to be terminated, and then rolls back the `PREPARED` XA transaction associated with it.) It should be possible to commit or roll back a `PREPARED` XA transaction, but this cannot be done without changes to the binary logging mechanism.

**`FLUSH TABLES WITH READ LOCK`** is not compatible with XA transactions.

### 13.4 Replication Statements

Replication can be controlled through the SQL interface using the statements described in this section. One group of statements controls replication source servers, the other controls replicas.
13.4.1 SQL Statements for Controlling Replication Source Servers

This section discusses statements for managing replication source servers. Section 13.4.2, “SQL Statements for Controlling Replica Servers”, discusses statements for managing replica servers.

In addition to the statements described here, the following `SHOW` statements are used with replication source servers. For information about these statements, see Section 13.7.5, “SHOW Statements”.

- `SHOW BINARY LOGS`
- `SHOW BINLOG EVENTS`
- `SHOW MASTER STATUS`
- `SHOW SLAVE HOSTS`

13.4.1.1 PURGE BINARY LOGS Statement

```
PURGE { BINARY | MASTER } LOGS { TO 'log_name' | BEFORE datetime_expr }
```

The binary log is a set of files that contain information about data modifications made by the MySQL server. The log consists of a set of binary log files, plus an index file (see Section 5.4.4, “The Binary Log”).

The `PURGE BINARY LOGS` statement deletes all the binary log files listed in the log index file prior to the specified log file name or date. `BINARY` and `MASTER` are synonyms. Deleted log files also are removed from the list recorded in the index file, so that the given log file becomes the first in the list.

This statement has no effect if the server was not started with the `--log-bin` option to enable binary logging.

Examples:

```
PURGE BINARY LOGS TO 'mysql-bin.010';
PURGE BINARY LOGS BEFORE '2019-04-02 22:46:26';
```

The `BEFORE` variant’s `datetime_expr` argument should evaluate to a `DATETIME` value (a value in `'YYYY-MM-DD hh:mm:ss'` format).

This statement is safe to run while replicas are replicating. You need not stop them. If you have an active replica that currently is reading one of the log files you are trying to delete, this statement does not delete the log file that is in use or any log files later than that one, but it deletes any earlier log files. In MySQL 5.6.12 and later, a warning message is issued in this situation. (Bug #13727933) However, if a replica is not connected and you happen to purge one of the log files it has yet to read, the replica will be unable to replicate after it reconnects.

To safely purge binary log files, follow this procedure:

1. On each replica server, use `SHOW SLAVE STATUS` to check which log file it is reading.
2. Obtain a listing of the binary log files on the source with `SHOW BINARY LOGS`.
3. Determine the earliest log file among all the replicas. This is the target file. If all the replicas are up to date, this is the last log file on the list.
4. Make a backup of all the log files you are about to delete. (This step is optional, but always advisable.)
5. Purge all log files up to but not including the target file.
You can also set the `expire_logs_days` system variable to expire binary log files automatically after a given number of days (see Section 5.1.7, “Server System Variables”). If you are using replication, you should set the variable no lower than the maximum number of days your replicas might lag behind the source.

`PURGE BINARY LOGS TO` and `PURGE BINARY LOGS BEFORE` both fail with an error when binary log files listed in the `.index` file had been removed from the system by some other means (such as using `rm` on Linux). (Bug #18199, Bug #18453) To handle such errors, edit the `.index` file (which is a simple text file) manually to ensure that it lists only the binary log files that are actually present, then run again the `PURGE BINARY LOGS` statement that failed.

### 13.4.1.2 RESET MASTER Statement

**RESET MASTER**

Deletes all binary log files listed in the index file, resets the binary log index file to be empty, and creates a new binary log file.

`RESET MASTER` also clears the values of the `gtid_purged` system variable as well as the global value of the `gtid_executed` system variable (but not its session value); that is, executing this statement sets each of these values to an empty string (`''`).

This statement is intended to be used only when the source is started for the first time.

**Important**

The effects of `RESET MASTER` differ from those of `PURGE BINARY LOGS` in 2 key ways:

1. `RESET MASTER` removes all binary log files that are listed in the index file, leaving only a single, empty binary log file with a numeric suffix of `.000001`, whereas the numbering is not reset by `PURGE BINARY LOGS`.

2. `RESET MASTER` is not intended to be used while any replicas are running. The behavior of `RESET MASTER` when used while replicas are running is undefined (and thus unsupported), whereas `PURGE BINARY LOGS` may be safely used while replicas are running.

See also Section 13.4.1.1, “PURGE BINARY LOGS Statement”.

`RESET MASTER` can prove useful when you first set up the source and the replica, so that you can verify the setup as follows:

1. Start the source and replica, and start replication (see Section 17.1.1, “How to Set Up Replication”).

2. Execute a few test queries on the source.

3. Check that the queries were replicated to the replica.

4. When replication is running correctly, issue `STOP SLAVE` followed by `RESET SLAVE` on the replica, then verify that any unwanted data no longer exists on the replica.

5. Issue `RESET MASTER` on the source to clean up the test queries.

After verifying the setup and getting rid of any unwanted and log files generated by testing, you can start the replica and begin replicating.

### 13.4.1.3 SET sql_log_bin Statement

**SET sql_log_bin = {OFF|ON}**
The `sql_log_bin` variable controls whether logging to the binary log is enabled for the current session (assuming that the binary log itself is enabled). The default value is `ON`. To disable or enable binary logging for the current session, set the session `sql_log_bin` variable to `OFF` or `ON`.

Set this variable to `OFF` for a session to temporarily disable binary logging while making changes to the source you do not want replicated to the replica.

Setting the session value of this system variable is a restricted operation. The session user must have privileges sufficient to set restricted session variables. See Section 5.1.8.1, "System Variable Privileges".

It is not possible to set the session value of `sql_log_bin` within a transaction or subquery.

Setting this variable to `OFF` prevents GTIDs from being assigned to transactions in the binary log. If you are using GTIDs for replication, this means that, even when binary logging is later enabled once again, the GTIDs written into the log from this point do not account for any transactions that occurred in the meantime—in effect, those transactions are lost.

As of MySQL 5.6.22, the global `sql_log_bin` variable is read only and cannot be modified. The global scope is deprecated and will be removed in a future MySQL release. Prior to 5.6.22, `sql_log_bin` can be set as a global or session variable. Setting `sql_log_bin` globally is only detected when a new session is started. Any sessions previously running are not impacted when setting `sql_log_bin` globally.

**Warning**

Incorrect use of `sql_log_bin` with a global scope means any changes made in an already running session are still being recorded to the binary log and therefore replicated. Exercise extreme caution using `sql_log_bin` with a global scope as the above situation could cause unexpected results including replication failure.

### 13.4.2 SQL Statements for Controlling Replica Servers

This section discusses statements for managing replica servers. Section 13.4.1, “SQL Statements for Controlling Replication Source Servers”, discusses statements for managing source servers.

In addition to the statements described here, `SHOW SLAVE STATUS` and `SHOW RELAYLOG EVENTS` are also used with replicas. For information about these statements, see Section 13.7.5.35, “SHOW SLAVE STATUS Statement”, and Section 13.7.5.33, “SHOW RELAYLOG EVENTS Statement”.

#### 13.4.2.1 CHANGE MASTER TO Statement

```
CHANGE MASTER TO option [, option] ...
```

<table>
<thead>
<tr>
<th>option</th>
</tr>
</thead>
<tbody>
<tr>
<td>MASTER_BIND = 'interface_name'</td>
</tr>
<tr>
<td>MASTER_HOST = 'host_name'</td>
</tr>
<tr>
<td>MASTER_USER = 'user_name'</td>
</tr>
<tr>
<td>MASTER_PASSWORD = 'password'</td>
</tr>
<tr>
<td>MASTER_PORT = port_num</td>
</tr>
<tr>
<td>MASTER_CONNECT_RETRY = interval</td>
</tr>
<tr>
<td>MASTER_RETRY_COUNT = count</td>
</tr>
<tr>
<td>MASTER_DELAY = interval</td>
</tr>
<tr>
<td>MASTER_HEARTBEAT_PERIOD = interval</td>
</tr>
<tr>
<td>MASTER_LOG_FILE = 'source_log_name'</td>
</tr>
<tr>
<td>MASTER_LOG_POS = source_log_pos</td>
</tr>
<tr>
<td>MASTER_AUTO_POSITION = {0</td>
</tr>
<tr>
<td>RELAY_LOG_FILE = 'relay_log_name'</td>
</tr>
<tr>
<td>RELAY_LOG_POS = relay_log_pos</td>
</tr>
<tr>
<td>MASTER_SSL = {0</td>
</tr>
<tr>
<td>MASTER_SSL_CA = 'ca_file_name'</td>
</tr>
<tr>
<td>MASTER_SSL_CAPATH = 'ca_directory_name'</td>
</tr>
</tbody>
</table>
SQL Statements for Controlling Replica Servers

```sql
| MASTER_SSL_CERT = 'cert_file_name' |
| MASTER_SSL_CRL = 'crl_file_name' |
| MASTER_SSL_CRLPATH = 'crl_directory_name' |
| MASTER_SSL_KEY = 'key_file_name' |
| MASTER_SSL_CIPHER = 'cipher_list' |
| MASTER_SSL_VERIFY_SERVER_CERT = {0|1} |
| IGNORE_SERVER_IDS = (server_id_list) |
```

`server_id_list:`

```sql
[server_id [, server_id] ... ]
```

CHANGE MASTER TO changes the parameters that the replica uses for connecting to the replication source server, for reading the source's binary log, and reading the replica's relay log. It also updates the contents of the replication metadata repositories (see Section 17.2.2, “Relay Log and Replication Metadata Repositories”). CHANGE MASTER TO requires the SUPER privilege.

To use CHANGE MASTER TO, the replication threads must be stopped (use STOP SLAVE if necessary). In MySQL 5.6.11 and later, gtid_next must also be set to AUTOMATIC (Bug #16062608).

Options not specified retain their value, except as indicated in the following discussion. Thus, in most cases, there is no need to specify options that do not change. For example, if the password to connect to your MySQL source has changed, issue these statements to tell the replica about the new password:

```sql
STOP SLAVE; -- if replication was running
CHANGE MASTER TO MASTER_PASSWORD='new3cret';
START SLAVE; -- if you want to restart replication
```

**MASTER_HOST, MASTER_USER, MASTER_PASSWORD, and MASTER_PORT** provide information to the replica about how to connect to its source:

- **MASTER_HOST** and **MASTER_PORT** are the host name (or IP address) of the source host and its TCP/IP port.

  ```sql
  Note
  Replication cannot use Unix socket files. You must be able to connect to the source MySQL server using TCP/IP.
  ```

  If you specify the **MASTER_HOST** or **MASTER_PORT** option, the replica assumes that the source server is different from before (even if the option value is the same as its current value). In this case, the old values for the source's binary log file name and position are considered no longer applicable, so if you do not specify **MASTER_LOG_FILE** and **MASTER_LOG_POS** in the statement, **MASTER_LOG_FILE=''** and **MASTER_LOG_POS=4** are silently appended to it.

  Setting **MASTER_HOST=''** (that is, setting its value explicitly to an empty string) is *not* the same as not setting **MASTER_HOST** at all. Beginning with MySQL 5.5, trying to set **MASTER_HOST** to an empty string fails with an error. Previously, setting **MASTER_HOST** to an empty string caused **START SLAVE** subsequently to fail. (Bug #28796)

  In MySQL 5.6.5 and later, values used for **MASTER_HOST** and other CHANGE MASTER TO options are checked for linefeed (\n or 0x0A) characters; the presence of such characters in these values causes the statement to fail with ER_MASTER_INFO. (Bug #11758581, Bug #50801)

- **MASTER_USER** and **MASTER_PASSWORD** are the user name and password of the account to use for connecting to the source. If you specify **MASTER_PASSWORD**, **MASTER_USER** is also required. The password used for a replication user account in a CHANGE MASTER TO statement is limited to 32 characters in length; if the password is longer, the statement succeeds, but any excess characters are silently truncated. This is an issue specific to MySQL Replication, which is fixed in MySQL 5.7. (Bug #11752299, Bug #43439)

  It is possible to set an empty user name by specifying **MASTER_USER=''**, but the replication channel cannot be started with an empty user name. Only set an empty **MASTER_USER** user name if you
need to clear previously used credentials from the replica’s repositories for security purposes, and do not attempt to use the channel afterwards. (Bug #13427949)

The text of a running CHANGE MASTER TO statement, including values for MASTER_USER and MASTER_PASSWORD, can be seen in the output of a concurrent SHOW PROCESSLIST statement. (The complete text of a START_SLAVE statement is also visible to SHOW PROCESSLIST.)

The MASTER_SSL_xxx options provide information about using SSL for the connection. They correspond to the --ssl-xxx options described in Command Options for Encrypted Connections, and Section 17.3.8, “Setting Up Replication to Use Encrypted Connections”. These options can be changed even on replicas that are compiled without SSL support. They are saved to the connection metadata repository, but are ignored if the replica does not have SSL support enabled. MASTER_SSL_CRL and MASTER_SSL_CRLPATH were added in MySQL 5.6.3.

MASTER_CONNECT_RETRY specifies how many seconds to wait between connect retries. The default is 60.

MASTER_RETRY_COUNT, added in MySQL 5.6.1, limits the number of reconnection attempts and updates the value of the Master_Retry_Count column in the output of SHOW SLAVE STATUS (also added in MySQL 5.6.1). The default value is 24 * 3600 = 86400. MASTER_RETRY_COUNT is intended to replace the older --master-retry-count server option, and is now the preferred method for setting this limit. You are encouraged not to rely on --master-retry-count in new applications and, when upgrading to MySQL 5.6.1 or later from earlier versions of MySQL, to update any existing applications that rely on it, so that they use CHANGE MASTER TO ... MASTER_RETRY_COUNT instead.

MASTER_DELAY specifies how many seconds behind the source the replica must lag. An event received from the source is not executed until at least interval seconds later than its execution on the source. The default is 0. An error occurs if interval is not a nonnegative integer in the range from 0 to $2^{31}−1$. For more information, see Section 17.3.10, “Delayed Replication”. This option was added in MySQL 5.6.0.

MASTER_BIND is for use on replicas having multiple network interfaces, and determines which of the replica’s network interfaces is chosen for connecting to the source.

The address configured with this option, if any, can be seen in the Master_Bind column of the output from SHOW SLAVE STATUS. If you are using tables for the replication metadata repositories (the server was started with master_info_repository=TABLE), the value can also be seen as the Master_bind column of the mysql.slave_master_info table.

The ability to bind a replica to a specific network interface was added in MySQL 5.6.2. This is also supported by MySQL NDB Cluster 7.3.1 and later.

MASTER_HEARTBEAT_PERIOD sets the interval in seconds between replication heartbeats. Whenever the source’s binary log is updated with an event, the waiting period for the next heartbeat is reset. interval is a decimal value having the range 0 to 4294967 seconds and a resolution in milliseconds; the smallest nonzero value is 0.001. Heartbeats are sent by the source only if there are no unsent events in the binary log file for a period longer than interval.

If you are logging source connection information to tables, MASTER_HEARTBEAT_PERIOD can be seen as the value of the Heartbeat column of the mysql.slave_master_info table.

Setting interval to 0 disables heartbeats altogether. The default value for interval is equal to the value of slave_net_timeout divided by 2.

Setting @@GLOBAL.slave_net_timeout to a value less than that of the current heartbeat interval results in a warning being issued. The effect of issuing RESET SLAVE on the heartbeat interval is to reset it to the default value.

MASTER_LOG_FILE and MASTER_LOG_POS are the coordinates at which the replication I/O thread should begin reading from the source the next time the thread starts. RELAY_LOG_FILE and
**RELAY_LOG_POS** are the coordinates at which the replication SQL thread should begin reading from the relay log the next time the thread starts. If you specify either of **MASTER_LOG_FILE** or **MASTER_LOG_POS**, you cannot specify **RELAY_LOG_FILE** or **RELAY_LOG_POS**. In MySQL 5.6.5 and later, if you specify either of **MASTER_LOG_FILE** or **MASTER_LOG_POS**, you also cannot specify **MASTER_AUTO_POSITION = 1** (described later in this section). If neither of **MASTER_LOG_FILE** or **MASTER_LOG_POS** is specified, the replica uses the last coordinates of the replication SQL thread before **CHANGE MASTER TO** was issued. This ensures that there is no discontinuity in replication, even if the replication SQL thread was late compared to the replication I/O thread, when you merely want to change, say, the password to use.

**MASTER_AUTO_POSITION** was added in MySQL 5.6.5. If **MASTER_AUTO_POSITION = 1** is used with **CHANGE MASTER TO**, the replica attempts to connect to the source using the GTID-based replication protocol.

When using GTIDs, the replica tells the source which transactions it has already received, executed, or both. To compute this set, it reads the global value of **gtid_executed** and the value of the **Retrieved_gtid_set** column from **SHOW SLAVE STATUS**. Since the GTID of the last transmitted transaction is included in **Retrieved_gtid_set** even if the transaction was only partially transmitted, the last received GTID is subtracted from this set. Thus, the replica computes the following set:

```
UNION(@@GLOBAL.gtid_executed, Retrieved_gtid_set - last_received_GTID)
```

This set is sent to the source as part of the initial handshake, and the source sends back all transactions that it has executed which are not part of the set. If any of these transactions have been already purged from the source's binary log, the source sends the error **ER_MASTER_HAS_PURGED_REQUIRED_GTIDS** to the replica, and replication does not start.

When GTID-based replication is employed, the coordinates represented by **MASTER_LOG_FILE** and **MASTER_LOG_POS** are not used, and global transaction identifiers are used instead. Thus the use of either or both of these options together with **MASTER_AUTO_POSITION** causes an error.

Beginning with MySQL 5.6.10, you can see whether replication is running with autoplacing enabled by checking the output of **SHOW SLAVE STATUS**. (Bug #15992220)

**gtid_mode** must also be enabled before issuing **CHANGE MASTER TO** ...
**MASTER_AUTO_POSITION = 1**. Otherwise, the statement fails with an error.

To revert to the older file-based replication protocol after using GTIDs, you can issue a new **CHANGE MASTER TO** statement that specifies **MASTER_AUTO_POSITION = 0**, as well as at least one of **MASTER_LOG_FILE** or **MASTER_LOG_POS**.

**CHANGE MASTER TO** deletes all relay log files and starts a new one, unless you specify **RELAY_LOG_FILE** or **RELAY_LOG_POS**. In that case, relay log files are kept; the **relay_log_purge** global variable is set silently to 0.

Prior to MySQL 5.6.2, **RELAY_LOG_FILE** required an absolute path. Beginning with MySQL 5.6.2, the path can be relative, in which case it is assumed to be relative to the replica's data directory. (Bug #12190)

**IGNORE_SERVER_IDS** takes a comma-separated list of 0 or more server IDs. Events originating from the corresponding servers are ignored, with the exception of log rotation and deletion events, which are still recorded in the relay log.

In circular replication, the originating server normally acts as the terminator of its own events, so that they are not applied more than once. Thus, this option is useful in circular replication when one of the servers in the circle is removed. Suppose that you have a circular replication setup with 4 servers, having server IDs 1, 2, 3, and 4, and server 3 fails. When bridging the gap by starting replication from server 2 to server 4, you can include **IGNORE_SERVER_IDS = (3)** in the **CHANGE MASTER TO** statement that you issue on server 4 to tell it to use server 2 as its source instead of server 3. Doing so causes it to ignore and not to propagate any statements that originated with the server that is no longer in use.
When a `CHANGE MASTER TO` statement is issued without any `IGNORE_SERVER_IDS` option, any existing list is preserved. To clear the list of ignored servers, it is necessary to use the option with an empty list:

```
CHANGE MASTER TO IGNORE_SERVER_IDS = ();
```

`RESET SLAVE ALL` has no effect on the server ID list. This issue is fixed in MySQL 5.7. (Bug #18816897)

If `IGNORE_SERVER_IDS` contains the server's own ID and the server was started with the `--replicate-same-server-id` option enabled, an error results.

In MySQL 5.6, the connection metadata repository and the output of `SHOW SLAVE STATUS` provide the list of servers that are currently ignored. For more information, see Section 17.2.2.2, “Replication Metadata Repositories”, and Section 13.7.5.35, “SHOW SLAVE STATUS Statement”.

In MySQL 5.6, invoking `CHANGE MASTER TO` causes the previous values for `MASTER_HOST`, `MASTER_PORT`, `MASTER_LOG_FILE`, and `MASTER_LOG_POS` to be written to the error log, along with other information about the replica's state prior to execution.

In MySQL 5.6.7 and later, `CHANGE MASTER TO` causes an implicit commit of an ongoing transaction. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

`CHANGE MASTER TO` is useful for setting up a replica when you have the snapshot of the source and have recorded the source binary log coordinates corresponding to the time of the snapshot. After loading the snapshot into the replica to synchronize it with the source, you can run `CHANGE MASTER TO MASTER_LOG_FILE='log_name', MASTER_LOG_POS=log_pos` on the replica to specify the coordinates at which the replica should begin reading the source's binary log.

The following example changes the source server the replica uses and establishes the source's binary log coordinates from which the replica begins reading. This is used when you want to set up the replica to replicate the source:

```
CHANGE MASTER TO
    MASTER_HOST='source2.example.com',
    MASTER_USER='replication',
    MASTER_PASSWORD='bigs3cret',
    MASTER_PORT=3306,
    MASTER_LOG_FILE='source2-bin.001',
    MASTER_LOG_POS=4,
    MASTER_CONNECT_RETRY=10;
```

The next example shows an operation that is less frequently employed. It is used when the replica has relay log files that you want it to execute again for some reason. To do this, the source need not be reachable. You need only use `CHANGE MASTER TO` and start the SQL thread (`START SLAVE SQL_THREAD`):

```
CHANGE MASTER TO
    RELAY_LOG_FILE='replica-relay-bin.006',
    RELAY_LOG_POS=4025;
```

The following table shows the maximum permissible length for the string-valued options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Maximum Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>MASTER_HOST</td>
<td>60</td>
</tr>
<tr>

</table>

#### 13.4.2.2 MASTER_POS_WAIT() Statement

`SELECT MASTER_POS_WAIT('source_log_file', source_log_pos [, timeout])`

This is actually a function, not a statement. It is used to ensure that the replica has read and executed events up to a given position in the source's binary log. See Section 12.20, “Miscellaneous Functions”, for a full description.

#### 13.4.2.3 RESET SLAVE Statement

`RESET SLAVE [ALL]`

`RESET SLAVE` makes the replica forget its replication position in the source's binary log. This statement is meant to be used for a clean start: It clears the replication metadata repositories, deletes all the relay log files, and starts a new relay log file. It also resets to 0 the replication delay specified with the `MASTER_DELAY` option to `CHANGE MASTER TO`. `RESET SLAVE` does not change the values of `gtid_executed` or `gtid_purged`. To use `RESET SLAVE`, the replication threads must be stopped, so on a running replica use `STOP SLAVE` before issuing `RESET SLAVE`.

**Note**

All relay log files are deleted, even if they have not been completely executed by the replication SQL thread. (This is a condition likely to exist on a replica if you have issued a `STOP SLAVE` statement or if the replica is highly loaded.)

In MySQL 5.6 (unlike the case in MySQL 5.1 and earlier), `RESET SLAVE` does not change any replication connection parameters such as the source's host name and port or the replication user account name and password, which are retained in memory. This means that `START SLAVE` can be issued without requiring a `CHANGE MASTER TO` statement following `RESET SLAVE`.

Connection parameters are reset if the replica `mysqld` is shut down following `RESET SLAVE`. In MySQL 5.6.3 and later, you can instead use `RESET SLAVE ALL` to reset these connection parameters (Bug #11809016).

`RESET SLAVE ALL` does not clear the `IGNORE_SERVER_IDS` list set by `CHANGE MASTER TO`. This issue is fixed in MySQL 5.7. (Bug #18816897)

In MySQL 5.6.7 and later, `RESET SLAVE` causes an implicit commit of an ongoing transaction. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

If the replication SQL thread was in the middle of replicating temporary tables when it was stopped, and `RESET SLAVE` is issued, these replicated temporary tables are deleted on the replica.

**Note**

When used on an NDB Cluster replica SQL node, `RESET SLAVE` clears the `mysql.ndb_apply_status` table. You should keep in mind when using this statement that `ndb_apply_status` uses the `NDB` storage engine and so is shared by all SQL nodes attached to the replica cluster.
Beginning with MySQL NDB Cluster 7.4.9, you can override this behavior by
issuing `SET GLOBAL @@ ndb_clear_apply_status=OFF` prior to executing
`RESET SLAVE`, which keeps the replica from purging the `ndb_apply_status`
table in such cases.

### 13.4.2.4 SET GLOBAL sql_slave_skip_counter Statement

```
SET GLOBAL sql_slave_skip_counter = N
```

This statement skips the next $N$ events from the source. This is useful for recovering from replication
stops caused by a statement.

This statement is valid only when the replication threads are not running. Otherwise, it produces an
error.

When using this statement, it is important to understand that the binary log is actually organized as a
sequence of groups known as `event groups`. Each event group consists of a sequence of events.

- For transactional tables, an event group corresponds to a transaction.
- For nontransactional tables, an event group corresponds to a single SQL statement.

**Note**

A single transaction can contain changes to both transactional and
nontransactional tables.

When you use `SET GLOBAL sql_slave_skip_counter` to skip events and the result is in the
middle of a group, the replica continues to skip events until it reaches the end of the group. Execution
then starts with the next event group.

### 13.4.2.5 START SLAVE Statement

```
START SLAVE [thread_types] [until_option] [connection_options]
```

**thread_types:**

```
[thread_type [, thread_type] ... ]
```

**thread_type:**

```
IO_THREAD | SQL_THREAD
```

**until_option:**

```
UNTIL {   {SQL_BEFORE_GTIDS | SQL_AFTER_GTIDS} = gtid_set
|   MASTER_LOG_FILE = 'log_name', MASTER_LOG_POS = log_pos
|   RELAY_LOG_FILE = 'log_name', RELAY_LOG_POS = log_pos
|   SQL_AFTER_MTS_GAPS  }
```

**connection_options:**

```
[USER='user_name'] [PASSWORD='user_pass'] [DEFAULT_AUTH='plugin_name'] [PLUGIN_DIR='plugin_dir']
```

**gtid_set:**

```
uuid_set [, uuid_set] ...
| ...
```

**uuid_set:**

```
uuid:interval[:interval]...
```

**uuid:**

```
hhhhhhh-hhhh-hhhh-hhhh-hhhhhhhhhhh
```

**h:**

```
[0-9,A-F]
```

**interval:**
START SLAVE with no thread_type options starts both of the replication threads. The I/O thread reads events from the replication source server and stores them in the relay log. The SQL thread reads events from the relay log and executes them. START SLAVE requires the SUPER privilege.

If START SLAVE succeeds in starting the replication threads, it returns without any error. However, even in that case, it might be that the replication threads start and then later stop (for example, because they do not manage to connect to the source or read its binary log, or some other problem). START SLAVE does not warn you about this. You must check the replica’s error log for error messages generated by the replication threads, or check that they are running satisfactorily with SHOW SLAVE STATUS.

START SLAVE causes an implicit commit of an ongoing transaction. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

Beginning with MySQL 5.6.11, gtid_next must be set to AUTOMATIC before issuing this statement (Bug #16062608).

START SLAVE supports pluggable user-password authentication with the USER, PASSWORD, DEFAULT_AUTH and PLUGIN_DIR options, as described in the following list:

- USER: User name. Cannot be set to an empty or null string, or left unset if PASSWORD is used.
- PASSWORD: Password.
- DEFAULT_AUTH: Name of plugin; default is MySQL native authentication.
- PLUGIN_DIR: Location of plugin.

You cannot use the SQL_THREAD option when specifying any of USER, PASSWORD, DEFAULT_AUTH, or PLUGIN_DIR, unless the IO_THREAD option is also provided.

For more information, see Section 6.2.11, “Pluggable Authentication”.

If an insecure connection is used with any these options, the server issues the warning Sending passwords in plain text without SSL/TLS is extremely insecure.

START SLAVE ... UNTIL supports two additional options for use with global transaction identifiers (GTIDs) (see Section 17.1.3, “Replication with Global Transaction Identifiers”). Each of these takes a set of one or more global transaction identifiers gtid_set as an argument (see GTID Sets, for more information).

When no thread_type is specified, START SLAVE UNTIL SQL_BEFORE_GTIDS causes the replication SQL thread to process transactions until it has reached the first transaction whose GTID is listed in the gtid_set. START SLAVE UNTIL SQL_AFTER_GTIDS causes the replication threads to process all transactions until the last transaction in the gtid_set has been processed by both threads. In other words, START SLAVE UNTIL SQL_BEFORE_GTIDS causes the replication SQL thread to process all transactions occurring before the first GTID in the gtid_set is reached, and START SLAVE UNTIL SQL_AFTER_GTIDS causes the replication threads to handle all transactions, including those whose GTIDs are found in gtid_set, until each has encountered a transaction whose GTID is not part of the set. SQL BEFORE GTIDS and SQL AFTER GTIDS each support the SQL_THREAD and IO_THREAD options, although using IO_THREAD with them currently has no effect.

For example, START SLAVE SQL_THREAD UNTIL SQL_BEFORE_GTIDS = 3E11FA47-71CA-11E1-9E33-C80AA9429562:11-56 causes the replication SQL thread to process all transactions originating from the source whose server_uuid is 3E11FA47-71CA-11E1-9E33-C80AA9429562 until it encounters the transaction having sequence number 11; it then stops without processing this transaction. In other words, all transactions up to and including the transaction...
with sequence number 10 are processed. Executing `START SLAVE SQL_THREAD UNTIL SQL_AFTER_GTIDS = 3E11FA47-71CA-11E1-9E33-C80AA9429562:11-56`, on the other hand, would cause the replication SQL thread to obtain all transactions just mentioned from the source, including all of the transactions having the sequence numbers 11 through 56, and then to stop without processing any additional transactions; that is, the transaction having sequence number 56 would be the last transaction fetched by the replication SQL thread.

Prior to MySQL 5.6.14, **SQL_AFTER_GTIDS** did not stop the replica once the indicated transaction was completed, but waited until another GTID event was received (Bug #14767986).

Use the **START SLAVE UNTIL SQL_AFTER_MTS_GAPS** statement to cause a multithreaded replica's SQL threads to run until no more gaps are found in the relay log, and then to stop. This statement can take an **SQL_THREAD** option, but the effects of the statement remain unchanged. It has no effect on the replication I/O thread (and cannot be used with the **IO_THREAD** option). **START SLAVE UNTIL SQL_AFTER_MTS_GAPS** should be used before switching the replica from multithreaded mode to single-threaded mode (that is, when resetting **slave_parallel_workers** back to 0 from a positive, nonzero value) after the replica has failed with errors in multithreaded mode.

To change a failed multithreaded replica to single-threaded mode, you can issue the following series of statements, in the order shown:

```
START SLAVE UNTIL SQL_AFTER_MTS_GAPS;
SET @@GLOBAL.slave_parallel_workers = 0;
START SLAVE SQL_THREAD;
```

If you were running the failed multithreaded replica with **relay_log_recovery** enabled, then you must issue **START SLAVE UNTIL SQL_AFTER_MTS_GAPS** prior to executing **CHANGE MASTER TO**. Otherwise the latter statement fails.

**Note**

It is possible to view the entire text of a running **START SLAVE ...** statement, including any **USER** or **PASSWORD** values used, in the output of **SHOW PROCESSLIST**. This is also true for the text of a running **CHANGE MASTER TO** statement, including any values it employs for **MASTER_USER** or **MASTER_PASSWORD**.

**START SLAVE** sends an acknowledgment to the user after both the I/O thread and the SQL thread have started. However, the I/O thread may not yet have connected. For this reason, a successful **START SLAVE** causes **SHOW SLAVE STATUS** to show **Slave_SQL_Running=Yes**, but this does not guarantee that **Slave_IO_Running=Yes** (because **Slave_IO_Running=Yes** only if the I/O thread is running and connected). For more information, see Section 13.7.5.35, “SHOW SLAVE STATUS Statement”, and Section 17.1.5.1, “Checking Replication Status”.

You can add **IO_THREAD** and **SQL_THREAD** options to the statement to name which of the threads to start. The **SQL_THREAD** option is disallowed when specifying any of **USER**, **PASSWORD**, **DEFAULT_AUTH**, or **PLUGIN_DIR**, unless the **IO_THREAD** option is also provided.

An **UNTIL** clause (**until_option**, in the preceding grammar) may be added to specify that the replica should start and run until the SQL thread reaches a given point in the source’s binary log, specified by the **MASTER_LOG_POS** and **MASTER_LOG_FILE** options, or a given point in the replica’s relay log, indicated with the **RELAY_LOG_POS** and **RELAY_LOG_FILE** options. When the SQL thread reaches the point specified, it stops. If the **SQL_THREAD** option is specified in the statement, it starts only the SQL thread. Otherwise, it starts both replication threads. If the SQL thread is running, the **UNTIL** clause is ignored and a warning is issued. You cannot use an **UNTIL** clause with the **IO_THREAD** option.

It is also possible with **START SLAVE UNTIL** to specify a stop point relative to a given GTID or set of GTIDs using one of the options **SQL_BEFORE_GTIDS** or **SQL_AFTER_GTIDS**, as explained previously.
in this section. When using one of these options, you can specify SQL_THREAD, IO_THREAD, both of these, or neither of them. If you specify only SQL_THREAD, then only the replication SQL thread is affected by the statement; if only IO_THREAD is used, then only the replication I/O thread is affected. If both SQL_THREAD and IO_THREAD are used, or if neither of them is used, then both the replication threads are affected by the statement.

The UNTIL clause is not supported for multithreaded replicas except when also using SQL_AFTER_MTS_GAPS.

For an UNTIL clause, you must specify any one of the following:

- Both a log file name and a position in that file
- Either of SQL_BEFORE_GTIDS or SQL_AFTER_GTIDS
- SQL_AFTER_MTS_GAPS

Do not mix binary log and relay log options. Do not mix log file options with GTID options.

Any UNTIL condition is reset by a subsequent STOP SLAVE statement, a START SLAVE statement that includes no UNTIL clause, or a server restart.

When specifying a log file and position, you can use the IO_THREAD option with START SLAVE ... UNTIL even though only the SQL thread is affected by this statement. The IO_THREAD option is ignored in such cases. The preceding restriction does not apply when using one of the GTID options (SQL_BEFORE_GTIDS and SQL_AFTER_GTIDS); the GTID options support both SQL_THREAD and IO_THREAD, as explained previously in this section.

The UNTIL clause can be useful for debugging replication, or to cause replication to proceed until just before the point where you want to avoid having the replica replicate an event. For example, if an unwise DROP TABLE statement was executed on the source, you can use UNTIL to tell the replica to execute up to that point but no farther. To find what the event is, use mysqlbinlog with the source’s binary log or the replica’s relay log, or by using a SHOW BINLOG EVENTS statement.

If you are using UNTIL to have the replica process replicated queries in sections, it is recommended that you start the replica with the --skip-slave-start option to prevent the SQL thread from running when the replica server starts. It is probably best to use this option in an option file rather than on the command line, so that an unexpected server restart does not cause it to be forgotten.

The SHOW SLAVE STATUS statement includes output fields that display the current values of the UNTIL condition.

### 13.4.2.6 STOP SLAVE Statement

<table>
<thead>
<tr>
<th>STOP SLAVE [thread_types]</th>
</tr>
</thead>
<tbody>
<tr>
<td>thread_types:</td>
</tr>
<tr>
<td>[thread_type [, thread_type] ... ]</td>
</tr>
<tr>
<td>thread_type: IO_THREAD</td>
</tr>
</tbody>
</table>

Stops the replication threads. STOP SLAVE requires the SUPER privilege. Recommended best practice is to execute STOP SLAVE on the replica before stopping the replica server (see Section 5.1.15, “The Server Shutdown Process”, for more information).

When using the row-based logging format: You should execute STOP SLAVE or STOP SLAVE SQL_THREAD on the replica prior to shutting down the replica server if you are replicating any tables that use a nontransactional storage engine (see the Note later in this section).

Like START SLAVE, this statement may be used with the IO_THREAD and SQL_THREAD options to name the thread or threads to be stopped.
**STOP SLAVE** causes an implicit commit of an ongoing transaction. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

Beginning with MySQL 5.6.11, `gtid_next` must be set to `AUTOMATIC` before issuing this statement (Bug #16062608).

In MySQL 5.6.13 and later, you can control how long **STOP SLAVE** waits before timing out by setting the `rpl_stop_slave_timeout` system variable. This can be used to avoid deadlocks between **STOP SLAVE** and other SQL statements using different client connections to the replica. When the timeout value is reached, the issuing client returns an error message and stops waiting, but the **STOP SLAVE** instruction remains in effect. Once the replication threads are no longer busy, the **STOP SLAVE** statement is executed and the replica stops. (Bug #16856735)

If the current replication event group has modified one or more nontransactional tables, **STOP SLAVE** waits for up to 60 seconds for the event group to complete, unless you issue a **KILL QUERY** or **KILL CONNECTION** statement for the replication SQL thread. If the event group remains incomplete after the timeout, an error message is logged. (Bug #319, Bug #38205)

In old versions of MySQL (before 4.0.5), this statement was called **SLAVE STOP**. That syntax is no longer accepted as of MySQL 5.6.1.

### 13.5 Prepared Statements

MySQL 5.6 provides support for server-side prepared statements. This support takes advantage of the efficient client/server binary protocol. Using prepared statements with placeholders for parameter values has the following benefits:

- Less overhead for parsing the statement each time it is executed. Typically, database applications process large volumes of almost-identical statements, with only changes to literal or variable values in clauses such as **WHERE** for queries and deletes, **SET** for updates, and **VALUES** for inserts.

- Protection against SQL injection attacks. The parameter values can contain unescaped SQL quote and delimiter characters.

- **Prepared Statements in Application Programs**
- **Prepared Statements in SQL Scripts**
- **PREPARE, EXECUTE, and DEALLOCATE PREPARE Statements**
- **SQL Syntax Permitted in Prepared Statements**

**Prepared Statements in Application Programs**

You can use server-side prepared statements through client programming interfaces, including the MySQL C API client library for C programs, MySQL Connector/J for Java programs, and MySQL Connector/NET for programs using .NET technologies. For example, the C API provides a set of function calls that make up its prepared statement API. See C API Prepared Statements. Other language interfaces can provide support for prepared statements that use the binary protocol by linking in the C client library, one example being the `mysqli` extension, available in PHP 5.0 and higher.

**Prepared Statements in SQL Scripts**

An alternative SQL interface to prepared statements is available. This interface is not as efficient as using the binary protocol through a prepared statement API, but requires no programming because it is available directly at the SQL level:

- You can use it when no programming interface is available to you.
- You can use it from any program that can send SQL statements to the server to be executed, such as the `mysql` client program.
PREPARE, EXECUTE, and DEALLOCATE PREPARE Statements

SQL syntax for prepared statements is intended to be used for situations such as these:

- To test how prepared statements work in your application before coding it.
- To use prepared statements when you do not have access to a programming API that supports them.
- To interactively troubleshoot application issues with prepared statements.
- To create a test case that reproduces a problem with prepared statements, so that you can file a bug report.

PREPARE, EXECUTE, and DEALLOCATE PREPARE Statements

SQL syntax for prepared statements is based on three SQL statements:

- **PREPARE** prepares a statement for execution (see Section 13.5.1, “PREPARE Statement”).
- **EXECUTE** executes a prepared statement (see Section 13.5.2, “EXECUTE Statement”).
- **DEALLOCATE PREPARE** releases a prepared statement (see Section 13.5.3, “DEALLOCATE PREPARE Statement”).

The following examples show two equivalent ways of preparing a statement that computes the hypotenuse of a triangle given the lengths of the two sides.

The first example shows how to create a prepared statement by using a string literal to supply the text of the statement:

```
mysql> PREPARE stmt1 FROM 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
mysql> SET @a = 3;
mysql> SET @b = 4;
mysql> EXECUTE stmt1 USING @a, @b;
+------------+
| hypotenuse |
+------------+
|          5  |
+------------+
mysql> DEALLOCATE PREPARE stmt1;
```

The second example is similar, but supplies the text of the statement as a user variable:

```
mysql> SET @s = 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
mysql> PREPARE stmt2 FROM @s;
mysql> SET @a = 6;
mysql> SET @b = 8;
mysql> EXECUTE stmt2 USING @a, @b;
+------------+
| hypotenuse |
| 10 |
+------------+
mysql> DEALLOCATE PREPARE stmt2;
```

Here is an additional example that demonstrates how to choose the table on which to perform a query at runtime, by storing the name of the table as a user variable:

```
mysql> USE test;
mysql> CREATE TABLE t1 (a INT NOT NULL);
mysql> INSERT INTO t1 VALUES (4), (8), (11), (32), (80);
mysql> SET @table = 't1';
mysql> SET @s = CONCAT('SELECT * FROM ', @table);
```
SQL Syntax Permitted in Prepared Statements

A prepared statement is specific to the session in which it was created. If you terminate a session without deallocating a previously prepared statement, the server deallocates it automatically.

A prepared statement is also global to the session. If you create a prepared statement within a stored routine, it is not deallocated when the stored routine ends.

To guard against too many prepared statements being created simultaneously, set the `max_prepared_stmt_count` system variable. To prevent the use of prepared statements, set the value to 0.

SQL Syntax Permitted in Prepared Statements

The following SQL statements can be used as prepared statements:

- `ALTER TABLE`
- `ALTER USER`
- `ANALYZE TABLE`
- `CACHE INDEX`
- `CALL`
- `CHANGE MASTER`
- `CHECKSUM {TABLE | TABLES}`
- `COMMIT`
- `{CREATE | RENAME | DROP} DATABASE`
- `{CREATE | RENAME | DROP} INDEX`
- `{CREATE | RENAME | DROP} TABLE`
- `{CREATE | DROP} USER`
- `{CREATE | DROP} VIEW`
- `DELETE`
- `DO`
- `FLUSH {TABLE | TABLES | TABLES WITH READ LOCK | HOSTS | PRIVILEGES |
  | LOGS | STATUS | MASTER | SLAVE | DES_KEY_FILE | USER_RESOURCES}`
- `GRANT`
- `INSERT`
- `INSTALL PLUGIN`
- `KILL`
- `LOAD INDEX INTO CACHE`
- `OPTIMIZE TABLE`
- `REPAIR TABLE`
- `REPLACE`
- `{CREATE | RENAME | DROP} VIEW`
- `REVOKE`
- `SELECT`
- `SHOW {AUTHORS | CONTRIBUTORS | WARNINGS | ERRORS}`
- `SHOW BINLOG EVENTS`
- `SHOW CREATE {PROCEDURE | FUNCTION | EVENT | TABLE | VIEW}`
- `SHOW {MASTER | BINARY} LOGS`
- `SHOW {MASTER | SLAVE} STATUS`
- `SLAVE {START | STOP}`
- `TRUNCATE TABLE`
- `UNINSTALL PLUGIN`
- `UPDATE`

Other statements are not supported.
Generally, statements not permitted in SQL prepared statements are also not permitted in stored programs. Exceptions are noted in Section 20.8, "Restrictions on Stored Programs".

Metadata changes to tables or views referred to by prepared statements are detected and cause automatic repreparation of the statement when it is next executed. For more information, see Section 8.10.4, "Caching of Prepared Statements and Stored Programs".

Placeholders can be used for the arguments of the LIMIT clause when using prepared statements. See Section 13.2.9, "SELECT Statement".

In prepared CALL statements used with PREPARE and EXECUTE, placeholder support for OUT and INOUT parameters is available beginning with MySQL 5.6. See Section 13.2.1, "CALL Statement", for an example and a workaround for earlier versions. Placeholders can be used for IN parameters regardless of version.

SQL syntax for prepared statements cannot be used in nested fashion. That is, a statement passed to PREPARE cannot itself be a PREPARE, EXECUTE, or DEALLOCATE PREPARE statement.

SQL syntax for prepared statements is distinct from using prepared statement API calls. For example, you cannot use the mysql_stmt_prepare() C API function to prepare a PREPARE, EXECUTE, or DEALLOCATE PREPARE statement.

SQL syntax for prepared statements can be used within stored procedures, but not in stored functions or triggers. However, a cursor cannot be used for a dynamic statement that is prepared and executed with PREPARE and EXECUTE. The statement for a cursor is checked at cursor creation time, so the statement cannot be dynamic.

SQL syntax for prepared statements does not support multi-statements (that is, multiple statements within a single string separated by ; characters).

Prepared statements use the query cache under the conditions described in Section 8.10.3.1, "How the Query Cache Operates".

To write C programs that use the CALL SQL statement to execute stored procedures that contain prepared statements, the CLIENT_MULTI_RESULTS flag must be enabled. This is because each CALL returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure.

CLIENT_MULTI_RESULTS can be enabled when you call mysql_real_connect(), either explicitly by passing the CLIENT_MULTI_RESULTS flag itself, or implicitly by passing CLIENT_MULTI_STATEMENTS (which also enables CLIENT_MULTI_RESULTS). For additional information, see Section 13.2.1, "CALL Statement".

### 13.5.1 PREPARE Statement

PREPARE stmt_name FROM preparable_stmt

The PREPARE statement prepares a SQL statement and assigns it a name, stmt_name, by which to refer to the statement later. The prepared statement is executed with EXECUTE and released with DEALLOCATE PREPARE. For examples, see Section 13.5, "Prepared Statements".

Statement names are not case-sensitive. preparable_stmt is either a string literal or a user variable that contains the text of the SQL statement. The text must represent a single statement, not multiple statements. Within the statement, ? characters can be used as parameter markers to indicate where data values are to be bound to the query later when you execute it. The ? characters should not be enclosed within quotation marks, even if you intend to bind them to string values. Parameter markers can be used only where data values should appear, not for SQL keywords, identifiers, and so forth.

If a prepared statement with the given name already exists, it is deallocated implicitly before the new statement is prepared. This means that if the new statement contains an error and cannot be prepared, an error is returned and no statement with the given name exists.
The scope of a prepared statement is the session within which it is created, which as several implications:

- A prepared statement created in one session is not available to other sessions.
- When a session ends, whether normally or abnormally, its prepared statements no longer exist. If auto-reconnect is enabled, the client is not notified that the connection was lost. For this reason, clients may wish to disable auto-reconnect. See C API Automatic Reconnection Control.
- A prepared statement created within a stored program continues to exist after the program finishes executing and can be executed outside the program later.
- A statement prepared in stored program context cannot refer to stored procedure or function parameters or local variables because they go out of scope when the program ends and would be unavailable were the statement to be executed later outside the program. As a workaround, refer instead to user-defined variables, which also have session scope; see Section 9.4, “User-Defined Variables”.

### 13.5.2 EXECUTE Statement

```sql
EXECUTE stmt_name
[USING @var_name [, @var_name] ...]
```

After preparing a statement with `PREPARE`, you execute it with an `EXECUTE` statement that refers to the prepared statement name. If the prepared statement contains any parameter markers, you must supply a `USING` clause that lists user variables containing the values to be bound to the parameters. Parameter values can be supplied only by user variables, and the `USING` clause must name exactly as many variables as the number of parameter markers in the statement.

You can execute a given prepared statement multiple times, passing different variables to it or setting the variables to different values before each execution.

For examples, see Section 13.5, “Prepared Statements”.

### 13.5.3 DEALLOCATE PREPARE Statement

```sql
{DEALLOCATE | DROP} PREPARE stmt_name
```

To deallocate a prepared statement produced with `PREPARE`, use a `DEALLOCATE PREPARE` statement that refers to the prepared statement name. Attempting to execute a prepared statement after deallocating it results in an error. If too many prepared statements are created and not deallocated by either the `DEALLOCATE PREPARE` statement or the end of the session, you might encounter the upper limit enforced by the `max_prepared_stmt_count` system variable.

For examples, see Section 13.5, “Prepared Statements”.

### 13.6 Compound Statements

This section describes the syntax for the `BEGIN ... END` compound statement and other statements that can be used in the body of stored programs: Stored procedures and functions, triggers, and events. These objects are defined in terms of SQL code that is stored on the server for later invocation (see Chapter 20, Stored Objects).

A compound statement is a block that can contain other blocks; declarations for variables, condition handlers, and cursors; and flow control constructs such as loops and conditional tests.

#### 13.6.1 BEGIN ... END Compound Statement

```sql
[begin_label:] BEGIN
 [statement_list]
```

1682
BEGIN ... END syntax is used for writing compound statements, which can appear within stored programs (stored procedures and functions, triggers, and events). A compound statement can contain multiple statements, enclosed by the BEGIN and END keywords. statement_list represents a list of one or more statements, each terminated by a semicolon (;) statement delimiter. The statement_list itself is optional, so the empty compound statement (BEGIN END) is legal.

BEGIN ... END blocks can be nested.

Use of multiple statements requires that a client is able to send statement strings containing the ; statement delimiter. In the mysql command-line client, this is handled with the delimiter command. Changing the ; end-of-statement delimiter (for example, to //) permit ; to be used in a program body. For an example, see Section 20.1, “Defining Stored Programs”.

A BEGIN ... END block can be labeled. See Section 13.6.2, “Statement Labels”.

The optional [NOT] ATOMIC clause is not supported. This means that no transactional savepoint is set at the start of the instruction block and the BEGIN clause used in this context has no effect on the current transaction.

Note
Within all stored programs, the parser treats BEGIN [WORK] as the beginning of a BEGIN ... END block. To begin a transaction in this context, use START TRANSACTION instead.

13.6.2 Statement Labels

```
[begin_label:] BEGIN
    [statement_list]
END [end_label]

[begin_label:] LOOP
    [statement_list]
END LOOP [end_label]

[begin_label:] REPEAT
    [statement_list]
UNTIL search_condition
END REPEAT [end_label]

[begin_label:] WHILE search_condition DO
    [statement_list]
END WHILE [end_label]
```

Labels are permitted for BEGIN ... END blocks and for the LOOP, REPEAT, and WHILE statements. Label use for those statements follows these rules:

- begin_label must be followed by a colon.
- begin_label can be given without end_label. If end_label is present, it must be the same as begin_label.
- end_label cannot be given without begin_label.
- Labels at the same nesting level must be distinct.
- Labels can be up to 16 characters long.

To refer to a label within the labeled construct, use an ITERATE or LEAVE statement. The following example uses those statements to continue iterating or terminate the loop:

```sql
CREATE PROCEDURE doiterate(p1 INT)
BEGIN
```
DECLARE Statement

```plaintext
label1: LOOP
  SET p1 = p1 + 1;
  IF p1 < 10 THEN ITERATE label1; END IF;
  LEAVE label1;
END LOOP label1;
END;
```

The scope of a block label does not include the code for handlers declared within the block. For details, see Section 13.6.7.2, “DECLARE ... HANDLER Statement”.

### 13.6.3 DECLARE Statement

The **DECLARE** statement is used to define various items local to a program:

- Local variables. See Section 13.6.4, “Variables in Stored Programs”.
- Conditions and handlers. See Section 13.6.7, “Condition Handling”.
- Cursors. See Section 13.6.6, “Cursors”.

**DECLARE** is permitted only inside a `BEGIN ... END` compound statement and must be at its start, before any other statements.

Declarations must follow a certain order. Cursor declarations must appear before handler declarations. Variable and condition declarations must appear before cursor or handler declarations.

### 13.6.4 Variables in Stored Programs

System variables and user-defined variables can be used in stored programs, just as they can be used outside stored-program context. In addition, stored programs can use **DECLARE** to define local variables, and stored routines (procedures and functions) can be declared to take parameters that communicate values between the routine and its caller.

- To declare local variables, use the **DECLARE** statement, as described in Section 13.6.4.1, “Local Variable DECLARE Statement”.
- Variables can be set directly with the **SET** statement. See Section 13.7.4.1, “SET Syntax for Variable Assignment”.
- Results from queries can be retrieved into local variables using **SELECT ... INTO var_list** or by opening a cursor and using **FETCH ... INTO var_list**. See Section 13.2.9.1, “SELECT ... INTO Statement”, and Section 13.6.6, “Cursors”.

For information about the scope of local variables and how MySQL resolves ambiguous names, see Section 13.6.4.2, “Local Variable Scope and Resolution”.

It is not permitted to assign the value **DEFAULT** to stored procedure or function parameters or stored program local variables (for example with a **SET var_name = DEFAULT** statement). As of MySQL 5.6.6, this results in a syntax error.

### 13.6.4.1 Local Variable DECLARE Statement

```plaintext
DECLARE var_name [, var_name] ... type [DEFAULT value]
```

This statement declares local variables within stored programs. To provide a default value for a variable, include a **DEFAULT** clause. The value can be specified as an expression; it need not be a constant. If the **DEFAULT** clause is missing, the initial value is **NULL**.

Local variables are treated like stored routine parameters with respect to data type and overflow checking. See Section 13.1.15, “CREATE PROCEDURE and CREATE FUNCTION Statements”.

Variable declarations must appear before cursor or handler declarations.
Local variable names are not case-sensitive. Permissible characters and quoting rules are the same as for other identifiers, as described in Section 9.2, “Schema Object Names”.

The scope of a local variable is the `BEGIN ... END` block within which it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

For examples of variable declarations, see Section 13.6.4.2, “Local Variable Scope and Resolution”.

### 13.6.4.2 Local Variable Scope and Resolution

The scope of a local variable is the `BEGIN ... END` block within which it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

Because local variables are in scope only during stored program execution, references to them are not permitted in prepared statements created within a stored program. Prepared statement scope is the current session, not the stored program, so the statement could be executed after the program ends, at which point the variables would no longer be in scope. For example, `SELECT ... INTO local_var` cannot be used as a prepared statement. This restriction also applies to stored procedure and function parameters. See Section 13.5.1, “PREPARE Statement”.

A local variable should not have the same name as a table column. If an SQL statement, such as a `SELECT ... INTO` statement, contains a reference to a column and a declared local variable with the same name, MySQL currently interprets the reference as the name of a variable. Consider the following procedure definition:

```sql
CREATE PROCEDURE sp1 (x VARCHAR(5))
BEGIN
  DECLARE xname VARCHAR(5) DEFAULT 'bob';
  DECLARE newname VARCHAR(5);
  DECLARE xid INT;
  SELECT xname, id INTO newname, xid
  FROM table1 WHERE xname = xname;
  SELECT newname;
END;
```

MySQL interprets `xname` in the `SELECT` statement as a reference to the `xname` variable rather than the `xname` column. Consequently, when the procedure `sp1()` is called, the `newname` variable returns the value 'bob' regardless of the value of the `table1.xname` column.

Similarly, the cursor definition in the following procedure contains a `SELECT` statement that refers to `xname`. MySQL interprets this as a reference to the variable of that name rather than a column reference.

```sql
CREATE PROCEDURE sp2 (x VARCHAR(5))
BEGIN
  DECLARE xname VARCHAR(5) DEFAULT 'bob';
  DECLARE newname VARCHAR(5);
  DECLARE xid INT;
  DECLARE done TINYINT DEFAULT 0;
  DECLARE cur1 CURSOR FOR SELECT xname, id FROM table1;
  DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = 1;
  OPEN cur1;
  read_loop: LOOP
    FETCH FROM cur1 INTO newname, xid;
    IF done THEN LEAVE read_loop; END IF;
    SELECT newname;
  END LOOP;
  CLOSE cur1;
END;
```

See also Section 20.8, “Restrictions on Stored Programs”.

13.6.5 Flow Control Statements

MySQL supports the `IF`, `CASE`, `ITERATE`, `LEAVE LOOP`, `WHILE`, and `REPEAT` constructs for flow control within stored programs. It also supports `RETURN` within stored functions.

Many of these constructs contain other statements, as indicated by the grammar specifications in the following sections. Such constructs may be nested. For example, an `IF` statement might contain a `WHILE` loop, which itself contains a `CASE` statement.

MySQL does not support `FOR` loops.

13.6.5.1 CASE Statement

```
CASE case_value
  WHEN when_value THEN statement_list
  [WHEN when_value THEN statement_list] ...
  [ELSE statement_list]
END CASE
```

Or:

```
CASE
  WHEN search_condition THEN statement_list
  [WHEN search_condition THEN statement_list] ...
  [ELSE statement_list]
END CASE
```

The `CASE` statement for stored programs implements a complex conditional construct.

**Note**

There is also a `CASE expr`, which differs from the `CASE statement` described here. See Section 12.5, “Flow Control Functions”. The `CASE` statement cannot have an `ELSE NULL` clause, and it is terminated with `END CASE` instead of `END`.

For the first syntax, `case_value` is an expression. This value is compared to the `when_value` expression in each `WHEN` clause until one of them is equal. When an equal `when_value` is found, the corresponding `THEN` clause `statement_list` executes. If no `when_value` is equal, the `ELSE` clause `statement_list` executes, if there is one.

This syntax cannot be used to test for equality with `NULL` because `NULL = NULL` is false. See Section 3.3.4.6, “Working with NULL Values”.

For the second syntax, each `WHEN` clause `search_condition` expression is evaluated until one is true, at which point its corresponding `THEN` clause `statement_list` executes. If no `search_condition` is equal, the `ELSE` clause `statement_list` executes, if there is one.

If no `when_value` or `search_condition` matches the value tested and the `CASE` statement contains no `ELSE` clause, a `Case not found for CASE statement` error results.

Each `statement_list` consists of one or more SQL statements; an empty `statement_list` is not permitted.

To handle situations where no value is matched by any `WHEN` clause, use an `ELSE` containing an empty `BEGIN` block, as shown in this example. (The indentation used here in the `ELSE` clause is for purposes of clarity only, and is not otherwise significant.)

```
DELIMITER |
CREATE PROCEDURE p()
  BEGIN
    DECLARE v INT DEFAULT 1;
```
CASE v
    WHEN 2 THEN SELECT v;
    WHEN 3 THEN SELECT 0;
ELSE
    BEGIN
    END;
END CASE;
END;

13.6.5.2 IF Statement

IF search_condition THEN statement_list
    [ELSEIF search_condition THEN statement_list] ...
    [ELSE statement_list]
END IF

The `IF` statement for stored programs implements a basic conditional construct.

Note

There is also an `IF()` function, which differs from the `IF` statement described here. See Section 12.5, “Flow Control Functions”. The `IF` statement can have `THEN`, `ELSE`, and `ELSEIF` clauses, and it is terminated with `END IF`.

If a given `search_condition` evaluates to true, the corresponding `THEN` or `ELSEIF` clause `statement_list` executes. If no `search_condition` matches, the `ELSE` clause `statement_list` executes.

Each `statement_list` consists of one or more SQL statements; an empty `statement_list` is not permitted.

An `IF ... END IF` block, like all other flow-control blocks used within stored programs, must be terminated with a semicolon, as shown in this example:

```sql
DELIMITER //
CREATE FUNCTION SimpleCompare(n INT, m INT)
RETURNS VARCHAR(20)
BEGIN
    DECLARE s VARCHAR(20);
    IF n > m THEN SET s = '>'; 
    ELSEIF n = m THEN SET s = '='; 
    ELSE SET s = '<';
    END IF;
    SET s = CONCAT(n, ' ', s, ' ', m);
    RETURN s;
END //
DELIMITER ;
```

As with other flow-control constructs, `IF ... END IF` blocks may be nested within other flow-control constructs, including other `IF` statements. Each `IF` must be terminated by its own `END IF` followed by a semicolon. You can use indentation to make nested flow-control blocks more easily readable by humans (although this is not required by MySQL), as shown here:

```sql
DELIMITER //
CREATE FUNCTION VerboseCompare (n INT, m INT)
RETURNS VARCHAR(50)
BEGIN
```
DECLARE s VARCHAR(50);

IF n = m THEN SET s = 'equals';
ELSE
  IF n > m THEN SET s = 'greater';
  ELSE SET s = 'less';
  END IF;
END IF;

SET s = CONCAT('is ', s, ' than');
END IF;

SET s = CONCAT(n, ' ', s, ' ', m, '.');
RETURN s;
END //
DELIMITER ;

In this example, the inner IF is evaluated only if \( n \) is not equal to \( m \).

### 13.6.5.3 ITERATE Statement

**ITERATE** label

**ITERATE** can appear only within **LOOP**, **REPEAT**, and **WHILE** statements. **ITERATE** means “start the loop again.”

For an example, see Section 13.6.5.5, “LOOP Statement”.

### 13.6.5.4 LEAVE Statement

**LEAVE** label

This statement is used to exit the flow control construct that has the given label. If the label is for the outermost stored program block, **LEAVE** exits the program.

**LEAVE** can be used within **BEGIN** ... **END** or loop constructs (**LOOP**, **REPEAT**, **WHILE**).

For an example, see Section 13.6.5.5, “LOOP Statement”.

### 13.6.5.5 LOOP Statement

```
[begin_label:] LOOP
  statement_list
END LOOP [end_label]
```

**LOOP** implements a simple loop construct, enabling repeated execution of the statement list, which consists of one or more statements, each terminated by a semicolon (;) statement delimiter. The statements within the loop are repeated until the loop is terminated. Usually, this is accomplished with a **LEAVE** statement. Within a stored function, **RETURN** can also be used, which exits the function entirely.

Neglecting to include a loop-termination statement results in an infinite loop.

A **LOOP** statement can be labeled. For the rules regarding label use, see Section 13.6.2, “Statement Labels”.

Example:

```sql
CREATE PROCEDURE doiterate(pl INT)
BEGIN
  label1: LOOP
    SET pl = pl + 1;
    IF pl < 10 THEN
      ITERATE label1;
    END IF;
  END IF;
  LEAVE label1;
END;
```

1688
Flow Control Statements

13.6.5.6 REPEAT Statement

```
[begin_label:] REPEAT
  statement_list
UNTIL search_condition
END REPEAT [end_label]
```

The statement list within a `REPEAT` statement is repeated until the `search_condition` expression is true. Thus, a `REPEAT` always enters the loop at least once. `statement_list` consists of one or more statements, each terminated by a semicolon (`;`) statement delimiter.

A `REPEAT` statement can be labeled. For the rules regarding label use, see Section 13.6.2, “Statement Labels”.

Example:

```
mysql> delimiter //
mysql> CREATE PROCEDURE dorepeat(p1 INT)
    
    BEGIN
    
    SET @x = 0;
    REPEAT
        SET @x = @x + 1;
        UNTIL @x > p1 END REPEAT;
    END
    //
Query OK, 0 rows affected (0.00 sec)
mysql> CALL dorepeat(1000)//
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT @x://
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1001</td>
</tr>
<tr>
<td>-----</td>
</tr>
</tbody>
</table>
1 row in set (0.00 sec)
```

13.6.5.7 RETURN Statement

```
RETURN expr
```

The `RETURN` statement terminates execution of a stored function and returns the value `expr` to the function caller. There must be at least one `RETURN` statement in a stored function. There may be more than one if the function has multiple exit points.

This statement is not used in stored procedures, triggers, or events. The `LEAVE` statement can be used to exit a stored program of those types.

13.6.5.8 WHILE Statement

```
[begin_label:] WHILE search_condition DO
  statement_list
END WHILE [end_label]
```

The statement list within a `WHILE` statement is repeated as long as the `search_condition` expression is true. `statement_list` consists of one or more SQL statements, each terminated by a semicolon (`;`) statement delimiter.

A `WHILE` statement can be labeled. For the rules regarding label use, see Section 13.6.2, “Statement Labels”.

END LOOP label1;
SET @x = p1;
END;
13.6.6 Cursors

MySQL supports cursors inside stored programs. The syntax is as in embedded SQL. Cursors have these properties:

- Asensitive: The server may or may not make a copy of its result table
- Read only: Not updatable
- Nonscrollable: Can be traversed only in one direction and cannot skip rows

Cursor declarations must appear before handler declarations and after variable and condition declarations.

Example:

```sql
CREATE PROCEDURE curdemo()
BEGIN
  DECLARE done INT DEFAULT FALSE;
  DECLARE a CHAR(16);
  DECLARE b, c INT;
  DECLARE cur1 CURSOR FOR SELECT id, data FROM test.t1;
  DECLARE cur2 CURSOR FOR SELECT i FROM test.t2;
  DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = TRUE;

  OPEN cur1;
  OPEN cur2;

  read_loop: LOOP
    FETCH cur1 INTO a, b;
    FETCH cur2 INTO c;
    IF done THEN
      LEAVE read_loop;
    END IF;
    IF b < c THEN
      INSERT INTO test.t3 VALUES (a, b);
    ELSE
      INSERT INTO test.t3 VALUES (a, c);
    END IF;
  END LOOP;

  CLOSE cur1;
  CLOSE cur2;
END;
```

13.6.6.1 Cursor CLOSE Statement

```
CLOSE cursor_name
```

This statement closes a previously opened cursor. For an example, see Section 13.6.6, “Cursors”.

An error occurs if the cursor is not open.

If not closed explicitly, a cursor is closed at the end of the `BEGIN ... END` block in which it was declared.
13.6.6.2 Cursor DECLARE Statement

```sql
DECLARE cursor_name CURSOR FOR select_statement
```

This statement declares a cursor and associates it with a `SELECT` statement that retrieves the rows to be traversed by the cursor. To fetch the rows later, use a `FETCH` statement. The number of columns retrieved by the `SELECT` statement must match the number of output variables specified in the `FETCH` statement.

The `SELECT` statement cannot have an `INTO` clause.

Cursor declarations must appear before handler declarations and after variable and condition declarations.

A stored program may contain multiple cursor declarations, but each cursor declared in a given block must have a unique name. For an example, see Section 13.6.6, “Cursors”.

For information available through `SHOW` statements, it is possible in many cases to obtain equivalent information by using a cursor with an `INFORMATION_SCHEMA` table.

13.6.6.3 Cursor FETCH Statement

```sql
FETCH [[NEXT] FROM] cursor_name INTO var_name [, var_name] ... 
```

This statement fetches the next row for the `SELECT` statement associated with the specified cursor (which must be open), and advances the cursor pointer. If a row exists, the fetched columns are stored in the named variables. The number of columns retrieved by the `SELECT` statement must match the number of output variables specified in the `FETCH` statement.

If no more rows are available, a No Data condition occurs with SQLSTATE value '02000'. To detect this condition, you can set up a handler for it (or for a `NOT FOUND` condition). For an example, see Section 13.6.6, “Cursors”.

Be aware that another operation, such as a `SELECT` or another `FETCH`, may also cause the handler to execute by raising the same condition. If it is necessary to distinguish which operation raised the condition, place the operation within its own `BEGIN ... END` block so that it can be associated with its own handler.

13.6.6.4 Cursor OPEN Statement

```sql
OPEN cursor_name
```

This statement opens a previously declared cursor. For an example, see Section 13.6.6, “Cursors”.

13.6.6.5 Restrictions on Server-Side Cursors

Server-side cursors are implemented in the C API using the `mysql_stmt_attr_set()` function. The same implementation is used for cursors in stored routines. A server-side cursor enables a result set to be generated on the server side, but not transferred to the client except for those rows that the client requests. For example, if a client executes a query but is only interested in the first row, the remaining rows are not transferred.

In MySQL, a server-side cursor is materialized into an internal temporary table. Initially, this is a `MEMORY` table, but is converted to a `MyISAM` table when its size exceeds the minimum value of the `max_heap_table_size` and `tmp_table_size` system variables. The same restrictions apply to internal temporary tables created to hold the result set for a cursor as for other uses of internal temporary tables. See Section 8.4.4, “Internal Temporary Table Use in MySQL”. One limitation of the implementation is that for a large result set, retrieving its rows through a cursor might be slow.

Cursors are read only; you cannot use a cursor to update rows.

`UPDATE WHERE CURRENT OF` and `DELETE WHERE CURRENT OF` are not implemented, because updatable cursors are not supported.
Cursors are nonholdable (not held open after a commit).

Cursors are asensitive.

Cursors are nonscrollable.

Cursors are not named. The statement handler acts as the cursor ID.

You can have open only a single cursor per prepared statement. If you need several cursors, you must prepare several statements.

You cannot use a cursor for a statement that generates a result set if the statement is not supported in prepared mode. This includes statements such as `CHECK TABLE`, `HANDLER READ`, and `SHOW BINLOG EVENTS`.

### 13.6.7 Condition Handling

Conditions may arise during stored program execution that require special handling, such as exiting the current program block or continuing execution. Handlers can be defined for general conditions such as warnings or exceptions, or for specific conditions such as a particular error code. Specific conditions can be assigned names and referred to that way in handlers.

To name a condition, use the `DECLARE ... CONDITION` statement. To declare a handler, use the `DECLARE ... HANDLER` statement. See Section 13.6.7.1, “DECLARE ... CONDITION Statement”, and Section 13.6.7.2, “DECLARE ... HANDLER Statement”. For information about how the server chooses handlers when a condition occurs, see Section 13.6.7.6, “Scope Rules for Handlers”.

To raise a condition, use the `SIGNAL` statement. To modify condition information within a condition handler, use `RESIGNAL`. See Section 13.6.7.1, “DECLARE ... CONDITION Statement”, and Section 13.6.7.2, “DECLARE ... HANDLER Statement”.

To retrieve information from the diagnostics area, use the `GET DIAGNOSTICS` statement (see Section 13.6.7.3, “GET DIAGNOSTICS Statement”). For information about the diagnostics area, see Section 13.6.7.7, “The MySQL Diagnostics Area”.

#### 13.6.7.1 DECLARE ... CONDITION Statement

```
DECLARE condition_name CONDITION FOR condition_value

condition_value: {
    mysql_error_code
    | SQLSTATE [VALUE] sqlstate_value
}
```

The `DECLARE ... CONDITION` statement declares a named error condition, associating a name with a condition that needs specific handling. The name can be referred to in a subsequent `DECLARE ... HANDLER` statement (see Section 13.6.7.2, “DECLARE ... HANDLER Statement”).

Condition declarations must appear before cursor or handler declarations.

The `condition_value` for `DECLARE ... CONDITION` indicates the specific condition or class of conditions to associate with the condition name. It can take the following forms:

- `mysql_error_code`: An integer literal indicating a MySQL error code.

  Do not use MySQL error code 0 because that indicates success rather than an error condition. For a list of MySQL error codes, see Server Error Message Reference.

- `SQLSTATE [VALUE] sqlstate_value`: A 5-character string literal indicating an SQLSTATE value.

  Do not use SQLSTATE values that begin with `00` because those indicate success rather than an error condition. For a list of SQLSTATE values, see Server Error Message Reference.
Condition names referred to in `SIGNAL` or use `RESIGNAL` statements must be associated with SQLSTATE values, not MySQL error codes.

Using names for conditions can help make stored program code clearer. For example, this handler applies to attempts to drop a nonexistent table, but that is apparent only if you know that 1051 is the MySQL error code for "unknown table":

```sql
DECLARE CONTINUE HANDLER FOR 1051
    BEGIN
    -- body of handler
END;
```

By declaring a name for the condition, the purpose of the handler is more readily seen:

```sql
DECLARE no_such_table CONDITION FOR 1051;
DECLARE CONTINUE HANDLER FOR no_such_table
    BEGIN
    -- body of handler
END;
```

Here is a named condition for the same condition, but based on the corresponding SQLSTATE value rather than the MySQL error code:

```sql
DECLARE no_such_table CONDITION FOR SQLSTATE '42S02';
DECLARE CONTINUE HANDLER FOR no_such_table
    BEGIN
    -- body of handler
END;
```

### 13.6.7.2 DECLARE ... HANDLER Statement

```sql
DECLARE handler_action HANDLER
    FOR condition_value [, condition_value] ...
    statement

handler_action: |
    CONTINUE
    | EXIT
    | UNDO

condition_value: |
    mysql_error_code
    | SQLSTATE [VALUE] sqlstate_value
    | condition_name
    | SQLWARNING
    | NOT FOUND
    | SQLEXCEPTION
```

The `DECLARE ... HANDLER` statement specifies a handler that deals with one or more conditions. If one of these conditions occurs, the specified `statement` executes. `statement` can be a simple statement such as `SET var_name = value`, or a compound statement written using `BEGIN` and `END` (see Section 13.6.1, "BEGIN ... END Compound Statement").

Handler declarations must appear after variable or condition declarations.

The `handler_action` value indicates what action the handler takes after execution of the handler statement:

- **CONTINUE**: Execution of the current program continues.
- **EXIT**: Execution terminates for the `BEGIN ... END` compound statement in which the handler is declared. This is true even if the condition occurs in an inner block.
- **UNDO**: Not supported.
The condition_value for DECLARE ... HANDLER indicates the specific condition or class of conditions that activates the handler. It can take the following forms:

- **mysql_error_code**: An integer literal indicating a MySQL error code, such as 1051 to specify "unknown table":

```sql
DECLARE CONTINUE HANDLER FOR 1051
BEGIN
    -- body of handler
END;
```

Do not use MySQL error code 0 because that indicates success rather than an error condition. For a list of MySQL error codes, see Server Error Message Reference.

- **SQLSTATE [VALUE] sqlstate_value**: A 5-character string literal indicating an SQLSTATE value, such as '42S01' to specify "unknown table":

```sql
DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
BEGIN
    -- body of handler
END;
```

Do not use SQLSTATE values that begin with '00' because those indicate success rather than an error condition. For a list of SQLSTATE values, see Server Error Message Reference.

- **condition_name**: A condition name previously specified with DECLARE ... CONDITION. A condition name can be associated with a MySQL error code or SQLSTATE value. See Section 13.6.7.1, "DECLARE ... CONDITION Statement".

- **SQLWARNING**: Shorthand for the class of SQLSTATE values that begin with '01'.

```sql
DECLARE CONTINUE HANDLER FOR SQLWARNING
BEGIN
    -- body of handler
END;
```

- **NOT FOUND**: Shorthand for the class of SQLSTATE values that begin with '02'. This is relevant within the context of cursors and is used to control what happens when a cursor reaches the end of a data set. If no more rows are available, a No Data condition occurs with SQLSTATE value '02000'. To detect this condition, you can set up a handler for it or for a NOT FOUND condition.

```sql
DECLARE CONTINUE HANDLER FOR NOT FOUND
BEGIN
    -- body of handler
END;
```

For another example, see Section 13.6.6, “Cursors”. The NOT FOUND condition also occurs for SELECT ... INTO var_list statements that retrieve no rows.

- **SQLEXCEPTION**: Shorthand for the class of SQLSTATE values that do not begin with '00', '01', or '02'.

```sql
DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
BEGIN
    -- body of handler
END;
```

For information about how the server chooses handlers when a condition occurs, see Section 13.6.7.6, “Scope Rules for Handlers”.

If a condition occurs for which no handler has been declared, the action taken depends on the condition class:

- For SQLEXCEPTION conditions, the stored program terminates at the statement that raised the condition, as if there were an EXIT handler. If the program was called by another stored program,
the calling program handles the condition using the handler selection rules applied to its own handlers.

- For SQLWARNING conditions, the program continues executing, as if there were a CONTINUE handler.

- For NOT FOUND conditions, if the condition was raised normally, the action is CONTINUE. If it was raised by SIGNAL or RESIGNAL, the action is EXIT.

The following example uses a handler for SQLSTATE '23000', which occurs for a duplicate-key error:

```
mysql> CREATE TABLE test.t (s1 INT, PRIMARY KEY (s1));
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE PROCEDURE handlerdemo ();
BEGIN
  DECLARE CONTINUE HANDLER FOR SQLSTATE '23000' SET @x2 = 1;
  SET @x = 1;
  INSERT INTO test.t VALUES (1);
  SET @x = 2;
  INSERT INTO test.t VALUES (1);
  SET @x = 3;
END;
//
Query OK, 0 rows affected (0.00 sec)

mysql> CALL handlerdemo();
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x;
+----+
| @x |
| 3  |
+----+
1 row in set (0.00 sec)
```

Notice that @x is 3 after the procedure executes, which shows that execution continued to the end of the procedure after the error occurred. If the DECLARE ... HANDLER statement had not been present, MySQL would have taken the default action (EXIT) after the second INSERT failed due to the PRIMARY KEY constraint, and SELECT @x would have returned 2.

To ignore a condition, declare a CONTINUE handler for it and associate it with an empty block. For example:

```
DECLARE CONTINUE HANDLER FOR SQLWARNING BEGIN END;
```

The scope of a block label does not include the code for handlers declared within the block. Therefore, the statement associated with a handler cannot use ITERATE or LEAVE to refer to labels for blocks that enclose the handler declaration. Consider the following example, where the REPEAT block has a label of retry:

```
CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 3;
  retry:
  REPEAT
    BEGIN
      DECLARE CONTINUE HANDLER FOR SQLWARNING
      BEGIN
        ITERATE retry;    # illegal
      END;
      IF i < 0 THEN
        LEAVE retry;      # legal
      END IF;
      SET i = i - 1;
    END;
  END;
END;
```

1695
The *retry* label is in scope for the *IF* statement within the block. It is not in scope for the *CONTINUE* handler, so the reference there is invalid and results in an error:

```
ERROR 1308 (42000): LEAVE with no matching label: retry
```

To avoid references to outer labels in handlers, use one of these strategies:

- To leave the block, use an *EXIT* handler. If no block cleanup is required, the *BEGIN ... END* handler body can be empty:

```
DECLARE EXIT HANDLER FOR SQLWARNING BEGIN END;
```

Otherwise, put the cleanup statements in the handler body:

```
DECLARE EXIT HANDLER FOR SQLWARNING
BEGIN
  block cleanup statements
END;
```

- To continue execution, set a status variable in a *CONTINUE* handler that can be checked in the enclosing block to determine whether the handler was invoked. The following example uses the variable *done* for this purpose:

```
CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 3;
  DECLARE done INT DEFAULT FALSE;
  retry:
  REPEAT
    BEGIN
      DECLARE CONTINUE HANDLER FOR SQLWARNING
      BEGIN
        SET done = TRUE;
        END;
      IF done OR i < 0 THEN
        LEAVE retry;
      END IF;
      SET i = i - 1;
      END;
    UNTIL FALSE END REPEAT;
END;
```

### 13.6.7.3 GET DIAGNOSTICS Statement

```
GET [CURRENT] DIAGNOSTICS {
  statement_information_item
  [, statement_information_item] ...
| CONDITION condition_number
  condition_information_item
  [, condition_information_item] ...
}
```

- `statement_information_item`:
  - `target = statement_information_item_name`
- `condition_information_item`:
  - `target = condition_information_item_name`
- `statement_information_item_name`
  - `NUMBER`
  - `ROW_COUNT`
- `condition_information_item_name`
  - `CLASS_ORIGIN`
SQL statements produce diagnostic information that populates the diagnostics area. The `GET DIAGNOSTICS` statement enables applications to inspect this information. It is available as of MySQL 5.6.4. (You can also use `SHOW WARNINGS` or `SHOW ERRORS` to see conditions or errors.)

No special privileges are required to execute `GET DIAGNOSTICS`.

The keyword `CURRENT` means to retrieve information from the current diagnostics area. In MySQL, it has no effect because that is the default behavior.

`GET DIAGNOSTICS` is typically used in a handler within a stored program, but it is a MySQL extension that it is permitted outside handler context to check the execution of any SQL statement. For example, if you invoke the `mysql` client program, you can enter these statements at the prompt:

```
mysql> DROP TABLE test.no_such_table;
ERROR 1051 (42S02): Unknown table 'test.no_such_table'
```

```
mysql> GET DIAGNOSTICS CONDITION 1
    @p1 = RETURNED_SQLSTATE, @p2 = MESSAGE_TEXT;
```

```
mysql> SELECT @p1, @p2;
+-------+------------------------------------+
<table>
<thead>
<tr>
<th>@p1</th>
<th>@p2</th>
</tr>
</thead>
<tbody>
<tr>
<td>42S02</td>
<td>Unknown table 'test.no_such_table'</td>
</tr>
</tbody>
</table>
+-------+------------------------------------+
```

For a description of the diagnostics area, see Section 13.6.7.7, “The MySQL Diagnostics Area”. Briefly, it contains two kinds of information:

- Statement information, such as the number of conditions that occurred or the affected-rows count.
- Condition information, such as the error code and message. If a statement raises multiple conditions, this part of the diagnostics area has a condition area for each one. If a statement raises no conditions, this part of the diagnostics area is empty.

For a statement that produces three conditions, the diagnostics area contains statement and condition information like this:

```
Statement information:
  row count
  ... other statement information items ...
Condition area list:
  Condition area 1:
    error code for condition 1
    error message for condition 1
    ... other condition information items ...
  Condition area 2:
    error code for condition 2:
    error message for condition 2
    ... other condition information items ...
  Condition area 3:
    error code for condition 3
    error message for condition 3
```
GET DIAGNOSTICS can obtain either statement or condition information, but not both in the same statement:

- To obtain statement information, retrieve the desired statement items into target variables. This instance of GET DIAGNOSTICS assigns the number of available conditions and the rows-affected count to the user variables @p1 and @p2:

```sql
GET DIAGNOSTICS @p1 = NUMBER, @p2 = ROW_COUNT;
```

- To obtain condition information, specify the condition number and retrieve the desired condition items into target variables. This instance of GET DIAGNOSTICS assigns the SQLSTATE value and error message to the user variables @p3 and @p4:

```sql
GET DIAGNOSTICS CONDITION 1
    @p3 = RETURNED_SQLSTATE, @p4 = MESSAGE_TEXT;
```

The retrieval list specifies one or more target = item_name assignments, separated by commas. Each assignment names a target variable and either a statement_information_item_name or condition_information_item_name designator, depending on whether the statement retrieves statement or condition information.

Valid target designators for storing item information can be stored procedure or function parameters, stored program local variables declared with DECLARE, or user-defined variables.

Valid condition_number designators can be stored procedure or function parameters, stored program local variables declared with DECLARE, user-defined variables, system variables, or literals. A character literal may include a _charset introducer. A warning occurs if the condition number is not in the range from 1 to the number of condition areas that have information. In this case, the warning is added to the diagnostics area without clearing it.

When a condition occurs, MySQL does not populate all condition items recognized by GET DIAGNOSTICS. For example:

```sql
mysql> GET DIAGNOSTICS CONDITION 1
    > @p5 = SCHEMA_NAME, @p6 = TABLE_NAME;

mysql> SELECT @p5, @p6;
+-------+-------+
| @p5   | @p6   |
|-------+-------|
|       |       |
+-------+-------+
```

In standard SQL, if there are multiple conditions, the first condition relates to the SQLSTATE value returned for the previous SQL statement. In MySQL, this is not guaranteed. To get the main error, you cannot do this:

```sql
GET DIAGNOSTICS CONDITION 1 @errno = MYSQL_ERRNO;
```

Instead, retrieve the condition count first, then use it to specify which condition number to inspect:

```sql
GET DIAGNOSTICS @cno = NUMBER;
GET DIAGNOSTICS CONDITION @cno @errno = MYSQL_ERRNO;
```

For information about permissible statement and condition information items, and which ones are populated when a condition occurs, see Diagnostics Area Information Items.

Here is an example that uses GET DIAGNOSTICS and an exception handler in stored procedure context to assess the outcome of an insert operation. If the insert was successful, the procedure uses GET DIAGNOSTICS to get the rows-affected count. This shows that you can use GET DIAGNOSTICS multiple times to retrieve information about a statement as long as the diagnostics area has not been cleared.
CREATE PROCEDURE do_insert(value INT)
BEGIN
  -- Declare variables to hold diagnostics area information
  DECLARE code CHAR(5) DEFAULT '00000';
  DECLARE msg TEXT;
  DECLARE nrows INT;
  DECLARE result TEXT;
  -- Declare exception handler for failed insert
  DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
  BEGIN
    GET DIAGNOSTICS CONDITION 1
    code = RETURNED_SQLSTATE, msg = MESSAGE_TEXT;
  END;
  -- Perform the insert
  INSERT INTO t1 (int_col) VALUES(value);
  -- Check whether the insert was successful
  IF code = '00000' THEN
    GET DIAGNOSTICS nrows = ROW_COUNT;
    SET result = CONCAT('insert succeeded, row count = ',nrows);
  ELSE
    SET result = CONCAT('insert failed, error = ',code,', message = ',msg);
  END IF;
  -- Say what happened
  SELECT result;
END;

Suppose that `t1.int_col` is an integer column that is declared as `NOT NULL`. The procedure produces these results when invoked to insert non-`NULL` and `NULL` values, respectively:

```
mysql> CALL do_insert(1);
+---------------------------------+
| result                          |
+---------------------------------+
| insert succeeded, row count = 1 |
+---------------------------------+
mysql> CALL do_insert(NULL);
+----------------------------------------------------------------------------------+
| result                                                                           |
+----------------------------------------------------------------------------------+
| insert failed, error = 23000, message = Column 'int_col' cannot be null          |
+----------------------------------------------------------------------------------+
```

Within a condition handler, `GET DIAGNOSTICS` should be used before other statements that might clear the diagnostics area and cause information to be lost about the condition that activated the handler. For information about when the diagnostics area is set and cleared, see Section 13.6.7.7, “The MySQL Diagnostics Area”.

### 13.6.7.4 RESIGNAL Statement

```
RESIGNAL [condition_value]
  [SET signal_information_item
   [, signal_information_item] ...]
condition_value: {
  SQLSTATE [VALUE] sqlstate_value
  | condition_name
}
signal_information_item:
  condition_information_item_name = simple_value_specification
condition_information_item_name: {
  CLASS_ORIGIN
  | SUBCLASS_ORIGIN
  | MESSAGE_TEXT
  | MYSQL_ERRNO
  | CONSTRAINT_CATALOG
  | CONSTRAINT_SCHEMA
```
RESIGNAL passes on the error condition information that is available during execution of a condition handler within a compound statement inside a stored procedure or function, trigger, or event. RESIGNAL may change some or all information before passing it on. RESIGNAL is related to SIGNAL, but instead of originating a condition as SIGNAL does, RESIGNAL relays existing condition information, possibly after modifying it.

RESIGNAL makes it possible to both handle an error and return the error information. Otherwise, by executing an SQL statement within the handler, information that caused the handler's activation is destroyed. RESIGNAL also can make some procedures shorter if a given handler can handle part of a situation, then pass the condition “up the line” to another handler.

No privileges are required to execute the RESIGNAL statement.

All forms of RESIGNAL require that the current context be a condition handler. Otherwise, RESIGNAL is illegal and a RESIGNAL when handler not active error occurs.

To retrieve information from the diagnostics area, use the GET DIAGNOSTICS statement (see Section 13.6.7.3, “GET DIAGNOSTICS Statement”). For information about the diagnostics area, see Section 13.6.7.7, “The MySQL Diagnostics Area”.

- RESIGNAL Overview
- RESIGNAL Alone
- RESIGNAL with New Signal Information
- RESIGNAL with a Condition Value and Optional New Signal Information
- RESIGNAL Requires Condition Handler Context

**RESIGNAL Overview**

For condition_value and signal_information_item, the definitions and rules are the same for RESIGNAL as for SIGNAL. For example, the condition_value can be an SQLSTATE value, and the value can indicate errors, warnings, or “not found.” For additional information, see Section 13.6.7.5, “SIGNAL Statement”.

The RESIGNAL statement takes condition_value and SET clauses, both of which are optional. This leads to several possible uses:

- **RESIGNAL alone:**

  RESIGNAL;

- **RESIGNAL with new signal information:**

  RESIGNAL SET signal_information_item [, signal_information_item] ...;

- **RESIGNAL with a condition value and possibly new signal information:**

  RESIGNAL condition_value
  [SET signal_information_item [, signal_information_item] ...];

These use cases all cause changes to the diagnostics and condition areas.
• A diagnostics area contains one or more condition areas.

• A condition area contains condition information items, such as the SQLSTATE value, MYSQL_ERRNO, or MESSAGE_TEXT.

The maximum number of condition areas in a diagnostics area is determined by the value of the max_error_count system variable. See Diagnostics Area-Related System Variables.

RESIGNAL Alone

A simple RESIGNAL alone means "pass on the error with no change." It restores the last diagnostics area and makes it the current diagnostics area. That is, it "pops" the diagnostics area stack.

Within a condition handler that catches a condition, one use for RESIGNAL alone is to perform some other actions, and then pass on without change the original condition information (the information that existed before entry into the handler).

Example:

DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    SET @error_count = @error_count + 1;
    IF @a = 0 THEN RESIGNAL; END IF;
  END;
  DROP TABLE xx;
END//
delimiter ;
SET @error_count = 0;
SET @a = 0;
CALL p();

Suppose that the DROP TABLE xx statement fails. The diagnostics area stack looks like this:

DA 1. ERROR 1051 (42S02): Unknown table 'xx'

Then execution enters the EXIT handler. It starts by pushing a diagnostics area to the top of the stack, which now looks like this:

DA 1. ERROR 1051 (42S02): Unknown table 'xx'
DA 2. ERROR 1051 (42S02): Unknown table 'xx'

At this point, the contents of the first (current) and second (stacked) diagnostics areas are the same. The first diagnostics area may be modified by statements executing subsequently within the handler.

Usually a procedure statement clears the first diagnostics area. BEGIN is an exception, it does not clear, it does nothing. SET is not an exception, it clears, performs the operation, and produces a result of "success." The diagnostics area stack now looks like this:

DA 1. ERROR 0000 (00000): Successful operation
DA 2. ERROR 1051 (42S02): Unknown table 'xx'

At this point, if @a = 0, RESIGNAL pops the diagnostics area stack, which now looks like this:

DA 1. ERROR 1051 (42S02): Unknown table 'xx'

And that is what the caller sees.

If @a is not 0, the handler simply ends, which means that there is no more use for the current diagnostics area (it has been "handled"), so it can be thrown away, causing the stacked diagnostics area to become the current diagnostics area again. The diagnostics area stack looks like this:
The details make it look complex, but the end result is quite useful: Handlers can execute without destroying information about the condition that caused activation of the handler.

**RESIGNAL with New Signal Information**

RESIGNAL with a SET clause provides new signal information, so the statement means “pass on the error with changes”:

```sql
RESIGNAL SET signal_information_item [, signal_information_item] ...;
```

As with RESIGNAL alone, the idea is to pop the diagnostics area stack so that the original information will go out. Unlike RESIGNAL alone, anything specified in the SET clause changes.

Example:

```sql
DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    SET @error_count = @error_count + 1;
    IF @a = 0 THEN RESIGNAL SET MYSQL_ERRNO = 5; END IF;
  END;
  DROP TABLE xx;
END;//
delimiter ;
SET @error_count = 0;
SET @a = 0;
CALL p();
```

Remember from the previous discussion that RESIGNAL alone results in a diagnostics area stack like this:

```
DA 1. ERROR 1051 (42S02): Unknown table 'xx'
```

The RESIGNAL SET MYSQL_ERRNO = 5 statement results in this stack instead, which is what the caller sees:

```
DA 1. ERROR 5 (42S02): Unknown table 'xx'
```

In other words, it changes the error number, and nothing else.

The RESIGNAL statement can change any or all of the signal information items, making the first condition area of the diagnostics area look quite different.

**RESIGNAL with a Condition Value and Optional New Signal Information**

RESIGNAL with a condition value means “push a condition into the current diagnostics area.” If the SET clause is present, it also changes the error information.

```sql
RESIGNAL condition_value
  [SET signal_information_item [, signal_information_item] ...];
```

This form of RESIGNAL restores the last diagnostics area and makes it the current diagnostics area. That is, it “pops” the diagnostics area stack, which is the same as what a simple RESIGNAL alone would do. However, it also changes the diagnostics area depending on the condition value or signal information.

Example:

```sql
DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
```
BEGIN
    SET @error_count = @error_count + 1;
    IF @a = 0 THEN RESIGNAL SQLSTATE '45000' SET MYSQL_ERRNO=5; END IF;
END;
DROP TABLE xx;
END;
de delimiter ;
SET @error_count = 0;
SET @a = 0;
SET @max_error_count = 2;
CALL p();
SHOW ERRORS;

This is similar to the previous example, and the effects are the same, except that if RESIGNAL happens, the current condition area looks different at the end. (The reason the condition adds to rather than replaces the existing condition is the use of a condition value.)

The RESIGNAL statement includes a condition value (SQLSTATE '45000'), so it adds a new condition area, resulting in a diagnostics area stack that looks like this:

DA 1. (condition 2) ERROR 1051 (42S02): Unknown table 'xx'
    (condition 1) ERROR 5 (45000) Unknown table 'xx'

The result of CALL p() and SHOW ERRORS for this example is:

mysql> CALL p();
ERROR 5 (45000): Unknown table 'xx'
mysql> SHOW ERRORS;
+-------+------+----------------------------------+
| Level | Code | Message                          |
|-------+------|----------------------------------|
| Error | 1051 | Unknown table 'xx'               |
| Error | 5    | Unknown table 'xx'               |
+-------+------+----------------------------------+

RESIGNAL Requires Condition Handler Context

All forms of RESIGNAL require that the current context be a condition handler. Otherwise, RESIGNAL is illegal and a RESIGNAL when handler not active error occurs. For example:

mysql> CREATE PROCEDURE p () RESIGNAL;
Query OK, 0 rows affected (0.00 sec)
mysql> CALL p();
ERROR 1645 (0K000): RESIGNAL when handler not active

Here is a more difficult example:

delimiter //
CREATE FUNCTION f () RETURNS INT
BEGIN
    RESIGNAL;
    RETURN 5;
END;
de delimiter ;
CREATE PROCEDURE p ()
BEGIN
    DECLARE EXIT HANDLER FOR SQLEXCEPTION SET @a=f();
    SIGNAL SQLSTATE '55555';
END;
de delimiter ;
CALL p();

RESIGNAL occurs within the stored function f(). Although f() itself is invoked within the context of the EXIT handler, execution within f() has its own context, which is not handler context. Thus, RESIGNAL within f() results in a "handler not active" error.

In MySQL 5.5, handler scope rules are less developed. f() is considered to execute within handler context and RESIGNAL within f() is legal.
13.6.7.5 SIGNAL Statement

```sql
SIGNAL condition_value
  [SET signal_information_item
  [, signal_information_item] ...]

condition_value: {
  SQLSTATE [VALUE] sqlstate_value
  | condition_name
}

signal_information_item:
  condition_information_item_name = simple_value_specification

condition_information_item_name: {
  CLASS_ORIGIN
  | SUBCLASS_ORIGIN
  | MESSAGE_TEXT
  | MYSQL_ERRNO
  | CONSTRAINT_CATALOG
  | CONSTRAINT_SCHEMA
  | CONSTRAINT_NAME
  | CATALOG_NAME
  | SCHEMA_NAME
  | TABLE_NAME
  | COLUMN_NAME
  | CURSOR_NAME
}

condition_name, simple_value_specification:
  (see following discussion)
```

*SIGNAL* is the way to “return” an error. *SIGNAL* provides error information to a handler, to an outer portion of the application, or to the client. Also, it provides control over the error’s characteristics (error number, *SQLSTATE* value, message). Without *SIGNAL*, it is necessary to resort to workarounds such as deliberately referring to a nonexistent table to cause a routine to return an error.

No privileges are required to execute the *SIGNAL* statement.

To retrieve information from the diagnostics area, use the *GET DIAGNOSTICS* statement (see Section 13.6.7.3, “GET DIAGNOSTICS Statement”). For information about the diagnostics area, see Section 13.6.7.7, “The MySQL Diagnostics Area”.

- **SIGNAL Overview**
- **Signal Condition Information Items**
- **Effect of Signals on Handlers, Cursors, and Statements**

**SIGNAL Overview**

The *condition_value* in a *SIGNAL* statement indicates the error value to be returned. It can be an *SQLSTATE* value (a 5-character string literal) or a *condition_name* that refers to a named condition previously defined with *DECLARE ... CONDITION* (see Section 13.6.7.1, “DECLARE ... CONDITION Statement”).

An *SQLSTATE* value can indicate errors, warnings, or “not found.” The first two characters of the value indicate its error class, as discussed in Signal Condition Information Items. Some signal values cause statement termination; see Effect of Signals on Handlers, Cursors, and Statements.

The *SQLSTATE* value for a *SIGNAL* statement should not start with '00' because such values indicate success and are not valid for signaling an error. This is true whether the *SQLSTATE* value is specified directly in the *SIGNAL* statement or in a named condition referred to in the statement. If the value is invalid, a Bad *SQLSTATE* error occurs.

To signal a generic *SQLSTATE* value, use '45000', which means “unhandled user-defined exception.”
The `SIGNAL` statement optionally includes a `SET` clause that contains multiple signal items, in a list of `condition_information_item_name = simple_value_specification` assignments, separated by commas.

Each `condition_information_item_name` may be specified only once in the `SET` clause. Otherwise, a Duplicate condition information item error occurs.

Valid `simple_value_specification` designators can be specified using stored procedure or function parameters, stored program local variables declared with `DECLARE`, user-defined variables, system variables, or literals. A character literal may include a `_charset` introducer.

For information about permissible `condition_information_item_name` values, see Signal Condition Information Items.

The following procedure signals an error or warning depending on the value of `pval`, its input parameter:

```sql
CREATE PROCEDURE p (pval INT)
BEGIN
  DECLARE specialty CONDITION FOR SQLSTATE '45000';
  IF pval = 0 THEN
    SIGNAL SQLSTATE '01000';
  ELSEIF pval = 1 THEN
    SIGNAL SQLSTATE '45000' SET MESSAGE_TEXT = 'An error occurred';
  ELSEIF pval = 2 THEN
    SIGNAL specialty
    SET MESSAGE_TEXT = 'An error occurred';
  ELSE
    SIGNAL SQLSTATE '01000'
    SET MESSAGE_TEXT = 'An error occurred', MYSQL_ERRNO = 1000;
    SIGNAL SQLSTATE '45000'
    SET MESSAGE_TEXT = 'An error occurred', MYSQL_ERRNO = 1001;
  END IF;
END;
```

If `pval` is 0, `p()` signals a warning because `SQLSTATE` values that begin with '01' are signals in the warning class. The warning does not terminate the procedure, and can be seen with `SHOW WARNINGS` after the procedure returns.

If `pval` is 1, `p()` signals an error and sets the `MESSAGE_TEXT` condition information item. The error terminates the procedure, and the text is returned with the error information.

If `pval` is 2, the same error is signaled, although the `SQLSTATE` value is specified using a named condition in this case.

If `pval` is anything else, `p()` first signals a warning and sets the message text and error number condition information items. This warning does not terminate the procedure, so execution continues and `p()` then signals an error. The error does terminate the procedure. The message text and error number set by the warning are replaced by the values set by the error, which are returned with the error information.

`SIGNAL` is typically used within stored programs, but it is a MySQL extension that it is permitted outside handler context. For example, if you invoke the `mysql` client program, you can enter any of these statements at the prompt:

```sql
SIGNAL SQLSTATE '77777';
CREATE TRIGGER t_bi BEFORE INSERT ON t
  FOR EACH ROW SIGNAL SQLSTATE '77777';
CREATE EVENT e ON SCHEDULE EVERY 1 SECOND
  DO SIGNAL SQLSTATE '77777';
```

`SIGNAL` executes according to the following rules:
If the `SIGNAL` statement indicates a particular `SQLSTATE` value, that value is used to signal the condition specified. Example:

```sql
CREATE PROCEDURE p (divisor INT)
BEGIN
  IF divisor = 0 THEN
    SIGNAL SQLSTATE '22012';
  END IF;
END;
```

If the `SIGNAL` statement uses a named condition, the condition must be declared in some scope that applies to the `SIGNAL` statement, and must be defined using an `SQLSTATE` value, not a MySQL error number. Example:

```sql
CREATE PROCEDURE p (divisor INT)
BEGIN
  DECLARE divide_by_zero CONDITION FOR SQLSTATE '22012';
  IF divisor = 0 THEN
    SIGNAL divide_by_zero;
  END IF;
END;
```

If the named condition does not exist in the scope of the `SIGNAL` statement, an `Undefined CONDITION` error occurs.

If `SIGNAL` refers to a named condition that is defined with a MySQL error number rather than an `SQLSTATE` value, a `SIGNAL/RESIGNAL` can only use a `CONDITION` defined with `SQLSTATE` error occurs. The following statements cause that error because the named condition is associated with a MySQL error number:

```sql
DECLARE no_such_table CONDITION FOR 1051;
SIGNAL no_such_table;
```

If a condition with a given name is declared multiple times in different scopes, the declaration with the most local scope applies. Consider the following procedure:

```sql
CREATE PROCEDURE p (divisor INT)
BEGIN
  DECLARE my_error CONDITION FOR SQLSTATE '45000';
  IF divisor = 0 THEN
    BEGIN
      DECLARE my_error CONDITION FOR SQLSTATE '22012';
      SIGNAL my_error;
    END;
    SIGNAL my_error;
  END IF;
END;
```

If `divisor` is 0, the first `SIGNAL` statement executes. The innermost `my_error` condition declaration applies, raising `SQLSTATE '22012'`.

If `divisor` is not 0, the second `SIGNAL` statement executes. The outermost `my_error` condition declaration applies, raising `SQLSTATE '45000'`.

For information about how the server chooses handlers when a condition occurs, see Section 13.6.7.6, “Scope Rules for Handlers”.

Signals can be raised within exception handlers:

```sql
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    SIGNAL SQLSTATE VALUE '99999'
    SET MESSAGE_TEXT = 'An error occurred';
  END;
```
DROP TABLE no_such_table;
END;

CALL p() reaches the DROP TABLE statement. There is no table named no_such_table, so the error handler is activated. The error handler destroys the original error ("no such table") and makes a new error with SQLSTATE '99999' and message An error occurred.

Signal Condition Information Items

The following table lists the names of diagnostics area condition information items that can be set in a SIGNAL (or RESIGNAL) statement. All items are standard SQL except MYSQL_ERRNO, which is a MySQL extension. For more information about these items see Section 13.6.7.7, "The MySQL Diagnostics Area".

<table>
<thead>
<tr>
<th>Item Name</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLASS_ORIGIN</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>SUBCLASS_ORIGIN</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>CONSTRAINT_CATALOG</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>CONSTRAINT_SCHEMA</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>CONSTRAINT_NAME</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>CATALOG_NAME</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>CURSOR_NAME</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>MESSAGE_TEXT</td>
<td>VARCHAR(128)</td>
</tr>
<tr>
<td>MYSQL_ERRNO</td>
<td>SMALLINT UNSIGNED</td>
</tr>
</tbody>
</table>

The character set for character items is UTF-8.

It is illegal to assign NULL to a condition information item in a SIGNAL statement.

A SIGNAL statement always specifies an SQLSTATE value, either directly, or indirectly by referring to a named condition defined with an SQLSTATE value. The first two characters of an SQLSTATE value are its class, and the class determines the default value for the condition information items:

- **Class = '00' (success)**
  
  Illegal. SQLSTATE values that begin with '00' indicate success and are not valid for SIGNAL.

- **Class = '01' (warning)**
  
  MESSAGE_TEXT = 'Unhandled user-defined warning condition';
  MYSQL_ERRNO = ER_SIGNAL_WARN

- **Class = '02' (not found)**
  
  MESSAGE_TEXT = 'Unhandled user-defined not found condition';
  MYSQL_ERRNO = ER_SIGNAL_NOT_FOUND

- **Class > '02' (exception)**
  
  MESSAGE_TEXT = 'Unhandled user-defined exception condition';
  MYSQL_ERRNO = ER_SIGNAL_EXCEPTION

For legal classes, the other condition information items are set as follows:

CLASS_ORIGIN = SUBCLASS_ORIGIN = ';
CONSTRAINT_CATALOG = CONSTRAINT_SCHEMA = CONSTRAINT_NAME = ';
CATALOG_NAME = SCHEMA_NAME = TABLE_NAME = COLUMN_NAME = ';
CURSOR_NAME = ';

The error values that are accessible after SIGNAL executes are the SQLSTATE value raised by the SIGNAL statement and the MESSAGE_TEXT and MYSQL_ERRNO items. These values are available from the C API:
Condition Handling

- `mysql_sqlstate()` returns the SQLSTATE value.
- `mysql_errno()` returns the MYSQL_ERRNO value.
- `mysql_error()` returns the MESSAGE_TEXT value.

At the SQL level, the output from `SHOW WARNINGS` and `SHOW ERRORS` indicates the MYSQL_ERRNO and MESSAGE_TEXT values in the Code and Message columns.

To retrieve information from the diagnostics area, use the `GET DIAGNOSTICS` statement (see Section 13.6.7.3, “GET DIAGNOSTICS Statement”). For information about the diagnostics area, see Section 13.6.7.7, “The MySQL Diagnostics Area”.

Effect of Signals on Handlers, Cursors, and Statements

Signals have different effects on statement execution depending on the signal class. The class determines how severe an error is. MySQL ignores the value of the `sql_mode` system variable; in particular, strict SQL mode does not matter. MySQL also ignores `IGNORE`: The intent of `SIGNAL` is to raise a user-generated error explicitly, so a signal is never ignored.

In the following descriptions, “unhandled” means that no handler for the signaled SQLSTATE value has been defined with `DECLARE ... HANDLER`.

- Class = '00' (success)
  Illegal. SQLSTATE values that begin with '00' indicate success and are not valid for SIGNAL.

- Class = '01' (warning)
  The value of the `warning_count` system variable goes up. `SHOW WARNINGS` shows the signal. SQLWARNING handlers catch the signal.

  Warnings cannot be returned from stored functions because the RETURN statement that causes the function to return clears the diagnostic area. The statement thus clears any warnings that may have been present there (and resets warning_count to 0).

- Class = '02' (not found)
  NOT_FOUND handlers catch the signal. There is no effect on cursors. If the signal is unhandled in a stored function, statements end.

- Class > '02' (exception)
  SQLEXCEPTION handlers catch the signal. If the signal is unhandled in a stored function, statements end.

- Class = '40'
  Treated as an ordinary exception.

13.6.7.6 Scope Rules for Handlers

A stored program may include handlers to be invoked when certain conditions occur within the program. The applicability of each handler depends on its location within the program definition and on the condition or conditions that it handles:

- A handler declared in a `BEGIN ... END` block is in scope only for the SQL statements following the handler declarations in the block. If the handler itself raises a condition, it cannot handle that condition, nor can any other handlers declared in the block. In the following example, handlers H1 and H2 are in scope for conditions raised by statements `stmt1` and `stmt2`. But neither H1 nor H2 are in scope for conditions raised in the body of H1 or H2.
Condition Handling

BEGIN -- outer block
   DECLARE EXIT HANDLER FOR ...; -- handler H1
   DECLARE EXIT HANDLER FOR ...; -- handler H2
      stmt1;
      stmt2;
   END;
END;

- A handler is in scope only for the block in which it is declared, and cannot be activated for conditions occurring outside that block. In the following example, handler H1 is in scope for stmt1 in the inner block, but not for stmt2 in the outer block:

BEGIN -- outer block
   BEGIN -- inner block
      DECLARE EXIT HANDLER FOR ...; -- handler H1
      stmt1;
   END;
   stmt2;
END;

- A handler can be specific or general. A specific handler is for a MySQL error code, SQLSTATE value, or condition name. A general handler is for a condition in the SQLWARNING, SQLEXCEPTION, or NOT FOUND class. Condition specificity is related to condition precedence, as described later.

Multiple handlers can be declared in different scopes and with different specificities. For example, there might be a specific MySQL error code handler in an outer block, and a general SQLWARNING handler in an inner block. Or there might be handlers for a specific MySQL error code and the general SQLWARNING class in the same block.

Whether a handler is activated depends not only on its own scope and condition value, but on what other handlers are present. When a condition occurs in a stored program, the server searches for applicable handlers in the current scope (current BEGIN ... END block). If there are no applicable handlers, the search continues outward with the handlers in each successive containing scope (block). When the server finds one or more applicable handlers at a given scope, it chooses among them based on condition precedence:

- A MySQL error code handler takes precedence over an SQLSTATE value handler.

- An SQLSTATE value handler takes precedence over general SQLWARNING, SQLEXCEPTION, or NOT FOUND handlers.

- An SQLEXCEPTION handler takes precedence over an SQLWARNING handler.

- It is possible to have several applicable handlers with the same precedence. For example, a statement could generate multiple warnings with different error codes, for each of which an error-specific handler exists. In this case, the choice of which handler the server activates is nondeterministic, and may change depending on the circumstances under which the condition occurs.

One implication of the handler selection rules is that if multiple applicable handlers occur in different scopes, handlers with the most local scope take precedence over handlers in outer scopes, even over those for more specific conditions.

If there is no appropriate handler when a condition occurs, the action taken depends on the class of the condition:

- For SQLEXCEPTION conditions, the stored program terminates at the statement that raised the condition, as if there were an EXIT handler. If the program was called by another stored program, the calling program handles the condition using the handler selection rules applied to its own handlers.

- For SQLWARNING conditions, the program continues executing, as if there were a CONTINUE handler.
• For **NOT FOUND** conditions, if the condition was raised normally, the action is **CONTINUE**. If it was raised by **SIGNAL** or **RESIGNAL**, the action is **EXIT**.

The following examples demonstrate how MySQL applies the handler selection rules.

This procedure contains two handlers, one for the specific **SQLSTATE** value (**'42S02'**) that occurs for attempts to drop a nonexistent table, and one for the general **SQLEXCEPTION** class:

```sql
CREATE PROCEDURE p1()
BEGIN
  DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
  SELECT 'SQLSTATE handler was activated' AS msg;
  DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
  SELECT 'SQLEXCEPTION handler was activated' AS msg;
  DROP TABLE test.t;
END;
```

Both handlers are declared in the same block and have the same scope. However, **SQLSTATE** handlers take precedence over **SQLEXCEPTION** handlers, so if the table **t** is nonexistent, the **DROP TABLE** statement raises a condition that activates the **SQLSTATE** handler:

```
mysql> CALL p1();
+----------------------------------+
<table>
<thead>
<tr>
<th>msg</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLSTATE handler was activated</td>
</tr>
</tbody>
</table>
+----------------------------------+
```

This procedure contains the same two handlers. But this time, the **DROP TABLE** statement and **SQLEXCEPTION** handler are in an inner block relative to the **SQLSTATE** handler:

```sql
CREATE PROCEDURE p2()
BEGIN -- outer block
  DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
  SELECT 'SQLSTATE handler was activated' AS msg;
  BEGIN -- inner block
    DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
    SELECT 'SQLEXCEPTION handler was activated' AS msg;
    DROP TABLE test.t; -- occurs within inner block
  END;
END;
```

In this case, the handler that is more local to where the condition occurs takes precedence. The **SQLEXCEPTION** handler activates, even though it is more general than the **SQLSTATE** handler:

```
mysql> CALL p2();
+-----------------------------------------------+
<table>
<thead>
<tr>
<th>msg</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLEXCEPTION handler was activated</td>
</tr>
</tbody>
</table>
+-----------------------------------------------+
```

This procedure contains one of the handlers is declared in a block inner to the scope of the **DROP TABLE** statement:

```sql
CREATE PROCEDURE p3()
BEGIN -- outer block
  DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
  SELECT 'SQLEXCEPTION handler was activated' AS msg;
  BEGIN -- inner block
    DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
    SELECT 'SQLSTATE handler was activated' AS msg;
  END;
  DROP TABLE test.t; -- occurs within outer block
END;
```
Only the `SQLEXCEPTION` handler applies because the other one is not in scope for the condition raised by the `DROP TABLE`:

```sql
mysql> CALL p3();
+------------------------------------+
<table>
<thead>
<tr>
<th>msg</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLEXCEPTION handler was activated</td>
</tr>
</tbody>
</table>
+------------------------------------+
```

In this procedure, both handlers are declared in a block inner to the scope of the `DROP TABLE` statement:

```sql
CREATE PROCEDURE p4()
BEGIN -- outer block
  BEGIN -- inner block
    DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
      SELECT 'SQLEXCEPTION handler was activated' AS msg;
    DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
      SELECT 'SQLSTATE handler was activated' AS msg;
    END;
  END;
  DROP TABLE test.t; -- occurs within outer block
END;
```

Neither handler applies because they are not in scope for the `DROP TABLE`. The condition raised by the statement goes unhandled and terminates the procedure with an error:

```sql
mysql> CALL p4();
ERROR 1051 (42S02): Unknown table 'test.t'
```

### 13.6.7.7 The MySQL Diagnostics Area

SQL statements produce diagnostic information that populates the diagnostics area. Standard SQL has a diagnostics area stack, containing a diagnostics area for each nested execution context. Standard SQL also supports `GET STACKED DIAGNOSTICS` syntax for referring to the second diagnostics area during condition handler execution. MySQL does not support the `STACKED` keyword until MySQL 5.7. In MySQL 5.6, there is a single diagnostics area containing information from the most recent statement that wrote to it.

The following discussion describes the structure of the diagnostics area in MySQL, the information items recognized by MySQL and how statements clear and set the diagnostics area.

- **Diagnostics Area Structure**
- **Diagnostics Area Information Items**
- **How the Diagnostics Area is Cleared and Populated**
- **Diagnostics Area-Related System Variables**

#### Diagnostics Area Structure

The diagnostics area contains two kinds of information:

- **Statement information**, such as the number of conditions that occurred or the affected-rows count.

- **Condition information**, such as the error code and message. If a statement raises multiple conditions, this part of the diagnostics area has a condition area for each one. If a statement raises no conditions, this part of the diagnostics area is empty.

For a statement that produces three conditions, the diagnostics area contains statement and condition information like this:

```sql
Statement information:
row count
```
Condition Handling

```
... other statement information items ...
Condition area list:
  Condition area 1:
    error code for condition 1
    error message for condition 1
    ... other condition information items ...
  Condition area 2:
    error code for condition 2:
    error message for condition 2
    ... other condition information items ...
  Condition area 3:
    error code for condition 3
    error message for condition 3
    ... other condition information items ...
```

Diagnostics Area Information Items

The diagnostics area contains statement and condition information items. Numeric items are integers. The character set for character items is UTF-8. No item can be \texttt{NULL}. If a statement or condition item is not set by a statement that populates the diagnostics area, its value is 0 or the empty string, depending on the item data type.

The statement information part of the diagnostics area contains these items:

- \textbf{NUMBER}: An integer indicating the number of condition areas that have information.
- \textbf{ROW_COUNT}: An integer indicating the number of rows affected by the statement. \texttt{ROW_COUNT} has the same value as the \texttt{ROW_COUNT()} function (see Section 12.16, \textit{Information Functions}).

The condition information part of the diagnostics area contains a condition area for each condition. Condition areas are numbered from 1 to the value of the \texttt{NUMBER} statement condition item. If \texttt{NUMBER} is 0, there are no condition areas.

Each condition area contains the items in the following list. All items are standard SQL except \texttt{MYSQL_ERRNO}, which is a MySQL extension. The definitions apply for conditions generated other than by a signal (that is, by a \texttt{SIGNAL} or \texttt{RESIGNAL} statement). For nonsignal conditions, MySQL populates only those condition items not described as always empty. The effects of signals on the condition area are described later.

- \textbf{CLASS_ORIGIN}: A string containing the class of the \texttt{RETURNED_SQLSTATE} value. If the \texttt{RETURNED_SQLSTATE} value begins with a class value defined in SQL standards document ISO 9075-2 (section 24.1, SQLSTATE), \texttt{CLASS_ORIGIN} is \texttt{'ISO 9075'}. Otherwise, \texttt{CLASS_ORIGIN} is \texttt{'MySQL'}.
- \textbf{SUBCLASS_ORIGIN}: A string containing the subclass of the \texttt{RETURNED_SQLSTATE} value. If \texttt{CLASS_ORIGIN} is \texttt{'ISO 9075'} or \texttt{RETURNED_SQLSTATE} ends with \texttt{'000'}, \texttt{SUBCLASS_ORIGIN} is \texttt{'ISO 9075'}. Otherwise, \texttt{SUBCLASS_ORIGIN} is \texttt{'MySQL'}.
- \textbf{RETURNED_SQLSTATE}: A string that indicates the \texttt{SQLSTATE} value for the condition.
- \textbf{MESSAGE_TEXT}: A string that indicates the error message for the condition.
- \textbf{MYSQL_ERRNO}: An integer that indicates the MySQL error code for the condition.
- \textbf{CONSTRAINT_CATALOG, CONSTRAINT_SCHEMA, CONSTRAINT_NAME}: Strings that indicate the catalog, schema, and name for a violated constraint. They are always empty.
- \textbf{CATALOG_NAME, SCHEMA_NAME, TABLE_NAME, COLUMN_NAME}: Strings that indicate the catalog, schema, table, and column related to the condition. They are always empty.
- \textbf{CURSOR_NAME}: A string that indicates the cursor name. This is always empty.

For the \texttt{RETURNED_SQLSTATE}, \texttt{MESSAGE_TEXT}, and \texttt{MYSQL_ERRNO} values for particular errors, see \textit{Server Error Message Reference}.
If a `SIGNAL` (or `RESIGNAL`) statement populates the diagnostics area, its `SET` clause can assign to any condition information item except `RETURNED_SQLSTATE` any value that is legal for the item data type. `SIGNAL` also sets the `RETURNED_SQLSTATE` value, but not directly in its `SET` clause. That value comes from the `SIGNAL` statement `SQLSTATE` argument.

`SIGNAL` also sets statement information items. It sets `NUMBER` to 1. It sets `ROW_COUNT` to –1 for errors and 0 otherwise.

**How the Diagnostics Area is Cleared and Populated**

Most nondiagnostic SQL statements populate the diagnostics area automatically, and its contents can be set explicitly with the `SIGNAL` and `RESIGNAL` statements. The diagnostics area can be examined with `GET DIAGNOSTICS` to extract specific items, or with `SHOW WARNINGS` or `SHOW ERRORS` to see conditions or errors.

SQL statements clear and set the diagnostics area as follows:

- When the server starts executing a statement after parsing it, it clears the diagnostics area for nondiagnostic statements that use tables. Diagnostic statements do not clear the diagnostics area. These statements are diagnostic:
  - `GET DIAGNOSTICS`
  - `SHOW ERRORS`
  - `SHOW WARNINGS`

- If a statement raises a condition, the diagnostics area is cleared of conditions that belong to earlier statements. The exception is that conditions raised by `GET DIAGNOSTICS` and `RESIGNAL` are added to the diagnostics area without clearing it.

Thus, even a statement that does not normally clear the diagnostics area when it begins executing clears it if the statement raises a condition.

The following example shows the effect of various statements on the diagnostics area, using `SHOW WARNINGS` to display information about conditions stored there.

This `DROP_TABLE` statement uses a table, so it clears the diagnostics area and populates it when the condition occurs:

```sql
mysql> DROP TABLE IF EXISTS test.no_such_table;
Query OK, 0 rows affected, 1 warning (0.01 sec)

mysql> SHOW WARNINGS;
+-------+------+------------------------------------+
| Level | Code | Message                            |
+-------+------+------------------------------------+
| Note  | 1051 | Unknown table 'test.no_such_table' |
+-------+------+------------------------------------+
1 row in set (0.00 sec)
```

This `SET` statement does not use tables and does not generate warnings, so it leaves the diagnostics area unchanged:

```sql
mysql> SET @x = 1;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW WARNINGS;
+-------+------+------------------------------------+
| Level | Code | Message                            |
+-------+------+------------------------------------+
| Note  | 1051 | Unknown table 'test.no_such_table' |
+-------+------+------------------------------------+
1 row in set (0.00 sec)
```
Condition Handling

This SET statement generates an error, so it clears and populates the diagnostics area:

```sql
mysql> SET @x = @@x;
ERROR 1193 (HY000): Unknown system variable 'x'
```

```sql
mysql> SHOW WARNINGS;
+-------+------+-----------------------------+
| Level | Code | Message                     |
|-------+------+-----------------------------+
| Error | 1193 | Unknown system variable 'x' |
+-------+------+-----------------------------+
1 row in set (0.00 sec)
```

The previous SET statement produced a single condition, so 1 is the only valid condition number for GET DIAGNOSTICS at this point. The following statement uses a condition number of 2, which produces a warning that is added to the diagnostics area without clearing it:

```sql
mysql> GET DIAGNOSTICS CONDITION 2 @p = MESSAGE_TEXT;
Query OK, 0 rows affected, 1 warning (0.00 sec)
```

```sql
mysql> SHOW WARNINGS;
+-------+------+------------------------------+
| Level | Code | Message                      |
|-------+------+------------------------------+
| Error | 1193 | Unknown system variable 'xx' |
| Error | 1753 | Invalid condition number     |
+-------+------+------------------------------+
2 rows in set (0.00 sec)
```

Now there are two conditions in the diagnostics area, so the same GET DIAGNOSTICS statement succeeds:

```sql
mysql> GET DIAGNOSTICS CONDITION 2 @p = MESSAGE_TEXT;
Query OK, 0 rows affected (0.00 sec)
```

```sql
mysql> SELECT @p;
+--------------------------+
| @p                       |
|----------------------------+
| Invalid condition number  |
+--------------------------+
1 row in set (0.01 sec)
```

Diagnostics Area-Related System Variables

Certain system variables control or are related to some aspects of the diagnostics area:

- `max_error_count` controls the number of condition areas in the diagnostics area. If more conditions than this occur, MySQL silently discards information for the excess conditions. (Conditions added by `RESIGNAL` are always added, with older conditions being discarded as necessary to make room.)

- `warning_count` indicates the number of conditions that occurred. This includes errors, warnings, and notes. Normally, `NUMBER` and `warning_count` are the same. However, as the number of conditions generated exceeds `max_error_count`, the value of `warning_count` continues to rise whereas `NUMBER` remains capped at `max_error_count` because no additional conditions are stored in the diagnostics area.

- `error_count` indicates the number of errors that occurred. This value includes “not found” and exception conditions, but excludes warnings and notes. Like `warning_count`, its value can exceed `max_error_count`.

- If the `sql_notes` system variable is set to 0, notes are not stored and do not increment `warning_count`.

Example: If `max_error_count` is 10, the diagnostics area can contain a maximum of 10 condition areas. Suppose that a statement raises 20 conditions, 12 of which are errors. In that case, the
diagnostics area contains the first 10 conditions, \texttt{NUMBER} is 10, \texttt{warning_count} is 20, and \texttt{error_count} is 12.

Changes to the value of \texttt{max_error_count} have no effect until the next attempt to modify the diagnostics area. If the diagnostics area contains 10 condition areas and \texttt{max_error_count} is set to 5, that has no immediate effect on the size or content of the diagnostics area.

Before MySQL 5.6, statement information items are not available directly. \texttt{ROW_COUNT} can be obtained by calling the \texttt{ROW_COUNT()} function. \texttt{NUMBER} is approximated by the value of the \texttt{warning_count} system variable. However, whereas \texttt{NUMBER} is capped to the value of \texttt{max_error_count}, \texttt{warning_count} is not.

### 13.6.7.8 Condition Handling and OUT or INOUT Parameters

If a stored procedure exits with an unhandled exception, modified values of \texttt{OUT} and \texttt{INOUT} parameters are not propagated back to the caller.

If an exception is handled by a \texttt{CONTINUE} or \texttt{EXIT} handler that contains a \texttt{RESIGNAL} statement, execution of \texttt{RESIGNAL} pops the Diagnostics Area stack, thus signalling the exception (that is, the information that existed before entry into the handler). If the exception is an error, the values of \texttt{OUT} and \texttt{INOUT} parameters are not propagated back to the caller.

### 13.6.7.9 Restrictions on Condition Handling

\texttt{SIGNAL}, \texttt{RESIGNAL}, and \texttt{GET DIAGNOSTICS} are not permissible as prepared statements. For example, this statement is invalid:

```sql
PREPARE stmt1 FROM 'SIGNAL SQLSTATE "02000"';
```

\texttt{SQLSTATE} values in class '04' are not treated specially. They are handled the same as other exceptions.

Standard SQL has a diagnostics area stack, containing a diagnostics area for each nested execution context. Standard SQL syntax includes \texttt{GET STACKED DIAGNOSTICS} for referring to stacked areas. MySQL does not support the \texttt{STACKED} keyword because there is a single diagnostics area containing information from the most recent statement that wrote to it. See also Section 13.6.7.7, “The MySQL Diagnostics Area”.

In standard SQL, the first condition relates to the \texttt{SQLSTATE} value returned for the previous SQL statement. In MySQL, this is not guaranteed, so to get the main error, you cannot do this:

```sql
GET DIAGNOSTICS CONDITION 1 @errno = MYSQL_ERRNO;
```

Instead, do this:

```sql
GET DIAGNOSTICS @cno = NUMBER;
GET DIAGNOSTICS CONDITION @cno @errno = MYSQL_ERRNO;
```

### 13.7 Database Administration Statements

#### 13.7.1 Account Management Statements

MySQL account information is stored in the tables of the \texttt{mysql} system database. This database and the access control system are discussed extensively in Chapter 5, \textit{MySQL Server Administration}, which you should consult for additional details.

\begin{itemize}
  \item \textbf{Important}
  
  Some MySQL releases introduce changes to the grant tables to add new privileges or features. To make sure that you can take advantage of any new
Account Management Statements

capabilities, update your grant tables to the current structure whenever you upgrade MySQL. See Section 2.11, “Upgrading MySQL”.

When the read_only system variable is enabled, account-management statements require the SUPER privilege, in addition to any other required privileges. This is because they modify tables in the mysql system database.

13.7.1.1 ALTER USER Statement

```
ALTER USER user_specification [, user_specification] ...
```

user_specification:
```
user PASSWORD EXPIRE
```

The ALTER USER statement modifies MySQL accounts. An error occurs if you try to modify a nonexistent account.

To use ALTER USER, you must have the global CREATE USER privilege or the UPDATE privilege for the mysql system database. When the read_only system variable is enabled, ALTER USER additionally requires the SUPER privilege.

Each account name uses the format described in Section 6.2.4, “Specifying Account Names”. The host name part of the account name, if omitted, defaults to '%'. It is also possible to specify CURRENT_USER or CURRENT_USER() to refer to the account associated with the current session.

For each account, ALTER USER expires its password. For example:

```
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE;
```

Password expiration for an account affects the corresponding row of the mysql.user system table: The server sets the password_expired column to 'Y'.

A client session operates in restricted mode if the account password has been expired. In restricted mode, operations performed within the session result in an error until the user establishes a new account password:

```
mysql> SELECT 1;
ERROR 1820 (HY000): You must SET PASSWORD before executing this statement
mysql> SET PASSWORD = PASSWORD('new_password');
Query OK, 0 rows affected (0.01 sec)
mysql> SELECT 1;
+---+
| 1 |
+---+
1 row in set (0.00 sec)
```

This restricted mode of operation permits SET statements, which is useful if the account password has a hashing format that requires oldPasswords to be set to a value different from its default before using SET PASSWORD.

It is possible for an administrative user to reset the account password, but any existing sessions for the account remain restricted. A client using the account must disconnect and reconnect before statements can be executed successfully.

**Note**

Although it is possible to “reset” an expired password by setting it to its current value, it is preferable, as a matter of good policy, to choose a different password.
13.7.1.2 CREATE USER Statement

CREATE USER
  user [auth_option] [, user [auth_option]] ...

user:
  (see Section 6.2.4, "Specifying Account Names")

auth_option: {
  IDENTIFIED BY [PASSWORD] 'auth_string'
  | IDENTIFIED WITH auth_plugin [AS 'auth_string']
}

The CREATE USER statement creates new MySQL accounts. An error occurs if you try to create an account that already exists.

To use CREATE USER, you must have the global CREATE USER privilege, or the INSERT privilege for the mysql system database. When the read_only system variable is enabled, CREATE USER additionally requires the SUPER privilege.

![Important]

Under some circumstances, CREATE USER may be recorded in server logs or on the client side in a history file such as ~/.mysql_history, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see Section 6.1.2.3, “Passwords and Logging”. For similar information about client-side logging, see Section 4.5.1.3, “mysql Client Logging”.

For each account, CREATE USER creates a new row in the mysql.user system table with no privileges and assigns the account an authentication plugin. Depending on the syntax used, CREATE USER may also assign the account a password.

An account when first created has no privileges. To assign privileges, use the GRANT statement.

Each user value naming an account may be followed by an optional auth_option value that specifies how authentication occurs for clients that use the account. This part of CREATE USER syntax is shared with GRANT, so the description here applies to GRANT as well.

Each account name uses the format described in Section 6.2.4, “Specifying Account Names”. For example:

CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';

The host name part of the account name, if omitted, defaults to '%'.

The server assigns an authentication plugin and password to each account as follows, depending on whether the user specification clause includes IDENTIFIED BY or IDENTIFIED WITH to specify authentication information:

- With IDENTIFIED BY, the server assigns the plugin implicitly. The 'auth_string' value is cleartext and is passed to the plugin for possible hashing. The result returned by the plugin is stored as the password. A plugin may use the value as specified, in which case no hashing occurs. If the optional PASSWORD keyword is given, the behavior is the same except that if the plugin requires a hashed string, the string is assumed to be already hashed in the format the plugin requires, and is stored as is as the password.

- With IDENTIFIED WITH, the server assigns the specified plugin and the account has no password. If the optional AS 'auth_string' clause is given, the string is stored as is as the password. If the plugin requires a hashed string, the string is assumed to be already hashed in the format the plugin requires.
Account Management Statements

• With neither IDENTIFIED BY nor IDENTIFIED WITH, the server assigns the plugin implicitly and the account has no password.

If the account has no password, the password information in the account row in the mysql.user table remains empty, which is insecure. To set the password, use SET_PASSWORD. See Section 13.7.1.7, “SET PASSWORD Statement”.

For implicit plugin assignment, the default plugin becomes the value of the plugin column in the account's mysql.user system table row. The default plugin is mysql_native_password unless the --default-authentication-plugin option is set otherwise at server startup.

For client connections that use a given account, the server invokes the authentication plugin assigned to the account and the client must provide credentials as required by the authentication method that the plugin implements. If the server cannot find the plugin, either at account-creation time or connect time, an error occurs.

If an account's mysql.user table row has a nonempty plugin column:

• The server authenticates client connection attempts using the named plugin.

• Changes to the account password using SET_PASSWORD with PASSWORD() must be made with the old_passwords system variable set to the value required by the authentication plugin, so that PASSWORD() uses the appropriate password hashing method. If the plugin is mysql_old_password, the password can also be changed using SET_PASSWORD with OLD_PASSWORD(), which uses pre-4.1 password hashing regardless of the value of old_passwords.

If an account's mysql.user table row has an empty plugin column:

• The server authenticates client connection attempts using the mysql_native_password or mysql_old_password authentication plugin, depending on the hash format of the password stored in the Password column.

• Changes to the account password using SET_PASSWORD can be made with PASSWORD(), with old_passwords set to 0 or 1 for 4.1 or pre-4.1 password hashing, respectively, or with OLD_PASSWORD(), which uses pre-4.1 password hashing regardless of the value of old_passwords.

CREATE USER examples:

• To specify an authentication plugin for an account, use IDENTIFIED WITH auth_plugin. The plugin name can be a quoted string literal or an unquoted name. 'auth_string' is an optional quoted string literal to pass to the plugin. The plugin interprets the meaning of the string, so its format is plugin specific and it is stored in the authentication_string column as given. (This value is meaningful only for plugins that use that column.) Consult the documentation for a given plugin for information about the authentication string values it accepts, if any.

CREATE USER 'jeffrey'@'localhost' IDENTIFIED WITH mysql_native_password;

The server assigns the given authentication plugin to the account but no password. Clients must provide no password when they connect. However, an account with no password is insecure. To ensure that an account uses a specific authentication plugin and has a password with the corresponding hash format, specify the plugin explicitly with IDENTIFIED WITH, then use SET_PASSWORD to set the password:

CREATE USER 'jeffrey'@'localhost' IDENTIFIED WITH mysql_native_password;
SET old_passwords = 0;
SET PASSWORD FOR 'jeffrey'@'localhost' = PASSWORD('password');

Changes to the account password using SET_PASSWORD with PASSWORD() must be made with the old_passwords system variable set to the value required by the account's authentication
plugin, so that PASSWORD() uses the appropriate password hashing method. Therefore, to use the sha256_password or mysql_old_password plugin instead, name that plugin in the CREATE USER statement and set old_passwords to 2 or 1, respectively, before using SET PASSWORD. (Use of mysql_old_password is not recommended. It is deprecated and support for it will be removed in a future MySQL release.)

• To specify a password for an account at account-creation time, use IDENTIFIED BY with the literal cleartext password value:

```sql
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';
```

The server assigns an authentication plugin to the account implicitly, as described previously, and assigns the given password. Clients must provide the given password when they connect.

If the implicitly assigned plugin is mysql_native_password, the old_passwords system variable must be set to 0. Otherwise, CREATE USER does not hash the password in the format required by the plugin and an error occurs:

```sql
mysql> SET old_passwords = 1;
mysql> CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';
ERROR 1827 (HY000): The password hash doesn't have the expected format. Check if the correct password algorithm is being used with the PASSWORD() function.
```

```sql
mysql> SET old_passwords = 0;
mysql> CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';
Query OK, 0 rows affected (0.00 sec)
```

• To avoid specifying the cleartext password if you know its hash value (the value that PASSWORD() would return for the password), specify the hash value preceded by the keyword PASSWORD:

```sql
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY PASSWORD '*90E462C37378CED12064BB3388B827D2BA3A9B689';
```

The server assigns an authentication plugin to the account implicitly, as described previously, and assigns the given password. The password hash must be in the format required by the assigned plugin. Clients must provide the password when they connect.

• To enable the user to connect with no password, include no IDENTIFIED BY clause:

```sql
CREATE USER 'jeffrey'@'localhost';
```

The server assigns an authentication plugin to the account implicitly, as described previously, but no password. Clients must provide no password when they connect. However, an account with no password is insecure. To avoid this, use SET PASSWORD to set the account password.

As mentioned previously, implicit plugin assignment depends on the default authentication plugin. Permitted values of --default-authentication-plugin are mysql_native_plugin and sha256_password, but not mysql_old_password. This means it is not possible to set the default plugin so as to be able to create an account that uses mysql_old_password with CREATE USER ... IDENTIFIED BY Password() syntax. To create an account that uses mysql_old_password, use CREATE USER ... IDENTIFIED WITH to name the plugin explicitly, then set the password:

```sql
CREATE USER 'jeffrey'@'localhost' IDENTIFIED WITH mysql_old_password;
SET old_passwords = 1;
SET PASSWORD FOR 'jeffrey'@'localhost' = PASSWORD('password');
```

However, the preceding procedure is not recommended because mysql_old_password is deprecated.

For additional information about setting passwords and authentication plugins, see Section 6.2.9, “Assigning Account Passwords”, and Section 6.2.11, “Pluggable Authentication”.

### 13.7.1.3 DROP USER Statement
The `DROP USER` statement removes one or more MySQL accounts and their privileges. It removes privilege rows for the account from all grant tables. An error occurs for accounts that do not exist.

To use `DROP USER`, you must have the global `CREATE USER` privilege, or the `DELETE` privilege for the `mysql` system database. When the `read_only` system variable is enabled, `DROP USER` additionally requires the `SUPER` privilege.

Each account name uses the format described in Section 6.2.4, “Specifying Account Names”. For example:

```
DROP USER 'jeffrey'@'localhost';
```

The host name part of the account name, if omitted, defaults to '%'.

**Important**

`DROP USER` does not automatically close any open user sessions. Rather, in the event that a user with an open session is dropped, the statement does not take effect until that user's session is closed. Once the session is closed, the user is dropped, and that user's next attempt to log in will fail. This is by design.

`DROP USER` does not automatically drop or invalidate databases or objects within them that the old user created. This includes stored programs or views for which the `DEFINER` attribute names the dropped user. Attempts to access such objects may produce an error if they execute in definer security context. (For information about security context, see Section 20.6, “Stored Object Access Control”.)

### 13.7.1.4 GRANT Statement

```
GRANT priv_type [(column_list)]
  [, priv_type [(column_list)]] ...
ON [object_type] priv_level
TO user [auth_option] [, user [auth_option]] ...
  [REQUIRE {NONE | tls_option [[AND] tls_option] ...}]
  [WITH {GRANT OPTION | resource_option} ...]
GRANT PROXY ON user
  TO user [, user] ...
  [WITH GRANT OPTION]
```

**object_type:**

- `TABLE`
- `FUNCTION`
- `PROCEDURE`

**priv_level:**

- `*`
- `*.*`
- `db_name.*`
- `db_name.tbl_name`
- `tbl_name`
- `db_name.routine_name`

**user:**

(see Section 6.2.4, “Specifying Account Names”)

**auth_option:**

- IDENTIFIED BY [PASSWORD] 'auth_string'
- IDENTIFIED WITH auth_plugin
- IDENTIFIED WITH auth_plugin AS 'auth_string'

**tls_option:**
The `GRANT` statement grants privileges to MySQL user accounts. There are several aspects to the `GRANT` statement, described under the following topics:

- **GRANT General Overview**
- **Object Quoting Guidelines**
- **Account Names and Passwords**
- **Privileges Supported by MySQL**
- **Global Privileges**
- **Database Privileges**
- **Table Privileges**
- **Column Privileges**
- **Stored Routine Privileges**
- **Proxy User Privileges**
- **Implicit Account Creation**
- **Other Account Characteristics**
- **MySQL and Standard SQL Versions of GRANT**

**GRANT General Overview**

The `GRANT` statement grants privileges to MySQL user accounts. `GRANT` also serves to specify other account characteristics such as use of secure connections and limits on access to server resources.

To grant a privilege with `GRANT`, you must have the `GRANT OPTION` privilege, and you must have the privileges that you are granting. (Alternatively, if you have the `UPDATE` privilege for the grant tables in the `mysql` system database, you can grant any account any privilege.) When the `read_only` system variable is enabled, `GRANT` additionally requires the `SUPER` privilege.

The `REVOKE` statement is related to `GRANT` and enables administrators to remove account privileges. See Section 13.7.1.6, “REVOKE Statement”.

Each account name uses the format described in Section 6.2.4, “Specifying Account Names”. For example:

```
GRANT ALL ON db1.* TO 'jeffrey'@'localhost';
```

The host name part of the account, if omitted, defaults to `'%'`.

Normally, a database administrator first uses `CREATE USER` to create an account, then `GRANT` to define its privileges and characteristics. For example:
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'password';
GRANT ALL ON db1.* TO 'jeffrey'@'localhost';
GRANT SELECT ON db2.invoice TO 'jeffrey'@'localhost';
GRANT USAGE ON *.* TO 'jeffrey'@'localhost' WITH MAX_QUERIES_PER_HOUR 90;

Note
Examples shown here include no IDENTIFIED clause. It is assumed that you establish passwords with CREATE USER at account-creation time to avoid creating insecure accounts.

If an account named in a GRANT statement does not already exist, GRANT may create it under the conditions described later in the discussion of the NO_AUTO_CREATE_USER SQL mode.

From the mysql program, GRANT responds with Query OK, 0 rows affected when executed successfully. To determine what privileges result from the operation, use SHOW GRANTS. See Section 13.7.5.22, “SHOW GRANTS Statement”.

Important
Under some circumstances, GRANT may be recorded in server logs or on the client side in a history file such as ~/.mysql_history, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see Section 6.1.2.3, “Passwords and Logging”. For similar information about client-side logging, see Section 4.5.1.3, “mysql Client Logging”.

GRANT supports host names up to 60 characters long. User names can be up to 16 characters. Database, table, column, and routine names can be up to 64 characters.

Warning
Do not attempt to change the permissible length for user names by altering the mysql.user system table. Doing so results in unpredictable behavior which may even make it impossible for users to log in to the MySQL server. Never alter the structure of tables in the mysql system database in any manner except by means of the procedure described in Section 2.11, “Upgrading MySQL”.

Object Quoting Guidelines
Several objects within GRANT statements are subject to quoting, although quoting is optional in many cases: Account, database, table, column, and routine names. For example, if a user_name or host_name value in an account name is legal as an unquoted identifier, you need not quote it. However, quotation marks are necessary to specify a user_name string containing special characters (such as -), or a host_name string containing special characters or wildcard characters such as % (for example, 'test-user'@'%.com'). Quote the user name and host name separately.

To specify quoted values:

- Quote database, table, column, and routine names as identifiers.
- Quote user names and host names as identifiers or as strings.
- Quote passwords as strings.

The _ and % wildcards are permitted when specifying database names in GRANT statements that grant privileges at the database level (GRANT ... ON db_name.*). This means, for example, that to
use a \_ character as part of a database name, specify it as \_ in the GRANT statement, to prevent the user from being able to access additional databases matching the wildcard pattern (for example, GRANT ... ON `foo\_bar`.* TO ...).

When a database name not is used to grant privileges at the database level, but as a qualifier for granting privileges to some other object such as a table or routine (for example, GRANT ... ON db_name.tbl_name), wildcard characters are treated as normal characters.

Account Names and Passwords

A user value in a GRANT statement indicates a MySQL account to which the statement applies. To accommodate granting rights to users from arbitrary hosts, MySQL supports specifying the user value in the form 'user_name'@'host_name'.

You can specify wildcards in the host name. For example, 'user_name'@'%.example.com' applies to user_name for any host in the example.com domain, and 'user_name'@'198.51.100.\%' applies to user_name for any host in the 198.51.100 class C subnet.

The simple form 'user_name' is a synonym for 'user_name'@'\%'.

MySQL does not support wildcards in user names. To refer to an anonymous user, specify an account with an empty user name with the GRANT statement:

```
GRANT ALL ON test.* TO ''@'localhost' ...;
```

In this case, any user who connects from the local host with the correct password for the anonymous user will be permitted access, with the privileges associated with the anonymous-user account.

For additional information about user name and host name values in account names, see Section 6.2.4, “Specifying Account Names”.

Warning

If you permit local anonymous users to connect to the MySQL server, you should also grant privileges to all local users as 'user_name'@'localhost'. Otherwise, the anonymous user account for localhost in the mysql.user system table (created during MySQL installation) is used when named users try to log in to the MySQL server from the local machine. For details, see Section 6.2.5, “Access Control, Stage 1: Connection Verification”.

To determine whether this issue applies to you, execute the following query, which lists any anonymous users:

```
SELECT Host, User FROM mysql.user WHERE User='';
```

To avoid the problem just described, delete the local anonymous user account using this statement:

```
DROP USER ''@'localhost';
```

For GRANT syntax that permits an auth_option value to follow a user value, auth_option begins with IDENTIFIED and indicates how the account authenticates by specifying an account authentication plugin, credentials (for example, a password), or both. Syntax of the auth_option clause is the same as for the CREATE USER statement. For details, see Section 13.7.1.2, “CREATE USER Statement”.

When IDENTIFIED is present and you have the global grant privilege (GRANT OPTION), any password specified becomes the new password for the account, even if the account exists and already has a password. Without IDENTIFIED, the account password remains unchanged.
Privileges Supported by MySQL

The following table summarizes the permissible \texttt{priv_type} privilege types that can be specified for the \texttt{GRANT} and \texttt{REVOKE} statements, and the levels at which each privilege can be granted. For additional information about each privilege, see Section 6.2.2, “Privileges Provided by MySQL”.

Table 13.8 Permissible Privileges for GRANT and REVOKE

<table>
<thead>
<tr>
<th>Privilege</th>
<th>Meaning and Grantable Levels</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL [PRIVILEGES]</td>
<td>Grant all privileges at specified access level except \texttt{GRANT OPTION} and \texttt{PROXY}.</td>
</tr>
<tr>
<td>ALTER</td>
<td>Enable use of \texttt{ALTER TABLE}. Levels: Global, database, table.</td>
</tr>
<tr>
<td>ALTER ROUTINE</td>
<td>Enable stored routines to be altered or dropped. Levels: Global, database, routine.</td>
</tr>
<tr>
<td>CREATE</td>
<td>Enable database and table creation. Levels: Global, database, table.</td>
</tr>
<tr>
<td>CREATE ROUTINE</td>
<td>Enable stored routine creation. Levels: Global, database.</td>
</tr>
<tr>
<td>CREATE TABLESPACE</td>
<td>Enable tablespaces and log file groups to be created, altered, or dropped. Level: Global.</td>
</tr>
<tr>
<td>CREATE TEMPORARY TABLES</td>
<td>Enable use of \texttt{CREATE TEMPORARY TABLE}. Levels: Global, database.</td>
</tr>
<tr>
<td>CREATE USER</td>
<td>Enable use of \texttt{CREATE USER}, \texttt{DROP USER}, \texttt{RENAME USER}, and \texttt{REVOKE ALL PRIVILEGES}. Level: Global.</td>
</tr>
<tr>
<td>CREATE VIEW</td>
<td>Enable views to be created or altered. Levels: Global, database, table.</td>
</tr>
<tr>
<td>DELETE</td>
<td>Enable use of \texttt{DELETE}. Level: Global, database, table.</td>
</tr>
<tr>
<td>DROP</td>
<td>Enable databases, tables, and views to be dropped. Levels: Global, database, table.</td>
</tr>
<tr>
<td>EVENT</td>
<td>Enable use of events for the Event Scheduler. Levels: Global, database.</td>
</tr>
<tr>
<td>EXECUTE</td>
<td>Enable the user to execute stored routines. Levels: Global, database, routine.</td>
</tr>
<tr>
<td>FILE</td>
<td>Enable the user to cause the server to read or write files. Level: Global.</td>
</tr>
<tr>
<td>GRANT OPTION</td>
<td>Enable privileges to be granted to or removed from other accounts. Levels: Global, database, routine, proxy.</td>
</tr>
<tr>
<td>INDEX</td>
<td>Enable indexes to be created or dropped. Levels: Global, database, table.</td>
</tr>
<tr>
<td>INSERT</td>
<td>Enable use of \texttt{INSERT}. Levels: Global, database, table, column.</td>
</tr>
<tr>
<td>LOCK TABLES</td>
<td>Enable use of \texttt{LOCK TABLES} on tables for which you have the \texttt{SELECT} privilege. Levels: Global, database.</td>
</tr>
<tr>
<td>PROCESS</td>
<td>Enable the user to see all processes with \texttt{SHOW PROCESSLIST}. Level: Global.</td>
</tr>
<tr>
<td>PROXY</td>
<td>Enable user proxying. Level: From user to user.</td>
</tr>
<tr>
<td>REFERENCES</td>
<td>Enable foreign key creation. Levels: Global, database, table, column.</td>
</tr>
<tr>
<td>RELOAD</td>
<td>Enable use of \texttt{FLUSH} operations. Level: Global.</td>
</tr>
<tr>
<td>REPLICATION CLIENT</td>
<td>Enable the user to ask where source or replica servers are. Level: Global.</td>
</tr>
<tr>
<td>REPLICATION SLAVE</td>
<td>Enable replicas to read binary log events from the source. Level: Global.</td>
</tr>
<tr>
<td>SELECT</td>
<td>Enable use of \texttt{SELECT}. Levels: Global, database, table, column.</td>
</tr>
<tr>
<td>SHOW DATABASES</td>
<td>Enable \texttt{SHOW DATABASES} to show all databases. Level: Global.</td>
</tr>
</tbody>
</table>
Privilege | Meaning and Grantable Levels
--- | ---
**SHOW VIEW** | Enable use of `SHOW CREATE VIEW`. Levels: Global, database, table.
**SHUTDOWN** | Enable use of `mysqladmin shutdown`. Level: Global.
**SUPER** | Enable use of other administrative operations such as `CHANGE MASTER TO, KILL, PURGE BINARY LOGS, SET GLOBAL, and mysqladmin debug` command. Level: Global.
**TRIGGER** | Enable trigger operations. Levels: Global, database, table.
**UPDATE** | Enable use of `UPDATE`. Levels: Global, database, table, column.
**USAGE** | Synonym for “no privileges”

A trigger is associated with a table. To create or drop a trigger, you must have the **TRIGGER** privilege for the table, not the trigger.

In **GRANT** statements, the **ALL [PRIVILEGES]** or **PROXY** privilege must be named by itself and cannot be specified along with other privileges. **ALL [PRIVILEGES]** stands for all privileges available for the level at which privileges are to be granted except for the **GRANT OPTION** and **PROXY** privileges.

**USAGE** can be specified to create a user that has no privileges, or to specify the **REQUIRE** or **WITH** clauses for an account without changing its existing privileges.

MySQL account information is stored in the tables of the **mysql** system database. For additional details, consult Section 6.2, “Access Control and Account Management”, which discusses the **mysql** system database and the access control system extensively.

If the grant tables hold privilege rows that contain mixed-case database or table names and the **lower_case_table_names** system variable is set to a nonzero value, **REVOKE** cannot be used to revoke these privileges. It will be necessary to manipulate the grant tables directly. (**GRANT** will not create such rows when **lower_case_table_names** is set, but such rows might have been created prior to setting that variable.)

Privileges can be granted at several levels, depending on the syntax used for the **ON** clause. For **REVOKE**, the same **ON** syntax specifies which privileges to remove.

For the global, database, table, and routine levels, **GRANT ALL** assigns only the privileges that exist at the level you are granting. For example, **GRANT ALL ON db_name.*** is a database-level statement, so it does not grant any global-only privileges such as **FILE**. Granting **ALL** does not assign the **GRANT OPTION** or **PROXY** privilege.

The **object_type** clause, if present, should be specified as **TABLE, FUNCTION, or PROCEDURE** when the following object is a table, a stored function, or a stored procedure.

The privileges that a user holds for a database, table, column, or routine are formed additively as the logical **OR** of the account privileges at each of the privilege levels, including the global level. It is not possible to deny a privilege granted at a higher level by absence of that privilege at a lower level. For example, this statement grants the **SELECT** and **INSERT** privileges globally:

```
GRANT SELECT, INSERT ON *.* TO u1;
```

The globally granted privileges apply to all databases, tables, and columns, even though not granted at any of those lower levels.

Details of the privilege-checking procedure are presented in Section 6.2.6, “Access Control, Stage 2: Request Verification”.

If you are using table, column, or routine privileges for even one user, the server examines table, column, and routine privileges for all users and this slows down MySQL a bit. Similarly, if you limit the number of queries, updates, or connections for any users, the server must monitor these values.
MySQL enables you to grant privileges on databases or tables that do not exist. For tables, the privileges to be granted must include the `CREATE` privilege. This behavior is by design, and is intended to enable the database administrator to prepare user accounts and privileges for databases or tables that are to be created at a later time.

**Important**

MySQL does not automatically revoke any privileges when you drop a database or table. However, if you drop a routine, any routine-level privileges granted for that routine are revoked.

### Global Privileges

Global privileges are administrative or apply to all databases on a given server. To assign global privileges, use `ON *.*` syntax:

```sql
GRANT ALL ON *.* TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON *.* TO 'someuser'@'somehost';
```

The `CREATE TABLESPACE`, `CREATE USER`, `FILE`, `PROCESS`, `RELOAD`, `REPLICATION CLIENT`, `REPLICATION_SLAVE`, `SHOW DATABASES`, `SHUTDOWN`, and `SUPER` privileges are administrative and can only be granted globally.

Other privileges can be granted globally or at more specific levels.

- `GRANT OPTION` granted at the global level for any global privilege applies to all global privileges.
- MySQL stores global privileges in the `mysql.user` system table.

### Database Privileges

Database privileges apply to all objects in a given database. To assign database-level privileges, use `ON db_name.*` syntax:

```sql
GRANT ALL ON mydb.* TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON mydb.* TO 'someuser'@'somehost';
```

If you use `ON *` syntax (rather than `ON *.*`), privileges are assigned at the database level for the default database. An error occurs if there is no default database.

- The `CREATE`, `DROP`, `EVENT`, `GRANT OPTION`, `LOCK TABLES`, and `REFERENCES` privileges can be specified at the database level. Table or routine privileges also can be specified at the database level, in which case they apply to all tables or routines in the database.

MySQL stores database privileges in the `mysql.db` system table.

### Table Privileges

Table privileges apply to all columns in a given table. To assign table-level privileges, use `ON db_name.tbl_name` syntax:

```sql
GRANT ALL ON mydb.mytbl TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON mydb.mytbl TO 'someuser'@'somehost';
```

If you specify `tbl_name` rather than `db_name.tbl_name`, the statement applies to `tbl_name` in the default database. An error occurs if there is no default database.

The permissible `priv_type` values at the table level are `ALTER`, `CREATE VIEW`, `CREATE`, `DELETE`, `DROP`, `GRANT OPTION`, `INDEX`, `INSERT`, `REFERENCES`, `SELECT`, `SHOW VIEW`, `TRIGGER`, and `UPDATE`.

Table-level privileges apply to base tables and views. They do not apply to tables created with `CREATE TEMPORARY TABLE`, even if the table names match. For information about `TEMPORARY` table privileges, see Section 13.1.17.2, “CREATE TEMPORARY TABLE Statement”.

1726
MySQL stores table privileges in the `mysql.tables_priv` system table.

### Column Privileges

Column privileges apply to single columns in a given table. Each privilege to be granted at the column level must be followed by the column or columns, enclosed within parentheses.

```
GRANT SELECT (col1), INSERT (col1, col2) ON mydb.mytbl TO 'someuser'@'somehost';
```

The permissible `priv_type` values for a column (that is, when you use a `column_list` clause) are `INSERT, REFERENCES, SELECT, and UPDATE`.

MySQL stores column privileges in the `mysql.columns_priv` system table.

### Stored Routine Privileges

The `ALTER ROUTINE, CREATE ROUTINE, EXECUTE, and GRANT OPTION` privileges apply to stored routines (procedures and functions). They can be granted at the global and database levels. Except for `CREATE ROUTINE`, these privileges can be granted at the routine level for individual routines.

```
GRANT CREATE ROUTINE ON mydb.* TO 'someuser'@'somehost';
GRANT EXECUTE ON PROCEDURE mydb.myproc TO 'someuser'@'somehost';
```

The permissible `priv_type` values at the routine level are `ALTER ROUTINE, EXECUTE, and GRANT OPTION`. `CREATE ROUTINE` is not a routine-level privilege because you must have the privilege at the global or database level to create a routine in the first place.

MySQL stores routine-level privileges in the `mysql.procs_priv` system table.

### Proxy User Privileges

The `PROXY` privilege enables one user to be a proxy for another. The proxy user impersonates or takes the identity of the proxied user; that is, it assumes the privileges of the proxied user.

```
GRANT PROXY ON 'localuser'@'localhost' TO 'externaluser'@'somehost';
```

When `PROXY` is granted, it must be the only privilege named in the `GRANT` statement, the `REQUIRE` clause cannot be given, and the only permitted `WITH` option is `WITH GRANT OPTION`.

Proxying requires that the proxy user authenticate through a plugin that returns the name of the proxied user to the server when the proxy user connects, and that the proxy user have the `PROXY` privilege for the proxied user. For details and examples, see Section 6.2.12, “Proxy Users”.

MySQL stores proxy privileges in the `mysql.proxies_priv` system table.

### Implicit Account Creation

If an account named in a `GRANT` statement does not exist, the action taken depends on the `NO_AUTO_CREATE_USER` SQL mode:

- If `NO_AUTO_CREATE_USER` is not enabled, `GRANT` creates the account. *This is very insecure* unless you specify a nonempty password using `IDENTIFIED BY`.

- If `NO_AUTO_CREATE_USER` is enabled, `GRANT` fails and does not create the account, unless you specify a nonempty password using `IDENTIFIED BY` or name an authentication plugin using `IDENTIFIED WITH`.

As of MySQL 5.6.12, if the account already exists, `IDENTIFIED WITH` is prohibited because it is intended only for use when creating new accounts.

### Other Account Characteristics
MySQL can check X.509 certificate attributes in addition to the usual authentication that is based on the user name and credentials. For background information on the use of SSL with MySQL, see Section 6.3, “Using Encrypted Connections”.

The optional REQUIRE clause specifies SSL-related options for a MySQL account, using one or more tls_option values.

Order of REQUIRE options does not matter, but no option can be specified twice. The AND keyword is optional between REQUIRE options.

GRANT permits these tls_option values:

- **NONE**
  Indicates that the account has no SSL or X.509 requirements.

  ```
  GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  REQUIRE NONE;
  ```

  Unencrypted connections are permitted if the user name and password are valid. Encrypted connections can be used, at the client's option, if the client has the proper certificate and key files. That is, the client need not specify any SSL command options, in which case the connection will be unencrypted. To use an encrypted connection, the client must specify either the --ssl-ca option, or all three of the --ssl-ca, --ssl-key, and --ssl-cert options.

  **NONE** is the default if no SSL-related REQUIRE options are specified.

- **SSL**
  Tells the server to permit only encrypted connections for the account.

  ```
  GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  REQUIRE SSL;
  ```

  To connect, the client must specify the --ssl-ca option to authenticate the server certificate, and may additionally specify the --ssl-key and --ssl-cert options. If neither the --ssl-ca option nor --ssl-capath option is specified, the client does not authenticate the server certificate.

- **X509**
  Requires that clients present a valid certificate, but the exact certificate, issuer, and subject do not matter. The only requirement is that it should be possible to verify its signature with one of the CA certificates. Use of X.509 certificates always implies encryption, so the **SSL** option is unnecessary in this case.

  ```
  GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  REQUIRE X509;
  ```

  For accounts with **REQUIRE X509**, clients must specify the --ssl-key and --ssl-cert options to connect. (It is recommended but not required that --ssl-ca also be specified so that the public certificate provided by the server can be verified.) This is true for ISSUER and SUBJECT as well because those REQUIRE options imply the requirements of **X509**.

- **ISSUER 'issuer'**
  Requires that clients present a valid X.509 certificate issued by CA 'issuer'. If a client presents a certificate that is valid but has a different issuer, the server rejects the connection. Use of X.509 certificates always implies encryption, so the **SSL** option is unnecessary in this case.

  ```
  GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  REQUIRE ISSUER '/C=SE/ST=Stockholm/L=Stockholm/O=MySQL/CN=CA/emailAddress=ca@example.com';
  ```
Account Management Statements

Because **ISSUER** implies the requirements of **X509**, clients must specify the **--ssl-key** and **--ssl-cert** options to connect. (It is recommended but not required that **--ssl-ca** also be specified so that the public certificate provided by the server can be verified.)

**Note**

If MySQL is linked against a version of OpenSSL older than 0.9.6h, use **Email** rather than **emailAddress** in the 'issuer' value.

- **SUBJECT 'subject'**

Requires that clients present a valid X.509 certificate containing the subject **subject**. If a client presents a certificate that is valid but has a different subject, the server rejects the connection. Use of X.509 certificates always implies encryption, so the **SSL** option is unnecessary in this case.

```
grant all privileges on test.* to 'root'@'localhost'
require subject '/C=SE/ST=Stockholm/L=Stockholm/
  cn=client/emailAddress=client@example.com';
```

MySQL does a simple string comparison of the 'subject' value to the value in the certificate, so lettercase and component ordering must be given exactly as present in the certificate.

**Note**

Regarding **emailAddress**, see the note in the description of **REQUIRE ISSUER**.

Because **SUBJECT** implies the requirements of **X509**, clients must specify the **--ssl-key** and **--ssl-cert** options to connect. (It is recommended but not required that **--ssl-ca** also be specified so that the public certificate provided by the server can be verified.)

- **CIPHER 'cipher'**

Requires a specific cipher method for encrypting connections. This option is needed to ensure that ciphers and key lengths of sufficient strength are used. SSL itself can be weak if old algorithms using short encryption keys are used.

```
grant all privileges on test.* to 'root'@'localhost'
require cipher 'EDH-RSA-DES-CBC3-SHA';
```

The **SUBJECT**, **ISSUER**, and **CIPHER** options can be combined in the **REQUIRE** clause like this:

```
grant all privileges on test.* to 'root'@'localhost'
require subject '/C=SE/ST=Stockholm/L=Stockholm/
  cn=client/emailAddress=client@example.com'
and issuer '/C=SE/ST=Stockholm/L=Stockholm/
  O=MySQL/CN=CA/emailAddress=ca@example.com'
and cipher 'EDH-RSA-DES-CBC3-SHA';
```

The optional **WITH** clause is used for these purposes:

- To enable a user to grant privileges to other users
- To specify resource limits for a user

The **WITH GRANT OPTION** clause gives the user the ability to give to other users any privileges the user has at the specified privilege level.

To grant the **GRANT OPTION** privilege to an account without otherwise changing its privileges, do this:

```
grant usage on *.* to 'someuser'@'somehost' with grant option;
```
Be careful to whom you give the `GRANT OPTION` privilege because two users with different privileges may be able to combine privileges!

You cannot grant another user a privilege which you yourself do not have; the `GRANT OPTION` privilege enables you to assign only those privileges which you yourself possess.

Be aware that when you grant a user the `GRANT OPTION` privilege at a particular privilege level, any privileges the user possesses (or may be given in the future) at that level can also be granted by that user to other users. Suppose that you grant a user the `INSERT` privilege on a database. If you then grant the `SELECT` privilege on the database, specify `WITH GRANT OPTION`, that user can give to other users not only the `SELECT` privilege, but also `INSERT`. If you then grant the `UPDATE` privilege to the user on the database, the user can grant `INSERT`, `SELECT`, and `UPDATE`.

For a nonadministrative user, you should not grant the `ALTER` privilege globally or for the `mysql` system database. If you do that, the user can try to subvert the privilege system by renaming tables!

For additional information about security risks associated with particular privileges, see Section 6.2.2, “Privileges Provided by MySQL”.

It is possible to place limits on use of server resources by an account, as discussed in Section 6.2.13, “Setting Account Resource Limits”. To do so, use a `WITH` clause that specifies one or more `resource_option` values. Limits not specified retain their current values.

Order of `WITH` options does not matter, except that if a given resource limit is specified multiple times, the last instance takes precedence.

`GRANT` permits these `resource_option` values:

- `MAX_QUERIES_PER_HOUR` `count`, `MAX_UPDATES_PER_HOUR` `count`, `MAX_CONNECTIONS_PER_HOUR` `count`

  These options restrict how many queries, updates, and connections to the server are permitted to this account during any given one-hour period. (Queries for which results are served from the query cache do not count against the `MAX_QUERIES_PER_HOUR` limit.) If `count` is 0 (the default), this means that there is no limitation for the account.

- `MAX_USER_CONNECTIONS` `count`

  Restricts the maximum number of simultaneous connections to the server by the account. A nonzero `count` specifies the limit for the account explicitly. If `count` is 0 (the default), the server determines the number of simultaneous connections for the account from the global value of the `max_user_connections` system variable. If `max_user_connections` is also zero, there is no limit for the account.

To specify resource limits for an existing user without affecting existing privileges, use `GRANT USAGE` at the global level (`ON *.*`) and name the limits to be changed. For example:

```
GRANT USAGE ON *.* TO ...
WITH MAX_QUERIES_PER_HOUR 500 MAX_UPDATES_PER_HOUR 100;
```

### MySQL and Standard SQL Versions of GRANT

The biggest differences between the MySQL and standard SQL versions of `GRANT` are:

- MySQL associates privileges with the combination of a host name and user name and not with only a user name.

- Standard SQL does not have global or database-level privileges, nor does it support all the privilege types that MySQL supports.

- MySQL does not support the standard SQL `UNDER` privilege.
• Standard SQL privileges are structured in a hierarchical manner. If you remove a user, all privileges the user has been granted are revoked. This is also true in MySQL if you use `DROP USER`. See Section 13.7.1.3, “DROP USER Statement”.

• In standard SQL, when you drop a table, all privileges for the table are revoked. In standard SQL, when you revoke a privilege, all privileges that were granted based on that privilege are also revoked. In MySQL, privileges can be dropped with `DROP USER` or `REVOKE` statements.

• In MySQL, it is possible to have the `INSERT` privilege for only some of the columns in a table. In this case, you can still execute `INSERT` statements on the table, provided that you insert values only for those columns for which you have the `INSERT` privilege. The omitted columns are set to their implicit default values if strict SQL mode is not enabled. In strict mode, the statement is rejected if any of the omitted columns have no default value. (Standard SQL requires you to have the `INSERT` privilege on all columns.) For information about strict SQL mode and implicit default values, see Section 5.1.10, “Server SQL Modes”, and Section 11.5, “Data Type Default Values”.

13.7.1.5 RENAME USER Statement

```sql
RENAME USER old_user TO new_user
[, old_user TO new_user] ...
```

The `RENAME USER` statement renames existing MySQL accounts. An error occurs for old accounts that do not exist or new accounts that already exist.

To use `RENAME USER`, you must have the global `CREATE USER` privilege, or the `UPDATE` privilege for the `mysql` system database. When the `read_only` system variable is enabled, `RENAME USER` additionally requires the `SUPER` privilege.

Each account name uses the format described in Section 6.2.4, "Specifying Account Names". For example:

```sql
RENAME USER 'jeffrey'@'localhost' TO 'jeff'@'127.0.0.1';
```

The host name part of the account name, if omitted, defaults to `'%`.

`RENAME USER` causes the privileges held by the old user to be those held by the new user. However, `RENAME USER` does not automatically drop or invalidate databases or objects within them that the old user created. This includes stored programs or views for which the `DEFINER` attribute names the old user. Attempts to access such objects may produce an error if they execute in definer security context. (For information about security context, see Section 20.6, “Stored Object Access Control”.)

The privilege changes take effect as indicated in Section 6.2.8, “When Privilege Changes Take Effect”.

13.7.1.6 REVOKE Statement

```sql
REVOKE
  priv_type [(column_list)]
  [, priv_type [(column_list)]] ...
ON [object_type] priv_level
FROM user [, user] ...

REVOKE ALL [PRIVILEGES], GRANT OPTION
FROM user [, user] ...

REVOKE PROXY ON user
FROM user [, user] ...
```

The `REVOKE` statement enables system administrators to revoke privileges from MySQL accounts.

For details on the levels at which privileges exist, the permissible `priv_type, priv_level, and object_type` values, and the syntax for specifying users and passwords, see Section 13.7.1.4, “GRANT Statement”.

1731
When the `read_only` system variable is enabled, `REVOKE` requires the `SUPER` privilege in addition to any other required privileges described in the following discussion.

Each account name uses the format described in Section 6.2.4, "Specifying Account Names". For example:

```
REVOKE INSERT ON *.* FROM 'jeffrey'@'localhost';
```

The host name part of the account name, if omitted, defaults to '%'.

To use the first `REVOKE` syntax, you must have the `GRANT OPTION` privilege, and you must have the privileges that you are revoking.

To revoke all privileges, use the second syntax, which drops all global, database, table, column, and routine privileges for the named user or users:

```
REVOKE ALL PRIVILEGES, GRANT OPTION FROM user [, user] ...
```

To use this `REVOKE` syntax, you must have the global `CREATE USER` privilege, or the `UPDATE` privilege for the `mysql` system database.

User accounts from which privileges are to be revoked must exist, but the privileges to be revoked need not be currently granted to them.

`REVOKE` removes privileges, but does not remove rows from the `mysql.user` system table. To remove a user account entirely, use `DROP USER`. See Section 13.7.1.3, "DROP USER Statement".

If the grant tables hold privilege rows that contain mixed-case database or table names and the `lower_case_table_names` system variable is set to a nonzero value, `REVOKE` cannot be used to revoke these privileges. It will be necessary to manipulate the grant tables directly. (`GRANT` will not create such rows when `lower_case_table_names` is set, but such rows might have been created prior to setting the variable.)

When successfully executed from the `mysql` program, `REVOKE` responds with Query OK, 0 rows affected. To determine what privileges remain after the operation, use `SHOW GRANTS`. See Section 13.7.5.22, "SHOW GRANTS Statement".

13.7.1.7 SET PASSWORD Statement

```
SET PASSWORD [FOR user] = password_option
```

```
password_option: {
    PASSWORD('auth_string')
    | OLD_PASSWORD('auth_string')
    | 'hash_string'
}
```

The `SET PASSWORD` statement assigns a password to a MySQL user account, specified as either a cleartext (uncrypted) or encrypted value:

- `''auth_string''` represents a cleartext password.
- `''hash_string''` represents an encrypted password.

**Important**

Under some circumstances, `SET PASSWORD` may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see Section 6.1.2.3, “Passwords and Logging”. For similar information about client-side logging, see Section 4.5.1.3, “mysql Client Logging”.

1732
SET PASSWORD can be used with or without a FOR clause that explicitly names a user account:

- With a FOR user clause, the statement sets the password for the named account, which must exist:

```
SET PASSWORD FOR 'jeffrey'@'localhost' = password_option;
```

- With no FOR user clause, the statement sets the password for the current user:

```
SET PASSWORD = password_option;
```

Any client who connects to the server using a nonanonymous account can change the password for that account. (In particular, you can change your own password.) To see which account the server authenticated you as, invoke the CURRENT_USER() function:

```
SELECT CURRENT_USER();
```

If a FOR user clause is given, the account name uses the format described in Section 6.2.4, "Specifying Account Names". For example:

```
SET PASSWORD FOR 'bob'@'%.example.org' = PASSWORD('auth_string');
```

The host name part of the account name, if omitted, defaults to '%'.

Setting the password for a named account (with a FOR clause) requires the UPDATE privilege for the mysql system database. Setting the password for yourself (for a nonanonymous account with no FOR clause) requires no special privileges. When the read_only system variable is enabled, SET PASSWORD requires the SUPER privilege in addition to any other required privileges.

The password can be specified in these ways:

- Use the PASSWORD() function

  The PASSWORD() argument is the cleartext (unencrypted) password. PASSWORD() hashes the password and returns the encrypted password string for storage in the account row in the mysql.user system table.

  The PASSWORD() function hashes the password using the hashing method determined by the value of the old_passwords system variable value. If SET PASSWORD rejects the hashed password value returned by PASSWORD() as not being in the correct format, it may be necessary to change old_passwords to change the hashing method. For example, if the account uses the mysql_native_password plugin, the old_passwords value must be 0:

  ```
  SET old_passwords = 0;
  SET PASSWORD FOR 'jeffrey'@'localhost' = PASSWORD('password');
  ```

  If the old_passwords value differs from that required by the authentication plugin, the hashed password value returned by PASSWORD() is not acceptable for that plugin, and attempts to set the password produce an error. For example:

  ```
  mysql> SET old_passwords = 1;
  mysql> SET PASSWORD FOR 'jeffrey'@'localhost' = PASSWORD('password');
  ERROR 1372 (HY000): Password hash should be a 41-digit hexadecimal number
  ```

  Permitted old_passwords values are described later in this section.

- Use the OLD_PASSWORD() function:

  The 'auth_string' function argument is the cleartext (unencrypted) password. OLD_PASSWORD() hashes the password using pre-4.1 hashing and returns the encrypted password string for storage in the account row in the mysql.user system table. This hashing method is appropriate only for accounts that use the mysql_old_password authentication plugin.

- Use an already encrypted password string
The password is specified as a string literal. It must represent the already encrypted password value, in the hash format required by the authentication method used for the account.

The following table shows, for each password hashing method, the permitted value of `old_passwords` and which authentication plugins use the hashing method.

<table>
<thead>
<tr>
<th>Password Hashing Method</th>
<th><code>old_passwords</code> Value</th>
<th>Associated Authentication Plugin</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 4.1 native hashing</td>
<td>0</td>
<td><code>mysql_native_password</code></td>
</tr>
<tr>
<td>Pre-4.1 (&quot;old&quot;) hashing</td>
<td>1</td>
<td><code>mysql_old_password</code></td>
</tr>
<tr>
<td>SHA-256 hashing</td>
<td>2</td>
<td><code>sha256_password</code></td>
</tr>
</tbody>
</table>

**Caution**

If you are connecting to a MySQL 4.1 or later server using a pre-4.1 client program, do not change your password without first reading Section 6.1.2.4, "Password Hashing in MySQL". The default password hashing format changed in MySQL 4.1, and if you change your password, it might be stored using a hashing format that pre-4.1 clients cannot generate, thus preventing you from connecting to the server afterward.

For additional information about setting passwords and authentication plugins, see Section 6.2.9, "Assigning Account Passwords", and Section 6.2.11, "Pluggable Authentication".

### 13.7.2 Table Maintenance Statements

#### 13.7.2.1 ANALYZE TABLE Statement

```sql
ANALYZE [NO_WRITE_TO_BINLOG | LOCAL] TABLE tbl_name [, tbl_name] ...
```

`ANALYZE TABLE` performs a key distribution analysis and stores the distribution for the named table or tables. For MyISAM tables, this statement is equivalent to using `myisamchk --analyze`.

This statement requires `SELECT` and `INSERT` privileges for the table.

`ANALYZE TABLE` works with InnoDB, NDB, and MyISAM tables. It does not work with views.

`ANALYZE TABLE` is supported for partitioned tables, and you can use `ALTER TABLE ... ANALYZE PARTITION` to analyze one or more partitions; for more information, see Section 13.1.7, "ALTER TABLE Statement", and Section 19.3.4, “Maintenance of Partitions”.

During the analysis, the table is locked with a read lock for InnoDB and MyISAM.

`ANALYZE TABLE` removes the table from the table definition cache, which requires a flush lock. If there are long running statements or transactions still using the table, subsequent statements and transactions must wait for those operations to finish before the flush lock is released. Because `ANALYZE TABLE` itself typically finishes quickly, it may not be apparent that delayed transactions or statements involving the same table are due to the remaining flush lock.

By default, the server writes `ANALYZE TABLE` statements to the binary log so that they replicate to replicas. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

- ANALYZE TABLE Output
- Key Distribution Analysis
- Other Considerations
**ANALYZE TABLE Output**

`ANALYZE TABLE` returns a result set with the columns shown in the following table.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table name</td>
</tr>
<tr>
<td>Op</td>
<td>Always <strong>analyze</strong></td>
</tr>
<tr>
<td><strong>Mag_type</strong></td>
<td><strong>status, error, info, note, or warning</strong></td>
</tr>
<tr>
<td><strong>Mag_text</strong></td>
<td>An informational message</td>
</tr>
</tbody>
</table>

**Key Distribution Analysis**

If the table has not changed since the last key distribution analysis, the table is not analyzed again.

MySQL uses the stored key distribution to decide the table join order for joins on something other than a constant. In addition, key distributions can be used when deciding which indexes to use for a specific table within a query.

To check the stored key distribution cardinality, use the `SHOW_INDEX` statement or the `INFORMATION_SCHEMA_STATISTICS` table. See Section 13.7.5.23, “SHOW INDEX Statement”, and Section 21.22, “The INFORMATION_SCHEMA STATISTICS Table”.

For **InnoDB** tables, `ANALYZE TABLE` determines index cardinality by performing random dives on each of the index trees and updating index cardinality estimates accordingly. Because these are only estimates, repeated runs of `ANALYZE TABLE` could produce different numbers. This makes `ANALYZE TABLE` fast on **InnoDB** tables but not 100% accurate because it does not take all rows into account.

You can make the statistics collected by `ANALYZE TABLE` more precise and more stable by enabling `innodb_stats_persistent`, as explained in Section 14.8.11.1, “Configuring Persistent Optimizer Statistics Parameters”. When `innodb_stats_persistent` is enabled, it is important to run `ANALYZE TABLE` after major changes to index column data, as statistics are not recalculated periodically (such as after a server restart).

If `innodb_stats_persistent` is enabled, you can change the number of random dives by modifying the `innodb_stats_persistent_sample_pages` system variable. If `innodb_stats_persistent` is disabled, modify `innodb_stats_transient_sample_pages` instead.

For more information about key distribution analysis in **InnoDB**, see Section 14.8.11.1, “Configuring Persistent Optimizer Statistics Parameters”, and Section 14.8.11.3, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”.

MySQL uses index cardinality estimates in join optimization. If a join is not optimized in the right way, try running `ANALYZE TABLE`. In the few cases that `ANALYZE TABLE` does not produce values good enough for your particular tables, you can use `FORCE INDEX` with your queries to force the use of a particular index, or set the `max_seeks_for_key` system variable to ensure that MySQL prefers index lookups over table scans. See Section B.3.5, “Optimizer-Related Issues”.

**Other Considerations**

`ANALYZE TABLE` clears table statistics from the `INFORMATION_SCHEMA.INNODB_SYS_TABLESTATS` table and sets the `STATS_INITIALIZED` column to `Uninitialized`. Statistics are collected again the next time the table is accessed.

In MySQL 5.6.11 only, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. (Bug #16062608, Bug #16715809, Bug #69045)

**13.7.2.2 CHECK TABLE Statement**
CHECK TABLE checks a table or tables for errors. For MyISAM tables, the key statistics are updated as well. CHECK TABLE can also check views for problems, such as tables that are referenced in the view definition that no longer exist.

To check a table, you must have some privilege for it.

CHECK TABLE works for InnoDB, MyISAM, ARCHIVE, and CSV tables.

Before running CHECK TABLE on InnoDB tables, see CHECK TABLE Usage Notes for InnoDB Tables.

CHECK TABLE is supported for partitioned tables, and you can use ALTER TABLE ... CHECK PARTITION to check one or more partitions; for more information, see Section 13.1.7, “ALTER TABLE Statement”, and Section 19.3.4, “Maintenance of Partitions”.

In MySQL 5.6.11 only, gtid_next must be set to AUTOMATIC before issuing this statement. (Bug #16062608, Bug #16715809, Bug #69045)

- CHECK TABLE Output
- Checking Version Compatibility
- Checking Data Consistency
- CHECK TABLE Usage Notes for InnoDB Tables

CHECK TABLE Output

CHECK TABLE returns a result set with the columns shown in the following table.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table name</td>
</tr>
<tr>
<td>Op</td>
<td>Always check</td>
</tr>
<tr>
<td>Msg_type</td>
<td>status, error, info, note, or warning</td>
</tr>
<tr>
<td>Msg_text</td>
<td>An informational message</td>
</tr>
</tbody>
</table>

The statement might produce many rows of information for each checked table. The last row has a Msg_type value of status and the Msg_text normally should be OK. For a MyISAM table, if you don’t get OK or Table is already up to date, you should normally run a repair of the table. See Section 7.6, “MyISAM Table Maintenance and Crash Recovery”. Table is already up to date means that the storage engine for the table indicated that there was no need to check the table.

Checking Version Compatibility

The FOR UPGRADE option checks whether the named tables are compatible with the current version of MySQL. With FOR UPGRADE, the server checks each table to determine whether there have been any incompatible changes in any of the table’s data types or indexes since the table was created. If not, the check succeeds. Otherwise, if there is a possible incompatibility, the server runs a full check on the table (which might take some time). If the full check succeeds, the server marks the table’s .frm file
with the current MySQL version number. Marking the .frm file ensures that further checks for the table with the same version of the server will be fast.

Incompatibilities might occur because the storage format for a data type has changed or because its sort order has changed. Our aim is to avoid these changes, but occasionally they are necessary to correct problems that would be worse than an incompatibility between releases.

FOR UPGRADE discovers these incompatibilities:

- The indexing order for end-space in TEXT columns for InnoDB and MyISAM tables changed between MySQL 4.1 and 5.0.
- The storage method of the new DECIMAL data type changed between MySQL 5.0.3 and 5.0.5.
- If your table was created by a different version of the MySQL server than the one you are currently running, FOR UPGRADE indicates that the table has an .frm file with an incompatible version. In this case, the result set returned by CHECK TABLE contains a line with a Msg_type value of error and a Msg_text value of Table upgrade required. Please do "REPAIR TABLE `tbl_name`" to fix it!
- Changes are sometimes made to character sets or collations that require table indexes to be rebuilt. For details about such changes, see Section 2.11.3, “Changes in MySQL 5.6”. For information about rebuilding tables, see Section 2.11.10, “Rebuilding or Repairing Tables or Indexes”.
- The YEAR(2) data type is deprecated as of MySQL 5.6.6. For tables containing YEAR(2) columns, CHECK TABLE recommends REPAIR TABLE, which converts 2-digit YEAR(2) columns to 4-digit YEAR columns.
- As of MySQL 5.6.4, MySQL permits fractional seconds for TIME, DATETIME, and TIMESTAMP column values. As a result, encoding and storage requirements for these temporal column types differ in tables created in MySQL 5.6.4 and later. This incompatible change is described in Section 2.11.3, “Changes in MySQL 5.6”. When upgrading to MySQL 5.6.4 or later, be aware that CHECK TABLE... FOR UPGRADE does not report temporal columns that use the pre-MySQL 5.6.4 format (Bug #73008, Bug #18985579). In MySQL 5.6.24, two new system variables, avoid_temporal_upgrade and show_old_temporals, were added to provide control over temporal column upgrades (Bug #72997, Bug #18985760).

## Checking Data Consistency

The following table shows the other check options that can be given. These options are passed to the storage engine, which may use or ignore them.

<table>
<thead>
<tr>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>QUICK</td>
<td>Do not scan the rows to check for incorrect links. Applies to InnoDB and MyISAM tables and views.</td>
</tr>
<tr>
<td>FAST</td>
<td>Check only tables that have not been closed properly. Applies only to MyISAM tables and views; ignored for InnoDB.</td>
</tr>
<tr>
<td>CHANGED</td>
<td>Check only tables that have been changed since the last check or that have not been closed properly. Applies only to MyISAM tables and views; ignored for InnoDB.</td>
</tr>
<tr>
<td>MEDIUM</td>
<td>Scan rows to verify that deleted links are valid. This also calculates a key checksum for the rows and verifies this with a calculated checksum for the keys. Applies only to MyISAM tables and views; ignored for InnoDB.</td>
</tr>
<tr>
<td>EXTENDED</td>
<td>Do a full key lookup for all keys for each row. This ensures that the table is 100% consistent, but takes a long time. Applies only to MyISAM tables and views; ignored for InnoDB.</td>
</tr>
</tbody>
</table>

If none of the options QUICK, MEDIUM, or EXTENDED are specified, the default check type for dynamic-format MyISAM tables is MEDIUM. This has the same result as running myisamchk --medium-check

1737
Table Maintenance Statements

`tbl_name` on the table. The default check type also is `MEDIUM` for static-format `MyISAM` tables, unless `CHANGED` or `FAST` is specified. In that case, the default is `QUICK`. The row scan is skipped for `CHANGED` and `FAST` because the rows are very seldom corrupted.

You can combine check options, as in the following example that does a quick check on the table to determine whether it was closed properly:

```
CHECK TABLE test_table FAST QUICK;
```

**Note**

If `CHECK TABLE` finds no problems with a table that is marked as “corrupted” or “not closed properly”, `CHECK TABLE` may remove the mark.

If a table is corrupted, the problem is most likely in the indexes and not in the data part. All of the preceding check types check the indexes thoroughly and should thus find most errors.

To check a table that you assume is okay, use no check options or the `QUICK` option. The latter should be used when you are in a hurry and can take the very small risk that `QUICK` does not find an error in the data file. (In most cases, under normal usage, MySQL should find any error in the data file. If this happens, the table is marked as “corrupted” and cannot be used until it is repaired.)

`FAST` and `CHANGED` are mostly intended to be used from a script (for example, to be executed from `cron`) to check tables periodically. In most cases, `FAST` is to be preferred over `CHANGED`. (The only case when it is not preferred is when you suspect that you have found a bug in the `MyISAM` code.)

`EXTENDED` is to be used only after you have run a normal check but still get errors from a table when MySQL tries to update a row or find a row by key. This is very unlikely if a normal check has succeeded.

Use of `CHECK TABLE ... EXTENDED` might influence execution plans generated by the query optimizer.

Some problems reported by `CHECK TABLE` cannot be corrected automatically:

- **Found row where the auto_increment column has the value 0.**

  This means that you have a row in the table where the `AUTO_INCREMENT` index column contains the value 0. (It is possible to create a row where the `AUTO_INCREMENT` column is 0 by explicitly setting the column to 0 with an `UPDATE` statement.)

  This is not an error in itself, but could cause trouble if you decide to dump the table and restore it or do an `ALTER TABLE` on the table. In this case, the `AUTO_INCREMENT` column changes value according to the rules of `AUTO_INCREMENT` columns, which could cause problems such as a duplicate-key error.

  To get rid of the warning, execute an `UPDATE` statement to set the column to some value other than 0.

**CHECK TABLE Usage Notes for InnoDB Tables**

The following notes apply to InnoDB tables:

- **If `CHECK TABLE` encounters a corrupt page, the server exits to prevent error propagation (Bug #10132).** If the corruption occurs in a secondary index but table data is readable, running `CHECK TABLE` can still cause a server exit.

- **If `CHECK TABLE` encounters a corrupted `DB_TRX_ID` or `DB_ROLL_PTR` field in a clustered index, `CHECK TABLE` can cause InnoDB to access an invalid undo log record, resulting in an `MVCC`-related server exit.**
• If `CHECK TABLE` encounters errors in InnoDB tables or indexes, it reports an error, and usually marks the index and sometimes marks the table as corrupted, preventing further use of the index or table. Such errors include an incorrect number of entries in a secondary index or incorrect links.

• If `CHECK TABLE` finds an incorrect number of entries in a secondary index, it reports an error but does not cause a server exit or prevent access to the file.

• `CHECK TABLE` surveys the index page structure, then surveys each key entry. It does not validate the key pointer to a clustered record or follow the path for BLOB pointers.

• When an InnoDB table is stored in its own .ibd file, the first 3 pages of the .ibd file contain header information rather than table or index data. The `CHECK TABLE` statement does not detect inconsistencies that affect only the header data. To verify the entire contents of an InnoDB .ibd file, use the `innochecksum` command.

• When running `CHECK TABLE` on large InnoDB tables, other threads may be blocked during `CHECK TABLE` execution. To avoid timeouts, the semaphore wait threshold (600 seconds) is extended by 2 hours (7200 seconds) for `CHECK TABLE` operations. If InnoDB detects semaphore waits of 240 seconds or more, it starts printing InnoDB monitor output to the error log. If a lock request extends beyond the semaphore wait threshold, InnoDB aborts the process. To avoid the possibility of a semaphore wait timeout entirely, run `CHECK TABLE QUICK` instead of `CHECK TABLE`.

### 13.7.2.3 CHECKSUM TABLE Statement

```
CHECKSUM TABLE tbl_name [, tbl_name] ... [QUICK | EXTENDED]
```

`CHECKSUM TABLE` reports a checksum for the contents of a table. You can use this statement to verify that the contents are the same before and after a backup, rollback, or other operation that is intended to put the data back to a known state.

This statement requires the `SELECT` privilege for the table.

This statement is not supported for views. If you run `CHECKSUM TABLE` against a view, the Checksum value is always `NULL`, and a warning is returned.

For a nonexistent table, `CHECKSUM TABLE` returns `NULL` and generates a warning.

During the checksum operation, the table is locked with a read lock for InnoDB and MyISAM.

**Performance Considerations**

By default, the entire table is read row by row and the checksum is calculated. For large tables, this could take a long time, thus you would only perform this operation occasionally. This row-by-row calculation is what you get with the `EXTENDED` clause, with InnoDB and all other storage engines other than MyISAM, and with MyISAM tables not created with the `CHECKSUM=1` clause.

For MyISAM tables created with the `CHECKSUM=1` clause, `CHECKSUM TABLE` or `CHECKSUM TABLE ... QUICK` returns the “live” table checksum that can be returned very fast. If the table does not meet all these conditions, the `QUICK` method returns `NULL`. The `QUICK` method is not supported with InnoDB tables. See Section 13.1.17, “CREATE TABLE Statement” for the syntax of the `CHECKSUM` clause.

The checksum value depends on the table row format. If the row format changes, the checksum also changes. For example, the change in storage format for temporal types such as `TIME`, `DATETIME`, and `TIMESTAMP` just described mean that, if a 5.5 table is upgraded to MySQL 5.6, the checksum value may change.

**Important**

If the checksums for two tables are different, then it is almost certain that the tables are different in some way. However, because the hashing function used
by CHECKSUM TABLE is not guaranteed to be collision-free, there is a slight chance that two tables which are not identical can produce the same checksum.

13.7.2.4 OPTIMIZE TABLE Statement

OPTIMIZE [NO_WRITE_TO_BINLOG | LOCAL] TABLE tbl_name [, tbl_name] ...

OPTIMIZE TABLE reorganizes the physical storage of table data and associated index data, to reduce storage space and improve I/O efficiency when accessing the table. The exact changes made to each table depend on the storage engine used by that table.

Use OPTIMIZE TABLE in these cases, depending on the type of table:

- After doing substantial insert, update, or delete operations on an InnoDB table that has its own .ibd file because it was created with the innodb_file_per_table option enabled. The table and indexes are reorganized, and disk space can be reclaimed for use by the operating system.

- After doing substantial insert, update, or delete operations on columns that are part of a FULLTEXT index in an InnoDB table. Set the configuration option innodb_optimize_fulltext_only=1 first. To keep the index maintenance period to a reasonable time, set the innodb_ft_num_word_optimize option to specify how many words to update in the search index, and run a sequence of OPTIMIZE TABLE statements until the search index is fully updated.

- After deleting a large part of a MyISAM or ARCHIVE table, or making many changes to a MyISAM or ARCHIVE table with variable-length rows (tables that have VARCHAR, VARBINARY, BLOB, or TEXT columns). Deleted rows are maintained in a linked list and subsequent INSERT operations reuse old row positions. You can use OPTIMIZE TABLE to reclaim the unused space and to defragment the data file. After extensive changes to a table, this statement may also improve performance of statements that use the table, sometimes significantly.

This statement requires SELECT and INSERT privileges for the table.

OPTIMIZE TABLE works for InnoDB, MyISAM, and ARCHIVE tables. OPTIMIZE TABLE is also supported for dynamic columns of in-memory NDB tables. It does not work for fixed-width columns of in-memory tables, nor does it work for Disk Data tables. The performance of OPTIMIZE on NDB Cluster tables can be tuned using --ndb-optimization-delay, which controls the length of time to wait between processing batches of rows by OPTIMIZE TABLE. For more information, see Section 18.1.7.11, “Previous NDB Cluster Issues Resolved in NDB Cluster 7.3”.

For NDB Cluster tables, OPTIMIZE TABLE can be interrupted by (for example) killing the SQL thread performing the OPTIMIZE operation.

By default, OPTIMIZE TABLE does not work for tables created using any other storage engine and returns a result indicating this lack of support. You can make OPTIMIZE TABLE work for other storage engines by starting mysqld with the --skip-new option. In this case, OPTIMIZE TABLE is just mapped to ALTER TABLE.

This statement does not work with views.

OPTIMIZE TABLE is supported for partitioned tables. For information about using this statement with partitioned tables and table partitions, see Section 19.3.4, “Maintenance of Partitions”.

By default, the server writes OPTIMIZE TABLE statements to the binary log so that they replicate to replicas. To suppress logging, specify the optional NO_WRITE_TO_BINLOG keyword or its alias LOCAL.

In MySQL 5.6.11 only, gtid_next must be set to AUTOMATIC before issuing this statement. (Bug #16062608, Bug #16715809, Bug #69045)

- OPTIMIZE TABLE Output
Table Maintenance Statements

- InnoDB Details
- MyISAM Details
- Other Considerations

OPTIMIZE TABLE Output

OPTIMIZE TABLE returns a result set with the columns shown in the following table.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table name</td>
</tr>
<tr>
<td>Op</td>
<td>Always optimize</td>
</tr>
<tr>
<td>Msg_type</td>
<td>status, error, info, note, or warning</td>
</tr>
<tr>
<td>Msg_text</td>
<td>An informational message</td>
</tr>
</tbody>
</table>

OPTIMIZE TABLE table catches and throws any errors that occur while copying table statistics from the old file to the newly created file. For example, if the user ID of the owner of the .frm, .MYD, or .MYI file is different from the user ID of the mysqld process, OPTIMIZE TABLE generates a "cannot change ownership of the file" error unless mysqld is started by the root user.

InnoDB Details

For InnoDB tables, OPTIMIZE TABLE is mapped to ALTER TABLE ... FORCE, which rebuilds the table to update index statistics and free unused space in the clustered index. This is displayed in the output of OPTIMIZE TABLE when you run it on an InnoDB table, as shown here:

```
mysql> OPTIMIZE TABLE foo;
+----------+----------+----------+-------------------------------------------------------------------+
<table>
<thead>
<tr>
<th>Table</th>
<th>Op</th>
<th>Msg_type</th>
<th>Msg_text</th>
</tr>
</thead>
<tbody>
<tr>
<td>test.foo</td>
<td>optimize</td>
<td>note</td>
<td>Table does not support optimize, doing recreate + analyze instead</td>
</tr>
<tr>
<td>test.foo</td>
<td>optimize</td>
<td>status</td>
<td>OK</td>
</tr>
</tbody>
</table>
+----------+----------+----------+-------------------------------------------------------------------+
```

Prior to Mysql 5.6.17, OPTIMIZE TABLE does not use online DDL. Consequently, concurrent DML (INSERT, UPDATE, DELETE) is not permitted on a table while OPTIMIZE TABLE is running, and secondary indexes are not created as efficiently.

As of MySQL 5.6.17, OPTIMIZE TABLE uses online DDL for regular and partitioned InnoDB tables, which reduces downtime for concurrent DML operations. The table rebuild triggered by OPTIMIZE TABLE and performed under the cover by ALTER TABLE ... FORCE is completed in place. An exclusive table lock is only taken briefly during the prepare phase and the commit phase of the operation. During the prepare phase, metadata is updated and an intermediate table is created. During the commit phase, table metadata changes are committed.

OPTIMIZE TABLE rebuilds the table using the table copy method under the following conditions:

- When the old_alter_table system variable is enabled.
- When the server is started with the --skip-new option.

OPTIMIZE TABLE using online DDL is not supported for InnoDB tables that contain FULLTEXT indexes. The table copy method is used instead.

InnoDB stores data using a page-allocation method and does not suffer from fragmentation in the same way that legacy storage engines (such as MyISAM) will. When considering whether or not to run optimize, consider the workload of transactions that your server will process:

- Some level of fragmentation is expected. InnoDB only fills pages 93% full, to leave room for updates without having to split pages.
Table Maintenance Statements

- Delete operations might leave gaps that leave pages less filled than desired, which could make it worthwhile to optimize the table.

- Updates to rows usually rewrite the data within the same page, depending on the data type and row format, when sufficient space is available. See Section 14.9.5, “How Compression Works for InnoDB Tables” and Section 14.11, “InnoDB Row Formats”.

- High-concurrency workloads might leave gaps in indexes over time, as InnoDB retains multiple versions of the same data due through its MVCC mechanism. See Section 14.3, “InnoDB Multi-Versioning”.

MyISAM Details

For MyISAM tables, OPTIMIZE TABLE works as follows:

1. If the table has deleted or split rows, repair the table.
2. If the index pages are not sorted, sort them.
3. If the table’s statistics are not up to date (and the repair could not be accomplished by sorting the index), update them.

Other Considerations

For InnoDB tables prior to 5.6.17 and other table types, MySQL locks the table during the time OPTIMIZE TABLE is running. As of MySQL 5.6.17, OPTIMIZE TABLE is performed online for regular and partitioned InnoDB tables.

OPTIMIZE TABLE does not sort R-tree indexes, such as spatial indexes on POINT columns. (Bug #23578)

13.7.2.5 REPAIR TABLE Statement

REPAIR [NO_WRITE_TO_BINLOG | LOCAL] TABLE tbl_name [, tbl_name] ...
[QUICK] [EXTENDED] [USE_FRM]

REPAIR TABLE repairs a possibly corrupted table, for certain storage engines only.

This statement requires SELECT and INSERT privileges for the table.

Although normally you should never have to run REPAIR TABLE, if disaster strikes, this statement is very likely to get back all your data from a MyISAM table. If your tables become corrupted often, try to find the reason for it, to eliminate the need to use REPAIR TABLE. See Section B.3.3.3, “What to Do If MySQL Keeps Crashing”, and Section 15.2.4, “MyISAM Table Problems”.

REPAIR TABLE checks the table to see whether an upgrade is required. If so, it performs the upgrade, following the same rules as CHECK TABLE ... FOR UPGRADE. See Section 13.7.2.2, “CHECK TABLE Statement”, for more information.

Important

- Make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors. See Chapter 7, Backup and Recovery.

- If the server exits during a REPAIR TABLE operation, it is essential after restarting it that you immediately execute another REPAIR TABLE statement for the table before performing any other operations on it. In the worst case, you might have a new clean index file without information about the data file.
and then the next operation you perform could overwrite the data file. This is an unlikely but possible scenario that underscores the value of making a backup first.

- In the event that a table on the source becomes corrupted and you run `REPAIR TABLE` on it, any resulting changes to the original table are not propagated to replicas.
- In MySQL 5.6.11 only, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. (Bug #16062608, Bug #16715809, Bug #69045)

**REPAIR TABLE Storage Engine and Partitioning Support**

`REPAIR TABLE` works for MyISAM, ARCHIVE, and CSV tables. For MyISAM tables, it has the same effect as `myisamchk --recover tbl_name` by default. This statement does not work with views.

`REPAIR TABLE` is supported for partitioned tables. However, the `USE_FRM` option cannot be used with this statement on a partitioned table.

You can use `ALTER TABLE ... REPAIR PARTITION` to repair one or more partitions; for more information, see Section 13.1.7, “ALTER TABLE Statement”, and Section 19.3.4, “Maintenance of Partitions”.

**REPAIR TABLE Options**

- **NO_WRITE_TO_BINLOG** or **LOCAL**

  By default, the server writes `REPAIR TABLE` statements to the binary log so that they replicate to replicas. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

- **QUICK**

  If you use the `QUICK` option, `REPAIR TABLE` tries to repair only the index file, and not the data file. This type of repair is like that done by `myisamchk --recover --quick`.

- **EXTENDED**

  If you use the `EXTENDED` option, MySQL creates the index row by row instead of creating one index at a time with sorting. This type of repair is like that done by `myisamchk --safe-recover`.

- **USE_FRM**

  The `USE_FRM` option is available for use if the `.MYI` index file is missing or if its header is corrupted. This option tells MySQL not to trust the information in the `.MYI` file header and to re-create it using information from the `.frm` file. This kind of repair cannot be done with `myisamchk`.

**Caution**

Use the `USE_FRM` option only if you cannot use regular `REPAIR` modes. Telling the server to ignore the `.MYI` file makes important table metadata stored in the `.MYI` unavailable to the repair process, which can have deleterious consequences:
The current AUTO_INCREMENT value is lost.

The link to deleted records in the table is lost, which means that free space for deleted records will remain unoccupied thereafter.

The .MYI header indicates whether the table is compressed. If the server ignores this information, it cannot tell that a table is compressed and repair can cause change or loss of table contents. This means that USE_FRM should not be used with compressed tables. That should not be necessary, anyway: Compressed tables are read only, so they should not become corrupt.

If you use USE_FRM for a table that was created by a different version of the MySQL server than the one you are currently running, REPAIR TABLE does not attempt to repair the table. In this case, the result set returned by REPAIR TABLE contains a line with a Msg_type value of error and a Msg_text value of Failed repairing incompatible .FRM file.

If USE_FRM is used, REPAIR TABLE does not check the table to see whether an upgrade is required.

### REPAIR TABLE Output

The REPAIR TABLE statement might produce many rows of information for each repaired table. The last row has a Msg_type value of status and Msg_text normally should be OK. For a MyISAM table, if you do not get OK, you should try repairing it with myisamchk --safe-recover. (REPAIR TABLE does not implement all the options of myisamchk. With myisamchk --safe-recover, you can also use options that REPAIR TABLE does not support, such as --max-record-length.)

REPAIR TABLE table catches and throws any errors that occur while copying table statistics from the old corrupted file to the newly created file. For example, if the user ID of the owner of the .frm, .MYD, or .MYI file is different from the user ID of the mysqld process, REPAIR TABLE generates a "cannot change ownership of the file" error unless mysqld is started by the root user.

### Table Repair Considerations

You may be able to increase REPAIR TABLE performance by setting certain system variables. See Section 8.6.3, "Optimizing REPAIR TABLE Statements".

### 13.7.3 Plugin and User-Defined Function Statements

#### 13.7.3.1 CREATE FUNCTION Statement for User-Defined Functions

```sql
CREATE [AGGREGATE] FUNCTION function_name
RETURNS {STRING|INTEGER|REAL|DECIMAL}
SONAME shared_library_name
```

This statement loads the user-defined function (UDF) named function_name. (CREATE FUNCTION is also used to created stored functions; see Section 13.1.15, “CREATE PROCEDURE and CREATE FUNCTION Statements”.)
A user-defined function is a way to extend MySQL with a new function that works like a native (built-in) MySQL function such as `ABS()` or `CONCAT()`. See Adding a User-Defined Function.

`function_name` is the name that should be used in SQL statements to invoke the function. The `RETURNS` clause indicates the type of the function's return value. `DECIMAL` is a legal value after `RETURNS`, but currently `DECIMAL` functions return string values and should be written like `STRING` functions.

The `AGGREGATE` keyword, if given, signifies that the UDF is an aggregate (group) function. An aggregate UDF works exactly like a native MySQL aggregate function such as `SUM()` or `COUNT()`.

`shared_library_name` is the base name of the shared library file containing the code that implements the function. The file must be located in the plugin directory. This directory is given by the value of the `plugin_dir` system variable. For more information, see Section 5.6.1, “Installing and Uninstalling User-Defined Functions”.

`CREATE_FUNCTION` requires the `INSERT` privilege for the `mysql` system database because it adds a row to the `mysql.func` system table to register the function.

During the normal startup sequence, the server loads UDFs registered in the `mysql.func` table. If the server is started with the `--skip-grant-tables` option, UDFs registered in the table are not loaded and are unavailable.

**Note**

To upgrade the shared library associated with a UDF, issue a `DROP_FUNCTION` statement, upgrade the shared library, and then issue a `CREATE_FUNCTION` statement. If you upgrade the shared library first and then use `DROP_FUNCTION`, the server may unexpectedly shut down.

### 13.7.3.2 DROP FUNCTION Statement for User-Defined Functions

```
DROP FUNCTION [IF EXISTS] function_name
```

This statement drops the user-defined function (UDF) named `function_name`. (`DROP FUNCTION` is also used to drop stored functions; see Section 13.1.26, “DROP PROCEDURE and DROP FUNCTION Statements”.)

`DROP FUNCTION` is the complement of `CREATE_FUNCTION`. It requires the `DELETE` privilege for the `mysql` system database because it removes the row from the `mysql.func` system table that registers the function.

During the normal startup sequence, the server loads UDFs registered in the `mysql.func` table. Because `DROP FUNCTION` removes the `mysql.func` row for the dropped function, the server does not load the function during subsequent restarts.

**Note**

To upgrade the shared library associated with a UDF, issue a `DROP_FUNCTION` statement, upgrade the shared library, and then issue a `CREATE_FUNCTION` statement. If you upgrade the shared library first and then use `DROP_FUNCTION`, the server may unexpectedly shut down.

### 13.7.3.3 INSTALL PLUGIN Statement

```
INSTALL PLUGIN plugin_name SONAME 'shared_library_name'
```

This statement installs a server plugin. It requires the `INSERT` privilege for the `mysql.plugin` system table because it adds a row to that table to register the plugin.

`plugin_name` is the name of the plugin as defined in the plugin descriptor structure contained in the library file (see Plugin Data Structures). Plugin names are not case-sensitive. For maximal
compatibility, plugin names should be limited to ASCII letters, digits, and underscore because they are used in C source files, shell command lines, M4 and Bourne shell scripts, and SQL environments.

`shared_library_name` is the name of the shared library that contains the plugin code. The name includes the file name extension (for example, `libmyplugin.so`, `libmyplugin.dll`, or `libmyplugin.dylib`).

The shared library must be located in the plugin directory (the directory named by the `plugin_dir` system variable). The library must be in the plugin directory itself, not in a subdirectory. By default, `plugin_dir` is the plugin directory under the directory named by the `pkglibdir` configuration variable, but it can be changed by setting the value of `plugin_dir` at server startup. For example, set its value in a `my.cnf` file:

```sql
[mysqld]
plugin_dir=/path/to/plugin/directory
```

If the value of `plugin_dir` is a relative path name, it is taken to be relative to the MySQL base directory (the value of the `basedir` system variable).

`INSTALL PLUGIN` loads and initializes the plugin code to make the plugin available for use. A plugin is initialized by executing its initialization function, which handles any setup that the plugin must perform before it can be used. When the server shuts down, it executes the deinitialization function for each plugin that is loaded so that the plugin has a chance to perform any final cleanup.

`INSTALL PLUGIN` also registers the plugin by adding a line that indicates the plugin name and library file name to the `mysql.plugin` system table. During the normal startup sequence, the server loads and initializes plugins registered in `mysql.plugin`. This means that a plugin is installed with `INSTALL PLUGIN` only once, not every time the server starts. If the server is started with the `--skip-grant-tables` option, plugins registered in the `mysql.plugin` table are not loaded and are unavailable.

A plugin library can contain multiple plugins. For each of them to be installed, use a separate `INSTALL PLUGIN` statement. Each statement names a different plugin, but all of them specify the same library name.

`INSTALL PLUGIN` causes the server to read option (`my.cnf`) files just as during server startup. This enables the plugin to pick up any relevant options from those files. It is possible to add plugin options to an option file even before loading a plugin (if the `loose` prefix is used). It is also possible to uninstall a plugin, edit `my.cnf`, and install the plugin again. Restarting the plugin this way enables it to use the new option values without a server restart.

For options that control individual plugin loading at server startup, see Section 5.5.1, “Installing and Uninstalling Plugins”. If you need to load plugins for a single server startup when the `--skip-grant-tables` option is given (which tells the server not to read system tables), use the `--plugin-load` option. See Section 5.1.6, “Server Command Options”.

To remove a plugin, use the `UNINSTALL PLUGIN` statement.

For additional information about plugin loading, see Section 5.5.1, “Installing and Uninstalling Plugins”.

To see what plugins are installed, use the `SHOW PLUGINS` statement or query the `INFORMATION_SCHEMA` the `PLUGINS` table.

If you recompile a plugin library and need to reinstall it, you can use either of the following methods:

- Use `UNINSTALL PLUGIN` to uninstall all plugins in the library, install the new plugin library file in the plugin directory, and then use `INSTALL PLUGIN` to install all plugins in the library. This procedure has the advantage that it can be used without stopping the server. However, if the plugin library contains many plugins, you must issue many `INSTALL PLUGIN` and `UNINSTALL PLUGIN` statements.

- Stop the server, install the new plugin library file in the plugin directory, and restart the server.
13.7.3.4 UNINSTALL PLUGIN Statement

**UNINSTALL PLUGIN** *plugin_name*

This statement removes an installed server plugin. **UNINSTALL PLUGIN** is the complement of **INSTALL PLUGIN**. It requires the **DELETE** privilege for the `mysql.plugin` system table because it removes the row from that table that registers the plugin.

*plugin_name* must be the name of some plugin that is listed in the `mysql.plugin` table. The server executes the plugin's deinitialization function and removes the row for the plugin from the `mysql.plugin` system table, so that subsequent server restarts will not load and initialize the plugin. **UNINSTALL PLUGIN** does not remove the plugin's shared library file.

You cannot uninstall a plugin if any table that uses it is open.

Plugin removal has implications for the use of associated tables. For example, if a full-text parser plugin is associated with a **FULLTEXT** index on the table, uninstalling the plugin makes the table unusable. Any attempt to access the table results in an error. The table cannot even be opened, so you cannot drop an index for which the plugin is used. This means that uninstalling a plugin is something to do with care unless you do not care about the table contents. If you are uninstalling a plugin with no intention of reinstalling it later and you care about the table contents, you should dump the table with `mysqldump` and remove the **WITH PARSER** clause from the dumped `CREATE TABLE` statement so that you can reload the table later. If you do not care about the table, **DROP TABLE** can be used even if any plugins associated with the table are missing.

For additional information about plugin loading, see Section 5.5.1, "Installing and Uninstalling Plugins".

13.7.4 SET Statements

The **SET** statement has several forms. Descriptions for those forms that are not associated with a specific server capability appear in subsections of this section:

- **SET var_name = value** enables you to assign values to variables that affect the operation of the server or clients. See Section 13.7.4.1, "SET Syntax for Variable Assignment".

- **SET CHARACTER SET** and **SET NAMES** assign values to character set and collation variables associated with the current connection to the server. See Section 13.7.4.2, "SET CHARACTER SET Statement" , and Section 13.7.4.3, "SET NAMES Statement".

Descriptions for the other forms appear elsewhere, grouped with other statements related to the capability they help implement:

- **SET PASSWORD** assigns account passwords. See Section 13.7.1.7, "SET PASSWORD Statement".

- **SET TRANSACTION ISOLATION LEVEL** sets the isolation level for transaction processing. See Section 13.3.6, "SET TRANSACTION Statement".

13.7.4.1 SET Syntax for Variable Assignment

**SET** syntax for variable assignment enables you to assign values to different types of variables that affect the operation of the server or clients:
SET Statements

- User-defined variables. See Section 9.4, “User-Defined Variables”.

- Stored procedure and function parameters, and stored program local variables. See Section 13.6.4, “Variables in Stored Programs”.

- System variables. See Section 5.1.7, “Server System Variables”. System variables also can be set at server startup, as described in Section 5.1.8, “Using System Variables”.

A SET statement that assigns variable values is not written to the binary log, so in replication scenarios it affects only the host on which you execute it. To affect all replication hosts, execute the statement on each host.

The following sections describe SET syntax for setting variables. They use the = assignment operator, but the := assignment operator is also permitted for this purpose.

- User-Defined Variable Assignment
- Parameter and Local Variable Assignment
- System Variable Assignment
- SET Error Handling
- Multiple Variable Assignment
- System Variable References in Expressions
- ONE_SHOT Assignment

**User-Defined Variable Assignment**

User-defined variables are created locally within a session and exist only within the context of that session; see Section 9.4, “User-Defined Variables”.

A user-defined variable is written as `@var_name` and is assigned an expression value as follows:

```
SET @var_name = expr;
```

Examples:

```
SET @name = 43;
SET @total_tax = (SELECT SUM(tax) FROM taxable_transactions);
```

As demonstrated by those statements, `expr` can range from simple (a literal value) to more complex (the value returned by a scalar subquery).

**Parameter and Local Variable Assignment**

`SET` applies to parameters and local variables in the context of the stored object within which they are defined. The following procedure uses the `increment` procedure parameter and `counter` local variable:

```
CREATE PROCEDURE p(increment INT)
BEGIN
  DECLARE counter INT DEFAULT 0;
  WHILE counter < 10 DO
    -- ... do work ...
    SET counter = counter + increment;
  END WHILE;
END;
```

**System Variable Assignment**

The MySQL server maintains system variables that configure its operation. A system variable can have a global value that affects server operation as a whole, a session value that affects the current session,
or both. Many system variables are dynamic and can be changed at runtime using the `SET` statement to affect operation of the current server instance. (To make a global system variable setting permanent so that it applies across server restarts, you should also set it in an option file.)

If you change a session system variable, the value remains in effect within your session until you change the variable to a different value or the session ends. The change has no effect on other sessions.

If you change a global system variable, the value is remembered and used to initialize the session value for new sessions until you change the variable to a different value or the server exits. The change is visible to any client that accesses the global value. However, the change affects the corresponding session value only for clients that connect after the change. The global variable change does not affect the session value for any current client sessions (not even the session within which the global value change occurs).

**Note**

Setting a global system variable value always requires special privileges.
Setting a session system variable value normally requires no special privileges and can be done by any user, although there are exceptions. For more information, see Section 5.1.8.1, “System Variable Privileges”.

The following discussion describes the syntax options for setting system variables:

- To assign a value to a global system variable, precede the variable name by the `GLOBAL` keyword or the `@@GLOBAL` qualifier:

  ```sql
  SET GLOBAL max_connections = 1000;
  SET @@GLOBAL.max_connections = 1000;
  ```

- To assign a value to a session system variable, precede the variable name by the `SESSION` or `LOCAL` keyword, by the `@@SESSION`, `@@LOCAL`, or `@@` qualifier, or by no keyword or no modifier at all:

  ```sql
  SET SESSION sql_mode = 'TRADITIONAL';
  SET LOCAL sql_mode = 'TRADITIONAL';
  SET @@SESSION.sql_mode = 'TRADITIONAL';
  SET @@LOCAL.sql_mode = 'TRADITIONAL';
  SET @sql_mode = 'TRADITIONAL';
  SET sql_mode = 'TRADITIONAL';
  ```

A client can change its own session variables, but not those of any other client.

To set a global system variable value to the compiled-in MySQL default value or a session system variable to the current corresponding global value, set the variable to the value `DEFAULT`. For example, the following two statements are identical in setting the session value of `max_join_size` to the current global value:

```sql
SET @@SESSION.max_join_size = DEFAULT;
SET @@SESSION.max_join_size = @@GLOBAL.max_join_size;
```

To display system variable names and values:

- Use the `SHOW VARIABLES` statement; see Section 13.7.5.40, “SHOW VARIABLES Statement”.

- Several `INFORMATION_SCHEMA` tables provide system variable information. See Section 21.10, “The `INFORMATION_SCHEMA GLOBAL_VARIABLES` and `SESSION_VARIABLES` Tables”.

**SET Error Handling**

If any variable assignment in a `SET` statement fails, the entire statement fails and no variables are changed.
**SET Statements**

`SET` produces an error under the circumstances described here. Most of the examples show `SET` statements that use keyword syntax (for example, `GLOBAL` or `SESSION`), but the principles are also true for statements that use the corresponding modifiers (for example, `@@GLOBAL` or `@@SESSION`).

- **Use of** `SET` (any variant) **to set a read-only variable:**
  ```sql
  mysql> SET GLOBAL version = 'abc';
  ERROR 1238 (HY000): Variable 'version' is a read only variable
  ```

- **Use of** `GLOBAL` **to set a variable that has only a session value:**
  ```sql
  mysql> SET GLOBAL sql_log_bin = ON;
  ERROR 1231 (42000): Variable 'sql_log_bin' can't be set to the value of 'ON'
  ```

- **Use of** `SESSION` **to set a variable that has only a global value:**
  ```sql
  mysql> SET SESSION max_connections = 1000;
  ERROR 1229 (HY000): Variable 'max_connections' is a GLOBAL variable and should be set with SET GLOBAL
  ```

- **Omission of** `GLOBAL` **to set a variable that has only a global value:**
  ```sql
  mysql> SET max_connections = 1000;
  ERROR 1229 (HY000): Variable 'max_connections' is a GLOBAL variable and should be set with SET GLOBAL
  ```

- **The** `@@GLOBAL`, `@@SESSION`, **and @@ modifiers apply only to system variables. An error occurs for attempts to apply them to user-defined variables, stored procedure or function parameters, or stored program local variables.**

- **Not all system variables can be set to** `DEFAULT`. **In such cases, assigning** `DEFAULT` **results in an error.**

- **An error occurs for attempts to assign** `DEFAULT` **to user-defined variables, stored procedure or function parameters, or stored program local variables.**

**Multiple Variable Assignment**

A `SET` statement can contain multiple variable assignments, separated by commas. This statement assigns a value to a user-defined variable and a system variable:

```sql
SET @x = 1, SESSION sql_mode = '';
```

If you set multiple system variables in a single statement, the most recent `GLOBAL` or `SESSION` keyword in the statement is used for following assignments that have no keyword specified.

Examples of multiple-variable assignment:

```sql
SET GLOBAL sort_buffer_size = 1000000, SESSION sort_buffer_size = 1000000;
SET @@GLOBAL.sort_buffer_size = 1000000, @@LOCAL.sort_buffer_size = 1000000;
SET GLOBAL max_connections = 1000, sort_buffer_size = 1000000;
```

The `@@GLOBAL`, `@@SESSION`, **and @@ modifiers apply only to the immediately following system variable, not any remaining system variables. This statement sets the** `sort_buffer_size` **global value to 50000 and the session value to 1000000:**

```sql
SET @@GLOBAL.sort_buffer_size = 50000, sort_buffer_size = 1000000;
```

**System Variable References in Expressions**

To refer to the value of a system variable in expressions, use one of the `@@`-modifiers. For example, you can retrieve system variable values in a `SELECT` statement like this:

```sql
SELECT @@GLOBAL.sql_mode, @@SESSION.sql_mode, @@sql_mode;
```
SHOW Statements

Note
A reference to a system variable in an expression as @@var_name (with @@ rather than @@GLOBAL. or @@SESSION.) returns the session value if it exists and the global value otherwise. This differs from SET @@var_name = expr, which always refers to the session value.

ONE_SHOT Assignment

The SET ONE_SHOT syntax is for internal use only, has been deprecated since MySQL 5.0, and was removed in MySQL 5.6.1.

13.7.4.2 SET CHARACTER SET Statement

```
SET {CHARACTER SET | CHARSET}
{'charset_name' | DEFAULT}
```

This statement maps all strings sent between the server and the current client with the given mapping. SET CHARACTER SET sets three session system variables: character_set_client and character_set_results are set to the given character set, and character_set_connection to the value of character_set_database. See Section 10.4, “Connection Character Sets and Collations”.

charset_name may be quoted or unquoted.

The default character set mapping can be restored by using the value DEFAULT. The default depends on the server configuration.

Some character sets cannot be used as the client character set. Attempting to use them with SET CHARACTER SET produces an error. See Impermissible Client Character Sets.

13.7.4.3 SET NAMES Statement

```
SET NAMES {'charset_name'
[COLLATE 'collation_name'] | DEFAULT}
```

This statement sets the three session system variables character_set_client, character_set_connection, and character_set_results to the given character set. Setting character_set_connection to charset_name also sets collation_connection to the default collation for charset_name. See Section 10.4, “Connection Character Sets and Collations”.

The optional COLLATE clause may be used to specify a collation explicitly. If given, the collation must one of the permitted collations for charset_name.

charset_name and collation_name may be quoted or unquoted.

The default mapping can be restored by using a value of DEFAULT. The default depends on the server configuration.

Some character sets cannot be used as the client character set. Attempting to use them with SET NAMES produces an error. See Impermissible Client Character Sets.

13.7.5 SHOW Statements

SHOW has many forms that provide information about databases, tables, columns, or status information about the server. This section describes those following:

```
SHOW AUTHORS
SHOW {BINARY | MASTER} LOGS
SHOW BINLOG EVENTS [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
SHOW CHARACTER SET [like_or_where]
```
SHOW COLLATION [like_or_where]
SHOW [FULL] COLUMNS FROM tbl_name [FROM db_name] [like_or_where]
SHOW CONTRIBUTORS
SHOW CREATE DATABASE db_name
SHOW CREATE EVENT event_name
SHOW CREATE FUNCTION func_name
SHOW CREATE PROCEDURE proc_name
SHOW CREATE TABLE tbl_name
SHOW CREATE TRIGGER trigger_name
SHOW CREATE VIEW view_name
SHOW DATABASES [like_or_where]
SHOW ENGINE engine_name [STATUS | MUTEX]
SHOW [STORAGE] ENGINES
SHOW ERRORS [LIMIT [offset,] row_count]
SHOW EVENTS
SHOW FUNCTION CODE func_name
SHOW FUNCTION STATUS [like_or_where]
SHOW GRANTS FOR user
SHOW INDEX FROM tbl_name [FROM db_name]
SHOW MASTER STATUS
SHOW OPEN TABLES [FROM db_name] [like_or_where]
SHOW PLUGINS
SHOW PROCEDURE CODE proc_name
SHOW PROCEDURE STATUS [like_or_where]
SHOW PRIVILEGES
SHOW [FULL] PROCESSLIST
SHOW PROFILE [types] [FOR QUERY n] [OFFSET n] [LIMIT n]
SHOW PROCESSES
SHOW RELAYLOG EVENTS [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
SHOW SLAVE HOSTS
SHOW SLAVE STATUS
SHOW [GLOBAL | SESSION] STATUS [like_or_where]
SHOW TABLE STATUS [FROM db_name] [like_or_where]
SHOW [FULL] TABLES [FROM db_name] [like_or_where]
SHOW TRIGGERS [FROM db_name] [like_or_where]
SHOW [GLOBAL | SESSION] VARIABLES [like_or_where]
SHOW WARNINGS [LIMIT [offset,] row_count]

like_or_where: {
    LIKE 'pattern'
    | WHERE expr
}

If the syntax for a given SHOW statement includes a LIKE 'pattern' part, ‘pattern’ is a string that can contain the SQL % and _ wildcard characters. The pattern is useful for restricting statement output to matching values.

Several SHOW statements also accept a WHERE clause that provides more flexibility in specifying which rows to display. See Section 21.35, “Extensions to SHOW Statements”.

Many MySQL APIs (such as PHP) enable you to treat the result returned from a SHOW statement as you would a result set from a SELECT; see Chapter 23, Connectors and APIs, or your API documentation for more information. In addition, you can work in SQL with results from queries on tables in the INFORMATION_SCHEMA database, which you cannot easily do with results from SHOW statements. See Chapter 21, INFORMATION_SCHEMA Tables.

### 13.7.5.1 SHOW AUTHORS Statement

SHOW AUTHORS

The SHOW AUTHORS statement displays information about the people who work on MySQL. For each author, it displays Name, Location, and Comment values.

This statement is removed as of MySQL 5.6.8.

### 13.7.5.2 SHOW BINARY LOGS Statement

SHOW BINARY LOGS
SHOW MASTER LOGS

Lists the binary log files on the server. This statement is used as part of the procedure described in Section 13.4.1.1, “PURGE BINARY LOGS Statement”, that shows how to determine which logs can be purged.

```sql
mysql> SHOW BINARY LOGS;
+---------------+-----------+
| Log_name      | File_size |
|---------------+-----------|
| binlog.000015 | 7124935   |
| binlog.000016 | 733481    |
+---------------+-----------+
```

SHOW MASTER LOGS is equivalent to SHOW BINARY LOGS.

A user with the SUPER or REPLICATION CLIENT privilege may execute this statement.

13.7.5.3 SHOW BINLOG EVENTS Statement

```sql
SHOW BINLOG EVENTS
    [IN 'log_name']
    [FROM pos]
    [LIMIT [offset,] row_count]
```

Shows the events in the binary log. If you do not specify `log_name`, the first binary log is displayed.

The LIMIT clause has the same syntax as for the SELECT statement. See Section 13.2.9, “SELECT Statement”.

Note

Issuing a SHOW BINLOG EVENTS with no LIMIT clause could start a very time- and resource-consuming process because the server returns to the client the complete contents of the binary log (which includes all statements executed by the server that modify data). As an alternative to SHOW BINLOG EVENTS, use the mysqlbinlog utility to save the binary log to a text file for later examination and analysis. See Section 4.6.8, "mysqlbinlog — Utility for Processing Binary Log Files".

SHOW BINLOG EVENTS displays the following fields for each event in the binary log:

- **Log_name**
  The name of the file that is being listed.

- **Pos**
  The position at which the event occurs.

- **Event_type**
  An identifier that describes the event type.

- **Server_id**
  The server ID of the server on which the event originated.

- **End_log_pos**
  The position at which the next event begins, which is equal to Pos plus the size of the event.

- **Info**
More detailed information about the event type. The format of this information depends on the event type.

**Note**

Some events relating to the setting of user and system variables are not included in the output from `SHOW BINLOG EVENTS`. To get complete coverage of events within a binary log, use `mysqlbinlog`.

**Note**

`SHOW BINLOG EVENTS` does *not* work with relay log files. You can use `SHOW RELAYLOG EVENTS` for this purpose.

### 13.7.5.4 SHOW CHARACTER SET Statement

```sql
SHOW CHARACTER SET [LIKE 'pattern' | WHERE expr]
```

The `SHOW CHARACTER SET` statement shows all available character sets. The `LIKE` clause, if present, indicates which character set names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 21.35, “Extensions to SHOW Statements”. For example:

```sql
mysql> SHOW CHARACTER SET LIKE 'latin%';
+-----------------+---------------------------------+----------------+--------+
| Charset  | Description            | Default collation | Maxlen |
+-----------------+---------------------------------+----------------+--------+
| latin1  | cp1252 West European          | latin1_swedish_ci |      1 |
| latin2  | ISO 8859-2 Central European    | latin2_general_ci |      1 |
| latin5  | ISO 8859-9 Turkish            | latin5_turkish_ci |      1 |
| latin7  | ISO 8859-13 Baltic            | latin7_general_ci |      1 |
+-----------------+---------------------------------+----------------+--------+
```

`SHOW CHARACTER SET` output has these columns:

- **Charset**
  
  The character set name.

- **Description**
  
  A description of the character set.

- **Default collation**
  
  The default collation for the character set.

- **Maxlen**
  
  The maximum number of bytes required to store one character.

The `filename` character set is for internal use only; consequently, `SHOW CHARACTER SET` does not display it.

Character set information is also available from the `INFORMATION_SCHEMA CHARACTER_SETS` table. See Section 21.2, “The INFORMATION_SCHEMA CHARACTER_SETS Table”.

### 13.7.5.5 SHOW COLLATION Statement

```sql
SHOW COLLATION [LIKE 'pattern' | WHERE expr]
```
SHOW Statements

This statement lists collations supported by the server. By default, the output from `SHOW COLLATION` includes all available collations. The `LIKE` clause, if present, indicates which collation names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 21.35, “Extensions to SHOW Statements”. For example:

```
mysql> SHOW COLLATION WHERE Charset = 'latin1';
+-------------------+---------+----+---------+----------+---------+
| Collation          | Charset | Id | Default | Compiled | Sortlen |
+-------------------+---------+----+---------+----------+---------+
| latin1_german1_ci | latin1  |  5 |         | Yes      |       1 |
| latin1_swedish_ci | latin1  |  8 | Yes     | Yes      |       1 |
| latin1_danish_ci  | latin1  | 15 |         | Yes      |       1 |
| latin1_german2_ci | latin1  | 31 |         | Yes      |       2 |
| latin1_bin        | latin1  | 47 |         | Yes      |       1 |
| latin1_general_ci | latin1  | 48 |         | Yes      |       1 |
| latin1_general_cs | latin1  | 49 |         | Yes      |       1 |
| latin1_spanish_ci | latin1  | 94 |         | Yes      |       1 |
+-------------------+---------+----+---------+----------+---------+
```

The `SHOW COLLATION` output has these columns:

- **Collation**
  
The collation name.

- **Charset**
  
The name of the character set with which the collation is associated.

- **Id**
  
The collation ID.

- **Default**
  
Whether the collation is the default for its character set.

- **Compiled**
  
Whether the character set is compiled into the server.

- **Sortlen**
  
This is related to the amount of memory required to sort strings expressed in the character set.

To see the default collation for each character set, use the following statement. `Default` is a reserved word, so to use it as an identifier, it must be quoted as such:

```
mysql> SHOW COLLATION WHERE 'Default' = 'Yes';
+---------------------+----------+----+---------+----------+---------+
| Collation            | Charset  | Id | Default | Compiled | Sortlen |
+---------------------+----------+----+---------+----------+---------+
| big5_chinese_ci     | big5     |  1 | Yes     | Yes      |       1 |
| dec8_swedish_ci     | dec8     |  3 | Yes     | Yes      |       1 |
| cp850_general_ci    | cp850    |  4 | Yes     | Yes      |       1 |
| hp8_english_ci      | hp8      |  6 | Yes     | Yes      |       1 |
| koi8r_general_ci    | koi8r    |  7 | Yes     | Yes      |       1 |
| latin1_swedish_ci   | latin1   |  8 | Yes     | Yes      |       1 |
+---------------------+----------+----+---------+----------+---------+
```

Collation information is also available from the `INFORMATION_SCHEMA COLLATIONS` table. See Section 21.3, “The INFORMATION_SCHEMA COLLATIONS Table”.

### 13.7.5.6 SHOW COLUMNS Statement

```
SHOW [FULL] \{COLUMNS | FIELDS\} \{FROM | IN\} tbl_name
```

1755
SHOW Statements

SHOW COLUMNS displays information about the columns in a given table. It also works for views. SHOW COLUMNS displays information only for those columns for which you have some privilege.

mysql> SHOW COLUMNS FROM City;

+-------------+----------+------+-----+---------+----------------+
| Field       | Type     | Null | Key | Default | Extra          |
|-------------+----------+------+-----+---------+----------------+
| ID          | int(11)  | NO   | PRI | NULL    | auto_increment |
| Name        | char(35) | NO   |     |         |                |
| CountryCode | char(3)  | NO   | MUL |         |                |
| District    | char(20) | NO   |     |         |                |
| Population  | int(11)  | NO   |     | 0       |                |
+-------------+----------+------+-----+---------+----------------+

An alternative to tbl_name FROM db_name syntax is db_name.tbl_name. These two statements are equivalent:

SHOW COLUMNS FROM mytable FROM mydb;
SHOW COLUMNS FROM mydb.mytable;

The optional FULL keyword causes the output to include the column collation and comments, as well as the privileges you have for each column.

The LIKE clause, if present, indicates which column names to match. The WHERE clause can be given to select rows using more general conditions, as discussed in Section 21.35, “Extensions to SHOW Statements”.

The data types may differ from what you expect them to be based on a CREATE TABLE statement because MySQL sometimes changes data types when you create or alter a table. The conditions under which this occurs are described in Section 13.1.17.6, “Silent Column Specification Changes”.

SHOW COLUMNS displays the following values for each table column:

- **Field**
  The column name.

- **Type**
  The column data type.

- **Collation**
  The collation for nonbinary string columns, or NULL for other columns. This value is displayed only if you use the FULL keyword.

- **Null**
  The column nullability. The value is YES if NULL values can be stored in the column, NO if not.

- **Key**
  Whether the column is indexed:
  - If Key is empty, the column either is not indexed or is indexed only as a secondary column in a multiple-column, nonunique index.
  - If Key is PRI, the column is a PRIMARY KEY or is one of the columns in a multiple-column PRIMARY KEY.
  - If Key is UNI, the column is the first column of a UNIQUE index. (A UNIQUE index permits multiple NULL values, but you can tell whether the column permits NULL by checking the Null field.)
• If `Key` is `MUL`, the column is the first column of a nonunique index in which multiple occurrences of a given value are permitted within the column.

If more than one of the `Key` values applies to a given column of a table, `Key` displays the one with the highest priority, in the order PRI, UNI, MUL.

A `UNIQUE` index may be displayed as PRI if it cannot contain `NULL` values and there is no PRIMARY KEY in the table. A `UNIQUE` index may display as MUL if several columns form a composite `UNIQUE` index: although the combination of the columns is unique, each column can still hold multiple occurrences of a given value.

• **Default**

The default value for the column. This is `NULL` if the column has an explicit default of `NULL`, or if the column definition includes no `DEFAULT` clause.

• **Extra**

Any additional information that is available about a given column. The value is nonempty in these cases: `auto_increment` for columns that have the AUTO_INCREMENT attribute; `on update CURRENT_TIMESTAMP` for `TIMESTAMP` or `DATETIME` columns that have the ON UPDATE CURRENT_TIMESTAMP attribute.

• **Privileges**

The privileges you have for the column. This value is displayed only if you use the `FULL` keyword.

• **Comment**

Any comment included in the column definition. This value is displayed only if you use the `FULL` keyword.

Table column information is also available from the INFORMATION_SCHEMA COLUMNS table. See Section 21.5, “The INFORMATION_SCHEMA COLUMNS Table”.

You can list a table's columns with the `mysqlshow db_name tbl_name` command.

The `DESCRIBE` statement provides information similar to `SHOW COLUMNS`. See Section 13.8.1, “DESCRIBE Statement”.

The `SHOW CREATE TABLE`, `SHOW TABLE STATUS`, and `SHOW INDEX` statements also provide information about tables. See Section 13.7.5, “SHOW Statements”.

### 13.7.5.7 SHOW CONTRIBUTORS Statement

The `SHOW CONTRIBUTORS` statement displays information about the people who contribute to MySQL source or to causes that we support. For each contributor, it displays Name, Location, and Comment values.

This statement is removed as of MySQL 5.6.8.

### 13.7.5.8 SHOW CREATE DATABASE Statement

The `SHOW CREATE DATABASE` statement displays information about the named database. If the `SHOW CREATE DATABASE` statement includes an IF NOT EXISTS clause, the output too includes such a clause. `SHOW CREATE DATABASE` is a synonym for `SHOW CREATE SCHEMA`.

```sql
mysql> SHOW CREATE DATABASE test
```

1757
SHOW Statements

13.7.5.9 SHOW CREATE EVENT Statement

This statement displays the `CREATE EVENT` statement needed to re-create a given event. It requires the `EVENT` privilege for the database from which the event is to be shown. For example (using the same event `e_daily` defined and then altered in Section 13.7.5.19, “SHOW EVENTS Statement”):

```
mysql> SHOW CREATE EVENT myschema.e_daily
```

```
Event: e_daily
sql_mode: NO_ENGINE_SUBSTITUTION
time_zone: SYSTEM
Create Event: CREATE DEFINER=`jon`@`ghidora` EVENT `e_daily`
  ON SCHEDULE EVERY 1 DAY
  STARTS CURRENT_TIMESTAMP + INTERVAL 6 HOUR
  ON COMPLETION NOT PRESERVE
  ENABLE
  COMMENT 'Saves total number of sessions then clears the table each day'
  DO BEGIN
    INSERT INTO site_activity.totals (time, total)
    SELECT CURRENT_TIMESTAMP, COUNT(*)
    FROM site_activity.sessions;
    DELETE FROM site_activity.sessions;
  END
collation_connection: utf8_general_ci
character_set_client: utf8
Database Collation: latin1_swedish_ci
```

`character_set_client` is the session value of the `character_set_client` system variable when the event was created. `collation_connection` is the session value of the `collation_connection` system variable when the event was created. `Database Collation` is the collation of the database with which the event is associated.

The output reflects the current status of the event (ENABLE) rather than the status with which it was created.

13.7.5.10 SHOW CREATE FUNCTION Statement

```
SHOW CREATE FUNCTION func_name
```

This statement is similar to `SHOW CREATE PROCEDURE` but for stored functions. See Section 13.7.5.11, “SHOW CREATE PROCEDURE Statement”.

13.7.5.11 SHOW CREATE PROCEDURE Statement

```
SHOW CREATE PROCEDURE proc_name
```

This statement is a MySQL extension. It returns the exact string that can be used to re-create the named stored procedure. A similar statement, `SHOW CREATE FUNCTION`, displays information about stored functions (see Section 13.7.5.10, “SHOW CREATE FUNCTION Statement”).

1758
SHOW Statements

To use either statement, you must be the user named in the routine `DEFINER` clause or have `SELECT` access to the `mysql.proc` table. If you do not have privileges for the routine itself, the value displayed for the `Create Procedure` or `Create Function` field will be `NULL`.

```
mysql> SHOW CREATE PROCEDURE test.citycount\G
*************************** 1. row ***************************
Procedure: citycount
sql_mode: STRICT_TRANS_TABLES,NO_ENGINE_SUBSTITUTION
Create Procedure: CREATE DEFINER=`me`@`localhost`
  PROCEDURE `citycount`(IN country CHAR(3), OUT cities INT)
  BEGIN
    SELECT COUNT(*) INTO cities FROM world.city
    WHERE CountryCode = country;
  END
character_set_client: utf8
collation_connection: utf8_general_ci
Database Collation: latin1_swedish_ci
```

```
mysql> SHOW CREATE FUNCTION test.hello\G
*************************** 1. row ***************************
Function: hello
sql_mode: STRICT_TRANS_TABLES,NO_ENGINE_SUBSTITUTION
Create Function: CREATE DEFINER=`me`@`localhost`
  FUNCTION `hello`(s CHAR(20))
  RETURNS char(50) CHARSET latin1
  DETERMINISTIC
  RETURN CONCAT('Hello, ',s,'!')
character_set_client: utf8
collation_connection: utf8_general_ci
Database Collation: latin1_swedish_ci
```

```
character_set_client` is the session value of the `character_set_client` system variable when the routine was created. `collation_connection` is the session value of the `collation_connection` system variable when the routine was created. `Database Collation` is the collation of the database with which the routine is associated.

### 13.7.5.12 SHOW CREATE TABLE Statement

```
SHOW CREATE TABLE tbl_name
```

Shows the `CREATE TABLE` statement that creates the named table. To use this statement, you must have some privilege for the table. This statement also works with views.

```
mysql> SHOW CREATE TABLE t\G
*************************** 1. row ***************************
Table: t
Create Table: CREATE TABLE `t`
  (`id` int(11) NOT NULL AUTO_INCREMENT,
   `s` char(60) DEFAULT NULL,
   PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

SHOW CREATE TABLE quotes table and column names according to the value of the `sql_quote_show_create` option. See Section 5.1.7, “Server System Variables”.

When altering the storage engine of a table, table options that are not applicable to the new storage engine are retained in the table definition to enable reverting the table with its previously defined options to the original storage engine, if necessary. For example, when changing the storage engine from InnoDB to MyISAM, InnoDB-specific options such as `ROW_FORMAT=COMPACT` are retained.

```
mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) ROW_FORMAT=COMPACT ENGINE=InnoDB;
mysql> ALTER TABLE t1 ENGINE=MyISAM;
mysql> SHOW CREATE TABLE t1\G
*************************** 1. row ***************************
Table: t1
Create Table: CREATE TABLE `t1` (c1` int(11) NOT NULL,
  PRIMARY KEY (`c1`)
```
When creating a table with strict mode disabled, the storage engine's default row format is used if the specified row format is not supported. The actual row format of the table is reported in the Row_format column in response to SHOW TABLE STATUS. SHOW CREATE TABLE shows the row format that was specified in the CREATE TABLE statement.

### 13.7.5.13 SHOW CREATE TRIGGER Statement

**SHOW CREATE TRIGGER** trigger_name

This statement shows the CREATE TRIGGER statement that creates the named trigger. This statement requires the TRIGGER privilege for the table associated with the trigger.

```
SHOW CREATE TRIGGER ins_sum
```

```
*************************** 1. row ***************************
| Trigger: ins_sum |
| sql_mode: NO_ENGINE_SUBSTITUTION |
| SQL Original Statement: CREATE DEFINER=`me`@`localhost` TRIGGER ins_sum BEFORE INSERT ON account FOR EACH ROW SET @sum = @sum + NEW.amount |
| character_set_client: utf8 |
| collation_connection: utf8_general_ci |
```

SHOW CREATE TRIGGER output has these columns:

- **Trigger**: The trigger name.
- **sql_mode**: The SQL mode in effect when the trigger executes.
- **SQL Original Statement**: The CREATE TRIGGER statement that defines the trigger.
- **character_set_client**: The session value of the character_set_client system variable when the trigger was created.
- **collation_connection**: The session value of the collation_connection system variable when the trigger was created.
- **Database Collation**: The collation of the database with which the trigger is associated.

Trigger information is also available from the INFORMATION_SCHEMA TRIGGERS table. See Section 21.27, "The INFORMATION_SCHEMA TRIGGERS Table".

### 13.7.5.14 SHOW CREATE VIEW Statement

**SHOW CREATE VIEW** view_name

This statement shows the CREATE VIEW statement that creates the named view.

```
SHOW CREATE VIEW v
```

```
*************************** 1. row ***************************
| View: v |
| Create View: CREATE ALGORITHM=UNDEFINED |
| DEFINER=`bob`@`localhost` |
| SQL SECURITY DEFINER VIEW |
| (`v` AS select 1 AS `a`,2 AS `b`) |
| character_set_client: utf8 |
| collation_connection: utf8_general_ci |
```

**character_set_client** is the session value of the character_set_client system variable when the view was created. **collation_connection** is the session value of the collation_connection system variable when the view was created.

Use of SHOW CREATE VIEW requires the SHOW VIEW privilege, and the SELECT privilege for the view in question.
SHOW Statements

View information is also available from the INFORMATION_SCHEMA VIEWS table. See Section 21.29, “The INFORMATION_SCHEMA VIEWS Table”.

MySQL lets you use different sql_mode settings to tell the server the type of SQL syntax to support. For example, you might use the ANSI SQL mode to ensure MySQL correctly interprets the standard SQL concatenation operator, the double bar (||), in your queries. If you then create a view that concatenates items, you might worry that changing the sql_mode setting to a value different from ANSI could cause the view to become invalid. But this is not the case. No matter how you write out a view definition, MySQL always stores it the same way, in a canonical form. Here is an example that shows how the server changes a double bar concatenation operator to a CONCAT() function:

```sql
mysql> SET sql_mode = 'ANSI';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE VIEW test.v AS SELECT 'a' || 'b' as col1;
Query OK, 0 rows affected (0.01 sec)

mysql> SHOW CREATE VIEW test.v\G
*************************** 1. row ***************************
View: v
Create View: CREATE VIEW "v" AS select concat('a','b') AS "col1"
...
1 row in set (0.00 sec)
```

The advantage of storing a view definition in canonical form is that changes made later to the value of sql_mode will not affect the results from the view. However an additional consequence is that comments prior to SELECT are stripped from the definition by the server.

13.7.5.15 SHOW DATABASES Statement

SHOW DATABASES lists the databases on the MySQL server host. SHOW SCHEMAS is a synonym for SHOW DATABASES. The LIKE clause, if present, indicates which database names to match. The WHERE clause can be given to select rows using more general conditions, as discussed in Section 21.35, “Extensions to SHOW Statements”.

You see only those databases for which you have some kind of privilege, unless you have the global SHOW DATABASES privilege. You can also get this list using the mysqlshow command.

If the server was started with the --skip-show-database option, you cannot use this statement at all unless you have the SHOW DATABASES privilege.

MySQL implements databases as directories in the data directory, so this statement simply lists directories in that location. However, the output may include names of directories that do not correspond to actual databases.

Database information is also available from the INFORMATION_SCHEMA SCHEMATA table. See Section 21.20, “The INFORMATION_SCHEMA SCHEMATA Table”.

Caution

Because a global privilege is considered a privilege for all databases, any global privilege enables a user to see all database names with SHOW DATABASES or by examining the INFORMATION_SCHEMA SCHEMATA table.

13.7.5.16 SHOW ENGINE Statement

SHOW ENGINE engine_name {STATUS | MUTEX}

SHOW ENGINE displays operational information about a storage engine. It requires the PROCESS privilege. The statement has these variants:
SHOW ENGINE INNODB STATUS displays extensive information from the standard InnoDB Monitor about the state of the InnoDB storage engine. For information about the standard monitor and other InnoDB Monitors that provide information about InnoDB processing, see Section 14.17, “InnoDB Monitors”.

SHOW ENGINE INNODB MUTEX displays InnoDB mutex and rw-lock statistics.

Note

Most SHOW ENGINE INNODB MUTEX output is removed in 5.6.14. SHOW ENGINE INNODB MUTEX output is removed entirely in MySQL 5.7.2. InnoDB mutexes can be monitored using Performance Schema tables. For an example, see Section 14.16.1, “Monitoring InnoDB Mutex Waits Using Performance Schema”.

- **Type**
  - Always InnoDB.

- **Name**
  - The source file where the mutex is implemented, and the line number in the file where the mutex is created. The line number is specific to your version of MySQL.

- **Status**
  - The mutex status. This field displays several values if WITH_DEBUG was defined at MySQL compilation time. If WITH_DEBUG was not defined, the statement displays only the os_waits value. In the latter case (without WITH_DEBUG), the information on which the output is based is insufficient to distinguish regular mutexes and mutexes that protect rw-locks (which permit multiple readers or a single writer). Consequently, the output may appear to contain multiple rows for the same mutex.
    - **count** indicates how many times the mutex was requested.
    - **spin_waits** indicates how many times the spinlock had to run.
    - **spin_rounds** indicates the number of spinlock rounds. (spin_rounds divided by spin_waits provides the average round count.)
    - **os_waits** indicates the number of operating system waits. This occurs when the spinlock did not work (the mutex was not locked during the spinlock and it was necessary to yield to the operating system and wait).
    - **os_yields** indicates the number of times a thread trying to lock a mutex gave up its timeslice and yielded to the operating system (on the presumption that permitting other threads to run will free the mutex so that it can be locked).
    - **os_wait_times** indicates the amount of time (in ms) spent in operating system waits. In MySQL 5.6 timing is disabled and this value is always 0.

SHOW ENGINE INNODB MUTEX does not list mutexes and rw-locks for each buffer pool block, as the amount of output would be overwhelming on systems with a large buffer pool. SHOW ENGINE INNODB MUTEX does, however, print aggregate BUF_BLOCK_MUTEX spin, wait, and call values for buffer pool block mutexes and rw-locks. SHOW ENGINE INNODB MUTEX also does not list any mutexes or rw-locks that have never been waited on (os_waits=0). Thus, SHOW ENGINE INNODB MUTEX only displays information about mutexes and rw-locks outside of the buffer pool that have caused at least one OS-level wait.
**SHOW Statements**

**SHOW ENGINE INNODB Mutex** information can be used to diagnose system problems. For example, large values of `spin_waits` and `spin_rounds` may indicate scalability problems.

Use **SHOW ENGINE PERFORMANCE_SCHEMA STATUS** to inspect the internal operation of the Performance Schema code:

```sql
mysql> SHOW ENGINE PERFORMANCE_SCHEMA STATUS\G
```

---

<table>
<thead>
<tr>
<th>Type</th>
<th>Name</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>performance_schema</td>
<td>events_waits_history.row_size</td>
<td>76</td>
</tr>
<tr>
<td>performance_schema</td>
<td>events_waits_history.row_count</td>
<td>10000</td>
</tr>
<tr>
<td>performance_schema</td>
<td>events_waits_history.memory</td>
<td>76000</td>
</tr>
<tr>
<td>performance_schema</td>
<td>events_waits_history.memory</td>
<td>26459600</td>
</tr>
</tbody>
</table>

This statement is intended to help the DBA understand the effects that different Performance Schema options have on memory requirements.

**Name** values consist of two parts, which name an internal buffer and a buffer attribute, respectively. Interpret buffer names as follows:

- An internal buffer that is not exposed as a table is named within parentheses. Examples: `pfs_cond_class).row_size`, `pfs_mutex_class).memory`.
- An internal buffer that is exposed as a table in the `performance_schema` database is named after the table, without parentheses. Examples: `events_waits_history.row_size`, `mutex_instances.row_count`.

Buffer attributes have these meanings:

- **row_size** is the size of the internal record used by the implementation, such as the size of a row in a table. `row_size` values cannot be changed.

- **row_count** is the number of internal records, such as the number of rows in a table. `row_count` values can be changed using Performance Schema configuration options.

- For a table, `tbl_name.memory` is the product of `row_size` and `row_count`. For the Performance Schema as a whole, `performance_schema.memory` is the sum of all the memory used (the sum of all other `memory` values).

In some cases, there is a direct relationship between a Performance Schema configuration parameter and a **SHOW ENGINE** value. For example, `events_waits_history_long.row_count` corresponds to `performance_schema.events_waits_history_long_size`. In other cases, the relationship is more complex. For example, `events_waits_history.row_count` corresponds to `performance_schema.events_waits_history_size` (the number of rows per thread) multiplied by `performance_schema.max_thread_instances` (the number of threads).

**SHOW ENGINE NDB STATUS.** If the server has the NDB storage engine enabled, **SHOW ENGINE NDB STATUS** displays cluster status information such as the number of connected data nodes, the
SHOW Statements

cluster connectstring, and cluster binary log epochs, as well as counts of various Cluster API objects created by the MySQL Server when connected to the cluster. Sample output from this statement is shown here:

```sql
mysql> SHOW ENGINE NDB STATUS;
+------------+-----------------------+--------------------------------------------------+
| Type       | Name                  | Status                                           |
+------------+-----------------------+--------------------------------------------------+
| ndbcluster | connection            | cluster_node_id=7, connected_host=198.51.100.103, connected_port=1186, number_of_data_nodes=4, number_of_ready_data_nodes=3, connect_count=0 |
| ndbcluster | NdbTransaction        | created=6, free=0, sizeof=212                   |
| ndbcluster | NdbOperation          | created=8, free=8, sizeof=660                   |
| ndbcluster | NdbIndexScanOperation | created=1, free=1, sizeof=744                   |
| ndbcluster | NdbIndexOperation     | created=0, free=0, sizeof=664                   |
| ndbcluster | NdbRecAttr            | created=1285, free=1285, sizeof=60              |
| ndbcluster | NdbApiSignal          | created=16, free=16, sizeof=136                 |
| ndbcluster | NdbLabel              | created=0, free=0, sizeof=196                   |
| ndbcluster | NdbBranch             | created=0, free=0, sizeof=24                    |
| ndbcluster | NdbSubroutine         | created=0, free=0, sizeof=68                    |
| ndbcluster | NdbCall               | created=0, free=0, sizeof=16                    |
| ndbcluster | NdbBlob               | created=0, free=0, sizeof=264                   |
| ndbcluster | NdbReceiver           | created=4, free=0, sizeof=16                    |
| ndbcluster | binlog                | latest_epoch=155467, latest_trans_epoch=148126, latest_received_binlog_epoch=0, latest_handled_binlog_epoch=0, latest_applied_binlog_epoch=0 |
+------------+-----------------------+--------------------------------------------------+
```

The **Status** column in each of these rows provides information about the MySQL server's connection to the cluster and about the cluster binary log's status, respectively. The **Status** information is in the form of comma-delimited set of name/value pairs.

The **connection** row's **Status** column contains the name/value pairs described in the following table.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>cluster_node_id</td>
<td>The node ID of the MySQL server in the cluster</td>
</tr>
<tr>
<td>connected_host</td>
<td>The host name or IP address of the cluster management server to which the MySQL server is connected</td>
</tr>
<tr>
<td>connected_port</td>
<td>The port used by the MySQL server to connect to the management server (connected_host)</td>
</tr>
<tr>
<td>number_of_data_nodes</td>
<td>The number of data nodes configured for the cluster (that is, the number of [ndbd] sections in the cluster config.ini file)</td>
</tr>
<tr>
<td>number_of_ready_data_nodes</td>
<td>The number of data nodes in the cluster that are actually running</td>
</tr>
<tr>
<td>connect_count</td>
<td>The number of times this mysqld has connected or reconnected to cluster data nodes</td>
</tr>
</tbody>
</table>

The **binlog** row's **Status** column contains information relating to NDB Cluster Replication. The name/value pairs it contains are described in the following table.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>latest_epoch</td>
<td>The most recent epoch most recently run on this MySQL server (that is, the sequence number of the most recent transaction run on the server)</td>
</tr>
<tr>
<td>latest_trans_epoch</td>
<td>The most recent epoch processed by the cluster's data nodes</td>
</tr>
<tr>
<td>latest_received_binlog_epoch</td>
<td>The most recent epoch received by the binary log thread</td>
</tr>
</tbody>
</table>
SHOW Statements

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>latest_handled_binlog_epoch</td>
<td>The most recent epoch processed by the binary log thread (for writing to the binary log)</td>
</tr>
<tr>
<td>latest_applied_binlog_epoch</td>
<td>The most recent epoch actually written to the binary log</td>
</tr>
</tbody>
</table>

See Section 18.6, “NDB Cluster Replication”, for more information.

The remaining rows from the output of `SHOW ENGINE NDB STATUS` which are most likely to prove useful in monitoring the cluster are listed here by Name:

- **NdbTransaction**: The number and size of `NdbTransaction` objects that have been created. An `NdbTransaction` is created each time a table schema operation (such as `CREATE TABLE` or `ALTER TABLE`) is performed on an NDB table.

- **NdbOperation**: The number and size of `NdbOperation` objects that have been created.

- **NdbIndexScanOperation**: The number and size of `NdbIndexScanOperation` objects that have been created.

- **NdbIndexOperation**: The number and size of `NdbIndexOperation` objects that have been created.

- **NdbRecAttr**: The number and size of `NdbRecAttr` objects that have been created. In general, one of these is created each time a data manipulation statement is performed by an SQL node.

- **NdbBlob**: The number and size of `NdbBlob` objects that have been created. An `NdbBlob` is created for each new operation involving a BLOB column in an NDB table.

- **NdbReceiver**: The number and size of any `NdbReceiver` object that have been created. The number in the `created` column is the same as the number of data nodes in the cluster to which the MySQL server has connected.

**Note**

`SHOW ENGINE NDB STATUS` returns an empty result if no operations involving NDB tables have been performed during the current session by the MySQL client accessing the SQL node on which this statement is run.

13.7.5.17 SHOW ENGINES Statement

`SHOW [STORAGE] ENGINES`

`SHOW ENGINES` displays status information about the server's storage engines. This is particularly useful for checking whether a storage engine is supported, or to see what the default engine is.

For information about MySQL storage engines, see Chapter 14, *The InnoDB Storage Engine*, and Chapter 15, *Alternative Storage Engines*.

```
mysql> SHOW ENGINES\G
*************************** 1. row ***************************
   Engine: FEDERATED
   Support: NO
   Comment: Federated MySQL storage engine
Transactions: NULL
XA: NULL
Savepoints: NULL
*************************** 2. row ***************************
   Engine: MRG_MYISAM
   Support: YES
   Comment: Collection of identical MyISAM tables
Transactions: NO
XA: NO
Savepoints: NO
```
The output from `SHOW ENGINES` may vary according to the MySQL version used and other factors.

`SHOW ENGINES` output has these columns:

- **Engine**
  The name of the storage engine.

- **Support**
  The server's level of support for the storage engine, as shown in the following table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>YES</strong></td>
<td>The engine is supported and is active</td>
</tr>
<tr>
<td><strong>DEFAULT</strong></td>
<td>Like <strong>YES</strong>, plus this is the default engine</td>
</tr>
<tr>
<td><strong>NO</strong></td>
<td>The engine is not supported</td>
</tr>
<tr>
<td><strong>DISABLED</strong></td>
<td>The engine is supported but has been disabled</td>
</tr>
</tbody>
</table>
A value of **NO** means that the server was compiled without support for the engine, so it cannot be enabled at runtime.

A value of **DISABLED** occurs either because the server was started with an option that disables the engine, or because not all options required to enable it were given. In the latter case, the error log should contain a reason indicating why the option is disabled. See Section 5.4.2, “The Error Log”.

You might also see **DISABLED** for a storage engine if the server was compiled to support it, but was started with a **--skip-engine_name** option. For the NDB storage engine, **DISABLED** means the server was compiled with support for NDB Cluster, but was not started with the **--ndbcluster** option.

All MySQL servers support **MyISAM** tables. It is not possible to disable **MyISAM**.

- **Comment**
  A brief description of the storage engine.

- **Transactions**
  Whether the storage engine supports transactions.

- **XA**
  Whether the storage engine supports XA transactions.

- **Savepoints**
  Whether the storage engine supports savepoints.

Storage engine information is also available from the **INFORMATION_SCHEMA ENGINES** table. See Section 21.7, “The INFORMATION_SCHEMA ENGINES Table”.

### 13.7.5.18 SHOW ERRORS Statement

```
SHOW ERRORS [LIMIT [offset,] row_count]
SHOW COUNT(*) ERRORS
```

**SHOW ERRORS** is a diagnostic statement that is similar to **SHOW WARNINGS**, except that it displays information only for errors, rather than for errors, warnings, and notes.

The **LIMIT** clause has the same syntax as for the **SELECT** statement. See Section 13.2.9, “SELECT Statement”.

The **SHOW COUNT(*) ERRORS** statement displays the number of errors. You can also retrieve this number from the **error_count** variable:

```
SHOW COUNT(*) ERRORS;
SELECT @error_count;
```

**SHOW ERRORS** and **error_count** apply only to errors, not warnings or notes. In other respects, they are similar to **SHOW WARNINGS** and **warning_count**. In particular, **SHOW ERRORS** cannot display information for more than **max_error_count** messages, and **error_count** can exceed the value of **max_error_count** if the number of errors exceeds **max_error_count**.

For more information, see Section 13.7.5.41, “SHOW WARNINGS Statement”.

### 13.7.5.19 SHOW EVENTS Statement

```
SHOW EVENTS [[FROM | IN] schema_name]
```

1767
This statement displays information about Event Manager events, which are discussed in Section 20.4, “Using the Event Scheduler”. It requires the EVENT privilege for the database from which the events are to be shown.

In its simplest form, SHOW EVENTS lists all of the events in the current schema:

```sql
SELECT CURRENT_USER(), SCHEMA();
```

```sql
+----------------+----------+
| CURRENT_USER() | SCHEMA() |
+----------------+----------+
| jon@ghidora    | myschema |
+----------------+----------+
1 row in set (0.00 sec)
```

To see events for a specific schema, use the `FROM` clause. For example, to see events for the `test` schema, use the following statement:

```sql
SHOW EVENTS FROM test;
```

The `LIKE` clause, if present, indicates which event names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 21.35, “Extensions to SHOW Statements”.

SHOW EVENTS output has these columns:

- **Db**
  The name of the schema (database) to which the event belongs.

- **Name**
  The name of the event.

- **Definer**
  The account of the user who created the event, in `'user_name'@'host_name'` format.

- **Time zone**
  The event time zone, which is the time zone used for scheduling the event and that is in effect within the event as it executes. The default value is `SYSTEM`.

- **Type**
  The event repetition type, either `ONE TIME` (transient) or `RECURRING` (repeating).

- **Execute At**
  The time and date of the event.
For a one-time event, this is the DATETIME value specified in the AT clause of the CREATE_EVENT statement used to create the event, or of the last ALTER_EVENT statement that modified the event. The value shown in this column reflects the addition or subtraction of any INTERVAL value included in the event's AT clause. For example, if an event is created using ON SCHEDULE AT CURRENT_TIMESTAMP + '1:6' DAY_HOUR, and the event was created at 2018-02-09 14:05:30, the value shown in this column would be '2018-02-10 20:05:30'. If the event's timing is determined by an EVERY clause instead of an AT clause (that is, if the event is recurring), the value of this column is NULL.

• Interval Value
For a recurring event, the number of intervals to wait between event executions. For a transient event, the value of this column is always NULL.

• Interval Field
The time units used for the interval which a recurring event waits before repeating. For a transient event, the value of this column is always NULL.

• Starts
The start date and time for a recurring event. This is displayed as a DATETIME value, and is NULL if no start date and time are defined for the event. For a recurring event, this column is always NULL. For a recurring event whose definition includes a STARTS clause, this column contains the corresponding DATETIME value. As with the Execute At column, this value resolves any expressions used. If there is no STARTS clause affecting the timing of the event, this column is NULL.

• Ends
For a recurring event whose definition includes a ENDS clause, this column contains the corresponding DATETIME value. As with the Execute At column, this value resolves any expressions used. If there is no ENDS clause affecting the timing of the event, this column is NULL.

• Status
The event status. One of ENABLED, DISABLED, or SLAVESIDE_DISABLED. SLAVESIDE_DISABLED indicates that the creation of the event occurred on another MySQL server acting as a replication source and replicated to the current MySQL server which is acting as a replica, but the event is not presently being executed on the replica. For more information, see Section 17.4.1.16, "Replication of Invoked Features".

• Originator
The server ID of the MySQL server on which the event was created; used in replication. This value may be updated by ALTER_EVENT to the server ID of the server on which that statement occurs, if executed on a source server. The default value is 0.

• character_set_client
The session value of the character_set_client system variable when the event was created.

• collation_connection
The session value of the collation_connection system variable when the event was created.

• Database Collation
The collation of the database with which the event is associated.

For more information about SLAVESIDE_DISABLED and the Originator column, see Section 17.4.1.16, “Replication of Invoked Features".
SHOW Statements

Times displayed by `SHOW EVENTS` are given in the event time zone, as discussed in Section 20.4.4, “Event Metadata”.

Event information is also available from the `INFORMATION_SCHEMA EVENTS` table. See Section 21.8, “The INFORMATION_SCHEMA EVENTS Table”.

The event action statement is not shown in the output of `SHOW EVENTS`. Use `SHOW CREATE EVENT` or the `INFORMATION_SCHEMA EVENTS` table.

### 13.7.5.20 SHOW FUNCTION CODE Statement

```sql
SHOW FUNCTION CODE `func_name`
```

This statement is similar to `SHOW PROCEDURE CODE` but for stored functions. See Section 13.7.5.28, “SHOW PROCEDURE CODE Statement”.

### 13.7.5.21 SHOW FUNCTION STATUS Statement

```sql
SHOW FUNCTION STATUS [LIKE `pattern` | WHERE `expr`]
```

This statement is similar to `SHOW PROCEDURE STATUS` but for stored functions. See Section 13.7.5.29, “SHOW PROCEDURE STATUS Statement”.

### 13.7.5.22 SHOW GRANTS Statement

```sql
SHOW GRANTS [FOR `user`]
```

This statement displays the privileges that are assigned to a MySQL user account, in the form of `GRANT` statements that must be executed to duplicate the privilege assignments.

`SHOW GRANTS` requires the `SELECT` privilege for the `mysql` system database, except to display privileges for the current user. For output that includes an `IDENTIFIED BY PASSWORD` clause displaying an account password hash value, the `SUPER` privilege is required to see the actual hash value. Otherwise, the value displays as `<secret>`.

To name the account for `SHOW GRANTS`, use the same format as for the `GRANT` statement (for example, `'jeffrey'@'localhost'`):

```
mysql> SHOW GRANTS FOR 'jeffrey'@'localhost';
+------------------------------------------------------------------+
| Grants for jeffrey@localhost                                     |
| GRANT USAGE ON *.* TO `jeffrey`@`localhost`                      |
| GRANT SELECT, INSERT, UPDATE ON `db1`.* TO `jeffrey`@`localhost` |
+------------------------------------------------------------------+
```

The host part, if omitted, defaults to `'%'`. For additional information about specifying account names, see Section 6.2.4, “Specifying Account Names”.

To display the privileges granted to the current user (the account you are using to connect to the server), you can use any of the following statements:

```sql
SHOW GRANTS;
SHOW GRANTS FOR CURRENT_USER;
SHOW GRANTS FOR CURRENT_USER();
```

If `SHOW GRANTS FOR CURRENT_USER` (or any equivalent syntax) is used in definer context, such as within a stored procedure that executes with definer rather than invoker privileges, the grants displayed are those of the definer and not the invoker.

`SHOW GRANTS` does not display privileges that are available to the named account but are granted to a different account. For example, if an anonymous account exists, the named account might be able to use its privileges, but `SHOW GRANTS` does not display them.
SHOW Statements

### 13.7.5.23 SHOW INDEX Statement

SHOW {INDEX | INDEXES | KEYS} {FROM | IN} tbl_name [{FROM | IN} db_name] [WHERE expr]

SHOW INDEX returns table index information. The format resembles that of the SQLStatistics call in ODBC. This statement requires some privilege for any column in the table.

```sql
mysql> SHOW INDEX FROM City\G
*************************** 1. row ***************************
Table: city
Non_unique: 0
Key_name: PRIMARY
Seq_in_index: 1
Column_name: ID
Collation: A
Cardinality: 4188
Sub_part: NULL
Packed: NULL
Null:
Index_type: BTREE
Comment:
Index_comment:
*************************** 2. row ***************************
Table: city
Non_unique: 1
Key_name: CountryCode
Seq_in_index: 1
Column_name: CountryCode
Collation: A
Cardinality: 4188
Sub_part: NULL
Packed: NULL
Null:
Index_type: BTREE
Comment:
Index_comment:
```

An alternative to `tbl_name FROM db_name` syntax is `db_name.tbl_name`. These two statements are equivalent:

```sql
SHOW INDEX FROM mytable FROM mydb;
SHOW INDEX FROM mydb.mytable;
```

The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 21.35, “Extensions to SHOW Statements”.

SHOW INDEX returns the following fields:

- **Table**
  - The name of the table.

- **Non_unique**
  - 0 if the index cannot contain duplicates, 1 if it can.

- **Key_name**
  - The name of the index. If the index is the primary key, the name is always PRIMARY.

- **Seq_in_index**
  - The column sequence number in the index, starting with 1.

- **Column_name**
  - The name of the column.
SHOW Statements

The name of the column.

- **Collation**

  How the column is sorted in the index. This can have values `A` (ascending) or `NULL` (not sorted).

- **Cardinality**

  An estimate of the number of unique values in the index. To update this number, run `ANALYZE TABLE` or (for MyISAM tables) `myisamchk -a`.

  Cardinality is counted based on statistics stored as integers, so the value is not necessarily exact even for small tables. The higher the cardinality, the greater the chance that MySQL uses the index when doing joins.

- **Sub_part**

  The index prefix. That is, the number of indexed characters if the column is only partly indexed, `NULL` if the entire column is indexed.

  **Note**

  Prefix *limits* are measured in bytes. However, prefix *lengths* for index specifications in `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements are interpreted as number of characters for nonbinary string types (`CHAR`, `VARCHAR`, `TEXT`) and number of bytes for binary string types (`BINARY`, `VARBINARY`, `BLOB`). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

  For additional information about index prefixes, see Section 8.3.4, “Column Indexes”, and Section 13.1.13, “CREATE INDEX Statement”.

- **Packed**

  Indicates how the key is packed. `NULL` if it is not.

- **Null**

  Contains `YES` if the column may contain `NULL` values and `''` if not.

- **Index_type**

  The index method used (`BTREE`, `FULLTEXT`, `HASH`, `RTREE`).

- **Comment**

  Information about the index not described in its own column, such as `disabled` if the index is disabled.

- **Index_comment**

  Any comment provided for the index with a `COMMENT` attribute when the index was created.

Information about table indexes is also available from the `INFORMATION_SCHEMA STATISTICS` table. See Section 21.22, “The INFORMATION_SCHEMA STATISTICS Table”.

You can list a table’s indexes with the `mysqlshow -k db_name tbl_name` command.

### 13.7.5.24 SHOW MASTER STATUS Statement

| SHOW MASTER STATUS | 1772 |
This statement provides status information about the binary log files of the source. It requires either the **SUPER** or **REPLICATION CLIENT** privilege.

Example:

```
mysql> SHOW MASTER STATUS\G
*************************** 1. row ***************************
  File: source-bin.000002
  Position: 1307
Binlog_Do_DB: test
Binlog_Ignore_DB: manual, mysql
Executed_Gtid_Set: 3E11FA47-71CA-11E1-9E33-C80AA9429562:1-5
1 row in set (0.00 sec)
```

When global transaction IDs are in use, this column shows the set of GTIDs for transactions that have been executed on the source. This is the same as the value for the `gtid_executed` system variable on this server, as well as the value for `Executed_Gtid_Set` in the output of `SHOW SLAVE STATUS` on this server.

### 13.7.5.25 SHOW OPEN TABLES Statement

```
SHOW OPEN TABLES
   [\{FROM | IN\} \{db_name\}]
   [LIKE 'pattern' | WHERE \{expr\}]
```

`SHOW OPEN TABLES` lists the non-TEMPORARY tables that are currently open in the table cache. See Section 8.4.3.1, “How MySQL Opens and Closes Tables”. The `FROM` clause, if present, restricts the tables shown to those present in the `db_name` database. The `LIKE` clause, if present, indicates which table names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 21.35, “Extensions to SHOW Statements”.

`SHOW OPEN TABLES` output has these columns:

- **Database**
  The database containing the table.

- **Table**
  The table name.

- **In_use**
  The number of table locks or lock requests there are for the table. For example, if one client acquires a lock for a table using `LOCK TABLE t1 WRITE`, `In_use` will be 1. If another client issues `LOCK TABLE t1 WRITE` while the table remains locked, the client will block waiting for the lock, but the lock request causes `In_use` to be 2. If the count is zero, the table is open but not currently being used. `In_use` is also increased by the `HANDLER ... OPEN` statement and decreased by `HANDLER ... CLOSE`.

- **Name_locked**
  Whether the table name is locked. Name locking is used for operations such as dropping or renaming tables.

If you have no privileges for a table, it does not show up in the output from `SHOW OPEN TABLES`.

### 13.7.5.26 SHOW PLUGINS Statement

```
SHOW PLUGINS
```

`SHOW PLUGINS` displays information about server plugins.
### Example of `SHOW PlumINS` output:

```sql
mysql> SHOW PLUGINS\G
*************************** 1. row ***************************
    Name: binlog
   Status: ACTIVE
     Type: STORAGE ENGINE
    Library: NULL
   License: GPL
*************************** 2. row ***************************
    Name: CSV
   Status: ACTIVE
     Type: STORAGE ENGINE
    Library: NULL
   License: GPL
*************************** 3. row ***************************
    Name: MEMORY
   Status: ACTIVE
     Type: STORAGE ENGINE
    Library: NULL
   License: GPL
*************************** 4. row ***************************
    Name: MyISAM
   Status: ACTIVE
     Type: STORAGE ENGINE
    Library: NULL
   License: GPL
...
```

`SHOW PLUGINS` output has these columns:

- **Name**
  
The name used to refer to the plugin in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`.

- **Status**
  
The plugin status, one of **ACTIVE**, **INACTIVE**, **DISABLED**, or **DELETED**.

- **Type**
  
The type of plugin, such as **STORAGE ENGINE**, **INFORMATION_SCHEMA**, or **AUTHENTICATION**.

- **Library**
  
The name of the plugin shared library file. This is the name used to refer to the plugin file in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`. This file is located in the directory named by the `plugin_dir` system variable. If the library name is **NULL**, the plugin is compiled in and cannot be uninstalled with `UNINSTALL PLUGIN`.

- **License**
  
  How the plugin is licensed (for example, **GPL**).

For plugins installed with `INSTALL PLUGIN`, the `Name` and `Library` values are also registered in the `mysql.plugin` system table.

For information about plugin data structures that form the basis of the information displayed by `SHOW PLUGINS`, see [The MySQL Plugin API](#).

Plugin information is also available from the `INFORMATION_SCHEMA.PLUGINS` table. See [Section 21.15, “The INFORMATION_SCHEMA PLUGINS Table”](#).

### 13.7.5.27 SHOW PRIVILEGES Statement

1774
SHOW PRIVILEGES

SHOW PRIVILEGES shows the list of system privileges that the MySQL server supports. The exact list of privileges depends on the version of your server.

```
SHOW PRIVILEGES\G
*************************** 1. row ***************************
Privilege: Alter
   Context: Tables
   Comment: To alter the table
*************************** 2. row ***************************
Privilege: Alter routine
   Context: Functions, Procedures
   Comment: To alter or drop stored functions/procedures
*************************** 3. row ***************************
Privilege: Create
   Context: Databases, Tables, Indexes
   Comment: To create new databases and tables
*************************** 4. row ***************************
Privilege: Create routine
   Context: Databases
   Comment: To use CREATE FUNCTION/PROCEDURE
*************************** 5. row ***************************
Privilege: Create temporary tables
   Context: Databases
   Comment: To use CREATE TEMPORARY TABLE
...```

Privileges belonging to a specific user are displayed by the SHOW GRANTS statement. See Section 13.7.5.22, “SHOW GRANTS Statement”, for more information.

### 13.7.5.28 SHOW PROCEDURE CODE Statement

```
SHOW PROCEDURE CODE proc_name

This statement is a MySQL extension that is available only for servers that have been built with debugging support. It displays a representation of the internal implementation of the named stored procedure. A similar statement, SHOW FUNCTION CODE, displays information about stored functions (see Section 13.7.5.20, “SHOW FUNCTION CODE Statement”).

To use either statement, you must be the owner of the routine or have SELECT access to the mysql.proc table.

If the named routine is available, each statement produces a result set. Each row in the result set corresponds to one “instruction” in the routine. The first column is Pos, which is an ordinal number beginning with 0. The second column is Instruction, which contains an SQL statement (usually changed from the original source), or a directive which has meaning only to the stored-routine handler.

```
mysql> DELIMITER //
mysql> CREATE PROCEDURE p1 ()
    
BEGIN
    DECLARE fanta INT DEFAULT 55;
    DROP TABLE t2;
    LOOP
        INSERT INTO t3 VALUES (fanta);
    END LOOP;
END//
Query OK, 0 rows affected (0.01 sec)
mysql> SHOW PROCEDURE CODE p1//
<table>
<thead>
<tr>
<th>Pos</th>
<th>Instruction</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>set fanta@0 55</td>
</tr>
<tr>
<td>1</td>
<td>stmt 9 &quot;DROP TABLE t2&quot;</td>
</tr>
<tr>
<td>2</td>
<td>stmt 5 &quot;INSERT INTO t3 VALUES (fanta)&quot;</td>
</tr>
<tr>
<td>3</td>
<td>jump 2</td>
</tr>
</tbody>
</table>
```

SHOW Statements

4 rows in set (0.00 sec)

mysql> CREATE FUNCTION test.hello (s CHAR(20))
    RETURNS CHAR(50) DETERMINISTIC
    RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW FUNCTION CODE test.hello;
+-----+---------------------------------------+
| Pos | Instruction                           |
+-----+---------------------------------------+
|  0  | freturn 254 concat('Hello, ',s@0,'!') |
+-----+---------------------------------------+
1 row in set (0.00 sec)

In this example, the nonexecutable BEGIN and END statements have disappeared, and for the DECLARE variable_name statement, only the executable part appears (the part where the default is assigned). For each statement that is taken from source, there is a code word stmt followed by a type (9 means DROP, 5 means INSERT, and so on). The final row contains an instruction jump 2, meaning GOTO instruction #2.

13.7.5.29 SHOW PROCEDURE STATUS Statement

SHOW PROCEDURE STATUS
[LIKE 'pattern' | WHERE expr]

This statement is a MySQL extension. It returns characteristics of a stored procedure, such as the database, name, type, creator, creation and modification dates, and character set information. A similar statement, SHOW FUNCTION STATUS, displays information about stored functions (see Section 13.7.5.21, “SHOW FUNCTION STATUS Statement”).

To use either statement, you must be the owner of the routine or have SELECT access to the mysql.proc table.

The LIKE clause, if present, indicates which procedure or function names to match. The WHERE clause can be given to select rows using more general conditions, as discussed in Section 21.35, “Extensions to SHOW Statements”.

mysql> SHOW PROCEDURE STATUS LIKE 'sp1'\G
*************************** 1. row ***************************
Db: test
Name: sp1
Type: PROCEDURE
Definer: testuser@localhost
Modified: 2018-08-08 13:54:11
Created: 2018-08-08 13:54:11
Security_type: DEFINER
Comment: character_set_client: utf8
collation_connection: utf8_general_ci
Database Collation: latin1_swedish_ci

mysql> SHOW FUNCTION STATUS LIKE 'hello'\G
*************************** 1. row ***************************
Db: test
Name: hello
Type: FUNCTION
Definer: testuser@localhost
Modified: 2020-03-10 11:14:27
Created: 2020-03-10 11:14:27
Security_type: DEFINER
Comment: character_set_client: utf8
collation_connection: utf8_general_ci
Database Collation: latin1_swedish_ci

character_set_client is the session value of the character_set_client system variable when the routine was created. collation_connection is the session value of the
collation_connection system variable when the routine was created. Database Collation is the collation of the database with which the routine is associated.

Stored routine information is also available from the INFORMATION_SCHEMA PARAMETERS and ROUTINES tables. See Section 21.13, "The INFORMATION_SCHEMA PARAMETERS Table", and Section 21.19, "The INFORMATION_SCHEMA ROUTINES Table".

13.7.5.30 SHOW PROCESSLIST Statement

SHOW [FULL] PROCESSLIST

The MySQL process list indicates the operations currently being performed by the set of threads executing within the server. The SHOW PROCESSLIST statement is one source of process information. For a comparison of this statement with other sources, see Sources of Process Information.

If you have the PROCESS privilege, you can see all threads, even those belonging to other users. Otherwise (without the PROCESS privilege), nonanonymous users have access to information about their own threads but not threads for other users, and anonymous users have no access to thread information.

Without the FULL keyword, SHOW PROCESSLIST displays only the first 100 characters of each statement in the Info field.

The SHOW PROCESSLIST statement is very useful if you get the “too many connections” error message and want to find out what is going on. MySQL reserves one extra connection to be used by accounts that have the SUPER privilege, to ensure that administrators should always be able to connect and check the system (assuming that you are not giving this privilege to all your users).

Threads can be killed with the KILL statement. See Section 13.7.6.4, “KILL Statement”.

Example of SHOW PROCESSLIST output:

```sql
mysql> SHOW FULL PROCESSLIST\G
*************************** 1. row ***************************
  Id: 1
  User: system user
  Host: 
  db: NULL
  Command: Connect
  Time: 103548
  State: Waiting for master to send event
  Info: NULL

*************************** 2. row ***************************
  Id: 2
  User: system user
  Host: 
  db: NULL
  Command: Connect
  Time: 1004
  State: Has read all relay log; waiting for the slave I/O thread to update it
  Info: NULL

*************************** 3. row ***************************
  Id: 3112
  User: replikator
  Host: artemis:2204
  db: NULL
  Command: Binlog Dump
  Time: 2144
  State: Has sent all binlog to slave; waiting for binlog to be updated
  Info: NULL

*************************** 4. row ***************************
  Id: 3113
  User: replikator
  Host: iconnect2:45781
  db: NULL
```
SHOW PROCESSLIST output has these columns:

- **Id**

  The connection identifier. This is the same value displayed in the ID column of the INFORMATION_SCHEMA.PROCESSLIST table, displayed in the PROCESSLIST_ID column of the Performance Schema threads table, and returned by the CONNECTION_ID() function within the thread.

- **User**

  The MySQL user who issued the statement. A value of system user refers to a nonclient thread spawned by the server to handle tasks internally, for example, a delayed-row handler thread or an I/O or SQL thread used on replica hosts. For system user, there is no host specified in the Host column. unauthenticated user refers to a thread that has become associated with a client connection but for which authentication of the client user has not yet occurred. event_scheduler refers to the thread that monitors scheduled events (see Section 20.4, “Using the Event Scheduler”).

- **Host**

  The host name of the client issuing the statement (except for system user, for which there is no host). The host name for TCP/IP connections is reported in host_name:client_port format to make it easier to determine which client is doing what.

- **db**

  The default database for the thread, or NULL if none has been selected.

- **Command**

  The type of command the thread is executing on behalf of the client, or Sleep if the session is idle. For descriptions of thread commands, see Section 8.14, “Examining Server Thread (Process) Information”. The value of this column corresponds to the COM_xxx commands of the client/server protocol and Com_xxx status variables. See Section 5.1.9, “Server Status Variables”.

- **Time**

  The time in seconds that the thread has been in its current state. For a replica SQL thread, the value is the number of seconds between the timestamp of the last replicated event and the real time of the replica host. See Section 17.2.1, “Replication Threads”.

- **State**

  An action, event, or state that indicates what the thread is doing. For descriptions of State values, see Section 8.14, “Examining Server Thread (Process) Information”.

  Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that needs to be investigated.

- **Info**
The statement the thread is executing, or NULL if it is executing no statement. The statement might be the one sent to the server, or an innermost statement if the statement executes other statements. For example, if a CALL statement executes a stored procedure that is executing a SELECT statement, the Info value shows the SELECT statement.

13.7.5.31 SHOW PROFILE Statement

```sql
SHOW PROFILE [type [, type] ... ]
  [FOR QUERY n]
  [LIMIT row_count [OFFSET offset]]
```

<table>
<thead>
<tr>
<th>type:</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL</td>
</tr>
<tr>
<td>BLOCK IO</td>
</tr>
<tr>
<td>CONTEXT SWITCHES</td>
</tr>
<tr>
<td>CPU</td>
</tr>
<tr>
<td>IPC</td>
</tr>
<tr>
<td>MEMORY</td>
</tr>
<tr>
<td>PAGE FAULTS</td>
</tr>
<tr>
<td>SOURCE</td>
</tr>
<tr>
<td>SWAPS</td>
</tr>
</tbody>
</table>

The SHOW PROFILE and SHOW_PROFILES statements display profiling information that indicates resource usage for statements executed during the course of the current session.

![Note]

These statements are deprecated as of MySQL 5.6.7 and will be removed in a future MySQL release. Use the Performance Schema instead; see Section 22.18.1, "Query Profiling Using Performance Schema".

To control profiling, use the profiling session variable, which has a default value of 0 (OFF). Enable profiling by setting profiling to 1 or ON:

```sql
mysql> SET profiling = 1;
```

SHOW_PROFILES displays a list of the most recent statements sent to the server. The size of the list is controlled by the profiling_history_size session variable, which has a default value of 15. The maximum value is 100. Setting the value to 0 has the practical effect of disabling profiling.

All statements are profiled except SHOW PROFILE and SHOW_PROFILES, so you will find neither of those statements in the profile list. Malformed statements are profiled. For example, SHOW PROFILING is an illegal statement, and a syntax error occurs if you try to execute it, but it will show up in the profiling list.

SHOW PROFILE displays detailed information about a single statement. Without the FOR QUERY n clause, the output pertains to the most recently executed statement. If FOR QUERY n is included, SHOW PROFILE displays information for statement n. The values of n correspond to the Query_ID values displayed by SHOW_PROFILES.

The LIMIT row_count clause may be given to limit the output to row_count rows. If LIMIT is given, OFFSET offset may be added to begin the output offset rows into the full set of rows.

By default, SHOW PROFILE displays Status and Duration columns. The Status values are like the State values displayed by SHOW_PROCESSLIST, although there might be some minor differences in interpretation for the two statements for some status values (see Section 8.14, “Examining Server Thread (Process) Information”).

Optional type values may be specified to display specific additional types of information:

- ALL displays all information
SHOW Statements

- **BLOCK IO** displays counts for block input and output operations
- **CONTEXT SWITCHES** displays counts for voluntary and involuntary context switches
- **CPU** displays user and system CPU usage times
- **IPC** displays counts for messages sent and received
- **MEMORY** is not currently implemented
- **PAGE FAULTS** displays counts for major and minor page faults
- **SOURCE** displays the names of functions from the source code, together with the name and line number of the file in which the function occurs
- **SWAPS** displays swap counts

Profiling is enabled per session. When a session ends, its profiling information is lost.

```sql
mysql> SELECT @@profiling;
+-------------+
| @@profiling |
| 0           |
+-------------+
1 row in set (0.00 sec)

mysql> SET profiling = 1;
Query OK, 0 rows affected (0.00 sec)

mysql> DROP TABLE IF EXISTS t1;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> CREATE TABLE t1 (id INT);
Query OK, 0 rows affected (0.01 sec)

mysql> SHOW PROFILES;
+----------+----------+--------------------------+
| Query_ID | Duration | Query                    |
|----------+----------+--------------------------|
|        0 | 0.000088 | SET PROFILING = 1        |
|        1 | 0.000136 | DROP TABLE IF EXISTS t1  |
|        2 | 0.011947 | CREATE TABLE t1 (id INT) |
+----------+----------+--------------------------+
3 rows in set (0.00 sec)

mysql> SHOW PROFILE;
+----------------------+----------+
<table>
<thead>
<tr>
<th>Status</th>
<th>Duration</th>
</tr>
</thead>
<tbody>
<tr>
<td>checking permissions</td>
<td>0.000040</td>
</tr>
<tr>
<td>creating table</td>
<td>0.000056</td>
</tr>
<tr>
<td>After create</td>
<td>0.011363</td>
</tr>
<tr>
<td>query end</td>
<td>0.000375</td>
</tr>
<tr>
<td>freeing items</td>
<td>0.000089</td>
</tr>
<tr>
<td>logging slow query</td>
<td>0.000019</td>
</tr>
<tr>
<td>cleaning up</td>
<td>0.000005</td>
</tr>
</tbody>
</table>
+----------------------+----------+
7 rows in set (0.00 sec)

mysql> SHOW PROFILE FOR QUERY 1;
+----------------------+----------+
<table>
<thead>
<tr>
<th>Status</th>
<th>Duration</th>
</tr>
</thead>
<tbody>
<tr>

+----------------------+----------+----------+------------+
7 rows in set (0.00 sec)

Note
Profiling is only partially functional on some architectures. For values that depend on the getrusage() system call, NULL is returned on systems such as Windows that do not support the call. In addition, profiling is per process and not per thread. This means that activity on threads within the server other than your own may affect the timing information that you see.

Profiling information is also available from the INFORMATION_SCHEMA PROFILING table. See Section 21.17, “The INFORMATION_SCHEMA PROFILING Table”. For example, the following queries are equivalent:

SHOW PROFILE FOR QUERY 2;

SELECT STATE, FORMAT(DURATION, 6) AS DURATION
FROM INFORMATION_SCHEMA.PROFILING
WHERE QUERY_ID = 2 ORDER BY SEQ;

13.7.5.32 SHOW PROFILES Statement

SHOW PROFILES

The SHOW PROFILES statement, together with SHOW PROFILE, displays profiling information that indicates resource usage for statements executed during the course of the current session. For more information, see Section 13.7.5.31, “SHOW PROFILE Statement”.

Note
These statements are deprecated as of MySQL 5.6.7 and will be removed in a future MySQL release. Use the Performance Schema instead; see Chapter 22, MySQL Performance Schema.

13.7.5.33 SHOW RELAYLOG EVENTS Statement

SHOW RELAYLOG EVENTS

   [IN 'log_name']
   [FROM pos]
   [LIMIT [offset,] row_count]

Shows the events in the relay log of a replica. If you do not specify 'log_name', the first relay log is displayed. This statement has no effect on the source.

The LIMIT clause has the same syntax as for the SELECT statement. See Section 13.2.9, “SELECT Statement”.

Note
Issuing a SHOW RELAYLOG EVENTS with no LIMIT clause could start a very time- and resource-consuming process because the server returns to the client the complete contents of the relay log (including all statements modifying data that have been received by the replica).
SHOW RELAYLOG EVENTS displays the following fields for each event in the relay log:

- **Log_name**
  The name of the file that is being listed.

- **Pos**
  The position at which the event occurs.

- **Event_type**
  An identifier that describes the event type.

- **Server_id**
  The server ID of the server on which the event originated.

- **End_log_pos**
  The value of `End_log_pos` for this event in the source's binary log.

- **Info**
  More detailed information about the event type. The format of this information depends on the event type.

**Note**
Some events relating to the setting of user and system variables are not included in the output from `SHOW RELAYLOG EVENTS`. To get complete coverage of events within a relay log, use `mysqlbinlog`.

### 13.7.5.34 SHOW SLAVE HOSTS Statement

**SHOW SLAVE HOSTS**
Displays a list of replicas currently registered with the source.

**SHOW SLAVE HOSTS** should be executed on a server that acts as a replication source. The statement displays information about servers that are or have been connected as replicas, with each row of the result corresponding to one replica server, as shown here:

```
mysql> SHOW SLAVE HOSTS;
+------------+-----------+------+-----------+--------------------------------------+
| Server_id  | Host      | Port | Master_id | Slave_UUID                           |
+------------+-----------+------+-----------+--------------------------------------+
| 192168010  | iconnect2 | 3306 | 192168011 | 14cb6624-7f93-11e0-b2c0-c80aa9429562 |
| 1921680101 | athena    | 3306 | 192168011 | 07af4990-f41f-11df-a566-7ac56fda6f65 |
+------------+-----------+------+-----------+--------------------------------------+
```

- **Server_id**: The unique server ID of the replica server, as configured in the replica server's option file, or on the command line with `--server-id=value`.

- **Host**: The host name of the replica server as specified on the replica with the `--report-host` option. This can differ from the machine name as configured in the operating system.

- **User**: The replica server user name as, specified on the replica with the `--report-user` option. Statement output includes this column only if the source server is started with the `--show-slave-auth-info` option.

- **Password**: The replica server password as, specified on the replica with the `--report-password` option. Statement output includes this column only if the source server is started with the `--show-slave-auth-info` option.
SHOW Statements

- **Port**: The port on the source to which the replica server is listening, as specified on the replica with the `--report-port` option.

  A zero in this column means that the replica port (`--report-port`) was not set.

- **Master_id**: The unique server ID of the source server that the replica server is replicating from. This is the server ID of the server on which `SHOW SLAVE HOSTS` is executed, so this same value is listed for each row in the result.

- **Slave_UUID**: The globally unique ID of this replica, as generated on the replica and found in the replica's `auto.cnf` file.

### 13.7.5.35 SHOW SLAVE STATUS Statement

**SHOW SLAVE STATUS**

This statement provides status information on essential parameters of the replica threads. It requires either the **SUPER** or **REPLICATION CLIENT** privilege.

If you issue this statement using the `mysql` client, you can use a `\G` statement terminator rather than a semicolon to obtain a more readable vertical layout:

```sql
mysql> SHOW SLAVE STATUS\G
*************************** 1. row ***************************
Slave_IO_State: Waiting for master to send event
Master_Host: localhost
Master_User: root
Master_Port: 13000
Connect_Retry: 60
Master_Log_File: source-bin.000002
Read_Master_Log_Pos: 1307
Relay_Log_File: replica-relay-bin.000003
Relay_Log_Pos: 1508
Relay_Master_Log_File: source-bin.000002
Slave_IO_Running: Yes
Slave_SQL_Running: Yes
Replicate_Do_DB: 
Replicate_Ignore_DB:
Replicate_Do_Table: 
Replicate_Ignore_Table: 
Replicate_Wild_Do_Table: 
Replicate_Wild_Ignore_Table: 
Last_Errno: 0
Last_Error: 
Skip_Counter: 0
Exec_Master_Log_Pos: 1307
Relay_Log_Space: 1858
Until_Condition: None
Until_Log_File: 
Until_Log_Pos: 0
Master_SSL_Allowed: No
Master_SSL_CA_File: 
Master_SSL_CA_Path: 
Master_SSL_Cert:

Master_UUID: 3e11fa47-71ca-11e1-9e33-c80aa9429562
Master_Info_File: /var/mysqld.2/data/master.info
SQL_Delay: 0
SQL_Remaining_Delay: NULL
Slave_SQL_Running_State: Reading event from the relay log
```
The following list describes the fields returned by `SHOW SLAVE STATUS`. For additional information about interpreting their meanings, see Section 8.14.7, “Replication Replica I/O Thread States”.

- **Slave_IO_State**
  A copy of the `State` field of the `SHOW PROCESSLIST` output for the replica I/O thread. This tells you what the thread is doing: trying to connect to the source, waiting for events from the source, reconnecting to the source, and so on. For a listing of possible states, see Section 8.14.7, “Replication Replica I/O Thread States”.

- **Master_Host**
  The source host that the replica is connected to.

- **Master_User**
  The user name of the account used to connect to the source.

- **Master_Port**
  The port used to connect to the source.

- **Connect_Retry**
  The number of seconds between connect retries (default 60). This can be set with the `CHANGE MASTER TO` statement.

- **Master_Log_File**
  The name of the source binary log file from which the I/O thread is currently reading.

- **Read_Master_Log_Pos**
  The position in the current source binary log file up to which the I/O thread has read.

- **Relay_Log_File**
  The name of the relay log file from which the SQL thread is currently reading and executing.

- **Relay_Log_Pos**
  The position in the current relay log file up to which the SQL thread has read and executed.

- **Relay_Master_Log_File**
  The name of the source binary log file containing the most recent event executed by the SQL thread.

- **Slave_IO_Running**
  Whether the I/O thread is started and has connected successfully to the source. Internally, the state of this thread is represented by one of the following three values:

  - **MYSQL_SLAVE_NOT_RUN**. The replica I/O thread is not running. For this state,
SHOW Statements

- **MYSQL_SLAVE_RUN_NOT_CONNECT.** The replica I/O thread is running, but is not connected to a replication source. For this state, Slave_IO_Running is Connecting.

- **MYSQL_SLAVE_RUN_CONNECT.** The replica I/O thread is running, and is connected to a replication source. For this state, Slave_IO_Running is Yes.

The value of the Slave_running system status variable corresponds with this value.

- **Slave_SQL_Running**
  Whether the SQL thread is started.

- **Replicate_Do_DB, Replicate_Ignore_DB**
  The lists of databases that were specified with the --replicate-do-db and --replicate-ignore-db options, if any.

- **Replicate_Do_Table, Replicate_Ignore_Table, Replicate_Wild_Do_Table, Replicate_Wild_Ignore_Table**
  The lists of tables that were specified with the --replicate-do-table, --replicate-ignore-table, --replicate-wild-do-table, and --replicate-wild-ignore-table options, if any.

- **Last_Errno, Last_Error**
  These columns are aliases for Last_SQL_Errno and Last_SQL_Error.

  Issuing **RESET MASTER** or **RESET SLAVE** resets the values shown in these columns.

  **Note**
  When the replica SQL thread receives an error, it reports the error first, then stops the SQL thread. This means that there is a small window of time during which **SHOW SLAVE STATUS** shows a nonzero value for Last_SQL_Errno even though Slave_SQL_Running still displays Yes.

- **Skip_Counter**
  The current value of the sql_slave_skip_counter system variable. See Section 13.4.2.4, “SET GLOBAL sql_slave_skip_counter Statement”.

- **Exec_Master_Log_Pos**
  The position in the current source binary log file to which the SQL thread has read and executed, marking the start of the next transaction or event to be processed. You can use this value with the CHANGE MASTER TO statement's MASTER_LOG_POS option when starting a new replica from an existing replica, so that the new replica reads from this point. The coordinates given by (Relay_Master_Log_File, Exec_Master_Log_Pos) in the source's binary log correspond to the coordinates given by (Relay_Log_File, Relay_Log_Pos) in the relay log.

  When using a multithreaded replica (by setting slave_parallel_workers to a nonzero value), the value in this column actually represents a “low-water” mark, before which no uncommitted transactions remain. Because the current implementation allows execution of transactions on different databases in a different order on the replica than on the source, this is not necessarily the position of the most recently executed transaction.

- **Relay_Log_Space**
  The total combined size of all existing relay log files.

- **Until_Condition, Until_Log_File, Until_Log_Pos**
The values specified in the **UNTIL** clause of the **START SLAVE** statement.

**Until_Condition** has these values:

- **None** if no **UNTIL** clause was specified
- **Master** if the replica is reading until a given position in the source’s binary log
- **Relay** if the replica is reading until a given position in its relay log
- **SQL_BEFORE_GTIDS** if the replica SQL thread is processing transactions until it has reached the first transaction whose GTID is listed in the **gtid_set**.
- **SQL_AFTER_GTIDS** if the replica threads are processing all transactions until the last transaction in the **gtid_set** has been processed by both threads.
- **SQL_AFTER_MTS_GAPS** if a multithreaded replica's SQL threads are running until no more gaps are found in the relay log.

**Until_Log_File** and **Until_Log_Pos** indicate the log file name and position that define the coordinates at which the SQL thread stops executing.

For more information on **UNTIL** clauses, see Section 13.4.2.5, “START SLAVE Statement”.

**Master_SSL_Allowed**, **Master_SSL_CA_File**, **Master_SSL_CA_Path**, **Master_SSL_Cert**, **Master_SSL_Cipher**, **Master_SSL_CRL_File**, **Master_SSL_CRL_Path**, **Master_SSL_Key**, **Master_SSL_Verify_Server_Cert**

These fields show the SSL parameters used by the replica to connect to the source, if any.

**Master_SSL_Allowed** has these values:

- **Yes** if an SSL connection to the source is permitted
- **No** if an SSL connection to the source is not permitted
- **Ignored** if an SSL connection is permitted but the replica server does not have SSL support enabled

The values of the other SSL-related fields correspond to the values of the **MASTER_SSL_CA**, **MASTER_SSL_CAPATH**, **MASTER_SSL_CERT**, **MASTER_SSL_CIPHER**, **MASTER_SSL_CRL**, **MASTER_SSL_CRLPATH**, **MASTER_SSL_KEY**, and **MASTER_SSL_VERIFY_SERVER_CERT** options to the **CHANGE MASTER TO** statement. See Section 13.4.2.1, “CHANGE MASTER TO Statement”.

**Seconds_Behind_Master**

This field is an indication of how “late” the replica is:

- When the replica is actively processing updates, this field shows the difference between the current timestamp on the replica and the original timestamp logged on the source for the event currently being processed on the replica.
- When no event is currently being processed on the replica, this value is 0.

In essence, this field measures the time difference in seconds between the replica SQL thread and the replica I/O thread. If the network connection between source and replica is fast, the replica I/O thread is very close to the source, so this field is a good approximation of how late the replica SQL thread is compared to the source. If the network is slow, this is not a good approximation; the replica SQL thread may quite often be caught up with the slow-reading replica I/O thread, so **Seconds_Behind_Master** often shows a value of 0, even if the I/O thread is late compared to the source. In other words, **this column is useful only for fast networks**.
SHOW Statements

This time difference computation works even if the source and replica do not have identical clock times, provided that the difference, computed when the replica I/O thread starts, remains constant from then on. Any changes—including NTP updates—can lead to clock skews that can make calculation of Seconds_Behind_Master less reliable.

In MySQL 5.6.9 and later, this field is NULL (undefined or unknown) if the replica SQL thread is not running, or if the SQL thread has consumed all of the relay log and the replica I/O thread is not running. Previously, this field was NULL if the replica SQL thread or the replica I/O thread was not running or was not connected to the source. (Bug #12946333) For example, if (prior to MySQL 5.6.9) the replica I/O thread was running but was not connected to the source and was sleeping for the number of seconds given by the CHANGE MASTER TO statement or --master-connect-retry option (default 60) before reconnecting, the value was NULL. Now in such cases, the connection to the source is not tested; instead, if the I/O thread is running but the relay log is exhausted, Seconds_Behind_Master is set to 0.

The value of Seconds_Behind_Master is based on the timestamps stored in events, which are preserved through replication. This means that if a source M1 is itself a replica of M0, any event from M1’s binary log that originates from M0’s binary log has M0’s timestamp for that event. This enables MySQL to replicate TIMESTAMP successfully. However, the problem for Seconds_Behind_Master is that if M1 also receives direct updates from clients, the Seconds_Behind_Master value randomly fluctuates because sometimes the last event from M1 originates from M0 and sometimes is the result of a direct update on M1.

When using a multithreaded replica, you should keep in mind that this value is based on Exec_Master_Log_Pos, and so may not reflect the position of the most recently committed transaction.

• Last_IO_Errno, Last_IO_Error

The error number and error message of the most recent error that caused the I/O thread to stop. An error number of 0 and message of the empty string mean “no error.” If the Last_IO_Error value is not empty, the error values also appear in the replica’s error log.

I/O error information includes a timestamp showing when the most recent I/O thread error occurred. This timestamp uses the format YYMMDD hh:mm:ss, and appears in the Last_IO_Error_Timestamp column.

Issuing RESET MASTER or RESET SLAVE resets the values shown in these columns.

• Last_SQL_Errno, Last_SQL_Error

The error number and error message of the most recent error that caused the SQL thread to stop. An error number of 0 and message of the empty string mean “no error.” If the Last_SQL_Error value is not empty, the error values also appear in the replica’s error log.

SQL error information includes a timestamp showing when the most recent SQL thread error occurred. This timestamp uses the format YYMMDD hh:mm:ss, and appears in the Last_SQL_Error_Timestamp column.

Issuing RESET MASTER or RESET SLAVE resets the values shown in these columns.

• Replicate_Ignore_Server_Ids

In MySQL 5.6, you set a replica to ignore events from 0 or more sources using the IGNORE_SERVER_IDS option of the CHANGE MASTER TO statement. By default this is blank, and is usually modified only when using a circular or other multi-source replication setup. The message shown for Replicate_Ignore_Server_Ids when not blank consists of a comma-delimited list of one or more numbers, indicating the server IDs to be ignored. For example:

| Replicate_Ignore_Server_Ids | 2, 6, 9 |
SHOW Statements

Note

Ignored_server_ids also shows the server IDs to be ignored, but is a space-delimited list, which is preceded by the total number of server IDs to be ignored. For example, if a CHANGE MASTER TO statement containing the \texttt{IGNORE_SERVER_IDS = \{2, 6, 9\}} option has been issued to tell a replica to ignore sources having the server ID 2, 6, or 9, that information appears as:

\begin{verbatim}
Ignored_server_ids: 3 2 6 9
\end{verbatim}

where 3 is the total number of server IDs being ignored.

Replicate_Ignore_Server_Ids filtering is performed by the I/O thread, rather than by the SQL thread, which means that events which are filtered out are not written to the relay log. This differs from the filtering actions taken by server options such \texttt{--replicate-do-table}, which apply to the SQL thread.

\begin{itemize}
  \item \textbf{Master_Server_Id}
  
  The \texttt{server_id} value from the source.

  \item \textbf{Master_UUID}
  
  The \texttt{server_uuid} value from the source.

  \item \textbf{Master_Info_File}
  
  The location of the \texttt{master.info} file.

  \item \textbf{SQL_Delay}
  
  The number of seconds that the replica must lag the source.

  \item \textbf{SQL_Remaining_Delay}

  \texttt{When Slave_SQL_Running_State is Waiting until MASTER_DELAY seconds after master executed event,} this field contains the number of delay seconds remaining. At other times, this field is \texttt{NULL}.

  \item \textbf{Slave_SQL_Running_State}

  The state of the SQL thread (analogous to \texttt{Slave_IO_State}). The value is identical to the \texttt{State} value of the SQL thread as displayed by \texttt{SHOW PROCESSLIST}; Section 8.14.8, “Replication Replica SQL Thread States”, provides a listing of possible states.

  \item \textbf{Master_Retry_Count}

  The number of times the replica can attempt to reconnect to the source in the event of a lost connection. This value can be set using the \texttt{MASTER_RETRY_COUNT} option of the \texttt{CHANGE MASTER TO} statement (preferred) or the older \texttt{--master-retry-count} server option (still supported for backward compatibility).

  \item \textbf{Master_Bind}

  The network interface that the replica is bound to, if any. This is set using the \texttt{MASTER_BIND} option for the \texttt{CHANGE MASTER TO} statement.

  \item \textbf{Last_IO_Error_Timestamp}

  A timestamp in \texttt{YYMMDD hh:mm:ss} format that shows when the most recent I/O error took place.

  \item \textbf{Last_SQL_Error_Timestamp}

\end{itemize}
SHOW Statements

A timestamp in YYMMDD \( hh:mm:ss \) format that shows when the most recent SQL error occurred.

- **Retrieved_Gtid_Set**

  The set of global transaction IDs corresponding to all transactions received by this replica. Empty if GTIDs are not in use.

  This is the set of all GTIDs that exist or have existed in the relay logs. Each GTID is added as soon as the \textit{Gtid_log_event} is received. This can cause partially transmitted transactions to have their GTIDs included in the set.

  When all relay logs are lost due to executing \texttt{RESET SLAVE} or \texttt{CHANGE MASTER TO}, or due to the effects of the \texttt|--relay-log-recovery} option, the set is cleared. When \texttt{relay_log_purge = 1}, the newest relay log is always kept, and the set is not cleared.

- **Executed_Gtid_Set**

  The set of global transaction IDs written in the binary log. This is the same as the value for the global \texttt{gtid_executed} system variable on this server, as well as the value for \texttt{Executed_Gtid_Set} in the output of \texttt{SHOW MASTER STATUS} on this server. Empty if GTIDs are not in use. See \textit{GTID Sets} for more information.

- **Auto_Position**

  1 if autopositioning is in use; otherwise 0.

### 13.7.5.36 SHOW STATUS Statement

```
SHOW [GLOBAL | SESSION] STATUS
[LIKE 'pattern' | WHERE expr]
```

\textit{SHOW STATUS} provides server status information (see Section 5.1.9, “Server Status Variables”). This statement does not require any privilege. It requires only the ability to connect to the server.

Status variable information is also available from these sources:

- The \texttt{GLOBAL_STATUS} and \texttt{SESSION_STATUS} tables. See Section 21.9, “The \textit{INFORMATION_SCHEMA GLOBAL_STATUS} and \textit{SESSION_STATUS} Tables”.

- The \texttt{mysqladmin extended-status} command. See Section 4.5.2, “\textit{mysqladmin} — A MySQL Server Administration Program”.

For \textit{SHOW STATUS}, a \texttt{LIKE} clause, if present, indicates which variable names to match. A \texttt{WHERE} clause can be given to select rows using more general conditions, as discussed in Section 21.35, “Extensions to SHOW Statements”.

\textit{SHOW STATUS} accepts an optional \texttt{GLOBAL} or \texttt{SESSION} variable scope modifier:

- With a \texttt{GLOBAL} modifier, the statement displays the global status values. A global status variable may represent status for some aspect of the server itself (for example, \texttt{Aborted_connects}), or the aggregated status over all connections to MySQL (for example, \texttt{Bytes_received} and \texttt{Bytes_sent}). If a variable has no global value, the session value is displayed.

- With a \texttt{SESSION} modifier, the statement displays the status variable values for the current connection. If a variable has no session value, the global value is displayed. \texttt{LOCAL} is a synonym for \texttt{SESSION}.

- If no modifier is present, the default is \texttt{SESSION}.

The scope for each status variable is listed at Section 5.1.9, “Server Status Variables”.

1789
Each invocation of the `SHOW STATUS` statement uses an internal temporary table and increments the global `Created_tmp_tables` value.

Partial output is shown here. The list of names and values may differ for your server. The meaning of each variable is given in Section 5.1.9, “Server Status Variables”.

```
mysql> SHOW STATUS;
+--------------------------+------------+
| Variable_name            | Value      |
+--------------------------+------------+
| Aborted_clients          | 0          |
| Aborted_connects         | 0          |
| Bytes_received           | 155372598  |
| Bytes_sent               | 1176560426 |
| Connections              | 30023      |
| Created_tmp_disk_tables  | 0          |
| Created_tmp_tables       | 8340       |
| Created_tmp_files        | 60         |
| ...                      |            |
| Open_tables              | 1          |
| Open_files               | 2          |
| Open_streams             | 0          |
| Opened_tables            | 44600      |
| Questions                | 2026873    |
| ...                      |            |
| Table_locks_immediate    | 1920382    |
| Table_locks_waited       | 0          |
| Threads_cached           | 0          |
| Threads_created          | 30022      |
| Threads_connected        | 1          |
| Threads_running          | 1          |
| Uptime                   | 80380      |
+--------------------------+------------+
```

With a `LIKE` clause, the statement displays only rows for those variables with names that match the pattern:

```
mysql> SHOW STATUS LIKE 'Key%';
+--------------------+----------+
| Variable_name      | Value    |
+--------------------+----------+
| Key_blocks_used    | 14955    |
| Key_read_requests  | 96854827 |
| Key_reads          | 162040   |
| Key_write_requests | 7589728  |
| Key_writes         | 3813196  |
+--------------------+----------+
```

### 13.7.5.37 SHOW TABLE STATUS Statement

```
SHOW TABLE STATUS
   [(FROM | IN) db_name]
   [LIKE 'pattern' | WHERE expr]
```

`SHOW TABLE STATUS` works like `SHOW TABLES`, but provides a lot of information about each non-`TEMPORARY` table. You can also get this list using the `mysqlshow --status db_name` command. The `LIKE` clause, if present, indicates which table names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 21.35, “Extensions to SHOW Statements”.

This statement also displays information about views.

`SHOW TABLE STATUS` output has these columns:

- Name

  The name of the table.
SHOW Statements

- **Engine**
  For partitioned tables, Engine shows the name of the storage engine used by all partitions.

- **Version**
  The version number of the table’s `.frm` file.

- **Row_format**
  The row-storage format (Fixed, Dynamic, Compressed, Redundant, Compact). For MyISAM tables, Dynamic corresponds to what myisamchk --dvv reports as Packed. InnoDB table format is either Redundant or Compact when using the Antelope file format, or Compressed or Dynamic when using the Barracuda file format.

- **Rows**
  The number of rows. Some storage engines, such as MyISAM, store the exact count. For other storage engines, such as InnoDB, this value is an approximation, and may vary from the actual value by as much as 40% to 50%. In such cases, use `SELECT COUNT(*)` to obtain an accurate count.
  The Rows value is NULL for INFORMATION_SCHEMA tables.
  For InnoDB tables, the row count is only a rough estimate used in SQL optimization. (This is also true if the InnoDB table is partitioned.)

- **Avg_row_length**
  The average row length.
  Refer to the notes at the end of this section for related information.

- **Data_length**
  For MyISAM, Data_length is the length of the data file, in bytes.
  For InnoDB, Data_length is the approximate amount of space allocated for the clustered index, in bytes. Specifically, it is the clustered index size, in pages, multiplied by the InnoDB page size.
  Refer to the notes at the end of this section for information regarding other storage engines.

- **Max_data_length**
  For MyISAM, Max_data_length is maximum length of the data file. This is the total number of bytes of data that can be stored in the table, given the data pointer size used.
  Unused for InnoDB.
  Refer to the notes at the end of this section for information regarding other storage engines.

- **Index_length**
  For MyISAM, Index_length is the length of the index file, in bytes.
  For InnoDB, Index_length is the approximate amount of space allocated for non-clustered indexes, in bytes. Specifically, it is the sum of non-clustered index sizes, in pages, multiplied by the InnoDB page size.
  Refer to the notes at the end of this section for information regarding other storage engines.
SHOW Statements

• **Data_free**

The number of allocated but unused bytes.

*InnoDB* tables report the free space of the tablespace to which the table belongs. For a table located in the shared tablespace, this is the free space of the shared tablespace. If you are using multiple tablespaces and the table has its own tablespace, the free space is for only that table. Free space means the number of bytes in completely free extents minus a safety margin. Even if free space displays as 0, it may be possible to insert rows as long as new extents need not be allocated.

For NDB Cluster, *Data_free* shows the space allocated on disk for, but not used by, a Disk Data table or fragment on disk. (In-memory data resource usage is reported by the *Data_length* column.)

For partitioned tables, this value is only an estimate and may not be absolutely correct. A more accurate method of obtaining this information in such cases is to query the *INFORMATION_SCHEMA PARTITIONS* table, as shown in this example:

```
SELECT SUM(DATA_FREE)
FROM INFORMATION_SCHEMA.PARTITIONS
WHERE TABLE_SCHEMA = 'mydb'
AND TABLE_NAME = 'mytable';
```

For more information, see Section 21.14, “The INFORMATION_SCHEMA PARTITIONS Table”.

• **Auto_increment**

The next *AUTO_INCREMENT* value.

• **Create_time**

When the table was created.

Prior to MySQL 5.6.25, for partitioned *InnoDB* tables, the *Create_time* column shows *NULL*. This column shows the correct table creation time for such tables in MySQL 5.6.25 and later. (Bug #17299181, Bug #69990)

• **Update_time**

When the data file was last updated. For some storage engines, this value is *NULL*. For example, *InnoDB* stores multiple tables in its *system tablespace* and the data file timestamp does not apply. Even with *file-per-table* mode with each *InnoDB* table in a separate .ibd file, *change buffering* can delay the write to the data file, so the file modification time is different from the time of the last insert, update, or delete. For *MyISAM*, the data file timestamp is used; however, on Windows the timestamp is not updated by updates, so the value is inaccurate.

For partitioned *InnoDB* tables, *Update_time* is always *NULL*.

• **Check_time**

When the table was last checked. Not all storage engines update this time, in which case, the value is always *NULL*.

For partitioned *InnoDB* tables, *Check_time* is always *NULL*.

• **Collation**

The table default collation. The output does not explicitly list the table default character set, but the collation name begins with the character set name.

• **Checksum**

The live checksum value, if any.
SHOW Statements

- **Create_options**

Extra options used with `CREATE TABLE`.

`Create_options` shows partitioned for partitioned tables.

When creating a table with `strict mode` disabled, the storage engine's default row format is used if the specified row format is not supported. The actual row format of the table is reported in the `Row_format` column. `Create_options` shows the row format that was specified in the `CREATE TABLE` statement.

When altering the storage engine of a table, table options that are not applicable to the new storage engine are retained in the table definition to enable reverting the table with its previously defined options to the original storage engine, if necessary. `Create_options` may show retained options.

- **Comment**

The comment used when creating the table (or information as to why MySQL could not access the table information).

**Notes**

- For InnoDB tables, `SHOW TABLE STATUS` does not give accurate statistics except for the physical size reserved by the table. The row count is only a rough estimate used in SQL optimization.

- For NDB tables, the output of this statement shows appropriate values for the `Avg_row_length` and `Data_length` columns, with the exception that BLOB columns are not taken into account.

- For NDB tables, `Data_length` includes data stored in main memory only; the `Max_data_length` and `Data_free` columns apply to Disk Data.

- For NDB Cluster Disk Data tables, `Max_data_length` shows the space allocated for the disk part of a Disk Data table or fragment. (In-memory data resource usage is reported by the `Data_length` column.)

- For MEMORY tables, the `Data_length`, `Max_data_length`, and `Index_length` values approximate the actual amount of allocated memory. The allocation algorithm reserves memory in large amounts to reduce the number of allocation operations.

- For views, all columns displayed by `SHOW TABLE STATUS` are NULL except that `Name` indicates the view name and `Comment` says VIEW.

Table information is also available from the `INFORMATION_SCHEMA TABLES` table. See Section 21.23, "The INFORMATION_SCHEMA TABLES Table".

### 13.7.5.38 SHOW TABLES Statement

```
SHOW [FULL] TABLES
   [{FROM | IN} db_name]
   [LIKE 'pattern' | WHERE expr]
```

`SHOW TABLES` lists the non-TEMPORARY tables in a given database. You can also get this list using the `mysqlshow db_name` command. The `LIKE` clause, if present, indicates which table names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 21.35, "Extensions to SHOW Statements".

Matching performed by the `LIKE` clause is dependent on the setting of the `lower_case_table_names` system variable.

This statement also lists any views in the database. The optional `FULL` modifier causes `SHOW TABLES` to display a second output column with values of `BASE TABLE` for a table, `VIEW` for a view, or `SYSTEM VIEW` for an `INFORMATION_SCHEMA` table.
If you have no privileges for a base table or view, it does not show up in the output from \texttt{SHOW TABLES} or \texttt{mysqlshow dbname}.

Table information is also available from the \texttt{INFORMATION_SCHEMA.TABLES} table. See Section 21.23, “The \texttt{INFORMATION_SCHEMA.TABLES} Table”.

### 13.7.5.39 \texttt{SHOW TRIGGERS} Statement

\texttt{SHOW TRIGGERS}\[{\text{\{FROM | IN\} db_name}}\]
\[{\text{\{LIKE 'pattern' | WHERE expr\}}\]

\texttt{SHOW TRIGGERS} lists the triggers currently defined for tables in a database (the default database unless a \texttt{FROM} clause is given). This statement returns results only for databases and tables for which you have the \texttt{TRIGGER} privilege. The \texttt{LIKE} clause, if present, indicates which table names (not trigger names) to match and causes the statement to display triggers for those tables. The \texttt{WHERE} clause can be given to select rows using more general conditions, as discussed in Section 21.35, “Extensions to \texttt{SHOW Statements}”.

For the \texttt{ins_sum} trigger defined in Section 20.3, “Using Triggers”, the output of \texttt{SHOW TRIGGERS} is as shown here:

```sql
mysql> SHOW TRIGGERS LIKE 'acc%'
G
*************************** 1. row ***************************
    Trigger: ins_sum
    Event: INSERT
    Table: account
    Statement: SET @sum = @sum + NEW.amount
    Timing: BEFORE
    Created: NULL
    sql_mode: NO_ENGINE_SUBSTITUTION
    Definer: me@localhost
    character_set_client: utf8
    collation_connection: utf8_general_ci
    Database Collation: latin1_swedish_ci
```

\texttt{SHOW TRIGGERS} output has these columns:

- **Trigger**
  
The name of the trigger.

- **Event**
  
The trigger event. This is the type of operation on the associated table for which the trigger activates. The value is \texttt{INSERT} (a row was inserted), \texttt{DELETE} (a row was deleted), or \texttt{UPDATE} (a row was modified).

- **Table**
  
The table for which the trigger is defined.

- **Statement**
  
The trigger body; that is, the statement executed when the trigger activates.

- **Timing**
  
  Whether the trigger activates before or after the triggering event. The value is \texttt{BEFORE} or \texttt{AFTER}.

- **Created**
  
The value of this column is always \texttt{NULL}.

- **sql_mode**

1794
The SQL mode in effect when the trigger was created, and under which the trigger executes. For the permitted values, see Section 5.1.10, “Server SQL Modes”.

- **Definer**

  The account of the user who created the trigger, in `user_name@host_name` format.

- **character_set_client**

  The session value of the `character_set_client` system variable when the trigger was created.

- **collation_connection**

  The session value of the `collation_connection` system variable when the trigger was created.

- **Database Collation**

  The collation of the database with which the trigger is associated.

Trigger information is also available from the `INFORMATION_SCHEMA TRIGGERS` table. See Section 21.27, “The INFORMATION_SCHEMA TRIGGERS Table”.

### 13.7.5.40 SHOW VARIABLES Statement

SHOW [GLOBAL | SESSION] VARIABLES

SHOW VARIABLES shows the values of MySQL system variables (see Section 5.1.7, “Server System Variables”). This statement does not require any privilege. It requires only the ability to connect to the server.

System variable information is also available from these sources:

- The `GLOBAL_VARIABLES` and `SESSION_VARIABLES` tables. See Section 21.10, “The INFORMATION_SCHEMA GLOBAL_VARIABLES and SESSION_VARIABLES Tables”.

- The `mysqladmin variables` command. See Section 4.5.2, “mysqladmin — A MySQL Server Administration Program”.

For `SHOW VARIABLES`, a `LIKE` clause, if present, indicates which variable names to match. A `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 21.35, “Extensions to SHOW Statements”.

`SHOW VARIABLES` accepts an optional `GLOBAL` or `SESSION` variable scope modifier:

- With a `GLOBAL` modifier, the statement displays global system variable values. These are the values used to initialize the corresponding session variables for new connections to MySQL. If a variable has no global value, no value is displayed.

- With a `SESSION` modifier, the statement displays the system variable values that are in effect for the current connection. If a variable has no session value, the global value is displayed. `LOCAL` is a synonym for `SESSION`.

- If no modifier is present, the default is `SESSION`.

The scope for each system variable is listed at Section 5.1.7, “Server System Variables”.

`SHOW VARIABLES` is subject to a version-dependent display-width limit. For variables with very long values that are not completely displayed, use `SELECT` as a workaround. For example:
SHOW Statements

SELECT @@GLOBAL.innodb_data_file_path;

Most system variables can be set at server startup (read-only variables such as `version_comment` are exceptions). Many can be changed at runtime with the `SET` statement. See Section 5.1.8, “Using System Variables”, and Section 13.7.4.1, “SET Syntax for Variable Assignment”.

Partial output is shown here. The list of names and values may differ for your server. Section 5.1.7, “Server System Variables”, describes the meaning of each variable, and Section 5.1.1, “Configuring the Server”, provides information about tuning them.

```
mysql> SHOW VARIABLES;
+-----------------------------------------+---------------------------+
| Variable_name                           | Value                     |
+-----------------------------------------+---------------------------+
| auto_increment_increment                | 1                         |
| auto_increment_offset                   | 1                         |
| autocommit                              | ON                        |
| automatic_sp_privileges                 | ON                        |
| back_log                                | 50                        |
| basedir                                 | /home/jon/bin/mysql-5.5   |
| big_tables                              | OFF                       |
| binlog_cache_size                       | 32768                     |
| binlog_direct_non_transactional_updates | OFF                       |
| binlog_format                           | STATEMENT                 |
| binlog_stmt_cache_size                  | 32768                     |
| bulk_insert_buffer_size                 | 8388608                   |
| max_allowed_packet                      | 4194304                   |
| max_binlog_cache_size                   | 18446744073709547520      |
| max_binlog_size                         | 1073741824                |
| max_binlog_stmt_cache_size              | 18446744073709547520      |
| max_connect_errors                      | 100                       |
| max_connections                         | 151                       |
| max_delayed_threads                     | 20                        |
| max_error_count                         | 64                        |
| max_heap_table_size                     | 16777216                  |
| max_insert_delayed_threads              | 20                        |
| max_join_size                           | 18446744073709551615      |
| max_join_stack                         | 262144                    |
| time_format                             | %H:%i:%s                  |
| time_zone                               | SYSTEM                    |
| transaction_alloc_block_size            | 8192                      |
| transaction_prealloc_size               | 4096                      |
| tx_isolation                            | REPEATABLE-READ           |
| version                                 | 5.5.17-log                |
| version_comment                         | Source distribution       |
| version_compile_machine                 | x86_64                    |
| version_compile_os                      | Linux                     |
| wait_timeout                            | 28800                     |
+-----------------------------------------+---------------------------+
```

With a `LIKE` clause, the statement displays only rows for those variables with names that match the pattern. To obtain the row for a specific variable, use a `LIKE` clause as shown:

```
SHOW VARIABLES LIKE 'max_join_size';
SHOW SESSION VARIABLES LIKE 'max_join_size';
```

To get a list of variables whose name match a pattern, use the `%` wildcard character in a `LIKE` clause:

```
SHOW VARIABLES LIKE '%size%';
```

1796
SHOW Statements

SHOW GLOBAL VARIABLES LIKE '%size%';

Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because _ is a wildcard that matches any single character, you should escape it as \_ to match it literally. In practice, this is rarely necessary.

13.7.5.41 SHOW WARNINGS Statement

SHOW WARNINGS [LIMIT [offset,] row_count]
SHOW COUNT(*) WARNINGS

SHOW WARNINGS is a diagnostic statement that displays information about the conditions (errors, warnings, and notes) resulting from executing a statement in the current session. Warnings are generated for DML statements such as INSERT, UPDATE, and LOAD DATA as well as DDL statements such as CREATE TABLE and ALTER TABLE.

The LIMIT clause has the same syntax as for the SELECT statement. See Section 13.2.9, “SELECT Statement”.

SHOW WARNINGS is also used following EXPLAIN EXTENDED, to display the extra information generated by EXPLAIN when the EXTENDED keyword is used. See Section 8.8.3, “Extended EXPLAIN Output Format”.

SHOW WARNINGS displays information about the conditions resulting from the most recent statement in the current session that generated messages. It shows nothing if the most recent statement used a table and generated no messages. (That is, statements that use a table but generate no messages clear the message list.) Statements that do not use tables and do not generate messages have no effect on the message list.

The SHOW COUNT(*) WARNINGS diagnostic statement displays the total number of errors, warnings, and notes. You can also retrieve this number from the warning_count system variable:

SHOW COUNT(*) WARNINGS;
SELECT @warning_count;

A related diagnostic statement, SHOW ERRORS, shows only error conditions (it excludes warnings and notes), and SHOW COUNT(*) ERRORS statement displays the total number of errors. See Section 13.7.5.18, “SHOW ERRORS Statement”. GET DIAGNOSTICS can be used to examine information for individual conditions. See Section 13.6.7.3, “GET DIAGNOSTICS Statement”.

Here is a simple example that shows data-conversion warnings for INSERT. The example assumes that strict SQL mode is disabled. With strict mode enabled, the warnings would become errors and terminate the INSERT.

mysql> CREATE TABLE t1 (a TINYINT NOT NULL, b CHAR(4));
Query OK, 0 rows affected (0.05 sec)

mysql> INSERT INTO t1 VALUES(10,'mysql'), (NULL,'test'), (300,'xyz');
Query OK, 3 rows affected, 3 warnings (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 3

mysql> SHOW WARNINGS\G
*************************** 1. row ***************************
Level: Warning
Code: 1265
Message: Data truncated for column 'b' at row 1

*************************** 2. row ***************************
Level: Warning
Code: 1048
Message: Column 'a' cannot be null

*************************** 3. row ***************************
Level: Warning
Code: 1264
Message: Out of range value for column 'a' at row 3

1797
The `max_error_count` system variable controls the maximum number of error, warning, and note messages for which the server stores information, and thus the number of messages that `SHOW WARNINGS` displays. To change the number of messages the server can store, change the value of `max_error_count`. The default is 64.

`max_error_count` controls only how many messages are stored, not how many are counted. The value of `warning_count` is not limited by `max_error_count`, even if the number of messages generated exceeds `max_error_count`. The following example demonstrates this. The `ALTER TABLE` statement produces three warning messages (strict SQL mode is disabled for the example to prevent an error from occurring after a single conversion issue). Only one message is stored and displayed because `max_error_count` has been set to 1, but all three are counted (as shown by the value of `warning_count`):

```
mysql> SHOW VARIABLES LIKE 'max_error_count';
+-----------------+-------+
| Variable_name   | Value |
+-----------------+-------+
| max_error_count | 64    |
+-----------------+-------+
1 row in set (0.00 sec)
```

```
mysql> SET max_error_count=1, sql_mode = '';
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> ALTER TABLE t1 MODIFY b CHAR;
Query OK, 3 rows affected, 3 warnings (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 3
```

```
mysql> SHOW WARNINGS;
+---------+------+----------------------------------------+
| Level   | Code | Message                                |
+---------+------+----------------------------------------+
| Warning | 1263 | Data truncated for column 'b' at row 1 |
+---------+------+----------------------------------------+
1 row in set (0.00 sec)
```

```
mysql> SELECT @@warning_count;
+-----------------+
| @@warning_count |
+-----------------+
|               3 |
+-----------------+
1 row in set (0.01 sec)
```

To disable message storage, set `max_error_count` to 0. In this case, `warning_count` still indicates how many warnings occurred, but messages are not stored and cannot be displayed.

The `sql_notes` system variable controls whether note messages increment `warning_count` and whether the server stores them. By default, `sql_notes` is 1, but if set to 0, notes do not increment `warning_count` and the server does not store them:

```
mysql> SET sql_notes = 1;
```

```
mysql> DROP TABLE IF EXISTS test.no_such_table;
Query OK, 0 rows affected, 1 warning (0.00 sec)
```

```
mysql> SHOW WARNINGS;
+-------+------+------------------------------------+
| Level | Code | Message                            |
+-------+------+------------------------------------+
| Note  | 1051 | Unknown table 'test.no_such_table' |
+-------+------+------------------------------------+
1 row in set (0.00 sec)
```

```
mysql> SET sql_notes = 0;
```

```
mysql> DROP TABLE IF EXISTS test.no_such_table;
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> SHOW WARNINGS;
```

---

1798
The MySQL server sends to each client a count indicating the total number of errors, warnings, and notes resulting from the most recent statement executed by that client. From the C API, this value can be obtained by calling `mysql_warning_count()`. See `mysql_warning_count()`.

In the `mysql` client, you can enable and disable automatic warnings display using the `warnings` and `nowarning` commands, respectively, or their shortcuts, `\W` and `\w` (see Section 4.5.1.2, "mysql Client Commands"). For example:

```
mysql> \W
Show warnings enabled.
mysql> SELECT 1/0;
+------+
| 1/0  |
+------+
| NULL |
+------+
1 row in set, 1 warning (0.03 sec)
Warning (Code 1365): Division by 0
mysql> \w
Show warnings disabled.
```

### 13.7.6 Other Administrative Statements

#### 13.7.6.1 BINLOG Statement

```
BINLOG 'str'
```

`BINLOG` is an internal-use statement. It is generated by the `mysqlbinlog` program as the printable representation of certain events in binary log files. (See Section 4.6.8, "mysqlbinlog — Utility for Processing Binary Log Files"). The `str` value is a base 64-encoded string the that server decodes to determine the data change indicated by the corresponding event. This statement requires the `SUPER` privilege.

This statement can execute only format description events and row events.

#### 13.7.6.2 CACHE INDEX Statement

```
CACHE INDEX {
    tbl_index_list [, tbl_index_list] ...
    | tbl_name PARTITION (partition_list)
} IN key_cache_name
```

The `CACHE INDEX` statement assigns table indexes to a specific key cache. It applies only to `MyISAM` tables, including partitioned `MyISAM` tables. After the indexes have been assigned, they can be preloaded into the cache if desired with `LOAD INDEX INTO CACHE`.

The following statement assigns indexes from the tables `t1`, `t2`, and `t3` to the key cache named `hot_cache`:

```
mysql> CACHE INDEX t1, t2, t3 IN hot_cache;
```

<table>
<thead>
<tr>
<th>Table</th>
<th>Op</th>
<th>Msg_type</th>
<th>Msg_text</th>
</tr>
</thead>
<tbody>
<tr>
<td>test.t1</td>
<td>assign_to_keycache</td>
<td>status</td>
<td>OK</td>
</tr>
<tr>
<td>test.t2</td>
<td>assign_to_keycache</td>
<td>status</td>
<td>OK</td>
</tr>
</tbody>
</table>
The syntax of `CACHE INDEX` enables you to specify that only particular indexes from a table should be assigned to the cache. However, the implementation assigns all the table's indexes to the cache, so there is no reason to specify anything other than the table name.

The key cache referred to in a `CACHE INDEX` statement can be created by setting its size with a parameter setting statement or in the server parameter settings. For example:

```
SET GLOBAL keycache1.key_buffer_size=128*1024;
```

Key cache parameters are accessed as members of a structured system variable. See Section 5.1.8.3, “Structured System Variables”.

A key cache must exist before you assign indexes to it, or an error occurs:

```
mysql> CACHE INDEX t1 IN non_existent_cache;
ERROR 1284 (HY000): Unknown key cache 'non_existent_cache'
```

By default, table indexes are assigned to the main (default) key cache created at the server startup. When a key cache is destroyed, all indexes assigned to it are reassigned to the default key cache.

Index assignment affects the server globally: If one client assigns an index to a given cache, this cache is used for all queries involving the index, no matter which client issues the queries.

`CACHE INDEX` is supported for partitioned `MyISAM` tables. You can assign one or more indexes for one, several, or all partitions to a given key cache. For example, you can do the following:

```
CREATE TABLE pt (c1 INT, c2 VARCHAR(50), INDEX i(c1))
ENGINE=MyISAM
PARTITION BY HASH(c1)
PARTITIONS 4;
SET GLOBAL kc_fast.key_buffer_size = 128 * 1024;
SET GLOBAL kc_slow.key_buffer_size = 128 * 1024;
CACHE INDEX pt PARTITION (p0) IN kc_fast;
CACHE INDEX pt PARTITION (p1, p3) IN kc_slow;
```

The previous set of statements performs the following actions:

- Creates a partitioned table with 4 partitions; these partitions are automatically named `p0`, ..., `p3`; this table has an index named `i` on column `c1`.
- Creates 2 key caches named `kc_fast` and `kc_slow`
- Assigns the index for partition `p0` to the `kc_fast` key cache and the index for partitions `p1` and `p3` to the `kc_slow` key cache; the index for the remaining partition (`p2`) uses the server's default key cache.

If you wish instead to assign the indexes for all partitions of table `pt` to a single key cache named `kc_all`, you can use either of the following two statements:

```
CACHE INDEX pt PARTITION (ALL) IN kc_all;
CACHE INDEX pt IN kc_all;
```

The two statements just shown are equivalent, and issuing either one has exactly the same effect. In other words, if you wish to assign indexes for all partitions of a partitioned table to the same key cache, the `PARTITION (ALL)` clause is optional.

When assigning indexes for multiple partitions to a key cache, the partitions need not be contiguous, and you need not list their names in any particular order. Indexes for any partitions not explicitly assigned to a key cache automatically use the server default key cache.
Index preloading is also supported for partitioned MyISAM tables. For more information, see Section 13.7.6.5, “LOAD INDEX INTO CACHE Statement”.

In MySQL 5.6.11 only, gtid_next must be set to AUTOMATIC before issuing this statement. (Bug #16062608, Bug #16715809, Bug #69045)

13.7.6.3 FLUSH Statement

```
FLUSH [NO_WRITE_TO_BINLOG | LOCAL] { 
  flush_option [, flush_option] ... 
  | tables_option 
}

flush_option: {
  BINARY LOGS |
  DES_KEY_FILE |
  ENGINE LOGS |
  ERROR LOGS |
  GENERAL LOGS |
  HOSTS |
  LOGS |
  PRIVILEGES |
  QUERY CACHE |
  RELAY LOGS |
  SLOW LOGS |
  STATUS |
  USER_RESOURCES |
}

tables_option: {
  TABLES |
  TABLES tbl_name [, tbl_name] ... |
  TABLES WITH READ LOCK |
  TABLES tbl_name [, tbl_name] ... WITH READ LOCK |
  TABLES tbl_name [, tbl_name] ... FOR EXPORT |
}
```

The FLUSH statement has several variant forms that clear or reload various internal caches, flush tables, or acquire locks. To execute FLUSH, you must have the RELOAD privilege. Specific flush options might require additional privileges, as described later.

**Note**

It is not possible to issue FLUSH statements within stored functions or triggers. However, you may use FLUSH in stored procedures, so long as these are not called from stored functions or triggers. See Section 20.8, “Restrictions on Stored Programs”.

By default, the server writes FLUSH statements to the binary log so that they replicate to replicas. To suppress logging, specify the optional NO_WRITE_TO_BINLOG keyword or its alias LOCAL.

**Note**

FLUSH LOGS, FLUSH BINARY LOGS, FLUSH TABLES WITH READ LOCK (with or without a table list), and FLUSH TABLES tbl_name ... FOR EXPORT are not written to the binary log in any case because they would cause problems if replicated to a replica.

The FLUSH statement causes an implicit commit. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

The mysqladmin utility provides a command-line interface to some flush operations, using commands such as flush-hosts, flush-logs, flush-privileges, flush-status, and flush-tables. See Section 4.5.2, “mysqladmin — A MySQL Server Administration Program”.

1801
Sending a SIGHUP signal to the server causes several flush operations to occur that are similar to various forms of the FLUSH statement. Signals can be sent by root or the account that owns the server process. They enable the applicable flush operations to be performed without having to connect to the server (which for these operations requires an account that has the RELOAD privilege). See Section 4.10, “Unix Signal Handling in MySQL”.

The RESET statement is similar to FLUSH. See Section 13.7.6.6, “RESET Statement”, for information about using the RESET statement with replication.

The following list describes the permitted FLUSH statement flush_option values. For descriptions of FLUSH TABLES variants, see FLUSH TABLES Syntax.

- **FLUSH BINARY LOGS**
  Closes and reopens any binary log file to which the server is writing. If binary logging is enabled, the sequence number of the binary log file is incremented by one relative to the previous file.

- **FLUSH DES_KEY_FILE**
  Reloads the DES keys from the file that was specified with the --des-key-file option at server startup time.

- **FLUSH ENGINE LOGS**
  Closes and reopens any flushable logs for installed storage engines. This causes InnoDB to flush its logs to disk.

- **FLUSH ERROR LOGS**
  Closes and reopens any error log file to which the server is writing.

- **FLUSH GENERAL LOGS**
  Closes and reopens any general query log file to which the server is writing.

- **FLUSH HOSTS**
  Empties the host cache and the Performance Schema host_cache table that exposes the cache contents, and unblocks any blocked hosts. See Section 5.1.11.2, “DNS Lookups and the Host Cache”.

  Flush the host cache if some of your hosts change IP address or if the error message Host 'host_name' is blocked occurs for connections from legitimate hosts. (See Section B.3.2.6, “Host 'host_name' is blocked”.) When more than max_connect_errors errors occur successively for a given host while connecting to the MySQL server, MySQL assumes that something is wrong and blocks the host from further connection requests. Flushing the host cache enables further connection attempts from the host. The default value of max_connect_errors is 100. To avoid this error message, start the server with max_connect_errors set to a large value.

- **FLUSH LOGS**
  Closes and reopens any log file to which the server is writing. If binary logging is enabled, the sequence number of the binary log file is incremented by one relative to the previous file. If relay logging is enabled, the sequence number of the relay log file is incremented by one relative to the previous file.

  FLUSH LOGS has no effect on tables used for the general query log or for the slow query log (see Section 5.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”). It also has no effect on tables used for the binary or relay log (as controlled by the master_info_repository and relay_log_info_repository system variables).

- **FLUSH PRIVILEGES**
Other Administrative Statements

Reloads the privileges from the grant tables in the mysql system database.

If the --skip-grant-tables option was specified at server startup to disable the MySQL privilege system, FLUSH PRIVILEGES provides a way to enable the privilege system at runtime.

Frees memory cached by the server as a result of GRANT, CREATE USER, CREATE SERVER, and INSTALL PLUGIN statements. This memory is not released by the corresponding REVOKE, DROP USER, DROP SERVER, and UNINSTALL PLUGIN statements, so for a server that executes many instances of the statements that cause caching, there will be an increase in cached memory use unless it is freed with FLUSH PRIVILEGES.

- **FLUSH QUERY CACHE**

  Defragment the query cache to better utilize its memory. FLUSH QUERY CACHE does not remove any queries from the cache, unlike FLUSH TABLES or RESET QUERY CACHE.

- **FLUSH RELAY LOGS**

  Closes and reopens any relay log file to which the server is writing. If relay logging is enabled, the sequence number of the relay log file is incremented by one relative to the previous file.

- **FLUSH SLOW LOGS**

  Closes and reopens any slow query log file to which the server is writing.

- **FLUSH STATUS**

  This option adds the current thread's session status variable values to the global values and resets the session values to zero. Some global variables may be reset to zero as well. It also resets the counters for key caches (default and named) to zero and sets Max_used_connections to the current number of open connections. This information may be of use when debugging a query. See Section 1.6, “How to Report Bugs or Problems”.

- **FLUSH USER_RESOURCES**

  Resets all per-hour user resources to zero. This enables clients that have reached their hourly connection, query, or update limits to resume activity immediately. FLUSH USER_RESOURCES does not apply to the limit on maximum simultaneous connections that is controlled by the max_user_connections system variable. See Section 6.2.13, “Setting Account Resource Limits”.

In MySQL 5.6.11 only, gtid_next must be set to AUTOMATIC before issuing this statement. (Bug #16062608, Bug #16715809, Bug #69045)

**FLUSH TABLES Syntax**

FLUSH TABLES flushes tables, and, depending on the variant used, acquires locks. Any TABLES variant used in a FLUSH statement must be the only option used. FLUSH TABLE is a synonym for FLUSH TABLES.

**Note**

The descriptions here that indicate tables are flushed by closing them apply differently for InnoDB, which flushes table contents to disk but leaves them open. This still permits table files to be copied while the tables are open, as long as other activity does not modify them.

- **FLUSH TABLES**

  Closes all open tables, forces all tables in use to be closed, and flushes the query cache and prepared statement cache. FLUSH TABLES also removes all query results from the query cache, like the RESET QUERY CACHE statement. For information about query caching and prepared statement...
caching, see Section 8.10.3, “The MySQL Query Cache”, and Section 8.10.4, “Caching of Prepared Statements and Stored Programs”.

`FLUSH TABLES` is not permitted when there is an active `LOCK TABLES ... READ`. To flush and lock tables, use `FLUSH TABLES tbl_name ... WITH READ LOCK` instead.

- `FLUSH TABLES tbl_name [, tbl_name] ...`

With a list of one or more comma-separated table names, this statement is like `FLUSH TABLES` with no names except that the server flushes only the named tables. If a named table does not exist, no error occurs.

- `FLUSH TABLES WITH READ LOCK`

Closes all open tables and locks all tables for all databases with a global read lock. This is a very convenient way to get backups if you have a file system such as Veritas or ZFS that can take snapshots in time. Use `UNLOCK TABLES` to release the lock.

`FLUSH TABLES WITH READ LOCK` acquires a global read lock rather than table locks, so it is not subject to the same behavior as `LOCK TABLES` and `UNLOCK TABLES` with respect to table locking and implicit commits:

- `UNLOCK TABLES` implicitly commits any active transaction only if any tables currently have been locked with `LOCK TABLES`. The commit does not occur for `UNLOCK TABLES` following `FLUSH TABLES WITH READ LOCK` because the latter statement does not acquire table locks.

- Beginning a transaction causes table locks acquired with `LOCK TABLES` to be released, as though you had executed `UNLOCK TABLES`. Beginning a transaction does not release a global read lock acquired with `FLUSH TABLES WITH READ LOCK`.

`FLUSH TABLES WITH READ LOCK` is not compatible with XA transactions.

`FLUSH TABLES WITH READ LOCK` does not prevent the server from inserting rows into the log tables (see Section 5.4.1, “Selecting General Query Log and Slow Query Log Output Destinations”).

- `FLUSH TABLES tbl_name [, tbl_name] ... WITH READ LOCK`

This statement flushes and acquires read locks for the named tables. The statement first acquires exclusive metadata locks for the tables, so it waits for transactions that have those tables open to complete. Then the statement flushes the tables from the table cache, reopens the tables, acquires table locks (like `LOCK TABLES ... READ`), and downgrades the metadata locks from exclusive to shared. After the statement acquires locks and downgrades the metadata locks, other sessions can read but not modify the tables.

Because this statement acquires table locks, you must have the `LOCK TABLES` privilege for each table, in addition to the `RELOAD` privilege that is required to use any `FLUSH` statement.

This statement applies only to existing base (non-TEMPORARY) tables. If a name refers to a base table, that table is used. If it refers to a TEMPORARY table, it is ignored. If a name applies to a view, an `ER_WRONG_OBJECT` error occurs. Otherwise, an `ER_NO_SUCH_TABLE` error occurs.

Use `UNLOCK TABLES` to release the locks, `LOCK TABLES` to release the locks and acquire other locks, or `START TRANSACTION` to release the locks and begin a new transaction.

This `FLUSH TABLES` variant enables tables to be flushed and locked in a single operation. It provides a workaround for the restriction that `FLUSH TABLES` is not permitted when there is an active `LOCK TABLES ... READ`.

This statement does not perform an implicit `UNLOCK TABLES`, so an error results if you use the statement while there is any active `LOCK TABLES` or use it a second time without first releasing the locks acquired.
If a flushed table was opened with `HANDLER`, the handler is implicitly flushed and loses its position.

- **FLUSH TABLES tbl_name [, tbl_name] ... FOR EXPORT**

This `FLUSH TABLES` variant applies to InnoDB tables. It ensures that changes to the named tables have been flushed to disk so that binary table copies can be made while the server is running.

The statement works like this:

1. It acquires shared metadata locks for the named tables. The statement blocks as long as other sessions have active transactions that have modified those tables or hold table locks for them. When the locks have been acquired, the statement blocks transactions that attempt to update the tables, while permitting read-only operations to continue.

2. It checks whether all storage engines for the tables support `FOR EXPORT`. If any do not, an `ER_ILLEGAL_HA` error occurs and the statement fails.

3. The statement notifies the storage engine for each table to make the table ready for export. The storage engine must ensure that any pending changes are written to disk.

4. The statement puts the session in lock-tables mode so that the metadata locks acquired earlier are not released when the `FOR EXPORT` statement completes.

The `FLUSH TABLES ... FOR EXPORT` statement requires that you have the `SELECT` privilege for each table. Because this statement acquires table locks, you must also have the `LOCK TABLES` privilege for each table, in addition to the `RELOAD` privilege that is required to use any `FLUSH` statement.

This statement applies only to existing base (non-`TEMPORARY`) tables. If a name refers to a base table, that table is used. If it refers to a `TEMPORARY` table, it is ignored. If a name applies to a view, an `ER_WRONG_OBJECT` error occurs. Otherwise, an `ER_NO_SUCH_TABLE` error occurs.

InnoDB supports `FOR EXPORT` for tables that have their own `.ibd` file (that is, tables created with the `innodb_file_per_table` setting enabled). InnoDB ensures when notified by the `FOR EXPORT` statement that any changes have been flushed to disk. This permits a binary copy of table contents to be made while the `FOR EXPORT` statement is in effect because the `.ibd` file is transaction consistent and can be copied while the server is running. `FOR EXPORT` does not apply to InnoDB system tablespace files, or to InnoDB tables that have FULLTEXT indexes.

`FLUSH TABLES ... FOR EXPORT` does not work with partitioned InnoDB tables prior to MySQL 5.6.17, but is supported for such tables in MySQL 5.6.17 and later. (Bug #16943907)

When notified by `FOR EXPORT`, InnoDB writes to disk certain kinds of data that is normally held in memory or in separate disk buffers outside the tablespace files. For each table, InnoDB also produces a file named `table_name.cfg` in the same database directory as the table. The `.cfg` file contains metadata needed to reimport the tablespace files later, into the same or different server.

When the `FOR EXPORT` statement completes, InnoDB will have flushed all dirty pages to the table data files. Any change buffer entries are merged prior to flushing. At this point, the tables are locked and quiescent: The tables are in a transactionally consistent state on disk and you can copy the
Other Administrative Statements

.ibd tablespace files along with the corresponding .cfg files to get a consistent snapshot of those tables.

For the procedure to reimport the copied table data into a MySQL instance, see Section 14.6.1.3, “Importing InnoDB Tables”.

After you are done with the tables, use UNLOCK TABLES to release the locks, LOCK TABLES to release the locks and acquire other locks, or START TRANSACTION to release the locks and begin a new transaction.

While any of these statements is in effect within the session, attempts to use FLUSH TABLES ... FOR EXPORT produce an error:

| FLUSH TABLES ... WITH READ LOCK |
| FLUSH TABLES ... FOR EXPORT |
| LOCK TABLES ... READ |
| LOCK TABLES ... WRITE |

While FLUSH TABLES ... FOR EXPORT is in effect within the session, attempts to use any of these statements produce an error:

| FLUSH TABLES WITH READ LOCK |
| FLUSH TABLES ... WITH READ LOCK |
| FLUSH TABLES ... FOR EXPORT |

13.7.6.4 KILL Statement

KILL [CONNECTION | QUERY] processlist_id

Each connection to mysqld runs in a separate thread. You can kill a thread with the KILL processlist_id statement.

Thread processlist identifiers can be determined from the ID column of the INFORMATION_SCHEMA PROCESSLIST table, the Id column of SHOW PROCESSLIST output, and the PROCESSLIST_ID column of the Performance Schema threads table. The value for the current thread is returned by the CONNECTION_ID() function.

KILL permits an optional CONNECTION or QUERY modifier:

• KILL CONNECTION is the same as KILL with no modifier: It terminates the connection associated with the given processlist_id, after terminating any statement the connection is executing.

• KILL QUERY terminates the statement the connection is currently executing, but leaves the connection itself intact.

The ability to see which threads are available to be killed depends on the PROCESS privilege:

• Without PROCESS, you can see only your own threads.

• With PROCESS, you can see all threads.

The ability to kill threads and statements depends on the SUPER privilege:

• Without SUPER, you can kill only your own threads and statements.

• With SUPER, you can kill all threads and statements.

You can also use the mysqladmin processlist and mysqladmin kill commands to examine and kill threads.

Note

You cannot use KILL with the Embedded MySQL Server library because the embedded server merely runs inside the threads of the host application. It does not create any connection threads of its own.
When you use `KILL`, a thread-specific kill flag is set for the thread. In most cases, it might take some time for the thread to die because the kill flag is checked only at specific intervals:

- During `SELECT` operations, for `ORDER BY` and `GROUP BY` loops, the flag is checked after reading a block of rows. If the kill flag is set, the statement is aborted.

- `ALTER TABLE` operations that make a table copy check the kill flag periodically for each few copied rows read from the original table. If the kill flag was set, the statement is aborted and the temporary table is deleted.

The `KILL` statement returns without waiting for confirmation, but the kill flag check aborts the operation within a reasonably small amount of time. Aborting the operation to perform any necessary cleanup also takes some time.

- During `UPDATE` or `DELETE` operations, the kill flag is checked after each block read and after each updated or deleted row. If the kill flag is set, the statement is aborted. If you are not using transactions, the changes are not rolled back.

- `GET_LOCK()` aborts and returns `NULL`.

- An `INSERT DELAYED` thread quickly flushes (inserts) all rows it has in memory and then terminates.

- If the thread is in the table lock handler (state: `Locked`), the table lock is quickly aborted.

- If the thread is waiting for free disk space in a write call, the write is aborted with a “disk full” error message.

**Warning**

Killing a `REPAIR TABLE` or `OPTIMIZE TABLE` operation on a `MyISAM` table results in a table that is corrupted and unusable. Any reads or writes to such a table fail until you optimize or repair it again (without interruption).

### 13.7.6.5 LOAD INDEX INTO CACHE Statement

```
LOAD INDEX INTO CACHE
tbl_index_list [, tbl_index_list] ...

tbl_index_list:
  tbl_name
  [PARTITION (partition_list)]
  [INDEX|KEY] (index_name[, index_name] ...)
  [IGNORE LEAVES]

partition_list: {
  partition_name[, partition_name] ...
  | ALL
}
```

The `LOAD INDEX INTO CACHE` statement preloads a table index into the key cache to which it has been assigned by an explicit `CACHE INDEX` statement, or into the default key cache otherwise.

`LOAD INDEX INTO CACHE` applies only to `MyISAM` tables, including partitioned `MyISAM` tables. In addition, indexes on partitioned tables can be preloaded for one, several, or all partitions.

The `IGNORE LEAVES` modifier causes only blocks for the nonleaf nodes of the index to be preloaded. `IGNORE LEAVES` is also supported for partitioned `MyISAM` tables.

The following statement preloads nodes (index blocks) of indexes for the tables `t1` and `t2`:

```
mysql> LOAD INDEX INTO CACHE t1, t2 IGNORE LEAVES;
+---------+--------------+----------+----------+
| Table   | Op           | Msg_type | Msg_text |
+---------+--------------+----------+----------+
| test.t1 | preload_keys | status   | OK       |
```
<table>
<thead>
<tr>
<th>test.t2</th>
<th>preload_keys</th>
<th>status</th>
<th>OK</th>
</tr>
</thead>
</table>

This statement preloads all index blocks from `t1`. It preloads only blocks for the nonleaf nodes from `t2`.

The syntax of `LOAD INDEX INTO CACHE` enables you to specify that only particular indexes from a table should be preloaded. However, the implementation preloads all the table’s indexes into the cache, so there is no reason to specify anything other than the table name.

In MySQL 5.6.11 only, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. (Bug #16062608, Bug #16715809, Bug #69045)

It is possible to preload indexes on specific partitions of partitioned `MyISAM` tables. For example, of the following 2 statements, the first preloads indexes for partition `p0` of a partitioned table `pt`, while the second preloads the indexes for partitions `p1` and `p3` of the same table:

```
LOAD INDEX INTO CACHE pt PARTITION (p0);
LOAD INDEX INTO CACHE pt PARTITION (p1, p3);
```

To preload the indexes for all partitions in table `pt`, you can use either of the following two statements:

```
LOAD INDEX INTO CACHE pt PARTITION (ALL);
LOAD INDEX INTO CACHE pt;
```

The two statements just shown are equivalent, and issuing either one has exactly the same effect. In other words, if you wish to preload indexes for all partitions of a partitioned table, the `PARTITION (ALL)` clause is optional.

When preloading indexes for multiple partitions, the partitions need not be contiguous, and you need not list their names in any particular order.

```
LOAD INDEX INTO CACHE ... IGNORE LEAVES
```

fails unless all indexes in a table have the same block size. To determine index block sizes for a table, use `mysqldump -dv` and check the `Blocksize` column.

### 13.7.6.6 RESET Statement

```
RESET reset_option [, reset_option] ...

reset_option: {
    MASTER |
    QUERY CACHE |
    SLAVE
}
```

The `RESET` statement is used to clear the state of various server operations. You must have the `RELOAD` privilege to execute `RESET`.

`RESET` acts as a stronger version of the `FLUSH` statement. See Section 13.7.6.3, “FLUSH Statement”.

The `RESET` statement causes an implicit commit. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

In MySQL 5.6.11 only, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. (Bug #16062608, Bug #16715809, Bug #69045)

The following list describes the permitted `RESET` statement `reset_option` values:

- **RESET MASTER**

  Deletes all binary logs listed in the index file, resets the binary log index file to be empty, and creates a new binary log file.

- **RESET QUERY CACHE**
Removes all query results from the query cache.

- **RESET SLAVE**

  Makes the replica forget its replication position in the source binary logs. Also resets the relay log by deleting any existing relay log files and beginning a new one.

### 13.8 Utility Statements

#### 13.8.1 DESCRIBE Statement

The `DESCRIBE` and `EXPLAIN` statements are synonyms, used either to obtain information about table structure or query execution plans. For more information, see Section 13.7.5.6, “SHOW COLUMNS Statement”, and Section 13.8.2, “EXPLAIN Statement”.

#### 13.8.2 EXPLAIN Statement

```
{EXPLAIN | DESCRIBE | DESC}
  tbl_name [col_name | wild]
{EXPLAIN | DESCRIBE | DESC}
  [explain_type]
  explainable_stmt
explain_type: {
  EXTENDED
  | PARTITIONS
  | FORMAT = format_name}
format_name: {
  TRADITIONAL
  | JSON
}
explainable_stmt: {
  SELECT statement
  | DELETE statement
  | INSERT statement
  | REPLACE statement
  | UPDATE statement
}
```

The `DESCRIBE` and `EXPLAIN` statements are synonyms. In practice, the `DESCRIBE` keyword is more often used to obtain information about table structure, whereas `EXPLAIN` is used to obtain a query execution plan (that is, an explanation of how MySQL would execute a query).

The following discussion uses the `DESCRIBE` and `EXPLAIN` keywords in accordance with those uses, but the MySQL parser treats them as completely synonymous.

- **Obtaining Table Structure Information**
- **Obtaining Execution Plan Information**

#### Obtaining Table Structure Information

`DESCRIBE` provides information about the columns in a table:

```
mysql> DESCRIBE City;
+------------+----------+------+-----+---------+----------------+
| Field      | Type     | Null | Key | Default | Extra          |
+------------+----------+------+-----+---------+----------------+
| Id         | int(11)  | NO   | PRI | NULL    | auto_increment |
| Name       | char(35) | NO   |     |         |                |
| Country    | char(3)  | NO   | UNI |         |                |
+------------+----------+------+-----+---------+----------------+
```

1809
DESCRIBE is a shortcut for SHOW COLUMNS. These statements also display information for views. The description for SHOW COLUMNS provides more information about the output columns. See Section 13.7.5.6, “SHOW COLUMNS Statement”.

By default, DESCRIBE displays information about all columns in the table. `col_name`, if given, is the name of a column in the table. In this case, the statement displays information only for the named column. `wild`, if given, is a pattern string. It can contain the SQL % and _ wildcard characters. In this case, the statement displays output only for the columns with names matching the string. There is no need to enclose the string within quotation marks unless it contains spaces or other special characters.

The DESCRIBE statement is provided for compatibility with Oracle.

The SHOW CREATE TABLE, SHOW TABLE STATUS, and SHOW INDEX statements also provide information about tables. See Section 13.7.5, “SHOW Statements”.

### Obtaining Execution Plan Information

The EXPLAIN statement provides information about how MySQL executes statements:

- **EXPLAIN** works with SELECT, DELETE, INSERT, REPLACE, and UPDATE statements.
- When EXPLAIN is used with an explainable statement, MySQL displays information from the optimizer about the statement execution plan. That is, MySQL explains how it would process the statement, including information about how tables are joined and in which order. For information about using EXPLAIN to obtain execution plan information, see Section 8.8.2, “EXPLAIN Output Format”.
- **EXPLAIN EXTENDED** produces additional execution plan information that can be displayed using SHOW WARNINGS. See Section 8.8.3, “Extended EXPLAIN Output Format”.
- **EXPLAIN PARTITIONS** is useful for examining queries involving partitioned tables. See Section 19.3.5, “Obtaining Information About Partitions”.
- The FORMAT option can be used to select the output format. TRADITIONAL presents the output in tabular format. This is the default if no FORMAT option is present. JSON format displays the information in JSON format. With FORMAT = JSON, the output includes extended and partition information.

EXPLAIN requires the same privileges required to execute the explained statement. Additionally, EXPLAIN also requires the SHOW VIEW privilege for any explained view.

With the help of EXPLAIN, you can see where you should add indexes to tables so that the statement executes faster by using indexes to find rows. You can also use EXPLAIN to check whether the optimizer joins the tables in an optimal order. To give a hint to the optimizer to use a join order corresponding to the order in which the tables are named in a SELECT statement, begin the statement with SELECT STRAIGHT_JOIN rather than just SELECT. (See Section 13.2.9, “SELECT Statement”.)

If you have a problem with indexes not being used when you believe that they should be, run ANALYZE TABLE to update table statistics, such as cardinality of keys, that can affect the choices the optimizer makes. See Section 13.7.2.1, “ANALYZE TABLE Statement”.

**Note**

MySQL Workbench has a Visual Explain capability that provides a visual representation of EXPLAIN output. See Tutorial: Using Explain to Improve Query Performance.

### 13.8.3 HELP Statement
HELP 'search_string'

The HELP statement returns online information from the MySQL Reference Manual. Its proper operation requires that the help tables in the mysql database be initialized with help topic information (see Section 5.1.14, "Server-Side Help Support").

The HELP statement searches the help tables for the given search string and displays the result of the search. The search string is not case-sensitive.

The search string can contain the wildcard characters % and _. These have the same meaning as for pattern-matching operations performed with the LIKE operator. For example, HELP 'rep%' returns a list of topics that begin with rep.

The HELP statement understands several types of search strings:

- At the most general level, use contents to retrieve a list of the top-level help categories:

  HELP 'contents'

- For a list of topics in a given help category, such as Data Types, use the category name:

  HELP 'data types'

- For help on a specific help topic, such as the ASCII() function or the CREATE TABLE statement, use the associated keyword or keywords:

  HELP 'ascii'
  HELP 'create table'

In other words, the search string matches a category, many topics, or a single topic. You cannot necessarily tell in advance whether a given search string will return a list of items or the help information for a single help topic. However, you can tell what kind of response HELP returned by examining the number of rows and columns in the result set.

The following descriptions indicate the forms that the result set can take. Output for the example statements is shown using the familiar "tabular" or "vertical" format that you see when using the mysql client.

Note

The mysql itself reformats HELP result sets in a different way.

- Empty result set
  No match could be found for the search string.

- Result set containing a single row with three columns
  This means that the search string yielded a hit for the help topic. The result has three columns:

  • name: The topic name.
  • description: Descriptive help text for the topic.
  • example: Usage example or examples. This column might be blank.

Example: HELP 'replace'

Yields:

<table>
<thead>
<tr>
<th>name</th>
<th>description</th>
<th>example</th>
</tr>
</thead>
<tbody>
<tr>
<td>REPLACE</td>
<td>Syntax:</td>
<td>REPLACE(str,from_str,to_str)</td>
</tr>
</tbody>
</table>
USE Statement

Returns the string str with all occurrences of the string from_str replaced by the string to_str. REPLACE() performs a case-sensitive match when searching for from_str.

Example: mysql> SELECT REPLACE('www.mysql.com', 'w', 'Ww');
-> 'WwWwWw.mysql.com'

- Result set containing multiple rows with two columns

This means that the search string matched many help topics. The result set indicates the help topic names:

- **name**: The help topic name.
- **is_it_category**:
  - Y if the name represents a help category,
  - N if it does not. If it does not, the
  - name value when specified as the argument to the HELP statement should yield a single-row result set containing a description for the named item.

Example: HELP 'status'

Yields:

<table>
<thead>
<tr>
<th>name</th>
<th>is_it_category</th>
</tr>
</thead>
<tbody>
<tr>
<td>SHOW</td>
<td>N</td>
</tr>
<tr>
<td>SHOW ENGINE</td>
<td>N</td>
</tr>
<tr>
<td>SHOW MASTER STATUS</td>
<td>N</td>
</tr>
<tr>
<td>SHOW PROCEDURE STATUS</td>
<td>N</td>
</tr>
<tr>
<td>SHOW SLAVE STATUS</td>
<td>N</td>
</tr>
<tr>
<td>SHOW STATUS</td>
<td>N</td>
</tr>
<tr>
<td>SHOW TABLE STATUS</td>
<td>N</td>
</tr>
</tbody>
</table>

- Result set containing multiple rows with three columns

This means the search string matches a category. The result set contains category entries:

- **source_category_name**: The help category name.
- **name**: The category or topic name
- **is_it_category**:
  - Y if the name represents a help category,
  - N if it does not. If it does not, the
  - name value when specified as the argument to the HELP statement should yield a single-row result set containing a description for the named item.

Example: HELP 'functions'

Yields:

<table>
<thead>
<tr>
<th>source_category_name</th>
<th>name</th>
<th>is_it_category</th>
</tr>
</thead>
<tbody>
<tr>
<td>Functions</td>
<td>CREATE FUNCTION</td>
<td>N</td>
</tr>
<tr>
<td>Functions</td>
<td>DROP FUNCTION</td>
<td>N</td>
</tr>
<tr>
<td>Functions</td>
<td>Bit Functions</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>Comparison operators</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>Control flow functions</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>Date and Time Functions</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>Encryption Functions</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>Information Functions</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>Logical operators</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>Miscellaneous Functions</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>Numeric Functions</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>String Functions</td>
<td>Y</td>
</tr>
</tbody>
</table>

### 13.8.4 USE Statement
USE db_name

The **USE** statement tells MySQL to use the named database as the default (current) database for subsequent statements. This statement requires some privilege for the database or some object within it.

The named database remains the default until the end of the session or another **USE** statement is issued:

```
USE db1;
SELECT COUNT(*) FROM mytable;  # selects from db1.mytable
USE db2;
SELECT COUNT(*) FROM mytable;  # selects from db2.mytable
```

The database name must be specified on a single line. Newlines in database names are not supported.

Making a particular database the default by means of the **USE** statement does not preclude accessing tables in other databases. The following example accesses the `author` table from the `db1` database and the `editor` table from the `db2` database:

```
USE db1;
SELECT author_name,editor_name FROM author,db2.editor WHERE author.editor_id = db2.editor.editor_id;
```

InnoDB is a general-purpose storage engine that balances high reliability and high performance. In MySQL 5.6, InnoDB is the default MySQL storage engine. Unless you have configured a different

---

14.1 Introduction to InnoDB
default storage engine, issuing a CREATE TABLE statement without an ENGINE= clause creates an InnoDB table.

InnoDB includes all the features that were part of the InnoDB Plugin for MySQL 5.1, plus new features specific to MySQL 5.5 and higher.

**Key Advantages of InnoDB**

- Its DML operations follow the ACID model, with transactions featuring commit, rollback, and crash-recovery capabilities to protect user data. See Section 14.2, “InnoDB and the ACID Model” for more information.

- InnoDB tables arrange your data on disk to optimize queries based on primary keys. Each InnoDB table has a primary key index called the clustered index that organizes the data to minimize I/O for primary key lookups. See Section 14.6.2.1, “Clustered and Secondary Indexes” for more information.

- To maintain data integrity, InnoDB supports FOREIGN KEY constraints. With foreign keys, inserts, updates, and deletes are checked to ensure they do not result in inconsistencies across different tables. See Section 13.1.17.5, “FOREIGN KEY Constraints” for more information.

To compare the features of InnoDB with other storage engines provided with MySQL, see the Storage Engine Features table in Chapter 15, Alternative Storage Engines.

InnoDB Enhancements and New Features

For information about InnoDB enhancements and new features, refer to:

- The InnoDB enhancements list in Section 1.3, “What Is New in MySQL 5.6”.
- The Release Notes.

Additional InnoDB Information and Resources

- For InnoDB-related terms and definitions, see the MySQL Glossary.
- For a forum dedicated to the InnoDB storage engine, see MySQL Forums::InnoDB.
- InnoDB is published under the same GNU GPL License Version 2 (of June 1991) as MySQL. For more information on MySQL licensing, see http://www.mysql.com/company/legal/licensing/.

14.1.1 Benefits of Using InnoDB Tables

You may find InnoDB tables beneficial for the following reasons:

- If your server unexpectedly exits because of a hardware or software issue, regardless of what was happening in the database at the time, you don’t need to do anything special after restarting the database. InnoDB crash recovery automatically finalizes any changes that were committed before the time of the crash, and undoes any changes that were in process but not committed. Just restart and continue where you left off.

- The InnoDB storage engine maintains its own buffer pool that caches table and index data in main memory as data is accessed. Frequently used data is processed directly from memory. This cache applies to many types of information and speeds up processing. On dedicated database servers, up to 80% of physical memory is often assigned to the buffer pool.

- If you split up related data into different tables, you can set up foreign keys that enforce referential integrity. Update or delete data, and the related data in other tables is updated or deleted automatically. Try to insert data into a secondary table without corresponding data in the primary table, and the bad data gets kicked out automatically.

- If data becomes corrupted on disk or in memory, a checksum mechanism alerts you to the bogus data before you use it.

- When you design your database with appropriate primary key columns for each table, operations involving those columns are automatically optimized. It is very fast to reference the primary key columns in WHERE clauses, ORDER BY clauses, GROUP BY clauses, and join operations.
• Inserts, updates, and deletes are optimized by an automatic mechanism called change buffering. **InnoDB** not only allows concurrent read and write access to the same table, it caches changed data to streamline disk I/O.

• Performance benefits are not limited to giant tables with long-running queries. When the same rows are accessed over and over from a table, a feature called the Adaptive Hash Index takes over to make these lookups even faster, as if they came out of a hash table.

• You can compress tables and associated indexes.

• You can create and drop indexes with much less impact on performance and availability.

• Truncating a file-per-table tablespace is very fast, and can free up disk space for the operating system to reuse, rather than freeing up space within the system tablespace that only **InnoDB** can reuse.

• The storage layout for table data is more efficient for **BLOB** and long text fields, with the **DYNAMIC** row format.

• You can monitor the internal workings of the storage engine by querying **INFORMATION_SCHEMA** tables.

• You can monitor the performance details of the storage engine by querying **Performance Schema** tables.

• You can freely mix **InnoDB** tables with tables from other MySQL storage engines, even within the same statement. For example, you can use a join operation to combine data from **InnoDB** and **MEMORY** tables in a single query.

• **InnoDB** has been designed for CPU efficiency and maximum performance when processing large data volumes.

• **InnoDB** tables can handle large quantities of data, even on operating systems where file size is limited to 2GB.

For **InnoDB**-specific tuning techniques you can apply in your application code, see Section 8.5, “Optimizing for InnoDB Tables”.

### 14.1.2 Best Practices for InnoDB Tables

This section describes best practices when using **InnoDB** tables.

• Specifying a primary key for every table using the most frequently queried column or columns, or an auto-increment value if there is no obvious primary key.

• Using joins wherever data is pulled from multiple tables based on identical ID values from those tables. For fast join performance, define foreign keys on the join columns, and declare those columns with the same data type in each table. Adding foreign keys ensures that referenced columns are indexed, which can improve performance. Foreign keys also propagate deletes or updates to all affected tables, and prevent insertion of data in a child table if the corresponding IDs are not present in the parent table.

• Turning off autocommit. Committing hundreds of times a second puts a cap on performance (limited by the write speed of your storage device).

• Grouping sets of related DML operations into transactions, by bracketing them with **START TRANSACTION** and **COMMIT** statements. While you don't want to commit too often, you also don't want to issue huge batches of **INSERT**, **UPDATE**, or **DELETE** statements that run for hours without committing.

• Not using **LOCK TABLES** statements. **InnoDB** can handle multiple sessions all reading and writing to the same table at once, without sacrificing reliability or high performance. To get exclusive write
access to a set of rows, use the `SELECT ... FOR UPDATE` syntax to lock just the rows you intend to update.

- Enabling the `innodb_file_per_table` option to put the data and indexes for individual tables into separate files, instead of the `system tablespace`. This setting is required to use other features, such as table compression. It is enabled by default.

- Evaluating whether your data and access patterns benefit from the InnoDB table compression feature. You can compress InnoDB tables without sacrificing read/write capability.

- Running your server with the option `--sql_mode=NO_ENGINE_SUBSTITUTION` to prevent tables being created with a different storage engine if there is an issue with the engine specified in the `ENGINE=` clause of `CREATE TABLE`.

### 14.1.3 Checking InnoDB Availability

To determine whether your server supports InnoDB:

- Issue the `SHOW ENGINES` statement to view the available MySQL storage engines. Look for `DEFAULT` in the InnoDB line.

  ```
  mysql> SHOW ENGINES;
  ```

  Alternatively, query the `INFORMATION_SCHEMA.ENGINES` table.

  ```
  mysql> SELECT * FROM INFORMATION_SCHEMA.ENGINES;
  ```

  (Now that InnoDB is the default MySQL storage engine, only very specialized environments might not support it.)

- If InnoDB is not present, you have a `mysqld` binary that was compiled without InnoDB support and you need to get a different one.

- If InnoDB is present but disabled, go back through your startup options and configuration file and get rid of any `--skip-innodb` option.

### 14.1.4 Testing and Benchmarking with InnoDB

If InnoDB is not your default storage engine, you can determine if your database server or applications work correctly with InnoDB by restarting the server with `--default-storage-engine=InnoDB` defined on the command line or with `default-storage-engine=innodb` defined in the `[mysqld]` section of your MySQL server option file.

Since changing the default storage engine only affects new tables as they are created, run all your application installation and setup steps to confirm that everything installs properly. Then exercise all the application features to make sure all the data loading, editing, and querying features work. If a table relies on a feature that is specific to another storage engine, you will receive an error; add the `ENGINE=other_engine_name` clause to the `CREATE TABLE` statement to avoid the error.

If you did not make a deliberate decision about the storage engine, and you want to preview how certain tables work when created using InnoDB, issue the command `ALTER TABLE table_name ENGINE=InnoDB;` for each table. Or, to run test queries and other statements without disturbing the original table, make a copy:

```
CREATE TABLE InnoDB_Table (...) ENGINE=InnoDB AS SELECT * FROM other_engine_table;
```

To assess performance with a full application under a realistic workload, install the latest MySQL server and run benchmarks.

Test the full application lifecycle, from installation, through heavy usage, and server restart. Kill the server process while the database is busy to simulate a power failure, and verify that the data is recovered successfully when you restart the server.
Test any replication configurations, especially if you use different MySQL versions and options on the source server and replicas.

## 14.1.5 Turning Off InnoDB

Oracle recommends InnoDB as the preferred storage engine for typical database applications, from single-user wikis and blogs running on a local system, to high-end applications pushing the limits of performance. In MySQL 5.6, InnoDB is the default storage engine for new tables.

If you do not want to use InnoDB tables:

- Start the server with the `--innodb=OFF` or `--skip-innodb` option to disable the InnoDB storage engine.

  **Note**

  As of MySQL 5.6.21, the `--skip-innodb` option still works but it is deprecated and will return a warning when used. It will be removed in a future MySQL release. This also applies to its synonyms (`--innodb=OFF`, `--disable-innodb`, and so forth).

- Because the default storage engine is InnoDB, the server will not start unless you also use `--default-storage-engine` and `--default-tmp-storage-engine` to set the default to some other engine for both permanent and TEMPORARY tables.

- To prevent the server from crashing when the InnoDB-related information_schema tables are queried, also disable the plugins associated with those tables. Specify in the `[mysqld]` section of the MySQL configuration file:

```ini
loose-innodb-trx=0
loose-innodb-locks=0
loose-innodb-lock-waits=0
loose-innodb-cmp=0
loose-innodb-cmp-per-index=0
loose-innodb-cmp-per-index-reset=0
loose-innodb-cmp-reset=0
loose-innodb-cmpmem=0
loose-innodb-cmpmem-reset=0

loose-innodb-sys-fields=0
loose-innodb-sys-foreign=0
loose-innodb-sys-foreign-cols=0
```

## 14.2 InnoDB and the ACID Model

The **ACID** model is a set of database design principles that emphasize aspects of reliability that are important for business data and mission-critical applications. MySQL includes components such as the InnoDB storage engine that adhere closely to the ACID model, so that data is not corrupted and results are not distorted by exceptional conditions such as software crashes and hardware malfunctions. When you rely on ACID-compliant features, you do not need to reinvent the wheel of consistency checking and crash recovery mechanisms. In cases where you have additional software
Atomicity

safeguards, ultra-reliable hardware, or an application that can tolerate a small amount of data loss or inconsistency, you can adjust MySQL settings to trade some of the ACID reliability for greater performance or throughput.

The following sections discuss how MySQL features, in particular the InnoDB storage engine, interact with the categories of the ACID model:

• A: atomicity.
• C: consistency.
• I: isolation.
• D: durability.

Atomicity

The atomicity aspect of the ACID model mainly involves InnoDB transactions. Related MySQL features include:

• Autocommit setting.
• COMMIT statement.
• ROLLBACK statement.
• Operational data from the INFORMATION_SCHEMA tables.

Consistency

The consistency aspect of the ACID model mainly involves internal InnoDB processing to protect data from crashes. Related MySQL features include:

• InnoDB doublewrite buffer.
• InnoDB crash recovery.

Isolation

The isolation aspect of the ACID model mainly involves InnoDB transactions, in particular the isolation level that applies to each transaction. Related MySQL features include:

• Autocommit setting.
• SET ISOLATION LEVEL statement.
• The low-level details of InnoDB locking. During performance tuning, you see these details through INFORMATION_SCHEMA tables.

Durability

The durability aspect of the ACID model involves MySQL software features interacting with your particular hardware configuration. Because of the many possibilities depending on the capabilities of your CPU, network, and storage devices, this aspect is the most complicated to provide concrete guidelines for. (And those guidelines might take the form of buy “new hardware”.) Related MySQL features include:

• InnoDB doublewrite buffer, turned on and off by the innodb_doublewrite configuration option.
• Configuration option innodb_flush_log_at_trx_commit.
• Configuration option sync_binlog.
• Configuration option innodb_file_per_table.
InnoDB Multi-Versioning

- Write buffer in a storage device, such as a disk drive, SSD, or RAID array.
- Battery-backed cache in a storage device.
- The operating system used to run MySQL, in particular its support for the `fsync()` system call.
- Uninterruptible power supply (UPS) protecting the electrical power to all computer servers and storage devices that run MySQL servers and store MySQL data.
- Your backup strategy, such as frequency and types of backups, and backup retention periods.
- For distributed or hosted data applications, the particular characteristics of the data centers where the hardware for the MySQL servers is located, and network connections between the data centers.

14.3 InnoDB Multi-Versioning

**InnoDB** is a multi-versioned storage engine: it keeps information about old versions of changed rows, to support transactional features such as concurrency and rollback. This information is stored in the tablespace in a data structure called a rollback segment (after an analogous data structure in Oracle). **InnoDB** uses the information in the rollback segment to perform the undo operations needed in a transaction rollback. It also uses the information to build earlier versions of a row for a consistent read.

Internally, **InnoDB** adds three fields to each row stored in the database. A 6-byte `DB_TRX_ID` field indicates the transaction identifier for the last transaction that inserted or updated the row. Also, a deletion is treated internally as an update where a special bit in the row is set to mark it as deleted. Each row also contains a 7-byte `DB_ROLL_PTR` field called the roll pointer. The roll pointer points to an undo log record written to the rollback segment. If the row was updated, the undo log record contains the information necessary to rebuild the content of the row before it was updated. A 6-byte `DB_ROW_ID` field contains a row ID that increases monotonically as new rows are inserted. If **InnoDB** generates a clustered index automatically, the index contains row ID values. Otherwise, the `DB_ROW_ID` column does not appear in any index.

Undo logs in the rollback segment are divided into insert and update undo logs. Insert undo logs are needed only in transaction rollback and can be discarded as soon as the transaction commits. Update undo logs are used also in consistent reads, but they can be discarded only after there is no transaction present for which **InnoDB** has assigned a snapshot that in a consistent read could need the information in the update undo log to build an earlier version of a database row.

Commit your transactions regularly, including those transactions that issue only consistent reads. Otherwise, **InnoDB** cannot discard data from the update undo logs, and the rollback segment may grow too big, filling up your tablespace.

The physical size of an undo log record in the rollback segment is typically smaller than the corresponding inserted or updated row. You can use this information to calculate the space needed for your rollback segment.

In the **InnoDB** multi-versioning scheme, a row is not physically removed from the database immediately when you delete it with an SQL statement. **InnoDB** only physically removes the corresponding row and its index records when it discards the update undo log record written for the deletion. This removal operation is called a **purge**, and it is quite fast, usually taking the same order of time as the SQL statement that did the deletion.

If you insert and delete rows in smallish batches at about the same rate in the table, the purge thread can start to lag behind and the table can grow bigger and bigger because of all the “dead” rows, making everything disk-bound and very slow. In such a case, throttle new row operations, and allocate more resources to the purge thread by tuning the `innodb_max_purge_lag` system variable. See Section 14.14, “**InnoDB Startup Options and System Variables**” for more information.

Multi-Versioning and Secondary Indexes

**InnoDB** multiversion concurrency control (MVCC) treats secondary indexes differently than clustered indexes. Records in a clustered index are updated in-place, and their hidden system columns point
undo log entries from which earlier versions of records can be reconstructed. Unlike clustered index records, secondary index records do not contain hidden system columns nor are they updated in-place.

When a secondary index column is updated, old secondary index records are delete-marked, new records are inserted, and delete-marked records are eventually purged. When a secondary index record is delete-marked or the secondary index page is updated by a newer transaction, InnoDB looks up the database record in the clustered index. In the clustered index, the record's DB_TRX_ID is checked, and the correct version of the record is retrieved from the undo log if the record was modified after the reading transaction was initiated.

If a secondary index record is marked for deletion or the secondary index page is updated by a newer transaction, the covering index technique is not used. Instead of returning values from the index structure, InnoDB looks up the record in the clustered index.

However, if the index condition pushdown (ICP) optimization is enabled, and parts of the WHERE condition can be evaluated using only fields from the index, the MySQL server still pushes this part of the WHERE condition down to the storage engine where it is evaluated using the index. If no matching records are found, the clustered index lookup is avoided. If matching records are found, even among delete-marked records, InnoDB looks up the record in the clustered index.

### 14.4 InnoDB Architecture

The following diagram shows in-memory and on-disk structures that comprise the InnoDB storage engine architecture. For information about each structure, see Section 14.5, “InnoDB In-Memory Structures”, and Section 14.6, “InnoDB On-Disk Structures”.

**Figure 14.1 InnoDB Architecture**
14.5 InnoDB In-Memory Structures

This section describes InnoDB in-memory structures and related topics.

14.5.1 Buffer Pool

The buffer pool is an area in main memory where InnoDB caches table and index data as it is accessed. The buffer pool permits frequently used data to be processed directly from memory, which speeds up processing. On dedicated servers, up to 80% of physical memory is often assigned to the buffer pool.

For efficiency of high-volume read operations, the buffer pool is divided into pages that can potentially hold multiple rows. For efficiency of cache management, the buffer pool is implemented as a linked list of pages; data that is rarely used is aged out of the cache using a variation of the LRU algorithm.

Knowing how to take advantage of the buffer pool to keep frequently accessed data in memory is an important aspect of MySQL tuning.

Buffer Pool LRU Algorithm

The buffer pool is managed as a list using a variation of the least recently used (LRU) algorithm. When room is needed to add a new page to the buffer pool, the least recently used page is evicted and a new page is added to the middle of the list. This midpoint insertion strategy treats the list as two sublists:

- At the head, a sublist of new (“young”) pages that were accessed recently
- At the tail, a sublist of old pages that were accessed less recently
The algorithm keeps frequently used pages in the new sublist. The old sublist contains less frequently used pages; these pages are candidates for eviction.

By default, the algorithm operates as follows:

- 3/8 of the buffer pool is devoted to the old sublist.
- The midpoint of the list is the boundary where the tail of the new sublist meets the head of the old sublist.
- When InnoDB reads a page into the buffer pool, it initially inserts it at the midpoint (the head of the old sublist). A page can be read because it is required for a user-initiated operation such as an SQL query, or as part of a read-ahead operation performed automatically by InnoDB.
- Accessing a page in the old sublist makes it “young”, moving it to the head of the new sublist. If the page was read because it was required by a user-initiated operation, the first access occurs immediately and the page is made young. If the page was read due to a read-ahead operation, the first access does not occur immediately and might not occur at all before the page is evicted.
Buffer Pool

- As the database operates, pages in the buffer pool that are not accessed “age” by moving toward the tail of the list. Pages in both the new and old sublists age as other pages are made new. Pages in the old sublist also age as pages are inserted at the midpoint. Eventually, a page that remains unused reaches the tail of the old sublist and is evicted.

By default, pages read by queries are immediately moved into the new sublist, meaning they stay in the buffer pool longer. A table scan, performed for a `mysqldump` operation or a `SELECT` statement with no `WHERE` clause, for example, can bring a large amount of data into the buffer pool and evict an equivalent amount of older data, even if the new data is never used again. Similarly, pages that are loaded by the read-ahead background thread and accessed only once are moved to the head of the new list. These situations can push frequently used pages to the old sublist where they become subject to eviction. For information about optimizing this behavior, see Section 14.8.3.2, “Making the Buffer Pool Scan Resistant”, and Section 14.8.3.3, “Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)

InnoDB Standard Monitor output contains several fields in the BUFFER POOL AND MEMORY section regarding operation of the buffer pool LRU algorithm. For details, see Monitoring the Buffer Pool Using the InnoDB Standard Monitor.

Buffer Pool Configuration

You can configure the various aspects of the buffer pool to improve performance.

- Ideally, you set the size of the buffer pool to as large a value as practical, leaving enough memory for other processes on the server to run without excessive paging. The larger the buffer pool, the more InnoDB acts like an in-memory database, reading data from disk once and then accessing the data from memory during subsequent reads. Buffer pool size is configured using the `innodb_buffer_pool_size` configuration option.

- On 64-bit systems with sufficient memory, you can split the buffer pool into multiple parts to minimize contention for memory structures among concurrent operations. For details, see Section 14.8.3.1, “Configuring Multiple Buffer Pool Instances”.

- You can keep frequently accessed data in memory regardless of sudden spikes of activity from operations that would bring large amounts of infrequently accessed data into the buffer pool. For details, see Section 14.8.3.2, “Making the Buffer Pool Scan Resistant”.

- You can control how and when to perform read-ahead requests to prefetch pages into the buffer pool asynchronously in anticipation that the pages will be needed soon. For details, see Section 14.8.3.3, “Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)”.

- You can control when background flushing occurs and whether or not the rate of flushing is dynamically adjusted based on workload. For details, see Section 14.8.3.4, “Configuring Buffer Pool Flushing”.

- You can configure how InnoDB preserves the current buffer pool state to avoid a lengthy warmup period after a server restart. For details, see Section 14.8.3.5, “Saving and Restoring the Buffer Pool State”.

Monitoring the Buffer Pool Using the InnoDB Standard Monitor

InnoDB Standard Monitor output, which can be accessed using `SHOW ENGINE INNODB STATUS`, provides metrics regarding operation of the buffer pool. Buffer pool metrics are located in the BUFFER POOL AND MEMORY section of InnoDB Standard Monitor output and appear similar to the following:

```
TOTAL
----------------------
BUFFER POOL AND MEMORY
----------------------
Total memory allocated 2197815296; in additional pool allocated 0
Dictionary memory allocated 155455
Buffer pool size 131071
Free buffers 92158
```

1827
The following table describes buffer pool metrics reported by the InnoDB Standard Monitor.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total memory allocated</td>
<td>The total memory allocated for the buffer pool in bytes.</td>
</tr>
<tr>
<td>additional pool allocated</td>
<td>The total memory allocated for the additional pool in bytes.</td>
</tr>
<tr>
<td>Dictionary memory allocated</td>
<td>The total memory allocated for the InnoDB data dictionary in bytes.</td>
</tr>
<tr>
<td>Buffer pool size</td>
<td>The total size in pages allocated to the buffer pool.</td>
</tr>
<tr>
<td>Free buffers</td>
<td>The total size in pages of the buffer pool free list.</td>
</tr>
<tr>
<td>Database pages</td>
<td>The total size in pages of the buffer pool LRU list.</td>
</tr>
<tr>
<td>Old database pages</td>
<td>The total size in pages of the buffer pool old LRU sublist.</td>
</tr>
<tr>
<td>Modified db pages</td>
<td>The current number of pages modified in the buffer pool.</td>
</tr>
<tr>
<td>Pending reads</td>
<td>The number of buffer pool pages waiting to be read into the buffer pool.</td>
</tr>
<tr>
<td>Pending writes LRU</td>
<td>The number of old dirty pages within the buffer pool to be written from the bottom of the LRU list.</td>
</tr>
<tr>
<td>Pending writes flush list</td>
<td>The number of buffer pool pages to be flushed during checkpointing.</td>
</tr>
<tr>
<td>Pending writes single page</td>
<td>The number of pending independent page writes within the buffer pool.</td>
</tr>
<tr>
<td>Pages made young</td>
<td>The total number of pages made young in the buffer pool LRU list (moved to the head of sublist of “new” pages).</td>
</tr>
<tr>
<td>Pages made not young</td>
<td>The total number of pages not made young in the buffer pool LRU list (pages that have remained in the “old” sublist without being made young).</td>
</tr>
<tr>
<td>youngs/s</td>
<td>The per second average of accesses to old pages in the buffer pool LRU list that have resulted in making pages young. See the notes that follow this table for more information.</td>
</tr>
<tr>
<td>non-youngs/s</td>
<td>The per second average of accesses to old pages in the buffer pool LRU list that have resulted in not making pages young. See the notes that follow this table for more information.</td>
</tr>
<tr>
<td>Pages read</td>
<td>The total number of pages read from the buffer pool.</td>
</tr>
<tr>
<td>Pages created</td>
<td>The total number of pages created within the buffer pool.</td>
</tr>
</tbody>
</table>
### Buffer Pool

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pages written</td>
<td>The total number of pages written from the buffer pool.</td>
</tr>
<tr>
<td>reads/s</td>
<td>The per second average number of buffer pool page reads per second.</td>
</tr>
<tr>
<td>creates/s</td>
<td>The per second average number of buffer pool pages created per second.</td>
</tr>
<tr>
<td>writes/s</td>
<td>The per second average number of buffer pool page writes per second.</td>
</tr>
<tr>
<td>Buffer pool hit rate</td>
<td>The buffer pool page hit rate for pages read from the buffer pool memory vs from disk storage.</td>
</tr>
<tr>
<td>young-making rate</td>
<td>The average hit rate at which page accesses have resulted in making pages young. See the notes that follow this table for more information.</td>
</tr>
<tr>
<td>not (young-making rate)</td>
<td>The average hit rate at which page accesses have not resulted in making pages young. See the notes that follow this table for more information.</td>
</tr>
<tr>
<td>Pages read ahead</td>
<td>The per second average of read ahead operations.</td>
</tr>
<tr>
<td>Pages evicted without access</td>
<td>The per second average of the pages evicted without being accessed from the buffer pool.</td>
</tr>
<tr>
<td>Random read ahead</td>
<td>The per second average of random read ahead operations.</td>
</tr>
<tr>
<td>LRU len</td>
<td>The total size in pages of the buffer pool LRU list.</td>
</tr>
<tr>
<td>unzip_LRU len</td>
<td>The total size in pages of the buffer pool unzip_LRU list.</td>
</tr>
<tr>
<td>I/O sum</td>
<td>The total number of buffer pool LRU list pages accessed, for the last 50 seconds.</td>
</tr>
<tr>
<td>I/O cur</td>
<td>The total number of buffer pool LRU list pages accessed.</td>
</tr>
<tr>
<td>I/O unzip sum</td>
<td>The total number of buffer pool unzip_LRU list pages accessed.</td>
</tr>
<tr>
<td>I/O unzip cur</td>
<td>The total number of buffer pool unzip_LRU list pages accessed.</td>
</tr>
</tbody>
</table>

### Notes:

- The **youngs/s** metric is applicable only to old pages. It is based on the number of accesses to pages and not the number of pages. There can be multiple accesses to a given page, all of which are counted. If you see very low **youngs/s** values when there are no large scans occurring, you might need to reduce the delay time or increase the percentage of the buffer pool used for the old sublist. Increasing the percentage makes the old sublist larger, so pages in that sublist take longer to move to the tail, which increases the likelihood that those pages will be accessed again and made young.

- The **non-youngs/s** metric is applicable only to old pages. It is based on the number of accesses to pages and not the number of pages. There can be multiple accesses to a given page, all of which are counted. If you do not see a higher **non-youngs/s** value when performing large table scans (and a higher **youngs/s** value), increase the delay value.

- The **young-making rate** accounts for accesses to all buffer pool pages, not just accesses to pages in the old sublist. The **young-making rate** and **not** rate do not normally add up to the overall buffer pool hit rate. Page hits in the old sublist cause pages to move to the new sublist, but page hits in the new sublist cause pages to move to the head of the list only if they are a certain distance from the head.

- **not (young-making rate)** is the average hit rate at which page accesses have not resulted in making pages young due to the delay defined by `innodb_old_blocks_time` not being met, or due to page hits in the new sublist that did not result in pages being moved to the head. This rate accounts for accesses to all buffer pool pages, not just accesses to pages in the old sublist.
Buffer pool server status variables and the `INNODB_BUFFER_POOL_STATS` table provide many of the same buffer pool metrics found in InnoDB Standard Monitor output. For more information, see Example 14.10, “Querying the `INNODB_BUFFER_POOL_STATS` Table”.

## 14.5.2 Change Buffer

The change buffer is a special data structure that caches changes to secondary index pages when those pages are not in the buffer pool. The buffered changes, which may result from `INSERT`, `UPDATE`, or `DELETE` operations (DML), are merged later when the pages are loaded into the buffer pool by other read operations.

![Change Buffer Diagram](image)

Unlike clustered indexes, secondary indexes are usually nonunique, and inserts into secondary indexes happen in a relatively random order. Similarly, deletes and updates may affect secondary index pages that are not adjacently located in an index tree. Merging cached changes at a later time, when affected pages are read into the buffer pool by other operations, avoids substantial random access I/O that would be required to read secondary index pages into the buffer pool from disk.

Periodically, the purge operation that runs when the system is mostly idle, or during a slow shutdown, writes the updated index pages to disk. The purge operation can write disk blocks for a series of index values more efficiently than if each value were written to disk immediately.

Change buffer merging may take several hours when there are many affected rows and numerous secondary indexes to update. During this time, disk I/O is increased, which can cause a significant slowdown for disk-bound queries. Change buffer merging may also continue to occur after a transaction is committed, and even after a server shutdown and restart (see Section 14.21.2, “Forcing InnoDB Recovery” for more information).

In memory, the change buffer occupies part of the buffer pool. On disk, the change buffer is part of the system tablespace, where index changes are buffered when the database server is shut down.

The type of data cached in the change buffer is governed by the `innodb_change_buffering` variable. For more information, see Configuring Change Buffering. You can also configure the maximum change buffer size. For more information, see Configuring the Change Buffer Maximum Size.

Change buffering is not supported for a secondary index if the index contains a descending index column or if the primary key includes a descending index column.
Configuring Change Buffering

When INSERT, UPDATE, and DELETE operations are performed on a table, the values of indexed columns (particularly the values of secondary keys) are often in an unsorted order, requiring substantial I/O to bring secondary indexes up to date. The change buffer caches changes to secondary index entries when the relevant page is not in the buffer pool, thus avoiding expensive I/O operations by not immediately reading in the page from disk. The buffered changes are merged when the page is loaded into the buffer pool, and the updated page is later flushed to disk. The InnoDB main thread merges buffered changes when the server is nearly idle, and during a slow shutdown.

Because it can result in fewer disk reads and writes, the change buffer feature is most valuable for workloads that are I/O-bound, for example applications with a high volume of DML operations such as bulk inserts.

However, the change buffer occupies a part of the buffer pool, reducing the memory available to cache data pages. If the working set almost fits in the buffer pool, or if your tables have relatively few secondary indexes, it may be useful to disable change buffering. If the working data set fits entirely within the buffer pool, change buffering does not impose extra overhead, because it only applies to pages that are not in the buffer pool.

You can control the extent to which InnoDB performs change buffering using the innodb_change_buffering configuration parameter. You can enable or disable buffering for inserts, delete operations (when index records are initially marked for deletion) and purge operations (when index records are physically deleted). An update operation is a combination of an insert and a delete. The default innodb_change_buffering value is all.

Permitted innodb_change_buffering values include:

- **all**
  - The default value: buffer inserts, delete-marking operations, and purges.
- **none**
  - Do not buffer any operations.
- **inserts**
  - Buffer insert operations.
- **deletes**
  - Buffer delete-marking operations.
- **changes**
  - Buffer both inserts and delete-marking operations.
- **purges**
  - Buffer physical deletion operations that happen in the background.

You can set the innodb_change_buffering parameter in the MySQL option file (my.cnf or my.ini) or change it dynamically with the SET GLOBAL statement, which requires privileges sufficient to set global system variables. See Section 5.1.8.1, "System Variable Privileges". Changing the setting affects the buffering of new operations; the merging of existing buffered entries is not affected.
Configuring the Change Buffer Maximum Size

The `innodb_change_buffer_max_size` variable permits configuring the maximum size of the change buffer as a percentage of the total size of the buffer pool. By default, `innodb_change_buffer_max_size` is set to 25. The maximum setting is 50.

Consider increasing `innodb_change_buffer_max_size` on a MySQL server with heavy insert, update, and delete activity, where change buffer merging does not keep pace with new change buffer entries, causing the change buffer to reach its maximum size limit.

Consider decreasing `innodb_change_buffer_max_size` on a MySQL server with static data used for reporting, or if the change buffer consumes too much of the memory space shared with the buffer pool, causing pages to age out of the buffer pool sooner than desired.

Test different settings with a representative workload to determine an optimal configuration. The `innodb_change_buffer_max_size` setting is dynamic, which permits modifying the setting without restarting the server.

Monitoring the Change Buffer

The following options are available for change buffer monitoring:

- **InnoDB Standard Monitor output** includes change buffer status information. To view monitor data, issue the `SHOW ENGINE INNODB STATUS` statement.

  ```
  mysql> SHOW ENGINE INNODB STATUS\G
  Change buffer status information is located under the INSERT BUFFER AND ADAPTIVE HASH INDEX heading and appears similar to the following:
  
  ------------------------------
  INSERT BUFFER AND ADAPTIVE HASH INDEX
  ------------------------------
  Ibuf: size 1, free list len 0, seg size 2, 0 merges
  merged operations:
  insert 0, delete mark 0, delete 0
discarded operations:
  insert 0, delete mark 0, delete 0
  Hash table size 4425293, used cells 32, node heap has 1 buffer(s)
  13577.57 hash searches/s, 202.47 non-hash searches/s
  
  For more information, see Section 14.17.3, “InnoDB Standard Monitor and Lock Monitor Output”.
  ```

- The `INFORMATION_SCHEMA.INNODB_METRICS` table provides most of the data points found in InnoDB Standard Monitor output, plus other data. To view change buffer metrics and a description of each, issue the following query:

  ```
  mysql> SELECT NAME, COMMENT FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME LIKE '%ibuf%'
  
  For `INNODB_METRICS` table usage information, see Section 14.15.6, “InnoDB INFORMATION_SCHEMA Metrics Table”.
  ```

- The `INFORMATION_SCHEMA.INNODB_BUFFER_PAGE` table provides metadata about each page in the buffer pool, including change buffer index and change buffer bitmap pages. Change buffer pages are identified by `PAGE_TYPE`. `IBUF_INDEX` is the page type for change buffer index pages, and `IBUF_BITMAP` is the page type for change buffer bitmap pages.

  Warning
  
  Querying the `INNODB_BUFFER_PAGE` table can introduce significant performance overhead. To avoid impacting performance, reproduce the issue you want to investigate on a test instance and run your queries on the test instance.
For example, you can query the INNODB_BUFFER_PAGE table to determine the approximate number of IBUF_INDEX and IBUF_BITMAP pages as a percentage of total buffer pool pages.

```sql
mysql> SELECT (SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE WHERE PAGE_TYPE LIKE 'IBUF%') AS change_buffer_pages,
     
     
     (SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE) AS total_pages,
     
     
     (SELECT ((change_buffer_pages/total_pages)*100)) AS change_buffer_page_percentage;
```

<table>
<thead>
<tr>
<th>change_buffer_pages</th>
<th>total_pages</th>
<th>change_buffer_page_percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>25</td>
<td>8192</td>
<td>0.3052</td>
</tr>
</tbody>
</table>

For information about other data provided by the INNODB_BUFFER_PAGE table, see Section 21.30.1, “The INFORMATION_SCHEMA INNODB_BUFFER_PAGE Table”. For related usage information, see Section 14.15.5, “InnoDB INFORMATION_SCHEMA Buffer Pool Tables”.

- Performance Schema provides change buffer mutex wait instrumentation for advanced performance monitoring. To view change buffer instrumentation, issue the following query:

```sql
mysql> SELECT * FROM performance_schema.setup_instruments WHERE NAME LIKE '%wait/synch/mutex/innodb/ibuf%';
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>ENABLED</th>
<th>TIMED</th>
</tr>
</thead>
<tbody>
<tr>
<td>wait/synch/mutex/innodb/ibuf_bitmap_mutex</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/synch/mutex/innodb/ibuf_mutex</td>
<td>YES</td>
<td>YES</td>
</tr>
<tr>
<td>wait/synch/mutex/innodb/ibuf_pessimistic_insert_mutex</td>
<td>YES</td>
<td>YES</td>
</tr>
</tbody>
</table>

For information about monitoring InnoDB mutex waits, see Section 14.16.1, “Monitoring InnoDB Mutex Waits Using Performance Schema”.

### 14.5.3 Adaptive Hash Index

The adaptive hash index feature enables InnoDB to perform more like an in-memory database on systems with appropriate combinations of workload and sufficient memory for the buffer pool without sacrificing transactional features or reliability. The adaptive hash index feature is enabled by the innodb_adaptive_hash_index variable, or turned off at server startup by `--skip-innodb-adaptive-hash-index`.

Based on the observed pattern of searches, a hash index is built using a prefix of the index key. The prefix can be any length, and it may be that only some values in the B-tree appear in the hash index. Hash indexes are built on demand for the pages of the index that are accessed often.

If a table fits almost entirely in main memory, a hash index can speed up queries by enabling direct lookup of any element, turning the index value into a sort of pointer. InnoDB has a mechanism that monitors index searches. If InnoDB notices that queries could benefit from building a hash index, it does so automatically.

With some workloads, the speedup from hash index lookups greatly outweighs the extra work to monitor index lookups and maintain the hash index structure. Access to the adaptive hash index can sometimes become a source of contention under heavy workloads, such as multiple concurrent joins. Queries with LIKE operators and % wildcards also tend not to benefit. For workloads that do not benefit from the adaptive hash index feature, turning it off reduces unnecessary performance overhead. Because it is difficult to predict in advance whether the adaptive hash index feature is appropriate for a particular system and workload, consider running benchmarks with it enabled and disabled. Architectural changes in MySQL 5.6 make it more suitable to disable the adaptive hash index feature than in earlier releases.
You can monitor adaptive hash index use and contention in the `SEMAPHORES` section of `SHOW ENGINE INNODB STATUS` output. If there are numerous threads waiting on an RW-latch created in `btr0sea.c`, it might be useful to disable the adaptive hash index feature.

For information about the performance characteristics of hash indexes, see `Section 8.3.8, “Comparison of B-Tree and Hash Indexes”`.

### 14.5.4 Log Buffer

The log buffer is the memory area that holds data to be written to the log files on disk. Log buffer size is defined by the `innodb_log_buffer_size` variable. The default size is 16MB. The contents of the log buffer are periodically flushed to disk. A large log buffer enables large transactions to run without the need to write redo log data to disk before the transactions commit. Thus, if you have transactions that update, insert, or delete many rows, increasing the size of the log buffer saves disk I/O.

The `innodb_flush_log_at_trx_commit` variable controls how the contents of the log buffer are written and flushed to disk. The `innodb_flush_log_at_timeout` variable controls log flushing frequency.

For related information, see `Memory Configuration`, and `Section 8.5.4, “Optimizing InnoDB Redo Logging”`.

### 14.6 InnoDB On-Disk Structures

This section describes InnoDB on-disk structures and related topics.

#### 14.6.1 Tables

This section covers topics related to InnoDB tables.

##### 14.6.1.1 Creating InnoDB Tables

To create an InnoDB table, use the `CREATE TABLE` statement.

```
CREATE TABLE t1 (a INT, b CHAR (20), PRIMARY KEY (a)) ENGINE=InnoDB;
```

You do not need to specify the `ENGINE=InnoDB` clause if InnoDB is defined as the default storage engine, which it is by default. To check the default storage engine, issue the following statement:

```
mysql> SELECT @@default_storage_engine;
+--------------------------+
| @@default_storage_engine |
+--------------------------+
| InnoDB                   |
+--------------------------+
```

You might still use `ENGINE=InnoDB` clause if you plan to use `mysqldump` or replication to replay the `CREATE TABLE` statement on a server where the default storage engine is not InnoDB.

An InnoDB table and its indexes can be created in the system tablespace or in a file-per-table tablespace. When `innodb_file_per_table` is enabled, which is the default as of MySQL 5.6.6, an InnoDB table is implicitly created in an individual file-per-table tablespace. Conversely, when `innodb_file_per_table` is disabled, an InnoDB table is implicitly created in the InnoDB system tablespace.

When you create an InnoDB table, MySQL creates a `.frm` file in the database directory under the MySQL data directory. For more information about `.frm` files, see `InnoDB Tables and .frm Files`. For a table created in a file-per-table tablespace, MySQL also creates an `.ibd` tablespace file in the database directory, by default. A table created in the InnoDB system tablespace is created in an existing `ibdata file`, which resides in the MySQL data directory.

Internally, InnoDB adds an entry for each table to the InnoDB data dictionary. The entry includes the database name. For example, if table `t1` is created in the `test` database, the data dictionary entry
for the database name is 'test/t1'. This means you can create a table of the same name (t1) in a
different database, and the table names do not collide inside InnoDB.

### InnoDB Tables and .frm Files

MySQL stores data dictionary information for tables in .frm files in database directories. Unlike other
MySQL storage engines, InnoDB also encodes information about the table in its own internal data
dictionary inside the system tablespace. When MySQL drops a table or a database, it deletes one or
more .frm files as well as the corresponding entries inside the InnoDB data dictionary. You cannot
move InnoDB tables between databases simply by moving the .frm files. For information about
moving InnoDB tables, see Section 14.6.1.4, “Moving or Copying InnoDB Tables”.

### InnoDB Tables and Row Formats

The default row format of an InnoDB table is Compact. Although this row format is fine for basic
experimentation, consider using the Dynamic or Compressed row format to take advantage of
InnoDB features such as table compression and efficient off-page storage of long column values.
Using these row formats requires that innodb_file_per_table is enabled (the default as of MySQL
5.6.6) and that innodb_file_format is set to Barracuda:

```
SET GLOBAL innodb_file_per_table=1;
SET GLOBAL innodb_file_format=barracuda;
```

For more information about InnoDB row formats, see Section 14.11, “InnoDB Row Formats”. For
how to determine the row format of an InnoDB table and the physical characteristics of InnoDB row
formats, see Section 14.11, “InnoDB Row Formats”.

### InnoDB Tables and Primary Keys

Always define a primary key for an InnoDB table, specifying the column or columns that:

- Are referenced by the most important queries.
- Are never left blank.
- Never have duplicate values.
- Rarely if ever change value once inserted.

For example, in a table containing information about people, you would not create a primary key on
(firstname, lastname) because more than one person can have the same name, some people
have blank last names, and sometimes people change their names. With so many constraints, often
there is not an obvious set of columns to use as a primary key, so you create a new column with a
numeric ID to serve as all or part of the primary key. You can declare an auto-increment column so that
ascending values are filled in automatically as rows are inserted:

```
# The value of ID can act like a pointer between related items in different tables.
CREATE TABLE t5 (id INT AUTO_INCREMENT, b CHAR (20), PRIMARY KEY (id));
```

Although the table works correctly without defining a primary key, the primary key is involved with
many aspects of performance and is a crucial design aspect for any large or frequently used table. It
is recommended that you always specify a primary key in the CREATE TABLE statement. If you create
the table, load data, and then run ALTER TABLE to add a primary key later, that operation is much
slower than defining the primary key when creating the table.

### Viewing InnoDB Table Properties

To view the properties of an InnoDB table, issue a SHOW TABLE STATUS statement:
### Creating Tables Externally

There are different reasons for creating InnoDB tables externally; that is, creating tables outside of the data directory. Those reasons might include space management, I/O optimization, or placing tables on a storage device with particular performance or capacity characteristics, for example.

You can create an InnoDB table in an external directory by specifying a `DATA DIRECTORY` clause in the `CREATE TABLE` statement.

```sql
CREATE TABLE t1 (c1 INT PRIMARY KEY) DATA DIRECTORY = '/external/directory';
```

The `DATA DIRECTORY` clause is supported for tables created in file-per-table tablespaces. Tables are implicitly created in file-per-table tablespaces when the `innodb_file_per_table` variable is enabled, which it is by default.

```sql
mysql> SELECT @innodb_file_per_table;
+-------------------------+
| @innodb_file_per_table |
+-------------------------+
| 1                      |
+-------------------------+
```

For more information about file-per-table tablespaces, see Section 14.6.3.2, “File-Per-Table Tablespaces”.

Be sure of the directory location you choose, as the `DATA DIRECTORY` clause cannot be used with `ALTER TABLE` to change the location later.
When you specify a `DATA DIRECTORY` clause in a `CREATE TABLE` statement, the table's data file (`table_name.ibd`) is created in a schema directory under the specified directory, and an `.isl` file (`table_name.isl`) that contains the data file path is created in the schema directory under the MySQL data directory. An `.isl` file is similar in function to a symbolic link. (Actual symbolic links are not supported for use with InnoDB data files.)

The following example demonstrates creating a table in an external directory using the `DATA DIRECTORY` clause. It is assumed that the `innodb_file_per_table` variable is enabled.

```sql
mysql> USE test;
Database changed

mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) DATA DIRECTORY = '/external/directory';

# MySQL creates the table's data file in a schema directory
# under the external directory

shell> cd /external/directory/test
shell> ls
  t1.ibd

# An .isl file that contains the data file path is created
# in the schema directory under the MySQL data directory

shell> cd /path/to/mysql/data/test
shell> ls
db.opt  t1.frm  t1.isl
```

Usage Notes:

- MySQL initially holds the tablespace data file open, preventing you from dismounting the device, but might eventually close the file if the server is busy. Be careful not to accidentally dismount an external device while MySQL is running, or start MySQL while the device is disconnected. Attempting to access a table when the associated data file is missing causes a serious error that requires a server restart.

  A server restart might fail if the data file is not found at the expected path. In this case, manually remove the `.isl` file from the schema directory. After restarting, drop the table to remove the `.frm` file and the information about the table from the data dictionary.

- Before placing a table on an NFS-mounted volume, review potential issues outlined in Using NFS with MySQL.

- If using an LVM snapshot, file copy, or other file-based mechanism to back up the table's data file, always use the `FLUSH TABLES ... FOR EXPORT` statement first to ensure that all changes buffered in memory are flushed to disk before the backup occurs.

- Using the `DATA DIRECTORY` clause to create a table in an external directory is an alternative to using symbolic links, which InnoDB does not support.

- The `DATA DIRECTORY` clause is not supported in a replication environment where the source and replica reside on the same host. The `DATA DIRECTORY` clause requires a full directory path. Replicating the path in this case would cause the source and replica to create the table in same location.

14.6.1.3 Importing InnoDB Tables

This section describes how to import tables using the `Transportable Tablespaces` feature, which permits importing tables that reside in file-per-table tablespaces. There are many reasons why you might want to import tables:

- To run reports on a non-production MySQL server instance to avoid placing extra load on a production server.

- To copy data to a new replica server.
• To restore a table from a backed-up tablespace file.

• As a faster way of moving data than importing a dump file, which requires reinserting data and rebuilding indexes.

• To move a data to a server with storage media that is better suited to your storage requirements. For example, you might move busy tables to an SSD device, or move large tables to a high-capacity HDD device.

The *Transportable Tablespaces* feature is described under the following topics in this section:

  - Prerequisites
  - Importing a Tablespace
  - Limitations
  - Usage Notes
  - Internals

### Prerequisites

  - The `innodb_file_per_table` variable must be enabled, which it is by default.

  - The page size of the tablespace must match the page size of the destination MySQL server instance. InnoDB page size is defined by the `innodb_page_size` variable, which is configured when initializing a MySQL server instance.

  - If the table is in a foreign key relationship, `foreign_key_checks` must be disabled before executing `DISCARD TABLESPACE`. Also, you should export all foreign key related tables at the same logical point in time, as the `ALTER TABLE ... IMPORT TABLESPACE` feature does not enforce foreign key constraints on imported data. To do so, stop updating the related tables, commit all transactions, acquire shared locks on the tables, and perform the export operations.

  - When importing a table from another MySQL server instance, both MySQL server instances must have General Availability (GA) status and must be the same version. Otherwise, the table must be created on the same MySQL server instance into which it is being imported.

  - If the table was created outside of the data directory by specifying the `DATA DIRECTORY` clause in the `CREATE TABLE` statement, the table that you replace on the destination instance must be defined with the same `DATA DIRECTORY` clause. A schema mismatch error is reported if the clauses do not match. To determine if the source table was defined with a `DATA DIRECTORY` clause, use `SHOW CREATE TABLE` to view the table definition. For information about using the `DATA DIRECTORY` clause, see Section 14.6.1.2, “Creating Tables Externally”.

### Importing a Tablespace

This example demonstrates how to import a table that resides in a file-per-table tablespace.

1. On the destination instance, create a table with the same definition as the table you intend to import. (You can obtain the table definition using `SHOW CREATE TABLE` syntax.) If the table definition does not match, a schema mismatch error will be reported when you attempt the import operation.

   ```sql
   mysql> USE test;
   mysql> CREATE TABLE t1 (c1 INT) ENGINE=INNODB;
   ```

2. On the destination instance, discard the tablespace of the table that you just created. (Before importing, you must discard the tablespace of the receiving table.)

   ```sql
   mysql> ALTER TABLE t1 DISCARD TABLESPACE;
   ```

3. On the source instance, run `FLUSH TABLES ... FOR EXPORT` to quiesce the table you intend to import. When a table is quiesced, only read-only transactions are permitted on the table.
Tables

```
mysql> USE test;
mysql> FLUSH TABLES t1 FOR EXPORT;
```

**FLUSH TABLES ... FOR EXPORT** ensures that changes to the named table are flushed to disk so that a binary table copy can be made while the server is running. When **FLUSH TABLES ... FOR EXPORT** is run, InnoDB generates a `.cfg` metadata file in the schema directory of the table. The `.cfg` file contains metadata that is used for schema verification during the import operation.

4. Copy the `.ibd` file and `.cfg` metadata file from the source instance to the destination instance. For example:

```
shell> scp /path/to/datadir/t1.{ibd,cfg} destination-server:/path/to/datadir/test
```

The `.ibd` file and `.cfg` file must be copied before releasing the shared locks, as described in the next step.

5. On the source instance, use **UNLOCK TABLES** to release the locks acquired by the **FLUSH TABLES ... FOR EXPORT** statement:

```
mysql> USE test;
mysql> UNLOCK TABLES;
```

6. On the destination instance, import the tablespace:

```
mysql> USE test;
mysql> ALTER TABLE t1 IMPORT TABLESPACE;
```

**Limitations**

- The **Transportable Tablespaces** feature is only supported for tables that reside in file-per-table tablespaces. It is not supported for the tables that reside in the system tablespace. Tables in the system tablespace cannot be quiesced.

- **DISCARD TABLESPACE** is not supported for partitioned tables, which means that importing partitioned tables is not supported. If you run **ALTER TABLE ... DISCARD TABLESPACE** on a partitioned table, the following error is returned: **ERROR 1031 (HY000): Table storage engine for 'part' doesn't have this option.**

- **FLUSH TABLES ... FOR EXPORT** is not supported on tables with a **FULLTEXT** index, as full-text search auxiliary tables cannot be flushed. After importing a table with a **FULLTEXT** index, run **OPTIMIZE TABLE** to rebuild the **FULLTEXT** indexes. Alternatively, drop **FULLTEXT** indexes before the export operation and recreate the indexes after importing the table on the destination instance.

**Usage Notes**

- A `.cfg` metadata file is not required to import a table. However, metadata checks are not performed when importing without a `.cfg` file, and a warning similar to the following is issued:

```
Message: InnoDB: IO Read error: (2, No such file or directory) Error opening '.\test\t.cfg', will attempt to import without schema verification
1 row in set (0.00 sec)
```

Importing without a `.cfg` metadata file should only be considered if no schema mismatches are expected. The ability to import without a `.cfg` file could be useful in crash recovery scenarios where metadata is not accessible.

- On Windows, InnoDB stores database, tablespace, and table names internally in lowercase. To avoid import problems on case-sensitive operating systems such as Linux and Unix, create all databases, tablespaces, and tables using lowercase names. A convenient way to accomplish this is to add **lower_case_table_names=1** to the `[mysqld]` section of your `my.cnf` or `my.ini` file before creating databases, tablespaces, or tables:

```
[mysqld]
lower_case_table_names=1
```
Internals

The following information describes internals and messages written to the error log during a table import procedure.

When `ALTER TABLE ... DISCARD TABLESPACE` is run on the destination instance:

- The table is locked in X mode.
- The tablespace is detached from the table.

When `FLUSH TABLES ... FOR EXPORT` is run on the source instance:

- The table being flushed for export is locked in shared mode.
- The purge coordinator thread is stopped.
- Dirty pages are synchronized to disk.
- Table metadata is written to the binary `.cfg` file.

Expected error log messages for this operation:

```
[Note] InnoDB: Sync to disk of '"test"."t1"' started.
[Note] InnoDB: Stopping purge
[Note] InnoDB: Writing table metadata to './test/t1.cfg'
[Note] InnoDB: Table '"test"."t1"' flushed to disk
```

When `UNLOCK TABLES` is run on the source instance:

- The binary `.cfg` file is deleted.
- The shared lock on the table being imported is released and the purge coordinator thread is restarted.

Expected error log messages for this operation:

```
[Note] InnoDB: Deleting the meta-data file './test/t1.cfg'
[Note] InnoDB: Resuming purge
```

When `ALTER TABLE ... IMPORT TABLESPACE` is run on the destination instance, the import algorithm performs the following operations for the tablespace being imported:

- Each tablespace page is checked for corruption.
- The space ID and log sequence numbers (LSNs) on each page are updated.
- Flags are validated and LSN updated for the header page.
- Btree pages are updated.
- The page state is set to dirty so that it is written to disk.

Expected error log messages for this operation:

```
[Note] InnoDB: Importing tablespace for table 'test/t1' that was exported from host 'host_name'
[Note] InnoDB: Phase I - Update all pages
[Note] InnoDB: Sync to disk
[Note] InnoDB: Sync to disk - done!
[Note] InnoDB: Phase III - Flush changes to disk
[Note] InnoDB: Phase IV - Flush complete
```

Note

You may also receive a warning that a tablespace is discarded (if you discarded the tablespace for the destination table) and a message stating that statistics could not be calculated due to a missing `.ibd` file:
14.6.1.4 Moving or Copying InnoDB Tables

This section describes techniques for moving or copying some or all InnoDB tables to a different server or instance. For example, you might move an entire MySQL instance to a larger, faster server; you might clone an entire MySQL instance to a new replica server; you might copy individual tables to another instance to develop and test an application, or to a data warehouse server to produce reports.

On Windows, InnoDB always stores database and table names internally in lowercase. To move databases in a binary format from Unix to Windows or from Windows to Unix, create all databases and tables using lowercase names. A convenient way to accomplish this is to add the following line to the [mysqld] section of your my.cnf or my.ini file before creating any databases or tables:

```
[mysqld]
lower_case_table_names=1
```

Techniques for moving or copying InnoDB tables include:

- Importing Tables
- MySQL Enterprise Backup
- Copying Data Files (Cold Backup Method)
- Restoring from a Logical Backup

Importing Tables

A table that resides in a file-per-table tablesapce can be imported from another MySQL server instance or from a backup using the Transportable Tablespace feature. See Section 14.6.1.3, “Importing InnoDB Tables”.

MySQL Enterprise Backup

The MySQL Enterprise Backup product lets you back up a running MySQL database with minimal disruption to operations while producing a consistent snapshot of the database. When MySQL Enterprise Backup is copying tables, reads and writes can continue. In addition, MySQL Enterprise Backup can create compressed backup files, and back up subsets of tables. In conjunction with the MySQL binary log, you can perform point-in-time recovery. MySQL Enterprise Backup is included as part of the MySQL Enterprise subscription.

For more details about MySQL Enterprise Backup, see Section 24.2, “MySQL Enterprise Backup Overview”.

Copying Data Files (Cold Backup Method)

You can move an InnoDB database simply by copying all the relevant files listed under "Cold Backups" in Section 14.18.1, “InnoDB Backup”.

InnoDB data and log files are binary-compatible on all platforms having the same floating-point number format. If the floating-point formats differ but you have not used FLOAT or DOUBLE data types in your tables, then the procedure is the same: simply copy the relevant files.

When you move or copy .ibd files, the database directory name must be the same on the source and destination systems. The table definition stored in the InnoDB shared tablespace includes the database name. The transaction IDs and log sequence numbers stored in the tablespace files also differ between databases.
To move an `.ibd` file and the associated table from one database to another, use a `RENAME TABLE` statement:

```
RENAME TABLE `db1.tbl_name` TO `db2.tbl_name`;
```

If you have a “clean” backup of an `.ibd` file, you can restore it to the MySQL installation from which it originated as follows:

1. The table must not have been dropped or truncated since you copied the `.ibd` file, because doing so changes the table ID stored inside the tablespace.
2. Issue this `ALTER TABLE` statement to delete the current `.ibd` file:

```
ALTER TABLE `tbl_name` DISCARD TABLESPACE;
```

3. Copy the backup `.ibd` file to the proper database directory.
4. Issue this `ALTER TABLE` statement to tell InnoDB to use the new `.ibd` file for the table:

```
ALTER TABLE `tbl_name` IMPORT TABLESPACE;
```

**Note**
The `ALTER TABLE ... IMPORT TABLESPACE` feature does not enforce foreign key constraints on imported data.

In this context, a “clean” `.ibd` file backup is one for which the following requirements are satisfied:

- There are no uncommitted modifications by transactions in the `.ibd` file.
- There are no unmerged insert buffer entries in the `.ibd` file.
- Purge has removed all delete-marked index records from the `.ibd` file.
- `mysqld` has flushed all modified pages of the `.ibd` file from the buffer pool to the file.

You can make a clean backup `.ibd` file using the following method:

1. Stop all activity from the `mysqld` server and commit all transactions.
2. Wait until `SHOW ENGINE INNODB STATUS` shows that there are no active transactions in the database, and the main thread status of InnoDB is `Waiting for server activity`. Then you can make a copy of the `.ibd` file.

Another method for making a clean copy of an `.ibd` file is to use the MySQL Enterprise Backup product:

1. Use MySQL Enterprise Backup to back up the InnoDB installation.
2. Start a second `mysqld` server on the backup and let it clean up the `.ibd` files in the backup.

### Restoring from a Logical Backup

You can use a utility such as `mysqldump` to perform a logical backup, which produces a set of SQL statements that can be executed to reproduce the original database object definitions and table data for transfer to another SQL server. Using this method, it does not matter whether the formats differ or if your tables contain floating-point data.

To improve the performance of this method, disable `autocommit` when importing data. Perform a commit only after importing an entire table or segment of a table.

### 14.6.1.5 Converting Tables from MyISAM to InnoDB

If you have MyISAM tables that you want to convert to InnoDB for better reliability and scalability, review the following guidelines and tips before converting.
Tables

- Adjusting Memory Usage for MyISAM and InnoDB
- Handling Too-Long Or Too-Short Transactions
- Handling Deadlocks
- Planning the Storage Layout
- Converting an Existing Table
- Cloning the Structure of a Table
- Transferring Existing Data
- Storage Requirements
- Defining a PRIMARY KEY for Each Table
- Application Performance Considerations
- Understanding Files Associated with InnoDB Tables

**Adjusting Memory Usage for MyISAM and InnoDB**

As you transition away from MyISAM tables, lower the value of the `key_buffer_size` configuration option to free memory no longer needed for caching results. Increase the value of the `innodb_buffer_pool_size` configuration option, which performs a similar role of allocating cache memory for InnoDB tables. The InnoDB buffer pool caches both table data and index data, speeding up lookups for queries and keeping query results in memory for reuse. For guidance regarding buffer pool size configuration, see Section 8.12.4.1, “How MySQL Uses Memory”.

On a busy server, run benchmarks with the query cache turned off. The InnoDB buffer pool provides similar benefits, so the query cache might be tying up memory unnecessarily. For information about the query cache, see Section 8.10.3, “The MySQL Query Cache”.

**Handling Too-Long Or Too-Short Transactions**

Because MyISAM tables do not support transactions, you might not have paid much attention to the `autocommit` configuration option and the `COMMIT` and `ROLLBACK` statements. These keywords are important to allow multiple sessions to read and write InnoDB tables concurrently, providing substantial scalability benefits in write-heavy workloads.

While a transaction is open, the system keeps a snapshot of the data as seen at the beginning of the transaction, which can cause substantial overhead if the system inserts, updates, and deletes millions of rows while a stray transaction keeps running. Thus, take care to avoid transactions that run for too long:

- If you are using a mysql session for interactive experiments, always `COMMIT` (to finalize the changes) or `ROLLBACK` (to undo the changes) when finished. Close down interactive sessions rather than leave them open for long periods, to avoid keeping transactions open for long periods by accident.

- Make sure that any error handlers in your application also `ROLLBACK` incomplete changes or `COMMIT` completed changes.

- `ROLLBACK` is a relatively expensive operation, because `INSERT`, `UPDATE`, and `DELETE` operations are written to InnoDB tables prior to the `COMMIT`, with the expectation that most changes are committed successfully and rollbacks are rare. When experimenting with large volumes of data, avoid making changes to large numbers of rows and then rolling back those changes.

- When loading large volumes of data with a sequence of `INSERT` statements, periodically `COMMIT` the results to avoid having transactions that last for hours. In typical load operations for data warehousing, if something goes wrong, you truncate the table (using `TRUNCATE TABLE`) and start over from the beginning rather than doing a `ROLLBACK`.

1843
The preceding tips save memory and disk space that can be wasted during too-long transactions. When transactions are shorter than they should be, the problem is excessive I/O. With each COMMIT, MySQL makes sure each change is safely recorded to disk, which involves some I/O.

- For most operations on InnoDB tables, you should use the setting autocommit=0. From an efficiency perspective, this avoids unnecessary I/O when you issue large numbers of consecutive INSERT, UPDATE, or DELETE statements. From a safety perspective, this allows you to issue a ROLLBACK statement to recover lost or garbled data if you make a mistake on the mysql command line, or in an exception handler in your application.

- The time when autocommit=1 is suitable for InnoDB tables is when running a sequence of queries for generating reports or analyzing statistics. In this situation, there is no I/O penalty related to COMMIT or ROLLBACK, and InnoDB can automatically optimize the read-only workload.

- If you make a series of related changes, finalize all the changes at once with a single COMMIT at the end. For example, if you insert related pieces of information into several tables, do a single COMMIT after making all the changes. Or if you run many consecutive INSERT statements, do a single COMMIT after all the data is loaded; if you are doing millions of INSERT statements, perhaps split up the huge transaction by issuing a COMMIT every ten thousand or hundred thousand records, so the transaction does not grow too large.

- Remember that even a SELECT statement opens a transaction, so after running some report or debugging queries in an interactive mysql session, either issue a COMMIT or close the mysql session.

Handling Deadlocks

You might see warning messages referring to “deadlocks” in the MySQL error log, or the output of SHOW ENGINE INNODB STATUS. Despite the scary-sounding name, a deadlock is not a serious issue for InnoDB tables, and often does not require any corrective action. When two transactions start modifying multiple tables, accessing the tables in a different order, they can reach a state where each transaction is waiting for the other and neither can proceed. MySQL immediately detects this condition and cancels (rolls back) the “smaller” transaction, allowing the other to proceed.

Your applications do need error-handling logic to restart a transaction that is forcibly cancelled like this. When you re-issue the same SQL statements as before, the original timing issue no longer applies. Either the other transaction has already finished and yours can proceed, or the other transaction is still in progress and your transaction waits until it finishes.

If deadlock warnings occur constantly, you might review the application code to reorder the SQL operations in a consistent way, or to shorten the transactions. You can test with the innodb_print_all_deadlocks option enabled to see all deadlock warnings in the MySQL error log, rather than only the last warning in the SHOW ENGINE INNODB STATUS output.

For more information, see Section 14.7.5, “Deadlocks in InnoDB”.

Planning the Storage Layout

To get the best performance from InnoDB tables, you can adjust a number of parameters related to storage layout.

When you convert MyISAM tables that are large, frequently accessed, and hold vital data, investigate and consider the innodb_file_per_table, innodb_file_format, and innodb_page_size configuration options, and the ROW_FORMAT and KEY_BLOCK_SIZE clauses of the CREATE TABLE statement.

During your initial experiments, the most important setting is innodb_file_per_table. When this setting is enabled, which is the default as of MySQL 5.6.6, new InnoDB tables are implicitly created in file-per-table tablespaces. In contrast with the InnoDB system tablespace, file-per-table tablespaces allow disk space to be reclaimed by the operating system when a table is truncated or dropped. File-per-table tablespaces also support the Barracuda file format and associated features such as table
Tables

Compression, efficient off-page storage for long variable-length columns, and large index prefixes. For more information, see Section 14.6.3.2, “File-Per-Table Tablespaces”.

Converting an Existing Table

To convert a non-InnoDB table to use InnoDB use ALTER TABLE:

```
ALTER TABLE table_name ENGINE=InnoDB;
```

**Warning**

Do not convert MySQL system tables in the `mysql` database from MyISAM to InnoDB tables. This is an unsupported operation. If you do this, MySQL does not restart until you restore the old system tables from a backup or regenerate them by reinitializing the data directory (see Section 2.10.1, “Initializing the Data Directory”).

Cloning the Structure of a Table

You might make an InnoDB table that is a clone of a MyISAM table, rather than using ALTER TABLE to perform conversion, to test the old and new table side-by-side before switching.

Create an empty InnoDB table with identical column and index definitions. Use `SHOW CREATE TABLE table_name` to see the full CREATE TABLE statement to use. Change the ENGINE clause to ENGINE=INNODB.

Transferring Existing Data

To transfer a large volume of data into an empty InnoDB table created as shown in the previous section, insert the rows with `INSERT INTO innodb_table SELECT * FROM myisam_table ORDER BY primary_key_columns`.

You can also create the indexes for the InnoDB table after inserting the data. Historically, creating new secondary indexes was a slow operation for InnoDB, but now you can create the indexes after the data is loaded with relatively little overhead from the index creation step.

If you have UNIQUE constraints on secondary keys, you can speed up a table import by turning off the uniqueness checks temporarily during the import operation:

```
SET unique_checks=0;
... import operation ...
SET unique_checks=1;
```

For big tables, this saves disk I/O because InnoDB can use its change buffer to write secondary index records as a batch. Be certain that the data contains no duplicate keys. `unique_checks` permits but does not require storage engines to ignore duplicate keys.

For better control over the insertion process, you can insert big tables in pieces:

```
INSERT INTO newtable SELECT * FROM oldtable
WHERE yourkey > something AND yourkey <= somethingelse;
```

After all records are inserted, you can rename the tables.

During the conversion of big tables, increase the size of the InnoDB buffer pool to reduce disk I/O, to a maximum of 80% of physical memory. You can also increase the size of InnoDB log files.

Storage Requirements

If you intend to make several temporary copies of your data in InnoDB tables during the conversion process, it is recommended that you create the tables in file-per-table tablespaces so that you can reclaim the disk space when you drop the tables. When the `innodb_file_per_table` configuration option is enabled (the default), newly created InnoDB tables are implicitly created in file-per-table tablespaces.
Whether you convert the MyISAM table directly or create a cloned InnoDB table, make sure that you have sufficient disk space to hold both the old and new tables during the process. InnoDB tables require more disk space than MyISAM tables. If an ALTER TABLE operation runs out of space, it starts a rollback, and that can take hours if it is disk-bound. For inserts, InnoDB uses the insert buffer to merge secondary index records to indexes in batches. That saves a lot of disk I/O. For rollback, no such mechanism is used, and the rollback can take 30 times longer than the insertion.

In the case of a runaway rollback, if you do not have valuable data in your database, it may be advisable to kill the database process rather than wait for millions of disk I/O operations to complete. For the complete procedure, see Section 14.21.2, “Forcing InnoDB Recovery”.

### Defining a PRIMARY KEY for Each Table

The PRIMARY KEY clause is a critical factor affecting the performance of MySQL queries and the space usage for tables and indexes. The primary key uniquely identifies a row in a table. Every row in the table must have a primary key value, and no two rows can have the same primary key value.

These are guidelines for the primary key, followed by more detailed explanations.

- Declare a PRIMARY KEY for each table. Typically, it is the most important column that you refer to in WHERE clauses when looking up a single row.

- Declare the PRIMARY KEY clause in the original CREATE TABLE statement, rather than adding it later through an ALTER TABLE statement.

- Choose the column and its data type carefully. Prefer numeric columns over character or string ones.

- Consider using an auto-increment column if there is not another stable, unique, non-null, numeric column to use.

- An auto-increment column is also a good choice if there is any doubt whether the value of the primary key column could ever change. Changing the value of a primary key column is an expensive operation, possibly involving rearranging data within the table and within each secondary index.

Consider adding a primary key to any table that does not already have one. Use the smallest practical numeric type based on the maximum projected size of the table. This can make each row slightly more compact, which can yield substantial space savings for large tables. The space savings are multiplied if the table has any secondary indexes, because the primary key value is repeated in each secondary index entry. In addition to reducing data size on disk, a small primary key also lets more data fit into the buffer pool, speeding up all kinds of operations and improving concurrency.

If the table already has a primary key on some longer column, such as a VARCHAR, consider adding a new unsigned AUTO_INCREMENT column and switching the primary key to that, even if that column is not referenced in queries. This design change can produce substantial space savings in the secondary indexes. You can designate the former primary key columns as UNIQUE NOT NULL to enforce the same constraints as the PRIMARY KEY clause, that is, to prevent duplicate or null values across all those columns.

If you spread related information across multiple tables, typically each table uses the same column for its primary key. For example, a personnel database might have several tables, each with a primary key of employee number. A sales database might have some tables with a primary key of customer number, and other tables with a primary key of order number. Because lookups using the primary key are very fast, you can construct efficient join queries for such tables.

If you leave the PRIMARY KEY clause out entirely, MySQL creates an invisible one for you. It is a 6-byte value that might be longer than you need, thus wasting space. Because it is hidden, you cannot refer to it in queries.

### Application Performance Considerations

The reliability and scalability features of InnoDB require more disk storage than equivalent MyISAM tables. You might change the column and index definitions slightly, for better space utilization, reduced
I/O and memory consumption when processing result sets, and better query optimization plans making efficient use of index lookups.

If you do set up a numeric ID column for the primary key, use that value to cross-reference with related values in any other tables, particularly for join queries. For example, rather than accepting a country name as input and doing queries searching for the same name, do one lookup to determine the country ID, then do other queries (or a single join query) to look up relevant information across several tables. Rather than storing a customer or catalog item number as a string of digits, potentially using up several bytes, convert it to a numeric ID for storing and querying. A 4-byte unsigned INT column can index over 4 billion items (with the US meaning of billion: 1000 million). For the ranges of the different integer types, see Section 11.1.2, “Integer Types (Exact Value) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT”.

Understanding Files Associated with InnoDB Tables

InnoDB files require more care and planning than MyISAM files do.

- You must not delete the ibdata files that represent the InnoDB system tablespace.
- Methods of moving or copying InnoDB tables to a different server are described in Section 14.6.1.4, “Moving or Copying InnoDB Tables”.

14.6.1.6 AUTO_INCREMENT Handling in InnoDB

InnoDB provides a configurable locking mechanism that can significantly improve scalability and performance of SQL statements that add rows to tables with AUTO_INCREMENT columns. To use the AUTO_INCREMENT mechanism with an InnoDB table, an AUTO_INCREMENT column must be defined as part of an index such that it is possible to perform the equivalent of an indexed SELECT MAX(ai_col) lookup on the table to obtain the maximum column value. Typically, this is achieved by making the column the first column of some table index.

This section describes the behavior of AUTO_INCREMENT lock modes, usage implications for different AUTO_INCREMENT lock mode settings, and how InnoDB initializes the AUTO_INCREMENT counter.

- InnoDB AUTO_INCREMENT Lock Modes
- InnoDB AUTO_INCREMENT Lock Mode Usage Implications
- InnoDB AUTO_INCREMENT Counter Initialization
- Notes

InnoDB AUTO_INCREMENT Lock Modes

This section describes the behavior of AUTO_INCREMENT lock modes used to generate auto-increment values, and how each lock mode affects replication. Auto-increment lock modes are configured at startup using the innodb_autoinc_lock_mode configuration parameter.

The following terms are used in describing innodb_autoinc_lock_mode settings:

- “INSERT-like” statements
  All statements that generate new rows in a table, including INSERT, INSERT ... SELECT, REPLACE, REPLACE ... SELECT, and LOAD DATA. Includes “simple-inserts”, “bulk-inserts”, and “mixed-mode” inserts.
- “Simple inserts”
  Statements for which the number of rows to be inserted can be determined in advance (when the statement is initially processed). This includes single-row and multiple-row INSERT and REPLACE statements that do not have a nested subquery, but not INSERT ... ON DUPLICATE KEY UPDATE.
• “Bulk inserts”

Statements for which the number of rows to be inserted (and the number of required auto-increment values) is not known in advance. This includes `INSERT ... SELECT`, `REPLACE ... SELECT`, and `LOAD DATA` statements, but not plain `INSERT`. `InnoDB` assigns new values for the `AUTO_INCREMENT` column one at a time as each row is processed.

• “Mixed-mode inserts”

These are “simple insert” statements that specify the auto-increment value for some (but not all) of the new rows. An example follows, where `c1` is an `AUTO_INCREMENT` column of table `t1`:

```sql
INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (5,'c'), (NULL,'d');
```

Another type of “mixed-mode insert” is `INSERT ... ON DUPLICATE KEY UPDATE`, which in the worst case is in effect an `INSERT` followed by a `UPDATE`, where the allocated value for the `AUTO_INCREMENT` column may or may not be used during the update phase.

There are three possible settings for the `innodb_autoinc_lock_mode` configuration parameter. The settings are 0, 1, or 2, for “traditional”, “consecutive”, or “interleaved” lock mode, respectively.

• `innodb_autoinc_lock_mode = 0` ("traditional" lock mode)

The traditional lock mode provides the same behavior that existed before the `innodb_autoinc_lock_mode` configuration parameter was introduced in MySQL 5.1. The traditional lock mode option is provided for backward compatibility, performance testing, and working around issues with “mixed-mode inserts”, due to possible differences in semantics.

In this lock mode, all “INSERT-like” statements obtain a special table-level `AUTO-INC` lock for inserts into tables with `AUTO_INCREMENT` columns. This lock is normally held to the end of the statement (not to the end of the transaction) to ensure that auto-increment values are assigned in a predictable and repeatable order for a given sequence of `INSERT` statements, and to ensure that auto-increment values assigned by any given statement are consecutive.

In the case of statement-based replication, this means that when an SQL statement is replicated on a replica server, the same values are used for the auto-increment column as on the source server. The result of execution of multiple `INSERT` statements is deterministic, and the replica reproduces the same data as on the source. If auto-increment values generated by multiple `INSERT` statements were interleaved, the result of two concurrent `INSERT` statements would be nondeterministic, and could not reliably be propagated to a replica server using statement-based replication.

To make this clear, consider an example that uses this table:

```sql
CREATE TABLE t1 (  
  c1 INT(11) NOT NULL AUTO_INCREMENT,  
  c2 VARCHAR(10) DEFAULT NULL,  
  PRIMARY KEY (c1)  
) ENGINE=InnoDB;
```

Suppose that there are two transactions running, each inserting rows into a table with an `AUTO_INCREMENT` column. One transaction is using an `INSERT ... SELECT` statement that inserts 1000 rows, and another is using a simple `INSERT` statement that inserts one row:

```sql
Tx1: INSERT INTO t1 (c2) SELECT 1000 rows from another table ...  
Tx2: INSERT INTO t1 (c2) VALUES ('xxx');
```

`InnoDB` cannot tell in advance how many rows are retrieved from the `SELECT` in the `INSERT` statement in Tx1, and it assigns the auto-increment values one at a time as the statement proceeds. With a table-level lock, held to the end of the statement, only one `INSERT` statement referring to table `t1` can execute at a time, and the generation of auto-increment numbers by different statements is not interleaved. The auto-increment value generated by the Tx1 `INSERT ... SELECT` statement is consecutive, and the (single) auto-increment value used by the `INSERT`
statement in Tx2 is either be smaller or larger than all those used for Tx1, depending on which statement executes first.

As long as the SQL statements execute in the same order when replayed from the binary log (when using statement-based replication, or in recovery scenarios), the results are the same as they were when Tx1 and Tx2 first ran. Thus, table-level locks held until the end of a statement make **INSERT** statements using auto-increment safe for use with statement-based replication. However, those table-level locks limit concurrency and scalability when multiple transactions are executing insert statements at the same time.

In the preceding example, if there were no table-level lock, the value of the auto-increment column used for the **INSERT** in Tx2 depends on precisely when the statement executes. If the **INSERT** of Tx2 executes while the **INSERT** of Tx1 is running (rather than before it starts or after it completes), the specific auto-increment values assigned by the two **INSERT** statements are nondeterministic, and may vary from run to run.

Under the **consecutive** lock mode, **InnoDB** can avoid using table-level **AUTO-INC** locks for “simple insert” statements where the number of rows is known in advance, and still preserve deterministic execution and safety for statement-based replication.

If you are not using the binary log to replay SQL statements as part of recovery or replication, the **interleaved** lock mode can be used to eliminate all use of table-level **AUTO-INC** locks for even greater concurrency and performance, at the cost of permitting gaps in auto-increment numbers assigned by a statement and potentially having the numbers assigned by concurrently executing statements interleaved.

- **innodb_autoinc_lock_mode = 1** (“consecutive” lock mode)

This is the default lock mode. In this mode, “bulk inserts” use the special **AUTO-INC** table-level lock and hold it until the end of the statement. This applies to all **INSERT ... SELECT**, **REPLACE ... SELECT**, and **LOAD DATA** statements. Only one statement holding the **AUTO-INC** lock can execute at a time. If the source table of the bulk insert operation is different from the target table, the **AUTO-INC** lock on the target table is taken after a shared lock is taken on the first row selected from the source table. If the source and target of the bulk insert operation are the same table, the **AUTO-INC** lock is taken after shared locks are taken on all selected rows.

“Simple inserts” (for which the number of rows to be inserted is known in advance) avoid table-level **AUTO-INC** locks by obtaining the required number of auto-increment values under the control of a mutex (a light-weight lock) that is only held for the duration of the allocation process, **not** until the statement completes. No table-level **AUTO-INC** lock is used unless an **AUTO-INC** lock is held by another transaction. If another transaction holds an **AUTO-INC** lock, a “simple insert” waits for the **AUTO-INC** lock, as if it were a “bulk insert”.

This lock mode ensures that, in the presence of **INSERT** statements where the number of rows is not known in advance (and where auto-increment numbers are assigned as the statement progresses), all auto-increment values assigned by any **INSERT-like** statement are consecutive, and operations are safe for statement-based replication.

Simply put, this lock mode significantly improves scalability while being safe for use with statement-based replication. Further, as with “traditional” lock mode, auto-increment numbers assigned by any given statement are **consecutive**. There is no **change** in semantics compared to “traditional” mode for any statement that uses auto-increment, with one important exception.

The exception is for “mixed-mode inserts”, where the user provides explicit values for an **AUTO_INCREMENT** column for some, but not all, rows in a multiple-row “simple insert”. For such inserts, **InnoDB** allocates more auto-increment values than the number of rows to be inserted. However, all values automatically assigned are consecutively generated (and thus higher than) the auto-increment value generated by the most recently executed previous statement. “Excess” numbers are lost.
• **innodb_autoinc_lock_mode = 2** ("interleaved" lock mode)

In this lock mode, no “INSERT-like” statements use the table-level AUTO-INC lock, and multiple statements can execute at the same time. This is the fastest and most scalable lock mode, but it is not safe when using statement-based replication or recovery scenarios when SQL statements are replayed from the binary log.

In this lock mode, auto-increment values are guaranteed to be unique and monotonically increasing across all concurrently executing "INSERT-like" statements. However, because multiple statements can be generating numbers at the same time (that is, allocation of numbers is interleaved across statements), the values generated for the rows inserted by any given statement may not be consecutive.

If the only statements executing are “simple inserts” where the number of rows to be inserted is known ahead of time, there are no gaps in the numbers generated for a single statement, except for “mixed-mode inserts”. However, when “bulk inserts” are executed, there may be gaps in the auto-increment values assigned by any given statement.

**InnoDB AUTO_INCREMENT Lock Mode Usage Implications**

• Using auto-increment with replication

If you are using statement-based replication, set `innodb_autoinc_lock_mode` to 0 or 1 and use the same value on the source and its replicas. Auto-increment values are not ensured to be the same on the replicas as on the source if you use `innodb_autoinc_lock_mode = 2` ("interleaved") or configurations where the source and replicas do not use the same lock mode.

If you are using row-based or mixed-format replication, all of the auto-increment lock modes are safe, since row-based replication is not sensitive to the order of execution of the SQL statements (and the mixed format uses row-based replication for any statements that are unsafe for statement-based replication).

• “Lost” auto-increment values and sequence gaps

In all lock modes (0, 1, and 2), if a transaction that generated auto-increment values rolls back, those auto-increment values are “lost”. Once a value is generated for an auto-increment column, it cannot be rolled back, whether or not the “INSERT-like” statement is completed, and whether or not the containing transaction is rolled back. Such lost values are not reused. Thus, there may be gaps in the values stored in an AUTO_INCREMENT column of a table.

• Specifying NULL or 0 for the AUTO_INCREMENT column

In all lock modes (0, 1, and 2), if a user specifies NULL or 0 for the AUTO_INCREMENT column in an INSERT, InnoDB treats the row as if the value was not specified and generates a new value for it.

• Assigning a negative value to the AUTO_INCREMENT column

In all lock modes (0, 1, and 2), the behavior of the auto-increment mechanism is not defined if you assign a negative value to the AUTO_INCREMENT column.

• If the AUTO_INCREMENT value becomes larger than the maximum integer for the specified integer type

In all lock modes (0, 1, and 2), the behavior of the auto-increment mechanism is not defined if the value becomes larger than the maximum integer that can be stored in the specified integer type.

• Gaps in auto-increment values for “bulk inserts”

With `innodb_autoinc_lock_mode` set to 0 ("traditional") or 1 ("consecutive"), the auto-increment values generated by any given statement are consecutive, without gaps, because the table-level AUTO-INC lock is held until the end of the statement, and only one such statement can execute at a time.
With `innodb_autoinc_lock_mode` set to 2 ("interleaved"), there may be gaps in the auto-increment values generated by "bulk inserts," but only if there are concurrently executing "INSERT-like" statements.

For lock modes 1 or 2, gaps may occur between successive statements because for bulk inserts the exact number of auto-increment values required by each statement may not be known and overestimation is possible.

- Auto-increment values assigned by "mixed-mode inserts"

Consider a "mixed-mode insert," where a "simple insert" specifies the auto-increment value for some (but not all) resulting rows. Such a statement behaves differently in lock modes 0, 1, and 2.

For example, assume `c1` is an `AUTO_INCREMENT` column of table `t1`, and that the most recent automatically generated sequence number is 100.

```sql
mysql> CREATE TABLE t1 (
  -> c1 INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
  -> c2 CHAR(1)
  -> ) ENGINE = INNODB;
```

Now, consider the following "mixed-mode insert" statement:

```sql
mysql> INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (5,'c'), (NULL,'d');
```

With `innodb_autoinc_lock_mode` set to 0 ("traditional"), the four new rows are:

```sql
mysql> SELECT c1, c2 FROM t1 ORDER BY c2;
```

```
<table>
<thead>
<tr>
<th>c1</th>
<th>c2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>a</td>
</tr>
<tr>
<td>101</td>
<td>b</td>
</tr>
<tr>
<td>5</td>
<td>c</td>
</tr>
<tr>
<td>102</td>
<td>d</td>
</tr>
</tbody>
</table>
```

The next available auto-increment value is 103 because the auto-increment values are allocated one at a time, not all at once at the beginning of statement execution. This result is true whether or not there are concurrently executing "INSERT-like" statements (of any type).

With `innodb_autoinc_lock_mode` set to 1 ("consecutive"), the four new rows are also:

```sql
mysql> SELECT c1, c2 FROM t1 ORDER BY c2;
```

```
<table>
<thead>
<tr>
<th>c1</th>
<th>c2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>a</td>
</tr>
<tr>
<td>101</td>
<td>b</td>
</tr>
<tr>
<td>5</td>
<td>c</td>
</tr>
<tr>
<td>102</td>
<td>d</td>
</tr>
</tbody>
</table>
```

However, in this case, the next available auto-increment value is 105, not 103 because four auto-increment values are allocated at the time the statement is processed, but only two are used. This result is true whether or not there are concurrently executing "INSERT-like" statements (of any type).

With `innodb_autoinc_lock_mode` set to mode 2 ("interleaved"), the four new rows are:

```sql
mysql> SELECT c1, c2 FROM t1 ORDER BY c2;
```

```
<table>
<thead>
<tr>
<th>c1</th>
<th>c2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>a</td>
</tr>
<tr>
<td>x</td>
<td>b</td>
</tr>
<tr>
<td>5</td>
<td>c</td>
</tr>
<tr>
<td>y</td>
<td>d</td>
</tr>
</tbody>
</table>
```
The values of $x$ and $y$ are unique and larger than any previously generated rows. However, the specific values of $x$ and $y$ depend on the number of auto-increment values generated by concurrently executing statements.

Finally, consider the following statement, issued when the most-recently generated sequence number is 100:

```sql
mysql> INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (101,'c'), (NULL,'d');
```

With any `innodb_autoinc_lock_mode` setting, this statement generates a duplicate-key error 23000 (Can't write; duplicate key in table) because 101 is allocated for the row (NULL,'b') and insertion of the row (101, 'c') fails.

**Modifying AUTO_INCREMENT column values in the middle of a sequence of INSERT statements**

In all lock modes (0, 1, and 2), modifying an `AUTO_INCREMENT` column value in the middle of a sequence of `INSERT` statements could lead to “Duplicate entry” errors. For example, if you perform an `UPDATE` operation that changes an `AUTO_INCREMENT` column value to a value larger than the current maximum auto-increment value, subsequent `INSERT` operations that do not specify an unused auto-increment value could encounter “Duplicate entry” errors. This behavior is demonstrated in the following example.

```sql
mysql> CREATE TABLE t1 (  -- c1 INT NOT NULL AUTO_INCREMENT,  -> PRIMARY KEY (c1)  -> ) ENGINE = InnoDB;

mysql> INSERT INTO t1 VALUES(0), (0), (3);

mysql> SELECT c1 FROM t1;
+----+
| c1 |
+----+
|  1 |
|  2 |
|  3 |
+----+

mysql> UPDATE t1 SET c1 = 4 WHERE c1 = 1;

mysql> SELECT c1 FROM t1;
+----+
| c1 |
+----+
|  2 |
|  3 |
|  4 |
+----+

mysql> INSERT INTO t1 VALUES(0);
ERROR 1062 (23000): Duplicate entry '4' for key 'PRIMARY'
```

**InnoDB AUTO_INCREMENT Counter Initialization**

This section describes how InnoDB initializes `AUTO_INCREMENT` counters.

If you specify an `AUTO_INCREMENT` column for an InnoDB table, the table handle in the InnoDB data dictionary contains a special counter called the auto-increment counter that is used in assigning new values for the column. This counter is stored only in main memory, not on disk.

To initialize an auto-increment counter after a server restart, InnoDB executes the equivalent of the following statement on the first insert into a table containing an `AUTO_INCREMENT` column.

```sql
SELECT MAX(ai_col) FROM table_name FOR UPDATE;
```
InnoDB increments the value retrieved by the statement and assigns it to the column and to the auto-increment counter for the table. By default, the value is incremented by 1. This default can be overridden by the `auto_increment_increment` configuration setting.

If the table is empty, InnoDB uses the value 1. This default can be overridden by the `auto_increment_offset` configuration setting.

If a `SHOW TABLE STATUS` statement examines the table before the auto-increment counter is initialized, InnoDB initializes but does not increment the value. The value is stored for use by later inserts. This initialization uses a normal exclusive-locking read on the table and the lock lasts to the end of the transaction. InnoDB follows the same procedure for initializing the auto-increment counter for a newly created table.

After the auto-increment counter has been initialized, if you do not explicitly specify a value for an `AUTO_INCREMENT` column, InnoDB increments the counter and assigns the new value to the column. If you insert a row that explicitly specifies the column value, and the value is greater than the current counter value, the counter is set to the specified column value.

InnoDB uses the in-memory auto-increment counter as long as the server runs. When the server is stopped and restarted, InnoDB reinitializes the counter for each table for the first `INSERT` to the table, as described earlier.

A server restart also cancels the effect of the `AUTO_INCREMENT = N` table option in `CREATE TABLE` and `ALTER TABLE` statements, which you can use with InnoDB tables to set the initial counter value or alter the current counter value.

Notes

- When an `AUTO_INCREMENT` integer column runs out of values, a subsequent `INSERT` operation returns a duplicate-key error. This is general MySQL behavior.

- When you restart the MySQL server, InnoDB may reuse an old value that was generated for an `AUTO_INCREMENT` column but never stored (that is, a value that was generated during an old transaction that was rolled back).

14.6.2 Indexes

This section covers topics related to InnoDB indexes.

14.6.2.1 Clustered and Secondary Indexes

Every InnoDB table has a special index called the clustered index where the data for the rows is stored. Typically, the clustered index is synonymous with the primary key. To get the best performance from queries, inserts, and other database operations, you must understand how InnoDB uses the clustered index to optimize the most common lookup and DML operations for each table.

- When you define a `PRIMARY KEY` on your table, InnoDB uses it as the clustered index. Define a primary key for each table that you create. If there is no logical unique and non-null column or set of columns, add a new `auto-increment` column, whose values are filled in automatically.

- If you do not define a `PRIMARY KEY` for your table, MySQL locates the first `UNIQUE` index where all the key columns are `NOT NULL` and InnoDB uses it as the clustered index.

- If the table has no `PRIMARY KEY` or suitable `UNIQUE` index, InnoDB internally generates a hidden clustered index named `GEN_CLUST_INDEX` on a synthetic column containing row ID values. The rows are ordered by the ID that InnoDB assigns to the rows in such a table. The row ID is a 6-byte field that increases monotonically as new rows are inserted. Thus, the rows ordered by the row ID are physically in insertion order.

How the Clustered Index Speeds Up Queries

Accessing a row through the clustered index is fast because the index search leads directly to the page with all the row data. If a table is large, the clustered index architecture often saves a disk I/O operation
Indexes

when compared to storage organizations that store row data using a different page from the index record.

How Secondary Indexes Relate to the Clustered Index

All indexes other than the clustered index are known as secondary indexes. In InnoDB, each record in a secondary index contains the primary key columns for the row, as well as the columns specified for the secondary index. InnoDB uses this primary key value to search for the row in the clustered index.

If the primary key is long, the secondary indexes use more space, so it is advantageous to have a short primary key.

For guidelines to take advantage of InnoDB clustered and secondary indexes, see Section 8.3, “Optimization and Indexes”.

14.6.2.2 The Physical Structure of an InnoDB Index

All InnoDB indexes are B-trees where the index records are stored in the leaf pages of the tree. The default size of an index page is 16KB.

When new records are inserted into an InnoDB clustered index, InnoDB tries to leave 1/16 of the page free for future insertions and updates of the index records. If index records are inserted in a sequential order (ascending or descending), the resulting index pages are about 15/16 full. If records are inserted in a random order, the pages are from 1/2 to 15/16 full. If the fill factor of an index page drops below 1/2, InnoDB tries to contract the index tree to free the page.

You can define the page size for all InnoDB tablespaces in a MySQL instance by setting the innodb_page_size configuration option prior to initializing the MySQL instance. Once the page size for an instance is defined, you cannot change it without reinitializing the instance. Supported sizes are 16KB, 8KB, and 4KB.

A MySQL instance using a particular InnoDB page size cannot use data files or log files from an instance that uses a different page size.

14.6.2.3 InnoDB FULLTEXT Indexes

FULLTEXT indexes are created on text-based columns (CHAR, VARCHAR, or TEXT columns) to help speed up queries and DML operations on data contained within those columns, omitting any words that are defined as stopwords.

A FULLTEXT index is defined as part of a CREATE TABLE statement or added to an existing table using ALTER TABLE or CREATE INDEX.

Full-text search is performed using MATCH() ... AGAINST syntax. For usage information, see Section 12.10, “Full-Text Search Functions”.

InnoDB FULLTEXT indexes are described under the following topics in this section:

- InnoDB Full-Text Index Design
- InnoDB Full-Text Index Tables
- InnoDB Full-Text Index Cache
- InnoDB Full-Text Index Document ID and FTS_DOC_ID Column
- InnoDB Full-Text Index Deletion Handling
- InnoDB Full-Text Index Transaction Handling
- Monitoring InnoDB Full-Text Indexes
InnoDB Full-Text Index Design

InnoDB FULLTEXT indexes have an inverted index design. Inverted indexes store a list of words, and for each word, a list of documents that the word appears in. To support proximity search, position information for each word is also stored, as a byte offset.

InnoDB Full-Text Index Tables

When creating an InnoDB FULLTEXT index, a set of index tables is created, as shown in the following example:

```sql
mysql> CREATE TABLE opening_lines (
    -> id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
    -> opening_line TEXT(500),
    -> author VARCHAR(200),
    -> title VARCHAR(200),
    -> FULLTEXT idx (opening_line)
) ENGINE=InnoDB;

mysql> SELECT table_id, name, space from INFORMATION_SCHEMA.INNODB_SYS_TABLES
WHERE name LIKE 'test/%';
+----------+----------------------------------------------------+-------+
| table_id | name                                               | space |
+----------+----------------------------------------------------+-------+
|      333 | test/FTS_0000000000000147_00000000000001c9_INDEX_1 |   289 |
|      334 | test/FTS_0000000000000147_00000000000001c9_INDEX_2 |   290 |
|      335 | test/FTS_0000000000000147_00000000000001c9_INDEX_3 |   291 |
|      336 | test/FTS_0000000000000147_00000000000001c9_INDEX_4 |   292 |
|      337 | test/FTS_0000000000000147_00000000000001c9_INDEX_5 |   293 |
|      338 | test/FTS_0000000000000147_00000000000001c9_INDEX_6 |   294 |
|      330 | test/FTS_0000000000000147_BEING_DELETED            |   286 |
|      331 | test/FTS_0000000000000147_BEING_DELETED_CACHE      |   287 |
|      332 | test/FTS_0000000000000147_CONFIG                   |   288 |
|      328 | test/FTS_0000000000000147_DELETED                  |   284 |
|      329 | test/FTS_0000000000000147_DELETED_CACHE            |   285 |
|      327 | test/opening_lines                                 |   283 |
+----------+----------------------------------------------------+-------+
```

The first six tables represent the inverted index and are referred to as auxiliary index tables. When incoming documents are tokenized, the individual words (also referred to as “tokens”) are inserted into the index tables along with position information and the associated Document ID (DOC_ID). The words are fully sorted and partitioned among the six index tables based on the character set sort weight of the word’s first character.

The inverted index is partitioned into six auxiliary index tables to support parallel index creation. By default, two threads tokenize, sort, and insert words and associated data into the index tables. The number of threads is configurable using the `innodb_ft_sort_pll_degree` option. Consider increasing the number of threads when creating FULLTEXT indexes on large tables.

Auxiliary index table names are prefixed with `FTS_` and postfixed with `INDEX_*`. Each index table is associated with the indexed table by a hex value in the index table name that matches the `table_id` of the indexed table. For example, the `table_id` of the `test/opening_lines` table is 327, for which the hex value is 0x147. As shown in the preceding example, the “147” hex value appears in the names of index tables that are associated with the `test/opening_lines` table.

A hex value representing the `index_id` of the FULLTEXT index also appears in auxiliary index table names. For example, in the auxiliary table name `test/FTS_0000000000000147_00000000000001c9_INDEX_1`, the hex value `1c9` has a decimal value of 457. The index defined on the `opening_lines` table (idx) can be identified by querying the `INFORMATION_SCHEMA.INNODB_SYS_INDEXES` table for this value (457).

```sql
mysql> SELECT index_id, name, table_id, space from INFORMATION_SCHEMA.INNODB_SYS_INDEXES
WHERE index_id=457;
+----------+-------+----------+-------+
| index_id | name  | table_id | space |
+----------+-------+----------+-------+
|      457 | idx   |      327 |   283 |
+----------+-------+----------+-------+
```
Indexes

Index tables are stored in their own tablespace when `innodb_file_per_table` is enabled. If `innodb_file_per_table` is disabled, index tables are stored in the InnoDB system tablespace (space 0).

**Note**

Due to a bug introduced in MySQL 5.6.5, index tables are created in the InnoDB system tablespace (space 0) when `innodb_file_per_table` is enabled. The bug is fixed in MySQL 5.6.20 and MySQL 5.7.5 (Bug#18635485).

The other index tables shown in the preceding example are referred to as common index tables and are used for deletion handling and storing the internal state of FULLTEXT indexes. Unlike the inverted index tables, which are created for each full-text index, this set of tables is common to all full-text indexes created on a particular table.

Common auxiliary tables are retained even if full-text indexes are dropped. When a full-text index is dropped, the `FTS_DOC_ID` column that was created for the index is retained, as removing the `FTS_DOC_ID` column would require rebuilding the table. Common auxiliary tables are required to manage the `FTS_DOC_ID` column.

- **FTS_*_DELETED** and **FTS_*_DELETED_CACHE**
  
  Contain the document IDs (DOC_ID) for documents that are deleted but whose data is not yet removed from the full-text index. The `FTS_*_DELETED_CACHE` is the in-memory version of the `FTS_*_DELETED` table.

- **FTS_*_BEING_DELETED** and **FTS_*_BEING_DELETED_CACHE**
  
  Contain the document IDs (DOC_ID) for documents that are deleted and whose data is currently in the process of being removed from the full-text index. The `FTS_*_BEING_DELETED_CACHE` table is the in-memory version of the `FTS_*_BEING_DELETED` table.

- **FTS_*_CONFIG**
  
  Stores information about the internal state of the FULLTEXT index. Most importantly, it stores the `FTS_SYNCED_DOC_ID`, which identifies documents that have been parsed and flushed to disk. In case of crash recovery, `FTS_SYNCED_DOC_ID` values are used to identify documents that have not been flushed to disk so that the documents can be re-parsed and added back to the FULLTEXT index cache. To view the data in this table, query the `INFORMATION_SCHEMA.INNODB_FT_CONFIG` table.

**InnoDB Full-Text Index Cache**

When a document is inserted, it is tokenized, and the individual words and associated data are inserted into the FULLTEXT index. This process, even for small documents, could result in numerous small insertions into the auxiliary index tables, making concurrent access to these tables a point of contention. To avoid this problem, InnoDB uses a FULLTEXT index cache to temporarily cache index table insertions for recently inserted rows. This in-memory cache structure holds insertions until the cache is full and then batch flushes them to disk (to the auxiliary index tables). You can query the `INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE` table to view tokenized data for recently inserted rows.

The caching and batch flushing behavior avoids frequent updates to auxiliary index tables, which could result in concurrent access issues during busy insert and update times. The batching technique also avoids multiple insertions for the same word, and minimizes duplicate entries. Instead of flushing each word individually, insertions for the same word are merged and flushed to disk as a single entry, improving insertion efficiency while keeping auxiliary index tables as small as possible.

The `innodb_ft_cache_size` variable is used to configure the full-text index cache size (on a per-table basis), which affects how often the full-text index cache is flushed. You can
Indexes

also define a global full-text index cache size limit for all tables in a given instance using the `innodb_ft_total_cache_size` option.

The full-text index cache stores the same information as auxiliary index tables. However, the full-text index cache only caches tokenized data for recently inserted rows. The data that is already flushed to disk (to the full-text auxiliary tables) is not brought back into the full-text index cache when queried. The data in auxiliary index tables is queried directly, and results from the auxiliary index tables are merged with results from the full-text index cache before being returned.

**InnoDB Full-Text Index Document ID and FTS_DOC_ID Column**

*InnoDB* uses a unique document identifier referred to as a Document ID (`DOC_ID`) to map words in the full-text index to document records where the word appears. The mapping requires an `FTS_DOC_ID` column on the indexed table. If an `FTS_DOC_ID` column is not defined, *InnoDB* automatically adds a hidden `FTS_DOC_ID` column when the full-text index is created. The following example demonstrates this behavior.

The following table definition does not include an `FTS_DOC_ID` column:

```
mysql> CREATE TABLE opening_lines (
    id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
    opening_line TEXT(500),
    author VARCHAR(200),
    title VARCHAR(200)
) ENGINE=InnoDB;
```

When you create a full-text index on the table using `CREATE FULLTEXT INDEX` syntax, a warning is returned which reports that *InnoDB* is rebuilding the table to add the `FTS_DOC_ID` column.

```
mysql> CREATE FULLTEXT INDEX idx ON opening_lines(opening_line);
Query OK, 0 rows affected, 1 warning (0.19 sec)
Records: 0  Duplicates: 0  Warnings: 1
mysql> SHOW WARNINGS;
+---------+------+--------------------------------------------------+
| Level   | Code | Message                                          |
|---------+------|--------------------------------------------------|
| Warning | 124  | InnoDB rebuilding table to add column FTS_DOC_ID |
+---------+------+--------------------------------------------------+
```

The same warning is returned when using `ALTER TABLE` to add a full-text index to a table that does not have an `FTS_DOC_ID` column. If you create a full-text index at `CREATE TABLE` time and do not specify an `FTS_DOC_ID` column, *InnoDB* adds a hidden `FTS_DOC_ID` column, without warning.

Defining an `FTS_DOC_ID` column at `CREATE TABLE` time is less expensive than creating a full-text index on a table that is already loaded with data. If an `FTS_DOC_ID` column is defined on a table prior to loading data, the table and its indexes do not have to be rebuilt to add the new column. If you are not concerned with `CREATE FULLTEXT INDEX` performance, leave out the `FTS_DOC_ID` column to have *InnoDB* create it for you. *InnoDB* creates a hidden `FTS_DOC_ID` column along with a unique index (`FTS_DOC_ID_INDEX`) on the `FTS_DOC_ID` column. If you want to create your own `FTS_DOC_ID` column, the column must be defined as `BIGINT UNSIGNED NOT NULL` and named `FTS_DOC_ID` (all uppercase), as in the following example:

```
Note
The `FTS_DOC_ID` column does not need to be defined as an `AUTO_INCREMENT` column but `AUTO_INCREMENT` could make loading data easier.
```

```
mysql> CREATE TABLE opening_lines (  
    FTS_DOC_ID BIGINT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
    opening_line TEXT(500),
    author VARCHAR(200),
    title VARCHAR(200)
) ENGINE=InnoDB;
```
Indexes

If you choose to define the `FTS_DOC_ID` column yourself, you are responsible for managing the column to avoid empty or duplicate values. `FTS_DOC_ID` values cannot be reused, which means `FTS_DOC_ID` values must be ever increasing.

Optionally, you can create the required unique `FTS_DOC_ID_INDEX` (all uppercase) on the `FTS_DOC_ID` column.

```sql
mysql> CREATE UNIQUE INDEX FTS_DOC_ID_INDEX on opening_lines(FTS_DOC_ID);
```

If you do not create the `FTS_DOC_ID_INDEX`, InnoDB creates it automatically.

Before MySQL 5.6.31, the permitted gap between the largest used `FTS_DOC_ID` value and new `FTS_DOC_ID` value is 10000. In MySQL 5.6.31 and later, the permitted gap is 65535.

To avoid rebuilding the table, the `FTS_DOC_ID` column is retained when dropping a full-text index.

### InnoDB Full-Text Index Deletion Handling

Deleting a record that has a full-text index column could result in numerous small deletions in the auxiliary index tables, making concurrent access to these tables a point of contention. To avoid this problem, the Document ID (`DOC_ID`) of a deleted document is logged in a special `FTS_*_DELETED` table whenever a record is deleted from an indexed table, and the indexed record remains in the full-text index. Before returning query results, information in the `FTS_*_DELETED` table is used to filter out deleted Document IDs. The benefit of this design is that deletions are fast and inexpensive. The drawback is that the size of the index is not immediately reduced after deleting records. To remove full-text index entries for deleted records, run `OPTIMIZE TABLE` on the indexed table with `innodb_optimize_fulltext_only=ON` to rebuild the full-text index. For more information, see Optimizing InnoDB Full-Text Indexes.

### InnoDB Full-Text Index Transaction Handling

InnoDB `FULLTEXT` indexes have special transaction handling characteristics due its caching and batch processing behavior. Specifically, updates and insertions on a `FULLTEXT` index are processed at transaction commit time, which means that a `FULLTEXT` search can only see committed data. The following example demonstrates this behavior. The `FULLTEXT` search only returns a result after the inserted lines are committed.

```sql
mysql> CREATE TABLE opening_lines (id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY, opening_line TEXT(500), author VARCHAR(200), title VARCHAR(200), FULLTEXT idx (opening_line) ) ENGINE=InnoDB;

mysql> BEGIN;

mysql> INSERT INTO opening_lines(opening_line,author,title) VALUES ('Call me Ishmael.','Herman Melville','Moby-Dick'), ('A screaming comes across the sky.','Thomas Pynchon','Gravity\'s Rainbow'), ('I am an invisible man.','Ralph Ellison','Invisible Man'), ('Where now? Who now? When now?','Samuel Beckett','The Unnamable'), ('It was love at first sight.','Joseph Heller','Catch-22'), ('All this happened, more or less.','Kurt Vonnegut','Slaughterhouse-Five'), ('Mrs. Dalloway said she would buy the flowers herself.','Virginia Woolf','Mrs. Dalloway'), ('It was a pleasure to burn.','Ray Bradbury','Fahrenheit 451');

mysql> SELECT COUNT(*) FROM opening_lines WHERE MATCH(opening_line) AGAINST('Ishmael');
+----------+
| COUNT(*) |
+----------+
|        0 |
+----------+

mysql> COMMIT;

mysql> SELECT COUNT(*) FROM opening_lines WHERE MATCH(opening_line) AGAINST('Ishmael');
```
Monitoring InnoDB Full-Text Indexes

You can monitor and examine the special text-processing aspects of InnoDB FULLTEXT indexes by querying the following INFORMATION_SCHEMA tables:

- INNODB_FT_CONFIG
- INNODB_FT_INDEX_TABLE
- INNODB_FT_INDEX_CACHE
- INNODB_FT_DEFAULT_STOPWORD
- INNODB_FT_DELETED
- INNODB_FT_BEING_DELETED

You can also view basic information for FULLTEXT indexes and tables by querying INNODB_SYS_INDEXES and INNODB_SYS_TABLES.

For more information, see Section 14.15.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”.

14.6.3 Tablespaces

This section covers topics related to InnoDB tablespaces.

14.6.3.1 The System Tablespace

The system tablespace is the storage area for the InnoDB data dictionary, the doublewrite buffer, the change buffer, and undo logs. It may also contain table and index data if tables are created in the system tablespace rather than file-per-table tablespaces.

The system tablespace can have one or more data files. By default, a single system tablespace data file, named ibdata1, is created in the data directory. The size and number of system tablespace data files is defined by the innodb_data_file_path startup option. For configuration information, see System Tablespace Data File Configuration.

Additional information about the system tablespace is provided under the following topics in the section:

- Resizing the System Tablespace
- Using Raw Disk Partitions for the System Tablespace

Resizing the System Tablespace

This section describes how to increase or decrease the size of the system tablespace.

Increasing the Size of the System Tablespace

The easiest way to increase the size of the system tablespace is to configure it to be auto-extending. To do so, specify the autoextend attribute for the last data file in the innodb_data_file_path setting, and restart the server. For example:

```
innodb_data_file_path=ibdata1:10M:autoextend
```

When the autoextend attribute is specified, the data file automatically increases in size by 8MB increments as space is required. The innodb_autoextend_increment variable controls the increment size.
You can also increase system tablespace size by adding another data file. To do so:

1. Stop the MySQL server.

2. If the last data file in the `innodb_data_file_path` setting is defined with the `autoextend` attribute, remove it, and modify the size attribute to reflect the current data file size. To determine the appropriate data file size to specify, check your file system for the file size, and round that value down to the closest MB value, where a MB is equal to 1024 x 1024.

3. Append a new data file to the `innodb_data_file_path` setting, optionally specifying the `autoextend` attribute. The `autoextend` attribute can be specified only for the last data file in the `innodb_data_file_path` setting.

4. Start the MySQL server.

For example, this tablespace has one auto-extending data file:

```
innodb_data_home_dir =
innodb_data_file_path = /ibdata/ibdata1:10M:autoextend
```

Suppose that the data file has grown to 988MB over time. This is the `innodb_data_file_path` setting after modifying the size attribute to reflect the current data file size, and after specifying a new 50MB auto-extending data file:

```
innodb_data_home_dir =
innodb_data_file_path = /ibdata/ibdata1:988M;/disk2/ibdata2:50M:autoextend
```

When adding a new data file, do not specify an existing file name. InnoDB creates and initializes the new data file when you start the server.

**Note**

You cannot increase the size of an existing system tablespace data file by changing its size attribute. For example, changing the `innodb_data_file_path` setting from `ibdata1:10M:autoextend` to `ibdata1:12M:autoextend` produces the following error when starting the server:

```
[ERROR] [MY-012263] [InnoDB] The Auto-extending innodb_system data file '
```

The error indicates that the existing data file size (expressed in InnoDB pages) is different from the size specified in the configuration file. If you encounter this error, restore the previous `innodb_data_file_path` setting, and refer to the system tablespace resizing instructions.

InnoDB page size is defined by the `innodb_page_size` variable. The default is 16384 bytes.

### Decreasing the Size of the InnoDB System Tablespace

You cannot remove a data file from the system tablespace. To decrease the system tablespace size, use this procedure:

1. Use `mysqldump` to dump all of your InnoDB tables, including InnoDB tables located in the `mysql` schema. Identify InnoDB tables in the `mysql` schema using the following query:

   ```
   mysql> SELECT table_name FROM information_schema.tables WHERE table_schema='mysql' and engine='InnoDB';
   +----------------------+
   | table_name           |
   +----------------------+
   | innodb_index_stats   |
   | innodb_table_stats   |
   | slave_master_info    |
   | slave_relay_log_info |
   +----------------------+
   ```

   Then:

   ```
   mysql> mysqldump -u username -p database_name table_name > table_name.sql
   ```

2. Stop the MySQL server.

3. Remove the existing data file.

4. Append a new data file to the `innodb_data_file_path` setting, optionally specifying the `autoextend` attribute. The `autoextend` attribute can be specified only for the last data file in the `innodb_data_file_path` setting.

5. Start the MySQL server.

6. Use `mysqlimport` or `mysql` to import the dump files:

   ```
   mysql> source table_name.sql
   ```

7. (Optional) Use `mysql` to verify that the data file is correctly updated.

   ```
   mysql> select * from table_name
   ```

   This will show the new data file size.

8. Repeat steps 1-7 as necessary to decrease the system tablespace size.
2. Stop the server.

3. Remove all of the existing tablespace files (*.ibd), including the ibdata and ib_log files. Do not forget to remove *.ibd files for tables located in the mysql schema.

4. Remove any .frm files for InnoDB tables.

5. Configure the data files for the new system tablespace. See System Tablespace Data File Configuration.

6. Restart the server.

7. Import the dump files.

**Note**

If your databases only use the InnoDB engine, it may be simpler to dump all databases, stop the server, remove all databases and InnoDB log files, restart the server, and import the dump files.

To avoid large system tablespaces, consider using file-per-table tablespaces for your data. File-per-table tablespaces are the default tablespace type and are used implicitly when creating an InnoDB table. Unlike the system tablespace, disk space is returned to the operating system after truncating or dropping a table created in a file-per-table tablespace. For more information, see Section 14.6.3.2, “File-Per-Table Tablespaces”.

### Using Raw Disk Partitions for the System Tablespace

You can use raw disk partitions as data files in the InnoDB system tablespace. This technique enables nonbuffered I/O on Windows and on some Linux and Unix systems without file system overhead. Perform tests with and without raw partitions to verify whether this change actually improves performance on your system.

When you use a raw disk partition, ensure that the user ID that runs the MySQL server has read and write privileges for that partition. For example, if you run the server as the mysql user, the partition must be readable and writeable by mysql. If you run the server with the --memlock option, the server must be run as root, so the partition must be readable and writeable by root.

The procedures described below involve option file modification. For additional information, see Section 4.2.2.2, “Using Option Files”.

### Allocating a Raw Disk Partition on Linux and Unix Systems

1. When you create a new data file, specify the keyword newraw immediately after the data file size for the innodb_data_file_path option. The partition must be at least as large as the size that you specify. Note that 1MB in InnoDB is 1024 × 1024 bytes, whereas 1MB in disk specifications usually means 1,000,000 bytes.

   ```
   [mysqld]
   innodb_data_home_dir=
   innodb_data_file_path=/dev/hdd1:3Gnewraw;/dev/hdd2:2Gnewraw
   ```

2. Restart the server. InnoDB notices the newraw keyword and initializes the new partition. However, do not create or change any InnoDB tables yet. Otherwise, when you next restart the server, InnoDB reinitializes the partition and your changes are lost. (As a safety measure InnoDB prevents users from modifying data when any partition with newraw is specified.)

3. After InnoDB has initialized the new partition, stop the server, change newraw in the data file specification to raw:
4. Restart the server. InnoDB now permits changes to be made.

Allocating a Raw Disk Partition on Windows

On Windows systems, the same steps and accompanying guidelines described for Linux and Unix systems apply except that the `innodb_data_file_path` setting differs slightly on Windows.

1. When you create a new data file, specify the keyword `newraw` immediately after the data file size for the `innodb_data_file_path` option:

```sql
[mysqld]
innoadb_data_home_dir=
innoadb_data_file_path=//./D::10Gnewraw
```

The `//./` corresponds to the Windows syntax of `\..\` for accessing physical drives. In the example above, `D:` is the drive letter of the partition.

2. Restart the server. InnoDB notices the `newraw` keyword and initializes the new partition.

3. After InnoDB has initialized the new partition, stop the server, change `newraw` in the data file specification to `raw`:

```sql
[mysqld]
innoadb_data_home_dir=
innoadb_data_file_path=//./D::10Graw
```

4. Restart the server. InnoDB now permits changes to be made.

14.6.3.2 File-Per-Table Tablespaces

A file-per-table tablespace contains data and indexes for a single InnoDB table, and is stored on the file system in its own data file.

File-per-table tablespace characteristics are described under the following topics in this section:

- File-Per-Table Tablespace Configuration
- File-Per-Table Tablespace Data Files
- File-Per-Table Tablespace Advantages
- File-Per-Table Tablespace Disadvantages

File-Per-Table Tablespace Configuration

InnoDB creates tables in file-per-table tablespaces by default. This behavior is controlled by the `innodb_file_per_table` variable. Disabling `innodb_file_per_table` causes InnoDB to create tables in the system tablespace.

An `innodb_file_per_table` setting can be specified in an option file or configured at runtime using a `SET GLOBAL` statement. Changing the setting at runtime requires privileges sufficient to set global system variables. See Section 5.1.8.1, "System Variable Privileges".

Option file:

```sql
[mysqld]
innoadb_file_per_table=ON
```

Using `SET GLOBAL` at runtime:

```sql
mysql> SET GLOBAL innodb_file_per_table=ON;
```
innodb_file_per_table is enabled by default in MySQL 5.6 and higher. You might consider disabling it if backward compatibility with earlier versions of MySQL is a concern.

**Warning**

Disabling `innodb_file_per_table` prevents table-copying `ALTER TABLE` operations from implicitly moving a table that resides in the system tablespace to a file-per-table tablespace. A table-copying `ALTER TABLE` operation recreates the table using the current `innodb_file_per_table` setting. This behavior does not apply when adding or dropping secondary indexes, nor does it apply to `ALTER TABLE` operations that use the `INPLACE` algorithm.

**File-Per-Table Tablespace Data Files**

A file-per-table tablespace is created in an `.idb` data file in a schema directory under the MySQL data directory. The `.ibd` file is named for the table (`table_name.ibd`). For example, the data file for table `test.t1` is created in the `test` directory under the MySQL data directory:

```
mysql> USE test;

mysql> CREATE TABLE t1 (
   id INT PRIMARY KEY AUTO_INCREMENT,
   name VARCHAR(100)
) ENGINE = InnoDB;

shell> cd /path/to/mysql/data/test

shell> ls t1.ibd
```

You can use the `DATA DIRECTORY` clause of the `CREATE TABLE` statement to implicitly create a file-per-table tablespace data file outside of the data directory. For more information, see Section 14.6.1.2, “Creating Tables Externally”.

**File-Per-Table Tablespace Advantages**

File-per-table tablespaces have the following advantages over the shared system tablespace.

- Disk space is returned to the operating system after truncating or dropping a table created in a file-per-table tablespace. Truncating or dropping a table stored in the system tablespace creates free space within the system tablespace, which can only be used for InnoDB data. In other words, a system tablespace does not shrink in size after a table is truncated or dropped.

- A table-copying `ALTER TABLE` operation on a table that resides in the system tablespace can increase the amount of disk space occupied by the tablespace. Such operations may require as much additional space as the data in the table plus indexes. This space is not released back to the operating system as it is for file-per-table tablespaces.

- `TRUNCATE TABLE` performance is better when executed on tables that reside in file-per-table tablespaces.

- File-per-table tablespace data files can be created on separate storage devices for I/O optimization, space management, or backup purposes. See Section 14.6.1.2, “Creating Tables Externally”.

- You can import table that resides in a file-per-table tablespace from another MySQL instance. See Section 14.6.1.3, “Importing InnoDB Tables”.

- Tables stored in individual tablespace data files can save time and improve chances for a successful recovery when data corruption occurs, when backups or binary logs are unavailable, or when the MySQL server instance cannot be restarted.
• You can backup or restore tables created in file-per-table tablespaces quickly using MySQL Enterprise Backup, without interrupting the use of other InnoDB tables. This is beneficial for tables on varying backup schedules or that require backup less frequently. See Making a Partial Backup for details.

• File-per-table tablespaces permit monitoring table size on the file system by monitoring the size of the tablespace data file.

• Common Linux file systems do not permit concurrent writes to a single file such as a system tablespace data file when innodb_flush_method is set to O_DIRECT. As a result, there are possible performance improvements when using file-per-table tablespaces in conjunction with this setting.

• Tables in the shared system tablespace, which contains other structures such as the InnoDB data dictionary and undo logs, are limited in size by the 64TB tablespace size limit. By comparison, each file-per-table tablespace has a 64TB size limit, which provides plenty of room for individual tables to grow in size.

**File-Per-Table Tablespace Disadvantages**

File-per-table tablespaces have the following disadvantages compared to the shared system tablespace.

• With file-per-table tablespaces, each table may have unused space that can only be utilized by rows of the same table, which can lead to wasted space if not properly managed.

• fsync operations are performed on multiple file-per-table data files instead of a shared system tablespace data file. Because fsync operations are per file, write operations for multiple tables cannot be combined, which can result in a higher total number of fsync operations.

• mysqld must keep an open file handle for each file-per-table tablespace, which may impact performance if you have numerous tables in file-per-table tablespaces.

• More file descriptors are required when each table has its own data file.

• There is potential for more fragmentation, which can impede DROP TABLE and table scan performance. However, if fragmentation is managed, file-per-table tablespaces can improve performance for these operations.

• The buffer pool is scanned when dropping a table that resides in a file-per-table tablespace, which can take several seconds for large buffer pools. The scan is performed with a broad internal lock, which may delay other operations.

• The innodb_autoextend_increment variable, which defines the increment size for extending the size of an auto-extending system tablespace file when it becomes full, does not apply to file-per-table tablespace files, which are auto-extending regardless of the innodb_autoextend_increment setting. Initial file-per-table tablespace extensions are by small amounts, after which extensions occur in increments of 4MB.

14.6.3.3 Undo Tablespaces

Undo tablespace contains undo logs, which are collections of undo log records that contain information about how to undo the latest change by a transaction to a clustered index record. Undo logs exist within undo log segments, which are contained within rollback segments. The innodb_rollback_segments variable defines the number of rollback segments allocated to each undo tablespace.

Undo logs can be stored in one or more undo tablespaces instead of the system tablespace. This layout differs from the default configuration in which undo logs reside in the system tablespace. The I/O patterns for undo logs make undo tablespaces good candidates for SSD storage, while keeping the system tablespace on hard disk storage.
The number of undo tablespaces used by InnoDB is controlled by the `innodb_undo_tablespaces` configuration option. This option can only be configured when initializing the MySQL instance. It cannot be changed afterward.

Undo tablespaces and individual segments inside those tablespaces cannot be dropped.

**Configuring Undo Tablespaces**

To configure undo tablespaces for a MySQL instance, perform the following steps. It is assumed that you are performing the procedure on a test instance prior to deploying the configuration to a production system.

1. Specify a directory location for undo tablespaces using the `innodb_undo_directory` configuration option. If a directory location is not specified, undo tablespaces are created in the data directory.

2. Define the number of rollback segments using the `innodb_rollback_segments` configuration option. Start with a relatively low value and increase it incrementally over time to examine the effect on performance. The default setting for `innodb_rollback_segments` is 128, which is also the maximum value.

   One rollback segment is always assigned to the system tablespace. Therefore, to allocate rollback segments to undo tablespaces, set `innodb_rollback_segments` to a value greater than 1. For example, if you have two undo tablespaces, set `innodb_rollback_segments` to 3 to assign one rollback segment to each of the two undo tablespaces. Rollback segments are distributed among undo tablespaces in a circular fashion.

   When you configure separate undo tablespaces, the rollback segment in the system tablespace is rendered inactive.

3. Define the number of undo tablespaces using the `innodb_undo_tablespaces` option. The specified number of undo tablespaces is fixed for the life of the MySQL instance, so if you are uncertain about an optimal value, estimate on the high side.

4. Create a new MySQL test instance using the option values you have chosen.

5. Use a realistic workload on your test instance with data volume similar to your production servers to test the configuration.

6. Benchmark the performance of I/O intensive workloads.

7. Periodically increase the value of `innodb_rollback_segments` and rerun performance tests until there are no further improvements in I/O performance.

### 14.6.4 InnoDB Data Dictionary

The InnoDB data dictionary is comprised of internal system tables that contain metadata used to keep track of objects such as tables, indexes, and table columns. The metadata is physically located in the InnoDB system tablespace. For historical reasons, data dictionary metadata overlaps to some degree with information stored in InnoDB table metadata files (.frm files).

### 14.6.5 Doublewrite Buffer

The doublewrite buffer is a storage area where InnoDB writes pages flushed from the buffer pool before writing the pages to their proper positions in the InnoDB data files. If there is an operating
system, storage subsystem, or unexpected MySQL process exit in the middle of a page write, InnoDB can find a good copy of the page from the doublewrite buffer during crash recovery.

Although data is written twice, the doublewrite buffer does not require twice as much I/O overhead or twice as many I/O operations. Data is written to the doublewrite buffer in a large sequential chunk, with a single fsync() call to the operating system (except in the case that innodb_flush_method is set to O_DIRECT_NO_FSYNC).

The doublewrite buffer is enabled by default. To disable the doublewrite buffer, set innodb_doublewrite to 0.

14.6.6 Redo Log

The redo log is a disk-based data structure used during crash recovery to correct data written by incomplete transactions. During normal operations, the redo log encodes requests to change table data that result from SQL statements or low-level API calls. Modifications that did not finish updating the data files before an unexpected shutdown are replayed automatically during initialization, and before the connections are accepted. For information about the role of the redo log in crash recovery, see Section 14.18.2, “InnoDB Recovery”.

By default, the redo log is physically represented on disk by two files named ib_logfile0 and ib_logfile1. MySQL writes to the redo log files in a circular fashion. Data in the redo log is encoded in terms of records affected; this data is collectively referred to as redo. The passage of data through the redo log is represented by an ever-increasing LSN value.

For related information, see Redo Log File Configuration, and Section 8.5.4, “Optimizing InnoDB Redo Logging”.

Changing the Number or Size of Redo Log Files

To change the number or size of InnoDB redo log files in MySQL 5.6.7 or earlier, perform the following steps:

1. If innodb_fast_shutdown is set to 2, set innodb_fast_shutdown to 1:
   
   ```
   mysql> SET GLOBAL innodb_fast_shutdown = 1;
   ```

2. After ensuring that innodb_fast_shutdown is not set to 2, stop the MySQL server and make sure that it shuts down without errors (to ensure that there is no information for outstanding transactions in the log).

3. Copy the old log files into a safe place in case something went wrong during the shutdown and you need them to recover the tablespace.

4. Delete the old log files from the log file directory.

5. Edit my.cnf to change the log file configuration.

6. Start the MySQL server again. mysqlld sees that no InnoDB log files exist at startup and creates new ones.

The innodb_fast_shutdown setting is no longer relevant when changing the number or the size of InnoDB log files. Additionally, you are no longer required to remove old log files, although you may still want to copy the old log files to a safe place, as a backup. To change the number or size of InnoDB log files, perform the following steps:

1. Stop the MySQL server and make sure that it shuts down without errors.

2. Edit my.cnf to change the log file configuration. To change the log file size, configure innodb_log_file_size. To increase the number of log files, configure innodb_log_files_in_group.
3. Start the MySQL server again.

If InnoDB detects that the `innodb_log_file_size` differs from the redo log file size, it writes a log checkpoint, closes and removes the old log files, creates new log files at the requested size, and opens the new log files.

**Group Commit for Redo Log Flushing**

InnoDB, like any other ACID-compliant database engine, flushes the redo log of a transaction before it is committed. InnoDB uses group commit functionality to group multiple such flush requests together to avoid one flush for each commit. With group commit, InnoDB issues a single write to the log file to perform the commit action for multiple user transactions that commit at about the same time, significantly improving throughput.

For more information about performance of COMMIT and other transactional operations, see Section 8.5.2, “Optimizing InnoDB Transaction Management”.

### 14.6.7 Undo Logs

An undo log is a collection of undo log records associated with a single read-write transaction. An undo log record contains information about how to undo the latest change by a transaction to a clustered index record. If another transaction needs to see the original data as part of a consistent read operation, the unmodified data is retrieved from undo log records. Undo logs exist within undo log segments, which are contained within rollback segments. By default, rollback segments are physically part of the system tablespace, but they can also reside in undo tablespaces. For more information, see Section 14.6.3.3, “Undo Tablespaces”.

InnoDB supports 128 rollback segments. The `innodb_rollback_segments` variable defines the number of rollback segments used by InnoDB.

The number of transactions that a rollback segment supports depends on the number of undo slots in the rollback segment and the number of undo logs required by each transaction.

The number of undo slots in a rollback segment differs according to InnoDB page size.

<table>
<thead>
<tr>
<th>InnoDB Page Size</th>
<th>Number of Undo Slots in a Rollback Segment (InnoDB Page Size / 16)</th>
</tr>
</thead>
<tbody>
<tr>
<td>4096 (4KB)</td>
<td>256</td>
</tr>
<tr>
<td>8192 (8KB)</td>
<td>512</td>
</tr>
<tr>
<td>16384 (16KB)</td>
<td>1024</td>
</tr>
</tbody>
</table>

A transaction is assigned up to two undo logs, one for each of the following operation types:

1. **INSERT** operations
2. **UPDATE** and **DELETE** operations

Undo logs are assigned as needed. For example, a transaction that performs **INSERT**, **UPDATE**, and **DELETE** operations is assigned two undo logs. A transaction that performs only **INSERT** operations is assigned a single undo log. Undo logs are assigned to a transaction from a rollback segment that is also assigned to the transaction.

An undo log assigned to a transaction remains tied to the transaction for its duration. For example, an undo log assigned to a transaction for an **INSERT** operation is used for all **INSERT** operations performed by that transaction.

Given the factors described above, the following formulas can be used to estimate the number of concurrent read-write transactions that InnoDB is capable of supporting.
**Note**
A transaction can encounter a concurrent transaction limit error before reaching the number of concurrent read-write transactions that InnoDB is capable of supporting. This occurs when the rollback segment assigned to a transaction runs out of undo slots. In such cases, try rerunning the transaction.

- If each transaction performs either an INSERT or an UPDATE or DELETE operation, the number of concurrent read-write transactions that InnoDB is capable of supporting is:

\[
\text{(innodb_page_size} / 16) \times \text{innodb_rollback_segments}
\]

- If each transaction performs an INSERT and an UPDATE or DELETE operation, the number of concurrent read-write transactions that InnoDB is capable of supporting is:

\[
\text{(innodb_page_size} / 16 / 2) \times \text{innodb_rollback_segments}
\]

### 14.7 InnoDB Locking and Transaction Model

To implement a large-scale, busy, or highly reliable database application, to port substantial code from a different database system, or to tune MySQL performance, it is important to understand InnoDB locking and the InnoDB transaction model.

This section discusses several topics related to InnoDB locking and the InnoDB transaction model with which you should be familiar.

- **Section 14.7.1, “InnoDB Locking”** describes lock types used by InnoDB.

- **Section 14.7.2, “InnoDB Transaction Model”** describes transaction isolation levels and the locking strategies used by each. It also discusses the use of autocommit, consistent non-locking reads, and locking reads.

- **Section 14.7.3, “Locks Set by Different SQL Statements in InnoDB”** discusses specific types of locks set in InnoDB for various statements.

- **Section 14.7.4, “Phantom Rows”** describes how InnoDB uses next-key locking to avoid phantom rows.

- **Section 14.7.5, “Deadlocks in InnoDB”** provides a deadlock example, discusses deadlock detection, and provides tips for minimizing and handling deadlocks in InnoDB.

#### 14.7.1 InnoDB Locking

This section describes lock types used by InnoDB.

- **Shared and Exclusive Locks**

- **Intention Locks**

- **Record Locks**

- **Gap Locks**

- **Next-Key Locks**

- **Insert Intention Locks**

- **AUTO-INC Locks**

**Shared and Exclusive Locks**

InnoDB implements standard row-level locking where there are two types of locks, shared (S) locks and exclusive (X) locks.
• A shared (S) lock permits the transaction that holds the lock to read a row.

• An exclusive (X) lock permits the transaction that holds the lock to update or delete a row.

If transaction T1 holds a shared (S) lock on row r, then requests from some distinct transaction T2 for a lock on row r are handled as follows:

• A request by T2 for an S lock can be granted immediately. As a result, both T1 and T2 hold an S lock on r.

• A request by T2 for an X lock cannot be granted immediately.

If a transaction T1 holds an exclusive (X) lock on row r, a request from some distinct transaction T2 for a lock of either type on r cannot be granted immediately. Instead, transaction T2 has to wait for transaction T1 to release its lock on row r.

InnoDB Locking

Intention Locks

InnoDB supports multiple granularity locking which permits coexistence of row locks and table locks. For example, a statement such as LOCK TABLES ... WRITE takes an exclusive lock (an X lock) on the specified table. To make locking at multiple granularity levels practical, InnoDB uses intention locks. Intention locks are table-level locks that indicate which type of lock (shared or exclusive) a transaction requires later for a row in a table. There are two types of intention locks:

• An intention shared lock (IS) indicates that a transaction intends to set a shared lock on individual rows in a table.

• An intention exclusive lock (IX) indicates that a transaction intends to set an exclusive lock on individual rows in a table.

For example, SELECT ... LOCK IN SHARE MODE sets an IS lock, and SELECT ... FOR UPDATE sets an IX lock.

The intention locking protocol is as follows:

• Before a transaction can acquire a shared lock on a row in a table, it must first acquire an IS lock or stronger on the table.

• Before a transaction can acquire an exclusive lock on a row in a table, it must first acquire an IX lock on the table.

Table-level lock type compatibility is summarized in the following matrix.

<table>
<thead>
<tr>
<th></th>
<th>X</th>
<th>IX</th>
<th>S</th>
<th>IS</th>
</tr>
</thead>
<tbody>
<tr>
<td>X</td>
<td>Conflict</td>
<td>Conflict</td>
<td>Conflict</td>
<td>Conflict</td>
</tr>
<tr>
<td>IX</td>
<td>Conflict</td>
<td>Compatible</td>
<td>Conflict</td>
<td>Compatible</td>
</tr>
<tr>
<td>S</td>
<td>Conflict</td>
<td>Conflict</td>
<td>Compatible</td>
<td>Compatible</td>
</tr>
<tr>
<td>IS</td>
<td>Conflict</td>
<td>Compatible</td>
<td>Compatible</td>
<td>Compatible</td>
</tr>
</tbody>
</table>

A lock is granted to a requesting transaction if it is compatible with existing locks, but not if it conflicts with existing locks. A transaction waits until the conflicting existing lock is released. If a lock request conflicts with an existing lock and cannot be granted because it would cause deadlock, an error occurs.

Intention locks do not block anything except full table requests (for example, LOCK TABLES ... WRITE). The main purpose of intention locks is to show that someone is locking a row, or going to lock a row in the table.

Transaction data for an intention lock appears similar to the following in SHOW ENGINE INNODB STATUS and InnoDB monitor output:

```
TABLE LOCK table 'test'.t' trx id 10080 lock mode IX
```
Record Locks

A record lock is a lock on an index record. For example, `SELECT c1 FROM t WHERE c1 = 10 FOR UPDATE;` prevents any other transaction from inserting, updating, or deleting rows where the value of `t.c1` is 10.

Record locks always lock index records, even if a table is defined with no indexes. For such cases, InnoDB creates a hidden clustered index and uses this index for record locking. See Section 14.6.2.1, “Clustered and Secondary Indexes”.

Transaction data for a record lock appears similar to the following in `SHOW ENGINE INNODB STATUS` and InnoDB monitor output:

```
RECORD LOCKS space id 58 page no 3 n bits 72 index `PRIMARY` of table `test`.`t`
trx id 10078 lock_mode X locks rec but not gap
  0: len 4; hex 8000000a; asc     
  1: len 6; hex 0000000274f; asc 'O';
  2: len 7; hex b60000019d0110; asc 
```

Gap Locks

A gap lock is a lock on a gap between index records, or a lock on the gap before the first or after the last index record. For example, `SELECT c1 FROM t WHERE c1 BETWEEN 10 and 20 FOR UPDATE;` prevents other transactions from inserting a value of 15 into column `t.c1`, whether or not there was already any such value in the column, because the gaps between all existing values in the range are locked.

A gap might span a single index value, multiple index values, or even be empty.

Gap locks are part of the tradeoff between performance and concurrency, and are used in some transaction isolation levels and not others.

Gap locking is not needed for statements that lock rows using a unique index to search for a unique row. (This does not include the case that the search condition includes only some columns of a multiple-column unique index; in that case, gap locking does occur.) For example, if the `id` column has a unique index, the following statement uses only an index-record lock for the row having `id` value 100 and it does not matter whether other sessions insert rows in the preceding gap:

```
SELECT * FROM child WHERE id = 100;
```

If `id` is not indexed or has a nonunique index, the statement does lock the preceding gap.

It is also worth noting here that conflicting locks can be held on a gap by different transactions. For example, transaction A can hold a shared gap lock (gap S-lock) on a gap while transaction B holds an exclusive gap lock (gap X-lock) on the same gap. The reason conflicting gap locks are allowed is that if a record is purged from an index, the gap locks held on the record by different transactions must be merged.

Gap locks in InnoDB are “purely inhibitive”, which means that their only purpose is to prevent other transactions from inserting to the gap. Gap locks can co-exist. A gap lock taken by one transaction does not prevent another transaction from taking a gap lock on the same gap. There is no difference between shared and exclusive gap locks. They do not conflict with each other, and they perform the same function.

Gap locking can be disabled explicitly. This occurs if you change the transaction isolation level to `READ COMMITTED` or enable the `innodb_locks_unsafe_for_binlog` system variable (which is now deprecated). Under these circumstances, gap locking is disabled for searches and index scans and is used only for foreign-key constraint checking and duplicate-key checking.

There are also other effects of using the `READ COMMITTED` isolation level or enabling `innodb_locks_unsafe_for_binlog`. Record locks for nonmatching rows are released after MySQL has evaluated the `WHERE` condition. For `UPDATE` statements, InnoDB does a “semi-consistent”
InnoDB Locking

read, such that it returns the latest committed version to MySQL so that MySQL can determine whether the row matches the \texttt{WHERE} condition of the \texttt{UPDATE}.

**Next-Key Locks**

A next-key lock is a combination of a record lock on the index record and a gap lock on the gap before the index record.

\textbf{InnoDB} performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index-record locks. A next-key lock on an index record also affects the “gap” before that index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the index record. If one session has a shared or exclusive lock on record \( R \) in an index, another session cannot insert a new index record in the gap immediately before \( R \) in the index order.

Suppose that an index contains the values 10, 11, 13, and 20. The possible next-key locks for this index cover the following intervals, where a round bracket denotes exclusion of the interval endpoint and a square bracket denotes inclusion of the endpoint:

\begin{verbatim}
(-\infty, 10]
(10, 11]
(11, 13]
(13, 20]
(20, +\infty)
\end{verbatim}

For the last interval, the next-key lock locks the gap above the largest value in the index and the “supremum” pseudo-record having a value higher than any value actually in the index. The supremum is not a real index record, so, in effect, this next-key lock locks only the gap following the largest index value.

By default, \textbf{InnoDB} operates in \texttt{REPEATABLE READ} transaction isolation level and with the \texttt{innodb_locks_unsafe_for_binlog} system variable disabled. In this case, \textbf{InnoDB} uses next-key locks for searches and index scans, which prevents phantom rows (see Section 14.7.4, “Phantom Rows”).

Transaction data for a next-key lock appears similar to the following in \texttt{SHOW ENGINE INNODB STATUS} and \textbf{InnoDB monitor} output:

\begin{verbatim}
RECORD LOCKS space id 58 page no 3 n bits 72 index `PRIMARY` of table `test`.`t`
trx id 10080 lock_mode X
Record lock, heap no 1 PHYSICAL RECORD: n_fields 1; compact format; info bits 0
  0: len 8; hex 73757072656d756d; asc supremum;;
Record lock, heap no 2 PHYSICAL RECORD: n_fields 3; compact format; info bits 0
  0: len 4; hex 8000000a; asc ;;
  1: len 6; hex 00000002746f; asc 'O;;
  2: len 7; hex b6000019d0110; asc ;;
\end{verbatim}

**Insert Intention Locks**

An insert intention lock is a type of gap lock set by \texttt{INSERT} operations prior to row insertion. This lock signals the intent to insert in such a way that multiple transactions inserting into the same index gap need not wait for each other if they are not inserting at the same position within the gap. Suppose that there are index records with values of 4 and 7. Separate transactions that attempt to insert values of 5 and 6, respectively, each lock the gap between 4 and 7 with insert intention locks prior to obtaining the exclusive lock on the inserted row, but do not block each other because the rows are nonconflicting.

The following example demonstrates a transaction taking an insert intention lock prior to obtaining an exclusive lock on the inserted record. The example involves two clients, A and B.

Client A creates a table containing two index records (90 and 102) and then starts a transaction that places an exclusive lock on index records with an ID greater than 100. The exclusive lock includes a gap lock before record 102:
Client B begins a transaction to insert a record into the gap. The transaction takes an insert intention lock while it waits to obtain an exclusive lock.

Transaction data for an insert intention lock appears similar to the following in `SHOW ENGINE INNODB STATUS` and InnoDB monitor output:

```
RECORD LOCKS space id 31 page no 3 n bits 72 index `PRIMARY` of table `test`.`child`
trx id 8731 lock_mode X locks gap before rec insert intention waiting
Record lock, heap no 3 PHYSICAL RECORD: n_fields 3; compact format; info bits 0
 0: len 4; hex 80000066; asc "f;"
 1: len 6; hex 000000002215; asc "">
 2: len 7; hex 900000172011c; asc "r;..."
```

**AUTO-INC Locks**

An AUTO-INC lock is a special table-level lock taken by transactions inserting into tables with AUTO_INCREMENT columns. In the simplest case, if one transaction is inserting values into the table, any other transactions must wait to do their own inserts into that table, so that rows inserted by the first transaction receive consecutive primary key values.

The `innodb_autoinc_lock_mode` configuration option controls the algorithm used for auto-increment locking. It allows you to choose how to trade off between predictable sequences of auto-increment values and maximum concurrency for insert operations.

For more information, see Section 14.6.1.6, “AUTO_INCREMENT Handling in InnoDB”.

### 14.7.2 InnoDB Transaction Model

In the InnoDB transaction model, the goal is to combine the best properties of a multi-versioning database with traditional two-phase locking. InnoDB performs locking at the row level and runs queries as nonlocking consistent reads by default, in the style of Oracle. The lock information in InnoDB is stored space-efficiently so that lock escalation is not needed. Typically, several users are permitted to lock every row in InnoDB tables, or any random subset of the rows, without causing InnoDB memory exhaustion.

#### 14.7.2.1 Transaction Isolation Levels

Transaction isolation is one of the foundations of database processing. Isolation is the I in the acronym ACID; the isolation level is the setting that fine-tunes the balance between performance and reliability, consistency, and reproducibility of results when multiple transactions are making changes and performing queries at the same time.

InnoDB offers all four transaction isolation levels described by the SQL:1992 standard: READ UNCOMMITTED, READ COMMITTED, REPEATABLE READ, and SERIALIZABLE. The default isolation level for InnoDB is REPEATABLE READ.

A user can change the isolation level for a single session or for all subsequent connections with the `SET TRANSACTION` statement. To set the server's default isolation level for all connections, use the `--transaction-isolation` option on the command line or in an option file. For detailed information about isolation levels and level-setting syntax, see Section 13.3.6, “SET TRANSACTION Statement”. 

1872
InnoDB supports each of the transaction isolation levels described here using different locking strategies. You can enforce a high degree of consistency with the default REPEATABLE READ level, for operations on crucial data where ACID compliance is important. Or you can relax the consistency rules with READ COMMITTED or even READ UNCOMMITTED, in situations such as bulk reporting where precise consistency and repeatable results are less important than minimizing the amount of overhead for locking. SERIALIZABLE enforces even stricter rules than REPEATABLE READ, and is used mainly in specialized situations, such as with XA transactions and for troubleshooting issues with concurrency and deadlocks.

The following list describes how MySQL supports the different transaction levels. The list goes from the most commonly used level to the least used.

• **REPEATABLE READ**

  This is the default isolation level for InnoDB. Consistent reads within the same transaction read the snapshot established by the first read. This means that if you issue several plain (nonlocking) SELECT statements within the same transaction, these SELECT statements are consistent also with respect to each other. See Section 14.7.2.3, “Consistent Nonlocking Reads”.

  For locking reads (SELECT with FOR UPDATE or LOCK IN SHARE MODE), UPDATE, and DELETE statements, locking depends on whether the statement uses a unique index with a unique search condition, or a range-type search condition.

  • For a unique index with a unique search condition, InnoDB locks only the index record found, not the gap before it.

  • For other search conditions, InnoDB locks the index range scanned, using gap locks or next-key locks to block insertions by other sessions into the gaps covered by the range. For information about gap locks and next-key locks, see Section 14.7.1, “InnoDB Locking”.

• **READ COMMITTED**

  Each consistent read, even within the same transaction, sets and reads its own fresh snapshot. For information about consistent reads, see Section 14.7.2.3, “Consistent Nonlocking Reads”.

  For locking reads (SELECT with FOR UPDATE or LOCK IN SHARE MODE), UPDATE statements, and DELETE statements, InnoDB locks only index records, not the gaps before them, and thus permits the free insertion of new records next to locked records. Gap locking is only used for foreign-key constraint checking and duplicate-key checking.

  Because gap locking is disabled, phantom problems may occur, as other sessions can insert new rows into the gaps. For information about phantoms, see Section 14.7.4, “Phantom Rows”.

  Only row-based binary logging is supported with the READ COMMITTED isolation level. If you use READ COMMITTED with binlog_format=MIXED, the server automatically uses row-based logging.

  Using READ COMMITTED has additional effects:

  • For UPDATE or DELETE statements, InnoDB holds locks only for rows that it updates or deletes. Record locks for nonmatching rows are released after MySQL has evaluated the WHERE condition. This greatly reduces the probability of deadlocks, but they can still happen.

  • For UPDATE statements, if a row is already locked, InnoDB performs a “semi-consistent” read, returning the latest committed version to MySQL so that MySQL can determine whether the row matches the WHERE condition of the UPDATE. If the row matches (must be updated), MySQL reads the row again and this time InnoDB either locks it or waits for a lock on it.

Consider the following example, beginning with this table:

```
CREATE TABLE t (a INT NOT NULL, b INT) ENGINE = InnoDB;
INSERT INTO t VALUES (1,2),(2,3),(3,2),(4,3),(5,2);
```
InnoDB Transaction Model

In this case, the table has no indexes, so searches and index scans use the hidden clustered index for record locking (see Section 14.6.2.1, “Clustered and Secondary Indexes”) rather than indexed columns.

Suppose that one session performs an `UPDATE` using these statements:

```
# Session A
START TRANSACTION;
UPDATE t SET b = 5 WHERE b = 3;
```

Suppose also that a second session performs an `UPDATE` by executing this statement following those of the first session:

```
# Session B
UPDATE t SET b = 4 WHERE b = 2;
```

As InnoDB executes each `UPDATE`, it first acquires an exclusive lock for each row that it reads, and then determines whether to modify it. If InnoDB does not modify the row, it releases the lock. Otherwise, InnoDB retains the lock until the end of the transaction. This affects transaction processing as follows.

When using the default `REPEATABLE READ` isolation level, the first `UPDATE` acquires an x-lock on each row that it reads and does not release any of them:

```
x-lock(1,2); retain x-lock
x-lock(2,3); update(2,3) to (2,5); retain x-lock
x-lock(3,2); retain x-lock
x-lock(4,3); update(4,3) to (4,5); retain x-lock
x-lock(5,2); retain x-lock
```

The second `UPDATE` blocks as soon as it tries to acquire any locks (because first update has retained locks on all rows), and does not proceed until the first `UPDATE` commits or rolls back:

```
x-lock(1,2); block and wait for first UPDATE to commit or roll back
```

If `READ COMMITTED` is used instead, the first `UPDATE` acquires an x-lock on each row that it reads and releases those for rows that it does not modify:

```
x-lock(1,2); unlock(1,2)
x-lock(2,3); update(2,3) to (2,5); retain x-lock
x-lock(3,2); unlock(3,2)
x-lock(4,3); update(4,3) to (4,5); retain x-lock
x-lock(5,2); unlock(5,2)
```

For the second `UPDATE`, InnoDB does a “semi-consistent” read, returning the latest committed version of each row that it reads to MySQL so that MySQL can determine whether the row matches the `WHERE` condition of the `UPDATE`:

```
x-lock(1,2); update(1,2) to (1,4); retain x-lock
x-lock(2,3); unlock(2,3)
x-lock(3,2); update(3,2) to (3,4); retain x-lock
x-lock(4,3); unlock(4,3)
x-lock(5,2); update(5,2) to (5,4); retain x-lock
```

However, if the `WHERE` condition includes an indexed column, and InnoDB uses the index, only the indexed column is considered when taking and retaining record locks. In the following example, the first `UPDATE` takes and retains an x-lock on each row where `b = 2`. The second `UPDATE` blocks when it tries to acquire x-locks on the same records, as it also uses the index defined on column `b`.

```
CREATE TABLE t (a INT NOT NULL, b INT, c INT, INDEX (b)) ENGINE = InnoDB;
INSERT INTO t VALUES (1,2,3),(2,2,4);
COMMIT;
```

# Session A
InnoDB Transaction Model

```sql
START TRANSACTION;
UPDATE t SET b = 3 WHERE b = 2 AND c = 3;
# Session B
UPDATE t SET b = 4 WHERE b = 2 AND c = 4;
```

The effects of using the `READ COMMITTED` isolation level are the same as enabling the deprecated `innodb_locks_unsafe_for_binlog` configuration option, with these exceptions:

- Enabling `innodb_locks_unsafe_for_binlog` is a global setting and affects all sessions, whereas the isolation level can be set globally for all sessions, or individually per session.

- `innodb_locks_unsafe_for_binlog` can be set only at server startup, whereas the isolation level can be set at startup or changed at runtime.

`READ COMMITTED` therefore offers finer and more flexible control than `innodb_locks_unsafe_for_binlog`.

- `READ UNCOMMITTED`

`SELECT` statements are performed in a nonlocking fashion, but a possible earlier version of a row might be used. Thus, using this isolation level, such reads are not consistent. This is also called a `dirty read`. Otherwise, this isolation level works like `READ COMMITTED`.

- `SERIALIZABLE`

This level is like `REPEATABLE READ`, but InnoDB implicitly converts all plain `SELECT` statements to `SELECT ... LOCK IN SHARE MODE` if `autocommit` is disabled. If `autocommit` is enabled, the `SELECT` is its own transaction. It therefore is known to be read only and can be serialized if performed as a consistent (nonlocking) read and need not block for other transactions. (To force a plain `SELECT` to block if other transactions have modified the selected rows, disable `autocommit`.)

### 14.7.2.2 `autocommit`, Commit, and Rollback

In InnoDB, all user activity occurs inside a transaction. If `autocommit` mode is enabled, each SQL statement forms a single transaction on its own. By default, MySQL starts the session for each new connection with `autocommit` enabled, so MySQL does a commit after each SQL statement if that statement did not return an error. If a statement returns an error, the commit or rollback behavior depends on the error. See Section 14.21.4, "InnoDB Error Handling".

A session that has `autocommit` enabled can perform a multiple-statement transaction by starting it with an explicit `START TRANSACTION` or `BEGIN` statement and ending it with a `COMMIT` or `ROLLBACK` statement. See Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Statements”.

If `autocommit` mode is disabled within a session with `SET autocommit = 0`, the session always has a transaction open. A `COMMIT` or `ROLLBACK` statement ends the current transaction and a new one starts.

If a session that has `autocommit` disabled ends without explicitly committing the final transaction, MySQL rolls back that transaction.

Some statements implicitly end a transaction, as if you had done a `COMMIT` before executing the statement. For details, see Section 13.3.3, “Statements That Cause an Implicit Commit”.

A `COMMIT` means that the changes made in the current transaction are made permanent and become visible to other sessions. A `ROLLBACK` statement, on the other hand, cancels all modifications made by the current transaction. Both `COMMIT` and `ROLLBACK` release all InnoDB locks that were set during the current transaction.

### Grouping DML Operations with Transactions

By default, connection to the MySQL server begins with `autocommit` mode enabled, which automatically commits every SQL statement as you execute it. This mode of operation might be
InnoDB Transaction Model

unfamiliar if you have experience with other database systems, where it is standard practice to issue a sequence of DML statements and commit them or roll them back all together.

To use multiple-statement transactions, switch autocommit off with the SQL statement `SET autocommit = 0` and end each transaction with `COMMIT` or `ROLLBACK` as appropriate. To leave autocommit on, begin each transaction with `START TRANSACTION` and end it with `COMMIT` or `ROLLBACK`. The following example shows two transactions. The first is committed; the second is rolled back.

```
shell> mysql test

mysql> CREATE TABLE customer (a INT, b CHAR (20), INDEX (a));
Query OK, 0 rows affected (0.00 sec)
mysql> -- Do a transaction with autocommit turned on.
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO customer VALUES (10, 'Heikki');
Query OK, 1 row affected (0.00 sec)
mysql> COMMIT;
Query OK, 0 rows affected (0.00 sec)
mysql> -- Do another transaction with autocommit turned off.
mysql> SET autocommit=0;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO customer VALUES (15, 'John');
Query OK, 1 row affected (0.00 sec)
mysql> INSERT INTO customer VALUES (20, 'Paul');
Query OK, 1 row affected (0.00 sec)
mysql> DELETE FROM customer WHERE b = 'Heikki';
Query OK, 1 row affected (0.00 sec)
mysql> -- Now we undo those last 2 inserts and the delete.
mysql> ROLLBACK;
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT * FROM customer;
+------+------+--------+
<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>Heikki</td>
</tr>
</tbody>
</table>
+------+------+--------+
1 row in set (0.00 sec)
mysql>
```

Transactions in Client-Side Languages

In APIs such as PHP, Perl DBI, JDBC, ODBC, or the standard C call interface of MySQL, you can send transaction control statements such as `COMMIT` to the MySQL server as strings just like any other SQL statements such as `SELECT` or `INSERT`. Some APIs also offer separate special transaction commit and rollback functions or methods.

14.7.2.3 Consistent Nonlocking Reads

A consistent read means that InnoDB uses multi-versioning to present to a query a snapshot of the database at a point in time. The query sees the changes made by transactions that committed before that point of time, and no changes made by later or uncommitted transactions. The exception to this rule is that the query sees the changes made by earlier statements within the same transaction. This exception causes the following anomaly: If you update some rows in a table, a `SELECT` sees the latest version of the updated rows, but it might also see older versions of any rows. If other sessions simultaneously update the same table, the anomaly means that you might see the table in a state that never existed in the database.

If the transaction isolation level is `REPEATABLE READ` (the default level), all consistent reads within the same transaction read the snapshot established by the first such read in that transaction. You can get a fresher snapshot for your queries by committing the current transaction and after that issuing new queries.

With `READ COMMITTED` isolation level, each consistent read within a transaction sets and reads its own fresh snapshot.
Consistent read is the default mode in which InnoDB processes SELECT statements in READ COMMITTED and REPEATABLE READ isolation levels. A consistent read does not set any locks on the tables it accesses, and therefore other sessions are free to modify those tables at the same time a consistent read is being performed on the table.

Suppose that you are running in the default REPEATABLE READ isolation level. When you issue a consistent read (that is, an ordinary SELECT statement), InnoDB gives your transaction a timepoint according to which your query sees the database. If another transaction deletes a row and commits after your timepoint was assigned, you do not see the row as having been deleted. Inserts and updates are treated similarly.

Note

The snapshot of the database state applies to SELECT statements within a transaction, not necessarily to DML statements. If you insert or modify some rows and then commit that transaction, a DELETE or UPDATE statement issued from another concurrent REPEATABLE READ transaction could affect those just-committed rows, even though the session could not query them. If a transaction does update or delete rows committed by a different transaction, those changes do become visible to the current transaction. For example, you might encounter a situation like the following:

```
SELECT COUNT(c1) FROM t1 WHERE c1 = 'xyz';  
-- Returns 0: no rows match.
DELETE FROM t1 WHERE c1 = 'xyz';  
-- Deletes several rows recently committed by other transaction.
SELECT COUNT(c2) FROM t1 WHERE c2 = 'abc';  
-- Returns 0: no rows match.
UPDATE t1 SET c2 = 'cba' WHERE c2 = 'abc';  
-- Affects 10 rows; another txn just committed 10 rows with 'abc' values.
SELECT COUNT(c2) FROM t1 WHERE c2 = 'cba';  
-- Returns 10: this txn can now see the rows it just updated.
```

You can advance your timepoint by committing your transaction and then doing another SELECT or START TRANSACTION WITH CONSISTENT SNAPSHOT.

This is called multi-versioned concurrency control.

In the following example, session A sees the row inserted by B only when B has committed the insert and A has committed as well, so that the timepoint is advanced past the commit of B.

```
<table>
<thead>
<tr>
<th>time</th>
<th>Session A</th>
<th>Session B</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>SET autocommit=0;</td>
<td>SET autocommit=0;</td>
</tr>
<tr>
<td></td>
<td>SELECT * FROM t;</td>
<td>INSERT INTO t VALUES (1, 2);</td>
</tr>
<tr>
<td></td>
<td>empty set</td>
<td>COMMIT;</td>
</tr>
<tr>
<td></td>
<td>SELECT * FROM t;</td>
<td>COMMIT;</td>
</tr>
<tr>
<td></td>
<td>empty set</td>
<td></td>
</tr>
<tr>
<td></td>
<td>COMMIT;</td>

</table>
```

If you want to see the “freshest” state of the database, use either the READ COMMITTED isolation level or a locking read.
SELECT * FROM t LOCK IN SHARE MODE;

With READ COMMITTED isolation level, each consistent read within a transaction sets and reads its own fresh snapshot. With LOCK IN SHARE MODE, a locking read occurs instead: A SELECT blocks until the transaction containing the freshest rows ends (see Section 14.7.2.4, “Locking Reads”).

Consistent read does not work over certain DDL statements:

- Consistent read does not work over DROP TABLE, because MySQL cannot use a table that has been dropped and InnoDB destroys the table.

- Consistent read does not work over ALTER TABLE operations that make a temporary copy of the original table and delete the original table when the temporary copy is built. When you reissue a consistent read within a transaction, rows in the new table are not visible because those rows did not exist when the transaction’s snapshot was taken. In this case, the transaction returns an error: ER_TABLE_DEF_CHANGED, “Table definition has changed, please retry transaction”.

The type of read varies for select operations in clauses like INSERT INTO ... SELECT, UPDATE ... (SELECT), and CREATE TABLE ... SELECT that do not specify FOR UPDATE or LOCK IN SHARE MODE:

- By default, InnoDB uses stronger locks in those statements and the SELECT part acts like READ COMMITTED, where each consistent read, even within the same transaction, sets and reads its own fresh snapshot.

- To perform a nonlocking read in such cases, enable the innodb_locks_unsafe_for_binlog option and set the isolation level of the transaction to READ UNCOMMITTED, READ COMMITTED, or REPEATABLE READ to avoid setting locks on rows read from the selected table.

14.7.2.4 Locking Reads

If you query data and then insert or update related data within the same transaction, the regular SELECT statement does not give enough protection. Other transactions can update or delete the same rows you just queried. InnoDB supports two types of locking reads that offer extra safety:

- SELECT ... LOCK IN SHARE MODE

  Sets a shared mode lock on any rows that are read. Other sessions can read the rows, but cannot modify them until your transaction commits. If any of these rows were changed by another transaction that has not yet committed, your query waits until that transaction ends and then uses the latest values.

- SELECT ... FOR UPDATE

  For index records the search encounters, locks the rows and any associated index entries, the same as if you issued an UPDATE statement for those rows. Other transactions are blocked from updating those rows, from doing SELECT ... LOCK IN SHARE MODE, or from reading the data in certain transaction isolation levels. Consistent reads ignore any locks set on the records that exist in the read view. (Old versions of a record cannot be locked; they are reconstructed by applying undo logs on an in-memory copy of the record.)

These clauses are primarily useful when dealing with tree-structured or graph-structured data, either in a single table or split across multiple tables. You traverse edges or tree branches from one place to another, while reserving the right to come back and change any of these “pointer” values.

All locks set by LOCK IN SHARE MODE and FOR UPDATE queries are released when the transaction is committed or rolled back.

Note

Locking reads are only possible when autocommit is disabled (either by beginning transaction with START TRANSACTION or by setting autocommit to 0.)
A locking read clause in an outer statement does not lock the rows of a table in a nested subquery unless a locking read clause is also specified in the subquery. For example, the following statement does not lock rows in table t2.

```
SELECT * FROM t1 WHERE c1 = (SELECT c1 FROM t2) FOR UPDATE;
```

To lock rows in table t2, add a locking read clause to the subquery:

```
SELECT * FROM t1 WHERE c1 = (SELECT c1 FROM t2 FOR UPDATE) FOR UPDATE;
```

**Locking Read Examples**

Suppose that you want to insert a new row into a table child, and make sure that the child row has a parent row in table parent. Your application code can ensure referential integrity throughout this sequence of operations.

First, use a consistent read to query the table PARENT and verify that the parent row exists. Can you safely insert the child row to table CHILD? No, because some other session could delete the parent row in the moment between your SELECT and your INSERT, without you being aware of it.

To avoid this potential issue, perform the SELECT using LOCK IN SHARE MODE:

```
SELECT * FROM parent WHERE NAME = 'Jones' LOCK IN SHARE MODE;
```

After the LOCK IN SHARE MODE query returns the parent 'Jones', you can safely add the child record to the CHILD table and commit the transaction. Any transaction that tries to acquire an exclusive lock in the applicable row in the PARENT table waits until you are finished, that is, until the data in all tables is in a consistent state.

For another example, consider an integer counter field in a table CHILD_CODES, used to assign a unique identifier to each child added to table CHILD. Do not use either consistent read or a shared mode read to read the present value of the counter, because two users of the database could see the same value for the counter, and a duplicate-key error occurs if two transactions attempt to add rows with the same identifier to the CHILD table.

Here, LOCK IN SHARE MODE is not a good solution because if two users read the counter at the same time, at least one of them ends up in deadlock when it attempts to update the counter.

To implement reading and incrementing the counter, first perform a locking read of the counter using FOR UPDATE, and then increment the counter. For example:

```
SELECT counter_field FROM child_codes FOR UPDATE;
UPDATE child_codes SET counter_field = counter_field + 1;
```

A SELECT ... FOR UPDATE reads the latest available data, setting exclusive locks on each row it reads. Thus, it sets the same locks a searched SQL UPDATE would set on the rows.

The preceding description is merely an example of how SELECT ... FOR UPDATE works. In MySQL, the specific task of generating a unique identifier actually can be accomplished using only a single access to the table:

```
UPDATE child_codes SET counter_field = LAST_INSERT_ID(counter_field + 1);
SELECT LAST_INSERT_ID();
```

The SELECT statement merely retrieves the identifier information (specific to the current connection). It does not access any table.

**14.7.3 Locks Set by Different SQL Statements in InnoDB**

A locking read, an UPDATE, or a DELETE generally set record locks on every index record that is scanned in the processing of the SQL statement. It does not matter whether there are WHERE conditions in the statement that would exclude the row. InnoDB does not remember the exact WHERE condition, but only knows which index ranges were scanned. The locks are normally next-key locks that also block inserts into the “gap” immediately before the record. However, gap locking can be disabled explicitly, which causes next-key locking not to be used. For more information, see
Section 14.7.1, “InnoDB Locking”. The transaction isolation level also can affect which locks are set; see Section 14.7.2.1, “Transaction Isolation Levels”.

If a secondary index is used in a search and index record locks to be set are exclusive, InnoDB also retrieves the corresponding clustered index records and sets locks on them.

If you have no indexes suitable for your statement and MySQL must scan the entire table to process the statement, every row of the table becomes locked, which in turn blocks all inserts by other users to the table. It is important to create good indexes so that your queries do not unnecessarily scan many rows.

InnoDB sets specific types of locks as follows.

• SELECT ... FROM is a consistent read, reading a snapshot of the database and setting no locks unless the transaction isolation level is set to SERIALIZABLE. For SERIALIZABLE level, the search sets shared next-key locks on the index records it encounters. However, only an index record lock is required for statements that lock rows using a unique index to search for a unique row.

• For locking reads (SELECT with FOR UPDATE or LOCK IN SHARE MODE), UPDATE, and DELETE statements, the locks that are taken depend on whether the statement uses a unique index with a unique search condition, or a range-type search condition.

• For a unique index with a unique search condition, InnoDB locks only the index record found, not the gap before it.

• For other search conditions, and for non-unique indexes, InnoDB locks the index range scanned, using gap locks or next-key locks to block insertions by other sessions into the gaps covered by the range. For information about gap locks and next-key locks, see Section 14.7.1, “InnoDB Locking”.

• For index records the search encounters, SELECT ... FOR UPDATE blocks other sessions from doing SELECT ... LOCK IN SHARE MODE or from reading in certain transaction isolation levels. Consistent reads ignore any locks set on the records that exist in the read view.

• UPDATE ... WHERE ... sets an exclusive next-key lock on every record the search encounters. However, only an index record lock is required for statements that lock rows using a unique index to search for a unique row.

• When UPDATE modifies a clustered index record, implicit locks are taken on affected secondary index records. The UPDATE operation also takes shared locks on affected secondary index records when performing duplicate check scans prior to inserting new secondary index records, and when inserting new secondary index records.

• DELETE FROM ... WHERE ... sets an exclusive next-key lock on every record the search encounters. However, only an index record lock is required for statements that lock rows using a unique index to search for a unique row.

• INSERT sets an exclusive lock on the inserted row. This lock is an index-record lock, not a next-key lock (that is, there is no gap lock) and does not prevent other sessions from inserting into the gap before the inserted row.

Prior to inserting the row, a type of gap lock called an insert intention gap lock is set. This lock signals the intent to insert in such a way that multiple transactions inserting into the same index gap need not wait for each other if they are not inserting at the same position within the gap. Suppose that there are index records with values of 4 and 7. Separate transactions that attempt to insert values of 5 and 6 each lock the gap between 4 and 7 with insert intention locks prior to obtaining the exclusive lock on the inserted row, but do not block each other because the rows are nonconflicting.

If a duplicate-key error occurs, a shared lock on the duplicate index record is set. This use of a shared lock can result in deadlock should there be multiple sessions trying to insert the same row if another session already has an exclusive lock. This can occur if another session deletes the row. Suppose that an InnoDB table $t_1$ has the following structure:
CREATE TABLE t1 (i INT, PRIMARY KEY (i)) ENGINE = InnoDB;

Now suppose that three sessions perform the following operations in order:

Session 1:
```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

Session 2:
```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

Session 3:
```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

Session 1:
```
ROLLBACK;
```

The first operation by session 1 acquires an exclusive lock for the row. The operations by sessions 2 and 3 both result in a duplicate-key error and they both request a shared lock for the row. When session 1 rolls back, it releases its exclusive lock on the row and the queued shared lock requests for sessions 2 and 3 are granted. At this point, sessions 2 and 3 deadlock: Neither can acquire an exclusive lock for the row because of the shared lock held by the other.

A similar situation occurs if the table already contains a row with key value 1 and three sessions perform the following operations in order:

Session 1:
```
START TRANSACTION;
DELETE FROM t1 WHERE i = 1;
```

Session 2:
```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

Session 3:
```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

Session 1:
```
COMMIT;
```

The first operation by session 1 acquires an exclusive lock for the row. The operations by sessions 2 and 3 both result in a duplicate-key error and they both request a shared lock for the row. When session 1 commits, it releases its exclusive lock on the row and the queued shared lock requests for sessions 2 and 3 are granted. At this point, sessions 2 and 3 deadlock: Neither can acquire an exclusive lock for the row because of the shared lock held by the other.

- **INSERT ... ON DUPLICATE KEY UPDATE** differs from a simple **INSERT** in that an exclusive lock rather than a shared lock is placed on the row to be updated when a duplicate-key error occurs. An exclusive index-record lock is taken for a duplicate primary key value. An exclusive next-key lock is taken for a duplicate unique key value.

- **REPLACE** is done like an **INSERT** if there is no collision on a unique key. Otherwise, an exclusive next-key lock is placed on the row to be replaced.
• **INSERT INTO T SELECT ... FROM S WHERE ...** sets an exclusive index record lock (without a gap lock) on each row inserted into T. If the transaction isolation level is `READ COMMITTED`, or `innodb_locks_unsafe_for_binlog` is enabled and the transaction isolation level is not `SERIALIZABLE`, InnoDB does the search on S as a consistent read (no locks). Otherwise, InnoDB sets shared next-key locks on rows from S. InnoDB has to set locks in the latter case: During roll-forward recovery using a statement-based binary log, every SQL statement must be executed in exactly the same way it was done originally.

```sql
CREATE TABLE ... SELECT ... performs the SELECT with shared next-key locks or as a consistent read, as for INSERT ... SELECT.
```

When a `SELECT` is used in the constructs `REPLACE INTO t SELECT ... FROM s WHERE ...` or `UPDATE t ... WHERE col IN (SELECT ... FROM s ...)`, InnoDB sets shared next-key locks on rows from table s.

• **InnoDB** sets an exclusive lock on the end of the index associated with the `AUTO_INCREMENT` column while initializing a previously specified `AUTO_INCREMENT` column on a table.

With `innodb_autoinc_lock_mode=0`, InnoDB uses a special `AUTO-INC` table lock mode where the lock is obtained and held to the end of the current SQL statement (not to the end of the entire transaction) while accessing the auto-increment counter. Other clients cannot insert into the table while the `AUTO-INC` table lock is held. The same behavior occurs for "bulk inserts" with `innodb_autoinc_lock_mode=1`. Table-level `AUTO-INC` locks are not used with `innodb_autoinc_lock_mode=2`. For more information, See Section 14.6.1.6, “AUTO_INCREMENT Handling in InnoDB”.

InnoDB fetches the value of a previously initialized `AUTO_INCREMENT` column without setting any locks.

• If a `FOREIGN KEY` constraint is defined on a table, any insert, update, or delete that requires the constraint condition to be checked sets shared record-level locks on the records that it looks at to check the constraint. InnoDB also sets these locks in the case where the constraint fails.

• **LOCK TABLES** sets table locks, but it is the higher MySQL layer above the InnoDB layer that sets these locks. InnoDB is aware of table locks if `innodb_table_locks = 1` (the default) and `autocommit = 0`, and the MySQL layer above InnoDB knows about row-level locks.

Otherwise, InnoDB's automatic deadlock detection cannot detect deadlocks where such table locks are involved. Also, because in this case the higher MySQL layer does not know about row-level locks, it is possible to get a table lock on a table where another session currently has row-level locks. However, this does not endanger transaction integrity, as discussed in Section 14.7.5.2, “Deadlock Detection”.

• **LOCK TABLES** acquires two locks on each table if `innodb_table_locks=1` (the default). In addition to a table lock on the MySQL layer, it also acquires an InnoDB table lock. Versions of MySQL before 4.1.2 did not acquire InnoDB table locks; the old behavior can be selected by setting `innodb_table_locks=0`. If no InnoDB table lock is acquired, LOCK TABLES completes even if some records of the tables are being locked by other transactions.

In MySQL 5.6, `innodb_table_locks=0` has no effect for tables locked explicitly with **LOCK TABLES ... WRITE.** It does have an effect for tables locked for read or write by **LOCK TABLES ... WRITE** implicitly (for example, through triggers) or by **LOCK TABLES ... READ**.

• All InnoDB locks held by a transaction are released when the transaction is committed or aborted. Thus, it does not make much sense to invoke **LOCK TABLES** on InnoDB tables in `autocommit=1` mode because the acquired InnoDB table locks would be released immediately.

• You cannot lock additional tables in the middle of a transaction because **LOCK TABLES** performs an implicit **COMMIT** and **UNLOCK TABLES**.

### 14.7.4 Phantom Rows

1882
The so-called *phantom* problem occurs within a transaction when the same query produces different sets of rows at different times. For example, if a *SELECT* is executed twice, but returns a row the second time that was not returned the first time, the row is a “phantom” row.

Suppose that there is an index on the *id* column of the *child* table and that you want to read and lock all rows from the table having an identifier value larger than 100, with the intention of updating some column in the selected rows later:

```
SELECT * FROM child WHERE id > 100 FOR UPDATE;
```

The query scans the index starting from the first record where *id* is bigger than 100. Let the table contain rows having *id* values of 90 and 102. If the locks set on the index records in the scanned range do not lock out inserts made in the gaps (in this case, the gap between 90 and 102), another session can insert a new row into the table with an *id* of 101. If you were to execute the same *SELECT* within the same transaction, you would see a new row with an *id* of 101 (a “phantom”) in the result set returned by the query. If we regard a set of rows as a data item, the new phantom child would violate the isolation principle of transactions that a transaction should be able to run so that the data it has read does not change during the transaction.

To prevent phantoms, *InnoDB* uses an algorithm called *next-key locking* that combines index-row locking with gap locking. *InnoDB* performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index-record locks. In addition, a next-key lock on an index record also affects the “gap” before that index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the index record. If one session has a shared or exclusive lock on record *R* in an index, another session cannot insert a new index record in the gap immediately before *R* in the index order.

When *InnoDB* scans an index, it can also lock the gap after the last record in the index. Just that happens in the preceding example: To prevent any insert into the table where *id* would be bigger than 100, the locks set by *InnoDB* include a lock on the gap following *id* value 102.

You can use next-key locking to implement a uniqueness check in your application: If you read your data in share mode and do not see a duplicate for a row you are going to insert, then you can safely insert your row and know that the next-key lock set on the successor of your row during the read prevents anyone meanwhile inserting a duplicate for your row. Thus, the next-key locking enables you to “lock” the nonexistence of something in your table.

Gap locking can be disabled as discussed in Section 14.7.1, “*InnoDB Locking*”. This may cause phantom problems because other sessions can insert new rows into the gaps when gap locking is disabled.

### 14.7.5 Deadlocks in *InnoDB*

A deadlock is a situation where different transactions are unable to proceed because each holds a lock that the other needs. Because both transactions are waiting for a resource to become available, neither ever release the locks it holds.

A deadlock can occur when transactions lock rows in multiple tables (through statements such as *UPDATE* or *SELECT ... FOR UPDATE*), but in the opposite order. A deadlock can also occur when such statements lock ranges of index records and gaps, with each transaction acquiring some locks but not others due to a timing issue. For a deadlock example, see Section 14.7.5.1, “An *InnoDB* Deadlock Example”.

To reduce the possibility of deadlocks, use transactions rather than *LOCK TABLES* statements; keep transactions that insert or update data small enough that they do not stay open for long periods of time; when different transactions update multiple tables or large ranges of rows, use the same order of operations (such as *SELECT ... FOR UPDATE*) in each transaction; create indexes on the columns used in *SELECT ... FOR UPDATE* and *UPDATE ... WHERE* statements. The possibility of deadlocks is not affected by the isolation level, because the isolation level changes the behavior.
Deadlocks in InnoDB

of read operations, while deadlocks occur because of write operations. For more information about avoiding and recovering from deadlock conditions, see Section 14.7.5.3, “How to Minimize and Handle Deadlocks”.

If a deadlock does occur, InnoDB detects the condition and rolls back one of the transactions (the victim). Thus, even if your application logic is correct, you must still handle the case where a transaction must be retried. To see the last deadlock in an InnoDB user transaction, use the SHOW ENGINE INNODB STATUS command. If frequent deadlocks highlight a problem with transaction structure or application error handling, run with the innodb_print_all_deadlocks setting enabled to print information about all deadlocks to the mysql error log. For more information about how deadlocks are automatically detected and handled, see Section 14.7.5.2, “Deadlock Detection”.

14.7.5.1 An InnoDB Deadlock Example

The following example illustrates how an error can occur when a lock request would cause a deadlock. The example involves two clients, A and B.

First, client A creates a table containing one row, and then begins a transaction. Within the transaction, A obtains an S lock on the row by selecting it in share mode:

```sql
mysql> CREATE TABLE t (i INT) ENGINE = InnoDB;
Query OK, 0 rows affected (1.07 sec)

mysql> INSERT INTO t (i) VALUES(1);
Query OK, 1 row affected (0.09 sec)

mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM t WHERE i = 1 LOCK IN SHARE MODE;
+------+
<table>
<thead>
<tr>
<th>i</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
<tr>
<td>------</td>
</tr>
</tbody>
</table>
```

Next, client B begins a transaction and attempts to delete the row from the table:

```sql
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> DELETE FROM t WHERE i = 1;
The delete operation requires an X lock. The lock cannot be granted because it is incompatible with the S lock that client A holds, so the request goes on the queue of lock requests for the row and client B blocks.

Finally, client A also attempts to delete the row from the table:

```sql
mysql> DELETE FROM t WHERE i = 1;
ERROR 1213 (40001): Deadlock found when trying to get lock; try restarting transaction
```

Deadlock occurs here because client A needs an X lock to delete the row. However, that lock request cannot be granted because client B already has a request for an X lock and is waiting for client A to release its S lock. Nor can the S lock held by A be upgraded to an X lock because of the prior request by B for an X lock. As a result, InnoDB generates an error for one of the clients and releases its locks. The client returns this error:

```sql
ERROR 1213 (40001): Deadlock found when trying to get lock; try restarting transaction
```

At that point, the lock request for the other client can be granted and it deletes the row from the table.

14.7.5.2 Deadlock Detection
InnoDB automatically detects transaction deadlocks and rolls back a transaction or transactions to break the deadlock. InnoDB tries to pick small transactions to roll back, where the size of a transaction is determined by the number of rows inserted, updated, or deleted.

InnoDB is aware of table locks if innodb_table_locks = 1 (the default) and autocommit = 0, and the MySQL layer above it knows about row-level locks. Otherwise, InnoDB cannot detect deadlocks where a table lock set by a MySQL LOCK TABLES statement or a lock set by a storage engine other than InnoDB is involved. Resolve these situations by setting the value of the innodb_lock_wait_timeout system variable.

If the LATEST DETECTED DEADLOCK section of InnoDB Monitor output includes a message stating, “TOO DEEP OR LONG SEARCH IN THE LOCK TABLE WAITS-FOR GRAPH, WE WILL ROLL BACK FOLLOWING TRANSACTION,” this indicates that the number of transactions on the wait-for list has reached a limit of 200. A wait-for list that exceeds 200 transactions is treated as a deadlock and the transaction attempting to check the wait-for list is rolled back. The same error may also occur if the locking thread must look at more than 1,000,000 locks owned by transactions on the wait-for list.

For techniques to organize database operations to avoid deadlocks, see Section 14.7.5, “Deadlocks in InnoDB”.

### 14.7.5.3 How to Minimize and Handle Deadlocks

This section builds on the conceptual information about deadlocks in Section 14.7.5.2, “Deadlock Detection”. It explains how to organize database operations to minimize deadlocks and the subsequent error handling required in applications.

Deadlocks are a classic problem in transactional databases, but they are not dangerous unless they are so frequent that you cannot run certain transactions at all. Normally, you must write your applications so that they are always prepared to re-issue a transaction if it fails due to deadlock.

InnoDB uses automatic row-level locking. You can get deadlocks even in the case of transactions that just insert or delete a single row. That is because these operations are not really "atomic"; they automatically set locks on the (possibly several) index records of the row inserted or deleted.

You can cope with deadlocks and reduce the likelihood of their occurrence with the following techniques:

- At any time, issue the SHOW ENGINE INNODB STATUS command to determine the cause of the most recent deadlock. That can help you to tune your application to avoid deadlocks.

- If frequent deadlock warnings cause concern, collect more extensive debugging information by enabling the innodb_print_all_deadlocks configuration option. Information about each deadlock, not just the latest one, is recorded in the MySQL error log. Disable this option when you are finished debugging.

- Always be prepared to re-issue a transaction if it fails due to deadlock. Deadlocks are not dangerous. Just try again.

- Keep transactions small and short in duration to make them less prone to collision.

- Commit transactions immediately after making a set of related changes to make them less prone to collision. In particular, do not leave an interactive mysql session open for a long time with an uncommitted transaction.

- If you use locking reads (SELECT ... FOR UPDATE or SELECT ... LOCK IN SHARE MODE), try using a lower isolation level such as READ COMMITTED.

- When modifying multiple tables within a transaction, or different sets of rows in the same table, do those operations in a consistent order each time. Then transactions form well-defined queues and do not deadlock. For example, organize database operations into functions within your application, or
InnoDB Configuration

call stored routines, rather than coding multiple similar sequences of INSERT, UPDATE, and DELETE statements in different places.

• Add well-chosen indexes to your tables. Then your queries need to scan fewer index records and consequently set fewer locks. Use EXPLAIN SELECT to determine which indexes the MySQL server regards as the most appropriate for your queries.

• Use less locking. If you can afford to permit a SELECT to return data from an old snapshot, do not add the clause FOR UPDATE or LOCK IN SHARE MODE to it. Using the READ COMMITTED isolation level is good here, because each consistent read within the same transaction reads from its own fresh snapshot.

• If nothing else helps, serialize your transactions with table-level locks. The correct way to use LOCK TABLES with transactional tables, such as InnoDB tables, is to begin a transaction with SET autocommit = 0 (not START TRANSACTION) followed by LOCK TABLES, and to not call UNLOCK TABLES until you commit the transaction explicitly. For example, if you need to write to table t1 and read from table t2, you can do this:

```sql
SET autocommit=0;
LOCK TABLES t1 WRITE, t2 READ, ...;
... do something with tables t1 and t2 here ...
COMMIT;
UNLOCK TABLES;
```

Table-level locks prevent concurrent updates to the table, avoiding deadlocks at the expense of less responsiveness for a busy system.

• Another way to serialize transactions is to create an auxiliary “semaphore” table that contains just a single row. Have each transaction update that row before accessing other tables. In that way, all transactions happen in a serial fashion. Note that the InnoDB instant deadlock detection algorithm also works in this case, because the serializing lock is a row-level lock. With MySQL table-level locks, the timeout method must be used to resolve deadlocks.

14.8 InnoDB Configuration

This section provides configuration information and procedures for InnoDB initialization, startup, and various components and features of the InnoDB storage engine. For information about optimizing database operations for InnoDB tables, see Section 8.5, “Optimizing for InnoDB Tables”.

14.8.1 InnoDB Startup Configuration

The first decisions to make about InnoDB configuration involve the configuration of data files, log files, page size, and memory buffers. It is recommended that you define data file, log file, and page size configuration before creating the InnoDB instance. Modifying data file or log file configuration after the InnoDB instance is created may involve a non-trivial procedure, and page size can only be defined when the InnoDB instance is first initialized.

In addition to these topics, this section provides information about specifying InnoDB options in a configuration file, viewing InnoDB initialization information, and important storage considerations.

• Specifying Options in a MySQL Configuration File
• Viewing InnoDB Initialization Information
• Important Storage Considerations
• System Tablespace Data File Configuration
• Redo Log File Configuration
• Undo Tablespace Configuration
• Page Size Configuration
InnoDB Startup Configuration

• Memory Configuration

Specifying Options in a MySQL Configuration File

Because MySQL uses data file, log file, and page size configuration settings to initialize the InnoDB instance, it is recommended that you define these settings in a configuration file that MySQL reads at startup, prior to initializing InnoDB for the first time. InnoDB is initialized when the MySQL server is started, and the first initialization of InnoDB normally occurs the first time you start the MySQL server.

You can place InnoDB options in the [mysqld] group of any option file that your server reads when it starts. The locations of MySQL option files are described in Section 4.2.2.2, “Using Option Files”.

To make sure that mysqld reads options only from a specific file, use the --defaults-file option as the first option on the command line when starting the server:

```
mysqld --defaults-file=path_to_configuration_file
```

Viewing InnoDB Initialization Information

To view InnoDB initialization information during startup, start mysqld from a command prompt. When mysqld is started from a command prompt, initialization information is printed to the console.

For example, on Windows, if mysqld is located in C:\Program Files\MySQL\MySQL Server 5.6\bin, start the MySQL server like this:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.6\bin\mysqld" --console
```

On Unix-like systems, mysqld is located in the bin directory of your MySQL installation:

```
shell> bin/mysqld --user=mysql &
```

If you do not send server output to the console, check the error log after startup to see the initialization information InnoDB printed during the startup process.

For information about starting MySQL using other methods, see Section 2.10.5, “Starting and Stopping MySQL Automatically”.

Note

InnoDB does not open all user tables and associated data files at startup. However, InnoDB does check for the existence of tablespace files (*.ibd files) that are referenced in the data dictionary. If a tablespace file is not found, InnoDB logs an error and continues the startup sequence. Tablespace files that are referenced in the redo log may be opened during crash recovery for redo application.

Important Storage Considerations

Review the following storage-related considerations before proceeding with your startup configuration.

• In some cases, database performance improves if the data is not all placed on the same physical disk. Putting log files on a different disk from data is very often beneficial for performance. For example, you can place system tablespace data files and log files on different disks. You can also use raw disk partitions (raw devices) for InnoDB data files, which may speed up I/O. See Using Raw Disk Partitions for the System Tablespace.

• InnoDB is a transaction-safe (ACID compliant) storage engine for MySQL that has commit, rollback, and crash-recovery capabilities to protect user data. However, it cannot do so if the underlying operating system or hardware does not work as advertised. Many operating systems or disk subsystems may delay or reorder write operations to improve performance. On some operating systems, the very ffsync() system call that should wait until all unwritten data for a file has been flushed might actually return before the data has been flushed to stable storage. Because of this, an operating system crash or a power outage may destroy recently committed data, or in the worst
case, even corrupt the database because of write operations having been reordered. If data integrity is important to you, perform some “pull-the-plug” tests before using anything in production. On macOS, InnoDB uses a special `fcntl()` file flush method. Under Linux, it is advisable to disable the write-back cache.

On ATA/SATA disk drives, a command such as `hdparm -W0 /dev/hda` may work to disable the write-back cache. Beware that some drives or disk controllers may be unable to disable the write-back cache.

• With regard to InnoDB recovery capabilities that protect user data, InnoDB uses a file flush technique involving a structure called the **doublewrite buffer**, which is enabled by default (**innodb_doublewrite=ON**). The doublewrite buffer adds safety to recovery following an unexpected exit or power outage, and improves performance on most varieties of Unix by reducing the need for `fsync()` operations. It is recommended that the **innodb_doublewrite** option remains enabled if you are concerned with data integrity or possible failures. For additional information about the doublewrite buffer, see Section 14.12.1, “InnoDB Disk I/O”.

• Before using NFS with InnoDB, review potential issues outlined in Using NFS with MySQL.

• Running MySQL server on a 4K sector hard drive on Windows is not supported with **innodb_flush_method=async_unbuffered**, which is the default setting. The workaround is to use **innodb_flush_method=normal**.

**System Tablespace Data File Configuration**

The **innodb_data_file_path** startup option defines the name, size, and attributes of InnoDB system tablespace data files. If you do not configure this option prior to initializing the MySQL server, the default behavior is to create a single auto-extending data file, slightly larger than 12MB, named ibdata1:

```
mysql> SHOW VARIABLES LIKE 'innodb_data_file_path';
+-----------------------+------------------------+
| Variable_name         | Value                  |
+-----------------------+------------------------+
| innodb_data_file_path | ibdata1:12M:autoextend |
+-----------------------+------------------------+
```

The full data file specification syntax includes the file name, file size, **autoextend** attribute, and **max** attribute:

```
file_name:file_size[:autoextend[:max:max_file_size]]
```

File sizes are specified in kilobytes, megabytes, or gigabytes by appending **K**, **M** or **G** to the size value. If specifying the data file size in kilobytes, do so in multiples of 1024. Otherwise, kilobyte values are rounded to nearest megabyte (MB) boundary. The sum of file sizes must be, at a minimum, slightly larger than 12MB.

You can specify more than one data file using a semicolon-separated list. For example:

```
[mysqld]
innodb_data_file_path=ibdata1:50M;ibdata2:50M:autoextend
```

The **autoextend** and **max** attributes can be used only for the data file that is specified last.

When the **autoextend** attribute is specified, the data file automatically increases in size by 64MB increments as space is required. The **innodb_autoextend_increment** variable controls the increment size.

To specify a maximum size for an auto-extending data file, use the **max** attribute following the **autoextend** attribute. Use the **max** attribute only in cases where constraining disk usage is of critical importance. The following configuration permits ibdata1 to grow to a limit of 500MB:

```
[mysqld]
innodb_data_file_path=ibdata1:12M:autoextend:max:500M
```
If your disk becomes full, you can add a data file on another disk. For instructions, see Resizing the System Tablespace.

The size limit for individual files is determined by your operating system. You can set the file size to more than 4GB on operating systems that support large files. You can also use raw disk partitions as data files. See Using Raw Disk Partitions for the System Tablespace.

InnoDB is not aware of the file system maximum file size, so be cautious on file systems where the maximum file size is a small value such as 2GB.

System tablespace files are created in the data directory by default (datadir). To specify an alternate location, use the innodb_data_home_dir option. For example, to create a system tablespace data file in a directory named myibdata, use this configuration:

```
[mysqld]
innodb_data_home_dir = /myibdata/
innodb_data_file_path=ibdata1:50M:autoextend
```

A trailing slash is required when specifying a value for innodb_data_home_dir. InnoDB does not create directories, so ensure that the specified directory exists before you start the server. Also, ensure that the MySQL server has the proper access rights to create files in the directory.

InnoDB forms the directory path for each data file by textually concatenating the value of innodb_data_home_dir to the data file name. If innodb_data_home_dir is not defined, the default value is "/" , which is the data directory. (The MySQL server changes its current working directory to the data directory when it begins executing.)

If you specify innodb_data_home_dir as an empty string, you can specify absolute paths for data files listed in the innodb_data_file_path value. The following configuration is equivalent to the preceding one:

```
[mysqld]
innodb_data_home_dir =
innodb_data_file_path=/myibdata/ibdata1:50M:autoextend
```

### Redo Log File Configuration

By default, InnoDB creates two 48MB redo log files in the data directory named ib_logfile0 and ib_logfile1.

The following options can be used to modify the default configuration:

- **innodb_log_group_home_dir** defines directory path to the InnoDB log files (the redo logs). If this option is not configured, InnoDB log files are created in the MySQL data directory (datadir).

You might use this option to place InnoDB log files in a different physical storage location than InnoDB data files to avoid potential I/O resource conflicts. For example:

```
[mysqld]
innodb_log_group_home_dir = /dr3/iblogs
```

#### Note

InnoDB does not create directories, so make sure that the log directory exists before you start the server. Use the Unix or DOS mkdir command to create any necessary directories.

Make sure that the MySQL server has the proper access rights to create files in the log directory. More generally, the server must have access rights in any directory where it needs to create log files.

- **innodb_log_files_in_group** defines the number of log files in the log group. The default and recommended value is 2.
InnoDB Startup Configuration

- **innodb_log_file_size** defines the size in bytes of each log file in the log group. The combined size of log files (\(\text{innodb_log_file_size} \times \text{innodb_log_files_in_group}\)) cannot exceed a maximum value that is slightly less than 512GB. A pair of 255 GB log files, for example, approaches the limit but does not exceed it. The default log file size is 48MB. Generally, the combined size of the log files should be large enough that the server can smooth out peaks and troughs in workload activity, which often means that there is enough redo log space to handle more than an hour of write activity. The larger the value, the less checkpoint flush activity is needed in the buffer pool, saving disk I/O. For additional information, see Section 8.5.4, “Optimizing InnoDB Redo Logging”.

Undo Tablespace Configuration

By default, InnoDB undo logs are part of the system tablespace. However, you can choose to store InnoDB undo logs in one or more separate undo tablespaces, typically on a different storage device.

The **innodb_undo_directory** configuration option defines the path where InnoDB creates separate tablespaces for the undo logs. This option is typically used in conjunction with the **innodb_rollback_segments** and **innodb_undo_tablespaces** options, which determine the disk layout of the undo logs outside the system tablespace.

For more information, see Section 14.6.3.3, “Undo Tablespaces”.

Page Size Configuration

The **innodb_page_size** option specifies the page size for all InnoDB tablespaces in a MySQL instance. This value is set when the instance is created and remains constant afterward. Valid values are 16KB (the default), 8KB, and 4KB. Alternatively, you can specify page size in bytes (16384, 8192, 4096).

The default page size of 16KB is appropriate for a wide range of workloads, particularly for queries involving table scans and DML operations involving bulk updates. Smaller page sizes might be more efficient for OLTP workloads involving many small writes, where contention can be an issue when a single page contains many rows. Smaller pages might also be efficient with SSD storage devices, which typically use small block sizes. Keeping the InnoDB page size close to the storage device block size minimizes the amount of unchanged data that is rewritten to disk.

Memory Configuration

MySQL allocates memory to various caches and buffers to improve performance of database operations. When allocating memory for InnoDB, always consider memory required by the operating system, memory allocated to other applications, and memory allocated for other MySQL buffers and caches. For example, if you use MyISAM tables, consider the amount of memory allocated for the key buffer (**key_buffer_size**). For an overview of MySQL buffers and caches, see Section 8.12.4.1, “How MySQL Uses Memory”.

Buffers specific to InnoDB are configured using the following parameters:

- **innodb_buffer_pool_size** defines size of the buffer pool, which is the memory area that holds cached data for InnoDB tables, indexes, and other auxiliary buffers. The size of the buffer pool is important for system performance, and it is typically recommended that **innodb_buffer_pool_size** is configured to 50 to 75 percent of system memory. The default buffer pool size is 128MB. For additional guidance, see Section 8.12.4.1, “How MySQL Uses Memory”. For information about how to configure InnoDB buffer pool size, see Configuring InnoDB Buffer Pool Size. Buffer pool size can be configured at startup.

On systems with a large amount of memory, you can improve concurrency by dividing the buffer pool into multiple buffer pool instances. The number of buffer pool instances is controlled by the **innodb_buffer_pool_instances** option. By default, InnoDB creates one buffer pool instance. The number of buffer pool instances can be configured at startup. For more information, see Section 14.8.3.1, “Configuring Multiple Buffer Pool Instances”.  

1890
Configuring InnoDB for Read-Only Operation

- **innodb_additional_mem_pool_size** defines size in bytes of a memory pool InnoDB uses to store data dictionary information and other internal data structures. The more tables you have in your application, the more memory you allocate here. If InnoDB runs out of memory in this pool, it starts to allocate memory from the operating system and writes warning messages to the MySQL error log. The default value is 8MB. **innodb_additional_mem_pool_size** is deprecated in MySQL 5.6.3.

- **innodb_log_buffer_size** defines the size in bytes of the buffer that InnoDB uses to write to the log files on disk. The default size is 8MB. A large log buffer enables large transactions to run without a need to write the log to disk before the transactions commit. If you have transactions that update, insert, or delete many rows, you might consider increasing the size of the log buffer to save disk I/O. **innodb_log_buffer_size** can be configured at startup. For related information, see Section 8.5.4, “Optimizing InnoDB Redo Logging”.

**Warning**

On 32-bit GNU/Linux x86, be careful not to set memory usage too high. glibc may permit the process heap to grow over thread stacks, which crashes your server. It is a risk if the memory allocated to the mysqld process for global and per-thread buffers and caches is close to or exceeds 2GB.

A formula similar to the following that calculates global and per-thread memory allocation for MySQL can be used to estimate MySQL memory usage. You may need to modify the formula to account for buffers and caches in your MySQL version and configuration. For an overview of MySQL buffers and caches, see Section 8.12.4.1, “How MySQL Uses Memory”.

\[
\text{innodb_buffer_pool_size} + \text{key_buffer_size} + \text{max_connections} \times (\text{sort_buffer_size} + \text{read_buffer_size} + \text{binlog_cache_size}) + \text{max_connections} \times 2\text{MB}
\]

Each thread uses a stack (often 2MB, but only 256KB in MySQL binaries provided by Oracle Corporation.) and in the worst case also uses \(\text{sort_buffer_size} + \text{read_buffer_size}\) additional memory.

On Linux, if the kernel is enabled for large page support, InnoDB can use large pages to allocate memory for its buffer pool and additional memory pool. See Section 8.12.4.2, “Enabling Large Page Support”.

### 14.8.2 Configuring InnoDB for Read-Only Operation

You can query InnoDB tables where the MySQL data directory is on read-only media by enabling the **--innodb-read-only** configuration option at server startup.

**How to Enable**

To prepare an instance for read-only operation, make sure all the necessary information is flushed to the data files before storing it on the read-only medium. Run the server with change buffering disabled (**innodb_change_buffering=0**) and do a slow shutdown.

To enable read-only mode for an entire MySQL instance, specify the following configuration options at server startup:

- **--innodb-read-only=1**

If the instance is on read-only media such as a DVD or CD, or the /var directory is not writeable by all: **--pid-file=path_on_writeable_media** and **--event-scheduler=disabled**

**Usage Scenarios**

This mode of operation is appropriate in situations such as:
InnoDB Buffer Pool Configuration

• Distributing a MySQL application, or a set of MySQL data, on a read-only storage medium such as a DVD or CD.

• Multiple MySQL instances querying the same data directory simultaneously, typically in a data warehousing configuration. You might use this technique to avoid bottlenecks that can occur with a heavily loaded MySQL instance, or you might use different configuration options for the various instances to tune each one for particular kinds of queries.

• Querying data that has been put into a read-only state for security or data integrity reasons, such as archived backup data.

Note

This feature is mainly intended for flexibility in distribution and deployment, rather than raw performance based on the read-only aspect. See Section 8.5.3, “Optimizing InnoDB Read-Only Transactions” for ways to tune the performance of read-only queries, which do not require making the entire server read-only.

How It Works

When the server is run in read-only mode through the --innodb-read-only option, certain InnoDB features and components are reduced or turned off entirely:

• No change buffering is done, in particular no merges from the change buffer. To make sure the change buffer is empty when you prepare the instance for read-only operation, disable change buffering (innodb_change_buffering=0) and do a slow shutdown first.

• There is no crash recovery phase at startup. The instance must have performed a slow shutdown before being put into the read-only state.

• Because the redo log is not used in read-only operation, you can set innodb_log_file_size to the smallest size possible (1 MB) before making the instance read-only.

• All background threads other than I/O read threads are turned off. As a consequence, a read-only instance cannot encounter any deadlocks.

• Information about deadlocks, monitor output, and so on is not written to temporary files. As a consequence, SHOW ENGINE INNODB STATUS does not produce any output.

• If the MySQL server is started with --innodb-read-only but the data directory is still on writeable media, the root user can still perform DCL operations such as GRANT and REVOKE.

• Changes to configuration option settings that would normally change the behavior of write operations, have no effect when the server is in read-only mode.

• The MVCC processing to enforce isolation levels is turned off. All queries read the latest version of a record, because update and deletes are not possible.

• The undo log is not used. Disable any settings for the innodb_undo_tablespaces and innodb_undo_directory configuration options.

14.8.3 InnoDB Buffer Pool Configuration

This section provides configuration and tuning information for the InnoDB buffer pool.

14.8.3.1 Configuring Multiple Buffer Pool Instances

For systems with buffer pools in the multi-gigabyte range, dividing the buffer pool into separate instances can improve concurrency, by reducing contention as different threads read and write to cached pages. This feature is typically intended for systems with a buffer pool size in the multi-gigabyte
Multiple buffer pool instances are configured using the `innodb_buffer_pool_instances` configuration option, and you might also adjust the `innodb_buffer_pool_size` value.

When the InnoDB buffer pool is large, many data requests can be satisfied by retrieving from memory. You might encounter bottlenecks from multiple threads trying to access the buffer pool at once. You can enable multiple buffer pools to minimize this contention. Each page that is stored in or read from the buffer pool is assigned to one of the buffer pools randomly, using a hashing function. Each buffer pool manages its own free lists, flush lists, LRUs, and all other data structures connected to a buffer pool, and is protected by its own buffer pool mutex.

To enable multiple buffer pool instances, set the `innodb_buffer_pool_instances` configuration option to a value greater than 1 (the default) up to 64 (the maximum). This option takes effect only when you set `innodb_buffer_pool_size` to a size of 1GB or more. The total size you specify is divided among all the buffer pools. For best efficiency, specify a combination of `innodb_buffer_pool_instances` and `innodb_buffer_pool_size` so that each buffer pool instance is at least 1GB.

### 14.8.3.2 Making the Buffer Pool Scan Resistant

Rather than using a strict LRU algorithm, InnoDB uses a technique to minimize the amount of data that is brought into the buffer pool and never accessed again. The goal is to make sure that frequently accessed ("hot") pages remain in the buffer pool, even as read-ahead and full table scans bring in new blocks that might or might not be accessed afterward.

Newly read blocks are inserted into the middle of the LRU list. All newly read pages are inserted at a location that by default is $\frac{3}{8}$ from the tail of the LRU list. The pages are moved to the front of the list (the most-recently used end) when they are accessed in the buffer pool for the first time. Thus, pages that are never accessed never make it to the front portion of the LRU list, and "age out" sooner than with a strict LRU approach. This arrangement divides the LRU list into two segments, where the pages downstream of the insertion point are considered "old" and are desirable victims for LRU eviction.

For an explanation of the inner workings of the InnoDB buffer pool and specifics about the LRU algorithm, see Section 14.5.1, "Buffer Pool".

You can control the insertion point in the LRU list and choose whether InnoDB applies the same optimization to blocks brought into the buffer pool by table or index scans. The configuration parameter `innodb_old_blocks_pct` controls the percentage of "old" blocks in the LRU list. The default value of `innodb_old_blocks_pct` is 37, corresponding to the original fixed ratio of $\frac{3}{8}$. The value range is 5 (new pages in the buffer pool age out very quickly) to 95 (only 5% of the buffer pool is reserved for hot pages, making the algorithm close to the familiar LRU strategy).

The optimization that keeps the buffer pool from being churned by read-ahead can avoid similar problems due to table or index scans. In these scans, a data page is typically accessed a few times in quick succession and is never touched again. The configuration parameter `innodb_old_blocks_time` specifies the time window (in milliseconds) after the first access to a page during which it can be accessed without being moved to the front (most-recently used end) of the LRU list. The default value of `innodb_old_blocks_time` is 1000. Increasing this value makes more and more blocks likely to age out faster from the buffer pool.

Both `innodb_old_blocks_pct` and `innodb_old_blocks_time` can be specified in the MySQL option file (`my.cnf` or `my.ini`) or changed at runtime with the `SET GLOBAL` statement. Changing the value at runtime requires privileges sufficient to set global system variables. See Section 5.1.8.1, "System Variable Privileges".

To help you gauge the effect of setting these parameters, the `SHOW ENGINE INNODB STATUS` command reports buffer pool statistics. For details, see Monitoring the Buffer Pool Using the InnoDB Standard Monitor.

Because the effects of these parameters can vary widely based on your hardware configuration, your data, and the details of your workload, always benchmark to verify the effectiveness before changing these settings in any performance-critical or production environment.
InnoDB Buffer Pool Configuration

In mixed workloads where most of the activity is OLTP type with periodic batch reporting queries which result in large scans, setting the value of `innodb_old_blocks_time` during the batch runs can help keep the working set of the normal workload in the buffer pool.

When scanning large tables that cannot fit entirely in the buffer pool, setting `innodb_old_blocks_pct` to a small value keeps the data that is only read once from consuming a significant portion of the buffer pool. For example, setting `innodb_old_blocks_pct=5` restricts this data that is only read once to 5% of the buffer pool.

When scanning small tables that do fit into memory, there is less overhead for moving pages around within the buffer pool, so you can leave `innodb_old_blocks_pct` at its default value, or even higher, such as `innodb_old_blocks_pct=50`.

The effect of the `innodb_old_blocks_time` parameter is harder to predict than the `innodb_old_blocks_pct` parameter, is relatively small, and varies more with the workload. To arrive at an optimal value, conduct your own benchmarks if the performance improvement from adjusting `innodb_old_blocks_pct` is not sufficient.

14.8.3.3 Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)

A read-ahead request is an I/O request to prefetch multiple pages in the buffer pool asynchronously, in anticipation that these pages will be needed soon. The requests bring in all the pages in one extent. InnoDB uses two read-ahead algorithms to improve I/O performance:

**Linear** read-ahead is a technique that predicts what pages might be needed soon based on pages in the buffer pool being accessed sequentially. You control when InnoDB performs a read-ahead operation by adjusting the number of sequential page accesses required to trigger an asynchronous read request, using the configuration parameter `innodb_read_ahead_threshold`. Before this parameter was added, InnoDB would only calculate whether to issue an asynchronous prefetch request for the entire next extent when it read the last page of the current extent.

The configuration parameter `innodb_read_ahead_threshold` controls how sensitive InnoDB is in detecting patterns of sequential page access. If the number of pages read sequentially from an extent is greater than or equal to `innodb_read_ahead_threshold`, InnoDB initiates an asynchronous read-ahead operation of the entire following extent. `innodb_read_ahead_threshold` can be set to any value from 0-64. The default value is 56. The higher the value, the more strict the access pattern check. For example, if you set the value to 48, InnoDB triggers a linear read-ahead request only when 48 pages in the current extent have been accessed sequentially. If the value is 8, InnoDB triggers an asynchronous read-ahead even if as few as 8 pages in the extent are accessed sequentially. You can set the value of this parameter in the MySQL configuration file, or change it dynamically with the `SET GLOBAL` statement, which requires privileges sufficient to set global system variables. See Section 5.1.8.1, “System Variable Privileges”.

**Random** read-ahead is a technique that predicts when pages might be needed soon based on pages already in the buffer pool, regardless of the order in which those pages were read. If 13 consecutive pages from the same extent are found in the buffer pool, InnoDB asynchronously issues a request to prefetch the remaining pages of the extent. To enable this feature, set the configuration variable `innodb_random_read_ahead` to ON.

The `SHOW ENGINE INNODB STATUS` command displays statistics to help you evaluate the effectiveness of the read-ahead algorithm. Statistics include counter information for the following global status variables:

- `Innodb_buffer_pool_readAhead`
- `Innodb_buffer_pool_readAhead_evicted`
- `Innodb_buffer_pool_readAhead_rnd`

This information can be useful when fine-tuning the `innodb_random_read_ahead` setting.
InnoDB Buffer Pool Configuration

For more information about I/O performance, see Section 8.5.8, “Optimizing InnoDB Disk I/O” and Section 8.12.2, “Optimizing Disk I/O”.

14.8.3.4 Configuring Buffer Pool Flushing

InnoDB performs certain tasks in the background, including flushing of dirty pages from the buffer pool. Dirty pages are those that have been modified but are not yet written to the data files on disk.

Buffer pool flushing is initiated when the percentage of dirty pages reaches the low water mark value defined by the `innodb_max_dirty_pages_pct_lwm` variable. The default low water mark is 0, which disables this early flushing behaviour.

The purpose of the `innodb_max_dirty_pages_pct_lwm` threshold is to control the percentage dirty pages in the buffer pool, and to prevent the amount of dirty pages from reaching the threshold defined by the `innodb_max_dirty_pages_pct` variable, which has a default value of 75. InnoDB aggressively flushes buffer pool pages if the percentage of dirty pages in the buffer pool reaches the `innodb_max_dirty_pages_pct` threshold.

Additional variables permit fine-tuning of buffer pool flushing behavior:

- The `innodb_flush_neighbors` variable defines whether flushing a page from the buffer pool also flushes other dirty pages in the same extent.
  - A setting of 0 disables `innodb_flush_neighbors`. Dirty pages in the same extent are not flushed.
  - The default setting of 1 flushes contiguous dirty pages in the same extent.
  - A setting of 2 flushes dirty pages in the same extent.

When table data is stored on a traditional HDD storage device, flushing neighbor pages in one operation reduces I/O overhead (primarily for disk seek operations) compared to flushing individual pages at different times. For table data stored on SSD, seek time is not a significant factor and you can disable this setting to spread out write operations.

- The `innodb_lru_scan_depth` variable specifies, per buffer pool instance, how far down the buffer pool LRU list the page cleaner thread scans looking for dirty pages to flush. This is a background operation performed by a page cleaner thread once per second.

  A setting smaller than the default is generally suitable for most workloads. A value that is significantly higher than necessary may impact performance. Only consider increasing the value if you have spare I/O capacity under a typical workload. Conversely, if a write-intensive workload saturates your I/O capacity, decrease the value, especially in the case of a large buffer pool.

When tuning `innodb_lru_scan_depth`, start with a low value and configure the setting upward with the goal of rarely seeing zero free pages. Also, consider adjusting `innodb_lru_scan_depth` when changing the number of buffer pool instances, since `innodb_lru_scan_depth * innodb_buffer_pool_instances` defines the amount of work performed by the page cleaner thread each second.

The `innodb_flush_neighbors` and `innodb_lru_scan_depth` variables are primarily intended for write-intensive workloads. With heavy DML activity, flushing can fall behind if it is not aggressive enough, or disk writes can saturate I/O capacity if flushing is too aggressive. The ideal settings depend on your workload, data access patterns, and storage configuration (for example, whether data is stored on HDD or SSD devices).

Adaptive Flushing

InnoDB uses an adaptive flushing algorithm to dynamically adjust the rate of flushing based on the speed of redo log generation and the current rate of flushing. The intent is to smooth overall performance by ensuring that flushing activity keeps pace with the current workload. Automatically
adjusting the flushing rate helps avoid sudden dips in throughput that can occur when bursts of I/O
activity due to buffer pool flushing affects the I/O capacity available for ordinary read and write activity.

Sharp checkpoints, which are typically associated with write-intensive workloads that generate a lot of
redo entries, can cause a sudden change in throughput, for example. A sharp checkpoint occurs when
InnoDB wants to reuse a portion of a log file. Before doing so, all dirty pages with redo entries in that
portion of the log file must be flushed. If log files become full, a sharp checkpoint occurs, causing a
temporary reduction in throughput. This scenario can occur even if innodb_max_dirty_pages_pct
threshold is not reached.

The adaptive flushing algorithm helps avoid such scenarios by tracking the number of dirty pages in
the buffer pool and the rate at which redo log records are being generated. Based on this information,
it decides how many dirty pages to flush from the buffer pool each second, which permits it to manage
sudden changes in workload.

The innodb_adaptive_flushing_lwm variable defines a low water mark for redo
log capacity. When that threshold is crossed, adaptive flushing is enabled, even if the
innodb_adaptive_flushing variable is disabled.

Internal benchmarking has shown that the algorithm not only maintains throughput over time, but can
also improve overall throughput significantly. However, adaptive flushing can affect the I/O pattern of
a workload significantly and may not be appropriate in all cases. It gives the most benefit when the
redo log is in danger of filling up. If adaptive flushing is not appropriate to the characteristics of your
workload, you can disable it. Adaptive flushing controlled by the innodb_adaptive_flushing
variable, which is enabled by default.

innodb_flushing_avg_loops defines the number of iterations that InnoDB keeps the previously
calculated snapshot of the flushing state, controlling how quickly adaptive flushing responds to
foreground workload changes. A high innodb_flushing_avg_loops value means that InnoDB
keeps the previously calculated snapshot longer, so adaptive flushing responds more slowly.
When setting a high value it is important to ensure that redo log utilization does not reach 75% (the
hardcoded limit at which asynchronous flushing starts), and that the innodb_max_dirty_pages_pct
threshold keeps the number of dirty pages to a level that is appropriate for the workload.

Systems with consistent workloads, a large log file size (innodb_log_file_size), and small spikes
that do not reach 75% log space utilization should use a high innodb_flushing_avg_loops value to
keep flushing as smooth as possible. For systems with extreme load spikes or log files that do not
provide a lot of space, a smaller value allows flushing to closely track workload changes, and helps to
avoid reaching 75% log space utilization.

Be aware that if flushing falls behind, the rate of buffer pool flushing can exceed the I/O capacity
available to InnoDB, as defined by innodb_io_capacity setting. The innodb_io_capacity_max
value defines an upper limit on I/O capacity in such situations, so that a spike in I/O activity does not
consume the entire I/O capacity of the server.

The innodb_io_capacity setting is applicable to all buffer pool instances. When dirty pages are
flushed, I/O capacity is divided equally among buffer pool instances.

14.8.3.5 Saving and Restoring the Buffer Pool State

To avoid a lengthy warmup period after restarting the server, particularly for instances with large buffer
pools, you can save the buffer pool state at server shutdown and restore the buffer pool to the same
state at server startup.

After restarting a busy server, there is typically a warmup period with steadily increasing throughput,
as disk pages that were in the buffer pool are brought back into memory (as the same data is queried,
updated, and so on). The ability to restore the buffer pool to the pre-shutdown state shortens the
warmup period by reloading disk pages that were in the buffer pool before the restart rather than
waiting for DML operations to access corresponding rows. Also, I/O requests can be performed in large
batches, making the overall I/O faster. Page loading happens in the background, and does not delay
database startup.
InnoDB Buffer Pool Configuration

In addition to saving the buffer pool state at shutdown and restoring it at startup, you can save and restore the buffer pool state at any time, while the server is running. For example, you can save the state of the buffer pool after reaching a stable throughput under a steady workload. You could also restore the previous buffer pool state after running reports or maintenance jobs that bring data pages into the buffer pool that are only required for those operations, or after running some other non-typical workload.

Even though a buffer pool can be many gigabytes in size, the buffer pool data that InnoDB saves to disk is tiny by comparison. Only tablespace IDs and page IDs necessary to locate the appropriate pages are saved to disk. This information is derived from the `INNODB_BUFFER_PAGE_LRU` `INFORMATION_SCHEMA` table. By default, tablespace ID and page ID data is saved in a file named `ib_buffer_pool`, which is saved to the InnoDB data directory. The file name and location can be modified using the `innodb_buffer_pool_filename` configuration parameter.

Because data is cached in and aged out of the buffer pool as it is with regular database operations, there is no problem if the disk pages are recently updated, or if a DML operation involves data that has not yet been loaded. The loading mechanism skips requested pages that no longer exist.

The underlying mechanism involves a background thread that is dispatched to perform the dump and load operations.

Disk pages from compressed tables are loaded into the buffer pool in their compressed form. Pages are uncompressed as usual when page contents are accessed during DML operations. Because uncompressing pages is a CPU-intensive process, it is more efficient for concurrency to perform the operation in a connection thread rather than in the single thread that performs the buffer pool restore operation.

Operations related to saving and restoring the buffer pool state are described in the following topics:

- Saving the Buffer Pool State at Shutdown and Restoring it at Startup
- Saving and Restoring the Buffer Pool State Online
- Displaying Buffer Pool Dump Progress
- Displaying Buffer Pool Load Progress
- Aborting a Buffer Pool Load Operation

**Saving the Buffer Pool State at Shutdown and Restoring it at Startup**

To save the state of the buffer pool at server shutdown, issue the following statement prior to shutting down the server:

```sql
SET GLOBAL innodb_buffer_pool_dump_at_shutdown=ON;
```

To restore the buffer pool state at server startup, specify the `--innodb-buffer-pool-load-at-startup` option when starting the server:

```bash
mysqld --innodb-buffer-pool-load-at-startup=ON;
```

**Saving and Restoring the Buffer Pool State Online**

To save the state of the buffer pool while MySQL server is running, issue the following statement:

```sql
SET GLOBAL innodb_buffer_pool_dump_now=ON;
```

To restore the buffer pool state while MySQL is running, issue the following statement:

```bash
SET GLOBAL innodb_buffer_pool_load_now=ON;
```

**Displaying Buffer Pool Dump Progress**

To display progress when saving the buffer pool state to disk, use one of the following options:
SHOW STATUS LIKE 'Innodb_buffer_pool_dump_status';

or:

SELECT variable_value FROM information_schema.global_status WHERE variable_name = 'INNODB_BUFFER_POOL_DUMP_STATUS';

If the operation has not yet started, “not started” is returned. If the operation is complete, the completion time is printed (e.g. Finished at 110505 12:18:02). If the operation is in progress, status information is provided (e.g. Dumping buffer pool 5/7, page 237/2873).

Displaying Buffer Pool Load Progress

To display progress when loading the buffer pool, use one of the following options:

SHOW STATUS LIKE 'Innodb_buffer_pool_load_status';

or:

SELECT variable_value FROM information_schema.global_status WHERE variable_name = 'INNODB_BUFFER_POOL_LOAD_STATUS';

If the operation has not yet started, “not started” is returned. If the operation is complete, the completion time is printed (e.g. Finished at 110505 12:23:24). If the operation is in progress, status information is provided (e.g. Loaded 123/22301 pages).

Aborting a Buffer Pool Load Operation

To abort a buffer pool load operation, issue the following statement:

SET GLOBAL innodb_buffer_pool_load_abort=ON;

14.8.4 Configuring the Memory Allocator for InnoDB

When InnoDB was developed, the memory allocators supplied with operating systems and run-time libraries were often lacking in performance and scalability. At that time, there were no memory allocator libraries tuned for multi-core CPUs. Therefore, InnoDB implemented its own memory allocator in the mem subsystem. This allocator is guarded by a single mutex, which may become a bottleneck. InnoDB also implements a wrapper interface around the system allocator (malloc and free) that is likewise guarded by a single mutex.

Today, as multi-core systems have become more widely available, and as operating systems have matured, significant improvements have been made in the memory allocators provided with operating systems. These new memory allocators perform better and are more scalable than they were in the past. Most workloads, especially those where memory is frequently allocated and released (such as multi-table joins), benefit from using a more highly tuned memory allocator as opposed to the internal, InnoDB-specific memory allocator.

You can control whether InnoDB uses its own memory allocator or an allocator of the operating system, by setting the value of the system configuration parameter innodb_use_sys_malloc in the MySQL option file (my.cnf or my.ini). If set to ON or 1 (the default), InnoDB uses the malloc and free functions of the underlying system rather than manage memory pools itself. This parameter is not dynamic, and takes effect only when the system is started. To continue to use the InnoDB memory allocator, set innodb_use_sys_malloc to 0.

When the InnoDB memory allocator is disabled, InnoDB ignores the value of the parameter innodb_additional_mem_pool_size. The InnoDB memory allocator uses an additional memory pool for satisfying allocation requests without having to fall back to the system memory allocator. When the InnoDB memory allocator is disabled, all such allocation requests are fulfilled by the system memory allocator.

On Unix-like systems that use dynamic linking, replacing the memory allocator may be as easy as making the environment variable LD_PRELOAD or LD_LIBRARY_PATH point to the dynamic library
that implements the allocator. On other systems, some relinking may be necessary. Please refer to the
documentation of the memory allocator library of your choice.

Since InnoDB cannot track all memory use when the system memory allocator is used
(innodb_use_sys_malloc is ON), the section “BUFFER POOL AND MEMORY” in the output of
the SHOW ENGINE INNODB STATUS command only includes the buffer pool statistics in the “Total
memory allocated”. Any memory allocated using the mem subsystem or using ut_malloc is excluded.

Note

innodb_use_sys_malloc and innodb_additional_mem_pool_size
were deprecated in MySQL 5.6.3 and are removed in MySQL 5.7.4.

For more information about the performance implications of InnoDB memory usage, see Section 8.10,
“Buffering and Caching”.

14.8.5 Configuring Thread Concurrency for InnoDB

InnoDB uses operating system threads to process requests from user transactions. (Transactions
may issue many requests to InnoDB before they commit or roll back.) On modern operating systems
and servers with multi-core processors, where context switching is efficient, most workloads run well
without any limit on the number of concurrent threads. Scalability improvements in MySQL 5.5 and up
reduce the need to limit the number of concurrently executing threads inside InnoDB.

In situations where it is helpful to minimize context switching between threads, InnoDB can use a
number of techniques to limit the number of concurrently executing operating system threads (and thus
the number of requests that are processed at any one time). When InnoDB receives a new request
from a user session, if the number of threads concurrently executing is at a pre-defined limit, the new
request sleeps for a short time before it tries again. A request that cannot be rescheduled after the
sleep is put in a first-in/first-out queue and eventually is processed. Threads waiting for locks are not
counted in the number of concurrently executing threads.

You can limit the number of concurrent threads by setting the configuration parameter
innodb_thread_concurrency. Once the number of executing threads reaches this limit,
additional threads sleep for a number of microseconds, set by the configuration parameter
innodb_thread_sleep_delay, before being placed into the queue.

Previously, it required experimentation to find the optimal value for innodb_thread_sleep_delay,
and the optimal value could change depending on the workload. In MySQL 5.6.3 and higher,
you can set the configuration option innodb_adaptive_max_sleep_delay to the highest
value you would allow for innodb_thread_sleep_delay, and InnoDB automatically adjusts
innodb_thread_sleep_delay up or down depending on the current thread-scheduling activity. This
dynamic adjustment helps the thread scheduling mechanism to work smoothly during times when the
system is lightly loaded and when it is operating near full capacity.

The default value for innodb_thread_concurrency and the implied default limit on the number of
concurrent threads has been changed in various releases of MySQL and InnoDB. The default value of
innodb_thread_concurrency is 0, so that by default there is no limit on the number of concurrently
executing threads.

InnoDB causes threads to sleep only when the number of concurrent threads is limited. When
there is no limit on the number of threads, all contend equally to be scheduled. That is, if
innodb_thread_concurrency is 0, the value of innodb_thread_sleep_delay is ignored.

When there is a limit on the number of threads (when innodb_thread_concurrency is >
0), InnoDB reduces context switching overhead by permitting multiple requests made during
the execution of a single SQL statement to enter InnoDB without observing the limit set by
innodb_thread_concurrency. Since an SQL statement (such as a join) may comprise multiple row
operations within InnoDB, InnoDB assigns a specified number of “tickets” that allow a thread to be
scheduled repeatedly with minimal overhead.
When a new SQL statement starts, a thread has no tickets, and it must observe `innodb_thread_concurrency`. Once the thread is entitled to enter InnoDB, it is assigned a number of tickets that it can use for subsequently entering InnoDB to perform row operations. If the tickets run out, the thread is evicted, and `innodb_thread_concurrency` is observed again which may place the thread back into the first-in/first-out queue of waiting threads. When the thread is once again entitled to enter InnoDB, tickets are assigned again. The number of tickets assigned is specified by the global option `innodb_concurrency_tickets`, which is 5000 by default. A thread that is waiting for a lock is given one ticket once the lock becomes available.

The correct values of these variables depend on your environment and workload. Try a range of different values to determine what value works for your applications. Before limiting the number of concurrently executing threads, review configuration options that may improve the performance of InnoDB on multi-core and multi-processor computers, such as `innodb_adaptive_hash_index`.

For general performance information about MySQL thread handling, see Section 5.1.11.1, “Connection Interfaces”.

### 14.8.6 Configuring the Number of Background InnoDB I/O Threads

InnoDB uses background threads to service various types of I/O requests. You can configure the number of background threads that service read and write I/O on data pages using the `innodb_read_io_threads` and `innodb_write_io_threads` configuration parameters. These parameters signify the number of background threads used for read and write requests, respectively. They are effective on all supported platforms. You can set values for these parameters in the MySQL option file (`my.cnf` or `my.ini`); you cannot change values dynamically. The default value for these parameters is 4 and permissible values range from 1-64.

The purpose of these configuration options to make InnoDB more scalable on high end systems. Each background thread can handle up to 256 pending I/O requests. A major source of background I/O is read-ahead requests. InnoDB tries to balance the load of incoming requests in such way that most background threads share work equally. InnoDB also attempts to allocate read requests from the same extent to the same thread, to increase the chances of coalescing the requests. If you have a high end I/O subsystem and you see more than 64 × `innodb_read_io_threads` pending read requests in `SHOW ENGINE INNODB STATUS` output, you might improve performance by increasing the value of `innodb_read_io_threads`.

On Linux systems, InnoDB uses the asynchronous I/O subsystem by default to perform read-ahead and write requests for data file pages. This behavior is controlled by the `innodb_use_native_aio` configuration option, which applies to Linux systems only and is enabled by default. On other Unix-like systems, InnoDB uses synchronous I/O only. Historically, InnoDB only used asynchronous I/O on Windows systems. Using the asynchronous I/O subsystem on Linux requires the `libaio` library.

With synchronous I/O, query threads queue I/O requests, and InnoDB background threads retrieve the queued requests one at a time, issuing a synchronous I/O call for each. When an I/O request is completed and the I/O call returns, the InnoDB background thread that is handling the request calls an I/O completion routine and returns to process the next request. The number of requests that can be processed in parallel is \( n \), where \( n \) is the number of InnoDB background threads. The number of InnoDB background threads is controlled by `innodb_read_io_threads` and `innodb_write_io_threads`. See Section 14.8.6, “Configuring the Number of Background InnoDB I/O Threads”.

For more information about InnoDB I/O performance, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

### 14.8.7 Using Asynchronous I/O on Linux

InnoDB uses the asynchronous I/O subsystem (native AIO) on Linux to perform read-ahead and write requests for data file pages. This behavior is controlled by the `innodb_use_native_aio` configuration option, which applies to Linux systems only and is enabled by default. On other Unix-like systems, InnoDB uses synchronous I/O only. Historically, InnoDB only used asynchronous I/O on Windows systems. Using the asynchronous I/O subsystem on Linux requires the `libaio` library.
Configuring InnoDB I/O Capacity

With native AIO, query threads dispatch I/O requests directly to the operating system, thereby removing the limit imposed by the number of background threads. InnoDB background threads wait for I/O events to signal completed requests. When a request is completed, a background thread calls an I/O completion routine and resumes waiting for I/O events.

The advantage of native AIO is scalability for heavily I/O-bound systems that typically show many pending reads/writes in `SHOW ENGINE INNODB STATUS\G` output. The increase in parallel processing when using native AIO means that the type of I/O scheduler or properties of the disk array controller have a greater influence on I/O performance.

A potential disadvantage of native AIO for heavily I/O-bound systems is lack of control over the number of I/O write requests dispatched to the operating system at once. Too many I/O write requests dispatched to the operating system for parallel processing could, in some cases, result in I/O read starvation, depending on the amount of I/O activity and system capabilities.

If a problem with the asynchronous I/O subsystem in the OS prevents InnoDB from starting, you can start the server with `innodb_use_native_aio=0`. This option may also be disabled automatically during startup if InnoDB detects a potential problem such as a combination of `tmpdir` location, `tmpfs` file system, and Linux kernel that does not support asynchronous I/O on `tmpfs`.

14.8.8 Configuring InnoDB I/O Capacity

The InnoDB master thread and other threads perform various tasks in the background, most of which are I/O related, such as flushing dirty pages from the buffer pool and writing changes from the change buffer to the appropriate secondary indexes. InnoDB attempts to perform these tasks in a way that does not adversely affect the normal working of the server. It tries to estimate the available I/O bandwidth and tune its activities to take advantage of available capacity.

The `innodb_io_capacity` variable defines the overall I/O capacity available to InnoDB. It should be set to approximately the number of I/O operations that the system can perform per second (IOPS). When `innodb_io_capacity` is set, InnoDB estimates the I/O bandwidth available for background tasks based on the set value.

You can set `innodb_io_capacity` to a value of 100 or greater. The default value is 200. Typically, values around 100 are appropriate for consumer-level storage devices, such as hard drives up to 7200 RPMs. Faster hard drives, RAID configurations, and solid state drives (SSDs) benefit from higher values.

Ideally, keep the setting as low as practical, but not so low that background activities fall behind. If the value is too high, data is removed from the buffer pool and change buffer too quickly for caching to provide a significant benefit. For busy systems capable of higher I/O rates, you can set a higher value to help the server handle the background maintenance work associated with a high rate of row changes. Generally, you can increase the value as a function of the number of drives used for InnoDB I/O. For example, you can increase the value on systems that use multiple disks or SSDs.

The default setting of 200 is generally sufficient for a lower-end SSD. For a higher-end, bus-attached SSD, consider a higher setting such as 1000, for example. For systems with individual 5400 RPM or 7200 RPM drives, you might lower the value to 100, which represents an estimated proportion of the I/O operations per second (IOPS) available to older-generation disk drives that can perform about 100 IOPS.

Although you can specify a high value such as a million, in practice such large values have little benefit. Generally, a value higher than 20000 is not recommended unless you are certain that lower values are insufficient for your workload.

Consider write workload when tuning `innodb_io_capacity`. Systems with large write workloads are likely to benefit from a higher setting. A lower setting may be sufficient for systems with a small write workload.

The `innodb_io_capacity` setting is not a per buffer pool instance setting. Available I/O capacity is distributed equally among buffer pool instances for flushing activities.
You can set the `innodb_io_capacity` value in the MySQL option file (`my.cnf` or `my.ini`) or modify it at runtime using a `SET GLOBAL` statement, which requires privileges sufficient to set global system variables. See Section 5.1.8.1, “System Variable Privileges”.

### Configuring an I/O Capacity Maximum

If flushing activity falls behind, InnoDB can flush more aggressively, at a higher rate of I/O operations per second (IOPS) than defined by the `innodb_io_capacity` variable. The `innodb_io_capacity_max` variable defines a maximum number of IOPS performed by InnoDB background tasks in such situations.

If you specify an `innodb_io_capacity` setting at startup but do not specify a value for `innodb_io_capacity_max`, `innodb_io_capacity_max` defaults to twice the value of `innodb_io_capacity`, with a minimum value of 2000.

When configuring `innodb_io_capacity_max`, twice the `innodb_io_capacity` is often a good starting point. The default value of 2000 is intended for workloads that use an SSD or more than one regular disk drive. A setting of 2000 is likely too high for workloads that do not use SSDs or multiple disk drives, and could allow too much flushing. For a single regular disk drive, a setting between 200 and 400 is recommended. For a high-end, bus-attached SSD, consider a higher setting such as 2500. As with the `innodb_io_capacity` setting, keep the setting as low as practical, but not so low that InnoDB cannot sufficiently extend rate of IOPS beyond the `innodb_io_capacity` setting.

Consider write workload when tuning `innodb_io_capacity_max`. Systems with large write workloads may benefit from a higher setting. A lower setting may be sufficient for systems with a small write workload.

`innodb_io_capacity_max` cannot be set to a value lower than the `innodb_io_capacity` value.

Setting `innodb_io_capacity_max` to DEFAULT using a `SET` statement (`SET GLOBAL innodb_io_capacity_max=DEFAULT`) sets `innodb_io_capacity_max` to the maximum value.

The `innodb_io_capacity_max` limit applies to all buffer pool instances. It is not a per buffer pool instance setting.

### 14.8.9 Configuring Spin Lock Polling

InnoDB mutexes and rw-locks are typically reserved for short intervals. On a multi-core system, it can be more efficient for a thread to continuously check if it can acquire a mutex or rw-lock for a period of time before it sleeps. If the mutex or rw-lock becomes available during this period, the thread can continue immediately, in the same time slice. However, too-frequent polling of a shared object such as a mutex or rw-lock by multiple threads can cause “cache ping pong”, which results in processors invalidating portions of each other’s cache. InnoDB minimizes this issue by forcing a random delay between polls to desynchronize polling activity. The random delay is implemented as a spin-wait loop.

The duration of a spin-wait loop is determined by the number of PAUSE instructions that occur in the loop. That number is generated by randomly selecting an integer ranging from 0 up to but not including the `innodb_spin_wait_delay` value, and multiplying that value by 50. For example, an integer is randomly selected from the following range for an `innodb_spin_wait_delay` setting of 6:

\{0,1,2,3,4,5\}

The selected integer is multiplied by 50, resulting in one of six possible PAUSE instruction values:

\{0,50,100,150,200,250\}

For that set of values, 250 is the maximum number of PAUSE instructions that can occur in a spin-wait loop. An `innodb_spin_wait_delay` setting of 5 results in a set of five possible values \{0,50,100,150,200\}, where 200 is the maximum number of PAUSE instructions, and so on. In this way, the `innodb_spin_wait_delay` setting controls the maximum delay between spin lock polls.
The duration of the delay loop depends on the C compiler and the target processor. In the 100MHz Pentium era, an `innodb_spin_wait_delay` unit was calibrated to be equivalent to one microsecond. That time equivalence did not hold, but PAUSE instruction duration has remained fairly constant in terms of processor cycles relative to other CPU instructions on most processor architectures.

On a system where all processor cores share a fast cache memory, you might reduce the maximum delay or disable the busy loop altogether by setting `innodb_spin_wait_delay=0`. On a system with multiple processor chips, the effect of cache invalidation can be more significant and you might increase the maximum delay.

The `innodb-spin_wait_delay` variable is dynamic. It can be specified in a MySQL option file or modified at runtime using a `SET GLOBAL` statement. Runtime modification requires privileges sufficient to set global system variables. See Section 5.1.8.1, “System Variable Privileges”.

### 14.8.10 Purge Configuration

**InnoDB** does not physically remove a row from the database immediately when you delete it with an SQL statement. A row and its index records are only physically removed when **InnoDB** discards the undo log record written for the deletion. This removal operation, which only occurs after the row is no longer required for multi-version concurrency control (MVCC) or rollback, is called a purge.

Purge runs on a periodic schedule. It parses and processes undo log pages from the history list, which is a list of undo log pages for committed transactions that is maintained by the **InnoDB** transaction system. Purge frees the undo log pages from the history list after processing them.

#### Configuring Purge Threads

Purge operations are performed in the background by one or more purge threads. The number of purge threads is controlled by the `innodb_purge_threads` variable. The default value is 1. If DML action is concentrated on a single table or a few tables, keep the setting low so that the threads do not contend with each other for access to the busy tables. If DML operations are spread across many tables, increase the setting. The maximum number of purge threads is 32.

The `innodb_purge_threads` setting is the maximum number of purge threads permitted. The purge system automatically adjusts the number of purge threads as necessary.

#### Configuring Purge Batch Size

The `innodb_purge_batch_size` variable defines the number of undo log pages that purge parses and processes in one batch from the history list. The default value is 300. In a multithreaded purge configuration, the coordinator purge thread divides `innodb_purge_batch_size` by `innodb_purge_threads` and assigns that number of pages to each purge thread.

The purge system also frees the undo log pages that are no longer required. It does so every 128 iterations through the undo logs. In addition to defining the number of undo log pages parsed and processed in a batch, the `innodb_purge_batch_size` variable defines the number of undo log pages that purge frees every 128 iterations through the undo logs.

The `innodb_purge_batch_size` variable is intended for advanced performance tuning and experimentation. Most users need not change `innodb_purge_batch_size` from its default value.

#### Configuring the Maximum Purge Lag

The `innodb_max_purge_lag` variable defines the desired maximum purge lag. When the purge lag exceeds the `innodb_max_purge_lag` threshold, a delay is imposed on `INSERT`, `UPDATE`, and `DELETE` operations to allow time for purge operations to catch up. The default value is 0, which means there is no maximum purge lag and no delay.

The InnoDB transaction system maintains a list of transactions that have index records delete-marked by `UPDATE` or `DELETE` operations. The length of the list is the purge lag. The purge lag delay is calculated by the following formula, which results in a minimum delay of 5000 microseconds:
Configuring Optimizer Statistics for InnoDB

The delay is calculated at the beginning of a purge batch.

A typical `innodb_max_purge_lag` setting for a problematic workload might be 1000000 (1 million), assuming that transactions are small, only 100 bytes in size, and it is permissible to have 100MB of unpurged table rows.

The purge lag is presented as the `History list length` value in the `TRANSACTIONS` section of `SHOW ENGINE INNODB STATUS` output.

```sql
mysql> SHOW ENGINE INNODB STATUS;
...
------------
TRANSACTIONS
------------
Trx id counter 0 290328385
Purge done for trx's n:o < 0 290315608 undo n:o < 0 17
History list length 20
```

The `History list length` is typically a low value, usually less than a few thousand, but a write-heavy workload or long running transactions can cause it to increase, even for transactions that are read only. The reason that a long running transaction can cause the `History list length` to increase is that under a consistent read transaction isolation level such as `REPEATABLE READ`, a transaction must return the same result as when the read view for that transaction was created. Consequently, the InnoDB multi-version concurrency control (MVCC) system must keep a copy of the data in the undo log until all transactions that depend on that data have completed. The following are examples of long running transactions that could cause the `History list length` to increase:

- A `mysqldump` operation that uses the `--single-transaction` option while there is a significant amount of concurrent DML.
- Running a `SELECT` query after disabling `autocommit`, and forgetting to issue an explicit `COMMIT` or `ROLLBACK`.

To prevent excessive delays in extreme situations where the purge lag becomes huge, you can limit the delay by setting the `innodb_max_purge_lag_delay` variable. The `innodb_max_purge_lag_delay` variable specifies the maximum delay in microseconds for the delay imposed when the `innodb_max_purge_lag` threshold is exceeded. The specified `innodb_max_purge_lag_delay` value is an upper limit on the delay period calculated by the `innodb_max_purge_lag` formula.

### 14.8.11 Configuring Optimizer Statistics for InnoDB

This section describes how to configure persistent and non-persistent optimizer statistics for InnoDB tables. Persistent optimizer statistics were introduced in MySQL 5.6.2 and were made the default in MySQL 5.6.6 (`innodb_stats_persistent=ON`).

Persistent optimizer statistics are persisted across server restarts, allowing for greater plan stability and more consistent query performance. Persistent optimizer statistics also provide control and flexibility with these additional benefits:

- You can use the `innodb_stats_auto_recalc` configuration option to control whether statistics are updated automatically after substantial changes to a table.
- You can use the `STATS_PERSISTENT, STATS_AUTO_RECALC, and STATS_SAMPLE_PAGES` clauses with `CREATE TABLE` and `ALTER TABLE` statements to configure optimizer statistics for individual tables.
- You can query optimizer statistics data in the `mysql.innodb_table_stats` and `mysql.innodb_index_stats` tables.
- You can view the `last_update` column of the `mysql.innodb_table_stats` and `mysql.innodb_index_stats` tables to see when statistics were last updated.
• You can manually modify the `mysql.innodb_table_stats` and `mysql.innodb_index_stats` tables to force a specific query optimization plan or to test alternative plans without modifying the database.

Non-persistent optimizer statistics are cleared on each server restart and after some other operations, and recomputed on the next table access. As a result, different estimates could be produced when recomputing statistics, leading to different choices in execution plans and variations in query performance.

This section also provides information about estimating `ANALYZE TABLE` complexity, which may be useful when attempting to achieve a balance between accurate statistics and `ANALYZE TABLE` execution time.

### 14.8.11.1 Configuring Persistent Optimizer Statistics Parameters

The persistent optimizer statistics feature improves plan stability by storing statistics to disk and making them persistent across server restarts so that the optimizer is more likely to make consistent choices each time for a given query.

Optimizer statistics are persisted to disk when `innodb_stats_persistent=ON` or when individual tables are defined with `STATS_PERSISTENT=1`. `innodb_stats_persistent` is enabled by default as of MySQL 5.6.6.

Formerly, optimizer statistics were cleared when restarting the server and after some other types of operations, and recomputed on the next table access. Consequently, different estimates could be produced when recalculating statistics leading to different choices in query execution plans and variation in query performance.

Persistent statistics are stored in the `mysql.innodb_table_stats` and `mysql.innodb_index_stats` tables. See InnoDB Persistent Statistics Tables.

If you prefer not to persist optimizer statistics to disk, see Section 14.8.11.2, “Configuring Non-Persistent Optimizer Statistics Parameters”

#### Configuring Automatic Statistics Calculation for Persistent Optimizer Statistics

The `innodb_stats_auto_recalc` variable, which is enabled by default, controls whether statistics are calculated automatically when a table undergoes changes to more than 10% of its rows. You can also configure automatic statistics recalculation for individual tables by specifying the `STATS_AUTO_RECALC` clause when creating or altering a table.

Because of the asynchronous nature of automatic statistics recalculation, which occurs in the background, statistics may not be recalculated instantly after running a DML operation that affects more than 10% of a table, even when `innodb_stats_auto_recalc` is enabled. Statistics recalculation can be delayed by few seconds in some cases. If up-to-date statistics are required immediately, run `ANALYZE TABLE` to initiate a synchronous (foreground) recalculation of statistics.

If `innodb_stats_auto_recalc` is disabled, you can ensure the accuracy of optimizer statistics by executing the `ANALYZE TABLE` statement after making substantial changes to indexed columns. You might also consider adding `ANALYZE TABLE` to setup scripts that you run after loading data, and running `ANALYZE TABLE` on a schedule at times of low activity.

When an index is added to an existing table, or when a column is added or dropped, index statistics are calculated and added to the `innodb_index_stats` table regardless of the value of `innodb_stats_auto_recalc`.

#### Configuring Optimizer Statistics Parameters for Individual Tables

`innodb_stats_persistent`, `innodb_stats_auto_recalc`, and `innodb_stats_persistent_sample_pages` are global variables. To override these system-wide settings and configure optimizer statistics parameters for individual tables, you can define
STATS_PERSISTENT, STATS_AUTO_RECALC, and STATS_SAMPLE_PAGES clauses in CREATE TABLE or ALTER TABLE statements.

- **STATS_PERSISTENT** specifies whether to enable persistent statistics for an InnoDB table. The value **DEFAULT** causes the persistent statistics setting for the table to be determined by the **innodb_stats_persistent** setting. A value of 1 enables persistent statistics for the table, while a value of 0 disables the feature. After enabling persistent statistics for an individual table, use **ANALYZE TABLE** to calculate statistics after table data is loaded.

- **STATS_AUTO_RECALC** specifies whether to automatically recalculate persistent statistics. The value **DEFAULT** causes the persistent statistics setting for the table to be determined by the **innodb_stats_auto_recalc** setting. A value of 1 causes statistics to be recalculated when 10% of table data has changed. A value of 0 prevents automatic recalculation for the table. When using a value of 0, use **ANALYZE TABLE** to recalculate statistics after making substantial changes to the table.

- **STATS_SAMPLE_PAGES** specifies the number of index pages to sample when cardinality and other statistics are calculated for an indexed column, by an **ANALYZE TABLE** operation, for example.

All three clauses are specified in the following CREATE TABLE example:

```sql
CREATE TABLE `t1` (
  `id` int(8) NOT NULL auto_increment,
  `data` varchar(255),
  `date` datetime,
  PRIMARY KEY  (`id`),
  INDEX `DATE_IX` (`date`)
) ENGINE=InnoDB,
STATS_PERSISTENT=1,
STATS_AUTO_RECALC=1,
STATS_SAMPLE_PAGES=25;
```

**Configuring the Number of Sampled Pages for InnoDB Optimizer Statistics**

The optimizer uses estimated statistics about key distributions to choose the indexes for an execution plan, based on the relative selectivity of the index. Operations such as **ANALYZE TABLE** cause InnoDB to sample random pages from each index on a table to estimate the cardinality of the index. This sampling technique is known as a random dive.

The **innodb_stats_persistent_sample_pages** controls the number of sampled pages. You can adjust the setting at runtime to manage the quality of statistics estimates used by the optimizer. The default value is 20. Consider modifying the setting when encountering the following issues:

1. **Statistics are not accurate enough and the optimizer chooses suboptimal plans**, as shown in **EXPLAIN** output. You can check the accuracy of statistics by comparing the actual cardinality of an index (determined by running **SELECT DISTINCT** on the index columns) with the estimates in the **mysql.innodb_index_stats** table.

   If it is determined that statistics are not accurate enough, the value of **innodb_stats_persistent_sample_pages** should be increased until the statistics estimates are sufficiently accurate. Increasing **innodb_stats_persistent_sample_pages** too much, however, could cause **ANALYZE TABLE** to run slowly.

2. **ANALYZE TABLE is too slow**. In this case **innodb_stats_persistent_sample_pages** should be decreased until **ANALYZE TABLE** execution time is acceptable. Decreasing the value too much, however, could lead to the first problem of inaccurate statistics and suboptimal query execution plans.

   If a balance cannot be achieved between accurate statistics and **ANALYZE TABLE** execution time, consider decreasing the number of indexed columns in the table or limiting the number of partitions to reduce **ANALYZE TABLE** complexity. The number of columns in the table’s primary key is also important to consider, as primary key columns are appended to each nonunique index.
Configuring Optimizer Statistics for InnoDB

For related information, see Section 14.8.11.3, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”.

Including Delete-marked Records in Persistent Statistics Calculations

By default, InnoDB reads uncommitted data when calculating statistics. In the case of an uncommitted transaction that deletes rows from a table, delete-marked records are excluded when calculating row estimates and index statistics, which can lead to non-optimal execution plans for other transactions that are operating on the table concurrently using a transaction isolation level other than READ UNCOMMITTED. To avoid this scenario, `innodb_stats_include_delete_marked` can be enabled to ensure that delete-marked records are included when calculating persistent optimizer statistics.

When `innodb_stats_include_delete_marked` is enabled, `ANALYZE TABLE` considers delete-marked records when recalculating statistics.

`innodb_stats_include_delete_marked` is a global setting that affects all InnoDB tables, and it is only applicable to persistent optimizer statistics.

`innodb_stats_include_delete_marked` was introduced in MySQL 5.6.34.

InnoDB Persistent Statistics Tables

The persistent statistics feature relies on the internally managed tables in the `mysql` database, named `innodb_table_stats` and `innodb_index_stats`. These tables are set up automatically in all install, upgrade, and build-from-source procedures.

<table>
<thead>
<tr>
<th>Table 14.3 Columns of innodb_table_stats</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Column name</strong></td>
</tr>
<tr>
<td>database_name</td>
</tr>
<tr>
<td>table_name</td>
</tr>
<tr>
<td>last_update</td>
</tr>
<tr>
<td>n_rows</td>
</tr>
<tr>
<td>clustered_index_size</td>
</tr>
<tr>
<td>sum_of_other_index_sizes</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Table 14.4 Columns of innodb_index_stats</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Column name</strong></td>
</tr>
<tr>
<td>database_name</td>
</tr>
<tr>
<td>table_name</td>
</tr>
<tr>
<td>index_name</td>
</tr>
<tr>
<td>last_update</td>
</tr>
<tr>
<td>stat_name</td>
</tr>
<tr>
<td>stat_value</td>
</tr>
<tr>
<td>sample_size</td>
</tr>
<tr>
<td>stat_description</td>
</tr>
</tbody>
</table>

The `innodb_table_stats` and `innodb_index_stats` tables include a `last_update` column that shows when index statistics were last updated:

```sql
mysql> SELECT * FROM innodb_table_stats \G
```
The `innodb_table_stats` and `innodb_index_stats` tables can be updated manually, which makes it possible to force a specific query optimization plan or test alternative plans without modifying the database. If you manually update statistics, use the `FLUSH TABLE tbl_name` statement to load the updated statistics.

Persistent statistics are considered local information, because they relate to the server instance. The `innodb_table_stats` and `innodb_index_stats` tables are therefore not replicated when automatic statistics recalculation takes place. If you run `ANALYZE TABLE` to initiate a synchronous recalculation of statistics, this statement is replicated (unless you suppressed logging for it), and recalculation takes place on the replicas.

**InnoDB Persistent Statistics Tables Example**

The `innodb_table_stats` table contains one row for each table. The following example demonstrates the type of data collected.

Table `t1` contains a primary index (columns `a`, `b`) secondary index (columns `c`, `d`), and unique index (columns `e`, `f`):

```sql
CREATE TABLE t1 (
    a INT, b INT, c INT, d INT, e INT, f INT,
    PRIMARY KEY (a, b), KEY i1 (c, d), UNIQUE KEY i2uniq (e, f)
) ENGINE=INNODB;
```

After inserting five rows of sample data, table `t1` appears as follows:

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>c</th>
<th>d</th>
<th>e</th>
<th>f</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>10</td>
<td>11</td>
<td>100</td>
<td>101</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>10</td>
<td>11</td>
<td>200</td>
<td>102</td>
</tr>
<tr>
<td>1</td>
<td>3</td>
<td>10</td>
<td>11</td>
<td>100</td>
<td>103</td>
</tr>
<tr>
<td>1</td>
<td>4</td>
<td>10</td>
<td>12</td>
<td>200</td>
<td>104</td>
</tr>
<tr>
<td>1</td>
<td>5</td>
<td>10</td>
<td>12</td>
<td>100</td>
<td>105</td>
</tr>
</tbody>
</table>

To immediately update statistics, run `ANALYZE TABLE` (if `innodb_stats_auto_recalc` is enabled, statistics are updated automatically within a few seconds assuming that the 10% threshold for changed table rows is reached):
Table statistics for table `t1` show the last time InnoDB updated the table statistics (2014-03-14 14:36:34), the number of rows in the table (5), the clustered index size (1 page), and the combined size of the other indexes (2 pages).

```sql
mysql> SELECT * FROM mysql.innodb_table_stats WHERE table_name like 't1'\G
*************************** 1. row ***************************
database_name: test
table_name: t1
last_update: 2014-03-14 14:36:34
n_rows: 5
clustered_index_size: 1
sum_of_other_index_sizes: 2
```

The `innodb_index_stats` table contains multiple rows for each index. Each row in the `innodb_index_stats` table provides data related to a particular index statistic which is named in the `stat_name` column and described in the `stat_description` column. For example:

```sql
mysql> SELECT index_name, stat_name, stat_value, stat_description
FROM mysql.innodb_index_stats WHERE table_name like 't1';
+------------+--------------+------------+-----------------------------------+
<table>
<thead>
<tr>
<th>index_name</th>
<th>stat_name</th>
<th>stat_value</th>
<th>stat_description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PRIMARY</td>
<td>n_diff_pfx01</td>
<td>1</td>
<td>a</td>
</tr>
<tr>
<td>PRIMARY</td>
<td>n_diff_pfx02</td>
<td>5</td>
<td>a,b</td>
</tr>
<tr>
<td>PRIMARY</td>
<td>n_leaf_pages</td>
<td>1</td>
<td>Number of leaf pages in the index</td>
</tr>
<tr>
<td>PRIMARY</td>
<td>size</td>
<td>1</td>
<td>Number of pages in the index</td>
</tr>
<tr>
<td>i1</td>
<td>n_diff_pfx01</td>
<td>1</td>
<td>c</td>
</tr>
<tr>
<td>i1</td>
<td>n_diff_pfx02</td>
<td>2</td>
<td>c,d</td>
</tr>
<tr>
<td>i1</td>
<td>n_diff_pfx03</td>
<td>2</td>
<td>c,d,a</td>
</tr>
<tr>
<td>i1</td>
<td>n_diff_pfx04</td>
<td>5</td>
<td>c,d,a,b</td>
</tr>
<tr>
<td>i1</td>
<td>n_leaf_pages</td>
<td>1</td>
<td>Number of leaf pages in the index</td>
</tr>
<tr>
<td>i1</td>
<td>size</td>
<td>1</td>
<td>Number of pages in the index</td>
</tr>
<tr>
<td>i2uniq</td>
<td>n_diff_pfx01</td>
<td>2</td>
<td>e</td>
</tr>
<tr>
<td>i2uniq</td>
<td>n_diff_pfx02</td>
<td>5</td>
<td>e,f</td>
</tr>
<tr>
<td>i2uniq</td>
<td>n_leaf_pages</td>
<td>1</td>
<td>Number of leaf pages in the index</td>
</tr>
<tr>
<td>i2uniq</td>
<td>size</td>
<td>1</td>
<td>Number of pages in the index</td>
</tr>
</tbody>
</table>
+------------+--------------+------------+-----------------------------------+
```

The `stat_name` column shows the following types of statistics:

- **size**: Where `stat_name=size`, the `stat_value` column displays the total number of pages in the index.

- **n_leaf_pages**: Where `stat_name=n_leaf_pages`, the `stat_value` column displays the number of leaf pages in the index.

- **n_diff_pfxNN**: Where `stat_name=n_diff_pfx01`, the `stat_value` column displays the number of distinct values in the first column of the index. Where `stat_name=n_diff_pfx02`, the `stat_value` column displays the number of distinct values in the first two columns of the index, and so on. Where `stat_name=n_diff_pfxNN`, the `stat_description` column shows a comma separated list of the index columns that are counted.

To further illustrate the `n_diff_pfxNN` statistic, which provides cardinality data, consider once again the `t1` table example that was introduced previously. As shown below, the `t1` table is created with a primary index (columns `a`, `b`), a secondary index (columns `c`, `d`), and a unique index (columns `e`, `f`):

```sql
CREATE TABLE t1 (a INT, b INT, c INT, d INT, e INT, f INT,
PRIMARY KEY (a, b), KEY i1 (c, d), UNIQUE KEY i2uniq (e, f)) ENGINE=INNODB;
```

After inserting five rows of sample data, table `t1` appears as follows:

```sql
mysql> SELECT * FROM t1;
+---+---+------+------+------+------+
| a | b | c    | d    | e    | f    |
+---+---+------+------+------+------+
| 1 | 2 | 3    | 4    | 5    | 6    |
| 1 | 2 | 3    | 4    | 5    | 6    |
| 1 | 2 | 3    | 4    | 5    | 6    |
| 1 | 2 | 3    | 4    | 5    | 6    |
| 1 | 2 | 3    | 4    | 5    | 6    |
```
When you query the `index_name`, `stat_name`, `stat_value`, and `stat_description`, where `stat_name` LIKE 'n_diff%', the following result set is returned:

```sql
mysql> SELECT index_name, stat_name, stat_value, stat_description
FROM mysql.innodb_index_stats
WHERE table_name like 't1' AND stat_name LIKE 'n_diff%';
```

<table>
<thead>
<tr>
<th>index_name</th>
<th>stat_name</th>
<th>stat_value</th>
<th>stat_description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PRIMARY</td>
<td>n_diff_pfx01</td>
<td>1</td>
<td>a</td>
</tr>
<tr>
<td>PRIMARY</td>
<td>n_diff_pfx02</td>
<td>5</td>
<td>a,b</td>
</tr>
<tr>
<td>i1</td>
<td>n_diff_pfx01</td>
<td>1</td>
<td>c</td>
</tr>
<tr>
<td>i1</td>
<td>n_diff_pfx02</td>
<td>2</td>
<td>c,d</td>
</tr>
<tr>
<td>i1</td>
<td>n_diff_pfx03</td>
<td>2</td>
<td>c,d,a</td>
</tr>
<tr>
<td>i1</td>
<td>n_diff_pfx04</td>
<td>5</td>
<td>c,d,a,b</td>
</tr>
<tr>
<td>i2uniq</td>
<td>n_diff_pfx01</td>
<td>2</td>
<td>e</td>
</tr>
<tr>
<td>i2uniq</td>
<td>n_diff_pfx02</td>
<td>5</td>
<td>e,f</td>
</tr>
</tbody>
</table>
```

For the PRIMARY index, there are two n_diff% rows. The number of rows is equal to the number of columns in the index.

**Note**

For nonunique indexes, InnoDB appends the columns of the primary key.

- Where `index_name`=PRIMARY and `stat_name`=n_diff_pfx01, the `stat_value` is 1, which indicates that there is a single distinct value in the first column of the index (column a). The number of distinct values in column a is confirmed by viewing the data in column a in table t1, in which there is a single distinct value (1). The counted column (a) is shown in the `stat_description` column of the result set.

- Where `index_name`=PRIMARY and `stat_name`=n_diff_pfx02, the `stat_value` is 5, which indicates that there are five distinct values in the two columns of the index (a, b). The number of distinct values in columns a and b is confirmed by viewing the data in columns a and b in table t1, in which there are five distinct values: (1, 1), (1, 2), (1, 3), (1, 4) and (1, 5). The counted columns (a, b) are shown in the `stat_description` column of the result set.

For the secondary index (i1), there are four n_diff% rows. Only two columns are defined for the secondary index (c, d) but there are four n_diff% rows for the secondary index because InnoDB suffixes all nonunique indexes with the primary key. As a result, there are four n_diff% rows instead of two to account for the both the secondary index columns (c, d) and the primary key columns (a, b).

- Where `index_name`=i1 and `stat_name`=n_diff_pfx01, the `stat_value` is 1, which indicates that there is a single distinct value in the first column of the index (column c). The number of distinct values in column c is confirmed by viewing the data in column c in table t1, in which there is a single distinct value: (10). The counted column (c) is shown in the `stat_description` column of the result set.

- Where `index_name`=i1 and `stat_name`=n_diff_pfx02, the `stat_value` is 2, which indicates that there are two distinct values in the first two columns of the index (c, d). The number of distinct values in columns c and d is confirmed by viewing the data in columns c and d in table t1, in which there are two distinct values: (10, 11) and (10, 12). The counted columns (c, d) are shown in the `stat_description` column of the result set.

- Where `index_name`=i1 and `stat_name`=n_diff_pfx03, the `stat_value` is 2, which indicates that there are two distinct values in the first three columns of the index (c, d, a). The number of
distinct values in columns \( c, d, \) and \( a \) is confirmed by viewing the data in column \( c, d, \) and \( a \) in table \( t1 \), in which there are two distinct values: \((10, 11, 1)\) and \((10, 12, 1)\). The counted columns \((c, d, a)\) are shown in the \texttt{stat_description} column of the result set.

- Where \texttt{index_name=i1} and \texttt{stat_name=n\_diff\_pfx04}, the \texttt{stat_value} is 5, which indicates that there are five distinct values in the four columns of the index \((c, d, a, b)\). The number of distinct values in columns \( c, d, a, \) and \( b \) is confirmed by viewing the data in columns \( c, d, a, \) and \( b \) in table \( t1 \), in which there are five distinct values: \((10, 11, 1, 1)\), \((10, 11, 1, 2)\), \((10, 11, 1, 3)\), \((10, 12, 1, 4)\), and \((10, 12, 1, 5)\). The counted columns \((c, d, a, b)\) are shown in the \texttt{stat_description} column of the result set.

For the unique index \((i2uniq)\), there are two \texttt{\text{n\_diff}\%} rows.

- Where \texttt{index_name=i2uniq} and \texttt{stat_name=n\_diff\_pfx01}, the \texttt{stat_value} is 2, which indicates that there are two distinct values in the first column of the index (column \( e \)). The number of distinct values in column \( e \) is confirmed by viewing the data in column \( e \) in table \( t1 \), in which there are two distinct values: \((100)\) and \((200)\). The counted column \((e)\) is shown in the \texttt{stat_description} column of the result set.

- Where \texttt{index_name=i2uniq} and \texttt{stat_name=n\_diff\_pfx02}, the \texttt{stat_value} is 5, which indicates that there are five distinct values in the two columns of the index \((e, f)\). The number of distinct values in columns \( e \) and \( f \) is confirmed by viewing the data in columns \( e \) and \( f \) in table \( t1 \), in which there are five distinct values: \((100,101)\), \((200,102)\), \((100,103)\), \((200,104)\), and \((100,105)\). The counted columns \((e, f)\) are shown in the \texttt{stat_description} column of the result set.

### Retrieving Index Size Using the innodb\_index\_stats Table

You can retrieve the index size for tables, partitions, or subpartitions can using the \texttt{innodb\_index\_stats} table. In the following example, index sizes are retrieved for table \( t1 \). For a definition of table \( t1 \) and corresponding index statistics, see InnoDB Persistent Statistics Tables Example.

```sql
mysql> SELECT SUM(stat_value) pages, index_name,
SUM(stat_value)*@@innodb_page_size size
FROM mysql.innodb_index_stats WHERE table_name='t1'
AND stat_name = 'size' GROUP BY index_name;
```

<table>
<thead>
<tr>
<th>pages</th>
<th>index_name</th>
<th>size</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>PRIMARY</td>
<td>16384</td>
</tr>
<tr>
<td>1</td>
<td>i1</td>
<td>16384</td>
</tr>
<tr>
<td>1</td>
<td>i2uniq</td>
<td>16384</td>
</tr>
</tbody>
</table>

For partitions or subpartitions, you can use the same query with a modified \texttt{WHERE} clause to retrieve index sizes. For example, the following query retrieves index sizes for partitions of table \( t1 \):

```sql
mysql> SELECT SUM(stat_value) pages, index_name,
SUM(stat_value)*@@innodb_page_size size
FROM mysql.innodb_index_stats WHERE table_name like 't1#P%'
AND stat_name = 'size' GROUP BY index_name;
```

### 14.8.11.2 Configuring Non-Persistent Optimizer Statistics Parameters

This section describes how to configure non-persistent optimizer statistics. Optimizer statistics are not persisted to disk when \texttt{innodb\_stats\_persistent=OFF} or when individual tables are created or altered with \texttt{STATS\_PERSISTENT=0}. Instead, statistics are stored in memory, and are lost when the server is shut down. Statistics are also updated periodically by certain operations and under certain conditions.

As of MySQL 5.6.6, optimizer statistics are persisted to disk by default, enabled by the \texttt{innodb\_stats\_persistent} configuration option. For information about persistent optimizer statistics, see Section 14.8.11.1, “Configuring Persistent Optimizer Statistics Parameters”.

Optimizer Statistics Updates

Non-persistent optimizer statistics are updated when:

- Running `ANALYZE TABLE`.
- Running `SHOW TABLE STATUS`, `SHOW INDEX`, or querying the `INFORMATION_SCHEMA.TABLES` or `INFORMATION_SCHEMA.STATISTICS` tables with the `innodb_stats_on_metadata` option enabled.

The default setting for `innodb_stats_on_metadata` was changed to `OFF` when persistent optimizer statistics were enabled by default in MySQL 5.6.6. Enabling `innodb_stats_on_metadata` may reduce access speed for schemas that have a large number of tables or indexes, and reduce stability of execution plans for queries that involve InnoDB tables. `innodb_stats_on_metadata` is configured globally using a `SET` statement.

```
SET GLOBAL innodb_stats_on_metadata=ON
```

Note: `innodb_stats_on_metadata` only applies when optimizer statistics are configured to be non-persistent (when `innodb_stats_persistent` is disabled).

- Starting a `mysql` client with the `--auto-rehash` option enabled, which is the default. The `auto-rehash` option causes all InnoDB tables to be opened, and the open table operations cause statistics to be recalculated.

To improve the start up time of the `mysql` client and to updating statistics, you can turn off `auto-rehash` using the `--disable-auto-rehash` option. The `auto-rehash` feature enables automatic name completion of database, table, and column names for interactive users.

- A table is first opened.
- InnoDB detects that 1 / 16 of table has been modified since the last time statistics were updated.

Configuring the Number of Sampled Pages

The MySQL query optimizer uses estimated statistics about key distributions to choose the indexes for an execution plan, based on the relative `selectivity` of the index. When InnoDB updates optimizer statistics, it samples random pages from each index on a table to estimate the `cardinality` of the index. (This technique is known as `random dives`.)

To give you control over the quality of the statistics estimate (and thus better information for the query optimizer), you can change the number of sampled pages using the parameter `innodb_stats_transient_sample_pages`. The default number of sampled pages is 8, which could be insufficient to produce an accurate estimate, leading to poor index choices by the query optimizer. This technique is especially important for large tables and tables used in joins. Unnecessary `full table scans` for such tables can be a substantial performance issue. See Section 8.2.1.19, “Avoiding Full Table Scans” for tips on tuning such queries. `innodb_stats_transient_sample_pages` is a global parameter that can be set at runtime.

The value of `innodb_stats_transient_sample_pages` affects the index sampling for all InnoDB tables and indexes when `innodb_stats_persistent=0`. Be aware of the following potentially significant impacts when you change the index sample size:

- Small values like 1 or 2 can result in inaccurate estimates of cardinality.
- Increasing the `innodb_stats_transient_sample_pages` value might require more disk reads. Values much larger than 8 (say, 100), can cause a significant slowdown in the time it takes to open a table or execute `SHOW TABLE STATUS`. 

Configuring Optimizer Statistics for InnoDB

• The optimizer might choose very different query plans based on different estimates of index selectivity.

Whatever value of `innodb_stats_transient_sample_pages` works best for a system, set the option and leave it at that value. Choose a value that results in reasonably accurate estimates for all tables in your database without requiring excessive I/O. Because the statistics are automatically recalculated at various times other than on execution of `ANALYZE TABLE`, it does not make sense to increase the index sample size, run `ANALYZE TABLE`, then decrease sample size again.

Smaller tables generally require fewer index samples than larger tables. If your database has many large tables, consider using a higher value for `innodb_stats_transient_sample_pages` than if you have mostly smaller tables.

### 14.8.11.3 Estimating ANALYZE TABLE Complexity for InnoDB Tables

`ANALYZE TABLE` complexity for InnoDB tables is dependent on:

• The number of pages sampled, as defined by `innodb_stats_persistent_sample_pages`.

• The number of indexed columns in a table

• The number of partitions. If a table has no partitions, the number of partitions is considered to be 1.

Using these parameters, an approximate formula for estimating `ANALYZE TABLE` complexity would be:

The value of `innodb_stats_persistent_sample_pages` * number of indexed columns in a table * the number of partitions

Typically, the greater the resulting value, the greater the execution time for `ANALYZE TABLE`.

### Note

`innodb_stats_persistent_sample_pages` defines the number of pages sampled at a global level. To set the number of pages sampled for an individual table, use the `STATS_SAMPLE_PAGES` option with `CREATE TABLE` or `ALTER TABLE`. For more information, see Section 14.8.11.1, “Configuring Persistent Optimizer Statistics Parameters”.

If `innodb_stats_persistent=OFF`, the number of pages sampled is defined by `innodb_stats_transient_sample_pages`. See Section 14.8.11.2, “Configuring Non-Persistent Optimizer Statistics Parameters” for additional information.

For a more in-depth approach to estimating `ANALYZE TABLE` complexity, consider the following example.

In **Big O notation**, `ANALYZE TABLE` complexity is described as:

```
O(n_sample
   * (n_cols_in uniq_i
      + n_cols_in nonuniq_i
      + n_cols_in_pk * (1 + n_nonuniq_i))
   * n_part)
```

where:

• `n_sample` is the number of pages sampled (defined by `innodb_stats_persistent_sample_pages`)

• `n_cols_in uniq_i` is total number of all columns in all unique indexes (not counting the primary key columns)

• `n_cols_in nonuniq_i` is the total number of all columns in all nonunique indexes
• \text{n_cols_in_pk} is the number of columns in the primary key (if a primary key is not defined, InnoDB creates a single column primary key internally).

• \text{n_non_uniq_i} is the number of nonunique indexes in the table.

• \text{n_part} is the number of partitions. If no partitions are defined, the table is considered to be a single partition.

Now, consider the following table (table \( t \)), which has a primary key (2 columns), a unique index (2 columns), and two nonunique indexes (two columns each):

```sql
CREATE TABLE t (
  a INT,
  b INT,
  c INT,
  d INT,
  e INT,
  f INT,
  g INT,
  h INT,
  PRIMARY KEY (a, b),
  UNIQUE KEY i1uniq (c, d),
  KEY i2nonuniq (e, f),
  KEY i3nonuniq (g, h)
);
```

For the column and index data required by the algorithm described above, query the \text{mysql.innodb_index_stats} persistent index statistics table for table \( t \). The \text{n_diff_pfx\%} statistics show the columns that are counted for each index. For example, columns \text{a} and \text{b} are counted for the primary key index. For the nonunique indexes, the primary key columns (\text{a} and \text{b}) are counted in addition to the user defined columns.

```sql
mysql> SELECT index_name, stat_name, stat_description
    FROM mysql.innodb_index_stats
    WHERE database_name='test' AND table_name='t' AND stat_name like 'n_diff_pfx%';
```

<table>
<thead>
<tr>
<th>index_name</th>
<th>stat_name</th>
<th>stat_description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PRIMARY</td>
<td>n_diff_pfx01</td>
<td>a</td>
</tr>
<tr>
<td>PRIMARY</td>
<td>n_diff_pfx02</td>
<td>a,b</td>
</tr>
<tr>
<td>i1uniq</td>
<td>n_diff_pfx01</td>
<td>c</td>
</tr>
<tr>
<td>i1uniq</td>
<td>n_diff_pfx02</td>
<td>c,d</td>
</tr>
<tr>
<td>i2nonuniq</td>
<td>n_diff_pfx01</td>
<td>e</td>
</tr>
<tr>
<td>i2nonuniq</td>
<td>n_diff_pfx02</td>
<td>e,f</td>
</tr>
<tr>
<td>i2nonuniq</td>
<td>n_diff_pfx03</td>
<td>e,f,a</td>
</tr>
<tr>
<td>i2nonuniq</td>
<td>n_diff_pfx04</td>
<td>e,f,a,b</td>
</tr>
<tr>
<td>i3nonuniq</td>
<td>n_diff_pfx01</td>
<td>g</td>
</tr>
<tr>
<td>i3nonuniq</td>
<td>n_diff_pfx02</td>
<td>g,h</td>
</tr>
<tr>
<td>i3nonuniq</td>
<td>n_diff_pfx03</td>
<td>g,h,a</td>
</tr>
<tr>
<td>i3nonuniq</td>
<td>n_diff_pfx04</td>
<td>g,h,a,b</td>
</tr>
</tbody>
</table>

Based on the index statistics data shown above and the table definition, the following values can be determined:

• \text{n_cols_in_uniq_i}, the total number of all columns in all unique indexes not counting the primary key columns, is 2 (\text{c} and \text{d})

• \text{n_cols_in_nonuniq_i}, the total number of all columns in all nonunique indexes, is 4 (\text{e}, \text{f}, \text{g} and \text{h})
Configuring the Merge Threshold for Index Pages

- n_cols_in_pk, the number of columns in the primary key, is 2 (a and b)
- n_non_uniq_i, the number of nonunique indexes in the table, is 2 (i2nonuniq and i3nonuniq)
- n_part, the number of partitions, is 1.

You can now calculate `innodb_stats_persistent_sample_pages` * (2 + 4 + 2 * (1 + 2)) * 1 to determine the number of leaf pages that are scanned. With `innodb_stats_persistent_sample_pages` set to the default value of 20, and with a default page size of 16 Kib (innodb_page_size=16384), you can then estimate that 20 * 12 * 16384 bytes are read for table t, or about 4 MiB.

Note
All 4 MiB may not be read from disk, as some leaf pages may already be cached in the buffer pool.

14.8.12 Configuring the Merge Threshold for Index Pages

Staring in MySQL 5.7.6, you can configure the `MERGE_THRESHOLD` value for index pages. If the “page-full” percentage for an index page falls below the `MERGE_THRESHOLD` value when a row is deleted or when a row is shortened by an `UPDATE` operation, InnoDB attempts to merge the index page with a neighboring index page. The default `MERGE_THRESHOLD` value is 50, which is the previously hardcoded value. The minimum `MERGE_THRESHOLD` value is 1 and the maximum value is 50.

When the “page-full” percentage for an index page falls below 50%, which is the default `MERGE_THRESHOLD` setting, InnoDB attempts to merge the index page with a neighboring page. If both pages are close to 50% full, a page split can occur soon after the pages are merged. If this merge-split behavior occurs frequently, it can have an adverse affect on performance. To avoid frequent merge-splits, you can lower the `MERGE_THRESHOLD` value so that InnoDB attempts page merges at a lower “page-full” percentage. Merging pages at a lower page-full percentage leaves more room in index pages and helps reduce merge-split behavior.

The `MERGE_THRESHOLD` for index pages can be defined for a table or for individual indexes. A `MERGE_THRESHOLD` value defined for an individual index takes priority over a `MERGE_THRESHOLD` value defined for the table. If undefined, the `MERGE_THRESHOLD` value defaults to 50.

Setting `MERGE_THRESHOLD` for a Table

You can set the `MERGE_THRESHOLD` value for a table using the `table_option COMMENT` clause of the `CREATE TABLE` statement. For example:

```sql
CREATE TABLE t1 (
    id INT,
    KEY id_index (id)
) COMMENT='MERGE_THRESHOLD=45';
```

You can also set the `MERGE_THRESHOLD` value for an existing table using the `table_option COMMENT` clause with `ALTER TABLE`:

```sql
CREATE TABLE t1 (
    id INT,
    KEY id_index (id)
);

ALTER TABLE t1 COMMENT='MERGE_THRESHOLD=40';
```

Setting `MERGE_THRESHOLD` for Individual Indexes

To set the `MERGE_THRESHOLD` value for an individual index, you can use the `index_option COMMENT` clause with `CREATE TABLE`, `ALTER TABLE`, or `CREATE INDEX`, as shown in the following examples:
Configuring the Merge Threshold for Index Pages

- **Setting** `MERGE_THRESHOLD` **for an individual index using** `CREATE TABLE`:

```sql
CREATE TABLE t1 (
    id INT,
    KEY id_index (id) COMMENT 'MERGE_THRESHOLD=40'
);
```

- **Setting** `MERGE_THRESHOLD` **for an individual index using** `ALTER TABLE`:

```sql
CREATE TABLE t1 (
    id INT,
    KEY id_index (id)
);
ALTER TABLE t1 DROP KEY id_index;
ALTER TABLE t1 ADD KEY id_index (id) COMMENT 'MERGE_THRESHOLD=40';
```

- **Setting** `MERGE_THRESHOLD` **for an individual index using** `CREATE INDEX`:

```sql
CREATE TABLE t1 (id INT);
CREATE INDEX id_index ON t1 (id) COMMENT 'MERGE_THRESHOLD=40';
```

**Note**
You cannot modify the `MERGE_THRESHOLD` value at the index level for `GEN_CLUST_INDEX`, which is the clustered index created by InnoDB when an InnoDB table is created without a primary key or unique key index. You can only modify the `MERGE_THRESHOLD` value for `GEN_CLUST_INDEX` by setting `MERGE_THRESHOLD` for the table.

**Querying the MERGE_THRESHOLD Value for an Index**

The current `MERGE_THRESHOLD` value for an index can be obtained by querying the `INNODB_SYS_INDEXES` table. For example:

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_INDEXES WHERE NAME='id_index' \G
*************************** 1. row ***************************
  INDEX_ID: 91
  NAME: id_index
  TABLE_ID: 68
  TYPE: 0
  N_FIELDS: 1
  PAGE_NO: 4
  SPACE: 57
  MERGE_THRESHOLD: 40
```

You can use `SHOW CREATE TABLE` to view the `MERGE_THRESHOLD` value for a table, if explicitly defined using the `table_option COMMENTS` clause:

```sql
mysql> SHOW CREATE TABLE t2 \G
*************************** 1. row ***************************
  Table: t2
Create Table: CREATE TABLE `t2` ( 
    `id` int(11) DEFAULT NULL,
    KEY `id_index` (`id`) COMMENT 'MERGE_THRESHOLD=40'
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

**Note**
A `MERGE_THRESHOLD` value defined at the index level takes priority over a `MERGE_THRESHOLD` value defined for the table. If undefined, `MERGE_THRESHOLD` defaults to 50% (`MERGE_THRESHOLD=50`, which is the previously hardcoded value.

Likewise, you can use `SHOW INDEX` to view the `MERGE_THRESHOLD` value for an index, if explicitly defined using the `index_option COMMENTS` clause:
InnoDB Table Compression

Measuring the Effect of MERGE_THRESHOLD Settings

The INNODB_METRICS table provides two counters that can be used to measure the effect of a MERGE_THRESHOLD setting on index page merges.

```sql
mysql> SELECT NAME, COMMENT FROM INFORMATION_SCHEMA.INNODB_METRICS
WHERE NAME like '%index_page_merge%';

<table>
<thead>
<tr>
<th>NAME</th>
<th>COMMENT</th>
</tr>
</thead>
<tbody>
<tr>
<td>index_page_merge_attempts</td>
<td>Number of index page merge attempts</td>
</tr>
<tr>
<td>index_page_merge_successful</td>
<td>Number of successful index page merges</td>
</tr>
</tbody>
</table>
```

When lowering the MERGE_THRESHOLD value, the objectives are:

- A smaller number of page merge attempts and successful page merges
- A similar number of page merge attempts and successful page merges

A MERGE_THRESHOLD setting that is too small could result in large data files due to an excessive amount of empty page space.

For information about using INNODB_METRICS counters, see Section 14.15.6, “InnoDB INFORMATION_SCHEMA Metrics Table”.

14.9 InnoDB Table Compression

By using the SQL syntax and MySQL configuration options for compression, you can create tables where the data is stored in compressed form. Compression can help to improve both raw performance and scalability. The compression means less data is transferred between disk and memory, and takes up less space on disk and in memory. The benefits are amplified for tables with secondary indexes, because index data is compressed also. Compression can be especially important for SSD storage devices, because they tend to have lower capacity than HDD devices.

14.9.1 Overview of Table Compression

Because processors and cache memories have increased in speed more than disk storage devices, many workloads are disk-bound. Data compression enables smaller database size, reduced I/O, and improved throughput, at the small cost of increased CPU utilization. Compression is especially valuable for read-intensive applications, on systems with enough RAM to keep frequently used data in memory.

An InnoDB table created with ROW_FORMAT=COMPRESSED can use a smaller page size on disk than the usual 16KB default. Smaller pages require less I/O to read from and write to disk, which is especially valuable for SSD devices.

The page size is specified through the KEY_BLOCK_SIZE parameter. The different page size means the table must be in its own .ibd file rather than in the system tablespace, which requires enabling...
the `innodb_file_per_table` option. The level of compression is the same regardless of the `KEY_BLOCK_SIZE` value. As you specify smaller values for `KEY_BLOCK_SIZE`, you get the I/O benefits of increasingly smaller pages. But if you specify a value that is too small, there is additional overhead to reorganize the pages when data values cannot be compressed enough to fit multiple rows in each page. There is a hard limit on how small `KEY_BLOCK_SIZE` can be for a table, based on the lengths of the key columns for each of its indexes. Specify a value that is too small, and the `CREATE TABLE` or `ALTER TABLE` statement fails.

In the buffer pool, the compressed data is held in small pages, with a page size based on the `KEY_BLOCK_SIZE` value. For extracting or updating the column values, MySQL also creates a 16KB page in the buffer pool with the uncompressed data. Within the buffer pool, any updates to the uncompressed page are also re-written back to the equivalent compressed page. You might need to size your buffer pool to accommodate the additional data of both compressed and uncompressed pages, although the uncompressed pages are evicted from the buffer pool when space is needed, and then uncompressed again on the next access.

**14.9.2 Enabling Compression for a Table**

Before creating a compressed table, make sure the `innodb_file_per_table` configuration option is enabled, and `innodb_file_format` is set to `Barracuda`. You can set these parameters in the MySQL configuration file `my.cnf` or `my.ini`, or with the `SET` statement without shutting down the MySQL server.

To enable compression for a table, you use the clauses `ROW_FORMAT=COMPRESSED`, `KEY_BLOCK_SIZE`, or both in a `CREATE TABLE` or `ALTER TABLE` statement.

To create a compressed table, you might use statements like these:

```sql
SET GLOBAL innodb_file_per_table=1;
SET GLOBAL innodb_file_format=Barracuda;
CREATE TABLE t1
(c1 INT PRIMARY KEY)
ROW_FORMAT=COMPRESSED
KEY_BLOCK_SIZE=8;
```

- If you specify `ROW_FORMAT=COMPRESSED`, you can omit `KEY_BLOCK_SIZE`; the default page size value is used, which is half the `innodb_page_size` value.

- If you specify `KEY_BLOCK_SIZE`, you can omit `ROW_FORMAT=COMPRESSED`; compression is enabled automatically.

- To determine the best value for `KEY_BLOCK_SIZE`, typically you create several copies of the same table with different values for this clause, then measure the size of the resulting `.ibd` files and see how well each performs with a realistic workload.

- The `KEY_BLOCK_SIZE` value is treated as a hint; a different size could be used by InnoDB if necessary. A value of 0 represents the default compressed page size, which is half of the `innodb_page_size` value. The `KEY_BLOCK_SIZE` can only be less than or equal to the `innodb_page_size` value. If you specify a value greater than the `innodb_page_size` value, the specified value is ignored, a warning is issued, and `KEY_BLOCK_SIZE` is set to half of the `innodb_page_size` value. If `innodb_strict_mode=ON`, specifying an invalid `KEY_BLOCK_SIZE` value returns an error.

- For additional performance-related configuration options, see Section 14.9.3, “Tuning Compression for InnoDB Tables”.

The default uncompressed size of InnoDB data pages is 16KB. Depending on the combination of option values, MySQL uses a page size of 1KB, 2KB, 4KB, 8KB, or 16KB for the `.ibd` file of the table. The actual compression algorithm is not affected by the `KEY_BLOCK_SIZE` value; the value determines how large each compressed chunk is, which in turn affects how many rows can be packed into each compressed page.
Setting `KEY_BLOCK_SIZE` equal to the InnoDB page size does not typically result in much compression. For example, setting `KEY_BLOCK_SIZE=16` typically would not result in much compression, since the normal InnoDB page size is 16KB. This setting may still be useful for tables with many long BLOB, VARCHAR or TEXT columns, because such values often do compress well, and might therefore require fewer overflow pages as described in Section 14.9.5, “How Compression Works for InnoDB Tables”.

All indexes of a table (including the clustered index) are compressed using the same page size, as specified in the `CREATE TABLE` or `ALTER TABLE` statement. Table attributes such as `ROW_FORMAT` and `KEY_BLOCK_SIZE` are not part of the `CREATE_INDEX` syntax for InnoDB tables, and are ignored if they are specified (although you see them in the output of the `SHOW CREATE TABLE` statement).

Restrictions on Compressed Tables

Because MySQL versions prior to 5.1 cannot process compressed tables, using compression requires specifying the configuration parameter `innodb_file_format=Barracuda`, to avoid accidentally introducing compatibility issues.

Table compression is also not available for the InnoDB system tablespace. The system tablespace (space 0, the `ibdata*` files) can contain user data, but it also contains internal system information, and therefore is never compressed. Thus, compression applies only to tables (and indexes) stored in their own tablespaces, that is, created with the `innodb_file_per_table` option enabled.

Compression applies to an entire table and all its associated indexes, not to individual rows, despite the clause name `ROW_FORMAT`.

14.9.3 Tuning Compression for InnoDB Tables

Most often, the internal optimizations described in InnoDB Data Storage and Compression ensure that the system runs well with compressed data. However, because the efficiency of compression depends on the nature of your data, you can make decisions that affect the performance of compressed tables:

- Which tables to compress.
- What compressed page size to use.
- Whether to adjust the size of the buffer pool based on run-time performance characteristics, such as the amount of time the system spends compressing and uncompressing data. Whether the workload is more like a data warehouse (primarily queries) or an OLTP system (mix of queries and DML).
- If the system performs DML operations on compressed tables, and the way the data is distributed leads to expensive compression failures at runtime, you might adjust additional advanced configuration options.

Use the guidelines in this section to help make those architectural and configuration choices. When you are ready to conduct long-term testing and put compressed tables into production, see Section 14.9.4, “Monitoring InnoDB Table Compression at Runtime” for ways to verify the effectiveness of those choices under real-world conditions.

When to Use Compression

In general, compression works best on tables that include a reasonable number of character string columns and where the data is read far more often than it is written. Because there are no guaranteed ways to predict whether or not compression benefits a particular situation, always test with a specific workload and data set running on a representative configuration. Consider the following factors when deciding which tables to compress.

Data Characteristics and Compression

A key determinant of the efficiency of compression in reducing the size of data files is the nature of the data itself. Recall that compression works by identifying repeated strings of bytes in a block of
data. Completely randomized data is the worst case. Typical data often has repeated values, and so compresses effectively. Character strings often compress well, whether defined in \texttt{CHAR}, \texttt{VARCHAR}, \texttt{TEXT} or \texttt{BLOB} columns. On the other hand, tables containing mostly binary data (integers or floating point numbers) or data that is previously compressed (for example JPEG or PNG images) may not generally compress well, significantly or at all.

You choose whether to turn on compression for each InnoDB table. A table and all of its indexes use the same (compressed) page size. It might be that the primary key (clustered) index, which contains the data for all columns of a table, compresses more effectively than the secondary indexes. For those cases where there are long rows, the use of compression might result in long column values being stored “off-page”, as discussed in \texttt{DYNAMIC Row Format}. Those overflow pages may compress well. Given these considerations, for many applications, some tables compress more effectively than others, and you might find that your workload performs best only with a subset of tables compressed.

To determine whether or not to compress a particular table, conduct experiments. You can get a rough estimate of how efficiently your data can be compressed by using a utility that implements LZ77 compression (such as \texttt{gzip} or WinZip) on a copy of the \texttt{.ibd} file for an uncompressed table. You can expect less compression from a MySQL compressed table than from file-based compression tools, because MySQL compresses data in chunks based on the page size, 16KB by default. In addition to user data, the page format includes some internal system data that is not compressed. File-based compression utilities can examine much larger chunks of data, and so might find more repeated strings in a huge file than MySQL can find in an individual page.

Another way to test compression on a specific table is to copy some data from your uncompressed table to a similar, compressed table (having all the same indexes) and look at the size of the resulting \texttt{.ibd} file. For example:

```
USE test;
SET GLOBAL innodb_file_per_table=1;
SET GLOBAL innodb_file_format=Barracuda;
SET GLOBAL autocommit=0;

-- Create an uncompressed table with a million or two rows.
CREATE TABLE big_table AS SELECT * FROM information_schema.columns;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
INSERT INTO big_table SELECT * FROM big_table;
COMMIT;
ALTER TABLE big_table ADD id int unsigned NOT NULL PRIMARY KEY auto_increment;
SHOW CREATE TABLE big_table\G

select count(id) from big_table;

-- Check how much space is needed for the uncompressed table.
\!/ ls -1 data/test/big_table.ibd

CREATE TABLE key_block_size_4 LIKE big_table;
ALTER TABLE key_block_size_4 key_block_size=4 row_format=compressed;

INSERT INTO key_block_size_4 SELECT * FROM big_table;
commit;

-- Check how much space is needed for a compressed table
-- with particular compression settings.
\!/ ls -1 data/test/key_block_size_4.ibd
```

This experiment produced the following numbers, which of course could vary considerably depending on your table structure and data:
To see whether compression is efficient for your particular workload:

- For simple tests, use a MySQL instance with no other compressed tables and run queries against the `INFORMATION_SCHEMA.INNODB_CMP` table.

- For more elaborate tests involving workloads with multiple compressed tables, run queries against the `INFORMATION_SCHEMA.INNODB_CMP_PER_INDEX` table. Because the statistics in the `INNODB_CMP_PER_INDEX` table are expensive to collect, you must enable the configuration option `innodb_cmp_per_index_enabled` before querying that table, and you might restrict such testing to a development server or a non-critical replica server.

- Run some typical SQL statements against the compressed table you are testing.

- Examine the ratio of successful compression operations to overall compression operations by querying the `INFORMATION_SCHEMA.INNODB_CMP` or `INFORMATION_SCHEMA.INNODB_CMP_PER_INDEX` table, and comparing `COMPRESS_OPS` to `COMPRESS_OPS_OK`.

- If a high percentage of compression operations complete successfully, the table might be a good candidate for compression.

- If you get a high proportion of compression failures, you can adjust `innodb_compression_level`, `innodb_compression_failure_threshold_pct`, and `innodb_compression_pad_pct_max` options as described in Section 14.9.6, “Compression for OLTP Workloads”, and try further tests.

**Database Compression versus Application Compression**

Decide whether to compress data in your application or in the table; do not use both types of compression for the same data. When you compress the data in the application and store the results in a compressed table, extra space savings are extremely unlikely, and the double compression just wastes CPU cycles.

**Compressing in the Database**

When enabled, MySQL table compression is automatic and applies to all columns and index values. The columns can still be tested with operators such as `LIKE`, and sort operations can still use indexes even when the index values are compressed. Because indexes are often a significant fraction of the total size of a database, compression could result in significant savings in storage, I/O or processor time. The compression and decompression operations happen on the database server, which likely is a powerful system that is sized to handle the expected load.

**Compressing in the Application**

If you compress data such as text in your application, before it is inserted into the database, You might save overhead for data that does not compress well by compressing some columns and not others. This approach uses CPU cycles for compression and uncompression on the client machine rather than the database server, which might be appropriate for a distributed application with many clients, or where the client machine has spare CPU cycles.

**Hybrid Approach**

Of course, it is possible to combine these approaches. For some applications, it may be appropriate to use some compressed tables and some uncompressed tables. It may be best to externally compress some data (and store it in uncompressed tables) and allow MySQL to compress (some of) the other tables in the application. As always, up-front design and real-life testing are valuable in reaching the right decision.

**Workload Characteristics and Compression**
In addition to choosing which tables to compress (and the page size), the workload is another key determinant of performance. If the application is dominated by reads, rather than updates, fewer pages need to be reorganized and recompressed after the index page runs out of room for the per-page “modification log” that MySQL maintains for compressed data. If the updates predominantly change non-indexed columns or those containing BLOBs or large strings that happen to be stored “off-page”, the overhead of compression may be acceptable. If the only changes to a table are INSERTs that use a monotonically increasing primary key, and there are few secondary indexes, there is little need to reorganize and recompress index pages. Since MySQL can “delete-mark” and delete rows on compressed pages “in place” by modifying uncompressed data, DELETE operations on a table are relatively efficient.

For some environments, the time it takes to load data can be as important as run-time retrieval. Especially in data warehouse environments, many tables may be read-only or read-mostly. In those cases, it might or might not be acceptable to pay the price of compression in terms of increased load time, unless the resulting savings in fewer disk reads or in storage cost is significant.

Fundamentally, compression works best when the CPU time is available for compressing and uncompressing data. Thus, if your workload is I/O bound, rather than CPU-bound, you might find that compression can improve overall performance. When you test your application performance with different compression configurations, test on a platform similar to the planned configuration of the production system.

Configuration Characteristics and Compression

Reading and writing database pages from and to disk is the slowest aspect of system performance. Compression attempts to reduce I/O by using CPU time to compress and uncompress data, and is most effective when I/O is a relatively scarce resource compared to processor cycles.

This is often especially the case when running in a multi-user environment with fast, multi-core CPUs. When a page of a compressed table is in memory, MySQL often uses additional memory, typically 16KB, in the buffer pool for an uncompressed copy of the page. The adaptive LRU algorithm attempts to balance the use of memory between compressed and uncompressed pages to take into account whether the workload is running in an I/O-bound or CPU-bound manner. Still, a configuration with more memory dedicated to the buffer pool tends to run better when using compressed tables than a configuration where memory is highly constrained.

Choosing the Compressed Page Size

The optimal setting of the compressed page size depends on the type and distribution of data that the table and its indexes contain. The compressed page size should always be bigger than the maximum record size, or operations may fail as noted in Compression of B-Tree Pages.

Setting the compressed page size too large wastes some space, but the pages do not have to be compressed as often. If the compressed page size is set too small, inserts or updates may require time-consuming recompression, and the B-tree nodes may have to be split more frequently, leading to bigger data files and less efficient indexing.

Typically, you set the compressed page size to 8K or 4K bytes. Given that the maximum row size for an InnoDB table is around 8K, KEY_BLOCK_SIZE=8 is usually a safe choice.

14.9.4 Monitoring InnoDB Table Compression at Runtime

Overall application performance, CPU and I/O utilization and the size of disk files are good indicators of how effective compression is for your application. This section builds on the performance tuning advice from Section 14.9.3, “Tuning Compression for InnoDB Tables”, and shows how to find problems that might not turn up during initial testing.

To dig deeper into performance considerations for compressed tables, you can monitor compression performance at runtime using the Information Schema tables described in Example 14.1, “Using the
How Compression Works for InnoDB Tables

Compression Information Schema Tables. These tables reflect the internal use of memory and the rates of compression used overall.

The `INNODB_CMP` table reports information about compression activity for each compressed page size (`KEY_BLOCK_SIZE`) in use. The information in these tables is system-wide: it summarizes the compression statistics across all compressed tables in your database. You can use this data to help decide whether or not to compress a table by examining these tables when no other compressed tables are being accessed. It involves relatively low overhead on the server, so you might query it periodically on a production server to check the overall efficiency of the compression feature.

The `INNODB_CMP_PER_INDEX` table reports information about compression activity for individual tables and indexes. This information is more targeted and more useful for evaluating compression efficiency and diagnosing performance issues one table or index at a time. (Because that each InnoDB table is represented as a clustered index, MySQL does not make a big distinction between tables and indexes in this context.) The `INNODB_CMP_PER_INDEX` table does involve substantial overhead, so it is more suitable for development servers, where you can compare the effects of different workloads, data, and compression settings in isolation. To guard against imposing this monitoring overhead by accident, you must enable the `innodb_cmp_per_index_enabled` configuration option before you can query the `INNODB_CMP_PER_INDEX` table.

The key statistics to consider are the number of, and amount of time spent performing, compression and uncompression operations. Since MySQL splits B-tree nodes when they are too full to contain the compressed data following a modification, compare the number of “successful” compression operations with the number of such operations overall. Based on the information in the `INNODB_CMP` and `INNODB_CMP_PER_INDEX` tables and overall application performance and hardware resource utilization, you might make changes in your hardware configuration, adjust the size of the buffer pool, choose a different page size, or select a different set of tables to compress.

If the amount of CPU time required for compressing and uncompressing is high, changing to faster or multi-core CPUs can help improve performance with the same data, application workload and set of compressed tables. Increasing the size of the buffer pool might also help performance, so that more uncompressed pages can stay in memory, reducing the need to uncompress pages that exist in memory only in compressed form.

A large number of compression operations overall (compared to the number of `INSERT`, `UPDATE` and `DELETE` operations in your application and the size of the database) could indicate that some of your compressed tables are being updated too heavily for effective compression. If so, choose a larger page size, or be more selective about which tables you compress.

If the number of “successful” compression operations (`COMPRESS_OPS_OK`) is a high percentage of the total number of compression operations (`COMPRESS_OPS`), then the system is likely performing well. If the ratio is low, then MySQL is reorganizing, recompressing, and splitting B-tree nodes more often than is desirable. In this case, avoid compressing some tables, or increase `KEY_BLOCK_SIZE` for some of the compressed tables. You might turn off compression for tables that cause the number of “compression failures” in your application to be more than 1% or 2% of the total. (Such a failure ratio might be acceptable during a temporary operation such as a data load).

14.9.5 How Compression Works for InnoDB Tables

This section describes some internal implementation details about compression for InnoDB tables. The information presented here may be helpful in tuning for performance, but is not necessary to know for basic use of compression.

Compression Algorithms

Some operating systems implement compression at the file system level. Files are typically divided into fixed-size blocks that are compressed into variable-size blocks, which easily leads into fragmentation. Every time something inside a block is modified, the whole block is recompressed before it is written to disk. These properties make this compression technique unsuitable for use in an update-intensive database system.
MySQL implements compression with the help of the well-known zlib library, which implements the
LZ77 compression algorithm. This compression algorithm is mature, robust, and efficient in both CPU
utilization and in reduction of data size. The algorithm is “lossless”, so that the original uncompressed
data can always be reconstructed from the compressed form. LZ77 compression works by finding
sequences of data that are repeated within the data to be compressed. The patterns of values in your
data determine how well it compresses, but typical user data often compresses by 50% or more.

**Note**
Prior to MySQL 5.6.42, InnoDB supports the zlib library up to version 1.2.3.
In MySQL 5.6.42 and later, InnoDB supports the zlib library up to version 1.2.11.

Unlike compression performed by an application, or compression features of some other database
management systems, InnoDB compression applies both to user data and to indexes. In many cases,
indexes can constitute 40-50% or more of the total database size, so this difference is significant.
When compression is working well for a data set, the size of the InnoDB data files (the .ibd files) is
25% to 50% of the uncompressed size or possibly smaller. Depending on the workload, this smaller
database can in turn lead to a reduction in I/O, and an increase in throughput, at a modest cost in
terms of increased CPU utilization. You can adjust the balance between compression level and CPU
overhead by modifying the `innodb_compression_level` configuration option.

**InnoDB Data Storage and Compression**

All user data in InnoDB tables is stored in pages comprising a B-tree index (the clustered index). In
some other database systems, this type of index is called an “index-organized table”. Each row in the
index node contains the values of the (user-specified or system-generated) primary key and all the
other columns of the table.

Secondary indexes in InnoDB tables are also B-trees, containing pairs of values: the index key and a
pointer to a row in the clustered index. The pointer is in fact the value of the primary key of the table,
which is used to access the clustered index if columns other than the index key and primary key are
required. Secondary index records must always fit on a single B-tree page.

The compression of B-tree nodes (of both clustered and secondary indexes) is handled differently from
compression of overflow pages used to store long `VARCHAR`, `BLOB`, or `TEXT` columns, as explained in
the following sections.

**Compression of B-Tree Pages**

Because they are frequently updated, B-tree pages require special treatment. It is important to
minimize the number of times B-tree nodes are split, as well as to minimize the need to uncompress
and recompress their content.

One technique MySQL uses is to maintain some system information in the B-tree node in
uncompressed form, thus facilitating certain in-place updates. For example, this allows rows to be
delete-marked and deleted without any compression operation.

In addition, MySQL attempts to avoid unnecessary uncompression and recompression of index pages
when they are changed. Within each B-tree page, the system keeps an uncompressed “modification
log” to record changes made to the page. Updates and inserts of small records may be written to this
modification log without requiring the entire page to be completely reconstructed.

When the space for the modification log runs out, InnoDB uncompresses the page, applies the
changes and recompresses the page. If recompression fails (a situation known as a compression
failure), the B-tree nodes are split and the process is repeated until the update or insert succeeds.

To avoid frequent compression failures in write-intensive workloads, such as for OLTP applications,
MySQL sometimes reserves some empty space (padding) in the page, so that the modification log
fills up sooner and the page is recompressed while there is still enough room to avoid splitting it.
The amount of padding space left in each page varies as the system keeps track of the frequency
How Compression Works for InnoDB Tables

of page splits. On a busy server doing frequent writes to compressed tables, you can adjust the `innodb_compression_failure_threshold_pct`, and `innodb_compression_pad_pct_max` configuration options to fine-tune this mechanism.

Generally, MySQL requires that each B-tree page in an InnoDB table can accommodate at least two records. For compressed tables, this requirement has been relaxed. Leaf pages of B-tree nodes (whether of the primary key or secondary indexes) only need to accommodate one record, but that record must fit, in uncompressed form, in the per-page modification log. If `innodb_strict_mode` is ON, MySQL checks the maximum row size during `CREATE TABLE` or `CREATE INDEX`. If the row does not fit, the following error message is issued: `ERROR HY000: Too big row`.

If you create a table when `innodb_strict_mode` is OFF, and a subsequent `INSERT` or `UPDATE` statement attempts to create an index entry that does not fit in the size of the compressed page, the operation fails with `ERROR 42000: Row size too large`. (This error message does not name the index for which the record is too large, or mention the length of the index record or the maximum record size on that particular index page.) To solve this problem, rebuild the table with `ALTER TABLE` and select a larger compressed page size (`KEY_BLOCK_SIZE`), shorten any column prefix indexes, or disable compression entirely with `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPACT`.

Compressing BLOB, VARCHAR, and TEXT Columns

In an InnoDB table, BLOB, VARCHAR, and TEXT columns that are not part of the primary key may be stored on separately allocated overflow pages. We refer to these columns as off-page columns. Their values are stored on singly-linked lists of overflow pages.

For tables created in `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPRESSED`, the values of BLOB, TEXT, or VARCHAR columns may be stored fully off-page, depending on their length and the length of the entire row. For columns that are stored off-page, the clustered index record only contains 20-byte pointers to the overflow pages, one per column. Whether any columns are stored off-page depends on the page size and the total size of the row. When the row is too long to fit entirely within the page of the clustered index, MySQL chooses the longest columns for off-page storage until the row fits on the clustered index page. As noted above, if a row does not fit by itself on a compressed page, an error occurs.

**Note**

For tables created in `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPRESSED`, TEXT and BLOB columns that are less than or equal to 40 bytes are always stored in-line.

Tables created in older versions of MySQL use the Antelope file format, which supports only `ROW_FORMAT=REDUNDANT` and `ROW_FORMAT=COMPACT`. In these formats, MySQL stores the first 768 bytes of BLOB, VARCHAR, and TEXT columns in the clustered index record along with the primary key. The 768-byte prefix is followed by a 20-byte pointer to the overflow pages that contain the rest of the column value.

When a table is in `COMPRESSED` format, all data written to overflow pages is compressed “as is”; that is, MySQL applies the zlib compression algorithm to the entire data item. Other than the data, compressed overflow pages contain an uncompressed header and trailer comprising a page checksum and a link to the next overflow page, among other things. Therefore, very significant storage savings can be obtained for longer BLOB, TEXT, or VARCHAR columns if the data is highly compressible, as is often the case with text data. Image data, such as JPEG, is typically already compressed and so does not benefit much from being stored in a compressed table; the double compression can waste CPU cycles for little or no space savings.

The overflow pages are of the same size as other pages. A row containing ten columns stored off-page occupies ten overflow pages, even if the total length of the columns is only 8K bytes. In an uncompressed table, ten uncompressed overflow pages occupy 160K bytes. In a compressed table with an 8K page size, they occupy only 80K bytes. Thus, it is often more efficient to use compressed table format for tables with long column values.
Using a 16K compressed page size can reduce storage and I/O costs for BLOB, VARCHAR, or TEXT columns, because such data often compress well, and might therefore require fewer overflow pages, even though the B-tree nodes themselves take as many pages as in the uncompressed form.

Compression and the InnoDB Buffer Pool

In a compressed InnoDB table, every compressed page (whether 1K, 2K, 4K or 8K) corresponds to an uncompressed page of 16K bytes (or a smaller size if innodb_page_size is set). To access the data in a page, MySQL reads the compressed page from disk if it is not already in the buffer pool, then uncompresses the page to its original form. This section describes how InnoDB manages the buffer pool with respect to pages of compressed tables.

To minimize I/O and to reduce the need to uncompress a page, at times the buffer pool contains both the compressed and uncompressed form of a database page. To make room for other required database pages, MySQL can evict from the buffer pool an uncompressed page, while leaving the compressed page in memory. Or, if a page has not been accessed in a while, the compressed form of the page might be written to disk, to free space for other data. Thus, at any given time, the buffer pool might contain both the compressed and uncompressed forms of the page, or only the compressed form of the page, or neither.

MySQL keeps track of which pages to keep in memory and which to evict using a least-recently-used (LRU) list, so that hot (frequently accessed) data tends to stay in memory. When compressed tables are accessed, MySQL uses an adaptive LRU algorithm to achieve an appropriate balance of compressed and uncompressed pages in memory. This adaptive algorithm is sensitive to whether the system is running in an I/O-bound or CPU-bound manner. The goal is to avoid spending too much processing time uncompressing pages when the CPU is busy, and to avoid doing excess I/O when the CPU has spare cycles that can be used for uncompressing compressed pages (that may already be in memory). When the system is I/O-bound, the algorithm prefers to evict the uncompressed copy of a page rather than both copies, to make more room for other disk pages to become memory resident. When the system is CPU-bound, MySQL prefers to evict both the compressed and uncompressed page, so that more memory can be used for “hot” pages and reducing the need to uncompress data in memory only in compressed form.

Compression and the InnoDB Redo Log Files

Before a compressed page is written to a data file, MySQL writes a copy of the page to the redo log (if it has been recompressed since the last time it was written to the database). This is done to ensure that redo logs are usable for crash recovery, even in the unlikely case that the zlib library is upgraded and that change introduces a compatibility problem with the compressed data. Therefore, some increase in the size of log files, or a need for more frequent checkpoints, can be expected when using compression. The amount of increase in the log file size or checkpoint frequency depends on the number of times compressed pages are modified in a way that requires reorganization and recompression.

Compressed tables use a different file format for the redo log and the per-table tablespaces than in MySQL 5.1 and earlier. The MySQL Enterprise Backup product supports this latest Barracuda file format for compressed InnoDB tables.

14.9.6 Compression for OLTP Workloads

Traditionally, the InnoDB compression feature was recommended primarily for read-only or read-mostly workloads, such as in a data warehouse configuration. The rise of SSD storage devices, which are fast but relatively small and expensive, makes compression attractive also for OLTP workloads: high-traffic, interactive websites can reduce their storage requirements and their I/O operations per second (IOPS) by using compressed tables with applications that do frequent INSERT, UPDATE, and DELETE operations.

Configuration options introduced in MySQL 5.6 let you adjust the way compression works for a particular MySQL instance, with an emphasis on performance and scalability for write-intensive operations:
• `innodb_compression_level` lets you turn the degree of compression up or down. A higher value lets you fit more data onto a storage device, at the expense of more CPU overhead during compression. A lower value lets you reduce CPU overhead when storage space is not critical, or you expect the data is not especially compressible.

• `innodb_compression_failure_threshold_pct` specifies a cutoff point for compression failures during updates to a compressed table. When this threshold is passed, MySQL begins to leave additional free space within each new compressed page, dynamically adjusting the amount of free space up to the percentage of page size specified by `innodb_compression_pad_pct_max`.

• `innodb_compression_pad_pct_max` lets you adjust the maximum amount of space reserved within each page to record changes to compressed rows, without needing to compress the entire page again. The higher the value, the more changes can be recorded without recompressing the page. MySQL uses a variable amount of free space for the pages within each compressed table, only when a designated percentage of compression operations “fail” at runtime, requiring an expensive operation to split the compressed page.

• `innodb_log_compressed_pages` lets you disable writing of images of re-compressed pages to the redo log. Re-compression may occur when changes are made to compressed data. This option is enabled by default to prevent corruption that could occur if a different version of the zlib compression algorithm is used during recovery. If you are certain that the zlib version will not change, disable `innodb_log_compressed_pages` to reduce redo log generation for workloads that modify compressed data.

Because working with compressed data sometimes involves keeping both compressed and uncompressed versions of a page in memory at the same time, when using compression with an OLTP-style workload, be prepared to increase the value of the `innodb_buffer_pool_size` configuration option.

### 14.9.7 SQL Compression Syntax Warnings and Errors

Specifying `ROW_FORMAT=COMPRESSED` or `KEY_BLOCK_SIZE` in `CREATE TABLE` or `ALTER TABLE` statements produces the following warnings if the Barracuda file format is not enabled. You can view them with the `SHOW WARNINGS` statement.

<table>
<thead>
<tr>
<th>Level</th>
<th>Code</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>Warning</td>
<td>1478</td>
<td>InnoDB: KEY_BLOCK_SIZE requires <code>innodb_file_per_table</code>.</td>
</tr>
<tr>
<td>Warning</td>
<td>1478</td>
<td>InnoDB: KEY_BLOCK_SIZE requires <code>innodb_file_format=1</code></td>
</tr>
<tr>
<td>Warning</td>
<td>1478</td>
<td>InnoDB: ignoring KEY_BLOCK_SIZE=4.</td>
</tr>
<tr>
<td>Warning</td>
<td>1478</td>
<td>InnoDB: ROW_FORMAT=COMPRESSED requires <code>innodb_file_per_table</code>.</td>
</tr>
<tr>
<td>Warning</td>
<td>1478</td>
<td>InnoDB: assuming ROW_FORMAT=COMPACT.</td>
</tr>
</tbody>
</table>

**Notes:**

- By default, these messages are only warnings, not errors, and the table is created without compression, as if the options were not specified.

- When `innodb_strict_mode` is enabled, MySQL generates an error, not a warning, for these cases. The table is not created if the current configuration does not permit using compressed tables.

The “non-strict” behavior lets you import a `mysqldump` file into a database that does not support compressed tables, even if the source database contained compressed tables. In that case, MySQL creates the table in `ROW_FORMAT=COMPACT` instead of preventing the operation.
To import the dump file into a new database, and have the tables re-created as they exist in the original database, ensure the server has the proper settings for the configuration parameters `innodb_file_format` and `innodb_file_per_table`.

The attribute `KEY_BLOCK_SIZE` is permitted only when `ROW_FORMAT` is specified as `COMPRESSED` or is omitted. Specifying a `KEY_BLOCK_SIZE` with any other `ROW_FORMAT` generates a warning that you can view with `SHOW WARNINGS`. However, the table is non-compressed; the specified `KEY_BLOCK_SIZE` is ignored.

<table>
<thead>
<tr>
<th>Level</th>
<th>Code</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>Warning</td>
<td>1478</td>
<td>innodb: ignoring KEY_BLOCK_SIZE=n unless ROW_FORMAT=COMPRESSED.</td>
</tr>
</tbody>
</table>

If you are running with `innodb_strict_mode` enabled, the combination of a `KEY_BLOCK_SIZE` with any `ROW_FORMAT` other than `COMPRESSED` generates an error, not a warning, and the table is not created.

Table 14.5, “ROW_FORMAT and KEY_BLOCK_SIZE Options” provides an overview the `ROW_FORMAT` and `KEY_BLOCK_SIZE` options that are used with `CREATE TABLE` or `ALTER TABLE`.

### Table 14.5 ROW_FORMAT and KEY_BLOCK_SIZE Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Usage Notes</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ROW_FORMAT=REDUNDANT</code></td>
<td>Storage format used prior to MySQL 5.0.3</td>
<td>Less efficient than <code>ROW_FORMAT=COMPACT</code>; for backward compatibility</td>
</tr>
<tr>
<td><code>ROW_FORMAT=COMPACT</code></td>
<td>Default storage format since MySQL 5.0.3</td>
<td>Stores a prefix of 768 bytes of long column values in the clustered index page, with the remaining bytes stored in an overflow page</td>
</tr>
<tr>
<td><code>ROW_FORMAT=DYNAMIC</code></td>
<td>Available only with <code>innodb_file_format=Barracuda</code></td>
<td>Store values within the clustered index page if they fit; if not, stores only a 20-byte pointer to an overflow page (no prefix)</td>
</tr>
<tr>
<td><code>ROW_FORMAT=COMPRESSED</code></td>
<td>Available only with <code>innodb_file_format=Barracuda</code></td>
<td>Compresses the table and indexes using zlib</td>
</tr>
<tr>
<td><code>KEY_BLOCK_SIZE=n</code></td>
<td>Available only with <code>innodb_file_format=Barracuda</code></td>
<td>Specifies compressed page size of 1, 2, 4, 8 or 16 kilobytes; implies <code>ROW_FORMAT=COMPRESSED</code></td>
</tr>
</tbody>
</table>

Table 14.6, “CREATE/ALTER TABLE Warnings and Errors when InnoDB Strict Mode is OFF” summarizes error conditions that occur with certain combinations of configuration parameters and options on the `CREATE TABLE` or `ALTER TABLE` statements, and how the options appear in the output of `SHOW TABLE STATUS`.

When `innodb_strict_mode` is `OFF`, MySQL creates or alters the table, but ignores certain settings as shown below. You can see the warning messages in the MySQL error log. When `innodb_strict_mode` is `ON`, these specified combinations of options generate errors, and the table is not created or altered. To see the full description of the error condition, issue the `SHOW ERRORS` statement: example:

```
mysql> CREATE TABLE x (id INT PRIMARY KEY, c INT)
   -> ENGINE=INNODB KEY_BLOCK_SIZE=33333;
ERROR 1005 (HY000): Can't create table 'test.x' (errno: 1478)
mysql> SHOW ERRORS;
```

1928
Table 14.6 CREATE/ALTER TABLE Warnings and Errors when InnoDB Strict Mode is OFF

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Warning or Error Condition</th>
<th>Resulting ROW_FORMAT, as shown in SHOW TABLE STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROW_FORMAT=REDUNDANT</td>
<td>None</td>
<td>REDUNDANT</td>
</tr>
<tr>
<td>ROW_FORMAT=COMPACT</td>
<td>None</td>
<td>COMPACT</td>
</tr>
<tr>
<td>ROW_FORMAT=COMPRESSED or ROW_FORMAT=DYNAMIC or KEY_BLOCK_SIZE is specified</td>
<td>Ignored unless both innodb_file_format=Barracuda and innodb_file_per_table are enabled</td>
<td>COMPACT</td>
</tr>
<tr>
<td>Invalid KEY_BLOCK_SIZE is specified (not 1, 2, 4, 8 or 16)</td>
<td>KEY_BLOCK_SIZE is ignored</td>
<td>the requested row format, or COMPACT by default</td>
</tr>
<tr>
<td>ROW_FORMAT=COMPRESSED and valid KEY_BLOCK_SIZE are specified</td>
<td>None; KEY_BLOCK_SIZE specified is used</td>
<td>COMPRESSED</td>
</tr>
<tr>
<td>KEY_BLOCK_SIZE is specified with REDUNDANT, COMPACT or DYNAMIC row format</td>
<td>KEY_BLOCK_SIZE is ignored</td>
<td>REDUNDANT, COMPACT or DYNAMIC</td>
</tr>
<tr>
<td>ROW_FORMAT is not one of REDUNDANT, COMPACT, DYNAMIC or COMPRESSED</td>
<td>Ignored if recognized by the MySQL parser. Otherwise, an error is issued.</td>
<td>COMPACT or N/A</td>
</tr>
</tbody>
</table>

When `innodb_strict_mode` is ON, MySQL rejects invalid ROW_FORMAT or KEY_BLOCK_SIZE parameters. For compatibility with earlier versions of MySQL, strict mode is not enabled by default; instead, MySQL issues warnings (not errors) for ignored invalid parameters.

It is not possible to see the chosen KEY_BLOCK_SIZE using SHOW TABLE STATUS. The statement SHOW CREATE TABLE displays the KEY_BLOCK_SIZE (even if it was ignored when creating the table). The real compressed page size of the table cannot be displayed by MySQL.

### 14.10 InnoDB File-Format Management

As InnoDB evolves, data file formats that are not compatible with prior versions of InnoDB are sometimes required to support new features. To help manage compatibility in upgrade and downgrade situations, and systems that run different versions of MySQL, InnoDB uses named file formats. InnoDB currently supports two named file formats, Antelope and Barracuda.

- **Antelope** is the original InnoDB file format, which previously did not have a name. It supports COMPACT and REDUNDANT row formats for InnoDB tables and is the default file format in MySQL 5.6 to ensure maximum compatibility with earlier MySQL versions that do not support the Barracuda file format.

- **Barracuda** is the newest file format. It supports all InnoDB row formats including the newer COMPRESSED and DYNAMIC row formats. The features associated with COMPRESSED and DYNAMIC row formats include compressed tables, efficient storage of off-page columns, and index key prefixes up to 3072 bytes (`innodb_large_prefix`). See Section 14.11, “InnoDB Row Formats”.

This section discusses enabling InnoDB file formats, verifying compatibility of different file formats between MySQL releases, identifying the file format in use, and downgrading the file format.
14.10.1 Enabling File Formats

The `innodb_file_format` configuration option enables an InnoDB file format for file-per-table tablespaces.

Antelope is the default `innodb_file_format`.

To preclude the use of features supported by the Barracuda file that make your database inaccessible to the built-in InnoDB in MySQL 5.1 and prior releases, set `innodb_file_format` to Antelope. Alternatively, you can disable `innodb_file_per_table` to have new tables created in the system tablespace. The system tablespace is stored in the original Antelope file format.

You can set the value of `innodb_file_format` on the command line when you start `mysqld`, or in the option file (`my.cnf` on Unix, `my.ini` on Windows). You can also change it dynamically with a `SET GLOBAL` statement.

```
SET GLOBAL innodb_file_format=Barracuda;
```

Although Oracle recommends using the Barracuda format for new tables where practical, in MySQL 5.6 the default file format is Antelope, for maximum compatibility with replication configurations containing earlier MySQL releases.

14.10.2 Verifying File Format Compatibility

InnoDB incorporates several checks to guard against the possible crashes and data corruptions that might occur if you run an old release of the MySQL server on InnoDB data files that use a newer file format. These checks take place when the server is started, and when you first access a table. This section describes these checks, how you can control them, and error and warning conditions that might arise.

Backward Compatibility

You only need to consider backward file format compatibility when using a recent version of InnoDB (MySQL 5.5 and higher with InnoDB) alongside an older version (MySQL 5.1 or earlier, with the built-in InnoDB rather than the InnoDB Plugin). To minimize the chance of compatibility issues, you can standardize on the InnoDB Plugin for all your MySQL 5.1 and earlier database servers.

In general, a newer version of InnoDB may create a table or index that cannot safely be read or written with an older version of InnoDB without risk of crashes, hangs, wrong results or corruptions. InnoDB includes a mechanism to guard against these conditions, and to help preserve compatibility among database files and versions of InnoDB. This mechanism lets you take advantage of some new features of an InnoDB release (such as performance improvements and bug fixes), and still preserve the option of using your database with a prior version of InnoDB, by preventing accidental use of new features that create downward-incompatible disk files.

If a version of InnoDB supports a particular file format (whether or not that format is the default), you can query and update any table that requires that format or an earlier format. Only the creation of new tables using new features is limited based on the particular file format enabled. Conversely, if a tablespace contains a table or index that uses a file format that is not supported, it cannot be accessed at all, even for read access.

The only way to “downgrade” an InnoDB tablespace to the earlier Antelope file format is to copy the data to a new table, in a tablespace that uses the earlier format.

The easiest way to determine the file format of an existing InnoDB tablespace is to examine the properties of the table it contains, using the `SHOW TABLE STATUS` command or querying the table `INFORMATION_SCHEMA.TABLES`. If the `Row_format` of the table is reported as 'Compressed' or 'Dynamic', the tablespace containing the table uses the Barracuda format. Otherwise, it uses the prior InnoDB file format, Antelope.
Verifying File Format Compatibility

Internal Details

Every InnoDB file-per-table tablespace (represented by a *.ibd file) file is labeled with a file format identifier. The system tablespace (represented by the ibdata files) is tagged with the “highest” file format in use in a group of InnoDB database files, and this tag is checked when the files are opened.

Creating a compressed table, or a table with **ROW_FORMAT=DYNAMIC**, updates the file header of the corresponding file-per-table .ibd file and the table type in the InnoDB data dictionary with the identifier for the Barracuda file format. From that point forward, the table cannot be used with a version of InnoDB that does not support the Barracuda file format. To protect against anomalous behavior, InnoDB performs a compatibility check when the table is opened. (In many cases, the `ALTER TABLE` statement recreates a table and thus changes its properties. The special case of adding or dropping indexes without rebuilding the table is described in Section 14.13.1, “Online DDL Operations”.)

**Definition of ib-file set**

To avoid confusion, for the purposes of this discussion we define the term “ib-file set” to mean the set of operating system files that InnoDB manages as a unit. The ib-file set includes the following files:

- The system tablespace (one or more ibdata files) that contain internal system information (including internal catalogs and undo information) and may include user data and indexes.
- Zero or more single-table tablespaces (also called “file per table” files, named *.ibd files).
- InnoDB log files; usually two, ib_logfile0 and ib_logfile1. Used for crash recovery and in backups.

An “ib-file set” does not include the corresponding .frm files that contain metadata about InnoDB tables. The .frm files are created and managed by MySQL, and can sometimes get out of sync with the internal metadata in InnoDB.

Multiple tables, even from more than one database, can be stored in a single “ib-file set”. (In MySQL, a “database” is a logical collection of tables, what other systems refer to as a “schema” or “catalog”.)

**14.10.2.1 Compatibility Check When InnoDB Is Started**

To prevent possible crashes or data corruptions when InnoDB opens an ib-file set, it checks that it can fully support the file formats in use within the ib-file set. If the system is restarted following a crash, or a “fast shutdown” (i.e., innodb_fast_shutdown is greater than zero), there may be on-disk data structures (such as redo or undo entries, or doublewrite pages) that are in a “too-new” format for the current software. During the recovery process, serious damage can be done to your data files if these data structures are accessed. The startup check of the file format occurs before any recovery process begins, thereby preventing consistency issues with the new tables or startup problems for the MySQL server.

Beginning with version InnoDB 1.0.1, the system tablespace records an identifier or tag for the “highest” file format used by any table in any of the tablespaces that is part of the ib-file set. Checks against this file format tag are controlled by the configuration parameter innodb_file_format_check, which is ON by default.

If the file format tag in the system tablespace is newer or higher than the highest version supported by the particular currently executing software and if `innodb_file_format_check` is ON, the following error is issued when the server is started:

```
InnoDB: Error: the system tablespace is in a file format that this version doesn't support
```

You can also set `innodb_file_format` to a file format name. Doing so prevents InnoDB from starting if the current software does not support the file format specified. It also sets the “high water mark” to the value you specify. The ability to set `innodb_file_format_check` is useful (with future releases) if you manually “downgrade” all of the tables in an ib-file set. You can then rely on the file format check at startup if you subsequently use an older version of InnoDB to access the ib-file set.
In some limited circumstances, you might want to start the server and use an ib-file set that is in a new file format that is not supported by the software you are using. If you set the configuration parameter `innodb_file_format_check` to OFF, InnoDB opens the database, but issues this warning message in the error log:

```
InnoDB: Warning: the system tablespace is in a file format that this version doesn't support
```

**Note**

This is a dangerous setting, as it permits the recovery process to run, possibly corrupting your database if the previous shutdown was an unexpected exit or “fast shutdown”. You should only set `innodb_file_format_check` to OFF if you are sure that the previous shutdown was done with `innodb_fast_shutdown=0`, so that essentially no recovery process occurs.

The parameter `innodb_file_format_check` affects only what happens when a database is opened, not subsequently. Conversely, the parameter `innodb_file_format` (which enables a specific format) only determines whether or not a new table can be created in the enabled format and has no effect on whether or not a database can be opened.

The file format tag is a “high water mark”, and as such it is increased after the server is started, if a table in a “higher” format is created or an existing table is accessed for read or write (assuming its format is supported). If you access an existing table in a format higher than the format the running software supports, the system tablespace tag is not updated, but table-level compatibility checking applies (and an error is issued), as described in Section 14.10.2.2, “Compatibility Check When a Table Is Opened”. Any time the high water mark is updated, the value of `innodb_file_format_check` is updated as well, so the command `SELECT @@innodb_file_format_check;` displays the name of the latest file format known to be used by tables in the currently open ib-file set and supported by the currently executing software.

### 14.10.2.2 Compatibility Check When a Table Is Opened

When a table is first accessed, InnoDB (including some releases prior to InnoDB 1.0) checks that the file format of the tablespace in which the table is stored is fully supported. This check prevents crashes or corruptions that would otherwise occur when tables using a “too new” data structure are encountered.

All tables using any file format supported by a release can be read or written (assuming the user has sufficient privileges). The setting of the system configuration parameter `innodb_file_format` can prevent creating a new table that uses a specific file format, even if the file format is supported by a given release. Such a setting might be used to preserve backward compatibility, but it does not prevent accessing any table that uses a supported format.

Versions of MySQL older than 5.0.21 cannot reliably use database files created by newer versions if a new file format was used when a table was created. To prevent various error conditions or corruptions, InnoDB checks file format compatibility when it opens a file (for example, upon first access to a table). If the currently running version of InnoDB does not support the file format identified by the table type in the InnoDB data dictionary, MySQL reports the following error:

```
ERROR 1146 (42S02): Table 'test.t1' doesn't exist
```

InnoDB also writes a message to the error log:

```
InnoDB: table test/t1: unknown table type 33
```

The table type should be equal to the tablespace flags, which contains the file format version as discussed in Section 14.10.3, “Identifying the File Format in Use”.

Versions of InnoDB prior to MySQL 4.1 did not include table format identifiers in the database files, and versions prior to MySQL 5.0.21 did not include a table format compatibility check. Therefore, there is no
way to ensure proper operations if a table in a newer file format is used with versions of InnoDB prior to 5.0.21.

The file format management capability in InnoDB 1.0 and higher (tablespace tagging and run-time checks) allows InnoDB to verify as soon as possible that the running version of software can properly process the tables existing in the database.

If you permit InnoDB to open a database containing files in a format it does not support (by setting the parameter `innodb_file_format_check` to `OFF`), the table-level checking described in this section still applies.

Users are strongly urged not to use database files that contain Barracuda file format tables with releases of InnoDB older than the MySQL 5.1 with the InnoDB Plugin. It may be possible to rebuild such tables to use the Antelope format.

### 14.10.3 Identifying the File Format in Use

If you enable a different file format using the `innodb_file_format` configuration option, the change only applies to newly created tables. Also, when you create a new table, the tablespace containing the table is tagged with the “earliest” or “simplest” file format that is required to support the table’s features. For example, if you enable the Barracuda file format, and create a new table that does not use the Dynamic or Compressed row format, the new tablespace that contains the table is tagged as using the Antelope file format.

It is easy to identify the file format used by a given table. The table uses the Antelope file format if the row format reported by `SHOW TABLE STATUS` is either Compact or Redundant. The table uses the Barracuda file format if the row format reported by `SHOW TABLE STATUS` is either Compressed or Dynamic.

```
mysql> SHOW TABLE STATUS\G
*************************** 1. row ***************************
    Name: t1
   Engine: InnoDB
     Version: 10
 Row_format: Compact
        Rows: 0
Avg_row_length: 0
  Data_length: 16384
Max_data_length: 0
     Index_length: 16384
        Data_free: 0
Auto_increment: 1
  Create_time: 2014-11-03 13:32:10
 Update_time: NULL
    Check_time: NULL
Collation: latin1_swedish_ci
     Checksum: NULL
Create_options: 
    Comment:
```

You can also identify the file format used by a given table or tablespace using `InnoDB INFORMATION_SCHEMA` tables. For example:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME='test/t1'\G
*************************** 1. row ***************************
  TABLE_ID: 44
      NAME: test/t1
        FLAG: 1
    N_COLS: 6
      SPACE: 30
 FILE_FORMAT: Antelope
  ROW_FORMAT: Compact
ZIP_PAGE_SIZE: 0
```

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES WHERE NAME='test/t1'\G
*************************** 1. row ***************************
```

1933
14.10.4 Modifying the File Format

Each InnoDB tablespace file (with a name matching *.ibd) is tagged with the file format used to create its table and indexes. The way to modify the file format is to re-create the table and its indexes. The easiest way to recreate a table and its indexes is to use the following command on each table that you want to modify:

```
ALTER TABLE t ROW_FORMAT=format_name;
```

If you are modifying the file format to downgrade to an older MySQL version, there may be incompatibilities in table storage formats that require additional steps. For information about downgrading to a previous MySQL version, see Section 2.12, “Downgrading MySQL”.

14.11 InnoDB Row Formats

The row format of a table determines how its rows are physically stored, which in turn can affect the performance of queries and DML operations. As more rows fit into a single disk page, queries and index lookups can work faster, less cache memory is required in the buffer pool, and less I/O is required to write out updated values.

The data in each table is divided into pages. The pages that make up each table are arranged in a tree data structure called a B-tree index. Table data and secondary indexes both use this type of structure. The B-tree index that represents an entire table is known as the clustered index, which is organized according to the primary key columns. The nodes of a clustered index data structure contain the values of all columns in the row. The nodes of a secondary index structure contain the values of index columns and primary key columns.

Variable-length columns are an exception to the rule that column values are stored in B-tree index nodes. Variable-length columns that are too long to fit on a B-tree page are stored on separately allocated disk pages called overflow pages. Such columns are referred to as off-page columns. The values of off-page columns are stored in singly-linked lists of overflow pages, with each such column having its own list of one or more overflow pages. Depending on column length, all or a prefix of variable-length column values are stored in the B-tree to avoid wasting storage and having to read a separate page.

The InnoDB storage engine supports four row formats: REDUNDANT, COMPACT, DYNAMIC, and COMPRESSED.

### Table 14.7 InnoDB Row Format Overview

The topics that follow describe row format storage characteristics and how to define and determine the row format of a table.

- REDUNDANT Row Format
- COMPACT Row Format
- DYNAMIC Row Format
- COMPRESSED Row Format
- Defining the Row Format of a Table
- Determining the Row Format of a Table

**REDUNDANT Row Format**

The **REDUNDANT** format provides compatibility with older versions of MySQL.

The **REDUNDANT** row format is supported by both InnoDB file formats (Antelope and Barracuda). For more information, see Section 14.10, "InnoDB File-Format Management".

Tables that use the **REDUNDANT** row format store the first 768 bytes of variable-length column values (VARCHAR, VARBINARY, and BLOB and TEXT types) in the index record within the B-tree node, with the remainder stored on overflow pages. Fixed-length columns greater than or equal to 768 bytes are encoded as variable-length columns, which can be stored off-page. For example, a **CHAR(255)** column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with utf8mb4.

If the value of a column is 768 bytes or less, an overflow page is not used, and some savings in I/O may result, since the value is stored entirely in the B-tree node. This works well for relatively short BLOB column values, but may cause B-tree nodes to fill with data rather than key values, reducing their efficiency. Tables with many BLOB columns could cause B-tree nodes to become too full, and contain too few rows, making the entire index less efficient than if rows were shorter or column values were stored off-page.

**REDUNDANT Row Format Storage Characteristics**

The **REDUNDANT** row format has the following storage characteristics:

- Each index record contains a 6-byte header. The header is used to link together consecutive records, and for row-level locking.

- Records in the clustered index contain fields for all user-defined columns. In addition, there is a 6-byte transaction ID field and a 7-byte roll pointer field.

- If no primary key is defined for a table, each clustered index record also contains a 6-byte row ID field.

- Each secondary index record contains all the primary key columns defined for the clustered index key that are not in the secondary index.

- A record contains a pointer to each field of the record. If the total length of the fields in a record is less than 128 bytes, the pointer is one byte; otherwise, two bytes. The array of pointers is called the record directory. The area where the pointers point is the data part of the record.

- Internally, fixed-length character columns such as **CHAR(10)** are stored in fixed-length format. Trailing spaces are not truncated from VARCHAR columns.

- Fixed-length columns greater than or equal to 768 bytes are encoded as variable-length columns, which can be stored off-page. For example, a **CHAR(255)** column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with utf8mb4.
COMPACT Row Format

- An SQL NULL value reserves one or two bytes in the record directory. An SQL NULL value reserves zero bytes in the data part of the record if stored in a variable-length column. For a fixed-length column, the fixed length of the column is reserved in the data part of the record. Reserving fixed space for NULL values permits columns to be updated in place from NULL to non-NULL values without causing index page fragmentation.

COMPACT Row Format

The COMPACT row format reduces row storage space by about 20% compared to the REDUNDANT row format, at the cost of increasing CPU use for some operations. If your workload is a typical one that is limited by cache hit rates and disk speed, COMPACT format is likely to be faster. If the workload is limited by CPU speed, compact format might be slower.

The COMPACT row format is supported by both InnoDB file formats (Antelope and Barracuda). For more information, see Section 14.10, “InnoDB File-Format Management”.

Tables that use the COMPACT row format store the first 768 bytes of variable-length column values (VARCHAR, VARBINARY, and BLOB and TEXT types) in the index record within the B-tree node, with the remainder stored on overflow pages. Fixed-length columns greater than or equal to 768 bytes are encoded as variable-length columns, which can be stored off-page. For example, a CHAR(255) column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with utf8mb4.

If the value of a column is 768 bytes or less, an overflow page is not used, and some savings in I/O may result, since the value is stored entirely in the B-tree node. This works well for relatively short BLOB column values, but may cause B-tree nodes to fill with data rather than key values, reducing their efficiency. Tables with many BLOB columns could cause B-tree nodes to become too full, and contain too few rows, making the entire index less efficient than if rows were shorter or column values were stored off-page.

COMPACT Row Format Storage Characteristics

- Each index record contains a 5-byte header that may be preceded by a variable-length header. The header is used to link together consecutive records, and for row-level locking.

- The variable-length part of the record header contains a bit vector for indicating NULL columns. If the number of columns in the index that can be NULL is \( N \), the bit vector occupies \( \text{CEILING}(N / 8) \) bytes. (For example, if there are anywhere from 9 to 16 columns that can be NULL, the bit vector uses two bytes.) Columns that are NULL do not occupy space other than the bit in this vector. The variable-length part of the header also contains the lengths of variable-length columns. Each length takes one or two bytes, depending on the maximum length of the column. If all columns in the index are NOT NULL and have a fixed length, the record header has no variable-length part.

- For each non-NULL variable-length field, the record header contains the length of the column in one or two bytes. Two bytes are only needed if part of the column is stored externally in overflow pages or the maximum length exceeds 255 bytes and the actual length exceeds 127 bytes. For an externally stored column, the 2-byte length indicates the length of the internally stored part plus the 20-byte pointer to the externally stored part. The internal part is 768 bytes, so the length is 768+20. The 20-byte pointer stores the true length of the column.

- The record header is followed by the data contents of non-NULL columns.

- Records in the clustered index contain fields for all user-defined columns. In addition, there is a 6-byte transaction ID field and a 7-byte roll pointer field.

- If no primary key is defined for a table, each clustered index record also contains a 6-byte row ID field.
• Each secondary index record contains all the primary key columns defined for the clustered index key that are not in the secondary index. If any of the primary key columns are variable length, the record header for each secondary index has a variable-length part to record their lengths, even if the secondary index is defined on fixed-length columns.

• Internally, for nonvariable-length character sets, fixed-length character columns such as `CHAR(10)` are stored in a fixed-length format.

Trailing spaces are not truncated from `VARCHAR` columns.

• Internally, for variable-length character sets such as `utf8mb3` and `utf8mb4`, InnoDB attempts to store `CHAR(N)` in `N` bytes by trimming trailing spaces. If the byte length of a `CHAR(N)` column value exceeds `N` bytes, trailing spaces are trimmed to a minimum of the column value byte length. The maximum length of a `CHAR(N)` column is the maximum character byte length × `N`.

A minimum of `N` bytes is reserved for `CHAR(N)`. Reserving the minimum space `N` in many cases enables column updates to be done in place without causing index page fragmentation. By comparison, `CHAR(N)` columns occupy the maximum character byte length × `N` when using the `RENDUNDANT` row format.

Fixed-length columns greater than or equal to 768 bytes are encoded as variable-length fields, which can be stored off-page. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.

### DYNAMIC Row Format

The `DYNAMIC` row format offers the same storage characteristics as the `COMPACT` row format but adds enhanced storage capabilities for long variable-length columns and supports large index key prefixes.

The `DYNAMIC` row format is supported by the Barracuda file format. For more information, see Section 14.10, “InnoDB File-Format Management”. To create tables that use the `DYNAMIC` row format, the `innodb_file_format` variable must be set to `Barracuda`, and the `innodb_file_per_table` variable must be enabled.

When a table is created with `ROW_FORMAT=DYNAMIC`, InnoDB can store long variable-length column values (for `VARCHAR`, `VARBINARY`, and `BLOB` and `TEXT` types) fully off-page, with the clustered index record containing only a 20-byte pointer to the overflow page. Fixed-length fields greater than or equal to 768 bytes are encoded as variable-length fields. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.

Whether columns are stored off-page depends on the page size and the total size of the row. When a row is too long, the longest columns are chosen for off-page storage until the clustered index record fits on the B-tree page. `TEXT` and `BLOB` columns that are less than or equal to 40 bytes are stored in line.

The `DYNAMIC` row format maintains the efficiency of storing the entire row in the index node if it fits (as do the `COMPACT` and `RENDUNDANT` formats), but the `DYNAMIC` row format avoids the problem of filling B-tree nodes with a large number of data bytes of long columns. The `DYNAMIC` row format is based on the idea that if a portion of a long data value is stored off-page, it is usually most efficient to store the entire value off-page. With `DYNAMIC` format, shorter columns are likely to remain in the B-tree node, minimizing the number of overflow pages required for a given row.

The `DYNAMIC` row format supports index key prefixes up to 3072 bytes. This feature is controlled by the `innodb_large_prefix` variable, which is disabled by default. See the `innodb_large_prefix` variable description for more information.

### DYNAMIC Row Format Storage Characteristics

The `DYNAMIC` row format is a variation of the `COMPACT` row format. For storage characteristics, see `COMPACT Row Format Storage Characteristics`.

1937
COMPRRESSED Row Format

The **COMPRRESSED** row format offers the same storage characteristics and capabilities as the **DYNAMIC** row format but adds support for table and index data compression.

The **COMPRRESSED** row format is supported by the Barracuda file format. For more information, see Section 14.10, "InnoDB File-Format Management". To create tables that use the **COMPRRESSED** row format, the `innodb_file_format` variable must be set to `Barracuda`, and the `innodb_file_per_table` variable must be enabled.

The **COMPRRESSED** row format uses similar internal details for off-page storage as the **DYNAMIC** row format, with additional storage and performance considerations from the table and index data being compressed and using smaller page sizes. With the **COMPRRESSED** row format, the **KEY_BLOCK_SIZE** option controls how much column data is stored in the clustered index, and how much is placed on overflow pages. For more information about the **COMPRRESSED** row format, see InnoDB Table Compression.

The **COMPRRESSED** row format supports index key prefixes up to 3072 bytes. This feature is controlled by the `innodb_large_prefix` variable, which is disabled by default. See the `innodb_large_prefix` variable description for more information.

**Compressed Row Format Storage Characteristics**

The **COMPRRESSED** row format is a variation of the **COMPACT** row format. For storage characteristics, see COMPACT Row Format Storage Characteristics.

**Defining the Row Format of a Table**

The default row format for InnoDB tables is **COMPACT**.

The row format of a table can be defined explicitly using the **ROW_FORMAT** table option in a **CREATE TABLE** or **ALTER TABLE** statement. For example:

```sql
CREATE TABLE t1 (c1 INT) ROW_FORMAT=COMPACT;
```

**ROW_FORMAT** options include **REDUNDANT**, **COMPACT**, **DYNAMIC**, and **COMPRRESSED**.

To create tables that use the **DYNAMIC** or **COMPRRESSED** row format, the `innodb_file_format` variable must be set to `Barracuda`, and the `innodb_file_per_table` variable must be enabled. Otherwise, if `innodb_strict_mode` is not enabled, InnoDB tables are created with the default **COMPACT** row format.

Oracle recommends enabling `innodb_strict_mode` when using the **ROW_FORMAT** table option in **CREATE TABLE** and **ALTER TABLE** statements.

**Determining the Row Format of a Table**

To determine the row format of a table, use **SHOW TABLE STATUS**:

```sql
mysql> SHOW TABLE STATUS IN test1\G
*************************** 1. row ***************************
Name: t1
Engine: InnoDB
Version: 10
Row_format: Compact
Rows: 0
Avg_row_length: 0
Data_length: 16384
Max_data_length: 0
Index_length: 16384
Data_free: 0
Auto_increment: 1
Create_time: 2014-10-31 16:02:01
```
Alternatively, query the `INFORMATION_SCHEMA.INNODB_SYS_TABLES` table:

```sql
mysql> SELECT NAME, ROW_FORMAT FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME='test1/t1';
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>ROW_FORMAT</th>
</tr>
</thead>
<tbody>
<tr>
<td>test1/t1</td>
<td>Dynamic</td>
</tr>
</tbody>
</table>

14.12 InnoDB Disk I/O and File Space Management

As a DBA, you must manage disk I/O to keep the I/O subsystem from becoming saturated, and manage disk space to avoid filling up storage devices. The ACID design model requires a certain amount of I/O that might seem redundant, but helps to ensure data reliability. Within these constraints, InnoDB tries to optimize the database work and the organization of disk files to minimize the amount of disk I/O. Sometimes, I/O is postponed until the database is not busy, or until everything needs to be brought to a consistent state, such as during a database restart after a fast shutdown.

This section discusses the main considerations for I/O and disk space with the default kind of MySQL tables (also known as InnoDB tables):

- Controlling the amount of background I/O used to improve query performance.
- Enabling or disabling features that provide extra durability at the expense of additional I/O.
- Organizing tables into many small files, a few larger files, or a combination of both.
- Balancing the size of redo log files against the I/O activity that occurs when the log files become full.
- How to reorganize a table for optimal query performance.

14.12.1 InnoDB Disk I/O

InnoDB uses asynchronous disk I/O where possible, by creating a number of threads to handle I/O operations, while permitting other database operations to proceed while the I/O is still in progress. On Linux and Windows platforms, InnoDB uses the available OS and library functions to perform “native” asynchronous I/O. On other platforms, InnoDB still uses I/O threads, but the threads may actually wait for I/O requests to complete; this technique is known as “simulated” asynchronous I/O.

Read-Ahead

If InnoDB can determine there is a high probability that data might be needed soon, it performs read-ahead operations to bring that data into the buffer pool so that it is available in memory. Making a few large read requests for contiguous data can be more efficient than making several small, spread-out requests. There are two read-ahead heuristics in InnoDB:

- In sequential read-ahead, if InnoDB notices that the access pattern to a segment in the tablespace is sequential, it posts in advance a batch of reads of database pages to the I/O system.
- In random read-ahead, if InnoDB notices that some area in a tablespace seems to be in the process of being fully read into the buffer pool, it posts the remaining reads to the I/O system.

For information about configuring read-ahead heuristics, see Section 14.8.3.3, “Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)”.

Doublewrite Buffer
**InnoDB** uses a novel file flush technique involving a structure called the **doublewrite buffer**, which is enabled by default (`innodb_doublewrite=ON`). It adds safety to recovery following an unexpected exit or power outage, and improves performance on most varieties of Unix by reducing the need for `fsync()` operations.

Before writing pages to a data file, **InnoDB** first writes them to a contiguous tablespace area called the doublewrite buffer. Only after the write and the flush to the doublewrite buffer has completed does **InnoDB** write the pages to their proper positions in the data file. If there is an operating system, storage subsystem, or unexpected **mysqld** process exit in the middle of a page write (causing a **torn page** condition), **InnoDB** can later find a good copy of the page from the doublewrite buffer during recovery.

### 14.12.2 File Space Management

The data files that you define in the configuration file using the `innodb_data_file_path` configuration option form the **InnoDB** system **tablespace**. The files are logically concatenated to form the system tablespace. There is no striping in use. You cannot define where within the system tablespace your tables are allocated. In a newly created system tablespace, **InnoDB** allocates space starting from the first data file.

To avoid the issues that come with storing all tables and indexes inside the system tablespace, you can enable the `innodb_file_per_table` configuration option (the default), which stores each newly created table in a separate tablespace file (with extension `.ibd`). For tables stored this way, there is less fragmentation within the disk file, and when the table is truncated, the space is returned to the operating system rather than still being reserved by **InnoDB** within the system tablespace.

#### Pages, Extents, Segments, and Tablespaces

Each tablespace consists of database **pages**. Every tablespace in a MySQL instance has the same page size. By default, all tablespaces have a page size of 16KB; you can reduce the page size to 8KB or 4KB by specifying the `innodb_page_size` option when you create the MySQL instance.

The pages are grouped into **extents** of size 1MB (64 consecutive 16KB pages, or 128 8KB pages, or 256 4KB pages). The “files” inside a tablespace are called **segments** in **InnoDB**. (These segments are different from the rollback segment, which actually contains many tablespace segments.)

When a segment grows inside the tablespace, **InnoDB** allocates the first 32 pages to it one at a time. After that, **InnoDB** starts to allocate whole extents to the segment. **InnoDB** can add up to 4 extents at a time to a large segment to ensure good sequentiality of data.

Two segments are allocated for each index in **InnoDB**. One is for nonleaf nodes of the B-tree, the other is for the leaf nodes. Keeping the leaf nodes contiguous on disk enables better sequential I/O operations, because these leaf nodes contain the actual table data.

Some pages in the tablespace contain bitmaps of other pages, and therefore a few extents in an **InnoDB** tablespace cannot be allocated to segments as a whole, but only as individual pages.

When you ask for available free space in the tablespace by issuing a `SHOW TABLE STATUS` statement, **InnoDB** reports the extents that are definitely free in the tablespace. **InnoDB** always reserves some extents for cleanup and other internal purposes; these reserved extents are not included in the free space.

When you delete data from a table, **InnoDB** contracts the corresponding B-tree indexes. Whether the freed space becomes available for other users depends on whether the pattern of deletes frees individual pages or extents to the tablespace. Dropping a table or deleting all rows from it is guaranteed to release the space to other users, but remember that deleted rows are physically removed only by the `purge` operation, which happens automatically some time after they are no longer needed for transaction rollbacks or consistent reads. (See Section 14.3, “**InnoDB Multi-Versioning**”.)

To see information about the tablespace, use the Tablespace Monitor. See Section 14.17, “**InnoDB Monitors**”.
How Pages Relate to Table Rows

The maximum row length is slightly less than half a database page. For example, the maximum row length is slightly less than 8KB for the default 16KB InnoDB page size, which is defined by the `innodb_page_size` configuration option.

If a row does not exceed the half page limit, all of it is stored locally within the page. If a row exceeds the half page limit, variable-length columns are chosen for external off-page storage until the row fits within half a page. External off-page storage for variable-length columns differs by row format:

- **COMPACT and REDUNDANT Row Formats**

  When a variable-length column is chosen for external off-page storage, InnoDB stores the first 768 bytes locally in the row, and the rest externally into overflow pages. Each such column has its own list of overflow pages. The 768-byte prefix is accompanied by a 20-byte value that stores the true length of the column and points into the overflow list where the rest of the value is stored. See Section 14.11, “InnoDB Row Formats”.

- **DYNAMIC and COMPRESSED Row Formats**

  When a variable-length column is chosen for external off-page storage, InnoDB stores a 20-byte pointer locally in the row, and the rest externally into overflow pages. See Section 14.11, “InnoDB Row Formats”.

`LONGBLOB` and `LONGTEXT` columns must be less than 4GB, and the total row length, including `BLOB` and `TEXT` columns, must be less than 4GB.

14.12.3 InnoDB Checkpoints

Making your log files very large may reduce disk I/O during checkpointing. It often makes sense to set the total size of the log files as large as the buffer pool or even larger. Although in the past large log files could make crash recovery take excessive time, starting with MySQL 5.5, performance enhancements to crash recovery make it possible to use large log files with fast startup after a crash. (Strictly speaking, this performance improvement is available for MySQL 5.1 with the InnoDB Plugin 1.0.7 and higher. It is with MySQL 5.5 that this improvement is available in the default InnoDB storage engine.)

How Checkpoint Processing Works

InnoDB implements a checkpoint mechanism known as fuzzy checkpointing. InnoDB flushes modified database pages from the buffer pool in small batches. There is no need to flush the buffer pool in one single batch, which would disrupt processing of user SQL statements during the checkpointing process.

During crash recovery, InnoDB looks for a checkpoint label written to the log files. It knows that all modifications to the database before the label are present in the disk image of the database. Then InnoDB scans the log files forward from the checkpoint, applying the logged modifications to the database.

14.12.4 Defragmenting a Table

Random insertions into or deletions from a secondary index can cause the index to become fragmented. Fragmentation means that the physical ordering of the index pages on the disk is not close to the index ordering of the records on the pages, or that there are many unused pages in the 64-page blocks that were allocated to the index.

One symptom of fragmentation is that a table takes more space than it “should” take. How much that is exactly, is difficult to determine. All InnoDB data and indexes are stored in B-trees, and their fill factor may vary from 50% to 100%. Another symptom of fragmentation is that a table scan such as this takes more time than it “should” take:
The preceding query requires MySQL to perform a full table scan, the slowest type of query for a large table.

To speed up index scans, you can periodically perform a “null” ALTER TABLE operation, which causes MySQL to rebuild the table:

```
ALTER TABLE tbl_name ENGINE=INNODB
```

As of MySQL 5.6.3, you can also use `ALTER TABLE tbl_name FORCE` to perform a “null” alter operation that rebuilds the table. Previously the `FORCE` option was recognized but ignored.

As of MySQL 5.6.17, both `ALTER TABLE tbl_name ENGINE=INNODB` and `ALTER TABLE tbl_name FORCE` use online DDL. For more information, see Section 14.13, “InnoDB and Online DDL”.

Another way to perform a defragmentation operation is to use `mysqldump` to dump the table to a text file, drop the table, and reload it from the dump file.

If the insertions into an index are always ascending and records are deleted only from the end, the InnoDB filesystem management algorithm guarantees that fragmentation in the index does not occur.

14.12.5 Reclaiming Disk Space with TRUNCATE TABLE

To reclaim operating system disk space when truncating an InnoDB table, the table must be stored in its own .ibd file. For a table to be stored in its own .ibd file, `innodb_file_per_table` must enabled when the table is created. Additionally, there cannot be a foreign key constraint between the table being truncated and other tables, otherwise the TRUNCATE TABLE operation fails. A foreign key constraint between two columns in the same table, however, is permitted.

When a table is truncated, it is dropped and re-created in a new .ibd file, and the freed space is returned to the operating system. This is in contrast to truncating InnoDB tables that are stored within the InnoDB system tablespace (tables created when `innodb_file_per_table=OFF`), where only InnoDB can use the freed space after the table is truncated.

The ability to truncate tables and return disk space to the operating system also means that physical backups can be smaller. Truncating tables that are stored in the system tablespace (tables created when `innodb_file_per_table=OFF`) leaves blocks of unused space in the system tablespace.

14.13 InnoDB and Online DDL

The online DDL feature provides support for in-place table alterations and concurrent DML. Benefits of this feature include:

- Improved responsiveness and availability in busy production environments, where making a table unavailable for minutes or hours is not practical.
- The ability to adjust the balance between performance and concurrency during DDL operations using the `LOCK` clause. See The LOCK clause.
- Less disk space usage and I/O overhead than the table-copy method.

The online DDL feature builds on the fast index creation feature that is available in MySQL 5.5, which optimized `CREATE INDEX` and `DROP INDEX` to avoid table-copying behavior.

The NDB Cluster NDB storage engine also supports online table schema changes, but uses its own syntax that is not compatible with the syntax used for InnoDB online DDL operations. For more information, see Section 18.5.11, “Online Operations with ALTER TABLE in NDB Cluster”.

Typically, you do not need to do anything special to enable online DDL. By default, MySQL performs the operation in place, as permitted, with as little locking as possible.
You can control aspects of a DDL operation using the `ALGORITHM` and `LOCK` clauses of the `ALTER TABLE` statement. These clauses are placed at the end of the statement, separated from the table and column specifications by commas. For example:

```sql
ALTER TABLE tbl_name ADD PRIMARY KEY (column), ALGORITHM=INPLACE, LOCK=NONE;
```

The `LOCK` clause is useful for fine-tuning the degree of concurrent access to the table. The `ALGORITHM` clause is primarily intended for performance comparisons and as a fallback to the older table-copying behavior in case you encounter any issues. For example:

- To avoid accidentally making the table unavailable for reads, writes, or both, specify a clause on the `ALTER TABLE` statement such as `LOCK=NONE` (permit reads and writes) or `LOCK=SHARED` (permit reads). The operation halts immediately if the requested level of concurrency is not available.

- To compare performance, run a statement with `ALGORITHM=INPLACE` and `ALGORITHM=COPY`. Alternatively, run a statement with the `old_alter_table` configuration option disabled and enabled.

- To avoid tying up the server with an `ALTER TABLE` operation that copies the table, include `ALGORITHM=INPLACE`. The statement halts immediately if it cannot use the in-place mechanism.

### 14.13.1 Online DDL Operations

Online support details, syntax examples, and usage notes for DDL operations are provided under the following topics in this section.

- Index Operations
- Primary Key Operations
- Column Operations
- Foreign Key Operations
- Table Operations
- Partitioning Operations

### Index Operations

The following table provides an overview of online DDL support for index operations. An asterisk indicates additional information, an exception, or a dependency. For details, see Syntax and Usage Notes.

<table>
<thead>
<tr>
<th>Operation</th>
<th>In Place</th>
<th>Rebuilds Table</th>
<th>Permits Concurrent DML</th>
<th>Only Modifies Metadata</th>
</tr>
</thead>

<td>No*</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Changing the index type</td>
<td>Yes</td>
<td>No</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

### Syntax and Usage Notes

- Creating or adding a secondary index
CREATE INDEX name ON table (col_list);

ALTER TABLE tbl_name ADD INDEX name (col_list);

The table remains available for read and write operations while the index is being created. The CREATE INDEX statement only finishes after all transactions that are accessing the table are completed, so that the initial state of the index reflects the most recent contents of the table.

Online DDL support for adding secondary indexes means that you can generally speed the overall process of creating and loading a table and associated indexes by creating the table without secondary indexes, then adding secondary indexes after the data is loaded.

A newly created secondary index contains only the committed data in the table at the time the CREATE INDEX or ALTER TABLE statement finishes executing. It does not contain any uncommitted values, old versions of values, or values marked for deletion but not yet removed from the old index.

If the server exits while creating a secondary index, upon recovery, MySQL drops any partially created indexes. You must re-run the ALTER TABLE or CREATE INDEX statement.

Some factors affect the performance, space usage, and semantics of this operation. For details, see Section 14.13.6, “Online DDL Limitations”.

• Dropping an index

DROP INDEX name ON table;

ALTER TABLE tbl_name DROP INDEX name;

The table remains available for read and write operations while the index is being dropped. The DROP INDEX statement only finishes after all transactions that are accessing the table are completed, so that the initial state of the index reflects the most recent contents of the table.

• Adding a FULLTEXT index

CREATE FULLTEXT INDEX name ON table(column);

Adding the first FULLTEXT index rebuilds the table if there is no user-defined FTS_DOC_ID column. Additional FULLTEXT indexes may be added without rebuilding the table.

• Changing the index type (USING {BTREE | HASH})

ALTER TABLE tbl_name DROP INDEX i1, ADD INDEX i1(key_part,...) USING BTREE, ALGORITHM=INPLACE;

Primary Key Operations

The following table provides an overview of online DDL support for primary key operations. An asterisk indicates additional information, an exception, or a dependency. See Syntax and Usage Notes.

Table 14.9 Online DDL Support for Primary Key Operations

<table>

<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>
Syntax and Usage Notes

- Adding a primary key

```sql
ALTER TABLE tbl_name ADD PRIMARY KEY (column), ALGORITHM=INPLACE, LOCK=NONE;
```

Rebuilds the table in place. Data is reorganized substantially, making it an expensive operation. `ALGORITHM=INPLACE` is not permitted under certain conditions if columns have to be converted to `NOT NULL`.

Restructuring the clustered index always requires copying table data. Thus, it is best to define the primary key when you create a table, rather than issuing `ALTER TABLE ... ADD PRIMARY KEY` later.

When you create a `UNIQUE` or `PRIMARY KEY` index, MySQL must do some extra work. For `UNIQUE` indexes, MySQL checks that the table contains no duplicate values for the key. For a `PRIMARY KEY` index, MySQL also checks that none of the `PRIMARY KEY` columns contains a `NULL`.

When you add a primary key using the `ALGORITHM=COPY` clause, MySQL converts `NULL` values in the associated columns to default values: 0 for numbers, an empty string for character-based columns and BLOBs, and 0000-00-00 00:00:00 for `DATETIME`. This is a non-standard behavior that Oracle recommends you not rely on. Adding a primary key using `ALGORITHM=INPLACE` is only permitted when the `SQL_MODE` setting includes the `strict_trans_tables` or `strict_all_tables` flags; when the `SQL_MODE` setting is strict, `ALGORITHM=INPLACE` is permitted, but the statement can still fail if the requested primary key columns contain `NULL` values. The `ALGORITHM=INPLACE` behavior is more standard-compliant.

If you create a table without a primary key, InnoDB chooses one for you, which can be the first `UNIQUE` key defined on `NOT NULL` columns, or a system-generated key. To avoid uncertainty and the potential space requirement for an extra hidden column, specify the `PRIMARY KEY` clause as part of the `CREATE TABLE` statement.

MySQL creates a new clustered index by copying the existing data from the original table to a temporary table that has the desired index structure. Once the data is completely copied to the temporary table, the original table is renamed with a different temporary table name. The temporary table comprising the new clustered index is renamed with the name of the original table, and the original table is dropped from the database.

The online performance enhancements that apply to operations on secondary indexes do not apply to the primary key index. The rows of an InnoDB table are stored in a clustered index organized based on the primary key, forming what some database systems call an “index-organized table”. Because the table structure is closely tied to the primary key, redefining the primary key still requires copying the data.

When an operation on the primary key uses `ALGORITHM=INPLACE`, even though the data is still copied, it is more efficient than using `ALGORITHM=COPY` because:

- No undo logging or associated redo logging is required for `ALGORITHM=INPLACE`. These operations add overhead to DDL statements that use `ALGORITHM=COPY`.
- The secondary index entries are pre-sorted, and so can be loaded in order.
- The change buffer is not used, because there are no random-access inserts into the secondary indexes.

If the server exits while creating a new clustered index, no data is lost, but you must complete the recovery process using the temporary tables that exist during the process. Since it is rare to re-create a clustered index or re-define primary keys on large tables, or to encounter a system crash during this operation, this manual does not provide information on recovering from this scenario.

- Dropping a primary key
Online DDL Operations

ALTER TABLE tbl_name DROP PRIMARY KEY, ALGORITHM=COPY;

Only ALGORITHM=COPY supports dropping a primary key without adding a new one in the same ALTER TABLE statement.

- Dropping a primary key and adding another

ALTER TABLE tbl_name DROP PRIMARY KEY, ADD PRIMARY KEY (column), ALGORITHM=INPLACE, LOCK=NONE;

Data is reorganized substantially, making it an expensive operation.

Column Operations

The following table provides an overview of online DDL support for column operations. An asterisk indicates additional information, an exception, or a dependency. For details, see Syntax and Usage Notes.

Table 14.10 Online DDL Support for Column Operations

<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Modifying the definition of an ENUM or SET column</td>
<td>Yes</td>
<td>No</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Syntax and Usage Notes

- Adding a column

ALTER TABLE tbl_name ADD COLUMN column_name column_definition, ALGORITHM=INPLACE, LOCK=NONE;

Concurrent DML is not permitted when adding an auto-increment column. Data is reorganized substantially, making it an expensive operation. At a minimum, ALGORITHM=INPLACE, LOCK=SHARED is required.
Online DDL Operations

- Dropping a column
  
  ```sql
  ALTER TABLE tbl_name DROP COLUMN column_name, ALGORITHM=INPLACE, LOCK=NONE;
  ```

  Data is reorganized substantially, making it an expensive operation.

- Renaming a column
  
  ```sql
  ALTER TABLE tbl CHANGE old_col_name new_col_name data_type, ALGORITHM=INPLACE, LOCK=NONE;
  ```

  To permit concurrent DML, keep the same data type and [NOT] NULL attribute, only changing the column name. The operation can always be performed online.

  You can also rename a column that is part of a foreign key constraint. The foreign key definition is automatically updated to use the new column name. Renaming a column participating in a foreign key only works with ALGORITHM=INPLACE. If you use the ALGORITHM=COPY clause, or some other condition causes the command to use ALGORITHM=COPY behind the scenes, the ALTER TABLE statement fails.

- Reordering columns
  
  To reorder columns, use FIRST or AFTER in CHANGE or MODIFY operations.
  
  ```sql
  ALTER TABLE tbl_name MODIFY COLUMN col_name column_definition FIRST, ALGORITHM=INPLACE, LOCK=NONE;
  ```

  Data is reorganized substantially, making it an expensive operation.

- Changing the column data type
  
  ```sql
  ALTER TABLE tbl_name CHANGE c1 c1 BIGINT, ALGORITHM=COPY;
  ```

  Changing the column data type is only supported with ALGORITHM=COPY.

- Setting a column default value
  
  ```sql
  ALTER TABLE tbl_name ALTER COLUMN col SET DEFAULT literal, ALGORITHM=INPLACE, LOCK=NONE;
  ```

  Only modifies table metadata. Default column values are stored in the .frm file for the table, not the InnoDB data dictionary.

- Dropping a column default value
  
  ```sql
  ALTER TABLE tbl ALTER COLUMN col DROP DEFAULT, ALGORITHM=INPLACE, LOCK=NONE;
  ```

- Changing the auto-increment value
  
  ```sql
  ALTER TABLE table AUTO_INCREMENT=next_value, ALGORITHM=INPLACE, LOCK=NONE;
  ```

  Modifies a value stored in memory, not the data file.

  In a distributed system using replication or sharding, you sometimes reset the auto-increment counter for a table to a specific value. The next row inserted into the table uses the specified value for its auto-increment column. You might also use this technique in a data warehousing environment where you periodically empty all the tables and reload them, and restart the auto-increment sequence from 1.

- Making a column NULL
  
  ```sql
  ALTER TABLE tbl_name MODIFY COLUMN column_name data_type NULL, ALGORITHM=INPLACE, LOCK=NONE;
  ```

  Rebuilds the table in place. Data is reorganized substantially, making it an expensive operation.

- Making a column NOT NULL
Online DDL Operations

ALTER TABLE tbl_name MODIFY COLUMN column_name data_type NOT NULL, ALGORITHM=INPLACE, LOCK=NONE;

Rebuilds the table in place. STRICT_ALL_TABLES or STRICT_TRANS_TABLES SQL MODE is required for the operation to succeed. The operation fails if the column contains NULL values. The server prohibits changes to foreign key columns that have the potential to cause loss of referential integrity. See Section 13.1.7, “ALTER TABLE Statement”. Data is reorganized substantially, making it an expensive operation.

• Modifying the definition of an ENUM or SET column

CREATE TABLE t1 (c1 ENUM('a', 'b', 'c'));
ALTER TABLE t1 MODIFY COLUMN c1 ENUM('a', 'b', 'c', 'd'), ALGORITHM=INPLACE, LOCK=NONE;

Modifying the definition of an ENUM or SET column by adding new enumeration or set members to the end of the list of valid member values may be performed in place, as long as the storage size of the data type does not change. For example, adding a member to a SET column that has 8 members changes the required storage per value from 1 byte to 2 bytes; this requires a table copy. Adding members in the middle of the list causes renumbering of existing members, which requires a table copy.

Foreign Key Operations

The following table provides an overview of online DDL support for foreign key operations. An asterisk indicates additional information, an exception, or a dependency. For details, see Syntax and Usage Notes.

Table 14.11 Online DDL Support for Foreign Key Operations

<table>
<thead>
<tr>
<th>Operation</th>
<th>In Place</th>
<th>Rebuilds Table</th>
<th>Permits Concurrent DML</th>
<th>Only Modifies Metadata</th>
</tr>
</thead>
<tbody>
<tr>
<td>Adding a foreign key constraint</td>
<td>Yes*</td>
<td>No</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Dropping a foreign key constraint</td>
<td>Yes</td>
<td>No</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Syntax and Usage Notes

• Adding a foreign key constraint

The INPLACE algorithm is supported when foreign_key_checks is disabled. Otherwise, only the COPY algorithm is supported.

ALTER TABLE tbl1 ADD CONSTRAINT fk_name FOREIGN KEY index (col1)
REFERENCES tbl2(col2) referential_actions;

• Dropping a foreign key constraint

ALTER TABLE tbl DROP FOREIGN KEY fk_name;

Dropping a foreign key can be performed online with the foreign_key_checks option enabled or disabled.

If you do not know the names of the foreign key constraints on a particular table, issue the following statement and find the constraint name in the CONSTRAINT clause for each foreign key:

SHOW CREATE TABLE table\G

Or, query the INFORMATION_SCHEMA.TABLE_CONSTRAINTS table and use the CONSTRAINT_NAME and CONSTRAINT_TYPE columns to identify the foreign key names.

You can also drop a foreign key and its associated index in a single statement:
ALTER TABLE table DROP FOREIGN KEY constraint, DROP INDEX index;

Note

If foreign keys are already present in the table being altered (that is, it is a child table containing a FOREIGN KEY ... REFERENCE clause), additional restrictions apply to online DDL operations, even those not directly involving the foreign key columns:

• An ALTER TABLE on the child table could wait for another transaction to commit, if a change to the parent table causes associated changes in the child table through an ON UPDATE or ON DELETE clause using the CASCADE or SET NULL parameters.

• In the same way, if a table is the parent table in a foreign key relationship, even though it does not contain any FOREIGN KEY clauses, it could wait for the ALTER TABLE to complete if an INSERT, UPDATE, or DELETE statement causes an ON UPDATE or ON DELETE action in the child table.

Table Operations

The following table provides an overview of online DDL support for table operations. An asterisk indicates additional information, an exception, or a dependency. For details, see Syntax and Usage Notes.

Table 14.12 Online DDL Support for Table Operations

<table>

<td>Yes*</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Renaming a table</td>
<td>Yes</td>
<td>No</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Syntax and Usage Notes

• Changing the ROW_FORMAT

ALTER TABLE tbl_name ROW_FORMAT = row_format, ALGORITHM=INPLACE, LOCK=NONE;

Data is reorganized substantially, making it an expensive operation.

For additional information about the ROW_FORMAT option, see Table Options.

• Changing the KEY_BLOCK_SIZE
Online DDL Operations

ALTER TABLE `tbl_name` KEY_BLOCK_SIZE = `value`, ALGORITHM=INPLACE, LOCK=NONE;

Data is reorganized substantially, making it an expensive operation.

For additional information about the `KEY_BLOCK_SIZE` option, see Table Options.

- Setting persistent table statistics options

```
ALTER TABLE `tbl_name` STATS_PERSISTENT=0, STATS_SAMPLE_PAGES=20, STATS_AUTO_RECALC=1, ALGORITHM=INPLACE, LOCK=NONE;
```

Only modifies table metadata.

Persistent statistics include `STATS_PERSISTENT`, `STATS_AUTO_RECALC`, and `STATS_SAMPLE_PAGES`. For more information, see Section 14.8.11.1, "Configuring Persistent Optimizer Statistics Parameters".

- Specifying a character set

```
ALTER TABLE `tbl_name` CHARACTER SET = `charset_name`, ALGORITHM=INPLACE, LOCK=NONE;
```

Rebuilds the table if the new character encoding is different.

- Converting a character set

```
ALTER TABLE `tbl_name` CONVERT TO CHARACTER SET `charset_name`, ALGORITHM=INPLACE;
```

Rebuilds the table if the new character encoding is different.

- Optimizing a table

```
OPTIMIZE TABLE `tbl_name`;
```

Performed in-place as of MySQL 5.6.17. In-place operation is not supported for tables with `FULLTEXT` indexes. The operation uses the `INPLACE` algorithm, but `ALGORITHM` and `LOCK` syntax is not permitted.

- Rebuilding a table with the FORCE option

```
ALTER TABLE `tbl_name` FORCE, ALGORITHM=INPLACE, LOCK=NONE;
```

Uses `ALGORITHM=INPLACE` as of MySQL 5.6.17. `ALGORITHM=INPLACE` is not supported for tables with `FULLTEXT` indexes.

- Performing a "null" rebuild

```
ALTER TABLE `tbl_name` ENGINE=InnoDB, ALGORITHM=INPLACE, LOCK=NONE;
```

Uses `ALGORITHM=INPLACE` as of MySQL 5.6.17. `ALGORITHM=INPLACE` is not supported for tables with `FULLTEXT` indexes.

- Renaming a table

```
ALTER TABLE `old_tbl_name` RENAME TO `new_tbl_name`, ALGORITHM=INPLACE, LOCK=NONE;
```

MySQL renames files that correspond to the table `tbl_name` without making a copy. (You can also use the `RENAME TABLE` statement to rename tables. See Section 13.1.32, "RENAME TABLE Statement"). Privileges granted specifically for the renamed table are not migrated to the new name. They must be changed manually.

Partitioning Operations

With the exception of `ALTER TABLE` partitioning clauses, online DDL operations for partitioned InnoDB tables follow the same rules that apply to regular InnoDB tables.
Online DDL Performance and Concurrency

`ALTER TABLE` partitioning clauses do not go through the same internal online DDL API as regular non-partitioned InnoDB tables, and most do not support `ALGORITHM` and `LOCK` clauses.

If you use a partitioning clause in an `ALTER TABLE` statement, the partitioned table is repartitioned using the `ALTER TABLE COPY` algorithm. In other words, a new partitioned table is created with the new partitioning scheme. The newly created table includes any changes applied by the `ALTER TABLE` statement and the table data is copied into the new table structure.

If you do not modify table partitioning using `ALTER TABLE` partitioning clauses that use the `COPY` algorithm or perform any other partition management in your `ALTER TABLE` statement, `ALTER TABLE` performs supported `INPLACE` operations on each table partition. Be aware, however, that when `INPLACE ALTER TABLE` operations are performed on each partition, there is increased demand on system resources due to operations being performed on multiple partitions.

Even though partitioning clauses of the `ALTER TABLE` statement do not go through the same internal online DDL API as regular non-partitioned InnoDB tables, MySQL still attempts to minimize data copying and locking where possible:

- `ADD PARTITION` and `DROP PARTITION` for tables partitioned by `RANGE` or `LIST` do not copy existing data.
- `TRUNCATE PARTITION` does not copy existing data.
- Concurrent queries are allowed during `ADD PARTITION` and `COALESCE PARTITION` for tables partitioned by `HASH` or `LIST`. MySQL copies the data while holding a shared lock.
- For `REORGANIZE PARTITION`, `REBUILD PARTITION`, or `ADD PARTITION` or `COALESCE PARTITION` for a table partitioned by `LINEAR HASH` or `LIST`, concurrent queries are allowed. Data from the affected partitions is copied while holding a shared metadata (read) lock on the table.
- `PARTITION BY` and `REMOVE PARTITIONING` permit concurrent queries.

`ALTER TABLE` statements that change a table's partitioning cannot use `ALGORITHM` with `DEFAULT`, `COPY`, or `INPLACE`. (MySQL 5.6.11 and later support such statements using `ALGORITHM=1` or `ALGORITHM=2` when performing upgrades or downgrades.) Such `ALTER TABLE` statements also do not support a `LOCK` clause.

For additional information about `ALTER TABLE` partitioning clauses, see `Partitioning Options`, and Section 13.1.7.1, “`ALTER TABLE` Partition Operations”. For information about partitioning in general, see Chapter 19, `Partitioning`.

### 14.13.2 Online DDL Performance and Concurrency

Online DDL improves several aspects of MySQL operation:

- Applications that access the table are more responsive because queries and DML operations on the table can proceed while the DDL operation is in progress. Reduced locking and waiting for MySQL server resources leads to greater scalability, even for operations that are not involved in the DDL operation.
- In-place operations avoid the disk I/O and CPU cycles associated with the table-copy method, which minimizes overall load on the database. Minimizing load helps maintain good performance and high throughput during the DDL operation.
- In-place operations read less data into the buffer pool than the table-copy operations, which reduces purging of frequently accessed data from memory. Purging of frequently accessed data can cause a temporary performance dip after a DDL operation.

**The LOCK clause**

By default, MySQL uses as little locking as possible during a DDL operation. The `LOCK` clause can be specified to enforce more restrictive locking, if required. If the `LOCK` clause specifies a less restrictive
level of locking than is permitted for a particular DDL operation, the statement fails with an error. LOCK clauses are described below, in order of least to most restrictive:

- **LOCK=NONE:**
  Permits concurrent queries and DML.
  For example, use this clause for tables involving customer signups or purchases, to avoid making the tables unavailable during lengthy DDL operations.

- **LOCK=SHARED:**
  Permits concurrent queries but blocks DML.
  For example, use this clause on data warehouse tables, where you can delay data load operations until the DDL operation is finished, but queries cannot be delayed for long periods.

- **LOCK=DEFAULT:**
  Permits as much concurrency as possible (concurrent queries, DML, or both). Omitting the LOCK clause is the same as specifying **LOCK=DEFAULT**.
  Use this clause when you know that the default locking level of the DDL statement will not cause availability problems for the table.

- **LOCK=EXCLUSIVE:**
  Blocks concurrent queries and DML.
  Use this clause if the primary concern is finishing the DDL operation in the shortest amount of time possible, and concurrent query and DML access is not necessary. You might also use this clause if the server is supposed to be idle, to avoid unexpected table accesses.

### Online DDL and Metadata Locks

Online DDL operations can be viewed as having three phases:

- **Phase 1: Initialization**

  In the initialization phase, the server determines how much concurrency is permitted during the operation, taking into account storage engine capabilities, operations specified in the statement, and user-specified ALGORITHM and LOCK options. During this phase, a shared upgradeable metadata lock is taken to protect the current table definition.

- **Phase 2: Execution**

  In this phase, the statement is prepared and executed. Whether the metadata lock is upgraded to exclusive depends on the factors assessed in the initialization phase. If an exclusive metadata lock is required, it is only taken briefly during statement preparation.

- **Phase 3: Commit Table Definition**

  In the commit table definition phase, the metadata lock is upgraded to exclusive to evict the old table definition and commit the new one. Once granted, the duration of the exclusive metadata lock is brief.

Due to the exclusive metadata lock requirements outlined above, an online DDL operation may have to wait for concurrent transactions that hold metadata locks on the table to commit or rollback. Transactions started before or during the DDL operation can hold metadata locks on the table being altered. In the case of a long running or inactive transaction, an online DDL operation can time out waiting for an exclusive metadata lock. Additionally, a pending exclusive metadata lock requested by an online DDL operation blocks subsequent transactions on the table.
The following example demonstrates an online DDL operation waiting for an exclusive metadata lock, and how a pending metadata lock blocks subsequent transactions on the table.

Session 1:

```sql
mysql> CREATE TABLE t1 (c1 INT) ENGINE=InnoDB;
```

```sql
mysql> START TRANSACTION;
```

```sql
mysql> SELECT * FROM t1;
```

The session 1 SELECT statement takes a shared metadata lock on table t1.

Session 2:

```sql
mysql> ALTER TABLE t1 ADD COLUMN x INT, ALGORITHM=INPLACE, LOCK=NONE;
```

The online DDL operation in session 2, which requires an exclusive metadata lock on table t1 to commit table definition changes, must wait for the session 1 transaction to commit or roll back.

Session 3:

```sql
mysql> SELECT * FROM t1;
```

The SELECT statement issued in session 3 is blocked waiting for the exclusive metadata lock requested by the ALTER TABLE operation in session 2 to be granted.

You can use SHOW FULL PROCESSLIST to determine if transactions are waiting for a metadata lock.

```sql
mysql> SHOW FULL PROCESSLIST\G
```

```
... 2. row ***************************
Id: 5
User: root
Host: localhost
db: test
Command: Query
Time: 44
State: Waiting for table metadata lock
Info: ALTER TABLE t1 ADD COLUMN x INT, ALGORITHM=INPLACE, LOCK=NONE
...
```

```
... 4. row ***************************
Id: 7
User: root
Host: localhost
db: test
Command: Query
Time: 5
State: Waiting for table metadata lock
Info: SELECT * FROM t1
```

**Online DDL Performance**

The performance of a DDL operation is largely determined by whether the operation is performed in place and whether it rebuilds the table.

To assess the relative performance of a DDL operation, you can compare results using ALGORITHM=INPLACE with results using ALGORITHM=COPY. Alternatively, you can compare results with old_alter_table disabled and enabled.

For DDL operations that modify table data, you can determine whether a DDL operation performs changes in place or performs a table copy by looking at the “rows affected” value displayed after the command finishes. For example:

- Changing the default value of a column (fast, does not affect the table data):

  ```sql
  Query OK, 0 rows affected (0.07 sec)
  ```

- Adding an index (takes time, but 0 rows affected shows that the table is not copied):
Before running a DDL operation on a large table, check whether the operation is fast or slow as follows:

1. Clone the table structure.
2. Populate the cloned table with a small amount of data.
3. Run the DDL operation on the cloned table.
4. Check whether the “rows affected” value is zero or not. A nonzero value means the operation copies table data, which might require special planning. For example, you might do the DDL operation during a period of scheduled downtime, or on each replica server one at a time.

**Note**

For a greater understanding of the MySQL processing associated with a DDL operation, examine `Performance Schema` and `INFORMATION_SCHEMA` tables related to InnoDB before and after DDL operations to see the number of physical reads, writes, memory allocations, and so on.

Because there is some processing work involved with recording the changes made by concurrent DML operations, then applying those changes at the end, an online DDL operation could take longer overall than the table-copy mechanism that blocks table access from other sessions. The reduction in raw performance is balanced against better responsiveness for applications that use the table. When evaluating the techniques for changing table structure, consider end-user perception of performance, based on factors such as load times for web pages.

### 14.13.3 Online DDL Space Requirements

Online DDL operations have the following space requirements:

- **Space for temporary log files**
  
  A temporary log file records concurrent DML when an online DDL operation creates an index or alters a table. The temporary log file is extended as required by the value of `innodb_sort_buffer_size` up to a maximum specified by `innodb_online_alter_log_max_size`. If a temporary log file exceeds the size limit, the online DDL operation fails, and uncommitted concurrent DML operations are rolled back. A large `innodb_online_alter_log_max_size` setting permits more DML during an online DDL operation, but it also extends the period of time at the end of the DDL operation when the table is locked to apply logged DML.

  If the operation takes a long time and concurrent DML modifies the table so much that the size of the temporary log file exceeds the value of `innodb_online_alter_log_max_size`, the online DDL operation fails with a `DB_ONLINE_LOG_TOO_BIG` error.

- **Space for temporary sort files**
  
  Online DDL operations that rebuild the table write temporary sort files to the MySQL temporary directory (`$TMPDIR` on Unix, `%TEMP%` on Windows, or the directory specified by `--tmpdir`) during index creation. Temporary sort files are not created in the directory that contains the original table. Each temporary sort file is large enough to hold one column of data, and each sort file is removed when its data is merged into the final table or index. Operations involving temporary sort files may require temporary space equal to the amount of data in the table plus indexes. An error is reported if online DDL operation uses all of the available disk space on the file system where the data directory resides.
If the MySQL temporary directory is not large enough to hold the sort files, set `tmpdir` to a different directory. Alternatively, define a separate temporary directory for online DDL operations using `innodb_tmpdir`. This option was introduced in MySQL 5.6.29 to help avoid temporary directory overflows that could occur as a result of large temporary sort files.

- Space for an intermediate table file

Some online DDL operations that rebuild the table create a temporary intermediate table file in the same directory as the original table. An intermediate table file may require space equal to the size of the original table. Intermediate table file names begin with `#sql-ib` prefix and only appear briefly during the online DDL operation.

The `innodb_tmpdir` option is not applicable to intermediate table files.

### 14.13.4 Simplifying DDL Statements with Online DDL

Before the introduction of online DDL, it was common practice to combine many DDL operations into a single `ALTER TABLE` statement. Because each `ALTER TABLE` statement involved copying and rebuilding the table, it was more efficient to make several changes to the same table at once, since those changes could all be done with a single rebuild operation for the table. The downside was that SQL code involving DDL operations was harder to maintain and to reuse in different scripts. If the specific changes were different each time, you might have to construct a new complex `ALTER TABLE` for each slightly different scenario.

For DDL operations that can be done in place, you can separate them into individual `ALTER TABLE` statements for easier scripting and maintenance, without sacrificing efficiency. For example, you might take a complicated statement such as:

```sql
ALTER TABLE t1 ADD INDEX i1(c1), ADD UNIQUE INDEX i2(c2),
   CHANGE c4_old_name c4_new_name INTEGER UNSIGNED;
```

and break it down into simpler parts that can be tested and performed independently, such as:

```sql
ALTER TABLE t1 ADD INDEX i1(c1);
ALTER TABLE t1 ADD UNIQUE INDEX i2(c2);
ALTER TABLE t1 CHANGE c4_old_name c4_new_name INTEGER UNSIGNED NOT NULL;
```

You might still use multi-part `ALTER TABLE` statements for:

- Operations that must be performed in a specific sequence, such as creating an index followed by a foreign key constraint that uses that index.
- Operations all using the same specific `LOCK` clause, that you want to either succeed or fail as a group.
- Operations that cannot be performed in place, that is, that still use the table-copy method.
- Operations for which you specify `ALGORITHM=COPY` or `old_alter_table=1`, to force the table-copying behavior if needed for precise backward-compatibility in specialized scenarios.

### 14.13.5 Online DDL Failure Conditions

The failure of an online DDL operation is typically due to one of the following conditions:

- An `ALGORITHM` clause specifies an algorithm that is not compatible with the particular type of DDL operation or storage engine.
- A `LOCK` clause specifies a low degree of locking (`SHARED` or `NONE`) that is not compatible with the particular type of DDL operation.
- A timeout occurs while waiting for an exclusive lock on the table, which may be needed briefly during the initial and final phases of the DDL operation.
• The `tmpdir` or `innodb_tmpdir` file system runs out of disk space, while MySQL writes temporary sort files on disk during index creation. For more information, see Section 14.13.3, “Online DDL Space Requirements”.

• The operation takes a long time and concurrent DML modifies the table so much that the size of the temporary online log exceeds the value of the `innodb_onlineAlter_log_max_size` configuration option. This condition causes a `DB_ONLINE_LOG_TOO_BIG` error.

• Concurrent DML makes changes to the table that are allowed with the original table definition, but not with the new one. The operation only fails at the very end, when MySQL tries to apply all the changes from concurrent DML statements. For example, you might insert duplicate values into a column while a unique index is being created, or you might insert NULL values into a column while creating a primary key index on that column. The changes made by the concurrent DML take precedence, and the `ALTER TABLE` operation is effectively rolled back.

### 14.13.6 Online DDL Limitations

The following limitations apply to online DDL operations:

• The table is copied when creating an index on a `TEMPORARY TABLE`.

• The `ALTER TABLE` clause `LOCK=NONE` is not permitted if there are `ON...CASCADE` or `ON...SET NULL` constraints on the table.

• Before an online DDL operation can finish, it must wait for transactions that hold metadata locks on the table to commit or roll back. An online DDL operation may briefly require an exclusive metadata lock on the table during its execution phase, and always requires one in the final phase of the operation when updating the table definition. Consequently, transactions holding metadata locks on the table can cause an online DDL operation to block. The transactions that hold metadata locks on the table may have been started before or during the online DDL operation. A long running or inactive transaction that holds a metadata lock on the table can cause an online DDL operation to timeout.

• An online DDL operation on a table in a foreign key relationship does not wait for a transaction executing on the other table in the foreign key relationship to commit or roll back. The transaction holds an exclusive metadata lock on the table it is updating and shared metadata lock on the foreign-key-related table (required for foreign key checking). The shared metadata lock permits the online DDL operation to proceed but blocks the operation in its final phase, when an exclusive metadata lock is required to update the table definition. This scenario can result in deadlocks as other transactions wait for the online DDL operation to finish.

• When running an online DDL operation, the thread that runs the `ALTER TABLE` statement applies an online log of DML operations that were run concurrently on the same table from other connection threads. When the DML operations are applied, it is possible to encounter a duplicate key entry error (error `1062 (23000): Duplicate entry`), even if the duplicate entry is only temporary and would be reverted by a later entry in the online log. This is similar to the idea of a foreign key constraint check in InnoDB in which constraints must hold during a transaction.

• `OPTIMIZE TABLE` for an `InnoDB` table is mapped to an `ALTER TABLE` operation to rebuild the table and update index statistics and free unused space in the clustered index. Prior to 5.6.17, there is no online DDL support for this operation. Secondary indexes are not created as efficiently because keys are inserted in the order they appeared in the primary key. As of 5.6.17, `OPTIMIZE TABLE` is supported with the addition of online DDL support for rebuilding regular and partitioned `InnoDB` tables.

• Tables created before MySQL 5.6 that include temporal columns (`DATE`, `DATETIME` or `TIMESTAMP`) and have not been rebuilt using `ALGORITHM=COPY` do not support `ALGORITHM=INPLACE`. In this case, an `ALTER TABLE ... ALGORITHM=INPLACE` operation returns the following error:

```
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported.
Reason: Cannot change column type INPLACE. Try ALGORITHM=COPY.
```

1956
The following limitations are generally applicable to online DDL operations on large tables that involve rebuilding the table:

- There is no mechanism to pause an online DDL operation or to throttle I/O or CPU usage for an online DDL operation.

- Progress monitoring capability for online DDL operations is limited until MySQL 5.7.6, which introduces Performance Schema stage events for monitoring ALTER TABLE progress. See Monitoring ALTER TABLE Progress for InnoDB Tables Using Performance Schema.

- Rollback of an online DDL operation can be expensive should the operation fail.

- Long running online DDL operations can cause replication lag. An online DDL operation must finish running on the source before it is run on the replica. Also, DML that was processed concurrently on the source is only processed on the replica after the DDL operation on the replica is completed.

For additional information related to running online DDL operations on large tables, see Section 14.13.2, “Online DDL Performance and Concurrency”.

### 14.14 InnoDB Startup Options and System Variables

System variables that are true or false can be enabled at server startup by naming them, or disabled by using a --skip- prefix. For example, to enable or disable the InnoDB adaptive hash index, you can use --innodb-adaptive-hash-index or --skip-innodb-adaptive-hash-index on the command line, or innodb_adaptive_hash_index or skip_innodb_adaptive_hash_index in an option file.

System variables that take a numeric value can be specified as --var_name=value on the command line or as var_name=value in option files.

Many system variables can be changed at runtime (see Section 5.1.8.2, “Dynamic System Variables”).

For information about GLOBAL and SESSION variable scope modifiers, refer to the SET statement documentation.

Certain options control the locations and layout of the InnoDB data files. Section 14.8.1, “InnoDB Startup Configuration” explains how to use these options.

Some options, which you might not use initially, help tune InnoDB performance characteristics based on machine capacity and your database workload.

For more information on specifying options and system variables, see Section 4.2.2, “Specifying Program Options”.

Controls loading of the InnoDB storage engine, if the server was compiled with InnoDB support. This option has a tristate format, with possible values of OFF, ON, or FORCE. See Section 5.5.1, “Installing and Uninstalling Plugins”.

To disable InnoDB, use `--innodb=OFF` or `--skip-innodb`. In this case, because the default storage engine is InnoDB, the server does not start unless you also use `--default-storage-engine` and `--default-tmp-storage-engine` to set the default to some other engine for both permanent and TEMPORARY tables.

As of MySQL 5.6.21, `--innodb=OFF` and `--skip-innodb` options are deprecated and their use results in a warning. These options will be removed in a future MySQL release.

- **--innodb-status-file**
### InnoDB System Variables

#### --innodb-status-file

| Command-Line Format | --innodb-status-file={OFF|ON} |
|---------------------|-------------------------------|
| Type                | Boolean                       |
| Default Value       | OFF                           |

The `--innodb-status-file` startup option controls whether InnoDB creates a file named `innodb_status.pid` in the data directory and writes `SHOW ENGINE INNODB STATUS` output to it every 15 seconds, approximately.

The `innodb_status.pid` file is not created by default. To create it, start `mysqld` with the `--innodb-status-file` option. InnoDB removes the file when the server is shut down normally. If an abnormal shutdown occurs, the status file may have to be removed manually.

The `--innodb-status-file` option is intended for temporary use, as `SHOW ENGINE INNODB STATUS` output generation can affect performance, and the `innodb_status.pid` file can become quite large over time.

For related information, see [Section 14.17.2, “Enabling InnoDB Monitors”](#).

- **--skip-innodb**

Disable the InnoDB storage engine. See the description of `--innodb`.

### InnoDB System Variables

- **daemon_memcached_enable_binlog**

| Command-Line Format | --daemon-memcached-enable-binlog={OFF|ON} |
|---------------------|------------------------------------------|
| System Variable     | daemon_memcached_enable_binlog           |
| Scope               | Global                                   |
| Dynamic             | No                                       |
| Type                | Boolean                                  |
| Default Value       | OFF                                      |

Enable this option on the source server to use the InnoDB memcached plugin (daemon_memcached) with the MySQL binary log. This option can only be set at server startup. You must also enable the MySQL binary log on the source server using the `--log-bin` option.

For more information, see [Section 14.20.6, “The InnoDB memcached Plugin and Replication”](#).

- **daemon_memcached_engine_lib_name**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--daemon-memcached-engine-lib-name=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>daemon_memcached_engine_lib_name</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>File name</td>
</tr>
<tr>
<td>Default Value</td>
<td>innodb_engine.so</td>
</tr>
</tbody>
</table>

Specifies the shared library that implements the InnoDB memcached plugin.

For more information, see [Section 14.20.3, “Setting Up the InnoDB memcached Plugin”](#).

- **daemon_memcached_engine_lib_path**

For information on this option, see Section 14.20.6, “The InnoDB memcached Plugin and Replication”.

---

1963

InnoDB System Variables

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--daemon-memcached-engine-lib-path=dir_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>daemon_memcached_engine_lib_path</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

The path of the directory containing the shared library that implements the InnoDB memcached plugin. The default value is NULL, representing the MySQL plugin directory. You should not need to modify this parameter unless specifying a memcached plugin for a different storage engine that is located outside of the MySQL plugin directory.

For more information, see Section 14.20.3, “Setting Up the InnoDB memcached Plugin”.

- daemon_memcached_option

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--daemon-memcached-option=options</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>daemon_memcached_option</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td></td>
</tr>
</tbody>
</table>

Used to pass space-separated memcached options to the underlying memcached memory object caching daemon on startup. For example, you might change the port that memcached listens on, reduce the maximum number of simultaneous connections, change the maximum memory size for a key-value pair, or enable debugging messages for the error log.

See Section 14.20.3, “Setting Up the InnoDB memcached Plugin” for usage details. For information about memcached options, refer to the memcached man page.

- daemon_memcached_r_batch_size

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--daemon-memcached-r-batch-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>daemon_memcached_r_batch_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
</tbody>
</table>

Specifies how many memcached read operations (get operations) to perform before doing a COMMIT to start a new transaction. Counterpart of daemon_memcached_w_batch_size.

This value is set to 1 by default, so that any changes made to the table through SQL statements are immediately visible to memcached operations. You might increase it to reduce the overhead from frequent commits on a system where the underlying table is only being accessed through the memcached interface. If you set the value too large, the amount of undo or redo data could impose some storage overhead, as with any long-running transaction.

For more information, see Section 14.20.3, “Setting Up the InnoDB memcached Plugin”.

1964
InnoDB System Variables

- **daemon_memcached_w_batch_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--daemon-memcached-w-batch-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>daemon_memcached_w_batch_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
</tbody>
</table>

  Specifies how many memcached write operations, such as `add`, `set`, and `incr`, to perform before doing a COMMIT to start a new transaction. Counterpart of `daemon_memcached_r_batch_size`.

  This value is set to 1 by default, on the assumption that data being stored is important to preserve in case of an outage and should immediately be committed. When storing non-critical data, you might increase this value to reduce the overhead from frequent commits; but then the last \( N-1 \) uncommitted write operations could be lost if an unexpected exit occurs.

  For more information, see Section 14.20.3, “Setting Up the InnoDB memcached Plugin”.

- **ignore_builtin_innodb**

  | Command-Line Format | --ignore-builtin-innodb[={OFF|ON}] |
  |---------------------|----------------------------------|
  | System Variable     | ignore_builtin_innodb            |
  | Scope               | Global                           |
  | Dynamic             | No                               |
  | Type                | Boolean                          |

  In earlier versions of MySQL, enabling this variable caused the server to behave as if the built-in InnoDB were not present, which enabled the InnoDB Plugin to be used instead. In MySQL 5.6, InnoDB is the default storage engine and InnoDB Plugin is not used, so this variable has no effect. As of MySQL 5.6.5, it is ignored.

- **innodb_adaptive_flushing**

  | Command-Line Format | --innodb-adaptive-flushing[={OFF|ON}] |
  |---------------------|----------------------------------|
  | System Variable     | innodb_adaptive_flushing         |
  | Scope               | Global                           |
  | Dynamic             | Yes                              |
  | Type                | Boolean                          |
  | Default Value       | ON                               |

  Specifies whether to dynamically adjust the rate of flushing dirty pages in the InnoDB buffer pool based on the workload. Adjusting the flush rate dynamically is intended to avoid bursts of I/O activity. This setting is enabled by default. See Section 14.8.3.4, “Configuring Buffer Pool Flushing” for more information. For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

- **innodb_adaptive_flushing_lwm**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-adaptive-flushing-lwm=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_adaptive_flushing_lwm</td>
</tr>
</tbody>
</table>

  1965
InnoDB System Variables

<table>
<thead>
<tr>
<th>Scope</th>
<th>Global</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>10</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>70</td>
</tr>
</tbody>
</table>

Defines the low water mark representing percentage of redo log capacity at which adaptive flushing is enabled. For more information, see Section 14.8.3.4, “Configuring Buffer Pool Flushing”.

- **innodb_adaptive_hash_index**

  | Command-Line Format | --innodb-adaptive-hash-index=[OFF|ON] |
  |---------------------|--------------------------------------|
  | System Variable     | innodb_adaptive_hash_index           |
  | Scope               | Global                               |
  | Dynamic             | Yes                                  |
  | Type                | Boolean                              |
  | Default Value       | ON                                   |

Whether the InnoDB adaptive hash index is enabled or disabled. It may be desirable, depending on your workload, to dynamically enable or disable adaptive hash indexing to improve query performance. Because the adaptive hash index may not be useful for all workloads, conduct benchmarks with it both enabled and disabled, using realistic workloads. See Section 14.5.3, “Adaptive Hash Index” for details.

This variable is enabled by default. You can modify this parameter using the SET GLOBAL statement, without restarting the server. Changing the setting at runtime requires privileges sufficient to set global system variables. See Section 5.1.8.1, “System Variable Privileges”. You can also use --skip-innodb-adaptive-hash-index at server startup to disable it.

Disabling the adaptive hash index empties the hash table immediately. Normal operations can continue while the hash table is emptied, and executing queries that were using the hash table access the index B-trees directly instead. When the adaptive hash index is re-enabled, the hash table is populated again during normal operation.

- **innodb_adaptive_max_sleep_delay**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-adaptive-max-sleep-delay=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_adaptive_max_sleep_delay</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>150000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1000000</td>
</tr>
</tbody>
</table>

Permits InnoDB to automatically adjust the value of innodb_thread_sleep_delay up or down according to the current workload. Any nonzero value enables automated, dynamic adjustment of the innodb_thread_sleep_delay value, up to the maximum value specified in the innodb_adaptive_max_sleep_delay option. The value represents the number of microseconds.
InnoDB System Variables

This option can be useful in busy systems, with greater than 16 InnoDB threads. (In practice, it is most valuable for MySQL systems with hundreds or thousands of simultaneous connections.)

For more information, see Section 14.8.5, “Configuring Thread Concurrency for InnoDB”.

• \texttt{innodb\_additional\_mem\_pool\_size}

<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

The size in bytes of a memory pool InnoDB uses to store data dictionary information and other internal data structures. The more tables you have in your application, the more memory you allocate here. If InnoDB runs out of memory in this pool, it starts to allocate memory from the operating system and writes warning messages to the MySQL error log. The default value is 8MB.

This variable relates to the InnoDB internal memory allocator, which is unused if \texttt{innodb\_use\_sys\_malloc} is enabled. For more information, see Section 14.8.4, “Configuring the Memory Allocator for InnoDB”.

As of MySQL 5.6.3, \texttt{innodb\_additional\_mem\_pool\_size} is deprecated and will be removed in a future MySQL release.

• \texttt{innodb\_api\_bk\_commit\_interval}

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-api-bk-commit-interval=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>\texttt{innodb_api_bk_commit_interval}</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1073741824</td>
</tr>
</tbody>
</table>

How often to auto-commit idle connections that use the InnoDB memcached interface, in seconds. For more information, see Section 14.20.5.4, “Controlling Transactional Behavior of the InnoDB memcached Plugin”.

• \texttt{innodb\_api\_disable\_rowlock}

| Command-Line Format | --innodb-api-disable-rowlock[={OFF|ON}] |
|---------------------|---------------------------------------|
| System Variable     | \texttt{innodb\_api\_disable\_rowlock} |
| Scope               | Global                                |
| Dynamic             | No                                    |
| Type                | Boolean                               |
InnoDB System Variables

Default Value | OFF

Use this option to disable row locks when InnoDB memcached performs DML operations. By default, `innodb_api_disable_rowlock` is disabled, which means that memcached requests row locks for `get` and `set` operations. When `innodb_api_disable_rowlock` is enabled, memcached requests a table lock instead of row locks.

`innodb_api_disable_rowlock` is not dynamic. It must be specified on the `mysqld` command line or entered in the MySQL configuration file. Configuration takes effect when the plugin is installed, which occurs when the MySQL server is started.

For more information, see Section 14.20.5.4, “Controlling Transactional Behavior of the InnoDB memcached Plugin”.

• `innodb_api_enable_binlog`

| Command-Line Format | `--innodb-api-enable-binlog[={OFF|ON}]` |
|---------------------|----------------------------------------|
| System Variable     | `innodb_api_enable_binlog`             |
| Scope               | Global                                 |
| Dynamic             | No                                     |
| Type                | Boolean                                |
| Default Value       | OFF                                    |

Lets you use the InnoDB memcached plugin with the MySQL binary log. For more information, see Enabling the InnoDB memcached Binary Log.

• `innodb_api_enable_mdl`

| Command-Line Format | `--innodb-api-enable-mdl[={OFF|ON}]` |
|---------------------|-------------------------------------|
| System Variable     | `innodb_api_enable_mdl`             |
| Scope               | Global                              |
| Dynamic             | No                                  |
| Type                | Boolean                             |
| Default Value       | OFF                                 |

Locks the table used by the InnoDB memcached plugin, so that it cannot be dropped or altered by DDL through the SQL interface. For more information, see Section 14.20.5.4, “Controlling Transactional Behavior of the InnoDB memcached Plugin”.

• `innodb_api_trx_level`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-api-trx-level=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_api_trx_level</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
</tbody>
</table>

Controls the transaction isolation level on queries processed by the memcached interface. The constants corresponding to the familiar names are:

• 0 = READ UNCOMMITTED
InnoDB System Variables

- 1 = READ COMMITTED
- 2 = REPEATABLE READ
- 3 = SERIALIZABLE

For more information, see Section 14.20.5.4, “Controlling Transactional Behavior of the InnoDB memcached Plugin”.

• innodb_autoextend_increment

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-autoextend-increment=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_autoextend_increment</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>64</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1000</td>
</tr>
</tbody>
</table>

The increment size (in megabytes) for extending the size of an auto-extending InnoDB system tablespace file when it becomes full. The default value is 64. For related information, see System Tablespace Data File Configuration, and Resizing the System Tablespace.

The innodb_autoextend_increment setting does not affect file-per-table tablespace files. These files are auto-extending regardless of the innodb_autoextend_increment setting. The initial extensions are by small amounts, after which extensions occur in increments of 4MB.

• innodb_autoinc_lock_mode

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-autoinc-lock-mode=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_autoinc_lock_mode</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Valid Values</td>
<td>0, 1, 2</td>
</tr>
</tbody>
</table>

The lock mode to use for generating auto-increment values. Permissible values are 0, 1, or 2, for traditional, consecutive, or interleaved, respectively. The default setting is 1 (consecutive). For the characteristics of each lock mode, see InnoDB AUTO_INCREMENT Lock Modes.

• innodb_buffer_pool_dump_at_shutdown

| Command-Line Format                  | --innodb-buffer-pool-dump-at-shutdown[={OFF|ON}] |
|--------------------------------------|-----------------------------------------------|
| System Variable                     | innodb_buffer_pool_dump_atShutdown            |
| Scope                                | Global                                        |
| Dynamic                              | Yes                                           |

1969
InnoDB System Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>Boolean</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Specifies whether to record the pages cached in the InnoDB buffer pool when the MySQL server is shut down, to shorten the warmup process at the next restart. Typically used in combination with innodb_buffer_pool_load_at_startup.

For more information, see Section 14.8.3.5, “Saving and Restoring the Buffer Pool State”.

- **innodb_buffer_pool_dump_now**

  Command-Line Format: `--innodb-buffer-pool-dump-now=[{OFF|ON}]`
  
  System Variable: `innodb_buffer_pool_dump_now`
  
  Scope: Global
  
  Dynamic: Yes
  
  Type: Boolean
  
  Default Value: OFF

Immediately records the pages cached in the InnoDB buffer pool. Typically used in combination with innodb_buffer_pool_load_now.

For more information, see Section 14.8.3.5, “Saving and Restoring the Buffer Pool State”.

- **innodb_buffer_pool_filename**

  Command-Line Format: `--innodb-buffer-pool-filename=file_name`
  
  System Variable: `innodb_buffer_pool_filename`
  
  Scope: Global
  
  Dynamic: Yes
  
  Type: File name
  
  Default Value: `ib_buffer_pool`

Specifies the name of the file that holds the list of tablespace IDs and page IDs produced by innodb_buffer_pool_dump_at_shutdown or innodb_buffer_pool_dump_now. Tablespace IDs and page IDs are saved in the following format: `space, page_id`. By default, the file is named `ib_buffer_pool` and is located in the InnoDB data directory. A non-default location must be specified relative to the data directory.

A file name can be specified at runtime, using a SET statement:

```
SET GLOBAL innodb_buffer_pool_filename='file_name';
```

You can also specify a file name at startup, in a startup string or MySQL configuration file. When specifying a file name at startup, the file must exist or InnoDB will return a startup error indicating that there is no such file or directory.

For more information, see Section 14.8.3.5, “Saving and Restoring the Buffer Pool State”.

- **innodb_buffer_pool_instances**

  Command-Line Format: `--innodb-buffer-pool-instances=#`
  
  System Variable: `innodb_buffer_pool_instances`
  
  Scope: Global
  
  Dynamic: No
InnoDB System Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value (Other)</td>
<td>8 (or 1 if innodb_buffer_pool_size &lt; 1GB)</td>
</tr>
<tr>
<td>Default Value (Windows, 32-bit platforms)</td>
<td>(autosized)</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>64</td>
</tr>
</tbody>
</table>

The number of regions that the InnoDB buffer pool is divided into. For systems with buffer pools in the multi-gigabyte range, dividing the buffer pool into separate instances can improve concurrency, by reducing contention as different threads read and write to cached pages. Each page that is stored in or read from the buffer pool is assigned to one of the buffer pool instances randomly, using a hashing function. Each buffer pool manages its own free lists, flush lists, LRU, and all other data structures connected to a buffer pool, and is protected by its own buffer pool mutex.

This option only takes effect when setting innodb_buffer_pool_size to a size of 1GB or more. The total size you specify is divided among all the buffer pools. For best efficiency, specify a combination of innodb_buffer_pool_instances and innodb_buffer_pool_size so that each buffer pool instance is at least 1GB.

Before MySQL 5.6.6, the default is 1. The default value in MySQL 5.6.6 and higher on 32-bit Windows systems depends on the value of innodb_buffer_pool_size, as described below:

- If innodb_buffer_pool_size is greater than 1.3GB, the default for innodb_buffer_pool_instances is innodb_buffer_pool_size/128MB, with individual memory allocation requests for each chunk. 1.3GB was chosen as the boundary at which there is significant risk for 32-bit Windows to be unable to allocate the contiguous address space needed for a single buffer pool.
- Otherwise, the default is 1.

On all other platforms, the default value in MySQL 5.6.6 and higher is 8 when innodb_buffer_pool_size is greater than or equal to 1GB. Otherwise, the default is 1.

Note

A bug in MySQL 5.6 causes SHOW VARIABLES to report an innodb_buffer_pool_instances value of 8 when innodb_buffer_pool_size is less than 1GB and only one buffer pool instance is present (Bug #18343670). As an alternative, you can use SHOW ENGINE INNODB STATUS to check the number of buffer pool instances. If there are multiple buffer pool instances, SHOW ENGINE INNODB STATUS output includes an INDIVIDUAL BUFFER POOL INFO section.

- innodb_buffer_pool_load_abort

Command-Line Format                      | --innodb-buffer-pool-load-abort[={OFF|ON}] |
System Variable                         | innodb_buffer_pool_load_abort |
Scope                                    | Global                        |
Dynamic                                  | Yes                           |
Type                                     | Boolean                       |
Default Value                            | OFF                           |

Interrupts the process of restoring InnoDB buffer pool contents triggered by innodb_buffer_pool_load_at_startup or innodb_buffer_pool_load_now.

For more information, see Section 14.8.3.5, “Saving and Restoring the Buffer Pool State”.

1971
InnoDB System Variables

- **innodb_buffer_pool_load_at_startup**

  | Command-Line Format | --innodb-buffer-pool-load-at-startup[={OFF|ON}] |
  |---------------------|-----------------------------------------------|
  | System Variable     | innodb_buffer_pool_load_at_startup             |
  | Scope               | Global                                        |
  | Dynamic             | No                                            |
  | Type                | Boolean                                       |
  | Default Value       | OFF                                           |

  Specifies that, on MySQL server startup, the InnoDB buffer pool is automatically warmed up by loading the same pages it held at an earlier time. Typically used in combination with innodb_buffer_pool_dump_at_shutdown.

  For more information, see Section 14.8.3.5, “Saving and Restoring the Buffer Pool State”.

- **innodb_buffer_pool_load_now**

  | Command-Line Format | --innodb-buffer-pool-load-now[={OFF|ON}] |
  |---------------------|-----------------------------------------------|
  | System Variable     | innodb_buffer_pool_load_now                 |
  | Scope               | Global                                        |
  | Dynamic             | Yes                                           |
  | Type                | Boolean                                       |
  | Default Value       | OFF                                           |

  Immediately warms up the InnoDB buffer pool by loading a set of data pages, without waiting for a server restart. Can be useful to bring cache memory back to a known state during benchmarking, or to ready the MySQL server to resume its normal workload after running queries for reports or maintenance.

  For more information, see Section 14.8.3.5, “Saving and Restoring the Buffer Pool State”.

- **innodb_buffer_pool_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-buffer-pool-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_buffer_pool_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>134217728</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>5242880</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>2**64-1</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>2**32-1</td>
</tr>
</tbody>
</table>

  The size in bytes of the buffer pool, the memory area where InnoDB caches table and index data. The default value is 134217728 bytes (128MB). The maximum value depends on the CPU architecture; the maximum is 4294967295 (2**32-1) on 32-bit systems and 18446744073709551615 (2**64-1) on 64-bit systems. On 32-bit systems, the CPU architecture and operating system may impose a lower practical maximum size than the stated maximum. When the size of the buffer pool is greater than 1GB, setting innodb_buffer_pool_instances to a value greater than 1 can improve the scalability on a busy server.
A larger buffer pool requires less disk I/O to access the same table data more than once. On a
dedicated database server, you might set the buffer pool size to 80% of the machine's physical
memory size. Be aware of the following potential issues when configuring buffer pool size, and be
prepared to scale back the size of the buffer pool if necessary.

- Competition for physical memory can cause paging in the operating system.
- **InnoDB** reserves additional memory for buffers and control structures, so that the total allocated
  space is approximately 10% greater than the specified buffer pool size.
- Address space for the buffer pool must be contiguous, which can be an issue on Windows
  systems with DLLs that load at specific addresses.
- The time to initialize the buffer pool is roughly proportional to its size. On instances with large
  buffer pools, initialization time might be significant. To reduce the initialization period, you can save
  the buffer pool state at server shutdown and restore it at server startup. See Section 14.8.3.5,
  “Saving and Restoring the Buffer Pool State”.

- **innodb_change_buffer_max_size**
  
  Command-Line Format: `--innodb-change-buffer-max-size=#`
  
  System Variable: `innodb_change_buffer_max_size`
  
  Scope: Global
  
  Dynamic: Yes
  
  Type: Integer
  
  Default Value: 25
  
  Minimum Value: 0
  
  Maximum Value: 50

  Maximum size for the **InnoDB change buffer**, as a percentage of the total size of the buffer pool.
  You might increase this value for a MySQL server with heavy insert, update, and delete activity,
  or decrease it for a MySQL server with unchanging data used for reporting. For more information,
  see Section 14.5.2, “Change Buffer”. For general I/O tuning advice, see Section 8.5.8, “Optimizing
  InnoDB Disk I/O”.

- **innodb_change_buffering**
  
  Command-Line Format: `--innodb-change-buffering=value`
  
  System Variable: `innodb_change_buffering`
  
  Scope: Global
  
  Dynamic: Yes
  
  Type: Enumeration
  
  Default Value: `all`
  
  Valid Values:
  
  - `none`
  - `inserts`
  - `deletes`
  - `changes`
  - `purges`
Whether InnoDB performs change buffering, an optimization that delays write operations to secondary indexes so that the I/O operations can be performed sequentially. Permitted values are described in the following table.

Table 14.14 Permitted Values for innodb_change_buffering

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>Do not buffer any operations.</td>
</tr>
<tr>
<td>inserts</td>
<td>Buffer insert operations.</td>
</tr>
<tr>
<td>deletes</td>
<td>Buffer delete marking operations; strictly speaking, the writes that mark index records for later deletion during a purge operation.</td>
</tr>
<tr>
<td>changes</td>
<td>Buffer inserts and delete-marking operations.</td>
</tr>
<tr>
<td>purges</td>
<td>Buffer the physical deletion operations that happen in the background.</td>
</tr>
<tr>
<td>all</td>
<td>The default. Buffer inserts, delete-marking operations, and purges.</td>
</tr>
</tbody>
</table>

For more information, see Section 14.5.2, “Change Buffer”. For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

- **innodb_change_buffering_debug**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-change-buffering-debug=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_change_buffering_debug</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2</td>
</tr>
</tbody>
</table>

Sets a debug flag for InnoDB change buffering. A value of 1 forces all changes to the change buffer. A value of 2 causes an unexpected exit at merge. A default value of 0 indicates that the change buffering debug flag is not set. This option is only available when debugging support is compiled in using the WITH_DEBUG CMake option.

- **innodb_checksum_algorithm**

<table>
<thead>
<tr>

<td>crc32</td>
</tr>
<tr>
<td></td>
<td>none</td>
</tr>
</tbody>
</table>
InnoDB System Variables

- **strict_innodb**
- **strict_crc32**
- **strict_none**

Specifies how to generate and verify the checksum stored in the disk blocks of InnoDB tablespaces.

- **innodb_checksum_algorithm** replaces the **innodb_checksums** option in MySQL 5.6.3. The following values are provided for compatibility:
  - **innodb_checksum_algorithm=innodb** is the same as **innodb_checksums=ON**
  - **innodb_checksum_algorithm=none** is the same as **innodb_checksums=OFF**

To avoid conflicts, remove references to **innodb_checksums** from MySQL configuration files and startup scripts.

The value **innodb** is backward-compatible with earlier versions of MySQL. The value **crc32** uses an algorithm that is faster to compute the checksum for every modified block, and to check the checksums for each disk read. It scans blocks 32 bits at a time, which is faster than the **innodb** checksum algorithm, which scans blocks 8 bits at a time. The value **none** writes a constant value in the checksum field rather than computing a value based on the block data. The blocks in a tablespace can use a mix of old, new, and no checksum values, being updated gradually as the data is modified; once blocks in a tablespace are modified to use the **crc32** algorithm, the associated tables cannot be read by earlier versions of MySQL.

The strict form of a checksum algorithm reports an error if it encounters a valid but non-matching checksum value in a tablespace. It is recommended that you only use strict settings in a new instance, to set up tablespaces for the first time. Strict settings are somewhat faster, because they do not need to compute all checksum values during disk reads.

**Note**

Prior to MySQL 5.6.25, a strict mode setting for **innodb_checksum_algorithm** caused InnoDB to halt when encountering a valid but non-matching checksum. In MySQL 5.6.25 and later, only an error message is printed, and the page is accepted as valid if it has a valid **innodb**, **crc32** or **none** checksum.

The following table shows the difference between the **none**, **innodb**, and **crc32** option values, and their strict counterparts. **none**, **innodb**, and **crc32** write the specified type of checksum value into each data block, but for compatibility accept other checksum values when verifying a block during a read operation. Strict settings also accept valid checksum values but print an error message when a valid non-matching checksum value is encountered. Using the strict form can make verification faster if all InnoDB data files in an instance are created under an identical **innodb_checksum_algorithm** value.

<table>

</tbody>
</table>

The default value for innodb_checksum_algorithm was changed from innodb to crc32 in MySQL 5.6.6, but switched back to innodb in 5.6.7 for backward compatibility of InnoDB data files, and for use with MySQL Enterprise Backup. The limitations encountered included:

- .ibd files containing CRC32 checksums could cause problems downgrading to MySQL versions prior to 5.6.3. MySQL 5.6.3 and up recognizes either the new or old checksum values for the block as correct when reading the block from disk, ensuring that data blocks are compatible during upgrade and downgrade regardless of the algorithm setting. If data written with new checksum values is processed by a version of MySQL earlier than 5.6.3, it could be reported as corrupted.

- Versions of MySQL Enterprise Backup up to 3.8.0 do not support backing up tablespaces that use CRC32 checksums. MySQL Enterprise Backup adds CRC32 checksum support in 3.8.1, with some limitations. Refer to the MySQL Enterprise Backup 3.8.1 Change History for more information.

innodb_checksums

**Command-Line Format**
```
--innodb-checksums=[OFF|ON]
```

**Deprecated**
Yes

**System Variable**
inndb_checkums

**Scope**
Global

**Dynamic**
No

**Type**
Boolean

**Default Value**
ON

InnoDB can use checksum validation on all tablespace pages read from disk to ensure extra fault tolerance against hardware faults or corrupted data files. This validation is enabled by default. Under specialized circumstances (such as when running benchmarks) this safety feature can be disabled with --skip-innodb-checksums. You can specify the method of calculating the checksum using the innodb_checksum_algorithm option.

In MySQL 5.6.3 and higher, innodb_checksums is deprecated, replaced by innodb_checksum_algorithm. innodb_checksum_algorithm=innodb is the same as
InnoDB System Variables

`innodb_checksums=ON` (the default), `innodb_checksum_algorithm=none` is the same as `innodb_checksums=OFF`. Remove `innodb_checksums` options from your configuration files and startup scripts to avoid conflicts with `innodb_checksum_algorithm;innodb_checksums=OFF` automatically sets `innodb_checksum_algorithm=none;innodb_checksums=ON` is ignored and overridden by any other setting for `innodb_checksum_algorithm`.

- `innodb_cmp_per_index_enabled`

  | Command-Line Format | `--innodb-cmp-per-index-enabled=[{OFF|ON}]` |
  |---------------------|-------------------------------------------|
  | System Variable     | `innodb_cmp_per_index_enabled`            |
  | Scope               | Global                                   |
  | Dynamic             | Yes                                      |
  | Type                | Boolean                                  |
  | Default Value       | OFF                                      |

  Enables per-index compression-related statistics in the `INFORMATION_SCHEMA.INNODB_CMP_PER_INDEX` table. Because these statistics can be expensive to gather, only enable this option on development, test, or replica instances during performance tuning related to InnoDB compressed tables.

  For more information, see Section 21.30.6, “The INFORMATION_SCHEMA INNODB_CMP_PER_INDEX and INNODB_CMP_PER_INDEX_RESET Tables”, and Section 14.9.4, “Monitoring InnoDB Table Compression at Runtime”.

- `innodb_commit_concurrency`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-commit-concurrency=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_commit_concurrency</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1000</td>
</tr>
</tbody>
</table>

  The number of threads that can commit at the same time. A value of 0 (the default) permits any number of transactions to commit simultaneously.

  The value of `innodb_commit_concurrency` cannot be changed at runtime from zero to nonzero or vice versa. The value can be changed from one nonzero value to another.

- `innodb_compression_failure_threshold_pct`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-compression-failure-threshold-pct=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_compression_failure_threshold_pct</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
</tbody>
</table>
### InnoDB System Variables

**Maximum Value** | 100

Defines the compression failure rate threshold for a table, as a percentage, at which point MySQL begins adding padding within compressed pages to avoid expensive compression failures. When this threshold is passed, MySQL begins to leave additional free space within each new compressed page, dynamically adjusting the amount of free space up to the percentage of page size specified by `innodb_compression_pad_pct_max`. A value of zero disables the mechanism that monitors compression efficiency and dynamically adjusts the padding amount.

For more information, see Section 14.9.6, “Compression for OLTP Workloads”.

- **innodb_compression_level**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-compression-level=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_compression_level</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>6</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>9</td>
</tr>
</tbody>
</table>

Specifies the level of zlib compression to use for InnoDB compressed tables and indexes. A higher value lets you fit more data onto a storage device, at the expense of more CPU overhead during compression. A lower value lets you reduce CPU overhead when storage space is not critical, or you expect the data is not especially compressible.

For more information, see Section 14.9.6, “Compression for OLTP Workloads”.

- **innodb_compression_pad_pct_max**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-compression-pad-pct-max=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_compression_pad_pct_max</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>50</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>75</td>
</tr>
</tbody>
</table>

Specifies the maximum percentage that can be reserved as free space within each compressed page, allowing room to reorganize the data and modification log within the page when a compressed table or index is updated and the data might be recompressed. Only applies when `innodb_compression_failure_threshold_pct` is set to a nonzero value, and the rate of compression failures passes the cutoff point.

For more information, see Section 14.9.6, “Compression for OLTP Workloads”.

- **innodb_concurrency_tickets**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-concurrency-tickets=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_concurrency_tickets</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
</tbody>
</table>

1978
Determines the number of threads that can enter InnoDB concurrently. A thread is placed in a queue when it tries to enter InnoDB if the number of threads has already reached the concurrency limit. When a thread is permitted to enter InnoDB, it is given a number of "tickets" equal to the value of `innodb_concurrency_tickets`, and the thread can enter and leave InnoDB freely until it has used up its tickets. After that point, the thread again becomes subject to the concurrency check (and possible queuing) the next time it tries to enter InnoDB. The default value is 5000 as of MySQL 5.6.6, 500 before that.

With a small `innodb_concurrency_tickets` value, small transactions that only need to process a few rows compete fairly with larger transactions that process many rows. The disadvantage of a small `innodb_concurrency_tickets` value is that large transactions must loop through the queue many times before they can complete, which extends the amount of time required to complete their task.

With a large `innodb_concurrency_tickets` value, large transactions spend less time waiting for a position at the end of the queue (controlled by `innodb_thread_concurrency`) and more time retrieving rows. Large transactions also require fewer trips through the queue to complete their task. The disadvantage of a large `innodb_concurrency_tickets` value is that too many large transactions running at the same time can starve smaller transactions by making them wait a longer time before executing.

With a nonzero `innodb_thread_concurrency` value, you may need to adjust the `innodb_concurrency_tickets` value up or down to find the optimal balance between larger and smaller transactions. The SHOW ENGINE INNODB STATUS report shows the number of tickets remaining for an executing transaction in its current pass through the queue. This data may also be obtained from the TRX_CONCURRENCY_TICKETS column of the INFORMATION_SCHEMA.INNODB_TRX table.

For more information, see Section 14.8.5, “Configuring Thread Concurrency for InnoDB”.

- `innodb_data_file_path`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-data-file-path=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_data_file_path</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>ibdata1:12M:autoextend</code></td>
</tr>
</tbody>
</table>

Defines the name, size, and attributes of InnoDB system tablespace data files. If you do not specify a value for `innodb_data_file_path`, the default behavior is to create a single auto-extending data file, slightly larger than 12MB, named ibdata1.

The full syntax for a data file specification includes the file name, file size, autoextend attribute, and max attribute:

```
file_name:file_size[:autoextend[:max:max_file_size]]
```

File sizes are specified in kilobytes, megabytes, or gigabytes by appending K, M or G to the size value. If specifying the data file size in kilobytes, do so in multiples of 1024. Otherwise, KB values are
rounded to nearest megabyte (MB) boundary. The sum of file sizes must be, at a minimum, slightly larger than 12MB.

For additional configuration information, see System Tablespace Data File Configuration. For resizing instructions, see Resizing the System Tablespace.

• **innodb_data_home_dir**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-data-home-dir=dir_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_data_home_dir</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
</tbody>
</table>

  The common part of the directory path for InnoDB system tablespace data files. The default value is the MySQL data directory. The setting is concatenated with the innodb_data_file_path setting. If you specify the value as an empty string, you can specify an absolute path for innodb_data_file_path.

  A trailing slash is required when specifying a value for innodb_data_home_dir. For example:

  ```
  [mysqld]
  innodb_data_home_dir = /path/to/myibdata/
  ```

  This setting does not affect the location of file-per-table tablespaces.

  For related information, see Section 14.8.1, “InnoDB Startup Configuration”.

• **innodb_disable_sort_file_cache**

  | Command-Line Format | --innodb-disable-sort-file-cache={OFF|ON} |
  |---------------------|----------------------------------------|
  | System Variable     | innodb_disable_sort_file_cache         |
  | Scope               | Global                                 |
  | Dynamic             | Yes                                    |
  | Type                | Boolean                                |
  | Default Value       | OFF                                    |

  Disables the operating system file system cache for merge-sort temporary files. The effect is to open such files with the equivalent of O_DIRECT.

• **innodb_doublewrite**

  | Command-Line Format | --innodb-doublewrite={OFF|ON} |
  |---------------------|-------------------------------|
  | System Variable     | innodb_doublewrite            |
  | Scope               | Global                        |
  | Dynamic             | No                            |
  | Type                | Boolean                       |
  | Default Value       | ON                            |

  When enabled (the default), InnoDB stores all data twice, first to the doublewrite buffer, then to the actual data files. This variable can be turned off with --skip-innodb-doublewrite for benchmarks or cases when top performance is needed rather than concern for data integrity or possible failures.

  For related information, see Section 14.6.5, "Doublewrite Buffer".
InnoDB System Variables

- **innodb_fast_shutdown**

  **Command-Line Format**
  --innodb-fast-shutdown=#

  **System Variable**
  innodb_fast_shutdown

  **Scope**
  Global

  **Dynamic**
  Yes

  **Type**
  Integer

  **Default Value**
  1

  **Valid Values**
  0
  1
  2

  The InnoDB shutdown mode. If the value is 0, InnoDB does a slow shutdown, a full purge and a change buffer merge before shutting down. If the value is 1 (the default), InnoDB skips these operations at shutdown, a process known as a fast shutdown. If the value is 2, InnoDB flushes its logs and shuts down cold, as if MySQL had crashed; no committed transactions are lost, but the crash recovery operation makes the next startup take longer.

  The slow shutdown can take minutes, or even hours in extreme cases where substantial amounts of data are still buffered. Use the slow shutdown technique before upgrading or downgrading between MySQL major releases, so that all data files are fully prepared in case the upgrade process updates the file format.

  Use innodb_fast_shutdown=2 in emergency or troubleshooting situations, to get the absolute fastest shutdown if data is at risk of corruption.

- **innodb_fil_make_page_dirty_debug**

  **Command-Line Format**
  --innodb-fil-make-page-dirty-debug=#

  **Introduced**
  5.6.17

  **System Variable**
  innodb_fil_make_page_dirty_debug

  **Scope**
  Global

  **Dynamic**
  Yes

  **Type**
  Integer

  **Default Value**
  0

  **Maximum Value**
  2**32-1

  By default, setting innodb_fil_make_page_dirty_debug to the ID of a tablespace immediately dirties the first page of the tablespace. If innodb_saved_page_number_debug is set to a non-default value, setting innodb_fil_make_page_dirty_debug dirties the specified page. The innodb_fil_make_page_dirty_debug option is only available if debugging support is compiled in using the WITH_DEBUG CMake option.

- **innodb_file_format**

  **Command-Line Format**
  --innodb-file-format=value

  **System Variable**
  innodb_file_format

  **Scope**
  Global

  **Dynamic**
  Yes

  **Type**
  String
Enables an InnoDB file format for file-per-table table spaces. Supported file formats are Antelope and Barracuda. Antelope is the original InnoDB file format, which supports REDUNDANT and COMPACT row formats for InnoDB tables. Barracuda is the newer file format, which supports COMPRESSED and DYNAMIC row formats.

COMPRESSED and DYNAMIC row formats enable important storage features for InnoDB tables. See Section 14.11, “InnoDB Row Formats”.

To create tables that use COMPRESSED or DYNAMIC row format, the Barracuda file format and `innodb_file_per_table` must be enabled.

Changing the `innodb_file_format` setting does not affect the file format of existing InnoDB table space files.

For more information, see Section 14.10, “InnoDB File-Format Management”.

### Command-Line Format
```
--innodb-file-format-check={OFF|ON}
```

### System Variable
`innodb_file_format_check`

### Scope
Global

### Dynamic
No

### Type
Boolean

### Default Value
ON

This variable can be set to 1 or 0 at server startup to enable or disable whether InnoDB checks the file format tag in the system table space (for example, Antelope or Barracuda). If the tag is checked and is higher than that supported by the current version of InnoDB, an error occurs and InnoDB does not start. If the tag is not higher, InnoDB sets the value of `innodb_file_format_max` to the file format tag.

**Note**

Despite the default value sometimes being displayed as ON or OFF, always use the numeric values 1 or 0 to turn this option on or off in your configuration file or command line string.

For more information, see Section 14.10.2.1, “Compatibility Check When InnoDB Is Started”.

### Command-Line Format
```
--innodb-file-format-max=value
```

### System Variable
`innodb_file_format_max`

### Scope
Global

### Dynamic
Yes

### Type
String

### Default Value
Antelope

### Valid Values
Antelope
At server startup, InnoDB sets the value of this variable to the file format tag in the system tablespace (for example, Antelope or Barracuda). If the server creates or opens a table with a “higher” file format, it sets the value of innodb_file_format_max to that format.

For related information, see Section 14.10, “InnoDB File-Format Management”.

**innodb_file_per_table**

| Command-Line Format                  | --innodb-file-per-table=[{OFF|ON}] |
|--------------------------------------|-----------------------------------|
| System Variable                     | innodb_file_per_table             |
| Scope                                | Global                            |
| Dynamic                              | Yes                               |
| Type                                 | Boolean                           |
| Default Value                        | ON                                |

When innodb_file_per_table is enabled, tables are created in file-per-table tablespaces. When disabled, tables are created in the system tablespace. For information about file-per-table tablespaces, see Section 14.6.3.2, “File-Per-Table Tablespaces”. For information about the InnoDB system tablespace, see Section 14.6.3.1, “The System Tablespace”.

The innodb_file_per_table variable can be configured at runtime using a SET GLOBAL statement, specified on the command line at startup, or specified in an option file. Configuration at runtime requires privileges sufficient to set global system variables (see Section 5.1.8.1, “System Variable Privileges”) and immediately affects the operation of all connections.

When a table that resides in a file-per-table tablespace is truncated or dropped, the freed space is returned to the operating system. Truncating or dropping a table that resides in the system tablespace only frees space in the system tablespace. Freed space in the system tablespace can be used again for InnoDB data but is not returned to the operating system, as system tablespace data files never shrink.

When innodb_file_per_table is enabled, a table-copying ALTER TABLE operation on a table that resides in the system tablespace implicitly re-creates the table in a file-per-table tablespace. To prevent this from occurring, disable innodb_file_per_table before executing table-copying ALTER TABLE operations on tables that reside in the system tablespace.

**innodb_flush_log_at_timeout**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-flush-log-at-timeout=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_flush_log_at_timeout</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2700</td>
</tr>
</tbody>
</table>

Write and flush the logs every $N$ seconds. innodb_flush_log_at_timeout allows the timeout period between flushes to be increased in order to reduce flushing and avoid impacting performance of binary log group commit. Prior to the introduction of this configuration option, flushing frequency was once per second. The default setting for innodb_flush_log_at_timeout is also once per second.
• `innodb_flush_log_at_trx_commit`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-flush-log-at-trx-commit=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_flush_log_at_trx_commit</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Valid Values</td>
<td>0, 1, 2</td>
</tr>
</tbody>
</table>

Controls the balance between strict ACID compliance for `commit` operations and higher performance that is possible when commit-related I/O operations are rearranged and done in batches. You can achieve better performance by changing the default value but then you can lose transactions in a crash.

- The default setting of 1 is required for full ACID compliance. Logs are written and flushed to disk at each transaction commit.
- With a setting of 0, logs are written and flushed to disk once per second. Transactions for which logs have not been flushed can be lost in a crash.
- With a setting of 2, logs are written after each transaction commit and flushed to disk once per second. Transactions for which logs have not been flushed can be lost in a crash.
- For settings 0 and 2, once-per-second flushing is not 100% guaranteed. Flushing may occur more frequently due to DDL changes and other internal InnoDB activities that cause logs to be flushed independently of the `innodb_flush_log_at_trx_commit` setting, and sometimes less frequently due to scheduling issues. If logs are flushed once per second, up to one second of transactions can be lost in a crash. If logs are flushed more or less frequently than once per second, the amount of transactions that can be lost varies accordingly.
- Log flushing frequency is controlled by `innodb_flush_log_at_timeout`, which allows you to set log flushing frequency to $N$ seconds (where $N$ is 1 ... 2700, with a default value of 1). However, any unexpected mysql process exit can erase up to $N$ seconds of transactions.
- DDL changes and other internal InnoDB activities flush the log independently of the `innodb_flush_log_at_trx_commit` setting.
- InnoDB crash recovery works regardless of the `innodb_flush_log_at_trx_commit` setting. Transactions are either applied entirely or erased entirely.

For durability and consistency in a replication setup that uses InnoDB with transactions:

- If binary logging is enabled, set `sync_binlog=1`.
- Always set `innodb_flush_log_at_trx_commit=1`.

Caution

Many operating systems and some disk hardware fool the flush-to-disk operation. They may tell mysql that the flush has taken place, even though it has not. In this case, the durability of transactions is not guaranteed even with the recommended settings, and in the worst case, a power outage can corrupt InnoDB data. Using a battery-backed disk cache in the SCSI disk
controller or in the disk itself speeds up file flushes, and makes the operation safer. You can also try to disable the caching of disk writes in hardware caches.

- **innodb_flush_method**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-flush-method=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_flush_method</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
<tr>
<td>Valid Values (Windows)</td>
<td>async_unbuffered</td>
</tr>
<tr>
<td></td>
<td>normal</td>
</tr>
<tr>
<td></td>
<td>unbuffered</td>
</tr>
<tr>
<td>Valid Values (Unix)</td>
<td>fsync</td>
</tr>
<tr>
<td></td>
<td>O_DSYNC</td>
</tr>
<tr>
<td></td>
<td>littlesync</td>
</tr>
<tr>
<td></td>
<td>nosync</td>
</tr>
<tr>
<td></td>
<td>O_DIRECT</td>
</tr>
<tr>
<td></td>
<td>O_DIRECT_NO_FSYNC</td>
</tr>
</tbody>
</table>

Defines the method used to flush data to InnoDB data files and log files, which can affect I/O throughput.

If `innodb_flush_method` is set to NULL on a Unix-like system, the `fsync` option is used by default. If `innodb_flush_method` is set to NULL on Windows, the `async_unbuffered` option is used by default.

The `innodb_flush_method` options for Unix-like systems include:

- **fsync**: InnoDB uses the `fsync()` system call to flush both the data and log files. `fsync` is the default setting.

- **O_DSYNC**: InnoDB uses `O_SYNC` to open and flush the log files, and `fsync()` to flush the data files. InnoDB does not use `O_DSYNC` directly because there have been problems with it on many varieties of Unix.

- **littlesync**: This option is used for internal performance testing and is currently unsupported. Use at your own risk.

- **nosync**: This option is used for internal performance testing and is currently unsupported. Use at your own risk.

- **O_DIRECT**: InnoDB uses `O_DIRECT` (or `directio()` on Solaris) to open the data files, and uses `fsync()` to flush both the data and log files. This option is available on some GNU/Linux versions, FreeBSD, and Solaris.
InnoDB System Variables

- **O_DIRECT_NO_FSYNC**: InnoDB uses O_DIRECT during flushing I/O, but skips the fsync() system call after each write operation.

  This setting is not suitable for file systems such as XFS and EXT4, which require an fsync() system call to synchronize file system metadata changes. If you are not sure whether your file system requires an fsync() system call to synchronize file system metadata changes, use O_DIRECT instead.

  Data loss is possible if redo log files and data files reside on different storage devices, and an unexpected exit occurs before data file writes are flushed from a device cache that is not battery-backed. If you use or intend to use different storage devices for redo log files and data files, and your data files reside on a device with a cache that is not battery-backed, use O_DIRECT instead.

The `innodb_flush_method` options for Windows systems include:

- **async_unbuffered**: InnoDB uses Windows asynchronous I/O and non-buffered I/O. async_unbuffered is the default setting on Windows systems.

  Running MySQL server on a 4K sector hard drive on Windows is not supported with async_unbuffered. The workaround is to use `innodb_flush_method=normal`.

- **normal**: InnoDB uses simulated asynchronous I/O and buffered I/O. This option is used for internal performance testing and is currently unsupported. Use at your own risk.

- **unbuffered**: InnoDB uses simulated asynchronous I/O and non-buffered I/O. This option is used for internal performance testing and is currently unsupported. Use at your own risk.

How each setting affects performance depends on hardware configuration and workload. Benchmark your particular configuration to decide which setting to use, or whether to keep the default setting. Examine the `Innodb_data_fsyncs` status variable to see the overall number of fsync() calls for each setting. The mix of read and write operations in your workload can affect how a setting performs. For example, on a system with a hardware RAID controller and battery-backed write cache, O_DIRECT can help to avoid double buffering between the InnoDB buffer pool and the operating system file system cache. On some systems where InnoDB data and log files are located on a SAN, the default value or O_DSYNC might be faster for a read-heavy workload with mostly SELECT statements. Always test this parameter with hardware and workload that reflect your production environment. For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

- **innodb_flush_neighbors**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-flush-neighbors=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_flush_neighbors</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Valid Values</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>1</td>
</tr>
</tbody>
</table>

The `innodb_flush_neighbors` system variable controls whether InnoDB flushes all pages of a pagefile before a flush to disk occurs. This is intended to be used only by library writers who need to flush large pagefiles. Setting this variable to 0 can be used to avoid flushing files that are not in use, which can improve performance. Setting this variable to 1 flushes all pages of a pagefile before a flush to disk occurs.

1986
InnoDB System Variables

2

Specifies whether flushing a page from the InnoDB buffer pool also flushes other dirty pages in the same extent.

• A setting of 0 disables innodb_flush_neighbors. Dirty pages in the same extent are not flushed.
• The default setting of 1 flushes contiguous dirty pages in the same extent.
• A setting of 2 flushes dirty pages in the same extent.

When the table data is stored on a traditional HDD storage device, flushing such neighbor pages in one operation reduces I/O overhead (primarily for disk seek operations) compared to flushing individual pages at different times. For table data stored on SSD, seek time is not a significant factor and you can turn this setting off to spread out write operations. For related information, see Section 14.8.3.4, “Configuring Buffer Pool Flushing”.

• innodb_flushing_avg_loops

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-flushing-avg-loops=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_flushing_avg_loops</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>30</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1000</td>
</tr>
</tbody>
</table>

Number of iterations for which InnoDB keeps the previously calculated snapshot of the flushing state, controlling how quickly adaptive flushing responds to changing workloads. Increasing the value makes the rate of flush operations change smoothly and gradually as the workload changes. Decreasing the value makes adaptive flushing adjust quickly to workload changes, which can cause spikes in flushing activity if the workload increases and decreases suddenly.

For related information, see Section 14.8.3.4, “Configuring Buffer Pool Flushing”.

• innodb_force_load_corrupted

| Command-Line Format | --innodb-force-load-corrupted[={OFF|ON}] |
|---------------------|-----------------------------------------|
| System Variable     | innodb_force_load_corrupted             |
| Scope               | Global                                  |
| Dynamic             | No                                      |
| Type                | Boolean                                 |
| Default Value       | OFF                                     |

Permits InnoDB to load tables at startup that are marked as corrupted. Use only during troubleshooting, to recover data that is otherwise inaccessible. When troubleshooting is complete, disable this setting and restart the server.

• innodb_force_recovery

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-force-recovery=#</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### InnoDB System Variables

#### System Variable: `innodb_force_recovery`

<table>
<thead>
<tr>
<th>Scope</th>
<th>Global</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>6</td>
</tr>
</tbody>
</table>

The **crash recovery** mode, typically only changed in serious troubleshooting situations. Possible values are from 0 to 6. For the meanings of these values and important information about `innodb_force_recovery`, see Section 14.21.2, “Forcing InnoDB Recovery”.

**Warning**

Only set this variable to a value greater than 0 in an emergency situation so that you can start InnoDB and dump your tables. As a safety measure, InnoDB prevents INSERT, UPDATE, or DELETE operations when `innodb_force_recovery` is greater than 0. As of 5.6.15, an `innodb_force_recovery` setting of 4 or greater places InnoDB into read-only mode.

These restrictions may cause replication administration commands to fail with an error because replication settings such as `relay_log_info_repository=TABLE` and `master_info_repository=TABLE` store information in InnoDB tables.

#### System Variable: `innodb_ft_aux_table`

<table>
<thead>
<tr>
<th>Scope</th>
<th>Global</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>

Specifies the qualified name of an InnoDB table containing a FULLTEXT index. This variable is intended for diagnostic purposes and can only be set at runtime. For example:

```sql
SET GLOBAL innodb_ft_aux_table = 'test/t1';
```

After you set this variable to a name in the format `db_name/table_name`, the INFORMATION_SCHEMA tables `INNODB_FT_INDEX_TABLE`, `INNODB_FT_INDEX_CACHE`, `INNODB_FT_CONFIG`, `INNODB_FT_DELETED`, and `INNODB_FT_BEING_DELETED` show information about the search index for the specified table.

For more information, see Section 14.15.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”.

#### System Variable: `innodb_ft_cache_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-ft-cache-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_ft_cache_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>8000000</td>
</tr>
</tbody>
</table>

• `innodb_ft_cache_size`
InnoDB System Variables

<table>
<thead>
<tr>
<th>Minimum Value</th>
<th>1600000</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum Value</td>
<td>8000000</td>
</tr>
</tbody>
</table>

The memory allocated, in bytes, for the InnoDB FULLTEXT search index cache, which holds a parsed document in memory while creating an InnoDB FULLTEXT index. Index inserts and updates are only committed to disk when the innodb_ft_cache_size size limit is reached. innodb_ft_cache_size defines the cache size on a per table basis. To set a global limit for all tables, see innodb_ft_total_cache_size.

For more information, see InnoDB Full-Text Index Cache.

• innodb_ft_enable_diag_print

| Command-Line Format | --innodb-ft-enable-diag-print[={OFF|ON}] |
|---------------------|-----------------------------------------|
| System Variable     | innodb_ft_enable_diag_print             |
| Scope               | Global                                  |
| Dynamic             | Yes                                     |
| Type                | Boolean                                 |
| Default Value       | OFF                                     |

Whether to enable additional full-text search (FTS) diagnostic output. This option is primarily intended for advanced FTS debugging and will not be of interest to most users. Output is printed to the error log and includes information such as:

• FTS index sync progress (when the FTS cache limit is reached). For example:

  FTS SYNC for table test, deleted count: 100 size: 10000 bytes
  SYNC words: 100

• FTS optimize progress. For example:

  FTS start optimize test
  FTS_OPTIMIZE: optimize "mysql"
  FTS_OPTIMIZE: processed "mysql"

• FTS index build progress. For example:

  Number of doc processed: 1000

• For FTS queries, the query parsing tree, word weight, query processing time, and memory usage are printed. For example:

  FTS Search Processing time: 1 secs: 100 millisec: row(s) 10000
  Full Search Memory: 245666 (bytes), Row: 10000

• innodb_ft_enable_stopword

| Command-Line Format | --innodb-ft-enable-stopword[={OFF|ON}] |
|---------------------|-----------------------------------------|
| System Variable     | innodb_ft_enable_stopword               |
| Scope               | Global, Session                         |
| Dynamic             | Yes                                     |
| Type                | Boolean                                 |
| Default Value       | ON                                      |

Specifies that a set of stopwords is associated with an InnoDB FULLTEXT index at the time the index is created. If the innodb_ft_user_stopword_table option is set, the stopwords are taken
from that table. Else, if the `innodb_ft_server_stopword_table` option is set, the stopwords are taken from that table. Otherwise, a built-in set of default stopwords is used.

For more information, see Section 12.10.4, "Full-Text Stopwords".

• `innodb_ft_max_token_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-ft-max-token-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_ft_max_token_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>84</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>10</td>
</tr>
<tr>
<td>Maximum Value (≥ 5.6.14)</td>
<td>84</td>
</tr>
<tr>
<td>Maximum Value (≤ 5.6.13)</td>
<td>252</td>
</tr>
</tbody>
</table>

Maximum character length of words that are stored in an InnoDB Fulltext index. Setting a limit on this value reduces the size of the index, thus speeding up queries, by omitting long keywords or arbitrary collections of letters that are not real words and are not likely to be search terms.

For more information, see Section 12.10.6, “Fine-Tuning MySQL Full-Text Search”.

• `innodb_ft_min_token_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-ft-min-token-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_ft_min_token_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>3</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>16</td>
</tr>
</tbody>
</table>

Minimum length of words that are stored in an InnoDB Fulltext index. Increasing this value reduces the size of the index, thus speeding up queries, by omitting common words that are unlikely to be significant in a search context, such as the English words “a” and “to”. For content using a CJK (Chinese, Japanese, Korean) character set, specify a value of 1.

For more information, see Section 12.10.6, “Fine-Tuning MySQL Full-Text Search”.

• `innodb_ft_num_word_optimize`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-ft-num-word-optimize=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_ft_num_word_optimize</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>
InnoDB System Variables

<table>
<thead>
<tr>
<th>Default Value</th>
<th>2000</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum Value</td>
<td>1000</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>10000</td>
</tr>
</tbody>
</table>

Number of words to process during each OPTIMIZE TABLE operation on an InnoDB FULLTEXT index. Because a bulk insert or update operation to a table containing a full-text search index could require substantial index maintenance to incorporate all changes, you might do a series of OPTIMIZE TABLE statements, each picking up where the last left off.

For more information, see Section 12.10.6, “Fine-Tuning MySQL Full-Text Search”.

- **innodb_ft_result_cache_limit**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-ft-result-cache-limit=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.6.13</td>
</tr>
<tr>
<td>System Variable</td>
<td>innodb_ft_result_cache_limit</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>20000000000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1000000</td>
</tr>
<tr>
<td>Maximum Value (Windows, ≥ 5.6.13, ≤ 5.6.16)</td>
<td>2**32-1</td>
</tr>
<tr>
<td>Maximum Value (Unix, 64-bit platforms, ≥ 5.6.13, ≤ 5.6.16)</td>
<td>2**64-1</td>
</tr>
<tr>
<td>Maximum Value (Unix, 32-bit platforms, ≥ 5.6.13, ≤ 5.6.16)</td>
<td>2**32-1</td>
</tr>
<tr>
<td>Maximum Value (≥ 5.6.17)</td>
<td>2**32-1</td>
</tr>
</tbody>
</table>

The InnoDB full-text search query result cache limit (defined in bytes) per full-text search query or per thread. Intermediate and final InnoDB full-text search query results are handled in memory. Use innodb_ft_result_cache_limit to place a size limit on the full-text search query result cache to avoid excessive memory consumption in case of very large InnoDB full-text search query results (millions or hundreds of millions of rows, for example). Memory is allocated as required when a full-text search query is processed. If the result cache size limit is reached, an error is returned indicating that the query exceeds the maximum allowed memory.

As of MySQL 5.6.17, the maximum value of innodb_ft_result_cache_limit for all platform types and bit sizes is 2**32-1.

- **innodb_ft_server_stopword_table**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-ft-server-stopword-table=db_name/table_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_ft_server_stopword_table</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
</tbody>
</table>
This option is used to specify your own InnoDB FULLTEXT index stopword list for all InnoDB tables. To configure your own stopword list for a specific InnoDB table, use `innodb_ft_user_stopword_table`.

Set `innodb_ft_server_stopword_table` to the name of the table containing a list of stopwords, in the format `db_name/table_name`.

The stopword table must exist before you configure `innodb_ft_server_stopword_table`.

For more information, see Section 12.10.4, “Full-Text Stopwords”.

- `innodb_ft_sort_pll_degree`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-ft-sort-pll-degree=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_ft_sort_pll_degree</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>2</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>32</td>
</tr>
</tbody>
</table>

Number of threads used in parallel to index and tokenize text in an InnoDB FULLTEXT index when building a search index.

For related information, see Section 14.6.2.3, “InnoDB FULLTEXT Indexes”, and `innodb_sort_buffer_size`.

- `innodb_ft_total_cache_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-ft-total-cache-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.6.13</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>innodb_ft_total_cache_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>6400000000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>32000000</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1600000000</td>
</tr>
</tbody>
</table>

The total memory allocated, in bytes, for the InnoDB full-text search index cache for all tables. Creating numerous tables, each with a FULLTEXT search index, could consume a significant portion of available memory. `innodb_ft_total_cache_size` defines a global memory limit for all full-text search indexes to help avoid excessive memory consumption. If the global limit is reached by an index operation, a forced sync is triggered.

For more information, see InnoDB Full-Text Index Cache.
InnoDB System Variables

• **innodb_ft_user_stopword_table**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-ft-user-stopword-table=db_name/table_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_ft_user_stopword_table</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>String</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

This option is used to specify your own InnoDB FULLTEXT index stopword list on a specific table. To configure your own stopword list for all InnoDB tables, use innodb_ft_server_stopword_table.

Set **innodb_ft_user_stopword_table** to the name of the table containing a list of stopwords, in the format db_name/table_name.

The stopword table must exist before you configure **innodb_ft_user_stopword_table**. **innodb_ft_enable_stopword** must be enabled and **innodb_ft_user_stopword_table** must be configured before you create the FULLTEXT index.

The stopword table must be an InnoDB table, containing a single VARCHAR column named value. For more information, see Section 12.10.4, “Full-Text Stopwords”.

• **innodb_io_capacity**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-io-capacity=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_io_capacity</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>200</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>100</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>2**64-1</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>2**32-1</td>
</tr>
</tbody>
</table>

The **innodb_io_capacity** variable defines the number of I/O operations per second (IOPS) available to InnoDB background tasks, such as flushing pages from the buffer pool and merging data from the change buffer.

For information about configuring the **innodb_io_capacity** variable, see Section 14.8.8, “Configuring InnoDB I/O Capacity”.

• **innodb_io_capacity_max**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-io-capacity-max=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_io_capacity_max</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
</tbody>
</table>
InnoDB System Variables

<table>
<thead>
<tr>
<th>Default Value</th>
<th>Minimum Value</th>
<th>Maximum Value (Windows, 64-bit platforms)</th>
<th>Maximum Value (Unix, 64-bit platforms)</th>
<th>Maximum Value (32-bit platforms)</th>
</tr>
</thead>
<tbody>
<tr>
<td>see description</td>
<td>100</td>
<td>2**32-1</td>
<td>2**64-1</td>
<td>2**32-1</td>
</tr>
</tbody>
</table>

If flushing activity falls behind, **InnoDB** can flush more aggressively, at a higher rate of I/O operations per second (IOPS) than defined by the `innodb_io_capacity` variable. The `innodb_io_capacity_max` variable defines a maximum number of IOPS performed by **InnoDB** background tasks in such situations.

For information about configuring the `innodb_io_capacity_max` variable, see Section 14.8.8, “Configuring InnoDB I/O Capacity”.

- **innodb_large_prefix**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>System Variable</th>
<th>Scope</th>
<th>Dynamic</th>
<th>Type</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>`--innodb-large-prefix=[{OFF</td>
<td>ON}]`</td>
<td><code>innodb_large_prefix</code></td>
<td>Global</td>
<td>Yes</td>
<td>Boolean</td>
</tr>
</tbody>
</table>

Enable this option to allow index key prefixes longer than 767 bytes (up to 3072 bytes) for **InnoDB** tables that use **DYNAMIC** or **COMPRESSED** row format. (Creating such tables also requires the option values `innodb_file_format=barracuda` and `innodb_file_per_table=true`.) See Section 14.22, “InnoDB Limits” for maximums associated with index key prefixes under various settings.

For tables that use **REduNDant** or **COMPACT** row format, this option does not affect the permitted index key prefix length.

- **innodb_limit_optimistic_insert_debug**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>System Variable</th>
<th>Scope</th>
<th>Dynamic</th>
<th>Type</th>
<th>Default Value</th>
<th>Minimum Value</th>
<th>Maximum Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--innodb-limit-optimistic-insert-debug=#</code></td>
<td><code>innodb_limit_optimistic_insert_debug</code></td>
<td>Global</td>
<td>Yes</td>
<td>Integer</td>
<td>0</td>
<td>0</td>
<td>2**32-1</td>
</tr>
</tbody>
</table>

Limits the number of records per B-tree page. A default value of 0 means that no limit is imposed. This option is only available if debugging support is compiled in using the `WITH_DEBUG` CMake option.
**InnoDB System Variables**

- **innodb_lock_wait_timeout**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-lock-wait-timeout=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_lock_wait_timeout</td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>50</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1073741824</td>
</tr>
</tbody>
</table>

  The length of time in seconds an InnoDB transaction waits for a row lock before giving up. The default value is 50 seconds. A transaction that tries to access a row that is locked by another InnoDB transaction waits at most this many seconds for write access to the row before issuing the following error:

  **ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction**

  When a lock wait timeout occurs, the current statement is rolled back (not the entire transaction). To have the entire transaction roll back, start the server with the `--innodb-rollback-on-timeout` option. See also Section 14.21.4, “InnoDB Error Handling”.

  You might decrease this value for highly interactive applications or OLTP systems, to display user feedback quickly or put the update into a queue for processing later. You might increase this value for long-running back-end operations, such as a transform step in a data warehouse that waits for other large insert or update operations to finish.

  **innodb_lock_wait_timeout** applies to InnoDB row locks only. A MySQL table lock does not happen inside InnoDB and this timeout does not apply to waits for table locks.

  The lock wait timeout value does not apply to deadlocks, because InnoDB detects them immediately and rolls back one of the deadlocked transactions. See Section 14.7.5.2, “Deadlock Detection”.

  **innodb_lock_wait_timeout** can be set at runtime with the SET GLOBAL or SET SESSION statement. Changing the GLOBAL setting requires privileges sufficient to set global system variables (see Section 5.1.8.1, “System Variable Privileges”) and affects the operation of all clients that subsequently connect. Any client can change the SESSION setting for **innodb_lock_wait_timeout**, which affects only that client.

- **innodb_locks_unsafe_for_binlog**

  | Command-Line Format | --innodb-locks-unsafe-for-binlog[={OFF|ON}] |
  |---------------------|---------------------------------------------|
  | Deprecated          | Yes                                         |
  | System Variable     | innodb_locks_unsafe_for_binlog              |
  | Scope               | Global                                      |

InnoDB System Variables

Default Value | OFF

This variable affects how InnoDB uses gap locking for searches and index scans. The variable `innodb_locks_unsafe_for_binlog` is deprecated and will be removed in a future MySQL release.

Normally, InnoDB uses an algorithm called next-key locking that combines index-row locking with gap locking. InnoDB performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, row-level locks are actually index-record locks. In addition, a next-key lock on an index record also affects the gap before the index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the index record. If one session has a shared or exclusive lock on record R in an index, another session cannot insert a new index record in the gap immediately before R in the index order. See Section 14.7.1, “InnoDB Locking”.

By default, the value of `innodb_locks_unsafe_for_binlog` is 0 (disabled), which means that gap locking is enabled: InnoDB uses next-key locks for searches and index scans. To enable the variable, set it to 1. This causes gap locking to be disabled: InnoDB uses only index-record locks for searches and index scans.

Enabling `innodb_locks_unsafe_for_binlog` does not disable the use of gap locking for foreign-key constraint checking or duplicate-key checking.

The effects of enabling `innodb_locks_unsafe_for_binlog` are the same as setting the transaction isolation level to `READ COMMITTED`, with these exceptions:

- Enabling `innodb_locks_unsafe_for_binlog` is a global setting and affects all sessions, whereas the isolation level can be set globally for all sessions, or individually per session.

- `innodb_locks_unsafe_for_binlog` can be set only at server startup, whereas the isolation level can be set at startup or changed at runtime.

`READ COMMITTED` therefore offers finer and more flexible control than `innodb_locks_unsafe_for_binlog`. For more information about the effect of isolation level on gap locking, see Section 14.7.2.1, “Transaction Isolation Levels”.

Enabling `innodb_locks_unsafe_for_binlog` may cause phantom problems because other sessions can insert new rows into the gaps when gap locking is disabled. Suppose that there is an index on the `id` column of the `child` table and that you want to read and lock all rows from the table having an identifier value larger than 100, with the intention of updating some column in the selected rows later:

```
SELECT * FROM child WHERE id > 100 FOR UPDATE;
```

The query scans the index starting from the first record where the `id` is greater than 100. If the locks set on the index records in that range do not lock out inserts made in the gaps, another session can insert a new row into the table. Consequently, if you were to execute the same `SELECT` again within the same transaction, you would see a new row in the result set returned by the query. This also means that if new items are added to the database, InnoDB does not guarantee serializability. Therefore, if `innodb_locks_unsafe_for_binlog` is enabled, InnoDB guarantees at most an
isolation level of **READ COMMITTED**. (Conflict serializability is still guaranteed.) For more information about phantoms, see Section 14.7.4, “Phantom Rows”.

Enabling `innodb_locks_unsafe_for_binlog` has additional effects:

- For **UPDATE** or **DELETE** statements, InnoDB holds locks only for rows that it updates or deletes. Record locks for nonmatching rows are released after MySQL has evaluated the **WHERE** condition. This greatly reduces the probability of deadlocks, but they can still happen.

- For **UPDATE** statements, if a row is already locked, InnoDB performs a “semi-consistent” read, returning the latest committed version to MySQL so that MySQL can determine whether the row matches the **WHERE** condition of the **UPDATE**. If the row matches (must be updated), MySQL reads the row again and this time InnoDB either locks it or waits for a lock on it.

Consider the following example, beginning with this table:

```sql
CREATE TABLE t (a INT NOT NULL, b INT) ENGINE = InnoDB;
INSERT INTO t VALUES (1,2),(2,3),(3,2),(4,3),(5,2);
COMMIT;
```

This case, table has no indexes, so searches and index scans use the hidden clustered index for record locking (see Section 14.6.2.1, “Clustered and Secondary Indexes”).

Suppose that one client performs an **UPDATE** using these statements:

```sql
SET autocommit = 0;
UPDATE t SET b = 5 WHERE b = 3;
```

Suppose also that a second client performs an **UPDATE** by executing these statements following those of the first client:

```sql
SET autocommit = 0;
UPDATE t SET b = 4 WHERE b = 2;
```

As **InnoDB** executes each **UPDATE**, it first acquires an exclusive lock for each row, and then determines whether to modify it. If **InnoDB** does not modify the row and `innodb_locks_unsafe_for_binlog` is enabled, it releases the lock. Otherwise, **InnoDB** retains the lock until the end of the transaction. This affects transaction processing as follows.

If **innodb_locks_unsafe_for_binlog** is disabled, the first **UPDATE** acquires x-locks and does not release any of them:

```sql
x-lock(1,2); retain x-lock
x-lock(2,3); update(2,3) to (2,5); retain x-lock
x-lock(3,2); unlock(3,2)
x-lock(4,3); update(4,3) to (4,5); retain x-lock
x-lock(5,2); retain x-lock
```

The second **UPDATE** blocks as soon as it tries to acquire any locks (because the first update has retained locks on all rows), and does not proceed until the first **UPDATE** commits or rolls back:

```sql
x-lock(1,2); block and wait for first UPDATE to commit or roll back
```

If **innodb_locks_unsafe_for_binlog** is enabled, the first **UPDATE** acquires x-locks and releases those for rows that it does not modify:

```sql
x-lock(1,2); unlock(1,2)
x-lock(2,3); update(2,3) to (2,5); retain x-lock
x-lock(3,2); unlock(3,2)
x-lock(4,3); update(4,3) to (4,5); retain x-lock
```
InnoDB System Variables

For the second `UPDATE`, InnoDB does a “semi-consistent” read, returning the latest committed version of each row to MySQL so that MySQL can determine whether the row matches the `WHERE` condition of the `UPDATE`:

\[
\begin{align*}
x\text{-lock}(5,2); & \quad \text{unlock}(5,2) \\
x\text{-lock}(1,2); & \quad \text{update}(1,2) \text{ to } (1,4); \text{ retain } x\text{-lock} \\
x\text{-lock}(2,3); & \quad \text{unlock}(2,3) \\
x\text{-lock}(3,2); & \quad \text{update}(3,2) \text{ to } (3,4); \text{ retain } x\text{-lock} \\
x\text{-lock}(4,3); & \quad \text{unlock}(4,3) \\
x\text{-lock}(5,2); & \quad \text{update}(5,2) \text{ to } (5,4); \text{ retain } x\text{-lock}
\end{align*}
\]

- `innodb_log_buffer_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-log-buffer-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_log_buffer_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>8388608</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>262144</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

The size in bytes of the buffer that InnoDB uses to write to the log files on disk. The default value is 8MB. A large log buffer enables large transactions to run without the need to write the log to disk before the transactions commit. Thus, if you have transactions that update, insert, or delete many rows, making the log buffer larger saves disk I/O. For related information, see Memory Configuration, and Section 8.5.4, “Optimizing InnoDB Redo Logging”. For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

- `innodb_log_checkpoint_now`

| Command-Line Format | `--innodb-log-checkpoint-now=[OFF|ON]` |
|---------------------|----------------------------------------|
| Introduced          | 5.6.12                                 |
| System Variable     | `innodb_log_checkpoint_now`            |
| Scope               | Global                                 |
| Dynamic             | Yes                                    |
| Type                | Boolean                                |
| Default Value       | OFF                                    |

Enable this debug option to force InnoDB to write a checkpoint. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

- `innodb_log_compressed_pages`

| Command-Line Format | `--innodb-log-compressed-pages=[OFF|ON]` |
|---------------------|----------------------------------------|
| Introduced          | 5.6.11                                 |
| System Variable     | `innodb_log_compressed_pages`          |
| Scope               | Global                                 |
| Dynamic             | Yes                                    |
| Type                | Boolean                                |
InnoDB System Variables

Default Value

| ON |

Specifies whether images of re-compressed pages are written to the redo log. Re-compression may occur when changes are made to compressed data.

innodb_log_compressed_pages is enabled by default to prevent corruption that could occur if a different version of the zlib compression algorithm is used during recovery. If you are certain that the zlib version will not change, you can disable innodb_log_compressed_pages to reduce redo log generation for workloads that modify compressed data.

To measure the effect of enabling or disabling innodb_log_compressed_pages, compare redo log generation for both settings under the same workload. Options for measuring redo log generation include observing the Log sequence number (LSN) in the LOG section of SHOW ENGINE INNODB STATUS output, or monitoring Innodb_os_log_written status for the number of bytes written to the redo log files.

For related information, see Section 14.9.6, “Compression for OLTP Workloads”.

• innodb_log_file_size

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-log-file-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_log_file_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>50331648</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1048576</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>512GB / innodb_log_files_in_group</td>
</tr>
</tbody>
</table>

The size in bytes of each log file in a log group. The combined size of log files (innodb_log_file_size * innodb_log_files_in_group) cannot exceed a maximum value that is slightly less than 512GB. A pair of 255 GB log files, for example, approaches the limit but does not exceed it. The default value is 48MB.

Generally, the combined size of the log files should be large enough that the server can smooth out peaks and troughs in workload activity, which often means that there is enough redo log space to handle more than an hour of write activity. The larger the value, the less checkpoint flush activity is required in the buffer pool, saving disk I/O. Larger log files also make crash recovery slower.

Important

Due to Bug #69477, redo log writes for large, externally stored BLOB fields could overwrite the most recent checkpoint. To address this bug, a patch introduced in MySQL 5.6.20 limits the size of redo log BLOB writes to 10% of the redo log file size. As a result of this limit, innodb_log_file_size should be set to a value greater than 10 times the largest BLOB data size found in the rows of your tables plus the length of other variable length fields (VARCHAR, VARBINARY, and TEXT type fields).

In MySQL 5.6.22, the redo log BLOB write limit is relaxed to 10% of the total redo log size (innodb_log_file_size * innodb_log_files_in_group). (Bug #19498877)

For related information, see Redo Log File Configuration. For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

• innodb_log_files_in_group
### InnoDB System Variables

#### --innodb-log-files-in-group=\#
- **System Variable**: `innodb_log_files_in_group`
- **Scope**: Global
- **Dynamic**: No
- **Type**: Integer
- **Default Value**: 2
- **Minimum Value**: 2
- **Maximum Value**: 100

The number of log files in the log group. InnoDB writes to the files in a circular fashion. The default (and recommended) value is 2. The location of the files is specified by `innodb_log_group_home_dir`. The combined size of log files (`innodb_log_file_size * innodb_log_files_in_group`) can be up to 512GB.

For related information, see Redo Log File Configuration.

#### --innodb-log-group-home-dir=dir_name
- **System Variable**: `innodb_log_group_home_dir`
- **Scope**: Global
- **Dynamic**: No
- **Type**: Directory name

The directory path to the InnoDB redo log files, whose number is specified by `innodb_log_files_in_group`. If you do not specify any InnoDB log variables, the default is to create two files named `ib_logfile0` and `ib_logfile1` in the MySQL data directory. Log file size is given by the `innodb_log_file_size` system variable.

For related information, see Redo Log File Configuration.

#### --innodb-lru-scan-depth=\#
- **System Variable**: `innodb_lru_scan_depth`
- **Scope**: Global
- **Dynamic**: Yes
- **Type**: Integer
- **Default Value**: 1024
- **Minimum Value**: 100
- **Maximum Value (64-bit platforms)**: $2^{64}-1$
- **Maximum Value (32-bit platforms)**: $2^{32}-1$

A parameter that influences the algorithms and heuristics for the flush operation for the InnoDB buffer pool. Primarily of interest to performance experts tuning I/O-intensive workloads. It specifies,
InnoDB System Variables

per buffer pool instance, how far down the buffer pool LRU page list the page cleaner thread scans looking for dirty pages to flush. This is a background operation performed once per second.

A setting smaller than the default is generally suitable for most workloads. A value that is much higher than necessary may impact performance. Only consider increasing the value if you have spare I/O capacity under a typical workload. Conversely, if a write-intensive workload saturates your I/O capacity, decrease the value, especially in the case of a large buffer pool.

When tuning innodb_lru_scan_depth, start with a low value and configure the setting upward with the goal of rarely seeing zero free pages. Also, consider adjusting innodb_lru_scan_depth when changing the number of buffer pool instances, since innodb_lru_scan_depth * innodb_buffer_pool_instances defines the amount of work performed by the page cleaner thread each second.

For related information, see Section 14.8.3.4, “Configuring Buffer Pool Flushing”. For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

• innodb_max_dirty_pages_pct

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-max-dirty-pages-pct=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_max_dirty_pages_pct</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>75</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>99</td>
</tr>
</tbody>
</table>

InnoDB tries to flush data from the buffer pool so that the percentage of dirty pages does not exceed this value. Specify an integer in the range from 0 to 99. The default value is 75.

The innodb_max_dirty_pages_pct setting establishes a target for flushing activity. It does not affect the rate of flushing. For information about managing the rate of flushing, see Section 14.8.3.4, “Configuring Buffer Pool Flushing”.

For related information, see Section 14.8.3.4, “Configuring Buffer Pool Flushing”. For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

• innodb_max_dirty_pages_pct_lwm

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-max-dirty-pages-pct-lwm=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_max_dirty_pages_pct_lwm</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Numeric</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>99</td>
</tr>
</tbody>
</table>

Defines a low water mark representing the percentage of dirty pages at which preflushing is enabled to control the dirty page ratio. The default of 0 disables the pre-flushing behavior entirely. For more information, see Section 14.8.3.4, “Configuring Buffer Pool Flushing”.

2001
### InnoDB System Variables

- **innodb_max_purge_lag**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-max-purge-lag=</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_max_purge_lag</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

Defines the desired maximum purge lag. If this value is exceeded, a delay is imposed on `INSERT`, `UPDATE`, and `DELETE` operations to allow time for purge to catch up. The default value is 0, which means there is no maximum purge lag and no delay.

For more information, see Section 14.8.10, “Purge Configuration”.

- **innodb_max_purge_lag_delay**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-max-purge-lag-delay=</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_max_purge_lag_delay</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>10000000</td>
</tr>
</tbody>
</table>

Specifies the maximum delay in microseconds for the delay imposed when the `innodb_max_purge_lag` threshold is exceeded. The specified `innodb_max_purge_lag_delay` value is an upper limit on the delay period calculated by the `innodb_max_purge_lag` formula.

For more information, see Section 14.8.10, “Purge Configuration”.

- **innodb_mirrored_log_groups**

  Has no effect. This variable is deprecated as of MySQL 5.6.11 and will be removed in a future MySQL release.

- **innodb_monitor_disable**

  | Command-Line Format | --innodb-monitor-disable={counter|module|pattern|all} |
  |---------------------|-----------------------------------------------|
  | System Variable     | innodb_monitor_disable                       |
  | Scope               | Global                                       |
  | Dynamic             | Yes                                          |
  | Type                | String                                       |

Disables InnoDB metrics counters. Counter data may be queried using the `INFORMATION_SCHEMA.INNODB_METRICS` table. For usage information, see Section 14.15.6, “InnoDB INFORMATION_SCHEMA Metrics Table”.

- **innodb_monitor_enable**
### InnoDB System Variables

#### Command-Line Format

<table>
<thead>
<tr>
<th>Command-Line Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>`--innodb-monitor-enable={counter</td>
</tr>
</tbody>
</table>

#### System Variable

<table>
<thead>
<tr>
<th>System Variable</th>

</tr>
</thead>
<tbody>
<tr>
<td>counter</td>
</tr>
<tr>
<td>module</td>
</tr>
<tr>
<td>pattern</td>
</tr>
<tr>
<td>all</td>
</tr>
</tbody>
</table>

Resets all values (minimum, maximum, and so on) for InnoDB metrics counters. Counter data may be queried using the `INFORMATION_SCHEMA.INNODB_METRICS` table. For usage information, see Section 14.15.6, “InnoDB INFORMATION_SCHEMA Metrics Table”.

#### `innodb_numa_interleave`

2003
InnoDB System Variables

### Command-Line Format

| Command-Line Format | --innodb-numa-interleave={OFF|ON} |
|---------------------|-----------------------------------|

### Introduced

5.6.27

### System Variable

`innodb_numa_interleave`

### Scope

Global

### Dynamic

No

### Type

Boolean

### Default Value

OFF

Enables the NUMA interleave memory policy for allocation of the InnoDB buffer pool. When `innodb_numa_interleave` is enabled, the NUMA memory policy is set to `MPOL_INTERLEAVE` for the `mysqld` process. After the InnoDB buffer pool is allocated, the NUMA memory policy is set back to `MPOL_DEFAULT`. For the `innodb_numa_interleave` option to be available, MySQL must be compiled on a NUMA-enabled Linux system.

- `innodb_old_blocks_pct`

#### Command-Line Format

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-old-blocks-pct=#</th>
</tr>
</thead>
</table>

#### System Variable

`innodb_old_blocks_pct`

#### Scope

Global

#### Dynamic

Yes

#### Type

Integer

#### Default Value

37

#### Minimum Value

5

#### Maximum Value

95

Specifies the approximate percentage of the InnoDB buffer pool used for the old block sublist. The range of values is 5 to 95. The default value is 37 (that is, 3/8 of the pool). Often used in combination with `innodb_old_blocks_time`.

For more information, see Section 14.8.3.2, “Making the Buffer Pool Scan Resistant”. For information about buffer pool management, the LRU algorithm, and eviction policies, see Section 14.5.1, “Buffer Pool”.

- `innodb_old_blocks_time`

#### Command-Line Format

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-old-blocks-time=#</th>
</tr>
</thead>
</table>

#### System Variable

`innodb_old_blocks_time`

#### Scope

Global

#### Dynamic

Yes

#### Type

Integer

#### Default Value

1000

#### Minimum Value

0

#### Maximum Value

$2^{32} - 1$

Non-zero values protect against the buffer pool being filled by data that is referenced only for a brief period, such as during a full table scan. Increasing this value offers more protection against full table scans interfering with data cached in the buffer pool.

Specifies how long in milliseconds a block inserted into the old sublist must stay there after its first access before it can be moved to the new sublist. If the value is 0, a block inserted into the old sublist
InnoDB System Variables

... moves immediately to the new sublist the first time it is accessed, no matter how soon after insertion the access occurs. If the value is greater than 0, blocks remain in the old sublist until an access occurs at least many milliseconds after the first access. For example, a value of 1000 causes blocks to stay in the old sublist for 1 second after the first access before they become eligible to move to the new sublist.

The default value is 1000 as of MySQL 5.6.6, 0 before that.

This variable is often used in combination with `innodb_old_blocks_pct`. For more information, see Section 14.8.3.2, “Making the Buffer Pool Scan Resistant”. For information about buffer pool management, the LRU algorithm, and eviction policies, see Section 14.5.1, “Buffer Pool”.

- **innodb_online_alter_log_max_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-online-alter-log-max-size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_online_alter_log_max_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>134217728</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>65536</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>2**64-1</td>
</tr>
</tbody>
</table>

Specifies an upper limit in bytes on the size of the temporary log files used during online DDL operations for InnoDB tables. There is one such log file for each index being created or table being altered. This log file stores data inserted, updated, or deleted in the table during the DDL operation. The temporary log file is extended when needed by the value of `innodb_sort_buffer_size`, up to the maximum specified by `innodb_online_alter_log_max_size`. If a temporary log file exceeds the upper size limit, the ALTER TABLE operation fails and all uncommitted concurrent DML operations are rolled back. Thus, a large value for this option allows more DML to happen during an online DDL operation, but also extends the period of time at the end of the DDL operation when the table is locked to apply the data from the log.

- **innodb_open_files**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-open-files=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_open_files</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>-1 (signifies autosizing; do not assign this literal value)</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>10</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

This variable is only relevant if you use multiple InnoDB tablespaces. It specifies the maximum number of .ibd files that MySQL can keep open at one time. The minimum value is 10. As of MySQL 5.6.6, the default value is 300 if `innodb_file_per_table` is not enabled, and the higher of 300 and `table_open_cache` otherwise. Before 5.6.6, the default value is 300.

The file descriptors used for .ibd files are for InnoDB tables only. They are independent of those specified by the `open_files_limit` system variable, and do not affect the operation of the table cache. For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

- **innodb_optimize_fulltext_only**
InnoDB System Variables

| Command-Line Format          | --innodb-optimize-fulltext-only={OFF|ON} |
|----------------------------|----------------------------------------|
| System Variable            | innodb_optimize_fulltext_only          |
| Scope                      | Global                                 |
| Dynamic                    | Yes                                    |
| Type                       | Boolean                                |
| Default Value              | OFF                                    |

Changes the way OPTIMIZE TABLE operates on InnoDB tables. Intended to be enabled temporarily, during maintenance operations for InnoDB tables with FULLTEXT indexes.

By default, OPTIMIZE TABLE reorganizes data in the clustered index of the table. When this option is enabled, OPTIMIZE TABLE skips the reorganization of table data, and instead processes newly added, deleted, and updated token data for InnoDB FULLTEXT indexes. For more information, see Optimizing InnoDB Full-Text Indexes.

- **innodb_page_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-page-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_page_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td>16384</td>
</tr>
<tr>
<td>Valid Values</td>
<td>4096 8192 16384</td>
</tr>
</tbody>
</table>

Specifies the page size for InnoDB tablespaces. Values can be specified in bytes or kilobytes. For example, a 16 kilobyte page size value can be specified as 16384, 16KB, or 16k.

innodb_page_size can only be configured prior to initializing the MySQL instance and cannot be changed afterward. If no value is specified, the instance is initialized using the default page size. See Section 14.8.1, "InnoDB Startup Configuration".

The default 16KB page size is appropriate for a wide range of workloads, particularly for queries involving table scans and DML operations involving bulk updates. Smaller page sizes might be more efficient for OLTP workloads involving many small writes, where contention can be an issue when single pages contain many rows. Smaller pages might also be efficient with SSD storage devices, which typically use small block sizes. Keeping the InnoDB page size close to the storage device block size minimizes the amount of unchanged data that is rewritten to disk. For general I/O tuning advice, see Section 8.5.8, "Optimizing InnoDB Disk I/O".

- **innodb_print_all_deadlocks**

| Command-Line Format          | --innodb-print-all-deadlocks={OFF|ON} |
|----------------------------|--------------------------------------|
| System Variable            | innodb_print_all_deadlocks           |
| Scope                      | Global                               |
| Dynamic                    | Yes                                  |
| Type                       | Boolean                              |
InnoDB System Variables

When this option is enabled, information about all deadlocks in InnoDB user transactions is recorded in the mysqld error log. Otherwise, you see information about only the last deadlock, using the SHOW ENGINE INNODB STATUS command. An occasional InnoDB deadlock is not necessarily an issue, because InnoDB detects the condition immediately and rolls back one of the transactions automatically. You might use this option to troubleshoot why deadlocks are occurring if an application does not have appropriate error-handling logic to detect the rollback and retry its operation. A large number of deadlocks might indicate the need to restructure transactions that issue DML or SELECT ... FOR UPDATE statements for multiple tables, so that each transaction accesses the tables in the same order, thus avoiding the deadlock condition.

For related information, see Section 14.7.5, “Deadlocks in InnoDB”.

- **innodb_purge_batch_size**

  Command-Line Format
  
  --innodb-purge-batch-size=#

  System Variable
  
  innodb_purge_batch_size

  Scope
  
  Global

  Dynamic
  
  Yes

  Type
  
  Integer

  Default Value
  
  300

  Minimum Value
  
  1

  Maximum Value
  
  5000

  Defines the number of undo log pages that purge parses and processes in one batch from the history list. In a multithreaded purge configuration, the coordinator purge thread divides innodb_purge_batch_size by innodb_purge_threads and assigns that number of pages to each purge thread. The innodb_purge_batch_size variable also defines the number of undo log pages that purge frees after every 128 iterations through the undo logs.

  The innodb_purge_batch_size option is intended for advanced performance tuning in combination with the innodb_purge_threads setting. Most users need not change innodb_purge_batch_size from its default value.

  For related information, see Section 14.8.10, “Purge Configuration”.

- **innodb_purge_threads**

  Command-Line Format
  
  --innodb-purge-threads=#

  System Variable
  
  innodb_purge_threads

  Scope
  
  Global

  Dynamic
  
  No

  Type
  
  Integer

  Default Value
  
  1

  Minimum Value
  
  1

  Maximum Value
  
  32

  The number of background threads devoted to the InnoDB purge operation. Increasing the value creates additional purge threads, which can improve efficiency on systems where DML operations are performed on multiple tables.

  For related information, see Section 14.8.10, “Purge Configuration”.

2007
InnoDB System Variables

- **innodb_random_readAhead**

  
  **Command-Line Format**
  ```
  --innodb-random-read-ahead=[{OFF|ON}]
  ```

  **System Variable**
  `innodb_random_read_ahead`

  **Scope**
  Global

  **Dynamic**
  Yes

  **Type**
  Boolean

  **Default Value**
  OFF

  Enables the random read-ahead technique for optimizing InnoDB I/O.

  For details about performance considerations for different types of read-ahead requests, see Section 14.8.3.3, “Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)”. For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

- **innodb_readAheadThreshold**

  
  **Command-Line Format**
  ```
  --innodb-read-ahead-threshold=#
  ```

  **System Variable**
  `innodb_read_ahead_threshold`

  **Scope**
  Global

  **Dynamic**
  Yes

  **Type**
  Integer

  **Default Value**
  56

  **Minimum Value**
  0

  **Maximum Value**
  64

  Controls the sensitivity of linear read-ahead that InnoDB uses to prefetch pages into the buffer pool. If InnoDB reads at least `innodb_readAheadThreshold` pages sequentially from an extent (64 pages), it initiates an asynchronous read for the entire following extent. The permissible range of values is 0 to 64. As of MySQL 5.6.1, a value of 0 disables read-ahead. Prior to 5.6.1, a value of 0 would trigger a read-ahead upon reading the boundary page of a 64 page extent. For the default of 56, InnoDB must read at least 56 pages sequentially from an extent to initiate an asynchronous read for the following extent.

  Knowing how many pages are read through the read-ahead mechanism, and how many of these pages are evicted from the buffer pool without ever being accessed, can be useful when fine-tuning the `innodb_readAheadThreshold` setting. `SHOW ENGINE INNODB STATUS` output displays counter information from the `Innodb_buffer_pool_read_ahead` and `Innodb_buffer_pool_read_ahead_evicted` global status variables, which report the number of pages brought into the buffer pool by read-ahead requests, and the number of such pages evicted from the buffer pool without ever being accessed, respectively. The status variables report global values since the last server restart.

  `SHOW ENGINE INNODB STATUS` also shows the rate at which the read-ahead pages are read and the rate at which such pages are evicted without being accessed. The per-second averages are based on the statistics collected since the last invocation of `SHOW ENGINE INNODB STATUS` and are displayed in the `BUFFER POOL AND MEMORY` section of the `SHOW ENGINE INNODB STATUS` output.

  For more information, see Section 14.8.3.3, “Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)”. For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

2008
InnoDB System Variables

• **innodb_read_io_threads**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-read-io-threads=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_read_io_threads</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>4</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>64</td>
</tr>
</tbody>
</table>

The number of I/O threads for read operations in InnoDB. Its counterpart for write threads is **innodb_write_io_threads**. For more information, see Section 14.8.6, “Configuring the Number of Background InnoDB I/O Threads”. For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

**Note**

On Linux systems, running multiple MySQL servers (typically more than 12) with default settings for **innodb_read_io_threads**, **innodb_write_io_threads**, and the Linux `aio-max-nr` setting can exceed system limits. Ideally, increase the `aio-max-nr` setting; as a workaround, you might reduce the settings for one or both of the MySQL variables.

• **innodb_read_only**

| Command-Line Format | --innodb-read-only[={OFF|ON}] |
|---------------------|--------------------------------|
| System Variable     | innodb_read_only               |
| Scope               | Global                         |
| Dynamic             | No                             |
| Type                | Boolean                        |
| Default Value       | OFF                            |

Starts InnoDB in read-only mode. For distributing database applications or data sets on read-only media. Can also be used in data warehouses to share the same data directory between multiple instances. For more information, see Section 14.8.2, “Configuring InnoDB for Read-Only Operation”.

• **innodb_replication_delay**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-replication-delay=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_replication_delay</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

The replication thread delay in milliseconds on a replica server if **innodb_thread_concurrency** is reached.
InnoDB System Variables

- **innodb_rollback_on_timeout**

  **Command-Line Format**  
  --innodb-rollback-on-timeout [=OFF|ON]

  **System Variable**  
  innodb_rollback_on_timeout

  **Scope**  
  Global

  **Dynamic**  
  No

  **Type**  
  Boolean

  **Default Value**  
  OFF

  InnoDB rollback only the last statement on a transaction timeout by default. If --innodb-rollback-on-timeout is specified, a transaction timeout causes InnoDB to abort and roll back the entire transaction (the same behavior as in MySQL 4.1).

  For more information, see Section 14.21.4, "InnoDB Error Handling".

- **innodb_rollback_segments**

  **Command-Line Format**  
  --innodb-rollback-segments=#

  **System Variable**  
  innodb_rollback_segments

  **Scope**  
  Global

  **Dynamic**  
  Yes

  **Type**  
  Integer

  **Default Value**  
  128

  **Minimum Value**  
  1

  **Maximum Value**  
  128

  Defines the number of rollback segments used by InnoDB for transactions that generate undo records. The number of transactions that each rollback segment supports depends on the InnoDB page size and the number of undo logs assigned to each transaction. For more information, see Section 14.6.7, “Undo Logs”.

  This setting is appropriate for tuning performance if you observe mutex contention related to the undo logs.

  Although you can increase or decrease the number of rollback segments used by InnoDB, the number of rollback segments physically present in the system never decreases. Thus, you might start with a low value and gradually increase it to avoid allocating rollback segments that are not required. The innodb_rollback_segments default and maximum value is 128.

  For related information, see Section 14.3, “InnoDB Multi-Versioning”. For information about configuring separate undo tablespaces, see Section 14.6.3.3, “Undo Tablespaces”.

- **innodb_saved_page_number_debug**

  **Command-Line Format**  
  --innodb-saved-page-number-debug=#

  **Introduced**  
  5.6.17

  **System Variable**  
  innodb_saved_page_number_debug

  **Scope**  
  Global

  **Dynamic**  
  Yes

  **Type**  
  Integer

  **Default Value**  
  0

  **Maximum Value**  
  $2^{23} - 1$
InnoDB System Variables

Saves a page number. Setting the `innodb_fill_make_page_dirty_debug` option dirties the page defined by `innodb_saved_page_number_debug`. The `innodb_saved_page_number_debug` option is only available if debugging support is compiled in using the `WITH_DEBUG` CMake option.

- `innodb_sort_buffer_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-sort-buffer-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_sort_buffer_size</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1048576</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>65536</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>67108864</td>
</tr>
</tbody>
</table>

Specifies the size of sort buffers used to sort data during creation of an InnoDB index. The specified size defines the amount of data that is read into memory for internal sorting and then written out to disk. This process is referred to as a “run”. During the merge phase, pairs of buffers of the specified size are read and merged. The larger the setting, the fewer runs and merges there are.

This sort area is only used for merge sorts during index creation, not during later index maintenance operations. Buffers are deallocated when index creation completes.

The value of this option also controls the amount by which the temporary log file is extended to record concurrent DML during online DDL operations.

Before this setting was made configurable, the size was hardcoded to 1048576 bytes (1MB), which remains the default.

During an `ALTER TABLE` or `CREATE TABLE` statement that creates an index, 3 buffers are allocated, each with a size defined by this option. Additionally, auxiliary pointers are allocated to rows in the sort buffer so that the sort can run on pointers (as opposed to moving rows during the sort operation).

For a typical sort operation, a formula such as this one can be used to estimate memory consumption:

\[
(6 \times \text{FTS_NUM_AUX_INDEX}) \times (3 \times \text{GLOBAL.innodb_sort_buffer_size}) \\
+ 2 \times \text{number_of_partitions} \times \text{number_of_secondary_indexes_created} \\
+ (\text{GLOBAL.innodb_sort_buffer_size/dict_index_get_min_size(index)}) \\
\times 8 \times \text{64-bit size of *buf->tuples*})
\]

\[@\text{GLOBAL.innodb_sort_buffer_size/dict_index_get_min_size(index)}\] indicates the maximum tuples held. \(2 \times (\text{GLOBAL.innodb_sort_buffer_size/}
\times \text{dict_index_get_min_size(index)}) \times 8 \times \text{64-bit size of *buf->tuples*})\) indicates auxiliary pointers allocated.

Note

For 32-bit, multiply by 4 instead of 8.

For parallel sorts on a full-text index, multiply by the `innodb_ft_sort_pll_degree` setting:

\[
(6 \times \text{FTS_NUM_AUX_INDEX}) \times \text{GLOBAL.innodb_ft_sort_pll_degree}
\]
• **innodb_spin_wait_delay**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-spin-wait-delay=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_spin_wait_delay</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>6</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms)</td>
<td>$2^{64}-1$</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms)</td>
<td>$2^{32}-1$</td>
</tr>
</tbody>
</table>

The maximum delay between polls for a spin lock. The low-level implementation of this mechanism varies depending on the combination of hardware and operating system, so the delay does not correspond to a fixed time interval. For more information, see Section 14.8.9, “Configuring Spin Lock Polling”.

• **innodb_stats_auto_recalc**

| Command-Line Format | --innodb-stats-auto-recalc[={OFF|ON}] |
|---------------------|---------------------------------------|
| System Variable     | innodb_stats_auto_recalc              |
| Scope               | Global                               |
| Dynamic             | Yes                                   |
| Type                | Boolean                              |
| Default Value       | ON                                    |

Causes InnoDB to automatically recalculate persistent statistics after the data in a table is changed substantially. The threshold value is 10% of the rows in the table. This setting applies to tables created when the `innodb_stats_persistent` option is enabled. Automatic statistics recalculation may also be configured by specifying `STATS_PERSISTENT=1` in a CREATE TABLE or ALTER TABLE statement. The amount of data sampled to produce the statistics is controlled by the `innodb_stats_persistent_sample_pages` variable.

For more information, see Section 14.8.11.1, “Configuring Persistent Optimizer Statistics Parameters”.

• **innodb_stats_include_delete_marked**

| Command-Line Format | --innodb-stats-include-delete-marked[={OFF|ON}] |
|---------------------|-----------------------------------------------|
| Introduced          | 5.6.35                                        |
| System Variable     | innodb_stats_include_delete_marked           |
| Scope               | Global                                        |
| Dynamic             | Yes                                           |
| Type                | Boolean                                       |
| Default Value       | OFF                                           |

By default, InnoDB reads uncommitted data when calculating statistics. In the case of an uncommitted transaction that deletes rows from a table, InnoDB excludes records that are delete-marked when calculating row estimates and index statistics, which can lead to non-
optimal execution plans for other transactions that are operating on the table concurrently using a transaction isolation level other than READ UNCOMMITTED. To avoid this scenario, `innodb_stats_include_delete_marked` can be enabled to ensure that InnoDB includes delete-marked records when calculating persistent optimizer statistics.

When `innodb_stats_include_delete_marked` is enabled, ANALYZE TABLE considers delete-marked records when recalculating statistics.

`innodb_stats_include_delete_marked` is a global setting that affects all InnoDB tables. It is only applicable to persistent optimizer statistics.

For related information, see Section 14.8.11.1, “Configuring Persistent Optimizer Statistics Parameters”.

• `innodb_stats_method`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-stats-method=value</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_stats_method</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Enumeration</td>
</tr>
<tr>
<td>Default Value</td>
<td><code>nulls_equal</code></td>
</tr>
<tr>
<td>Valid Values</td>
<td><code>nulls_equal</code></td>
</tr>
<tr>
<td></td>
<td><code>nulls_unequal</code></td>
</tr>
<tr>
<td></td>
<td><code>nulls_ignored</code></td>
</tr>
</tbody>
</table>

How the server treats NULL values when collecting statistics about the distribution of index values for InnoDB tables. Permitted values are `nulls_equal`, `nulls_unequal`, and `nulls_ignored`. For `nulls_equal`, all NULL index values are considered equal and form a single value group with a size equal to the number of NULL values. For `nulls_unequal`, NULL values are considered unequal, and each NULL forms a distinct value group of size 1. For `nulls_ignored`, NULL values are ignored.

The method used to generate table statistics influences how the optimizer chooses indexes for query execution, as described in Section 8.3.7, “InnoDB and MyISAM Index Statistics Collection”.

• `innodb_stats_on_metadata`

| Command-Line Format | `--innodb-stats-on-metadata[={OFF|ON}]` |
|---------------------|----------------------------------------|
| System Variable     | `innodb_stats_on_metadata`             |
| Scope               | Global                                 |
| Dynamic             | Yes                                    |
| Type                | Boolean                                |
| Default Value       | OFF                                    |

This option only applies when optimizer statistics are configured to be non-persistent. Optimizer statistics are not persisted to disk when `innodb_stats_persistent` is disabled or when individual tables are created or altered with `STATS_PERSISTENT=0`. For more information, see Section 14.8.11.2, “Configuring Non-Persistent Optimizer Statistics Parameters”.

When `innodb_stats_on_metadata` is enabled, InnoDB updates non-persistent statistics when metadata statements such as `SHOW TABLE STATUS` or `SHOW INDEX` are run, or when accessing the `INFORMATION_SCHEMA.TABLES` or `INFORMATION_SCHEMA.STATISTICS` tables. (These
InnoDB System Variables

updates are similar to what happens for \texttt{ANALYZE TABLE}. When disabled, InnoDB does not update statistics during these operations. Leaving the setting disabled can improve access speed for schemas that have a large number of tables or indexes. It can also improve the stability of execution plans for queries that involve InnoDB tables.

To change the setting, issue the statement \texttt{SET GLOBAL innodb_stats_on_metadata=mode}, where \texttt{mode} is either \texttt{ON} or \texttt{OFF} (or \texttt{1} or \texttt{0}). Changing the setting requires privileges sufficient to set global system variables (see Section 5.1.8.1, “System Variable Privileges”) and immediately affects the operation of all connections.

\begin{itemize}
\item \texttt{innodb_stats_persistent}
\end{itemize}

\begin{table}[h]
\begin{tabular}{|l|l|}
\hline
Command-Line Format & \texttt{--innodb-stats-persistent=[\{OFF|ON\}]} \\
System Variable & \texttt{innodb_stats_persistent} \\
Scope & Global \\
Dynamic & Yes \\
Type & Boolean \\
Default Value & ON \\
\hline
\end{tabular}
\end{table}

Specifies whether InnoDB index statistics are persisted to disk. Otherwise, statistics may be recalculated frequently which can lead to variations in query execution plans. This setting is stored with each table when the table is created. You can set \texttt{innodb_stats_persistent} at the global level before creating a table, or use the \texttt{STATS_PERSISTENT} clause of the \texttt{CREATE TABLE} and \texttt{ALTER TABLE} statements to override the system-wide setting and configure persistent statistics for individual tables.

For more information, see Section 14.8.11.1, “Configuring Persistent Optimizer Statistics Parameters”.

\begin{itemize}
\item \texttt{innodb_stats_persistent_sample_pages}
\end{itemize}

\begin{table}[h]
\begin{tabular}{|l|l|}
\hline
Command-Line Format & \texttt{--innodb-stats-persistent-sample-pages=#} \\
System Variable & \texttt{innodb_stats_persistent_sample_pages} \\
Scope & Global \\
Dynamic & Yes \\
Type & Integer \\
Default Value & 20 \\
\hline
\end{tabular}
\end{table}

The number of index pages to sample when estimating cardinality and other statistics for an indexed column, such as those calculated by \texttt{ANALYZE TABLE}. Increasing the value improves the accuracy of index statistics, which can improve the query execution plan, at the expense of increased I/O during the execution of \texttt{ANALYZE TABLE} for an InnoDB table. For more information, see Section 14.8.11.1, “Configuring Persistent Optimizer Statistics Parameters”.

\begin{itemize}
\item \texttt{innodb_stats_persistent_sample_pages}
\end{itemize}

\textbf{Note}

Setting a high value for \texttt{innodb_stats_persistent_sample_pages} could result in lengthy \texttt{ANALYZE TABLE} execution time. To estimate the number of database pages accessed by \texttt{ANALYZE TABLE}, see Section 14.8.11.3, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”.

\texttt{innodb_stats_persistent_sample_pages} only applies when \texttt{innodb_stats_persistent} is enabled for a table; when \texttt{innodb_stats_persistent} is disabled, \texttt{innodb_stats_transient_sample_pages} applies instead.
• **innodb_stats_sample_pages**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-stats-sample-pages=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>Yes</td>
</tr>
<tr>
<td>System Variable</td>
<td>innodb_stats_sample_pages</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>8</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>$2^{64}-1$</td>
</tr>
</tbody>
</table>

  Deprecated. Use **innodb_stats_transient_sample_pages** instead.

• **innodb_stats_transient_sample_pages**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-stats-transient-sample-pages=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_stats_transient_sample_pages</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>8</td>
</tr>
</tbody>
</table>

  The number of index pages to sample when estimating cardinality and other statistics for an indexed column, such as those calculated by **ANALYZE TABLE**. The default value is 8. Increasing the value improves the accuracy of index statistics, which can improve the query execution plan, at the expense of increased I/O when opening an InnoDB table or recalculating statistics. For more information, see Section 14.8.11.2, “Configuring Non-Persistent Optimizer Statistics Parameters”.

  **Note**

  Setting a high value for **innodb_stats_transient_sample_pages** could result in lengthy **ANALYZE TABLE** execution time. To estimate the number of database pages accessed by **ANALYZE TABLE**, see Section 14.8.11.3, “Estimating **ANALYZE TABLE** Complexity for InnoDB Tables”.

  **innodb_stats_transient_sample_pages** only applies when **innodb_stats.persistent** is disabled for a table; when **innodb_stats.persistent** is enabled, **innodb_stats.persistent_sample_pages** applies instead. Takes the place of **innodb_stats_sample_pages**. For more information, see Section 14.8.11.2, “Configuring Non-Persistent Optimizer Statistics Parameters”.

• **innodb_status_output**

  | Command-Line Format | --innodb-status-output [=(OFF | ON)] |
  |---------------------|-------------------------------------|
  | Introduced          | 5.6.16                              |
  | System Variable     | innodb_status_output                |
  | Scope               | Global                              |
  | Dynamic             | Yes                                 |
  | Type                | Boolean                             |
InnoDB System Variables

**Default Value**: OFF

Enables or disables periodic output for the standard InnoDB Monitor. Also used in combination with `innodb_status_output_locks` to enable or disable periodic output for the InnoDB Lock Monitor. For more information, see Section 14.17.2, “Enabling InnoDB Monitors”.

- **innodb_status_output_locks**

| Command-Line Format         | `--innodb-status-output-locks[={OFF|ON}]` |
|-----------------------------|------------------------------------------|
| Introduced                  | 5.6.16                                    |
| System Variable             | `innodb_status_output_locks`              |
| Scope                       | Global                                    |
| Dynamic                     | Yes                                       |
| Type                        | Boolean                                   |
| Default Value               | OFF                                       |

Enables or disables the InnoDB Lock Monitor. When enabled, the InnoDB Lock Monitor prints additional information about locks in `SHOW ENGINE INNODB STATUS` output and in periodic output printed to the MySQL error log. Periodic output for the InnoDB Lock Monitor is printed as part of the standard InnoDB Monitor output. The standard InnoDB Monitor must therefore be enabled for the InnoDB Lock Monitor to print data to the MySQL error log periodically. For more information, see Section 14.17.2, “Enabling InnoDB Monitors”.

- **innodb_strict_mode**

| Command-Line Format         | `--innodb-strict-mode[={OFF|ON}]` |
|-----------------------------|----------------------------------|
| System Variable             | `innodb_strict_mode`              |
| Scope                       | Global, Session                   |
| Dynamic                     | Yes                               |
| Type                        | Boolean                           |
| Default Value               | OFF                               |

When `innodb_strict_mode` is enabled, InnoDB returns errors rather than warnings for certain conditions.

**Strict mode** helps guard against ignored typos and syntax errors in SQL, or other unintended consequences of various combinations of operational modes and SQL statements. When `innodb_strict_mode` is enabled, InnoDB raises error conditions in certain cases, rather than issuing a warning and processing the specified statement (perhaps with unintended behavior). This is analogous to `sql_mode` in MySQL, which controls what SQL syntax MySQL accepts, and determines whether it silently ignores errors, or validates input syntax and data values.

The `innodb_strict_mode` setting affects the handling of syntax errors for `CREATE TABLE`, `ALTER TABLE` and `CREATE INDEX` statements. `innodb_strict_mode` also enables a record size check, so that an `INSERT` or `UPDATE` never fails due to the record being too large for the selected page size.

Oracle recommends enabling `innodb_strict_mode` when using `ROW_FORMAT` and `KEY_BLOCK_SIZE` clauses in `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements. When `innodb_strict_mode` is disabled, InnoDB ignores conflicting clauses and creates the table or index with only a warning in the message log. The resulting table might have different characteristics than intended, such as lack of compression support when attempting to create a
InnoDB System Variables

compressed table. When `innodb_strict_mode` is enabled, such problems generate an immediate error and the table or index is not created.

You can enable or disable `innodb_strict_mode` on the command line when starting `mysqld`, or in a MySQL configuration file. You can also enable or disable `innodb_strict_mode` at runtime with the statement `SET [GLOBAL|SESSION] innodb_strict_mode=mode`, where mode is either `ON` or `OFF`. Changing the `GLOBAL` setting requires privileges sufficient to set global system variables (see Section 5.1.8.1, “System Variable Privileges”) and affects the operation of all clients that subsequently connect. Any client can change the `SESSION` setting for `innodb_strict_mode`, and the setting affects only that client.

- `innodb_support_xa`

| Command-Line Format | --innodb-support-xa=[OFF|ON] |
|---------------------|-----------------------------|
| System Variable     | `innodb_support_xa`         |
| Scope               | Global, Session             |
| Dynamic             | Yes                         |
| Type                | Boolean                     |
| Default Value       | ON                          |

Enables InnoDB support for two-phase commit in XA transactions, causing an extra disk flush for transaction preparation. The XA mechanism is used internally and is essential for any server that has its binary log turned on and is accepting changes to its data from more than one thread. If you disable `innodb_support_xa`, transactions can be written to the binary log in a different order than the live database is committing them, which can produce different data when the binary log is replayed in disaster recovery or on a replica. Do not disable `innodb_support_xa` on a replication source server unless you have an unusual setup where only one thread is able to change data.

For a server that is accepting data changes from only one thread, it is safe and recommended to disable this option to improve performance for InnoDB tables. For example, you can turn it off on replicas where only the replication SQL thread is changing data.

You can also disable this option if you do not need it for safe binary logging or replication, and you also do not use an external XA transaction manager.

- `innodb_sync_array_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-sync-array-size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_sync_array_size</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>1</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1024</td>
</tr>
</tbody>
</table>

Defines the size of the mutex/lock wait array. Increasing the value splits the internal data structure used to coordinate threads, for higher concurrency in workloads with large numbers of waiting threads. This setting must be configured when the MySQL instance is starting up, and cannot be changed afterward. Increasing the value is recommended for workloads that frequently produce a large number of waiting threads, typically greater than 768.
• `innodb_sync_spin_loops`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-sync-spin-loops=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_sync_spin_loops</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>30</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>4294967295</td>
</tr>
</tbody>
</table>

The number of times a thread waits for an InnoDB mutex to be freed before the thread is suspended.

• `innodb_table_locks`

| Command-Line Format | --innodb-table-locks={OFF|ON} |
|---------------------|-------------------------------|
| System Variable     | `innodb_table_locks`          |
| Scope               | Global, Session               |
| Dynamic             | Yes                           |
| Type                | Boolean                       |
| Default Value       | ON                            |

If `autocommit = 0`, InnoDB honors `LOCK TABLES`; MySQL does not return from `LOCK TABLES ... WRITE` until all other threads have released all their locks to the table. The default value of `innodb_table_locks` is 1, which means that `LOCK TABLES` causes InnoDB to lock a table internally if `autocommit = 0`.

`innodb_table_locks = 0` has no effect for tables locked explicitly with `LOCK TABLES ... WRITE`. It does have an effect for tables locked for read or write by `LOCK TABLES ... WRITE` implicitly (for example, through triggers) or by `LOCK TABLES ... READ`.

For related information, see Section 14.7, “InnoDB Locking and Transaction Model”.

• `innodb_thread_concurrency`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-thread-concurrency=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_thread_concurrency</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>1000</td>
</tr>
</tbody>
</table>

Defines the maximum number of threads permitted inside of InnoDB. A value of 0 (the default) is interpreted as infinite concurrency (no limit). This variable is intended for performance tuning on high concurrency systems.

InnoDB tries to keep the number of threads inside InnoDB less than or equal to the `innodb_thread_concurrency` limit. Once the limit is reached, additional threads are placed into
InnoDB System Variables

a “First In, First Out” (FIFO) queue for waiting threads. Threads waiting for locks are not counted in the number of concurrently executing threads.

The correct setting depends on workload and computing environment. Consider setting this variable if your MySQL instance shares CPU resources with other applications or if your workload or number of concurrent users is growing. Test a range of values to determine the setting that provides the best performance. `innodb_thread_concurrency` is a dynamic variable, which permits experimenting with different settings on a live test system. If a particular setting performs poorly, you can quickly set `innodb_thread_concurrency` back to 0.

Use the following guidelines to help find and maintain an appropriate setting:

- If the number of concurrent user threads for a workload is consistently small and does not affect performance, set `innodb_thread_concurrency=0` (no limit).
- If your workload is consistently heavy or occasionally spikes, set an `innodb_thread_concurrency` value and adjust it until you find the number of threads that provides the best performance. For example, suppose that your system typically has 40 to 50 users, but periodically the number increases to 60, 70, or more. Through testing, you find that performance remains largely stable with a limit of 80 concurrent users. In this case, set `innodb_thread_concurrency` to 80.
- If you do not want InnoDB to use more than a certain number of virtual CPUs for user threads (20 virtual CPUs, for example), set `innodb_thread_concurrency` to this number (or possibly lower, depending on performance testing). If your goal is to isolate MySQL from other applications, consider binding the `mysqld` process exclusively to the virtual CPUs. Be aware, however, that exclusive binding can result in non-optimal hardware usage if the `mysqld` process is not consistently busy. In this case, you can bind the `mysqld` process to the virtual CPUs but allow other applications to use some or all of the virtual CPUs.

Note
From an operating system perspective, using a resource management solution to manage how CPU time is shared among applications may be preferable to binding the `mysqld` process. For example, you could assign 90% of virtual CPU time to a given application while other critical processes are not running, and scale that value back to 40% when other critical processes are running.

- In some cases, the optimal `innodb_thread_concurrency` setting can be smaller than the number of virtual CPUs.
- An `innodb_thread_concurrency` value that is too high can cause performance regression due to increased contention on system internals and resources.
- Monitor and analyze your system regularly. Changes to workload, number of users, or computing environment may require that you adjust the `innodb_thread_concurrency` setting.

A value of 0 disables the queries inside InnoDB and queries in queue counters in the `ROW OPERATIONS` section of `SHOW ENGINE INNODB STATUS` output.

For related information, see Section 14.8.5, “Configuring Thread Concurrency for InnoDB”.

- `innodb_thread_sleep_delay`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-thread-sleep-delay=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td><code>innodb_thread_sleep_delay</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
</tbody>
</table>
### InnoDB System Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>Integer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Value</td>
<td>10000</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value (64-bit platforms, ≤ 5.6.16)</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Maximum Value (32-bit platforms, ≤ 5.6.16)</td>
<td>4294967295</td>
</tr>
<tr>
<td>Maximum Value (≥ 5.6.17)</td>
<td>1000000</td>
</tr>
</tbody>
</table>

Defines how long InnoDB threads sleep before joining the InnoDB queue, in microseconds. The default value is 10000. A value of 0 disables sleep. You can set `innodb_adaptive_max_sleep_delay` to the highest value you would allow for `innodb_thread_sleep_delay`, and InnoDB automatically adjusts `innodb_thread_sleep_delay` up or down depending on current thread-scheduling activity. This dynamic adjustment helps the thread scheduling mechanism to work smoothly during times when the system is lightly loaded or when it is operating near full capacity.

For more information, see Section 14.8.5, “Configuring Thread Concurrency for InnoDB”.

- **innodb_tmpdir**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb-tmpdir=dir_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.6.29</td>
</tr>
<tr>
<td>System Variable</td>
<td><code>innodb_tmpdir</code></td>
</tr>
<tr>
<td>Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Directory name</td>
</tr>
<tr>
<td>Default Value</td>
<td>NULL</td>
</tr>
</tbody>
</table>

Used to define an alternate directory for temporary sort files created during online `ALTER TABLE` operations that rebuild the table.

Online `ALTER TABLE` operations that rebuild the table also create an intermediate table file in the same directory as the original table. The `innodb_tmpdir` option is not applicable to intermediate table files.

A valid value is any directory path other than the MySQL data directory path. If the value is NULL (the default), temporary files are created MySQL temporary directory (`$TMPDIR` on Unix, `%TEMP` % on Windows, or the directory specified by the `--tmpdir` configuration option). If a directory is specified, existence of the directory and permissions are only checked when `innodb_tmpdir` is configured using a `SET` statement. If a symlink is provided in a directory string, the symlink is resolved and stored as an absolute path. The path should not exceed 512 bytes. An online `ALTER TABLE` operation reports an error if `innodb_tmpdir` is set to an invalid directory. `innodb_tmpdir` overrides the MySQL `tmpdir` setting but only for online `ALTER TABLE` operations.

The `FILE` privilege is required to configure `innodb_tmpdir`.

The `innodb_tmpdir` option was introduced to help avoid overflowing a temporary file directory located on a `tmpfs` file system. Such overflows could occur as a result of large temporary sort files created during online `ALTER TABLE` operations that rebuild the table.

In replication environments, only consider replicating the `innodb_tmpdir` setting if all servers have the same operating system environment. Otherwise, replicating the `innodb_tmpdir` setting could result in a replication failure when running online `ALTER TABLE` operations that rebuild the table.
InnoDB System Variables

If server operating environments differ, it is recommended that you configure `innodb_tmpdir` on each server individually.

For more information, see Section 14.13.3, “Online DDL Space Requirements”. For information about online `ALTER TABLE` operations, see Section 14.13, “InnoDB and Online DDL”.

- `innodb_trx_purge_view_update_only_debug`

  Command-Line Format
  
  ```
  --innodb-trx-purge-view-update-only-debug=[{OFF|ON}]
  ```

  System Variable
  `innodb_trx_purge_view_update_only_debug`

  Scope
  Global

  Dynamic
  Yes

  Type
  Boolean

  Default Value
  OFF

  Pauses purging of delete-marked records while allowing the purge view to be updated. This option artificially creates a situation in which the purge view is updated but purges have not yet been performed. This option is only available if debugging support is compiled in using the `WITH_DEBUG` CMake option.

- `innodb_trx_rseg_n_slots_debug`

  Command-Line Format
  
  ```
  --innodb-trx-rseg-n-slots-debug=#
  ```

  System Variable
  `innodb_trx_rseg_n_slots_debug`

  Scope
  Global

  Dynamic
  Yes

  Type
  Integer

  Default Value
  0

  Maximum Value
  1024

  Sets a debug flag that limits `TRX_RSEG_N_SLOTS` to a given value for the `trx_rsegf_undo_find_free` function that looks for free slots for undo log segments. This option is only available if debugging support is compiled in using the `WITH_DEBUG` CMake option.

- `innodb_undo_directory`

  Command-Line Format
  
  ```
  --innodb-undo-directory=dir_name
  ```

  System Variable
  `innodb_undo_directory`

  Scope
  Global

  Dynamic
  No

  Type
  Directory name

  Default Value
  .

  The relative or absolute directory path where InnoDB creates undo tablespaces. Typically used to place undo logs on a different storage device. Used in conjunction with
InnoDB System Variables

\textbf{innodb_rollback_segments} and \textbf{innodb_undo_tablespaces}. The default value of "." represents the same directory where InnoDB creates its other log files by default.

\textbf{Note}

An absolute directory path must be set for embedded MySQL installations. Otherwise, the server may not be able to locate undo tablespaces that are created when the MySQL instance is initialized.

For more information, see Section 14.6.3.3, “Undo Tablespaces”.

• \textbf{innodb_undo_logs}

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-undo-logs=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>\textbf{innodb_undo_logs}</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>Yes</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>128</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>128</td>
</tr>
</tbody>
</table>

Defines the number of rollback segments used by InnoDB. The \textbf{innodb_undo_logs} option is an alias for \textbf{innodb_rollback_segments}. For more information, see the description of \textbf{innodb_rollback_segments}.

• \textbf{innodb_undo_tablespaces}

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-undo-tablespaces=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>\textbf{innodb_undo_tablespaces}</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>0</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>0</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>126</td>
</tr>
</tbody>
</table>

The number of undo tablespaces used by InnoDB. The default value is 0.

Because undo logs can become large during long-running transactions, having undo logs in multiple tablespaces reduces the maximum size of any one tablespace. The undo tablespace files are created in the location defined by \textbf{innodb_undo_directory}, with names in the form of \textbf{undoN}, where \textit{N} is a sequential series of integers (including leading zeros) representing the space ID. The default size of an undo tablespace file is 10MiB.

\textbf{Important}

\textbf{innodb_undo_tablespaces} can only be configured prior to initializing the MySQL instance and cannot be changed afterward. If no value is specified, the instance is initialized using the default setting of 0. Attempting to restart InnoDB with a greater number of undo tablespaces than specified when the
MySQL instance was initialized results in a startup failure and an error stating that InnoDB did not find the expected number of undo tablespaces.

For more information, see Section 14.6.3.3, “Undo Tablespaces”.

- **innodb_use_native_aio**

  Command-Line Format
  
  `--innodb-use-native-aio=[{OFF|ON}]`

  System Variable
  `innodb_use_native_aio`

  Scope
  Global

  Dynamic
  No

  Type
  Boolean

  Default Value
  ON

  Specifies whether to use the Linux asynchronous I/O subsystem. This variable applies to Linux systems only, and cannot be changed while the server is running. Normally, you do not need to configure this option, because it is enabled by default.

  The asynchronous I/O capability that InnoDB has on Windows systems is available on Linux systems. (Other Unix-like systems continue to use synchronous I/O calls.) This feature improves the scalability of heavily I/O-bound systems, which typically show many pending reads/writes in `SHOW ENGINE INNODB STATUS\G` output.

  Running with a large number of InnoDB I/O threads, and especially running multiple such instances on the same server machine, can exceed capacity limits on Linux systems. In this case, you may receive the following error:

  ```
  EAGAIN: The specified maxevents exceeds the user's limit of available events.
  ```

  You can typically address this error by writing a higher limit to `/proc/sys/fs/aio-max-nr`.

  However, if a problem with the asynchronous I/O subsystem in the OS prevents InnoDB from starting, you can start the server with `innodb_use_native_aio=0`. This option may also be disabled automatically during startup if InnoDB detects a potential problem such as a combination of `tmpdir` location, `tmpfs` file system, and Linux kernel that does not support AIO on `tmpfs`.

  For more information, see Section 14.8.7, “Using Asynchronous I/O on Linux”.

- **innodb_use_sys_malloc**

  Command-Line Format
  
  `--innodb-use-sys-malloc=[{OFF|ON}]`

  Deprecated
  Yes

  System Variable
  `innodb_use_sys_malloc`

  Scope
  Global

  Dynamic
  No

  Type
  Boolean

  Default Value
  ON

  Enables the operating system memory allocator. If disabled, InnoDB uses its own allocator. The default value is ON. For more information, see Section 14.8.4, “Configuring the Memory Allocator for InnoDB”.

  `innodb_use_sys_malloc` is deprecated and will be removed in a future MySQL release.
InnoDB INFORMATION_SCHEMA Tables

- innodb_version

The InnoDB version number. Starting in MySQL 5.6.11, separate version numbering for InnoDB is discontinued and this value is the same the version number of the server.

- innodb_write_io_threads

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-write-io-threads=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable</td>
<td>innodb_write_io_threads</td>
</tr>
<tr>
<td>Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic</td>
<td>No</td>
</tr>
<tr>
<td>Type</td>
<td>Integer</td>
</tr>
<tr>
<td>Default Value</td>
<td>4</td>
</tr>
<tr>
<td>Minimum Value</td>
<td>1</td>
</tr>
<tr>
<td>Maximum Value</td>
<td>64</td>
</tr>
</tbody>
</table>

The number of I/O threads for write operations in InnoDB. The default value is 4. Its counterpart for read threads is innodb_read_io_threads. For more information, see Section 14.8.6, “Configuring the Number of Background InnoDB I/O Threads”. For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

Note

On Linux systems, running multiple MySQL servers (typically more than 12) with default settings for innodb_read_io_threads, innodb_write_io_threads, and the Linux aio-max-nr setting can exceed system limits. Ideally, increase the aio-max-nr setting; as a workaround, you might reduce the settings for one or both of the MySQL variables.

Also take into consideration the value of sync_binlog, which controls synchronization of the binary log to disk.

For general I/O tuning advice, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.

14.15 InnoDB INFORMATION_SCHEMA Tables

This section provides information and usage examples for InnoDB INFORMATION_SCHEMA tables.

InnoDB INFORMATION_SCHEMA tables provide metadata, status information, and statistics about various aspects of the InnoDB storage engine. You can view a list of InnoDB INFORMATION_SCHEMA tables by issuing a SHOW TABLES statement on the INFORMATION_SCHEMA database:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB%';
```

For table definitions, see Section 21.30, “INFORMATION_SCHEMA InnoDB Tables”. For general information regarding the MySQL INFORMATION_SCHEMA database, see Chapter 21, INFORMATION_SCHEMA Tables.

14.15.1 InnoDB INFORMATION_SCHEMA Tables about Compression

There are two pairs of InnoDB INFORMATION_SCHEMA tables about compression that can provide insight into how well compression is working overall:

- INNODB_CMP and INNODB_CMP_RESET provide information about the number of compression operations and the amount of time spent performing compression.
14.15.1.1 INNODB_CMP and INNODB_CMP_RESET

The INNODB_CMP and INNODB_CMP_RESET tables provide status information about operations related to compressed tables, which are described in Section 14.9, “InnoDB Table Compression”. The PAGE_SIZE column reports the compressed page size.

These two tables have identical contents, but reading from INNODB_CMP_RESET resets the statistics on compression and uncompression operations. For example, if you archive the output of INNODB_CMP_RESET every 60 minutes, you see the statistics for each hourly period. If you monitor the output of INNODB_CMP (making sure never to read INNODB_CMP_RESET), you see the cumulative statistics since InnoDB was started.

For the table definition, see Section 21.30.4, “The INFORMATION_SCHEMA INNODB_CMP and INNODB_CMP_RESET Tables”.

14.15.1.2 INNODB_CMPMEM and INNODB_CMPMEM_RESET

The INNODB_CMPMEM and INNODB_CMPMEM_RESET tables provide status information about compressed pages that reside in the buffer pool. Please consult Section 14.9, “InnoDB Table Compression” for further information on compressed tables and the use of the buffer pool. The INNODB_CMP and INNODB_CMP_RESET tables should provide more useful statistics on compression.

Internal Details

InnoDB uses a buddy allocator system to manage memory allocated to pages of various sizes, from 1KB to 16KB. Each row of the two tables described here corresponds to a single page size.

The INNODB_CMPMEM and INNODB_CMPMEM_RESET tables have identical contents, but reading from INNODB_CMPMEM_RESET resets the statistics on relocation operations. For example, if every 60 minutes you archived the output of INNODB_CMPMEM_RESET, it would show the hourly statistics. If you never read INNODB_CMPMEM_RESET and monitored the output of INNODB_CMPMEM instead, it would show the cumulative statistics since InnoDB was started.

For the table definition, see Section 21.30.5, “The INFORMATION_SCHEMA INNODB_CMPMEM and INNODB_CMPMEM_RESET Tables”.

14.15.1.3 Using the Compression Information Schema Tables

Example 14.1 Using the Compression Information Schema Tables

The following is sample output from a database that contains compressed tables (see Section 14.9, “InnoDB Table Compression”, INNODB_CMP, INNODB_CMP_PER_INDEX, and INNODB_CMPMEM).

The following table shows the contents of INFORMATION_SCHEMA.INNODB_CMP under a light workload. The only compressed page size that the buffer pool contains is 8K. Compressing or uncompressing pages has consumed less than a second since the time the statistics were reset, because the columns COMPRESS_TIME and UNCOMPRESS_TIME are zero.

<table>
<thead>
<tr>
<th>page size</th>
<th>compress ops</th>
<th>compress ops ok</th>
<th>compress time</th>
<th>uncompress ops</th>
<th>uncompress time</th>
</tr>
</thead>
<tbody>
<tr>
<td>1024</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>2048</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>4096</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>8192</td>
<td>1048</td>
<td>921</td>
<td>0</td>
<td>61</td>
<td>0</td>
</tr>
<tr>
<td>16384</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>
According to `INNODB_CMPMEM`, there are 6169 compressed 8KB pages in the buffer pool. The only other allocated block size is 64 bytes. The smallest `PAGE_SIZE` in `INNODB_CMPMEM` is used for block descriptors of those compressed pages for which no uncompressed page exists in the buffer pool. We see that there are 5910 such pages. Indirectly, we see that 259 (6169-5910) compressed pages also exist in the buffer pool in uncompressed form.

The following table shows the contents of `INFORMATION_SCHEMA.INNODB_CMPMEM` under a light workload. Some memory is unusable due to fragmentation of the memory allocator for compressed pages: `SUM(PAGE_SIZE*PAGES_FREE)=6784`. This is because small memory allocation requests are fulfilled by splitting bigger blocks, starting from the 16K blocks that are allocated from the main buffer pool, using the buddy allocation system. The fragmentation is this low because some allocated blocks have been relocated (copied) to form bigger adjacent free blocks. This copying of `SUM(PAGE_SIZE*RELOCATION_OPS)` bytes has consumed less than a second (`SUM(RELOCATION_TIME)=0`).

<table>

</tbody>
</table>

### 14.15.2 InnoDB INFORMATION_SCHEMA Transaction and Locking Information

Three `InnoDB INFORMATION_SCHEMA` tables enable you to monitor transactions and diagnose potential locking problems:

- **INNODB_TRX**: Provides information about every transaction currently executing inside InnoDB, including the transaction state (for example, whether it is running or waiting for a lock), when the transaction started, and the particular SQL statement the transaction is executing.

- **INNODB_LOCKS**: Each transaction in InnoDB that is waiting for another transaction to release a lock (`INNODB_TRX.TRX_STATE` is `LOCK WAIT`) is blocked by exactly one blocking lock request. That blocking lock request is for a row or table lock held by another transaction in an incompatible mode. A lock that blocks a transaction is always held in a mode incompatible with the mode of requested lock (read vs. write, shared vs. exclusive). The blocked transaction cannot proceed until the other transaction commits or rolls back, thereby releasing the requested lock. For every blocked transaction, `INNODB_LOCKS` contains one row that describes each lock the transaction has requested, and for which it is waiting. `INNODB_LOCKS` also contains one row for each lock that is blocking another transaction, whatever the state of the transaction that holds the lock (`INNODB_TRX.TRX_STATE` is `RUNNING`, `LOCK WAIT`, `ROLLING BACK` or `COMMITTING`).

- **INNODB_LOCK_WAITS**: This table indicates which transactions are waiting for a given lock, or for which lock a given transaction is waiting. This table contains one or more rows for each blocked transaction, indicating the lock it has requested and any locks that are blocking that request. The `REQUESTED_LOCK_ID` value refers to the lock requested by a transaction, and the `BLOCKING_LOCK_ID` value refers to the lock (held by another transaction) that prevents the first transaction from proceeding. For any given blocked transaction, all rows in `INNODB_LOCK_WAITS` have the same value for `REQUESTED_LOCK_ID` and different values for `BLOCKING_LOCK_ID`. 
For more information about the preceding tables, see Section 21.30.25, “The INFORMATION_SCHEMA INNODB_TRX Table”, Section 21.30.13, “The INFORMATION_SCHEMA INNODB_LOCKS Table”, and Section 21.30.14, “The INFORMATION_SCHEMA INNODB_LOCK_WAITS Table”.

### 14.15.2.1 Using InnoDB Transaction and Locking Information

#### Identifying Blocking Transactions

It is sometimes helpful to identify which transaction blocks another. The tables that contain information about InnoDB transactions and data locks enable you to determine which transaction is waiting for another, and which resource is being requested. (For descriptions of these tables, see Section 14.15.2, “InnoDB INFORMATION_SCHEMA Transaction and Locking Information”.)

Suppose that three sessions are running concurrently. Each session corresponds to a MySQL thread, and executes one transaction after another. Consider the state of the system when these sessions have issued the following statements, but none has yet committed its transaction:

- **Session A:**
  ```sql
  BEGIN;
  SELECT a FROM t FOR UPDATE;
  SELECT SLEEP(100);
  ```
- **Session B:**
  ```sql
  SELECT b FROM t FOR UPDATE;
  ```
- **Session C:**
  ```sql
  SELECT c FROM t FOR UPDATE;
  ```

In this scenario, use the following query to see which transactions are waiting and which transactions are blocking them:

```sql
SELECT
  r.trx_id waiting_trx_id,
  r.trx_mysql_thread_id waiting_thread,
  r.trx_query waiting_query,
  b.trx_id blocking_trx_id,
  b.trx_mysql_thread_id blocking_thread,
  b.trx_query blocking_query
FROM       information_schema.innodb_lock_waits w
INNER JOIN information_schema.innodb_trx b
ON b.trx_id = w.blocking_trx_id
INNER JOIN information_schema.innodb_trx r
ON r.trx_id = w.requesting_trx_id;
```

<table>
<thead>
<tr>
<th>waiting trx id</th>
<th>waiting thread</th>
<th>waiting query</th>
<th>blocking trx id</th>
<th>blocking thread</th>
<th>blocking query</th>
</tr>
</thead>
<tbody>
<tr>
<td>A4</td>
<td>6</td>
<td>SELECT b FROM t FOR UPDATE</td>
<td>A3</td>
<td>5</td>
<td>SELECT SLEEP(100)</td>
</tr>
<tr>
<td>A5</td>
<td>7</td>
<td>SELECT c FROM t FOR UPDATE</td>
<td>A3</td>
<td>5</td>
<td>SELECT SLEEP(100)</td>
</tr>
<tr>
<td>A5</td>
<td>7</td>
<td>SELECT c FROM t FOR UPDATE</td>
<td>A4</td>
<td>6</td>
<td>SELECT b FROM t FOR UPDATE</td>
</tr>
</tbody>
</table>

In the preceding table, you can identify sessions by the “waiting query” or “blocking query” columns. As you can see:

- Session B (trx id A4, thread 6) and Session C (trx id A5, thread 7) are both waiting for Session A (trx id A3, thread 5).
- Session C is waiting for Session B as well as Session A.
You can see the underlying data in the tables **INNODB_TRX**, **INNODB_LOCKS**, and **INNODB_LOCK_WAITS**.

The following table shows some sample contents of **INFORMATION_SCHEMA.INNODB_TRX**.

<table>
<thead>
<tr>
<th>trx id</th>
<th>trx state</th>
<th>trx started</th>
</tr>
</thead>
<tbody>
<tr>
<td>A3</td>
<td>RUNNING</td>
<td>2008-01-15 16:44:54</td>
</tr>
<tr>
<td>A4</td>
<td>LOCK WAIT</td>
<td>2008-01-15 16:45:09</td>
</tr>
<tr>
<td>A5</td>
<td>LOCK WAIT</td>
<td>2008-01-15 16:45:14</td>
</tr>
</tbody>
</table>

The following table shows some sample contents of **INFORMATION_SCHEMA.INNODB_LOCKS**.

</tr>
</tbody>
</table>

The following table shows some sample contents of **INFORMATION_SCHEMA.INNODB_LOCK_WAITS**.

<table>
<thead>
<tr>
<th>requesting trx id</th>
<th>requested lock id</th>
<th>blocking trx id</th>
<th>blocking lock id</th>
</tr>
</thead>
<tbody>
<tr>
<td>A5</td>
<td>A5:1:3:2</td>
<td>A3</td>
<td>A3:1:3:2</td>
</tr>
<tr>
<td>A5</td>
<td>A5:1:3:2</td>
<td>A4</td>
<td>A4:1:3:2</td>
</tr>
</tbody>
</table>

**Correlating InnoDB Transactions with MySQL Sessions**

Sometimes it is useful to correlate internal InnoDB locking information with the session-level information maintained by MySQL. For example, you might like to know, for a given InnoDB transaction ID, the corresponding MySQL session ID and name of the session that may be holding a lock, and thus blocking other transactions.

The following output from the **INFORMATION_SCHEMA** tables is taken from a somewhat loaded system. As can be seen, there are several transactions running.

The following **INNODB_LOCKS** and **INNODB_LOCK_WAITS** tables show that:

- Transaction **77F** (executing an **INSERT**) is waiting for transactions **77E**, **77D**, and **77B** to commit.
- Transaction **77E** (executing an **INSERT**) is waiting for transactions **77D** and **77B** to commit.
- Transaction **77D** (executing an **INSERT**) is waiting for transaction **77B** to commit.
- Transaction **77B** (executing an **INSERT**) is waiting for transaction **77A** to commit.
- Transaction **77A** is running, currently executing **SELECT**.
- Transaction **E56** (executing an **INSERT**) is waiting for transaction **E55** to commit.
- Transaction **E55** (executing an **INSERT**) is waiting for transaction **19C** to commit.
- Transaction **19C** is running, currently executing an **INSERT**.

**Note**

There may be inconsistencies between queries shown in the **INFORMATION_SCHEMAPROCESSLIST** and **INNODB_TRX** tables. For an explanation, see Section 14.15.2.3, “Persistence and Consistency of InnoDB Transaction and Locking Information”.

</tbody>
</table>

14.15.2.2 InnoDB Lock and Lock-Wait Information

When a transaction updates a row in a table, or locks it with SELECT FOR UPDATE, InnoDB establishes a list or queue of locks on that row. Similarly, InnoDB maintains a list of locks on a table for table-level locks. If a second transaction wants to update a row or lock a table already locked by a prior transaction in an incompatible mode, InnoDB adds a lock request for the row to the corresponding queue. For a lock to be acquired by a transaction, all incompatible lock requests previously entered into the lock queue for that row or table must be removed (which occurs when the transactions holding or requesting those locks either commit or roll back).

A transaction may have any number of lock requests for different rows or tables. At any given time, a transaction may request a lock that is held by another transaction, in which case it is blocked by that other transaction. The requesting transaction must wait for the transaction that holds the blocking lock to commit or roll back. If a transaction is not waiting for a lock, it is in a running state. If a transaction is waiting for a lock, it is in a lock wait state. (The INFORMATION_SCHEMA INNODB_TRX table indicates transaction state values.)

The INNODB_LOCKS table holds one or more rows for each lock wait transaction, indicating any lock requests that prevent its progress. This table also contains one row describing each lock in a queue of locks pending for a given row or table. The INNODB_LOCK_WAITS table shows which locks already held by a transaction are blocking locks requested by other transactions.

14.15.2.3 Persistence and Consistency of InnoDB Transaction and Locking Information

The data exposed by the transaction and locking tables (INNODB_TRX, INNODB_LOCKS, and INNODB_LOCK_WAITS) represents a glimpse into fast-changing data. This is not like user tables, where the data changes only when application-initiated updates occur. The underlying data is internal system-managed data, and can change very quickly.

For performance reasons, and to minimize the chance of misleading joins between the transaction and locking tables, InnoDB collects the required transaction and locking information into an intermediate
buffer whenever a `SELECT` on any of the tables is issued. This buffer is refreshed only if more than 0.1 seconds has elapsed since the last time the buffer was read. The data needed to fill the three tables is fetched atomically and consistently and is saved in this global internal buffer, forming a point-in-time “snapshot”. If multiple table accesses occur within 0.1 seconds (as they almost certainly do when MySQL processes a join among these tables), then the same snapshot is used to satisfy the query.

A correct result is returned when you join any of these tables together in a single query, because the data for the three tables comes from the same snapshot. Because the buffer is not refreshed with every query of any of these tables, if you issue separate queries against these tables within a tenth of a second, the results are the same from query to query. On the other hand, two separate queries of the same or different tables issued more than a tenth of a second apart may see different results, since the data come from different snapshots.

Because InnoDB must temporarily stall while the transaction and locking data is collected, too frequent queries of these tables can negatively impact performance as seen by other users.

As these tables contain sensitive information (at least `INNODB_LOCKS.LOCK_DATA` and `INNODB_TRX.TRX_QUERY`), for security reasons, only the users with the PROCESS privilege are allowed to `SELECT` from them.

As described previously, the data that fills the transaction and locking tables (`INNODB_TRX`, `INNODB_LOCKS` and `INNODB_LOCK_WAITS`) is fetched automatically and saved to an intermediate buffer that provides a “point-in-time” snapshot. The data across all three tables is consistent when queried from the same snapshot. However, the underlying data changes so fast that similar glimpses at other, similarly fast-changing data, may not be in synchrony. Thus, you should be careful when comparing data in the InnoDB transaction and locking tables with data in the `PROCESSLIST` table. The data from the `PROCESSLIST` table does not come from the same snapshot as the data about locking and transactions. Even if you issue a single `SELECT` (joining `INNODB_TRX` and `PROCESSLIST`, for example), the content of those tables is generally not consistent. `INNODB_TRX` may reference rows that are not present in `PROCESSLIST` or the currently executing SQL query of a transaction shown in `INNODB_TRX.TRX_QUERY` may differ from the one in `PROCESSLIST.INFO`.

**14.15.3 InnoDB INFORMATION_SCHEMA System Tables**

As of MySQL 5.6, you can extract metadata about schema objects managed by InnoDB using `INNODB INFORMATION_SCHEMA` system tables. This information comes from the InnoDB internal system tables (also referred to as the InnoDB data dictionary), which cannot be queried directly like regular InnoDB tables. Traditionally, you would get this type of information using the techniques from Section 14.17, “InnoDB Monitors”, setting up InnoDB monitors and parsing the output from the `SHOW ENGINE INNODB STATUS` statement. The InnoDB INFORMATION_SCHEMA table interface allows you to query this data using SQL.

With the exception of `INNODB_SYS_TABLESTATS`, for which there is no corresponding internal system table, InnoDB INFORMATION_SCHEMA system tables are populated with data read directly from internal InnoDB system tables rather than from metadata that is cached in memory.

InnoDB INFORMATION_SCHEMA system tables include the tables listed below. `INNODB_SYS_DATAFILES` and `INNODB_SYS_TABLESPACES` were added in MySQL 5.6.6 with the introduction of support for the `DATA DIRECTORY='directory'` clause of the `CREATE TABLE` statement, which allows InnoDB file-per-table tablespaces (.ibd files) to be created in a location outside the MySQL data directory.

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB_SYS\%';
+--------------------------------------------+
| Tables_in_information_schema (INNODB_SYS%) |
+--------------------------------------------+
| INNODB_SYS_DATAFILES                      |
| INNODB_SYS_TABLESTATS                     |
| INNODB_SYS_FOREIGN                        |
| INNODB_SYS_COLUMNS                        |
| INNODB_SYS_INDEXES                        |
| INNODB_SYS_FIELDS                         |
```
The table names are indicative of the type of data provided:

- **INNODB_SYS_TABLES** provides metadata about InnoDB tables, equivalent to the information in the SYS_TABLES table in the InnoDB data dictionary.

- **INNODB_SYS_COLUMNS** provides metadata about InnoDB table columns, equivalent to the information in the SYS_COLUMNS table in the InnoDB data dictionary.

- **INNODB_SYS_INDEXES** provides metadata about InnoDB indexes, equivalent to the information in the SYS_INDEXES table in the InnoDB data dictionary.

- **INNODB_SYS_FIELDS** provides metadata about the key columns (fields) of InnoDB indexes, equivalent to the information in the SYS_FIELDS table in the InnoDB data dictionary.

- **INNODB_SYS_TABLESTATS** provides a view of low-level status information about InnoDB tables that is derived from in-memory data structures. There is no corresponding internal InnoDB system table.

- **INNODB_SYS_DATAFILES** provides data file path information for InnoDB file-per-table tablespaces, equivalent to information in the SYS_DATAFILES table in the InnoDB data dictionary.

- **INNODB_SYS_TABLESPACES** provides metadata about InnoDB file-per-table tablespaces, equivalent to the information in the SYS_TABLESPACES table in the InnoDB data dictionary.

- **INNODB_SYS_FOREIGN** provides metadata about foreign keys defined on InnoDB tables, equivalent to the information in the SYS_FOREIGN table in the InnoDB data dictionary.

- **INNODB_SYS_FOREIGN_COLS** provides metadata about the columns of foreign keys that are defined on InnoDB tables, equivalent to the information in the SYS_FOREIGN_COLS table in the InnoDB data dictionary.

InnoDB INFORMATION_SCHEMA system tables can be joined together through fields such as `TABLE_ID`, `INDEX_ID`, and `SPACE`, allowing you to easily retrieve all available data for an object you want to study or monitor.

Refer to the InnoDB INFORMATION_SCHEMA documentation for information about the columns of each table.

**Example 14.2 InnoDB INFORMATION_SCHEMA System Tables**

This example uses a simple table (t1) with a single index (i1) to demonstrate the type of metadata found in the InnoDB INFORMATION_SCHEMA system tables.

1. Create a test database and table **t1**:

   ```
   mysql> CREATE DATABASE test;
   mysql> USE test;
   mysql> CREATE TABLE t1 (   
       col1 INT, 
       col2 CHAR(10), 
       col3 VARCHAR(10)) 
       ENGINE = InnoDB;
   mysql> CREATE INDEX i1 ON t1(col1);
   ```

2. After creating the table **t1**, query **INNODB_SYS_TABLES** to locate the metadata for **test/t1**:

   ```
   mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME='test/t1' \G
   ```
Table \textit{t1} has a \texttt{TABLE_ID} of 71. The \texttt{FLAG} field provides bit level information about table format and storage characteristics. There are six columns, three of which are hidden columns created by InnoDB (\texttt{DB\_ROW\_ID}, \texttt{DB\_TRX\_ID}, and \texttt{DB\_ROLL\_PTR}). The ID of the table's \texttt{SPACE} is 57 (a value of 0 would indicate that the table resides in the system tablespace). The \texttt{FILE\_FORMAT} is Antelope, and the \texttt{ROW\_FORMAT} is Compact. \texttt{ZIP\_PAGE\_SIZE} only applies to tables with a Compressed row format.

3. Using the \texttt{TABLE_ID} information from \texttt{INNODB\_SYS\_TABLES}, query the \texttt{INNODB\_SYS\_COLUMNS} table for information about the table's columns.

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_COLUMNS where TABLE_ID = 71 \G
```

<table>
<thead>
<tr>
<th>TABLE_ID</th>
<th>NAME</th>
<th>POS</th>
<th>MTYPE</th>
<th>PRTYPE</th>
<th>LEN</th>
</tr>
</thead>
<tbody>
<tr>
<td>71</td>
<td>col1</td>
<td>0</td>
<td>6</td>
<td>1027</td>
<td>4</td>
</tr>
<tr>
<td>71</td>
<td>col2</td>
<td>1</td>
<td>2</td>
<td>524542</td>
<td>10</td>
</tr>
<tr>
<td>71</td>
<td>col3</td>
<td>2</td>
<td>1</td>
<td>524303</td>
<td>10</td>
</tr>
</tbody>
</table>

In addition to the \texttt{TABLE_ID} and column \texttt{NAME}, \texttt{INNODB\_SYS\_COLUMNS} provides the ordinal position (\texttt{POS}) of each column (starting from 0 and incrementing sequentially), the column \texttt{MTYPE} or “main type” (6 = INT, 2 = CHAR, 1 = VARCHAR), the \texttt{PRTYPE} or “precise type” (a binary value with bits that represent the MySQL data type, character set code, and nullability), and the column length (\texttt{LEN}).

4. Using the \texttt{TABLE_ID} information from \texttt{INNODB\_SYS\_TABLES} once again, query \texttt{INNODB\_SYS\_INDEXES} for information about the indexes associated with table \textit{t1}.

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_INDEXES WHERE TABLE_ID = 71 \G
```

<table>
<thead>
<tr>
<th>INDEX_ID</th>
<th>NAME</th>
<th>TABLE_ID</th>
<th>TYPE</th>
<th>N_FIELDS</th>
<th>PAGE_NO</th>
<th>SPACE</th>
</tr>
</thead>
<tbody>
<tr>
<td>111</td>
<td>GEN_CLUST_INDEX</td>
<td>71</td>
<td>1</td>
<td>0</td>
<td>3</td>
<td>57</td>
</tr>
<tr>
<td>112</td>
<td>i1</td>
<td>71</td>
<td>0</td>
<td>1</td>
<td>4</td>
<td></td>
</tr>
</tbody>
</table>
**InnoDB INFORMATION_SCHEMA System Tables**

**SPACE**: 57

**INNODB_SYS_INDEXES** returns data for two indexes. The first index is **GEN_CLUST_INDEX**, which is a clustered index created by InnoDB if the table does not have a user-defined clustered index. The second index (i1) is the user-defined secondary index.

The **INDEX_ID** is an identifier for the index that is unique across all databases in an instance. The **TABLE_ID** identifies the table that the index is associated with. The index **TYPE** value indicates the type of index (1 = Clustered Index, 0 = Secondary index). The **N_FILEDS** value is the number of fields that comprise the index. **PAGE_NO** is the root page number of the index B-tree, and **SPACE** is the ID of the tablespace where the index resides. A nonzero value indicates that the index does not reside in the system tablespace.

5. Using the **INDEX_ID** information from **INNODB_SYS_INDEXES**, query **INNODB_SYS_FIELDS** for information about the fields of index i1.

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FIELDS where INDEX_ID = 112 \G
```

```
*************************** 1. row ***************************
INDEX_ID: 112
NAME: col1
POS: 0

INNODB_SYS_FIELDS provides the **NAME** of the indexed field and its ordinal position within the index. If the index (i1) had been defined on multiple fields, INNODB_SYS_FIELDS would provide metadata for each of the indexed fields.
```

6. Using the **SPACE** information from **INNODB_SYS_TABLES**, query **INNODB_SYS_TABLESPACES** table for information about the table's tablespace.

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES WHERE SPACE = 57 \G
```

```
*************************** 1. row ***************************
SPACE: 57
NAME: test/t1
FLAG: 0
FILE_FORMAT: Antelope
ROW_FORMAT: Compact or Redundant
PAGE_SIZE: 16384
ZIP_PAGE_SIZE: 0

In addition to the **SPACE** ID of the tablespace and the **NAME** of the associated table, INNODB_SYS_TABLESPACES provides tablespace **FLAG** data, which is bit level information about tablespace format and storage characteristics. Also provided are tablespace **FILE_FORMAT**, **ROW_FORMAT**, **PAGE_SIZE**, and several other tablespace metadata items.
```

7. Using the **SPACE** information from **INNODB_SYS_TABLES** once again, query **INNODB_SYS_DATAFILES** for the location of the tablespace data file.

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_DATAFILES WHERE SPACE = 57 \G
```

```
*************************** 1. row ***************************
SPACE: 57
PATH: ./test/t1.ibd

The datafile is located in the **test** directory under MySQL's **data** directory. If a **file-per-table** tablespace were created in a location outside the MySQL data directory using the **DATA DIRECTORY** clause of the CREATE TABLE statement, the tablespace **PATH** would be a fully qualified directory path.
```

8. As a final step, insert a row into table **t1** (**TABLE_ID = 71**) and view the data in the **INNODB_SYS_TABLESTATS** table. The data in this table is used by the MySQL optimizer to calculate which index to use when querying an InnoDB table. This information is derived from in-memory data structures. There is no corresponding internal InnoDB system table.

```sql
mysql> INSERT INTO t1 VALUES(5, 'abc', 'def');
Query OK, 1 row affected (0.06 sec)
```
The `STATS_INITIALIZED` field indicates whether or not statistics have been collected for the table. `NUM_ROWS` is the current estimated number of rows in the table. The `CLUST_INDEX_SIZE` and `OTHER_INDEX_SIZE` fields report the number of pages on disk that store clustered and secondary indexes for the table, respectively. The `MODIFIED_COUNTER` value shows the number of rows modified by DML operations and cascade operations from foreign keys. The `AUTOINC` value is the next number to be issued for any autoincrement-based operation. There are no autoincrement columns defined on table `t1`, so the value is 0. The `REF_COUNT` value is a counter. When the counter reaches 0, it signifies that the table metadata can be evicted from the table cache.

**Example 14.3 Foreign Key INFORMATION_SCHEMA System Tables**

The `INNODB_SYS_FOREIGN` and `INNODB_SYS_FOREIGN_COLS` tables provide data about foreign key relationships. This example uses a parent table and child table with a foreign key relationship to demonstrate the data found in the `INNODB_SYS_FOREIGN` and `INNODB_SYS_FOREIGN_COLS` tables.

1. Create the test database with parent and child tables:

```sql
mysql> CREATE DATABASE test;
mysql> USE test;
mysql> CREATE TABLE parent (id INT NOT NULL,
PRIMARY KEY (id)) ENGINE=INNODB;
mysql> CREATE TABLE child (id INT, parent_id INT,
INDEX par_ind (parent_id),
CONSTRAINT fk1
FOREIGN KEY (parent_id) REFERENCES parent(id)
ON DELETE CASCADE) ENGINE=INNODB;
```

2. After the parent and child tables are created, query `INNODB_SYS_FOREIGN` and locate the foreign key data for the `test/child` and `test/parent` foreign key relationship:

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN WHERE ID = 'test/fk1' \G
*************************** 1. row ***************************
  ID: test/fk1
  FOR_NAME: test/child
  REF_NAME: test/parent
  N_COLS: 1
  TYPE: 1
```

Metadata includes the foreign key ID (`fk1`), which is named for the `CONSTRAINT` that was defined on the child table. The `FOR_NAME` is the name of the child table where the foreign key is defined. `REF_NAME` is the name of the parent table (the "referenced" table). `N_COLS` is the number of columns in the foreign key index. `TYPE` is a numerical value representing bit flags that provide additional information about the foreign key column. In this case, the `TYPE` value is 1, which indicates that the `ON DELETE CASCADE` option was specified for the foreign key. See the `INNODB_SYS_FOREIGN` table definition for more information about `TYPE` values.

3. Using the foreign key ID, query `INNODB_SYS_FOREIGN_COLS` to view data about the columns of the foreign key:

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN_COLS WHERE ID = 'test/fk1' \G
*************************** 1. row ***************************
```

**Example 14.4 Joining InnoDB INFORMATION_SCHEMA System Tables**

This example demonstrates joining three InnoDB INFORMATION_SCHEMA system tables (`INNODB_SYS_TABLES`, `INNODB_SYS_TABLESPACES`, and `INNODB_SYS_TABLESTATS`) to gather file format, row format, page size, and index size information about tables in the employees sample database.

The following table name aliases are used to shorten the query string:

- `INFORMATION_SCHEMA.INNODB_SYS_TABLES`: `a`
- `INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES`: `b`
- `INFORMATION_SCHEMA.INNODB_SYS_TABLESTATS`: `c`

An `IF()` control flow function is used to account for compressed tables. If a table is compressed, the index size is calculated using `ZIP_PAGE_SIZE` rather than `PAGE_SIZE`, `CLUST_INDEX_SIZE` and `OTHER_INDEX_SIZE`, which are reported in bytes, are divided by `1024*1024` to provide index sizes in megabytes (MBs). MB values are rounded to zero decimal spaces using the `ROUND()` function.

```sql
mysql> SELECT a.NAME, a.FILE_FORMAT, a.ROW_FORMAT,
    @page_size := IF(a.ROW_FORMAT='Compressed',
    b.ZIP_PAGE_SIZE, b.PAGE_SIZE)
    AS page_size,
    ROUND((@page_size * c.CLUST_INDEX_SIZE)
    /(1024*1024)) AS pk_mb,
    ROUND((@page_size * c.OTHER_INDEX_SIZE)
    /(1024*1024)) AS secidx_mb
FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES a
INNER JOIN INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES b on a.NAME = b.NAME
INNER JOIN INFORMATION_SCHEMA.INNODB_SYS_TABLESTATS c on b.NAME = c.NAME
WHERE a.NAME LIKE 'employees/%'
ORDER BY a.NAME DESC;
```

<table>
<thead>
<tr>
<th>NAME</th>
<th>FILE_FORMAT</th>
<th>ROW_FORMAT</th>
<th>page_size</th>
<th>pk_mb</th>
<th>secidx_mb</th>
</tr>
</thead>
<tbody>
<tr>
<td>employees/titles</td>
<td>Antelope</td>
<td>Compact</td>
<td>16384</td>
<td>20</td>
<td>11</td>
</tr>
<tr>
<td>employees/salaries</td>
<td>Antelope</td>
<td>Compact</td>
<td>16384</td>
<td>91</td>
<td>33</td>
</tr>
<tr>
<td>employees/employees</td>
<td>Antelope</td>
<td>Compact</td>
<td>16384</td>
<td>15</td>
<td>0</td>
</tr>
<tr>
<td>employees/dept_manager</td>
<td>Antelope</td>
<td>Compact</td>
<td>16384</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>employees/dept_emp</td>
<td>Antelope</td>
<td>Compact</td>
<td>16384</td>
<td>12</td>
<td>10</td>
</tr>
</tbody>
</table>

### 14.15.4 InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables

The following tables provide metadata for FULLTEXT indexes:

```sql
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB_FT%';
```

<table>
<thead>
<tr>
<th>Tables_in_INFORMATION_SCHEMA (INNODB_FT%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>INNODB_FT_CONFIG</td>
</tr>
<tr>
<td>INNODB_FT_BEING_DELETED</td>
</tr>
<tr>
<td>INNODB_FT_DELETED</td>
</tr>
<tr>
<td>INNODB_FT_DEFAULT_STOPWORD</td>
</tr>
<tr>
<td>INNODB_FT_INDEX_TABLE</td>
</tr>
<tr>
<td>INNODB_FT_INDEX_CACHE</td>
</tr>
</tbody>
</table>

---

**FOR_COL_NAME** is the name of the foreign key column in the child table, and **REF_COL_NAME** is the name of the referenced column in the parent table. The **POS** value is the ordinal position of the key field within the foreign key index, starting at zero.
Table Overview

- **INNODB_FT_CONFIG**: Provides metadata about the FULLTEXT index and associated processing for an InnoDB table.

- Provides a snapshot of the INNODB_FT_DELETED table; it is used only during an OPTIMIZE TABLE maintenance operation. When OPTIMIZE TABLE is run, the INNODB_FT_BEING_DELETED table is emptied, and DOC_ID values are removed from the INNODB_FT_DELETED table. Because the contents of INNODB_FT_BEING_DELETED typically have a short lifetime, this table has limited utility for monitoring or debugging. For information about running OPTIMIZE TABLE on tables with FULLTEXT indexes, see Section 12.10.6, “Fine-Tuning MySQL Full-Text Search”.

- **INNODB_FT_DELETED**: Stores rows that are deleted from the FULLTEXT index for an InnoDB table. To avoid expensive index reorganization during DML operations for an InnoDB FULLTEXT index, the information about newly deleted words is stored separately, filtered out of search results when you do a text search, and removed from the main search index only when you issue an OPTIMIZE TABLE statement for the InnoDB table.

- **INNODB_FT_DEFAULT_STOPWORD**: Holds a list of stopwords that are used by default when creating a FULLTEXT index on InnoDB tables. For information about the INNODB_FT_DEFAULT_STOPWORD table, see Section 12.10.4, “Full-Text Stopwords”.

- **INNODB_FT_INDEX_TABLE**: Provides information about the inverted index used to process text searches against the FULLTEXT index of an InnoDB table.

- **INNODB_FT_INDEX_CACHE**: Provides token information about newly inserted rows in a FULLTEXT index. To avoid expensive index reorganization during DML operations, the information about newly indexed words is stored separately, and combined with the main search index only when OPTIMIZE TABLE is run, when the server is shut down, or when the cache size exceeds a limit defined by the innodb_ft_cache_size or innodb_ft_total_cache_size system variable.

Note
With the exception of the INNODB_FT_DEFAULT_STOPWORD table, these tables are empty initially. Before querying any of them, set the value of the innodb_ft_aux_table system variable to the name (including the database name) of the table that contains the FULLTEXT index (for example, test/articles).

Example 14.5 InnoDB FULLTEXT Index INFORMATION_SCHEMA Tables

This example uses a table with a FULLTEXT index to demonstrate the data contained in the FULLTEXT index INFORMATION_SCHEMA tables.

1. Create a table with a FULLTEXT index and insert some data:

```sql
mysql> CREATE TABLE articles {
    id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
    title VARCHAR(200),
    body TEXT,
    FULLTEXT (title,body)
} ENGINE=InnoDB;

mysql> INSERT INTO articles (title,body) VALUES
    ('MySQL Tutorial','DBMS stands for DataBase ...'),
    ('How To Use MySQL Well','After you went through a ...'),
    ('Optimizing MySQL','In this tutorial we will show ...'),
    ('1001 MySQL Tricks','1. Never run mysql as root. 2. ...'),
    ('MySQL vs. YourSQL','In the following database comparison ...'),
    ('MySQL Security','When configured properly, MySQL ...');
```
2. Set the `innodb_ft_aux_table` variable to the name of the table with the FULLTEXT index. If this variable is not set, the InnoDB FULLTEXT INFORMATION_SCHEMA tables are empty, with the exception of `INNODB_FT_DEFAULT_STOPWORD`.

```sql
SET GLOBAL innodb_ft_aux_table = 'test/articles';
```

3. Query the `INNODB_FT_INDEX_CACHE` table, which shows information about newly inserted rows in a FULLTEXT index. To avoid expensive index reorganization during DML operations, data for newly inserted rows remains in the FULLTEXT index cache until `OPTIMIZE TABLE` is run (or until the server is shut down or cache limits are exceeded).

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE LIMIT 5;
+------------+--------------+-------------+-----------+--------+----------+
| WORD       | FIRST_DOC_ID | LAST_DOC_ID | DOC_COUNT | DOC_ID | POSITION |
+------------+--------------+-------------+-----------+--------+----------+
| 1001       | 5            | 5           | 1         | 5      | 0        |
| after      | 3            | 3           | 1         | 3      | 22       |
| comparison | 6            | 6           | 1         | 6      | 44       |
| configured | 7            | 7           | 1         | 7      | 20       |
| database   | 2            | 6           | 2         | 2      | 31       |
+------------+--------------+-------------+-----------+--------+----------+
```

4. Enable the `innodb_optimize_fulltext_only` system variable and run `OPTIMIZE TABLE` on the table that contains the FULLTEXT index. This operation flushes the contents of the FULLTEXT index cache to the main FULLTEXT index. `innodb_optimize_fulltext_only` changes the way the `OPTIMIZE TABLE` statement operates on InnoDB tables, and is intended to be enabled temporarily, during maintenance operations on InnoDB tables with FULLTEXT indexes.

```sql
mysql> SET GLOBAL innodb_optimize_fulltext_only=ON;

mysql> OPTIMIZE TABLE test/articles;
```

5. Query the `INNODB_FT_INDEX_TABLE` table to view information about data in the main FULLTEXT index, including information about the data that was just flushed from the FULLTEXT index cache.

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_TABLE LIMIT 5;
+------------+--------------+-------------+-----------+--------+----------+
| WORD       | FIRST_DOC_ID | LAST_DOC_ID | DOC_COUNT | DOC_ID | POSITION |
+------------+--------------+-------------+-----------+--------+----------+
| 1001       | 5            | 5           | 1         | 5      | 0        |
| after      | 3            | 3           | 1         | 3      | 22       |
| comparison | 6            | 6           | 1         | 6      | 44       |
| configured | 7            | 7           | 1         | 7      | 20       |
| database   | 2            | 6           | 2         | 2      | 31       |
+------------+--------------+-------------+-----------+--------+----------+
```

The `INNODB_FT_INDEX_CACHE` table is now empty since the `OPTIMIZE TABLE` operation flushed the FULLTEXT index cache.

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE LIMIT 5;
Empty set (0.00 sec)
```

6. Delete some records from the `test/articles` table.

```sql
mysql> DELETE FROM test/articles WHERE id < 4;
```

7. Query the `INNODB_FT_DELETED` table. This table records rows that are deleted from the FULLTEXT index. To avoid expensive index reorganization during DML operations, information about newly deleted records is stored separately, filtered out of search results when you do a text search, and removed from the main search index when you run `OPTIMIZE TABLE`.

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DELETED;
+--------+
| 2038   |
+--------+
```
8. Run `OPTIMIZE TABLE` to remove the deleted records.

```sql
mysql> OPTIMIZE TABLE articles;
```

<table>
<thead>
<tr>
<th>Table</th>
<th>Op</th>
<th>Msg_type</th>
<th>Msg_text</th>
</tr>
</thead>
<tbody>
<tr>
<td>test.articles</td>
<td>optimize</td>
<td>status</td>
<td>OK</td>
</tr>
</tbody>
</table>

The `INNODB_FT_DELETED` table should now be empty.

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DELETED;
Empty set (0.00 sec)
```

9. Query the `INNODB_FT_CONFIG` table. This table contains metadata about the FULLTEXT index and related processing:

- `optimize_checkpoint_limit`: The number of seconds after which an `OPTIMIZE TABLE` run stops.
- `synced_doc_id`: The next `DOC_ID` to be issued.
- `stopword_table_name`: The database/table name for a user-defined stopword table. The `VALUE` column is empty if there is no user-defined stopword table.
- `use_stopword`: Indicates whether a stopword table is used, which is defined when the FULLTEXT index is created.

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_CONFIG;
```

<table>
<thead>
<tr>
<th>KEY</th>
<th>VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>optimize_checkpoint_limit</td>
<td>180</td>
</tr>
<tr>
<td>synced_doc_id</td>
<td>8</td>
</tr>
<tr>
<td>stopword_table_name</td>
<td></td>
</tr>
<tr>
<td>use_stopword</td>
<td>1</td>
</tr>
</tbody>
</table>

10. Disable `innodb_optimize_fulltext_only`, since it is intended to be enabled only temporarily:

```sql
mysql> SET GLOBAL innodb_optimize_fulltext_only=OFF;
```

14.15.5 InnoDB INFORMATION_SCHEMA Buffer Pool Tables

The `InnoDB INFORMATION_SCHEMA` buffer pool tables provide buffer pool status information and metadata about the pages within the InnoDB buffer pool.

The `InnoDB INFORMATION_SCHEMA` buffer pool tables include those listed below:

```sql
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB_BUFFER%';
```

<table>
<thead>
<tr>

Table Overview

- **INNODB_BUFFER_PAGE**: Holds information about each page in the InnoDB buffer pool.
InnoDB INFORMATION_SCHEMA Buffer Pool Tables

- **INNODB_BUFFER_PAGE_LRU**: Holds information about the pages in the InnoDB buffer pool, in particular how they are ordered in the LRU list that determines which pages to evict from the buffer pool when it becomes full. The **INNODB_BUFFER_PAGE_LRU** table has the same columns as the **INNODB_BUFFER_PAGE** table, except that the **INNODB_BUFFER_PAGE_LRU** table has an `LRU_POSITION` column instead of a `BLOCK_ID` column.

- **INNODB_BUFFER_POOL_STATS**: Provides buffer pool status information. Much of the same information is provided by `SHOW ENGINE INNODB STATUS` output, or may be obtained using InnoDB buffer pool server status variables.

**Warning**

Querying the **INNODB_BUFFER_PAGE** or **INNODB_BUFFER_PAGE_LRU** table can affect performance. Do not query these tables on a production system unless you are aware of the performance impact and have determined it to be acceptable. To avoid impacting performance on a production system, reproduce the issue you want to investigate and query buffer pool statistics on a test instance.

**Example 14.6 Querying System Data in the INNODB_BUFFER_PAGE Table**

This query provides an approximate count of pages that contain system data by excluding pages where the `TABLE_NAME` value is either `NULL` or includes a slash `/` or period `. in the table name, which indicates a user-defined table.

```sql
mysql> SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME IS NULL OR (INSTR(TABLE_NAME, '/') = 0 AND INSTR(TABLE_NAME, '.') = 0);
+----------+
| COUNT(*) |
+----------+
|     1320 |
+----------+
```

This query returns the approximate number of pages that contain system data, the total number of buffer pool pages, and an approximate percentage of pages that contain system data.

```sql
mysql> SELECT
(SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME IS NULL OR (INSTR(TABLE_NAME, '/') = 0 AND INSTR(TABLE_NAME, '.') = 0)) AS system_pages,
(SELECT COUNT(*)) AS total_pages,
(SELECT ROUND((system_pages/total_pages) * 100)) AS system_page_percentage;
+--------------+-------------+------------------------+
| system_pages | total_pages | system_page_percentage |
+--------------+-------------+------------------------+
|         1320 |        8192 |                     16 |
+--------------+-------------+------------------------+
```

The type of system data in the buffer pool can be determined by querying the `PAGE_TYPE` value. For example, the following query returns eight distinct `PAGE_TYPE` values among the pages that contain system data:

```sql
mysql> SELECT DISTINCT PAGE_TYPE FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME IS NULL OR (INSTR(TABLE_NAME, '/') = 0 AND INSTR(TABLE_NAME, '.') = 0);
+-------------------+
| PAGE_TYPE         |
+-------------------+
| SYSTEM            |
| IBUF_BITMAP       |
| UNDO_LOG          |
| UNKNOWN           |
+-------------------+
```

2040
Example 14.7 Querying User Data in the INNODB_BUFFER_PAGE Table

This query provides an approximate count of pages containing user data by counting pages where the TABLE_NAME value is NOT NULL and NOT LIKE '%INNODB_SYS_TABLES%'.

```sql
mysql> SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME IS NOT NULL;
+----------+
| COUNT(*) |
+----------+
|     6872 |
+----------+
```

This query returns the approximate number of pages that contain user data, the total number of buffer pool pages, and an approximate percentage of pages that contain user data.

```sql
mysql> SELECT
(SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME IS NOT NULL AND (INSTR(TABLE_NAME, '/') > 0 OR INSTR(TABLE_NAME, '.') > 0)) AS user_pages,
(SELECT COUNT(*)
FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE) AS total_pages,
(SELECT ROUND((user_pages/total_pages) * 100)) AS user_page_percentage;
+------------+-------------+----------------------+
| user_pages | total_pages | user_page_percentage |
+------------+-------------+----------------------+
|       6872 |        8192 |                   84 |
+------------+-------------+----------------------+
```

This query identifies user-defined tables with pages in the buffer pool:

```sql
mysql> SELECT DISTINCT TABLE_NAME FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME IS NOT NULL AND (INSTR(TABLE_NAME, '/') > 0 OR INSTR(TABLE_NAME, '.') > 0)
AND TABLE_NAME NOT LIKE 'mysql.'innodb_%';
+-------------------------+
| TABLE_NAME              |
+-------------------------+
| `employees`.`salaries`  |
| `employees`.`employees` |
+-------------------------+
```

Example 14.8 Querying Index Data in the INNODB_BUFFER_PAGE Table

For information about index pages, query the INDEX_NAME column using the name of the index. For example, the following query returns the number of pages and total data size of pages for the emp_no index that is defined on the employees.salaries table:

```sql
mysql> SELECT INDEX_NAME, COUNT(*) AS Pages,
ROUND(SUM(IF(COMPRESSED_SIZE = 0, @@GLOBAL.innodb_page_size, COMPRESSED_SIZE))/1024/1024)
AS 'Total Data (MB)'
FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE INDEX_NAME='emp_no' AND TABLE_NAME = `employees`.`salaries`;
+------------+-------+-----------------+
| INDEX_NAME | Pages | Total Data (MB) |
+------------+-------+-----------------+
| emp_no     |  1756 |              27 |
+------------+-------+-----------------+
```

This query returns the number of pages and total data size of pages for all indexes defined on the employees.salaries table:
Example 14.9 Querying LRU_POSITION Data in the INNODB_BUFFER_PAGE_LRU Table

The INNODB_BUFFER_PAGE_LRU table holds information about the pages in the InnoDB buffer pool, in particular how they are ordered that determines which pages to evict from the buffer pool when it becomes full. The definition for this page is the same as for INNODB_BUFFER_PAGE, except this table has an LRU_POSITION column instead of a BLOCK_ID column.

This query counts the number of positions at a specific location in the LRU list occupied by pages of the employees.employees table.

```
mysql> SELECT COUNT(LRU_POSITION) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE_LRU
    WHERE TABLE_NAME='`employees`.`employees`' AND LRU_POSITION < 3072;
```

```
+---------------------+
| COUNT(LRU_POSITION) |
+---------------------+
|                 275 |
+---------------------+
```

Example 14.10 Querying the INNODB_BUFFER_POOL_STATS Table

The INNODB_BUFFER_POOL_STATS table provides information similar to SHOW ENGINE INNODB STATUS and InnoDB buffer pool status variables.

```
mysql> SELECT * FROM information_schema.INNODB_BUFFER_POOL_STATS \G
```

```
*************************** 1. row ***************************
POOL_ID: 0
POOL_SIZE: 8192
FREE_BUFFERS: 1024
DATABASE_PAGES: 7029
OLD_DATABASE_PAGES: 2574
MODIFIED_DATABASE_PAGES: 0
PENDING_DECOMPRESS: 0
PENDING_READS: 0
PENDING_FLUSH_LRU: 0
PENDING_FLUSH_LIST: 0
PAGES_MADE_YOUNG: 173
PAGES_MADE_NOT_YOUNG: 3721891
PAGES_MADE_YOUNG_RATE: 0
PAGES_MADE_NOT_YOUNG_RATE: 0
NUMBER_PAGES_READ: 1075
NUMBER_PAGES_CREATED: 12594
NUMBER_PAGES_WRITTEN: 13525
PAGES_READ_RATE: 0
PAGES_CREATE_RATE: 0
PAGES_WRITE_RATE: 0
NUMBER_PAGES_GET: 27873240
HIT_RATE: 0
YOUNG_MAKE_PER_THOUSAND_GETS: 0
NOT_YOUNG_MAKE_PER_THOUSAND_GETS: 0
NUMBER_PAGES_READ_AHEAD: 576
NUMBER_READ_AHEAD_EVICTED: 0
READ_AHEAD_RATE: 0
READ_AHEAD_EVICTED_RATE: 0
LRU_IO_TOTAL: 0
LRU_IO_CURRENT: 0
UNCOMPRESS_TOTAL: 0
UNCOMPRESS_CURRENT: 0
```
For comparison, `SHOW ENGINE INNODB STATUS` output and InnoDB buffer pool status variable output is shown below, based on the same data set.

For more information about `SHOW ENGINE INNODB STATUS` output, see Section 14.17.3, “InnoDB Standard Monitor and Lock Monitor Output”.

```sql
mysql> SHOW ENGINE INNODB STATUS \G
...
----------------------
BUFFER POOL AND MEMORY
----------------------
Total memory allocated 137363456; in additional pool allocated 0
Dictionary memory allocated 99725
Buffer pool size 8192
Free buffers 1024
Database pages 7029
Old database pages 2574
Modified db pages 0
Pending reads 0
Pending writes: LRU 0, flush list 0, single page 0
Pages made young 173, not young 3721891
0.00 youngs/s, 0.00 non-youngs/s
Pages read 1075, created 12594, written 13525
0.00 reads/s, 0.00 creates/s, 0.00 writes/s
No buffer pool page gets since the last printout
I/O sum[0]:cur[0], unzip sum[0]:cur[0]
...
```

For status variable descriptions, see Section 5.1.9, “Server Status Variables”.

```sql
mysql> SHOW STATUS LIKE 'Innodb_buffer%';
+---------------------------------------+-------------+
| Variable_name                         | Value       |
+---------------------------------------+-------------+
| Innodb_buffer_pool_dump_status        | not started |
| Innodb_buffer_pool_load_status        | not started |
| Innodb_buffer_pool_pages_data         | 7029        |
| Innodb_buffer_pool_pages_dirty        | 0           |
| Innodb_buffer_pool_pages_free         | 1024        |
| Innodb_buffer_pool_pages_total        | 8192        |
| Innodb_buffer_pool_read_ahead_rnd     | 0           |
| Innodb_buffer_pool_read_ahead         | 576         |
| Innodb_buffer_pool_read_ahead_evicted | 0           |
| Innodb_buffer_pool_read_requests      | 27873240    |
| Innodb_buffer_pool_reads              | 500         |
| Innodb_buffer_pool_wait_free          | 0           |
| Innodb_buffer_pool_write_requests     | 11966441    |
+---------------------------------------+-------------+
```

### 14.15.6 InnoDB INFORMATION_SCHEMA Metrics Table

The `INNODB_METRICS` table provides information about InnoDB performance and resource-related counters.

`INNODB_METRICS` table columns are shown below. For column descriptions, see Section 21.30.15, “The INFORMATION_SCHEMA INNODB_METRICS Table”.

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts" \G
*************************** 1. row ***************************
NAME: dml_inserts
SUBSYSTEM: dml
COUNT: 46273
MAX_COUNT: 46273
MIN_COUNT: NULL
```
Enabling, Disabling, and Resetting Counters

You can enable, disable, and reset counters using the following variables:

- **innodb_monitor_enable**: Enables counters.
  
  ```
  SET GLOBAL innodb_monitor_enable = [counter-name,module_name,pattern,all];
  ```

- **innodb_monitor_disable**: Disables counters.
  
  ```
  SET GLOBAL innodb_monitor_disable = [counter-name,module_name,pattern,all];
  ```

- **innodb_monitor_reset**: Resets counter values to zero.
  
  ```
  SET GLOBAL innodb_monitor_reset = [counter-name,module_name,pattern,all];
  ```

- **innodb_monitor_reset_all**: Resets all counter values. A counter must be disabled before using `innodb_monitor_reset_all`.
  
  ```
  SET GLOBAL innodb_monitor_reset_all = [counter-name,module_name,pattern,all];
  ```

Counters and counter modules can also be enabled at startup using the MySQL server configuration file. For example, to enable the `log` module, `metadata_table_handles_opened` and `metadata_table_handles_closed` counters, enter the following line in the `[mysqld]` section of the MySQL server configuration file.

```
[mysqld]
innodb_monitor_enable = module_recovery,metadata_table_handles_opened,metadata_table_handles_closed
```

When enabling multiple counters or modules in a configuration file, specify the `innodb_monitor_enable` variable followed by counter and module names separated by a comma, as shown above. Only the `innodb_monitor_enable` variable can be used in a configuration file. The `innodb_monitor_disable` and `innodb_monitor_reset` variables are supported on the command line only.

**Note**

Because each counter adds a degree of runtime overhead, use counters conservatively on production servers to diagnose specific issues or monitor specific functionality. A test or development server is recommended for more extensive use of counters.

Counters

The list of available counters is subject to change. Query the `INFORMATION_SCHEMA.INNODB_METRICS` table for counters available in your MySQL server version.

The counters enabled by default correspond to those shown in `SHOW ENGINE INNODB STATUS` output. Counters shown in `SHOW ENGINE INNODB STATUS` output are always enabled at a system level but can be disable for the `INNODB_METRICS` table. Counter status is not persistent. Unless configured otherwise, counters revert to their default enabled or disabled status when the server is restarted.
If you run programs that would be affected by the addition or removal of counters, it is recommended that you review the releases notes and query the `INNODB_METRICS` table to identify those changes as part of your upgrade process.

```sql
SELECT name, subsystem, status FROM INFORMATION_SCHEMA.INNODB_METRICS ORDER BY NAME;
```

### Counter Modules

Each counter is associated with a particular module. Module names can be used to enable, disable, or reset all counters for a particular subsystem. For example, use `module_dml` to enable all counters associated with the `dml` subsystem.

```sql
mysql> SET GLOBAL innodb_monitor_enable = module_dml;
```

```sql
mysql> SELECT name, subsystem, status FROM INFORMATION_SCHEMA.INNODB_METRICS
WHERE subsystem = 'dml';
```

<table>
<thead>
<tr>
<th>name</th>
<th>subsystem</th>
<th>status</th>
</tr>
</thead>
<tbody>
<tr>
<td>dml_reads</td>
<td>dml</td>
<td>enabled</td>
</tr>
<tr>
<td>dml Inserts</td>
<td>dml</td>
<td>enabled</td>
</tr>
<tr>
<td>dml Deletes</td>
<td>dml</td>
<td>enabled</td>
</tr>
<tr>
<td>dml Updates</td>
<td>dml</td>
<td>enabled</td>
</tr>
</tbody>
</table>

Module names can be used with `innodb_monitor_enable` and related variables.

### Module Names

Module names and corresponding `SUBSYSTEM` names are listed below.

- `module_adaptive_hash` (subsystem = `adaptive_hash_index`)
- `module_buffer` (subsystem = `buffer`)
- `module_buffer_page` (subsystem = `buffer_page_io`)
- `module_compact` (subsystem = `compression`)
- `module_ddl` (subsystem = `ddl`)
- `module_dml` (subsystem = `dml`)
- `module_file` (subsystem = `file_system`)
- `module_ibuf_system` (subsystem = `change_buffer`)
- `module_icp` (subsystem = `icp`)
- `module_index` (subsystem = `index`)
- `module_innodb` (subsystem = `innodb`)
- `module_lock` (subsystem = `lock`)
- `module_log` (subsystem = `recovery`)
- `module_metadata` (subsystem = `metadata`)
- `module_os` (subsystem = `os`)
- `module_purge` (subsystem = `purge`)
- `module_trx` (subsystem = `transaction`)
Example 14.11 Working with INNODB_METRICS Table Counters

This example demonstrates enabling, disabling, and resetting a counter, and querying counter data in the INNODB_METRICS table.

1. Create a simple InnoDB table:

```sql
mysql> USE test;
Database changed

mysql> CREATE TABLE t1 (c1 INT) ENGINE=INNODB;
Query OK, 0 rows affected (0.02 sec)
```

2. Enable the dml_inserts counter.

```sql
mysql> SET GLOBAL innodb_monitor_enable = dml_inserts;
Query OK, 0 rows affected (0.01 sec)
```

A description of the dml_inserts counter can be found in the COMMENT column of the INNODB_METRICS table:

```sql
mysql> SELECT NAME, COMMENT FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts";
+-------------+-------------------------+
| NAME        | COMMENT                 |
+-------------+-------------------------+
| dml_inserts | Number of rows inserted |
+-------------+-------------------------+
```

3. Query the INNODB_METRICS table for the dml_inserts counter data. Because no DML operations have been performed, the counter values are zero or NULL. The TIME_ENABLED and TIME_ELAPSED values indicate when the counter was last enabled and how many seconds have elapsed since that time.

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts" \G
*************************** 1. row ***************************
NAME: dml_inserts
SUBSYSTEM: dml
COUNT: 0
MAX_COUNT: 0
MIN_COUNT: NULL
AVG_COUNT: 0
COUNT_RESET: 0
MAX_COUNT_RESET: 0
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: NULL
TIME_ENABLED: 2014-12-04 14:18:28
TIME_DISABLED: NULL
TIME_ELAPSED: 28
TIME_RESET: NULL
STATUS: enabled
TYPE: status_counter
COMMENT: Number of rows inserted
```

4. Insert three rows of data into the table.

```sql
mysql> INSERT INTO t1 values(1);
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t1 values(2);
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t1 values(3);
Query OK, 1 row affected (0.00 sec)
```

5. Query the INNODB_METRICS table again for the dml_inserts counter data. A number of counter values have now incremented including COUNT, MAX_COUNT, AVG_COUNT, and COUNT_RESET. Refer to the INNODB_METRICS table definition for descriptions of these values.

```sql
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts" \G
2049
```
6. Reset the `dml_inserts` counter and query the `INNODB_METRICS` table again for the `dml_inserts` counter data. The `_RESET` values that were reported previously, such as `COUNT_RESET` and `MAX_COUNT_RESET`, are set back to zero. Values such as `COUNT`, `MAX_COUNT`, and `AVG_COUNT`, which cumulatively collect data from the time the counter is enabled, are unaffected by the reset.

```
mysql> SET GLOBAL innodb_monitor_reset = dml_inserts;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts"
```

```
*************************** 1. row ***************************
NAME: dml_inserts
SUBSYSTEM: dml
COUNT: 3
MAX_COUNT: 3
MIN_COUNT: NULL
AVG_COUNT: 0.03529411764705882
COUNT_RESET: 0
MAX_COUNT_RESET: 0
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: 0
TIME_ENABLED: 2014-12-04 14:18:28
TIME_DISABLED: NULL
TIME_ELAPSED: 85
TIME_RESET: NULL
STATUS: enabled
TYPE: status_counter
COMMENT: Number of rows inserted
```

7. To reset all counter values, you must first disable the counter. Disabling the counter sets the `STATUS` value to `disabled`.

```
mysql> SET GLOBAL innodb_monitor_disable = dml_inserts;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts"
```

```
*************************** 1. row ***************************
NAME: dml_inserts
SUBSYSTEM: dml
COUNT: 3
MAX_COUNT: 3
MIN_COUNT: NULL
AVG_COUNT: 0.030612244897959183
COUNT_RESET: 0
MAX_COUNT_RESET: 0
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: 0
TIME_ENABLED: 2014-12-04 14:18:28
TIME_DISABLED: 2014-12-04 14:20:06
TIME_ELAPSED: 98
TIME_RESET: NULL
STATUS: disabled
```

InnoDB Integration with MySQL Performance Schema

8. After the counter is disabled, you can reset all counter values using the `innodb_monitor_reset_all` option. All values are set to zero or NULL.

```
SET GLOBAL innodb_monitor_reset_all = dml_inserts;
```

```
SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts"
```

*************************** 1. row ***************************
NAME: dml_inserts
SUBSYSTEM: dml
COUNT: 0
MAX_COUNT: NULL
MIN_COUNT: NULL
AVG_COUNT: NULL
COUNT_RESET: 0
MAX_COUNT_RESET: NULL
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: NULL
TIME_ENABLED: NULL
TIME_DISABLED: NULL
TIME_ELAPSED: NULL
TIME_RESET: NULL
STATUS: disabled
TYPE: status_counter
COMMENT: Number of rows inserted

14.16 InnoDB Integration with MySQL Performance Schema

This section provides a brief introduction to InnoDB integration with Performance Schema. For comprehensive Performance Schema documentation, see Chapter 22, MySQL Performance Schema.

You can profile certain internal InnoDB operations using the MySQL Performance Schema feature. This type of tuning is primarily for expert users who evaluate optimization strategies to overcome performance bottlenecks. DBAs can also use this feature for capacity planning, to see whether their typical workload encounters any performance bottlenecks with a particular combination of CPU, RAM, and disk storage; and if so, to judge whether performance can be improved by increasing the capacity of some part of the system.

To use this feature to examine InnoDB performance:

- You must be generally familiar with how to use the Performance Schema feature. For example, you should know how enable instruments and consumers, and how to query performance_schema tables to retrieve data. For an introductory overview, see Section 22.1, “Performance Schema Quick Start”.

- You should be familiar with Performance Schema instruments that are available for InnoDB. To view InnoDB-related instruments, you can query the setup_instruments table for instrument names that contain 'innodb'.

```
SELECT *
FROM performance_schema.setup_instruments
WHERE NAME LIKE '%innodb%';
```

62 rows in set (0.00 sec)

For additional information about the instrumented InnoDB objects, you can query Performance Schema instances tables, which provide additional information about instrumented objects. Instance tables relevant to InnoDB include:

- The mutex_instances table
- The rwlock_instances table
- The cond_instances table
- The file_instances table

**Note**

Mutexes and RW-locks related to the InnoDB buffer pool are not included in this coverage; the same applies to the output of the SHOW ENGINE INNODB MUTEX command.

For example, to view information about instrumented InnoDB file objects seen by the Performance Schema when executing file I/O instrumentation, you might issue the following query:

```sql
mysql> SELECT * FROM performance_schema.file_instances WHERE EVENT_NAME LIKE '%innodb%'

*************************** 1. row ***************************
FILE_NAME: /path/to/mysql-5.6/data/ibdata1
EVENT_NAME: wait/io/file/innodb/innodb_data_file
OPEN_COUNT: 2
*************************** 2. row ***************************
FILE_NAME: /path/to/mysql-5.6/data/ib_logfile0
EVENT_NAME: wait/io/file/innodb/innodb_log_file
OPEN_COUNT: 2
*************************** 3. row ***************************
FILE_NAME: /path/to/mysql-5.6/data/ib_logfile1
EVENT_NAME: wait/io/file/innodb/innodb_log_file
```
Monitoring InnoDB Mutex Waits Using Performance Schema

A mutex is a synchronization mechanism used in the code to enforce that only one thread at a given time can have access to a common resource. When two or more threads executing in the server need to access the same resource, the threads compete against each other. The first thread to obtain a lock on the mutex causes the other threads to wait until the lock is released.

For InnoDB mutexes that are instrumented, mutex waits can be monitored using Performance Schema. Wait event data collected in Performance Schema tables can help identify mutexes with the most waits or the greatest total wait time, for example.

The following example demonstrates how to enable InnoDB mutex wait instruments, how to enable associated consumers, and how to query wait event data.

1. To view available InnoDB mutex wait instruments, query the Performance Schema setup_instruments table, as shown below. All InnoDB mutex wait instruments are disabled by default.

   ```sql
   mysql> SELECT * FROM performance_schema.setup_instruments WHERE NAME LIKE '%wait/synch/mutex/innodb%';
   +-------------------------------------------------------+---------+-------+
   | NAME                                                  | ENABLED | TIMED |
   +-------------------------------------------------------+---------+-------+
   | wait/synch/mutex/innodb/commit_cond_mutex             | NO      | NO    |
   | wait/synch/mutex/innodb/innobase_share_mutex          | NO      | NO    |
   | wait/synch/mutex/innodb/autoinc_mutex                 | NO      | NO    |
   | wait/synch/mutex/innodb/buf_pool_mutex                | NO      | NO    |
   | wait/synch/mutex/innodb/buf_pool_zip_mutex            | NO      | NO    |
   | wait/synch/mutex/innodb/cache_last_read_mutex         | NO      | NO    |
   | wait/synch/mutex/innodb/dict_foreign_err_mutex        | NO      | NO    |
   | wait/synch/mutex/innodb/dict_sys_mutex                | NO      | NO    |
   | wait/synch/mutex/innodb/file_format_max_mutex         | NO      | NO    |
   | wait/synch/mutex/innodb/fil_system_mutex              | NO      | NO    |
   | wait/synch/mutex/innodb/flush_list_mutex              | NO      | NO    |
   | wait/synch/mutex/innodb/hash_table_mutex              | NO      | NO    |
   | wait/synch/mutex/innodb/ibuf_bitmap_mutex             | NO      | NO    |
   | wait/synch/mutex/innodb/ibuf_mutex                    | NO      | NO    |
   | wait/synch/mutex/innodb/ibuf_pessimistic_insert_mutex| NO      | NO    |
   | wait/synch/mutex/innodb/log_sys_mutex                 | NO      | NO    |
   | wait/synch/mutex/innodb/mem_pool_mutex                | NO      | NO    |
   | wait/synch/mutex/innodb/mutex_list_mutex              | NO      | NO    |
   | wait/synch/mutex/innodb/page_zip_stat_per_index_mutex| NO      | NO    |
   | wait/synch/mutex/innodb/recv_sys_mutex                | NO      | NO    |

</tbody>
</table>

#### 2. Some InnoDB mutex instances are created at server startup and are only instrumented if the associated instrument is also enabled at server startup. To ensure that all InnoDB mutex instances are instrumented and enabled, add the following performance-schema-instrument rule to your MySQL configuration file:

```sql
performance-schema-instrument='wait/synch/mutex/innodb/%=ON'
```

If you do not require wait event data for all InnoDB mutexes, you can disable specific instruments by adding additional performance-schema-instrument rules to your MySQL configuration file. For example, to disable InnoDB mutex wait event instruments related to full-text search, add the following rule:

```sql
performance-schema-instrument='wait/synch/mutex/innodb/fts%=OFF'
```

**Note**

Rules with a longer prefix such as `wait/synch/mutex/innodb/fts%` take precedence over rules with shorter prefixes such as `wait/synch/mutex/innodb/%`.

After adding the `performance-schema-instrument` rules to your configuration file, restart the server. All the InnoDB mutexes except for those related to full text search are enabled. To verify, query the `setup_instruments` table. The `ENABLED` and `TIMED` columns should be set to `YES` for the instruments that you enabled.

```sql
mysql> SELECT * 
   FROM performance_schema.setup_instruments 
  WHERE NAME LIKE '%wait/synch/mutex/innodb%';
```

```
+-------------------------------------------------------+---------+-------+
| NAME                                                  | ENABLED | TIMED |
+-------------------------------------------------------+---------+-------+
| wait/synch/mutex/innodb/commit_cond_mutex             | YES     | YES   |
| wait/synch/mutex/innodb/innobase_share_mutex          | YES     | YES   |

+-------------------------------------------------------+---------+-------+
46 rows in set (0.00 sec)
```

#### 3. Enable wait event consumers by updating the `setup_consumers` table. Wait event consumers are disabled by default.

```sql
mysql> UPDATE performance_schema.setup_consumers 
   SET enabled = 'YES' 
  WHERE name like 'events_waits%';
```

Query OK, 3 rows affected (0.00 sec)
Rows matched: 3  Changed: 3  Warnings: 0
You can verify that wait event consumers are enabled by querying the `setup_consumers` table. The `events_waits_current`, `events_waits_history`, and `events_waits_history_long` consumers should be enabled.

```sql
mysql> SELECT * FROM performance_schema.setup_consumers;
```

```
+--------------------------------+---------+
| NAME                           | ENABLED |
+--------------------------------+---------+
| events_stages_current          | NO      |
| events_stages_history          | NO      |
| events_stages_history_long     | NO      |
| events_statements_current      | YES     |
| events_statements_history      | NO      |
| events_statements_history_long | NO      |
| events_waits_current           | YES     |
| events_waits_history           | YES     |
| events_waits_history_long      | YES     |
| global_instrumentation         | YES     |
| thread_instrumentation         | YES     |
| statements_digest              | YES     |
+--------------------------------+---------+
```

4. Once instruments and consumers are enabled, run the workload that you want to monitor. In this example, the `mysqlslap` load emulation client is used to simulate a workload.

```shell
shell> ./mysqlslap --auto-generate-sql --concurrency=100 --iterations=10 --number-of-queries=1000 --number-char-cols=6 --number-int-cols=6;
```

5. Query the wait event data. In this example, wait event data is queried from the `events_waits_summary_global_by_event_name` table which aggregates data found in the `events_waits_current`, `events_waits_history`, and `events_waits_history_long` tables. Data is summarized by event name (`EVENT_NAME`), which is the name of the instrument that produced the event. Summarized data includes:

- **COUNT_STAR**
  
  The number of summarized wait events.

- **SUM_TIMER_WAIT**
  
  The total wait time of the summarized timed wait events.

- **MIN_TIMER_WAIT**
  
  The minimum wait time of the summarized timed wait events.

- **AVG_TIMER_WAIT**
  
  The average wait time of the summarized timed wait events.

- **MAX_TIMER_WAIT**
  
  The maximum wait time of the summarized timed wait events.

The following query returns the instrument name (`EVENT_NAME`), the number of wait events (`COUNT_STAR`), and the total wait time for the events for that instrument (`SUM_TIMER_WAIT`). Because waits are timed in picoseconds (trillions of a second) by default, wait times are divided by 1000000000 to show wait times in milliseconds. Data is presented in descending order, by the number of summarized wait events (`COUNT_STAR`). You can adjust the `ORDER BY` clause to order the data by total wait time.

```sql
mysql> SELECT EVENT_NAME, COUNT_STAR, SUM_TIMER_WAIT/1000000000 SUM_TIMER_WAIT_MS
FROM performance_schema.events_waits_summary_global_by_event_name
WHERE SUM_TIMER_WAIT > 0 AND EVENT_NAME LIKE 'wait/synch/mutex/innodb/';
```
InnoDB Monitors

</table>

28 rows in set (0.03 sec)

Note

The preceding result set includes wait event data produced during the startup process. To exclude this data, you can truncate the `events_waits_summary_global_by_event_name` table immediately after startup and before running your workload. However, the truncate operation itself may produce a negligible amount wait event data.

```sql
TRUNCATE performance_schema.events_waits_summary_global_by_event_name;
```

14.17 InnoDB Monitors

InnoDB monitors provide information about the InnoDB internal state. This information is useful for performance tuning.

14.17.1 InnoDB Monitor Types

There are four types of InnoDB monitors:

- The standard InnoDB Monitor displays the following types of information:
  - Work done by the main background thread
  - Semaphore waits
  - Data about the most recent foreign key and deadlock errors
  - Lock waits for transactions
  - Table and record locks held by active transactions
  - Pending I/O operations and related statistics

2056
Enabling InnoDB Monitors

- Insert buffer and adaptive hash index statistics
- Redo log data
- Buffer pool statistics
- Row operation data

- The InnoDB Lock Monitor prints additional lock information as part of the standard InnoDB Monitor output.
- The InnoDB Tablespace Monitor prints a list of file segments in the shared tablespace and validates the tablespace allocation data structures.
- The InnoDB Table Monitor prints the contents of the InnoDB internal data dictionary.

**Note**
The Tablespace Monitor and Table Monitor are deprecated and will be removed in a future MySQL release. Similar information for the Table Monitor can be obtained from InnoDB INFORMATION_SCHEMA tables. See Section 21.30, "INFORMATION_SCHEMA InnoDB Tables".

For additional information about InnoDB table and tablespace monitors, see Mark Leith: InnoDB Table and Tablespace Monitors.

### 14.17.2 Enabling InnoDB Monitors

When InnoDB monitors are enabled for periodic output, InnoDB writes the output to mysql server standard error output (stderr) every 15 seconds, approximately.

InnoDB sends the monitor output to stderr rather than to stdout or fixed-size memory buffers to avoid potential buffer overflows.

On Windows, stderr is directed to the default log file unless configured otherwise. If you want to direct the output to the console window rather than to the error log, start the server from a command prompt in a console window with the --console option. For more information, see Section 5.4.2.1, "Error Logging on Windows".

On Unix and Unix-like systems, stderr is typically directed to the terminal unless configured otherwise. For more information, see Section 5.4.2.2, "Error Logging on Unix and Unix-Like Systems".

InnoDB monitors should only be enabled when you actually want to see monitor information because output generation causes some performance decrement. Also, if monitor output is directed to the error log, the log may become quite large if you forget to disable the monitor later by dropping the monitor table.

**Note**
To assist with troubleshooting, InnoDB temporarily enables standard InnoDB Monitor output under certain conditions. For more information, see Section 14.21, "InnoDB Troubleshooting".

Each monitor begins with a header containing a timestamp and the monitor name. For example:

```
2014-10-16 16:28:15 7fefe43c5700 INNODB MONITOR OUTPUT
```

The header for the standard InnoDB Monitor (INNODB MONITOR OUTPUT) is also used for the Lock Monitor because the latter produces the same output with the addition of extra lock information.
Enabling InnoDB Monitors

Enabling the **InnoDB** Standard Monitor and Lock Monitor for periodic output may be performed in one of two ways:

- Using a `CREATE TABLE` statement to create a specially named **InnoDB** table that is associated with the monitor. For example, to enable the standard **InnoDB** Monitor, you would create an **InnoDB** table named `innodb_monitor`. The Tablespace Monitor and Table Monitor are also enabled using the `CREATE TABLE` method.

  Using `CREATE TABLE` syntax is just a way to pass a command to the **InnoDB** engine through MySQL’s SQL parser. The only things that matter are the table name and that it be an **InnoDB** table. The structure of the table and the database where the table is created are not relevant. If you shut down the server, the monitor does not restart automatically when you restart the server. Drop the monitor table and issue a new `CREATE TABLE` statement to start the monitor.

  **Note**

  The `CREATE TABLE` method of enabling **InnoDB** monitors is deprecated and may be removed in a future release. As of MySQL 5.6.16, you can enable the standard **InnoDB** Monitor and **InnoDB** Lock Monitor using the `innodb_status_output` and `innodb_status_output_locks` system variables.

- Using the `innodb_status_output` and `innodb_status_output_locks` system variables, introduced in MySQL 5.6.16.

  The `PROCESS` privilege is required to enable or disable **InnoDB** Monitors.

**Enabling the Standard InnoDB Monitor**

To enable the standard **InnoDB** Monitor for periodic output, create the `innodb_monitor` table:

```sql
CREATE TABLE innodb_monitor (a INT) ENGINE=INNODB;
```

To disable the standard **InnoDB** Monitor, drop the table:

```sql
DROP TABLE innodb_monitor;
```

As of MySQL 5.6.16, you can also enable the standard **InnoDB** Monitor by setting the `innodb_status_output` system variable to `ON`.

```sql
SET GLOBAL innodb_status_output=ON;
```

To disable the standard **InnoDB** Monitor, set `innodb_status_output` to `OFF`.

When you shut down the server, the `innodb_status_output` variable is set to the default `OFF` value.

**Enabling the InnoDB Lock Monitor**

To enable the **InnoDB** Lock Monitor for periodic output, create the `innodb_lock_monitor` table:

```sql
CREATE TABLE innodb_lock_monitor (a INT) ENGINE=INNODB;
```

To disable the **InnoDB** Lock Monitor, drop the table:

```sql
DROP TABLE innodb_lock_monitor;
```

As of MySQL 5.6.16, you can also enable the **InnoDB** Lock Monitor by setting the `innodb_status_output_locks` system variable to `ON`. As with the `CREATE TABLE` method for enabling **InnoDB** Monitors, both the **InnoDB** standard Monitor and **InnoDB** Lock Monitor must be enabled to have **InnoDB** Lock Monitor data printed periodically:

```sql
SET GLOBAL innodb_status_output=ON;
SET GLOBAL innodb_status_output_locks=ON;
```
Enabling InnoDB Monitors

When you shut down the server, the `innodb_status_output` and `innodb_status_output_locks` variables are set to the default OFF value.

To disable the InnoDB Lock Monitor, set `innodb_status_output_locks` to OFF. Set `innodb_status_output` to OFF to also disable the standard InnoDB Monitor.

**Note**

To enable the InnoDB Lock Monitor for `SHOW ENGINE INNODB STATUS` output, you are only required to enable `innodb_status_output_locks`.

**Obtaining Standard InnoDB Monitor Output On Demand**

As an alternative to enabling the standard InnoDB Monitor for periodic output, you can obtain standard InnoDB Monitor output on demand using the `SHOW ENGINE INNODB STATUS` SQL statement, which fetches the output to your client program. If you are using the `mysql` interactive client, the output is more readable if you replace the usual semicolon statement terminator with `\G`:

```sql
mysql> SHOW ENGINE INNODB STATUS\G
```

SHOW ENGINE INNODB STATUS output also includes InnoDB Lock Monitor data if the InnoDB Lock Monitor is enabled.

**Directing Standard InnoDB Monitor Output to a Status File**

Standard InnoDB Monitor output can be enabled and directed to a status file by specifying the `--innodb-status-file` option at startup. When this option is used, InnoDB creates a file named `innodb_status.pid` in the data directory and writes output to it every 15 seconds, approximately.

InnoDB removes the status file when the server is shut down normally. If an abnormal shutdown occurs, the status file may have to be removed manually.

The `--innodb-status-file` option is intended for temporary use, as output generation can affect performance, and the `innodb_status.pid` file can become quite large over time.

**Enabling the InnoDB Tablespace Monitor**

To enable the InnoDB Tablespace Monitor for periodic output, create the `innodb_tablespace_monitor` table:

```sql
CREATE TABLE innodb_tablespace_monitor (a INT) ENGINE=INNODB;
```

To disable the standard InnoDB Tablespace Monitor, drop the table:

```sql
DROP TABLE innodb_tablespace_monitor;
```

**Note**

The Tablespace Monitor is deprecated and will be removed in a future MySQL release.

**Enabling the InnoDB Table Monitor**

To enable the InnoDB Table Monitor for periodic output, create the `innodb_table_monitor` table:

```sql
CREATE TABLE innodb_table_monitor (a INT) ENGINE=INNODB;
```

To disable the InnoDB Table Monitor, drop the table:

```sql
DROP TABLE innodb_table_monitor;
```

**Note**

The Tablespace Monitor is deprecated and will be removed in a future MySQL release.
14.17.3 InnoDB Standard Monitor and Lock Monitor Output

The Lock Monitor is the same as the Standard Monitor except that it includes additional lock information. Enabling either monitor for periodic output turns on the same output stream, but the stream includes extra information if the Lock Monitor is enabled. For example, if you enable the Standard Monitor and Lock Monitor, that turns on a single output stream. The stream includes extra lock information until you disable the Lock Monitor.

Standard Monitor output is limited to 1MB when produced using the `SHOW ENGINE INNODB STATUS` statement. This limit does not apply to output written to server standard error output (`stderr`).

Example Standard Monitor output:

```
mysql> SHOW ENGINE INNODB STATUS\G
*************************** 1. row ***************************
Type: InnoDB
Name: InnoDB Monitor Output
Status: 2014-10-17 10:33:50 7f47bcd64700 INNODB MONITOR OUTPUT

END OF INNODB MONITOR OUTPUT  
============================================================

Standard Monitor Output Sections

For a description of each metric reported by the Standard Monitor, refer to the Metrics chapter in the Oracle Enterprise Manager for MySQL Database User’s Guide.

• **Status**

  This section shows the timestamp, the monitor name, and the number of seconds that per-second averages are based on. The number of seconds is the elapsed time between the current time and the last time InnoDB Monitor output was printed.

• **BACKGROUND THREAD**

  The srv_master_thread lines shows work done by the main background thread.

• **SEMAPHORES**

  This section reports threads waiting for a semaphore and statistics on how many times threads have needed a spin or a wait on a mutex or a rw-lock semaphore. A large number of threads waiting for semaphores may be a result of disk I/O, or contention problems inside InnoDB. Contention can be due to heavy parallelism of queries or problems in operating system thread scheduling. Setting the innodb_thread_concurrency system variable smaller than the default value might help in such situations. The Spin rounds per wait line shows the number of spinlock rounds per OS wait for a mutex.

• **LATEST FOREIGN KEY ERROR**
This section provides information about the most recent foreign key constraint error. It is not present if no such error has occurred. The contents include the statement that failed as well as information about the constraint that failed and the referenced and referencing tables.

• **LATEST DETECTED DEADLOCK**

This section provides information about the most recent deadlock. It is not present if no deadlock has occurred. The contents show which transactions are involved, the statement each was attempting to execute, the locks they have and need, and which transaction InnoDB decided to roll back to break the deadlock. The lock modes reported in this section are explained in Section 14.7.1, “InnoDB Locking”.

• **TRANSACTIONS**

If this section reports lock waits, your applications might have lock contention. The output can also help to trace the reasons for transaction deadlocks.

• **FILE I/O**

This section provides information about threads that InnoDB uses to perform various types of I/O. The first few of these are dedicated to general InnoDB processing. The contents also display information for pending I/O operations and statistics for I/O performance.

The number of these threads are controlled by the `innodb_read_io_threads` and `innodb_write_io_threads` parameters. See Section 14.14, “InnoDB Startup Options and System Variables”.

• **INSERT BUFFER AND ADAPTIVE HASH INDEX**

This section shows the status of the InnoDB insert buffer (also referred to as the change buffer) and the adaptive hash index.

For related information, see Section 14.5.2, “Change Buffer”, and Section 14.5.3, “Adaptive Hash Index”.

• **LOG**

This section displays information about the InnoDB log. The contents include the current log sequence number, how far the log has been flushed to disk, and the position at which InnoDB last took a checkpoint. (See Section 14.12.3, “InnoDB Checkpoints”.) The section also displays information about pending writes and write performance statistics.

• **BUFFER POOL AND MEMORY**

This section gives you statistics on pages read and written. You can calculate from these numbers how many data file I/O operations your queries currently are doing.

For buffer pool statistics descriptions, see Monitoring the Buffer Pool Using the InnoDB Standard Monitor. For additional information about the operation of the buffer pool, see Section 14.5.1, “Buffer Pool”.

• **ROW OPERATIONS**

This section shows what the main thread is doing, including the number and performance rate for each type of row operation.
The **InnoDB Tablespace Monitor** prints information about the file segments in the shared tablespace and validates the tablespace allocation data structures. The Tablespace Monitor does not describe file-per-table tablespaces created with the `innodb_file_per_table` option.

**Example InnoDB Tablespace Monitor output:**

```plaintext
090408 21:28:09 INNODB TABLESPACE MONITOR OUTPUT

FILE SPACE INFO: id 0
size 13440, free limit 3136, free extents 28
not full frag extents 2: used pages 78, full frag extents 3

END OF INNODB TABLESPACE MONITOR OUTPUT
```

The Tablespace Monitor output includes information about the shared tablespace as a whole, followed by a list containing a breakdown for each segment within the tablespace.

In this example using the default `page size`, the tablespace consists of database pages that are 16KB each. The pages are grouped into `extents` of size 1MB (64 consecutive pages).

The initial part of the output that displays overall tablespace information has this format:

```plaintext
FILE SPACE INFO: id 0
size 13440, free limit 3136, free extents 28
not full frag extents 2: used pages 78, full frag extents 3
first seg id not used 0 23845
```

Overall tablespace information includes these values:

- **id**
  
  The tablespace ID. A value of 0 refers to the shared tablespace.

- **size**
InnoDB Tablespace Monitor Output

The current tablespace size in pages.

• **free limit**
  The minimum page number for which the free list has not been initialized. Pages at or above this limit are free.

• **free extents**
  The number of free extents.

• **not full frag extents, used pages**
  The number of fragment extents that are not completely filled, and the number of pages in those extents that have been allocated.

• **full frag extents**
  The number of completely full fragment extents.

• **first seg id not used**
  The first unused segment ID.

Individual segment information has this format:

```
SEGMENT id 0 15 space 0; page 2; res 160 used 160; full ext 2
  fragm pages 32; free extents 0; not full extents 0; pages 0
```

Segment information includes these values:

• **id**
  The segment ID.

• **space, page**
  The tablespace number and page within the tablespace where the segment “inode” is located. A tablespace number of 0 indicates the shared tablespace. InnoDB uses inodes to keep track of segments in the tablespace. The other fields displayed for a segment (id, res, and so forth) are derived from information in the inode.

• **res**
  The number of pages allocated (reserved) for the segment.

• **used**
  The number of allocated pages in use by the segment.

• **full ext**
  The number of extents allocated for the segment that are completely used.

• **fragm pages**
  The number of initial pages that have been allocated to the segment.

• **free extents**
  The number of extents allocated for the segment that are completely unused.

• **not full extents**
  The number of extents allocated for the segment that are partially used.
• pages

The number of pages used within the not-full extents.

When a segment grows, it starts as a single page, and InnoDB allocates the first pages for it one at a time, up to 32 pages (this is the fragm pages value). After that, InnoDB allocates complete extents. InnoDB can add up to 4 extents at a time to a large segment to ensure good sequentiality of data.

For the example segment shown earlier, it has 32 fragment pages, plus 2 full extents (64 pages each), for a total of 160 pages used out of 160 pages allocated. The following segment has 32 fragment pages and one partially full extent using 14 pages for a total of 46 pages used out of 96 pages allocated:

```
SEGMENT id 0 1 space 0; page 2; res 96 used 46; full ext 0
fragm pages 32; free extents 0; not full extents 1: pages 14
```

It is possible for a segment that has extents allocated to it to have a fragm pages value less than 32 if some of the individual pages have been deallocated subsequent to extent allocation.

14.17.5 InnoDB Table Monitor Output

**Note**

The InnoDB Table Monitor is deprecated and may be removed in a future release. Similar information can be obtained from InnoDB INFORMATION_SCHEMA tables. See Section 21.30, “INFORMATION_SCHEMA InnoDB Tables”.

The InnoDB Table Monitor prints the contents of the InnoDB internal data dictionary.

The output contains one section per table. The SYS_FOREIGN and SYS_FOREIGN_COLS sections are for internal data dictionary tables that maintain information about foreign keys. There are also sections for the Table Monitor table and each user-created InnoDB table. Suppose that the following two tables have been created in the test database:

```sql
CREATE TABLE parent
(
    par_id    INT NOT NULL,
    fname      CHAR(20),
    lname      CHAR(20),
    PRIMARY KEY (par_id),
    UNIQUE INDEX (lname, fname)
) ENGINE = INNODB;

CREATE TABLE child
(
    par_id      INT NOT NULL,
    child_id    INT NOT NULL,
    name        VARCHAR(40),
    birth       DATE,
    weight      DECIMAL(10,2),
    misc_info   VARCHAR(255),
    last_update TIMESTAMP,
    PRIMARY KEY (par_id, child_id),
    INDEX (name),
    FOREIGN KEY (par_id) REFERENCES parent (par_id)
    ON DELETE CASCADE
    ON UPDATE CASCADE
) ENGINE = INNODB;
```

Then the Table Monitor output will look something like this (reformatted slightly):

```
090420 12:09:32 INNODB TABLE MONITOR OUTPUT

TABLE: name SYS_FOREIGN, id 0 11, columns 7, indexes 3, appr.rows 1
   COLUMNS: ID: DATAVARCHAR DATA_ENGLISH len 0;
```
| FOR_NAME          | DATA_VARCHAR DATA_ENGLISH len 0; |
| REF_NAME          | DATA_VARCHAR DATA_ENGLISH len 0; |
| N_COLS            | DATA_INT len 4;                  |

END OF INNODB TABLE MONITOR OUTPUT

2068
For each table, Table Monitor output contains a section that displays general information about the table and specific information about its columns, indexes, and foreign keys.

The general information for each table includes the table name (in `db_name/tbl_name` format except for internal tables), its ID, the number of columns and indexes, and an approximate row count.

The `COLUMNS` part of a table section lists each column in the table. Information for each column indicates its name and data type characteristics. Some internal columns are added by InnoDB, such as `DB_ROW_ID` (row ID), `DB_TRX_ID` (transaction ID), and `DB_ROLL_PTR` (a pointer to the rollback/undo data).

- **DATA.xxx**
  These symbols indicate the data type. There may be multiple `DATA.xxx` symbols for a given column.

- **prtype**
  The column's "precise" type. This field includes information such as the column data type, character set code, nullability, signedness, and whether it is a binary string. This field is described in the `innobase/include/data0type.h` source file.

- **len**
  The column length in bytes.

Each `INDEX` part of the table section provides the name and characteristics of one table index:

- **name**
  The index name. If the name is `PRIMARY`, the index is a primary key. If the name is `GEN_CLUST_INDEX`, the index is the clustered index that is created automatically if the table definition doesn't include a primary key or non-`NULL` unique index. See Section 14.6.2.1, "Clustered and Secondary Indexes".

- **id**
  The index ID.

- **fields**
  The number of fields in the index, as a value in `m/n` format:
  - `m` is the number of user-defined columns; that is, the number of columns you would see in the index definition in a `CREATE TABLE` statement.
  - `n` is the total number of index columns, including those added internally. For the clustered index, the total includes the other columns in the table definition, plus any columns added internally. For a secondary index, the total includes the columns from the primary key that are not part of the secondary index.

- **uniq**
  The number of leading fields that are enough to determine index values uniquely.

- **type**
  The index type. This is a bit field. For example, 1 indicates a clustered index and 2 indicates a unique index, so a clustered index (which always contains unique values), will have a `type` value of 3. An index with a `type` value of 0 is neither clustered nor unique. The flag values are defined in the `innobase/include/dict0mem.h` source file.

- **root page**
The index root page number.

- **appr. key vals**
  The approximate index cardinality.

- **leaf pages**
  The approximate number of leaf pages in the index.

- **size pages**
  The approximate total number of pages in the index.

- **FIELDS**
  The names of the fields in the index. For a clustered index that was generated automatically, the field list begins with the internal DB_ROW_ID (row ID) field. DB_TRX_ID and DB_ROLL_PTR are always added internally to the clustered index, following the fields that comprise the primary key. For a secondary index, the final fields are those from the primary key that are not part of the secondary index.

The end of the table section lists the FOREIGN KEY definitions that apply to the table. This information appears whether the table is a referencing or referenced table.

### 14.18 InnoDB Backup and Recovery

This section covers topics related to InnoDB backup and recovery.

- For information about backup techniques applicable to InnoDB, see Section 14.18.1, “InnoDB Backup”.

- For information about point-in-time recovery, recovery from disk failure or corruption, and how InnoDB performs crash recovery, see Section 14.18.2, “InnoDB Recovery”.

#### 14.18.1 InnoDB Backup

The key to safe database management is making regular backups. Depending on your data volume, number of MySQL servers, and database workload, you can use these backup techniques, alone or in combination: hot backup with MySQL Enterprise Backup; cold backup by copying files while the MySQL server is shut down; logical backup with mysqldump for smaller data volumes or to record the structure of schema objects. Hot and cold backups are physical backups that copy actual data files, which can be used directly by the mysqld server for faster restore.

Using MySQL Enterprise Backup is the recommended method for backing up InnoDB data.

**Note**

InnoDB does not support databases that are restored using third-party backup tools.

### Hot Backups

The mysqlbackup command, part of the MySQL Enterprise Backup component, lets you back up a running MySQL instance, including InnoDB tables, with minimal disruption to operations while producing a consistent snapshot of the database. When mysqlbackup is copying InnoDB tables, reads and writes to InnoDB tables can continue. MySQL Enterprise Backup can also create compressed backup files, and back up subsets of tables and databases. In conjunction with the MySQL binary log, users can perform point-in-time recovery. MySQL Enterprise Backup is part of the MySQL Enterprise subscription. For more details, see Section 24.2, “MySQL Enterprise Backup Overview”.
Cold Backups

If you can shut down the MySQL server, you can make a physical backup that consists of all files used by InnoDB to manage its tables. Use the following procedure:

1. Perform a slow shutdown of the MySQL server and make sure that it stops without errors.
2. Copy all InnoDB data files (ibdata files and .ibd files) into a safe place.
3. Copy all the .frm files for InnoDB tables to a safe place.
4. Copy all InnoDB log files (ib_logfile files) to a safe place.
5. Copy your my.cnf configuration file or files to a safe place.

Logical Backups Using mysqldump

In addition to physical backups, it is recommended that you regularly create logical backups by dumping your tables using mysqldump. A binary file might be corrupted without you noticing it. Dumped tables are stored into text files that are human-readable, so spotting table corruption becomes easier. Also, because the format is simpler, the chance for serious data corruption is smaller. mysqldump also has a --single-transaction option for making a consistent snapshot without locking out other clients. See Section 7.3.1, “Establishing a Backup Policy”.

Replication works with InnoDB tables, so you can use MySQL replication capabilities to keep a copy of your database at database sites requiring high availability. See Section 14.19, “InnoDB and MySQL Replication”.

14.18.2 InnoDB Recovery

This section describes InnoDB recovery. Topics include:

- Point-in-Time Recovery
- Recovery from Data Corruption or Disk Failure
- InnoDB Crash Recovery

Point-in-Time Recovery

To recover an InnoDB database to the present from the time at which the physical backup was made, you must run MySQL server with binary logging enabled, even before taking the backup. To achieve point-in-time recovery after restoring a backup, you can apply changes from the binary log that occurred after the backup was made. See Section 7.5, “Point-in-Time (Incremental) Recovery Using the Binary Log”.

Recovery from Data Corruption or Disk Failure

If your database becomes corrupted or disk failure occurs, you must perform the recovery using a backup. In the case of corruption, first find a backup that is not corrupted. After restoring the base backup, do a point-in-time recovery from the binary log files using mysqlbinlog and mysql to restore the changes that occurred after the backup was made.

In some cases of database corruption, it is enough to dump, drop, and re-create one or a few corrupt tables. You can use the CHECK TABLE statement to check whether a table is corrupt, although CHECK TABLE naturally cannot detect every possible kind of corruption. You can use the Tablespace Monitor to check the integrity of the file space management inside the tablespace files.

In some cases, apparent database page corruption is actually due to the operating system corrupting its own file cache, and the data on disk may be okay. It is best to try restarting the computer first. Doing so may eliminate errors that appeared to be database page corruption. If MySQL still has trouble
InnoDB Recovery

starting because of InnoDB consistency problems, see Section 14.21.2, “Forcing InnoDB Recovery” for steps to start the instance in recovery mode, which permits you to dump the data.

InnoDB Crash Recovery

To recover from an unexpected MySQL server exit, the only requirement is to restart the MySQL server. InnoDB automatically checks the logs and performs a roll-forward of the database to the present. InnoDB automatically rolls back uncommitted transactions that were present at the time of the crash. During recovery, mysqld displays output similar to this:

```
InnoDB: Log scan progressed past the checkpoint lsn 430875675
InnoDB: Database was not shutdown normally!
InnoDB: Starting crash recovery.
InnoDB: Reading tablespace information from the .ibd files...
InnoDB: Restoring possible half-written data pages
InnoDB: from the doublewrite buffer...
InnoDB: Doiing recovery: scanned up to log sequence number 436118528
InnoDB: Doing recovery: scanned up to log sequence number 441361408
InnoDB: Doing recovery: scanned up to log sequence number 446604288
InnoDB: Doing recovery: scanned up to log sequence number 451847168
InnoDB: Doing recovery: scanned up to log sequence number 457090048
InnoDB: Doing recovery: scanned up to log sequence number 462332928
InnoDB: Doing recovery: scanned up to log sequence number 467575808
InnoDB: Doing recovery: scanned up to log sequence number 472818688
InnoDB: Doing recovery: scanned up to log sequence number 478061568
InnoDB: Starting an apply batch of log records to the database...
InnoDB: Progress in percent: 0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15
16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31 32 33 34 35 36 37

./mysqld: ready for connections.
```

The InnoDB crash recovery process consists of several steps:

- Redo log application

Redo log application is the first step and is performed during initialization, before accepting any connections. If all changes are flushed from the buffer pool to the tablespaces (ibdata* and *.ibd files) at the time of the shutdown or crash, redo log application is skipped. InnoDB also skips redo log application if redo log files are missing at startup.

Removing redo logs to speed up recovery is not recommended, even if some data loss is acceptable. Removing redo logs should only be considered after a clean shutdown, with innodb_fast_shutdown set to 0 or 1.
• Roll back of incomplete transactions

Incomplete transactions are any transactions that were active at the time of unexpected exit or fast shutdown. The time it takes to roll back an incomplete transaction can be three or four times the amount of time a transaction is active before it is interrupted, depending on server load.

You cannot cancel transactions that are being rolled back. In extreme cases, when rolling back transactions is expected to take an exceptionally long time, it may be faster to start InnoDB with an innodb_force_recovery setting of 3 or greater. See Section 14.21.2, “Forcing InnoDB Recovery”.

• Change buffer merge

Applying changes from the change buffer (part of the system tablespace) to leaf pages of secondary indexes, as the index pages are read to the buffer pool.

• Purge

Deleting delete-marked records that are no longer visible to active transactions.

The steps that follow redo log application do not depend on the redo log (other than for logging the writes) and are performed in parallel with normal processing. Of these, only rollback of incomplete transactions is special to crash recovery. The insert buffer merge and the purge are performed during normal processing.

After redo log application, InnoDB attempts to accept connections as early as possible, to reduce downtime. As part of crash recovery, InnoDB rolls back transactions that were not committed or in XA PREPARE state when the server exited. The rollback is performed by a background thread, executed in parallel with transactions from new connections. Until the rollback operation is completed, new connections may encounter locking conflicts with recovered transactions.

In most situations, even if the MySQL server was killed unexpectedly in the middle of heavy activity, the recovery process happens automatically and no action is required of the DBA. If a hardware failure or severe system error corrupted InnoDB data, MySQL might refuse to start. In this case, see Section 14.21.2, “Forcing InnoDB Recovery”.

For information about the binary log and InnoDB crash recovery, see Section 5.4.4, “The Binary Log”.

14.19 InnoDB and MySQL Replication

It is possible to use replication in a way where the storage engine on the replica is not the same as the storage engine on the source. For example, you can replicate modifications to an InnoDB table on the source to a MyISAM table on the replica. For more information see, Section 17.3.3, “Using Replication with Different Source and Replica Storage Engines”.

For information about setting up a replica, see Section 17.1.1.8, “Setting Up Replication with Existing Data”. To make a new replica without taking down the source or an existing replica, use the MySQL Enterprise Backup product.

Transactions that fail on the source do not affect replication. MySQL replication is based on the binary log where MySQL writes SQL statements that modify data. A transaction that fails (for example, because of a foreign key violation, or because it is rolled back) is not written to the binary log, so it is not sent to replicas. See Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Statements”.

Replication and CASCADE. Cassading actions for InnoDB tables on the source are replicated on the replica only if the tables sharing the foreign key relation use InnoDB on both the source and replica. This is true whether you are using statement-based or row-based replication. Suppose that you have started replication, and then create two tables on the source using the following CREATE TABLE statements:
CREATE TABLE fc1 (
    i INT PRIMARY KEY,
    j INT
) ENGINE = InnoDB;

CREATE TABLE fc2 (
    m INT PRIMARY KEY,
    n INT,
    FOREIGN KEY ni (n) REFERENCES fc1 (i)
    ON DELETE CASCADE
) ENGINE = InnoDB;

If the replica does not have InnoDB support enabled, the tables on the replica are created, but they use the MyISAM storage engine, and the FOREIGN KEY option is ignored. Now we insert some rows into the tables on the source:

source> INSERT INTO fc1 VALUES (1, 1), (2, 2);
Query OK, 2 rows affected (0.09 sec)
Records: 2  Duplicates: 0  Warnings: 0

source> INSERT INTO fc2 VALUES (1, 1), (2, 2), (3, 1);
Query OK, 3 rows affected (0.19 sec)
Records: 3  Duplicates: 0  Warnings: 0

At this point, on both the source and the replica, table fc1 contains 2 rows, and table fc2 contains 3 rows, as shown here:

source> SELECT * FROM fc1;
+---+------+
| i | j    |
+---+------+
| 1 | 1    |
| 2 | 2    |
+---+------+
2 rows in set (0.00 sec)

source> SELECT * FROM fc2;
+---+---+
| m | n |
+---+---+
| 1 | 1 |
| 2 | 2 |
| 3 | 1 |
+---+---+
3 rows in set (0.00 sec)

replica> SELECT * FROM fc1;
+---+------+
| i | j    |
+---+------+
| 1 | 1    |
| 2 | 2    |
+---+------+
2 rows in set (0.00 sec)

replica> SELECT * FROM fc2;
+---+---+
| m | n |
+---+---+
| 1 | 1 |
| 2 | 2 |
| 3 | 1 |
+---+---+
3 rows in set (0.00 sec)

Now suppose that you perform the following DELETE statement on the source:

source> DELETE FROM fc1 WHERE i=1;
Query OK, 1 row affected (0.09 sec)

Due to the cascade, table fc2 on the source now contains only 1 row:
However, the cascade does not propagate on the replica because on the replica the DELETE for fc1 deletes no rows from fc2. The replica’s copy of fc2 still contains all of the rows that were originally inserted:

```
replica> SELECT * FROM fc2;
+---+---+
| m | n |
+---+---+
| 1 | 1 |
| 3 | 1 |
| 2 | 2 |
+---+---+
3 rows in set (0.00 sec)
```

This difference is due to the fact that the cascading deletes are handled internally by the InnoDB storage engine, which means that none of the changes are logged.

### 14.20 InnoDB memcached Plugin

The InnoDB memcached plugin (daemon_memcached) provides an integrated memcached daemon that automatically stores and retrieves data from InnoDB tables, turning the MySQL server into a fast “key-value store”. Instead of formulating queries in SQL, you can use simple get, set, and incr operations that avoid the performance overhead associated with SQL parsing and constructing a query optimization plan. You can also access the same InnoDB tables through SQL for convenience, complex queries, bulk operations, and other strengths of traditional database software.

This “NoSQL-style” interface uses the memcached API to speed up database operations, letting InnoDB handle memory caching using its buffer pool mechanism. Data modified through memcached operations such as add, set, and incr are stored to disk, in InnoDB tables. The combination of memcached simplicity and InnoDB reliability and consistency provides users with the best of both worlds, as explained in Section 14.20.1, “Benefits of the InnoDB memcached Plugin”. For an architectural overview, see Section 14.20.2, “InnoDB memcached Architecture”.

#### 14.20.1 Benefits of the InnoDB memcached Plugin

This section outlines advantages the daemon_memcached plugin. The combination of InnoDB tables and memcached offers advantages over using either by themselves.

- Direct access to the InnoDB storage engine avoids the parsing and planning overhead of SQL.
- Running memcached in the same process space as the MySQL server avoids the network overhead of passing requests back and forth.
- Data written using the memcached protocol is transparently written to an InnoDB table, without going through the MySQL SQL layer. You can control frequency of writes to achieve higher raw performance when updating non-critical data.
- Data requested through the memcached protocol is transparently queried from an InnoDB table, without going through the MySQL SQL layer.
- Subsequent requests for the same data is served from the InnoDB buffer pool. The buffer pool handles the in-memory caching. You can tune performance of data-intensive operations using InnoDB configuration options.
- Data can be unstructured or structured, depending on the type of application. You can create a new table for data, or use existing tables.
**InnoDB memcached Architecture**

- **InnoDB** can handle composing and decomposing multiple column values into a single **memcached** item value, reducing the amount of string parsing and concatenation required in your application. For example, you can store the string value 2|4|6|8 in the **memcached** cache, and have **InnoDB** split the value based on a separator character, then store the result in four numeric columns.

- The transfer between memory and disk is handled automatically, simplifying application logic.

- Data is stored in a MySQL database to protect against crashes, outages, and corruption.

- You can access the underlying **InnoDB** table through SQL for reporting, analysis, ad hoc queries, bulk loading, multi-step transactional computations, set operations such as union and intersection, and other operations suited to the expressiveness and flexibility of SQL.

- You can ensure high availability by using the daemon_memcached plugin on a source server in combination with MySQL replication.

- The integration of **memcached** with MySQL provides a way to make in-memory data persistent, so you can use it for more significant kinds of data. You can use more `add`, `incr`, and similar write operations in your application without concern that data could be lost. You can stop and start the **memcached** server without losing updates made to cached data. To guard against unexpected outages, you can take advantage of **InnoDB** crash recovery, replication, and backup capabilities.

- The way **InnoDB** does fast primary key lookups is a natural fit for **memcached** single-item queries. The direct, low-level database access path used by the daemon_memcached plugin is much more efficient for key-value lookups than equivalent SQL queries.

- The serialization features of **memcached**, which can turn complex data structures, binary files, or even code blocks into storeable strings, offer a simple way to get such objects into a database.

- Because you can access the underlying data through SQL, you can produce reports, search or update across multiple keys, and call functions such as `AVG()` and `MAX()` on **memcached** data. All of these operations are expensive or complicated using **memcached** by itself.

- You do not need to manually load data into **memcached** at startup. As particular keys are requested by an application, values are retrieved from the database automatically, and cached in memory using the **InnoDB** buffer pool.

- Because **memcached** consumes relatively little CPU, and its memory footprint is easy to control, it can run comfortably alongside a MySQL instance on the same system.

- Because data consistency is enforced by mechanisms used for regular **InnoDB** tables, you do not have to worry about stale **memcached** data or fallback logic to query the database in the case of a missing key.

### 14.20.2 InnoDB memcached Architecture

The **InnoDB memcached** plugin implements **memcached** as a MySQL plugin daemon that accesses the **InnoDB** storage engine directly, bypassing the MySQL SQL layer.

The following diagram illustrates how an application accesses data through the daemon_memcached plugin, compared with SQL.
Features of the `daemon_memcached` plugin:

- `memcached` as a daemon plugin of `mysqld`. Both `mysqld` and `memcached` run in the same process space, with very low latency access to data.

- Direct access to `InnoDB` tables, bypassing the SQL parser, the optimizer, and even the Handler API layer.

- Standard `memcached` protocols, including the text-based protocol and the binary protocol. The `daemon_memcached` plugin passes all 55 compatibility tests of the `memcapable` command.

- Multi-column support. You can map multiple columns into the “value” part of the key-value store, with column values delimited by a user-specified separator character.

- By default, the `memcached` protocol is used to read and write data directly to `InnoDB`, letting MySQL manage in-memory caching using the `InnoDB buffer pool`. The default settings represent a combination of high reliability and the fewest surprises for database applications. For example, default settings avoid uncommitted data on the database side, or stale data returned for `memcached get` requests.

- Advanced users can configure the system as a traditional `memcached` server, with all data cached only in the `memcached` engine (memory caching), or use a combination of the “`memcached` engine” (memory caching) and the `InnoDB memcached` engine (`InnoDB` as back-end persistent storage).

- Control over how often data is passed back and forth between `InnoDB` and `memcached` operations through the `innodb_api_bk_commit_interval`, `daemon_memcached_r_batch_size`, and `daemon_memcached_w_batch_size` configuration options. Batch size options default to a value of 1 for maximum reliability.
InnoDB memcached Architecture

- The ability to specify `memcached` options through the `daemon_memcached_option` configuration parameter. For example, you can change the port that `memcached` listens on, reduce the maximum number of simultaneous connections, change the maximum memory size for a key-value pair, or enable debugging messages for the error log.

- The `innodb_api_trx_level` configuration option controls the transaction isolation level on queries processed by `memcached`. Although `memcached` has no concept of transactions, you can use this option to control how soon `memcached` sees changes caused by SQL statements issued on the table used by the `daemon_memcached` plugin. By default, `innodb_api_trx_level` is set to `READ UNCOMMITTED`.

- The `innodb_api_enable_mdl` option can be used to lock the table at the MySQL level, so that the mapped table cannot be dropped or altered by DDL through the SQL interface. Without the lock, the table can be dropped from the MySQL layer, but kept in InnoDB storage until `memcached` or some other user stops using it. “MDL” stands for “metadata locking”.

Differences Between InnoDB memcached and Traditional memcached

You may already be familiar with using `memcached` with MySQL, as described in Section 16.2, “Using MySQL with `memcached`”. This section describes how features of the integrated InnoDB memcached plugin differ from traditional `memcached`.

- Installation: The `memcached` library comes with the MySQL server, making installation and setup relatively easy. Installation involves running the `innodb_memcached_config.sql` script to create a demo_test table for `memcached` to use, issuing an `INSTALL PLUGIN` statement to enable the `daemon_memcached` plugin, and adding desired `memcached` options to a MySQL configuration file or startup script. You might still install the traditional `memcached` distribution for additional utilities such as `memcp`, `memcat`, and `memcapable`.

For comparison with traditional `memcached`, see Section 16.2.1, “Installing `memcached`”.

- Deployment: With traditional `memcached`, it is typical to run large numbers of low-capacity `memcached` servers. A typical deployment of the `daemon_memcached` plugin, however, involves a smaller number of moderate or high-powered servers that are already running MySQL. The benefit of this configuration is in improving efficiency of individual database servers rather than exploiting unused memory or distributing lookups across large numbers of servers. In the default configuration, very little memory is used for `memcached`, and in-memory lookups are served from the InnoDB buffer pool, which automatically caches the most recently and frequently used data. As with a traditional MySQL server instance, keep the value of the `innodb_buffer_pool_size` configuration option as high as practical (without causing paging at the OS level), so that as much work as possible is performed in memory.

For comparison with traditional `memcached`, see Section 16.2.2.2, “`memcached` Deployment”.

- Expiry: By default (that is, using the `innodb_only` caching policy), the latest data from the InnoDB table is always returned, so the expiry options have no practical effect. If you change the caching policy to `caching` or `cache_only`, the expiry options work as usual, but requested data might be stale if it is updated in the underlying table before it expires from the memory cache.

For comparison with traditional `memcached`, see Section 16.2.2.4, “Data Expiry”.

- Namespaces: `memcached` is like a large directory where you give files elaborate names with prefixes and suffixes to keep the files from conflicting. The `daemon_memcached` plugin lets you use similar naming conventions for keys, with one addition. Key names in the format `@@table_id.key:table_id` are decoded to reference a specific a table, using mapping data from the `innodb_memcache.containers` table. The `key` is looked up in or written to the specified table.

The `@@` notation only works for individual calls to `get`, `add`, and `set` functions, but not others such as `incr` or `delete`. To designate a default table for subsequent `memcached` operations within a
InnoDB memcached Architecture

session, perform a `get` request using the `@@` notation with a `table_id`, but without the key portion. For example:

```
get @@table_id
```

Subsequent `get`, `set`, `incr`, `delete`, and other operations use the table designated by `table_id` in the `innodb_memcache.containers.name` column.

For comparison with traditional memcached, see Section 16.2.2.3, “Using Namespaces”.

• Hashing and distribution: The default configuration, which uses the `innodb_only` caching policy, is suitable for a traditional deployment configuration where all data is available on all servers, such as a set of replica servers.

If you physically divide data, as in a sharded configuration, you can split data across several machines running the `daemon_memcached` plugin, and use the traditional `memcached` hashing mechanism to route requests to a particular machine. On the MySQL side, you would typically let all data be inserted by `add` requests to `memcached` so that appropriate values are stored in the database on the appropriate server.

For comparison with traditional memcached, see Section 16.2.2.5, “memcached Hashing/Distribution Types”.

• Memory usage: By default (with the `innodb_only` caching policy), the `memcached` protocol passes information back and forth with InnoDB tables, and the InnoDB buffer pool handles in-memory lookups instead of `memcached` memory usage growing and shrinking. Relatively little memory is used on the `memcached` side.

If you switch the caching policy to `caching` or `cache_only`, the normal rules of `memcached` memory usage apply. Memory for `memcached` data values is allocated in terms of “slabs”. You can control slab size and maximum memory used for `memcached`.

Either way, you can monitor and troubleshoot the `daemon_memcached` plugin using the familiar `statistics` system, accessed through the standard protocol, over a `telnet` session, for example. Extra utilities are not included with the `daemon_memcached` plugin. You can use the `memcached-tool` script to install a full `memcached` distribution.

For comparison with traditional memcached, see Section 16.2.2.7, “Memory Allocation within memcached”.

• Thread usage: MySQL threads and `memcached` threads co-exist on the same server. Limits imposed on threads by the operating system apply to the total number of threads.

For comparison with traditional memcached, see Section 16.2.2.8, “memcached Thread Support”.

• Log usage: Because the `memcached` daemon is run alongside the MySQL server and writes to `stderr`, the `-v`, `-vv`, and `-vvv` options for logging write output to the MySQL error log.

For comparison with traditional memcached, see Section 16.2.2.9, “memcached Logs”.

• `memcached` operations: Familiar `memcached` operations such as `get`, `set`, `add`, and `delete` are available. Serialization (that is, the exact string format representing complex data structures) depends on the language interface.

For comparison with traditional memcached, see Section 16.2.3.1, “Basic memcached Operations”.

• Using `memcached` as a MySQL front end: This is the primary purpose of the InnoDB `memcached` plugin. An integrated `memcached` daemon improves application performance, and having InnoDB handle data transfers between memory and disk simplifies application logic.

For comparison with traditional memcached, see Section 16.2.3.2, “Using memcached as a MySQL Caching Layer”.
Setting Up the InnoDB memcached Plugin

- Utilities: The MySQL server includes the libmemcached library but not additional command-line utilities. To use commands such as memcp, memcat, and memcapable commands, install a full memcached distribution. When memrm and memflush remove items from the cache, the items are also removed from the underlying InnoDB table.

For comparison with traditional memcached, see libmemcached Command-Line Utilities.

- Programming interfaces: You can access the MySQL server through the daemon_memcached plugin using all supported languages: C and C++, Java, Perl, Python, PHP, and Ruby. Specify the server hostname and port as with a traditional memcached server. By default, the daemon_memcached plugin listens on port 11211. You can use both the text and binary protocols. You can customize the behavior of memcached functions at runtime. Serialization (that is, the exact string format representing complex data structures) depends on the language interface.

For comparison with traditional memcached, see Section 16.2.3, “Developing a memcached Application”.

- Frequently asked questions: MySQL has an extensive FAQ for traditional memcached. The FAQ is mostly applicable, except that using InnoDB tables as a storage medium for memcached data means that you can use memcached for more write-intensive applications than before, rather than as a read-only cache.

See Section 16.2.5, “memcached FAQ”.

14.20.3 Setting Up the InnoDB memcached Plugin

This section describes how to set up the daemon_memcached plugin on a MySQL server. Because the memcached daemon is tightly integrated with the MySQL server to avoid network traffic and minimize latency, you perform this process on each MySQL instance that uses this feature.

Note

Before setting up the daemon_memcached plugin, consult Section 14.20.4, “Security Considerations for the InnoDB memcached Plugin” to understand the security procedures required to prevent unauthorized access.

Prerequisites

- The daemon_memcached plugin is only supported on Linux, Solaris, and macOS platforms. Other operating systems are not supported.

- When building MySQL from source, you must build with -DWITH_INNODB_MEMCACHED=ON. This build option generates two shared libraries in the MySQL plugin directory (plugin_dir) that are required to run the daemon_memcached plugin:

  • libmemcached.so: the memcached daemon plugin to MySQL.
  • innodb_engine.so: an InnoDB API plugin to memcached.
  • libevent must be installed.

- If you did not build MySQL from source, the libevent library is not included in your installation. Use the installation method for your operating system to install libevent 1.4.12 or later. For example, depending on the operating system, you might use apt-get, yum, or port install. For example, on Ubuntu Linux, use:

    sudo apt-get install libevent-dev

- If you installed MySQL from a source code release, libevent 1.4.12 is bundled with the package and is located at the top level of the MySQL source code directory. If you use the bundled version of libevent, no action is required. If you want to use a local system version of libevent, you must build MySQL with the -DWITH_LIBEVENT build option set to system or yes.
Installing and Configuring the InnoDB memcached Plugin

1. Configure the `daemon_memcached` plugin so it can interact with InnoDB tables by running the `innodb_memcached_config.sql` configuration script, which is located in `MYSQL_HOME/share`. This script installs the `innodb_memcache` database with three required tables (`cache_policies`, `config_options`, and `containers`). It also installs the `demo_test` sample table in the `test` database.

   ```sql
   mysql> source MYSQL_HOME/share/innodb_memcached_config.sql
   ``"

   Running the `innodb_memcached_config.sql` script is a one-time operation. The tables remain in place if you later uninstall and re-install the `daemon_memcached` plugin.

   ```sql
   mysql> USE innodb_memcache;
   mysql> SHOW TABLES;
   +---------------------------+
   | Tables_in_innodb_memcache |
   +---------------------------+
   | cache_policies            |
   | config_options            |
   | containers                |
   +---------------------------+
   mysql> USE test;
   mysql> SHOW TABLES;
   +------------------+
   | Tables_in_test   |
   +------------------+
   | demo_test        |
   +------------------+
   
   Of these tables, the `innodb_memcache.containers` table is the most important. Entries in the `containers` table provide a mapping to InnoDB table columns. Each InnoDB table used with the `daemon_memcached` plugin requires an entry in the `containers` table.

   The `innodb_memcached_config.sql` script inserts a single entry in the `containers` table that provides a mapping for the `demo_test` table. It also inserts a single row of data into the `demo_test` table. This data allows you to immediately verify the installation after the setup is completed.

   ```sql
   mysql> SELECT * FROM innodb_memcache.containers\G
   *************************** 1. row ***************************
   name: aaa
   db_schema: test
   db_table: demo_test
   key_columns: c1
   value_columns: c2
   flags: c3
   cas_column: c4
   expire_time_column: c5
   unique_idx_name_on_key: PRIMARY
   
   mysql> SELECT * FROM test.demo_test;
   +----+------------------+------+------+------+
   | c1 | c2               | c3   | c4   | c5   |
   +----+------------------+------+------+------+
   | AA | HELLO, HELLO     |    8 |    0 |    0 |
   +----+------------------+------+------+------+
   
   For more information about `innodb_memcache` tables and the `demo_test` sample table, see Section 14.20.7, “InnoDB memcached Plugin Internals”.

2. Activate the `daemon_memcached` plugin by running the `INSTALL PLUGIN` statement:

   ```sql
   mysql> INSTALL PLUGIN daemon_memcached soname "libmemcached.so";
   
   Once the plugin is installed, it is automatically activated each time the MySQL server is restarted.
Verifying the InnoDB and memcached Setup

To verify the `daemon_memcached` plugin setup, use a telnet session to issue `memcached` commands. By default, the `memcached` daemon listens on port 11211.

1. Retrieve data from the `test.demo_test` table. The single row of data in the `demo_test` table has a key value of `AA`.

```
telnet localhost 11211
Trying 127.0.0.1...
Connected to localhost.
Escape character is '^]'.
get AA
VALUE AA 8 12
HELLO, HELLO
END
```

2. Insert data using a `set` command.

```
set BB 10 0 16
GOODBYE, GOODBYE
STORED
```

where:
- `set` is the command to store a value
- `BB` is the key
- `10` is a flag for the operation; ignored by `memcached` but may be used by the client to indicate any type of information; specify `0` if unused
- `0` is the expiration time (TTL); specify `0` if unused
- `16` is the length of the supplied value block in bytes
- `GOODBYE, GOODBYE` is the value that is stored

3. Verify that the data inserted is stored in MySQL by connecting to the MySQL server and querying the `test.demo_test` table.

```
mysql> SELECT * FROM test.demo_test;
+----+------------------+------+------+------+
| c1 | c2               | c3   | c4   | c5   |
+----+------------------+------+------+------+
| AA | HELLO, HELLO     |    8 |    0 |    0 |
| BB | GOODBYE, GOODBYE |   10 |    1 |    0 |
+----+------------------+------+------+------+
```

4. Return to the telnet session and retrieve the data that you inserted earlier using key `BB`.

```
get BB
VALUE BB 10 16
GOODBYE, GOODBYE
END
```

If you shut down the MySQL server, which also shuts off the integrated `memcached` server, further attempts to access the `memcached` data fail with a connection error. Normally, the `memcached` data also disappears at this point, and you would require application logic to load the data back into memory when `memcached` is restarted. However, the InnoDB `memcached` plugin automates this process for you.

When you restart MySQL, `get` operations once again return the key-value pairs you stored in the earlier `memcached` session. When a key is requested and the associated value is not already in the memory cache, the value is automatically queried from the MySQL `test.demo_test` table.
Creating a New Table and Column Mapping

This example shows how to setup your own InnoDB table with the daemon_memcached plugin.

1. Create an InnoDB table. The table must have a key column with a unique index. The key column of the city table is city_id, which is defined as the primary key. The table must also include columns for flags, cas, and expiry values. There may be one or more value columns. The city table has three value columns (name, state, country).

   ```
   mysql> CREATE TABLE city (
      | city_id VARCHAR(32),
      | name VARCHAR(1024),
      | state VARCHAR(1024),
      | country VARCHAR(1024),
      | flags INT,
      | cas BIGINT UNSIGNED,
      | expiry INT,
      | primary key(city_id)
   ) ENGINE=InnoDB;
   ```

   **Note**
   There is no special requirement with respect to column names as along as a valid mapping is added to the innodb_memcache.containers table.

2. Add an entry to the innodb_memcache.containers table so that the daemon_memcached plugin knows how to access the InnoDB table. The entry must satisfy the innodb_memcache.containers table definition. For a description of each field, see Section 14.20.7, “InnoDB memcached Plugin Internals”.

   ```
   mysql> DESCRIBE innodb_memcache.containers;
   +------------------------+--------------+------+-----+---------+-------+
   | Field                  | Type         | Null | Key | Default | Extra |
   +------------------------+--------------+------+-----+---------+-------+
   | name                   | varchar(50)  | NO   | PRI | NULL    |       |
   | db_schema              | varchar(250) | NO   |     | NULL    |       |
   | db_table               | varchar(250) | NO   |     | NULL    |       |
   | key_columns            | varchar(250) | NO   |     | NULL    |       |
   | value_columns          | varchar(250) | YES  |     | NULL    |       |
   | flags                  | varchar(250) | NO   |     | 0       |       |
   | cas_column             | varchar(250) | YES  |     | NULL    |       |
   | expire_time_column     | varchar(250) | YES  |     | NULL    |       |
   | unique_idx_name_on_key | varchar(250) | NO   |     | NULL    |       |
   +------------------------+--------------+------+-----+---------+-------+
   ```

   The innodb_memcache.containers table entry for the city table is defined as:

   ```
   mysql> INSERT INTO `innodb_memcache`.containers (name, db_schema, db_table, key_columns, value_columns, flags, cas_column, expire_time_column, unique_idx_name_on_key) VALUES ('default', 'test', 'city', 'city_id', 'name|state|country', 'flags','cas','expiry','PRIMARY');
   ```

   • default is specified for the containers.name column to configure the city table as the default InnoDB table to be used with the daemon_memcached plugin.

   • Multiple InnoDB table columns (name, state, country) are mapped to containers.value_columns using a "|" delimiter.

   • The flags, cas_column, and expire_time_column fields of the innodb_memcache.containers table are typically not significant in applications using the daemon_memcached plugin. However, a designated InnoDB table column is required for each. When inserting data, specify 0 for these columns if they are unused.

3. After updating the innodb_memcache.containers table, restart the daemon_memcached plugin to apply the changes.
mysql> UNINSTALL PLUGIN daemon_memcached;

mysql> INSTALL PLUGIN daemon_memcached soname "libmemcached.so";

4. Using telnet, insert data into the city table using a memcached set command.

```
telnet localhost 11211
Trying 127.0.0.1...
Connected to localhost.
Escape character is '^]'.
set B 0 0 22
BANGALORE|BANGALORE|IN
STORED
```

5. Using MySQL, query the test.city table to verify that the data you inserted was stored.

```
mysql> SELECT * FROM test.city;
+---------+-----------+-----------+---------+-------+------+--------+
| city_id | name      | state     | country | flags | cas  | expiry |
+---------+-----------+-----------+---------+-------+------+--------+
| B       | BANGALORE | BANGALORE | IN      |     0 |    3 |      0 |
+---------+-----------+-----------+---------+-------+------+--------+
```

6. Using MySQL, insert additional data into the test.city table.

```
mysql> INSERT INTO city VALUES ('C','CHENNAI','TAMIL NADU','IN', 0, 0, 0);
mysql> INSERT INTO city VALUES ('D','DELHI','DELHI','IN', 0, 0, 0);
mysql> INSERT INTO city VALUES ('H','HYDERABAD','TELANGANA','IN', 0, 0, 0);
mysql> INSERT INTO city VALUES ('M','MUMBAI','MAHARASHTRA','IN', 0, 0, 0);
```

Note
It is recommended that you specify a value of 0 for the flags, cas_column, and expire_time_column fields if they are unused.

7. Using telnet, issue a memcached get command to retrieve data you inserted using MySQL.

```
get H
VALUE H 0 22
HYDERABAD|TELANGANA|IN
END
```

Configuring the InnoDB memcached Plugin

Traditional memcached configuration options may be specified in a MySQL configuration file or a mysqld startup string, encoded in the argument of the daemon_memcached_option configuration parameter. memcached configuration options take effect when the plugin is loaded, which occurs each time the MySQL server is started.

For example, to make memcached listen on port 11222 instead of the default port 11211, specify -p11222 as an argument of the daemon_memcached_option configuration option:

```
mysqld .... --daemon_memcached_option="-p11222"
```

Other memcached options can be encoded in the daemon_memcached_option string. For example, you can specify options to reduce the maximum number of simultaneous connections, change the maximum memory size for a key-value pair, or enable debugging messages for the error log, and so on.

There are also configuration options specific to the daemon_memcached plugin. These include:

- **daemon_memcached_engine_lib_name**: Specifies the shared library that implements the InnoDB memcached plugin. The default setting is innodb_engine.so.

- **daemon_memcached_engine_lib_path**: The path of the directory containing the shared library that implements the InnoDB memcached plugin. The default is NULL, representing the plugin directory.
• **daemon_memcached_r_batch_size**: Defines the batch commit size for read operations (get). It specifies the number of memcached read operations after which a commit occurs. `daemon_memcached_r_batch_size` is set to 1 by default so that every get request accesses the most recently committed data in the InnoDB table, whether the data was updated through memcached or by SQL. When the value is greater than 1, the counter for read operations is incremented with each get call. A flush_all call resets both read and write counters.

• **daemon_memcached_w_batch_size**: Defines the batch commit size for write operations (set, replace, append, prepend, incr, decr, and so on). `daemon_memcached_w_batch_size` is set to 1 by default so that no uncommitted data is lost in case of an outage, and so that SQL queries on the underlying table access the most recent data. When the value is greater than 1, the counter for write operations is incremented for each add, set, incr, decr, and delete call. A flush_all call resets both read and write counters.

By default, you do not need to modify `daemon_memcached_engine_lib_name` or `daemon_memcached_engine_lib_path`. You might configure these options if, for example, you want to use a different storage engine for memcached (such as the NDB memcached engine).

`daemon_memcached` plugin configuration parameters may be specified in the MySQL configuration file or in a `mysqld` startup string. They take effect when you load the `daemon_memcached` plugin.

When making changes to `daemon_memcached` plugin configuration, reload the plugin to apply the changes. To do so, issue the following statements:

```sql
mysql> UNINSTALL PLUGIN daemon_memcached;
mysql> INSTALL PLUGIN daemon_memcached soname "libmemcached.so";
```

Configuration settings, required tables, and data are preserved when the plugin is restarted.

For additional information about enabling and disabling plugins, see Section 5.5.1, “Installing and Uninstalling Plugins”.

### 14.20.4 Security Considerations for the InnoDB memcached Plugin

**Caution**

Consult this section before deploying the `daemon_memcached` plugin on a production server, or even on a test server if the MySQL instance contains sensitive data.

Because `memcached` does not use an authentication mechanism by default, and the optional SASL authentication is not as strong as traditional DBMS security measures, only keep non-sensitive data in the MySQL instance that uses the `daemon_memcached` plugin, and wall off any servers that use this configuration from potential intruders. Do not allow `memcached` access to these servers from the Internet; only allow access from within a firewalled intranet, ideally from a subnet whose membership you can restrict.

**Password-Protecting memcached Using SASL**

SASL support provides the capability to protect your MySQL database from unauthenticated access through `memcached` clients. This section explains how to enable SASL with the `daemon_memcached` plugin. The steps are almost identical to those performed to enabled SASL for a traditional `memcached` server.

SASL stands for “Simple Authentication and Security Layer”, a standard for adding authentication support to connection-based protocols. `memcached` added SASL support in version 1.4.3.

SASL authentication is only supported with the binary protocol.
memcached clients are only able to access InnoDB tables that are registered in the innodb_memcache.containers table. Even though a DBA can place access restrictions on such tables, access through memcached applications cannot be controlled. For this reason, SASL support is provided to control access to InnoDB tables associated with the daemon_memcached plugin.

The following section shows how to build, enable, and test an SASL-enabled daemon_memcached plugin.

Building and Enabling SASL with the InnoDB memcached Plugin

By default, an SASL-enabled daemon_memcached plugin is not included in MySQL release packages, since an SASL-enabled daemon_memcached plugin requires building memcached with SASL libraries. To enable SASL support, download the MySQL source and rebuild the daemon_memcached plugin after downloading the SASL libraries:

1. Install the SASL development and utility libraries. For example, on Ubuntu, use `apt-get` to obtain the libraries:

   ```
   sudo apt-get -f install libsasl2-2 sasl2-bin libsasl2-2 libsasl2-dev libsasl2-modules
   ```

2. Build the daemon_memcached plugin shared libraries with SASL capability by adding `ENABLE_MEMCACHED_SASL=1` to your cmake options. memcached also provides simple cleartext password support, which facilitates testing. To enable simple cleartext password support, specify the `ENABLE_MEMCACHED_SASL_PWDB=1` cmake option.

   In summary, add following three cmake options:

   ```
   cmake ... -DWITH_INNODB_MEMCACHED=1 -DENABLE_MEMCACHED_SASL=1 -DENABLE_MEMCACHED_SASL_PWDB=1
   ```

3. Install the daemon_memcached plugin, as described in Section 14.20.3, “Setting Up the InnoDB memcached Plugin”.

4. Configure a user name and password file. (This example uses memcached simple cleartext password support.)

   a. In a file, create a user named `testname` and define the password as `testpasswd`:

   ```
   echo "testname:testpasswd:::::::" >/home/jy/memcached-sasl-db
   ```

   b. Configure the `MEMCACHED_SASL_PWDB` environment variable to inform memcached of the user name and password file:

   ```
   export MEMCACHED_SASL_PWDB=/home/jy/memcached-sasl-db
   ```

   c. Inform memcached that a cleartext password is used:

   ```
   echo "mech_list: plain" > /home/jy/work2/msasl/clients/memcached.conf
   export SASL_CONF_PATH=/home/jy/work2/msasl/clients
   ```

5. Enable SASL by restarting the MySQL server with the memcached `-S` option encoded in the daemon_memcached_option configuration parameter:

   ```
   mysqld ... --daemon_memcached_option="-S"
   ```

6. To test the setup, use an SASL-enabled client such as SASL-enabled libmemcached.

   ```
   memcp --servers=localhost:11211 --binary --username=testname --password=password myfile.txt
   memcat --servers=localhost:11211 --binary --username=testname --password=password myfile.txt
   ```
If you specify an incorrect user name or password, the operation is rejected with a memcache error AUTHENTICATION FAILURE message. In this case, examine the cleartext password set in the memcached-sasl-db file to verify that the credentials you supplied are correct.

There are other methods to test SASL authentication with memcached, but the method described above is the most straightforward.

14.20.5 Writing Applications for the InnoDB memcached Plugin

Typically, writing an application for the InnoDB memcached plugin involves some degree of rewriting or adapting existing code that uses MySQL or the memcached API.

- With the daemon_memcached plugin, instead of many traditional memcached servers running on low-powered machines, you have the same number of memcached servers as MySQL servers, running on relatively high-powered machines with substantial disk storage and memory. You might reuse some existing code that works with the memcached API, but adaptation is likely required due to the different server configuration.

- The data stored through the daemon_memcached plugin goes into VARCHAR, TEXT, or BLOB columns, and must be converted to do numeric operations. You can perform the conversion on the application side, or by using the CAST() function in queries.

- Coming from a database background, you might be used to general-purpose SQL tables with many columns. The tables accessed by memcached code likely have only a few or even a single column holding data values.

- You might adapt parts of your application that perform single-row queries, inserts, updates, or deletes, to improve performance in critical sections of code. Both queries (read) and DML (write) operations can be substantially faster when performed through the InnoDB memcached interface. The performance improvement for writes is typically greater than the performance improvement for reads, so you might focus on adapting code that performs logging or records interactive choices on a website.

The following sections explore these points in more detail.

14.20.5.1 Adapting an Existing MySQL Schema for the InnoDB memcached Plugin

Consider these aspects of memcached applications when adapting an existing MySQL schema or application to use the daemon_memcached plugin:

- memcached keys cannot contain spaces or newlines, because these characters are used as separators in the ASCII protocol. If you are using lookup values that contain spaces, transform or hash them into values without spaces before using them as keys in calls to add(), set(), get(), and so on. Although theoretically these characters are allowed in keys in programs that use the binary protocol, you should restrict the characters used in keys to ensure compatibility with a broad range of clients.

- If there is a short numeric primary key column in an InnoDB table, use it as the unique lookup key for memcached by converting the integer to a string value. If the memcached server is used for multiple applications, or with more than one InnoDB table, consider modifying the name to ensure that it is unique. For example, prepend the table name, or the database name and the table name, before the numeric value.

```
Note

The daemon_memcached plugin supports inserts and reads on mapped InnoDB tables that have an INTEGER defined as the primary key.
```

- You cannot use a partitioned table for data queried or stored using memcached.
• The **memcached** protocol passes numeric values around as strings. To store numeric values in the underlying **InnoDB** table, to implement counters that can be used in SQL functions such as **SUM()** or **AVG()**, for example:

• Use **VARCHAR** columns with enough characters to hold all the digits of the largest expected number (and additional characters if appropriate for the negative sign, decimal point, or both).

• In any query that performs arithmetic using column values, use the **CAST()** function to convert the values from string to integer, or to some other numeric type. For example:

```sql
# Alphabetic entries are returned as zero.
SELECT CAST(c2 as unsigned integer) FROM demo_test;

# Since there could be numeric values of 0, can't disqualify them.
# Test the string values to find the ones that are integers, and average only those.
SELECT AVG(cast(c2 as unsigned integer)) FROM demo_test
    WHERE c2 BETWEEN '0' and '9999999999';

# Views let you hide the complexity of queries. The results are already converted;
# no need to repeat conversion functions and WHERE clauses each time.
CREATE VIEW numbers AS SELECT c1 KEY, CAST(c2 AS UNSIGNED INTEGER) val
    FROM demo_test WHERE c2 BETWEEN '0' and '9999999999';
SELECT SUM(val) FROM numbers;
```

**Note**

Any alphabetic values in the result set are converted into 0 by the call to **CAST()**. When using functions such as **AVG()**, which depend on the number of rows in the result set, include **WHERE** clauses to filter out non-numeric values.

• If the **InnoDB** column used as a key could have values longer than 250 bytes, hash the value to less than 250 bytes.

• To use an existing table with the **daemon_memcached** plugin, define an entry for it in the **innodb_memcache.containers** table. To make that table the default for all **memcached** requests, specify a value of **default** in the **name** column, then restart the MySQL server to make the change take effect. If you use multiple tables for different classes of **memcached** data, set up multiple entries in the **innodb_memcache.containers** table with **name** values of your choice, then issue a **memcached** request in the form of **get @name** or **set @name** within the application to specify the table to be used for subsequent **memcached** requests.

For an example of using a table other than the predefined **test.demo_test** table, see **Example 14.12, “Using Your Own Table with an InnoDB memcached Application”**. For the required table layout, see **Section 14.20.7, “InnoDB memcached Plugin Internals”**.

• To use multiple **InnoDB** table column values with **memcached** key-value pairs, specify column names separated by comma, semicolon, space, or pipe characters in the **value_columns** field of the **innodb_memcache.containers** entry for the **InnoDB** table. For example, specify **col1,col2,col3** or **col1|col2|col3** in the **value_columns** field.

Concatenate the column values into a single string using the pipe character as a separator before passing the string to **memcached add** or **set** calls. The string is unpacked automatically into the correct column. Each **get** call returns a single string containing the column values that is also delimited by the pipe character. You can unpack the values using the appropriate application language syntax.

**Example 14.12 Using Your Own Table with an InnoDB memcached Application**

This example shows how to use your own table with a sample Python application that uses **memcached** for data manipulation.
The example assumes that the `daemon_memcached` plugin is installed as described in Section 14.20.3, “Setting Up the InnoDB memcached Plugin”. It also assumes that your system is configured to run a Python script that uses the `python-memcache` module.

1. Create the `multicol` table which stores country information including population, area, and driver side data (`'R'` for right and `'L'` for left).

   ```sql
   mysql> USE test;
   mysql> CREATE TABLE `multicol` (
       `country` varchar(128) NOT NULL DEFAULT '',
       `population` varchar(10) DEFAULT NULL,
       `area_sq_km` varchar(9) DEFAULT NULL,
       `drive_side` varchar(1) DEFAULT NULL,
       `c3` int(11) DEFAULT NULL,
       `c4` bigint(20) unsigned DEFAULT NULL,
       `c5` int(11) DEFAULT NULL,
       PRIMARY KEY (`country`)
   ) ENGINE=InnoDB DEFAULT CHARSET=latin1;
   ```

2. Insert a record into the `innodb_memcache.containers` table so that the `daemon_memcached` plugin can access the `multicol` table.

   ```sql
   mysql> INSERT INTO innodb_memcache.containers
          (name,db_schema,db_table,key_columns,value_columns,flags,cas_column,
           expire_time_column,unique_idx_name_on_key)
      VALUES
          ('bbb','test','multicol','country','population,area_sq_km,drive_side',
           'c3','c4','c5','PRIMARY');
   mysql> COMMIT;
   ```

   • The `innodb_memcache.containers` record for the `multicol` table specifies a `name` value of `'bbb'`, which is the table identifier.

   • The `db_schema` column is set to `test`, which is the name of the database where the `multicol` table resides.

   • The `db_table` column is set to `multicol`, which is the name of the InnoDB table.

   • `key_columns` is set to the unique `country` column. The `country` column is defined as the primary key in the `multicol` table definition.

   • Rather than a single InnoDB table column to hold a composite data value, data is divided among three table columns (`population, area_sq_km, and drive_side`). To accommodate multiple value columns, a comma-separated list of columns is specified in the `value_columns` field. The columns defined in the `value_columns` field are the columns used when storing or retrieving values.

   • Values for the `flags`, `expire_time`, and `cas_column` fields are based on values used in the `demo.test` sample table. These fields are typically not significant in applications that use the `daemon_memcached` plugin because MySQL keeps data synchronized, and there is no need to worry about data expiring or becoming stale.

   • The `unique_idx_name_on_key` field is set to `PRIMARY`, which refers to the primary index defined on the unique `country` column in the `multicol` table.

   **Note**

   If a single InnoDB table is used for all memcached applications, the `name` value can be set to `default` to avoid using `@@` notation to switch tables.
3. Copy the sample Python application into a file. In this example, the sample script is copied to a file named `multicol.py`.

The sample Python application inserts data into the `multicol` table and retrieves data for all keys, demonstrating how to access an InnoDB table through the `daemon_memcached` plugin.

```python
import sys, os
import memcache

def connect_to_memcached():
    memc = memcache.Client(['127.0.0.1:11211'], debug=0);
    print "Connected to memcached."
    return memc

def banner(message):
    print
    print "=" * len(message)
    print message
    print "=" * len(message)

country_data = [
    ("Canada","34820000","9984670","R"),
    ("USA","314242000","9826675","R"),
    ("Ireland","6399152","84421","L"),
    ("UK","62262000","243610","L"),
    ("Mexico","113910608","1972550","R"),
    ("Denmark","5543453","43094","R"),
    ("Norway","5002942","385252","R"),
    ("UAE","8264070","83600","R"),
    ("India","1210193422","3287263","L"),
    ("China","1347350000","9640821","R"),
]

def switch_table(memc,table):
    key = "@" + table
    print "Switching default table to " + table + " by issuing GET for " + key + ":".
    result = memc.get(key)

def insert_country_data(memc):
    banner("Inserting initial data via memcached interface")
    for item in country_data:
        country = item[0]
        population = item[1]
        area = item[2]
        drive_side = item[3]

        key = country
        value = "|".join([population,area,drive_side])
        print "Key = " + key
        print "Value = " + value

        if memc.add(key,value):
            print "Added new key, value pair."
        else:
            print "Updating value for existing key."
            memc.set(key,value)

    def query_country_data(memc):
        banner("Retrieving data for all keys (country names)")
        for item in country_data:
            key = item[0]
            result = memc.get(key)
            print "Here is the result retrieved from the database for key " + key + ":"
            print result
            (m_population, m_area, m_drive_side) = result.split("|")
            print "Unpacked population value: " + m_population
            print "Unpacked area value : " + m_area
            print "Unpacked drive side value: " + m_drive_side

if __name__ == '__main__':
```
Writing Applications for the InnoDB memcached Plugin

```python
cmem = connect_to_memcached()
switch_table(cmec, "bbb")
insert_country_data(cmec)
query_country_data(cmec)
sys.exit(0)
```

Sample Python application notes:

- No database authorization is required to run the application, since data manipulation is performed through the `memcached` interface. The only required information is the port number on the local system where the `memcached` daemon listens.

- To make sure the application uses the `multicol` table, the `switch_table()` function is called, which performs a dummy `get` or `set` request using `@` notation. The `name` value in the request is `bbb`, which is the `multicol` table identifier defined in the `innodb_memcache.containers.name` field.

  A more descriptive `name` value might be used in a real-world application. This example simply illustrates that a table identifier is specified rather than the table name in `get @@...` requests.

- The utility functions used to insert and query data demonstrate how to turn a Python data structure into pipe-separated values for sending data to MySQL with `add` or `set` requests, and how to unpack the pipe-separated values returned by `get` requests. This extra processing is only required when mapping a single `memcached` value to multiple MySQL table columns.

4. Run the sample Python application.

```
shell> python multicol.py
```

If successful, the sample application returns this output:

```
Connected to memcached.
Switching default table to 'bbb' by issuing GET for '@b...bbb'.

```
5. Query the `innodb_memcache.containers` table to view the record you inserted earlier for the `multicol` table. The first record is the sample entry for the `demo_test` table that is created during the initial `daemon_memcached` plugin setup. The second record is the entry you inserted for the `multicol` table.

```
mysql> SELECT * FROM innodb_memcache.containers\G
*************************** 1. row ***************************
name: aaa
db_schema: test
db_table: demo_test
key_columns: c1
value_columns: c2
flags: c3
cas_column: c4
expire_time_column: c5
unique_idx_name_on_key: PRIMARY
```
Writing Applications for the InnoDB memcached Plugin

2. Query the `multicol` table to view data inserted by the sample Python application. The data is available for MySQL queries, which demonstrates how the same data can be accessed using SQL or through applications (using the appropriate MySQL Connector or API).

```
mysql> SELECT * FROM test.multicol;
+---------+------------+------------+------------+------+------+------+
<table>
<thead>
<tr>
<th>country</th>
<th>population</th>
<th>area_sq_km</th>
<th>drive_side</th>
<th>c3</th>
<th>c4</th>
<th>c5</th>
</tr>
</thead>
<tbody>

<td>0</td>
</tr>
</tbody>
</table>
+---------+------------+------------+------------+------+------+------+
```

**Note**

Always allow sufficient size to hold necessary digits, decimal points, sign characters, leading zeros, and so on when defining the length for columns that are treated as numbers. Too-long values in a string column such as a `VARCHAR` are truncated by removing some characters, which could produce nonsensical numeric values.

7. Optionally, run report-type queries on the `InnoDB` table that stores the `memcached` data.

You can produce reports through SQL queries, performing calculations and tests across any columns, not just the `country` key column. (Because the following examples use data from only a few countries, the numbers are for illustration purposes only.) The following queries return the average population of countries where people drive on the right, and the average size of countries whose names start with “U”:

```
mysql> SELECT AVG(population) FROM multicol WHERE drive_side = 'R';
```

```
+-------------------+
<table>
<thead>
<tr>
<th>avg(population)</th>
</tr>
</thead>
<tbody>
<tr>
<td>261304724.7142857</td>
</tr>
</tbody>
</table>
+-------------------+
```

```
mysql> SELECT SUM(area_sq_km) FROM multicol WHERE country LIKE 'U%';
```

```
+-----------------+
<table>
<thead>
<tr>
<th>sum(area_sq_km)</th>
</tr>
</thead>
<tbody>
<tr>
<td>40153885</td>
</tr>
</tbody>
</table>
+-----------------+
```

Because the `population` and `area_sq_km` columns store character data rather than strongly typed numeric data, functions such as `AVG()` and `SUM()` work by converting each value to a number first. This approach does not work for operators such as `<` or `>`, for example, when comparing character-based values, `9 > 1000`, which is not expected from a clause such as `ORDER BY population DESC`. For the most accurate type treatment, perform queries against views that cast numeric columns to the appropriate types. This technique lets you issue simple
**Writing Applications for the InnoDB memcached Plugin**

**SELECT** * queries from database applications, while ensuring that casting, filtering, and ordering is correct. The following example shows a view that can be queried to find the top three countries in descending order of population, with the results reflecting the latest data in the multicol table, and with population and area figures treated as numbers:

```sql
CREATE VIEW populous_countries AS
    SELECT
        country,
        cast(population as unsigned integer) population,
        cast(area_sq_km as unsigned integer) area_sq_km,
        drive_side
    FROM multicol
    ORDER BY CAST(population as unsigned integer) DESC
    LIMIT 3;
```

```sql
SELECT * FROM populous_countries;
```

<table>
<thead>
<tr>
<th>country</th>
<th>population</th>
<th>area_sq_km</th>
<th>drive_side</th>
</tr>
</thead>
<tbody>
<tr>
<td>China</td>

<td>NULL</td>
<td></td>
</tr>
</tbody>
</table>

### 14.20.5.2 Adapting a memcached Application for the InnoDB memcached Plugin

Consider these aspects of MySQL and InnoDB tables when adapting existing memcached applications to use the daemon_memcached plugin:

- If there are key values longer than a few bytes, it may be more efficient to use a numeric auto-increment column as the primary key of the InnoDB table, and to create a unique secondary index on the column that contains the memcached key values. This is because InnoDB performs best for large-scale insertions if primary key values are added in sorted order (as they are with auto-increment values). Primary key values are included in secondary indexes, which takes up unnecessary space if the primary key is a long string value.

- If you store several different classes of information using memcached, consider setting up a separate InnoDB table for each type of data. Define additional table identifiers in the innodb_memcache.containers table, and use the @@table_id.key notation to store and retrieve items from different tables. Physically dividing different types of information allows you tune the characteristics of each table for optimum space utilization, performance, and reliability. For example, you might enable compression for a table that holds blog posts, but not for a table that holds thumbnail images. You might back up one table more frequently than another because it holds critical data. You might create additional secondary indexes on tables that are frequently used to generate reports using SQL.

- Preferably, configure a stable set of table definitions for use with the daemon_memcached plugin, and leave the tables in place permanently. Changes to the innodb_memcache.containers table take effect the next time the innodb_memcache.containers table is queried. Entries in the containers table are processed at startup, and are consulted whenever an unrecognized table identifier (as defined by containers.name) is requested using @@ notation. Thus, new entries are visible as soon as you use the associated table identifier, but changes to existing entries require a server restart before they take effect.

- When you use the default innodb_only caching policy, calls to add(), set(), incr(), and so on can succeed but still trigger debugging messages such as while expecting 'STORED',

---

2094
got unexpected response 'NOT_STORED'. Debug messages occur because new and updated values are sent directly to the InnoDB table without being saved in the memory cache, due to the innodb_only caching policy.

14.20.5.3 Tuning InnoDB memcached Plugin Performance

Because using InnoDB in combination with memcached involves writing all data to disk, whether immediately or sometime later, raw performance is expected to be somewhat slower than using memcached by itself. When using the InnoDB memcached plugin, focus tuning goals for memcached operations on achieving better performance than equivalent SQL operations.

Benchmarks suggest that queries and DML operations (inserts, updates, and deletes) that use the memcached interface are faster than traditional SQL. DML operations typically see a larger improvements. Therefore, consider adapting write-intensive applications to use the memcached interface first. Also consider prioritizing adaptation of write-intensive applications that use fast, lightweight mechanisms that lack reliability.

Adapting SQL Queries

The types of queries that are most suited to simple GET requests are those with a single clause or a set of AND conditions in the WHERE clause:

SQL:
```
SELECT col FROM tbl WHERE key = 'key_value';
```

memcached:
```
get key_value
```

SQL:
```
SELECT col1 FROM tbl WHERE col1 = val1 and col2 = val2 and col3 = val3;
```

memcached:
```
# Since you must always know these 3 values to look up the key,
# combine them into a unique string and use that as the key
# for all ADD, SET, and GET operations.
key_value = val1 + ":" + val2 + ":" + val3
get key_value
```

SQL:
```
SELECT 'key exists!' FROM tbl
WHERE EXISTS (SELECT col1 FROM tbl WHERE KEY = 'key_value') LIMIT 1;
```

memcached:
```
# Test for existence of key by asking for its value and checking if the call succeeds,
# ignoring the value itself. For existence checking, you typically only store a very
# short value such as "1".
get key_value
```

Using System Memory

For best performance, deploy the daemon_memcached plugin on machines that are configured as typical database servers, where the majority of system RAM is devoted to the InnoDB buffer pool, through the innodb_buffer_pool_size configuration option. For systems with multi-gigabyte buffer pools, consider raising the value of innodb_buffer_pool_instances for maximum throughput when most operations involve data that is already cached in memory.

Reducing Redundant I/O

InnoDB has a number of settings that let you choose the balance between high reliability, in case of a crash, and the amount of I/O overhead during high write workloads. For example, consider setting the innodb_doublewrite to 0 and innodb_flush_log_at_trx_commit to 2. Measure performance with different innodb_flush_method settings.

For other ways to reduce or tune I/O for table operations, see Section 8.5.8, “Optimizing InnoDB Disk I/O”.
Reducing Transactional Overhead

A default value of 1 for `daemon_memcached_r_batch_size` and `daemon_memcached_w_batch_size` is intended for maximum reliability of results and safety of stored or updated data.

Depending on the type of application, you might increase one or both of these settings to reduce the overhead of frequent commit operations. On a busy system, you might increase `daemon_memcached_r_batch_size`, knowing that changes to data made through SQL may not become visible to memcached immediately (that is, until \( N \) more get operations are processed). When processing data where every write operation must be reliably stored, leave `daemon_memcached_w_batch_size` set to 1. Increase the setting when processing large numbers of updates intended only for statistical analysis, where losing the last \( N \) updates in an unexpected exit is an acceptable risk.

For example, imagine a system that monitors traffic crossing a busy bridge, recording data for approximately 100,000 vehicles each day. If the application counts different types of vehicles to analyze traffic patterns, changing `daemon_memcached_w_batch_size` from 1 to 100 reduces I/O overhead for commit operations by 99%. In case of an outage, a maximum of 100 records are lost, which may be an acceptable margin of error. If instead the application performed automated toll collection for each car, you would set `daemon_memcached_w_batch_size` to 1 to ensure that each toll record is immediately saved to disk.

Because of the way InnoDB organizes memcached key values on disk, if you have a large number of keys to create, it may be faster to sort the data items by key value in the application and add them in sorted order, rather than create keys in arbitrary order.

The `memslap` command, which is part of the regular memcached distribution but not included with the daemon_memcached plugin, can be useful for benchmarking different configurations. It can also be used to generate sample key-value pairs to use in your own benchmarks. See libmemcached Command-Line Utilities for details.

14.20.5.4 Controlling Transactional Behavior of the InnoDB memcached Plugin

Unlike traditional memcached, the daemon_memcached plugin allows you to control durability of data values produced through calls to add, set, incr, and so on. By default, data written through the memcached interface is stored to disk, and calls to get return the most recent value from disk. Although the default behavior does not offer the best possible raw performance, it is still fast compared to the SQL interface for InnoDB tables.

As you gain experience using the daemon_memcached plugin, you can consider relaxing durability settings for non-critical classes of data, at the risk of losing some updated values in the event of an outage, or returning data that is slightly out-of-date.

Frequency of Commits

One tradeoff between durability and raw performance is how frequently new and changed data is committed. If data is critical, it should be committed immediately so that it is safe in case of an unexpected exit or outage. If data is less critical, such as counters that are reset after an unexpected exit or logging data that you can afford to lose, you might prefer higher raw throughput that is available with less frequent commits.

When a memcached operation inserts, updates, or deletes data in the underlying InnoDB table, the change might be committed to the InnoDB table instantly (if `daemon_memcached_w_batch_size=1`) or some time later (if the `daemon_memcached_w_batch_size` value is greater than 1). In either case, the change cannot be rolled back. If you increase the value of `daemon_memcached_w_batch_size` to avoid high I/O overhead during busy times, commits could become infrequent when the workload decreases. As a safety measure, a background thread automatically commits changes made through the memcached API at regular intervals. The interval
Writing Applications for the InnoDB memcached Plugin

is controlled by the `innodb_api_bk_commit_interval` configuration option, which has a default setting of 5 seconds.

When a `memcached` operation inserts or updates data in the underlying InnoDB table, the changed data is immediately visible to other `memcached` requests because the new value remains in the memory cache, even if it is not yet committed on the MySQL side.

**Transaction Isolation**

When a `memcached` operation such as `get` or `incr` causes a query or DML operation on the underlying InnoDB table, you can control whether the operation sees the very latest data written to the table, only data that has been committed, or other variations of transaction isolation level. Use the `innodb_api_trx_level` configuration option to control this feature. The numeric values specified for this option correspond to isolation levels such as `REPEATABLE READ`. See the description of the `innodb_api_trx_level` option for information about other settings.

A strict isolation level ensures that data you retrieve is not rolled back or changed suddenly causing subsequent queries to return different values. However, strict isolation levels require greater locking overhead, which can cause waits. For a NoSQL-style application that does not use long-running transactions, you can typically use the default isolation level or switch to a less strict isolation level.

**Disabling Row Locks for memcached DML Operations**

The `innodb_api_disable_rowlock` option can be used to disable row locks when `memcached` requests through the `daemon_memcached` plugin cause DML operations. By default, `innodb_api_disable_rowlock` is set to `OFF` which means that `memcached` requests row locks for `get` and `set` operations. When `innodb_api_disable_rowlock` is set to `ON`, `memcached` requests a table lock instead of row locks.

The `innodb_api_disable_rowlock` option is not dynamic. It must be specified at startup on the `mysqld` command line or entered in a MySQL configuration file.

**Allowing or Disallowing DDL**

By default, you can perform DDL operations such as `ALTER TABLE` on tables used by the `daemon_memcached` plugin. To avoid potential slowdowns when these tables are used for high-throughput applications, disable DDL operations on these tables by enabling `innodb_api_enable_mdl` at startup. This option is less appropriate when accessing the same tables through both `memcached` and SQL, because it blocks `CREATE INDEX` statements on the tables, which could be important for running reporting queries.

**Storing Data on Disk, in Memory, or Both**

The `innodb_memcache.cache_policies` table specifies whether to store data written through the `memcached` interface to disk (`innodb_only`, the default); in memory only, as with traditional `memcached` (`cache_only`); or both (`caching`).

With the `caching` setting, if `memcached` cannot find a key in memory, it searches for the value in an InnoDB table. Values returned from `get` calls under the `caching` setting could be out-of-date if the values were updated on disk in the InnoDB table but are not yet expired from the memory cache.

The caching policy can be set independently for `get`, `set` (including `incr` and `decr`), `delete`, and `flush` operations.

For example, you might allow `get` and `set` operations to query or update a table and the `memcached` memory cache at the same time (using the `caching` setting), while making `delete`, `flush`, or both operate only on the in-memory copy (using the `cache_only` setting). That way, deleting or flushing an item only expires the item from the cache, and the latest value is returned from the InnoDB table the next time the item is requested.
Writing Applications for the InnoDB memcached Plugin

```sql
mysql> SELECT * FROM innodb_memcache.cache_policies;
+--------------+-------------+-------------+---------------+--------------+
| policy_name  | get_policy  | set_policy  | delete_policy | flush_policy |
|--------------+-------------+-------------+---------------+--------------+
| cache_policy | innodb_only | innodb_only | innodb_only   | innodb_only  |
|--------------+-------------+-------------+---------------+--------------+
mysql>
```

innodb_memcache.cache_policies values are only read at startup. After changing values in this table, uninstall and reinstall the daemon_memcached plugin to ensure that changes take effect.

```sql
mysql> UNINSTALL PLUGIN daemon_memcached;
mysql> INSTALL PLUGIN daemon_memcached soname "libmemcached.so";
```

### 14.20.5.5 Adapting DML Statements to memcached Operations

Benchmarks suggest that the daemon_memcached plugin speeds up DML operations (inserts, updates, and deletes) more than it speeds up queries. Therefore, consider focussing initial development efforts on write-intensive applications that are I/O-bound, and look for opportunities to use MySQL with the daemon_memcached plugin for new write-intensive applications.

Single-row DML statements are the easiest types of statements to turn into memcached operations. **INSERT** becomes **add**, **UPDATE** becomes **set**, **incr** or **decr**, and **DELETE** becomes **delete**. These operations are guaranteed to only affect one row when issued through the memcached interface, because the **key** is unique within the table.

In the following SQL examples, **t1** refers to the table used for memcached operations, based on the configuration in the `innodb_memcache.containers` table. **key** refers to the column listed under `key_columns`, and **val** refers to the column listed under `value_columns`.

```
INSERT INTO t1 (key,val) VALUES ('some_key','some_value');
SELECT val FROM t1 WHERE key = 'some_key';
UPDATE t1 SET val = new_value WHERE key = 'some_key';
UPDATE t1 SET val = val + x WHERE key = 'some_key';
DELETE FROM t1 WHERE key = 'some_key';
```

The following **TRUNCATE TABLE** and **DELETE** statements, which remove all rows from the table, correspond to the **flush_all** operation, where **t1** is configured as the table for memcached operations, as in the previous example.

```
TRUNCATE TABLE t1;
DELETE FROM t1;
```

### 14.20.5.6 Performing DML and DDL Statements on the Underlying InnoDB Table

You can access the underlying InnoDB table (which is `test.demo_test` by default) through standard SQL interfaces. However, there are some restrictions:

- When querying a table that is also accessed through the memcached interface, remember that memcached operations can be configured to be committed periodically rather than after every write operation. This behavior is controlled by the daemon_memcached_w_batch_size option. If this option is set to a value greater than 1, use **READ UNCOMMITTED** queries to find rows that were just inserted.

```
mysql> SET SESSION TRANSACTION ISOLATION LEVEL READ UNCOMMITTED;
mysql> SELECT * FROM demo_test;
+--------+--------+-----+-----+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+--------+        

2098
• When modifying a table using SQL that is also accessed through the memcached interface, you can configure memcached operations to start a new transaction periodically rather than for every read operation. This behavior is controlled by the daemon_memcached_r_batch_size option. If this option is set to a value greater than 1, changes made to the table using SQL are not immediately visible to memcached operations.

• The InnoDB table is either IS (intention shared) or IX (intention exclusive) locked for all operations in a transaction. If you increase daemon_memcached_r_batch_size and daemon_memcached_w_batch_size substantially from their default value of 1, the table is most likely locked between each operation, preventing DDL statements on the table.

14.20.6 The InnoDB memcached Plugin and Replication

Because the daemon_memcached plugin supports the MySQL binary log, updates made on a source server through the memcached interface can be replicated for backup, balancing intensive read workloads, and high availability. All memcached commands are supported with binary logging.

You do not need to set up the daemon_memcached plugin on replica servers. The primary advantage of this configuration is increased write throughput on the source. The speed of the replication mechanism is not affected.

The following sections show how to use the binary log capability when using the daemon_memcached plugin with MySQL replication. It is assumed that you have completed the setup described in Section 14.20.3, “Setting Up the InnoDB memcached Plugin”.

Enabling the InnoDB memcached Binary Log

1. To use the daemon_memcached plugin with the MySQL binary log, enable the innodb_api_enable_binlog configuration option on the source server. This option can only be set at server startup. You must also enable the MySQL binary log on the source server using the --log-bin option. You can add these options to the MySQL configuration file, or on the mysqld command line.

   mysqld ... --log-bin --innodb_api_enable_binlog=1

2. Configure the source and replica server, as described in Section 17.1.1, “How to Set Up Replication”.

3. Use mysqldump to create a source data snapshot, and sync the snapshot to the replica server.

   source shell> mysqldump --all-databases --lock-all-tables > dbdump.db
   replica shell> mysql < dbdump.db

4. On the source server, issue SHOW MASTER STATUS to obtain the source binary log coordinates.

   mysql> SHOW MASTER STATUS;

5. On the replica server, use a CHANGE MASTER TO statement to set up a replica server using the source binary log coordinates.

   mysql> CHANGE MASTER TO
       MASTER_HOST='localhost',
       MASTER_USER='root',
       MASTER_PASSWORD='',
       MASTER_PORT = 13000,
       MASTER_LOG_FILE='0.000001,'
       MASTER_LOG_POS=114;

6. Start the replica.

   mysql> START SLAVE;
If the error log prints output similar to the following, the replica is ready for replication.

2013-09-24T13:04:38.639684Z 49 [Note] Slave I/O thread: connected to master 'root@localhost:13000', replication started in log '0.000001' at position 114

Testing the InnoDB memcached Replication Configuration

This example demonstrates how to test the InnoDB memcached replication configuration using the memcached and telnet to insert, update, and delete data. A MySQL client is used to verify results on the source and replica servers.

The example uses the demo_test table, which was created by the innodb_memcached_config.sql configuration script during the initial setup of the daemon_memcached plugin. The demo_test table contains a single example record.

1. Use the set command to insert a record with a key of test1, a flag value of 10, an expiration value of 0, a cas value of 1, and a value of t1.

   telnet 127.0.0.1 11211
   Trying 127.0.0.1...
   Connected to 127.0.0.1.
   Escape character is '^]'.
   set test1 10 0 1 t1
   STORED

2. On the source server, check that the record was inserted into the demo_test table. Assuming the demo_test table was not previously modified, there should be two records. The example record with a key of AA, and the record you just inserted, with a key of test1. The c1 column maps to the key, the c2 column to the value, the c3 column to the flag value, the c4 column to the cas value, and the c5 column to the expiration time. The expiration time was set to 0, since it is unused.

   mysql> SELECT * FROM test.demo_test;
   +-------+--------------+------+------+------+
   | c1    | c2           | c3   | c4   | c5   |
   +-------+--------------+------+------+------+
   | AA    | HELLO, HELLO |     8 |     0 |     0 |
   | test1 | t1           |    10 |     1 |     0 |
   +-------+--------------+------+------+------+

3. Check to verify that the same record was replicated to the replica server.

   mysql> SELECT * FROM test.demo_test;
   +-------+--------------+------+------+------+
   | c1    | c2           | c3   | c4   | c5   |
   +-------+--------------+------+------+------+
   | AA    | HELLO, HELLO |     8 |     0 |     0 |
   | test1 | t1           |    10 |     1 |     0 |
   +-------+--------------+------+------+------+

4. Use the set command to update the key to a value of new.

   telnet 127.0.0.1 11211
   Trying 127.0.0.1...
   Connected to 127.0.0.1.
   Escape character is '^]'.
   set test1 10 0 2 new
   STORED

   The update is replicated to the replica server (notice that the cas value is also updated).

   mysql> SELECT * FROM test.demo_test;
   +-------+--------------+------+------+------+
   | c1    | c2           | c3   | c4   | c5   |
   +-------+--------------+------+------+------+
   | AA    | HELLO, HELLO |     8 |     0 |     0 |
   | test1 | new          |    10 |     1 |     0 |
   +-------+--------------+------+------+------+
5. Delete the `test1` record using a `delete` command.

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
delete test1
DELETED
```

When the `delete` operation is replicated to the replica, the `test1` record on the replica is also deleted.

```
mysql> SELECT * FROM test.demo_test;
+----+--------------+------+------+------+
| c1 | c2           | c3   | c4   | c5   |
+----+--------------+------+------+------+
| AA | HELLO, HELLO |    8 |    0 |    0 |
+----+--------------+------+------+------+
```
